- **Amazon EC2** – *Amazon Elastic Compute Cloud* (Amazon EC2) provides scalable computing capacity in the AWS cloud. Your Amazon DocumentDB cluster should be running in your default virtual private cloud (VPC). To interact with your Amazon DocumentDB cluster, you must launch an EC2 instance into your default VPC, in the same AWS Region where you created your Amazon DocumentDB cluster. For details, refer to *Launch an Amazon EC2 instance* in the Amazon DocumentDB documentation.

Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT

Created by Veeranjaneyulu Grandhi (AWS) and vinod kumar (AWS)

Environment: PoC or pilot
Source: Databases: Relational
Target: Amazon RDS for MariaDB
R Type: Re-architect
Workload: Oracle
Technologies: Migration; Databases
AWS services: Amazon RDS

Summary

This pattern walks you through the steps for migrating an Oracle database on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon Relational Database Service (Amazon RDS) for MariaDB DB instance. The pattern uses AWS Data Migration Service (AWS DMS) for data migration and AWS Schema Conversion Tool (AWS SCT) for schema conversion.

Managing Oracle databases on EC2 instances requires more resources and is more costly than using a database on Amazon RDS. Amazon RDS makes it easy to set up, operate, and scale a relational database in the cloud. Amazon RDS provides cost-efficient and resizable capacity while automating time-consuming administration tasks such as hardware provisioning, database setup, patching, and backups.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• A source Oracle database with instance and listener services up and running. This database should be in ARCHIVELOG mode.
• Familiarity with Using an Oracle Database as a Source for AWS DMS.
• Familiarity with Using Oracle as a Source for AWS SCT.

Limitations

• Database size limit: 64 TB

Product versions

• All Oracle database editions for versions 10.2 and later, 11g and up to 12.2, and 18c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS and the AWS SCT version table in the AWS documentation.
- Amazon RDS supports MariaDB Server Community Server versions 10.3, 10.4, 10.5, and 10.6. For the latest list of supported versions, see the Amazon RDS documentation.

**Architecture**

**Source technology stack**
- An Oracle database on an EC2 instance

**Target technology stack**
- Amazon RDS for MariaDB

**Data migration architecture**

![Architecture Diagram]

**Target architecture**

![Target Architecture Diagram]
Tools

- **AWS Schema Conversion Tool** (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects—including views, stored procedures, and functions—to a format compatible with the target database. After converting your database schema and code objects using AWS SCT, you can use AWS DMS to migrate data from the source database to the target database to complete your migration projects. For more information, see Using Oracle as a Source for AWS SCT in the AWS SCT documentation.

- **AWS Database Migration Service** (AWS DMS) helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases. AWS DMS supports homogeneous migrations such as Oracle to Oracle, as well as heterogeneous migrations between different database platforms, such as Oracle or Microsoft SQL Server to Amazon Aurora. To learn more about migrating Oracle databases, see Using an Oracle Database as a Source for AWS DMS in the AWS DMS documentation.

**Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT**

*Created by Sergey Dmitriev (AWS)*

| R Type: Re-architect | Source: Databases: Relational | Target: Amazon RDS for MySQL | Created by: AWS | Environment: PoC or pilot | Technologies: Databases; Migration | Workload: Oracle | AWS services: Amazon RDS |

**Summary**

This pattern walks you through the migration of an on-premises Oracle database to an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance. It uses AWS Database Migration Service (AWS DMS) to migrate the data, and AWS Schema Conversion Tool (AWS SCT) to convert the source database schema and objects to a format that's compatible with Amazon RDS for MySQL.

**Prerequisites and limitations**

**Prerequisites**
- An active AWS account
- A source Oracle database in an on-premises data center

**Limitations**

- Database size limit: 64 TB

**Product versions**

- All Oracle database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.
- AWS DMS currently supports MySQL versions 5.5, 5.6, and 5.7. For the latest list of supported versions, see Using a MySQL-Compatible Database as a Target for AWS DMS in the AWS documentation.

**Architecture**

**Source technology stack**

- On-premises Oracle database

**Target technology stack**

- Amazon RDS for MySQL DB instance

**Data migration architecture**
Tools

- **AWS DMS - AWS Database Migration Services** (AWS DMS) helps you migrate relational databases, data warehouses, NoSQL databases, and other types of data stores. You can use AWS DMS to migrate your data into the AWS Cloud, between on-premises instances (through an AWS Cloud setup), or between combinations of cloud and on-premises setups.

- **AWS SCT - AWS Schema Conversion Tool** (AWS SCT) is used to convert your database schema from one database engine to another. The custom code that the tool converts includes views, stored procedures, and functions. Any code that the tool cannot convert automatically is clearly marked so that you can convert it yourself.

Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL using an Oracle bystander and AWS DMS

Created by Cady Motyka (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Databases: Relational</th>
<th>Target:</th>
<th>Amazon RDS for PostgreSQL/Amazon Aurora PostgreSQL</th>
</tr>

</tr>
</tbody>
</table>

Summary

This pattern describes how you can migrate an on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL, using AWS Database Migration Service (AWS DMS) to migrate the data, AWS Schema Conversion Tool (AWS SCT) to convert the database schema, and an Oracle bystander to help manage the migration.

This pattern helps users who want to minimize database downtime. In this implementation, the downtime would be restricted to the length of time it takes to create or validate all the foreign keys on the database.

The pattern uses Amazon Elastic Compute Cloud (Amazon EC2) instances with an Oracle bystander database to help control the stream of data through AWS DMS. You can temporarily pause streaming replication from the on-premises Oracle database to the Oracle bystander to enable AWS DMS to catch up on data validation or to use another data validation tool. The Amazon RDS for PostgreSQL DB instance and the bystander database will have the same data when AWS DMS has finished migrating current changes.

Prerequisites and limitations

Prerequisites

- An active AWS account
• A source Oracle database in an on-premises data center with an Active Data Guard standby database configured
• AWS Direct Connect configured between the on-premises data center and AWS Secrets Manager for storing the database secrets
• Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed either on a local machine or on the EC2 instance where AWS SCT is installed
• Familiarity with using an Oracle database as a source for AWS DMS
• Familiarity with using a PostgreSQL database as a target for AWS DMS

Limitations

• Database size limit: 64 TB

Product versions

• All Oracle database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS and Using a MySQL-Compatible Database as a Target for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.
• AWS DMS supports PostgreSQL versions 9.4 and later (for 9.x), 10.x, and 11.x. For the latest information, see Using a PostgreSQL Database as a Target for AWS DMS in the AWS documentation.

Architecture

Source technology stack

• An on-premises Oracle database
• An EC2 instance that holds a bystander for the Oracle database

Target technology stack

• Amazon RDS for PostgreSQL, PostgreSQL 9.3 and later

Database migration architecture
Tools

- **AWS DMS - AWS Database Migration Service** (DMS) helps you migrate databases quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.

- **AWS SCT - AWS Schema Conversion Tool** (SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database. Objects that cannot be automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan your application source code for embedded SQL statements and convert them as part of a database schema conversion project. During this process, AWS SCT performs cloud-native code optimization by converting legacy Oracle and SQL Server functions to their AWS equivalents, to help you modernize your applications while migrating your databases. When schema conversion is complete, AWS SCT can help migrate data from a range of data warehouses to Amazon Redshift by using built-in data migration agents.

- **Amazon RDS - Amazon Relational Database Service** (Amazon RDS) makes it easy to set up, operate, and scale a relational database in the cloud. It provides cost-efficient and resizable capacity while automating time-consuming administration tasks such as hardware provisioning, database setup, patching, and backups.

Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate

*Created by Dhairya Jindani (AWS), Rajeshkumar Sabankar (AWS), and Sindhusha Paturu (AWS)*
AWS services: Amazon RDS

Summary

This pattern shows how to migrate an Oracle database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL by using Oracle Cloud Infrastructure (OCI) GoldenGate.

By using Oracle GoldenGate, you can replicate data between your source database and one or more destination databases with minimal downtime.

Note: The source Oracle database can be either on-premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. You can use a similar procedure when using on-premises replication tools.

Prerequisites and limitations

Prerequisites

• An active AWS account
• An Oracle GoldenGate license
• Java Database Connectivity (JDBC) driver to connect to the PostgreSQL database
• Schema and tables created with the AWS Schema Conversion Tool (AWS SCT) on the target Amazon RDS for PostgreSQL database

Limitations

• Oracle GoldenGate can replicate existing table data (initial load) and ongoing changes (change data capture) only

Product versions

• Oracle Database Enterprise Edition 10g or newer versions
• Oracle GoldenGate 12.2.0.1.1 for Oracle or newer versions
• Oracle GoldenGate 12.2.0.1.1 for PostgreSQL or newer versions

Architecture

The following diagram shows an example workflow for migrating an Oracle database to Amazon RDS for PostgreSQL by using Oracle GoldenGate:
The diagram shows the following workflow:

1. The Oracle GoldenGate Extract process runs against the source database to extract data.
2. The Oracle GoldenGate Replicat process delivers the extracted data to the target Amazon RDS for PostgreSQL database.

**Tools**

- Oracle GoldenGate helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.

**Epics**

**Download and install Oracle GoldenGate**

<table>

Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT
Summary

This pattern provides guidance for migrating Oracle databases to an Amazon Redshift cloud data warehouse in the Amazon Web Services (AWS) Cloud by using AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT). The pattern covers source Oracle databases that are on premises or installed on an Amazon Elastic Compute Cloud (Amazon EC2) instance. It also covers Amazon Relational Database Service (Amazon RDS) for Oracle databases.

Prerequisites and limitations

Prerequisites

- An Oracle database that is running in an on-premises data center or in the AWS Cloud
- An active AWS account
- Familiarity with using an Oracle database as a source for AWS DMS
- Familiarity with using an Amazon Redshift database as a target for AWS DMS
- Knowledge of Amazon RDS, Amazon Redshift, the applicable database technologies, and SQL
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, where AWS SCT is installed

Product versions

- For self-managed Oracle databases, AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g and up to 12.2, 18c, and 19c. For Amazon RDS for Oracle databases that AWS manages, AWS DMS supports all Oracle database editions for versions 11g (versions 11.2.0.4 and later) and up to 12.2, 18c, and 19c. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

Architecture

Source technology stack

One of the following:
- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

Target technology stack

- Amazon Redshift
Target architecture

From an Oracle database running in the AWS Cloud to Amazon Redshift:

From an Oracle database running in an on-premises data center to Amazon Redshift:
Tools

- **AWS DMS** - AWS Data Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from most widely used commercial and open-source databases.

- **AWS SCT** - AWS Schema Conversion Tool (AWS SCT) can be used to convert your existing database schema from one database engine to another. It supports various database engines, including Oracle, SQL Server, and PostgreSQL, as sources.

Epics

Prepare for the migration

</table>

Summary

This pattern describes how to migrate an Oracle database to Amazon Aurora PostgreSQL-Compatible Edition by using AWS Data Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT).

The pattern covers source Oracle databases that are on premises, Oracle databases that are installed on Amazon Elastic Compute Cloud (Amazon EC2) instances, and Amazon Relational Database Service (Amazon RDS) for Oracle databases. The pattern converts these databases to Aurora PostgreSQL-Compatible.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Oracle database in an on-premises data center or in the AWS Cloud.
- SQL clients installed either on a local machine or on an EC2 instance.
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed on either a local machine or an EC2 instance where AWS SCT is installed.

Limitations

- Database size limit: 128 TB
- If the source database supports a commercial off-the-shelf (COTS) application or is vendor-specific, you might not be able to convert it to another database engine. Before using this pattern, confirm that the application supports Aurora PostgreSQL-Compatible.

Product versions
For self-managed Oracle databases, AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g, and up to 12.2, 18c, and 19c. For the latest list of supported Oracle database versions (both self-managed and Amazon RDS for Oracle), see Using an Oracle database as a source for AWS DMS and Using a PostgreSQL database as a target for AWS DMS.

We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.

Aurora supports the PostgreSQL versions listed in Amazon Aurora PostgreSQL releases and engine versions.

Architecture

Source technology stack

One of the following:

- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

Target technology stack

- Aurora PostgreSQL-Compatible

Target architecture

Data migration architecture

- From an Oracle database running in the AWS Cloud
• From an Oracle database running in an on-premises data center
Tools

- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- **AWS Schema Conversion Tool (AWS SCT)** supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

Summary

This pattern provides guidance for data migration from an on-premises Oracle database to Amazon Aurora PostgreSQL-Compatible Edition. It targets an online data migration strategy with a minimal amount of downtime for multi-terabyte Oracle databases that contain large tables with high data manipulation language (DML) activities. An Oracle Active Data Guard standby database is used as the source to offload data migration from the primary database. The replication from the Oracle primary database to standby can be suspended during the full load to avoid ORA-01555 errors.

Table columns in primary keys (PKs) or foreign keys (FKs), with data type NUMBER, are commonly used to store integers in Oracle. We recommend that you convert these to INT or BIGINT in PostgreSQL for better performance. You can use the AWS Schema Conversion Tool (AWS SCT) to change the default
data type mapping for PK and FK columns. (For more information, see the AWS blog post Convert the NUMBER data type from Oracle to PostgreSQL.) The data migration in this pattern uses AWS Database Migration Service (AWS DMS) for both full load and change data capture (CDC).

You can also use this pattern to migrate an on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL, or an Oracle database that's hosted on Amazon Elastic Compute Cloud (Amazon EC2) to either Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Oracle source database in an on-premises data center with Active Data Guard standby configured
- AWS Direct Connect configured between the on-premises data center and the AWS Cloud
- Familiarity with using an Oracle database as a source for AWS DMS
- Familiarity with using a PostgreSQL database as a target for AWS DMS

Limitations

- Amazon Aurora database clusters can be created with up to 128 TiB of storage. Amazon RDS for PostgreSQL database instances can be created with up to 64 TiB of storage. For the latest storage information, see Amazon Aurora storage and reliability and Amazon RDS DB instance storage in the AWS documentation.

Product versions

- AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g and up to 12.2, 18c, and 19c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS in the AWS documentation.

Architecture

Source technology stack

- On-premises Oracle databases with Oracle Active Data Guard standby configured

Target technology stack

- Aurora PostgreSQL-Compatible

Data migration architecture
Tools

- **AWS DMS** - *AWS Database Migration Service* (AWS DMS) supports several source and target databases. See [Using an Oracle Database as a Source for AWS DMS](#) in the AWS DMS documentation for a list of supported Oracle source and target database versions and editions. If the source database is not supported by AWS DMS, you must select another method for migrating the data in Phase 6 (in the Epics section). **Important note:** Because this is a heterogeneous migration, you must first check to see whether the database supports a commercial off-the-shelf (COTS) application. If the application is COTS, consult the vendor to confirm that Aurora PostgreSQL-Compatible is supported before proceeding. For more information, see [AWS DMS Step-by-Step Migration Walkthroughs](#) in the AWS documentation.

- **AWS SCT** - The *AWS Schema Conversion Tool* (AWS SCT) facilitates heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. The custom code that the tool converts includes views, stored procedures, and functions. Any code that the tool cannot convert automatically is clearly marked so that you can convert it yourself.

Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS

Created by Sergey Dmitriev (AWS)

<table>
<thead>
<tr>
<th>R Type: Re-architect</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon RDS for SQL Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>Workload: SAP</td>
<td>AWS services: Amazon RDS</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides guidance for migrating an SAP Adaptive Server Enterprise (ASE) database to an Amazon Relational Database Service (Amazon RDS) DB instance that’s running Microsoft SQL Server. The source database can be located in an on-premises data center or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. The pattern uses AWS Database Migration Service (AWS DMS) to migrate data and (optionally) computer-aided software engineering (CASE) tools to convert the database schema.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An SAP ASE database in an on-premises data center or on an EC2 instance

Limitations

- Database size limit: 64 TB

Product versions

- SAP ASE version 15.x or 16.x and later. For the latest information, see Using an SAP Database as a Source for AWS DMS.
about supported versions, see the AWS DMS documentation. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

Architecture

Source technology stack

- An SAP ASE database that’s on premises or on an Amazon EC2 instance

Target technology stack

- An Amazon RDS for SQL Server DB instance

Source and target architecture

*From an SAP ASE database on Amazon EC2 to an Amazon RDS for SQL Server DB instance:*

*From an on-premises SAP ASE database to an Amazon RDS for SQL Server DB instance:*
**Tools**

- **AWS DMS** - *AWS Database Migration Service* (AWS DMS) is a web service you can use to migrate data from your database that is on-premises, on an Amazon RDS DB instance, or in a database on an EC2 instance, to a database on an AWS service such as Amazon RDS for SQL Server or an EC2 instance. You can also migrate a database from an AWS service to an on-premises database. You can migrate data between heterogeneous or homogenous database engines.

- **CASE tools** - For schema conversions, you can optionally use *erwin Data Modeler* or *SAP PowerDesigner*.

**Epics**

Migrate an SAP ASE database to Aurora PostgreSQL using AWS DMS

*Created by Sergey Dmitriev (AWS)*

| R Type: Re-architect | Source: Databases: Relational | Target: Amazon Aurora PostgreSQL |
Summary

This pattern describes how to migrate an SAP Adaptive Server Enterprise (ASE) database to an Amazon Aurora PostgreSQL-Compatible Edition instance by using AWS Database Migration Service (AWS DMS). The pattern applies to SAP ASE source databases in an on-premises data center or on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An SAP ASE database in an on-premises data center or on an EC2 instance

Limitations

- The source database must be less than 64 TB

Product versions

- SAP ASE version 15.x and 16.x or later (for the latest information, see Using an SAP Database as a Source for AWS DMS)
- PostgreSQL 9.6 or later (for details, see Using a PostgreSQL Database as a Target for AWS DMS)
- Amazon Aurora 1.x or later (for the latest information, see Aurora PostgreSQL-Compatible releases and engine versions)

Architecture

Source technology stack

- SAP ASE database (on premises or on an EC2 instance)

Target technology stack

- Aurora PostgreSQL-Compatible DB instance

Data migration architecture

From an SAP ASE database on Amazon EC2 to Aurora PostgreSQL-Compatible
From an on-premises SAP ASE database to Aurora PostgreSQL-Compatible
Tools

- **AWS DMS** - AWS Data Migration Service (AWS DMS) supports several different source and target databases. For more information, see Sources for Data Migration and Targets for Data Migration. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

- An optional, third-party CASE (computer-aided software engineering) tool.

Epics

Product versions
• SAP ASE version 15.x or 16.x and later. For the latest information, see Using an SAP Database as a Source for AWS DMS.
• AWS DMS supports PostgreSQL version 9.4 and later (for 9.x), 10.x, and 11.x. For the latest information about supported versions, see the AWS DMS documentation. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

Architecture

Source technology stack
• An on-premises SAP ASE database

Target technology stack
• A PostgreSQL database on an EC2 instance

Database migration architecture
Tools

- **AWS DMS - AWS Database Migration Service** (AWS DMS) is a web service you can use to migrate data from your database that is on-premises, on an Amazon RDS DB instance, or in a database on an EC2 instance, to a database on an AWS service such as Amazon RDS for SQL Server or an EC2 instance. You can also migrate a database from an AWS service to an on-premises database. You can migrate data between heterogeneous or homogenous database engines.

Epics

Plan the migration

**Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS**

*Created by Mark Szalkiewicz (AWS)*

<table>
<thead>
<tr>
<th>R Type: Re-architect</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon Redshift</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>Workload: Microsoft</td>
<td>AWS services: Amazon Redshift</td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern provides guidance for migrating an on-premises Microsoft SQL Server database to Amazon Redshift using AWS Data Migration Service (AWS DMS).
Prerequisites and limitations

Prerequisites

• An active AWS account
• A source Microsoft SQL Server database in an on-premises data center

Product versions

• SQL Server 2005-2017, Enterprise, Standard, Workgroup, and Developer editions. For the latest list of supported versions, see Using a Microsoft SQL Server Database as a Source for AWS DMS in the AWS documentation/

Architecture

Source technology stack

• An on-premises Microsoft SQL Server database

Target technology stack

• Amazon Redshift

Data migration architecture
Tools

- **AWS DMS - AWS Database Migration Services** (AWS DMS) supports several types of source and target databases. For information about the Microsoft SQL Server database versions and editions that are supported for use with AWS DMS, see Using a Microsoft SQL Server Database as a Source for AWS DMS in the AWS DMS documentation. If AWS DMS doesn't support your source database, you must select an alternative method for data migration.

Epics

Plan the migration

Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents

Created by Mark Szalkiewicz (AWS)

<table>
<thead>
<tr>
<th>R Type: Re-architect</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon Redshift</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>Workload: Microsoft</td>
<td>AWS services: Amazon Redshift</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern outlines steps for migrating an on-premises Microsoft SQL Server source database to an Amazon Redshift target database using AWS Schema Conversion Tool (SCT) data extraction agents. An agent is an external program that is integrated with AWS SCT but performs data transformation elsewhere and interacts with other AWS services on your behalf.

Prerequisites and limitations

Prerequisites

- A Microsoft SQL Server source database used for the data warehouse workload in an on-premises data center
- An active AWS account

Product versions

- Microsoft SQL Server version 2008 or later. For the latest list of supported versions, see AWS SCT documentation.

Architecture

technology stackSource

- An on-premises Microsoft SQL Server database

technology stackTarget

- Amazon Redshift
### Data migration architecture

![Data migration architecture diagram](image)

**Tools**

- **AWS SCT** – *AWS Schema Conversion Tool* (AWS SCT) handles heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. When the source and target databases are very different from one another, you can use an AWS SCT agent to perform additional data transformation. For more information, see *Migrating Data from an On-Premises Data Warehouse to Amazon Redshift* in the AWS documentation.

Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents

*Created by Sergey Dmitriev (AWS)*

<table>
<thead>
<tr>
<th>R Type:</th>
<th>Source: Database: Relational</th>
<th>Target: Amazon Redshift</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern walks you through the steps for migrating a Teradata database, used as a data warehouse in an on-premises data center, to an Amazon Redshift database. The pattern uses AWS Schema Conversion Tool (AWS SCT) data extraction agents. An agent is an external program that is integrated with AWS SCT but performs data transformation elsewhere and interacts with other AWS services on your behalf.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Teradata source database in an on-premises data center

Product versions

- Teradata version 13 and later. For the latest list of supported versions, see the AWS SCT documentation.

Architecture

Source technology stack

- On-premises Teradata database
Target technology stack

- Amazon Redshift cluster

Data migration architecture

Tools

- **AWS SCT** – **AWS Schema Conversion Tool** (AWS SCT) handles heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. When the source and target databases are very different from one another, you can use an AWS SCT agent to perform additional data transformation. For more information, see [Migrating Data from an On-Premises Data Warehouse to Amazon Redshift](#) in the AWS documentation.

AWS services: Amazon Redshift

Summary

This pattern provides guidance for migrating an on-premises Vertica database to an Amazon Redshift cluster using AWS Schema Conversion Tool (AWS SCT) data extraction agents. An agent is an external program that is integrated with AWS SCT but performs data transformation elsewhere and interacts with other AWS services on your behalf.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Vertica source database used for the data warehouse workload in an on-premises data center
- An Amazon Redshift target cluster

Product versions

- Vertica version 7.2.2 and later. For the latest list of supported versions, see the AWS SCT documentation.
Architecture

Source technology stack

• An on-premises Vertica database

Target technology stack

• An Amazon Redshift cluster

Data migration architecture

Tools

• AWS SCT - AWS Schema Conversion Tool (AWS SCT) handles heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. When the source and target databases are very different from one another, you can use an AWS SCT agent to perform additional data transformation. For more information, see Migrating Data from an On-Premises Data Warehouse to Amazon Redshift in the AWS documentation.

### Migrate an on-premises MySQL database to Aurora MySQL

*Created by Mark Szalkiewicz (AWS)*

<table>
<thead>
<tr>
<th>R Type:</th>
<th>Re-architect</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon Aurora MySQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by:</td>
<td>AWS</td>

</tr>
<tr>
<td>Workload:</td>
<td>Open-source</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Summary

This pattern explains how to migrate an on-premises MySQL source database to Amazon Aurora MySQL. It describes two options for migration: using AWS Database Migration Service (AWS DMS) or using native MySQL tools such as `mysqldbcopy` and `mysqldump`.

### Prerequisites and limitations

**Prerequisites**
- An active AWS account
AWS Prescriptive Guidance Patterns
Migrate from on-premises MySQL to Aurora MySQL

• A source MySQL database in an on-premises data center

Limitations
• Database size limit: 64 TB

Product versions
• MySQL versions 5.5, 5.6, 5.7, 8.0. For the latest list of supported versions, see MySQL on Amazon RDS in the AWS documentation. If you’re using AWS DMS, see also Using a MySQL-Compatible Database as a Target for AWS DMS for MySQL versions supported by AWS DMS.

Architecture

Source technology stack
• An on-premises MySQL database

Target technology stack
• Amazon Aurora MySQL

Target architecture
Data migration architecture

*Using AWS DMS:*

*Using native MySQL tools:*

---

1203
Tools

- **AWS DMS - AWS Database Migration Service** (AWS DMS) supports several source and target databases. For information about MySQL source and target databases supported by AWS DMS, see [Migrating MySQL-Compatible Databases to AWS](#). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- **Native MySQL tools** - `mysqlbecopy` and `mysqldump`.

Migrate legacy applications from Oracle Pro*C to ECPG

*Created by Sai Parthasaradhi (AWS) and Mahesh Balumuri (AWS)*

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Oracle</th>
<th>Target: PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Re-architect</td>
<td>Workload: Oracle</td>
<td>Technologies: Migration; Databases</td>
</tr>
</tbody>
</table>

Summary

Most legacy applications that have embedded SQL code use the Oracle Pro*C precompiler to access the database. When you migrate these Oracle databases to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition, you have to convert your application code to a format that’s compatible with the precompiler in PostgreSQL, which is called ECPG. This pattern describes how to convert Oracle Pro*C code to its equivalent in PostgreSQL ECPG.
For more information about Pro*C, see the Oracle documentation. For a brief introduction to ECPG, see the Additional information (p. 1216) section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database
- An Oracle database running on premises

Tools

- The PostgreSQL packages listed in the next section.
- AWS CLI – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

Epics

Set the build environment on CentOS or RHEL

## Migrate legacy applications from Oracle Pro*C to ECPG

### Task
<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Apply common migration patterns.** | • Change SQL queries so they're compatible with PostgreSQL.  
  • Move anonymous blocks, when they aren't supported in ECPG, to the database.  
  • Remove `dbms_application_info` logic, which isn't supported by PostgreSQL.  
  • Move `EXEC SQL COMMIT` statements after the cursor close. If you commit queries while in the loop to fetch the records from the cursor, the cursor is closed and a cursor doesn’t exist error is displayed.  
  • For information about handling exceptions in ECPG and error codes, see [Error Handling](#) in the PostgreSQL documentation. | App developer, App owner |

### Enable debugging, if required.

To run the ECPG program in debug mode, add the following command inside the main function block.

```c
ECPGdebug(1, stderr);
```

### Compile ECPG programs

**Related resources**

- ECPG - Embedded SQL in C ([PostgreSQL documentation](#))
- Error Handling ([PostgreSQL documentation](#))
- Why Use the Oracle Pro*C/C++ Precompiler ([Oracle documentation](#))

**Additional information**

PostgreSQL has an embedded SQL precompiler, ECPG, which is equivalent to the Oracle Pro*C precompiler. ECPG converts C programs that have embedded SQL statements to standard C code by replacing the SQL calls with special function calls. The output files can then be processed with any C compiler tool chain.

**Input and output files**

ECPG converts each input file you specify on the command line to the corresponding C output file. If an input file name doesn’t have a file extension, .pgc is assumed. The file’s extension is replaced by .c to construct the output file name. However, you can override the default output file name by using the -o option.

If you use a dash (-) as the input file name, ECPG reads the program from standard input and writes to standard output, unless you override that by using the -o option.

**Header files**

When the PostgreSQL compiler compiles the pre-processed C code files, it looks for the ECPG header files in the PostgreSQL include directory. Therefore, you might have to use the -I option to point the compiler to the correct directory (for example, -I/usr/local/pgsql/include).

**Libraries**
Programs that use C code with embedded SQL have to be linked against the libecpg library. For example, you can use the linker options `-L/usr/local/pgsql/lib -lepg`.

Converted ECPG applications call functions in the libpq library through the embedded SQL library (ecpglib), and communicate with the PostgreSQL server by using the standard frontend/backend protocol.

**Migrate virtual generated columns from Oracle to PostgreSQL**

*Created by Veeranjaneyulu Grandhi (AWS) and Rajesh Madiwale (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Source:</th>
<th>Oracle Database</th>
<th>Target:</th>
<th>Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible</th>
</tr>
</thead>
<tbody>
<tr>

<td>Re-architect</td>
<td>Workload:</td>
<td>Oracle</td>
<td>Technologies:</td>
<td>Migration; Databases</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon Aurora; Amazon RDS; AWS DMS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

In PostgreSQL versions before version 12 (PG12), handling virtual generated columns while migrating from Oracle Database to PostgreSQL was difficult for two reasons:

- Virtual columns aren't visible during migration.
- PostgreSQL didn't support the `generate` expression before version 12.

When you use AWS Database Migration Service (AWS DMS) to migrate data from Oracle Database to PostgreSQL version 11 and earlier, you can use trigger functions to populate the values in virtual generated columns. This pattern provides examples of Oracle Database and PostgreSQL code that you can use for this purpose. On AWS, you can use Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition for your PostgreSQL database.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- Source Oracle and target PostgreSQL databases (on Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible)
- PL/pgSQL coding expertise

**Limitations**

- Applies only to PostgreSQL versions before version 12.
- Applies to Oracle Database version 11g or later.
- Virtual columns are not supported in data migration tools.
AWS Prescriptive Guidance Patterns
Migrate virtual generated columns from Oracle to PostgreSQL

- Applies only to columns defined in the same table.
- If a virtual generated column refers to a deterministic user-defined function, it cannot be used as a partitioning key column.
- The output of the expression must be a scalar value. It cannot return an Oracle supplied datatype, a user-defined type, LOB, or LONG RAW.
- Indexes that are defined against virtual columns are equivalent to function-based indexes in PostgreSQL.
- Table statistics must be gathered.

Tools

- pgAdmin 4 is an open source management tool for PostgreSQL. This tool provides a graphical interface that simplifies the creation, maintenance, and use of database objects.
- Oracle SQL Developer is a free, integrated development environment for working with SQL in Oracle databases in both traditional and cloud deployments.

Epics

Create source and target database tables

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a source Oracle Database table.</td>
<td>In Oracle Database, create a table with virtual generated columns by using the following statement.</td>
<td>DBA, App developer</td>
</tr>
</tbody>
</table>

```
CREATE TABLE test.generated_column
(CODE NUMBER,
STATUS VARCHAR2(12) DEFAULT 'PreOpen',
FLAG CHAR(1) GENERATED ALWAYS AS (CASE UPPER(STATUS) WHEN 'OPEN' THEN 'N' ELSE 'Y' END)
VIRTUAL VISIBLE);
```

In this source table, the data in the STATUS column is migrated through AWS DMS to the target database. The FLAG column, however, is populated by using generate by functionality, so this column isn't visible to AWS DMS during migration. To implement the functionality of generated by, you must use triggers and functions in the target database to populate the values in the FLAG column, as shown in the next epic.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a target PostgreSQL table on AWS. | Create a PostgreSQL table by using the following statement.  

```sql
CREATE TABLE test.generated_column  
  (code integer not null,  
  status character varying(12) not null,  
  flag character(1)  
);
```

In this table, the `status` column is a standard column. The `flag` column will be a generated column based on the data in the `status` column. | DBA, App developer |
|-----------------|------------------|

**Create a trigger function to handle the virtual column in PostgreSQL**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a PostgreSQL trigger. | In PostgreSQL, create a trigger.  

```sql
CREATE TRIGGER tgr_gen_column  
AFTER INSERT OR UPDATE OF status ON  
test.generated_column  
FOR EACH ROW  
EXECUTE FUNCTION  
test.tgf_gen_column();
```

DBA, App developer |
|-----------------|------------------|

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a PostgreSQL trigger function. | In PostgreSQL, create a function for the trigger. This function populates a virtual column that is inserted or updated by the application or AWS DMS, and validates the data.  

```sql
CREATE OR REPLACE FUNCTION  
test.tgf_gen_column()  
RETURNS trigger AS $VIRTUAL_COL$  
BEGIN  
IF (TG_OP = 'INSERT') THEN  
IF (NEW.flag IS NOT NULL) THEN  
    RAISE EXCEPTION 'ERROR: cannot insert into column "flag"' USING DETAIL = 'Column "flag" is a generated column.';  
END IF;  
END IF;  
IF (TG_OP = 'UPDATE') THEN  
```

DBA, App developer |
Migrate virtual generated columns from Oracle to PostgreSQL

<table>

<tr>
<td>Amazon S3; Amazon Aurora</td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

As part of your migration journey from Oracle to Amazon Aurora PostgreSQL-Compatible Edition on the Amazon Web Services (AWS) Cloud, you might encounter multiple challenges. For example, migrating code that relies on the Oracle UTL_FILE utility is always a challenge. In Oracle PL/SQL, the UTL_FILE package is used for file operations, such as read and write, in conjunction with the underlying operating system. The UTL_FILE utility works for both server and client machine systems.

Amazon Aurora PostgreSQL-Compatible is a managed database offering. Because of this, it isn’t possible to access files on the database server. This pattern walks you through the integration of Amazon Simple Storage Service (Amazon S3) and Amazon Aurora PostgreSQL-Compatible to achieve a subset of UTL_FILE functionality. Using this integration, we can create and consume files without using third-party extract, transform, and load (ETL) tools or services.

Optionally, you can set up Amazon CloudWatch monitoring and Amazon SNS notifications.

We recommend thoroughly testing this solution before implementing it in a production environment.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- AWS Database Migration Service (AWS DMS) expertise
- Expertise in PL/pgSQL coding
- An Amazon Aurora PostgreSQL-Compatible cluster
• An S3 bucket

Limitations

This pattern doesn't provide the functionality to act as a replacement for the Oracle UTL_FILE utility. However, the steps and sample code can be enhanced further to achieve your database modernization goals.

Product versions

• Amazon Aurora PostgreSQL-Compatible Edition 11.9

Architecture

Target technology stack

• Amazon Aurora PostgreSQL-Compatible
• Amazon CloudWatch
• Amazon Simple Notification Service (Amazon SNS)
• Amazon S3

Target architecture

The following diagram shows a high-level representation of the solution.

1. Files are uploaded from the application into the S3 bucket.
2. The aws_s3 extension accesses the data, using PL/pgSQL, and uploads the data to Aurora PostgreSQL-Compatible.
Tools

- **Amazon Aurora PostgreSQL-Compatible** – Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine. It combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases.

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. With only one tool to download and configure, you can control multiple AWS services from the command line and automate them through scripts.

- **Amazon CloudWatch** – Amazon CloudWatch monitors Amazon S3 resources and use.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. In this pattern, Amazon S3 provides a storage layer to receive and store files for consumption and transmission to and from the Aurora PostgreSQL-Compatible cluster.

- **aws_s3** – The aws_s3 extension integrates Amazon S3 and Aurora PostgreSQL-Compatible.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients. In this pattern, Amazon SNS is used to send notifications.

- **pgAdmin** – pgAdmin is an open-source management tool for Postgres. pgAdmin 4 provides a graphical interface for creating, maintaining, and using database objects.

Code

To achieve the required functionality, the pattern creates multiple functions with naming similar to `UTL_FILE`. The **Additional information** section contains the code base for these functions.

In the code, replace `testaurorabucket` with the name of your test S3 bucket. Replace `us-east-1` with the AWS Region where your test S3 bucket is located.

**Additional information**

**Set up IAM policies**

Create the following policies.

<table>
<thead>
<tr>
<th>Policy name</th>
<th>JSON</th>
</tr>
</thead>
</table>
Set up Oracle UTL_FILE functionality on Amazon Aurora

**S3IntRead**

```
{  
  "Version": "2012-10-17",
  "Statement": [
    
    "Sid": "S3integrationtest",
    "Effect": "Allow",
    "Action": [
      "s3:GetObject",
      "s3:ListBucket"
    ],
    "Resource": [
      "arn:aws:s3:::testaurorabucket/*",
      "arn:aws:s3:::testaurorabucket"
    ]
  ]
}
```

**S3IntWrite**

```
{  
  "Version": "2012-10-17",
  "Statement": [
    
    "Sid": "S3integrationtest",
    "Effect": "Allow",
    "Action": [
      "s3:PutObject",
      "s3:ListBucket"
    ],
    "Resource": [
      "arn:aws:s3:::testaurorabucket/*",
      "arn:aws:s3:::testaurorabucket"
    ]
  ]
}
```

**Create the init function**

To initialize common variables, such as bucket or region, create the `init` function by using the following code.

```sql
CREATE OR REPLACE FUNCTION utl_file_utility.init()
RETURNS void
LANGUAGE 'plpgsql'
COST 100
VOLATILE
AS $BODY$
BEGIN
  perform set_config
  ( format( '%s.%s', 'UTL_FILE.Utility', 'region' )
    , 'us-east-1':text
    , false );

  perform set_config
  ( format( '%s.%s', 'UTL_FILE.Utility', 's3bucket' )
    , 'testaurorabucket':text
    , false );
END;
```

1226
Create the wrapper functions

Create the fopen, put_line, and fclose wrapper functions.

fopen

```sql
CREATE OR REPLACE FUNCTION utl_file_utility.fopen(

Test your setup and wrapper functions

Use the following anonymous code blocks to test your setup.

Test the write mode

The following code writes a file named s3inttest in the S3 bucket.

do $$
declare
  l_file_name varchar := 's3inttest';
l_path varchar := 'integration_test';
l_mode char(1) := 'W';
l_fs utl_file_utility.file_type;
l_status boolean;
begin
  select * from
    utl_file_utility.fopen( l_file_name, l_path , l_mode ) into l_fs ;
  raise notice 'fopen : l_fs : %', l_fs;

  select * from
    utl_file_utility.put_line( l_file_name, l_path ,'this is test file:in s3bucket: for test purpose', l_mode ) into l_status ;
  raise notice 'put_line : l_status %', l_status ;

  select * from utl_file_utility.fclose( l_file_name , l_path ) into l_status ;
  raise notice 'fclose : l_status %', l_status ;
end;
Test the append mode

The following code appends lines onto the s3inttest file that was created in the previous test.

```sql
do $$
declare
l_file_name varchar := 's3inttest' ;
l_path varchar := 'integration_test' ;
l_mode char(1) := 'A';
l_fs utl_file_utility.file_type ;
l_status boolean;
begin
select * from utl_file_utility.fopen( l_file_name, l_path , l_mode ) into l_fs ;
raise notice 'fopen : l_fs : %', l_fs;
select * from utl_file_utility.put_line( l_file_name, l_path ,'this is test file:in s3bucket: for test purpose : append 1', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;
select * from utl_file_utility.put_line( l_file_name, l_path ,'this is test file:in s3bucket : for test purpose : append 2', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;
select * from utl_file_utility.fclose( l_file_name , l_path ) into l_status ;
raise notice 'fclose : l_status %', l_status;
end;
$$
```

Amazon SNS notifications

Optionally, you can set up Amazon CloudWatch monitoring and Amazon SNS notifications on the S3 bucket. For more information, see [Monitoring Amazon S3](#) and [Setting up Amazon SNS Notifications](#).

Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL

Created by Venkatramana Chynthia (AWS)

<td></td>
</tr>
</tbody>
</table>
Summary

This pattern describes a step-by-step approach to validate objects after migrating an Oracle database to Amazon Aurora PostgreSQL-Compatible Edition.

This pattern outlines usage scenarios and steps for database object validation; for more detailed information, see Validating database objects after migration using AWS SCT and AWS DMS on the AWS Database blog.

Prerequisites and limitations

Prerequisites:

• An active AWS account.
• An on-premises Oracle database that was migrated to an Aurora PostgreSQL-Compatible database.
• An AWS Identity and Access Management (IAM) user with an AmazonRDSDataFullAccess policy for the Aurora PostgreSQL-Compatible database.
• This pattern uses the query editor for Aurora Serverless DB clusters, which is available in the Amazon Relational Database Service (Amazon RDS) console. However, you can use this pattern with any other query editor.

Limitations:

• Oracle SYNONYM objects are not available in PostgreSQL but can be partially validated through views or SET search_path queries.
• The Amazon RDS query editor is available only in certain AWS Regions and for certain MySQL and PostgreSQL versions.

Architecture

Tools

Tools
• **Amazon Aurora PostgreSQL-Compatible Edition** – Aurora PostgreSQL-Compatible is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases.

• **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

• **Query Editor for Aurora Serverless** – Query editor helps you run SQL queries in the Amazon RDS console. You can run any valid SQL statement on the Aurora Serverless DB cluster, including data manipulation and data definition statements.

To validate the objects, use the full scripts in the "Object validation scripts" file in the “Attachments” section. Use the following table for reference.

<table>
<thead>
<tr>
<th>Oracle object</th>
<th>Script to use</th>
</tr>
</thead>

AWS services: AWS CloudFormation; AWS Managed Services; AWS Systems Manager; Amazon S3
Summary

On the Amazon Web Services (AWS) Cloud, AWS Managed Services (AMS) uses AMS workload ingest (WIGS) to move existing workloads into an AMS managed VPC. This pattern describes a solution to automate common pre-workload ingestion activities, such as upgrading .NET and Windows PowerShell and running Windows WIGS pre-ingestion validation maintained by AMS. The pattern also provides a unified user interface for the run results. It packages an AWS Systems Manager Command document, which performs the pre-ingestion activities, into an AWS CloudFormation template. The template can be deployed repeatedly without requiring access to Systems Manager itself or conflicting with automations from AMS.

Business background

Migrations to AMS require the provision of new Amazon Elastic Compute Cloud (Amazon EC2) instances using AMS managed Amazon Machine Images (AMIs) that include AMS components. Any workloads or applications running in existing data centers must be redeployed to fresh EC2 instances launched from these AMS AMIs. To avoid the potentially massive amount of manual work during the process, the AMS team built the AMS workload ingest (WIGS) workflow to onboard your custom images to AMS.

Windows instances must satisfy a few prerequisites before the WIGS process takes place. Windows PowerShell scripts are usually used to perform the necessary preparations (WIGS prep) and check if the instances are ready for WIGs (WIGS pre-ingestion validation). The prep and validation processes require an engineer to spend 15–30 minutes on each server, manually logging in and running the scripts one by one.

Business driver

Traditionally, using Systems Manager, you can automate operational tasks such as running Windows PowerShell scripts. However, because of elevated risks and frequent conflicts between automations from AMS and those from the users, AMS does not usually grant its users access to Systems Manager.

For mass migrations using AWS Application Migration Service (AWS MGN), Windows PowerShell scripts in the C:\Program Files (x86)\AWS Replication Agent\post_launch folder usually run automatically when a test or cutover instance is launched. However, these scripts, if run immediately during an instance launch, frequently conflict with automations from AMS. As a result, the launch might fail without providing the run results that you need to troubleshoot the failure.

This pattern tackles these problems and provides a working automated solution.

Prerequisites and limitations

Prerequisites

- An active AWS account with AMS onboarding completed.
- An Amazon Simple Storage Service (Amazon S3) bucket in the AWS account. If there is no S3 bucket over which you have control in the account, use a request for change (RFC) to create one.
- The PreWIGs_CFN.json template downloaded from the ams-auto-prewigs-windows repository.
- A server to which you apply this pattern must meet the following requirements:
  - Run Windows Server 2012 or later.
  - Be launched or ready to launch in the sandbox VPC migration subnet.
  - Have an AWS Systems Manager Agent (SSM Agent) installed.
  - Have an AWS Identity and Access Management (IAM) instance profile attached. The instance profile must have permissions to download files from S3 buckets in the same AWS account. An instance profile that satisfies the above-mentioned requirement is usually already established during earlier setups of a migration.
  - Be viewable from AWS Systems Manager Fleet Manager.
Limitations

- Pre-WIGS activities vary depending on your environment and business requirements. You might need to make minor modifications to this pattern to suit your specific needs.

Product versions

Architecture

The architecture diagram shows the following:

1. A sandbox VPC with a migration subnet containing servers that have not been prepped.
2. The S3 bucket that stores scripts that are used by the CloudFormation template.
3. The CloudFormation template deploys the Systems Manager Command document. The process iterates until the steps complete.
4. The instances are prepped and RFCs for WIGS are made.
5. In the AMS managed VPC, the AMS managed subnet contains the servers after workload ingestion.

How it works

- This pattern is packaged into an AWS CloudFormation template that allows infrastructure as code (IaC) repeatable deployments. You need to deploy this template only one time for each AWS account that requires this automation.
- The automation is applied to all EC2 instances with a tag key AutoPreWIGs in the AWS account where this pattern is deployed. The first time an Amazon EC2 Windows instance with the tag key AutoPreWIGs starts, the automation performs the following tasks.
1. Upgrades Windows PowerShell to version 5.1 and .NET to version 4.5.2. The instance might reboot several times, depending on its existing Windows PowerShell and .NET versions. After each reboot, the upgrades continue until they are complete. This step uses embedded code in the CloudFormation template modified from a Windows PowerShell script, as well as specific Systems Manager guidance on server reboots.

2. Downloads from Amazon S3 and runs a Windows PowerShell script that you have customized to prepare the Amazon EC2 Windows instance for WIGS. For more information see the Epics section.

3. Installs the Windows WIGS pre-ingestion validation PowerShell module from AWS.

4. Runs the Windows WIGS pre-ingestion validation and makes the results viewable in Systems Manager State Manager.

**Tools**

- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources. You can use a CloudFormation template to automate deployment of the resources in this pattern.

- **AWS Managed Services** – AWS Managed Services (AMS) is an enterprise service that provides ongoing management of your AWS infrastructure. Changes made to the infrastructure in an AMS environment must be made through an RFC.

- **AWS Systems Manager** – AWS Systems Manager (formerly known as SSM) is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources. This pattern uses Systems Manager to run and view the run results of the pre-WIGS activities.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance. This pattern uses Amazon S3 to store the CloudFormation template and a Windows PowerShell script that is downloaded.

Create an approval process for firewall requests during a rehost migration to AWS

Created by Srikanth Rangavajhala (AWS)

**R Type:** Rehost  **Environment:** Production  **Technologies:** Migration

**Source:** On premises  **Target:** AWS Cloud

**Summary**

If you want to use AWS Application Migration Service or Cloud Migration Factory on AWS for a rehost migration to the Amazon Web Services (AWS) Cloud, one of the prerequisites is that you must keep TCP ports 443 and 1500 open. Typically, opening these firewall ports requires approval from your information security (InfoSec) team.

This pattern outlines the process to obtain a firewall request approval from an InfoSec team during a rehost migration to the AWS Cloud. You can use this process to avoid rejections of your firewall request by the InfoSec team, which can become expensive and time consuming. The firewall request process has two review and approval steps between AWS migration consultants and leads who work with your InfoSec and application teams to open the firewall ports.

This pattern assumes that you are planning a rehost migration with AWS consultants or migration specialists from your organization. You can use this pattern if your organization doesn't have a firewall approval process or firewall request blanket approval form. For more information about this, see the Limitations section of this pattern. For more information on network requirements for Application Migration Service, see Network requirements in the Application Migration Service documentation.

Prerequisites and limitations

Prerequisites

- A planned rehost migration with AWS consultants or migration specialists from your organization
- The required port and IP information to migrate the stack
- Existing and future state architecture diagrams
- Firewall information about the on-premises and destination infrastructure, ports, and zone-to-zone traffic flow
- A firewall request review checklist (attached)
- A firewall request document, configured according to your organization's requirements
- A contact list for the firewall reviewers and approvers, including the following roles:
  - Firewall request submitter – AWS migration specialist or consultant. The firewall request submitter can also be a migration specialist from your organization.
  - Firewall request reviewer – Typically, this is the single point of contact (SPOC) from AWS.
  - Firewall request approver – An InfoSec team member.

Limitations

- This pattern describes a generic firewall request approval process. Requirements can vary for individual organizations.
- Make sure that you track changes to your firewall request document.

The following table shows the use cases for this pattern.

<table>
<thead>
<tr>
<th>Does your organization have an existing firewall approval process?</th>
<th>Does your organization have an existing firewall request form?</th>
<th>Suggested action</th>

### Ingest and migrate EC2 Windows instances into an AWS Managed Services account

*Created by Anil Kunapareddy (AWS) and Venkatramana Chintha (AWS)*
**Summary**

This pattern explains the step-by-step process of migrating and ingesting Amazon Elastic Compute Cloud (Amazon EC2) Windows instances into an Amazon Web Services (AWS) Managed Services (AMS) account. AMS can help you manage the instance more efficiently and securely. AMS provides operational flexibility, enhances security and compliance, and helps you optimize capacity and reduce costs.

This pattern starts with an EC2 Windows instance that you have migrated to a staging subnet in your AMS account. A variety of migration services and tools are available to perform this task, such as AWS Application Migration Service or AWS Server Migration Service (SMS).

To make a change to your AMS-managed environment, you create and submit a request for change (RFC) for a particular operation or action. Using an AMS workload ingest (WIGS) RFC, you ingest the instance into the AMS account and create a custom Amazon Machine Image (AMI). You then create the AMS-managed EC2 instance by submitting another RFC to create an EC2 stack. For more information, see [AMS Workload Ingest](#) in the AMS documentation.

**Prerequisites and limitations**

**Prerequisites**

- An active, AMS-managed AWS account
- An existing landing zone
- An AWS Identity and Access Management (IAM) user with permissions to make changes in the AMS-managed VPC
- An Amazon EC2 Windows instance in a staging subnet in your AMS account
- Completion of the [general prerequisites](#) for migrating workloads using AMS WIGS
- Completion of the [Windows prerequisites](#) for migrating workloads using AMS WIGS

**Limitations**

- This pattern is for EC2 instances operating Windows Server. This pattern doesn’t apply to instances running other operating systems, such as Linux.

**Architecture**

**Source technology stack**

Amazon EC2 Windows instance in a staging subnet in your AMS account

**Target technology stack**

Amazon EC2 Windows instance managed by AWS Managed Services (AMS)
Ingest EC2 Windows instances into an AMS account

Target architecture

Tools

AWS services

- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
AWS Prescriptive Guidance Patterns
Ingest EC2 Windows instances into an AMS account

- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
- **AMS** – AWS Managed Services (AMS) helps you to operate your cloud-based infrastructure more efficiently and securely by providing ongoing management of your Amazon Web Services (AWS) infrastructure, including monitoring, incident management, security guidance, patch support, and backup for AWS workloads.

Other services

- **PowerShell** – PowerShell is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.

Migrate SAP workloads to an SAP database on Amazon EC2 using Application Migration Service

Created by Pavel Rubin (AWS) and Diego Valverde (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Source:</th>
<th>On-premises SAP ASE database</th>
<th>Target:</th>
<th>SAP database on Amazon EC2</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

Summary

This pattern outlines the steps for migrating SAP workloads from an SAP source database to an SAP target database on Amazon Elastic Compute Cloud (Amazon EC2) by using AWS Application Migration Service. Application Migration Service facilitates cutovers by maintaining replication volumes that continually sync from their sources using block-level replication.

SAP workloads include SAP Customer Relationship Management (CRM), SAP Enterprise Resource Planning (ERP), and SAP S/4HANA.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An SAP Adaptive Server Enterprise (ASE) source database for Linux or Windows in an on-premises data center

Limitations

- The target operating system must be supported by Amazon EC2; for more information, see Amazon EC2 FAQs.

Product versions

- SAP ASE version 15.7 and later

Architecture

Source technology stack

- An SAP ASE database

Target technology stack

- Amazon EC2
- Amazon Elastic Block Store (Amazon EBS)
Source and target architecture

The following diagram shows migration from the on-premises servers through the Replication Agent to the Application Migration Service endpoint. An Amazon Simple Storage Service (Amazon S3) endpoint is used to access installation and configuration files. The subnets for the staging area and the migrated resources contain EC2 instances, with data storage on EBS volumes. Port TCP 443 is used to connect the source machine network to Application Migration Service, and to connect the staging area subnets to the Application Migration Service, Amazon EC2, and Amazon S3 Regional endpoints. Port TCP 1500 is used for data replication between the local network and the staging area.

Tools

- **AWS Application Migration Service** helps you rehost (lift-and-shift) applications to the AWS Cloud without change and with minimal downtime.
- **Amazon Elastic Block Store (Amazon EBS)** provides block-level storage volumes for use with Amazon EC2 instances.

Epics

Initialize Application Migration Service

<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialize Application Migration Service.</td>
<td>Initialize Application Migration Service in the AWS Region where you want to deploy the SAP ASE database. AWS provides an automated setup the first.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
## Migrate SAP workloads by using Application Migration Service

### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>time that you navigate to the Application Migration Service page in each Region.</td>
<td></td>
</tr>
</tbody>
</table>

Manually create service roles.  
(Optional) If you want to use automation (for example, AWS Control Tower) to set up the account, you can manually create the six AWS Identity and Access Management (IAM) roles that are required for installation, replication, and launches. For instructions, see the [AWS documentation](https://aws.amazon.com/documentation/).  
AWS administrator

Create a Replication Settings template.  
The Replication Settings template defines the subnet, instance type, Amazon Elastic Block Store (Amazon EBS) encryption, and how data is routed. For detailed settings information, see the [AWS documentation](https://aws.amazon.com/documentation/).  
General AWS

### Generate credentials for Agent installation

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a new IAM user.</td>
<td>On the IAM console, navigate to <strong>Users</strong>, choose <strong>Add user</strong>, assign the user a name, and then set <strong>Programmatic access</strong>.</td>
<td>AWS systems administrator</td>
</tr>
</tbody>
</table>

Attach `AWSApplicationMigrationAgentPolicy` to the IAM user.  
The AWS managed `AWSApplicationMigrationAgentPolicy` policy contains the necessary permissions to perform Application Migration Service Agent installation.  
AWS systems administrator

Save your AWS access key ID and secret access key.  
The access key ID and secret access key are used during agent installation.

Summary

This pattern walks you through the steps for rehosting (“lift-and-shift”) an on-premises Linux server by migrating it to a supported Amazon Elastic Compute Cloud (Amazon EC2) Linux instance, using AWS Server Migration Service (AWS SMS).

For information about migrating databases (such as Oracle) that are associated with the servers and applications you are migrating, see the database migration patterns in this catalog.

Prerequisites and limitations

Prerequisites

General requirements:
- You must have an active AWS account.
- Disable any antivirus or intrusion detection software on the virtual machine (VM).
- Disconnect any CD-ROM drives (virtual or physical) connected to the VM.

Linux VMs:
- Enable Secure Shell (SSH) for remote access, and enable host firewall access to SSH.
- Make sure that your Linux VM uses GRUB (GRUB legacy) or GRUB 2 as its bootloader.
- The root volume of your Linux VM must use one of the following file systems: ext2, ext3, ext4, Btrfs, JFS, XFS.
Hardware requirements:

- VMware vCenter version 5.5 or higher (validated up to 6.5)
- ESXi 5.1 or higher (validated up to 6.5)
- Minimum 4 GB RAM
- Minimum available disk storage of 20 GB (thin-provisioned) or 250 GB (thick-provisioned)

Software requirements:

- If VMware vCenter Server is configured to use a non-default port, enter the vCenter hostname and port, separated by a colon (for example, HOSTNAME: PORT or IP: PORT) in the vCenter Service Account page in Connector setup.
- Make sure that your system supports the following network services (you might need to reconfigure your firewall to permit stateful outbound connections from the connector to these services):
  - Domain Name System (DNS) - Allow the connector to initiate connections to port 53 for name resolution.
  - HTTPS on vCenter - Allow the connector to initiate secure web connections to port 443 of vCenter. You can also configure a non-default port at your discretion.
  - HTTPS on ESXi - Allow the connector to initiate secure web connections to port 443 of the ESXi hosts that contain the VMs you intend to migrate.
  - Internet Control Message Protocol (ICMP) - Allow the connector to initiate connections using ICMP.
  - Network Time Protocol (NTP) - The connector must be able to reach a time server on port 123.
- Allow outbound connections from the connector to the following URL ranges:
  - *.amazonaws.com
  - *.aws.amazon.com
  - *.ntp.org (optional; used only to validate that connector time is in sync with NTP)

For additional information, see AWS SMS Requirements in the AWS SMS documentation.

Linux licensing options:

When you create a new replication job, the AWS SMS console provides a License type option that provides these values:

- Auto (default) - Detects the source system operating system (OS) and applies the appropriate license to the migrated VM.
- AWS - Replaces the source system license with an AWS license, if appropriate, on the migrated VM.
- BYOL - Retains the source system license, if appropriate, on the migrated VM.

If you choose a license type that is incompatible with your VM, the replication job fails with an error message.

Linux operating systems support only BYOL licenses, so if you choose Auto (the default), AWS SMS will use a BYOL license.

Migrated Red Hat Enterprise Linux (RHEL) VMs must use Cloud Access (BYOL) licenses. For more information, see Red Hat Cloud Access on the Red Hat website.

Migrated SUSE Linux Enterprise Server (SLES) VMs must use SUSE Public Cloud Program (BYOS) licenses. For more information, see SUSE Public Cloud Program—Bring Your Own Subscription on the SUSE website.

Limitations
• The migration source must be a VMware server. The use of AWS SMS is limited as follows:
  • 50 concurrent VM migrations per account
  • 90 days of service usage per VM (not per account), beginning with the initial replication of a VM
• The target operating system must be supported by Amazon EC2. Supported systems include RHEL, SLES, CentOS, Ubuntu, Oracle Linux, Fedora, and Debian Linux. RHEL 6.0 is not supported. For a complete list, see Amazon EC2 FAQs.
• Linux/Unix (64-bit) volume types and file systems: MBR-partitioned volumes that are formatted using the ext2, ext3, ext4, Btrfs, JFS, or XFS file system.
• For operating system licensing policies and limitations, see AWS SMS Requirements.
• AWS SMS partially supports vMotion, Storage vMotion, and other features based on virtual machine migration, with the following limitations:
  • Migrating a virtual machine to a new ESXi host or datastore after one replication run ends, and before the next replication run begins, is supported as long the Server Migration Connector’s vCenter service account has sufficient permissions on the destination ESXi host, datastores, and data center, and on the virtual machine itself at the new location.
  • Migrating a virtual machine to a new ESXi host, datastore, or data center while a replication run is active—that is, while a virtual machine upload is in progress—is not supported.
  • Cross vCenter vMotion is not supported for use with AWS SMS.

Architecture

Source technology stack
On-premises application/web servers:
• Red Hat Enterprise Linux (RHEL)
• SUSE Linux Enterprise Server (SLES)
• CentOS
• Ubuntu
• Oracle Linux
• Fedora
• Debian Linux

Target technology stack
EC2 instances running the following operating systems (supporting migrations from the same system on premises):
• RHEL
• SLES
• CentOS
• Ubuntu
• Oracle Linux
• Fedora
• Debian Linux

Target architecture
Tools

AWS SMS - AWS Server Migration Service (AWS SMS) automates the migration of virtual machines to AWS. It provides the following features:

- **Automated migration of an on-premises VMware server fleet to the AWS Cloud.**
- **Incremental replication of VMs to Amazon Machine Images (AMIs).** AWS SMS transfers only the delta to the cloud, so you can test small changes iteratively and save network bandwidth.
- **Multi-server migration to AWS, including scheduling and periodic replication for a group of servers.**

To migrate VMs, you need to set up the AWS Server Migration Connector in your on-premises virtualization environment. To deploy the Server Migration Connector, choose **Get Started** from the AWS SMS console.

- **Schedule the connector download.** The connector is an OVA image that's nearly 10 GB in size, so it could take a long time to download, depending on the speed of your internet connection. We recommend that you schedule an appropriate time to download the appliance, based on your connection speed and traffic priority. The downloaded OVA should be made available to vCenter for later deployment. For step-by-step instructions, see the [AWS SMS documentation](#).
- **Create a vCenter account.** The connector requires a vCenter service account with (at the minimum) Create Snapshot and Delete Snapshot permissions on VMs that you plan to migrate to AWS. We recommend that you create a service account that has access only to the vCenter data centers and ESXi hosts, folders, and datastores that you plan to migrate.
- **Create an IAM user.** The connector requires AWS Identity and Access Management (IAM) credentials to communicate with AWS. Use the following AWS CloudFormation template to create an IAM user with the `ServerMigrationConnector` AWS managed policy attached. After you create the IAM user, navigate to the IAM console and search for the IAM user `ServerMigrationServiceConnector`. Create an IAM access key for this user, and then download and save the access key securely. The credential will be used in the connector configuration.

```yaml
AWSTemplateFormatVersion: '2010-09-09' Description: |

# Copyright 2017 Amazon.com, Inc. or its affiliates. All Rights Reserved.
# Licensed under the Amazon Software License (the "License").
# You may not use this file except in compliance with the License. A copy of the License is located at
# http://aws.amazon.com/asl/
# or in the "license" file accompanying this file. This file is
# distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
# CONDITIONS OF ANY KIND, express or implied. See the License
```
Create an IAM role. AWS SMS requires a service role to access AWS resources. Use the following AWS CloudFormation template to create a service role.

```yaml
AWSTemplateFormatVersion: '2010-09-09' Description: |

# Copyright 2017 Amazon.com, Inc. or its affiliates. All Rights Reserved.
# Licensed under the Amazon Software License (the "License").
# You may not use this file except in compliance with the
# License. A copy of the License is located at
# http://aws.amazon.com/asl/
# or in the "license" file accompanying this file. This file is
distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR
CONDITIONS OF ANY KIND, express or implied. See the License
for the specific language governing permissions and
limitations under the License.

# IAM Role for AWS Server Migration Service (SMS)

Resources:
smsRole:
  Properties:
  AssumeRolePolicyDocument:
    Version: '2012-10-17'
    Statement:
      - Sid: SmsServiceRoleAssumeRolePolicyDocument
        Effect: Allow
        Principal:
          Service: sms.amazonaws.com
        Action: sts:AssumeRole
        Condition:
          StringEquals:
            sts:ExternalId: sms
          RoleName: sms
    Type: AWS::IAM::Role
  policy:
    Properties:
      Description: IAMManagedPolicyForSmsServiceRole
    PolicyDocument:
      Version: '2012-10-17'
      Statement:
        - Sid: SmsServiceRolePolicyDocument
          Effect: Allow
          Resource: "*"
          Action:
          - ec2:ModifySnapshotAttribute
```
**Plan your firewall configurations.** When the connector operates, it needs to connect to in-scope vCenter and ESXi hosts on the HTTPS port (443), NTP servers, DNS servers, and AWS endpoints that have the patterns *.amazonaws.com and *.aws.amazon.com. Please plan your network configurations, including IP allocation, firewall change, and monitoring updates. You might need to submit change requests to get approvals for these changes in your organization.

**Prepare storage space and VM resources.** When deploying the connector, the appliance requires 20 GB of disk space and 8 GB of RAM at the minimum. The disk in each connector may grow up to 250 GB if you choose thin provisioning, so make sure that your VMware storage has this capacity.

**Install additional connectors if necessary.** If you’re migrating multiple data centers, we recommend that you install at least one connector in each data center. For step-by-step installation instructions, see the AWS SMS documentation. For information about configuring vCenter, see the blog post [AWS Server Migration Service – Server Migration to the Cloud Made Easy](https://aws.amazon.com/blogs/migration-service/aws-server-migration-service-server-migration-to-the-cloud-made-easy/).

**Validate after installation.** After deploying the connector, verify the registration by signing in to the AWS Management console and opening the AWS SMS console. You should see the connector registered on the Connectors page.

### Migrate an F5 BIG-IP workload to F5 BIG-IP VE on the AWS Cloud

*Created by Will Bauer (AWS)*

<table>
<thead>
<tr>
<th>Source: F5 BIG-IP TMOS 13.1 and later</th>
<th>Target: F5 BIG-IP VE on AWS</th>
<th>R Type: Rehost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment: Production</td>
<td>Technologies: Migration; Security, identity, compliance; Networking</td>
<td>Workload: All other workloads</td>
</tr>
</tbody>
</table>

### Summary

Organizations are looking to migrate to the Amazon Web Services (AWS) Cloud to increase their agility and resilience. After you migrate your F5 BIG-IP security and traffic management solutions to the AWS Cloud, you can focus on agility and adoption of high-value operational models across your enterprise architecture.

This pattern describes how to migrate an F5 BIG-IP workload to an F5 BIG-IP Virtual Edition (VE) workload on the AWS Cloud. The workload will be migrated by rehosting the existing environment and deploying aspects of replatforming, such as service discovery and API integrations. [AWS CloudFormation templates](#) accelerate your workload’s migration to the AWS Cloud.

This pattern is intended for technical engineering and architectural teams that are migrating F5 security and traffic management solutions, and accompanies the guide [Migrating from F5 BIG-IP to F5 BIG-IP VE on the AWS Cloud](#) on the AWS Prescriptive Guidance website.

### Prerequisites and limitations

#### Prerequisites

- An existing on-premises F5 BIG-IP workload.
Existing F5 licenses for BIG-IP VE versions.

An active AWS account.

An existing virtual private cloud (VPC) configured with an egress through a NAT gateway or Elastic IP address, and configured with access to the following endpoints: Amazon Simple Storage Service (Amazon S3), Amazon Elastic Compute Cloud (Amazon EC2), AWS Security Token Service (AWS STS), and Amazon CloudWatch. You can also modify the Modular and scalable VPC architecture Quick Start as a building block for your deployments.

One or two existing Availability Zones, depending on your requirements.

Three existing private subnets in each Availability Zone.

AWS CloudFormation templates, available in the F5 GitHub repository.

During the migration, you might also use the following, depending on your requirements:

- An F5 Cloud Failover Extension to manage Elastic IP address mapping, secondary IP mapping, and route table changes.
- If you use multiple Availability Zones, you will need to use the F5 Cloud Failover Extensions to handle the Elastic IP mapping to virtual servers.
- You should consider using F5 Application Services 3 (AS3), F5 Application Services Templates (FAST), or another infrastructure as code (IaC) model to manage the configurations. Preparing the configurations in an IaC model and using code repositories will help with the migration and your ongoing management efforts.

Expertise

- This pattern requires familiarity with how one or more VPCs can be connected to existing data centers. For more information about this, see Network-to-Amazon VPC connectivity options in the Amazon VPC documentation.
- Familiarity is also required with F5 products and modules, including Traffic Management Operating System (TMOS), Local Traffic Manager (LTM), Global Traffic Manager (GTM), Access Policy Manager (APM), Application Security Manager (ASM), Advanced Firewall Manager (AFM), and BIG-IQ.

Product versions

- We recommend that you use F5 BIG-IP version 13.1 or later, although the pattern supports F5 BIG-IP version 12.1 or later.

Architecture

Source technology stack

- F5 BIG-IP workload

Target technology stack

- Amazon CloudFront
- Amazon CloudWatch
- Amazon EC2
- Amazon S3
- Amazon VPC
- AWS Global Accelerator
- AWS STS
- AWS Transit Gateway
- F5 BIG-IP VE

Target architecture

Tools

- **AWS CloudFormation** – AWS CloudFormation helps you to create and provision AWS infrastructure deployments predictably and repeatedly.

- **Amazon CloudFront** - CloudFront speeds up distribution of your static and dynamic web content, such as .html, .css, .php, image, and media files.

- **Amazon CloudWatch** – CloudWatch provides a reliable, scalable, and flexible monitoring solution that you can start using within minutes.

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity for you to build and host your software systems.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you’ve defined.

- **AWS Identity and Access Management (IAM)** – IAM is a web service for securely controlling access to AWS services.

- **AWS Landing Zone** – AWS Landing Zone is a solution that helps customers quickly set up a secure, multi-account AWS environment based on AWS best practices.

- **AWS STS** – AWS Security Token Service (AWS STS) is a web service that helps you request temporary, limited-privilege credentials for IAM users or for users that you authenticate (federated users).

- **AWS Transit Gateway** – AWS Transit Gateway is a highly available and scalable service to consolidate the Amazon VPC routing configuration for a Region with a hub-and-spoke architecture.

Migrate an on-premises Go web application to AWS Elastic Beanstalk by using the binary method

Created by Suhas Basavaraj (AWS)

<table>
<thead>
<tr>
<th>R Type: Rehost</th>
<th>Source: Applications</th>
<th>Target: Elastic Beanstalk</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Websites &amp; web apps; Migration</td>
</tr>
<tr>
<td>AWS services: AWS Elastic Beanstalk</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to migrate an on-premises Go web application to AWS Elastic Beanstalk. After the application is migrated, Elastic Beanstalk builds the binary for the source bundle and deploys it to an Amazon Elastic Compute Cloud (Amazon EC2) instance.

As a rehost migration strategy, this pattern's approach is fast and requires no code changes, which means less testing and migration time.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An on-premises Go web application.
- A GitHub repository that contains your Go application’s source code. If you do not use GitHub, there are other ways to create an application source bundle for Elastic Beanstalk.

Product versions

- The most recent Go 1.14.x version supported by Elastic Beanstalk. For more information, see the “Related resources” section.

Architecture

Source technology stack

- An on-premises Go web application

Target technology stack

- AWS Elastic Beanstalk
- Amazon CloudWatch
Tools

- AWS Elastic Beanstalk – AWS Elastic Beanstalk quickly deploys and manages applications in the AWS Cloud without users having to learn about the infrastructure that runs those applications. Elastic Beanstalk reduces management complexity without restricting choice or control.
- GitHub – An open-source distributed version control system.

Epics

Create the Go web application source bundle .zip file

<table>

Migrate an on-premises SFTP server to AWS using AWS Transfer for SFTP

Created by Akash Kumar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Source:</th>
<th>Storage</th>
<th>Target:</th>
<th>Amazon S3</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Rehost</td>
<td>Technologies:</td>
<td>Migration; Storage &amp; backup; Websites &amp; web apps</td>
<td>AWS services:</td>
<td>Amazon S3; AWS Transfer Family; Amazon CloudWatch Logs</td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to migrate an on-premises file transfer solution that uses the Secure Shell (SSH) File Transfer Protocol (SFTP) to the Amazon Web Services (AWS) Cloud by using the AWS Transfer for SFTP service. Users generally connect to an SFTP server either through its domain name or by fixed IP. This pattern covers both cases.

AWS Transfer for SFTP is a member of the AWS Transfer Family. It is a secure transfer service that you can use to transfer files into and out of AWS storage services over SFTP. You can use AWS Transfer for SFTP with Amazon Simple Storage Service (Amazon S3) or Amazon Elastic File System (Amazon EFS). This pattern uses Amazon S3 for storage.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing SFTP domain name or fixed SFTP IP.
Limitations

- The data files to be transferred must be smaller than 5 TB in size. For files over 5 TB, you can perform a multipart upload to Amazon S3 or choose another data transfer method.

Architecture

Source technology stack

- On-premises flat files or database dump files

Target technology stack

- AWS Transfer for SFTP
- Amazon S3
- Amazon Virtual Private Cloud (Amazon VPC)
- AWS Identity and Access Management (IAM) roles and policies
- Elastic IP addresses
- Security groups
- Amazon CloudWatch Logs (optional)

Target architecture
AWS Prescriptive Guidance Patterns

Automation and scale

To automate the target architecture for this pattern, use the attached AWS CloudFormation templates:

- `amazon-vpc-subnets.yml` provisions a virtual private cloud (VPC) with two public and two private subnets.
- `amazon-sftp-server.yml` provisions the SFTP server.
- `amazon-sftp-customer.yml` adds users.

Tools

AWS services

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses Amazon S3 as the storage system for file transfers.
• **AWS Transfer for SFTP** – AWS Transfer for SFTP is a service in the AWS Transfer Family. It enables you to transfer files into and out of AWS storage services over SFTP.

• **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

• **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you define. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

• **Amazon CloudWatch Logs** – Amazon CloudWatch Logs centralizes the logs from all your systems, applications, and AWS services that you use. You can view and monitor the logs, search them for specific error codes or patterns, filter them based on specific fields, or archive them securely for future analysis.

## Epics

### Create a VPC

</tr>
</thead>
<tbody>
<tr>
<td>Create a VPC with subnets.</td>
<td>Open the Amazon VPC console at <a href="https://console.aws.amazon.com/vpc/">https://console.aws.amazon.com/vpc/</a>. Create a virtual private cloud (VPC) with two public subnets. (The second subnet provides high availability.) —or— You can deploy the attached CloudFormation template, amazon-vpc-subnets.yml, in the CloudFormation console to automate the tasks in this epic.</td>
<td>Developer, Systems administrator</td>
</tr>
<tr>
<td>Add an internet gateway.</td>
<td>Provision an internet gateway and attach it to the VPC.</td>
<td>Developer, Systems administrator</td>
</tr>
<tr>
<td>Migrate an existing IP.</td>
<td>Attach an existing IP to the Elastic IP address. You can create an Elastic IP address from your address pool and use it.</td>
<td>Developer, Systems administrator</td>
</tr>
</tbody>
</table>

### Provision an SFTP server

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an SFTP server.</td>
<td>Open the AWS Transfer Family console at <a href="https://console.aws.amazon.com/transfer/">https://console.aws.amazon.com/transfer/</a>. Follow the instructions in Create an internet-facing</td>
<td>Developer, Systems administrator</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>endpoint for your server in the AWS Transfer Family documentation to create an SFTP server with an internet-facing endpoint. For <strong>Endpoint type</strong>, choose <strong>VPC hosted</strong>. For <strong>Access</strong>, choose <strong>Internet Facing</strong>. For <strong>VPC</strong>, choose the VPC you created in the previous epic. —or— You can deploy the attached CloudFormation template, amazon-sftp-server.yml, in the CloudFormation console to automate the tasks in this epic.</td>
<td>Developer, Systems administrator</td>
<td></td>
</tr>
<tr>
<td>Migrate the domain name.</td>
<td>Attach the existing domain name to the custom hostname. If you’re using a new domain name, use the Amazon Route 53 DNS alias. For an existing domain name, choose <strong>Other DNS</strong>. For more information, see Working with custom hostnames in the AWS Transfer Family documentation.</td>
<td>Developer, Systems administrator</td>
</tr>
<tr>
<td>Add a CloudWatch logging role.</td>
<td>(Optional) if you want to enable CloudWatch logging, create a Transfer role with the CloudWatch Logs API operations <code>logs:CreateLogGroup</code>, <code>logs:CreateLogStream</code>, <code>logs:DescribeLogStreams</code>, and <code>logs:PutLogEvents</code>. For more information, see Log activity with CloudWatch in the AWS Transfer Family documentation.</td>
<td>Developer, system admin</td>
</tr>
<tr>
<td>Save and submit.</td>
<td>Choose <strong>Save</strong>. For <strong>Actions</strong>, choose <strong>Start</strong> and wait for the SFTP server to be created with the status <strong>Online</strong>.</td>
<td>Developer, Systems administrator</td>
</tr>
<tr>
<td><strong>Map Elastic IP addresses to the SFTP server</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Stop the server so you can modify settings.</td>
<td>On the AWS Transfer Family console, choose <strong>Servers</strong>, and then select the SFTP server you created. For <strong>Actions</strong>, choose <strong>Stop</strong>. When the server is offline,</td>
<td>Developer, system admin</td>
</tr>
</tbody>
</table>
### Choose Availability Zones and subnets.

In the **Availability Zones** section, choose the Availability Zones and subnets for your VPC.

**Skills required:** Developer, Systems administrator

### Add Elastic IP addresses.

For **IPv4 Addresses**, choose an Elastic IP address for each subnet, and then choose **Save**.

**Skills required:** Developer, Systems administrator

## Add users

### Create an IAM role for users to access the S3 bucket.

Create a IAM role for Transfer and add `s3:ListBucket`, `s3:GetBucketLocation`, and `s3:PutObject` with the S3 bucket name as a resource. For more information, see [Create an IAM role and policy](https://docs.aws.amazon.com/transfer/latest/userguide/iam_create_role.html) in the AWS Transfer Family documentation.

— or —

You can deploy the attached CloudFormation template, `amazon-sftp-customer.yml`, in the CloudFormation console to automate the tasks in this epic.

**Skills required:** Developer, Systems administrator

### Create an S3 bucket.

Create a S3 bucket for the application.

**Skills required:** Developer, Systems administrator

### Create optional folders.

(Optional) If you want to store files for users separately, in specific Amazon S3 folders, add folders as appropriate.

**Skills required:** Developer, Systems administrator

### Create an SSH public key.

To create an SSH key pair, see [Generate SSH keys](https://docs.aws.amazon.com/transfer/latest/userguide/generate_ssh_keys.html) in the AWS Transfer Family documentation.

**Skills required:** Developer, Systems administrator

### Add users.

On the **AWS Transfer Family console**, choose **Servers**, select the SFTP server you created, and then choose **Add user**. For **Home directory**, choose the S3 bucket you created. For **SSH public key**, specify the public key portion of the SSH key pair. Add users for the SFTP server, and then choose **Add**.

**Skills required:** Developer, Systems administrator
## Test the SFTP server

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update the security group.</td>
<td>In the <strong>Security Groups</strong> section of your SFTP server, add your test machine's IP to gain SFTP access.</td>
<td>Developer</td>
</tr>
<tr>
<td>Use an SFTP client utility to test the server.</td>
<td>Test file transfers by using any SFTP client utility. For a list of clients and instructions, see <a href="https://docs.aws.amazon.com/transfer/latest/userguide/">Transferring files using a client in the AWS Transfer Family documentation</a>.</td>
<td>Developer</td>

## Migrate small sets of data from on premises to Amazon S3 using AWS SFTP

*Created by Charles Gibson (AWS)*

<table>
<thead>
<tr>
<th>R Type: Rehost</th>
<th>Source: Storage</th>
<th>Target: Amazon S3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: Production</td>
<td>Technologies: Storage &amp; backup; Migration</td>
</tr>
</tbody>
</table>

**AWS services:** Amazon S3

## Summary
This pattern describes how to migrate small sets of data (5 TB or less) from on-premises data centers to Amazon Simple Storage Service (Amazon S3) by using AWS Transfer for SFTP (AWS SFTP). The data can be either database dumps or flat files.

## Prerequisites and limitations

**Prerequisites**
• An active AWS account
• An AWS Direct Connect link established between your data center and AWS

Limitations
• The data files must be less than 5 TB. For files over 5 TB, you can perform a multipart upload to Amazon S3 or choose another data transfer method.

Architecture

Source technology stack
• On-premises flat files or database dumps

Target technology stack
• Amazon S3

Source and target architecture

Tools
• AWS SFTP – Enables the transfer of files directly into and out of Amazon S3 using Secure File Transfer Protocol (SFTP).
• AWS Direct Connect – Establishes a dedicated network connection from your on-premises data centers to AWS.
• VPC endpoints – Enable you to privately connect a VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink without an internet gateway, network address translation (NAT) device, VPN connection, or AWS Direct Connect connection. Instances in a VPC don't require public IP addresses to communicate with resources in the service.
## Epics

### Prepare for the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document the current SFTP requirements.</td>
<td></td>
<td>Application owner, SA</td>
</tr>
<tr>
<td>Identify the authentication requirements.</td>

## Migrate from Oracle GlassFish to AWS Elastic Beanstalk

*Created by Sandeep Bondugula (AWS)*
Summary

This pattern describes how to migrate a Java application running on an on-premises Oracle GlassFish server to AWS Elastic Beanstalk in the AWS Cloud.

On AWS, the Java application is deployed on a Docker GlassFish server with AWS Elastic Beanstalk, which runs in an Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group.

Additional features:

- Amazon Elastic Beanstalk acts as a wrapper for several underlying resources. It sets up Elastic Load Balancing (which handles incoming traffic from Amazon Route 53), disperses the traffic to one or more EC2 instances, and also serves as a deployment tool.
- To migrate an on-premises database to Amazon Relational Database Service (Amazon RDS), update the database connection details. In the backend database, you can configure Amazon RDS Multi-AZ deployments and choose the database engine type.
- You can use Multi-AZ deployment for high availability along with the Auto Scaling group and scaling policy to improve resiliency.
- You can set up a scaling policy based on Amazon CloudWatch metrics.
- In AWS Elastic Beanstalk, you can configure the underlying Elastic Load Balancing settings and Amazon EC2 Auto Scaling.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An on-premises Java application running on GlassFish
- A Java Web Application Resource (WAR) file

Product versions

- Oracle Glassfish 4.1.2 and 5.0
- Java 7 GlassFish 4.0
- Java 8 GlassFish 4.1 or later

Architecture

Source technology stack

- Applications developed in GlassFish
Target technology stack

- Elastic Beanstalk

Target architecture

Deployment workflow
**Tools**

- **Amazon Elastic Beanstalk** – A service for deploying and scaling web applications and services developed with Java, .NET, PHP, Node.js, Python, Ruby, Go, and Docker on servers including Apache, NGINX, Passenger, and IIS.

- **Amazon CloudWatch** – Provides data and actionable insights to monitor applications, responds to systemwide performance changes, optimizes resource utilization, and provides a unified view of operational health.

- **Docker** – A platform that packages software into standardized units to build, test, and deploy applications quickly.

- **Java** – A general-purpose programming language. Java is class-based, object-oriented, and designed to have fewer implementation dependencies.

Migrate an on-premises Oracle database to Oracle on Amazon EC2

Created by Baji Shaik (AWS) and Pankaj Choudhary (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Databases: Relational</th>
<th>Target: Oracle on Amazon EC2</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Rehost</td>
<td>Workload: Oracle</td>
<td>Technologies: Migration; Databases</td>
</tr>
<tr>
<td>AWS services: Amazon EC2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern walks you through the steps for migrating an on-premises Oracle database to Oracle on an Amazon Elastic Compute Cloud (Amazon EC2) instance. It describes two options for migration: using AWS Data Migration Service (AWS DMS) or using native Oracle tools such as RMAN, Data Pump import/export, transportable tablespaces, and Oracle GoldenGate.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle database in an on-premises data center

Limitations

- The target operating system (OS) must be supported by Amazon EC2. For a complete list of supported systems, see Amazon EC2 FAQs.

Product versions

- Oracle versions 10.2 and later (for versions 10.x), 11g and up to 12.2, and 18c for the Enterprise, Standard, Standard One, and Standard Two editions. For the latest list of versions supported by AWS DMS, see “On-premises and Amazon EC2 instance databases” in Sources for Data Migration in the AWS DMS documentation.
Architecture

Source technology stack

- An on-premises Oracle database

Target technology stack

- An Oracle database instance on Amazon EC2

Target architecture

Data migration architecture

Using AWS DMS:
Using native Oracle tools:
Tools

- **AWS DMS** - AWS Database Migration Services (AWS DMS) supports several types of source and target databases. For information about the database versions and editions that are supported, see *Using an Oracle Database as a Source for AWS DMS*. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

- **Native Oracle tools** - RMAN, Data Pump import/export, transportable tablespaces, Oracle GoldenGate

Migrate an on-premises Oracle database to Amazon EC2 by using Oracle Data Pump

Created by Navakanth Talluri (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: On-premises Oracle database</th>
<th>Target: Oracle database on Amazon EC2</th>
</tr>
</thead>
<tbody>

<tr>
<td>AWS services: Amazon EC2; AWS Direct Connect</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

When migrating databases, you must consider factors such as the source and target database engines and versions, migration tools and services, and acceptable downtime periods. If you're migrating an on-premises Oracle database to Amazon Elastic Compute Cloud (Amazon EC2), you can use Oracle tools, such as Oracle Data Pump and Oracle Recovery Manager (RMAN). For more information about strategies, see Migrating Oracle databases to the AWS Cloud.

Oracle Data Pump helps you extract the logical, consistent backup of the database and restore it to the target EC2 instance. This pattern describes how to migrate an on-premises Oracle database to an EC2 instance by using Oracle Data Pump, with minimal downtime.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• An on-premises Oracle database that:
  • Isn't an Oracle Real Application Clusters (RAC) database
  • Isn't an Oracle Automatic Storage Management (Oracle ASM) database
  • Is in read-write mode.
• You have created an AWS Direct Connect link between your on-premises data center and AWS. For more information, see Create a connection (Direct Connect documentation).

Product versions

• Oracle Database 10g release 1 (10.1) and later

Architecture

Source technology stack

Non-RAC and non-ASM Oracle database in an on-premises data center
**Target technology stack**

Primary and standby Oracle databases on EC2 instances

**Target architecture**

In this pattern, you use an Oracle Active Data Guard configuration to set up primary and standby databases on EC2 instances. For high availability, the EC2 instances should be in different Availability Zones. However, the Availability Zones can be in the same AWS Region or in different AWS Regions.

Active Data Guard provides read-only access to a physical standby database and applies redo changes continuously from the primary database. Based on your recovery point objective (RPO) and recovery time objective (RTO), you can choose between synchronous and asynchronous redo transport options.

The following image shows the target architecture if the primary and standby EC2 instances are in different AWS Regions.

![Target architecture diagram](image)

**Data migration architecture**

After you have finished setting up the target architecture, you use Oracle Data Pump to migrate the on-premises data and schemas to the primary EC2 instance. During cutover, applications can’t access the on-premises database or the target database. You shut down these applications until they can be connected to the new target database on the primary EC2 instance.

The following image shows the architecture during the data migration. In this sample architecture, the primary and standby EC2 instances are in different AWS Regions.
Tools

AWS services

- **AWS Direct Connect** links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.

- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

Other tools and services

- **Oracle Active Data Guard** helps you create, maintain, manage, and monitor standby databases.
- **Oracle Data Pump** helps you move data and metadata from one database to another at high speeds.

Epics

Set up the EC2 instances on AWS

Summary
This pattern describes how to migrate an SAP Adaptive Server Enterprise (ASE) database from an on-premises host to an Amazon Elastic Compute Cloud (Amazon EC2) instance. The pattern covers the use of AWS Database Migration Service (AWS DMS) or SAP ASE native tools such as ASE Cockpit, Sybase Central for ASE, and DBA Cockpit for migration.

Prerequisites and limitations

Prerequisites
- An active AWS account
• An SAP ASE source database in an on-premises data center

**Limitations**

• The source database must be less than 64 TB

**Product versions**

• SAP ASE version 15.x and 16.x or later

**Architecture**

**Source technology stack**

• On-premises SAP ASE database

**Target technology stack**

• SAP ASE database on an EC2 instance

**Database migration architecture**

*Using AWS DMS:*

*Using native SAP ASE tools:*
Tools

- **AWS DMS** - AWS Data Migration Service (AWS DMS) supports several different source and target databases. For more information, see Sources for Data Migration and Targets for Data Migration. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

- **SAP ASE** - Native tools include ASE Cockpit, Sybase Central for ASE, and DBA Cockpit.

Epics

Analyze the migration

Summary

This pattern describes how to migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on an Amazon Elastic Compute Cloud (Amazon EC2) instance. It covers two options for migration: using AWS Data Migration Service (AWS DMS) or using native Microsoft SQL Server tools such as backup and restore, Copy Database Wizard, or copy and attach database.

Prerequisites and limitations

Prerequisites

- An active AWS account
• An operating system supported by Amazon EC2 (for a complete list of supported operating system versions, see Amazon EC2 FAQs)
• A Microsoft SQL Server source database in an on-premises data center

Product versions
• Microsoft SQL Server versions 2005, 2008, 2008R2, 2012, 2014, 2016, and 2017 for the Enterprise, Standard, Workgroup, and Developer editions, if you’re using AWS DMS. To migrate Microsoft SQL Server Web or Express edition, use native or third-party tools. For the latest list of supported versions, see Using a Microsoft SQL Server Database as a Target for AWS DMS.

Architecture

Source technology stack
• On-premises Microsoft SQL Server database

Target technology stack
• Microsoft SQL Server database on an EC2 instance

Target architecture

Data migration architecture
• Using AWS DMS
AWS Prescriptive Guidance Patterns
Migrate from SQL Server to Amazon EC2

- Using native SQL Server tools
Tools

- **AWS DMS - AWS Data Migration Service** (AWS DMS) helps you migrate your data to and from widely used commercial and open-source databases, including Oracle, SQL Server, MySQL, and PostgreSQL. You can use AWS DMS to migrate your data into the AWS Cloud, between on-premises instances (through an AWS Cloud setup), or between combinations of cloud and on-premises setups.

- **Native Microsoft SQL Server tools** - These include backup and restore, Copy Database Wizard, and copy and attach database.

### Summary

This pattern provides guidance for migrating an on-premises MySQL database to a MySQL database on an Amazon Elastic Compute Cloud (Amazon EC2) instance. The pattern discusses the use of AWS...
Database Migration Service (AWS DMS) or native MySQL tools such as `mysqldbcopy` and `mysqldump` for the migration.

**Prerequisites and limitations**

**Prerequisites**
- An active AWS account
- A MySQL source database in an on-premises data center

**Product versions**
- MySQL versions 5.5, 5.6, and 5.7
- For a list of target operating systems supported by Amazon EC2, see [Amazon EC2 FAQs](https://aws.amazon.com/ec2/faq/)

**Architecture**

**Source technology stack**
- An on-premises MySQL database

**Target technology stack**
- A MySQL database instance on Amazon EC2

**AWS data migration methods**
- AWS DMS
- Native MySQL tools (`mysqldbcopy`, `mysqldump`)

**Target architecture**
AWS data migration architecture

Using AWS DMS:
Using native MySQL tools:

**Tools**

- **AWS DMS - AWS Database Migration Service** (AWS DMS) supports several source and target databases. For information about MySQL source and target databases supported by AWS DMS, see [Migrating MySQL-Compatible Databases to AWS](#). If your source database isn't supported by AWS DMS, you must choose another method to migrate your data.

- **Native MySQL tools - mysqldbcopy and mysqldump**

Rehost on-premises workloads in the AWS Cloud: migration checklist

Created by Srikanth Rangavajhala (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: On-premises workloads</th>
<th>Target: AWS Cloud</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Rehost</td>
<td>Technologies: Migration</td>
<td>AWS services: AWS Application Migration Service</td>
</tr>
</tbody>
</table>

Summary

Rehosting on-premises workloads in the Amazon Web Services (AWS) Cloud involves the following migration phases: planning, pre-discovery, discovery, build, test, and cutover. This pattern outlines the phases and their related tasks. The tasks are described at a high level and support about 75% of all application workloads. You can implement these tasks over two to three weeks in an agile sprint cycle.

You should review and vet these tasks with your migration team and consultants. After the review, you can gather the input, eliminate or re-evaluate tasks as necessary to meet your requirements, and modify other tasks to support at least 75% of the application workloads in your portfolio. You can then use an agile project management tool such as Atlassian Jira or Rally Software to import the tasks, assign them to resources, and track your migration activities.

The pattern assumes that you’re using AWS Cloud Migration Factory to rehost your workloads, but you can use your migration tool of choice.

Prerequisites and limitations

Prerequisites

- Project management tool for tracking migration tasks (for example, Atlassian Jira or Rally Software)
- Migration tool for rehosting your workloads on AWS (for example, Cloud Migration Factory)

Architecture

Source platform
- On-premises source stack (including technologies, applications, databases, and infrastructure)

**Target platform**

- AWS Cloud target stack (including technologies, applications, databases, and infrastructure)

**Architecture**

The following diagram illustrates rehosting (discovering and migrating servers from an on-premises source environment to AWS) by using Cloud Migration Factory and AWS Application Migration Service.
Tools

- You can use a migration and project management tool of your choice.

Epics

Planning phase

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Groom the pre-discovery backlog.</td>
<td>Conduct the pre-discovery backlog grooming working session with department leads and application owners.</td>
<td>Project manager, Agile scrum leader</td>
</tr>
<tr>
<td>Conduct the sprint planning working session.</td>
<td>As a scoping exercise, distribute the applications that you want to migrate across sprints and waves.</td>
<td>Project manager, Agile scrum leader</td>
</tr>
</tbody>
</table>

Pre-discovery phase

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confirm application knowledge.</td>
<td>Confirm and document the application owner and their knowledge of the application. Determine whether there's another point person for technical questions.</td>
<td>Migration specialist (interviewer)</td>
</tr>
<tr>
<td>Determine application compliance requirements.</td>
<td>Confirm with the application owner that the application doesn't have to comply with requirements for Payment Card Industry Data Security Standard (PCI DSS), Sarbanes-Oxley Act (SOX), personally identifiable information (PII), or other standards. If compliance requirements exist, teams must finish their compliance checks on the servers that will be migrated.</td>
<td>Migration specialist (interviewer)</td>
</tr>
<tr>
<td>Confirm production release requirements.</td>

Summary

This guide provides query examples and steps to help you extract data from your on-premises infrastructure and applications by using BMC Discovery. The pattern shows you how to use BMC Discovery queries to scan your infrastructure and extract software, service, and dependency information. The extracted data is required for the assess and mobilize phases of a large-scale migration to the Amazon Web Services (AWS) Cloud. You can use this data to make critical decisions about which applications to migrate together as part of your migration plan.

Prerequisites and limitations

Prerequisites

- A license for BMC Discovery (formerly BMC ADDM) or the software as a service (SaaS) version of BMC Helix Discovery
- On-premises or SaaS version of BMC Discovery, installed **Note:** For on-premises versions of BMC Discovery, you must install the application on a client network with access to all networking and server devices that are in scope for a migration across multiple data centers. Access to the client network...
must be provided according to application installation instructions. If the scanning of Windows Server information is required, then you must set up a Windows proxy manager device in the network.)

- **Networking access** to allow the application to scan devices across data centers, if you’re using BMC Helix Discovery

**Product versions**

- BMC Discovery 21.05 (12.2)
- BMC Discovery 20.08 (12.1)
- BMC Discovery 20.02 (12.0)
- BMC Discovery 11.3
- BMC Discovery 11.2
- BMC Discovery 11.1
- BMC Discovery 11.0
- BMC Atrium Discovery 10.2
- BMC Atrium Discovery 10.1
- BMC Atrium Discovery 10.0

**Architecture**

The following diagram shows how asset managers can use BMC Discovery queries to scan a BMC-modeled application in both SaaS and on-premises environments:

The diagram shows the following workflow: An asset manager uses BMC Discovery or BMC Helix Discovery to scan database and software instances running on virtual servers hosted on multiple physical servers. The tool can model applications with components spanning multiple virtual and physical servers.

**Technology stack**

- BMC Discovery
- BMC Helix Discovery
Tools

- **BMC Discovery** is a data center discovery tool that helps you automatically discover your data center.
- **BMC Helix Discovery** is a SaaS-based discovery and dependency modeling system that helps you dynamically model your data assets and their dependencies.

Epics

**Identify and evaluate discovery tooling**

Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication

_Created by Durga Prasad Cheepuri (AWS)_

<table>
<thead>
<tr>
<th>R Type: Relocate</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon RDS for Oracle</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Databases; Migration</td>

<td>Workload: Oracle</td>
<td>AWS services: Amazon RDS</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern walks you through the steps for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle source database to a different AWS account and AWS Region. The pattern uses a DB snapshot for a one-time full data load, and enables AWS Database Migration Service (AWS DMS) for ongoing replication.

Prerequisites and limitations

Prerequisites

- An active AWS account that contains the source Amazon RDS for Oracle database, which has been encrypted using a non-default AWS Key Management Service (AWS KMS) key
- An active AWS account in a different AWS Region from the source database, to use for the target Amazon RDS for Oracle database
- Virtual private cloud (VPC) peering between the source and target VPCs
- Familiarity with using an Oracle database as a source for AWS DMS
- Familiarity with using an Oracle database as a target for AWS DMS

Product versions

- Oracle versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c. For the latest list of supported versions and editions, see Using an Oracle Database as a Source for AWS DMS and with
Using an Oracle database as a target for AWS DMS in the AWS documentation. For Oracle versions supported by Amazon RDS, see Oracle on Amazon RDS.

Architecture

Source and target technology stacks

- Amazon RDS for Oracle DB instance

Ongoing replication architecture

Tools

Tools used for one-time full data load:

- **Amazon RDS DB snapshot** - Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot
a name so you can restore from it later. The amount of time it takes to create a snapshot varies with the size of your databases. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot. For more information about using DB snapshots, see Creating a DB Snapshot in the Amazon RDS documentation.

- **KMS key for Amazon RDS encryption** - When you create an encrypted DB instance, you can also supply the KMS key identifier for your encryption key. If you don't specify a KMS key identifier, Amazon RDS uses your default encryption key for your new DB instance. AWS KMS creates your default encryption key for your AWS account. Your AWS account has a different default encryption key for each AWS Region. For this pattern, the Amazon RDS DB instance should be encrypted using the non-default KMS key. For more information about using KMS keys for Amazon RDS encryption, see Encrypting Amazon RDS Resources in the Amazon RDS documentation.

**Tools used for ongoing replication:**

- **AWS DMS** - This pattern uses AWS DMS to replicate ongoing changes and to keep the source and target databases in sync. For more information about using AWS DMS for ongoing replication, see Working with an AWS DMS Replication Instance in the AWS DMS documentation.

Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX

Created by Handan Selamoglu (AWS) and Deepak Kumar (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Networking</th>
<th>Target: VMware Cloud on AWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Relocate</td>
<td>Technologies: Migration; Infrastructure</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes the use of VMware Hybrid Cloud Extension (HCX) to migrate your on-premises virtual machines (VMs) and applications to VMware Cloud on Amazon Web Services (AWS). The migration uses VMware enterprise-class software-defined data center (SDDC) software on the AWS Cloud to provide optimized access to AWS services.

VMware Cloud on AWS integrates compute, storage, and network virtualization products (vSphere, vSAN, and VMware NSX) with VMware vCenter server management, which is optimized to run on dedicated, elastic, bare-metal AWS infrastructure. The resulting infrastructure is low-maintenance, simplified, and hyper-converged.

With this service, IT teams can manage their cloud-based resources with familiar VMware tools. For more information, see VMware Cloud on AWS on the VMware website.

VMware HCX supports three types of cloud migrations:

• **Hybridity (data center extension):** Extending an existing, on-premises VMware SDDC to AWS to provide footprint expansion, on-demand capacity, a testing/development environment, and virtual desktops.

• **Cloud evacuation (data center-wide infrastructure refresh):** Consolidating data centers and moving completely to the AWS Cloud (including handling data center co-location or end of lease).

• **Application-specific:** Moving individual applications to the AWS Cloud to meet specific business needs.

Prerequisites and limitations

Prerequisites

• Sign up for an AWS account (required for VMware Cloud SDDC creation).
• Sign up for a My VMware account. Register at https://my.vmware.com/web/vmware/ and fill out all fields.
• Check the version of vCenter and hosts, and collect the number of VMs. If possible, ask for an RVTools export to display information about your virtual environments. We recommend vCenter version 6.0 or later.
- You must deploy distributed virtual switches if you want to extend data center networks (L2), test vMotion by using HCX, or analyze application dependency by using vRealize Network Insight.
- Pick a non-conflicting on-premises current management subnet network to create the SDDC on VMware Cloud on AWS.
- Validate HCX requirements by reviewing the prerequisites provided in the *VMware HCX User Guide*.
- Identify and group VMs for waves of migration. Check for VMs that you can use for testing.
- Collect any data about relative bandwidth consumption, WAN compression, and data transfer speed.

**Notes**
- No need for VMware NSX-V or NSX-T on premises.
- No additional costs for HCX (it's included in VMware Cloud on AWS).

**Architecture**

The following diagram shows the HCX solution built on multiple component services. Each component supports a specific function in the HCX solution. For more information about each HCX component, see the blog post *Migrating Workloads to VMware Cloud on AWS with Hybrid Cloud Extension (HCX)*.

**Source technology stack**
- On-premises VMs and applications managed by VMware vSphere
Target technology stack

- VMware Cloud on AWS

Tools

- VMware HCX – VMware HCX is a tool that you can use to migrate your applications and workloads across data centers and cloud environments. It is included with VMware Cloud on AWS.

Migrate an Amazon RDS DB instance to another VPC or account

*Created by Virender Singla (AWS)*
Summary

This pattern provides guidance for migrating an Amazon Relational Database Service (Amazon RDS) DB instance from one virtual private cloud (VPC) to another in the same AWS account, or from one AWS account to another AWS account.

This pattern is useful if you want to migrate your Amazon RDS DB instances to another VPC or account for segregation or security reasons. (For example, you might want to place your application stack and database in different accounts.)

Because this migration causes database downtime, you need to plan accordingly. Migrating a DB instance to another AWS account causes more downtime than migrating it to another VPC, because taking a manual snapshot, sharing it, and restoring the snapshot to the target account takes time. Alternatively, you can use AWS Data Migration Service (AWS DMS) to minimize downtime for the change. However, this process can also be time-consuming, depending on the database changes and transaction rates.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) permissions required for the VPC, subnets, and Amazon RDS console.

Limitations

- Migrate during low peak times, because changes to a VPC cause a database reboot, resulting in application outages.
- Limitations when migrating Amazon RDS to another VPC:
  - Amazon RDS should not be in multiple Availability Zones.
  - Amazon RDS should not have any read replicas.
  - The subnet group created in the target VPC must have subnets from the Availability Zone where the source database runs.
- Limitations when migrating Amazon RDS to another AWS account:
  - Sharing snapshots encrypted with the default service key for Amazon RDS is currently not supported.

Architecture

Source technology stack

- Amazon RDS DB instances in a VPC / AWS account

Target technology stack
• Amazon RDS DB instances in another VPC / AWS account

**Tools**

• **AWS DMS** – If database downtime is a concern when migrating an Amazon RDS DB instance to another account, use **AWS Data Migration Services** (AWS DMS). This service provides data replication, which generally causes less than 5 minutes of outage time.

**Epics**

Migrate to a different VPC in the same AWS account

<table>
<thead>
<tr>

Migrate an Amazon RDS for Oracle DB instance to another VPC

Created by Pinesh Singal (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Databases: Relational</th>
<th>Target:</th>
<th>Amazon RDS for Oracle</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Relocate</td>
<td>Workload:</td>
<td>Oracle</td>
<td>Technologies: Migration; Databases</td>
<td></td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon RDS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This migration pattern provides step-by-step guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle database (DB) instance from one virtual private cloud (VPC) to another VPC in same Amazon Web Services (AWS) account. For example, you can use this pattern if your business requires that the database and the Amazon Elastic Compute Cloud (Amazon EC2) application server are in the same VPC.

The pattern describes an online migration strategy with almost no downtime for a multi-terabyte Oracle source database with a high number of transactions.

To move an Amazon RDS for Oracle DB instance to another VPC, you must change the Amazon RDS subnet group. This subnet group needs to be preconfigured with the new VPC and required subnets. During the VPC change from one network to another, the Amazon RDS instance reboots, so the database won’t be accessible while the movement is in progress.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Two VPCs with private subnets
- An Amazon RDS for Oracle database instance (up and running), configured with inbound and outbound security groups

Limitations
• A DB instance that spans multiple Availability Zones (Multi-AZ) is not supported. This pattern, however, provides a way to work around this limitation.
• The DB instance can’t be migrated while a read replica is turned on.
• The subnet group in the new VPC should be in the same Availability Zone as the database.
• Migration should occur during scheduled maintenance period or low-traffic times, because moving the DB to another VPC causes a database reboot, resulting in application outages for few minutes.

Product versions
• Amazon RDS for Oracle DB instance, 12.1.0.2 and later

Architecture

Source technology stack
• An Amazon RDS for Oracle 12.1.0.2.v22 DB instance in a VPC
• A VPC configured in a separate route table
• Amazon RDS subnet groups configured in a VPC
• Amazon RDS option groups (if needed)

Target technology stack
• Amazon RDS for Oracle database instance with version 12.1.0.2.v22 in another VPC
• Amazon VPC configured in separate route
• Amazon RDS Subnet Groups configured in new VPC
• Amazon RDS Option Groups (if needed)

Source and target architecture

The following diagram shows using the console to move the Amazon RDS for Oracle DB from a private subnet in one VPC to a private subnet in a different VPC.

1. Use the console to modify the source Amazon RDS for Oracle DB instance.
2. In the target VPC, modify the subnet group, and modify the option group if used.
**Tools**

- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks. This pattern uses Amazon RDS for Oracle.

**Epics**

**Change the configuration of the Amazon RDS for Oracle database in the existing VPC**

**Migrate an Amazon Redshift cluster to an AWS Region in China**

*Created by Jing Yan (AWS)*
Summary

This pattern provides a step-by-step approach to migrate an Amazon Redshift cluster to an AWS Region in China from another AWS Region.

This pattern uses SQL commands to recreate all the database objects, and uses the UNLOAD command to move this data from Amazon Redshift to an Amazon Simple Storage Service (Amazon S3) bucket in the source Region. The data is then migrated to an S3 bucket in the AWS Region in China. The COPY command is used to load data from the S3 bucket and transfer it to the target Amazon Redshift cluster.

Amazon Redshift doesn't currently support cross-Region features such as snapshot copying to AWS Regions in China. This pattern provides a way to work around that limitation. You can also reverse the steps in this pattern to migrate data from an AWS Region in China to another AWS Region.

Prerequisites and limitations

Prerequisites
- Active AWS accounts in both a China Region and an AWS Region outside China
- Existing Amazon Redshift clusters in both a China Region and an AWS Region outside China

Limitations
- This is an offline migration, which means the source Amazon Redshift cluster cannot perform write operations during the migration.

Architecture

Source technology stack
- Amazon Redshift cluster in an AWS Region outside China

Target technology stack
- Amazon Redshift cluster in an AWS Region in China

Target architecture
Tools

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers scalability, data availability, security, and performance. You can use Amazon S3 to store data from Amazon Redshift, and you can copy data from an S3 bucket to Amazon Redshift.

• **Amazon Redshift** – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud.

• **psql** – psql is a terminal-based front-end to PostgreSQL.

Epics

Prepare for migration in the source Region

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch and configure an EC2 instance in the source Region.</td>
<td>Sign in to the AWS Management Console and open the Amazon Elastic Compute Cloud (Amazon EC2) console. Your current Region is displayed in the navigation bar at the top of the screen. This Region cannot be an AWS Region in China. From the Amazon EC2 console dashboard, choose &quot;Launch instance,&quot; and create and configure an EC2 instance.</td>

Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport

Created by Raunak Rishabh (AWS)

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes the steps for migrating extremely large databases between two Amazon Relational Database Service (Amazon RDS) for PostgreSQL DB instances by using the pg_transport extension. This extension provides a physical transport mechanism to move each database. By streaming the database files with minimal processing, it provides an extremely fast method for migrating large
Transport PostgreSQL databases between Amazon RDS DB instances with minimal downtime. This extension uses a pull model where the target DB instance imports the database from the source DB instance.

**Prerequisites and limitations**

**Prerequisites**

- Both DB instances must run the same major version of PostgreSQL.
- The database must not exist on the target. Otherwise, the transport fails.
- No extension other than `pg_transport` must be enabled in the source database.
- All source database objects must be in the default `pg_default` tablespace.
- The security group of the source DB instance should allow traffic from the target DB instance.
- Install a PostgreSQL client like `psql` or `PgAdmin` to work with the Amazon RDS PostgreSQL DB instance. You can install the client either in your local system or use an Amazon Elastic Compute Cloud (Amazon EC2) instance. In this pattern, we use `psql` on an EC2 instance.

**Limitations**

- You can't transport databases between different major versions of RDS PostgreSQL.
- The access privileges and ownership from the source database are not transferred to the target database.
- You can't transport databases on read replicas or on parent instances of read replicas.
- You can't use `reg` data types in any database tables that you plan to transport with this method.
- You can run up to 32 total transports (including both imports and exports) at the same time on a DB instance.
- You do not have an option to rename, include/exclude tables on the go. Everything is migrated as it is.

**Caution**

- Make backups before removing the extension, because removing the extension also removes dependent objects and some data that's critical to the operation of the database.
- Consider the instance class and processes running on other database on source instance while deciding on the number of workers and `work_mem` values for `pg_transport`.

*Note: While the transport is running on one database, there is no effect of the same on the other databases.*

**Product versions**

- Amazon RDS for PostgreSQL 10.10 and later, and 11.5 and later. For the latest version information, see [Transporting PostgreSQL Databases Between DB Instances](#) in the Amazon RDS documentation.

**Tools**

- `pg_transport` extension - This extension provides a physical transport mechanism to move each database. By streaming the database files with minimal processing, physical transport moves data much faster than traditional dump and load processes and takes minimal downtime. PostgreSQL transportable databases use a pull model where the destination DB instance imports the database from the source DB instance. You install this extension on your DB instances when you prepare the source and target environments, as explained in this pattern.

Configure links between Oracle Database and Aurora PostgreSQL-Compatible

Created by Jeevan Shetty (AWS), Bhanu Ganesh Gudivada (AWS), Sushant Deshmukh (AWS), Uttiya Gupta (AWS), and Vikas Gupta (AWS)

### Summary

As part of the migration to the Amazon Web Services (AWS) Cloud, you can modernize your applications to use cloud-native databases. Migrating from Oracle Database to Amazon Aurora PostgreSQL-Compatible Edition is one such step toward modernization. As part of that migration, native Oracle database links also require conversion.

Using a database link, one database can access objects in another database. After migration from Oracle Database to Aurora PostgreSQL-Compatible, the database links from the Oracle Database server to other Oracle Database servers must be converted to PostgreSQL-to-Oracle database links.

This pattern shows how you can set up database links from an Oracle Database server to the Aurora PostgreSQL-Compatible database. Because database links are one-way, the pattern also covers converting database links from the PostgreSQL database to Oracle Database.

After migration and conversion from Oracle Database to an Aurora PostgreSQL-Compatible database, the following steps are required to set up database links between databases:

1. To set up a database link with Oracle Database as the source and Aurora PostgreSQL-Compatible as the target, Oracle Database Gateways must be configured for communication between heterogeneous databases.
2. If you are setting up a database link between Aurora PostgreSQL-Compatible version 12.6 and earlier as the source database and Oracle Database as the target, the `oracle_fdw` extension is not
available natively. Instead, you can use the `postgres_fdw` extension in the Aurora PostgreSQL-Compatible database and configure `oracle_fdw` in a PostgreSQL database created on Amazon Elastic Compute Cloud (Amazon EC2). This database acts as an intermediary between the Aurora PostgreSQL-Compatible database and Oracle Database. This pattern includes two options for setting up the database link with Aurora PostgreSQL 12.6 and earlier:

- Configure the EC2 instance in an Amazon EC2 Auto Scaling group with an Amazon EC2 startup script that updates an internal Domain Name System (DNS) entry in Amazon Route 53.
- Configure the EC2 instance in an Amazon EC2 Auto Scaling group, with a Network Load Balancer for high availability (HA).

If you are setting up a database link between Aurora PostgreSQL-Compatible version 12.7 and later, you can use the `oracle_fdw` extension.

Prerequisites and limitations

Prerequisites

- Amazon Aurora PostgreSQL-Compatible database in a virtual private cloud (VPC)
- Network connectivity between the Oracle and Aurora PostgreSQL-Compatible databases

Limitations

- Currently, database links cannot be set up with Amazon Relational Database Service (Amazon RDS) for Oracle as the source database and Aurora PostgreSQL-Compatible as the target database.

Product versions

- Oracle Database 11g and later
- Aurora PostgreSQL-Compatible 11 and later

Architecture

Source technology stack

Before migration, the source Oracle database can access objects in other Oracle databases using database links. This works natively between Oracle databases on premises or in the AWS Cloud.

Target technology stack

Option 1

- Amazon Aurora PostgreSQL-Compatible Edition
- PostgreSQL database on an Amazon EC2 instance
- Amazon EC2 Auto Scaling group
- Amazon Route 53
- Amazon Simple Notification Service (Amazon SNS)
- AWS Identity and Access Management (IAM)
- AWS Direct Connect

Option 2
Configure links between Oracle Database and Aurora

- Amazon Aurora PostgreSQL-Compatible Edition
- PostgreSQL database on an Amazon EC2 instance
- Amazon EC2 Auto Scaling group
- Network Load Balancer
- Amazon SNS
- Direct Connect

**Option 3**

- Amazon Aurora PostgreSQL-Compatible Edition
- Direct Connect

**Target architecture**

**Option 1**

The following diagram shows database link setup using the `oracle_fdw` and `postgres_fdw` extensions, with HA provided by an Amazon EC2 Auto Scaling group and Route 53.

1. An Aurora PostgreSQL-Compatible instance with the `postgres_fdw` extension connects to the PostgreSQL database on Amazon EC2.
2. The PostgreSQL database with the `oracle_fdw` extension is in an Auto Scaling group.
3. The PostgreSQL database on Amazon EC2 uses Direct Connect to connect to Oracle Database on premises.
4. Oracle Database is configured with Oracle Database Gateways for connections from Oracle Database to the PostgreSQL database on AWS.
5. IAM grants permission to Amazon EC2 to update Route 53 records.
6. Amazon SNS sends alerts for automatic scaling actions.

7. The Domain Name configured in Route 53 points to the PostgreSQL Amazon EC2 instance IP address.

**Option 2**

The following diagram shows database link setup using the **oracle_fdw** and **postgres_fdw** extensions, with HA provided by an Auto Scaling group and a Network Load Balancer.

1. An Aurora PostgreSQL-Compatible instance with the **postgres_fdw** extension connects to the Network Load Balancer.

2. The Network Load Balancer distributes the connection from the Aurora PostgreSQL-Compatible database to the PostgreSQL database on Amazon EC2.

3. The PostgreSQL database with the **oracle_fdw** extension is in an Auto Scaling group.

4. The PostgreSQL database on Amazon EC2 uses Direct Connect to connect to Oracle Database on premises.

5. Oracle Database is configured with Oracle Database Gateways for connections from Oracle Database to the PostgreSQL database on AWS.

6. Amazon SNS sends alerts for automatic scaling actions.

**Option 3**

The following diagram shows database link setup using the **oracle_fdw** extension in an Aurora PostgreSQL-Compatible database.
Configure links between Oracle Database and Aurora

1. An Aurora PostgreSQL-Compatible instance with the oracle_fdw extension uses Direct Connect to connect to Oracle Database.

2. Oracle Database Gateways set up on Oracle Server enables connectivity through Direct Connect to the Aurora PostgreSQL-Compatible database.

Tools

AWS services

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **AWS Direct Connect** links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down. In this pattern, options 1 and 2 use an EC2 instance to host a PostgreSQL database.
- **Amazon EC2 Auto Scaling** helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **Amazon Route 53** is a highly available and scalable DNS web service.
- **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- **Elastic Load Balancing (ELB)** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances,
Configure links between Oracle Database and Aurora containers, and IP addresses in one or more Availability Zones. This pattern uses a Network Load Balancer.

Other services

- Oracle Database Gateways provides Oracle Database with the ability to access data in a non-Oracle system.

Epics

Common setup tasks for Option 1 and Option 2

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an EC2 instance and configure the oracle_fdw PostgreSQL extension. | 1. Create an EC2 instance with the Amazon Linux 2 operating system.  
2. To install PostgreSQL, log in to the EC2 instance as ec2-user, and run the following commands.  

```bash
sudo su - root
sudo tee /etc/yum.repos.d/pgdg.repo<<EOF
[pgdg12]
name=PostgreSQL 12 for RHEL/CentOS 7 - x86_64
baseurl=https://download.postgresql.org/pub/repos/yum/12/redhat/rhel-7-x86_64
enabled=1
gpgcheck=0
EOF
sudo yum install -y postgresql12-server
sudo yum install postgresql12-devel
sudo /usr/pgsql-12/bin/postgresql-12-setup initdb
sudo systemctl enable postgresql-12
sudo systemctl start postgresql-12

3. Download the oracle_fdw source code from GitHub.  

```bash
mkdir -p /var/lib/pgsql/oracle_fdw/
cd /var/lib/pgsql/oracle_fdw/
wget https://github.com/laurenz/oracle_fdw/

```bash
#!/bin/bash
v_zone_id='Hosted zone ID'
v_domain_name='Domain Name'
aws route53 change-resource-record-sets
  --hosted-zone-id $v_zone_id
  --change-batch '(
    "Changes":
      ["Action":"UPSERT","ResourceRecordSet":
        {"Name":"'$v_domain_name'","Type":"A","TTL":10,"ResourceRecords":
          [{"Value":"'$v_local_ipv4'"}]
      }]
  )'
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Set up the Auto Scaling group.| 1. To set up an Auto Scaling group, use the launch template that you created in the previous step.  
2. Configure appropriate VPC and subnets that will be used to launch the EC2 instance. Option 1 setup does not use **Load Balancer**.  
3. Set the **Desired**, **Minimum**, and **Maximum** capacity to 1 under **Scaling policies**.  
4. To send alerts to the operations team, add notifications for events such as Launch or Terminate.  
5. Review the configuration, and choose **Create Auto Scaling group**.  

On completion, the Auto Scaling group starts the EC2 instance containing the `oracle_fdw` PostgreSQL extension, which connects to Oracle Database.  

**Note:** When you need to access a new Oracle table or change the structure of an Oracle table, those changes must be reflected in the PostgreSQL foreign table. After you implement the changes, you must create a new AMI of the EC2 instance and use it to configure the launch template. | Cloud administrator, DBA |
### Configure the postgres_fdw extension in the Aurora PostgreSQL-Compatible instance.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>Configure <code>postgres_fdw</code> in the Aurora PostgreSQL-Compatible instance. This connects to the PostgreSQL database on Amazon EC2, which acts as an intermediate node between the Aurora PostgreSQL-Compatible instance and Oracle Database.</td>
<td>Cloud administrator, DBA</td>
</tr>
<tr>
<td>2.</td>
<td>Connect to the Aurora PostgreSQL-Compatible instance and run the following commands.</td>
<td></td>
</tr>
</tbody>
</table>

```sql
create extension postgres_fdw;
CREATE SERVER pgoradb FOREIGN DATA WRAPPER postgres_fdw OPTIONS (dbname 'postgres', host 'Domain Name', port '5432');
CREATE USER MAPPING for pgoradb OPTIONS (user 'pguser', password '<password>');
CREATE FOREIGN TABLE data_mart.name_data(
    name_type CHARACTER VARYING(15) NOT NULL,
    name CHARACTER VARYING(45) NOT NULL
) SERVER pgoradb OPTIONS (schema_name 'public', table_name 'name_data');
select count(*) from data_mart.name_data;
```

This completes the setup of a database link from Aurora PostgreSQL-Compatible to Oracle Database.

The solution provides a disaster recovery (DR) strategy, in case the EC2 instance hosting the PostgreSQL database fails. The Auto Scaling group starts a new EC2 instance and updates the DNS with the IP address of the new EC2 instance. This ensures that the foreign tables in the Aurora PostgreSQL-
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Configure links between Oracle Database and Aurora</strong></td>
<td>Compatible instance can access the Oracle tables without manual intervention.</td>
<td></td>
</tr>
</tbody>
</table>

**Option 2: Set up a database link with the oracle_fdw and postgres_fdw extensions, an Auto Scaling group, and a Network Load Balancer**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an EC2 launch template. | 1. Create an AMI of the EC2 instance that contains the oracle_fdw PostgreSQL extension.  
2. Use the AMI to create an EC2 launch template. | Cloud administrator, DBA |
| Set up a target group, Network Load Balancer, and Auto Scaling group. | 1. To create a target group, choose **Instances** as the target type. For **Protocol**, choose TCP, and for **Port**, choose 5432. Then choose the VPC where you want the target group, and select the appropriate **Health check**.  
2. Create an internal Network Load Balancer in the VPC. Configure the load balancer to listen on protocol:port TCP:5432. Set the **Default action** as **Forward to**, and choose the target group that you created.  
3. Set up an Auto Scaling group using the launch template that you created.  
4. Configure the Auto Scaling group with the appropriate VPC and subnets that will be used to launch the EC2 instances.  
5. For the **Load Balancing** option, choose, **Attach to an existing load balancer**, and select the **Target Group** that you created. For **Health checks**, select **ELB**.  
6. Set the **Desired** and **Minimum** capacity to 2, and set the **Maximum** capacity to a higher number, as required to support the load with HA, under **Scaling policies**. | Cloud administrator, DBA |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>7.</td>
<td>To send alerts to the operations team, add notifications for events such as <strong>Launch</strong> or <strong>Terminate</strong>.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>Review the configuration, and choose <strong>Create Auto Scaling group</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

On completion, the Auto Scaling group starts the desired number of EC2 instances containing the **oracle_fdw** PostgreSQL extension that connects to Oracle Database.

**Note**: When you need to access a new Oracle table or change the structure of an Oracle table, those changes must be reflected in the PostgreSQL foreign table. After you implement the changes, you must create a new AMI of the EC2 instance and use it to configure the launch template.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the <code>postgres_fdw</code> extension in the Aurora PostgreSQL-Compatible instance.</td>
<td>Configure <code>postgres_fdw</code> in the Aurora PostgreSQL-Compatible instance. This connects to PostgreSQL Database on EC2 through a Network Load Balancer. The PostgreSQL instance on EC2 acts as an intermediate node between Aurora PostgreSQL-Compatible instance and Oracle Database. Connect to the Aurora PostgreSQL-Compatible instance and run the following commands.</td>
<td>Cloud administrator, DBA</td>
</tr>
</tbody>
</table>

```sql
create extension postgres_fdw;
CREATE SERVER pgoradb
FOREIGN DATA WRAPPER postgres_fdw OPTIONS (dbname 'postgres', host 'DNS name of Network Load Balancer', port '5432');
CREATE USER MAPPING for postgres SERVER pgoradb OPTIONS (user 'pguser', password '<password>');
CREATE FOREIGN TABLE data_mart.name_data(
    name_type CHARACTER VARYING(15) NOT NULL,
    name CHARACTER VARYING(45) NOT NULL
) SERVER pgoradb OPTIONS (schema_name 'public', table_name 'name_data');
select count(*) from data_mart.name_data;
```

This completes the setup of database link from Aurora PostgreSQL-Compatible to Oracle Database.

In case of EC2 hosting the PostgreSQL database fails, the Network Load Balancer identifies the failure and stops the traffic to failed EC2 instance. The Auto Scaling group starts a new EC2 instance and registers it with the load balancer. This ensures that after the original

### Set up Oracle Database Gateways for connectivity from on-premises Oracle Database to Aurora PostgreSQL-Compatible

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the gateway in the on-premises Oracle Database server.</td>
<td>1. As the root user, install the latest unixODBC driver manager.</td>
<td>DBA</td>
</tr>
<tr>
<td></td>
<td>sudo yum install unixODBC*</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Install the PostgreSQL ODBC driver (psql10DBC).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>sudo wget <a href="https://download.postgresql.org/pub/repos/yum/reporpms/EL-7-x86_64/pgdg-redhat-repo-latest.noarch.rpm">https://download.postgresql.org/pub/repos/yum/reporpms/EL-7-x86_64/pgdg-redhat-repo-latest.noarch.rpm</a> sudo yum install pgdg-redhat-repo-latest.noarch.rpm</td>
<td></td>
</tr>
</tbody>
</table>
### Task | Description | Skills required
--- | --- | ---
| | | 

3. Create an ODBC Data Source Name (DSN) for the driver.

The unixODBC driver manager provides the `odbcinst`, `odbc_config`, and `isql` command line utilities used to configure and test the driver. Using `odbcinst` or `odbc_config` utilities, you can locate the unixODBC driver manager files to pass driver information to create the DSN.

```bash
odbcinst -j
```

The following code shows example output.

```bash
unixODBC 2.3.1
DRIVERS............: /etc/odbcinst.ini
SYSTEM DATA SOURCES: /etc/odbc.ini
FILE DATA SOURCES..: /etc/ODBCDataSources
USER DATA SOURCES..: /root/.odbc.ini
SQLULEN Size.......: 8
SQLLEN Size........: 8
SQLSETPOSIROW Size.: 8

odbc_config --odbcini --odbcinstini
/etc/odbc.ini
/etc/odbcinst.ini
```

From the example output, you can see the `odbcinst.ini` and `odbc.ini` files. Basically, `odbcinst.ini` is a registry and configuration file for ODBC drivers in an environment, while `odbc.ini` is a registry and configuration file for ODBC DSNs. To enable the drivers, you need to modify these two files.

4. Configure the psqlODBC driver libraries in the ODBC driver file `/etc/`
## Configure links between Oracle Database and Aurora

Additional information

Although the `oracle_fdw` extension is available with Aurora PostgreSQL-Compatible version 12.7 and later, this pattern includes solutions for earlier versions of Aurora PostgreSQL-Compatible databases, because many customers support older versions of Aurora PostgreSQL-Compatible databases, and
upgrading a database involves multiple levels of application and performance testing. Also, the database link feature is extensively used, and providing options for all versions of Aurora PostgreSQL-Compatible is the objective of this article.

### Migrate ML Build, Train, and Deploy workloads to Amazon SageMaker using AWS Developer Tools

*Created by Scot Marvin (AWS)*

### Summary

This pattern provides guidance for migrating an on-premises machine learning (ML) application running on Unix or Linux servers to be trained and deployed on AWS using Amazon SageMaker. This deployment uses a continuous integration and continuous deployment (CI/CD) pipeline. The migration pattern is deployed using an AWS CloudFormation stack.

### Prerequisites and limitations

**Prerequisites**

- An active AWS account using [AWS Landing Zone](https://aws.amazon.com/landingzone/)
- [AWS Command Line Interface (AWS CLI)](https) installed and configured on your Unix or Linux server
- An ML source code repository in either GitHub, AWS CodeCommit, or Amazon Simple Storage Service (Amazon S3)

**Limitations**

- Only 300 individual pipelines can be deployed in one AWS Region.
- This pattern is intended for supervised ML workloads with train-and-deploy code in Python.

### Product versions

- Docker version 19.03.5, build 633a0ea, using Python 3.6

### Architecture

**Source technology stack**

- On-premises Linux compute instance with data on either the local file system or in a relational database
Source architecture

Target technology stack

- AWS CodePipeline deployed with Amazon S3 for data storage and Amazon DynamoDB as metadata store for tracking or logging pipeline runs

Target architecture
Application migration architecture

- Native Python package and AWS CodeCommit repository (and an SQL client, for on-premises datasets on database instance)
**Tools**

- Python
- Git
- AWS CLI – The **AWS CLI** deploys the AWS CloudFormation stack and moves data to the S3 bucket. The S3 bucket, in turn, leads to the target.

**Epics**

**Plan the migration**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate source code and datasets.</td>
<td></td>
<td>Data scientist</td>
</tr>
</tbody>
</table>
Table:

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Configure the infrastructure**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Upload the data and code**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This is required for AWS CloudFormation stack deployment.

You need the repository's branch name to deploy the AWS CloudFormation template for migration.
### Migrate the application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Follow the ML workload migration strategy.</td>
<td></td>
<td>Application owner, ML engineer</td>
</tr>
<tr>
<td>Deploy the AWS CloudFormation stack.</td>
<td>Use the AWS CLI to create the stack declared in the YAML template provided with this solution.</td>
<td>Data scientist, ML engineer</td>
</tr>
</tbody>
</table>

### Cut over

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch the application clients over to the new infrastructure.</td>
<td></td>
<td>Application owner, Data scientist, ML engineer</td>
</tr>
</tbody>
</table>

### Close the project

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Shut down the temporary AWS resources.</td>
<td>Shut down any custom resources from the AWS CloudFormation template (for example, any AWS Lambda functions that aren't being used).</td>
<td>Data scientist, ML engineer</td>
</tr>
<tr>
<td>Review and validate the project documents.</td>
<td></td>
<td>Application owner, Data scientist</td>
</tr>
<tr>
<td>Validate the results and the ML model evaluation metrics with operators.</td>
<td>Make sure that model performance matches the application users' expectations and is comparable to the on-premises state.</td>
<td>Application owner, Data scientist</td>
</tr>
<tr>
<td>Close out the project and provide feedback.</td>
<td></td>
<td>Application owner, ML engineer</td>
</tr>
</tbody>
</table>

Migrate OpenText TeamSite workloads to the AWS Cloud

Created by Battulga Purevragchaa (AWS), Michael Stewart (TBSCG), and Carlos Marruenda Molina (TBSCG)

**Environment:** Production  
**Source:** On premises  
**Target:** AWS

<table>
<thead>
<tr>
<th>R Type</th>
<th>Workload</th>
<th>Technologies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Replatform</td>
<td>All other workloads</td>
<td>Migration; Websites &amp; web apps</td>
</tr>
</tbody>
</table>

**AWS services:** Amazon EC2; Amazon RDS

**Summary**

Many OpenText Experience Platform instances are hosted on premises or on traditional hosting solutions with fixed capacity and legacy cost models. Migrating your OpenText Experience Platform workloads to the Amazon Web Services (AWS) Cloud provides additional capabilities and value by increasing your business agility and integration opportunities, in addition to reducing your overall ownership cost.

This pattern provides steps and a template to migrate OpenText TeamSite workloads to the AWS Cloud. The pattern helps you understand how to scope and budget your migration projects by providing a detailed Epics section that guides you through an OpenText TeamSite migration process.

This pattern was developed by AWS and TBSCG, an AWS Partner, and accompanies the guide Migrating OpenText TeamSite and Media Management workloads to the AWS Cloud on the AWS Prescriptive Guidance website.

**Prerequisites and limitations**

**Prerequisites**

- At least one active AWS account
- An OpenText workload hosted in an on-premises data center or on another cloud provider
- Active OpenText licenses

The migration process also requires the roles and responsibilities that are described in the following table.

<table>
<thead>
<tr>
<th>Role</th>
<th>Responsibilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sponsor</td>
<td>Internal sponsorship</td>
</tr>
<tr>
<td>Delivery manager</td>
<td>Migration delivery</td>
</tr>
<tr>
<td>Solutions architect</td>
<td>Define the current and new architecture</td>
</tr>
<tr>
<td>DevOps engineer</td>
<td>DevOps activities</td>
</tr>
</tbody>
</table>
## AWS Prescriptive Guidance Patterns

**Migrate OpenText TeamSite workloads to AWS**

<table>
<thead>
<tr>
<th>Role</th>
<th>Task/Role Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QA tester</td>
<td>System-level testing</td>
</tr>
<tr>
<td>Product owner</td>
<td>Task prioritization based on business requirements</td>
</tr>
<tr>
<td>TeamSite authors</td>
<td>Migration user acceptance testing (UAT)</td>
</tr>
<tr>
<td>TeamSite administrator</td>
<td>Migration UAT</td>
</tr>
<tr>
<td>OpenText lead</td>
<td>OpenText product specialist</td>
</tr>
<tr>
<td>OpenText developer</td>
<td>OpenText product specialist</td>
</tr>
<tr>
<td>Pricing specialist</td>
<td>AWS and OpenText licensing</td>
</tr>
<tr>
<td>IT security</td>
<td>IT security baseline</td>
</tr>
<tr>
<td>Third-party integration developer</td>
<td>Rework existing integrations</td>
</tr>
<tr>
<td>Front-end developer</td>
<td>Make changes to migrated front-end code</td>
</tr>
<tr>
<td>Database administrator</td>
<td>Database configuration</td>
</tr>
</tbody>
</table>

### Limitations

- Ensure compatibility with your target operating systems (OSs). You can use the compatibility matrix from the product release notes of the OpenText product version that you are migrating.

### Architecture

#### Source technology stack

- OpenText customer experience solutions hosted on premises or on another cloud provider:
  - OpenText TeamSite
  - OpenText LiveSite
  - OpenText Media Management
  - OpenText MediaBin

#### Target technology stack

- An OpenText Customer Experience platform hosted on the AWS Cloud and that uses the following AWS services:
  - Amazon Elastic Compute Cloud (Amazon EC2)
  - Amazon Elastic Container Service (Amazon ECS)
  - Amazon Elasticsearch Service (Amazon ES)
  - Elastic Load Balancing
  - AWS Lambda
  - Amazon API Gateway
  - Amazon Relational Database Service (Amazon RDS)
  - Amazon Elastic Block Store (Amazon EBS)
  - Amazon Simple Storage Service (Amazon S3)

### Target architecture
Tools

- **AWS Database Migration Service (AWS DMS)** – AWS DMS is a cloud service that makes it easy to migrate relational databases, data warehouses, NoSQL databases, and other types of data stores.
- **AWS Server Migration Service (AWS SMS)** – AWS SMS combines data collection tools with automated server replication to speed up the migration of on-premises servers to AWS.

Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS

Created by Sai Krishna Namburu (AWS) and Sindhusa Paturu (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Oracle Database</th>
<th>Target:</th>
<th>Aurora PostgreSQL-Compatible or Amazon RDS for PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Replatform</td>
<td>Workload:</td>
<td>Oracle; Open-source</td>
<td>Technologies:</td>
<td>Migration; Storage &amp; backup; Databases</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon Aurora; AWS DMS; Amazon S3; Amazon RDS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to split Oracle character large object (CLOB) values into individual rows in Amazon Aurora PostgreSQL-Compatible Edition and Amazon Relational Database Service (Amazon RDS) for PostgreSQL. PostgreSQL doesn't support the CLOB data type.

Tables with interval partitions are identified in the source Oracle database, and the table name, the type of partition, the interval of the partition, and other metadata are captured and loaded into the target database. You can load CLOB data that is less than 1 GB in size into target tables as text by using AWS.
AWS Prescriptive Guidance Patterns
Migrate Oracle CLOB values to individual rows in PostgreSQL

Database Migration Service (AWS DMS), or you can export the data in CSV format, load it into an Amazon Simple Storage Service (Amazon S3) bucket, and migrate it to your target PostgreSQL database.

After migration, you can use the custom PostgreSQL code that is provided with this pattern to split the CLOB data into individual rows based on the new line character identifier (CHR(10)) and populate the target table.

Prerequisites and limitations

Prerequisites
- An Oracle database table that has interval partitions and records with a CLOB data type.
- An Aurora PostgreSQL-Compatible or Amazon RDS for PostgreSQL database that has a table structure that's similar to the source table (same columns and data types).

Limitations
- The CLOB value cannot exceed 1 GB.
- Each row in the target table must have a new line character identifier.

Product versions
- Oracle 12c
- Aurora Postgres 11.6

Architecture

The following diagram shows a source Oracle table with CLOB data, and the equivalent PostgreSQL table in Aurora PostgreSQL-Compatible version 11.6.

Tools

AWS services
- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
AWS Prescriptive Guidance Patterns
Migrate Oracle CLOB values to individual rows in PostgreSQL

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

You can use the following client tools to connect to, access, and manage your Aurora PostgreSQL-Compatible and Amazon RDS for PostgreSQL databases. (These tools aren't used within this pattern.)

- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
- DBeaver is an open-source database tool for developers and database administrators. You can use the tool to manipulate, monitor, analyze, administer, and migrate your data.

Best practices

For best practices for migrating your database from Oracle to PostgreSQL, see the AWS blog post Best practices for migrating an Oracle database to Amazon RDS PostgreSQL or Amazon Aurora PostgreSQL: Migration process and infrastructure considerations.

For best practices for configuring the AWS DMS task for migrating large binary objects, see Migrating large binary objects (LOBs) in the AWS DMS documentation.

Epics

Identify the CLOB data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Analyze the CLOB data.</td>
<td>In the source Oracle database, analyze the CLOB data to see whether it contains column headers, so you can determine the method for loading the data into the target table. To analyze the input data, use the following query. SELECT * FROM clobdata_or;</td>
<td>Developer</td>
</tr>
<tr>
<td>Load the CLOB data to the target database.</td>
<td>Migrate the table that has CLOB data to an interim (staging) table in the Aurora or Amazon RDS target database. You can use AWS DMS or upload the data as a CSV file to an Amazon S3 bucket. For information about using AWS DMS for this task, see Using an Oracle database as a source and Using a PostgreSQL migration engine, DBA</td>
<td></td>
</tr>
</tbody>
</table>

### Additional information

PostgreSQL function for splitting CLOB data

---

1411
Migrate Oracle CLOB values to individual rows in PostgreSQL

```sql
do
$$
declare
totalstr varchar;
str1 varchar;
str2 varchar;
pos1 integer := 1;
pos2 integer;
len integer;

begin
    select rawdata||chr(10) into totalstr from clobdata_pg;
    len := length(totalstr);
    raise notice 'Total length : %',len;
    raise notice 'totalstr : %',totalstr;
    raise notice 'Before while loop';

    while pos1 < len loop
        select position (chr(10) in totalstr) into pos2;
        raise notice '1st position of new line : %',pos2;

        str1 := substring (totalstr,pos1,pos2-1);
        raise notice 'str1 : %',str1;

        insert into clobdatatarget(data) values (str1);
        totalstr := substring(totalstr,pos2+1,len);
        raise notice 'new totalstr :%',totalstr;
        len := length(totalstr);
    end loop;
end
$$
LANGUAGE 'plpgsql' ;
```

**Input and output examples**

You can use the following examples to try out the PostgreSQL code before you migrate your data.

Create an Oracle database with three input lines.

```sql
CREATE TABLE clobdata_or (  
id INTEGER GENERATED ALWAYS AS IDENTITY,  
rawdata clob );

insert into clobdata_or(rawdata) values (to_clob('test line 1') || chr(10) || to_clob('test line 2') || chr(10) || to_clob('test line 3') || chr(10));
COMMIT;

SELECT * FROM clobdata_or;
```

This displays the following output.

<table>
<thead>
<tr>
<th>id</th>
<th>rawdata</th>
</tr>
</thead>
</table>
|    | test line 1
|    | test line 2
|    | test line 3 |
Load the source data into a PostgreSQL staging table (clobdata_pg) for processing.

```sql
SELECT * FROM clobdata_pg;
CREATE TEMP TABLE clobdatatarget (id1 SERIAL, data VARCHAR);
```

<Run the code in the additional information section.>

```sql
SELECT * FROM clobdatatarget;
```

This displays the following output.

<table>
<thead>
<tr>
<th>id1</th>
<th>data</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>test line 1</td>
</tr>
<tr>
<td>2</td>
<td>test line 2</td>
</tr>
<tr>
<td>3</td>
<td>test line 3</td>
</tr>
</tbody>
</table>

Migrate Oracle E-Business Suite to Amazon RDS Custom

*Created by Simon Cunningham (AWS) and Nitin Saxena*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Source: Amazon EC2 or on premises</th>
<th>Target: Amazon RDS Custom</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

Oracle E-Business Suite is an Enterprise Resource Planning (ERP) solution for automating enterprise-wide processes such as financials, human resources, supply chains, and manufacturing. It has a three-tier architecture: client, application, and database. Previously, you had to run your E-Business Suite database on a self-managed Amazon Elastic Compute Cloud (Amazon EC2) instance, but you can now benefit from Amazon Relational Database Service (Amazon RDS) Custom.

**Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks and operations while making it possible for you, as a database administrator, to access and customize your database environment and operating system. When you
migrate your Oracle database to Amazon RDS Custom, Amazon Web Services (AWS) takes care of heavy lifting such as backup tasks and ensuring high availability, while you can focus on maintaining your E-Business Suite application and functionality. For key factors to consider for a migration, see Oracle database migration strategies in AWS Prescriptive Guidance.

This pattern focuses on the steps to migrate a standalone Oracle database on Amazon EC2 to Amazon RDS Custom by using an Oracle Recovery Manager (RMAN) backup and an Amazon Elastic File System (Amazon EFS) shared file system between the EC2 instance and Amazon RDS Custom. The pattern uses an RMAN full backup (sometimes referred to as a level 0 backup). For simplicity, it uses a cold backup where the application is shut down and the database is mounted and not open. (You can also use Oracle Data Guard or RMAN duplication for backup. However, this pattern doesn’t cover those options.)

For information about architecting E-Business Suite on AWS for high availability and disaster recovery, see the pattern Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database.

Prerequisites and limitations

Prerequisites

- An Oracle version 12.1.0.2 source database that is running on Amazon EC2 with Oracle Linux 7 or Red Hat Enterprise Linux (RHEL) version 7.x. This pattern assumes that the source database name is VIS, but this isn’t a requirement.

  Note: You can also use this pattern with on-premises Oracle source databases, as long as you have the appropriate network connectivity between the on-premises network and Amazon Virtual Private Cloud (Amazon VPC).

- An E-Business Suite version 12.2.11 application (vision instance).

- A single E-Business Suite application tier. However, you can adapt this pattern to work with multiple application tiers.

- Amazon RDS Custom configured with at least 16 GB swap space. Otherwise, the 12c Examples CD displays a warning.

Complete the following steps before you start your migration:

1. In the Amazon RDS console, create an Amazon RDS Custom for Oracle DB instance with a DB name called VIS (or your source database name). For instructions, see Working with Amazon RDS Custom in the AWS documentation and the Amazon RDS Custom for Oracle – New Control Capabilities in Database Environment blog post. This ensures that the database name is set to the same name as the source database. (If left blank, the EC2 instance and database name will be set to ORCL.)

2. Configure the Amazon RDS Custom DB instance with enough storage, vCPU, and memory to match the Amazon EC2 source database. To do this, you can match the Amazon EC2 instance types based on vCPU and memory.

3. Create an Amazon EFS file system and mount it on the Amazon EC2 and Amazon RDS Custom instances. For instructions, see the Integrate Amazon RDS Custom for Oracle with Amazon EFS blog post. This pattern assumes that you have mounted the EFS volume on /RMAN on both the source Amazon EC2 and target Amazon RDS Custom DB instances, and that network connectivity is possible between the source and target.

Assumptions

This pattern assumes that your application and database are using logical hostnames, which reduce the number of migration steps. You can adjust these steps to use physical hostnames, but logical hostnames reduce the complexity of the migration process. For information about the advantages of using logical hostnames, see Oracle Support Note 2246690.1 (requires an Oracle Support account).
Limitations

This pattern doesn’t support the following features and configurations:

- Setting the database `ARCHIVE_LAG_TARGET` parameter to a value outside the 60–7200 range
- Disabling the DB instance log mode (`NOARCHIVELOG`)
- Turning off the EBS-optimized attribute of the EC2 instance
- Modifying the original Amazon Elastic Block Store (Amazon EBS) volumes attached to the EC2 instance
- Adding new EBS volumes or changing the volume type from `gp2` to `gp3`
- Changing the suffix for the `LOG_ARCHIVE_FORMAT` parameter (requires `*.arc`)
- Support for the TNS file
- Changing the `control_file` location and name (it has to be `/rdsdbdata/db/VIS_X/controlfile/control-01.ctl`)

For additional information about these and other unsupported configurations, see the Amazon RDS documentation.

Product versions

For Oracle Database versions and instance classes supported by Amazon RDS Custom, see Requirements and limitations for Amazon RDS Custom for Oracle.

Architecture

The following architecture diagram represents an E-Business Suite system running in a single Availability Zone on AWS. The application tier is accessed through an Application Load Balancer, both the application and the databases are in private subnets, and the Amazon RDS Custom and Amazon EC2 database tier uses an Amazon EFS shared file system to store and access the RMAN backup files.
**Tools**

**AWS services**

- **Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks and operations while making it possible for you, as a database administrator, to access and customize your database environment and operating system.

- **Amazon Elastic File System (Amazon EFS)** is a simple, serverless, elastic file system for adding and removing files with no need for management or provisioning. This pattern uses an Amazon EFS shared file system to store and access the RMAN backup files.

- **AWS Secrets Manager** is an AWS managed service that enables you to easily rotate, manage, and retrieve database credentials, API keys, and other secret information. Amazon RDS Custom stores the key pair and database user credentials in Secrets Manager upon database creation. In this pattern, you
retrieve the database user passwords from Secrets Manager to create the RDSADMIN and ADMIN users and to change the sys and system passwords.

Other tools

- RMAN is a tool that provides backup and recovery support for Oracle databases. This pattern uses RMAN to perform a cold backup of the source Oracle database on Amazon EC2 that is restored on Amazon RDS Custom.

Best practices

- Use logical hostnames. This significantly reduces the number of post clone scripts that you need to run. For more information, see Oracle Support Note 2246690.1 (requires an Oracle Support account).
- Amazon RDS Custom uses Oracle Automatic Memory Management (AMM) by default. If you want to use the hugemem kernel, you can configure Amazon RDS Custom to use Automatic Shared Memory Management (ASMM) instead.
- Leave the memory_max_target parameter enabled by default. The framework uses this in the background to create read replicas.
- Enable Oracle Flashback Database. This feature is useful in failover (not switchover) testing scenarios to reinstate the standby.
- For database initialization parameters, customize the standard pfile that’s provided by the Amazon RDS Custom DB instance for E-Business Suite instead of using the spfile from the Oracle source database. This is because white spaces and comments cause issues when creating read replicas in Amazon RDS Custom. For more information about database initialization parameters, see Oracle Support Note 396009.1 (requires an Oracle Support account).

</tbody>
</table>
### AWS Prescriptive Guidance Patterns
#### Migrate Oracle E-Business Suite to Amazon RDS Custom

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Install the 12c Examples CD.| 1. Download the installation files from [https://edelivery.oracle.com/](https://edelivery.oracle.com/). For Oracle E-Business Suite 12.2.11 – Oracle Database 12c Release 1 (12.1.0.2), look for Examples for Linux x86-64 [V100102-01.zip](https://edelivery.oracle.com/).  
2. Create a directory to store the Examples CD.  
   
   ```bash
   $ mkdir /RMAN/12cexamples
   ```  
3. Copy the Examples CD zip file to this directory.  
   ```bash
   V100102-01.zip
   ```  
4. Change ownership to rdsdb.  
   ```bash
   $ chown -R rdsdb:rdsdb /RMAN/12cexamples
   ```  
5. As the rdsdb user, unzip the file.  
   ```bash
   $ unzip V100102-01.zip
   ```  
6. Connect from a client that has access to the VNC client and Amazon RDS Custom. Make sure that you have the necessary network connectivity and firewall ports open to allow access for VNC. For example, a VNC server running on display:1 will need port 5901 opening on the security group that is associated with the Amazon RDS Custom EC2 host.  
7. Change to the directory where you copied the Examples CD.  
   ```bash
   $ cd /RMAN/12cexamples/examples
   ```  
8. Run the installer. Make sure to verify the location of the `oraInst.loc` file. | DBA |

<td></td>
</tr>
<tr>
<td></td>
<td>$ mkdir -p /rdsdbdata/db/VIS_A/controlfile</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$ mkdir -p /rdsdbdata/db/VIS_A/datafile</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$ mkdir -p /rdsdbdata/db/VIS_A/onlinelog</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Create and modify the parameter file for E-Business Suite.</td>
<td>Create and modify the pfile for E-Business Suite.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

In this step, you won't copy the spfile from the source database. Instead, you'll use the standard pfile created with the Amazon RDS Custom DB instance and add the parameters you need for E-Business Suite.

When you drop the database, Amazon RDS automation creates a backup of the init.ora file, which is associated with the Amazon RDS Custom database. This file is called oracle_pfile and is located in /rdsdbdata/config.

1. Copy the /rdsdbdata/config/oracle_pfile to $ORACLE_HOME.

   ```
   $ cp /rdsdbdata/config/oracle_pfile $ORACLE_HOME/dbs/initVIS.ora
   ```

2. Edit the initVIS.ora file on the Amazon RDS Custom DB instance. Validate all the parameters on the source and add any parameters as needed. For details, see Oracle Support Note 396009.1 (requires an Oracle Support account).

   **Important:** Make sure that there are no comments in the parameters that you add. If there are comments, they will cause issues with the automation, such as creating read replicas and issuing point-in-time recoveries (PITRs). The following code provides examples of adding and amending parameters to the initVIS.ora file.

3. Add parameters similar to the following, based on your requirements.

   ```
   *.workarea_size_policy='AUTO'
   ```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>

</tr>
<tr>
<td></td>
<td>6. Grant privileges to RDSADMIN.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SQL&gt; grant dba to rdsadmin; SQL&gt; grant inherit any privileges to rdsadmin; SQL&gt; grant alter system to rdsadmin; SQL&gt; grant alter database to rdsadmin; SQL&gt; grant administer database trigger to rdsadmin; SQL&gt; grant connect to rdsadmin with admin option;</td>
<td></td>
</tr>
</tbody>
</table>
## Create the master user.

Because the starter database was dropped and the target database was restored from the source by using RMAN, you must recreate the master user. In this example, the master username is `admin`.

```
SQL> create user admin identified by <password>;
SQL> grant dba to admin
```

### Skills required

- **DBA**

## Change the system passwords.

Change the system passwords by using the password you retrieved from Secrets Manager.

```
SQL> alter user sys identified by xxxxxxxxxxx;
SQL> alter user system identified by xxxxxxxxxxx;
SQL> alter user ebs_system identified by xxxxxxxxxxx;
```

If you don't change these passwords, Amazon RDS Custom displays the error message, "The database monitoring user or user credentials have changed."

### Skills required

- **DBA**

## Create directories for E-Business Suite, install ETCC, and run Autoconfig

### Task Description

1. On the Amazon RDS Custom Oracle database, run the following script to create the `9idata` directory in `$ORACLE_HOME/nls/data/9idata`. This directory is required for E-Business Suite.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>perl $ORACLE_HOME/nls/data/old/cr9idata.pl</td>
<td>Ignore the ORA_NLS10 message, because you will create the context environment setup in later steps.</td>
<td></td>
</tr>
<tr>
<td>2. Copy the appsutil.tar file, which you created earlier from the shared Amazon EFS file system, and untar it on the Amazon RDS Custom Oracle home directory. This creates the appsutil directory in the $ORACLE_HOME directory.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$ cd /RMAN/appsutil</td>
<td>$ cp sourceappsutil.tar $ORACLE_HOME</td>
<td></td>
</tr>
<tr>
<td>$ cd $ORACLE_HOME</td>
<td>$ tar xvf sourceappsutil.tar appsutil</td>
<td></td>
</tr>
<tr>
<td>3. Copy the appsutil.zip file, which you saved on the Amazon EFS shared file system earlier. This was the file you created on the application tier.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>As the rdsdb user on the Amazon RDS Custom DB instance:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$ cp /RMAN/appsutil/appsutil.zip $ORACLE_HOME</td>
<td>$ cd $ORACLE_HOME</td>
<td></td>
</tr>
<tr>
<td>4. Unzip the appsutil.zip file to create the appsutil directory and subdirectories in the Oracle home directory.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>$ unzip -o appsutil.zip</td>
<td>The -o option means that some of the files will be overwritten.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Configure the tsanames file.</td>
<td>You have to configure the tnsnames.ora file so you can connect to the database with the Autoconfig tool. In the following example, you can see that the tnsnames.ora file is softlinked, but the file is empty by default.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

```
$ cd /rdsdbbin/oracle/network/admin
$ ls -litr
-rw-r--r-- 1 rdsdb database 373 Oct 31 2013 shrept.lst
lrwxrwxrwx 1 rdsdb database 30 Feb 9 17:17 listener.ora -> /rdsdbdata/config/listener.ora
lrwxrwxrwx 1 rdsdb database 28 Feb 9 17:17 sqlnet.ora -> /rdsdbdata/config/sqlnet.ora
lrwxrwxrwx 1 rdsdb database 30 Feb 9 17:17 tnsnames.ora -> /rdsdbdata/config/tnsnames.ora
```

1. Create the tnsnames.ora entry. Because of the way Amazon RDS automation parses the files, you have to make sure that the entry doesn't contain any white spaces, comments, or extra lines. Otherwise, you might run into issues when using some of the APIs such as create-db-instance-read-replica. Use the following as an example.

   ```
   $ vi tnsnames.ora
   VIS = (DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP) (PORT = 1521) (HOST = xx.xx.xx.xx))) (CONNECT_DATA = (SID = VIS) (SERVER = DEDICATED)))
   ```

   Note there are lines in the file. If you don't remove the lines, you won't be able to create a read replica in the future. The creation will

2. Replace the port, host, and SID in accordance with your requirements.

### Task
Install ETCC and run Autoconfig.

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Install the E-Business Suite Technology Codelevel Checker (ETCC).</td>
<td>DBA</td>
</tr>
<tr>
<td>Download patch 17537119 from My Oracle Support, and follow the instructions in README.txt. You will create a directory called etcc in the $ORACLE_HOME directory, unzip the patch to create a script called checkMTpatch.sh, and then run the script to check the patch versions.</td>
<td></td>
</tr>
<tr>
<td>2. Run the Autoconfig utility, and pass the new logical hostname context file.</td>
<td></td>
</tr>
</tbody>
</table>

```bash
cd $ORACLE_HOME/appsutil/bin
cd $.
adconfig.sh
cd $ORACLE_HOME/appsutil/clone/bin/VIS_oebss-db01log.xml
```

### Configure the TNS entries for Amazon RDS Custom and E-Business Suite

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the TNS entries for Amazon RDS Custom and E-Business Suite</td>
<td>Autoconfig generates the TNS files in the default location $ORACLE_HOME/network/admin/$&lt;CONTEXT_NAME&gt;, which is defined as $TNS_ADMIN, in the context file you created in the previous steps. You won't use these because the tnsnames.ora and listener.ora files generated by Autoconfig do not adhere to the Amazon RDS requirements, such as no white spaces or comments. Instead, you use the generic files provided with the Amazon RDS Custom database to ensure compliance with what the system is expecting and to reduce the margin for error. For example, Amazon RDS Custom expects the following naming format:</td>
<td>DBA</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>L_&lt;INSTANCE_NAME&gt;_001</td>
<td>In this pattern, for VIS this would be: L_VIS_001</td>
<td></td>
</tr>
</tbody>
</table>

Here's an example of the listener.ora file that you will be using. This was generated when you created the Amazon RDS Custom database. At this point, you haven't made any changes to this file and you will be leaving it as the default.

```bash
$ cd $ORACLE_HOME/network/admin
$ cat listener.ora
ADR_BASE_L_VIS_001=/rdsdbdata/log/
SID_LIST_L_VIS_001=(SID_LIST = (SID_DESC = (SID_NAME = VIS)(GLOBAL_DBNAME = VIS)(ORACLE_HOME = /rdsdbbin/oracle))
L_VIS_001=(DESCRIPTION_LIST = (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(PORT = 1521)(HOST = xx.xx.xx.xx))) (DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(PORT = 1521)(HOST = 127.0.0.1))))
SUBSCRIBE_FOR_NODE_DOWN_EVENT_L_VIS_001=OFF
```

Edit the E-Business Suite environment file to change the $TNS_ADMIN path to use the Amazon RDS Custom generic TNS files. The environment file was created when you ran Autoconfig earlier. Edit the TNS_ADMIN variable by removing the <CONTEXT_NAME> postfix. For example, edit the file:

```bash
$ vi /rdsdbbin/oracle/VIS_oebsoejs-db01log.env
```

Change the path from:
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>TNS_ADMIN=&quot;/rdsdbbin/oracle/network/admin/VIS_oebse\db01log&quot; export TNS_ADMIN</td>
<td></td>
</tr>
<tr>
<td></td>
<td>to:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>TNS_ADMIN=&quot;/rdsdbbin/oracle/network/admin&quot; export TNS_ADMIN</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** Every time you run Autoconfig, you must repeat this step to make sure that the correct TNS files are being used.
### Task: Set the environment for the rdsdb user.

**Description:** Now that you have completed Autoconfig and TNS entries, you need to load the environment file by setting it in the rdsdb user’s profile.

1. Update the `.bash_profile` to call the E-Business Suite database .env file. You need to update the profile to ensure that the environment is loaded. This environment file was created when you ran Autoconfig earlier.

   Here's the example environment file that is created when you run Autoconfig:

   ```bash
   . /rdsdbbin/oracle/VIS_oebs-db01log.env
   ```

   As the rdsdb user:

   ```bash
   cd $HOME
   vi .bash_profile
   export LD_LIBRARY_PATH=
   ${ORACLE_HOME}/lib:
   ${ORACLE_HOME}/ctx/lib
   export SHLIB_PATH=
   ${ORACLE_HOME}/lib
   export PATH=$PATH:
   ${ORACLE_HOME}/bin
   alias sql='rlwrap -c
   sqlplus / as sysdba'
   . /rdsdbbin/oracle/VIS_oebs-
   db01log.env
   ```

2. Log out and log back in as the rdsdb user to confirm that the profile has been updated by checking `$TNS_ADMIN`.

   ```bash
   $ echo $TNS_ADMIN
   /rdsdbbin/oracle/network/admin
   ```

3. Resume automation to confirm that everything is working.

   ```bash
   aws rds modify-db-instance \
   --db-instance-identifier vis \
   --automation-mode full
   ```

**Skills required:** DBA
The database will now be managed by Amazon RDS Custom. For example, if the listener or database goes down, the Amazon RDS Custom agent will restart them. To test this, run commands such as the following.

Example stop listener:

```bash
-bash-4.2$ lsnrctl stop vis
```

Example shutdown database:

```sql
SQL> shutdown immediate
```
## Task
Configure the application for Amazon RDS Custom.

### Description
1. On the application tier, edit `/etc/hosts` and change the IP address for the database to the Amazon RDS Custom IP address.

```
xx.xx.xx.xx  OEB5-db01.localdomain  OEB5-db01
OEB5-db01log.localdomain  OEB5-db01log
```

Because you are using logical hostnames, you can replace the database node almost seamlessly.

2. On the Amazon RDS Custom DB instance, add or amend the security group that is assigned to the source EC2 instance to reflect the Amazon RDS Custom DB instance, to ensure that the application can access the node.

3. Run Autoconfig. As application owner (for example, Applmgr), run:

```
$ cd $INST_TOP/admin/scripts
$ ./adautocfg.sh
SQL> select node_name from apps.fnd_nodes
```

<table>
<thead>
<tr>
<th>NODE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTHENTICATION</td>
</tr>
<tr>
<td>OEB5-APP01LOG</td>
</tr>
<tr>
<td>OEB5-DB01LOG</td>
</tr>
</tbody>
</table>

4. Confirm that you can log in.

```
$ ./adstrtal.sh apps/*** 
```

### Skills required
DBA

### Perform post-migration steps

## Task
Validate schema, connections, and maintenance tasks.

### Description
To finalize the migration, you will need to perform the following tasks, at a minimum.

- Gather schema statistics.
- Ensure that external interfaces and systems can connect to...
Migrate Oracle PeopleSoft to Amazon RDS Custom

**Migrate Oracle PeopleSoft to Amazon RDS Custom**

**Environment:** Production  
**Source:** Amazon EC2  
**Target:** Amazon RDS Custom

**R Type:** Replatform  
**Workload:** Oracle  
**Technologies:** Migration; Infrastructure; Databases

**AWS services:** Amazon RDS; Amazon S3; AWS Secrets Manager; Amazon EFS

**Summary**

**Oracle PeopleSoft** is an enterprise resource planning (ERP) solution for enterprise-wide processes. PeopleSoft has a three-tier architecture: client, application, and database. PeopleSoft can be run on **Amazon Relational Database Service** (Amazon RDS). Now, you can also run PeopleSoft on **Amazon RDS Custom**, which provides access to the underlying operating system.

**Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. When you migrate your Oracle database to Amazon RDS Custom, Amazon Web Services (AWS) can manage backup tasks and high availability, while you can focus on maintaining your PeopleSoft application and functionality. For key factors to consider for a migration, see **Oracle database migration strategies** in AWS Prescriptive Guidance.

This pattern focuses on the steps to migrate a PeopleSoft database on Amazon Elastic Compute Cloud (Amazon EC2) to Amazon RDS Custom by using an Oracle Recovery Manager (RMAN) backup. It uses an **Amazon Elastic File System** (Amazon EFS) shared file system between the EC2 instance and Amazon RDS.
RDS Custom, although you can also use Amazon FSx or any shared drive. The pattern uses an RMAN full backup (sometimes referred to as a level 0 backup).

**Prerequisites and limitations**

**Prerequisites**

- An Oracle version 19C source database that is running on Amazon EC2 with Oracle Linux 7, Oracle Linux 8, Red Hat Enterprise Linux (RHEL) 7, or RHEL 8. In the examples for this pattern, the source database name is FSDM092, but this isn’t a requirement.

  **Note:** You can also use this pattern with on-premises Oracle source databases. You must have the appropriate network connectivity between the on-premises network and a virtual private cloud (VPC).

- A PeopleSoft 9.2 demo instance.

- A single PeopleSoft application tier. However, you can adapt this pattern to work with multiple application tiers.

- Amazon RDS Custom configured with at least 8 GB of swap space.

**Limitations**

This pattern doesn’t support the following configurations:

- Setting the database ARCHIVE_LAG_TARGET parameter to a value outside the 60–7200 range
- Disabling the DB instance log mode (NOARCHIVELOG)
- Turning off the Amazon Elastic Block Store (Amazon EBS) optimized attribute of the EC2 instance
- Modifying the original EBS volumes attached to the EC2 instance
- Adding new EBS volumes or changing the volume type from gp2 to gp3
- Changing the extension format for the LOG_ARCHIVE_FORMAT parameter (requires *.arc)
- Multiplexing or changing the control file location and name (it has to be /rdsdbdata/db/*DBNAME*/controlfile/control-01.ctl)

For additional information about these and other unsupported configurations, see the Amazon RDS documentation.

**Product versions**

For Oracle Database versions and instance classes supported by Amazon RDS Custom, see Requirements and limitations for Amazon RDS Custom for Oracle.

**Architecture**

**Target technology stack**

- Application Load Balancer
- Amazon EFS
- Amazon RDS Custom for Oracle
- AWS Secrets Manager
- Amazon Simple Storage Service (Amazon S3)

**Target architecture**

The following architecture diagram represents a PeopleSoft system running in a single Availability Zone on AWS. The application tier is accessed through an Application Load Balancer. Both the application and
the databases are in private subnets, and the Amazon RDS Custom and Amazon EC2 database instance use an Amazon EFS shared file system to store and access the RMAN backup files. Amazon S3 is used for creating the custom RDS Oracle engine and for storing the redo logs metadata.
• **Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks, such as backups and high availability.

• **Amazon Elastic File System (Amazon EFS)** helps you create and configure shared file systems in the AWS Cloud. This pattern uses an Amazon EFS shared file system to store and access the RMAN backup files.

• **AWS Secrets Manager** helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager to create the RDSADMIN and ADMIN users and to change the sys and system passwords.

• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

• **Elastic Load Balancing (ELB)** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones. This pattern uses an Application Load Balancer.

**Other tools**

• **Oracle Recovery Manager (RMAN)** provides backup and recovery support for Oracle databases. This pattern uses RMAN to perform a hot backup of the source Oracle database on Amazon EC2 that is restored on Amazon RDS Custom.

**Best practices**

• For database initialization parameters, customize the standard pfile that’s provided by the Amazon RDS Custom DB instance for PeopleSoft instead of using the spfile from the Oracle source database. This is because white spaces and comments cause issues when creating read replicas in Amazon RDS Custom. For more information about database initialization parameters, see Oracle Support Note 1100831.1 (requires an Oracle Support account).

• Amazon RDS Custom uses Oracle automatic memory management by default. If you want to use the Hugemem kernel, you can configure Amazon RDS Custom to use automatic shared memory management instead.

• Leave the memory_max_target parameter enabled by default. The framework uses this in the background to create read replicas.

• Enable Oracle Flashback Database. This feature is useful when reinstating the standby in failover (not switchover) testing scenarios.

**Epics**

<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Pause automation mode. | You have to pause automation mode on your Amazon RDS Custom DB instance before you proceed with the next steps, to make sure that automation doesn't interfere with the RMAN restore activity.  
You can pause the automation by using the AWS console or the AWS Command Line Interface (AWS CLI) command (make sure that you have configured the AWS CLI first).  
aws rds modify-db-instance --db-instance-identifier peoplesoft-fscm-92 --automation-mode all-paused --resume-full-automation-mode-minute 360 --region eu-west-1 | DBA |

When you specify the duration of the pause, make sure that you leave enough time for the RMAN restore. This depends on the size of the source database, so modify the 360 value accordingly.  
Also, make sure that the total time of the paused automation does not overlap with the backup or maintenance window of the database. |

Create and modify the parameter file for PeopleSoft | To create and modify the pfile for PeopleSoft, use the standard pfile created with the Amazon RDS Custom DB instance. Add the parameters you need for PeopleSoft. | DBA |

#### Retrieve passwords from Secrets Manager, create users, and change passwords

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Retrieve the password from Secrets Manager. | You can perform this step by using the AWS console or the AWS CLI. The following steps show instructions for the console.  
1. Sign in to the AWS Management Console and open the Amazon RDS console.  
2. In the navigation pane, choose **Databases**, and then select the Amazon RDS database.  
3. Choose the **Configuration** tab, and note the resource ID for the instance. It will be in the format db-<ID> (for example, db-73GJNHLDGDNZD0XNWSECUW6LE).  
4. Open the Secrets Manager console.  
5. Choose the secret that has the same name as do-not-delete-custom-<resource_id>, where resource-id refers to the resource ID that you noted in step 3.  
6. Choose **Retrieve secret value**.  
   This password will be same for the sys, system, rdsadmin, and admin users. | DBA |
<p>| Create the RDSADMIN user. | RDSADMIN is the database user for monitoring and orchestrating the Amazon RDS Custom DB instance. Because the starter database was dropped and the target database was restored from the source using RMAN, you must recreate this user after the restore operation to make sure that Amazon RDS Custom monitoring works as expected. | DBA |</p>

### AWS Prescriptive Guidance Patterns

#### Migrate Oracle PeopleSoft to Amazon RDS Custom

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SQL</strong></td>
<td>set echo on feedback on serverout on</td>
<td>DBA</td>
</tr>
<tr>
<td></td>
<td>alter user SYS profile RDSADMIN;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>alter user SYSTEM profile RDSADMIN;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>alter user DBSNMP profile RDSADMIN;</td>
<td></td>
</tr>
</tbody>
</table>

**Create the master user.**

Because the starter database was dropped and the target database was restored from the source by using RMAN, you must recreate the master user. In this example, the master user name is `admin`.

```sql
SQL> create user admin identified by <password>;
SQL> grant dba to admin
```

**Change the system passwords.**

Change the system passwords by using the password you retrieved from Secrets Manager.

```sql
SQL> alter user sys identified by xxxxxxxxxxx;
SQL> alter user system identified by xxxxxxxxxxx;
```

If you don’t change these passwords, Amazon RDS Custom displays the error message, "The database monitoring user or user credentials have changed."

---

#### Configure the TNS entries for Amazon RDS Custom and PeopleSoft

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Configure the tnsnames file.</strong></td>
<td>To connect to the database from the application tier, configure the tnsnames.ora file so you can connect to the database from the application tier. In the following example, you can see that there is a soft link to the tnsnames.ora file, but the file is empty by default.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

```bash
$ cd /rdsdbbin/oracle/network/admin
$ ls -ltr
```

---

1462
### Task: Migrate Oracle PeopleSoft to Amazon RDS Custom

- **Description:**
  1. Create the `tnsnames.ora` entry. Because of the way Amazon RDS automation parses the files, you have to make sure that the entry doesn't contain any white spaces, comments, or extra lines. Otherwise, you might run into issues when using some of the APIs, such as `create-db-instance-read-replica`.
  2. Replace the port, host, and SID in accordance with your PeopleSoft database requirements. Use the following code as an example.

```sh
$ vi tnsnames.ora

FSDMO92=(DESCRIPTION =
 (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP)(HOST = x.x.x.x)(PORT = 1521))
 (CONNECT_DATA = (SERVER = DEDICATED) (SID = FSDMO92)))
```
  3. To confirm that the PeopleSoft database can be reached, run the following command.

```sh
$ tnsping FSDMO92

TNS Ping Utility for Linux: Version 19.0.0.0.0
- Production on 14-JUL-2022 10:16:45
```

- **Skills required:**

```sh
-rw-r--r-- 1 rdsdb database 1536 Feb 14  2018
shrept.lst
lrwxrwxrwx 1 rdsdb database 30 Apr  5 13:19
listener.ora -> /rdsdbdata/config/listener.ora
lrwxrwxrwx 1 rdsdb database 28 Apr  5 13:19 sqlnet.ora

### Migrate Oracle ROWID functionality to PostgreSQL on AWS

*Created by Rakesh Raghav (AWS)*

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Oracle Database</th>
<th>Target: PostgreSQL database on AWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Replatform</td>
<td>Workload: Oracle</td>
<td>Technologies: Migration; Databases</td>
</tr>
</tbody>
</table>

**AWS services:** Amazon Aurora; Amazon RDS; AWS SCT; AWS CLI

### Summary

This pattern describes options for migrating the ROWID pseudocolumn functionality in Oracle Database to a PostgreSQL database in Amazon Relational Database Service (Amazon RDS) for PostgreSQL, Amazon Aurora PostgreSQL-Compatible Edition, or Amazon Elastic Compute Cloud (Amazon EC2).

In an Oracle database, the ROWID pseudocolumn is a physical address of a row in a table. This pseudocolumn is used to uniquely identify a row even if the primary key isn't present on a table. PostgreSQL has a similar pseudocolumn called ctid, but it cannot be used as a ROWID. As explained in the PostgreSQL documentation, ctid might change if it's updated or through the vacuuming process.

There are three ways you can create the ROWID pseudocolumn functionality in PostgreSQL:

- Use a primary key column instead of ROWID to identify a row in a table.
- Use a logical primary/unique key (which might be a composite key) in the table.
- Add a column with auto-generated values and make it a primary/unique key to mimic ROWID.

This pattern walks you through all three implementations and describes the advantages and disadvantages of each option.
Prerequisites and limitations

Prerequisites

- An active AWS account
- Procedural Language/PostgreSQL (PL/pgSQL) coding expertise
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible cluster, or an EC2 instance to host the PostgreSQL database

Limitations

- This pattern provides workarounds for the ROWID functionality. PostgreSQL doesn’t provide an equivalent to ROWID in Oracle Database.

Product versions

- PostgreSQL 11.9 or later

Architecture

Source technology stack

- Oracle Database

Target technology stack

- Aurora PostgreSQL-Compatible, Amazon RDS for PostgreSQL, or an EC2 instance with a PostgreSQL database

Implementation options

There are three options to work around the lack of ROWID support in PostgreSQL, depending on whether your table has a primary key or unique index, a logical primary key, or an identity attribute. Your choice depends on your project timelines, your current migration phase, and dependencies on application and database code.

Option 1. Primary key or unique index

If your Oracle table has a primary key, you can use the attributes of this key to uniquely identify a row.

Advantages:

- No dependency on proprietary database features.
- Minimal impact on performance, because primary key fields are indexed.

Disadvantages:

- Requires changes to application and database code that relies on ROWID to switch to primary key fields.

Option 2. Logical primary/unique key
If your Oracle table has a logical primary key, you can use the attributes of this key to uniquely identify a row. A logical primary key consists of an attribute or a set of attributes that can uniquely identify a row, but it isn’t enforced on the database through a constraint.

Advantages:

- No dependency on proprietary database features.

Disadvantages:

- Requires changes to application and database code that relies on ROWID to switch to primary key fields.
- Significant impact on performance if the attributes of the logical primary key aren’t indexed. However, you can add a unique index to prevent performance issues.

**Option 3. Identity attribute**

If your Oracle table doesn’t have a primary key, you can create an additional field as GENERATED ALWAYS AS IDENTITY. This attribute generates a unique value whenever data is inserted into the table, so it can be used to uniquely identify a row for Data Manipulation Language (DML) operations.

Advantages:

- No dependency on proprietary database features.
- PostgreSQL database populates the attribute and maintains its uniqueness.

Disadvantages:

- Requires changes to application and database code that relies on ROWID to switch to identity attribute.
- Significant impact on performance if the additional field isn’t indexed. However, you can add an index to prevent performance issues.

**Tools**

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell. In this pattern, you can use the AWS CLI to run SQL commands through pgAdmin.
- **pgAdmin** is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
- **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- **AWS Schema Conversion Tool (AWS SCT)** supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.
## Epics

**Identify the source tables**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Identify Oracle tables that use the ROWID attribute. | Use the AWS Schema Conversion Tool (AWS SCT) to identify Oracle tables that have ROWID functionality. For more information, see the AWS SCT documentation.  
  —or—  
  In Oracle, use the DBA_TAB_COLUMNS view to identify tables that have a ROWID attribute. These fields might be used to store alphanumeric 10-byte characters. Determine the usage and convert these to a VARCHAR field if appropriate. | DBA or developer |
| Identify code that references these tables.   | Use AWS SCT to generate a migration assessment report to identify procedures affected by ROWID. For more information, see the AWS SCT documentation.  
  —or—  
  In the source Oracle database, use the text field of the dba_source table to identify objects that use ROWID functionality. | DBA or developer |

## Determine primary key usage

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Identify tables that don't have primary keys. | In the source Oracle database, use DBA_CONSTRAINTS to identify tables that don't have primary keys. This information will help you determine the strategy for each table. For example:  
  ```sql
  select dt.*
  from dba_tables dt
  where not exists (select 1
  ``` | DBA or developer |
Identify and apply the solution

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply changes for tables that have a defined or logical primary key.</td>
<td>Make the application and database code changes shown in the Additional information (p. 1469) section to use a unique primary key or a logical primary key to identify a row in your table.</td>
<td>DBA or developer</td>
</tr>
<tr>
<td>Add an additional field to tables that don't have a defined or logical primary key.</td>
<td>Add an attribute of type GENERATED ALWAYS AS IDENTITY. Make the application and database code changes shown in the Additional information (p. 1469) section.</td>
<td>DBA or developer</td>
</tr>
<tr>
<td>Add an index if necessary.</td>
<td>Add an index to the additional field or logical primary key to improve SQL performance.</td>
<td>DBA or developer</td>
</tr>
</tbody>
</table>

Additional information

The following sections provide Oracle and PostgreSQL code examples to illustrate the three approaches.

Scenario 1: Using a primary unique key

In the following examples, emp_id is the primary key.

Oracle code:

```sql
create table testrowid (emp_id integer, name varchar2(10), CONSTRAINT testrowid_pk PRIMARY KEY (emp_id));
```
**AWS Prescriptive Guidance Patterns**

**Migrate Oracle ROWID functionality to PostgreSQL**

---

**Oracle code:**

```sql
INSERT INTO testrowid(emp_id,name) values (1,DBMS_RANDOM.string('a',4));
INSERT INTO testrowid(emp_id,name) values (2,DBMS_RANDOM.string('b',4));
INSERT INTO testrowid(emp_id,name) values (3,DBMS_RANDOM.string('c',4));
INSERT INTO testrowid(emp_id,name) values (4,DBMS_RANDOM.string('d',4));

SELECT rowid,id,name FROM testrowid;
AAASFeAAAAAAANlAAA,1, qHoM
AAASFeAAAAAAANlAAB,2, TORU
AAASFeAAAAAAANlAAC,3, KKYK
AAASFeAAAAAAANlAAD,4, MKPA

UPDATE testrowid SET name = 'Rakesh' WHERE rowid = 'AAASFeAAAAAAANlAAB' ;

SELECT rowid,name FROM testrowid;
AAASFeAAAAAAANlAAA,1    qHoM
AAASFeAAAAAAANlAAB,2    Rakesh
AAASFeAAAAAAANlAAC,3    KKYK
AAASFeAAAAAAANlAAD,4    MKPA
```

**PostgreSQL code:**

```sql
CREATE TABLE public.testrowid
(
    emp_id integer,
    name character varying,
    primary key (emp_id)
);

insert into public.testrowid (emp_id,name)
select i,
    left(md5(i::text), 10)
from generate_series(1, 5) s(i)

select emp_id,name from testrowid;
1    "c4ca4238a0"
2    "c81e728d9d"
3    "eccbc87e4b"
4    "a87ff679a2"
5    "e4da3b7fbb"

update testrowid set name = 'Rakesh' where emp_id = 3 ;

select emp_id,name from testrowid;
1    "c4ca4238a0"
2    "c81e728d9d"
4    "a87ff679a2"
5    "e4da3b7fbb"
3    "Rakesh"
```

---

**Scenario 2: Using a logical primary key**

In the following examples, emp_id is the logical primary key.

**Oracle code:**

```sql
create table testrowid (emp_id integer, name varchar2(10) );
INSERT INTO testrowid(emp_id,name) values (1,DBMS_RANDOM.string('a',4));
INSERT INTO testrowid(emp_id,name) values (2,DBMS_RANDOM.string('b',4));
INSERT INTO testrowid(emp_id,name) values (3,DBMS_RANDOM.string('c',4));
INSERT INTO testrowid(emp_id,name) values (4,DBMS_RANDOM.string('d',4));
```

---

1470
Oracle code:

create table testrowid (name varchar2(10));
insert into testrowid (name) values (DBMS_RANDOM.string('a',4));
insert into testrowid (name) values (DBMS_RANDOM.string('b',4));
insert into testrowid (name) values (DBMS_RANDOM.string('c',4));
insert into testrowid (name) values (DBMS_RANDOM.string('d',4));

SELECT rowid,name FROM testrowid;
AAASFeAAAAAAAANlAAA, qHoM
AAASFeAAAAAAAANlAAB, TORU
AAASFeAAAAAAAANlAAC, KKYK
AAASFeAAAAAAAANlAAD, MKPA

UPDATE testrowid SET name = 'Rakesh' WHERE rowid = 'AAASFeAAAAAAAANlAAB';

Scenario 3: Using an identity attribute

Oracle code:

create table testrowid (name varchar2(10));
INSERT INTO testrowid(name) values (DBMS_RANDOM.string('a',4));
INSERT INTO testrowid(name) values (DBMS_RANDOM.string('b',4));
INSERT INTO testrowid(name) values (DBMS_RANDOM.string('c',4));
INSERT INTO testrowid(name) values (DBMS_RANDOM.string('d',4));

SELECT rowid,name FROM testrowid;
AAASFeAAAAAAAANlAAA, qHoM
AAASFeAAAAAAAANlAAB, TORU
AAASFeAAAAAAAANlAAC, KKYK
AAASFeAAAAAAAANlAAD, MKPA

UPDATE testrowid SET name = 'Rakesh' WHERE rowid = 'AAASFeAAAAAAAANlAAB';
PostgreSQL code:

```
CREATE TABLE public.testrowid
(
    rowid_seq bigint generated always as identity,
    name character varying
);

insert into public.testrowid (name)
select
    left(md5(i::text), 10)
from generate_series(1, 5) s(i);

select rowid_seq, name from testrowid;
1   "c4ca4238a0"
2   "c81e728d9d"
3   "eccbc87e4b"
4   "a87ff679a2"
5   "e4da3b7fbb"

update testrowid set name = 'Rakesh' where rowid_seq = 3;

select rowid_seq, name from testrowid;
1   "c4ca4238a0"
2   "c81e728d9d"
3   "Rakesh"
4   "a87ff679a2"
5   "e4da3b7fbb"
```

Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database

*Created by Sai Parthasaradhi (AWS) and Veeranjaneyulu Grandhi (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Oracle</th>
<th>Target:</th>
<th>PostgreSQL</th>

<td>Amazon Aurora</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern shows how to migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible Edition database by using a predefined metadata table.

Oracle Database error codes don't always have a corresponding PostgreSQL error code. This difference in error codes can make it difficult to configure the processing logic of the procedures or functions in the target PostgreSQL architecture.
You can simplify the process by storing the source and target database error codes that are meaningful to your PL/pgSQL program in a metadata table. Then, configure the table to flag valid Oracle Database error codes and map them to their PostgreSQL equivalents before continuing with the remaining process logic. If the Oracle Database error code isn’t in the metadata table, the process exits with the exception. Then, you can manually review the error details and add the new error code to the table if your program requires it.

By using this configuration, your Amazon Aurora PostgreSQL-Compatible database can handle errors in the same way that your source Oracle database does.

**Note:** Configuring a PostgreSQL database to handle Oracle Database error codes correctly usually requires changes to the database and application code.

### Prerequisites and limitations

#### Prerequisites

- An active AWS account
- A source Oracle Database with instance and listener services up and running
- An Amazon Aurora PostgreSQL-Compatible cluster that’s up and running
- Familiarity with Oracle Database
- Familiarity with PostgreSQL databases

#### Architecture

The following diagram shows an example Amazon Aurora PostgreSQL-Compatible database workflow for data error code validation and handling:

The diagram shows the following workflow:

1. A table holds Oracle Database error codes and classifications and their equivalent PostgreSQL error codes and classifications. The table includes a `valid_error` column that classifies if specific, predefined error codes are valid or not.
2. When a PL/pgSQL function \texttt{(func_processdata)} throws an exception, it invokes a second PL/pgSQL function \texttt{(error_validation)}.

3. The \texttt{error_validation} function accepts the Oracle Database error code as an input argument. Then, the function checks the incoming error code against the table to see if the error is included in the table.

4. If the Oracle Database error code is included in the table, then the \texttt{error_validation} function returns a \texttt{TRUE} value and the process logic continues. If the error code isn't included in the table, then the function returns a \texttt{FALSE} value, and the process logic exits with an exception.

5. When the function returns a \texttt{FALSE} value, then the error details are manually reviewed by the application’s functional lead to determine its validity.

6. The new error code is then either manually added to the table or not. If the error code is valid and added to the table, then the \texttt{error_validation} function returns a \texttt{TRUE} value the next time the exception occurs. If the error code isn't valid, and the process must fail when the exception occurs, then the error code isn't added to the table.

**Technology stack**

- Amazon Aurora PostgreSQL
- pgAdmin
- Oracle SQL Developer

**Tools**

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- pgAdmin is an open-source administration and development tool for PostgreSQL. It provides a graphical interface that simplifies the creation, maintenance, and use of database objects.
- Oracle SQL Developer is a free, integrated development environment that simplifies the development and management of Oracle Database in both traditional and cloud deployments.

**Epics**

Migrate Oracle Database error codes to your Amazon Aurora PostgreSQL-Compatible database

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a table in the Amazon Aurora PostgreSQL-Compatible database. | Run the following PostgreSQL \texttt{CREATE TABLE} command: \[
\text{(}
  \text{source_error_code}
  \text{numeric \ NOT \ NULL},
  \text{target_error_code}
  \text{character \ varying \ NOT \ NULL},
  \text{valid_error}
  \text{character \ varying(1) \ NOT \ NULL}
\text{)};
\] | PostgreSQL Developer, Oracle, RDS/Aurora for PostgreSQL |
| Add PostgreSQL error codes and their corresponding Oracle | Run the PostgreSQL \texttt{INSERT} command to add the required | PostgreSQL Developer, Oracle, RDS/Aurora for PostgreSQL |
## Migrate Oracle error codes to an Amazon Aurora PostgreSQL-Compatible database

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Database error codes to the table. | error code values to the `error_codes` table.  

The PostgreSQL error codes must use the character varying data type (`SQLSTATE` value). The Oracle error codes must use the numeric data type (`SQLCODE` value).  

**Example Insert statements:**

```sql
insert into error_codes values (-1817,'22007','Y');
insert into error_codes values (-1816,'22007','Y');
insert into error_codes values (-3114,'08006','N');
```

**Note:** If you're catching Oracle-specific Java database connectivity (JDBC) exceptions, you must replace those exceptions with either generic cross-database exceptions or switch to PostgreSQL-specific exceptions.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a PL/pgSQL function to validate error codes. | Create a PL/pgSQL function by running the PostgreSQL `CREATE FUNCTION` command. Make sure that the function does the following:  

- Accepts the Oracle error codes thrown by a program.  
- Checks if error codes are present in the `error_codes` table.  
- Returns `TRUE` or `FALSE` value, based on if the error code is present in the metadata table or not. | PostgreSQL Developer, Oracle, RDS/Aurora for PostgreSQL |

### Migrate Windows SSL certificates to an Application Load Balancer using ACM

*Created by Chandra Sekhar Yaratha (AWS)*

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manually review new error codes as they're recorded by the PL/pgSQL function.</td>
<td>Manually review the new error codes. If a new error code is valid for your use case, add it to the <code>error_codes</code> table by running the PostgreSQL <code>INSERT</code> command. <strong>-or-</strong> If a new error code isn't valid for your use case, don't add it to the table. The process logic will continue to fail and exit with exception when the error occurs.</td>
<td>PostgreSQL Developer, Oracle, RDS/Aurora for PostgreSQL</td>
</tr>
</tbody>
</table>

## Summary

The pattern provides guidance for using AWS Certificate Manager (ACM) to migrate existing Secure Sockets Layer (SSL) certificates from websites hosted on-premises on Microsoft Internet Information Services (IIS) on Windows servers. The SSL certificates can then be used with Elastic Load Balancing on AWS. SSL protects your data, affirms your identity, provides better search engine rankings, helps to satisfy Payment Card Industry Data Security Standard (PCI DSS) requirements, and improves customer trust. Developers and IT teams that manage these workloads want their web applications and infrastructure, including the IIS server and Windows Server, to remain compliant with their baseline policies.
This pattern covers manually exporting existing SSL certificates from Windows IIS and then importing them into ACM in your AWS account, creating an Application Load Balancer for your application, and configuring the Application Load Balancer to use your imported certificates. HTTPS connections are then terminated on the Application Load Balancer, and you don't need further configuration overhead on the web server. For more details, see Create an HTTPS listener for your Application Load Balancer.

Windows servers use .pfx/.p12 files to contain the public key file (SSL certificate) and its unique private key file. The Certificate Authority (CA) provides you with your public key file. You use your server to generate the associated private key file where the certificate signing request (CSR) was created.

Prerequisites and limitations

Prerequisites

- An active AWS account. You must have a virtual private cloud (VPC) with at least one private subnet in each of the Availability Zones used by your targets. The public subnets must include Network Address Translation (NAT) gateways and Remote Desktop Gateway instances.
- A web application running on IIS.
- The Administrator role on the on-premises IIS Windows server.
- For the Windows server, full internet access to AWS.

Limitations

- There can be one HTTP protocol and one HTTPS protocol bound to the website. The protocols are bound to ports tcp/80 and tcp/443, respectively.

Product versions

- IIS version 8.0 or above running on Windows Server 2012 or above

Architecture

Source technology stack

- Any HTTP Server (IIS or Apache HTTP Server or NGINX) implementation with SSL to ensure that data is transmitted securely in an encrypted connection (HTTPS)

Source architecture
AWS Prescriptive Guidance Patterns
Migrate Windows SSL certificates to an Application Load Balancer using ACM

**Target technology stack**
- ACM certificates in your AWS account
- An Application Load Balancer configured to use your imported certificates
- Windows Server instances in the private subnets

**Target architecture**
Tools

- **AWS Certificate Manager** – AWS Certificate Manager (ACM) is a service that you use to provision, manage, and deploy public and private Secure Sockets Layer/Transport Layer Security (SSL/TLS) certificates for use with AWS services. SSL/TLS certificates are used to secure network communications and establish the identity of websites over the internet as well as resources on private networks. ACM removes the time-consuming manual process of purchasing, uploading, and renewing SSL/TLS certificates.

- **Elastic Load Balancing** – Elastic Load Balancing automatically distributes incoming application traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, IP addresses, and AWS Lambda functions.

Import a certificate into ACM
Migrate a messaging queue from Microsoft Azure Service Bus to Amazon SQS

**Summary**

This pattern describes how to migrate a .NET Framework or .NET Core web or console application from using the Microsoft Azure Service Bus queue messaging platform to Amazon Simple Queue Service (Amazon SQS).

Applications use messaging services to send data to, and receive data from, other applications. These services help build decoupled, highly scalable microservices, distributed systems, and serverless applications in the cloud.

Azure Service Bus queues are part of a broader Azure messaging infrastructure that supports queuing and publish/subscribe messaging.

Amazon SQS is a fully managed message queuing service that enables you to decouple and scale microservices, distributed systems, and serverless applications. Amazon SQS eliminates the complexity and overhead associated with managing and operating message-oriented middleware, and enables developers to focus on differentiating work. Using Amazon SQS, you can send, store, and receive messages between software components at any volume, without losing messages or requiring other services to be available.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- A .NET Framework or .NET Core web or console application that uses Azure Service Bus queues (sample code attached)
Product versions

- .NET Framework 3.5 or later, or .NET Core 1.0.1, 2.0.0, or later

Architecture

Source technology stack

- A .NET (Core or Framework) web or console application that uses an Azure Service Bus queue to send messages

Target technology stack

- Amazon SQS

Tools

- Microsoft Visual Studio

Code

To create an AWS Identity and Access management (IAM) policy for Amazon SQS:

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. In the navigation pane on the left, choose Policies, and then choose Create policy.

3. Choose the JSON tab, and paste the following code:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor0",
      "Effect": "Allow",
      "Action": [
        "sqs:DeleteMessage",
        "sqs:GetQueueUrl",
        "sqs:ChangeMessageVisibility",
        "sqs:SendMessageBatch",
        "sqs:ReceiveMessage",
        "sqs:SendMessage",
        "sqs:GetQueueAttributes",
        "sqs:ListQueueTags",

- Messaging Using Amazon SQS
- Creating and Using an Amazon SQS Queue with the AWS SDK for .NET
- Send an Amazon SQS Message
- Receive a Message from an Amazon SQS Queue
- Delete a Message from an Amazon SQS Queue
- AWS Toolkit for Visual Studio
Additional information

This pattern includes two sample applications (see the attachments section):

- **AzureSbTestApp** includes code that uses the Azure Service Bus queue.
- **AmazonSqsTestApp** uses Amazon SQS. This is a console application that uses .NET Core 2.2 and includes examples for sending and receiving messages.

Notes:

- `queueClient` is an object of `IQueueClient`, which is part of the Microsoft.Azure.ServiceBus namespace (included in the Microsoft.Azure.ServiceBus NuGet package).
- `amazonSqsClient` is an object of `AmazonSQSClient`, which is part of the Amazon.SQS namespace (included in the AWSSDK.SQS NuGet package).
- Depending upon where the code is running, say if its running on EC2, the role needs to have permission to write into the SQS Queue.

Migrate data from Microsoft Azure Blob to Amazon S3 by using Rclone

*Created by Suhas Basavaraj (AWS), Aidan Keane (AWS), and Corey Lane (AWS)*

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Microsoft Azure storage container</th>
<th>Target: Amazon S3 bucket</th>

</tr>
</tbody>
</table>

| AWS services: Amazon S3 |

Summary

This pattern describes how to use Rclone to migrate data from Microsoft Azure Blob object storage to an Amazon Simple Storage Service (Amazon S3) bucket. You can use this pattern to perform a one-time migration or an ongoing synchronization of the data. Rclone is a command-line program written in Go and is used to move data across various storage technologies from cloud providers.

Prerequisites and limitations

**Prerequisites**

- AWS account
- Data stored in Azure Blob container service
Architecture

Source technology stack

- Azure Blob storage container

Target technology stack

- Amazon S3 bucket
- Amazon Elastic Compute Cloud (Amazon EC2) Linux instance

Architecture

Tools

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Rclone is an open-source command-line program inspired by rsync. It is used to manage files across many cloud storage platforms.

Epics

Prepare AWS and Azure cloud resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prepare a destination S3 bucket.</td>
<td>Create a new S3 bucket in the appropriate AWS Region or choose an existing bucket as the destination for the data you want to migrate.</td>
<td>AWS administrator</td>
</tr>
<tr>
<td>Create an IAM instance role for Amazon EC2.</td>
<td>Create a new AWS Identity and Access Management (IAM) role for Amazon EC2. This role gives your EC2 instance write access to the destination S3 bucket.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
### Migrate data from Azure Blob to Amazon S3

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach a policy to the IAM instance role.</td>
<td>Use the IAM console or AWS Command Line Interface (AWS CLI) to create an inline policy for the EC2 instance role that allows write access permissions to the destination S3 bucket. For an example policy, see the Additional information (p. 1491) section.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
| Launch an EC2 instance.                   | Launch an Amazon Linux 2 EC2 instance that is configured to use the newly created IAM service role. This instance will also need access to Azure public API endpoints through the Internet.  
**Note:** Consider using AWS Graviton-based EC2 instances to lower costs. Rclone provides ARM-compiled binaries. | AWS administrator                      |
| Create an Azure AD service principal.     | Use the Azure CLI to create an Azure Active Directory (Azure AD) service principal that has read-only access to the source Azure Blob storage container. For instructions, see the Additional information (p. 1491) section. Store these credentials on your EC2 instance to the location ~/azure-principal.json. | Cloud administrator, Azure             |

#### Install and configure Rclone

<table>
<thead>
<tr>

</tbody>
</table>
### Migrate data using Rclone

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Migrate data from your containers.</td>
<td>Run the Rclone <code>copy</code> or <code>sync</code> command.</td>
<td>General AWS, Cloud administrator</td>
</tr>
<tr>
<td></td>
<td><strong>Example: copy</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>This command copies data from the source Azure Blob container to the destination S3 bucket.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>rclone copy</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AZStorageAccount:blob-container</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>s3:examplebucket-01</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Example: sync</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>This command synchronizes data between the source Azure Blob container and the destination S3 bucket.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>rclone sync</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AZStorageAccount:blob-container</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>s3:examplebucket-01</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Important:</strong> When you use the <code>sync</code> command, data that isn't present in the source container will be deleted from the destination S3 bucket.</td>
<td></td>
</tr>
<tr>
<td>Synchronize your containers.</td>
<td>After the initial copy is complete, run the Rclone <code>sync</code> command for ongoing migration so that only new files that are missing from the destination S3 bucket will be copied.</td>
<td>General AWS, Cloud administrator</td>
</tr>
<tr>
<td>Verify that data has been migrated successfully.</td>
<td>To check that data was successfully copied to the destination S3 bucket, run the Rclone <code>lsd</code> and <code>ls</code> commands.</td>
<td>General AWS, Cloud administrator</td>
</tr>
</tbody>
</table>

- Creating a Microsoft Azure Blob container (Microsoft Azure documentation)
- Rclone commands (Rclone documentation)

Additional information

Best practices

When you migrate data from Azure to Amazon S3, be mindful of these considerations to avoid unnecessary costs or slow transfer speeds:

- Create your AWS infrastructure in the same geographical Region as the Azure storage account and Blob container—for example, AWS Region us-east-1 (N. Virginia) and Azure region East US.
- Avoid using NAT Gateway if possible, because it accrues data transfer fees for both ingress and egress bandwidth.
- Use a VPC gateway endpoint for Amazon S3 to increase performance.
- Consider using an AWS Graviton2 (ARM) processor-based EC2 instance for lower cost and higher performance over Intel x86 instances. Rclone is heavily cross-compiled and provides a precompiled ARM binary.

Example role policy for EC2 instances

This policy gives your EC2 instance read and write access to a specific bucket in your account. If your bucket uses a customer managed key for server-side encryption, the policy might need additional access to AWS Key Management Service (AWS KMS).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:DeleteObject",
                "s3:GetObject",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": [
                "arn:aws:s3:::BUCKET_NAME/*",
                "arn:aws:s3:::BUCKET_NAME"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "arn:aws:s3:::*"
        }
    ]
}
```

Creating a read-only Azure AD service principal
1. Log in to your Microsoft Azure cloud account portal and launch a Cloud Shell in PowerShell or use the Azure command-line interface (CLI) on your workstation.

2. Create a service principal and configure it with read-only access to your Azure Blob storage account. Save the JSON output of this command to a local file called azure-principal.json. The file will be uploaded to your EC2 instance. Replace the placeholder variables in brackets with your Azure subscription ID, resource group name, and storage account name.

```
az ad sp create-for-rbac \
--name AWS-Rclone-Reader \
--role "Storage Blob Data Reader" \
--scopes /subscriptions/{Subscription ID}/resourceGroups/{Resource Group Name}/providers/Microsoft.Storage/storageAccounts/{Storage Account Name}
```

3. Note the appId value from the output of the previous command, and modify the following command to include it. Remember to replace the variables in the command with your Azure subscription ID, resource group name, and storage account name.

```
az role assignment create --assignee "{appId from previous command output}" \
--role "Reader" \
--scope "/subscriptions/{Subscription ID}/resourceGroups/{Resource Group Name}/providers/Microsoft.Storage/storageAccounts/{Storage Account Name}"
```

Migrate from Couchbase Server to Couchbase Capella on AWS

*Created by Battulga Purevragchaa (AWS), Mark Gamble, and Sourabh Shanbhag (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Source:</th>
<th>Couchbase Server</th>
<th>Target:</th>
<th>Couchbase Capella</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Replatform</td>
<td>Workload:</td>
<td>All other workloads</td>
<td>Technologies:</td>
<td>Migration; Analytics; Databases</td>
</tr>
</tbody>
</table>

**Summary**

Couchbase Capella is a fully managed, NoSQL database as a service (DBaaS) for mission-critical applications (for example, user profiles or online catalogs and inventory management). Couchbase Capella manages your DBaaS workload in a Couchbase-managed Amazon Web Services (AWS) account. Capella makes it easy to run and manage multiple-cluster, multiple-AWS Region, multicloud, and hybrid-cloud replication within a single interface.

Couchbase Capella helps you instantly scale your Couchbase Server applications, helping you create multi-node clusters in minutes. Couchbase Capella supports all Couchbase Server features, including N1QL, Full Text Search, Eventing Service, and Analytics Service. It also removes the need to manage installations, upgrades, backups, and general database maintenance.

This pattern describes the steps and best practices for migrating a self-managed Couchbase Server environment to the AWS Cloud. The pattern provides a repeatable process for migrating data and indexes from Couchbase Server clusters, running either on premises or in the cloud, to Couchbase Capella. Using these steps helps you avoid issues during your migration and speeds up your overall migration process.

This pattern provides the following two migration options:
• **Option 1** is appropriate if you have fewer than 50 indexes to migrate.

• **Option 2** is appropriate if you have more than 50 indexes to migrate.

You can also set up sample data on your self-managed Couchbase Server to follow along with the migration guide.

If you choose migration option 2, or if you are using scopes or collections other than the default value, you must use the example configuration file, which is in the Additional information section.

**Prerequisites and limitations**

**Prerequisites**

• An existing Couchbase Capella paid account. You can also create a Couchbase Capella account on AWS and use the Couchbase Capella free trial, and then upgrade to a paid account to configure your cluster for the migration. To start with the trial version, follow the instructions in Getting Started with Couchbase Capella.

• An existing self-managed Couchbase Server environment either on premises or deployed on a cloud service provider.

• For migration option 2, Couchbase Shell and a configuration file. To create the configuration file, you can use the example file that's in the Additional information section.

• Familiarity with administering Couchbase Server and Couchbase Capella.

• Familiarity with opening TCP ports and running commands in a command line interface (CLI).

The migration process also requires the roles and expertise described in the following table.

<table>
<thead>
<tr>
<th>Role</th>
<th>Expertise</th>
<th>Responsibilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>Couchbase administrator</td>
<td>• Familiarity with Couchbase Server and Couchbase Capella</td>
<td>• Couchbase Server and Capella–specific tasks</td>
</tr>
<tr>
<td></td>
<td>• Basic command line knowledge is helpful but not required</td>
<td></td>
</tr>
<tr>
<td>Systems administrator, IT administrator</td>
<td>• Familiarity with the self-managed Couchbase Server system environment and administration</td>
<td>• Opening ports and determining IP addresses on self-managed Couchbase Server cluster nodes</td>
</tr>
</tbody>
</table>

**Limitations**

• This pattern is used to migrate data, indexes, and Couchbase Full Text Search indexes from Couchbase Server to Couchbase Capella on AWS. The pattern doesn't apply to migrating Couchbase Eventing Service, or to Couchbase Analytics.

• Couchbase Capella is available in multiple AWS Regions. For up-to-date information on the Regions that Capella supports, see Cloud Provider Requirements.

**Product versions**
AWS Prescriptive Guidance Patterns
Migrate from Couchbase Server to Couchbase Capella

- **Couchbase Server (Community or Enterprise) Edition version 5.x or later**

**Architecture**

**Source technology stack**
- Couchbase Server

**Target technology stack**
- Couchbase Capella

**Target architecture**

1. You access Couchbase Capella by using the **Capella Control Plane**. You can use the Capella Control Plane to do the following:
   - Control and monitor your account.
   - Manage clusters and data, indexes, users and groups, access permissions, monitoring, and events.
2. Clusters are created.
3. The **Capella Data Plane** is in the Couchbase-managed AWS account. After you create a new cluster, Couchbase Capella deploys it across multiple Availability Zones in the selected AWS Region.
4. You can develop and deploy Couchbase applications in a VPC in your AWS account. Typically, this VPC accesses the Capella Data Plane through **VPC peering**.

**Tools**

- **Couchbase Cross Data Center Replication (XDCR)** helps replicate data across clusters that are located in different cloud providers and different data centers. It is used to migrate data into Couchbase Capella from self-managed Couchbase Server clusters.

  **Note:** XDCR cannot be used with Couchbase Server Community Edition to migrate to Couchbase Capella. Instead, you can use **cbexport**. For more information, see the Migrate data from Community Edition epic.

- **Couchbase Shell** is a command line shell for Couchbase Server and Couchbase Capella to access local and remote Couchbase clusters. In this pattern, Couchbase Shell is used to migrate indexes.

- **cbexport** is a Couchbase utility for exporting data from Couchbase cluster. Included in Couchbase Server CLI tools.
## Epics

**Prepare the migration**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Evaluate the size of the self-managed Couchbase Server cluster. | Log in to the Couchbase Web Console for Couchbase Server, and assess your self-managed cluster’s nodes and buckets.  
1. To show a list of cluster nodes, choose the Servers tab in the navigation bar.  
2. Record the number of nodes, and then choose each node on the list to display its properties.  
3. Record the memory and storage for each individual node.  
4. Choose the Buckets tab in the navigation bar, and then choose each bucket in the list to display its properties. Record the RAM quota and conflict resolution setting for each bucket.  
You will use your self-managed Couchbase Server cluster configurations as a general guide for sizing and configuring the target cluster on Couchbase Capella.  
For help with a more detailed Couchbase Capella sizing exercise, contact Couchbase. | Couchbase administrator |
| Record Couchbase Service distribution on the self-managed Couchbase Server cluster. | 1. On the Couchbase Web Console, choose the Servers tab to display the list of cluster nodes.  
2. Choose each node to display its properties and then record the Couchbase Service distribution for each node (Data Service, Query Service, Index Service, Search Service, Analytics Service, and Eventing Service). | Couchbase administrator |
## AWS Prescriptive Guidance Patterns

### Migrate from Couchbase Server to Couchbase Capella

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Record the IP addresses of the self-managed Couchbase Server cluster nodes.</td>
<td>(Ignore this step if you are using Community Edition.) Record the IP address for each node in your cluster. They will be added to the allow list on your Couchbase Capella cluster later.</td>
<td>Couchbase administrator, Systems administrator</td>
</tr>
</tbody>
</table>

### Deploy and configure resources on Couchbase Capella

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Choose a template.                | 1. Log in to your Couchbase Capella Control Plane, choose the Dashboard tab or the Clusters tab in the main navigation, and then choose Create Cluster.
2. Using the information that you recorded from the evaluation of your self-managed Couchbase Server cluster, choose the cluster template that meets the configuration’s requirements. If you don't find an appropriate template, choose Custom Template in the Cluster Sizing editor. | Couchbase administrator |
<p>| Choose and configure the nodes.   | Choose and configure the nodes to match your self-managed Couchbase Server cluster environment, including the number of nodes, services distribution, compute or RAM, and storage. Couchbase Capella uses multidimensional scaling best practices. Services and nodes can be chosen only according to deployment best practices. This might mean that you can’t exactly match your self-managed Couchbase Server cluster’s configurations. | Couchbase administrator |
| Deploy the cluster.              | Choose a support zone and support package, and then deploy the cluster. For detailed steps and instructions, see Create a cluster in the Couchbase documentation.                                                     | Couchbase administrator |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Important:</strong> If you are using the Couchbase Capella free trial, you must convert it to a paid account before beginning your migration. To convert your account, open the <strong>Billing</strong> section of the Couchbase Capella Control Plane, and then choose <strong>Add Activation ID</strong>. The Activation ID is sent to your billing contact email address after you complete a purchase agreement with Couchbase Sales, or after you make a purchase through <a href="https://aws.amazon.com/marketplace">AWS Marketplace</a>.</td>
<td>1497</td>
<td></td>
</tr>
<tr>
<td>Create a database credential user.</td>
<td>A database credential user is specific to a cluster and consists of a user name, password, and a set of bucket privileges. This user is required for creating buckets and accessing bucket data. In the Couchbase Capella Control Plane, create a database credential for the new cluster by following the instructions in Configure database credentials in the Couchbase Capella documentation. <strong>Note:</strong> An organization user needs organizational role credentials assigned to them if they want to access bucket data on a particular cluster, either remotely or through the Couchbase Capella UI. This is separate from database credentials, which are typically used by apps and integrations. Creating the organizational user allows you to create and manage the target buckets on your Couchbase Capella cluster.</td>
<td>Couchbase administrator</td>
</tr>
</tbody>
</table>
### AWS Prescriptive Guidance Patterns

**Migrate from Couchbase Server to Couchbase Capella**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>If using migration option 2, install Couchbase Shell.</td>
<td>You can install Couchbase Shell on any system that has network access to both your self-managed Couchbase Server and the Couchbase Capella clusters. For more information, see <a href="#">Install Couchbase Shell version 1.0.0-beta.5</a> in the Couchbase Shell documentation. Confirm that Couchbase Shell is installed by testing a connection to your self-managed cluster in a command line terminal.</td>
<td>Couchbase administrator, Systems administrator</td>
</tr>
</tbody>
</table>
| Allow IP addresses. | 1. In the Couchbase Capella Control Plane, choose Clusters, and then choose your target cluster.  
2. Choose the Connect tab for the cluster, and record the connection endpoint for your cluster that is listed under Manage Allowed IP.  
3. To add the IP address for the system where you installed Couchbase Shell and the IP address of your self-managed Couchbase Server cluster instances as allowed IP addresses, do the following:  
  a. Under Wide Area Network, choose Manage Allowed IP.  
  b. Choose Add Allowed IP, enter the IP address for the system where you installed Couchbase Shell, and then choose Add IP.  
  c. Repeat the previous step to add the IP address of your self-managed Couchbase Server cluster instance. | Couchbase administrator, Systems administrator |

For more information about allowed IP addresses, see [Configure allowed IP addresses](#) in the Couchbase documentation.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure certificates.                       | 1. To download the root certificate for your cluster, under **Root Certificate**, choose **Download**.  
2. Save the root certificate using the .pem file extension in a folder on the system that will run Couchbase Shell.  
3. Next, log in to your self-managed Couchbase Server Web Console, choose **Security** in the left navigation bar, and then choose the **Certificates** tab.  
4. Copy the root certificate for your self-managed Couchbase Server cluster and save it as a .pem file to the same folder where you saved the root certificate file for your Couchbase Capella cluster. For more information about the root certificate, see [Root certificate in the Couchbase Server documentation](#). | Couchbase administrator, Systems administrator          |
| Create the configuration file for Couchbase Shell. | Create a configuration dotfile in the Couchbase Shell installation’s home directory (for example, `/<HOME_DIRECTORY>/config`). For more information, see [Config dotfiles](#) in the Couchbase documentation.  
Add connection properties for the source and target clusters to the configuration file. You can use the example configuration file that’s in the Additional information section and edit the settings for your clusters.  
Save the configuration file with the updated settings to the .cbsh folder (for example, `/<HOME_DIRECTORY>/cbsh/config`). | Couchbase administrator, Systems administrator          |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create target buckets.</td>
<td>For each source bucket, create one target bucket in your Couchbase Capella cluster by following the instructions in Create a bucket in the Couchbase documentation. Your target bucket configurations must match the bucket names, memory settings, and conflict resolution settings of the buckets in your self-managed Couchbase Server cluster.</td>
<td>Couchbase administrator</td>
</tr>
</tbody>
</table>
### Migrate from Couchbase Server to Couchbase Capella

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create scopes and collections.</td>
<td>Every bucket contains a default scope and collection with the keyspace <code>_default._default</code>. If you are using any other keyspaces for your scope and collection, you must create identical keyspaces in the target Capella cluster.</td>
<td>Couchbase administrator</td>
</tr>
</tbody>
</table>

1. Open the command line terminal on the system where you installed Couchbase Shell.

2. To start Couchbase Shell, run the following command.

   ```
   ./cbsh
   ```

3. For each bucket that you want to migrate, create scopes and collections in the Capella cluster by running the following commands. Make sure that you replace `<BUCKET_NAME>` with the name of the bucket that you want to migrate.

   ```
   scopes --clusters "On-Prem-Cluster" --bucket <BUCKET_NAME> | select scope | where scope != ".default" | each { |it| scopes create $it.scope --clusters "Capella-Cluster" }
   collections --clusters "On-Prem-Cluster" --bucket <BUCKET_NAME> | select scope collection | where $it.scope != ".default" | where $it.collection != ".default" | each { |it| collections create $it.collection --clusters "Capella-Cluster" --bucket <BUCKET_NAME> --scope $it.scope }
   ```
# Migrate from Couchbase Server to Couchbase Capella

## Migrate the data from Enterprise Edition

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Open TCP ports on the self-managed Couchbase Server cluster nodes.</td>
<td>Make sure that the appropriate ports are open for XDCR communication on the self-managed Couchbase Server cluster’s nodes. For more information, see the Couchbase Server ports documentation.</td>
<td>Couchbase administrator, Systems administrator</td>
</tr>
</tbody>
</table>

**If you are using Couchbase Server Enterprise Edition, set up Couchbase XDCR.**

1. In the Couchbase Capella Control Plane main navigation, choose Clusters, and then choose the target cluster for migration.
3. Log in to your self-managed Couchbase Server Web Console, and in the main navigation, choose XDCR. Then choose Add Remote.
4. Enter the following settings:
   - Cluster Name – A name for the Capella cluster connection
   - IP/Hostname – The connection endpoint for your Couchbase Capella cluster
   - Username for Remote Cluster – The database user for your Couchbase Capella cluster
   - Password – The database user password for your Couchbase Capella cluster
   - Enable Secure Connection – Selected
   - Full (TLS encrypt password and data) – Selected
5. Paste the Capella cluster root certificate you copied earlier, and then choose Save.

Migrate full-text search indexes

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Migrate self-managed cluster full-text search indexes to Couchbase Capella. | 1. In the Couchbase Web Console, choose Search.  
2. In the list of full-text search (FTS) indexes, choose the first FTS index that you want to migrate, choose Show index definition JSON, and choose Copy to Clipboard. Make a note of the index name and the bucket it belongs to.  
3. In the Couchbase Capella Control Plane, choose Clusters and then choose the target cluster.  
5. Choose Import Index, and paste the FTS index definition.  
6. Enter the Index Name, select the correct Bucket, as noted on the self-managed cluster, and then choose Create.  
7. Repeat this process for each FTS index that must be migrated. | Couchbase administrator          |

Migrate data from Couchbase Community Edition

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
To export data from the source bucket, use cbexport at the command line.  
The following command is provided as an example.                       | Couchbase administrator          |

```
cbexport json  
--cluster localhost 
--bucket <SOURCE_BUCKET NAME> 
```
### AWS Prescriptive Guidance Patterns
#### Migrate from Couchbase Server to Couchbase Capella

<table>

<tr>
<td>Import data into Couchbase Capella</td>
<td>1. In the Couchbase Capella Control Plane, choose <strong>Clusters</strong>, and then choose the target cluster.</td>
<td>Couchbase administrator</td>
</tr>
<tr>
<td></td>
<td>2. In the <strong>Tools</strong> dropdown list, choose <strong>Import</strong>. This will open a wizard with the following six steps:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>a. <strong>Bucket</strong> – Choose the target bucket.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>b. <strong>File</strong> – Choose <strong>JSON</strong>, choose <strong>Lines</strong>, and then choose <strong>Using your web browser</strong>. If you have a large amount of data, you can explore the <strong>Manually</strong> option. Select the file created by cbexport.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>c. <strong>Collections</strong> – Choose <strong>Custom Collection Mapping</strong>. If your Community Edition database does not use scopes or collections, or it uses only <code>_default</code>, you can choose the <strong>Select Single Collection</strong> option instead.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For <strong>Collection Mapping Expression</strong>, enter <code>%cbscope%.%cbcoll%</code>. To verify that this expression works correctly, you can paste example data, such as the following.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>{ &quot;cbscope&quot;: &quot;inventory&quot;, &quot;cbcoll&quot;: &quot;landmark&quot;, &quot;cbkey&quot;: &quot;landmark_3991&quot; }</td>
<td></td>
</tr>
<tr>
<td></td>
<td>d. <strong>Key</strong> – Choose <strong>Customer Generation</strong>. (If you don't care about preserving the keys of the data you're importing, you can select <strong>Automatically Generated UUID</strong> instead and proceed to step 5.) For <strong>Key Name Generator Expression</strong>, enter <code>%cbkey%</code>. To verify that this expression works correctly, paste some example data.</td>
<td></td>
</tr>
</tbody>
</table>

Additional information

The following code is an example configuration file for Couchbase Shell.

```
Version = 1
[[clusters]]
  identifier = "On-Prem-Cluster"
  hostnames = ["<SELF_MANAGED_COUCHBASE_CLUSTER>"]
  default-bucket = "travel-sample"
  username = "<SELF_MANAGED_ADMIN>"
  password = "<SELF_MANAGED_ADMIN_PWD>"
  tls-cert-path = "/<ABSOLUTE_PATH_TO_SELF_MANAGED_ROOT_CERT>"
  data-timeout = "2500ms"
  connect-timeout = "7500ms"
  query-timeout = "75s"

[[clusters]]
  identifier = "Capella-Cluster"
  hostnames = ["<COUCHBASE_CAPELLA_ENDPOINT>"]
  default-bucket = "travel-sample"
  username = "<CAPELLA_DATABASE_USER>"
  password = "<CAPELLA_DATABASE_USER_PWD>"
  tls-cert-path = "/<ABSOLUTE_PATH_TO_COUCHBASE_CAPELLA_ROOT_CERT>"
  data-timeout = "2500ms"
  connect-timeout = "7500ms"
  query-timeout = "75s"
```

Before you save the configuration file, use the following table to make sure that you added your own source and target cluster information.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;SELF_MANAGED_COUCHBASE_CLUSTER&gt;</code></td>
<td>Use the IP address for your self-managed Couchbase Server cluster.</td>
</tr>
<tr>
<td><code>&lt;SELF_MANAGED_ADMIN&gt;</code></td>
<td>Use the administrator user for your self-managed Couchbase Server cluster.</td>
</tr>
<tr>
<td><code>&lt;ABSOLUTE_PATH_TO_SELF_MANAGED_ROOT_CERT&gt;</code></td>
<td>Use the absolute path to the saved root certificate file for your self-managed Couchbase Server cluster.</td>
</tr>
<tr>
<td><code>&lt;COUCHBASE_CAPELLA_ENDPOINT&gt;</code></td>
<td>Use the connection endpoint for your Couchbase Capella cluster.</td>
</tr>
<tr>
<td><code>&lt;CAPELLA_DATABASE_USER&gt;</code></td>
<td>Use the database user for your Couchbase Capella cluster.</td>
</tr>
<tr>
<td><code>&lt;CAPELLA_DATABASE_USER_PWD&gt;</code></td>
<td>Use the database user password for your Couchbase Capella cluster.</td>
</tr>
<tr>
<td><code>&lt;ABSOLUTE_PATH_TO_COUCHBASE_CAPELLA_ROOT_CERT&gt;</code></td>
<td>Use the absolute path to the saved root certificate file for your Couchbase Capella cluster.</td>
</tr>
</tbody>
</table>

Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2
Summary

This pattern walks you through the steps for migrating from an on-premises Red Hat Enterprise Linux (RHEL) 6.9 system running IBM WebSphere to RHEL 7.4 running Apache Tomcat on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

The pattern can be applied to the following source and target versions:

- WebSphere 7 to Tomcat 6 (with Java 1.6)
- WebSphere 7 to Tomcat 7 (with Java 1.6)
- WebSphere 8.5.5 to Tomcat 7 (with Java 1.6 or higher)

Prerequisites and limitations

Prerequisites

- An active AWS account
- Source Java code, with the following assumptions:
  - Uses the Java Development Kit (JDK) version of Java 1.6 or higher
  - Uses the Spring or Apache Struts framework
  - Doesn't use the Enterprise Java Beans (EJB) framework or any other WebSphere server functionality that's not readily available for Tomcat
  - Primarily uses servlets or Java Server Pages (JSPs)
  - Uses Java Database Connectivity (JDBC) connectors to connect to databases
- Source IBM WebSphere version 7 or higher
- Target Tomcat version 6 or higher

Architecture

Source technology stack

- A web application built using the Apache Struts Model-View-Controller (MVC) framework
- A web application running on IBM WebSphere version 7 or 8.5.5.
- A web application that uses a Lightweight Directory Access Protocol (LDAP) connector to connect to an LDAP directory (iPlanet/eTrust)
- An application that uses IBM Tivoli Access Manager (TAM) connectivity to update the TAM user password (in the present implementation, applications use PD.jar)

On-premises databases
• Oracle 11g Standard Edition (SE)
• Oracle 11g Standard Edition 1 (SE1)
• Oracle 11g Standard Edition 2 (SE2)
• Oracle 11g Enterprise Edition (EE)

**Target technology stack**

• Apache Tomcat version 7 running on RHEL on an EC2 instance
• Amazon Relational Database Service (Amazon RDS) for Oracle

For more information about the Oracle versions supported by Amazon RDS, see the Amazon RDS for Oracle website.

**Target architecture**
**Tools**

- Application tier: Rebuilding Java application into a WAR file
- Database tier: Oracle native backup and restore
## Epics

### Plan the migration

<table>
<thead>

### Additional information

**Migrating database objects and data**

For example, if you're using native Oracle backup/restore utilities:

1. Create the Amazon Simple Storage Service (Amazon S3) backup for database backup files (optional).
2. Back up the Oracle DB data to the network shared folder.
3. Log in to the migration staging server to map the network share folder.
4. Copy data from the network share folder to the S3 bucket.
5. Request an Amazon RDS Multi-AZ deployment for Oracle.
6. Restore the on-premises database backup to Amazon RDS for Oracle.

**Setting up the application tier**

1. Install Tomcat 7 from the Apache Tomcat website.
2. Package the application and shared libraries into a WAR file.
3. Deploy the WAR file in Tomcat.
4. Monitor the start log to Linux `cat` any missing shared libraries from WebSphere.
5. Watch the start record to Linux `cat` any WebSphere-specific deployment descriptor extensions.
6. Collect any missing dependent Java libraries from the WebSphere server.
7. Amend WebSphere-specific deployment descriptor elements with Tomcat-compatible equivalents.
8. Rebuild the WAR file with the dependent Java libraries and updated deployment descriptors.
9. Update the LDAP configuration, database configuration, and test connections (see Realm Configuration HOW-TO and JNDI Datasource HOW-TO in the Apache Tomcat documentation).
10. Test the installed application against the restored Amazon RDS for Oracle database.
11. Create an Amazon Machine Image (AMI) for Linux from the EC2 instance.
12. Launch the completed architecture with the Application Load Balancer and Auto Scaling group.
13. Update the URLs (by using the WebSEAL junction) to point to the Application Load Balancer.
14. Update the configuration management database (CMDB).

Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2 with Auto Scaling

Created by Kevin Yung (AWS)

</tr>
</tbody>
</table>

**Summary**

This pattern provides guidance for migrating a Java application from IBM WebSphere Application Server to Apache Tomcat on an Amazon Elastic Compute Cloud (Amazon EC2) instance with Amazon EC2 Auto Scaling enabled.

By using this pattern, you can achieve:

- A reduction in IBM licensing costs
- High availability using Multi-AZ deployment
- Improved application resiliency with Amazon EC2 Auto Scaling

**Prerequisites and limitations**

**Prerequisites**

- Java applications (version 7.x or 8.x) should be developed in LAMP stacks.
- The target state is to host Java applications on Linux hosts. This pattern has been successfully implemented in a Red Hat Enterprise Linux (RHEL) 7 environment. Other Linux distributions can follow this pattern, but the configuration of the Apache Tomcat distribution should be referenced.
- You should understand the Java application's dependencies.
- You must have access to the Java application source code to make changes.

**Limitations and replatforming changes**
• You should understand the enterprise archive (EAR) components and verify that all libraries are packaged in the web component WAR files. You need to configure the Apache Maven WAR Plugin and produce WAR file artifacts.

• When using Apache Tomcat 8, there is a known conflict between servlet-api.jar and the application package built-in jar files. To resolve this issue, delete servlet-api.jar from the application package.

• You must configure WEB-INF/resources located in the classpath of the Apache Tomcat configuration. By default, the JAR libraries are not loaded in the directory. Alternatively, you can deploy all the resources under src/main/resources.

• Check for any hard-coded context roots within the Java application, and update the new context root of Apache Tomcat.

• To set JVM runtime options, you can create the configuration file setenv.sh in the Apache Tomcat bin folder; for example, JAVA_OPTS, JAVA_HOME, etc.

• Authentication is configured at the container level and is set up as a realm in Apache Tomcat configurations. Authentication is established for any of the following three realms:
  • JDBC Database Realm looks up users in a relational database accessed by the JDBC driver.
  • DataSource Database Realm looks up users in a database that is accessed by JNDI.
  • JNDI Directory Realm looks up users in the Lightweight Directory Access Protocol (LDAP) directory that is accessed by the JNDI provider. The look-ups require:
    • LDAP connection details: user search base, search filter, role base, role filter
    • The key JNDI Directory Realm: Connects to LDAP, authenticates users, and retrieves all groups in which a user is a member

• Authorization: In the case of a container with a role-based authorization that checks the authorization constraints in web.xml, web resources must be defined and compared to the roles defined in the constraints. If LDAP doesn’t have group-role mapping, you must set the attribute <security-role-ref> in web.xml to achieve group-role mapping. To see an example of a configuration document, see the Oracle documentation.

• Database connection: Create a resource definition in Apache Tomcat with an Amazon Relational Database Service (Amazon RDS) endpoint URL and connection details. Update the application code to reference a DataSource by using JNDI lookup. An existing DB connection defined in WebSphere would not work, as it uses WebSphere's JNDI names. You can add a <resource-ref> entry in web.xml with the JNDI name and DataSource type definition. To see a sample configuration document, see the Apache Tomcat documentation.

• Logging: By default, Apache Tomcat logs to the console or to a log file. You can enable realm-level tracing by updating logging.properties (see Logging in Tomcat). If you are using Apache Log4j to append logs to a file, you must download tomcat-juli and add it to the classpath.

• Session management: If you are retaining IBM WebSEAL for application load balancing and session management, no change is required. If you are using an Application Load Balancer or Network Load Balancer on AWS to replace the IBM WebSEAL component, you must set up session management by using an Amazon ElastiCache instance with a Memcached cluster and set up Apache Tomcat to use open-source session management.

• If you are using the IBM WebSEAL forward proxy, you must set up a new Network Load Balancer on AWS. Use the IPs provided by the Network Load Balancer for WebSEAL junction configurations.

• SSL configuration: We recommend that you use Secure Sockets Layer (SSL) for end-to-end communications. To set up an SSL server configuration in Apache Tomcat, follow the instructions in the Apache Tomcat documentation.

Architecture

Source technology stack

• IBM WebSphere Application Server
**Target technology stack**

- The architecture uses **Elastic Load Balancing (version 2)**. If you are using IBM WebSEAL for Identify management and load balancing, you can select a Network Load Balancer on AWS to integrate with the IBM WebSEAL reverse proxy.

- Java applications are deployed to an Apache Tomcat application server, which runs on an EC2 instance in an **Amazon EC2 Auto Scaling group**. You can set up a scaling policy based on Amazon CloudWatch metrics such as CPU utilization.

- If you’re retiring the use of IBM WebSEAL for load balancing, you can use **Amazon ElastiCache for Memcached** for session management.

- For the back-end database, you can deploy **High Availability (Multi-AZ) for Amazon RDS** and select a database engine type.

**Target architecture**

Migrate a .NET application from Microsoft Azure App Service to AWS Elastic Beanstalk

Created by Raghavender Madamshitti (AWS)

<table>
<thead>
<tr>
<th>R Type: Replatform</th>
<th>Source: Applications</th>
<th>Target: AWS Elastic Beanstalk</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Created by:</strong> AWS</td>
<td><strong>Environment:</strong> PoC or pilot</td>

</tr>
<tr>
<td><strong>Workload:</strong> Microsoft</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to migrate a .NET web application hosted on Microsoft Azure App Service to AWS Elastic Beanstalk. There are two ways to migrate applications to Elastic Beanstalk:

• Use AWS Toolkit for Visual Studio - This plugin for the Microsoft Visual Studio IDE provides the easiest and most straightforward way to deploy custom .NET applications to AWS. You can use this approach to deploy .NET code directly to AWS and to create supporting resources, such as Amazon Relational Database Service (Amazon RDS) for SQL Server databases, directly from Visual Studio.

• Upload and deploy to Elastic Beanstalk - Each Azure App Service includes a background service called Kudu, which is useful for capturing memory dumps and deployment logs, viewing configuration parameters, and accessing deployment packages. You can use the Kudu console to access Azure App Service content, extract the deployment package, and then upload the package to Elastic Beanstalk by using the upload and deploy option in the Elastic Beanstalk console.

This pattern describes the second approach (uploading your application to Elastic Beanstalk through Kudu). The pattern also uses the following AWS services: AWS Elastic Beanstalk, Amazon Virtual Private Cloud (Amazon VPC), Amazon CloudWatch, Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling, Amazon Simple Storage Service (Amazon S3), and Amazon Route 53.

The .NET web application is deployed to AWS Elastic Beanstalk, which runs in an Amazon EC2 Auto Scaling Group. You can set up a scaling policy based on Amazon CloudWatch metrics such as CPU...
utilization. For a database, you can use Amazon RDS in a Multi-AZ environment, or Amazon DynamoDB, depending on your application and business requirements.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A .NET web application running in Azure App Service
- Permission to use the Azure App Service Kudu console

Product versions

- .NET Core (x64) 1.0.1, 2.0.0, or later, or .NET Framework 4.x, 3.5 (see .NET on Windows Server platform history)
- Internet Information Services (IIS) version 8.0 or later, running on Windows Server 2012 or later
- .NET 2.0 or 4.0 Runtime.

Architecture

Source technology stack

- Application developed using .NET Framework 3.5 or later, or .NET Core 1.0.1, 2.0.0, or later, and hosted on Azure App Service (web app or API app)

Target technology stack

- AWS Elastic Beanstalk running in an Amazon EC2 Auto Scaling group

Migration architecture
AWS Prescriptive Guidance Patterns
Migrate from Microsoft Azure App Service to AWS Elastic Beanstalk

Deployment workflow

Tools

Tools
- .NET Core or .NET Framework
- C#
- IIS
- Kudu console

AWS services and features
• **Amazon EC2 Auto Scaling group** – Elastic Beanstalk includes an Auto Scaling group that manages the Amazon EC2 instances in the environment. In a single-instance environment, the Auto Scaling group ensures that there is always one instance running. In a load-balanced environment, you can configure the group with a range of instances to run, and Amazon EC2 Auto Scaling adds or removes instances as needed, based on load.

• **Elastic Load Balancing** – When you enable load balancing in AWS Elastic Beanstalk, it creates a load balancer that distributes traffic among the EC2 instances in the environment.

• **Amazon CloudWatch** – Elastic Beanstalk automatically uses Amazon CloudWatch to provide information about your application and environment resources. Amazon CloudWatch supports standard metrics, custom metrics, and alarms.

• **Amazon Route 53** – Amazon Route 53 is a highly available and scalable cloud Domain Name System (DNS) web service. You can use Route 53 alias records to map custom domain names to AWS Elastic Beanstalk environments.

</tr>
</thead>
<tbody>
<tr>
<td>Access the Azure App Service Kudu console.</td>
<td>Access Kudu through the Azure portal by navigating to the App Service dashboard, and then choosing “Advanced Tools,” “Go.” Or, you can modify the Azure App Service URL as follows: https://&lt;appservicename&gt;.scm.azurewebsites.net.</td>
<td>System Admin/ Application Developer</td>
</tr>
<tr>
<td>Download the deployment package from Kudu.</td>
<td>Navigate to Windows PowerShell by choosing the DebugConsole option. This will open the Kudo console. Go to the wwwroot folder and download it. This will download the Azure App Service deployment package as a zip file. For an example, see the attachment.</td>
<td>System Admin/ Application Developer</td>
</tr>
</tbody>
</table>
## Task | Description | Skills required
--- | --- | ---
Create a package for Elastic Beanstalk. | Unzip the deployment package that you downloaded from Azure App Service. Create a JSON file called aws-windows-deployment-manifest.json (this file is required only for .NET Core applications). Create a zip file that includes aws-windows-deployment-manifest.json and the Azure App Service deployment package file. For an example, see the attachment. | System Admin/ Application Developer
Create a new Elastic Beanstalk application. | Open the Elastic Beanstalk console. Choose an existing application or create a new application. | System Admin/ Application Developer
Create the environment. | In the Elastic Beanstalk console, Actions menu, choose "Create environment." Select the web server environment and .NET/ IIS platform. For application code, choose "Upload." Upload the zip file that you prepared for Elastic Beanstalk, and then choose "Create Environment." | System Admin/ Application Developer
Configure Amazon CloudWatch. | By default, basic CloudWatch monitoring is enabled. If you want to change the configuration, in the Elastic Beanstalk wizard, choose the published application, and then choose "Monitoring." | System Admin
Verify that the deployment package is in Amazon S3. | When the application environment has been created, you can find the deployment package in the S3 bucket. | System Admin/ Application Developer
Test the application. | When the environment has been created, use the URL provided in the Elastic Beanstalk console to test the application. | System Admin

Summary

This pattern describes the steps for migrating from a self-managed MongoDB environment (including MongoDB Community Server, Enterprise Server, Enterprise Advanced, mLab, or any managed MongoDB cluster) to MongoDB Atlas on the Amazon Web Services (AWS) Cloud. It uses the Atlas Live Migration Service to help accelerate the data migration from MongoDB to MongoDB Atlas.

The pattern accompanies the guide Migrating from MongoDB to MongoDB Atlas on the AWS Cloud on the AWS Prescriptive Guidance website. It provides the implementation steps for the migration.

The pattern is intended for AWS Service Integrator Partners (SI Partners) and AWS users.

Prerequisites and limitations

Prerequisites
AWS Prescriptive Guidance Patterns
Migrate from MongoDB to MongoDB Atlas on AWS

- A source MongoDB environment to migrate to MongoDB Atlas

**Expertise**

- This pattern requires familiarity with MongoDB, MongoDB Atlas, and AWS services. For more information, see Roles and responsibilities in the guide *Migrating from MongoDB to MongoDB Atlas on the AWS Cloud* on the AWS Prescriptive Guidance website.

**Product versions**

- MongoDB version 2.6 or later

**Architecture**

For MongoDB Atlas reference architectures that support different usage scenarios, see MongoDB Atlas reference architectures on AWS in the guide *Migrating from MongoDB to MongoDB Atlas on the AWS Cloud* on the AWS Prescriptive Guidance website.

**Tools**

- Atlas Live Migration Service – A free MongoDB utility that helps migrate databases to Atlas. This service keeps the source database in sync with the destination database until cutover. When you’re ready to cut over, you stop your application instances, point them to the destination Atlas cluster, and restart them.

**Epics**

**Discovery and assessment**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Determine the cluster size.</td>
<td>Estimate the working set size by using the information from db.stats() for the total index space. Assume that a percentage of your data space will be accessed frequently. Or, you can estimate your memory requirements based on your own assumptions. This task should take approximately one week. For more information and examples for this and the other stories in this epic, see the links in the “Related resources” section.</td>
<td>MongoDB DBA, Application architect</td>
</tr>
<tr>
<td>Estimate network bandwidth</td>
<td>To estimate your network bandwidth requirements, multiply the average document size by the number of documents served per second. Consider the maximum traffic</td>
<td>MongoDB DBA</td>
</tr>
</tbody>
</table>
that any node on your cluster will bear as the basis. To calculate downstream data transfer rates from your cluster to client applications, use the sum of the total documents returned over a period of time. If your applications read from secondary nodes, divide this number of total documents by the number of nodes that can serve read operations. To find the average document size for a database, use the `db.stats().avgObjSize` command. This task will typically take one day.

Select the Atlas tier. Follow the instructions in the MongoDB documentation to select the correct Atlas cluster tier.

Plan for application cutover.

**Set up a new MongoDB Atlas environment on AWS**

Migrate from Oracle WebLogic to Apache Tomcat (TomEE) on Amazon ECS

Summary

This pattern discusses the steps for migrating an on-premises Oracle Solaris SPARC system running Oracle WebLogic to a Docker container-based installation running Apache TomEE (Apache Tomcat with added container support) with Amazon Elastic Container Service (Amazon ECS).

For information about migrating databases that are associated with the applications you are migrating from Oracle WebLogic to Tomcat, see the database migration patterns in this catalog.

Best practices

Steps for migrating Java and Java Enterprise Edition (Java EE) web applications vary, depending on the number of container-specific resources used by the application. Spring-based applications are typically easier to migrate, because they have a small number of dependencies on the deployment container. In contrast, Java EE applications that use Enterprise JavaBeans (EJBs) and managed container resources such as thread pools, Java Authentication and Authorization Service (JAAS), and Container-Managed Persistence (CMP) require more effort.

Applications developed for Oracle Application Server frequently use the Oracle Identity Management suite. Customers migrating to open-source application servers frequently choose to re-implement identity and access management using SAML-based federation. Others use Oracle HTTP Server Webgate for cases when migrating from the Oracle Identity Management suite isn’t an option.

Java and Java EE web applications are great candidates for deployment on AWS services that are Docker-based, such as AWS Fargate and Amazon ECS. Customers frequently choose a Docker image with the latest version of the target application server (such as TomEE) and the Java Development Kit (JDK) pre-installed. They install their applications on top of the base Docker image, publish it in their Amazon Elastic Container Registry (Amazon ECR) registry, and use it for scalable deployment of their applications on AWS Fargate or Amazon ECS.

Ideally, application deployment is elastic; that is, the number of application instances scales in or out, depending on traffic or workload. This means that application instances need to come online or be terminated to adjust capacity for demand.

When moving a Java application to AWS, consider making it stateless. This is a key architectural principle of the AWS Well-Architected Framework that will enable horizontal scaling using containerization. For example, most Java-based web applications store user-session information locally. To survive application
instance termination due to automatic scaling in Amazon Elastic Compute Cloud (Amazon EC2) or for other reasons, user-session information should be stored globally so that web application users can continue to work seamlessly and transparently without reconnecting or relogging into a web application. There are several architectural options for this approach, including Amazon ElastiCache for Redis, or storing session state in a global database. Application servers such as TomEE have plugins, which enable session storage and management via Redis, databases, and other global data stores.

Use a common, centralized logging and debugging tool that is easily integrated with Amazon CloudWatch and AWS X-Ray. Migration provides an opportunity to improve application lifecycle capabilities. For example, you might want to automate the build process so that changes are easily made using a continuous integration and continuous delivery (CI/CD) pipeline. This may require changes to the application so that it can be deployed without any downtime.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Source Java code and JDK
- Source application built with Oracle WebLogic
- Defined solution for identity and access management (SAML or Oracle Webgate)
- Defined solution for application session management (moving like-for-like or with Amazon ElastiCache, or making the application stateless if needed)
- Understanding if the team needs to refactor J2EE-specific libraries for portability to Apache TomEE (see Java EE 7 Implementation Status on the Apache website)
- Hardened TomEE image based on your security requirements
- Container image with pre-installed target TomEE
- Application remediation agreed and implemented if needed (for example, logging debug build, authentication)

Product versions

- Oracle WebLogic OC4J, 9i, 10g
- Tomcat 7 (with Java 1.6 or later)

Architecture

Source technology stack

- Web application built using Oracle WebLogic
- Web application using Oracle Webgate or SAML authentication
- Web applications connected to Oracle Database version 10g and later

Target technology stack

- TomEE (Apache Tomcat with added container support) running on Amazon ECS (see also Deploying Java Web Applications and Java Microservices on Amazon ECS)
- Amazon Relational Database Service (Amazon RDS) for Oracle; for Oracle versions supported by Amazon RDS, see Amazon RDS for Oracle

Target architecture
Tools

To operate on TomEE, a Java application must be rebuilt into a .war file. In some cases, application changes may be required to operate the application on TomEE; you should check to make sure that the necessary configuration options and environment properties are defined correctly.

Also, Java Naming and Directory Interface (JNDI) lookups and JavaServer Pages (JSP) namespaces should be defined correctly. Consider checking file names used by the application to avoid naming collisions with built-in T libraries. For example, persistence.xml is a file name used by the Apache OpenJPA framework (which is bundled with OpenEJB in TomEE) for configuration purposes. The persistence.xml file in PUI contains Spring framework bean declarations.

TomEE version 7.0.3 and later (Tomcat 8.5.7 and later) returns an HTTP 400 response (bad request) for raw (unencoded) URLs with special characters. The server response appears as a blank page to the end-user. Earlier versions of TomEE and Tomcat allowed the use of certain unencoded special characters in URLs; however, it’s considered unsafe, as stated on the [CVE-2016-6816 website](https://cve.mitre.org/cgi-bin/cvename.cgi?name=CVE-2016-6816). To resolve the URL encoding issue, the URLs passed to the browser directly via JavaScript must be encoded with the `encodeURIComponent()` method instead of being used as raw strings.

After you deploy the .war file in TomEE, monitor `start log` to `Linux cat` for any missing shared libraries and Oracle-specific extensions to add missing components from Tomcat libraries.

General procedure

- Configure the application on TomEE.
- Identify and reconfigure application server-specific configuration files and resources from source to target format.
- Identify and reconfigure JNDI resources.
- Adjust EJB namespace and lookups to the format required by the target application server (if applicable).
- Reconfigure JAAS application container-specific security roles and principle mappings (if applicable).
- Package the application and shared libraries into a .war file.
- Deploy the .war file in TomEE by using the Docker container provided.
- Monitor start log to identify any missing shared library and deployment descriptor extensions. If any are found, go back to the first task.
- Test the installed application against the restored Amazon RDS database.
- Launch the complete architecture with a load balancer and Amazon ECS cluster by following the instructions in Deploy Docker Containers.
- Update the URLs to point to the load balancer.
- Update the configuration management database (CMDB).

Summary

This pattern describes the steps for migrating an Oracle database on Amazon Elastic Compute Cloud (Amazon EC2) to Amazon Relational Database Service (Amazon RDS) for Oracle by using AWS Database Migration Service (AWS DMS). The pattern also uses Oracle SQL Developer or SQL *Plus to connect to your Oracle DB instance, and includes an AWS CloudFormation template that automates some of the tasks.

Migrating to Amazon RDS for Oracle enables you to focus on your business and applications while Amazon RDS takes care of database administration tasks such as provisioning databases, backup and recovery, security patches, version upgrades, and storage management.

Prerequisites and limitations

Prerequisites

• An active AWS account
• An Amazon Machine Image (AMI) for Oracle Database on Amazon EC2
Product versions

- AWS DMS supports Oracle versions 11g (version 11.2.0.3.v1 and later), 12c, and 18c for Amazon RDS instance databases for the Enterprise, Standard, Standard One, and Standard Two editions. For the latest information about supported versions, see Using an Oracle Database as a Target for AWS DMS in the AWS documentation. (The attached AWS CloudFormation templates use Oracle version 12c as the source database.)
- Oracle SQL Developer 4.0.3

Architecture

Source architecture

- Oracle Database on Amazon EC2

Target architecture

- Amazon RDS for Oracle

Migration architecture

Tools

- AWS DMS – AWS Database Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. It supports both homogeneous and heterogeneous migrations. For information about the Oracle database versions and editions that are supported, see Using an Oracle Database as a Source for AWS DMS and Using an Oracle Database as a Target for AWS DMS in the AWS documentation.
- Oracle SQL Developer or SQL *Plus – These tools enable you to connect to the Amazon RDS for Oracle DB instance.
Epics

Set up your target database

Migrate an on-premises Oracle database to Amazon OpenSearch Service using Logstash

*Created by Aditya Goteti (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Databases: Relational</th>
<th>Target:</th>
<th>Amazon ES</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>

<td>Workload:</td>
<td>Oracle</td>
<td>Technologies:</td>
<td>Migration; Databases</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon OpenSearch Service</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to move data from an on-premises Oracle database to Amazon OpenSearch Service (successor to Amazon Elasticsearch Service) using Logstash. It includes architectural considerations and some required skill sets and recommendations. The data can be from a single table or from multiple tables in which a full-text search will need to be performed.
Amazon OpenSearch Service can be configured within a virtual private cloud (VPC), or it can be placed publicly with IP-based restrictions. This pattern describes a scenario where Amazon OpenSearch Service is configured within a VPC. Logstash is used to collect the data from the Oracle database, parse it to JSON format, and then feed the data into Amazon OpenSearch Service.

Prerequisites and limitations

Prerequisites

• An active AWS account
• Java 8 (required by Logstash 6.4.3)
• Connectivity between the on-premises database servers and Amazon Elastic Compute Cloud (Amazon EC2) instances in a VPC, established using AWS Virtual Private Network (AWS VPN)
• A query to retrieve the required data to be pushed to Amazon OpenSearch Service from the database
• Oracle Java Database Connectivity (JDBC) drivers

Limitations

• Logstash cannot identify records that are hard-deleted from the database

Product versions

• Oracle Database 12c
• Amazon OpenSearch Service 6.3
• Logstash 6.4.3

Architecture

Source technology stack

• On-premises Oracle database
• On-premises AWS VPN

Target technology stack

• VPC
• EC2 instance
• Amazon OpenSearch Service
• Logstash
• NAT Gateway (for operating system updates on EC2 instances and to install Java 8, Logstash, and plugins)

Data migration architecture
Tools

- Logstash 6.4.3
- JDBC input plugin (download and more information)
- Logstash output plugin (logstash-output-amazon_es)
- Oracle JDBC drivers

Epics

Plan the migration

<td>Amazon RDS; AWS DMS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Summary

This pattern describes the steps for migrating on-premises Oracle databases to Amazon Relational Database Service (Amazon RDS) for Oracle. As part of the migration process, you create a migration plan and consider important factors about your target database infrastructure based on your source database. You can choose one of two migration options based on your business requirements and use case:
1. AWS Database Migration Service (AWS DMS) – You can use AWS DMS to migrate databases to the AWS Cloud quickly and securely. Your source database remains fully operational during the migration, which minimizes downtime to applications that rely on the database. You can reduce migration time by using AWS DMS to create a task that captures ongoing changes after you complete an initial full-load migration through a process called change data capture (CDC). For more information, see Migrate from Oracle to Amazon RDS with AWS DMS in the AWS documentation.

2. Native Oracle tools – You can migrate databases by using native Oracle tools, such as Oracle and Data Pump Export and Data Pump Import with Oracle GoldenGate for CDC. You can also use native Oracle tools such as the original Export utility and original Import utility to reduce the full-load time.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An on-premises Oracle database
- An Amazon RDS Oracle database (DB) instance

**Limitations**

- Database size limit: 64 TB

**Product versions**

- Oracle versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2 and 18c. For the latest list of supported versions and editions, see Amazon RDS for Oracle in the AWS documentation. For Oracle versions supported by AWS DMS, see Using an Oracle database as a source for AWS DMS in the AWS DMS documentation.

**Architecture**

**Source technology stack**

- On-premises Oracle databases

**Target technology stack**

- Amazon RDS for Oracle

**Source and target architecture**

The following diagram shows how to migrate an on-premises Oracle database to Amazon RDS for Oracle by using AWS DMS.
Migrate from Oracle to Amazon RDS for Oracle

The diagram shows the following workflow:

1. Create or use an existing database user, grant the required AWS DMS permissions to that user, turn on ARCHIVELOG mode, and then set up supplemental logging.
2. Configure the internet gateway between the on-premises and AWS network.
3. Configure source and target endpoints for AWS DMS.
4. Configure AWS DMS replication tasks to migrate the data from the source database to the target database.
5. Complete the post-migration activities on the target database.

The following diagram shows how to migrate an on-premises Oracle database to Amazon RDS for Oracle by using native Oracle tools.
The diagram shows the following workflow:

1. Create or use an existing database user and grant the required permissions to back up the Oracle database by using Oracle Export (exp) and Import (imp) utilities.
2. Configure the internet gateway between the on-premises and AWS network.
3. Configure the Oracle client on the Bastion host to take the backup database.
4. Upload the backup database to an Amazon Simple Storage Service (Amazon S3) bucket.
5. Restore the database backup from Amazon S3 to an Amazon RDS for Oracle database.
6. Configure Oracle GoldenGate for CDC.
7. Complete the post-migration activities on the target database.

Tools

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Native Oracle tools help you perform a homogenous migration. You can use Oracle Data Pump to migrate data between your source and target databases. This pattern uses Oracle Data Pump to perform the full load from the source database to the target database.
- Oracle GoldenGate helps you perform logical replication between two or more databases. This pattern uses GoldenGate to replicate the delta changes after the initial load by using Oracle Data Pump.
## Epics

Plan the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create project documents and record database details. | 1. Document your migration goals, migration requirements, key project stakeholders, project milestones, project deadlines, key metrics, migration risks, and risk mitigation plans.  
2. Document critical information about your source database, including RAM, IOPS, and CPUs. You will later use this information to determine the appropriate target DB instance.  
3. Validate the versions of your source and target databases. | DBA             |
| Identify storage requirements.                   | Identify and document your storage requirements, including the following:  
1. Calculate the storage allocated for the source DB instance.  
2. Gather the historical growth metrics from the source DB instance.  
3. Forecast future growth for the target DB instance.  

**Note:** For General Purpose (gp2) SSD volumes, you get three IOPS per 1 GB of storage. Allocate storage by calculating the total number of read and write IOPS on the source database. | DBA, SysAdmin |
| Choose the proper instance type based on compute requirements. | 1. Determine the compute requirements of the target DB instance.  
2. Identify performance issues.  
3. Consider the factors for determining the appropriate instance type:  
   • CPU utilization of the source DB instance  
   • IOPS (read and write) for the source DB instance | SysAdmin  |
## Identify network access security requirements.

1. Identify and document the network access security requirements for your source and target databases.
2. Configure the appropriate security groups for enabling the application to communicate with the database.

*Skills required:* DBA, SysAdmin

## Identify the application migration strategy.

1. Determine and document the migration cutover strategy.
2. Determine and document your application’s recovery time objective (RTO) and recovery point objective (RPO), and then plan for the cutover accordingly.

*Skills required:* DBA, SysAdmin, App owner

## Identify migration risks.

Assess the database and document migration specific risks and mitigations. For example:

- Identify no-logging tables and highlight the risk of data loss in the event of recovery.
- Extract the source database users and privileges, and highlight the conflicts with Amazon RDS privileges.
- Review the alert log for any Oracle-specific errors and warnings.
- Identify the supported and unsupported features of the target DB instance.
- Review the deprecated features of the target DB version engine.

*Skills required:* DBA

## Configure the infrastructure

</tr>
<tr>
<td>11.</td>
<td>Resolve any discrepancies found between object counts.</td>
<td></td>
</tr>
</tbody>
</table>

**Task**

### (Option 2) Use AWS DMS to migrate data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Prepare the data. | 1. Clean the data in the source database.  
2. Create a replication instance.  
3. Create a source endpoint and target endpoint.  
4. Identify the number of tables and objects to be migrated. | DBA |
| Migrate the data. | 1. Drop foreign key constraints and triggers on the target database.  
2. Drop secondary indexes on the target database.  
3. Configure AWS DMS full-load task settings from the source database to the target database.  
4. Enable foreign keys.  
5. Enable AWS DMS CDC to replicate ongoing changes.  
6. Enable triggers.  
7. Update the sequences.  
8. Validate the source and target data. | DBA |

### Cut over to the target database

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Switch the application clients to the new infrastructure. | 1. Stop all application services and client connections pointing to Oracle.  
2. Run the AWS DMS tasks.  
3. Set up a rollback task (for example, reverse CDC from the Amazon RDS database to the on-premises Oracle database).  
4. Validate the data. | DBA, SysAdmin, App owner |
### Migrate from Oracle to Amazon RDS for Oracle

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.</td>
<td>Start the application services on the new target database by configuring Amazon Route 53 to the new Amazon RDS for Oracle DB instance.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>Add Amazon CloudWatch monitoring to your new Amazon RDS for Oracle DB instance.</td>
<td></td>
</tr>
</tbody>
</table>

#### Implement your rollback plan.

1. Stop all application services pointing to the Amazon RDS for Oracle DB instance.
2. Roll back the changes to the source on-premises Oracle database by using an AWS DMS task.
3. Stop the AWS DMS tasks running from the on-premises Oracle database to the Amazon RDS for Oracle database.
4. Configure the applications back on the source Oracle database.
5. Confirm the rollback deployment is complete.

#### Close out the migration project

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clean up resources.</td>
<td>Shut down or remove the temporary AWS resources, such as the AWS DMS replication instance and S3 bucket.</td>
<td>DBA, SysAdmin</td>
</tr>
<tr>
<td>Review project documents.</td>
<td>Review your migration planning documents and goals, and then confirm that you completed all required migration steps.</td>
<td>DBA, SysAdmin, App owner</td>
</tr>
<tr>
<td>Gather metrics.</td>
<td>Record key migration metrics, including how long it took to complete the migration, the percentage of manual vs. tool-based tasks, cost savings, and other relevant metrics.</td>
<td>DBA, SysAdmin, App owner</td>
</tr>
<tr>
<td>Close out the project.</td>
<td>Close out the migration project and capture feedback about the effort.</td>
<td>DBA, SysAdmin, App owner</td>

<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to migrate an Oracle database from an on-premises data center to an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance by using Oracle Data Pump.

The pattern involves creating a data dump file from the source database, storing the file in an Amazon Simple Storage Service (Amazon S3) bucket, and then restoring the data to an Amazon RDS for Oracle DB instance. This pattern is useful when you encounter limitations using AWS Database Migration Service (AWS DMS) for the migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The required permissions to create roles in AWS Identity and Access Management (IAM) and for an Amazon S3 multipart upload
- The required permissions to export data from the source database

Product versions

- Oracle Data Pump is available only for Oracle Database 10g Release 1 (10.1) and later versions.
**Architecture**

**Source technology stack**
- On-premises Oracle databases

**Target technology stack**
- Amazon RDS for Oracle
- SQL client (Oracle SQL Developer)
- An S3 bucket

**Source and target architecture**

**Tools**
- **Oracle Data Pump** – *Oracle Data Pump* is used to export the data dump (.dmp) file to the Oracle server, and to import it into Amazon RDS for Oracle. For more information, see *Importing Data with Oracle Data Pump and an Amazon S3 Bucket* in the Amazon RDS documentation.
- **Amazon S3** – *Amazon Simple Storage Service (Amazon S3)* is a durable storage service that provides faster import to Amazon RDS. This pattern uses an S3 bucket to store the data dump file.
- **AWS IAM** – *AWS Identity and Access Management (IAM)* is used to create the roles and policies necessary for migrating data from Amazon S3 to Amazon RDS for Oracle.
- **Oracle SQL Developer** – *SQL Developer* interacts with both the on-premises Oracle database and Amazon RDS for Oracle, to run SQL commands required for exporting and importing data.
Epics

Set up the migration

<table>

AWS Prescriptive Guidance Patterns
Migrate from Oracle to Amazon
RDS using Oracle Data Pump

Additional information

Creating a data dump file

To create a dump file named sample.dmp in the DATA_PUMP_DIR directory, use this script:

```sql
DECLARE
  hdnl NUMBER;
BEGIN
  hdnl := DBMS_DATAPUMP.OPEN( operation => 'EXPORT', job_mode => 'SCHEMA', job_name=>null);
  DBMS_DATAPUMP.ADD_FILE(handle => hdnl, filename => 'sample.dmp', directory => 'DATA_PUMP_DIR', filetype => dbms_datapump.ku$_file_type_dump_file);
  DBMS_DATAPUMP.ADD_FILE( handle => hdnl, filename => 'exp.log', directory => 'DATA_PUMP_DIR', filetype => dbms_datapump.ku$_file_type_log_file);
  DBMS_DATAPUMP.METADATA_FILTER(hdnl,'SCHEMA_EXPR','IN (''ADMIN'')');
  DBMS_DATAPUMP.METADATA_FILTER(hdnl,'EXCLUDE_NAME_EXPR',q'
    SELECT NAME FROM sys.OBJ$
    WHERE TYPE# IN (66,67,74,79,59,62,46) and OWNER# IN (SELECT USER# from sys.user$ where
    NAME in ('RDSADMIN','SYS','SYSTEM','RDS_DATAGUARD','RDSSEC'))','PROCOBJ');
  DBMS_DATAPUMP.START_JOB(hdnl);
END;
```

Uploading the data dump file

Use the following command-line interface (CLI) command from the folder where the dump file was created. This will upload the dump file to Amazon S3 by using multipart upload:

```
aws s3api create-multipart-upload --bucket <bucket_to_store_dumpfile> --key sample.dmp
```

Uploading the data dump file to Amazon RDS

To import the dump file into the target database:

1. Connect to the target Amazon RDS for Oracle database from Oracle SQL Developer, and then run the following SQL command to create the user to import the database:

```
create user <USER NAME> identified by <PASSWORD>;
grant create session, resource to <USER NAME>;
alter user <USER NAME> quota 100M on users;
```

2. Run the following SQL command to import the dump file from the S3 bucket to the Amazon RDS for Oracle database:

```
SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(
  p_bucket_name   =>  'my-s3-integration1',
  p_directory_name =>  'DATA_PUMP_DIR')
AS TASK_ID FROM DUAL;
```

Restoring the schema and data to Amazon RDS

Run the following SQL command from Oracle SQL Developer to restore the schema and data from the imported dump file:

```sql
DECLARE
  hdnl NUMBER;
BEGIN
  hdnl := DBMS_DATAPUMP.OPEN( operation => 'IMPORT', job_mode => 'SCHEMA', job_name=>null);
```

Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical

Created by Rajesh Madiwale (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Amazon EC2</th>
<th>Target:</th>
<th>Amazon RDS for PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>

<td>Migration; Databases</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon RDS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern outlines steps for migrating a PostgreSQL database (version 9.5 and later) from Amazon Elastic Compute Cloud (Amazon EC2) to Amazon Relational Database Service (Amazon RDS) for PostgreSQL by using the PostgreSQL pglogical extension. Amazon RDS now supports the pglogical extension for PostgreSQL version 10.

Prerequisites and limitations

Prerequisites

- Choose the right type of Amazon RDS instance. For more information, see Amazon RDS Instance Types.
- Make sure that the source and target versions of PostgreSQL are the same.
- Install and integrate the pglogical extension with PostgreSQL on Amazon EC2.

Product versions

- PostgreSQL version 10 and later on Amazon RDS, with the features supported on Amazon RDS (see PostgreSQL on Amazon RDS in the AWS documentation). This pattern was tested by migrating PostgreSQL 9.5 to PostgreSQL version 10 on Amazon RDS, but it also applies to later versions of PostgreSQL on Amazon RDS.

Architecture

Data migration architecture
Tools

- `pglogical` extension
- PostgreSQL native utilities: `pg_dump` and `pg_restore`

Epics

Migrate data by using the `pglogical` extension

<table>
<thead>
<tr>

Migrate an on-premises PostgreSQL database to Aurora PostgreSQL

Created by Baji Shaik (AWS) and Jitender Kumar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>On-premises PostgreSQL database</th>
<th>Target:</th>
<th>Aurora PostgreSQL-Compatible</th>
</tr>
</thead>
<tbody>
<tr>

<td>Amazon Aurora; AWS DMS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Amazon Aurora PostgreSQL-Compatible Edition combines the performance and availability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. Aurora provides these benefits by scaling storage across three Availability Zones in the same AWS Region, and supports up to 15 read replica instances for scaling out read workloads and providing high availability within a single Region. By using an Aurora global database, you can replicate PostgreSQL databases in up to five Regions for remote read access and disaster recovery in the event of a Region failure. This pattern describes the steps for migrating an on-premises PostgreSQL source database to an Aurora PostgreSQL-Compatible database. The pattern includes two migration options: using AWS Data Migration Service (AWS DMS) or using native PostgreSQL tools (such as `pg_dump`, `pg_restore`, and `psql`) or third-party tools.

The steps described in this pattern also apply to target PostgreSQL databases on Amazon Relational Database Service (Amazon RDS) and Amazon Elastic Compute Cloud (Amazon EC2) instances.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A PostgreSQL source database in an on-premises data center
- An Aurora PostgreSQL-Compatible DB instance or an Amazon RDS for PostgreSQL DB instance

Limitations

- Database size limits are 64 TB for Amazon RDS for PostgreSQL and 128 TB for Aurora PostgreSQL-Compatible.
- If you’re using the AWS DMS migration option, review AWS DMS limitations on using a PostgreSQL database as a source.
Product versions

- For PostgreSQL major and minor version support in Amazon RDS, see Amazon RDS for PostgreSQL updates in the Amazon RDS documentation.
- For PostgreSQL support in Aurora, see Amazon Aurora PostgreSQL updates in the Aurora documentation.
- If you’re using the AWS DMS migration option, see supported PostgreSQL versions in the AWS DMS documentation.

Architecture

Source technology stack

Data migration architecture

Using AWS DMS
Using native PostgreSQL tools
Tools

- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises configurations. This service supports different sources and target databases. For information about how to validate the PostgreSQL source and target database versions and editions supported for use with AWS DMS, see [Using a PostgreSQL database as an AWS DMS source](#). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

- Native PostgreSQL tools include `pg_dump`, `pg_restore`, and `psql`.

**Epics**

**Analyze the migration**

<table>
<thead>
<tr>
<th>Task</th>

Migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on Amazon EC2 running Linux

Created by Tirumala Rama Chandra Murty Dasari (AWS)

<table>
<thead>
<tr>
<th>R Type: Replatform</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon EC2 Linux with Microsoft SQL Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>Workload: Microsoft</td>
<td>AWS services: Amazon EC2</td>
<td></td>
</tr>
</tbody>
</table>
Summary

This pattern describes how to migrate from an on-premises Microsoft SQL Server database running on Microsoft Windows, to Microsoft SQL Server on an Amazon Elastic Compute Cloud (Amazon EC2) Linux instance by using backup and restore utilities.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Amazon EC2 Linux AMI (Amazon Machine Image) with Microsoft SQL Server
- AWS Direct Connect between on-premises Windows and Microsoft SQL Server on the Linux EC2 instance

Architecture

Source technology stack

- On-premises Microsoft SQL Server database

Target technology stack

- Linux EC2 instance with a Microsoft SQL Server database

Database migration architecture
Tools

- **WinSCP** - This tool enables Windows users to easily share files with Linux users.
- **Sqlcmd** - This command-line utility lets you submit T-SQL statements or batches to local and remote instances of SQL Server. The utility is extremely useful for repetitive database tasks such as batch processing or unit testing.

Epics

Prepare the EC2 Linux instance with SQL Server

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select an AMI that provides the Linux operating system and includes Microsoft SQL Server.</td>
<td></td>
<td>Sysadmin</td>
</tr>
<tr>
<td>Configure the AMI to create an EC2 instance.</td>
<td></td>
<td>Sysadmin</td>
</tr>
</tbody>
</table>
Create inbound and outbound rules for security groups.

Configure the Linux EC2 instance for a Microsoft SQL Server database.

Create users and provide permissions as in the source database.

Install SQL Server tools and the sqlcmd utility on the Linux EC2 instance.

Back up the on-premises SQL Server database.

Install WinSCP on Microsoft SQL Server.

Move the backup file to the Linux EC2 instance running Microsoft SQL Server.

Restore the database from the database backup file by using the sqlcmd utility.

Validate database objects and data.

Validate database objects and data.

Cut over from the on-premises Microsoft SQL Server database to the Linux EC2 instance running Microsoft SQL Server.

Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server

Created by Mark Szalkiewicz (AWS)

| R Type: Replatform | Source: Databases: Relational | Target: Amazon RDS for Microsoft SQL Server |
| Created by: AWS | Environment: PoC or pilot | Technologies: Databases; Migration |
| Workload: Microsoft | AWS services: Amazon RDS |

Summary

This pattern provides guidance for migrating from an on-premises Microsoft SQL Server database to Amazon Relational Database Service (Amazon RDS) for Microsoft SQL Server. It describes two options for migration: using AWS Data Migration Service (AWS DMS) or using native Microsoft SQL Server tools such as Copy Database Wizard.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Microsoft SQL Server database in an on-premises data center

Limitations

- Database size limit: 16 TB

Product versions

- SQL Server 2012-2017, Enterprise, Standard, Workgroup, and Developer editions. For the latest list of supported versions and features, see Microsoft SQL Server on Amazon RDS in the AWS documentation. If you’re using AWS DMS, see also Using a Microsoft SQL Server Database as a Target for AWS DMS for SQL Server versions supported by AWS DMS.

Architecture

Source technology stack
• An on-premises Microsoft SQL Server database

Target technology stack
• An Amazon RDS for Microsoft SQL Server DB instance

Source and target architecture

Using AWS DMS:

Using native Microsoft SQL Server tools:
Tools

- **AWS DMS** - AWS Database Migration Service (AWS DMS) supports several types of source and target databases. For details, see [AWS DMS Step-by-Step Walkthroughs](#). If AWS DMS doesn’t support the source database, select another method for migrating the data.

- **Native Microsoft SQL Server tools** - Backup and restore; Copy Database Wizard: copy and attach database

Epics

Plan the migration

<table>

Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using Amazon S3 and SSMS
Summary

This pattern describes how to migrate an on-premises Microsoft SQL Server database to an Amazon Relational Database Service (Amazon RDS) for SQL Server DB instance. The migration process includes making a backup and restoring the backup in an Amazon Simple Storage Service (Amazon S3) bucket, and using SQL Server Management Studio (SSMS).

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) user policies to access S3 buckets and the Amazon RDS for SQL Server DB instance

Product versions

- SQL Server 2012-2017 (for the latest list of supported versions and features, see Microsoft SQL Server on Amazon RDS in the AWS documentation)

Architecture

Source technology stack

- An on-premises Microsoft SQL Server database

Target technology stack

- An Amazon RDS for SQL Server DB instance

Data migration architecture
Tools

- **SSMS** - Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

Epics

Create an Amazon RDS for Microsoft SQL Server DB instance

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Select SQL Server as the database engine in Amazon RDS for SQL Server.</td>
<td>DBA</td>
</tr>
<tr>
<td></td>
<td>Choose the SQL Server Express Edition.</td>
<td>DBA</td>
</tr>
<tr>
<td></td>
<td>Specify database details.</td>
<td>DBA, App owner</td>
</tr>
</tbody>
</table>

Create a backup file from the on-premises Microsoft SQL Server database

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Connect to the on-premises SQL Server database through SSMS.</td>
<td>DBA</td>
</tr>
</tbody>
</table>
Create a backup of the database.
- **DBA, App owner**

Upload the backup file to Amazon S3

Create a bucket in Amazon S3.
- **DBA**

Upload the backup file to the S3 bucket using AWS Direct Connect.
- **SysopsAdmin**

Restore the database in Amazon RDS for SQL Server

Open the Amazon RDS console at https://console.aws.amazon.com/rds/.
- **SysopsAdmin**

Choose Option groups in the navigation pane.
- **SysopsAdmin**

Choose the Create group button.
- **SysopsAdmin**

Add the SQLSERVER_BACKUP_RESTORE option to the option group.
- **SysopsAdmin**

Add the option group to Amazon RDS for SQL Server.
- **SysopsAdmin**

Connect to Amazon RDS for SQL Server through SSMS.
- **DBA**

Call the msdb.dbo.rds_restore_database stored procedure to restore the database.
- **DBA**

Validate the target database

Validate the objects and data between the source database and Amazon RDS for SQL Server.
- **App owner, DBA**
Cut over

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>After validation, redirect application traffic to the Amazon RDS for SQL Server DB instance.</td>
<td></td>
<td>App owner, DBA</td>
</tr>
</tbody>
</table>

Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using linked servers

*Created by Kevin Yung (AWS)*

<table>
<thead>
<tr>
<th>R Type:</th>
<th>Replatform</th>
<th>Source:</th>
<th>Databases: Relational</th>
<th>Target:</th>
<th>Amazon RDS for Microsoft SQL Server</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by:</td>
<td>AWS</td>
<td>Environment:</td>
<td>Production</td>
<td>Technologies:</td>
<td>Databases; Migration</td>
</tr>
<tr>
<td>Workload:</td>
<td>Microsoft</td>
<td>AWS services:</td>
<td>Amazon RDS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Linked servers enable Microsoft SQL Server to run SQL statements on other instances of database servers. This pattern describes how you can migrate your on-premises Microsoft SQL Server database to Amazon Relational Database Service (Amazon RDS) for Microsoft SQL Server to achieve lower cost and higher availability. Currently, Amazon RDS for Microsoft SQL Server doesn't support connections outside an Amazon Virtual Private Cloud (Amazon VPC) network.

You can use this pattern to achieve the following objectives:

- To migrate Microsoft SQL Server to Amazon RDS for Microsoft SQL Server without breaking linked server capabilities.
- To prioritize and migrate linked Microsoft SQL Server in different waves.

Prerequisites and limitations

Prerequisites
- Check whether Microsoft SQL Server on Amazon RDS supports the features you require.
- Make sure that you can use either Amazon RDS for Microsoft SQL Server with default collations or collations set over database levels.

Architecture

Source technology stack
- On-premises databases (Microsoft SQL Server)

Target technology stack
- Amazon RDS for SQL Server

Source state architecture

Target state architecture
In the target state, you migrate Microsoft SQL Server to Amazon RDS for Microsoft SQL Server by using linked servers. This architecture uses a Network Load Balancer to proxy the traffic from Amazon RDS for Microsoft SQL Server to on-premises servers running Microsoft SQL Server. The following diagram shows the reverse proxy capability for the Network Load Balancer.

**Tools**

- AWS CloudFormation
- Network Load Balancer
- Amazon RDS for SQL Server in multiple Availability Zones (Multi-AZs)
- AWS Database Migration Service (AWS DMS)
Epics

Create a landing zone VPC

**Migrate a Microsoft SQL Server database to Aurora MySQL by using AWS DMS and AWS SCT**

*Created by Mark Szalkiewicz (AWS)*

<table>
<thead>
<tr>
<th>R Type: Replatform</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon Aurora MySQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>Workload: Microsoft</td>
<td>AWS services: Amazon Aurora</td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern describes how to migrate a Microsoft SQL Server database that is either on premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance to Amazon Aurora MySQL. The pattern uses AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT) for data migration and schema conversion.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- A Microsoft SQL Server source database in an on-premises data center or on an EC2 instance
• Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed on either a local machine or an EC2 instance where AWS SCT is installed

Limitations

• Database size limit: 64 TB

Product versions

• Microsoft SQL Server 2008, 2008R2, 2012, 2014, 2016, and 2017 for the Enterprise, Standard, Workgroup, and Developer editions. The Web and Express editions aren't supported by AWS DMS. For the latest list of supported versions, see Using a Microsoft SQL Server Database as a Source for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Microsoft SQL Server versions supported by AWS SCT, see the AWS SCT documentation.

• MySQL versions 5.5, 5.6, and 5.7. For the latest list of supported versions, see Using a MySQL-Compatible Database as a Target for AWS DMS.

Architecture

Source technology stack

One of the following:

• An on-premises Microsoft SQL Server database

• A Microsoft SQL Server database on an EC2 instance

Target technology stack

• Aurora MySQL

Data migration architecture

• From a Microsoft SQL Server database running in the AWS Cloud
• From a Microsoft SQL Server database running in an on-premises data center
Tools

- **AWS DMS - AWS Data Migration Service** (AWS DMS) helps you migrate your data to and from widely used commercial and open-source databases, including Oracle, SQL Server, MySQL, and PostgreSQL. You can use AWS DMS to migrate your data into the AWS Cloud, between on-premises instances (through an AWS Cloud setup), or between combinations of cloud and on-premises setups.

- **AWS SCT - AWS Schema Conversion Tool** (AWS SCT) makes heterogeneous database migrations easy by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

Epics

Prepare for the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>

Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools

Created by Sergey Dmitriev (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source: Databases: Relational</th>
<th>Target:</th>
<th>Amazon RDS for MariaDB</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Replatform</td>
<td>Workload: Open-source</td>
<td>Technologies: Migration; Databases</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides guidance for migrating an on-premises MariaDB database to Amazon Relational Database Service (Amazon RDS) for MariaDB by using native tools. If you have MySQL tools installed, you can use `mysql` and `mysqldump`. If you have MariaDB tools installed, you can use `mariadb` and `mariadb-dump`. MySQL and MariaDB tools have the same origin, but there are minor differences in MariaDB version 10.6 and later.
Prerequisites and limitations

Prerequisites

• An active AWS account
• A MariaDB source database in an on-premises data center

Limitations

• Database size limit: 64 TB

Product versions

• MariaDB versions 10.0-10.6 (for the latest list of supported versions, see MariaDB on Amazon RDS in the AWS documentation)

Architecture

Source technology stack

• MariaDB database in an on-premises data center

Target technology stack

• Amazon RDS for MariaDB DB instance

Target architecture
Data migration architecture

Tools

- Native MySQL tools: `mysql` and `mysqldump`
- Native MariaDB tools: `mariadb` and `mariadb-dump`

Epics

Plan the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate source and target database versions and engines.</td>

Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3

*Created by Rohan Jamadagni (AWS) and Udayasimha Theepireddy (AWS)*
Summary

This pattern describes how to migrate large, on-premises MySQL databases efficiently to Amazon Aurora MySQL by using Percona XtraBackup. Percona XtraBackup is an open-source, non-blocking backup utility for MySQL-based servers. The pattern shows how to use Amazon Elastic File System (Amazon EFS) to reduce the time to upload the backup to Amazon Simple Storage Service (Amazon S3) and to restore the backup to Amazon Aurora MySQL. The pattern also provides details on how to make incremental Percona backups to minimize the number of binary logs to be applied to the target Aurora MySQL database.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS Identity and Access Management (IAM) user with permissions to create IAM roles and policies.
- Network connectivity between the on-premises MySQL database and the virtual private cloud (VPC) on AWS.

Limitations

- The source servers must be Linux-based systems that can install a Network File System (NFS) client (nfs-utils/nfs-common).
- The S3 bucket used for uploading backup files supports server-side encryption (SSE-S3/SSE-KMS) only.
- Amazon S3 limits the size of the backup files to 5 TB. If your backup file exceeds 5 TB, you can split it into multiple, smaller files.
- The number of source files uploaded to the S3 bucket cannot exceed one million files.
- The pattern supports Percona XtraBackup full backup and incremental backup only. It doesn't support partial backups that use --tables, --tables-exclude, --tables-file, --databases, --databases-exclude, or --databases-file.
- Aurora doesn't restore user accounts, functions, stored procedures, or time zone information from the source MySQL database.

Product versions

- The source database must be MySQL version 5.5, 5.6, or 5.7.
- For MySQL 5.7, you must use Percona XtraBackup 2.4.
- For MySQL 5.6 and 5.6, you must use Percona XtraBackup 2.3 or 2.4.
AWS Prescriptive Guidance Patterns
Migrate from on-premises MySQL to Aurora MySQL using Percona XtraBackup

Architecture

Source technology stack

- Linux-based operating system
- MySQL server
- Percona XtraBackup

Target technology stack

- Amazon Aurora
- Amazon S3
- Amazon EFS

Target architecture

Tools

- Percona XtraBackup – An open-source utility that performs streaming, compressed, and incremental backups of MySQL databases without disrupting or blocking your databases.
- Amazon Aurora – A fully managed relational database engine that makes it simple and cost-effective to set up, operate, and scale MySQL deployments. Aurora MySQL is a drop-in replacement for MySQL.
- Amazon S3 – An object storage service that offers scalability, data availability, security, and performance. You can use Amazon S3 to store and protect any amount of data for a range of use cases, such as websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics.
- Amazon EFS – A scalable, fully managed, elastic NFS file system that you can use with AWS Cloud services and on-premises resources. Amazon EFS is built to scale on demand to petabytes without disrupting applications, and automatically grows and shrinks as you add and remove files.
## Epics

Create an Amazon EFS file system

</table>

**Make a backup of the MySQL source database**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install Percona XtraBackup.</td>
<td>Install Percona XtraBackup 2.3 or 2.4 (depending on the version of your MySQL database) on the on-premises database server. For installation links, see the &quot;Related resources&quot; section.</td>
<td>Database administrator</td>
</tr>
<tr>
<td>Count the schemas and tables in the source database.</td>
<td>Gather and note the number of schemas and objects in the source MySQL database. You will use these counts to validate the Aurora MySQL database after migration.</td>
<td>Database administrator</td>
</tr>
<tr>
<td>(Optional) Note the latest binary log sequence from the source database.</td>
<td>Perform this step if you want to establish binary log replication between the source database and Aurora MySQL to minimize downtime. log-bin must be enabled, and server_id must be unique. Note the current binary log sequence from the source database, just before initiating a backup. Perform this step just before full backup if you're planning to use only full backup. If you're planning to make incremental backups after a full backup, perform this step just before the final incremental backup.</td>
<td>Database administrator</td>
</tr>
</tbody>
</table>
### AWS Prescriptive Guidance Patterns
### Migrate from on-premises MySQL to Aurora MySQL using Percona XtraBackup

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start a full backup of the source MySQL database.</td>
<td>Make a full backup of the MySQL source database using Percona XtraBackup. For example commands for full and incremental backups, see the &quot;Additional information&quot; section.</td>
<td>Database administrator</td>
</tr>
<tr>
<td>(Optional) Make incremental backups using Percona XtraBackup.</td>
<td>Incremental backups can be used to reduce the amount of binary logs you need to apply to sync the source database with Aurora MySQL. Large-size and transaction-heavy databases might generate a large number of binary logs during backups. By taking incremental backups and storing them on a shared Amazon EFS file system, you can significantly reduce the time for backing up and uploading your database. For details, see the &quot;Additional information&quot; section. Continue to make incremental backups until you're ready to begin the migration process to Aurora.</td>
<td>Database administrator</td>
</tr>
<tr>
<td>Prepare backups.</td>
<td>In this step, transactional logs are applied to the backup for transactions that were in flight during the backup. Continue to apply transactional logs (--apply-log-only) to each incremental backup to merge the backups, except for the last backup. For examples, see the &quot;Additional information&quot; section. After this step, the complete, merged backup will be in ~/&lt;efs_mount_name&gt;/fullbackup.</td>
<td>Database administrator</td>
</tr>
<tr>
<td>Zip and split the final merged backup.</td>
<td>After you prepare the final, merged backup, use tar, zip, and split commands to create smaller zipped files of the backup. For examples, see the &quot;Additional information&quot; section.</td>
<td>Database administrator</td>
</tr>
</tbody>
</table>
## Restore the backup to an Aurora MySQL DB cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Upload the backup to Amazon S3.</strong></td>
<td>The Amazon EFS file system where the backup files are stored is mounted on both the on-premises database and an EC2 instance, so the backup files are readily available to the EC2 instance. Connect to the EC2 instance by using Secure Shell (SSH) and upload the zipped backup files to a new or existing S3 bucket; for example: <code>aws s3 sync ~/&lt;efs_mount_name&gt;/fullbackup s3://&lt;bucket_name&gt;/fullbackup</code>. For additional details, see the links in the &quot;Related resources&quot; section.</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td><strong>Create a service role for Aurora to access Amazon S3.</strong></td>
<td>Create an IAM role with trust &quot;rds.amazonaws.com&quot; and a policy that will enable Aurora to access the S3 bucket where the backup files are stored. The required permissions are ListBucket, GetObject, and GetObjectVersion.</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td><strong>Create the networking configuration for Aurora.</strong></td>
<td>Create a cluster DB subnet group with at least two Availability Zones and a subnet route table configuration that allows outbound connectivity to the source database. Create a security group that allows outbound connections to the on-premises database, and allows administrators to connect to the Aurora DB cluster. For more information, see the links in the &quot;Related resources&quot; section.</td>
<td>AWS DevOps/database administrator</td>
</tr>
<tr>
<td><strong>Restore the backup to an Aurora MySQL DB cluster.</strong></td>
<td>Restore your data from the backup that you uploaded to Amazon S3. Specify the MySQL version of your source database, provide the S3 bucket name and folder path prefix where you uploaded the backup file (for example, &quot;fullbackup&quot; for the examples in the &quot;Additional information&quot; section), and provide the IAM role you created.</td>
<td>AWS DevOps/database administrator</td>
</tr>
</tbody>
</table>

- **Amazon EFS setup and mount** (video)

**Additional information**

**Installing an NFS client**

- If you are using Red Hat or a similar Linux operating system, use the command:

```bash
$ sudo yum -y install nfs-utils
```

- If you are using Ubuntu or a similar Linux operating system, use the command:

```bash
$ sudo apt-get -y install nfs-common
```

For more information, see the walkthrough in the Amazon EFS documentation.

**Mounting the Amazon EFS file system**

Use the commands:

```bash
mkdir ~/<efs_mount_name>
$ sudo mount -t nfs -o 
  nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport mount-target-IP:/ ~/<efs_mount_name>
```
For more information, see the walkthrough and Mounting EFS File Systems in the Amazon EFS documentation.

**Making backups of the MySQL source database**

**Full backups**

Use a command like the following, which takes the backup, zips it, and splits it into smaller chunks of 1 GB each:

```
xtrabackup --backup --user=dbuser --password=<password> --binlog-info=AUTO --stream=tar --target-dir=~/<efs_mount_name>/fullbackup | gzip - | split -d --bytes=1024MB - ~/<efs_mount_name>/fullbackup/backup.tar.gz &
```

If you're planning to make subsequent incremental backups after the full backup, do not zip and split the backup. Instead, use a command similar to the following:

```
xtrabackup --backup --user=dbuser --password=<password> --target-dir=~/<efs_mount_name>/fullbackup/
```

**Incremental backups**

Use the full backup path for the --incremental-basedir parameter, for example:

```
xtrabackup --backup --user=dbuser --password=<password> --target-dir=./<efs_mount_name>/fullbackup/ --incremental-basedir=./<efs_mount_name>/fullbackup/06062020
```

where `basedir` is the path to the full backup and the xtrabackup_checkpoints file.

For more information about making backups, see Migrating Data from an External MySQL Database to an Amazon Aurora MySQL DB Cluster in the Aurora documentation.

**Preparing backups**

To prepare a full backup:

```
xtrabackup --prepare --apply-log-only --target-dir=~/<efs_mount_name>/fullbackup
```

To prepare an incremental backup:

```
xtrabackup --prepare --apply-log-only --target-dir=~/<efs_mount_name>/fullbackup --incremental-dir=~/<efs_mount_name>/incremental/06062020
```

To prepare the final backup:

```
xtrabackup --prepare --target-dir=~/<efs_mount_name>/fullbackup --incremental-dir=~/<efs_mount_name>/incremental/06072020
```

For more information, see Incremental backups in the Percona XtraBackup documentation.

**Zipping and splitting the merged backup**

To zip the merged backup at `~/<efs_mount_name>/fullbackup`:

```
tar -zcvf <backupfilename.tar.gz> ~/<efs_mount_name>/fullbackup
```

To split the backup:
Setting up binlog replication

To create a replication user on the source database and provide the appropriate privileges:

```bash
CREATE USER 'repl_user'@'' IDENTIFIED BY ''; GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'';
```

To enable replication on Aurora by connecting to the Aurora DB cluster:

```sql
CALL mysql.rds_set_external_master ('sourcedbinstanceIP', sourcedbport, 'repl_user', '', 'binlog_file_name', binlog_file_position, 0); CALL mysql.rds_start_replication;
```

To confirm that the replication is in sync:

```sql
SHOW Slave Status \G;
```

The **Seconds behind master** field shows how far behind Aurora is from the on-premises database.

**Migrate on-premises Java applications to AWS using AWS App2Container**

*Created by Dhananjay Karanjkar (AWS)*

<table>
<thead>
<tr>
<th>Source: Applications</th>
<th>Target: Containerized application deployed on Amazon ECS</th>
<th>R Type: Replatform</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment: PoC or pilot</td>
<td>Technologies: Migration; Websites &amp; web apps</td>
<td>Workload: Open-source</td>
</tr>
<tr>
<td>AWS services: AWS EC2 Container Registry; Amazon ECS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

AWS App2Container (A2C) is a command line tool that helps transform existing applications running in virtual machines into containers, without needing any code changes. A2C discovers applications running on a server, identifies dependencies, and generates relevant artifacts for seamless deployment to Amazon Elastic Container Service (Amazon ECS) and Amazon Elastic Kubernetes Service (Amazon EKS).

This pattern provides the steps for remotely migrating on-premises Java applications deployed on an application server to AWS Fargate or Amazon EKS by using App2Container through the worker machine.

The worker machine can be used in the following use cases:

- Docker installation is not allowed or not available on the application servers where the Java applications are running.
- You must manage the migration of multiple applications deployed on different physical or virtual servers.
Prerequisites and limitations

Prerequisites

- An application server with a Java application running on a Linux server
- A worker machine with a Linux operating system
- A worker machine with at least 20 GB of available disk space

Limitations

- Not all applications are supported. For more information, see Supported applications for Linux.

Architecture

Source technology stack

- Java applications running on Linux server

Target technology stack

- AWS CodeBuild
- AWS CodeCommit
- AWS CodeDeploy
- AWS CodePipeline
- Amazon Elastic Container Registry
- AWS Fargate

Target architecture
Tools

- **AWS App2Container** – AWS App2Container (A2C) is a command line tool to help you lift and shift applications that run in your on-premises data centers or on virtual machines, so that they run in containers that are managed by Amazon ECS or Amazon EKS.

- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.

- **AWS CodeCommit** – AWS CodeCommit is a version control service hosted by Amazon Web Services that you can use to privately store and manage assets (such as documents, source code, and binary files) in the cloud.

- **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.

- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that for running, stopping, and managing containers on a cluster.

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

- **AWS Fargate** – AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon Elastic Compute Cloud (Amazon EC2) instances. With Fargate, you no longer have to provision, configure, or scale clusters of virtual machines to run containers.

## Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters

*Created by Dhairya Jindani (AWS) and Baji Shaik (AWS)*

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

### Summary

Oracle GoldenGate is a real-time data capture and replication service for heterogeneous databases and IT environments. However, this service doesn't currently support Amazon Relational Database Service (Amazon RDS) for Oracle. For a list of supported databases, see Oracle GoldenGate for Heterogeneous Databases (Oracle documentation). This pattern describes how to use Oracle GoldenGate and Oracle GoldenGate flat file adapters to generate flat files from the source Oracle database, which can be on-premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. You can then import those flat files to an Amazon RDS for Oracle database instance.

In this pattern, you use Oracle GoldenGate to extract the trail files from your source Oracle database. The data pump copies the trail files to an integration server, which is an EC2 instance. On the integration server, the flat files are generated and then imported to the Amazon RDS for Oracle database instance.
server, Oracle GoldenGate uses the flat file adapter to generate a series of sequential flat files based on the transnational data capture of the trail files. Oracle GoldenGate formats the data as either delimiter-separated values or length-delimited values. You then use Oracle SQL*Loader to import the flat files into the target Amazon RDS for Oracle database instance.

Target audience

This pattern is intended for those who have experience with and knowledge of an Oracle GoldenGate’s fundamental building blocks. For more information, see [Overview of the Oracle GoldenGate Architecture](Oracle documentation).

Prerequisites and limitations

**Prerequisites**

- An active Amazon Web Services (AWS) account.
- An Oracle GoldenGate license.
- A separate license for an Oracle GoldenGate adapter.
- A source Oracle database, either running on-premises or on an EC2 instance.
- An EC2 Linux instance that is used as the integration server. For more information, see [Get started with Amazon EC2 Linux instances](Amazon EC2 documentation).
- A target Amazon RDS for Oracle database instance. For more information, see [Creating an Oracle DB instance](Amazon RDS documentation).

**Product versions**

- Oracle Database Enterprise Edition version 10g, 11g, 12c, or later
- Oracle GoldenGate version 12.2.0.1.1 or later

**Architecture**

**Source technology stack**

An Oracle database (on premises or on an EC2 instance)

**Target technology stack**

Amazon RDS for Oracle

**Source and target architecture**
1. Oracle GoldenGate extracts trails from the source database logs.
2. The data pump extracts the trails and migrates them to an integration server.
3. The Oracle GoldenGate flat file adapter reads the trails, source definitions, and extract parameters.
4. You exit the extraction, which generates a control file and flat data files.
5. You migrate the flat data files to an Amazon RDS for Oracle database instance in the AWS Cloud.

**Tools**

**AWS services**

- *Amazon Elastic Compute Cloud (Amazon EC2)* provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
• **Amazon Relational Database Service (Amazon RDS)** for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.

**Other services**

• **Oracle GoldenGate** is a service that helps you to replicate, filter, and transform data from one database to another heterogeneous database or to another target topology, such as flat files.

• **Oracle GoldenGate application adapters** enable Oracle GoldenGate to produce a series of sequential flat files and control files from transactional data captured in the trail files of a source database. These adapters are widely used for extract, transform, and load (ETL) operations in data warehouse applications and proprietary or legacy applications. Oracle GoldenGate performs this capture and applies it in near real-time across heterogeneous databases, platforms, and operating systems. The adapters support different formats for the output files, such as CSV or Apache Parquet. You can load these generated files in order to load the data into different heterogeneous databases.

**Epics**

**Set up Oracle GoldenGate on the source database server**

<table>
<thead>

</tr>
</tbody>
</table>

Summary

This pattern shows you how to modernize your business-critical mainframe batch printing workloads on the Amazon Web Services (AWS) Cloud by using Micro Focus Enterprise Server as a runtime for a modernized mainframe application and LRS VPSX/MFI (Micro Focus Interface) as a print server. The pattern is based on the replatform mainframe modernization approach. In this approach, you migrate your mainframe batch jobs to Amazon Elastic Compute Cloud (Amazon EC2) and migrate your mainframe database, such as IBM DB2 for z/OS, to Amazon Relational Database Service (Amazon RDS). The authentication and authorization for the modernized print workflow is performed by AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD. The LRS Directory Information Server (LRS/DIS) is integrated with AWS Managed Microsoft AD. By modernizing your batch printing workloads, you can reduce IT infrastructure costs, mitigate the technical debt of maintaining legacy systems, remove data silos, increase agility and efficiency with a DevOps model, and take advantage of on-demand resources and automation in the AWS Cloud.
AWS Prescriptive Guidance Patterns
Modernize your mainframe batch printing workloads on AWS

Prerequisites and limitations

Prerequisites

• An active AWS account
• A mainframe printing or output management workload
• Basic knowledge of how to rebuild and deliver a mainframe application that runs on Micro Focus Enterprise Server (For more information, see the Enterprise Server data sheet in the Micro Focus documentation.)
• Basic knowledge of LRS cloud printing solutions and concepts (For more information, see Output Modernization in the LRS documentation.)
• Micro Focus Enterprise Server software and license (For more information, contact Micro Focus sales.)
• LRS VPSX/MFI, LRS/Queue, and LRS/DIS software and licenses (For more information, contact LRS sales.)

Note: For more information about configuration considerations for mainframe batch printing workloads, see Considerations in the Additional information section of this pattern.

Product versions

• Micro Focus Enterprise Server 6.0 (product update 7)
• LRS VPSX/MFI V1R3 or higher

Architecture

Source technology stack

• Operating system – IBM z/OS
• Programming language – Common Business-Oriented Language (COBOL), Job Control Language (JCL), and Customer Information Control System (CICS)
• Database – IBM DB2 for z/OS and Virtual Storage Access Method (VSAM)
• Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
• Printing and output management – IBM mainframe z/OS printing products (IBM Tivoli Output Manager for z/OS, LRS, and CA View)

Target technology stack

• Operating system – Microsoft Windows Server running on Amazon EC2
• Compute – Amazon EC2
• Programming language – COBOL, JCL, and CICS
• Database – Amazon RDS
• Security – AWS Managed Microsoft AD
• Printing and output management – LRS printing solution on AWS
• Mainframe runtime environment – Micro Focus Enterprise Server

Source architecture

The following diagram shows a typical current state architecture for a mainframe batch printing workload:
Modernize your mainframe batch printing workloads on AWS

The diagram shows the following workflow:

1. Users perform business transactions on a system of engagement (SoE) that’s built on an IBM CICS application written in COBOL.
2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM DB2 for z/OS.
3. The SoR persists the business data from the SoE.
4. The batch job scheduler initiates a batch job to generate print output.
5. The batch job extracts data from the database, formats the data according to business requirements, and then generates business output such as billing statements, ID cards, or loan statements. Finally, the batch job routes the output to printing output management for processing and output delivery, based on the business requirements.
6. Printing output management receives print output from the batch job, and then delivers that output to a specified destination, such as email, a file share that uses secure FTP, a physical printer that uses LRS printing solutions (as demonstrated in this pattern), or IBM Tivoli.

**Target architecture**

The following diagram shows an architecture for a mainframe batch printing workload that’s deployed in the AWS Cloud:
The diagram shows the following workflow:

1. The batch job scheduler initiates a batch job to create print output, such as billing statements, ID cards, or loan statements.

2. The mainframe batch job (replatformed to Amazon EC2) uses the Micro Focus Enterprise Server runtime to extract data from the application database, apply business logic to the data, format the data, and then send the data to a print destination by using Micro Focus Print Exit (Micro Focus documentation).

3. The application database (an SoR that runs on Amazon RDS) persists data for print output.

4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2 and its operational data is stored in Amazon Elastic Block Store (Amazon EBS). LRS VPSX/MFI uses the TCP/IP-based LRS/Queue transmission agent to collect print data through the Micro Focus JES Print Exit API and deliver the data to a specified printer destination.

**Note:** The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM Advanced Function Presentation (AFP) or Xerox Line Condition Data Stream (LCDS). For more information about using Micro Focus for mainframe application migration and modernization on AWS, see **Empowering Enterprise Mainframe Workloads on AWS with Micro Focus** in the AWS documentation.

**AWS infrastructure architecture**

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe batch printing workload:
The diagram shows the following workflow:

1. The batch scheduler initiates the batch process and is deployed on Amazon EC2 across multiple Availability Zones for high availability (HA). Note: This pattern doesn't cover the implementation of the batch scheduler. For more information about implementation, see the software vendor documentation for your scheduler.

2. The mainframe batch job (written on a programming language such as JCL or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The job is deployed on Amazon EC2 across two Availability Zones for HA and uses Micro Focus Print Exit to route print output to LRS VPSX/MFI for end-user printing.

3. LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data from the Micro Focus JES Print Exit programming interface. Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the spool file and dynamically build LRS/Queue commands. The commands are then run using a standard built-in function from Micro Focus. Note: For more information on print data passed from Micro Focus Print Exit to LRS/Queue and LRS VPSX/MFI supported mainframe batch mechanisms, see Print data capture in the Additional information section of this pattern.

4. A Network Load Balancer provides a DNS name to integrate Micro Focus Enterprise Server with LRS VPSX/MFI. Note: LRS VPSX/MFI supports a Layer 4 load balancer. The Network Load Balancer also does a basic health check on LRS VPSX/MFI and routes traffic to the registered targets that are healthy.

5. The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA and uses Amazon EBS as an operational data store. LRS VPSX/MFI supports both the active-active and active-passive service modes. This architecture uses multiple AZs in an active-passive pair as an active and hot standby. The Network Load Balancer performs a health check on LRS VPSX/MFI EC2 instances and routes traffic to hot standby instances in the other AZ if an active instance is in an unhealthy state. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of recovery, a failed instance has to be restarted for the LRS services to resume processing the print request. Note: LRS VPSX/MFI can also perform health checks at the printer fleet level. For more information, see Printer fleet health checks in the Additional information section of this pattern.

6. AWS Managed Microsoft AD integrates with LRS/DIS to perform print workflow authentication and authorization. For more information, see Print authentication and authorization in the Additional information section of this pattern.
7. LRS VPSX/MFI uses Amazon EBS for block storage. You can back up Amazon EBS data from active EC2 instances to Amazon S3 as point-in-time snapshots and restore them to hot standby EBS volumes. To automate the creation, retention, and deletion of Amazon EBS volume snapshots, you can use Amazon Data Lifecycle Manager to set the frequency of automated snapshots and restore them based on your RTO/RPO requirements.

**Tools**

**AWS services**
- **Amazon EBS** – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.
- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks.
- **AWS Managed Microsoft AD** – AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft Active Directory, enables your directory-aware workloads and AWS resources to use managed Active Directory in AWS.

**Other tools**
- **LRS VPSX/MFI (Micro Focus Interface)** – VPSX/MFI, co-developed by LRS and Micro Focus, captures output from a Micro Focus Enterprise Server JES spool and reliably delivers it to a specified print destination.
- **LRS Directory Information Server (LRS/DIS)** – LRS/DIS is used for authentication and authorization during the print workflow.
- **LRS/Queue** – LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data through the Micro Focus JES Print Exit programming interface.
- **Micro Focus Enterprise Server** – Micro Focus Enterprise Server is an application deployment environment for mainframe applications. It provides the execution environment for mainframe applications that are migrated or created by using any version of Micro Focus Enterprise Developer.

</thead>
</table>
| Install LRS/DIS. | 1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from Step 2: Connect to your instance in the Amazon EC2 documentation.  
2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/DIS, and then unzip the file.  
3. Go to the location where you downloaded the files, and then launch the LRS Product Installer.  
4. In the LRS Product Installer, expand LRS Misc Tools, select LRS DIS, and then choose Next.  
5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process. | Cloud architect |
| Create a target group and register LRS VPSX/MFI EC2 as the target. | Create a target group by following the instructions from Create a target group for your Network Load Balancer in the Elastic Load Balancing documentation.  
When you create the target group, do the following:  
1. On the Specify group details page, for Choose a Target Type, choose Instances.  
2. For Protocol, choose TCP.  
3. For Port, choose 5500.  
4. On the Register targets page, in the Available instances section, select the LRS VPSX/MFI EC2 instances. | Cloud architect |
### Create a Network Load Balancer.

**Follow the instructions from [Create a Network Load Balancer](#) in the Elastic Load Balancing documentation.** Your Network Load Balancer routes traffic from Micro Focus Enterprise Server to LRS VPSX/MFI EC2.

When you create the Network Load Balancer, do the following on the **Listeners and Routing** page:

1. For **Protocol**, choose **TCP**.
2. For **Port**, choose **5500**.
3. For **Default action**, choose **Forward to** for the target group that you created earlier.

### Integrate Micro Focus Enterprise Server with LRS VPSX/MFI and LRS/Queue

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure Micro Focus Enterprise Server for LRS/Queue integration. | 1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation.  
2. In the Windows Start menu, open the Micro Focus Enterprise Server Administration UI.  
3. In the menu bar, choose **NATIVE**.  
4. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO**.  
5. From **General** in the left navigation pane, scroll down to the **Additional** section to configure the environment variables (LRSQ_ADDRESS, LRSQ_PORT, LRSQ_COMMAND) to point to LRSQ.  
6. For **LRSQ_ADDRESS**, enter the IP address or DNS name of the Network Load Balancer that you created earlier. | Cloud architect |
### AWS Prescriptive Guidance Patterns

**Modernize your mainframe batch printing workloads on AWS**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>7.</td>
<td>For <strong>LRSQ_PORT</strong>, enter <strong>VPSX LRSQ Listener Port (5500)</strong>.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>For <strong>LRSQ_COMMAND</strong>, enter the path location of the LRSQ executable.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** LRS currently supports a maximum character limit of 50 for DNS names, but this is subject to change in the future. If your DNS name is greater than 50, then you can use the IP address of the Network Load Balancer as an alternative.

### Additional information

#### Considerations

During your modernization journey, you may consider a wide variety of configurations for both mainframe batch processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform may incorporate the IBM Advanced Function Presentation (AFP) or the Xerox Line Condition Data Stream (LCDS) into the current workflow. Additionally, mainframe carriage control characters and channel command words can affect the look of the printed page and may need...
special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

Print data capture

Micro Focus Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the spool file. The information consists of fields passed in the relevant control blocks, such as:

- JOBNAME
- OWNER (USERID)
- DESTINATION
- FORM
- FILENAME
- WRITER

LRS VPSX/MFI supports the following mainframe batch mechanisms for capturing data from Micro Focus Enterprise Server.

- BATCH COBOL print/spool processing using standard z/OS JCL SYSOUT DD/OUTPUT statements
- BATCH COBOL print/spool processing using standard z/OS JCL CA-SPOOL SUBSYS DD statements
- IMS/COBOL print/spool processing using the CBLTDLI interface (For a full list of supported methods and programming examples, see the LRS documentation that’s included with your product license.)

Printer fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep dive health checks for printer fleets, see the LRS documentation that’s included with your product license.

Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or an LDAP server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks. For example, command-level security such as hold/release, purge, modify, copy, and reroute. Security can be set up by either the User-ID or Group (similar to AD group or LDAP group).

Populate your CMDB after integrating AWS Config with ServiceNow

Created by Rahul Goyal (AWS) and Andrew Wageh (AWS)
This pattern demonstrates how to integrate AWS Config with ServiceNow so that you can update your configuration management database (CMDB) after you spin up an Amazon Elastic Compute Cloud (Amazon EC2) instance in the Amazon Web Services (AWS) Cloud. The pattern works by using Amazon Simple Notification Service (Amazon SNS) to issue a notification after your EC2 instance spins up. The notification creates a server record in your CMDB and then tests the integration by creating an EC2 instance from an AWS CloudFormation stack.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An active ServiceNow account (developer accounts are valid)
- A CMDB
- Basic knowledge of ServiceNow, AWS Config, and Amazon SNS

**Architecture**

The following diagram shows you how to update your CMDB by integrating AWS Config with ServiceNow.

The diagram shows the following workflow:
1. The user provisions the EC2 instance by using an AWS CloudFormation stack.
2. AWS Config records the information about the EC2 instance from the AWS CloudFormation stack.
3. The information that AWS Config captures about the EC2 instance gets published to the Amazon SNS topic.
4. Amazon SNS pushes the SNS topic to HTTP/S webhooks.
5. The ServiceNow REST API receives information about the EC2 instance from the HTTP/S webhooks.
6. JavaScript processes the API data.
7. A JSON handler extracts the server information.
8. The CMDB gets updated with the server information.

**Technology stack**

- Amazon SNS
- AWS CloudFormation
- AWS Config
- ServiceNow

**Tools**

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.
- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- **AWS Config** – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.
- **ServiceNow** – ServiceNow is a cloud management solution that integrates with the AWS Cloud to provide comprehensive service lifecycle management.

</table>

#### Related resources

- AWS Config ([AWS Config documentation](#))
- ServiceNow ([ServiceNow documentation](#))
- Amazon Simple Notification Service ([Amazon SNS documentation](#))
- AWS CloudFormation ([AWS CloudFormation documentation](#))

#### Additional information

This pattern demonstrates a mechanism for integrating AWS Config with your ServiceNow CMDB, which captures instance details as configuration items in the CMDB server table whenever EC2 instances are created by using AWS CloudFormation.
You can use this mechanism to do the following:

- Use ServiceNow handlers to update the CMDB record with instance details.
- Customize your handlers to scale the integration of AWS Config with your ServiceNow CMDB.
- Get updated instance details and other information.
- Send notifications and perform actions, including discovery, workflow, and more. For example, if you make a small change across a list of resource types (such as adding a tag), then you can bypass discovery needs and discover existing resources. A change recording is initiated in AWS Config, which then creates those resources in the CMDB.

Change Python and Perl applications to support database migration from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition

Created by Dwarika Patra (AWS) and Deepesh J (AWS)

<table>
<thead>
<tr>

<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern describes changes to application repositories that might be required when you migrate databases from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition. The pattern assumes that these applications are Python-based or Perl-based, and provides separate instructions for these scripting languages.

Migrating SQL Server databases to Aurora PostgreSQL-Compatible involves schema conversion, database object conversion, data migration, and data loading. Because of the differences between PostgreSQL and SQL Server (relating to data types, connection objects, syntax, and logic), the most difficult migration task involves making the necessary changes to the code base so that it works correctly with PostgreSQL.

For a Python-based application, connection objects and classes are scattered throughout the system. Also, the Python code base might use multiple libraries to connect to the database. If the database connection interface changes, the objects that run the application’s inline queries also require changes.

For a Perl-based application, changes involve connection objects, database connection drivers, static and dynamic inline SQL statements, and how the application handles complex dynamic DML queries and results sets.

When you migrate your application, you can also consider possible enhancements on AWS, such as replacing the FTP server with Amazon Simple Storage Service (Amazon S3) access.

The application migration process involves the following challenges:

- Connection objects. If connection objects are scattered in the code with multiple libraries and function calls, you might have to find a generalized way to change them to support PostgreSQL.
- Error or exception handling during record retrieval or updates. If you have conditional create, read, update, and delete (CRUD) operations on the database that return variables, results sets, or data
frames, any errors or exceptions might result in application errors with cascading effects. These should be handled carefully with proper validations and save points. One such save point is to call large inline SQL queries or database objects inside BEGIN . . . EXCEPTION . . . END blocks.

- Controlling transactions and their validation. These includes manual and automatic commits and rollbacks. The PostgreSQL driver for PERL requires you to always explicitly set the auto-commit attribute.
- Handling dynamic SQL queries. This requires a strong understanding of the query logic and iterative testing to ensure that queries work as expected.
- Performance. You should ensure that code changes don't result in degraded application performance.

This pattern explains the conversion process in detail. You can automate some of these steps through small scripts.

**Prerequisites and limitations**

**Prerequisites**

- Working knowledge of Python and Perl syntax.
- Basic skills in SQL Server and PostgreSQL.
- Understanding of your existing application architecture.
- Access to your application code, SQL Server database, and PostgreSQL database.
- Access to Windows, Linux (or other Unix) development environment with credentials for developing, testing, and validating application changes.
- For a Python-based application, standard Python libraries that your application might require, such as Pandas to handle data frames, and psycopg2 or SQLAlchemy for database connections.
- For a Perl-based application, required Perl packages with dependent libraries or modules. The Comprehensive Perl Archive Network (CPAN) module can support most application requirements.
- All required dependent customized libraries or modules.
- Database credentials for read access to SQL Server and read/write access to Aurora.
- PostgreSQL to validate and debug application changes with service and user accounts.
- Access to development tools during application migration such as Visual Studio Code, Sublime Text, or pgAdmin.

**Limitations**

- Some Python or Perl versions, modules, libraries, and packages aren't compatible with the cloud environment.
- Some third-party libraries and frameworks used for SQL Server cannot be replaced to support PostgreSQL migration.
- Performance variations might require changes to your application, to inline Transact-SQL (T-SQL) queries, database functions, and stored procedures.
- PostgreSQL supports lowercase names for table names, column names, and other database objects.
- Some data types, such as UUID columns, are stored in lowercase only. Python and Perl applications must handle such case differences.
- Character encoding differences must be handled with the correct data type for the corresponding text columns in the PostgreSQL database.

**Product versions**
AWS Prescriptive Guidance Patterns
Python and Perl application changes to support database migrations

- Python 3.6 or later (use the version that supports your operating system)
- Perl 5.8.3 or later (use the version that supports your operating system)
- Aurora PostgreSQL-Compatible Edition 4.2 or later (see details)

Architecture

Source technology stack
- Scripting (application programming) language: Python 2.7 or later, or Perl 5.8
- Database: Microsoft SQL Server version 13
- Operating system: Red Hat Enterprise Linux (RHEL) 7

Target technology stack
- Scripting (application programming) language: Python 3.6 or later, or Perl 5.8 or later
- Database: Aurora PostgreSQL-Compatible 4.2
- Operating system: RHEL 7

Migration architecture

Tools

AWS services and tools
- **Aurora PostgreSQL–Compatible** – Amazon Aurora PostgreSQL–Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases. Aurora PostgreSQL is a drop-in replacement for PostgreSQL and makes it easier and more cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services by using commands in your command-line shell.

Other tools
- **Python** and PostgreSQL database connection libraries such as **psycopg2** and **SQLAlchemy**
- **Perl** and its **DBI modules**
- **PostgreSQL interactive terminal** (**psql**)
## Epics

### Migrate your application repository to PostgreSQL – high-level steps

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Follow these code conversion steps to migrate your application to PostgreSQL. | 1. Set database-specific ODBC drivers and libraries for PostgreSQL. For example, you can use one of the CPAN modules for Perl and **pyodbc**, **psycopg2**, or **SQLAlchemy** for Python.  
2. Convert database objects by using these libraries to connect to Aurora PostgreSQL-Compatible.  
3. Apply code changes in existing application modules to get compatible T-SQL statements.  
4. Rewrite database-specific function calls and stored procedures in application code.  
5. Handle changes to your application's variables and their data types that are used for inline SQL queries.  
6. Handle incompatible database-specific functions.  
7. Complete end-to-end testing of converted application code for database migration.  
8. Compare results from Microsoft SQL Server against the application you migrated to PostgreSQL.  
9. Perform application performance benchmarking between Microsoft SQL Server and PostgreSQL.  
10. Revise stored procedures or inline T-SQL statements called by the application to improve performance. | App developer |

The following epics provide detailed instructions for some of these conversion tasks for Python and Perl applications.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use a checklist for each step of the migration.</td>
<td>Add the following to your checklist for each step of</td>
<td>App developer</td>
</tr>
</tbody>
</table>
### Task Description

Application migration, including the final step:

- Review PostgreSQL documentation to ensure that all your changes are compatible with the PostgreSQL standard.
- Check for integer and floating values for columns.
- Identify the number of rows inserted, updated, and extracted, along with the column names and date/time stamps. You can use a diff utility or write a script to automate these checks.
- Complete performance checks for large inline SQL statements, and check the overall performance of the application.
- Check for correct error handling for database operations and graceful program exit by using multiple `try/catch` blocks.
- Check to ensure that proper logging processes are in place.

### Analyze and update your application – Python code base

#### Task Description

Your analysis should include the following to facilitate the application migration process:

- Identify all connection objects in the code.
- Identify all incompatible inline SQL queries (such as T-SQL statements and stored procedures) and analyze required changes.
- Review the documentation for your code and track the control flow to understand code functionality. This will be helpful later when you test the application.
<table>
<thead>
<tr>

</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Convert your database connections to support PostgreSQL.</td>
<td>Most Python applications use the <strong>pyodbc</strong> library to connect with SQL Server databases as follows.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

```python
import pyodbc
....
try:
    conn_string = "Driver=ODBC Driver 17 for SQL Server;UID={};PWD={};Server={};Database={}".format(conn_user, conn_password, conn_server, conn_database)
    conn = pyodbc.connect(conn_string)
    cur = conn.cursor()
    result = cur.execute(query_string)
    for row in result:
        print (row)
except Exception as e:
    print(str(e))
```

Convert the database connection to support PostgreSQL as follows.

```python
import pyodbc
import psycopg2
....
try:
    conn_string = 'postgresql+psycopg2://'+ conn_user +':'+conn_password +'@'+conn_server +'/' +conn_database
    conn = pyodbc.connect(conn_string,
                          connect_args={'options': '-csearch_path=dbo'}))
    cur = conn.cursor()
    result = cur.execute(query_string)
    for row in result:
        print (row)
except Exception as e:
    print(str(e))
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change inline SQL queries to PostgreSQL.</td>
<td>Convert your inline SQL queries to a PostgreSQL-compatible format. For example, the following SQL Server query retrieves a string from a table.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

```python
dtype = "type1"  
stm = "'\nSELECT TOP 1  
    searchcode FROM TypesTable  
    (NOLOCK)  
WHERE code=" + "'" +  
str(dtype) + "'" 
# For Microsoft SQL Server  
Database Connection  
engine =  
    create_engine('mssql  
+pyodbc:///?  
odbc_connect=%s' %  
    urllib.parse.quote_plus(conn_string),  
    connect_args={'connect_timeout':login_timeout})  
conn = engine.connect()  
rs = conn.execute(stm)  
for row in rs:    
    print(row)
```

After conversion, the PostgreSQL-compatible inline SQL query looks like the following.

```python
dtype = "type1"  
stm = "'\nSELECT searchcode  
FROM TypesTable  
WHERE code=" + "'" +  
str(dtype) + "' LIMIT 1" 
# For PostgreSQL Database  
Connection  
engine =  
    create_engine('postgresql  
+psycopg2://%s' %  
    conn_string,  
    connect_args={'connect_timeout':login_timeout})  
conn = engine.connect()  
rs = conn.execute(stm)  
for row in rs:    
    print(row)
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Handle dynamic SQL queries.| Dynamic SQL can be present in one script or in multiple Python scripts. Earlier examples showed how to use Python’s string replace function to insert variables for constructing dynamic SQL queries. An alternate approach is to append the query string with variables wherever applicable. In the following example, the query string is constructed on the fly based on the values returned by a function:  
query = "SELECT id from equity e join issues i on e.permId=i.permId where e.id"  
query += get_id_filter(ids) + " e.id is NOT NULL"  
These types of dynamic queries are very common during application migration. Follow these steps to handle dynamic queries:  
• Check the overall syntax (for example, the syntax for the SELECT statement with a JOIN clause).  
• Verify all variables or column names used in the query, such as i and id.  
• Check the functions, arguments, and return values used in the query (for example, get_id_filter and its argument ids). | App developer         |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Handle results sets, variables, and data frames.</td>
<td>For Microsoft SQL Server, you use Python methods such as <code>fetchone()</code> or <code>fetchall()</code> to retrieve the results set from the database. You can also use <code>fetchmany(size)</code> and specify the number of records to return from the results set. To do this, you can use the <code>pyodbc</code> connection object as shown in the following example.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

**pyodbc (Microsoft SQL Server)**

```python
import pyodbc
server = 'tcp:myserver.database.windows.net'
database = 'exampledb'
username = 'exampleusername'
password = 'examplepassword'
conn = pyodbc.connect('DRIVER={ODBC Driver 17 for SQL Server};SERVER='+server+';DATABASE='+database+';UID='+username+';PWD='+password)
cursor = conn.cursor()
cursor.execute("SELECT * FROM ITEMS")
row = cursor.fetchone()
while row:
    print(row[0])
    row = cursor.fetchone()
```

In Aurora, to perform similar tasks such as connecting to PostgreSQL and fetching results sets, you can use either `psycopg2` or `SQLAlchemy`.

These Python libraries provide the connection module and cursor object to traverse through the PostgreSQL database records, as shown in the following example.

**psycopg2 (Aurora PostgreSQL-Compatible)**

```python
import psycopg2
query = "SELECT * FROM ITEMS;"
//Initialize variables
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>host=dbname=user=password=port=sslmode=connect_timeout=&quot;&quot;</td>
<td>host=dbname=user=password=port=sslmode=connect_timeout=&quot;&quot;</td>
</tr>
<tr>
<td></td>
<td>connstring = &quot;host='{host}' dbname='{dbname}' user='{user}' password='{password}' port='{port}'&quot;.format(host=host,dbname=dbname, user=user,password=password,port=port)</td>
<td>connstring = &quot;host='{host}' dbname='{dbname}' user='{user}' password='{password}' port='{port}'&quot;.format(host=host,dbname=dbname, user=user,password=password,port=port)</td>
</tr>
<tr>
<td></td>
<td>conn = psycopg2.connect(connstring)</td>
<td>conn = psycopg2.connect(connstring)</td>
</tr>
<tr>
<td></td>
<td>cursor = conn.cursor()</td>
<td>cursor = conn.cursor()</td>
</tr>
<tr>
<td></td>
<td>cursor.execute(query)</td>
<td>cursor.execute(query)</td>
</tr>
<tr>
<td></td>
<td>column_names = [column[0] for column in cursor.description]</td>
<td>column_names = [column[0] for column in cursor.description]</td>
</tr>
<tr>
<td></td>
<td>print(&quot;Column Names: &quot;, column_names)</td>
<td>print(&quot;Column Names: &quot;, column_names)</td>
</tr>
<tr>
<td></td>
<td>print(&quot;Column values: &quot; for row in cursor: print(&quot;itemid &quot;, row[0])</td>
<td>print(&quot;Column values: &quot; for row in cursor: print(&quot;itemid &quot;, row[0])</td>
</tr>
<tr>
<td></td>
<td>print(&quot;itemdescription: &quot;, row[1])</td>
<td>print(&quot;itemdescription: &quot;, row[1])</td>
</tr>
<tr>
<td></td>
<td>print(&quot;itemprice: &quot;, row[3])</td>
<td>print(&quot;itemprice: &quot;, row[3])</td>
</tr>
</tbody>
</table>

**SQLAlchemy: (Aurora PostgreSQL-Compatible)**

```python
from sqlalchemy import create_engine
from pandas import DataFrame
conn_string = 'postgresql://core:database=localhost:5432/exampledatabase'
engine = create_engine(conn_string)
conn = engine.connect()
dataid = 1001
result = conn.execute("SELECT * FROM ITEMS")
df = DataFrame(result.fetchall())
df.columns = result.keys()
df = pd.DataFrame()
df = pd.read_sql_query(sql_query, engine, coerce_float=False)
print("df=", df)
```
### Test your application during and after migration.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test your application during and after migration. | Testing the migrated Python application is an ongoing process. Because the migration includes connection object changes (**psycopg2** or **SQLAlchemy**), error handling, new features (data frames), inline SQL changes, bulk copy functionalities (**bcp** instead of **COPY**) and similar changes, it must be tested carefully during and after application migration. Check for:  
  - Error conditions and handling  
  - Any record mismatches after migration  
  - Record updates or deletions  
  - Time required to run the application | App developer |

#### Analyze and update your application – Perl code base

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Analyze your existing Perl code base. | Your analysis should include the following to facilitate the application migration process. You should identify:  
  - Any INI or configuration-based code  
  - Database-specific standard Open Database Connectivity (ODBC) Perl drivers or any customized drivers  
  - Code changes required for inline and T-SQL queries  
  - Interactions among various Perl modules (for example, a single Perl ODBC connection object that is called or used by multiple functional components)  
  - Dataset and results set handling  
  - External, dependent Perl libraries  
  - Any APIs that are used in the application | App developer |
### Task Description

- Perl version compatibility and driver compatibility with Aurora PostgreSQL-Compatible

**Convert the connections from the Perl application and DBI module to support PostgreSQL.**

Perl-based applications generally use the Perl DBI module, which is a standard database access module for the Perl programming language. You can use the same DBI module with different drivers for SQL Server and PostgreSQL.

For more information about required Perl modules, installations, and other instructions, see the **DBD::Pg documentation**. The following example connects to Aurora PostgreSQL-Compatible at exampletest-aurorapg-database.cluster-samplecluster.us-east-.rds.amazonaws.com.

```perl
#!/usr/bin/perl
use DBI;
use strict;
my $driver = "Pg";
my $hostname = "exampletest-aurorapg-database-samplecluster.us-east.rds.amazonaws.com"
my $dsn = "DBI:$driver:
dbname = $hostname;host = 127.0.0.1;port = 5432";
my $username = "postgres";
my $password = "pass123";
$dbh = DBI->connect("dbi:Pg:dbname=
$username;host=$host;port=
$port;options="$options",
$username,
$password,
{AutoCommit => 0,
RaiseError => 1, PrintError => 0});
```

### Skills required

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Convert the connections from the Perl application and DBI module to support PostgreSQL.</td>
<td>Perl version compatibility and driver compatibility with Aurora PostgreSQL-Compatible</td>

</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Change Inline SQL queries to PostgreSQL.</td>
<td>Your application might have inline SQL queries with SELECT, DELETE, UPDATE, and similar statements that include query clauses that PostgreSQL doesn't support. For example, query keywords such as TOP and NOLOCK aren't supported in PostgreSQL. The following examples show how you can handle TOP, NOLOCK, and Boolean variables.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

In SQL Server:

```
$sqlStr = $sqlStr . "WHERE a.student_id in (SELECT TOP $numofRecords c_student_id 
FROM active_student_record b 
INNER JOIN student_contributor c 
ON c.contributor_id = b.student_contributor_id)"
```

For PostgreSQL, convert to:

```
$sqlStr = $sqlStr . "WHERE a.student_id in (SELECT TOP $numofRecords c_student_id 
FROM active_student_record b 
INNER JOIN student_contributor c 
on c.contributor_id = b.student_contributor_id WHERE b_current_l is true 
LIMIT $numofRecords)"
```
Task | Description | Skills required
--- | --- | ---
Handle dynamic SQL queries and Perl variables. | Dynamic SQL queries are SQL statements that are built at application runtime. These queries are constructed dynamically when the application is running, depending on certain conditions, so the full text of the query isn’t known until runtime. An example is a financial analytics application that analyzes the top 10 shares on a daily basis, and these shares change every day. The SQL tables are created based on top performers, and the values aren’t known until runtime. Let’s say that the inline SQL queries for this example are passed to a wrapper function to get the results set in a variable, and then a variable uses a condition to determine whether the table exists:  
- If the table exists, don’t create it; do some processing.  
- If the table doesn’t exist, create the table and also do some processing.  
Here’s an example of variable handling, followed by the SQL Server and PostgreSQL queries for this use case. | App developer

```perl
my $tableexists = db_read( arg 1, $sql_qry, undef, 'writer');
my $table_already_exists = $tableexists->[0] {table_exists};
if ($table_already_exists){
    # do some thing
} else {
    # do something else
}

SQL Server:

```perl
my $sql_qry = "SELECT
OBJECT_ID('$backendTable',
```

Additional information

Both Microsoft SQL Server and Aurora PostgreSQL-Compatible are ANSI SQL-compliant. However, you should still be aware of any incompatibilities in syntax, column data types, native database-specific functions, bulk inserts, and case sensitivity when you migrate your Python or Perl application from SQL Server to PostgreSQL.

The following sections provide more information about possible inconsistencies.

Data type comparison

Data type changes from SQL Server to PostgreSQL can lead to significant differences in the resulting data that applications operate on. For a comparison of data types, see the table on the Sqlines website.

Native or built-in SQL functions
The behavior of some functions differs between SQL Server and PostgreSQL databases. The following table provides a comparison.

<table>
<thead>
<tr>
<th>Microsoft SQL Server</th>
<th>Description</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAST</td>
<td>Converts a value from one data type to another.</td>
<td>PostgreSQL type :: operator</td>
</tr>
<tr>
<td>GETDATE()</td>
<td>Returns the current database system date and time, in a YYYY-MM-DD hh:mm:ss.mmm format.</td>
<td>CLOCK_TIMESTAMP</td>
</tr>
<tr>
<td>DATEADD</td>
<td>Adds a time/date interval to a date.</td>
<td>INTERVAL expression</td>
</tr>
<tr>
<td>CONVERT</td>
<td>Converts a value to a specific data format.</td>
<td>TO_CHAR</td>
</tr>
<tr>
<td>DATEDIFF</td>
<td>Returns the difference between two dates.</td>
<td>DATE_PART</td>
</tr>
<tr>
<td>TOP</td>
<td>Limits the number of rows in a SELECT results set.</td>
<td>LIMIT/FETCH</td>
</tr>
</tbody>
</table>

**Anonymous blocks**

A structured SQL query is organized into sections such as declaration, executables, and exception handling. The following table compares the Microsoft SQL Server and PostgreSQL versions of a simple anonymous block. For complex anonymous blocks, we recommend that you call a custom database function within your application.

<table>
<thead>
<tr>
<th>Microsoft SQL Server</th>
<th>PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>my $sql_qry1=</td>
<td>my $sql_qry1=</td>
</tr>
<tr>
<td>my $sql_qry2 =</td>
<td>my $sql_qry2 =</td>
</tr>
<tr>
<td>my sqlqry = &quot;BEGIN TRAN $sql_qry1 $sql_qry2 if @@error !=0 ROLLBACK TRAN else COMIT TRAN&quot;;</td>
<td>my sqlqry = &quot; DO $$ BEGIN $header_sql $content_sql END $$&quot;;</td>
</tr>
</tbody>
</table>

**Other differences**

- **Bulk inserts of rows**: The PostgreSQL equivalent of the Microsoft SQL Server bcp utility is COPY.
- **Case sensitivity**: Column names are case-sensitive in PostgreSQL, so you have to convert your SQL Server column names to lowercase or uppercase. This becomes a factor when you extract or compare data, or place column names in results sets or variables. The following example identifies columns where values might be stored in uppercase or lowercase.

```sql
my $sql_qry = "SELECT $record_id FROM $exampleTable WHERE LOWER($record_name) = 'failed transaction";"
```
• **Concatenation:** SQL Server uses `+` as an operator for string concatenation, whereas PostgreSQL uses `||`.

• **Validation:** You should test and validate inline SQL queries and functions before you use them in application code for PostgreSQL.

- Create an approval process for firewall requests during a rehost migration to AWS (p. 1243)

Open-source

- Migrate an on-premises Linux server to an Amazon EC2 Linux instance using AWS SMS (p. 1258)
- Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools (p. 1598)
- Migrate an on-premises MySQL database to Amazon EC2 (p. 1314)
- Migrate an on-premises MySQL database to Amazon RDS for MySQL (p. 994)
- Migrate an on-premises MySQL database to Aurora MySQL (p. 1201)
- Migrate an on-premises PostgreSQL database to Aurora PostgreSQL (p. 1566)
- Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2 with Auto Scaling (p. 1518)
- Migrate from Oracle GlassFish to AWS Elastic Beanstalk (p. 1286)
- Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical (p. 1562)
- Migrate on-premises Java applications to AWS using AWS App2Container (p. 1612)
- Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3 (p. 1602)
- Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible Edition (p. 1049)
- Restart the AWS Replication Agent automatically without disabling SELinux after rebooting a RHEL source server (p. 1007)
- Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport (p. 1359)

Oracle

- Configure links between Oracle Database and Aurora PostgreSQL-Compatible (p. 1366)
- Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL (p. 1013)
- Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database (p. 1020)
- Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT (p. 1025)
- Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible (p. 1029)
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation (p. 1040)
- Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication (p. 1335)
- Migrate an Amazon RDS for Oracle DB instance to another VPC (p. 1346)
- Migrate an on-premises Oracle database to Amazon EC2 by using Oracle Data Pump (p. 1298)
- Migrate an on-premises Oracle database to Amazon OpenSearch Service using Logstash (p. 1544)
AWS Prescriptive Guidance Patterns

• Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT (p. 1136)
• Migrate an on-premises Oracle database to Amazon RDS for Oracle (p. 1549)
• Migrate an on-premises Oracle database to Amazon RDS for Oracle using Oracle Data Pump (p. 1558)
• Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL using an Oracle bystander and AWS DMS (p. 1140)
• Migrate an on-premises Oracle database to Oracle on Amazon EC2 (p. 1291)
• Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT (p. 1130)
• Migrate an Oracle database from Amazon EC2 to Amazon RDS for Oracle using AWS DMS (p. 1540)
• Migrate an Oracle database to Amazon DynamoDB using AWS DMS (p. 1077)
• Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters (p. 1619)
• Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT (p. 1152)
• Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT (p. 1160)
• Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS (p. 1081)
• Migrate data from an on-premises Oracle database to Aurora PostgreSQL (p. 1168)
• Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL (p. 1095)
• Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS (p. 1111)
• Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS (p. 1104)
• Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate (p. 1147)
• Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT (p. 1118)
• Migrate from Oracle to Amazon DocumentDB using AWS DMS (p. 1125)
• Migrate from Oracle WebLogic to Apache Tomcat (TomEE) on Amazon ECS (p. 1534)
• Migrate function-based indexes from Oracle to PostgreSQL (p. 1054)
• Migrate legacy applications from Oracle Pro*C to ECPG (p. 1206)
• Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS (p. 1408)
• Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database (p. 1472)
• Migrate Oracle E-Business Suite to Amazon RDS Custom (p. 1413)
• Migrate Oracle native functions to PostgreSQL using extensions (p. 1058)
• Migrate Oracle PeopleSoft to Amazon RDS Custom (p. 1448)
• Migrate Oracle ROWID functionality to PostgreSQL on AWS (p. 1465)
• Migrate virtual generated columns from Oracle to PostgreSQL (p. 1217)
• Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible (p. 1221)
• Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL (p. 1231)

SAP

• Migrate an on-premises SAP ASE database to Amazon EC2 (p. 1303)
• Migrate an SAP ASE database to Aurora PostgreSQL using AWS DMS (p. 1179)
• Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS (p. 1175)
• Migrate from SAP ASE to PostgreSQL on Amazon EC2 using AWS DMS (p. 1184)
• Migrate SAP workloads to an SAP database on Amazon EC2 using Application Migration Service (p. 1253)
More patterns

- Assess application readiness for migration to the AWS Cloud by using CAST Highlight (p. 1678)
- Back up and archive mainframe data to Amazon S3 using Model9 Manager (p. 2346)
- Build an advanced mainframe file viewer in the AWS Cloud (p. 2263)
- Configure a data center extension to VMware Cloud on AWS using Hybrid Linked Mode (p. 751)
- Connect to Application Migration Service data and control planes over a private network (p. 1936)
- Convert the Teradata NORMALIZE temporal feature to Amazon Redshift SQL (p. 21)
- Convert the Teradata RESET WHEN feature to Amazon Redshift SQL (p. 26)
- Copy Amazon DynamoDB tables across accounts using AWS Backup (p. 408)
- Copy data from an S3 bucket in one account and Region to another account and Region (p. 150)
- Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing (p. 786)
- Deploy multiple-stack applications using AWS CDK with TypeScript (p. 1764)
- Emulate Oracle RAC workloads using custom endpoints in Aurora PostgreSQL (p. 426)
- Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible (p. 451)
- Integrate Stonebranch Universal Controller with AWS Mainframe Modernization (p. 1815)
- Migrate Apache Cassandra workloads to Amazon Keyspaces using AWS Glue (p. 56)
- Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS (p. 498)
- Migrate from Oracle to a PostgreSQL database by using a standby database (p. 492)
- Migrate Hadoop data to Amazon S3 by using WANdisco LiveData Migrator (p. 391)
- Migrate Oracle OUT bind variables to a PostgreSQL database (p. 469)
- Migrate SAP HANA to AWS using SAP HSR with the same hostname (p. 475)
- Migrate SQL Server to AWS using distributed availability groups (p. 485)
- Migrate VMs to VMware Cloud on AWS by using HCX OS Assisted Migration (p. 767)
- Modernize mainframe online printing workloads on AWS by using Micro Focus Enterprise Server and LRS VPSX/MFI (p. 1854)
- Modify HTTP headers when you migrate from F5 to an Application Load Balancer on AWS (p. 1970)
- Resolve connection errors after migrating Microsoft SQL Server to the AWS Cloud (p. 1994)
- Simplify private certificate management by using AWS Private CA and AWS RAM (p. 2199)
Modernization

Topics

- Analyze and visualize software architecture in CAST Imaging (p. 1672)
- Assess application readiness for migration to the AWS Cloud by using CAST Highlight (p. 1678)
- Automatically archive items to Amazon S3 using DynamoDB TTL (p. 1690)
- Build a Micro Focus Enterprise Server PAC with Amazon EC2 Auto Scaling and Systems Manager (p. 1701)
- Build a multi-tenant serverless architecture in Amazon OpenSearch Service (p. 1715)
- Cache secrets using AWS Lambda extensions (p. 1747)
- Convert and unpack data from EBCDIC to ASCII (p. 1755)
- Deploy multiple-stack applications using AWS CDK with TypeScript (p. 1764)
- Automate deployment of nested applications using AWS SAM (p. 1772)
- Implement SaaS tenant isolation for Amazon S3 by using an AWS Lambda token vending machine (p. 1791)
- Implement the serverless saga pattern by using AWS Step Functions (p. 1804)
- Integrate Stonebranch Universal Controller with AWS Mainframe Modernization (p. 1815)
- Manage on-premises container applications by setting up Amazon ECS Anywhere with the AWS CDK (p. 1838)
- Modernize ASP.NET Web Forms applications on AWS (p. 1845)
- Modernize mainframe online printing workloads on AWS by using Micro Focus Enterprise Server and LRS VPSX/MFI (p. 1854)
- Run event-driven and scheduled workloads at scale with AWS Fargate (p. 1875)
- Set up CI/CD for AWS AppSync GraphQL API updates (p. 1882)
- Tenant onboarding in SaaS architecture for the silo model using C# and AWS CDK (p. 1890)
- Decompose monoliths into microservices by using CQRS and event sourcing (p. 1906)
- More patterns (p. 1925)

Analyze and visualize software architecture in CAST Imaging

_Edited by Arpita Sinha (Cast Software) and James Hurrell (Cast Software)_

| Environment: Production | Technologies: Modernization | Workload: All other workloads |

**Summary**

This pattern shows how you can use CAST Imaging to navigate a complex software system visually and perform a precise analysis of the software structure. By using CAST Imaging in this way, you can make more informed decisions about your application's architecture, especially for modernization purposes.
To view your application’s architecture in CAST Imaging, you must first onboard your application’s source code through the CAST Console. The console then publishes your application’s data to CAST Imaging, where you can visualize and navigate your application architecture layer by layer.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The Amazon Machine Image (AMI) for CAST Imaging
- An Amazon Elastic Compute Cloud (Amazon EC2) instance that includes the following (a memory optimized r5.xlarge Amazon EC2 instance is recommended):
  - 4 vCPU
  - 32 GB RAM
  - 500 GB minimum General Purpose solid state drive (SSD) (gp3) volume
- CAST Console and CAST Imaging license keys (to get the required license keys, contact CAST at aws.contact-me@castsoftware.com)
- The complete source code of the application that you want to analyze in compressed (.zip) format
- Microsoft Edge, Mozilla Firefox, or Google Chrome

Architecture

The following diagram shows an example workflow for onboarding an application's source code through the CAST Console and then viewing it in CAST Imaging:

The diagram shows the following workflow:

1. CAST generates application source code metadata by reverse-engineering front-end, middleware, and back-end code.
2. The application data that is generated by CAST is automatically imported into CAST Imaging, where it can be visualized and analyzed.
Here's a snapshot of how this process works:

**Tools**

- **CAST Imaging** is a browser-based application that helps you view and navigate your software system visually, so you can make informed decisions about its architecture.
- **CAST Console** is a browser-based application that helps you configure, run, and manage CAST AIP analyses.

**Note:** CAST Imaging and CAST Console are included in the AMI for CAST Imaging.
## Epics

### Set up the CAST Imaging environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Run the initial CAST Console configuration. | 1. Open your web browser and connect to the CAST Console by entering the following URL: [http://localhost:8081](http://localhost:8081)  
2. When prompted, enter your CAST Console license key. Then, choose Next.  
3. Review the configuration settings. If no changes are needed, choose Save and Finish. | Software architects, Developers, Technical leaders |

| Run the initial CAST Imaging configuration. | 1. Open your web browser and connect to CAST Imaging by entering the following URL: [http://localhost:8083](http://localhost:8083)  
2. When prompted, log in by entering admin for both the username and password.  
3. When prompted, enter your CAST Imaging license key. Then, choose Update to save the key. | Software architects, Developers, Technical leaders |

### Onboard your application to CAST Imaging

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prepare your application's source code.</td>
<td>Save your application's source code in a single, compressed .zip file.</td>
<td>Software architects, Developers, Technical leaders</td>
</tr>
</tbody>
</table>

| Add your application to the CAST Console. | 1. Open your web browser and connect to the CAST Console by entering the following URL: [http://localhost:8081](http://localhost:8081)  
2. When prompted, log in by entering admin for both the username and password.  
3. Choose Add application. Then, enter the application name and choose Add. | Software architects, Developers, Technical leaders |

| Open the source code delivery wizard. | Find the application that you created in the CAST Console. Then, choose Add version. | Software architects, Developers, Technical leaders |
## Upload your application's source code

**Description**

Do one of the following:
- Drag and drop the .zip file that contains your application's source code into the source code delivery wizard.
- Choose the **upload cloud icon**. Then, open the .zip file that contains your application's source code.

**Skills required**

Software architects, Developers, Technical leaders

## Start the analysis process

**Description**

1. In the delivery wizard, provide the version details and specify the configuration options. For more information, see **Standard onboarding for CAST Imaging** in the CAST Imaging documentation.
2. Make sure that the **Publish to CAST Imaging** option is selected. Then, choose **Proceed**.

**Note:** Choosing **Proceed** starts the analysis process for the source code. The progress window in the CAST Console shows each step of the analysis process, and displays a notification when the analysis is complete.

**Skills required**

Software architects, Developers, Technical leaders

### Verify the analysis results and data published to CAST Imaging

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>

Assess application readiness for migration to the AWS Cloud by using CAST Highlight

Created by Greg Rivera (Cast Software)

<table>
<thead>
<tr>
<th>R Type: Re-architect</th>
<th>Environment: Production</th>
<th>Technologies: Modernization; Migration; Containers &amp; microservices</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Workload:</strong> IBM; Microsoft; Open-source; Oracle</td>
<td><strong>AWS services:</strong> Amazon ECS; Amazon EMR; Amazon RDS; Amazon S3; Amazon Athena; AWS Batch; Amazon ElastiCache</td>
<td><strong>Source:</strong> Legacy application source code</td>
</tr>
</tbody>
</table>

**Target:** Refactored application code in AWS

**Summary**

CAST Highlight is a software as a service (SaaS) solution for performing rapid application portfolio analysis. This pattern describes how to configure and use CAST Highlight to assess the cloud readiness of custom software applications across an organization’s IT portfolio, and to plan for modernization or migration to the Amazon Web Services (AWS) Cloud.

CAST Highlight generates insights into an application’s cloud readiness, identifies code blockers that need to be removed before a migration, estimates the effort to remove these blockers, and recommends AWS services that individual applications could use after the migration.

This pattern describes the procedure for setting up and using CAST Highlight, which consists of five steps: new user setup, application management, campaign management, source code analysis, and results analysis. You must complete all the steps in the *Epics* section of this pattern to ensure a successful application scan and analysis.

**Prerequisites and limitations**

**Prerequisites**

- An active CAST Highlight account with Portfolio Manager permissions.
- At least 300 MB free disk space and 4 GB memory on your local computer to install the CAST Highlight Local Agent.
- Microsoft Windows 8 or later.
- Your application source code must be stored in text files that are accessible from the machine where the Local Agent is installed. No source code leaves the premises and all code is locally scanned.
Architecture

The following diagram illustrates the workflow for using CAST Highlight.

The workflow consists of the following steps:

1. Log in to the CAST Highlight portal, download the Local Agent, and install it on your local computer. Amazon Simple Storage Service (Amazon S3) stores the Local Agent installation package.
2. Scan your source code files and produce a results file.
3. Upload the results file to the CAST Highlight portal. **Important**: No source code is included in the results file.
4. Answer survey questions for each application that you scanned.
5. View the dashboards and reports available in the CAST Highlight portal. Amazon Relational Database Service (Amazon RDS) stores the code scan, analysis results, and the CAST Highlight software data.

**Technology stack**

CAST Highlight supports the following technologies to analyze application cloud readiness:

- Java
- COBOL
- C#
- PHP
- JavaScript
- TypeScript
- Python
- Microsoft Transact-SQL
- VB.Net
- Kotlin
- Swift

**Automation and scale**

- A CLI analyzer can be used to automate the CAST Highlight analysis process.

**Tools**

No tools are required for this pattern if all the prerequisites are met. However, you can choose to use optional tools such as source code management (SCM) utilities, code extractors, or other tools to manage your source code files.

**Epics**

**New user setup**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate your CAST Highlight account and choose your password.</td>
<td>All first-time CAST Highlight users receive an account activation email. Follow the activation link to activate your CAST Highlight account and enter a password to complete the activation process.</td>
<td>N/A</td>
</tr>
<tr>
<td>Log in to the CAST Highlight portal.</td>
<td>The CAST Highlight homepage appears after you enter your new password. Log in to the CAST Highlight portal with your user credentials.</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Application management**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an application record.</td>
<td>In the CAST Highlight portal, navigate to the Manage Application tab in the Manage Portfolio section and choose + Create Application.</td>
<td>N/A</td>
</tr>
<tr>
<td>Choose an application name.</td>
<td>Enter a name for your application. This name is used</td>
<td>N/A</td>
</tr>
</tbody>
</table>
### Task | Description | Skills required
--- | --- | ---
| | for your application record in CAST Highlight. | N/A
| Repeat the steps for all applications. | Repeat these steps for each application that you want to scan. | N/A

### Campaign management

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a campaign.</td>
<td>CAST Highlight uses “campaign” to describe a set of applications that will be analyzed at a specific time. In the CAST Highlight portal, navigate to the <strong>Manage Campaigns</strong> tab in the <strong>Manage Portfolio</strong> section. Choose <strong>Create Campaign</strong> to launch the campaign creation screen.</td>
<td>N/A</td>
</tr>
<tr>
<td>Enter a name and choose a closing date for the campaign.</td>
<td>Enter a name for your campaign and choose a closing date for it. <strong>Important:</strong> Contributors cannot submit application analysis results after the campaign’s closing date.</td>
<td>N/A</td>
</tr>
<tr>
<td>Decide to include source code scan, survey answers, and domain and application scope.</td>
<td>Choose one or more of the standard surveys that are used to enhance the source code analysis data with qualitative information. The survey categories are <strong>Business impact</strong>, <strong>Software maintenance effort</strong>, <strong>CloudReady</strong>, and <strong>Application properties</strong>. Choose the domain and applications that are analyzed during the campaign. <strong>Important:</strong> Make sure that you add all applications you want to scan in the <strong>Manage Applications</strong> section before you begin the campaign.</td>
<td>N/A</td>
</tr>
<tr>
<td>Customize the launch message.</td>
<td>Customize the launch message that will be sent by email to all contributors associated with the applications in the campaign.</td>
<td>N/A</td>
</tr>
<tr>
<td>Launch the campaign.</td>
<td>Choose <strong>Complete</strong> to launch the campaign.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
## Source code analysis

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download the CAST Highlight Local Agent.</td>
<td>In the CAST Highlight portal, choose <strong>Application Scans</strong> and download the Local Agent to your local computer.</td>
<td>N/A</td>
</tr>
<tr>
<td>Install the Local Agent.</td>
<td>Launch the CASTHighlightSetup.exe installation program and follow the setup instructions that appear. After the Local Agent is installed, you are ready to analyze your applications.</td>
<td>N/A</td>
</tr>
<tr>
<td>Define the scope of the Local Agent code scan.</td>
<td>The code analysis is performed at the file level and doesn't consider the logical links or dependencies among files. All files are considered equal and part of the application. To provide accurate and consistent results, prepare your code scan scope by using the file or folder exclusion features available in the Local Agent.</td>
<td>N/A</td>
</tr>
<tr>
<td>Include open-source or COTS packages.</td>
<td>(Optional) If you want to include open-source or commercial off-the-shelf (COTS) packages, make sure they're included in the folders that you're planning to scan. Typically, external libraries are grouped in a subfolder called “third-party” or something similar, and the main code is often located in the “src/main” file folder.</td>
<td>N/A</td>
</tr>
<tr>
<td>Exclude test classes.</td>
<td>Test classes are typically excluded from the source code analysis because they are generally not part of the compiled application. However, you can choose to include them in the scan if required.</td>
<td>N/A</td>
</tr>
<tr>
<td>Exclude SCM, build, and deployment folders.</td>
<td>For more consistent results, you should avoid including SCM, build, or deployment folders (for example, .git or .svn files) in your scan.</td>
<td>N/A</td>
</tr>
<tr>
<td>Include dependency files.</td>
<td>If you want insights into frameworks and dependencies</td>
<td>N/A</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>whose physical files are not part of the folder you're scanning, then make sure you include the dependency files (such as pom.xml, build.gradle, package.json, or .vcsproj files).</td>
<td></td>
<td>N/A</td>
</tr>
<tr>
<td>Invoke the Local Agent.</td>
<td>Run the Local Agent on your local Windows machine.</td>
<td>N/A</td>
</tr>
<tr>
<td>Choose the folder that contains your source code.</td>
<td>Choose the folder that contains your source code. You can add multiple folders to be discovered by the Local Agent. Although the Local Agent does support source discovery through network paths, you should make sure source folders are located on your local machine. <strong>Important:</strong> We recommend running multiple scans if there are more than 10,000 files in your source folders.</td>
<td>N/A</td>
</tr>
<tr>
<td>Start file discovery.</td>
<td>On the Local Agent dashboard, choose Discover Files. The Local Agent discovers files in your folders and subfolders, and detects their technologies. You can choose the Cancel button to cancel the discovery at any time. After the file discovery finishes, the Local Agent lists the folders and files that were found. The Technologies column shows associated technologies and file count. The Path column shows the location of the folders and files.</td>
<td>N/A</td>
</tr>

<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Confirm scan results.</td>
<td>Choose <strong>Confirm Results</strong> if the scan results meet your requirements.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
| View frameworks and software libraries found by the Local Agent. | View the frameworks and software libraries used or referenced by your applications, and discovered by the Local Agent during the code scan.  
The first group lists frameworks that are officially referenced and discovered by the Local Agent.  
The second group lists potential relevant frameworks and libraries based on exploiting configuration files in your source code folders (for example, Maven pom.xml, build.gradle, .vcproj, or .json dependency files). You can keep or ignore elements from these lists by choosing their individual switch button.  
**Important:** If a framework is turned off, it is not listed in the CAST Highlight portal or attached to your application. | N/A             |
<p>| Manually add a framework or library.     | (Optional) You can manually add a framework or a library that is not referenced by CAST Highlight. In the Local Agent, choose the + icon and provide the technology, name, version number, functional type, and license type (for example, MIT, Apache, or LGPL). Choose <strong>Confirm Frameworks</strong> to add them to your results. | N/A             |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Save code scan results.</strong></td>
<td>The Local Agent displays a summary of your code scan results grouped by technology. Choose <strong>Save Results</strong> and specify the folder you want the results to be saved to. The Local Agent generates one .zip file per scan, which contains all the analysis results. Depending on the number of distinct technologies and root source folders, the Local Agent automatically generates one or several .csv files with the <code>FolderName.Technology.date.csv</code> naming structure.</td>
<td>N/A</td>
</tr>
<tr>
<td><strong>Upload the code scan results to the CAST Highlight portal.</strong></td>
<td>In the CAST Highlight portal, choose the applications you analyzed in the <strong>Application Scans</strong> section. Choose <strong>Upload Results</strong> and choose the .csv files. You can also upload the .csv files individually. After each file is uploaded, a record of the upload appears on your screen.</td>
<td>N/A</td>
</tr>
<tr>
<td><strong>Delete analysis result files, if required.</strong></td>
<td>(Optional) An analysis results file can be deleted at any time during the upload process by choosing the trash can icon. <strong>Important:</strong> Only users with Portfolio Manager privileges or the contributor who uploaded the results can delete the results.</td>
<td>N/A</td>
</tr>
<tr>
<td><strong>Answer application survey.</strong></td>
<td>A <strong>Survey</strong> button appears on applications that require a survey. Choose <strong>Survey</strong>, answer the questions for each section of the survey, and choose <strong>Submit</strong> after you finish. The progress of your survey is displayed at the top of your screen. You are able to submit your results after all mandatory information is submitted. However, you can enrich the data in your organization's CAST Highlight instance by answering all the questions.</td>
<td>N/A</td>
</tr>
</tbody>
</table>
### Submit code scan results.

**Description**
After you upload all the .csv result files for the application and complete the survey questions, choose **Submit** in the **Application Scans** section. This step is required to complete the process and ensure that the results are available in the CAST Highlight portal.

**Skills required**
N/A

### Results analysis

#### View CAST Highlight portal homepage.

**Description**
The CAST Highlight portal homepage includes tiles that have high-level information about your application portfolio, such as software health, CloudReady, and open-source safety scores for your entire portfolio. The homepage also includes the number of onboarded applications. For more information about the CAST Highlight metrics definitions and measurement methodology, see [CAST Highlight – Metrics and methodology (Microsoft PowerPoint presentation)](#).

**Skills required**
N/A

#### View the CloudReady dashboard.

**Description**
Choose the **CloudReady** tile to open the CloudReady dashboard. This is the primary portfolio-level dashboard for assessing the cloud readiness of your applications. It helps you plan and develop a portfolio roadmap for your cloud migration.

**Skills required**
N/A

#### Identify cloud migration roadblocks.

**Description**
The CloudReady dashboard shows all onboarded applications as bubbles on a chart. The chart has **Business impact** on the vertical axis, which is based on the answers to the business impact survey about each application.

On the horizontal axis is **Cloud readiness**, which is based on a combination of code analysis.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>data and the CloudReady survey answers for each application. The bubble size represents the number of cloud migration roadblocks found in the source code analysis. This can be changed if you choose other options from the dropdown menu, such as lines of code and full-time equivalent employees (FTEs).</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>Perform portfolio segmentation. You can perform a portfolio segmentation with the following segment filters: Core Cloud, Quick Wins, Long-Term Bets and Pursue Later. • The Core Cloud segment shows applications that could be modernized and refactored for platform as a service (PaaS). • The Quick Wins segment shows applications that might be good places to start your migration. • The Long-Term Bets segment shows applications that could initially be rehosted to infrastructure as a service (IaaS). • The Pursue Later segment shows applications that could be replaced or retired.</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td>Choose an application to analyze. On the CloudReady dashboard, choose an application bubble to analyze that application. Choose the name of the application in the table after the bubble chart to begin the deeper analysis. Different dashboards are available to analyze individual applications, such as Code Insights (software health patterns), Trends, and Software Composition (open-source risks).</td>
<td>N/A</td>
</tr>
</tbody>
</table>

<th>Skills required</th>
</tr>
</thead>
</table>
| Analyze the CloudReady results of an individual application. | Choose the **CloudReady** tab, which shows the application's overall CloudReady score. This score is a weighted average based on a combination of the CloudReady survey answers and the CloudReady code scan. The answers to the survey questions appear in the table below the tiles. Choose **CloudReady Code Scan** to view the code scan results. There is a list of CloudReady patterns that the application code was scanned for. This list includes the following columns:  

- **Cloud Requirement** is the specific code pattern.  
- **Technology** is the pattern's programming language. “Impact” is the pattern's impact on the application (C = code, F = framework, A = architecture).  
- **Criticality** is the level of importance of addressing this pattern before migrating.  
- **Contribution** is how this pattern contributes to the overall CloudReady score. If the pattern is green, it is a booster and increases the CloudReady score. If the pattern is red, it is a blocker and decreases the CloudReady score. If the pattern has no color, it is a blocker that was not detected and increases the CloudReady score.  
- **Roadblocks** are the number of individual occurrences of a blocker pattern. Choose the roadblock number to show a list of the source code files where the pattern was detected.  
- **Est. Effort** is an estimate of the number of days it will take to remediate the roadblocks in each row. | N/A |

Automatically archive items to Amazon S3 using DynamoDB TTL

*Created by Tabby Ward (AWS), HARI OHM PRASATH RAJAGOPAL (AWS), and Sunny Goel*
Summary

This pattern provides steps to remove older data from an Amazon DynamoDB table and archive it to an Amazon Simple Storage Service (Amazon S3) bucket on Amazon Web Services (AWS) without having to manage a fleet of servers.

This pattern uses Amazon DynamoDB Time to Live (TTL) to automatically delete old items and Amazon DynamoDB Streams to capture the TTL-expired items. It then connects DynamoDB Streams to AWS Lambda, which runs the code without provisioning or managing any servers.

When new items are added to the DynamoDB stream, the Lambda function is initiated and writes the data to an Amazon Kinesis Data Firehose delivery stream. Kinesis Data Firehose provides a simple, fully managed solution to load the data as an archive into Amazon S3.

DynamoDB is often used to store time series data, such as webpage click-stream data or Internet of Things (IoT) data from sensors and connected devices. Rather than deleting less frequently accessed items, many customers want to archive them for auditing purposes. TTL simplifies this archiving by automatically deleting items based on the timestamp attribute.

Items deleted by TTL can be identified in DynamoDB Streams, which captures a time-ordered sequence of item-level modifications and stores the sequence in a log for up to 24 hours. This data can be consumed by a Lambda function and archived in an Amazon S3 bucket to reduce the storage cost. To further reduce the costs, Amazon S3 lifecycle rules can be created to automatically transition the data (as soon as it gets created) to lowest-cost storage classes, such as S3 Glacier Instant Retrieval or S3 Glacier Flexible Retrieval, or Amazon S3 Glacier Deep Archive for long-term storage.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) 1.7 or later, installed and configured on macOS, Linux, or Windows.
- Python 3.7 or later.
- Boto3, installed and configured. If Boto3 is not already installed, run the python -m pip install boto3 command to install it.

Architecture

Technology stack

- Amazon DynamoDB
- Amazon DynamoDB Streams
AWS Prescriptive Guidance Patterns

Tools

- Amazon Kinesis Data Firehose
- AWS Lambda
- Amazon S3

1. Items are deleted by TTL.
2. The DynamoDB stream trigger invokes the Lambda stream processor function.
3. The Lambda function puts records in the Kinesis Data Firehose delivery stream in batch format.
4. Data records are archived in the S3 bucket.

Tools

- AWS CLI – The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services.
- Amazon DynamoDB – Amazon DynamoDB is a key-value and document database that delivers single-digit millisecond performance at any scale.
- Amazon DynamoDB Time to Live (TTL) – Amazon DynamoDB TTL helps you define a per-item timestamp to determine when an item is no longer required.
- Amazon DynamoDB Streams – Amazon DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table and stores this information in a log for up to 24 hours.
- Amazon Kinesis Data Firehose – Amazon Kinesis Data Firehose is the easiest way to reliably load streaming data into data lakes, data stores, and analytics services.
- AWS Lambda – AWS Lambda runs code without the need to provision or manage servers. You pay only for the compute time you consume.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance.

Code

The code for this pattern is available in the GitHub Archive items to S3 using DynamoDB TTL repository.

Epics

Set up a DynamoDB table, TTL, and a DynamoDB stream

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a DynamoDB table.</td>
<td>Use the AWS CLI to create a table in DynamoDB called Reservation. Choose random read capacity unit (RCU) and write capacity unit (WCU), and give your table two</td>
<td>Cloud architect, App developer</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
| attributes: ReservationID and ReservationDate. | aws dynamodb create-table \
--table-name Reservation \
--attribute-definitions 
AttributeName=ReservationID,AttributeType=S 
AttributeName=ReservationDate,AttributeType=N \
--key-schema 
AttributeName=ReservationID,KeyType=HASH 
AttributeName=ReservationDate,KeyType=RANGE \
--provisioned-throughput 
ReadCapacityUnits=100,WriteCapacityUnits=100 | Cloud architect, App developer |
| ReservationDate is an epoch timestamp that will be used to turn on TTL. | | |
| Turn on DynamoDB TTL. | Use the AWS CLI to turn on DynamoDB TTL for the ReservationDate attribute. | |
| | aws dynamodb update-time-to-live \
--table-name Reservation\ 
--time-to-live-specification 
Enabled=true,AttributeName=ReservationDate | |
### Turn on a DynamoDB stream.

**Description:** Use the AWS CLI to turn on a DynamoDB stream for the Reservation table by using the `NEW_AND_OLD_IMAGES` stream type.

```bash
aws dynamodb update-table --table-name Reservation --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES
```

This stream will contain records for new items, updated items, deleted items, and items that are deleted by TTL. The records for items that are deleted by TTL contain an additional metadata attribute to distinguish them from items that were deleted manually. The `userIdentity` field for TTL deletions indicates that the DynamoDB service performed the delete action.

In this pattern, only the items deleted by TTL are archived, but you could archive only the records where `eventName` is `REMOVE` and `userIdentity` contains `principalId` equal to `dynamodb.amazonaws.com`.

**Skills required:** Cloud architect, App developer

---

### Create and configure an S3 bucket

**Task:** Create an S3 bucket.

**Description:** Use the AWS CLI to create a destination S3 bucket in your AWS Region, replacing `us-east-1` with your Region.

```bash
aws s3api create-bucket --bucket reservationfirehosedestinationbucket --region us-east-1
```

Make sure that the S3 bucket's name is globally unique, because the namespace is shared by all AWS accounts.

**Skills required:** Cloud architect, App developer
## Create a 30-day lifecycle policy for the S3 bucket.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a 30-day lifecycle policy for the S3 bucket. | 1. Sign in to the AWS Management Console and open the Amazon S3 console.  
2. Choose the S3 bucket that contains the data from Kinesis Data Firehose.  
3. In the S3 bucket, choose the Management tab, and choose Add lifecycle rule.  
4. Enter a name for your rule in the Lifecycle rule dialog box, and configure a 30-day lifecycle rule for your bucket. | Cloud architect, App developer |

## Create a Kinesis Data Firehose delivery stream

### Task | Description | Skills required
|------|-------------|-----------------|
| Create and configure a Kinesis Data Firehose delivery stream. | Download and edit the CreateFireHoseToS3.py code example from the GitHub repository.  
This code is written in Python and shows you how to create a Kinesis Data Firehose delivery stream and an AWS Identity and Access Management (IAM) role. The IAM role will have a policy that can be used by Kinesis Data Firehose to write to the destination S3 bucket.  
To run the script, use the following command and command line arguments.  
Argument 1= `<Your_S3_bucket_ARN>`, which is the Amazon Resource Name (ARN) for the bucket that you created earlier  
Argument 2= Your Kinesis Data Firehose name (This pilot is using firehose_to_s3_stream.)  
Argument 3= Your IAM role name (This pilot is using firehose_to_s3.) | Cloud architect, App developer |
### CreateFireHoseToS3.py

**Description**

Create a Lambda function to process the Kinesis Data Firehose delivery stream.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create a trust policy for the Lambda function.</strong></td>
<td>Create a trust policy file with the following information.</td>
<td>Cloud architect, App developer</td>
</tr>
</tbody>
</table>
| | ```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": 
        "lambda.amazonaws.com"
      },
      "Action": 
      "sts:AssumeRole"
    }
  ]
}
``` | |
| | This gives your function permission to access AWS resources. | |

If the specified IAM role does not exist, the script will create an assume role with a trusted relationship policy, as well as a policy that grants sufficient Amazon S3 permission. For examples of these policies, see the Additional information section.

Verify the Kinesis Data Firehose delivery stream.

**Description**

Describe the Kinesis Data Firehose delivery stream by using the AWS CLI to verify that the delivery stream was successfully created.

Additional information

Create and configure a Kinesis Data Firehose delivery stream – Policy examples

Kinesis Data Firehose trusted relationship policy example document

```json
firehose_assume_role = {
    'Version': '2012-10-17',
    'Statement': [
        {'Sid': '',
         'Effect': 'Allow',
         'Principal': {
             'Service': 'firehose.amazonaws.com'
         },
        'Action': 'sts:AssumeRole'
    ]
}
```

S3 permissions policy example

```json
s3_access = {
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Action": [
                "s3:AbortMultipartUpload",
                "s3:GetBucketLocation",
                "s3:GetObject",
                "s3:ListBucket",
                "s3:ListBucketMultipartUploads",
                "s3:PutObject"
            ],
            "Resource": [
                "{your s3_bucket ARN}/*",
                "{Your s3 bucket ARN}"
            ]
        }
    ]
}
```

Test the functionality – Amazon S3 configuration

The Amazon S3 configuration with the following Prefix and ErrorOutputPrefix is chosen to optimize data retrieval.

Prefix

```bash
firehoseexample/year=! {timestamp: yyyy}/month=! {timestamp:MM}/day=! {timestamp:dd}/
hour=!{timestamp:HH}/
```

Kinesis Data Firehose first creates a base folder called firehoseexample directly under the S3 bucket. It then evaluates the expressions !{timestamp:yyyy}, !{timestamp:MM}, !{timestamp:dd}, and !{timestamp:HH} to year, month, day, and hour using the Java `DateTimeFormatter` format.

For example, an approximate arrival timestamp of 1604683577 in Unix epoch time evaluates to year=2020, month=11, day=06, and hour=05. Therefore, the location in Amazon S3, where data
records are delivered, evaluates to `firehosetos3example/year=2020/month=11/day=06/hour=05/`.

**ErrorOutputPrefix**

```plaintext
firehosetos3erroroutputbase/{firehose:random-string}/!{firehose:error-output-type}/!{timestamp:yyyy/MM/dd}/
```

The `ErrorOutputPrefix` results in a base folder called `firehosetos3erroroutputbase` directly under the S3 bucket. The expression `{firehose:random-string}` evaluates to an 11-character random string such as `ztWxkdg3Thg`. The location for an Amazon S3 object where failed records are delivered could evaluate to `firehosetos3erroroutputbase/ztWxkdg3Thg/processing-failed/2020/11/06/`.

---

## Build a Micro Focus Enterprise Server PAC with Amazon EC2 Auto Scaling and Systems Manager

*Created by Kevin Yung (AWS), Peter Woods (Micro Focus), Abraham Rondon (Micro Focus), and Krithika Palani Selvam (AWS)*

### Environment

- **Production**

### Technologies

- Modernization;
- Cloud-native; DevOps;
- Infrastructure

### Summary

This pattern introduces a scalable architecture for mainframe applications using Micro Focus Enterprise Server in Scale-Out Performance and Availability Cluster (PAC) and an Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group on Amazon Web Services (AWS). The solution is fully automated with AWS Systems Manager and Amazon EC2 Auto Scaling lifecycle hooks. By using this pattern, you can set up your mainframe online and batch applications to achieve high resiliency by automatically scaling in and out based on your capacity demands.

### Prerequisites and limitations

#### Prerequisites

- An active AWS account.
- Micro Focus Enterprise Server software and license. For details, contact Micro Focus sales.
- An understanding of the concept of rebuilding and delivering a mainframe application to run in Micro Focus Enterprise Server. For a high-level overview, see Micro Focus Enterprise Server Data Sheet.
- An understanding of the concepts in Micro Focus Enterprise Server scale-out Performance and Availability Cluster. For more information, see the Micro Focus Enterprise Server documentation.
- An understanding of the overall concept of mainframe application DevOps with continuous integration (CI). For an AWS Prescriptive Guidance pattern that was developed by AWS and Micro Focus, see Mainframe modernization: DevOps on AWS with Micro Focus.

#### Limitations

- For a list of platforms that are supported by Micro Focus Enterprise Server, see the Micro Focus Enterprise Server Data Sheet.
• The scripts and tests used in this pattern are based on Amazon EC2 Windows Server 2019; other Windows Server versions and operating systems were not tested for this pattern.

• The pattern is based on Micro Focus Enterprise Server 6.0 for Windows; earlier or later releases were not tested in the development of this pattern.

Product versions

• Micro Focus Enterprise Server 6.0
• Windows Server 2019

Architecture

In the conventional mainframe environment, you must provision hardware to host your applications and corporate data. To cater for and meet the spikes in seasonal, monthly, quarterly, or even unprecedented or unexpected demands, mainframe users must scale out by purchasing additional storage and compute capacity. Increasing the number of storage and compute capacity resources improves overall performance, but the scaling is not linear.

This is not the case when you start adopting an on-demand consumption model on AWS by using Amazon EC2 Auto Scaling and Micro Focus Enterprise Servers. The following sections explain detail how to build a fully automated, scalable mainframe application architecture using Micro Focus Enterprise Server Scale-Out Performance and Availability Cluster (PAC) with an Amazon EC2 Auto Scaling group.

Micro Focus Enterprise Server automatic scaling architecture

First, it is important to understand the basic concepts of Micro Focus Enterprise Server. This environment provides a mainframe-compatible, x86 deployment environment for applications that have traditionally run on the IBM mainframe. It delivers both online and batch runs and a transaction environment that supports the following:

• IBM COBOL
• IBM PL/I
• IBM JCL batch jobs
• IBM CICS and IMS TM transactions
• Web services
• Common batch utilities, including SORT

Micro Focus Enterprise Server enables mainframe applications to run with minimal changes. Existing mainframe workloads can be moved to x86 platforms and modernized to take advantage of AWS Cloud native extensions for rapid expansion to new markets or geographies.

The AWS Prescriptive Guidance pattern Mainframe modernization: DevOps on AWS with Micro Focus introduced the architecture to accelerate the development and testing of mainframe applications on AWS using Micro Focus Enterprise Developer and Enterprise Test Server with AWS CodePipeline and AWS CodeBuild. This pattern focuses on the deployment of mainframe applications to the AWS production environment to achieve high availability and resiliency.

In a mainframe production environment, you might have set up IBM Parallel Sysplex in the mainframe to achieve high performance and high availability. To create a scale-out architecture similar to Sysplex, Micro Focus introduced the Performance and Availability Cluster (PAC) to Enterprise Server. PACs support mainframe application deployment onto multiple Enterprise Server regions managed as a single image and scaled out in Amazon EC2 instances. PACs also support predictable application performance and system throughput on demand.
In a PAC, multiple Enterprise Server instances work together as a single logical entity. Failure of one Enterprise Server instance, therefore, will not interrupt business continuity because capacity is shared with other regions while new instances are automatically started using industry standard functionality such as an Amazon EC2 Auto Scaling group. This removes single points of failure, improving resilience to hardware, network, and application issues. Scaled-out Enterprise Server instances can be operated and managed by using the Enterprise Server Common Web Administration (ESCWA) APIs, simplifying the operational maintenance and serviceability of Enterprise Servers.

**Note:** Micro Focus recommends that the Performance and Availability Cluster (PAC) should consist of at least three Enterprise Server regions so that availability is not compromised in the event an Enterprise Server region fails or requires maintenance.

PAC configuration requires a supported relational database management service (RDBMS) to manage the region database, a cross-region database, and optional data store databases. A data store database should be used to managed Virtual Storage Access Method (VSAM) files using the Micro Focus Database File Handler support to improve availability and scalability. Supported RDBMSSs include the following:

- Microsoft SQL Server 2009 R2 and later
- PostgreSQL 10.x, including Amazon Aurora PostgreSQL-Compatible Edition
- DB2 10.4 and later

For details of supported RDBMS and PAC requirements, see Micro Focus Enterprise Server - Prerequisites and Micro Focus Enterprise Server - Recommended PAC Configuration.

The following diagram shows a typical AWS architecture setup for a Micro Focus PAC.
1. **Enterprise Server instances automatic scaling group**
   - **Description**: Set up an automatic scaling group deployed with Enterprise Server instances in a PAC. The number of instances can be scaled out or in initiated by Amazon CloudWatch alarms using CloudWatch metrics.

2. **Enterprise Server ESCWA instances automatic scaling group**
   - **Description**: Set up an automatic scaling group deployed with Enterprise Server Common Web Administration (ESCWA). ESCWA provides cluster management APIs. The ESCWA servers act as a control plane to add or remove Enterprise Servers and start or stop Enterprise Server regions.
3. Amazon Aurora instance in a Multi-AZ setup

Set up a relational database management system (RDBMS) to host both user and system data files to be shared across the Enterprise Server instances.

4. Amazon ElastiCache for Redis instance and replica

Set up an ElastiCache Redis primary instance and at least one replica to host user data and act as a scale-out repository (SOR) for the Enterprise Server instances. You can configure one or more scale-out repository to store specific types of user data. Enterprise Server uses a Redis NoSQL database as an SOR, a requirement to maintain PAC integrity.

5. Network Load Balancer

Set up a load balancer, providing a hostname for applications to connect to the services provided by Enterprise Server instances (for example, accessing the application through a 3270 emulator).

These components form the minimum requirement for a Micro Focus Enterprise Server PAC cluster. The next section covers cluster management automation.

**Using AWS Systems Manager Automation for scaling**

After the PAC cluster is deployed on AWS, the PAC is managed through the Enterprise Server Common Web Administration (ESCWA) APIs.

To automate the cluster management tasks during automatic scaling events, you can use Systems Manager Automation runbooks and Amazon EC2 Auto Scaling with Amazon EventBridge. The architecture of these automations is shown in the following diagram.
<table>

Tools

- **Micro Focus Enterprise Server** – Micro Focus Enterprise Server provides the run environment for applications created with any integrated development environment (IDE) variant of Enterprise Developer.

- **Amazon EC2 Auto Scaling** – Amazon EC2 Auto Scaling helps you ensure that you have the correct number of Amazon EC2 instances available to handle the load for your application. You create collections of EC2 instances, called Auto Scaling groups, and specify minimum and maximum numbers of instances.

- **Amazon ElastiCache for Redis** – Amazon ElastiCache is a web service for setting up, managing, and scaling a distributed in-memory data store or cache environment in the cloud. It provides a high-performance, scalable, and cost-effective caching solution.

- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks.

- **AWS Systems Manager** – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting on (or taking corrective action on) any policy violations it detects.

Additional information

The following scenarios must be automated for scaling in or scaling out the PAC clusters.

**Automation for starting or recreating a PAC**

At the start of a PAC cluster, Enterprise Server requires ESCWA to invoke APIs to create a PAC configuration. This starts and adds Enterprise Server regions into the PAC. To create or recreate a PAC, use the following steps:

1. Configure a PAC Scale-Out Repository (PSOR) in ESCWA with a given name.

   ```
   POST /server/v1/config/groups/sors
   ```

2. Create a PAC with a given name and attach the PSOR to it.

   ```
   POST /server/v1/config/groups/pacs
   ```

3. Configure the region database and cross-region database if this is the first time you are setting up a PAC.

   **Note:** This step uses SQL queries and the Micro Focus Enterprise Suite command line `dbhfhadmin` tool to create the database and import initial data.

4. Install the PAC definition into the Enterprise Server regions.

   ```
   POST /server/v1/config/mfds
   POST /native/v1/config/groups/pacs/${pac_uid}/install
   ```

5. Start Enterprise Server regions in the PAC.

   ```
   POST /native/v1/regions/${host_ip}/${port}/${region_name}/start
   ```

The previous steps can be implemented by using a Windows PowerShell script.

The following steps explain how to build an automation for creating a PAC by reusing the Windows PowerShell script.

1. Create an Amazon EC2 launch template that downloads or creates the Windows PowerShell script as part of the bootstrap process. For example, you can use EC2 user data to download the script from an Amazon Simple Storage Service (Amazon S3) bucket.

2. Create an AWS Systems Manager Automation runbook to invoke the Windows PowerShell script.

3. Associate the runbook to the ESCWA instance by using the instance tag.

4. Create an ESCWA automatic scaling group by using the launch template.

You can use the following example AWS CloudFormation snippet to create the Automation runbook.

**Example CloudFormation snippet for a Systems Manager Automation runbook used for PAC creation**

```yaml
PACInitDocument:
  Type: AWS::SSM::Document
  Properties:
    DocumentType: Command
    Content:
      schemaVersion: '2.2'
      description: Operation Runbook to create Enterprise Server PAC
      mainSteps:
```
For more information, see Micro Focus Enterprise Server - Configuring a PAC.

Automation for scaling out with a new Enterprise Server instance

When an Enterprise Server instance is scaled out, its Enterprise Server region must be added to the PAC. The following steps explain how to invoke ESCWA APIs and add the Enterprise Server region into the PAC.

1. Install the PAC definition into the Enterprise Server regions.

```
POST '/server/v1/config/mfds'
POST /native/v1/config/groups/pacs/${pac_uid}/install
```

2. Warm Start the region in the PAC.

```
POST /native/v1/regions/${host_ip}/${port}/${region_name}/start
```

3. Add the Enterprise Server instance to the load balancer by associating the automatic scaling group to the load balancer.

The previous steps can be implemented by using a Windows PowerShell script. For more information, see Micro Focus Enterprise Server - Configuring a PAC.

The following steps can be used to build an event driven automation to add a newly launched Enterprise Server instance into a PAC by reusing the Windows PowerShell script.
1. Create an Amazon EC2 launch template for Enterprise Server instance that provisions an Enterprise Server Region during its bootstrap. For example, you can use the Micro Focus Enterprise Server command mfds to import a region configuration. For further details and options available for this command, see the Enterprise Server Reference.

2. Create an Enterprise Server automatic scaling group that uses the launch template created in the previous step.

3. Create a Systems Manager Automation runbook to invoke the Windows PowerShell script.

4. Associate the runbook to the ESCWA instance by using the instance tag.

5. Create an Amazon EventBridge rule to filter for the EC2 Instance Launch Successful event for the Enterprise Server automatic scaling group, and create the target to use the Automation runbook.

You can use the following example CloudFormation snippet to create the Automation runbook and the EventBridge rule.

**Example CloudFormation snippet for Systems Manager used for scaling out Enterprise Server instances**

```yaml
ScaleOutDocument:
  Type: AWS::SSM::Document
  Properties:
    DocumentType: Command
    Content:
      schemaVersion: '2.2'
      description: Operation Runbook to Adding MFDS Server into an existing PAC
      parameters:
        MfdsPort:
          type: String
        InstanceIpAddress:
          type: String
          default: "Not-Available"
        InstanceId:
          type: String
          default: "Not-Available"
      mainSteps:
        - action: aws:runPowerShellScript
          name: Add_MFDS
          inputs:
            onFailure: Abort
            timeoutSeconds: "300"
            runCommand:
              - $ip = "{{ InstanceIpAddress }}"
                if ( ($ip) -eq "Not-Available" ) {
                  $ip = aws ec2 describe-instances --instance-id {{ InstanceId }} --output
text --query "Reservations[0].Instances[0].PrivateIpAddress"
                }
                C:\Scripts\Scale-Out.ps1 -host_ip $ip -port {{ MfdsPort }}

PacScaleOutAutomation:
  Type: AWS::SSM::Document
  Properties:
    DocumentType: Automation
    Content:
      parameters:
        MfdsPort:
          type: String
        InstanceIpAddress:
          type: String
          default: "Not-Available"
        InstanceId:
          type: String
          default: "Not-Available"
```
**Automation for scaling in an Enterprise Server instance**

Similar to scaling out, when an Enterprise Server instance is scaled in, the event EC2 Instance-terminate Lifecycle Action is initiated, and the following process and API calls are needed to remove a Micro Focus Enterprise Server instance from the PAC.

1. **Stop the region in the terminating Enterprise Server instance.**

   ```
   POST "/native/v1/regions/${host_ip}/${port}/${region_name}/stop"
   ```

2. **Remove the Enterprise Server Instance from the PAC.**

   ```
   DELETE "/server/v1/config/mfds/${uid}"
   ```

3. **Send signal to continue terminating the Enterprise Server instance.**

   The previous steps can be implemented in a Windows PowerShell script. For additional details of this process, see [Micro Focus Enterprise Server document - Administering a PAC](https://example.com).

   The following steps explain how to build an event-driven automation to terminate an Enterprise Server instance from a PAC by reusing the Windows PowerShell script.

   1. **Create a Systems Manager Automation runbook to invoke the Windows PowerShell script.**
   2. **Associate the runbook to the ESCWA instance by using the instance tag.**
   3. **Create an automatic scaling group lifecycle hook for EC2 instance termination.**
   4. **Create an Amazon EventBridge rule to filter EC2 Instance-terminate Lifecycle Action event for the Enterprise Server automatic scaling group, and create the target to use the Automation runbook.**

   You can use the following example CloudFormation template for creating a Systems Manager Automation runbook, lifecycle hook, and EventBridge rule.

   **Example CloudFormation snippet for a Systems Manager Automation runbook used for scaling in an Enterprise Server instance**

   ```
   ScaleInDocument:
   Type: AWS::SSM::Document
   Properties:
   DocumentType: Command
   ```
Content:
  schemaVersion: '2.2'
  description: Operation Runbook to Remove MFDS Server from PAC
  parameters:
    MfdsPort:
      type: String
    InstanceIpAddress:
      type: String
      default: "Not-Available"
    InstanceId:
      type: String
      default: "Not-Available"
  mainSteps:
    - action: aws:runPowerShellScript
      name: Remove_MFDS
      inputs:
        onFailure: Abort
        runCommand:
          - $ip = "{{InstanceIpAddress}}"
          if ( $ip -eq "Not-Available" ) {
            $ip = (aws ec2 describe-instances --instance-id {{InstanceId}} --output text --query "Reservations[0].Instances[0].PrivateIpAddress")
          }
          C:\Scripts\Scale-In.ps1 -host_ip ${ip} -port {{MfdsPort}}

PacScaleInAutomation:
  Type: AWS::SSM::Document

Summary

Amazon OpenSearch Service (successor to Amazon Elasticsearch Service) is a managed service that makes it easy to deploy, operate, and scale Elasticsearch, which is a popular open-source search and analytics engine. Amazon OpenSearch Service provides free-text search as well as near real-time ingestion and dashboarding for streaming data such as logs and metrics.

Software as a service (SaaS) providers frequently use Amazon OpenSearch Service to address a broad range of use cases, such as gaining customer insights in a scalable and secure way while reducing complexity and downtime.

Using Amazon OpenSearch Service in a multi-tenant environment introduces a series of considerations that affect partitioning, isolation, deployment, and management of your SaaS solution. SaaS providers have to consider how to effectively scale their Elasticsearch clusters with continually shifting workloads. They also need to consider how tiering and noisy neighbor conditions could impact their partitioning model.

This pattern reviews the models that are used to represent and isolate tenant data with Elasticsearch constructs. In addition, the pattern focuses on a simple serverless reference architecture as an example to demonstrate indexing and searching using Amazon OpenSearch Service in a multi-tenant environment. It implements the pool data partitioning model, which shares the same index among all tenants while maintaining a tenant's data isolation. This pattern uses the following Amazon Web Services (AWS) services: Amazon API Gateway, AWS Lambda, Amazon Simple Storage Service (Amazon S3), and Amazon OpenSearch Service.

For more information about the pool model and other data partitioning models, see the Additional information (p. 1741) section.
Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2.x, installed and configured on macOS, Linux, or Windows
- Python version 3.7
- pip3 – The Python source code is provided as a .zip file to be deployed in a Lambda function. If you want to use the code locally or customize it, follow these steps to develop and recompile the source code:
  1. Generate the requirements.txt file by running the following command in the same directory as the Python scripts: `pip3 freeze > requirements.txt`
  2. Install the dependencies: `pip3 install -r requirements.txt`

Limitations

- This code runs in Python, and doesn’t currently support other programming languages.
- The sample application doesn’t include AWS cross-Region or disaster recovery (DR) support.
- This pattern is intended for demonstration purposes only. It is not intended to be used in a production environment.

Architecture

The following diagram illustrates the high-level architecture of this pattern. The architecture includes the following:

- AWS Lambda to index and query the content
- Amazon OpenSearch Service to perform search
- Amazon API Gateway to provide an API interaction with the user
- Amazon S3 to store raw (non-indexed) data
- Amazon CloudWatch to monitor logs
- AWS Identity and Access Management (IAM) to create tenant roles and policies
Automation and scale

For simplicity, the pattern uses AWS CLI to provision the infrastructure and to deploy the sample code. You can create an AWS CloudFormation template or AWS Cloud Development Kit (AWS CDK) scripts to automate the pattern.

Tools

AWS services

- **AWS CLI** - AWS Command Line Interface (AWS CLI) is a unified tool for managing AWS services and resources by using commands in your command-line shell.
- **AWS Lambda** – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **Amazon API Gateway** – Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.
- **Amazon S3** - Amazon Simple Storage Service (Amazon S3) is an object storage service that lets you store and retrieve any amount of information at any time, from anywhere on the web.
- **Amazon OpenSearch Service** – Amazon OpenSearch Service (successor to Amazon Elasticsearch) is a fully managed service that makes it easy for you to deploy, secure, and run Elasticsearch cost-effectively at scale.

Code

The attachment provides sample files for this pattern. These include:

- **index_lambda_package.zip** – The Lambda function for indexing data in Amazon OpenSearch Service by using the pool model.
- **search_lambda_package.zip** – The Lambda function for searching for data in Amazon OpenSearch Service.
**Epics**

**Create and configure an S3 bucket**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an S3 bucket.      | Create an S3 bucket in your AWS Region. This bucket will hold the non-indexed tenant data for the sample application. Make sure that the S3 bucket’s name is globally unique, because the namespace is shared by all AWS accounts. To create an S3 bucket, you can use the AWS CLI `create-bucket` command as follows:  
  ```bash
  aws s3api create-bucket \
  --bucket tenantrawdata \
  --region <your-AWS-Region>
  ```  
  where `tenantrawdata` is the S3 bucket name. (You can use any unique name that follows the bucket naming guidelines.) | Cloud architect, Cloud administrator |

**Create and configure an Elasticsearch cluster**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an Amazon OpenSearch Service domain. | Run the AWS CLI `create-elasticsearch-domain` command to create an Amazon OpenSearch Service domain:   
  ```bash
  aws es create-elasticsearch-domain \
  --domain-name vpc-cli-example \
  --elasticsearch-version 7.10 \
  --elasticsearch-cluster-config InstanceType=t3.medium.elasticsearch,InstanceCount=1
  ``` | Cloud architect, Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>--ebs-options</td>
<td><code>EBSEnabled=true, VolumeType=gp2, VolumeSize=10</code></td>
<td></td>
</tr>
<tr>
<td>--domain-endpoint-options</td>
<td><code>&quot;EnforceHTTPS&quot;: true</code></td>
<td></td>
</tr>
<tr>
<td>--encryption-at-rest-options</td>
<td><code>&quot;Enabled&quot;: true</code></td>
<td></td>
</tr>
<tr>
<td>--node-to-node-encryption-options</td>
<td><code>&quot;Enabled&quot;: true</code></td>
<td></td>
</tr>
<tr>
<td>--encryption-at-rest-options</td>
<td><code>&quot;Enabled&quot;: true</code></td>
<td></td>
</tr>
<tr>
<td>--advanced-security-options</td>
<td><code>&quot;Enabled&quot;: true, &quot;InternalUserDatabaseEnabled&quot;: true, &quot;MasterUserOptions&quot;: {&quot;MasterUserName&quot;: &quot;KibanaUser&quot;, &quot;MasterUserPassword&quot;: &quot;NewKibanaPassword@123&quot;}</code></td>
<td></td>
</tr>
<tr>
<td>--vpc-options</td>
<td><code>&quot;SubnetIds&quot;: [&quot;&lt;subnet-id&gt;&quot;, &quot;SecurityGroupId&quot;: [&quot;&lt;sg-id&gt;&quot;]</code></td>
<td></td>
</tr>
</tbody>
</table>

The instance count is set to 1 because the domain is for testing purposes. You need to enable fine-grained access control by using the advanced-security-options parameter, because the details cannot be changed after the domain has been created.

This command creates a master user name (`KibanaUser`) and a password that you can use to log in to the Kibana console.

Because the domain is part of a virtual private cloud (VPC), you have to make sure that you can reach the Elasticsearch instance.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>by specifying the access policy to use. For more information, see Launching your Amazon OpenSearch Service domains using a VPC in the Amazon ES documentation.</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
<tr>
<td>Set up a bastion host.</td>
<td>Set up a Amazon Elastic Compute Cloud (Amazon EC2) Windows instance as a bastion host to access the Kibana console. The Elasticsearch security group must allow traffic from the Amazon EC2 security group. For instructions, see the blog post Controlling Network Access to EC2 Instances Using a Bastion Server. When the bastion host has been set up, and you have the security group that is associated with the instance available, use the AWS CLI authorize-security-group-ingress command to add permission to the Elasticsearch security group to allow port 443 from the Amazon EC2 (bastion host) security group.</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>aws ec2 authorize-security-group-ingress \ --group-id \ &lt;SecurityGroupIdOfElasticSearch&gt; \ --protocol tcp \ --port 443 \ --source-group \ &lt;SecurityGroupIdOfBashionHostEC2&gt;</td>
<td></td>

### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attach managed policies to the Lambda role.</td>
<td><strong>Run the AWS CLI</strong> <code>attach-role-policy</code> <strong>command to attach managed policies to the role created in the previous step. These two policies give the role permissions to create an elastic network interface and to write logs to CloudWatch Logs.</strong></td>
<td>Cloud architect, Cloud administrator</td>
</tr>
</tbody>
</table>

```bash
aws iam attach-role-policy \
  --role-name index-lambda-role \
  --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole

aws iam attach-role-policy \
  --role-name index-lambda-role \
  --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaVPCAccessExecutionRole
```

---

**--assume-role-policy-document** file://lambda_assume_role.json

where `lambda_assume_role.json` is a JSON document in the current folder that grants `AssumeRole` permissions to the Lambda function, as follows:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "Service": "lambda.amazonaws.com"
      },
      "Action": "sts:AssumeRole"
    }
  ]
}
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a policy to give the Lambda index function permission to read the S3 objects. | Run the AWS CLI `create-policy` command to give the Lambda index function `s3:GetObject` permission to read the objects in the S3 bucket:  
```bash
aws iam create-policy 
--policy-name s3-permission-policy 
--policy-document file://s3-policy.json
```

The file `s3-policy.json` is a JSON document in the current folder that grants `s3:GetObject` permissions to allow read access to S3 objects. If you used a different name when you created the S3 bucket, provide the correct bucket name in the `Resource` section in the following:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::tenantrawdata/*"
        }
    ]
}
```

| Attach the Amazon S3 permission policy to the Lambda execution role. | Run the AWS CLI `attach-role-policy` command to attach the Amazon S3 permission policy you created in the previous step to the Lambda execution role:  
```bash
aws iam attach-role-policy 
--role-name index-lambda-role 
--policy-arn <PolicyARN>
```

where PolicyARN is the Amazon Resource Name (ARN) of the Amazon S3 permission policy. You can get this value from the output of the previous command. | Cloud architect, Cloud administrator |
<table>

</table>
### Add a Lambda trigger for the Amazon S3 event

**Task**: Add a Lambda trigger for the Amazon S3 event.

**Description**: Run the AWS CLI `put-bucket-notification-configuration` command to send notifications to the Lambda index function when the Amazon S3 ObjectCreated event is detected. The index function runs whenever an object is uploaded to the S3 bucket.

```bash
aws s3api put-bucket-notification-configuration
    --bucket tenantrawdata
    --notification-configuration file://s3-trigger.json
```

The file `s3-trigger.json` is a JSON document in the current folder that adds the resource policy to the Lambda function when the Amazon S3 ObjectCreated event occurs.

**Skills required**: Cloud architect, Cloud administrator

### Create and configure the Lambda search function

**Task**: Create the Lambda execution role.

**Description**: Run the AWS CLI `create-role` command to grant the Lambda search function access to AWS services and resources:

```bash
aws iam create-role
    --role-name search-lambda-role
    --assume-role-policy-document file://lambda_assume_role.json
```

where `lambda_assume_role.json` is a JSON document in the current folder that grants AssumeRole permissions to the Lambda function, as follows:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
```

``` | Cloud architect, Cloud administrator |
### Attach the policy to the Lambda execution role.

**Task**
Attach the policy to the Lambda execution role.

**Description**
Run the AWS CLI `attach-role-policy` command to attach the policy created in the previous step to the Lambda index and search execution roles you created earlier:

```bash
aws iam attach-role-policy
  --policy-arn arn:aws:iam::account-id:policy/assume-tenant-role-policy
  --role-name index-lambda-role

aws iam attach-role-policy
  --policy-arn arn:aws:iam::account-id:policy/assume-tenant-role-policy
  --role-name search-lambda-role

aws iam attach-role-policy
  --policy-arn arn:aws:iam::account-id:policy/s3-permission-policy
  --role-name index-lambda-role
```

The policy ARN is from the output of the previous step.

**Skills required**
Cloud architect, Cloud administrator

### Create and configure a search API

**Task**
Create a REST API in API Gateway.

**Description**
Run the CLI `create-rest-api` command to create a REST API resource:

```bash
aws apigateway create-rest-api
  --name Test-Api
  --endpoint-configuration
    "{ "types": ["REGIONAL"] }"
```

For the endpoint configuration type, you can specify EDGE instead of REGIONAL to use edge locations instead of a particular AWS Region.

**Skills required**
Cloud architect, Cloud administrator
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a resource for the search API.</td>
<td>The search API resource starts the Lambda search function with the resource name search. (You don’t have to create an API for the Lambda index function, because it runs automatically when objects are uploaded to the S3 bucket.)</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
</tbody>
</table>

1. Run the AWS CLI `get-resources` command to get the parent ID for the root path:

   ```
   aws apigateway get-resources
   --rest-api-id <API-ID>
   ```

   Note the value of the ID field. You will use this parent ID in the next command.

   ```
   { "items": [ 
   { "id": "zpsri964ck", "path": "/" }
   ] }
   ```

2. Run the AWS CLI `create-resource` command to create a resource for the search API. For `parent-id`, specify the ID from the previous command.

   ```
   aws apigateway create-resource \
   --rest-api-id <API-ID> \
   --parent-id <Parent-ID> \
   --path-part search
   ```
<table>
<thead>

<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a GET method for the search API. | Run the AWS CLI `put-method` command to create a GET method for the search API:  
```
aws apigateway put-method \
  --rest-api-id <API-ID> \
  --resource-id <ID from the previous command output> \
  --http-method GET \
  --authorization-type "NONE" \
  --no-api-key-required
```
For resource-id, specify the ID from the output of the create-resource command. | Cloud architect, Cloud administrator |
| Create a method response for the search API. | Run the AWS CLI `put-method-response` command to add a method response for the search API:  
```
aws apigateway put-method-response \
  --rest-api-id <API-ID> \
  --resource-id <ID from the create-resource command output> \
  --http-method GET \
  --status-code 200 \
  --response-models 
"{"application/json" : 
"Empty"}"
```
For resource-id, specify the ID from the output of the earlier create-resource command. | Cloud architect, Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up a proxy Lambda integration for the search API.</td>
<td>Run the AWS CLI command <code>put-integration</code> command to set up an integration with the Lambda search function:</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
</tbody>
</table>
| | ```
aws apigateway put-integration \
  --rest-api-id <API-ID> \
  --resource-id <ID from the create-resource command output> \
  --http-method GET \
  --type AWS_PROXY \
  --integration-http-method GET \
arn:aws:lambda:<region>:<account-id>:function:<function-name>/invocations
``` | |
|  | For resource-id, specify the ID from the earlier create-resource command. | |
| Grant API Gateway permission to call the Lambda search function. | Run the AWS CLI `add-permission` command to give API Gateway permission to use the search function: | Cloud architect, Cloud administrator |
| | ```
aws lambda add-permission \
  --function-name <function-name> \
  --statement-id apigateway-get \
  --action lambda:InvokeFunction \
  --principal apigateway.amazonaws.com \
  --source-arn "arn:aws:execute-api:<region>:<account-id>:api-id/*/GET/search"
``` | |
|  | Change the source-arn path if you used a different API resource name instead of search. | |
### Deploy the search API.

**Description:** Run the AWS CLI `create-deployment` command to create a stage resource named dev:

```bash
aws apigateway create-deployment \
   --rest-api-id <API-ID> \
   --stage-name dev
```

If you update the API, you can use the same CLI command to redeploy it to the same stage.

**Skills required:** Cloud architect, Cloud administrator

### Create and configure Kibana roles

#### Log in to the Kibana console.

1. Find the link to Kibana on your domain dashboard on the Amazon OpenSearch Service console. The URL is in the form: `<domain-endpoint>/_plugin/kibana/`.
2. Use the bastion host you configured in the first epic to access the Kibana console.
3. Log in to the Kibana console by using the master user name and password from the earlier step, when you created the Amazon OpenSearch Service domain.
4. When prompted to select a tenant, choose **Private**.

**Skills required:** Cloud architect, Cloud administrator

#### Create and configure Kibana roles.

To provide data isolation and to make sure that one tenant cannot retrieve the data of another tenant, you need to use document security, which allows tenants to access only documents that contain their tenant ID.

1. On the Kibana console, in the navigation pane, choose **Security, Role**.
2. Create a new tenant role.
3. Set cluster permissions to `indices_all`, which gives create, read, update, and
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>delete (CRUD) permissions on the Amazon OpenSearch Service index.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>Restrict index permissions to the tenant-data index. (The index name should match the name in the Lambda search and index functions.)</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>Set index permissions to indices_all, to enable users to perform all index-related operations. (You can restrict operations for more granular access, depending on your requirements.)</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>For document-level security, use the following policy to filter documents by tenant ID, to provide data isolation for tenants in a shared index:</td>
<td></td>
</tr>
</tbody>
</table>

```
{
  "bool": {
    "must": {
      "match": {
        "TenantId": "Tenant-1"
      }
    }
  }
}
```

The index name, properties, and values are case-sensitive.
### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Map users to roles.   | 1. Choose the **Mapped users** tab for the role, and then choose **Map users**.  
2. In the **Backend roles** section, specify the ARN of the IAM tenant role that you created earlier, and then choose **Map**. This maps the IAM tenant role to the Kibana role so that tenant-specific search returns data for that tenant only. For example, if the IAM role name for Tenant-1 is Tenant-1-Role, specify the ARN for Tenant-1-Role (from the Create and configure tenant roles epic) in the **Backend roles** box for the Tenant-1 Kibana role.  
3. Repeat steps 1 and 2 for Tenant-2.  
We recommend that you automate the creation of the tenant and Kibana roles at the time of tenant onboarding. | Cloud architect, Cloud administrator |
| Create the tenant-data index. | In the navigation pane, under Management, choose Dev Tools, and then run the following command. This command creates the tenant-data index to define the mapping for the TenantId property.  
```plaintext
PUT /tenant-data
{
  "mappings": {
    "properties": {
      "TenantId": { "type": "keyword"}
    }
  }
}
``` | Cloud architect, Cloud administrator |

### Create VPC endpoints for Amazon S3 and AWS STS

<tr>
<td>S3.</td>
<td>The endpoint enables the Lambda index function in the VPC to access the Amazon S3 service.</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>aws ec2 create-vpc-endpoint \ --vpc-id &lt;VPC-ID&gt; \ --service-name com.amazonaws.us-east-1.s3 \ --route-table-ids &lt;route-table-ID&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For <code>vpc-id</code>, specify the VPC that you're using for the Lambda index function. For <code>service-name</code>, use the correct URL for the Amazon S3 endpoint. For <code>route-table-ids</code>, specify the route table that's associated with the VPC endpoint.</td>
<td></td>
</tr>
<tr>
<td>Create a VPC endpoint for AWS STS.</td>
<td>Run the AWS CLI <code>create-vpc-endpoint</code> command to create a VPC endpoint for AWS Security Token Service (AWS STS). The endpoint enables the Lambda index and search functions in the VPC to access the AWS STS service. The functions use AWS STS when they assume the IAM role.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>aws ec2 create-vpc-endpoint \ --vpc-id &lt;VPC-ID&gt; \ --vpc-endpoint-type Interface \ --service-name com.amazonaws.us-east-1.sts \ --subnet-id &lt;subnet-ID&gt; \ --security-group-id &lt;security-group-ID&gt;</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>For <code>vpc-id</code>, specify the VPC that you're using for the Lambda index and search functions. For <code>subnet-id</code>, provide the subnet in which this endpoint should be created. For <code>security-group-id</code>, specify the security group to associate this endpoint with. (It could be the same as the security group Lambda uses.)</td>
<td></td>
</tr>
</tbody>
</table>
# Test multi-tenancy and data isolation

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Update the Python files for the index and search functions. | 1. In the `index_lambda_package.zip` file, edit the `lamba_index.py` file to update the AWS account ID, AWS Region, and Elasticsearch endpoint information.  
2. In the `search_lambda_package.zip` file, edit the `lambda_search.py` file to update the AWS account ID, AWS Region, and Elasticsearch endpoint information.  
You can get the Elasticsearch endpoint from the **Overview** tab of the Amazon OpenSearch Service console. It has the format `<AWS-Region>.es.amazonaws.com`. | Cloud architect, App developer |
<p>| Update the Lambda code. | Use the AWS CLI <code>update-function-code</code> command to update the Lambda code with the changes you made to the Python files:  <code>bash  aws lambda update-function-code  --function-name index-lambda-function  --zip-file fileb://index_lambda_package.zip  </code>  <code>bash  aws lambda update-function-code  --function-name search-lambda-function  --zip-file fileb://search_lambda_package.zip </code> | Cloud architect, App developer |
| Upload raw data to the S3 bucket. | Use the AWS CLI <code>cp</code> command to upload data for the Tenant-1 and Tenant-2 objects to the <code>tenantrawdata</code> bucket (specify the name of the S3 bucket you created for this purpose):  <code>bash  aws s3 cp tenant-1-data s3://tenantrawdata  </code> | Cloud architect, Cloud administrator |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>aws s3 cp tenant-2-data s3://tenantrawdata</td>
<td>The S3 bucket is set up to run the Lambda index function whenever data is uploaded so that the document is indexed in Elasticsearch.</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
</tbody>
</table>
| Search data from the Kibana console. | On the Kibana console, run the following query:  

GET tenant-data/_search  

This query displays all the documents indexed in Elasticsearch. In this case, you should see two, separate documents for Tenant-1 and Tenant-2. | Cloud architect, App developer |
| Test the search API from API Gateway. | 1. In the API Gateway console, open the search API, choose the GET method inside the search resource, and then choose Test.  
2. In the test window, provide the following query string (case-sensitive) for the tenant ID, and then choose Test.  

TenantId=Tenant-1  

The Lambda function sends a query to Amazon OpenSearch Service that filters the tenant document based on the document-level security. The method returns the document that belongs to Tenant-1.  
3. Change the query string to:  

TenantId=Tenant-2  

This query returns the document that belongs to Tenant-2. | Cloud architect, App developer |

For screen illustrations, see the Additional information (p. 1741) section.

Additional information

Data partitioning models

There are three common data partitioning models used in multi-tenant systems: silo, pool, and hybrid. The model you choose depends on the compliance, noisy neighbor, operations, and isolation needs of your environment.

Silo model

In the silo model, each tenant’s data is stored in a distinct storage area where there is no commingling of tenant data. You can use two approaches to implement the silo model with Amazon OpenSearch Service: domain per tenant and index per tenant.

- **Domain per tenant** – You can use a separate Amazon OpenSearch Service domain (synonymous with an Elasticsearch cluster) per tenant. Placing each tenant in its own domain provides all the benefits associated with having data in a standalone construct. However, this approach introduces management and agility challenges. Its distributed nature makes it harder to aggregate and assess the operational health and activity of tenants. This is a costly option that requires each Amazon OpenSearch Service domain to have three master nodes and two data nodes for production workloads at the minimum.
• **Index per tenant** – You can place tenant data in separate indexes within an Amazon OpenSearch Service cluster. With this approach, you use a tenant identifier when you create and name the index, by pre-pending the tenant identifier to the index name. The index per tenant approach helps you achieve your silo goals without introducing a completely separate cluster for each tenant. However, you might encounter memory pressure if the number of indexes grows, because this approach requires more shards, and the master node has to handle more allocation and rebalancing.
Isolation in the silo model – In the silo model, you use IAM policies to isolate the domains or indexes that hold each tenant’s data. These policies prevent one tenant from accessing another tenant’s data. To implement your silo isolation model, you can create a resource-based policy that controls access to your tenant resource. This is often a domain access policy that specifies which actions a principal can perform on the domain’s sub-resources, including Elasticsearch indexes and APIs. With IAM identity-based policies, you can specify allowed or denied actions on the domain, indexes, or APIs within Amazon OpenSearch Service. The Action element of an IAM policy describes the specific action or actions that are allowed or denied by the policy, and the Principal element specifies the affected accounts, users, or roles.

The following sample policy grants Tenant-1 full access (as specified by es:* ) to the sub-resources on the tenant-1 domain only. The trailing */* in the Resource element indicates that this policy applies to the domain’s sub-resources, not to the domain itself. When this policy is in effect, tenants are not allowed to create a new domain or modify settings on an existing domain.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::aws-account-id:user/Tenant-1"
            },
            "Action": "es:*",
        }
    ]
}
```

To implement the tenant per Index silo model, you would need to modify this sample policy to further restrict Tenant-1 to the specified index or indexes, by specifying the index name. The following sample policy restricts Tenant-1 to the tenant-index-1 index.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::aws-account-id:user/Tenant-1"
            },
            "Action": "es:*",
        }
    ]
}
```
Pool model

In the pool model, all tenant data is stored in an index within the same domain. The tenant identifier is included in the data (document) and used as the partition key, so you can determine which data belongs to which tenant. This model reduces the management overhead. Operating and managing the pooled index is easier and more efficient than managing multiple indexes. However, because tenant data is commingled within the same index, you lose the natural tenant isolation that the silo model provides. This approach might also degrade performance because of the noisy neighbor effect.

Tenant isolation in the pool model – In general, tenant isolation is challenging to implement in the pool model. The IAM mechanism used with the silo model doesn’t allow you to describe isolation based on the tenant ID stored in your document.

An alternative approach is to use the fine-grained access control (FGAC) support provided by the Open Distro for Elasticsearch. FGAC allows you to control permissions at an index, document, or field level. With each request, FGAC evaluates the user credentials and either authenticates the user or denies access. If FGAC authenticates the user, it fetches all roles mapped to that user and uses the complete set of permissions to determine how to handle the request.
To achieve the required isolation in the pooled model, you can use document-level security, which lets you restrict a role to a subset of documents in an index. The following sample role restricts queries to Tenant-1. By applying this role to Tenant-1, you can achieve the necessary isolation.

```json
{
  "bool": {
    "must": {
      "match": {
        "tenantId": "Tenant-1"
      }
    }
  }
}
```

**Hybrid model**

The hybrid model uses a combination of the silo and pool models in the same environment to offer unique experiences to each tenant tier (such as free, standard, and premium tiers). Each tier follows the same security profile that was used in the pool model.

**Tenant isolation in the hybrid model** – In the hybrid model, you follow the same security profile as in the pool model, where using the FGAC security model at the document level provided tenant isolation. Although this strategy simplifies cluster management and offers agility, it complicates other aspects of the architecture. For example, your code requires additional complexity to determine which model is associated with each tenant. You also have to ensure that single-tenant queries don’t saturate the entire domain and degrade the experience for other tenants.

**Testing in API Gateway**

Test window for Tenant-1 query
Test window for Tenant-2 query

Cache secrets using AWS Lambda extensions

Created by HARI OHM PRASATH RAJAGOPAL (AWS), Karan Shah (AWS), and Giridhar Shyam Sankararaman (AWS)

AWS services: AWS Lambda; AWS Secrets Manager
Summary

This pattern demonstrates how to host an HTTP server that caches secrets required for an AWS Lambda function. The Lambda extension does the following:

- Hosts a local HTTP server, which is invoked by a Lambda function to retrieve the secret instead of retrieving it directly from AWS Secrets Manager.
- Uses a config.yaml file inside the Lambda function to get the list of secrets that must be cached in memory.
- Refreshes the secrets cache based on the value (in minutes) set in the environment variable CACHE_TIMEOUT. If no value is specified, it defaults to 10.

This extension is helpful in the following use cases:

- If the Lambda function needs access to Secrets Manager for reading a secret, the secret can get cached as part of the extension startup instead of being fetched as part of Lambda's first request. This helps to avoid a cold start.
- The Lambda function specifies which secrets are cached by using the configuration file (config.yaml), which is part of the deployment package.
- The Lambda function allows the expiration of in-memory cache, which can be configured as a Lambda environment variable.
- The business can maintain the cache layer in-memory instead of using a /tmp storage for reading and writing values in Secrets Manager.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
- Zip utility installed in the local system.
- The code that is in the Attachments section, which contains the code for creating a Lambda extension as a layer. Details are in the Additional information section.

Architecture

Architecture

The following diagram provides a high-level view of all the components.
1. Secrets are cached based on the `config.yaml` file defined inside the deployment package of the Lambda function, and the cache is refreshed based on environment variables.

2. Based on the keys specified inside `config.yaml`, the secrets are read and cached in-memory from Secrets Manager.

3. The Lambda function reads the secret by making an HTTP GET call to the extension, and the extension returns the value from the in-memory cache.

**Initializing the extension and reading secrets from the cache**

The following sequence diagram shows the initialization of the Lambda extension and how the Lambda function reads cached secrets by using the HTTP server that is hosted inside the extension.
The sequence of events inside the Lambda function and the extension includes the following.

1. The extension is initialized first before the Lambda function, based on the lifecycle. As part of the initialization, the extension reads the `config.yaml` file from the Lambda function under the default path (`/var/task`) and gets the list of secrets that need to be cached.
2. When the extension has a list of keys that needs to be fetched, it invokes Secrets Manager to get all the secrets (specified in `config.yaml`) and stores them in memory.
3. The extension starts a local HTTP server.
4. To get the secret value, the Lambda function makes an HTTP GET `/cache/<secretname>` call to the extension.
   
   **Note:** The web server is made available locally to the Lambda runtime environment. The communication between the Lambda function and the web server is in HTTP. It is assumed that this is fine, as this example is to demonstrate the capability to communicate to the cache locally.
5. The extension returns the cached value to the Lambda function based on the `secretname` path parameter.

**Technology**

- AWS Lambda
- AWS Secrets Manager
- HTTP web server

**Tools**

- AWS CLI – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services.
- AWS Lambda – AWS Lambda supports running code without provisioning or managing servers.
- **AWS Secrets Manager** – AWS Secrets Manager enables the replacement of hardcoded credentials, including passwords, with an API call to Secrets Manager to retrieve the secret. Because Secrets Manager can automatically rotate the secret according to a schedule, you can replace long-term secrets with short-term ones, reducing the risk of compromise.

- **Git client** – Git provides GUI tools, or you can use the command line or a desktop tool to check out the required artifacts from GitHub.

- **Node.js** – Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications. The runtime for Node.js should be installed on the local system.

## Epics

### Create a secret in Secrets Manager

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

Additional information

Create secret

The following command assumes that you placed your secret, such as this example JSON text structure{"username":"janedoe","password":"aBC1D2*!3EE"}, in a file named mycreds.json.
aws secretsmanager create-secret --name secret_now --secret-string file://mycreds.json

**Update the handler code**

An example with the following code is in example-function/index.js in the zipped files that are provided in the *Attachments* section.

```javascript
exports.handler = function(event, context, callback) {
  const https = require('http')
  const options = {
    hostname: 'localhost',
    port: 8080,
    path: '/cache/secret_now',
    method: 'GET'
  }
  const req = https.request(options, res => {
    res.on('data', d => {
      console.log("Response from cache: " + d);
      return d;
    })
  })
  req.on('error', error => {
    console.error(error)
  })
  req.end();
};
```

**Create a secrets cache configuration file**

Create a *config.yaml* file in the Lambda function Code tab under the root directory. In the example, secret_now is the name of the secret that was created in the previous step and will be cached by the extension. To cache additional secrets, add them to this file.

```yaml
SecretManagers:
  - secrets:
    - secret_now
```

**Deploy the Lambda extension**

```bash
> chmod +x deploy.sh
> ./deploy.sh
```

**Invoke the Lambda function**

```bash
aws lambda invoke \
  --function-name "Secrets-Extension-Lambda-Test" \
  --payload "{"payload": "hello"}" /tmp/invite-result \ 
  --cli-binary-format raw-in-base64-out \ 
  --log-type Tail
```

The function should return "StatusCode": 200.

Convert and unpack data from EBCDIC to ASCII

Summary

Because mainframes typically host critical business data, modernizing data is one of the most important tasks when migrating data to the Amazon Web Services (AWS) Cloud or other American Standard Code for Information Interchange (ASCII) environment. On mainframes, data is typically encoded in extended binary-coded decimal interchange code (EBCDIC) format. Exporting database, Virtual Storage Access Method (VSAM), or flat files generally produces packed, binary EBCDIC files, which are more complex to migrate. The most commonly used database migration solution is change data capture (CDC), which, in most cases, automatically converts data encoding. However, CDC mechanisms may not be available for these database, VSAM, or flat files. For these files, an alternative approach is required to modernize the data.

This pattern describes how to modernize EBCDIC data by converting it to ASCII format. After conversion, you can load the data into modern databases or have applications in the cloud process the data directly. The pattern uses the conversion script and sample files in the mainframe-data-utilities GitHub repository.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An EBCDIC input file and its corresponding common business-oriented language (COBOL) copybook. A sample EBCDIC file and COBOL copybook are included in the mainframe-data-utilities GitHub repository. For more information about COBOL copybooks, see Enterprise COBOL for z/OS 6.3 Programming Guide on the IBM website.

Limitations

- The current Python solution doesn't support Variable Blocked files (IBM documentation).
- File layouts defined inside COBOL programs are not supported. They must be made available separately.

<td>Amazon EBS; Amazon EC2</td>
</tr>
</tbody>
</table>
- EBCDIC data on a mainframe
- COBOL copybook

**Target technology stack**

- Amazon Elastic Compute Cloud (Amazon EC2) instance in a virtual private cloud (VPC)
- Amazon Elastic Block Store (Amazon EBS)
- Python and its required packages, JavaScript Object Notation (JSON), sys, and datetime
- ASCII flat file ready to be read by a modern application or loaded in a relational database table

**Target architecture**

The architecture diagram shows the process of converting an EBCDIC file to an ASCII file on an EC2 instance:
1. Using the `parse_copybook_to_json.py` script, you convert the COBOL copybook to a JSON file.
2. Using the JSON file and the `extract_ebcdic_to_ascii.py` script, you convert the EBCDIC data to an ASCII file.

**Automation and scale**

After the resources needed for the first manual file conversions are in place, you can automate file conversion. This pattern doesn't include instructions for automation. There are multiple ways to automate the conversion. The following is an overview of one possible approach:

1. Encapsulate the AWS Command Line Interface (AWS CLI) and Python script commands into a shell script.
2. Create an AWS Lambda function that asynchronously submits the shell script job into an EC2 instance. For more information, see [Scheduling SSH jobs using AWS Lambda](#).
3. Create an Amazon Simple Storage Service (Amazon S3) trigger that invokes the Lambda function every time a legacy file is uploaded. For more information, see [Using an Amazon S3 trigger to invoke a Lambda function](#).

**Tools**

**AWS services**

- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- **Amazon Elastic Block Store (Amazon EBS)** provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

**Other tools**

- **GitHub** is a code-hosting service that provides collaboration tools and version control.
- **Python** is a high-level programming language.

**Code**

The code for this pattern is available in the `mainframe-data-utilities` GitHub repository.

**Epics**

**Prepare the EC2 instance**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch an EC2 instance.</td>
<td>The EC2 instance must be running Linux and have outbound internet access. This allows the instance to access the Python source code available on GitHub. To create the instance:</td>
<td>General AWS</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
</tbody>
</table>
2. Launch an EC2 Linux instance. Use a public IP address and allow inbound access through port 22. Ensure that the storage size of the instance is at least twice the size of the EBCDIC data file. For instructions, see the Amazon EC2 documentation. | General AWS, Linux          |
| Install Python and Git. | 1. Using a secure shell (SSH) client, connect to the EC2 instance you just launched. For more information, see Connect to your Linux instance.  
2. Install Python 3.8 or later from the Python website.  
3. In the Amazon EC2 console, run the following command. This installs Git on the EC2 instance.  
   ```bash
   sudo yum install git
   ```  
4. Run the following command and confirm that Git has been successfully installed.  
   ```bash
   git --version
   ```                                                                 | General AWS, Linux          |
| Clone the GitHub repository. | 1. In the Amazon EC2 console, run the following command. This clones the mainframe-data-utilities repository from GitHub and opens the default copy location, the home folder.  
   ```bash
   git clone git://github.com/aws-samples/mainframe-data-utilities.git
   ```  
2. In the home folder, confirm that the mainframe-data-utilities folder is present. | General AWS, GitHub          |
Create the ASCII file from the EBCDIC data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parse the COBOL copybook into the JSON layout file.</td>
<td>Inside the mainframe-data-utilities folder, run the parse_copybook_to_json.py script. This automation module reads the file layout from a COBOL copybook and creates a JSON file. The JSON file contains the information required to interpret and extract the data from the source file. This creates the JSON metadata from the COBOL copybook. Use the command from Parse COBOL copybook to JSON in the Additional information section. The script prints the received arguments.</td>
<td>General AWS, Linux</td>
</tr>
</tbody>
</table>

For more information about the arguments, see the README file in the GitHub repository.

| Inspect the JSON layout file. | 1. Navigate to the output path defined in the parse_copybook_to_json.py script.  
2. Check the creation time of the sample-data/cobpack2-list.json file to confirm | General AWS, JSON |

---

Copybook
File..................| LegacyReference/COBPACK2.cpy
Parsed copybook (JSON List).| sample-data/cobpack2-list.json
JSON Dict (documentation)...| sample-data/cobpack2-dict.json
ASCII file...............| sample-data/COBPACK.ASCII.txt
EBCDIC file...............| sample-data/COBPACK.OUTFILE.txt
Print each.................| 10000
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>that you have selected the appropriate JSON layout file. 3. Examine the JSON file and confirm that the contents are similar to the following:</td>
<td></td>
</tr>
</tbody>
</table>

```json
"input": "extract-ebcdic-to-ascii/COBPACK.OUTFILE.txt",
"output": "extract-ebcdic-to-ascii/COBPACK.ASCII.txt",
"max": 0,
"skip": 0,
"print": 10000,
"lrecl": 150,
"rem-low-values": true,
"separator": "\|",
"transf": [
  {
    "type": "ch",
    "bytes": 19,
    "name": "OUTFILE-TEXT"
  }
]
```

The most important attributes of the JSON layout file are:

- **input** – Contains the path of the EBCDIC file to be converted
- **output** – Defines the path where the ASCII file will be generated
- **lrecl** – Specifies the size in bytes of the logical record length
- **transf** – Lists all fields and their size in bytes

For more information about the JSON layout file, see the **README file** in the GitHub repository.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the ASCII file</td>
<td>Run the <code>extract_ebcdic_to_ascii.py</code> script, which is included in the cloned GitHub repository. This script reads the EBCDIC file and writes a converted and readable ASCII file.</td>
<td>General AWS</td>
</tr>
<tr>
<td></td>
<td>python3 extract_ebcdic_to_ascii.py -local-json sample-data/cobpack2-list.json</td>
<td></td>
</tr>
<tr>
<td></td>
<td>As the script processes the EBCDIC data, it prints a message for every batch of 10,000 records. See the following example.</td>

</tr>
<tr>
<td></td>
<td>For information about how to change the print frequency, see the README file in the GitHub repository.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
| Examine the ASCII file. | 1. Check the creation time of the `extract-ebcdic-to-ascii/COBPACK.ASCII.txt` file to verify that it was recently created.  
2. In the Amazon EC2 console, enter the following command. This opens the first record of the ASCII file.  
```bash
head sample-data/COBPACK.ASCII.txt -n 1
```
3. Examine the contents of the first record. Because EBCDIC files are usually binary, they don't have carriage return and line feed (CRLF) special characters. The `extract_ebcdic_to_ascii.py` script adds a pipe character as a column separator, which is defined in the script parameters. If you used the sample EBCDIC data provided, for the result, see **Sample ASCII data** in the Additional information section. | General AWS, Linux |
<table>

0000001c: 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000
0000001d: 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000
0000001e: 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000
0000001f: 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000 0000
```                                                                                                                                                                                                         |                                            |

To evaluate the equivalence between the source and target files, comprehensive knowledge of EBCDIC is required. For example, the first character of the sample EBCDIC file is a hyphen (-). In hexadecimal notation of the EBCDIC file, this character is represented by 60, and in hexadecimal notation of the ASCII file, this character is represented by 2D. For an EBCDIC-to-ASCII conversion table, see [EBCDIC to ASCII](https://www.ibm.com) on the IBM website.

Deploy multiple-stack applications using AWS CDK with TypeScript

Created by Rahul Gaikwad (AWS)

</tr>
</tbody>
</table>
Summary

This pattern provides a step-by-step approach for application deployment on Amazon Web Services (AWS) using AWS Cloud Development Kit (AWS CDK) with TypeScript. As an example, the pattern deploys a serverless real-time analytics application.

The pattern builds and deploys nested stack applications. The parent AWS CloudFormation stack calls the child, or nested, stacks. Each child stack builds and deploys the AWS resources that are defined in the CloudFormation stack. AWS CDK Toolkit, the command line interface (CLI) command `cdk`, is the primary interface for the CloudFormation stacks.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Existing virtual private cloud (VPC) and subnets
- AWS CDK Toolkit installed and configured
- A user with administrator permissions and a set of access keys.
- Node.js
- AWS Command Line Interface (AWS CLI)

Limitations

- Because AWS CDK uses AWS CloudFormation, AWS CDK applications are subject to CloudFormation service quotas. For more information, see [AWS CloudFormation quotas](#).

Product versions

This pattern has been built and tested using the following tools and versions.

- AWS CDK Toolkit 1.83.0
- Node.js 14.13.0
- npm 7.0.14

The pattern should work with any version of AWS CDK or npm. Note that Node.js versions 13.0.0 through 13.6.0 are not compatible with the AWS CDK.

Architecture

Target technology stack

- AWS Amplify Console
- Amazon API Gateway
- AWS CDK
- Amazon CloudFront
- Amazon Cognito
- Amazon DynamoDB
- Amazon Kinesis Data Firehose
• Amazon Kinesis Data Streams
• AWS Lambda
• Amazon Simple Storage Service (Amazon S3)

**Target architecture**

The following diagram shows multiple-stack application deployment using AWS CDK with TypeScript.

The following diagram shows the architecture of the example serverless real-time application.
Tools

**Tools**

- **AWS Amplify Console** – The AWS Amplify Console is the control center for fullstack web and mobile application deployments in AWS. Amplify Console hosting provides a git-based workflow for hosting fullstack serverless web apps with continuous deployment. The Admin UI is a visual interface for frontend web and mobile developers to create and manage app backends outside the AWS console.

- **Amazon API Gateway** – Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.

- **AWS CDK** – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.

- **AWS CDK Toolkit** – The AWS CDK Toolkit, the CLI command cdk, is the primary tool for interacting with your AWS CDK app. It runs your app, interrogates the application model you defined, and produces and deploys the AWS CloudFormation templates generated by the AWS CDK.

- **Amazon CloudFront** – Amazon CloudFront is a web service that speeds up distribution of static and dynamic web content, such as .html, .css, .js, and image files. CloudFront delivers your content through a worldwide network of data centers called edge locations for lower latency and improved performance.

- **Amazon Cognito** – Amazon Cognito provides authentication, authorization, and user management for your web and mobile apps. Your users can sign in directly with a user name and password, or through a third party.

- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

- **Amazon Kinesis Data Firehose** – Amazon Kinesis Data Firehose is a fully managed service for delivering real-time streaming data to destinations such as Amazon S3, Amazon Redshift, Amazon OpenSearch Service (successor to Amazon Elasticsearch Service), Splunk, and any custom HTTP endpoint or HTTP endpoints owned by supported third-party service providers.

- **Amazon Kinesis Data Streams** – Amazon Kinesis Data Streams is a service for collecting and processing large streams of data records in real time.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.

**Code**

The code for this pattern is attached.

- AWS sample example - Serverless real-time analytics

### Additional information

#### Directory and file details

This pattern sets up the following three stacks.

- `parent-cdk-stack.ts` – This stack acts as the parent stack and calls the two child applications as nested stacks.
- `real-time-analytics-poc-stack.ts` – This nested stack contains the infrastructure and application code.
- `real-time-analytics-web-stack.ts` – This nested stack contains only the static web application code.

#### Important files and their functionality

- `bin/real-time-analytics-poc.ts` – Entry point of the AWS CDK application. It loads all stacks defined under `lib/`.
- `lib/real-time-analytics-web-stack.ts` – Definition of the AWS CDK application's stack (`real-time-analytics-web-stack`).
- `lib/parent-cdk-stack.ts` – Definition of the AWS CDK application's stack (`parent-cdk`).
- `package.json` – npm module manifest, which includes the application name, version, and dependencies.
- `package-lock.json` – Maintained by npm.
- `tsconfig.json` – The project's TypeScript configuration.
- `.gitignore` – List of files that Git should exclude from source control.
- `node_modules` – Maintained by npm; includes the project's dependencies.

The following section of code in the parent stack calls child applications as a nested AWS CDK stacks.
import * as cdk from '@aws-cdk/core';
import { Construct, Stack, StackProps } from '@aws-cdk/core';
import { RealTimeAnalyticsPocStack } from './real-time-analytics-poc-stack';
import { RealTimeAnalyticsWebStack } from './real-time-analytics-web-stack';

export class CdkParentStack extends Stack {
    constructor(scope: Construct, id: string, props?: StackProps) {
        super(scope, id, props);

        new RealTimeAnalyticsPocStack(this, 'RealTimeAnalyticsPocStack');
        new RealTimeAnalyticsWebStack(this, 'RealTimeAnalyticsWebStack');
    }
}

Code for testing

session={{date.now('YYYYMMDD')}}|sequence={{date.now('x')}}|reception={{date.now('x')}}|instrument={{random.number(9)}}|l={{random.number(20)}}|price_0={{random.number({'min':10000, "max":30000})}}|price_1={{random.number({'min':10000, "max":30000})}}|price_2={{random.number({'min':10000, "max":30000})}}|price_3={{random.number({'min':10000, "max":30000})}}|price_4={{random.number({'min':10000, "max":30000})}}|price_5={{random.number({'min':10000, "max":30000})}}|price_6={{random.number({'min':10000, "max":30000})}}|price_7={{random.number({'min':10000, "max":30000})}}|price_8={{random.number({'min':10000, "max":30000})}}|price_9={{random.number({'min':10000, "max":30000})}}

Testing API Gateway

On the API Gateway console, test API Gateway by using the GET method.

![API Gateway Test](image)
Automate deployment of nested applications using AWS SAM

Created by Rahul Sharad Gaikwad (AWS), Dmitry Gulin (AWS), and Tabby Ward (AWS)

<table>

</tr>
<tr>
<td>AWS services:</td>
<td>AWS Serverless Application Repository</td>
</tr>
</tbody>
</table>

Summary

You can build serverless applications on the Amazon Web Services (AWS) Cloud by using the AWS Serverless Application Model (AWS SAM). An open-source framework, AWS SAM provides shorthand syntax to express functions, APIs, databases, and event source mappings. With a few lines of configuration, you can define the application you want and model it.

This pattern uses AWS SAM templates to automate the deployment of nested applications. A nested application is an application within another application. Parent applications call their child applications. These are loosely coupled components of a serverless architecture.

Using nested applications, you can rapidly build highly sophisticated serverless architectures by reusing services or components that are independently authored and maintained but are composed using AWS SAM and the Serverless Application Repository. Nested applications help you to build applications that are more powerful, avoid duplicated work, and ensure consistency and best practices across your teams and organizations. To demonstrate nested applications, the pattern deploys a sample AWS serverless shopping cart application.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An existing virtual private cloud (VPC) and subnets
- An integrated development environment, such as AWS Cloud9 or Visual Studio Code (for more information, see Start building with SDKs and tools)
- Python wheel library installed using `pip install wheel`, if it's not already installed

Limitations

- The maximum number of applications that can be nested in a serverless application is 200.
- The maximum number of parameters for a nested application can have 60.
Product versions

- This solution is built on AWS SAM command line interface (AWS SAM CLI) version 1.21.1, but this architecture should work with later AWS SAM CLI versions.

Architecture

Target technology stack

- Amazon API Gateway
- AWS SAM
- Amazon Cognito
- Amazon DynamoDB
- AWS Lambda
- Amazon Simple Queue Service (Amazon SQS) queue

Target architecture

The following diagram shows the architecture of sample AWS serverless shopping cart application.

In this solution setup, AWS SAM CLI serves as the interface for AWS CloudFormation stacks. AWS SAM templates automatically deploy nested applications. The parent SAM template calls the child templates, and the parent CloudFormation stack deploys the child stacks. Each child stack builds the AWS resources that are defined in the AWS SAM CloudFormation templates.
Tools

• **Amazon API Gateway** – Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.

• **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run on AWS. You create a template that describes all the AWS resources that you want, and CloudFormation provisions and configures those resources for you.

• **Amazon Cognito** – Amazon Cognito provides authentication, authorization, and user management for your web and mobile apps.

• **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. With DynamoDB, you can create database tables that can store and retrieve any amount of data and serve any level of request traffic.

• **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

• **AWS SAM** – AWS Serverless Application Model (AWS SAM) is an open-source framework that you can use to build serverless applications on AWS. A serverless application is a combination of Lambda functions, event sources, and other resources that work together to perform tasks. Note that a serverless application is more than a Lambda function—it can include additional resources such as APIs, databases, and event source mappings.

• **Amazon SQS** – Amazon Simple Queue Service (Amazon SQS) offers a secure, durable, and available hosted queue. You can use Amazon SQS to integrate and decouple distributed software systems and components.
**Code**

The code for this pattern is attached.

**Epics**

**Install AWS SAM CLI**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install AWS SAM CLI.</td>
<td>To install AWS SAM CLI, see the instructions in the <a href="https://aws.amazon.com/">AWS SAM documentation</a></td>
<td>DevOps</td>
</tr>
<tr>
<td>Set up AWS credentials.</td>
<td>To set AWS credentials so that the AWS SAM CLI can make calls to AWS services on your behalf, run the <code>aws configure</code> command and follow the prompts:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$aws configure</td>
<td>DevOps</td>
</tr>
<tr>
<td></td>
<td>AWS Access Key ID [None]: &lt;your_access_key_id&gt;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>AWS Secret Access Key [None]: your_secret_access_key</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Default region name [None]:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Default output format [None]:</td>
<td></td>
</tr>
</tbody>
</table>

**Initialize the AWS SAM project**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy templates to initialize the project.</td>
<td>To initialize the project, run the <code>sam init</code> command. When prompted to choose a template source, choose Custom Template Location.</td>
<td>DevOps</td>
</tr>
</tbody>
</table>

**Create, compile, and build the SAM template code**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the AWS SAM application templates.</td>
<td>Create the templates for the nested applications. In this example, the nested application templates are <code>auth.yaml</code>, <code>product-mock.yaml</code>, and <code>shoppingcart-service.yaml</code>. For more</td>
<td>DevOps</td>
</tr>
</tbody>
</table>
### Create the parent template.

Create the template that will invoke the nested application templates. In this example, the parent template is `template.yml`.

**Skills required:** DevOps

### Compile and build the AWS SAM template code.

Using the AWS SAM CLI, run the following command:

```
sam build
```

**Skills required:** DevOps

### Deploy the AWS SAM template

**Task**

- Deploy the applications.

**Description**

To launch the SAM template code that creates the nested application CloudFormation stacks and deploys code in the AWS environment, run the following command:

```
sam deploy --guided --stack-name shopping-cart-nested-stack --capabilities CAPABILITY_IAM CAPABILITY_AUTO_EXPAND
```

For more information, see the Additional information section.

**Skills required:** DevOps

### Verify the deployment

**Task**

- Verify the stacks.

**Description**

To review and verify the AWS CloudFormation stacks and all AWS resources that were defined in the AWS SAM templates, log in to the AWS Management Console. For more information, see the Additional information section.

**Skills required:** DevOps

Additional information

Directory structure of the applications

After all the code is in place, the example has the following directory structure:

• **layers** – A layer is a file archive that contains libraries, a custom runtime, or other dependencies. With layers, you can use libraries in your function without needing to include them in a deployment package.
• **product-mock-service** – This folder contains all product-related Lambda functions and files.
• **shopping-cart-service** – This folder contains all shopping-related Lambda functions and files.
**Nested application templates**

For the independent applications, the example includes the following three `.yaml` files.

**auth.yaml**

This template sets up authentication-related resources, such as Amazon Cognito and AWS Systems Manager Parameter Store.

```yaml
AWSTemplateFormatVersion: '2010-09-09'
Transform: AWS::Serverless-2016-10-31
Description: >
  auth-resources

SAM Template for auth resources

Globals:
  Function:
    Timeout: 3

Resources:
  CognitoUserPool:
    Type: AWS::Cognito::UserPool
    Properties:
      UserPoolName: !Sub ${AWS::StackName}-UserPool
      AutoVerifiedAttributes:
        - email
  UserPoolClient:
    Type: AWS::Cognito::UserPoolClient
    Properties:
      ClientName: my-app
      GenerateSecret: false
      UserPoolId: !Ref CognitoUserPool
      ExplicitAuthFlows:
        - ADMIN_NO_SRP_AUTH

The parent template

The `template.yaml` file calls all the independent child stacks. All separate applications would be work as nested application in single parent SAM template.

AWSTemplateFormatVersion: '2010-09-09'
Transform: AWS::Serverless-2016-10-31
Description: >
  SAM Template for Nested application resources
Resources:
  Auth:
    Type: AWS::Serverless::Application
    Properties:
      Location: auth.yaml
  Product:
    Type: AWS::Serverless::Application
    Properties:
      Location: product-mock.yaml
      Parameters:
        AllowedOrigin: 'http://localhost:8080'
    DependsOn: Auth
  Shopping:
    Type: AWS::Serverless::Application
    Properties:
      Location: shoppingcart-service.yaml
      Parameters:
        AllowedOrigin: 'http://localhost:8080'
    DependsOn: Product

Running the sam deploy command

When you run the command `sam deploy --guided --stack-name shopping-cart-nested-stack --capabilities CAPABILITY_IAM CAPABILITY_AUTO_EXPAND`, it will prompt with a few questions. Answer all questions with y, and then you will see the following screen outputs.
$sam deploy --guided --stack-name shopping-cart-nested-stack --capabilities CAPABILITY_IAM CAPABILITY_AUTO_EXPAND

Configuring SAM deploy

- Looking for config file [samconfig.toml] : Not found

Setting default arguments for 'sam deploy'

Stack Name [shopping-cart-nested-stack]:
AWS Region [us-east-1]:
- Shows you resources changes to be deployed and require a 'Y' to initiate deploy
- Confirm changes before deploy [y/N]: Y
- You need permission to be able to create roles to connect to the resources in your template
- Allow IAM user creation [Y/n]: Y
- GetProductFunction may not have authorization defined, Is this okay? [y/N]: Y
- GetProductsFunction may not have authorization defined, Is this okay? [y/N]: Y
- Save arguments to configuration file [Y/n]: Y
- SAM configuration file [samconfig.toml]:
- SAM configuration environment [default]:

- Looking for resources needed for deployment: Found:
  - Managed S3 bucket: aws-sam-cli-managed-default-samclisourcebucket-hth4gd7vq1l9k
  - A different default S3 bucket can be set in samconfig.toml

- Saved arguments to config file
- Running 'sam deploy' for future deployments will use the parameters saved above.
- The above parameters can be changed by modifying samconfig.toml
- Learn more about samconfig.toml syntax at https://docs.aws.amazon.com/serverless-application-model/latest/developerguide/serverless-sam-cli-config.html

Deploying with following values

- Stack name: shopping-cart-nested-stack
- Region: us-east-1
- Confirm changeset: True
- Deployment S3 bucket: aws-sam-cli-managed-default-samclisourcebucket-hth4gd7vq1l9k
- Capabilities: ["CAPABILITY_IAM", "CAPABILITY_AUTO_EXPAND"]
- Parameter overrides: {}
- Signing Profiles: {}

Successfully created/updated stack - shopping-cart-nested-stack in us-east-1

Stacks on the console

1789
Log in to the console and choose to the CloudFormation service to see the parent and child stacks. In this example, `sam-shopping-cart` is the parent stack that calls the nested Auth, Product and Shopping stacks.

The product stack gives the Product API Gateway URL link as an output.

The following figure shows the output of the Product API Gateway /GET method.

Implement SaaS tenant isolation for Amazon S3 by using an AWS Lambda token vending machine

Created by Tabby Ward (AWS), sravan periyathambi (AWS), and Thomas Davis (AWS)

| Environment: PoC or pilot | Technologies: Modernization; SaaS | AWS services: AWS Identity and Access Management; AWS Lambda; Amazon S3; AWS STS |

Summary

Multitenant SaaS applications must implement systems to ensure that tenant isolation is maintained. When you store tenant data on the same Amazon Web Services (AWS) resource—such as multiple tenants storing data in the same Amazon Simple Storage Service (Amazon S3) bucket—you must ensure that cross-tenant access cannot occur. Token vending machines (TVMs) are one way to guarantee tenant data isolation. These machines provide a mechanism for obtaining tokens while abstracting the complexity of how these tokens are generated. Developers can use a TVM without having detailed knowledge of how it produces tokens.

This pattern implements a TVM by using AWS Lambda. The TVM generates a token that consists of temporary security token service (STS) credentials that limit access to a single SaaS tenant's data in an S3 bucket.

TVMs, and the code that's provided with this pattern, are typically used with claims that are derived from JSON Web Tokens (JWTs) to associate requests for AWS resources with a tenant-scoped AWS Identity and Access Management (IAM) policy. You can use the code in this pattern as a basis to implement a SaaS application that generates scoped, temporary STS credentials based on the claims provided in a JWT token.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 1.19.0 or later, installed and configured on macOS, Linux, or Windows. Alternatively, you can use AWS CLI version 2.1 or later.

Limitations

- This code runs in Java and doesn't currently support other programming languages.
- The sample application does not include AWS cross-Region or disaster recovery (DR) support.
- This pattern demonstrates how a Lambda TVM for a SaaS application can provide scoped tenant access. It is not intended to be used in production environments.

Architecture

Target technology stack

- AWS Lambda
Tools

AWS services

- **AWS CLI** – AWS Command Line Interface (AWS CLI) is a unified tool for interacting with AWS services by using commands in your command-line shell.
- **AWS Lambda** – AWS Lambda lets you run code without provisioning or managing servers. You pay only for the compute time you consume.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers scalability, data availability, security, and performance.
- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services.
- **AWS STS** - AWS Security Token Service (AWS STS) enables you to request temporary, limited-privilege credentials for IAM users or for users whom you authenticate (federated users).

Code

The source code for this pattern is available as an attachment and includes the following files:

- `s3UploadSample.jar` provides the source code for a Lambda function that uploads a JSON document to an S3 bucket.
- `tvm-layer.zip` provides a reusable Java library that supplies a token (STS temporary credentials) for the Lambda function to access the S3 bucket and upload the JSON document.
- token-vending-machine-sample-app.zip provides the source code used to create these artifacts and compilation instructions.

To use these files, follow the instructions in the next section.

**Epics**

**Determine variable values**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Determine variable values.</td>
<td>The implementation of this pattern requires includes several variable names that must be used consistently. Determine the values that should be used for each variable, and provide that value when requested in subsequent steps.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

<AWS Account ID> — The 12-digit account ID that is associated with the AWS account you are implementing this pattern in. For information about how to find your AWS account ID, see Your AWS account ID and its alias in the IAM documentation.

<AWS Region> — The AWS Region that you are implementing this pattern in. For more information on AWS Regions, see Regions and Availability Zones on the AWS website.

<sample-tenant-name> — The name of a tenant to use in the application. We recommend that you use only alphanumeric characters in this value for simplicity, but you can use any valid name for an S3 object key.

<sample-tvm-role-name> — The name of the IAM role attached to the Lambda function that runs the TVM and sample application. The role name is a string that consists of uppercase and lowercase alphanumeric characters with no spaces. You can also include any of the
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;sample-app-role-name&gt;</td>
<td>The name of the IAM role that is assumed by the Lambda function when it generates scoped, temporary STS credentials. The role name is a string that consists of uppercase and lowercase alphanumeric characters with no spaces. You can also include any of the following characters: underscore (_), plus sign (+), equal sign (=), comma (,), period (.), at sign (@), and hyphen (-). The role name must be unique within the account.</td>
<td></td>
</tr>
<tr>
<td>&lt;sample-app-function-name&gt;</td>
<td>The name of the Lambda function. This is a string that's up to 64 characters in length.</td>
<td></td>
</tr>
</tbody>
</table>
| <sample-app-bucket-name> | The name of an S3 bucket that must be accessed with permissions that are scoped to a specific tenant. S3 bucket names:  

- Must be between 3 and 63 characters long.  
- Must consist of only lowercase letters, numbers, periods (.), and hyphens (-).  
- Must begin and end with a letter or number.  
- Must not be formatted as an IP address (for example, 192.168.5.4).  
- Must be unique within a partition. A partition is a grouping of Regions. AWS currently has three partitions: aws (Standard Regions), aws-cn (China Regions), and aws-us-gov (AWS GovCloud [US] Regions). |  |
### Create an S3 bucket

<tr>
<td>Create an inline TVM role policy.</td>
<td>Use one of the following AWS CLI commands to create an IAM policy. Provide the <code>&lt;sample-tvm-role-name&gt;</code>, <code>&lt;AWS Account ID&gt;</code>, and <code>&lt;sample-app-role-name&gt;</code> values in the command.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>For macOS or Linux shells:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For the Windows command line:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>This policy is attached to the TVM role. It gives the code the capability to assume the application role, which has broader permissions to access the S3 bucket.</td>
<td></td>
</tr>
</tbody>
</table>
### Attach the managed Lambda policy.

**Task:** Use the following AWS CLI command to attach the AWSLambdaBasicExecutionRole IAM policy. Provide the `<sample-tvm-role-name>` value in the command:

```
aws iam attach-role-policy
  --role-name <sample-tvm-role-name>
  --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole
```

This managed policy is attached to the TVM role to permit Lambda to send logs to Amazon CloudWatch.

### Create the IAM application role and policy

**Task:** Use one of the following AWS CLI commands to create an IAM role. Provide the `<sample-app-role-name>`, `<AWS Account ID>`, and `<sample-tvm-role-name>` values in the command.

For macOS or Linux shells:

```
aws iam create-role
  --role-name <sample-app-role-name>
  --assume-role-policy-document
```

For the Windows command line:

```
aws iam create-role
  --role-name <sample-app-role-name>
  --assume-role-policy-document
  "\"Version\": "2012-10-17\", \"Statement\": [{\"Effect\": "Allow \", \"Principal\": {\"AWS\": \"arn:aws:iam::<AWS Account ID>:role/<sample-tvm-role-name>\"} },\"Action": "sts:AssumeRole"]"
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>tvm-role-name:&gt;&quot;},{&quot;Action &quot;: &quot;sts:AssumeRole&quot;}]}}&quot;</td>
<td>The Lambda sample application assumes this role with a scoped policy to get tenant-based access to an S3 bucket.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Create an inline application role policy.</td>
<td>Use one of the following AWS CLI commands to create an IAM policy. Provide the <code>&lt;sample-app-role-name&gt;</code> and <code>&lt;sample-app-bucket-name&gt;</code> values in the command.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

For macOS or Linux shells:

```bash
aws iam put-role-policy
--role-name <sample-app-role-name> --policy-name s3-bucket-access --policy-document:
```

For the Windows command line:

```bash
aws iam put-role-policy
--role-name <sample-app-role-name> --policy-name s3-bucket-access --policy-document: \"{"Version": \"2012-10-17\", \"Statement \": \n\{"\"Effect\": \"Allow\", \n\"Action\": [\"s3:PutObject \", \"s3:GetObject\", \n\"s3:DeleteObject \"], \n\"Resource\": \n\"arn:aws:s3:::<sample-app-bucket-name>/*\"}, \n\{"\"Effect\": \"Allow\", \n\"Action\": [\"s3:ListBucket \"], \n\"Resource\": \n\"arn:aws:s3:::<sample-app-bucket-name>\"}\}"
```

This policy is attached to the application role. It provides broad access to objects in the S3 bucket. When the sample application assumes the role, these permissions are scoped to a specific tenant with the TVM's dynamically generated policy.
## Create the Lambda sample application with TVM

<table>
<thead>

aws lambda create-function --function-name `<sample-
```                                                                        |                                      |
### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This command creates a Lambda function with the sample application code and the TVM layer attached. It also sets two environment variables: S3_BUCKET and ROLE. The sample application uses these variables to determine the role to assume and the S3 bucket to upload JSON documents to.

### Test the sample application and TVM

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Invoke the Lambda sample application. | Use one of the following AWS CLI commands to start the Lambda sample application with its expected payload. Provide the `<sample-app-function-name>` and `<sample-tenant-name>` values in the command. For macOS and Linux shells:  
```bash
aws lambda invoke --function-name <sample-app-function-name> --invocation-type RequestResponse --payload '{"tenant": "<sample-tenant-name>"}' --cli-binary-format raw-in-base64-out response.json
```
|                        | For the Windows command line:  
```powershell
Invoke-LambdaFunction -FunctionName <sample-app-function-name> -InvocationType RequestResponse -Payload 
{"tenant": "<sample-tenant-name>"} 
```
<p>|                        |                                                             | Cloud administrator, App developer |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| aws lambda invoke --function `<sample-app-function-name>` --invocation-type RequestResponse --payload 
  "{"tenant": "<sample-tenant-name>"}" --cli-binary-format raw-in-base64-out response.json | This command calls the Lambda function and returns the result in a `response.json` document. On many Unix-based systems, you can change `response.json` to `/dev/stdout` to output the results directly to your shell without creating another file.  
  
  **Note:** Changing the `<sample-tenant-name>` value in subsequent invocations of this Lambda function alters the location of the JSON document and the permissions the token provides. | Cloud administrator    |
| View the S3 bucket to see created objects.                         | Browse to the S3 bucket (`<sample-app-bucket-name>`) that you created earlier. This bucket contains an S3 object prefix with the value of `<sample-tenant-name>`. Under that prefix, you will find a JSON document named with a UUID. Invoking the sample application multiple times adds more JSON documents. | Cloud administrator    |
## Task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| View Cloudwatch logs for the sample application. | View the Cloudwatch logs associated with the Lambda function named `<sample-app-function-name>`. For instructions, see [Accessing Amazon CloudWatch logs for AWS Lambda](#) in the AWS Lambda documentation. You can view the tenant-scoped policy generated by the TVM in these logs. This tenant-scoped policy gives permissions for the sample application to the Amazon S3 **PutObject**, **GetObject**, **DeleteObject**, and **ListBucket** APIs, but only for the object prefix associated with `<sample-tenant-name>`. In subsequent invocations of the sample application, if you change the `<sample-tenant-name>`, the TVM updates the scoped policy to correspond to the tenant provided in the invocation payload. This dynamically generated policy shows how tenant-scoped access can be maintained with a TVM in SaaS applications.  

The TVM functionality is provided in a Lambda layer so that it can be attached to other Lambda functions used by an application without having to replicate the code.  

For an illustration of the dynamically generated policy, see the [Additional information (p. 1804)](#) section. | Cloud administrator |

- [AWS SaaS Boost](#) (an open-source reference environment that helps you move your SaaS offering to AWS)
Additional information

The following Amazon Cloudwatch log shows the dynamically generated policy produced by the TVM code in this pattern. In this screenshot, the `<sample-app-bucket-name>` is DOC-EXAMPLE-BUCKET and the `<sample-tenant-name>` is test-tenant-1. The STS credentials returned by this scoped policy are unable to perform any actions on objects in the S3 bucket except for objects that are associated with the object key prefix test-tenant-1.

Implement the serverless saga pattern by using AWS Step Functions

*Created by Tabby Ward (AWS)*

| Environment: PoC or pilot | Technologies: Modernization; Serverless; Cloud-native | Workload: Open-source |
Summary

In a microservices architecture, the main goal is to build decoupled and independent components to promote agility, flexibility, and faster time to market for your applications. As a result of decoupling, each microservice component has its own data persistence layer. In a distributed architecture, business transactions can span multiple microservices. Because these microservices cannot use a single atomicity, consistency, isolation, durability (ACID) transaction, you might end up with partial transactions. In this case, some control logic is needed to undo the transactions that have already been processed. The distributed saga pattern is typically used for this purpose.

The saga pattern is a failure management pattern that helps establish consistency in distributed applications and coordinates transactions between multiple microservices to maintain data consistency. When you use the saga pattern, every service that performs a transaction publishes an event that triggers subsequent services to perform the next transaction in the chain. This continues until the last transaction in the chain is complete. If a business transaction fails, saga orchestrates a series of compensating transactions that undo the changes that were made by the preceding transactions.

This pattern demonstrates how to automate the setup and deployment of a sample application (which handles travel reservations) by using the AWS Cloud Development Kit (AWS CDK) along with serverless technologies such as AWS Step Functions, AWS Lambda, and Amazon DynamoDB. The sample application also uses Amazon API Gateway and Amazon Simple Notification Service (Amazon SNS) to implement a saga execution coordinator.

For more information about the saga pattern and other data persistence patterns, see the guide Enabling data persistence in microservices on the AWS Prescriptive Guidance website.

Prerequisites and limitations

Prerequisites

- An active AWS account with programmatic access
- AWS CDK Toolkit stack, which is used to provision resources from this pattern, deployed to your target AWS Region
- NodeJS, which is required for the AWS CDK
- AWS CDK CLI with AWS account configuration, so that you can create AWS resources by using the cdk deploy command
- A code editor of your choice (such as Visual Studio Code, Sublime, or Atom)

Product versions

- NodeJS version 14
- AWS CDK version 1.89.0

Limitations
Event sourcing is a natural way to implement the saga orchestration pattern in a microservices architecture where all components are loosely coupled and don’t have direct knowledge of one another. If your transaction involves a small number of steps (three to five), the saga pattern might be a great fit. However, complexity increases with the number of microservices and the number of steps.

Testing and debugging can become difficult when you’re using this design, because you have to have all services running in order to simulate the transaction pattern.

**Architecture**

**Target architecture**

The proposed architecture uses AWS Step Functions to build a saga pattern to book flights, book car rentals, and process payments for a vacation.

The following workflow diagram illustrates the typical flow of the travel reservation system. The workflow consists of reserving air travel (“ReserveFlight”), reserving a car (“ReserveCarRental”), processing payments (“ProcessPayment”), confirming flight reservations (“ConfirmFlight”), and confirming car rentals (“ConfirmCarRental”) followed by a success notification when these steps are complete. However, if the system encounters any errors in running any of these transactions, it starts to fail backward. For example, an error with payment processing (“ProcessPayment”) triggers a refund (“RefundPayment”), which then triggers a cancellation of the rental car and flight (“CancelRentalReservation” and “CancelFlightReservation”), which ends the entire transaction with a failure message.

This pattern deploys separate Lambda functions for each task that is highlighted in the diagram as well as three DynamoDB tables for flights, car rentals, and payments. Each Lambda function creates, updates, or deletes the rows in the respective DynamoDB tables, depending on whether a transaction is confirmed or rolled back. The pattern uses Amazon SNS to send text (SMS) messages to subscribers, notifying them of failed or successful transactions.
**Automation and scale**

You can create the configuration for this architecture by using an AWS CloudFormation template or AWS CDK scripts. See the attachment for the AWS CDK scripts, which are written in TypeScript.

**Tools**

**AWS services**

- **AWS Step Functions** – AWS Step Functions is a serverless orchestration service that lets you combine AWS Lambda functions and other AWS services to build business-critical applications. Through the Step Functions graphical console, you see your application’s workflow as a series of event-driven steps.

- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. You can use DynamoDB to create a database table that can store and retrieve any amount of data, and serve any level of request traffic.

- **AWS Lambda** – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

- **Amazon API Gateway** – Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.
• **AWS CDK** – The AWS Cloud Development Kit (AWS CDK) is a software development framework for defining your cloud application resources by using familiar programming languages such as TypeScript, JavaScript, Python, Java, and C#/.Net.

**Code**

The code for a sample application that demonstrates the saga pattern, including the AWS CDK scripts, the Lambda functions, and the DynamoDB tables, is attached as an archive. Follow the instructions in the first epic to install these.

**Epics**

**Install packages, compile, and build**

<table>
<thead>
<tr>
<th>Task</th>

</table>
# Deploy resources to the target AWS account

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the demo stack to AWS. | **Important:** The cluster is AWS Region-agnostic. If you use a profile, you must declare the Region explicitly in either the AWS Command Line Interface (AWS CLI) profile or through AWS CLI environment variables. In the `/cdk-serverless-saga` folder, run the following command to create a deployment assembly and to deploy it to the default AWS account and Region:  

```
cdk deploy
```
This step might take several minutes to complete. This command uses the default credentials that were configured for the AWS CLI. To specify named profile credentials, use the command:

```
cdk deploy --profile <aws_cli_profile_name>
```
Note the API Gateway URL that is displayed on the console after deployment is complete. You will need this information to test the saga execution flow. | Developer, Cloud architect |
| Compare the deployed stack with the current state. | In the `/cdk-serverless-saga` folder, run the following command to compare the deployed stack with the current state after making changes to the source code:  

```
cdk diff
```
 | Developer, Cloud architect |
| Create an AWS CloudFormation template. | In the `/cdk-serverless-saga` folder, run the following command to synthesize the stack into a CloudFormation template:  

```
cdk synth
```
 | Developer, Cloud architect |
Test the execution flow

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test the saga execution flow.| Navigate to the API Gateway URL that you noted in the earlier step, when you deployed the stack. This URL triggers the state machine to start. For more information about how to manipulate the flow of the state machine by passing different URL parameters, see the Additional information section.  
To view the results, sign in to the AWS Management Console, and navigate to the Step Functions console. Here, you can see every step of the saga state machine. You can also view the DynamoDB table to see the records inserted, updated, or deleted. If you refresh the screen frequently, you can watch the transaction status change from pending to confirmed.  
You can subscribe to the SNS topic by updating the code in the stateMachine.ts file with your cell phone number to receive SMS messages upon successful or failed reservations. For more information, see Amazon SNS in the Additional information section. | Developer, Cloud architect               |

Additional information

Code

For testing purposes, this pattern deploys API Gateway and a test Lambda function that triggers the Step Functions state machine. With Step Functions, you can control the functionality of the travel reservation system by passing a run_type parameter to mimic failures in "ReserveFlight," "ReserveCarRental," "ProcessPayment," "ConfirmFlight," and "ConfirmCarRental."

The saga Lambda function (sagaLambda.ts) takes input from the query parameters in the API Gateway URL, creates the following JSON object, and passes it to Step Functions for execution:

```javascript
let input = {
  "trip_id": tripID, // value taken from query parameter, default is AWS request ID
  "depart_city": "Detroit",
  "depart_time": "2021-07-07T06:00:00.000Z",
  "arrive_city": "Frankfurt",
  "arrive_time": "2021-07-09T08:00:00.000Z",
  "rental": "BMW",
  "rental_from": "2021-07-09T00:00:00.000Z",
  "rental_to": "2021-07-17T00:00:00.000Z",
  "run_type": runType // value taken from query parameter, default is "success"
};
```

You can experiment with different flows of the Step Functions state machine by passing the following URL parameters:

- **Successful Execution** – https://{api gateway url}
- **Reserve Flight Fail** – https://{api gateway url}?runType=failFlightsReservation
- **Confirm Flight Fail** – https://{api gateway url}?runType=failFlightsConfirmation
- **Reserve Car Rental Fail** – https://{api gateway url}?runType=failCarRentalReservation
- **Confirm Car Rental Fail** – https://{api gateway url}?runType=failCarRentalConfirmation
- **Process Payment Fail** – https://{api gateway url}?runType=failPayment
- **Pass a Trip ID** – https://{api gateway url}?tripID={by default, trip ID will be the AWS request ID}

AWS CDK script

The attached archive includes an AWS CDK script that you can use to create the entire sample travel reservation application.

DynamoDB tables

The attached code creates the following DynamoDB tables. These tables hold flight reservations, car rental reservations, and payment information.

```javascript
const flightTable = new dynamodb.Table(this,'Flights',{partitionKey:{name:'pk', type:dynamodb.AttributeType.STRING},sortKey:{name:'sk', type: dynamodb.AttributeType.STRING}})
```
const rentalTable = new dynamodb.Table(this, 'Rentals', {
  partitionKey: {name: 'pk', type: dynamodb.AttributeType.STRING},
  sortKey: {name: 'sk', type: dynamodb.AttributeType.STRING}
});

const paymentTable = new dynamodb.Table(this, 'Payments', {
  partitionKey: {name: 'pk', type: dynamodb.AttributeType.STRING},
  sortKey: {name: 'sk', type: dynamodb.AttributeType.STRING}
});

Flight Data Model:
var params = {
  TableName: process.env.TABLE_NAME,
  Item: {
    'pk': {S: event.trip_id},
    'sk': {S: flightReservationID},
    'trip_id': {S: event.trip_id},
    'id': {S: flightReservationID},
    'depart_city': {S: event.depart_city},
    'depart_time': {S: event.depart_time},
    'arrive_city': {S: event.arrive_city},
    'arrive_time': {S: event.arrive_time},
    'transaction_status': {S: 'pending'}
  }
};

Car Rental Data Model:
var params = {
  TableName: process.env.TABLE_NAME,
  Item: {
    'pk': {S: event.trip_id},
    'sk': {S: carRentalReservationID},
    'trip_id': {S: event.trip_id},
    'id': {S: carRentalReservationID},
    'rental': {S: event.rental},
    'rental_from': {S: event.rental_from},
    'rental_to': {S: event.rental_to},
    'transaction_status': {S: 'pending'}
  }
};

Payment Data Model:
var params = {
  TableName: process.env.TABLE_NAME,
  Item: {
    'pk': {S: event.trip_id},
    'sk': {S: paymentID},
    'trip_id': {S: event.trip_id},
    'id': {S: paymentID},
    'amount': {S: "750.00"}, // hard coded for simplicity as implementing any monetary
    'currency': {S: "USD"},
    'transaction_status': {S: "confirmed"}
  }
};

Lambda functions
The following functions will be created to support the state machine flow and execution in Step Functions:

- **Reserve Flights**: Inserts a record into the DynamoDB Flights table with a transaction_status of pending, to book a flight.
• **Confirm Flight**: Updates the record in the DynamoDB Flights table, to set transaction_status to confirmed, to confirm the flight.

• **Cancel Flights Reservation**: Deletes the record from the DynamoDB Flights table, to cancel the pending flight.

• **Reserve Car Rentals**: Inserts a record into the DynamoDB CarRentals table with a transaction_status of pending, to book a car rental.

• **Confirm Car Rentals**: Updates the record in the DynamoDB CarRentals table, to set transaction_status to confirmed, to confirm the car rental.

• **Cancel Car Rentals Reservation**: Deletes the record from the DynamoDB CarRentals table, to cancel the pending car rental.

• **Process Payment**: Inserts a record into the DynamoDB Payment table for the payment.

• **Cancel Payment**: Deletes the record from the DynamoDB Payments table for the payment.

```javascript
let fn = new lambda.Function(scope, id, {
  runtime: lambda.Runtime.NODEJS_16_X,
  code: lambda.Code.fromAsset('lambdas'),
  handler:handler,
  environment: {
    TABLE_NAME: table.tableName
  }
});
```

**Amazon SNS**

The sample application creates the following topic and subscription for sending SMS messages and notifying the customer about successful or failed reservations. If you want to receive text messages while testing the sample application, update the SMS subscription with your valid phone number in the stateMachine.ts file (in the second line of the following code):

```javascript
const topic = new sns.Topic(this, 'Topic');
topic.addSubscription(new subscriptions.SmsSubscription('+11111111111'));
const snsNotificationFailure = new tasks.SnsPublish(this, 'SendingSMSFailure', {
  topic:topic,
  integrationPattern: sfn.IntegrationPattern.REQUEST_RESPONSE,
  message: sfn.TaskInput.fromText('Your Travel Reservation Failed'),
});

const snsNotificationSuccess = new tasks.SnsPublish(this, ' SendingSMSSuccess', {
  topic:topic,
  integrationPattern: sfn.IntegrationPattern.REQUEST_RESPONSE,
  message: sfn.TaskInput.fromText('Your Travel Reservation is Successful'),
});
```

**Successful reservations**

The following flow illustrates a successful reservation with “ReserveFlight,” “ReserveCarRental,” and “ProcessPayment” followed by “ConfirmFlight” and “ConfirmCarRental.” The customer is notified about the successful booking through SMS messages that are sent to the subscriber of the SNS topic.
Failed reservations

This flow is an example of failure in the saga pattern. If, after booking flights and car rentals, “ProcessPayment” fails, steps are canceled in reverse order. The reservations are released, and the customer is notified of the failure through SMS messages that are sent to the subscriber of the SNS topic.
Integrate Stonebranch Universal Controller with AWS Mainframe Modernization

Created by Vaidy Sankaran (AWS), Robert Lemieux (Stonebranch), Huseyin Gomleksizoglu (Stonebranch), and Pablo Alonso Prieto (AWS)
Summary

This pattern explains how to integrate Stonebranch Universal Automation Center (UAC) workload orchestration with Amazon Web Services (AWS) Mainframe Modernization service. AWS Mainframe Modernization service migrates and modernizes mainframe applications to the AWS Cloud. It offers two patterns: AWS Mainframe Modernization Replatform with Micro Focus Enterprise Technology and AWS Mainframe Modernization Automated Refactor with AWS Blu Age.

Stonebranch UAC is a real-time IT automation and orchestration platform. UAC is designed to automate and orchestrate jobs, activities, and workflows across hybrid IT systems, from on-premises to AWS. Enterprise clients using mainframe systems are transitioning to cloud-centric modernized infrastructures and applications. Stonebranch’s tools and professional services facilitate the migration of existing schedulers and automation capabilities to the AWS Cloud.

When you migrate or modernize your mainframe programs to the AWS Cloud using AWS Mainframe Modernization service, you can use this integration to automate batch scheduling, increase agility, improve maintenance, and decrease costs.

This pattern provides instructions for integrating Stonebranch scheduler with mainframe applications migrated to the AWS Mainframe Modernization service Micro Focus Enterprise runtime. This pattern is for solutions architects, developers, consultants, migration specialists, and others working in migrations, modernizations, operations, or DevOps.

Targeted outcome

This pattern focuses on providing the following target outcomes:

- The ability to schedule, automate, and run mainframe batch jobs running in AWS Mainframe Modernization service (Microfocus runtime) from Stonebranch Universal Controller.
- Monitor the application’s batch processes from the Stonebranch Universal Controller.
- Start/Restart/Rerun/Stop batch processes automatically or manually from the Stonebranch Universal Controller.
- Retrieve the results of the AWS Mainframe Modernization batch processes.
- Capture the AWS CloudWatch logs of the batch jobs in Stonebranch Universal Controller.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Micro Focus Bankdemo application with Job Control Language (JCL) files, and a batch process deployed in a AWS Mainframe Modernization service (Micro Focus runtime) environment
• Basic knowledge of how to build and deploy a mainframe application that runs on Micro Focus Enterprise Server
• Basic knowledge of Stonebranch Universal Controller
• Stonebranch trial license (contact Stonebranch)
• Windows or Linux Amazon Elastic Compute Cloud (Amazon EC2) instances (for example, xlarge) with a minimum of four cores, 8 GB memory, and 2 GB disk space
• Apache Tomcat version 8.5.x or 9.0.x
• Oracle Java Runtime Environment (JRE) or OpenJDK version 8 or 11
• Amazon Aurora MySQL–Compatible Edition
• Amazon Simple Storage Service (Amazon S3) bucket for export repository
• Amazon Elastic File System (Amazon EFS) for agent Stonebranch Universal Message Service (OMS) connections for high availability (HA)
• Stonebranch Universal Controller 7.2 Universal Agent 7.2 Installation Files
• AWS Mainframe Modernization task scheduling template (latest released version of the .zip file)

Limitations
• The product and solution has been tested and compatibility validated only with OpenJDK 8 and 11.
• The aws-mainframe-modernization-stonebranch-integration task scheduling template will work only with AWS Mainframe Modernization service.
• This task scheduling template will work on only a Unix, Linux, or Windows edition of Stonebranch agents.

Architecture

Target state architecture

The following diagram shows the example AWS environment that is required for this pilot.

1. Stonebranch Universal Automation Center (UAC) includes two main components: Universal Controller and Universal Agents. Stonebranch OMS is used as a message bus between the controller and individual agents.
2. Stonebranch UAC Database is used by Universal Controller. The database can be MySQL, Microsoft SQL Server, Oracle, or Aurora MySQL–Compatible.
3. **AWS Mainframe Modernization service** – Micro Focus runtime environment with the BankDemo application deployed. The BankDemo application files will be stored in an S3 bucket. This bucket also contains the mainframe JCL files.

4. Stonebranch UAC can run the following functions for the batch run:
   a. Start a batch job using the JCL file name that exists in the S3 bucket linked to the AWS mainframe modernization service.
   b. Get the status of the batch job run.
   c. Wait until the batch job run is completed.
   d. Fetch logs of the batch job run.
   e. Rerun the failed batch jobs.
   f. Cancel the batch job while the job is running.

5. Stonebranch UAC can run the following functions for the application:
   a. Start Application
   b. Get Status of the Application
   c. Wait until the Application is started or stopped
   d. Stop Application
   e. Fetch Logs of Application operation

### Stonebranch jobs conversion

The following diagram represents Stonebranch’s job conversion process during the modernization journey. It describes how the job schedules and tasks definitions are converted into a compatible format that can run AWS Mainframe Modernization batch tasks.

1. For the conversion process, the job definitions are exported from the existing mainframe system.
2. JCL files can be uploaded to the S3 bucket for the Mainframe Modernization application so that these JCL files can be deployed by the AWS Mainframe Modernization service.
3. The conversion tool converts the exported job definitions to UAC tasks.
4. After all the task definitions and job schedules are created, these objects will be imported to the Universal Controller. The converted tasks then run the processes in the AWS Mainframe Modernization service instead of running them on the mainframe.
Stonebranch UAC architecture

The following architecture diagram represents an active-active-passive model of high availability (HA) Universal Controller. Stonebranch UAC is deployed in multiple Availability Zones to provide high availability and support disaster recovery (DR).

Universal Controller

Two Linux servers are provisioned as Universal Controllers. Both connect to the same database endpoint. Each server houses a Universal Controller application and OMS. The most recent version of Universal Controller is used at the time it is provisioned.

The Universal Controllers are deployed in the Tomcat webapp as the document ROOT and are served on port 80. This deployment eases the configuration of the frontend load balancer.

HTTP over TLS or HTTPS is enabled using the Stonebranch wildcard certificate (for example, https://customer.stonebranch.cloud). This secures communication between the browser and the application.

OMS

A Universal Agent and OMS (Opswise Message Service) reside on each Universal Controller server. All deployed Universal Agents from the customer end are set up to connect to both OMS services. OMS acts as a common messaging service between the Universal Agents and the Universal Controller.

Amazon EFS mounts a spool directory on each server. OMS uses this shared spool directory to keep the connection and task information from controllers and agents. OMS works in a high-availability mode. If the active OMS goes down, the passive OMS has access to all the data, and it resumes active operations automatically. Universal Agents detect this change and automatically connect to the new active OMS.

Database

Amazon Relational Database Service (Amazon RDS) houses the UAC database, with Amazon Aurora MySQL-Compatible as its engine. Amazon RDS is helps in managing and offering scheduled backups at regular intervals. Both Universal Controller instances connect to the same database endpoint.
**Load balancer**

An Application Load Balancer is set-up for each instance. The load balancer directs traffic to the active controller at any given moment. Your instance domain names point to the respective load balancer endpoints.

**URLs**

Each of your instances has a URL, as shown in the following example.

<table>
<thead>
<tr>
<th>Environment</th>
<th>Instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Production</td>
<td>customer.stonebranch.cloud</td>
</tr>
<tr>
<td>Development (non-production)</td>
<td>customerdev.stonebranch.cloud</td>
</tr>
<tr>
<td>Testing (non-production)</td>
<td>customertest.stonebranch.cloud</td>
</tr>
</tbody>
</table>

**Note:** Non-production instance names can be set based on your needs.

**High availability**

High availability (HA) is the ability of a system to operate continuously without failure for a designated period of time. Such failures include, but are not limited to, storage, server communication response delays caused by CPU or memory issues, and networking connectivity.

To meet HA requirements:

- All EC2 instances, databases, and other configurations are mirrored across two separate Availability Zones within the same AWS Region.
- The controller is provisioned through an Amazon Machine Image (AMI) on two Linux servers in the two Availability Zones. For example, if you are provisioned in the Europe eu-west-1 Region, you have a Universal Controller in Availability Zone eu-west-1a and Availability Zone eu-west-1c.
- No jobs are allowed to run directly on the application servers and no data is allowed to be stored on these servers.
- The Application Load Balancer runs health checks on each Universal Controller to identify the active one and direct traffic to it. In the event that one server incurs issues, the load balancer automatically promotes the passive Universal Controller to an active state. The load balancer then identifies the new active Universal Controller instance from the health checks and starts directing traffic. The failover happens within four minutes with no job loss, and the frontend URL remains the same.
- The Aurora MySQL–Compatible database service stores Universal Controller data. For production environments, a database cluster is built with two database instances in two different Availability Zones within a single AWS Region. Both Universal Controllers use a Java Database Connectivity (JDBC) interface that points to a single database cluster endpoint. In the event that one database instance incurs issues, the database cluster endpoint dynamically points to the healthy instance. No manual intervention is required.

**Backup and purge**

Stonebranch Universal Controller is set to back up and purge old data following the schedule shown in the table.

<table>
<thead>
<tr>
<th>Type</th>
<th>Schedule</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activity</td>
<td>7 days</td>
</tr>
</tbody>
</table>

1820
Backup data older than the dates shown is exported to .xml format and stored in the file system. After the backup process is complete, older data is purged from the database and archived in an S3 bucket for up to one year for production instances.

You can adjust this schedule in your Universal Controller interface. However, increasing these time-frames might cause a longer downtime during maintenance.

**Tools**

**AWS services**

- **AWS Mainframe Modernization** is an AWS cloud-native platform that helps you modernize your mainframe applications to AWS managed runtime environments. It provides tools and resources to help you plan and implement migration and modernization.
- **Amazon Elastic Block Store (Amazon EBS)** provides block-level storage volumes for use with Amazon EC2 instances.
- **Amazon Elastic File System (Amazon EFS)** helps you create and configure shared file systems in the AWS Cloud.
- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon Aurora MySQL–Compatible Edition.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **Elastic Load Balancing (ELB)** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon EC2 instances, containers, and IP addresses in one or more Availability Zones. This pattern uses an Application Load Balancer.

**Stonebranch**

- **Universal Automation Center (UAC)** is a system of enterprise workload automation products. This pattern uses the following UAC components:
  - **Universal Controller**, a Java web application running in a Tomcat web container, is the enterprise job scheduler and workload automation broker solution of Universal Automation Center. The Controller presents a user interface for creating, monitoring, and configuring Controller information; handles the scheduling logic; processes all messages to and from Universal Agents; and synchronizes much of the high availability operation of Universal Automation Center.
  - **Universal Agent** is a vendor-independent scheduling agent that collaborates with existing job scheduler on all major computing platforms, both legacy and distributed. All schedulers that run on z/Series, i/Series, Unix, Linux, or Windows are supported.
  - **Stonebranch aws-mainframe-modernization-stonebranch-integration** AWS Mainframe Modernization Universal Extension is the integration template to run, monitor and rerun batch jobs in AWS Mainframe Modernization platform.

**Code**

The code for this pattern is available in the [aws-mainframe-modernization-stonebranch-integration](https://github.com/aws-amazon-oss-mainframe-modernization-stonebranch-integration) GitHub repository.
## Epics

Install Universal Controller and Universal Agent on Amazon EC2

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download the installation files.</td>
<td>Download the installation from Stonebranch servers. To get the installation files, contact with Stonebranch.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Launch the EC2 instance.</td>
<td>You will need about 3 GB of extra space for the Universal Controller and Universal Agent installations. So provide at least 30 GB of disk space for the instance. Add port 8080 to the security group so that it's accessible.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Check prerequisites.</td>
<td>Before the installation, do the following:</td>
<td>Cloud administrator, Linux administrator</td>
</tr>
<tr>
<td></td>
<td>1. Install Java as described in Downloading Java Runtime Environment.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$ sudo yum -y update</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$ sudo yum install</td>
<td></td>
</tr>
<tr>
<td></td>
<td>java-11-amazon-corretto</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Be sure to use one of the supported JAVA versions. The previous command should install java-11. Check the Java version and be sure you are using version 11 before continuing.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. As described in Installing Apache Tomcat document, run the following commands.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$ sudo yum install tomcat</td>
<td></td>
</tr>
<tr>
<td></td>
<td>tomcat-admin-webapps</td>
<td></td>
</tr>
<tr>
<td></td>

<td>-----------------------------------------------</td>
</tr>
</tbody>
</table>
| Install Universal Controller. | 1. Upload the universal-controller-7.2.0.0.tar installation file to the EC2 instance.  
2. Unarchive the installation files to a temp folder.  
   $ tar -xvf universal-controller-7.2.0.0.tar  
3. Give the installation script run permission.  
   $ chmod a+x install-controller.sh  
4. Install the controller. This example uses the following command to install Universal Controller under `/usr/share/tomcat`. Use the Amazon Aurora database that you created in the previous steps.  
   The last line of the output of the script should be “Installation complete.”  
5. Navigate to the following URL in the EC2 instance.  
   http://<public_ip>:8080/uc  
6. On the login screen, enter **ops.admin** in the **Username** section, and keep the **Password** field empty.  
7. Set a new password for the **ops.admin** user. | Cloud architect, Linux administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Install Universal Agent. | 1. Upload the sb-7.2.0.1-linux-3.10-x86_64.tar.Z installation file to the EC2 instance.  
2. Log in to the EC2 instance.  
3. Unarchive the Universal Agent installation package.  
\> $ zcat sb-7.2.0.1-linux-3.10-x86_64.tar.Z | tar xvf -  
4. Run the following command.  
\> $ sudo ./unvinst --oms_servers 7878@localhost --oms_autostart yes --python yes  
5. Create a PAM file.  
\> $ cp /etc/pam.d/login /etc/pam.d/ucmd  
6. Enable Autostart for Universal Agent.  
\> $ /sbin/restorecon -v /etc/rc.d/init.d/ubrokerd | Cloud administrator, Linux administrator |
| Add OMS to Universal Controller. | 1. Log in to Universal Controller with the ops.admin user.  
2. Choose the Services menu at the top left corner of the screen, and then choose the OMS Servers menu in the System.  
3. In the OMS Server Address field, type localhost, and then save.  
4. You will see the status of the OMS server as Connected and the Session Status as Operational. | Universal Controller administrator |

**Import AWS Mainframe Modernization Universal Extension and create a task**

</tbody>
</table>
| Enable resolvable credentials. | 1. Navigate to **Services, AWS Mainframe Modernization Tasks**.  
2. On the right panel, fill in the required fields:  
  - **Name**: New Mainframe Modernization Task  
  - **Agent**: Select the only agent (AGNT0001).  

Under **AWS Mainframe Modernization Details**:  
  - **Action**: List Environments  
  - **AWS Credentials**: If you have an AWS Identity and Access Management (IAM) role added to the EC2 instance, you can keep this field empty. If you will use AWSAccessKeyId and AWSSecretKey, choose the icon ( ) next to the field.  

In the **Credential Details** window that opens, enter the following information and then save.  
  - **Name**: AWS Mainframe Modernization Credentials  
  - **Runtime User**: Write the AWS access key ID in this field.  
  - **Runtime Password**: Write the AWS secret key in this field.  
  - **End Point**: Be sure that the endpoint has the correct AWS Region. The default is **https://m2.us-east-1.amazonaws.com**.  
  - **Region**: Enter the Region of the AWS Mainframe Modernization service. The default is **us-east-1**.  
3. Keep the default values in the rest of the fields, and save the task. | Universal Controller administrator |
Launch the task.

1. At the top of the right panel, choose **Launch Task**.
2. In the **Confirm** window, choose **Launch**. After that, the Universal Controller Console will display a message similar to the following message.

   2022-08-24 10:11:49 AM

   Successfully launched the Universal task "New Mainframe Modernization Task" with task instance sys_id 1661291493634146313NC8E3BDBB80ZJY.

3. Navigate to the **Instances** If you don’t see the **Instances** tab, choose the right arrow to scroll right.

4. Open the context (right-click) menu for the task instance in the list, choose **Retrieve Output**, and then choose **Submit** in the **Retrieve Output**

5. In the **Retrieve Output** window, you will see the list of environments in STDOUT.

</table>
| Fix the failed task and rerun. | 1. Open (double-click) the failed task to see the error for the task.  
2. You have two options for fixing the failed task.  
   • Fix the JCL file name, and set it to `FOOBAR.jcl`.  
   • Add the correct JCL file name to the **JCL File Name (Temp)**. This field will overwrite the **JCL File Name** field.  
   For this pilot, choose the second option, and save the task instance.  
3. In the **Workflow Monitor**, open the context (right-click) menu for the failed task, and choose **Commands, Re-run**.  
4. After that, all the tasks will complete successfully. | **Universal Controller administrator** |
## Create Start Application and Stop Application tasks

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the Start Application action.      | 1. Navigate to **Services, AWS Mainframe Modernization Tasks**.  
2. On the right panel, fill in the required fields.  
  • **Name**: Mainframe Modernization Start Application  
  • **Agent**: Select the only agent (AGNT0001)  
Under **AWS Mainframe Modernization Details**:  
  • **Action**: Start Application  
  • **AWS Credentials**: If you have an IAM role added to the EC2 instance, you can keep this field empty. If you will use AWSAccessKeyId and AWSSecretKey, select the credential that you created before.  
  • **End Point**: Be sure that the endpoint has the correct Region. The default is **https://m2.us-east-1.amazonaws.com**.  
  • **Region**: Enter the Region of the AWS Mainframe Modernization service. The default is **us-east-1**.  
  • **Application**: Choose the icon next to the field (), and choose Submit in the **Refresh Application Choices**. This will connect to the AWS Mainframe Modernization service and return the list of applications. Now you can select the application from the dropdown list. Select the application you want to run the batch job.  
  • **Wait for Success or Failure**: If this option is selected, the task will wait until the status of the batch job is success or failure. | Universal Controller administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Polling Interval</td>
<td>This is the amount of time between each polling.</td>
<td></td>
</tr>
<tr>
<td>Fetch Execution Logs</td>
<td>If selected, logs will be fetched automatically when the batch job has completed.</td>
<td></td>
</tr>
<tr>
<td>Log Format</td>
<td>This is the format of the logs to be printed out. It can be Text or JSON format.</td>
<td></td>
</tr>
</tbody>
</table>

3. Keep the default values in the rest of the fields, and save the task.
4. Now copy this task and create a task for Stop Application. Change the name to **Mainframe Modernization Stop Application**, and change the action to **Stop Application**.

### Create a Cancel Batch Execution task

1. Navigate to **Services, AWS Mainframe Modernization Tasks**.
2. On the right panel, fill in the required fields.
   - **Name**: Mainframe Modernization Cancel Batch Execution
   - **Agent**: Select the only agent (AGNT0001)

Under **AWS Mainframe Modernization Details**:
- **Action**: Cancel Batch Execution
- **AWS Credentials**: If you have an IAM role added to the EC2 instance, you can keep this field empty. If you will use AWSAccessKeyId and AWSSecretKey, select the credential that you created before.
### Task Description

Manage on-premises container applications by setting up Amazon ECS Anywhere with the AWS CDK

Created by Rahul Gaikwad (AWS)

<table>

Summary

Amazon ECS Anywhere is an extension of the Amazon Elastic Container Service (Amazon ECS). You can use ECS Anywhere to deploy native Amazon ECS tasks in an on-premises or customer-managed environment. This feature helps reduce costs and mitigate complex local container orchestration and operations. You can use ECS Anywhere to deploy and run container applications in both on-premises and cloud environments. It removes the need for your team to learn multiple domains and skill sets, or to manage complex software on their own.

This pattern demonstrates the steps to set up ECS Anywhere by using AWS Cloud Development Kit (AWS CDK) stacks.
Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. (See Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.)
- AWS CDK Toolkit, installed and configured. (See AWS CDK Toolkit in the AWS CDK documentation, and follow the instructions to install the latest version globally.)
- Node package manager (npm), installed and configured for the AWS CDK in TypeScript. (See Downloading and installing Node.js and npm in the npm documentation.)

Limitations

- For limitations and considerations, see External instances (Amazon ECS Anywhere) in the Amazon ECS documentation.

Product versions

- AWS CDK Toolkit version 1.116.0 or later
- npm version 7.20.3 or later
- Node.js version 16.6.1 or later

Architecture

Target technology stack

- AWS CloudFormation
- AWS CDK
- Amazon ECS Anywhere
- AWS Identity and Access Management (IAM)

Target architecture

The following diagram illustrates a high-level system architecture of ECS Anywhere setup using the AWS CDK with TypeScript, as implemented by this pattern.

1. When you deploy the AWS CDK stack, it creates a CloudFormation stack on AWS.
2. The CloudFormation stack provisions an Amazon ECS cluster and related AWS resources.
3. To register an external instance with an Amazon ECS cluster, you must install AWS Systems Manager Agent (SSM Agent) on your virtual machine (VM) and register the VM as an AWS Systems Manager managed instance.
4. You must also install the Amazon ECS container agent and Docker on your VM to register it as an external instance with the Amazon ECS cluster.
5. When the external instance is registered and configured with the Amazon ECS cluster, it can run multiple containers on your VM, which is registered as an external instance.
Tools

- **AWS CDK** – The AWS Cloud Development Kit (AWS CDK) helps you define your cloud infrastructure as code in one of five supported programming languages: TypeScript, JavaScript, Python, Java, and C#.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is a unified tool that provides a consistent command-line interface for interacting with AWS services and resources.

Code

The source code for this pattern is available on GitHub, in the **ECS Anywhere CDK Samples** repository. To clone and use the repository, follow the instructions in the next section.

Modernize ASP.NET Web Forms applications on AWS

*Created by Vijai Anand Ramalingam (AWS) and Sreelaxmi Pai (AWS)*

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Technologies: Modernization; Containers &amp; microservices; Web hosting; Websites &amp; web apps; Software development &amp; testing</th>
<th>Workload: Microsoft</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: Amazon CloudWatch; Amazon ECS; AWS Systems Manager</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes the steps for modernizing a legacy, monolith ASP.NET Web Forms application by porting it to ASP.NET Core on Amazon Web Services (AWS).

Porting ASP.NET Web Forms applications to ASP.NET Core helps you take advantage of the performance, cost savings, and robust ecosystem of Linux. However, it can be a significant manual effort. In this pattern, the legacy application is modernized incrementally by using a phased approach, and then containerized in the AWS Cloud.

Consider a legacy, monolith application for a shopping cart. Let’s assume that it was created as an ASP.NET Web Forms application and consists of .aspx pages with a code-behind (.aspx.cs) file. The modernization process consists of these steps:
1. Break the monolith into microservices by using the appropriate decomposition patterns. For more information, see the guide Decomposing monoliths into microservices on the AWS Prescriptive Guidance website.

2. Port your legacy ASP.NET Web Forms (.NET Framework) application to ASP.NET Core in .NET 5 or later. In this pattern, you use Porting Assistant for .NET to scan your ASP.NET Web Forms application and identify incompatibilities with ASP.NET Core. This reduces the manual porting effort.

3. Redevelop the Web Forms UI layer by using React. This pattern doesn’t cover UI redevelopment. For instructions, see Create a New React App in the React documentation.

4. Redevelop the Web Forms code-behind file (business interface) as an ASP.NET Core web API. This pattern uses NDepend reports to help identify required files and dependencies.

5. Upgrade shared/common projects, such as Business Logic and Data Access, in your legacy application to .NET 5 or later by using Porting Assistant for .NET.

6. Add AWS services to complement your application. For example, you can use Amazon CloudWatch Logs to monitor, store, and access your application’s logs, and AWS Systems Manager to store your application settings.

7. Containerize the modernized ASP.NET Core application. This pattern creates a Docker file that targets Linux in Visual Studio and uses Docker Desktop to test it locally. This step assumes that your legacy application is already running on an on-premises or Amazon Elastic Compute Cloud (Amazon EC2) Windows instance. For more information, see the pattern Run an ASP.NET Core web API Docker container on an Amazon EC2 Linux instance.

8. Deploy the modernized ASP.NET core application to Amazon Elastic Container Service (Amazon ECS). This pattern doesn’t cover the deployment step. For instructions, see the Amazon ECS Workshop.

Note  This pattern doesn’t cover UI development, database modernization, or container deployment steps.

## Prerequisites and limitations

### Prerequisites

- **Visual Studio** or **Visual Studio Code**, downloaded and installed.
- Access to an AWS account using the AWS Management Console and the AWS Command Line Interface (AWS CLI) version 2. (See the instructions for configuring the AWS CLI.)
- The AWS Toolkit for Visual Studio (see setup instructions).
- Docker Desktop, downloaded and installed.
- .NET SDK, downloaded and installed.
- NDepend tool, downloaded and installed. To install the NDepend extension for Visual Studio, run NDepend.VisualStudioExtension.Installer (see instructions). You can select Visual Studio 2019 or 2022, depending on your requirements.
- Porting Assistant for .NET, downloaded and installed.

### Architecture

**Modernizing the shopping cart application**

The following diagram illustrates the modernization process for a legacy ASP.NET shopping cart application.
Target architecture

The following diagram illustrates the architecture of the modernized shopping cart application on AWS. ASP.NET Core web APIs are deployed to an Amazon ECS cluster. Logging and configuration services are provided by Amazon CloudWatch Logs and AWS Systems Manager.
AWS services

• **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of EC2 instances that you manage.

• **Amazon CloudWatch Logs** – Amazon CloudWatch Logs centralizes the logs from all your systems, applications, and AWS services that you use. You can view and monitor the logs, search them for specific error codes or patterns, filter them based on specific fields, or archive them securely for future analysis.

• **AWS Systems Manager** – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting (or taking corrective action) on any policy violations it detects.

Tools

• **Visual Studio** or **Visual Studio Code** – Tools for building .NET applications, web APIs, and other programs.

• **AWS Toolkit for Visual Studio** – An extension for Visual Studio that helps develop, debug, and deploy .NET applications that use AWS services.

• **Docker Desktop** – A tool that simplifies building and deploying containerized applications.

• **NDepend** – An analyzer that monitors .NET code for dependencies, quality issues, and code changes.
• Porting Assistant for .NET – An analysis tool that scans .NET code to identify incompatibilities with .NET Core and to estimate the migration effort.

## Epics

### Port your legacy application to .NET 5 or later version

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upgrade your .NET Framework legacy application to .NET 5.</td>
<td>You can use Porting Assistant for .NET to convert your legacy ASP.NET Web Forms application to .NET 5 or later. Follow the instructions in the Porting Assistant for .NET documentation.</td>
<td>App developer</td>
</tr>
</tbody>
</table>
| Generate NDepend reports. | When you modernize your ASP.NET Web Forms application by decomposing it into microservices, you might not need all the .cs files from the legacy application. You can use NDepend to generate a report for any code-behind (.cs) file, to get all the callers and callees. This report helps you identify and use only the required files in your microservices. After you install NDepend (see the Prerequisites (p. 1846) section), open the solution (.sln file) for your legacy application in Visual Studio and follow these steps:  
   1. Build the legacy application in Visual Studio.  
   2. On the Visual Studio menu bar, choose NDepend, Attach new NDepend project to current VS solution.  
   3. Choose Analyze .NET assemblies.  
   4. When analysis is complete, navigate to the project in Solution Explorer. Right-click any code-behind file (for example, listproducts.aspx.cs) that you want to generate the report for, and then choose Show on Dependency Graph. | App developer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>

</tr>
<tr>
<td>6.</td>
<td>In the <strong>Queries and Rules Edit pane</strong>, choose the download arrow, and then choose <strong>Export to Excel</strong>.</td>
<td>Task</td>
</tr>
<tr>
<td></td>
<td>This process generates a report for the code-behind file that lists all callers and callees. For more information about the dependency graph, see the <strong>NDepend documentation</strong>.</td>
<td>Task</td>
</tr>
<tr>
<td>Create a new .NET 5 solution.</td>
<td>To create a new .NET 5 (or later) structure for your modernized ASP.NET Core web APIs:</td>
<td>App developer</td>
</tr>
<tr>
<td></td>
<td>1. Open Visual Studio.</td>
<td>Task</td>
</tr>
<tr>
<td></td>
<td>2. Create a new, blank solution.</td>
<td>Task</td>
</tr>
<tr>
<td></td>
<td>3. Create new projects that target .NET 5 (or later), based on your legacy application. For examples of legacy and new projects for a shopping cart application, see the <strong>Additional information (p. 1854)</strong> section.</td>
<td>Task</td>
</tr>
<tr>
<td></td>
<td>4. Use the NDepend report from the previous step to identify all required files. Copy these files from the application you upgraded earlier and add them to the new solution.</td>
<td>Task</td>
</tr>
<tr>
<td></td>
<td>5. Build the solution and fix all issues.</td>
<td>Task</td>
</tr>
<tr>
<td></td>
<td>For more information about creating projects and solutions, see the <strong>Visual Studio documentation</strong>.</td>
<td>Task</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong> As you build the solution and verify functionality, you might identify several additional files to be added to the solution, in addition to the files that NDepend identified.</td>
<td>Task</td>
</tr>
</tbody>
</table>
### Update your application code

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Implement web APIs with ASP.NET Core. | Let’s assume that one of the microservices that you identified in your legacy monolith shopping cart application is *Products*. You created a new ASP.NET Core web API project for *Products* in the previous epic. In this step, you identify and modernize all the web forms (.aspx pages) that are related to *Products*. Let’s assume that *Products* consists of four web forms, as illustrated earlier in the *Architecture* (p. 1846) section:  
  - List Products  
  - View Product  
  - Add/Edit Product  
  - Delete Product  

  You should analyze each web form, identify all the requests that are sent to the database to perform some logic, and get responses. You can implement each request as a web API endpoint. Given its web forms, *Products* can have the following possible endpoints:  
  - /api/products  
  - /api/products/{id}  
  - /api/products/add  
  - /api/products/update/{id}  
  - /api/products/delete/{id}  

  As mentioned previously, you can also reuse all the other projects that you upgraded to .NET 5, including Business Logic, Data Access, and shared/common projects. | App developer |
| Configure Amazon CloudWatch Logs. | You can use [Amazon CloudWatch Logs](https://aws.amazon.com/cloudwatch/logs/) to monitor, store, and access your application’s logs. You can log | App developer |
### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>data into Amazon CloudWatch Logs by using an AWS SDK. You can also integrate .NET applications with CloudWatch Logs by using popular .NET logging frameworks such as NLog, Log4Net, and ASP.NET Core logging framework.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>For more information about this step, see the blog post Amazon CloudWatch Logs and .NET Logging Frameworks.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Configure AWS Systems Manager Parameter Store.</td>
<td>You can use AWS Systems Manager Parameter Store to store application settings such as connection strings separately from your application's code. The NuGet package Amazon.Extensions.Configuration.SystemsManager simplifies how your application loads these settings from the AWS Systems Manager Parameter Store into the .NET Core configuration system.</td>
<td>App developer</td>
</tr>
<tr>
<td>For more information about this step, see the blog post .NET Core configuration provider for AWS Systems Manager.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Add authentication and authorization

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use a shared cookie for authentication.</td>
<td>Modernizing a legacy monolith application is an iterative process and requires the monolith and its modernized version to co-exist. You can use a shared cookie to achieve seamless authentication between the two versions. The legacy ASP.NET application continues to validate user credentials and issues the cookie while the modernized ASP.NET Core application validates the cookie.</td>
<td>App developer</td>
</tr>
<tr>
<td>For instructions and sample code, see the sample GitHub project.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Build and run the container locally

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a Docker image by using Visual Studio. | In this step, you create a Docker file by using the Visual Studio for .NET Core web API.  
2. In Solution Explorer, from the context (right-click) menu of your project, choose Add, **Docker Support**.  
3. Select **Linux** as the target operating system.  
Visual Studio creates a Docker file for your project. For a sample Docker file, see [Visual Studio Container Tools for Docker](https://docs.microsoft.com/en-us/visualstudio/container-tools) on the Microsoft website. | App developer |
| Build and run the container by using Docker Desktop. | Now you can build, create and run the container in Docker Desktop.  
1. Open a Command Prompt window. Navigate to the solution folder where the Docker file is located. Run the following command to create the Docker image:  
```bash  
docker build -t aspnetcorewebapiimage -f Dockerfile .  
```
2. Run the following command to view all Docker images:  
```bash  
docker images  
```
3. Run the following command to create and run a container:  
```bash  
docker run -d -p 8080:80 --name aspnetcorewebapicontainer aspnetcorewebapiimage  
```
4. Open Docker Desktop, and then choose **Containers/ Apps**. You can see a new container named aspnetcorewebapicontainer running. | App developer |

Modernize mainframe online printing workloads on AWS by using Micro Focus Enterprise Server and LRS VPSX/MFI
Summary

This pattern shows you how to modernize your business-critical mainframe online printing workloads on the Amazon Web Services (AWS) Cloud by using Micro Focus Enterprise Server as a runtime for a modernized mainframe application and LRS VPSX/MFI (Micro Focus Interface) as a print server. The pattern is based on the replatform mainframe modernization approach. In this approach, you migrate your mainframe online application to Amazon Elastic Compute Cloud (Amazon EC2) and migrate your mainframe database, such as IBM DB2 for z/OS, to Amazon Relational Database Service (Amazon RDS). The authentication and authorization for the modernized print workflow is performed by AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD. The LRS Directory Information Server (LRS/DIS) is integrated with AWS Managed Microsoft AD for print workflow authentication and authorization. By modernizing your online printing workloads, you can reduce IT infrastructure costs, mitigate the technical debt of maintaining legacy systems, remove data silos, increase agility and efficiency with a DevOps model, and take advantage of on-demand resources and automation in the AWS Cloud.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A mainframe online printing or output management workload
- Basic knowledge of how to rebuild and deliver a mainframe application that runs on Micro Focus Enterprise Server (For more information, see the Enterprise Server data sheet in the Micro Focus documentation.)
- Basic knowledge of LRS cloud printing solutions and concepts (For more information, see Output Modernization in the LRS documentation.)
- Micro Focus Enterprise Server software and license (For more information, contact Micro Focus sales.)
- LRS VPSX/MFI, LRS/Queue, and LRS/DIS software and licenses (For more information, contact LRS sales.)

Note: For more information about configuration considerations for mainframe online printing workloads, see Considerations in the Additional information section of this pattern.

Product versions

- Micro Focus Enterprise Server 6.0 (product update 7)
- LRS VPSX/MFI V1R3 or later
# Architecture

## Source technology stack

- Operating system – IBM z/OS
- Programming language – Common Business-Oriented Language (COBOL) and Customer Information Control System (CICS)
- Database – IBM DB2 for z/OS IBM Information Management System (IMS) and Virtual Storage Access Method (VSAM)
- Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
- Printing and output management – IBM mainframe z/OS printing products (IBM Infoprint Server for z/OS, LRS, and CA View)

## Target technology stack

- Operating system – Microsoft Windows Server running on Amazon EC2
- Compute – Amazon EC2
- Programming language – COBOL and CICS
- Database – Amazon RDS
- Security – AWS Managed Microsoft AD
- Printing and output management – LRS printing solution on AWS
- Mainframe runtime environment – Micro Focus Enterprise Server

## Source architecture

The following diagram shows a typical current state architecture for a mainframe online printing workload:

![Diagram](image)

The diagram shows the following workflow:
1. Users perform business transactions on a system of engagement (SoE) that’s built on an IBM CICS application written in COBOL.
2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM DB2 for z/OS.
3. The SoR persists the business data from the SoE.
4. A user initiates a request to generate print output from the CICS SoE, which initiates a print transaction application to process the print request.
5. The print transaction application (such as a CICS and COBOL program) extracts data from the database, formats the data according to business requirements, and generates business output (print data) such as billing statements, ID cards, or loan statements. Then, the application sends a print request by using Virtual Telecommunications Access Method (VTAM). A z/OS print server (such as IBM Infoprint Server) uses NetSpool or a similar VTAM component to intercept the print requests, and then creates print output datasets on the JES spool by using JES output parameters. The JES output parameters specify routing information that the print server uses to transmit the output to a particular network printer. The term VTAM refers to the z/OS Communications Server and the System Network Architecture (SNA) services element of z/OS.
6. The printing output transmission component transmits the output print datasets from the JES spool to remote printers or print servers, such as LRS (as demonstrated in this pattern), IBM Infoprint Server, or email destinations.

**Target architecture**

The following diagram shows an architecture for a mainframe online printing workload that’s deployed in the AWS Cloud:

![Diagram of mainframe online printing workload](image)

The diagram shows the following workflow:

1. A user initiates a print request from an online (CICS) user-interface to create print output, such as billing statements, ID cards, or loan statements.
2. The mainframe online application (replatted to Amazon EC2) uses the Micro Focus Enterprise Server runtime to extract data from the application database, apply business logic to the data,
format the data, and then send the data to a print destination by using Micro Focus CICS Print Exit (DFHUPRNT).

3. The application database (an SoR that runs on Amazon RDS) persists data for print output.

4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2, and its operational data is stored in Amazon Elastic Block Store (Amazon EBS). LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect print data through the Micro Focus CICS Print Exit API (DFHUPRNT) and deliver the data to a specified printer destination. The original TERMD (TERM) that's used in the modernized CICS application is used as the VPSX/MFI Queue name.

**Note:** The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM Advanced Function Presentation (AFP) or Xerox Line Condition Data Stream (LCDS). For more information about using Micro Focus for mainframe application migration and modernization on AWS, see Empowering Enterprise Mainframe Workloads on AWS with Micro Focus in the AWS documentation.

**AWS infrastructure architecture**

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe online printing workload:

The diagram shows the following workflow:

1. The mainframe online application (written on a programming language such as CICS or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The online application is deployed on Amazon EC2 across two Availability Zones (AZ) for high availability (HA) and uses Micro Focus CICS Print Exit to route print output to LRS VPSX/MFI for end-user printing.

2. LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data from the Micro Focus online Print Exit programming interface. Online Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the print file and dynamically build LRS/Queue commands. **Note:** For more information on various CICS application programing methods for print and how they are supported in Micro Focus Enterprise server and LRS VPSX/MFI, see Print data capture in the Additional information section of this pattern.
3. A **Network Load Balancer** provides a DNS name to integrate Micro Focus Enterprise Server with LRS VPSX/MFI. **Note:** LRS VPSX/MFI supports a Layer 4 load balancer. The Network Load Balancer also does a basic health check on LRS VPSX/MFI and routes traffic to the registered targets that are healthy.

4. The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA and uses **Amazon EBS** as an operational data store. LRS VPSX/MFI supports both the active-active and active-passive service modes. This architecture uses multiple Availability Zones in an active-passive pair as an active and hot standby. The Network Load Balancer performs a health check on LRS VPSX/MFI EC2 instances and routes traffic to hot standby instances in another Availability Zone if an active instance is in an unhealthy state. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of recovery, a failed instance has to be restarted for the LRS services to resume processing the print request. **Note:** LRS VPSX/MFI can also perform health checks at the printer fleet level. For more information, see *Printer fleet health checks* in the Additional information section of this pattern.

5. **AWS Managed Microsoft AD** integrates with LRS/DIS to perform print workflow authentication and authorization. For more information, see *Print authentication and authorization* in the Additional information section of this pattern.

6. LRS VPSX/MFI uses Amazon EBS for block storage. You can back up Amazon EBS data from active EC2 instances to Amazon S3 as point-in-time snapshots and restore them to hot standby EBS volumes. To automate the creation, retention, and deletion of Amazon EBS volume snapshots, you can use **Amazon Data Lifecycle Manager** to set the frequency of automated snapshots and restore them based on your RTO/RPO requirements.

### Tools

**AWS services**

- **Amazon EBS** – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.

- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks.

- **AWS Managed Microsoft AD** – AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft Active Directory, enables your directory-aware workloads and AWS resources to use managed Active Directory in AWS.

**Other tools**

- **LRS VPSX/MFI (Micro Focus Interface)** – VPSX/MFI, co-developed by LRS and Micro Focus, captures output from a Micro Focus Enterprise Server JES spool and reliably delivers it to a specified print destination.

- **LRS Directory Information Server (LRS/DIS)** – LRS/DIS is used for authentication and authorization during the print workflow.

- **LRS/Queue** – LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data through the Micro Focus online Print Exit programming interface.

- **Micro Focus Enterprise Server** – Micro Focus Enterprise Server is an application deployment environment for mainframe applications. It provides the execution environment for mainframe applications that are migrated or created by using any version of Micro Focus Enterprise Developer.
# Epics

**Set up Micro Focus Enterprise Server on Amazon EC2 and deploy a mainframe online application**

<table>
<thead>
<tr>
<th><strong>Task</strong></th>
<th><strong>Description</strong></th>
<th><strong>Skills required</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up Micro Focus Enterprise Server and deploy a demo online application.</td>
<td>Set up Micro Focus Enterprise Server on Amazon EC2, and then deploy the Micro Focus Account Demo application (ACCT Demo) on Amazon EC2 by following the instructions from Tutorial: CICS Support in the Micro Focus documentation. The ACCT Demo application is a mainframe online (CICS) application that creates and then initiates print output.</td>
<td>Cloud architect</td>
</tr>

</table>

**Set up an LRS print server on Amazon EC2**

<table>
<thead>
<tr>
<th><strong>Task</strong></th>
<th><strong>Description</strong></th>
<th><strong>Skills required</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Get an LRS product license for printing.</td>
<td>To get an LRS product license for LRS VPSX/MFI, LRS/Queue, and LRS/DIS, contact the LRS Output Management team. You must provide the host names of the EC2 instances where the LRS products will be installed.</td>
<td>Build lead</td>
</tr>
</tbody>
</table>
| Create an Amazon EC2 Windows instance to install LRS VPSX/MFI. | Launch an Amazon EC2 Windows instance by following the instructions from Step 1: Launch an instance in the Amazon EC2 documentation. Your instance must meet the following hardware and software requirements for LRS VPSX/MFI:  
  • CPU – Dual Core  
  • RAM – 16 GB  
  • Drive – 500 GB  
  • Minimum EC2 instance – m5.xlarge  
  • OS – Windows/Linux  
  • Software – Internet Information Service (IIS) or Apache | Cloud architect |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>

**Note:** The preceding hardware and software requirements are intended for a small printer fleet (around 500–1000). To get the full requirements, consult with your LRS and AWS contacts.

When you create your Windows instance, do the following:

1. Confirm that the EC2 host name is the same host name used for the LRS product license.
2. Enable CGI in Amazon EC2 by completing the following:
   a. Connect to your EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation.
   b. In the Windows Start menu, find and open Server Manager.
   c. In Server Manager, choose **Dashboard, Quick Start, Add roles and features**. Then, choose **Server roles**.
   d. In **Server roles**, choose **WebServer (IIS)**, and then choose **Application Development**.
   e. In **Application Development**, select the **CGI** check box.
   f. Follow the instructions on the Windows Server Manager **Add roles and features** wizard to install CGI.
   g. Open port 5500 in the Windows firewall of the EC2 instance for LRS/Queue communication.

</table>
| Install LRS VPSX/MFI on the EC2 instance. | 1. Connect to your EC2 instance by following the instructions from Step 2: Connect to your instance in the Amazon EC2 documentation.  
2. Open the link to the product download page from the LRS email that you should receive. **Note:** LRS products are distributed by electronic file transfer (EFT).  
3. Download LRS VPSX/MFI and unzip the file (default folder: c:\LRS).  
4. Launch the LRS Product Installer from the unzipped folder to install LRS VPSX/MFI.  
5. In the **Select Features** menu, select **VPSX® Server (V1R3.022)**, and then choose **Next** to start the installation process. You will receive a success message when installation is complete. | Cloud architect |
| Install LRS/Queue. | 1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from Step 2: Connect to your instance in the Amazon EC2 documentation.  
2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/Queue, and then unzip the file.  
3. Go to the location where you downloaded the files, and then launch the LRS product installer to install LRS/Queue. | Cloud architect |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Install LRS/DIS.                          | 1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from Step 2: Connect to your instance in the Amazon EC2 documentation.  
2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/DIS, and then unzip the file.  
3. Go to the location where you downloaded the files, and then launch the LRS Product Installer.  
4. In the LRS Product Installer, expand LRS Misc Tools, select LRS DIS, and then choose Next.  
5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process. | Cloud architect |
| Create a target group and register LRS VPSX/MFI EC2 as the target. | Create a target group by following the instructions from Create a target group for your Network Load Balancer in the Elastic Load Balancing documentation.  
When you create the target group, do the following:  
1. On the Specify group details page, for Choose a Target Type, choose Instances.  
2. For Protocol, choose TCP.  
3. For Port, choose 5500.  
4. On the Register targets page, in the Available instances section, select the LRS VPSX/MFI EC2 instances. | Cloud architect |
Create a Network Load Balancer.

Follow the instructions from Create a Network Load Balancer in the Elastic Load Balancing documentation. Your Network Load Balancer routes traffic from Micro Focus Enterprise Server to LRS VPSX/MFI EC2.

When you create the Network Load Balancer, do the following on the Listeners and Routing page:

1. For **Protocol**, choose **TCP**.
2. For **Port**, choose **5500**.
3. For **Default action**, choose **Forward to** for the target group that you created earlier.

Integrate Micro Focus Enterprise Server with LRS VPSX/MFI and LRS/Queue

## Additional information

### Considerations

During your modernization journey, you may consider a wide variety of configurations for mainframe online processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform may incorporate the IBM Advanced Function Presentation (AFP) or the Xerox Line Condition Data Stream (LCDS) into the current workflow. Additionally, **mainframe carriage control characters** and **channel command words** can affect the look of the printed page and may need special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

### Print data capture

This section summarizes the CICS application programming methods that you can use in an IBM mainframe environment for printing. LRS VPSX/MFI components provide techniques to allow the same application programs to create data in the same way. The following table describes how each application programming method is supported in a modernized CICS application running in AWS and Micro Focus Enterprise Server with an LRS VPSX/MFI print server.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
<th>Support for the method in a modernized environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXEC CICS SEND TEXT.. or EXEC CICS SEND MAP..</td>
<td>These CICS and VTAM methods are responsible for creating and delivering 3270/SCS print data streams to LUTYPE0, LUTYPE1, and LUTYPE3 print devices.</td>
<td>A Micro Focus online Print Exit (DFHUPRNT) application program interface (API) enables print data to be processed by VPSX/MFI when 3270/SCS print data streams are created by using either of these methods.</td>
</tr>
<tr>
<td>EXEC CICS SEND TEXT.. or EXEC CICS SEND MAP.. (with third-party IBM mainframe software)</td>
<td>The CICS and VTAM methods are responsible for creating and delivering 3270/SCS print data streams to LUTYPE0, LUTYPE1, and LUTYPE3 print devices. Third-party software products intercept the print data, convert the data to standard print format data with an ASA/MCH control character, and place the data on the JES spool to be processed by mainframe-based printing systems that use JES.</td>
<td>A Micro Focus online Print Exit (DFHUPRNT) API enables print data to be processed by VPSX/MFI when 3270/SCS print data streams are created by using either of these methods.</td>
</tr>
<tr>
<td>EXEC CICS SPOOLOPEN</td>
<td>This method is used by CICS application programs to write data directly to the JES spool. The data then becomes available to be processed by mainframe-based printing systems that use JES.</td>
<td>Micro Focus Enterprise Server spools the data to the Enterprise Server spool where it can be processed by the VPSX/MFI Batch Print Exit (LRSPRTE6) that spools the data to VPSX.</td>
</tr>
<tr>
<td>DRS/API</td>
<td>An LRS-supplied programmatic interface is used for writing print data to JES.</td>
<td>VPSX/MFI supplies a replacement interface that spools the print data directly to VPSX.</td>
</tr>
</tbody>
</table>
Printer fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep dive health checks for printer fleets, see the LRS documentation that’s included with your product license.

Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or an LDAP server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks. For example, command-level security such as hold/release, purge, modify, copy, and reroute. Security can be set up by either the User-ID or Group (similar to AD group or LDAP group).

Run event-driven and scheduled workloads at scale with AWS Fargate

Created by HARI OHM PRASATH RAJAGOPAL (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Modernization; Serverless; Operations</th>
<th>Workload:</th>
<th>Open-source</th>
</tr>
</thead>
<tbody>

<td>AWS EC2 Container Registry; Amazon ECS; AWS CodeCommit; AWS Fargate; AWS Lambda; Amazon SNS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to run scheduled and event-driven workloads at scale on the Amazon Web Services (AWS) Cloud by using AWS Fargate.

In the use case that this pattern sets up, code is scanned for AWS sensitive information, such as the AWS account number and credentials, whenever a pull request is submitted. The pull request initiates a Lambda function. The Lambda function invokes a Fargate task that takes care of the code scan. Lambda is initiated whenever a new pull request is raised. If the scan finds any sensitive information, Amazon Simple Notification Service (Amazon SNS) sends the scan results are sent in an email message.

This pattern is helpful in the following business use cases:
• If your business must run many scheduled and event-driven workloads that cannot be run by AWS Lambda because of limitations around runtime (a 15-minute limit) or memory
• If you want AWS to manage the instances provisioned for these workloads

When you use this pattern, you have the option of creating a new virtual private cloud (VPC).

Prerequisites and limitations

Prerequisites

• An active AWS account
• AWS CodeCommit for hosting the code base and creating pull requests
• AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows
• Workloads running in containers
• Apache Maven executable set up in classpath

Architecture

The overall flow includes the following steps.

1. Whenever a new pull request is submitted in CodeCommit, a Lambda function is initiated. The Lambda function listens through the CodeCommit Pull Request State Change event via Amazon EventBridge.
2. The Lambda function submits a new Fargate task with the following environment parameters for checking out the code and scanning it.

```python
RUNNER # <<TaskARN>>
SNS_TOPIC # <<SNSTopicARN>>
SUBNET # <<Subnet in which Fargate task gets launched>>
```

If the scan finds sensitive information in the code, Fargate pushes a new message to the Amazon SNS topic.
3. An SNS subscriber reads the message from the topic and sends an email message.

Technology
- AWS CodeCommit
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon Elastic Container Service (Amazon ECS)
- Amazon EventBridge
- AWS Fargate
- AWS Lambda
- Amazon SNS
- Docker

## Tools

### Tools

- **AWS CLI** – AWS Command Line Interface (CLI) is a unified tool to manage your AWS services.
- **AWS CodeCommit** – AWS CodeCommit is a fully managed source control service that hosts secure Git-based repositories. Using CodeCommit, teams can collaborate on code in a secure and highly scalable environment.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that developers can use to store, manage, and deploy Docker container images.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service. You can use Amazon ECS to run, stop, and manage containers on a cluster.
- **AWS Fargate** – AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon EC2 instances.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers). Publishers communicate asynchronously with subscribers by sending messages to a topic, which is a logical access point and communication channel. Clients that subscribe to the SNS topic receive published messages using a supported protocol, such as Lambda, email, mobile push notifications, and mobile text messages (SMS).
- **Docker** – Docker helps you build, test, and deliver applications in packages called containers.
- **Git client** – Command line or desktop tool to check out the required artifacts
- **Maven** – Apache Maven is a project management tool for centrally managing a project's build, reporting, and documentation.

Set up CI/CD for AWS AppSync GraphQL API updates

Created by Apoorva Kulkarni (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Modernization; Cloud-native; Software development &amp; testing; Serverless; DevOps</th>
<th>Workload:</th>
<th>Open-source</th>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Continuous integration and continuous delivery (CI/CD) are critical to recognizing the value of modern application development. Amazon Web Services (AWS) provides multiple services and open-source frameworks that help developers set up a CI/CD pipeline quickly. By automating build, testing and deployment, developers can focus on rapidly delivering new functionality instead of on maintaining and securing CI servers, manually testing their applications, and performing any error-prone deployments of the application stack due to a missed step.

This pattern demonstrates how to apply CI/CD best practices to the development, testing, and deployment of the AWS AppSync (GraphQL) backend API. The pattern builds on the AWS Blog post Building Scalable GraphQL APIs on AWS with CDK, TypeScript, AWS AppSync, Amazon DynamoDB, and AWS Lambda. The pattern sets up a CI/CD pipeline for deploying GraphQL API updates to AWS AppSync, a fully managed GraphQL API service. The pattern uses the AWS Cloud Development Kit (AWS CDK) pipelines module to provision a CI/CD pipeline. AWS CodePipeline orchestrates the building and testing of source code using AWS CodeBuild and the deployment of AWS resources using AWS CloudFormation stacks that are synthesized as a build artifact of the AWS CDK code.

Prerequisites and limitations

Prerequisites

- An active AWS account

Package versions
The source code (attached) has been tested with the following package versions in the development environment:

- AWS CDK 1.82.0
- Node.js 15.5.0
- npm 6.14.10
- TypeScript 3.9.7

For additional dependencies and libraries used, see package.json in the attached source code. Those dependencies and libraries are installed as a part of setting up your development environment as described in the Epics section.

Architecture

Target technology stack

Application resources

- AWS AppSync GraphQL API, GraphQL schema, resolvers, API key, data source
- AWS CloudFormation stack
- Amazon DynamoDB table
- AWS Identity and Access Management (IAM) roles and policies
- AWS Lambda function

Pipeline resources

- AWS CloudFormation stack
- AWS CodeBuild projects
- AWS CodePipeline pipeline, webhook
- IAM roles and policies
- AWS Key Management Service (AWS KMS) key and alias
- AWS Secrets Manager
- Amazon Simple Storage Service (Amazon S3) bucket

Target architecture
The following diagram shows details of the stack update architecture.

**Automation and scaling**
To add target environments for deployment of the application stack in different accounts and Regions, use the `pipeline.addApplicationStage()` API of the AWS CDK pipeline module. For more information about cross-account deployments, see the [documentation](#).

## Tools

- **AWS AppSync** – AWS AppSync provides a robust, scalable GraphQL interface for application developers to combine data from multiple sources, including Amazon DynamoDB and AWS Lambda.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services.
- **AWS Cloud Development Kit** – The AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources.
- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.
- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- **AWS Lambda** – AWS Lambda supports running code without provisioning or managing servers.
- **Node.js runtime** – Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.
- **Git client** – A Git client is a command line or desktop tool for checking out the required artifacts from a Git repository.

## Code

The source code is attached as a .zip file.

- Snapshot testing with Jest

## Additional information

### Testing

#### Unit testing

The example shows how to perform unit testing of the application’s synthesized CloudFormation stack by using the Jest library’s snapshot testing capabilities. A snapshot test case renders a stack, takes a snapshot, then compares it to a reference snapshot file stored alongside the test. If the two snapshots do not match, the test will fail. Snapshot mismatches can occur either because the change is unexpected or because the reference snapshot must be updated to the new version of the stack.

```javascript
test('Snapshot test - AppsyncCdkApp', () => {
  const stack = new Stack();
  // WHEN
  new AppSyncCdkApp.AppsyncCdkAppStack(stack, 'MyTestConstruct');
  // THEN
```
Updating tests

To update the unit tests when adding test cases or making changes to the AWS CDK code of the application stack, first update snapshot files. To update the snapshot files, run the following command.

$ npm test -- -u --group=unit

End-to-end testing

Testing your AWS AppSync GraphQL API backend through its API interface gives you the most confidence to determine whether your API is working as expected for your customers. The following example shows how to use the Amplify JavaScript library combined with the Jest snapshot testing described in the Unit testing section. You can use this approach to perform end-to-end tests that mimic an API client performing operations against the Alpha environment.

```javascript
import Amplify, { API } from 'aws-amplify';
Amplify.configure({
  aws_appsync_region: process.env.AWS_DEFAULT_REGION, // Stack region
  aws_appsync_graphqlEndpoint: process.env.API_URL, // AWS AppSync endpoint
  aws_appsync_authenticationType: "API_KEY", //Primary AWS AppSync authentication type
  aws_appsync_apiKey: process.env.API_KEY // AppSync API Key
});
describe('List Empty Notes', () => {
  it('List Notes, should be empty', async () => {
    const query = `query listNotes {
      listNotes {
        id name completed
      }
    }
    `;
    const response = await API.graphql({ query });
    expect(response).toMatchSnapshot();
  });
});
```

Updating Tests

To update either the end-to-end tests when updating the `graphql` schema or making other changes, run the following command.

$ npm test -- -u --group=e2e

Pipeline stages

After the pipeline has been deployed successfully, further changes to the application code or the pipeline can be deployed by pushing commits to GitHub. The following sections describe what the different stages in the pipeline do.

Source

Creates a webhook for integrating with GitHub so that any commit to the main branch initiates the pipeline process.
**Build**

Creates a CodeBuild project to build the source code. The AWS CDK pipelines module uses this stage to synthesize CloudFormation stacks. Additionally, in this pattern, a TypeScript Lambda function, which is included in the application source code, is also compiled.

**UpdatePipeline (self-mutate)**

Applies any changes to the pipeline itself through self-mutation using a CloudFormation change set. For more information, see the AWS CDK pipeline module documentation.

**Assets**

Creates a CodeBuild project to prepare and publish AWS CDK assets. For more information, see the AWS CDK pipeline module documentation.

**UnitTests**

Creates a CodeBuild project to run any unit tests that exist in the source code. In addition, you can use this stage to validate the `graphql` schema using `graphql-schema-utilities`, an open-source package for validating and merging `graphql` schemas.

**DeployAlpha**

Uses a CloudFormation change set to deploy the application stack that provisions application resources, such as AWS AppSync, DynamoDB tables, and Lambda functions, to an Alpha environment where you can run integration tests, end-to-end tests, and so forth.

**E2ETesting**

Creates a CodeBuild project to perform end-to-end testing against the Alpha environment.

**DeployProd**

Uses a CloudFormation change set to deploy the application stack that provisions application resources to the production environment.

**Tenant onboarding in SaaS architecture for the silo model using C# and AWS CDK**

*Created by Tabby Ward (AWS), Susmitha Reddy Gankidi (AWS), Vijai Anand Ramalingam (AWS), and Danil Ko (AWS)*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Modernization; Cloud-native; SaaS; DevOps</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tennat Onboarding Silo</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**Summary**

Software as a service (SaaS) applications can be built with a variety of different architectural models. The *silo model* refers to an architecture where tenants are provided dedicated resources.

SaaS applications rely on a frictionless model for introducing new tenants into their environment. This often requires the orchestration of a number of components to successfully provision and configure all the elements needed to create a new tenant. This process, in SaaS architecture, is referred to as tenant on-boarding. On-boarding should be fully automated for every SaaS environment by utilizing infrastructure as code in your on-boarding process.

This pattern guides you through an example of creating a tenant and provisioning a basic infrastructure for the tenant on Amazon Web Services (AWS). The pattern uses C# and the AWS Cloud Development Kit (AWS CDK).

Because this pattern creates a billing alarm, we recommend deploying the stack in the US East (N. Virginia), or us-east-1, AWS Region. For more information, see the AWS documentation.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- User with sufficient AWS Identity and Access Management (IAM) access to create AWS resources for this pattern. For more information, see IAM roles.
- User with programmatic access keys. For more information, see Creating an IAM user in your AWS account.
- Amazon Command Line Interface (AWS CLI).
- Visual Studio 2022 downloaded and installed or Visual Studio Code downloaded and installed.
- AWS Toolkit for Visual Studio set up.
- .NET Core 3.1 or later (required for C# AWS CDK applications)
- Amazon.Lambda.Tools installed.

**Limitations**

- AWS CDK uses AWS CloudFormation, so AWS CDK applications are subject to CloudFormation service quotas. For more information, see AWS CloudFormation quotas.
- The tenant CloudFormation stack is created with a CloudFormation service role infra-cloudformation-role with wildcard characters on actions (sns* and sqs*) but with resources locked down to the tenant-cluster prefix. For a production use case, evaluate this setting and provide only required access to this service role. The InfrastructureProvision Lambda function also uses a wildcard character (cloudformation*) to provision the CloudFormation stack but with resources locked down to the tenant-cluster prefix.
- This example code's docker build uses --platform=linux/amd64 to force linux/amd64 based images. This is to ensure that the final image artifacts will be suitable for Lambda, which by default
uses x86-64 architecture. If you need to change the target Lambda architecture, be sure to change both the Dockerfiles and the AWS CDK codes. For more information, see the blog post Migrating AWS Lambda functions to Arm-based AWS Graviton2 processors.

- The stack deletion process will not clean up CloudWatch Logs (log groups and logs) generated by the stack. You must manually clean up the logs through the AWS Management Console Amazon CloudWatch console or through the API.

This pattern is set up as an example. For production use, evaluate the following setups and make changes based on your business requirements:

- The AWS Simple Storage Service (Amazon S3) bucket in this example does not have versioning enabled for simplicity. Evaluate and update the setup as needed.

- This example sets up Amazon API Gateway REST API endpoints without authentication, authorization, or throttling for simplicity. For production use, we recommend integrating the system with the business security infrastructure. Evaluate this setting and add required security settings as needed.

- For this tenant infrastructure example, Amazon Simple Notification Service (Amazon SNS) and Amazon Simple Queue Service (Amazon SQS) have only minimum setups. The AWS Key Management Service (AWS KMS) for each tenant opens to Amazon CloudWatch and Amazon SNS services in the account to consume based on the AWS KMS key policy. The setup is only an example placeholder. Adjust the setups as needed based on your business use case.

- The entire setup, which includes but isn’t limited to API endpoints and backend tenant provisioning and deletion by using AWS CloudFormation, covers only the basic happy path case. Evaluate and update the setup with the necessary retry logic, additional error handling logic, and security logic based on your business needs.

- The example code is tested with up-to-date cdk-nag to check for policies at the time of this writing. New policies might be enforced in the future. These new policies might require you to manually modify the stack based on the recommendations before the stack can be deployed. Review the existing code to ensure that it aligns with your business requirements.

- The code relies on the AWS CDK to generate a random suffix instead of relying on static assigned physical names for most created resources. This setup is to ensure that these resources are unique and do not conflict with other stacks. For more information, see the AWS CDK documentation. Adjust this based on your business requirements.

- This example code packages .NET Lambda artifacts into Docker based images and runs with the Lambda provided Container image runtime. The container image runtime has advantages for standard transfer and store mechanisms (container registries) and more accurate local test environments (through the container image). You can switch the project to use Lambda provided .NET runtimes to reduce the build time of the Docker images, but you will then need to set up transfer and store mechanisms and ensure that the local setup matches the Lambda setup. Adjust the code to align with users’ business requirements.

**Product versions**

- AWS CDK version 2.45.0 or later
- Visual Studio 2022

**Architecture**

**Technology stack**

- Amazon API Gateway
- AWS CloudFormation
- Amazon CloudWatch
- Amazon DynamoDB
- AWS Identity and Access Management (IAM)
- AWS KMS
- AWS Lambda
- Amazon S3
- Amazon SNS
- Amazon SQS

Architecture

The following diagram shows the tenant stack creation flow. For more information about the control-plane and tenant technology stacks, see the Additional information section.

Tenant stack creation flow

1. User sends a POST API request with new tenant payload (tenant name, tenant description) in JSON to a REST API hosted by Amazon API Gateway. The API Gateway processes the request and forwards it to the backend Lambda Tenant On-boarding function. In this example, there is no authorization or authentication. In a production setup, this API should be integrated with the SaaS infrastructure security system.

2. The Tenant On-boarding function verifies the request. Then it attempts to store the tenant record, which includes the tenant name, generated tenant universally unique identifier (UUID), and tenant description, into the Amazon DynamoDB Tenant On-boarding table.

3. After DynamoDB stores the record, a DynamoDB stream initiates the downstream Lambda Tenant Infrastructure function.

4. The Tenant Infrastructure Lambda function acts based on the received DynamoDB stream. If the stream is for the INSERT event, the function uses the stream’s NewImage section (latest update record, Tenant Name field) to invoke CloudFormation to create a new tenant infrastructure using the template that is stored in the S3 bucket. The CloudFormation template requires the Tenant Name parameter.
5. AWS CloudFormation creates the tenant infrastructure based on the CloudFormation template and input parameters.
6. Each tenant infrastructure setup has a CloudWatch alarm, a billing alarm, and an alarm event.
7. The alarm event becomes a message to an SNS topic, which is encrypted by the tenant's AWS KMS key.
8. The SNS topic forwards the received alarm message to the SQS queue, which is encrypted by the tenant's AWS KMS for encryption key.

Other systems can be integrated with Amazon SQS to perform actions based on messages in queue. In this example, to keep the code generic, incoming messages remain in queue and require manual deletion.

**Tenant stack deletion flow**

1. User sends a DELETE API request with new tenant payload (tenant name, tenant description) in JSON to the REST API hosted by Amazon API Gateway, which will process the request and forward to Tenant On-boarding function. In this example, there is no authorization or authentication. In a production setup, this API will be integrated with the SaaS infrastructure security system.
2. The Tenant On-boarding function will verify the request and then attempt to delete the tenant record (tenant name) from the Tenant On-boarding table.
3. After DynamoDB deletes the record successfully (the record exists in the table and is deleted), a DynamoDB stream initiates the downstream Lambda Tenant Infrastructure function.
4. The Tenant Infrastructure Lambda function acts based on the received DynamoDB stream record. If the stream is for the REMOVE event, the function uses the record's OldImage section (record information and Tenant Name field, before the latest change, which is delete) to initiate deletion of an existing stack based on that record information.
5. AWS CloudFormation deletes the target tenant stack according to the input.

**Tools**

**AWS services**

- **Amazon API Gateway** helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- **AWS Cloud Development Kit (AWS CDK)** is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- **AWS CDK Toolkit** is a command line cloud development kit that helps you interact with your AWS Cloud Development Kit (AWS CDK) app.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to help protect your data.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
AWS Prescriptive Guidance Patterns
Epics

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- **Amazon Simple Queue Service (Amazon SQS)** provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- **AWS Toolkit for Visual Studio** is a plugin for the Visual Studio integrated development environment (IDE). The Toolkit for Visual Studio supports developing, debugging, and deploying .NET applications that use AWS services.

**Other tools**

- **Visual Studio** is an IDE that includes compilers, code completion tools, graphical designers, and other features that support software development.

**Code**

The code for this pattern is in the Tenant onboarding in SaaS Architecture for Silo Model APG Example repository.

Additional information

Control-plane technology stack

The CDK code written in .NET is used to provision the control-plane infrastructure, which consists of the following resources:

1. **API Gateway**
   
   Serves as the REST API entry point for the control-plane stack.

2. **Tenant on-boarding Lambda function**
   
   This Lambda function is initiated by API Gateway using the m method.

   A POST method API request results in (tenant name, tenant description) being inserted into the DynamoDB Tenant Onboarding table.

   In this code example, the tenant name is also used as part of the tenant stack name and the names of resources within that stack. This is to make these resources easier to identify. This tenant name must be unique across the setup to avoid conflicts or errors. Detailed input validation setup is explained in the IAM roles documentation and the Limitations section.

   The persistence process to the DynamoDB table will succeed only if the tenant name is not used in any other record in the table.

   The tenant name in this case is the partition key for this table, because only the partition key can be used as a PutItem condition expression.

   If the tenant name was never recorded before, the record will be saved into the table successfully.

   However, if the tenant name is already used by an existing record in the table, the operation will fail and initiate a DynamoDB ConditionalCheckFailedException exception. The exception will be used to return a failure message (HTTP BadRequest) indicating that the tenant name already exists.

   A DELETE method API request will remove the record for a specific tenant name from the Tenant Onboarding table.

   The DynamoDB record deletion in this example will succeed even if the record does not exist.

   If the target record exists and is deleted, it will create a DynamoDB stream record. Otherwise, no downstream record will be created.

3. **Tenant on-boarding DynamoDB, with Amazon DynamoDB Streams enabled**
   
   This records the tenant metadata information, and any record save or deletion will send a stream downstream to the Tenant Infrastructure Lambda function.

4. **Tenant infrastructure Lambda function**
   
   This Lambda function is initiated by the DynamoDB stream record from the previous step. If the record is for an INSERT event, it invokes AWS CloudFormation to create a new tenant infrastructure with the CloudFormation template that is stored in an S3 bucket. If the record is for REMOVE, it initiates deletion of an existing stack based on the stream record's Tenant Name field.

5. **S3 bucket**
   
   This is for storing the CloudFormation template.

6. **IAM roles for each Lambda function and a service role for CloudFormation**
Each Lambda function has its unique IAM role with least-privilege permissions to achieve its task. For example, the Tenant On-boarding Lambda function has read/write access to DynamoDB, and the Tenant Infrastructure Lambda function can only read the DynamoDB stream.

A custom CloudFormation service role is created for tenant stack provisioning. This service role contains additional permissions for CloudFormation stack provisioning (for example, the AWS KMS key). This divides roles between Lambda and CloudFormation to avoid all permissions on a single role (Infrastructure Lambda role).

Permissions that allow powerful actions (such as creating and deleting CloudFormation stacks) are locked down and allowed only on resources that start with tenantcluster-. The exception is AWS KMS, because of its resource naming convention. The ingested tenant name from the API will be prepended with tenantcluster- along with other validation checks (alphanumeric with dash only, and limited to less than 30 characters to fit into most AWS resource naming). This ensures that the tenant name will not accidentally result in disruption of core infrastructure stacks or resources.

**Tenant technology stack**

A CloudFormation template is stored in the S3 bucket. The template provisions the tenant-specific AWS KMS key, a CloudWatch alarm, an SNS topic, an SQS queue, and an SQS policy.

The AWS KMS key is used for data encryption by Amazon SNS and Amazon SQS for their messages. The security practices for AwsSolutions-SNS2 and AwsSolutions-SQS2 recommend that you set up Amazon SNS and Amazon SQS with encryption. However, CloudWatch alarms don’t work with Amazon SNS when using an AWS managed key, so you must use a customer managed key in this case. For more information, see the AWS Knowledge Center.

The SQS policy is used on the Amazon SQS queue to allow the created SNS topic to deliver the message to the queue. Without the SQS policy, the access will be denied. For more information, see the Amazon SNS documentation.

**AWS services:** Amazon DynamoDB; AWS Lambda; Amazon SNS

---

**Summary**

This pattern combines two patterns, using both the command query responsibility separation (CQRS) pattern and the event sourcing pattern. The CQRS pattern separates responsibilities of the command
and query models. The event sourcing pattern takes advantage of asynchronous event-driven communication to improve the overall user experience.

You can use CQRS and Amazon Web Services (AWS) services to maintain and scale each data model independently while refactoring your monolith application into microservices architecture. Then you can use the event sourcing pattern to synchronize data from the command database to the query database.

This pattern uses example code that includes a solution (*.sln) file that you can open using the latest version of Visual Studio. The example contains Reward API code to showcase how CQRS and event sourcing work in AWS serverless and traditional or on-premises applications.

To learn more about CQRS and event sourcing, see the Additional information section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Amazon CloudWatch
- Amazon DynamoDB tables
- Amazon DynamoDB Streams
- AWS Identity and Access Management (IAM) access key and secret key; for more information, see the video in the Related resources section
- AWS Lambda
- Familiarity with Visual Studio
- Familiarity with AWS Toolkit for Visual Studio; for more information, see the AWS Toolkit for Visual Studio demo video in the Related resources section

Product versions

- .NET Core 3.1. This component is an option in the Visual Studio installation. To include .NET Core during installation, select NET Core cross-platform development.

Limitations

- The example code for a traditional on-premises application (ASP.NET Core Web API and data access objects) does not come with a database. However, it comes with the CustomerData in-memory object, which acts as a mock database. The code provided is enough for you to test the pattern.

Architecture

Source technology stack

- ASP.NET Core Web API project
- IIS Web Server
- Data access object
- CRUD model

Source architecture
In the source architecture, the CRUD model contains both command and query interfaces in one application. For example code, see `CustomerDAO.cs` (attached).

**Target technology stack**

- Amazon DynamoDB
- Amazon DynamoDB Streams
- AWS Lambda
- (Optional) Amazon API Gateway
- (Optional) Amazon Simple Notification Service (Amazon SNS)

**Target architecture**

In the target architecture, the command and query interfaces are separated. The architecture shown in the following diagram can be extended with API Gateway and Amazon SNS. For more information, see the Additional information section.
1. Command Lambda functions perform write operations, such as create, update, or delete, on the database.
2. Query Lambda functions perform read operations, such as get or select, on the database.
3. This Lambda function processes the DynamoDB streams from the Command database and updates the Query database for the changes.

**Tools**

- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- **Amazon DynamoDB Streams** – DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table. It then stores this information in a log for up to 24 hours. Encryption at rest encrypts the data in DynamoDB streams.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- **AWS Management Console** – The AWS Management Console is a web application that comprises a broad collection of service consoles for managing AWS services.
AWS Prescriptive Guidance Patterns

Epics

- **AWS Toolkit for Visual Studio** – The AWS Toolkit for Visual Studio is a plugin for the Visual Studio IDE. The AWS Toolkit for Visual Studio makes it easier for you to develop, debug, and deploy .NET applications that use AWS services.

**Code**

The example code is attached. For instructions on deploying the example code, see the *Epics* section.

**Epics**

**Open and build the solution**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Open the solution.        | 1. Download the example source code (CQRS-ES Code.zip) from the *Attachments* section, and extract the files.  
2. In the Visual Studio IDE, choose *File, Open, Project Solution*, and navigate to the folder where you extracted the source code.  
3. Choose *AWS.APG.CQRSES.sln*, and then choose *Open*. The entire solution is loaded into Visual Studio. | App developer   |
| Build the solution.       | Open the context (right-click) menu for the solution, and then choose *Build Solution*. This will build and compile all the projects in the solution. It should compile successfully.  
Visual Studio Solution Explorer should show the directory structure.  
- CQRS On-Premises Code Sample contains an example of using CQRS on premises.  
- CQRS AWS Serverless contains all the CQRS and event-sourcing example code using AWS serverless services. | App developer   |
## Build the DynamoDB tables

<table>

</tr>
<tr>
<td>2.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>For the remaining fields, keep the default values, and choose Next.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>In Role Name dropdown list, select AWSLambdaFullAccess.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>To provide your account keys, choose Add, and enter AccessKey as the variable and your access key as the value. Then choose Add again, enter SecretKey as the variable and your secret key as the value.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>For the remaining fields, keep the default values, and choose Upload. After the Lambda test function uploads, it appears in Visual Studio automatically.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>Repeat steps 1-6 for the following projects:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS.APG.CQRSES.CommandDeleteLambda</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS.APG.CQRSES.CommandUpdateLambda</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS.APG.CQRSES.CommandAddRewardLambda</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS.APG.CQRSES.CommandRedeemRewardLambda</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS.APG.CQRSES.QueryCustomerListLambda</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS.APG.CQRSES.QueryRewardLambda</td>
<td></td>
</tr>
<tr>
<td>Verify the function upload.</td>
<td>(Optional) You can verify that the function was successfully loaded by navigating to AWS Explorer and expanding AWS Lambda. To open the test window, choose the Lambda function (double-click).</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Test the Lambda function.

1. Enter the request data, or copy an example request data from **Test data** in the **Additional information** section. Make sure that you select data that is for the function you are testing.

2. To run the test, choose **Invoke**. The response and any errors are displayed in the **Response** text box, and logs are shown in the **Logs** text box or in CloudWatch Logs.

3. To verify the data, in AWS Explorer, choose the DynamoDB table (double-click).

All CQRS Lambda projects are found under the CQRS AWS Serverless\CQRS\Command Microservice and CQRS AWS Serverless\CQRS\Command Microservice solution folders. For the solution directory and projects, see **Source code directory** in the **Additional information** section.

### Publish the remaining functions.

Repeat the previous steps for the following projects:

- AWS.APG.CQRSES.CommandDeleteLambda
- AWS.APG.CQRSES.CommandUpdateLambda
- AWS.APG.CQRSES.CommandAddRewardLambda
- AWS.APG.CQRSES.CommandRedeemRewardLambda
- AWS.APG.CQRSES.QueryCustomerListLambda
- AWS.APG.CQRSES.QueryRewqardLambda

### Set up the Lambda function as an event listener

#### Task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Publish the Customer and Reward Lambda event handlers.</td>
<td>To publish each event handler, follow the steps in the preceding epic. The projects are under the CQRS AWS Serverless\Event Source\Customer Event and CQRS AWS Serverless</td>
<td>App developer</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
| Attach the event-sourcing Lambda event listener. | 1. Log in to the AWS Management Console using the same account you use when you publish the Lambda projects.  
2. For the Region, select US East 1 or the Region where you deployed the Lambda functions in the previous epic.  
3. Navigate to the Lambda service.  
4. Select the EventSourceCustomer Lambda function.  
5. Choose Add Trigger.  
6. In the Trigger configuration dropdown list, select DynamoDB.  
7. In the DynamoDB table dropdown list, select cqrses-customer-cmd.  
8. In the Starting position dropdown list, select Trim horizon from . Trim horizon means that the DynamoDB trigger will start reading at the last (untrimmed) stream record, which is the oldest record in the shard.  
9. Select the Enable trigger check box.  
10. For the remaining fields, keep the default values, and choose Add.  

After the listener is successfully attached to the DynamoDB table, it will be displayed on the Lambda designer page. | App developer |
| Publish and attach the EventSourceReward Lambda function. | To publish and attach the EventSourceReward Lambda function, repeat the steps in the previous two stories, selecting cqrses-reward-cmd from the DynamoDB table dropdown list. | App developer |
## Test and validate the DynamoDB streams and Lambda trigger

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test the stream and the Lambda trigger.   | 1. In Visual Studio, navigate to AWS Explorer.  
2. Expand AWS Lambda, and choose the **CommandRedeemReward** function (double-click). In the function window that opens, you can test the function.  
3. In the **Request** text box, enter the request data in JavaScript Object Notation (JSON) format. For an example request, see **Test data** in the **Additional information** section.  
4. Choose **Invoke**.                                                                         | App developer    |
| Validate, using the DynamoDB reward query table. | 1. Open the **cqrses-reward-query** table.  
2. Check the points of the customer that redeemed the reward. The redeemed points should be subtracted from the customer's total aggregated points.                                      | App developer    |
| Validate, using CloudWatch Logs.          | 1. Navigate to CloudWatch and choose **Log groups**.  
2. The **/aws/lambda/EventSourceReward** log group contains the logs for the EventSourceReward trigger. All Lambda calls are logged, including the messages you placed in **context.Logger.LogLine** and **Console.WriteLine** in the Lambda code. | App developer    |
| Validate the EventSourceCustomer trigger. | To validate the EventSourceCustomer trigger, repeat the steps in this epic, using the EventSourceCustomer trigger's respective customer table and CloudWatch logs.                                           | App developer    |

Additional information

CQRS and event sourcing

CQRS

The CQRS pattern separates a single conceptual operations model, such as a data access object single CRUD (create, read, update, delete) model, into command and query operations models. The command model refers to any operation, such as create, update, or delete, that changes the state. The query model refers to any operation that returns a value.

1. The Customer CRUD model includes the following interfaces:
   • CreateCustomer()
   • UpdateCustomer()
   • DeleteCustomer()
   • AddPoints()
   • RedeemPoints()
   • GetVIPCustomers()
   • GetCustomerList()
   • GetCustomerPoints()

As your requirements become more complex, you can move from this single-model approach. CQRS uses a command model and a query model to separate the responsibility for writing and reading data. That way, the data can be independently maintained and managed. With a clear separation of responsibilities, enhancements to each model do not impact the other. This separation improves maintenance and performance, and it reduces the complexity of the application as it grows.
1. Interfaces in the Customer Command model:
   - Create Customer()
   - UpdateCustomer()
   - DeleteCustomer()
   - AddPoints()
   - RedeemPoints()

2. Interfaces in the Customer Query model:
   - GetVIPCustomers()
   - GetCustomerList()
   - GetCustomerPoints()
   - GetMonthlyStatement()

For example code, see Source code directory.

The CQRS pattern then decouples the database. This decoupling leads to the total independence of each service, which is the main ingredient of microservice architecture.
Using CQRS in the AWS Cloud, you can further optimize each service. For example, you can set different compute settings or choose between a serverless or a container-based microservice. You can replace your on-premises caching with Amazon ElastiCache. If you have an on-premises publish/subscribe messaging, you can replace it with Amazon Simple Notification Service (Amazon SNS). Additionally, you can take advantage of pay-as-you-go pricing and the wide array of AWS services that you pay only for what you use.

CQRS includes the following benefits:

- **Independent scaling** – Each model can have its scaling strategy adjusted to meet the requirements and demand of the service. Similar to high-performance applications, separating read and write enables the model to scale independently to address each demand. You can also add or reduce compute resources to address the scalability demand of one model without affecting the other.
- **Independent maintenance** – Separation of query and command models improves the maintainability of the models. You can make code changes and enhancements to one model without affecting the other.
- **Security** – It’s easier to apply the permissions and policies to separate models for read and write.
- **Optimized reads** – You can define a schema that is optimized for queries. For example, you can define a schema for the aggregated data and a separate schema for the fact tables.
- **Integration** – CQRS fits well with event-based programming models.
- **Managed complexity** – The separation into query and command models is suited to complex domains.

When using CQRS, keep in mind the following caveats:

- **The CQRS pattern applies only to a specific portion of an application and not the whole application. If implemented on a domain that does not fit the pattern, it can reduce productivity, increase risk, and introduce complexity.**
- **The pattern works best for frequently used models that have an imbalance read and write operations.**
- **For read-heavy applications, such as large reports that take time to process, CQRS gives you the option to select the right database and create a schema to store your aggregated data. This improves the response time of reading and viewing the report by processing the report data only one time and dumping it in the aggregated table.**
- **For the write-heavy applications, you can configure the database for write operations and allow the command microservice to scale independently when the demand for write increases. For examples, see the AWS.APG.CQRSES.CommandRedeemRewardLambda and AWS.APG.CQRSES.CommandAddRewardLambda microservices.**

**Event sourcing**

The next step is to use event sourcing to synchronize the query database when a command is run. For example, consider the following events:

- A customer reward point is added that requires the customer total or aggregated reward points in the query database to be updated.
- A customer’s last name is updated in the command database, which requires the surrogate customer information in the query database to be updated.

In the traditional CRUD model, you ensure consistency of data by locking the data until it finishes a transaction. In event sourcing, the data are synchronized through publishing a series of events that will be consumed by a subscriber to update its respective data.

The event-sourcing pattern ensures and records a full series of actions taken on the data and publishes it through a sequence of events. These events represent a set of changes to the data that subscribers...
of that event must process to keep their record updated. These events are consumed by the subscriber, synchronizing the data on the subscriber's database. In this case, that's the query database.

The following diagram shows event sourcing used with CQRS on AWS.

1. Command Lambda functions perform write operations, such as create, update, or delete, on the database.
2. Query Lambda functions perform read operations, such as get or select, on the database.
3. This Lambda function processes the DynamoDB streams from the Command database and updates the Query database for the changes. You can also use this function also to publish a message to Amazon SNS so that its subscribers can process the data.
4. (Optional) The Lambda event subscriber processes the message published by Amazon SNS and updates the Query database.
5. (Optional) Amazon SNS sends email notification of the write operation.

On AWS, the query database can be synchronized by DynamoDB Streams. DynamoDB captures a time-ordered sequence of item-level modifications in a DynamoDB table in near-real time and durably stores the information within 24 hours.

Activating DynamoDB Streams enables the database to publish a sequence of events that makes the event sourcing pattern possible. The event sourcing pattern adds the event subscriber. The event subscriber application consumes the event and processes it depending on the subscriber's responsibility. In the previous diagram, the event subscriber pushes the changes to the Query DynamoDB database to keep the data synchronized. The use of Amazon SNS, the message broker, and the event subscriber application keeps the architecture decoupled.

Event sourcing includes the following benefits:

- Consistency for transactional data
- A reliable audit trail and history of the actions, which can be used to monitor actions taken in the data
- Allows distributed applications such as microservices to synchronize their data across the environment
- Reliable publication of events whenever the state changes
- Reconstructing or replaying of past states
- Loosely coupled entities that exchange events for migration from a monolithic application to microservices
• Reduction of conflicts caused by concurrent updates; event sourcing avoids the requirement to update objects directly in the data store
• Flexibility and extensibility from decoupling the task and the event
• External system updates
• Management of multiple tasks in a single event

When using event sourcing, keep in mind the following caveats:

• Because there is some delay in updating data between the source subscriber databases, the only way to undo a change is to add a compensating event to the event store.
• Implementing event sourcing has a learning curve since its different style of programming.

Test data

Use the following test data to test the Lambda function after successful deployment.

**CommandCreate Customer**

```
{  "Id":1501,  "Firstname":"John",  "Lastname":"Done",  "Companyname":"AnyCompany",  "Address": "USA",  "VIP":true }
```

**CommandUpdate Customer**

```
{  "Id":1501,  "Firstname":"John",  "Lastname":"Doe",  "Companyname":"Example Corp.",  "Address": "Seattle, USA",  "VIP":true }
```

**CommandDelete Customer**

Enter the customer ID as request data. For example, if the customer ID is 151, enter 151 as request data.

151

**QueryCustomerList**

This is blank. When it is invoked, it will return all customers.

**CommandAddReward**

This will add 40 points to customer with ID 1 (Richard).

```
{"Id":10101,  "CustomerId":1,  "Points":40 }
```

**CommandRedeemReward**

This will deduct 15 points to customer with ID 1 (Richard).

```
{"Id":10110,  "CustomerId":1,  "Points":15 }
```

**QueryReward**
Enter the ID of the customer. For example, enter 1 for Richard, 2 for Arnav, and 3 for Shirley.

2

**Source code directory**

Use the following table as a guide to the directory structure of the Visual Studio solution.

*CQRS On-Premises Code Sample solution directory*

---

**Customer CRUD model**
CQRS On-Premises Code Sample\CRUD Model\AWS.APG.CQRSES.DAL project

CQRS version of the Customer CRUD model

- Customer command: CQRS On-Premises Code Sample\CQRS Model\Command Microservice \AWS.APG.CQRSES.Command project
- Customer query: CQRS On-Premises Code Sample\CQRS Model\Query Microservice \AWS.APG.CQRSES.Query project

Command and Query microservices

The Command microservice is under the solution folder CQRS On-Premises Code Sample\CQRS Model\Command Microservice:

- AWS.APG.CQRSES.CommandMicroservice ASP.NET Core API project acts as the entry point where consumers interact with the service.
- AWS.APG.CQRSES.Command .NET Core project is an object that hosts command-related objects and interfaces.

The query microservice is under the solution folder CQRS On-Premises Code Sample\CQRS Model\Query Microservice:

- AWS.APG.CQRSES.QueryMicroservice ASP.NET Core API project acts as the entry point where consumers interact with the service.
- AWS.APG.CQRSES.Query .NET Core project is an object that hosts query-related objects and interfaces.

CQRS AWS Serverless code solution directory
This code is the AWS version of the on-premises code using AWS serverless services.

In C# .NET Core, each Lambda function is represented by one .NET Core project. In this pattern's example code, there is a separate project for each interface in the command and query models.

**CQRS using AWS services**

You can find the root solution directory for CQRS using AWS serverless services is in the CQRS\AWS Serverless\CQRS folder. The example includes two models: Customer and Reward.

The command Lambda functions for Customer and Reward are under CQRS\Command Microservice\Customer and CQRS\Command Microservice\Reward folders. They contain the following Lambda projects:

- Customer command: CommandCreateLambda, CommandDeleteLambda, and CommandUpdateLambda
- Reward command: CommandAddRewardLambda and CommandRedeemRewardLambda

The query Lambda functions for Customer and Reward are found under the CQRS\Query Microservice\Customer and CQRS\QueryMicroservice\Reward folders. They contain the QueryCustomerListLambda and QueryRewardLambda Lambda projects.

**CQRS test project**
The test project is under the CQRS\Tests folder. This project contains a test script to automate testing the CQRS Lambda functions.

**Event sourcing using AWS services**

The following Lambda event handlers are initiated by the Customer and Reward DynamoDB streams to process and synchronize the data in query tables.

- The EventSourceCustomer Lambda function is mapped to the Customer table (cqrses-customer-cmd) DynamoDB stream.
- The EventSourceReward Lambda function is mapped to the Reward table (cqrses-reward-cmd) DynamoDB stream.

Automate the setup of inter-Region peering with AWS Transit Gateway

Created by Ram Kandaswamy (AWS)

| Environment: Production | Technologies: Networking; Hybrid cloud | AWS services: AWS Transit Gateway; AWS Step Functions; AWS Lambda |

Summary

AWS Transit Gateway connects virtual private clouds (VPCs) and on-premises networks through a central hub. Transit Gateway traffic always stays on the global Amazon Web Services (AWS) backbone and doesn’t traverse the public internet, which reduces threat vectors, such as common exploits and distributed denial of service (DDoS) attacks.

If you need to communicate between two or more AWS Regions, you can use inter-Region Transit Gateway peering to establish peering connections between transit gateways in different Regions. However, manually configuring inter-Region peering with Transit Gateway can be a time-consuming process that has multiple steps. This pattern provides an automated process to remove these manual steps by using code to perform the peering. You can use this approach if you have to repeatedly configure several Regions and AWS accounts during a multi-Region organization setup.

This pattern uses an AWS CloudFormation stack that includes the AWS Step Functions workflow, AWS Lambda functions, AWS Identity and Access Management (IAM) roles, and log groups in Amazon
CloudWatch Logs. You can then start a Step Functions execution and create the inter-Region peering connection for your transit gateways.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon Simple Storage Service (Amazon S3) bucket.
- Transit gateways, created and configured in the requestor Region and the acceptor Regions. The requestor Region is where a peering request is originated and the acceptor Regions accept the peering request. For more information about this, see Creating and accepting a VPC peering connection in the Amazon VPC documentation.
- VPCs, installed and configured in the acceptor and requester Regions. For steps to create a VPC, see Create the VPC from Get Started with Amazon VPC in the Amazon VPC documentation.
- The VPCs must use the addToTransitGateway tag and true value.
- Security groups and network access control lists (ACLs) for your VPCs, configured according to your requirements. For more information about this, see Security groups for your VPC and Network ACLs in the Amazon VPC documentation.

AWS Regions and limitations

- Only certain AWS Regions support inter-Region peering. For a full list of Regions that support inter-Region peering, see the AWS Transit Gateway FAQs.
- In the attached sample code, the requestor Region is assumed to be us-east-2, and the acceptor Region is assumed to be us-west-2. If you want to configure different Regions, you must edit these values in all Python files. To implement a more complex setup that involves more than two Regions, you can change the Step Function to pass the Regions as a parameter to the Lambda function and run the function for each combination.

Architecture
The diagram shows a workflow with the following steps:

1. The user creates an AWS CloudFormation stack.
2. AWS CloudFormation creates a Step Functions state machine that uses a Lambda function. For more information about this, see Creating a Step Functions state machine that uses Lambda in the AWS Step Functions documentation.
3. Step Functions calls a Lambda function for peering.
4. The Lambda function creates a peering connection between transit gateways.
5. Step Functions calls a Lambda function for route table modifications.
6. The Lambda function modifies the route tables by adding the Classless Inter-Domain Routing (CIDR) block of the VPCs.

**Step Functions workflow**

The diagram shows the following Step Functions workflow:

1. The Step Functions workflow calls the Lambda function for the transit gateway peering.
2. There is a timer call to wait for one minute.
3. The peering status is retrieved and sent to the condition block. The block is responsible for the looping.
4. If the success condition is not met, the workflow is coded to enter the timer stage.
5. If the success condition is met, a Lambda function is called to modify the route tables. After this call, the Step Functions workflow ends.
Tools

- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources.
- **Amazon CloudWatch Logs** – CloudWatch Logs helps you centralize the logs from all of your systems, applications, and AWS services that you use.
- **AWS Identity and Access Management (IAM)** – IAM is a web service for securely controlling access to AWS services.
- **AWS Lambda** – Lambda runs your code on a high-availability compute infrastructure and performs all of the administration of the compute resources.
- **AWS Step Functions** – Step Functions makes it easy to coordinate the components of distributed applications as a series of steps in a visual workflow.

Centralize network connectivity using AWS Transit Gateway

Created by Mydhili Palagummi (AWS)

| Environment: Production | Technologies: Networking | AWS services: AWS Transit Gateway; Amazon VPC |

Summary

This pattern describes the simplest configuration in which AWS Transit Gateway can be used to connect an on-premises network to virtual private clouds (VPCs) in multiple AWS accounts within an AWS Region. Using this setup, you can establish a hybrid network that connects multiple VPC networks in a Region and an on-premises network. This is accomplished by using a transit gateway and a virtual private network (VPN) connection to the on-premises network.

Prerequisites and limitations

Prerequisites

• AWS accounts and AWS Organizations set up
• VPCs in multiple AWS accounts, without overlapping Classless Inter-Domain Routing (CIDR) blocks

Limitations

This pattern does not support the isolation of traffic between certain VPCs or the on-premises network. All the networks attached to the transit gateway will be able to reach each other. To isolate traffic, you need to use custom route tables on the transit gateway. This pattern only connects the VPCs and on-premises network by using a single default transit gateway route table, which is the simplest configuration.

Architecture

Target technology stack

• AWS Transit Gateway
• AWS Site-to-Site VPN
• VPC
• AWS Resource Access Manager (AWS RAM)
Target architecture

Tools

• AWS Transit Gateway – AWS Transit Gateway acts as a cloud router and simplifies network architecture by allowing you to connect Amazon VPCs in multiple AWS accounts and on-premises network to a single gateway.

• AWS Resource Access Manager – AWS Resource Access Manager (AWS RAM) supports the secure sharing of AWS resources with your AWS accounts, organizational units, or your entire organization from AWS Organizations.

Connect to Application Migration Service data and control planes over a private network

Created by Dipin Jain (AWS) and Mike Kuznetsov (AWS)

<table>
<thead>

</table>

Summary

This pattern explains how you can connect to an AWS Application Migration Service (AWS MGN) data plane and control plane on a private, secured network by using interface VPC endpoints.

Application Migration Service is a highly automated lift-and-shift (rehost) solution that simplifies, expedites, and reduces the cost of migrating applications to AWS. It enables companies to rehost a large number of physical, virtual, or cloud servers without compatibility issues, performance disruption, or long cutover windows. Application Migration Service is available from the AWS Management Console. This enables seamless integration with other AWS services, such as AWS CloudTrail, Amazon CloudWatch, and AWS Identity and Access Management (IAM).

You can connect from a source data center to a data plane—that is, to a subnet that serves as a staging area for data replication in the destination VPC—over a private connection by using AWS VPN services, AWS Direct Connect, or VPC peering in Application Migration Service. You can also use interface VPC endpoints powered by AWS PrivateLink to connect to an Application Migration Service control plane over a private network.

Prerequisites and limitations

Prerequisites

- **Staging area subnet** – Before you set up Application Migration Service, create a subnet to be used as a staging area for data replicated from your source servers to AWS (that is, a data plane). You must specify this subnet in the Replication Settings template when you first access the Application Migration Service console. You can override this subnet for specific source servers in the Replication Settings template. Although you can use an existing subnet in your AWS account, we recommend that you create a new, dedicated subnet for this purpose.

- **Network requirements** – The replication servers that are launched by Application Migration Service in your staging area subnet have to be able to send data to the Application Migration Service API endpoint at https://mgn.<region>.amazonaws.com/, where <region> is the code for the AWS Region you are replicating to (for example, https://mgn.us-east-1.amazonaws.com). Amazon Simple Storage Service (Amazon S3) service URLs are required for downloading Application Migration Service software.

  - The AWS Replication Agent installer should have access to the S3 bucket URL of the AWS Region you are using with Application Migration Service.

  - The staging area subnet should have access to Amazon S3.

  - The source servers on which the AWS Replication Agent is installed must be able to send data to the replication servers in the staging area subnet and to the Application Migration Service API endpoint at https://mgn.<region>.amazonaws.com./
The following table lists the required ports.

<table>
<thead>
<tr>
<th>Source</th>
<th>Destination</th>
<th>Port</th>

<td>443 (TCP)</td>
<td>Communication over TCP port 443</td>
</tr>
</tbody>
</table>

**Limitations**

Application Migration Service isn't currently available in all AWS Regions and operating systems.

- **Supported AWS Regions**
- **Supported operating systems**

**Architecture**

The following diagram illustrates the network architecture for a typical migration. For more information about this architecture, see the Application Migration Service documentation and the Application Migration Service service architecture and network architecture video.
The following detailed view shows the configuration of interface VPC endpoints in the staging area VPC to connect Amazon S3 and Application Migration Service.
Tools

- **AWS Application Migration Service** is an AWS service that simplifies, expedites, and reduces the cost of rehosting applications on AWS.
- **Interface VPC endpoints** enable you to connect to services that are powered by AWS PrivateLink without requiring an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC do not require public IP addresses to communicate with resources in the service. Traffic between your VPC and the other service does not leave the Amazon network.

Epics

Create endpoints for Application Migration Service, Amazon EC2, and Amazon S3

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure the interface endpoint for Application Migration Service. | The source data center and staging area VPC connect privately to the Application Migration Service control plane through the interface endpoint that you create in the target staging area VPC. To create the endpoint:  
1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.  
2. In the navigation pane, choose **Endpoints, Create Endpoint**.  
3. For **Service category**, choose AWS services.  
4. For **Service Name**, enter `com.amazonaws.<region>.mgn`. For **Type**, choose Interface.  
5. For **VPC**, select a target staging area VPC to create the endpoint.  
6. For **Subnets**, select the subnets (Availability Zones) in which to create the endpoint network interfaces.  
7. To turn on private DNS for the interface endpoint, in the **Additional settings** section, select Enable DNS Name.  
8. Select a security group that allows ingress from the staging area VPC subnet over TCP 443. | Migration lead |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>9.</td>
<td>Choose <strong>Create endpoint</strong>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For more information, see <a href="#">Interface VPC endpoints</a> in the Amazon VPC documentation.</td>
<td></td>
</tr>
<tr>
<td>Configure the interface endpoint for Amazon EC2.</td>
<td>The staging area VPC connects privately to the Amazon EC2 API through the interface endpoint that you create in the target staging area VPC. To create the endpoint, follow the instructions provided in the previous story.</td>
<td>Migration lead</td>
</tr>
<tr>
<td></td>
<td>• For service name, enter <code>com.amazonaws.&lt;region&gt;.ec2</code>. For <strong>Type</strong>, choose <strong>Interface</strong>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The security group must allow inbound HTTPS traffic from the staging area VPC subnet over port 443.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• In the <strong>Additional settings</strong> section, select <strong>Enable DNS name</strong>.</td>
<td></td>
</tr>
<tr>
<td>Configure the interface endpoint for Amazon S3.</td>
<td>The source data center and staging area VPC connect privately to the Amazon S3 API through the interface endpoint that you create in the target staging area VPC. To create the endpoint, follow the instructions provided in the first story.</td>
<td>Migration lead</td>
</tr>
<tr>
<td></td>
<td>• For <strong>Service Name</strong>, enter <code>com.amazonaws.&lt;region&gt;.s3</code>. For <strong>Type</strong>, choose <strong>Interface</strong>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The VPC security group must allow inbound HTTPS traffic from the staging area VPC subnet over port 443.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• In the <strong>Additional settings</strong> section, clear <strong>Enable DNS name</strong>. Amazon S3 interface endpoints do not support private DNS names.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** You use an interface endpoint because gateway endpoint connections cannot be extended out of a VPC. (For details, see the Amazon VPC documentation.)
Configure the Amazon S3 Gateway endpoint.

During the configuration phase, the replication server has to connect to an S3 bucket to download the AWS Replication Server's software updates. However, Amazon S3 interface endpoints do not support private DNS names, and there is no way to supply an Amazon S3 endpoint DNS name to a replication server.

To mitigate this issue, you create an Amazon S3 gateway endpoint in the VPC that the staging area subnet belongs to, and update the staging subnet's route tables with the relevant routes. For more information, see Create a gateway endpoint in the AWS PrivateLink documentation.

Skills required: Cloud administrator

Configure on-premises DNS to resolve private DNS names for endpoints.

The interface endpoints for Application Migration Service and Amazon EC2 have private DNS names that can be resolved in the VPC. However, you also need to configure on-premises servers to resolve private DNS names for these interface endpoints.

There are multiple ways to configure these servers. In this pattern, we tested this functionality by forwarding on-premises DNS queries to the Amazon Route 53 Resolver inbound endpoint in the staging area VPC. For more information, see Resolving DNS queries between VPCs and your network in the Route 53 documentation.

Skills required: Migration engineer

Connect to the Application Migration Service control plane over a private link

Install AWS Replication Agent by using AWS PrivateLink.

1. Download the AWS Replication Agent to a private S3 bucket in the destination Region.

Skills required: Migration engineer
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.</td>
<td>Log in to the source servers to be migrated. The AWS Replication Agent installer needs network access to the Application Migration Service and Amazon S3 endpoints. Because your on-premises network isn’t open to Application Migration Service and Amazon S3 public endpoints, you must install the Agent with the help of the interface endpoints you created in the previous steps by using AWS PrivateLink.</td>
<td></td>
</tr>
</tbody>
</table>

Here’s an example for Linux:

1. Download the Agent by using the command:

```
wget -O ./aws-replication-installer-init.py \
https://aws-application-migration-service-<aws_region>.bucket.<s3-endpoint-DNS-name>/latest/linux/aws-replication-installer-init.py
```

**Note:** `bucket` is a static keyword that you must add before the Amazon S3 interface endpoint DNS name. For more information, see the Amazon S3 documentation.

For example, if the DNS name of the Amazon S3 interface endpoint is `vpce-009c8b07adb052a11-qgf8q50y.s3.us-west-1.vpce.amazonaws.com` and the AWS Region is `us-west-1`, you would use the command:

```
wget -O ./aws-replication-installer-init.py \\
https://aws-application-migration-service-us-west-1.bucket.vpce-009c8b07adb052a11-qgf8q50y.s3.us-west-1.vpce.amazonaws.com/latest/linux/aws-
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>replication-installer-init.py</td>
<td>2. Install the Agent:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If you selected <strong>Enable DNS name</strong> when you created an interface endpoint for Application Migration Service, run the command:</td>
<td></td>
</tr>
</tbody>
</table>
|                                                                      | sudo python3 aws-replication-installer-init.py \
|                                                                      |   --region <aws_region> \
|                                                                      |   --aws-access-key-id <access-key> \
|                                                                      |   --aws-secret-access-key <secret-key> \
|                                                                      |   --no-prompt \
|                                                                      |   --s3-endpoint <s3-endpoint-DNS-name> |                                                                                 |
|                                                                      | • If you didn't select **Enable DNS name** when you created the interface endpoint for Application Migration Service, run the command: |                                                                                 |
|                                                                      | sudo python3 aws-replication-installer-init.py \
|                                                                      |   --region <aws_region> \
|                                                                      |   --aws-access-key-id <access-key> \
|                                                                      |   --aws-secret-access-key <secret-key> \
|                                                                      |   --no-prompt \
|                                                                      |   --s3-endpoint <s3-endpoint-DNS-name> \ 
|                                                                      |   --endpoint <mgn-endpoint-DNS-name> |                                                                                 |
| For more information, see **AWS Replication Agent installation instructions** in the Application Migration Service documentation. |                                                                                 |                                                                                 |
| After you have established your connection with Application Migration Service and installed the AWS Replication Agent, follow the instructions in the **Application Migration Service** |                                                                                 |                                                                                 |

AWS services: Amazon SNS; AWS CloudFormation; AWS KMS; AWS Lambda; AWS Organizations

Summary

Infoblox Domain Name System (DNS), Dynamic Host Configuration Protocol (DHCP), and IP address management (Infoblox DDI) enables you to centralize and efficiently control a complex hybrid...
Prerequisites and limitations

Prerequisites

- An existing Infoblox appliance or grid, installed on the AWS Cloud, on premises, or both, and configured with an admin user that can administer IPAM and DNS actions. For more information about this, see About admin accounts in the Infoblox documentation.
- An existing DNS authoritative zone that you want to add records on the Infoblox appliance. For more information about this, see Configuring authoritative zones in the Infoblox documentation.
- Two active AWS accounts in AWS Organizations. One account is the hub account and the other account is the spoke account.
- The hub and spoke accounts must be in the same AWS Region.
- The hub account’s VPC must connect to the Infoblox appliance; for example, by using AWS Transit Gateway or VPC peering.
- AWS Serverless Application Model (AWS SAM), locally installed and configured with AWS Cloud9 or AWS CloudShell.
- The Infoblox-Hub.zip and ClientTest.yaml files (attached), downloaded to the local environment that contains AWS SAM.

Limitations

- The AWS CloudFormation custom resource’s service token must be from the same Region where the stack is created. We recommend that you use a hub account in each Region, instead of creating an Amazon Simple Notification Service (Amazon SNS) topic in one Region and calling the Lambda function in another Region.
• Infoblox WAPI version 2.7

Architecture

The following diagrams shows this pattern’s workflow.

The diagram shows the following components for this pattern's solution:

1. AWS CloudFormation custom resources enable you to write custom provisioning logic in templates that AWS CloudFormation runs when you create, update, or delete stacks. When you create a stack, AWS CloudFormation sends a create request to an SNS topic that's monitored by an application running on an EC2 instance.

2. The Amazon SNS notification from the AWS CloudFormation custom resource is encrypted through a specific AWS Key Management Service (AWS KMS) key and access is restricted to accounts in your organization in Organizations. The SNS topic initiates the Lambda resource that calls the Infoblox WAPI API.

3. Amazon SNS invokes the following Lambda functions that take the Infoblox WAPI URL, the username, and password AWS Secrets Manager Amazon Resource Names (ARNs) as environment variables:
   - dnsapi.lambda_handler – Receives the DNSName, DNSType, and DNSValue values from the AWS CloudFormation custom resource and uses these to create DNS A records and CNAMEs.
   - ipaddr.lambda_handler – Receives the VPCCIDR, Type, SubnetPrefix, and Network Name values from the AWS CloudFormation custom resource and uses these to add the network data into the Infoblox IPAM database or provide the custom resource with the next available network that can be used to create new subnets.
   - describeprefixes.lambda_handler – Calls the describe_managed_prefix_lists AWS API by using the "com.amazonaws."+Region+".s3" filter to retrieve the required prefix ID.

   **Important:** These Lambda functions are written in Python and are similar to each other but call different APIs.

4. You can deploy the Infoblox grid as physical, virtual, or cloud-based network appliances. It can be deployed on-premises or as a virtual appliance using a range of hypervisors, including VMware ESXi,
Microsoft Hyper-V, Linux KVM, and Xen. You can also deploy the Infoblox grid on the AWS Cloud with an Amazon Machine Image (AMI).

5. The diagram shows a hybrid solution for the Infoblox grid that provides DNS and IPAM to resources on the AWS Cloud and on premises.

**Technology stack**

- AWS CloudFormation
- IAM
- AWS KMS
- AWS Lambda
- AWS SAM
- AWS Secrets Manager
- Amazon SNS
- Amazon VPC

**Tools**

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

- **AWS KMS** – AWS Key Management Service (AWS KMS) is an encryption and key management service scaled for the cloud. AWS KMS keys and functionality are used by other AWS services, and you can use them to protect data in your own applications that use AWS.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- **AWS Organizations** – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.

- **AWS SAM** – AWS Serverless Application Model (AWS SAM) is an open-source framework that you can use to build serverless applications on AWS. AWS SAM provides you with a template specification to define your serverless application, and a command line interface (CLI) tool.

- **AWS Secrets Manager** – AWS Secrets Manager is a service for credential storage and retrieval. Using Secrets Manager, you can replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
## Code

You can use the ClientTest.yaml sample AWS CloudFormation template (attached) to test the Infoblox hub. You can customize the AWS CloudFormation template to include the custom resources from the following table:

<table>
<thead>
<tr>
<th>Create an A record using the Infoblox spoke custom resource</th>
<th>Return values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>infobloxref – Infoblox references</td>
<td></td>
</tr>
</tbody>
</table>

**Example resource:**

```yaml
ARECORDCustomResource:
  Type: "Custom::InfobloxAPI"
  Properties:
    ServiceToken: !Sub arn:aws:sns:${AWS::Region}:${HubAccountID}:RunInfobloxDNSFunction
    DNSName: 'arecordtest.company.com'
    DNSType: 'ARecord'
    DNSValue: '10.0.0.1'
```

<table>
<thead>
<tr>
<th>Create a CNAME record using the Infoblox spoke custom resource</th>
<th>Return values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>infobloxref – Infoblox references</td>
<td></td>
</tr>
</tbody>
</table>

**Example resource:**

```yaml
CNAMECustomResource:
  Type: "Custom::InfobloxAPI"
  Properties:
    ServiceToken: !Sub arn:aws:sns:${AWS::Region}:${HubAccountID}:RunInfobloxDNSFunction
    DNSName: 'cnametest.company.com'
    DNSType: 'cname'
    DNSValue: 'aws.amazon.com'
```

<table>
<thead>
<tr>
<th>Create a network object using the Infoblox spoke custom resource</th>
<th>Return values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>infobloxref – Infoblox references</td>
<td></td>
</tr>
<tr>
<td>network – Network range (the same as VPCCIDR)</td>
<td></td>
</tr>
</tbody>
</table>

**Example resource:**

```yaml
CreateNetworkCustomResource:
  Type: "Custom::InfobloxAPI"
  Properties:
    ServiceToken: !Sub arn:aws:sns:${AWS::Region}:${HubAccountID}:RunInfoblox
    DNSFunction
    DNSName: 'networktest.company.com'
    DNSType: 'network'
    DNSValue: '1948'
```
Retrieved the next available subnet using the Infoblox spoke custom resource

Example resource:

Subnet1CustomResource:
  Type: 'Custom::InfobloxAPI'
  DependsOn: VPCCustomResource
  Properties:
    ServiceToken: !Sub
      arn:aws:sns:${AWS::Region}:
      ${HubAccountID}:RunInfobloxNextSubnetFunction
      VPCCIDR: !Ref VpcCIDR
    Type: Subnet
      SubnetPrefix: !Ref SubnetPrefix
    NetworkName: My-Subnet

</thead>
<tbody>
<tr>
<td></td>
<td>and location expected for the following story.</td>
<td></td>
</tr>
</tbody>
</table>
## Task
Deploy the AWS SAM template.

### Description
The `sam deploy` command takes the required parameters and saves them into the `samconfig.toml` file, stores the AWS CloudFormation template and Lambda functions in an S3 bucket, and then deploys the AWS CloudFormation template into your hub account.

The following sample code shows how to deploy the AWS SAM template:

```bash
$ sam deploy --guided
```

Configuring SAM deploy

```
Looking for config file [samconfig.toml] : Found
Reading default arguments : Success
Setting default arguments for 'sam deploy'
```

Stack Name: [Infoblox-Hub]:
AWS Region [eu-west-1]:
Parameter InfobloxUsername:
Parameter InfobloxPassword:
Parameter InfobloxIPAddress [xxx.xxx.xx.xxx]:
Parameter AWSOrganisationID [o-xxxxxxxx]:
Parameter VPCID [vpc-xxxxxxxx]:
Parameter VPCCIDR [xxx.xxx.xxx.xxx/16]:
Parameter VPCSubnetID1 [subnet-xxx]:
Parameter VPCSubnetID2 [subnet-xxx]:
Parameter VPCSubnetID3 [subnet-xxx]:
Parameter VPCSubnetID4 []:
#Shows you resources changes to be deployed and require a 'Y' to initiate deploy
Confirm changes before deploy [Y/n]: y
```

### Skills required
Developer, System administrator

---

1952
# Task Description

SAM needs permission to be able to create roles to connect to the resources in your template. Allow SAM CLI IAM role creation [Y/n]: n

Capabilities

['CAPABILITY_NAMED_IAM']:
  Save arguments to configuration file [Y/n]: y
  SAM configuration file [samconfig.toml]:
  SAM configuration environment [default]:

**Important:** You must use the --guided option each time because the Infoblox username and password are not stored in the samconfig.toml file.

## Customize Amazon CloudWatch alerts for AWS Network Firewall

*Created by Jason Owens (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Networking; Security, identity, compliance</td>
</tr>
<tr>
<td>Workload:</td>
<td>Open-source</td>
</tr>
</tbody>
</table>

**AWS services:**

- Amazon CloudWatch Logs
- AWS Network Firewall
- AWS CLI
Summary

The pattern helps you customize the Amazon CloudWatch alerts that are generated by Amazon Web Services (AWS) Network Firewall. You can use predefined rules or create custom rules that determine the message, metadata, and severity of the alerts. You can then act upon these alerts or automate responses by other Amazon services, such as Amazon EventBridge.

In this pattern, you generate Suricata-compatible firewall rules. Suricata is an open-source threat detection engine. You first create simple rules and then test them to confirm that the CloudWatch alerts are generated and logged. Once you have successfully tested the rules, you modify them to define custom messages, metadata, and severities, and you then test once more to confirm the updates.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured on your Linux, macOS, or Windows workstation. For more information, see Installing or updating the latest version of the AWS CLI.
- AWS Network Firewall installed and configured to use CloudWatch Logs. For more information, see Logging network traffic from AWS Network Firewall.
- An Amazon Elastic Compute Cloud (Amazon EC2) instance in a private subnet of a virtual private cloud (VPC) that is protected by Network Firewall.

Product versions

- For version 1 of AWS CLI, use 1.18.180 or later. For version 2 of AWS CLI, use 2.1.2 or later.
- The classification.config file from Suricata version 5.0.2. For a copy of this configuration file, see the Additional information (p. 1964) section.

Architecture

Target technology stack

- Network Firewall
- Amazon CloudWatch Logs

Target architecture
The architecture diagram shows the following workflow:

1. An EC2 instance in a private subnet makes a request by using either curl or Wget.
2. Network Firewall processes the traffic and generates an alert.
3. Network Firewall sends the logged alerts to CloudWatch Logs.

Tools

AWS services

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Network Firewall is a stateful, managed, network firewall and intrusion detection and prevention service for virtual private clouds (VPCs) in the AWS Cloud.

Other tools and services

- curl – curl is an open-source command line tool and library.
- Wget – GNU Wget is a free command line tool.
## Epics

### Create the firewall rules and rule group

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create rules.</strong></td>
<td>1. In a text editor, create a list of rules that you want to add to the firewall. Each rule must be on a separate line. The value in the classtype parameter is from the default Suricata classification configuration file. For the full configuration file contents, see the Additional information section. The following are two examples of rules.</td>
<td>AWS systems administrator, Network administrator</td>
</tr>
<tr>
<td></td>
<td>alert http any any -&gt; any any (content:&quot;badstuff&quot;; classtype:misc-activity; sid:3; rev:1;) alert http any any -&gt; any any (content:&quot;morebadstuff&quot;; classtype:bad-unknown; sid:4; rev:1;)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Save the rules in a file named custom.rules.</td>
<td></td>
</tr>
<tr>
<td><strong>Create the rule group.</strong></td>
<td>In the AWS CLI, enter the following command. This creates the rule group.</td>
<td>AWS systems administrator</td>
</tr>
<tr>
<td></td>
<td># aws network-firewall create-rule-group \ --rule-group-name custom --type STATEFUL \ --capacity 10 --rules file://custom.rules \ --tags Key=environment,Value=development</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The following is an example output. Make note of the RuleGroupArn, which you need in a later step.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>{ &quot;UpdateToken&quot;: &quot;4f998d72-973c-490a-bed2-fc3460547e23&quot;, &quot;RuleGroupResponse&quot;: { &quot;RuleGroupArn&quot;: &quot;arn:aws:network-</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Update the firewall policy</td>
<td></td>
<td>AWS systems administrator</td>
</tr>
<tr>
<td>Get the ARN of the firewall policy.</td>
<td>In the AWS CLI, enter the following command. This returns the Amazon Resource Name (ARN) of the firewall policy. Record the ARN for use later in this pattern.</td>
<td>AWS systems administrator</td>
</tr>
</tbody>
</table>

```bash
# aws network-firewall
describe-firewall \
 --firewall-name aws-network-firewall-anfw \ 
 --query 'Firewall.FirewallPolicyArn'
```

The following is an example ARN that is returned by this command.

```
```

Update the firewall policy. | In a text editor, copy the paste the following code. Replace <RuleGroupArn> with the value you recorded in the previous epic. Save the file as firewall-policy-anfw.json. | AWS systems administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;StatelessDefaultActions&quot;: [</td>
</tr>
<tr>
<td></td>
<td>&quot;aws:forward_to_sfe&quot;</td>
</tr>
<tr>
<td></td>
<td>],</td>
</tr>
<tr>
<td></td>
<td>&quot;StatelessFragmentDefaultActions&quot;: [</td>
</tr>
<tr>
<td></td>
<td>&quot;aws:forward_to_sfe&quot;</td>
</tr>
<tr>
<td></td>
<td>],</td>
</tr>
<tr>
<td></td>
<td>&quot;StatefulRuleGroupReferences&quot;: [</td>
</tr>
<tr>
<td></td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>&quot;ResourceArn&quot;: &quot;&lt;RuleGroupArn&gt;&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>]</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>

Enter the following command in the AWS CLI. This command requires an update token to add the new rules. The token is used to confirm that the policy hasn't changed since you last retrieved it.

```
UPDATE_TOKEN=(`aws network-firewall describe-firewall-policy \     --firewall-policy-name firewall-policy-anfw \     --output text \     --query UpdateToken`)  
aws network-firewall update-firewall-policy \     --update-token $UPDATE_TOKEN \     --firewall-policy-name firewall-policy-anfw \     --firewall-policy file://firewall-policy-anfw.json
```
### Task 1: Confirm the policy updates

**Description:**
(Optional) If you would like to confirm the rules were added and view the policy format, enter the following command in the AWS CLI.

```bash
# aws network-firewall describe-firewall-policy --firewall-policy-name firewall-policy-anfw --query FirewallPolicy
```

The following is an example output.

```
{
    "StatelessDefaultActions": [
        "aws:forward_to_sfe"
    ],
    "StatelessFragmentDefaultActions": [
        "aws:forward_to_sfe"
    ],
    "StatefulRuleGroupReferences": [
        {
        }
    ]
}
```

**Skills required:** AWS systems administrator

### Task 2: Test alert functionality

**Description:**
1. Log in to a test workstation within the firewall subnet.
2. Enter commands that should generate alerts. For example, you can use `wget` or `curl`.

```bash
wget -U "badstuff" http://www.amazon.com -o /dev/null
```

**Skills required:** AWS systems administrator
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Validate that the alerts are logged. | 1. Open the CloudWatch console at [https://console.aws.amazon.com/cloudwatch/](https://console.aws.amazon.com/cloudwatch/)  
2. Navigate to the correct log group and stream. For more information, see [View log data sent to CloudWatch Logs](https://docs.aws.amazon.com/lambda/latest/dg/sending-logs.html) (CloudWatch Logs documentation).  
3. Confirm the logged events are similar to the following examples. The examples show only the relevant portion of the alert.  
**Example 1**
```
"alert": {
  "action": "allowed",
  "signature_id": 3,
  "rev": 1,
  "signature": "",
  "category": "Misc activity",
  "severity": 3
}
```
**Example 2**
```
"alert": {
  "action": "allowed",
  "signature_id": 4,
  "rev": 1,
  "signature": "",
  "category": "Potentially Bad Traffic",
  "severity": 2
}
``` | AWS systems administrator |
# Update the firewall rules and rule group

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Update the firewall rules. | 1. In a text editor, open the `custom.rules` file.  
2. Change the first rule to be similar to the following. This rule must be entered on a single line in the file.                                                                                       | AWS systems administrator              |
|                           | ```                                                                                                                                                                                                        |                                        |
|                           | alert http any any -> any any (msg:"Watch out - Bad Stuff!!"; content:"badstuff"; classstype:misc-activity; priority:2; sid:3; rev:2; metadata:custom-field-2 Danger!, custom-field More Info;) |                                        |
|                           | This makes the following changes to the rule:  
  • Adds a `msg` (Suricata website) string that provides text information about the signature or alert. In the generated alert, this maps to the signature.  
  • Adjusts the default `priority` (Suricata website) of `misc-activity` from 3 to 2. For the default values of the various `classestypes`, see the Additional information (p. 1964) section.  
  • Adds custom `metadata` (Suricata website) to the alert. This is additional information that that is added to the signature. It is recommended that you use key-value pairs.  
  • Changes the `rev` (Suricata website) from 1 to 2. This represents the version of the signature. |                                        |
<p>| Update the rule group.    | In the AWS CLI, run the following commands. Use the ARN of your firewall policy. These commands get an update token and update the rule group with the rule changes.                                                                           | AWS systems administrator              |</p>
<table>
<thead>

## Additional information

The following is the classification configuration file from Suricata 5.0.2. These classifications are used when creating the firewall rules.

```plaintext
# config classification: shortname, short description, priority

config classification: not-suspicious, Not Suspicious Traffic, 3
config classification: unknown, Unknown Traffic, 3
config classification: bad-unknown, Potentially Bad Traffic, 2
config classification: attempted-recon, Attempted Information Leak, 2
config classification: successful-recon-limited, Information Leak, 2
config classification: successful-recon-largescale, Large Scale Information Leak, 2
config classification: attempted-dos, Attempted Denial of Service, 2
config classification: successful-dos, Denial of Service, 2
config classification: attempted-user, Attempted User Privilege Gain, 1
config classification: unsuccessful-user, Unsuccessful User Privilege Gain, 1
config classification: successful-user, Successful User Privilege Gain, 1
config classification: attempted-admin, Attempted Administrator Privilege Gain, 1
config classification: successful-admin, Successful Administrator Privilege Gain, 1

# NEW CLASSIFICATIONS

config classification: rpc-portmap-decode, Decode of an RPC Query, 2
config classification: shellcode-detect, Executable code was detected, 1
config classification: string-detect, A suspicious string was detected, 3
config classification: suspicious-filename-detect, A suspicious filename was detected, 2
config classification: suspicious-login, An attempted login using a suspicious username was detected, 2
config classification: system-call-detect, A system call was detected, 2
config classification: tcp-connection, A TCP connection was detected, 4
config classification: trojan-activity, A Network Trojan was detected, 1
config classification: unusual-client-port-connection, A client was using an unusual port, 2
config classification: network-scan, Detection of a Network Scan, 3
config classification: denial-of-service, Detection of a Denial of Service Attack, 2
config classification: non-standard-protocol, Detection of a non-standard protocol or event, 2
config classification: protocol-command-decode, Generic Protocol Command Decode, 3
config classification: web-application-activity, Access to a potentially vulnerable web application, 2
config classification: web-application-attack, Web Application Attack, 1
config classification: misc-activity, Misc activity, 3
config classification: misc-attack, Misc Attack, 2
config classification: icmp-event, Generic ICMP event, 3
config classification: inappropriate-content, Inappropriate Content was Detected, 1
config classification: policy-violation, Potential Corporate Privacy Violation, 1
config classification: default-login-attempt, Attempt to login by a default username and password, 2

# Update

config classification: targeted-activity, Targeted Malicious Activity was Detected, 1
config classification: exploit-kit, Exploit Kit Activity Detected, 1
config classification: external-ip-check, Device Retrieving External IP Address Detected, 2
config classification: domain-c2, Domain Observed Used for C2 Detected, 1
config classification: pup-activity, Possibly Unwanted Program Detected, 2
config classification: coin-mining, Crypto Currency Mining Activity Detected, 2
config classification: command-and-control, Malware Command and Control Activity Detected, 1

Migrate DNS records in bulk to an Amazon Route 53 private hosted zone

Created by Ram Kandaswamy (AWS)

| Environment: Production | Technologies: Networking; Cloud-native; DevOps; Infrastructure | AWS services: AWS Cloud9; Amazon Route 53; Amazon S3 |

Summary

Network engineers and cloud administrators need an efficient and simple way to add Domain Name System (DNS) records to private hosted zones in Amazon Route 53. Using a manual approach to copy entries from a Microsoft Excel worksheet to appropriate locations in the Route 53 console is tedious and error prone. This pattern describes an automated approach that reduces the time and effort required to add multiple records. It also provides a repeatable set of steps for multiple hosted zone creation.

This pattern uses the AWS Cloud9 integrated development environment (IDE) for development and testing, and Amazon Simple Storage Service (Amazon S3) to store records. To work with data efficiently, the pattern uses the JSON format because of its simplicity and its ability to support a Python dictionary (dict data type).

Note: If you can generate a zone file from your system, consider using the Route 53 import feature instead.

Prerequisites and limitations

Prerequisites

- An Excel worksheet that contains private hosted zone records
- Familiarity with different types of DNS records such as A record, Name Authority Pointer (NAPTR) record, and SRV record (see Supported DNS record types)
- Familiarity with the Python language and its libraries

Limitations

- The pattern doesn’t provide extensive coverage for all use case scenarios. For example, the change_resource_record_sets call doesn’t use all the available properties of the API.
- In the Excel worksheet, the value in each row is assumed to be unique. Multiple values for each fully qualified domain name (FQDN) are expected to appear in the same row. If that is not true, you should modify the code provided in this pattern to perform the necessary concatenation.
- The pattern uses the AWS SDK for Python (Boto3) to call the Route 53 service directly. You can enhance the code to use an AWS CloudFormation wrapper for the create_stack and update_stack commands, and use the JSON values to populate template resources.

Architecture

Technology stack

- Route 53 private hosted zones for routing traffic
• AWS Cloud9 IDE for development and testing
• Amazon S3 for storing the output JSON file

The workflow consists of these steps, as illustrated in the previous diagram and discussed in the Epics section:

1. Upload an Excel worksheet that has the record set information to an S3 bucket.
2. Create and run a Python script that converts the Excel data to JSON format.
3. Read the records from the S3 bucket and clean the data.
4. Create record sets in your private hosted zone.

Tools

• Route 53 – Amazon Route 53 is a highly available and scalable DNS web service that handles domain registration, DNS routing, and health checking.
• AWS Cloud9 – AWS Cloud9 is an IDE that offers a rich code editing experience with support for several programming languages and runtime debuggers, and a built-in terminal. It contains a collection of tools that you use to code, build, run, test, and debug software, and helps you release software to the cloud.
• Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

**Modify HTTP headers when you migrate from F5 to an Application Load Balancer on AWS**
Summary

When you migrate an application that uses an F5 Load balancer to Amazon Web Services (AWS) and want to use an Application Load Balancer on AWS, migrating F5 rules for header modifications is a common problem. An Application Load Balancer doesn't support header modifications, but you can use Amazon CloudFront as a content delivery network (CDN) and Lambda@Edge to modify headers.

This pattern describes the required integrations and provides sample code for header modification by using AWS CloudFront and Lambda@Edge.

Prerequisites and limitations

Prerequisites

- An on-premises application that uses an F5 load balancer with a configuration that replaces the HTTP header value by using if, else. For more information about this configuration, see HTTP::header in the F5 product documentation.

Limitations

- This pattern applies to F5 load balancer header customization. For other third-party load balancers, please check the load balancer documentation for support information.
- The Lambda functions that you use for Lambda@Edge must be in the US East (N. Virginia) Region.

Architecture

The following diagram shows the architecture on AWS, including the integration flow between the CDN and other AWS components.
**Tools**

**AWS services**

- **Application Load Balancer** – An Application Load Balancer is an AWS fully managed load balancing service that functions at the seventh layer of the Open Systems Interconnection (OSI) model. It balances traffic across multiple targets and supports advanced routing requests based on HTTP headers and methods, query strings, and host-based or path-based routing.

- **Amazon CloudFront** – Amazon CloudFront is a web service that speeds up the distribution of your static and dynamic web content, such as .html, .css, .js, and image files, to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations for lower latency and improved performance.

- **Lambda@Edge** – Lambda@Edge is an extension of AWS Lambda that lets you run functions to customize the content that CloudFront delivers. You can author functions in the US East (N. Virginia) Region, and then associate the function with a CloudFront distribution to automatically replicate your code around the world, without provisioning or managing servers. This reduces latency and improves the user experience.

**Code**

The following sample code provides a blueprint for modifying CloudFront response headers. Follow the instructions in the *Epics* section to deploy the code.

```javascript
exports.handler = async (event, context) => {
    const response = event.Records[0].cf.response;
    const headers = response.headers;

    const headerNameSrc = 'content-security-policy';
    const headerNameValue = '*.xyz.com';

    if (headers[headerNameSrc.toLowerCase()]) {
        headers[headerNameSrc.toLowerCase()] = [{
            key: headerNameSrc,
            value: headerNameValue,
        }]
        console.log(`Response header 
```

Create a CDN distribution

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a CloudFront web distribution.</td>
<td>In this step, you create a CloudFront distribution to tell CloudFront where you want content to be delivered from, and the details about how to track and manage content delivery. To create a distribution by using the console, sign in to the AWS Management Console, open the CloudFront console, and then follow the steps in the CloudFront documentation.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

Create and deploy the Lambda@Edge function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create and deploy a Lambda@Edge function.</td>
<td>You can create a Lambda@Edge function by using a blueprint for modifying CloudFront response headers. (Other blueprints are available for different use cases; for more information, see Lambda@Edge example functions in the CloudFront documentation.) To create a Lambda@Edge function: 1. Sign in to the AWS Management Console and open the AWS Lambda console at <a href="https://console.aws.amazon.com/lambda/">https://console.aws.amazon.com/lambda/</a>. 2. Make sure that you’re in the US East (N. Virginia) Region. CloudFront blueprints are available only in this Region.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
3. Choose **Create function**.
4. Choose **Use a blueprint**, and then enter `cloudfront` in the **Blueprints** search field.
5. Choose the **cloudfront-modify-response-header** blueprint, and then choose **Configure**.
6. On the **Basic information** page, enter the following information:
   a. Enter a function name.
   b. For **Execution role**, choose **Create a new role from AWS policy templates**.
   c. Associate the required AWS Identity and Access Management (IAM) role name.
7. Choose **Create function**.
8. In the **Designer** section of the page, choose your function name.
9. In the **Function code** section, replace the template code with the sample code provided previously in this pattern, in the **Code** section.
10. In the sample code, replace `xyz.com` with your domain name.
11. Choose **Save**.

**Deploy the Lambda@Edge function.**

Follow the instructions in step 4 of the **Tutorial: Creating a simple Lambda@Edge function** in the Amazon CloudFront documentation to configure the CloudFront trigger and deploy the function.

**AWS administrator**

Privately access a central AWS service endpoint from multiple VPCs

AWS services: AWS RAM; Amazon Route 53; Amazon VPC; AWS Transit Gateway

Summary

Security and compliance requirements for your environment might specify that traffic to Amazon Web Services (AWS) services or endpoints must not traverse the public internet. This pattern is a solution that is designed for a hub-and-spoke topology, where a central hub VPC is connected to multiple, distributed spoke VPCs. In this solution, you use AWS PrivateLink to create an interface VPC endpoint for the AWS service in the hub account. Then, you use transit gateways and a distributed Domain Name System (DNS) rule to resolve requests to the private IP address of the endpoint, across the connected VPCs.

This pattern describes how to use AWS Transit Gateway, an inbound Amazon Route 53 Resolver endpoint, and a shared Route 53 forwarding rule in order to resolve the DNS queries from the resources in connected VPCs. You create the endpoint, transit gateway, Resolver, and forwarding rule in the hub account. Then, you use AWS Resource Access Manager (AWS RAM) to share the transit gateway and the forwarding rule with the spoke VPCs. The AWS CloudFormation templates provided help you deploy and configure the resources in the hub VPC and spoke VPCs.

Prerequisites and limitations

Prerequisites

- A hub account and one or more spoke accounts, managed in the same organization in AWS Organizations. For more information, see Creating and managing an organization.
- AWS Resource Access Manager (AWS RAM) is configured as a trusted service in AWS Organizations. For more information, see Using AWS Organizations with other AWS services.
- DNS resolution must be enabled in the hub and spoke VPCs. For more information, see DNS attributes for your VPC (Amazon Virtual Private Cloud documentation).

Limitations

- This pattern connects hub and spoke accounts in the same AWS Region. For multi-Region deployments, you must repeat this pattern for each Region.
- The AWS service must integrate with PrivateLink as an interface VPC endpoint. For a complete list, see AWS services that integrate with AWS PrivateLink (PrivateLink documentation).

Architecture

Target technology stack
- A hub VPC in the hub AWS account
- One or more spoke VPCs in a spoke AWS account
- One or more interface VPC endpoints in the hub account
- Inbound and outbound Route 53 Resolvers in the hub account
- A Route 53 Resolver forwarding rule deployed in the hub account and shared with the spoke account
- A transit gateway deployed in the hub account and shared with the spoke account
- AWS Transit Gateway connecting the hub and spoke VPCs

**Target architecture**

The following image shows a sample architecture for this solution. In this architecture, the Route 53 Resolver forwarding rule in the hub account has the following relationship with the other architecture components:

1. The forwarding rule is shared with the spoke VPC by using AWS RAM.
2. The forwarding rule is associated with the outbound Resolver in the hub VPC.
3. The forwarding rule targets the inbound Resolver in the hub VPC.

The following image shows the flow of traffic through the sample architecture:

1. A resource, such as an Amazon Elastic Compute Cloud (Amazon EC2) instance, in the spoke VPC makes a DNS request to `<service>.<region>.amazonaws.com`. The request is received by the spoke Amazon DNS Resolver.
2. The Route 53 forwarding rule, which is shared from the hub account and associated to the spoke VPC, intercepts the request.
3. In the hub VPC, the outbound Resolver uses the forwarding rule to forward the request to the inbound Resolver.

4. The inbound Resolver uses the hub VPC Amazon DNS Resolver to resolve the IP address for `<service>..<region>.amazonaws.com` to the private IP address of a VPC endpoint. If no VPC endpoint is present, it resolves to the public IP address.

Tools

AWS tools and services

- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Resource Access Manager (AWS RAM)** helps you securely share your resources across AWS accounts to reduce operational overhead and provide visibility and auditability.
- **Amazon Route 53** is a highly available and scalable Domain Name System (DNS) web service.
- **AWS Systems Manager** helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.
- **AWS Transit Gateway** is a central hub that connects VPCs and on-premises networks.
- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
Other tools and services

- `nslookup` is a command-line tool used to query DNS records. In this pattern, you use this tool to test the solution.

Code repository

The code for this pattern is available on GitHub, in the `vpc-endpoint-sharing` repository. This pattern provides two AWS CloudFormation templates:

- A template for deploying the following resources in the hub account:
  - rSecurityGroupEndpoints – The security group that controls access to the VPC endpoint.
  - rSecurityGroupResolvers – The security group that controls access to the Route 53 Resolver.
  - rKMSEndpoint, rSSMMessagesEndpoint, rSSMEndpoint, and rEC2MessagesEndpoint – Example interface VPC endpoints in the hub account. Customize these endpoints for your use case.
  - rInboundResolver – A Route 53 Resolver that resolves DNS queries against the hub Amazon DNS Resolver.
  - rOutboundResolver – An outbound Route 53 Resolver that forwards queries to the inbound Resolver.
  - rAWSApiResolverRule – The Route 53 Resolver forwarding rule that is shared with all spoke VPCs.
  - rRamShareAWSResolverRule – The AWS RAM share that allows the spoke VPCs to use the rAWSApiResolverRule forwarding rule.
  - *rVPC – The hub VPC, used to model the shared services.
  - *rSubnet1 – A private subnet used to house the hub resources.
  - *rRouteTable1 – The route table for the hub VPC.
  - *rRouteTableAssociation1 – For the rRouteTable1 route table in the hub VPC, the association for the private subnet.
  - *rRouteSpoke – The route from the hub VPC to the spoke VPC.
  - *rTgw – The transit gateway that is shared with all spoke VPCs.
  - *rTgwAttach – The attachment that allows the hub VPC to route traffic to the rTgw transit gateway.
  - *rTgwShare – The AWS RAM share that allows the spoke accounts to use the rTgw transit gateway.
- A template for deploying the following resources in the spoke accounts:
  - rAWSApiResolverRuleAssociation – An association that allows the spoke VPC to use the shared forwarding rule in the hub account.
  - *rVPC – The spoke VPC.
  - *rSubnet1, rSubnet2, rSubnet3 – A subnet for each Availability Zone, used to house the spoke private resources.
  - *rTgwAttach – The attachment that allows the spoke VPC to route traffic to the rTgw transit gateway.
  - *rRouteTable1 – The route table for the spoke VPC.
  - *rRouteEndpoints – The route from the resources in the spoke VPC to the transit gateway.
  - *rRouteTableAssociation1/2/3 – For the rRouteTable1 route table in the spoke VPC, the associations for the private subnets.
  - *rInstanceRole – The IAM role used to test the solution.
  - *rInstancePolicy – The IAM policy used to test the solution.
  - *rInstanceSg – The security group used to test the solution.
  - *rInstanceProfile – The IAM instance profile used to test the solution.
* rInstance – An EC2 instance preconfigured for access through AWS Systems Manager. Use this instance to test the solution.

* These resources support the sample architecture and might not be required when implementing this pattern in an existing landing zone.

</thead>
<tbody>
<tr>
<td></td>
<td>values for the parameters in the template. For more information, see [Creating a stack](CloudFormation documentation).</td>
<td>Cloud architect, Network administrator</td>
</tr>
</tbody>
</table>

**Deploy the spoke resources.**

Using the `spoke.yml` template, create a CloudFormation stack. When prompted, provide values for the parameters in the template. For more information, see [Creating a stack](CloudFormation documentation).

---

### Test the solution

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test private DNS queries to the AWS service. | 1. Connect to the Instance EC2 instance by using Session Manager, a capability of AWS Systems Manager. For more information, see [Connect to your Linux instance using Session Manager](Amazon EC2 documentation).  
2. For an AWS service that has a VPC endpoint in the hub account, use `nslookup` to confirm that the private IP addresses for the inbound Route 53 Resolver are returned.  
The following is an example of using `nslookup` to reach an Amazon Systems Manager endpoint.  
```
nslookup ssm.<region>.amazonaws.com
```
3. In the AWS Command Line Interface (AWS CLI), enter a command that can help you confirm that the changes did not affect the service functionality. For a list of commands, see [AWS CLI Command Reference]().  
For example, the following command should return a list | Network administrator |
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test public DNS queries to an AWS service.</td>
<td>Network administrator</td>
</tr>
</tbody>
</table>

1. For an AWS service that does **not** have a VPC endpoint in the hub account, use `nslookup` to confirm that the public IP addresses are returned. The following is an example of using `nslookup` to reach an Amazon Simple Notification Service (Amazon SNS) endpoint.

   ```bash
   nslookup sns.<region>.amazonaws.com
   ```

2. In the AWS CLI, enter a command that can help you confirm that the changes did not affect the service functionality. For a list of commands, see [AWS CLI Command Reference](#).

   For example, if any Amazon SNS topics are present in the hub account, the following command should return a list of topics.

   ```bash
   aws sns list-topics
   ```

### Tag Transit Gateway attachments automatically using AWS Organizations

*Created by Richard Milner-Watts (AWS), Haris Bin Ayub, and John Capps (AWS)*
Summary

On Amazon Web Services (AWS), you can use AWS Resource Access Manager to share AWS Transit Gateway across AWS account boundaries. When you create Transit Gateway attachments across account boundaries, however, the attachments are created without a Name tag. That can make identifying attachments time consuming.

This solution provides an automated mechanism to gather information about each Transit Gateway attachment for accounts within an organization that is managed by AWS Organizations. The process includes looking up the Classless Inter-Domain Routing (CIDR) range from the Transit Gateway route table. The solution then applies a Name tag in the form of `<CIDR-range>-<AccountName>` to the attachment within the account that holds the transit gateway.

This solution can be used alongside a solution such as the Serverless Transit Network Orchestrator from the AWS Solutions Library. Serverless Transit Network Orchestrator enables the automated creation of Transit Gateway attachments at scale.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- An AWS Organizations organization that contains all related accounts
- Access to the organization management account, under the organization’s root, to create the required AWS Identity and Access Management (IAM) role
- A Shared Networking member account containing one or more transit gateways that are shared with the organization and have attachments

**Architecture**

The following screenshot of the AWS Management Console shows examples of Transit Gateway attachments with no associated Name tag and two Transit Gateway attachments with Name tags generated by this solution. The structure of the generated Name tag is `<CIDR-range>-<AccountName>`.

---

**Code repository:**

- Transit Gateway Attachment Tagger

**Environment:** Production

**Technologies:** Networking; Infrastructure; Management & governance; Operations

**AWS services:** AWS Step Functions; AWS Transit Gateway; Amazon VPC; AWS Lambda
This solution uses **AWS CloudFormation** to deploy an **AWS Step Functions** workflow that manages the creation of Transit Gateway Name tags across all configured Regions. The workflow invokes **AWS Lambda** functions, which perform the underlying tasks.

After the solution has obtained the account names from AWS Organizations, the Step Functions state machine gets all Transit Gateway attachment IDs. These are processed in parallel by AWS Region. This processing includes looking up the CIDR range for each attachment. The CIDR range is obtained by searching the Transit Gateway route tables within the Region for a matching Transit Gateway attachment ID. If all the required information is available, the solution applies a Name tag to the attachment. The solution will not overwrite any existing Name tags.

The solution runs on a schedule controlled by an **Amazon EventBridge** event. The event initiates the solution each day at 6:00 AM UTC.

**Target technology stack**

- Amazon EventBridge
- AWS Lambda
- AWS Organizations
- AWS Transit Gateway
- Amazon Virtual Private Cloud (Amazon VPC)
- AWS X-Ray

**Target architecture**

The solution architecture and workflow are shown in the following diagram.
1. The scheduled event initiates the rule.
2. The EventBridge rule starts the Step Functions state machine.
3. The state machine invokes the `tgw-tagger-organizations-account-query` Lambda function.
4. The `tgw-tagger-organizations-account-query` Lambda function assumes the role in the organization management account.
5. The `tgw-tagger-organizations-account-query` Lambda function calls the Organizations API to return AWS account metadata.
6. The state machine invokes the `tgw-tagger-attachment-query` Lambda function.
7. For each Region, in parallel, the state machine invokes `tgw-tagger-rtb-query` Lambda function to read the CIDR range for each attachment.
8. For each Region, in parallel, the state machine invokes `tgw-tagger-attachment-tagger` Lambda function.
9. Name tags are created for Transit Gateway attachments in the Shared Networking account.

**Automation and scale**

The solution processes each Region in parallel to reduce the total duration of the run.

**Tools**

**AWS services**

- **AWS CloudFormation** – AWS CloudFormation provides a way to model a collection of related AWS and third-party resources, provision them quickly and consistently, and manage them throughout their lifecycles, by treating infrastructure as code.

- **Amazon EventBridge** – Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge receives an event, an indicator of a change in environment, and applies a rule to route the event to a target. Rules match events to targets based on either the structure of the event, called an event pattern, or on a schedule.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests each day to thousands each second. You pay only for the compute time that you consume. There is no charge when your code is not running.

- **AWS Organizations** – AWS Organizations helps you centrally manage and govern your environment as you grow and scale your AWS resources. Using AWS Organizations, you can programmatically create new AWS accounts and allocate resources, group accounts to organize your workflows, apply policies to accounts or groups for governance, and simplify billing by using a single payment method for all of your accounts.

- **AWS Step Functions** – AWS Step Functions is a low-code visual workflow service used to orchestrate AWS services, automate business processes, and build serverless applications. Workflows manage failures, retries, parallelization, service integrations, and observability so developers can focus on higher-value business logic.

- **AWS Transit Gateway** – AWS Transit Gateway connects VPCs and on-premises networks through a central hub. This simplifies your network and puts an end to complex peering relationships. It acts as a cloud router, so that each new connection is made only one time.

- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) is a service for launching AWS resources in a logically isolated virtual network that you define.

- **AWS X-Ray** – AWS X-Ray collects data about requests that your application serves, and provides tools that you can use to view, filter, and gain insights into that data to identify issues and opportunities for optimization.

**Code**

The source code for this solution is available in the [Transit Gateway Attachment Tagger](https://github.com) GitHub repository. The repository includes the following files:

- `tgw-attachment-tagger-main-stack.yaml` creates all the resources to support this solution within the Shared Networking account.

- `tgw-attachment-tagger-organizations-stack.yaml` creates a role in the management account of the organization.

### Verify that ELB load balancers require TLS termination

*Created by Priyanka Chaudhary (AWS)*

**Environment:** Production  
**Technologies:** Networking; Security, identity, compliance  
**AWS services:** Amazon CloudWatch Events; Elastic Load Balancing (ELB); AWS Lambda
Summary

On the Amazon Web Services (AWS) Cloud, Elastic Load Balancing (ELB) automatically distributes incoming application traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, IP addresses, and AWS Lambda functions. The load balancers use listeners to define the ports and protocols that the load balancer uses to accept traffic from users. Application Load Balancers make routing decisions at the application layer and use the HTTP/HTTPS protocols. Classic Load Balancers make routing decisions at either the transport layer, by using TCP or Secure Sockets Layer (SSL) protocols, or at the application layer, by using HTTP/HTTPS.

This pattern provides a security control that examines multiple event types for Application Load Balancers and Classic Load Balancers. When the function is invoked, AWS Lambda inspects the event and ensures that the load balancer is compliant.

The function initiates an Amazon CloudWatch Events event on the following API calls: CreateLoadBalancer, CreateLoadBalancerListeners, DeleteLoadBalancerListeners, CreateLoadBalancerPolicy, SetLoadBalancerPoliciesOfListener, CreateListener, DeleteListener, and ModifyListener. When the event detects one of these APIs, it calls AWS Lambda, which runs a Python script. The Python script evaluates to see if the listener contains an SSL certificate, and if the policy that is applied is using Transport Layer Security (TLS). If the SSL policy is determined to be anything other than TLS, the function sends an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information.

Prerequisites and limitations

Prerequisites

- An active AWS account

Limitations

- This security control does not check for existing load balancers, unless an update is made to the load balancer listeners.
- This security control is regional. You must deploy it in each AWS Region you want to monitor.

Architecture

Target architecture

Automation and scale
If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually.

- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

This pattern includes the following attachments:

- **ELBRequirestlstermination.zip** – The Lambda code for the security control.
- **ELBRequirestlstermination.yml** – The CloudFormation template that sets up the event and Lambda function.

Epics

Set up the S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define the S3 bucket.</td>
<td>On the Amazon S3 console, choose or create an S3 bucket to host the Lambda code .zip file. This S3 bucket must be in the same AWS Region as the load balancer that you want to evaluate. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Upload the Lambda code</td>
<td>Upload the Lambda code (ELBRequirestlstermination.zip)</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
### Deploy the CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch the AWS CloudFormation template.</td>
<td>Open the AWS CloudFormation console in the same AWS Region as your S3 bucket and deploy the attached template ELBRequertStartTermination.yml. For more information about deploying AWS CloudFormation templates, see Creating a stack on the AWS CloudFormation console in the CloudFormation documentation.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
| Complete the parameters in the template. | When you launch the template, you'll be prompted for the following information:  
  - **S3 bucket**: Specify the bucket that you created or selected in the first epic. This is where you uploaded the attached Lambda code (ELBRequertStartTermination.zip file).  
  - **S3 key**: Specify the location of the Lambda .zip file in your S3 bucket (for example, ELBRequertStartTermination.zip or controls/ELBRequertStartTermination.zip). Do not include leading slashes.  
  - **Notification email**: Provide an active email address where you want to receive Amazon SNS notifications.  
  - **Lambda logging level**: Specify the logging level and frequency for the Lambda function. Use **Info** to log detailed informational messages on progress, **Error** for error events that would still allow the deployment to continue, and **Warning** for potentially harmful situations. | Cloud architect |
Confirm the subscription

<td>Microsoft</td>
</tr>
</tbody>
</table>

AWS services: Amazon EC2

Summary

After you migrate Microsoft SQL Server running on Windows Server 2008 R2, 2012, or 2012 R2 to Amazon Elastic Compute Cloud (Amazon EC2) instances on the Amazon Web Services (AWS) Cloud, the connection to SQL Server fails and the following errors appear:

- [Microsoft][ODBC SQL Server Driver][DBNETLIB] General Network error
- ERROR [08S01] [Microsoft][SQL Native Client]Communication link failure. System.Data.SqlClient.SqlException: A transport-level error has occurred when sending the request to the server. (provider: TCP Provider, error: 0 - An existing connection was forcibly closed by the remote host.)
- TCP Provider: The semaphore timeout period has expired

This pattern describes how you can resolve these errors by turning off the Windows Scalable Networking Pack (SNP) features at the operating system (OS) and network interface level for SQL Server running on Windows Server 2008 R2, 2012, or 2012 R2.

Prerequisites and limitations

Prerequisites

- Administrator privileges for Windows Server.
- If you used AWS Application Migration Service as your migration tool, you require one of the following Windows Server versions:
  - Windows Server 2008 R2 Service Pack 1, 2012, or 2012 R2
If you used CloudEndure Migration as your migration tool, you require one of the following Windows Server versions:

**Tools**

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- **Windows Server** – Windows Server is a platform for building an infrastructure of connected applications, networks, and web services.

**Epics**

**Turn off SNP features at the OS and elastic network interface levels**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Turn off SNP features at the OS level. | 1. Sign in to Windows Server and open a command prompt as an administrator.  
2. Run the `netsh int tcp show global` command.  
3. In the output, check if either Receive-Side Scaling or Chimney Offload is in enabled mode. If either of them is enabled, run the following commands:  
- `netsh int tcp set global chimney=disabled`  
- `netsh int tcp set global rss=disabled` | AWS administrator, AWS systems administrator, Migration engineer, Cloud administrator |
| Turn off SNP features at the elastic network interface level. | 1. Choose **Start**, enter `ncpa.cpl`, and then press **Enter**.  
2. Right-click **Elastic Network Adapter**.  
3. In the popup menu, choose **Properties**.  
4. In the **Ethernet Adapter Properties** window, choose **Configure**.  
5. In the **Amazon Elastic Network Adapter Properties** popup window, choose the **Advanced** tab.  
6. In the **Property** section, turn off all offloads and RSS. | AWS administrator, Cloud administrator, AWS systems administrator |

Automatically create an RFC in AMS using Python

*Created by Gnanasekaran Kailasam (AWS)*

**Environment:** Production  
**Technologies:** Operations; Cloud-native  
**AWS services:** AWS Managed Services

**Summary**

AWS Managed Services (AMS) helps you to operate your cloud-based infrastructure more efficiently and securely by providing ongoing management of your Amazon Web Services (AWS) infrastructure. To make a change to your managed environment, you need to create and submit a new request for change (RFC) that includes a change type (CT) ID for a particular operation or action.

However, manually creating an RFC can take around five minutes and teams in your organization might need to submit multiple RFCs every day. This pattern helps you to automate the RFC creation process, reduce the creation time for each RFC, and eliminate manual errors.

This pattern describes how to use Python code to automatically create the Stop EC2 instance RFC that stops Amazon Elastic Compute Cloud (Amazon EC2) instances in your AMS account. You can then apply this pattern's approach and the Python automation to other RFC types.

**Prerequisites and limitations**

**Prerequisites**
- An AMS Advanced account. For more information about this, see AMS operations plans in the AWS Managed Services documentation.
- At least one existing EC2 instance in your AMS account.
- An understanding of how to create and submit RFCs in AMS.
- Familiarity with Python.

**Limitations**
You can only use RFCs for changes in your AMS account. Your AWS account uses different processes for similar changes.

Architecture

Technology stack

- AMS
- AWS Command Line Interface (AWS CLI)
- AWS SDK for Python (Boto3)
- Python and its required packages (JSON and Boto3)

Automation and scale

This pattern provides sample code to automate the Stop EC2 instance RFC, but you can use this pattern's sample code and approach for other RFCs.

Tools

- AWS Managed Services – AMS helps you to operate your AWS infrastructure more efficiently and securely.
- AWS CLI – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. In AMS, the change management API provides operations to create and manage RFCs.
- AWS SDK for Python (Boto3) – SDK for Python makes it easy to integrate your Python application, library, or script with AWS services.

Code

The AMS Stop EC2 Instance.zip file (attached) contains the Python code for creating a Stop EC2 instance RFC. You can also configure this code to submit a single RFC for multiple EC2 instances.

Epics

Create an AWS Cloud9 IDE that uses Amazon EBS volumes with default encryption

*Created by Janardhan Malyala (AWS)*

Environment: Production  
Technologies: Operations  
Workload: All other workloads

AWS services: AWS Cloud9; AWS KMS

Summary

You can use encryption by default to enforce the encryption of your Amazon Elastic Block Store (Amazon EBS) volumes and snapshot copies on the Amazon Web Services (AWS) Cloud.

You can create an AWS Cloud9 integrated development environment (IDE) that uses EBS volumes encrypted by default. However, the AWS Identity and Access Management (IAM) service-linked role for
AWS Cloud9 requires access to the AWS Key Management Service (AWS KMS) key for these EBS volumes. If access is not provided, the AWS Cloud9 IDE might fail to launch and debugging might be difficult.

This pattern provides the steps to add the service-linked role for AWS Cloud9 to the AWS KMS key that is used by your EBS volumes. The setup described by this pattern helps you successfully create and launch an IDE that uses EBS volumes with encryption by default.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- Default encryption turned on for EBS volumes. For more information about encryption by default, see Amazon EBS encryption in the Amazon Elastic Compute Cloud (Amazon EC2) documentation.
- An existing customer managed KMS key for encrypting your EBS volumes.

**Architecture**

![Architecture Diagram]

**Technology stack**

- AWS Cloud9
- IAM
- AWS KMS
Tools

- **AWS Cloud9** – AWS Cloud9 is a cloud-based IDE that you use to write, run, and debug code.
- **Amazon EBS** – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances.
- **AWS KMS** – AWS Key Management Service (AWS KMS) is an encryption and key management service.
- **AWS Identity and Access Management (IAM)** – IAM is a web service that helps you securely control access to AWS resources.

Epics

Find the default encryption key value

<table>

```
Find AWS resources based on their creation date by using AWS Config advanced queries

*Created by Inna Saman (AWS)*

**Environment:** Production  
**Technologies:** Operations; Security, identity, compliance  
**AWS services:** AWS Config; Amazon EBS; Amazon EC2; Amazon S3; AWS Lambda

**Summary**

This pattern shows how to find AWS resources based on their creation date by using the AWS Config advanced query feature.

AWS Config advanced queries use a subset of SQL to query the configuration state of AWS resources for inventory management, operational intelligence, security, and compliance. You can use these queries to find AWS resources in a single AWS account and AWS Region or across multiple accounts and Regions. By running a query that uses the `resourceCreationTime` property, you can return a list of your AWS resources based on their specific creation date. You can run AWS config advanced queries by using either of the following:

- The AWS Config **Query editor** in the AWS Config console
- The AWS Command Line Interface (AWS CLI)

The example query in the Additional information section of this pattern returns a list of AWS resources created within a specific 60-day time period. The query's output includes information on the following for each identified resource:

- Account ID
- Region
- Resource name
The example query also shows how the inventory list can be scoped to specific resource types with a "WHERE ... IN" statement. You can use a similar query to find other AWS resource types that also work with tags.

**Note:** To query resources across multiple AWS accounts and Regions or across an AWS Organizations organization, you must use an AWS Config aggregator. For more information, see [Multi-account multi-Region data aggregation](https://docs.aws.amazon.com/config/latest/developerguide/multi-account-multi-region-data-aggregation.html) in the [AWS Config Developer Guide](https://docs.aws.amazon.com/config/latest/developerguide/). Global resources are recorded only in their home Region. For example, AWS Identity and Access Management (IAM) is a global resource and is recorded in **us-east-1 (N. Virginia Region)**.

### Prerequisites and limitations

#### Prerequisites

- One or more active AWS accounts with AWS Config activated to record all supported resource types (**default configuration**)
- (For multi-account, multi-Region queries) An activated AWS Config aggregator

#### Limitations

- AWS Config advanced query results are paginated. When you choose **export**, up to 500 results are exported from the AWS Management Console. You can also use APIs to retrieve up to 100 paginated results at a time.
- AWS Config advanced queries use a subset of SQL that has its own syntax limitations. For more information, see **Limitations** in [Querying the current configuration state of AWS resources](https://docs.aws.amazon.com/config/latest/developerguide/querying-current-state.html) in the [AWS Config Developer Guide](https://docs.aws.amazon.com/config/latest/developerguide/).

### Tools

**Tools**

- **AWS Config** provides a detailed view of the resources in your AWS account and how they’re configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

### Epics

**Run an AWS Config advanced query**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify that the resources you’re querying are supported by AWS Config.</td>
<td>For a complete list of AWS resources that AWS Config supports, see <a href="https://docs.aws.amazon.com/config/latest/developerguide/querying-current-state.html">Supported</a></td>

</table>

**resource types** in the *AWS Config Developer Guide*. 

Cloud administrator
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the query.</td>
<td>Follow the instructions in Query using the SQL query editor (console) or Query using the SQL query editor (AWS CLI) in the AWS Config Developer Guide. Note: If you receive errors when running AWS CLI commands, make sure that you’re using the most recent version of the AWS CLI. For single AWS account and Region queries On the Query editor page, in the Query scope section, make sure that you choose This account and Region only. For multi-account and multi-Region queries On the Query editor page, in the Query scope section, make sure that you create and select an AWS Config aggregator. For more information, see Multi-account multi-Region data aggregation in the AWS Config Developer Guide. If queries across multiple accounts or Regions aren’t working, follow the instructions in Troubleshooting for multi-account multi-Region data aggregation in the AWS Config Developer Guide. Note: To modify the scope of the query based on resource type, use the WHERE resourceType IN (...) construct. For an example query, see the Example AWS Config advanced query in the Additional information section.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

### Additional information

**Example AWS Config advanced query**

The following example query returns a list of AWS resources created within a specific 60-day time period. For more AWS Config advanced query examples, see Example Queries in the AWS Config Developer Guide.
AWS Prescriptive Guidance Patterns
View EBS snapshot details for your AWS account or organization

```sql
SELECT
    accountId, awsRegion, resourceName, resourceId, resourceType, resourceCreationTime, tags
WHERE
    resourceType IN ('AWS::CloudFormation::Stack', 'AWS::EC2::VPC', 'AWS::EC2::Volume', 'AWS::EC2::Instance', 'AWS::RDS::DBInstance', 'AWS::ElasticLoadBalancingV2::LoadBalancer', 'AWS::ServiceCatalog::CloudFormationProvisionedProduct', 'AWS::EC2::NetworkInterface', 'AWS::EC2::Subnet', 'AWS::EC2::SecurityGroup', 'AWS::AutoScaling::AutoScalingGroup', 'AWS::Lambda::Function', 'AWS::DynamoDB::Table', 'AWS::S3::Bucket')
AND resourceCreationTime BETWEEN '2022-05-23T00:00:00.000Z' AND '2022-07-23T17:59:51.000Z'
ORDER BY
    accountId ASC,
    resourceType ASC
```

Data privacy and protection

AWS Config is activated in each AWS Region separately. To comply with regulatory requirements, special considerations need to apply—such as creating separate Regional aggregators. For more information, see Data protection in AWS Config in the AWS Config Developer Guide.

IAM permissions

The AWS_ConfigRole AWS managed policy is required as a minimum set of permissions to run AWS Config advanced queries. For more information, see IAM role policy for getting configuration details in the Permissions for the IAM role assigned to AWS Config section of the AWS Config Developer Guide.

View EBS snapshot details for your AWS account or organization

Created by Arun Chandapillai (AWS) and Parag Nagwekar (AWS)

| Environment: Production | Technologies: Operations; Storage & backup | AWS services: Amazon EBS |
Summary

This pattern describes how you can automatically generate an on-demand report of all Amazon Elastic Block Store (Amazon EBS) snapshots in your Amazon Web Services (AWS) account or organizational unit (OU) in AWS Organizations.

Amazon EBS is an easy-to-use, scalable, high-performance block-storage service designed for Amazon Elastic Compute Cloud (Amazon EC2). An EBS volume provides durable and persistent storage that you can attach to your EC2 instances. You can use EBS volumes as primary storage for your data and take a point-in-time backup of your EBS volumes by creating a snapshot. You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to view the details of specific EBS snapshots. This pattern provides a programmatic way to retrieve information about all EBS snapshots in your AWS account or OU.

You can use the script provided by this pattern to generate a comma-separated values (CSV) file that has the following information about each snapshot: account ID, snapshot ID, volume ID and size, the date the snapshot was taken, instance ID, and description. If your EBS snapshots are tagged, the report also includes the owner and team attributes.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS CLI version 2 installed and configured
- AWS Identity and Access Management (IAM) role with the appropriate permissions (access permissions for a specific account or for all accounts in an OU if you’re planning to run the script from AWS Organizations)

Architecture

The following diagram shows the script workflow that generates an on-demand report of EBS snapshots that are spread across multiple AWS accounts in an OU.
Tools

AWS services

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **Amazon Elastic Block Store (Amazon EBS)** provides block-level storage volumes for use with EC2 instances.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Organizations** is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

Code

The code for the sample application used in this pattern is available on GitHub, in the `aws-ebs-snapshots-awsorganizations` repository. Follow the instructions in the next section to use the sample files.

Epics

**Download the script**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download the Python script.</td>
<td>Download the script GetSnapshotDetailsAllAccountsOU.py from the GitHub repository.</td>
<td>General AWS</td>
</tr>
</tbody>
</table>

**Get EBS snapshot details for an AWS account**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the Python script.</td>
<td>Run the command: python3 getsnapshotinfo.py --file &lt;output-file&gt;.csv --region &lt;region-name&gt;</td>
<td>General AWS</td>
</tr>
</tbody>
</table>

where `<output-file>` refers to the CSV output file where you want information about the EBS snapshots placed, and `<region-name>` is the AWS Region where the snapshots are stored. For example:

```
python3 getsnapshotinfo.py --file snapshots.csv --region us-east-1
```
Get EBS snapshot details for an organization

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the Python script.</td>
<td>Run the command: python3 getsnapshotinfo.py --file &lt;output-file&gt;.csv --role &lt;IAM-role&gt; --region &lt;region-name&gt;</td>
<td>General AWS</td>
</tr>
</tbody>
</table>

where `<output-file>` refers to the CSV output file where you want information about the EBS snapshots placed, `<IAM-role>` is a role that provides permissions to access AWS Organizations, and `<region-name>` is the AWS Region where the snapshots are stored. For example:

```bash
python3 getsnapshotinfo.py --file snapshots.csv --role <IAM role> --region us-west-2
```

Additional information

EBS snapshot types

Amazon EBS provides three types of snapshots, based on ownership and access:

- **Owned by you** – By default, only you can create volumes from snapshots that you own.
- **Public snapshots** – You can share snapshots publicly with all other AWS accounts. To create a public snapshot, you modify the permissions for a snapshot to share it with the AWS accounts that you specify. Users that you will authorize can then use the snapshots you share by creating their own EBS volumes, while your original snapshot remains unaffected. You can also make your unencrypted snapshots available publicly to all AWS users. However, you can’t make your encrypted snapshots available publicly for security reasons. Public snapshots pose a significant security risk because of the possibility of exposing personal and sensitive data. We strongly recommend against sharing your
EBS snapshots with all AWS accounts. For more information about sharing snapshots, see the AWS documentation.

- **Private snapshots** – You can share snapshots privately with individual AWS accounts that you specify. To share the snapshot privately with specific AWS accounts, follow the instructions in the AWS documentation, and choose Private for the permissions setting. Users that you have authorized can use the snapshots that you share to create their own EBS volumes, while your original snapshot remains unaffected.

**Overviews and procedures**

The following table provides links to more information about EBS snapshots, including how you can lower EBS volume costs by finding and deleting unused snapshots, and archive rarely accessed snapshots that do not require frequent or fast retrieval.

<table>

**FAQ**

**What is the minimum archive period?**

The minimum archive period is 90 days.
How long would it take to restore an archived snapshot?

It can take up to 72 hours to restore an archived snapshot from the archive tier to the standard tier, depending on the size of the snapshot.

Are archived snapshots full snapshots?

Archived snapshots are always full snapshots.

Which snapshots can a user archive?

You can archive only snapshots that you own in your account.

Can you archive a snapshot of the root device volume of a registered Amazon Machine Image (AMI)?

No, you can't archive a snapshot of the root device volume of a registered AMI.

What are security considerations for sharing a snapshot?

When you share a snapshot, you are giving others access to all the data on the snapshot. Share snapshots only with people that you trust with your data.

How do you share a snapshot with another AWS Region?

Snapshots are constrained to the Region in which they were created. To share a snapshot with another Region, copy the snapshot to that Region and then share the copy.

Can you share snapshots that are encrypted?

You can't share snapshots that are encrypted with the default AWS managed key. You can share snapshots that are encrypted with a customer managed key only. When you share an encrypted snapshot, you must also share the customer managed key that was used to encrypt the snapshot.

What about unencrypted snapshots?

You can share unencrypted snapshots publicly.

Summary

This pattern discusses how you can configure Amazon Cognito user pools and identity pools, and then enable an ASP.NET Core app to access AWS resources after successful authentication.

Amazon Cognito provides authentication, authorization, and user management for your web and mobile apps. The two main components of Amazon Cognito are user pools and identity pools.

A user pool is a user directory in Amazon Cognito. With a user pool, your users can sign in to your web or mobile app through Amazon Cognito. Your users can also sign in through social identity providers like Google, Facebook, Amazon, or Apple, and through SAML identity providers.

Amazon Cognito identity pools (federated identities) enable you to create unique identities for your users and federate them with identity providers. With an identity pool, you can obtain temporary, limited-privilege AWS credentials to access other AWS services. Before you can begin using your new Amazon Cognito identity pool, you must assign one or more AWS Identity and Access Management (IAM) roles to determine the level of access you want your application users to have to your AWS resources. Identity pools define two types of identities: authenticated and unauthenticated. Each identity type can be assigned its own role in IAM. Authenticated identities belong to users who are authenticated by a public login provider (Amazon Cognito user pools, Facebook, Google, SAML, or any OpenID Connect providers) or a developer provider (your own backend authentication process), whereas unauthenticated identities typically belong to guest users. When Amazon Cognito receives a user request, the service determines whether the request is authenticated or unauthenticated, determines which role is associated with that authentication type, and then uses the policy attached to that role to respond to the request.
Prerequisites and limitations

**Prerequisites**

- An AWS account with Amazon Cognito and AWS Identity and Access Management (IAM) permissions
- Access to the AWS resources you want to use
- ASP.NET Core 2.0.0 or later

**Architecture**

**Technology stack**

- Amazon Cognito
- ASP.NET Core

**Target architecture**

```
1. Authenticate and get tokens
2. Exchange tokens for AWS credentials
3. Access AWS services with credentials
```

**Tools**

**Tools, SDKs, and AWS services**

- Visual Studio or Visual Studio Code
- Amazon.AspNetCore.Identity.Cognito (1.0.4) - NuGet package
- AWSSDK.S3 (3.3.110.32) - NuGet package
- Amazon Cognito
Code
The attached .zip file includes sample files that illustrate the following:

- How to retrieve an access token for the logged in user
- How to exchange an access token for AWS credentials
- How to access the Amazon Simple Storage Service (Amazon S3) service with AWS credentials

IAM role for authenticated identities

```json
{
    "Version": "2012-10-17",
    "Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "mobileanalytics:PutEvents",
            "cognito-sync:*",
            "cognito-identity:*",
            "s3:ListAllMyBuckets"
        ],
        "Resource": [
            "*"
        ]
    }
]
}
```

</tbody>
</table>

Summary

This pattern describes how to create an AWS Directory Service directory and use it to authenticate Microsoft SQL Server on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

AWS Directory Service provides multiple ways to use Amazon Cloud Directory and Microsoft Active Directory (AD) with other AWS services. Directories store information about users, groups, and devices, and administrators use them to manage access to information and resources. AWS Directory Service provides multiple directory choices for customers who want to use existing Microsoft AD or Lightweight Directory Access Protocol (LDAP)-aware applications in the cloud. It also offers those same choices to developers who need a directory to manage users, groups, devices, and access.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a minimum of two private subnets and two public subnets
- An AWS Identity and Access Management (IAM) role to join the server into the domain

Architecture

Source technology stack

- The source can be an on-premises Active Directory

Target technology stack

- AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD)

Target architecture
Tools

- SQL Server Management Studio (SSMS) - SSMS is a tool for managing Microsoft SQL Server, including accessing, configuring, and administering SQL Server components.

Epics

Set up a directory

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select AWS Managed Microsoft AD as the directory type.</td>
<td>In the AWS Directory Service console, choose Directories, Set up directory, AWS Managed Microsoft AD, Next.</td>
<td>DevOps</td>
</tr>
<tr>
<td>Select edition.</td>
<td>Choose Standard Edition from the available editions for AWS Managed Microsoft AD.</td>
<td>DevOps</td>
</tr>
<tr>
<td>Specify the directory DNS name.</td>
<td>Use a fully qualified domain name. This name will resolve inside your VPC only. It does not need to be publicly resolvable.</td>
<td>DevOps</td>
</tr>
</tbody>
</table>
### AWS Prescriptive Guidance Patterns

#### Epics

<table>

Automate SAML 2.0 federation for AWS multi-account environments that use Azure AD

Created by Adam Spicer (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Security, identity, compliance; Infrastructure; Management &amp; governance; Hybrid cloud</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Control Tower Customizations to automate SAML 2.0 Federation with Azure AD</td>
<td>AWS services: AWS CloudFormation; AWS Identity and Access Management; AWS Organizations; AWS Secrets Manager; AWS Control Tower</td>
<td></td>
</tr>
</tbody>
</table>

Summary

Organizations that operate a multi-account strategy in Amazon Web Services (AWS) with AWS Control Tower or AWS Organizations might have a requirement to use Microsoft Azure Active Directory (Azure AD) single sign-on (SSO) for federation into the AWS Management Console. In these situations, AWS IAM Identity Center (successor to AWS Single Sign-On) might not always fit into an organization’s requirements. When this occurs, federation is achieved by using an enterprise application within Azure AD named AWS Single-Account Access. The application is deployed within Azure AD for each AWS account.

As described in a Microsoft tutorial on integrating Azure AD SSO with AWS, programmatic access to each integrated account must be configured by using an AWS Identity and Access Management (IAM) user in each account. Azure AD uses the IAM user to retrieve IAM roles to synchronize with Azure AD. Domain administrators map those synchronized roles to groups of users within Azure AD to enable those users to federate into AWS with the appropriate IAM role.

If you have a multi-account strategy, the process of manually deploying the integration steps can be cumbersome and can slow down the process of enabling federation into a new AWS account. As each new AWS account gets created, domain administrators often rely on their cloud administrator to create the IAM user, generate the programmatic access keys, and provide the keys to domain administrators in a secure manner. This is often a manual process that prolongs the time from account creation until users can federate into the account. The solution provided in this pattern accelerates this process by providing prescriptive guidance and automation to enable domain administrators to directly obtain the IAM user programmatic access keys in a least privileged manner, without having to involve a third party. As a result, configuring federation for a new AWS account is streamlined through an improved process and automation.

Prerequisites and limitations

Prerequisites
• An AWS multi-account configuration that uses AWS Control Tower or AWS Organizations
• Azure AD Enterprise Applications (EA) created for AWS management and member accounts, with the identity provider (IdP) configured by using the EA metadata

Limitations
• The accounts in scope must be a member of the management account's AWS organization.
• All accounts in scope must be within an AWS organizational unit (OU).

Architecture

Target technology stack

After you implement this pattern, resources will be deployed into the management account and each member account. The following tables list these resources.

Management account

<table>
<thead>
<tr>
<th>AWS resource</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM role</td>
<td>AzureAdFederationAdminRole</td>
<td>An IAM role with a trust policy configured for the SAML identity provider (IdP) that allows the role to be assumed only by a companion role for member accounts in the organization. This IAM role acts as an intermediate role so that users can be configured to federate into the management account with this role and then assume the appropriate role in member accounts.</td>
</tr>
<tr>
<td>AWS CloudFormation stack set</td>
<td>AzureAdFederationStackSet</td>
<td>A stack set that enables you to deploy a stack to all accounts within the organization.</td>

<tr>
<td>IAM user</td>
<td>AzureADAutomationUser</td>
<td>The IAM user to be used by Azure AD SSO to synchronize the roles for federation.</td>
</tr>
<tr>
<td>IAM group</td>
<td>AzureADAutomationGroup</td>
<td>The IAM group that contains the IAM user AzureADAutomationUser.</td>
</tr>
<tr>
<td>IAM managed policy</td>
<td>AzureADAllowIAMListRoles</td>
<td>A policy that allows the iam:ListRoles action on all resources. The policy is attached to the IAM group AzureADAutomationGroup to enable Azure AD to synchronize IAM roles.</td>
</tr>
</tbody>
</table>
AWS Prescriptive Guidance Patterns

Architecture

| AWS Secrets Manager secret access key | AzureAdFederation / CFNUserSecretAccessKey | The programmatic access keys for the IAM user AzureAdAutomationUser, which are generated and stored as a secret within Secrets Manager. |

Member accounts

The resources deployed into the member accounts are created from the stack set (AzureAdFederationStackSet) that is configured in the management account.

<table>
<thead>
<tr>
<th>AWS resource</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM role</td>
<td>AzureAdFederationAssumeRole</td>
<td>An IAM role with a trust policy that is configured to allow to be assumed by a companion role created in the management account. The role allows access only to get the secret value that is stored in Secrets Manager.</td>
</tr>
<tr>
<td>IAM user</td>
<td>AzureADAutomationUser</td>
<td>The IAM user to be used by Azure AD SSO to synchronize the roles for federation.</td>
</tr>
<tr>
<td>IAM group</td>
<td>AzureADAutomationGroup</td>
<td>The IAM group that contains the IAM user AzureADAutomationUser.</td>
</tr>
<tr>
<td>IAM managed policy</td>
<td>AzureADAllowIAMLListRoles</td>
<td>A policy that allows the iam:ListRoles action on all resources. The policy is attached to the IAM group AzureADAutomationGroup to enable Azure AD to synchronize IAM roles.</td>
</tr>
<tr>
<td>Secrets Manager secret access key</td>
<td>AzureAdFederation / CFNUserSecretAccessKey</td>
<td>The programmatic access keys for the IAM user AzureAdAutomationUser, which are generated and stored as a secret within Secrets Manager.</td>
</tr>
</tbody>
</table>

Target architecture

The solution deploys a target architecture that uses AWS CloudFormation stacks and stack sets to create the federation components in all accounts. The following diagram illustrates the target architecture.
The following diagram shows the workflow for enabling and configuring the synchronization of member account IAM roles.
After member accounts have been created (step 1 in the diagram), a domain administrator can obtain the IAM user programmatic access keys to all member accounts by following these remaining steps:

- **Step 2.** Federate into the management account by using the IAM role `AzureAdFederationAdminRole`.
- **Step 3.** In the AWS Management Console, switch role to a new member account by using the IAM role `AzureAdFederationAssumeRole`.
- **Step 4.** Navigate to Secrets Manager and retrieve the keys in the `AzureADFederation / CFNUserSecretAccessKey` secret.
- **Step 5.** In the appropriate AWS enterprise application within Azure, configure the provisioning administrator credentials by using the retrieved secrets.

**Tools**

**AWS services**

- **AWS CloudFormation** – AWS CloudFormation enables you to create and provision AWS infrastructure deployments predictably and repeatedly.
- **IAM** – AWS Identity and Access Management (IAM) helps you secure access to AWS services and resources. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
- **AWS Organizations** – AWS Organizations is an account management service that lets you consolidate multiple AWS accounts into an organization that you create and centrally manage.
• **AWS Control Tower** – AWS Control Tower provides the easiest way to set up and govern a secure, compliant, multi-account AWS environment based on best practices established by working with thousands of enterprises.

• **AWS Secrets Manager** – AWS Secrets Manager enables you to rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle.

**Code**

The source code for this pattern is available on GitHub, in the [AWS Control Tower Customizations repository](https://github.com/AWSControlTowerCustom/AWSControlTowerCustomizations). The source code includes two CloudFormation templates (YAML files) that you can use to deploy the target architecture. The epics and stories in the next section provide detailed instructions for using these templates.

## Epics

### Create the federation administrator role and management account secrets

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the CloudFormation template to create the administrator role and IAM user in the management account.</td>
<td>From the management account, run the CloudFormation script named <code>azuread-fed-management-account.yaml</code> (see the <a href="https://github.com/AWSControlTowerCustom/AWSControlTowerCustomizations">GitHub repository</a>). You will need to specify your AWS organization ID and the name of the SAML provider that exists in the management account.</td>
<td>CloudFormation</td>
</tr>
</tbody>
</table>

### Create federation assume-role resources in all member accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a CloudFormation stack set for all member accounts. | From the management account, use the `azuread-fed-member-account.yaml` template (see the [GitHub repository](https://github.com/AWSControlTowerCustom/AWSControlTowerCustomizations)) to create a new stack set with the following stack set deployment options. Deploy stacks in organization units:  
  - Specify all top-level parent OUs for member accounts that will receive this stack.  
  - Be sure that the management account and all other core accounts are within one of these top-level OUs. | CloudFormation |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

### Automate incident response and forensics
Summary

This pattern deploys a set of processes that use AWS Lambda functions to provide the following:

- A way to initiate the incident-response process with minimum knowledge
- Automated, repeatable processes that are aligned with the AWS Security Incident Response Guide
- Separation of accounts to operate the automation steps, store artifacts, and create forensic environments

The Automated Incident Response and Forensics framework follows a standard digital forensic process consisting of the following phases:

1. Containment
2. Acquisition
3. Examination
4. Analysis

You can perform investigations on static data (for example, acquired memory or disk images) and on dynamic data that is live but on separated systems.

For more details, see the Additional information (p. 2044) section.

Prerequisites and limitations

Prerequisites

- Two AWS accounts:
  - Security account, which can be an existing account, but is preferably new
  - Forensics account, preferably new
- AWS Organizations set up
- In the Organizations member accounts:
  - The Amazon Elastic Compute Cloud (Amazon EC2) role must have Get and List access to Amazon Simple Storage Service (Amazon S3) and be accessible by AWS Systems Manager. We recommend using the AmazonSSMManagedInstanceCore AWS managed role. Note that this role will automatically be attached to the EC2 instance when incident response is initiated. After the response has finished, AWS Identity and Access Management (IAM) will remove all rights to the instance.
  - Virtual private cloud (VPC) endpoints in the AWS member account and in the Incident Response and Analysis VPCs. Those endpoints are: S3 Gateway, EC2 Messages, SSM, and SSM Messages.
AWS Command Line Interface (AWS CLI) installed on the EC2 instances. If the EC2 instances don’t have AWS CLI installed, internet access will be required for the disk snapshot and memory acquisition to work. In this case, the scripts will reach out to the internet to download the AWS CLI installation files and will install them on the instances.

**Limitations**

- This framework does not intend to generate artifacts that can be considered as electronic evidence, submissible in court.
- Currently, this pattern supports only Linux based instances running on x86 architecture.

**Architecture**

**Target technology stack**

- AWS CloudFormation
- AWS CloudTrail
- AWS Config
- IAM
- Lambda
- Amazon S3
- AWS Key Management System (AWS KMS)
- AWS Security Hub
- Amazon Simple Notification Service (Amazon SNS)
- AWS Step Functions

**Target architecture**

In addition to the member account, the target environment consists of two main accounts: a Security account and a Forensics account. Two accounts are used for the following reasons:

- To separate them from any other customer accounts to reduce blast radius in case of a failed forensic analysis
- To help ensure the isolation and protection of the integrity of the artifacts being analyzed
- To keep the investigation confidential
- To avoid situations where the threat actors might have used all the resources immediately available to your compromised AWS account by hitting service quotas and so preventing you from instantiating an Amazon EC2 instance to perform investigations.

Also, having separate Security and Forensics accounts allows for creating separate roles—a Responder for acquiring evidence and an Investigator for analyzing it. Each role would have access to its separate account.

The following diagram shows only the interaction between the accounts. Details of each account are shown in subsequent diagrams, and a complete diagram is attached.
The following diagram shows the member account.

1. An event is sent to the Slack Amazon SNS topic.

The following diagram shows the Security account.
2. The SNS topic in the Security account initiates Forensics events.

The following diagram shows the Forensics account.
The Security account is where the two main AWS Step Functions workflows are created for memory and disk image acquisition. After the workflows are running, they access the member account that has the EC2 instances involved in an incident, and they initiate a set of Lambda functions that will gather a memory dump or a disk dump. Those artifacts are then stored in the Forensics account.

The Forensics account will hold the artifacts gathered by the Step Functions workflow in the Analysis artifacts S3 bucket. The Forensics account will also have an EC2 Image Builder pipeline that builds an Amazon Machine Image (AMI) of a Forensics instance. Currently, the image is based on SANS SIFT Workstation.

The build process uses the Maintenance VPC, which has connectivity to the internet. The image can be later used for spinning up the EC2 instance for analysis of the gathered artifacts in the Analysis VPC.

The Analysis VPC does not have internet connectivity. By default, the pattern creates three private analysis subnets. You can create up to 200 subnets, which is the quota for the number of subnets in a VPC, but the VPC endpoints need to have those subnets added for AWS Systems Manager Sessions Manager to automate running commands in them.

From a best-practices perspective, we recommend using AWS CloudTrail and AWS Config to do the following:

- Track changes made in your Forensics account
- Monitor access and integrity of the artifacts that are stored and analyzed

Workflow
The following diagram shows the key steps of a workflow that includes the process and decision tree from when an instance is compromised until it is analyzed and contained.

1. Has the SecurityIncidentStatus tag been set with the value Analyze? If yes, do the following:
   a. Attach the correct IAM profiles for AWS Systems Manager and Amazon S3.
   b. Send an Amazon SNS message to the Amazon SNS queue in Slack.
   c. Send an Amazon SNS message to the SecurityIncident queue.
   d. Invoke the Memory and Disk Acquisition state machine.
2. Have memory and disk been acquired? If no, there is an error.
3. Tag the EC2 instance with the Contain tag.
4. Attach the IAM role and security group to fully isolate the instance.
Instance compromised

Has tag SecurityIncidentStatus with value Forensics set?

Yes

Attach the correct IAM profiles for Systems Manager and Amazon S3

Send SNS message to the Slack Amazon SNS queue

Send SNS message to the SecurityIncident queue

Invoke Memory and Disk Acquisition state machine

Have memory and disk been acquired?

No

Do nothing

Error

Success

Tag the EC2 instance with tag SecurityIncident
Automation and scale

The intent of this pattern is to provide a scalable solution to perform incident response and forensics across several accounts within a single AWS Organizations organization.

Tools

AWS Services

- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool for interacting with AWS services through commands in your command-line shell.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to protect your data.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS Security Hub** provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.
- **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- **AWS Step Functions** is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- **AWS Systems Manager** helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

Code

For the code and specific implementation and usage guidance, see the GitHub [Automated Incident Response and Forensics Framework](https://github.com) repository.

Epics

Deploy the CloudFormation templates

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>

</tr>
</thead>
<tbody>
<tr>
<td>Deploy CloudFormation templates.</td>
<td>The CloudFormation templates are marked 1 through 7 with the first word of the script name indicating in which account the template needs to be deployed. Note that the order of launching the CloudFormation templates is important.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>

1-forensic-AnalysisVPCnS3Buckets.yaml
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deployed in the forensics account. It creates the S3 buckets and the Analysis VPC, and it activates CloudTrail. | • 2-forensic-MaintenanceVPCnEC2ImageBuilderPipeline.yaml: Deploys the maintenance VPC and image builder pipeline based on SANS SIFT.  
• 3-security_IR-Disk_Mem_automation.yaml: Deploys the functions in the security account that enable disk and memory acquisition.  
• 4-security_LIME_Volatility_Factory.yaml: Initiates a build function to start creating the memory modules based on the given AMI IDs. Note that AMI IDs are different across AWS Regions. Whenever you need new memory modules, you can rerun this script with the new AMI IDs. Consider integrating this with your golden image AMI builder pipelines (if used in your environment).  
• 5-member-IR-automation.yaml: Creates the member incident-response automation function, which initiates the incident-response process. It allows sharing Amazon Elastic Block Store (Amazon EBS) volumes across accounts, automated posting to Slack channels during the incident-response process, initiating the forensics process, and isolating the instances after the process finishes.  
• 6-forensic-artifact-s3-policies.yaml: After all the scripts have been deployed this script fixes the permissions required for all the cross-account interactions.  
• 7-security-IR-vpc.yaml: Configures a VPC used for incident response volume processing. |
### AWS Prescriptive Guidance Patterns

**Related resources**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Initiate the incident response framework for a specific EC2 instance.</strong></td>
<td>To initiate the incident response framework for a specific EC2 instance, create a tag with the key SecurityIncidentStatus and the value Analyze. This will initiate the member Lambda function that will automatically start isolation and memory as well as disk acquisition.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>

**Operate the framework.**

- The Lambda function will also retag the asset at the end (or on failure) with Contain. This initiates the containment, which fully isolates the instance with a no INBOUND/OUTBOUND security group and with an IAM role that disallows all access.
- Follow the steps in the [GitHub repository](https://github.com).  

**Deploy custom Security Hub actions**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the custom Security Hub actions by using a CloudFormation template.</td>
<td>To create a custom action so that you can use the dropdown list from Security Hub, deploy the Modules/SecurityHub Custom Actions/SecurityHubCustomActions.yaml CloudFormation template. Then modify the IRAutomation role in each of the member accounts to allow the Lambda function that runs the action to assume the IRAutomation role. For more information, see the <a href="https://github.com">GitHub repository</a>.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>

**Related resources**

**Additional information**

By using this environment, a Security Operations Center (SOC) team can improve their security incident response process through the following:
• Having the ability to perform forensics in a segregated environment to avoid accidental compromise of production resources
• Having a standardized, repeatable, automated process to do containment and analysis.
• Giving any account owner or administrator the ability to initiate the incident-response process with the minimal knowledge of how to use tags
• Having a standardized, clean environment for performing incident analysis and forensics without the noise of a larger environment
• Having the ability to create multiple analysis environments in parallel
• Focusing SOC resources on incident response instead of on maintenance and documentation of a cloud forensics environment
• Moving away from a manual process toward an automated one to achieve scalability
• Using CloudFormation templates for consistency and to avoid repeatable tasks

Additionally, you avoid using persistent infrastructure, and you pay for resources when you need them.

Automate remediation for AWS Security Hub standard findings

Created by Chandini Penmetsa (AWS) and Aromal Raj Jayarajan (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Security, identity, compliance</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: AWS</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>

<td></td>
</tr>
<tr>
<td></td>
<td>CloudWatch; AWS Lambda; AWS</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Security Hub; Amazon SNS</td>
<td></td>
</tr>
</tbody>
</table>

Summary

With AWS Security Hub, you can enable checks for standard best practices such as the following:

• AWS Foundational Security Best Practices
• CIS AWS Foundations Benchmark
• Payment Card Industry Data Security Standard (PCI DSS)

Each of these standards has predefined controls. Security Hub checks for the control in a given AWS account and reports the findings.

AWS Security Hub sends all findings to Amazon EventBridge by default. This pattern provides a security control that deploys an EventBridge rule to identify AWS Foundational Security Best Practices standard...
findings. The rule identifies the following findings for automatic scaling, virtual private clouds (VPCs), Amazon Elastic Block Store (Amazon EBS), and Amazon Relational Database Service (Amazon RDS) from the AWS Foundational Security Best Practices standard:

- [AutoScaling.1] Auto Scaling groups associated with a load balancer should use load balancer health checks
- [EC2.2] The VPC default security group should not allow inbound and outbound traffic
- [EC2.6] VPC flow logging should be enabled in all VPCs
- [EC2.7] EBS default encryption should be enabled
- [RDS.1] RDS snapshots should be private
- [RDS.6] Enhanced monitoring should be configured for RDS DB instances and clusters
- [RDS.7] RDS clusters should have deletion protection enabled

The EventBridge rule forwards these findings to an AWS Lambda function, which remediates the finding. The Lambda function then sends a notification with remediation information to an Amazon Simple Notification Service (Amazon SNS) topic.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An email address where you want to receive the remediation notification
- Security Hub and AWS Config enabled in the AWS Region where you intend to deploy the control
- An Amazon Simple Storage Service (Amazon S3) bucket in same Region as the control to upload the AWS Lambda code

Limitations

- This security control automatically remediates new findings reported after the security control deployment. To remediate existing findings, select the findings manually on the Security Hub console. Then, under Actions, select the AFSBPRemedy custom action that was created as part of the deployment by AWS CloudFormation.
- This security control is regional and must be deployed in the AWS Regions that you intend to monitor.
- For the EC2.6 remedy, to enable VPC Flow Logs, an Amazon CloudWatch Logs log group will be created with /VpcFlowLogs/vpc_id format. If a log group exists with same name, the existing log group will be used.
- For the EC2.7 remedy, to enable Amazon EBS default encryption, the default AWS Key Management Service (AWS KMS) key is used. This change prevents the use of certain instances that do not support encryption.

Architecture

Target technology stack

- Lambda function
- Amazon SNS topic
- EventBridge rule
- AWS Identity and Access Management (IAM) roles for Lambda function, VPC Flow Logs, and Amazon Relational Database Service (Amazon RDS) Enhanced Monitoring
Tools

Tools

- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up AWS resources by using infrastructure as code.
- **EventBridge** – Amazon EventBridge delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services, routing that data to targets such as Lambda functions.
- **Lambda** – AWS Lambda supports running code without provisioning or managing servers.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Automate security scans for cross-account workloads using Amazon Inspector and AWS Security Hub**

*Created by Ramya Pulipaka (AWS) and Mikesh Khanal (AWS)*

| Environment: Production | Technologies: Security, identity, compliance; Operations | AWS services: Amazon Inspector; Amazon SNS; AWS Lambda; AWS Security Hub; Amazon CloudWatch |
Summary

This pattern describes how to automatically scan for vulnerabilities in cross-account workloads on the Amazon Web Services (AWS) Cloud.

The pattern helps create a schedule for host-based scans of Amazon Elastic Compute Cloud (Amazon EC2) instances that are grouped by tags or for network-based Amazon Inspector scans. An AWS CloudFormation stack deploys all the required AWS resources and services to your AWS accounts.

The Amazon Inspector findings are exported to AWS Security Hub and provide insights into vulnerabilities across your accounts, AWS Regions, virtual private clouds (VPCs), and EC2 instances. You can receive these findings by email or you can create an Amazon Simple Notification Service (Amazon SNS) topic that uses an HTTP endpoint to send the findings to ticketing tools, security information and event management (SIEM) software, or other third-party security solutions.

Prerequisites and limitations

Prerequisites

- An existing email address to receive email notifications from Amazon SNS.
- An existing HTTP endpoint used by ticketing tools, SIEM software, or other third-party security solutions.
- Active AWS accounts that host cross-account workloads, including a central audit account.
- Security Hub, enabled and configured. You can use this pattern without Security Hub, but we recommend using Security Hub because of the insights it generates. For more information, see Setting up Security Hub in the AWS Security Hub documentation.
- An Amazon Inspector agent must be installed on each EC2 instance that you want to scan. You can install the Amazon Inspector agent on multiple EC2 instances by using AWS Systems Manager Run Command.

Skills

- Experience using self-managed and service-managed permissions for stack sets in AWS CloudFormation. If you want to use self-managed permissions to deploy stack instances to specific accounts in specific Regions, you must create the required AWS Identity and Access Management (IAM) roles. If you want to use service-managed permissions to deploy stack instances to accounts managed by AWS Organizations in specific Regions, you don't need to create the required IAM roles. For more information, see Create a stack set in the AWS CloudFormation documentation.

Limitations

- If no tags are applied to EC2 instances in an account, then Amazon Inspector scans all the EC2 instances in that account.
- The AWS CloudFormation stack sets and the onboard-audit-account.yaml file (attached) must be deployed in the same Region.
- By default, Amazon Inspector Classic doesn't support aggregated findings. Security Hub is the recommended solution to viewing assessments for multiple accounts or AWS Regions.
- This pattern’s approach can scale under the publish quota of 30,000 transactions per second (TPS) for an SNS topic in the US East (N. Virginia) Region (us-east-1), although limits vary by Region. To scale more effectively and avoid data loss, we recommend using Amazon Simple Queue Service (Amazon SQS) in front of the SNS topic.
Architecture

The following diagram illustrates the workflow for automatically scanning EC2 instances.

The workflow consists of the following steps:

1. An Amazon EventBridge rule uses a cron expression to self-initiate on a specific schedule and initiates Amazon Inspector.

2. Amazon Inspector scans the tagged EC2 instances in the account.

3. Amazon Inspector sends the findings to Security Hub, which generates insights for workflow, prioritization, and remediation.

4. Amazon Inspector also sends the assessment’s status to an SNS topic in the audit account. An AWS Lambda function is invoked if a findings reported event is published to the SNS topic.

5. The Lambda function fetches, formats, and sends the findings to another SNS topic in the audit account.

6. Findings are sent to the email addresses that are subscribed to the SNS topic. The full details and recommendations are sent in JSON format to the subscribed HTTP endpoint.

Technology stack

- AWS Control Tower
- EventBridge
- IAM
- Amazon Inspector
Tools

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications.
- **AWS CloudFormation StackSets** – AWS CloudFormation StackSets extends the functionality of stacks by enabling you to create, update, or delete stacks across multiple accounts and Regions with a single operation.
- **AWS Control Tower** – AWS Control Tower creates an abstraction or orchestration layer that combines and integrates the capabilities of several other AWS services, including AWS Organizations.
- **Amazon EventBridge** – EventBridge is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources.
- **AWS Lambda** – Lambda is a compute service that helps you run code without provisioning or managing servers.
- **AWS Security Hub** – Security Hub provides you with a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.

Epics

Deploy the AWS CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the AWS CloudFormation template in the audit account.</td>
<td>Download and save the onboard-audit-account.yaml file (attached) to a local path on your computer. Sign in to the AWS Management Console for your audit account, open the AWS CloudFormation console, and then choose <strong>Create stack</strong>. Choose <strong>Prepare template</strong> in the <strong>Prerequisites</strong> section, and then choose <strong>Template is ready</strong>. Choose <strong>Template source</strong> in the <strong>Specify template</strong> section, and then choose <strong>Template is ready</strong>. Upload the onboard-audit-account.yaml file and then configure the remaining options according to your requirements.</td>
<td>Developer, Security engineer</td>
</tr>
</tbody>
</table>
### Important
Make sure that you configure the following input parameters:

- **DestinationEmailAddress** – Enter an email address to receive findings.
- **HTTPEndpoint** – Provide an HTTP endpoint for your ticketing or SIEM tools.

You can also deploy the AWS CloudFormation template by using AWS Command Line Interface (AWS CLI). For more information about this, see [Creating a stack](#) in the AWS CloudFormation documentation.

### Confirm the Amazon SNS subscription.
Open your email inbox and choose Confirm subscription in the email that you receive from Amazon SNS. This opens a web browser window and displays the subscription confirmation.

### Create AWS CloudFormation stack sets to automate the Amazon Inspector scan schedule

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create stack sets in the audit account. | Download the vulnerability-management-program.yaml file (attached) to a local path on your computer.  

On the AWS CloudFormation console, choose View stacksets and then choose Create StackSet. Choose Template is ready, choose Upload a template file, and then upload the vulnerability-management-program.yaml file.

If you want to use self-managed permissions, follow the instructions from Create a stack set with self-managed permissions in the AWS CloudFormation documentation. | Developer, Security engineer |
## Task

Automatically re-enable AWS CloudTrail by using a custom remediation rule in AWS Config

Created by Manigandan Shri (AWS)

| Environment: Production | Technologies: Infrastructure; Operations; Security, identity, compliance | AWS services: Amazon S3; AWS Config; AWS KMS; AWS Identity and Access Management; AWS Systems Manager; AWS CloudTrail |

Summary

Visibility over activity in your Amazon Web Services (AWS) account is an important security and operational best practice. AWS CloudTrail helps you with the governance, compliance, and operational and risk auditing of your account.

To ensure that CloudTrail remains enabled in your account, AWS Config provides the cloudtrail-enabled managed rule. If CloudTrail is turned off, the cloudtrail-enabled rule automatically re-enables it by using automatic remediation.

However, you must make sure that you follow security best practices for CloudTrail if you use automatic remediation. These best practices include enabling CloudTrail in all AWS Regions, logging read and write workloads, enabling insights, and encrypting log files with server-side encryption using AWS Key Management Service (AWS KMS) managed keys (SSE-KMS).

This pattern helps you follow these security best practices by providing a custom remediation action to automatically re-enable CloudTrail in your account.

Important: We recommend using service control policies (SCPs) to prevent any tampering with CloudTrail. For more information about this, see the Prevent tampering with AWS CloudTrail section of How to use AWS Organizations to simplify security at enormous scale on the AWS Security Blog.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) user and role permissions to create an AWS Systems Manager Automation runbook
- An existing trail for your account

Limitations

This pattern doesn’t support the following actions:
• Setting an Amazon Simple Storage Service (Amazon S3) prefix key for the storage location
• Publishing to an Amazon Simple Notification Service (Amazon SNS) topic
• Configuring Amazon CloudWatch Logs to monitor your CloudTrail logs

Architecture

Technology stack
• AWS Config
• CloudTrail
• Systems Manager
• Systems Manager Automation

Tools

AWS Config – AWS Config provides a detailed view of the configuration of AWS resources in your account.

AWS CloudTrail – CloudTrail helps you enable governance, compliance, and operational and risk auditing of your account.

AWS KMS – AWS Key Management Service (AWS KMS) is an encryption and key management service.

AWS Systems Manager – Systems Manager helps you view and control your infrastructure on AWS.
**AWS Systems Manager Automation** – Systems Manager Automation simplifies common maintenance and deployment tasks of Amazon Elastic Compute Cloud (Amazon EC2) instances and other AWS resources.

**Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

**Code**

The cloudtrail-remediation-action.yml file (attached) helps you create a Systems Manager Automation runbook to set up and re-enable CloudTrail using security best practices.

## Epics

### Configure CloudTrail

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an S3 bucket.</td>
<td>Sign in to the AWS Management Console, open the Amazon S3 console, and then create an S3 bucket to store the CloudTrail logs. For more information, see <a href="https://docs.aws.amazon.com/AmazonS3/latest/userguide/how-to-create-bucket.html">Create an S3 bucket</a> in the Amazon S3 documentation.</td>
<td>Systems administrator</td>
</tr>
<tr>
<td>Add a bucket policy to allow CloudTrail to deliver log files to the S3 bucket.</td>
<td>CloudTrail must have the required permissions to deliver log files to your S3 bucket. On the Amazon S3 console, choose the S3 bucket that you created earlier and then choose Permissions. Create an S3 bucket policy by using the Amazon S3 bucket policy for CloudTrail from the CloudTrail documentation.</td>
<td>Systems administrator</td>
</tr>
<tr>
<td></td>
<td>For steps on how to add a policy to an S3 bucket, see <a href="https://docs.aws.amazon.com/AmazonS3/latest/userguide/how-to-set-permissions-bucket.html">Adding a bucket policy using the Amazon S3 console</a> in the Amazon S3 documentation.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Important:</strong> If you specified a prefix when you created your trail in CloudTrail, make sure that you include it in the S3 bucket policy. The prefix is an optional addition to the S3 object key that creates a folder-like organization in your S3 bucket. For more information about this, see <a href="https://docs.aws.amazon.com/awscloudtrail/latest/userguide/how-to-create-trail.html">Creating a trail</a> in the CloudTrail documentation.</td>
<td></td>

Automatically remediate unencrypted Amazon RDS DB instances and clusters

*Created by Ajay Rawat (AWS) and Josh Joy (AWS)*

<table>

</tbody>
</table>

Summary

This pattern describes how to automatically remediate unencrypted Amazon Relational Database Service (Amazon RDS) DB instances and clusters on Amazon Web Services (AWS) by using AWS Config, AWS Systems Manager runbooks, and AWS Key Management Service (AWS KMS) keys.

Encrypted RDS DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the AWS Cloud, and to fulfill compliance requirements for encryption at rest. You can enable encryption for an RDS DB instance when you create it, but not after it's created. However, you can add encryption to an unencrypted RDS DB instance by creating a snapshot of your DB instance, and then creating an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot to get an encrypted copy of your original DB instance.

This pattern uses AWS Config rules to evaluate RDS DB instances and clusters. It applies remediation by using AWS Systems Manager runbooks, which define the actions to be performed on noncompliant Amazon RDS resources, and AWS KMS keys to encrypt the DB snapshots. It then enforces service control policies (SCPs) to prevent the creation of new DB instances and clusters without encryption.

The code for this pattern is provided in [GitHub](https://github.com).

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- Files from the [GitHub source code repository](https://github.com) for this pattern downloaded to your computer
- An unencrypted RDS DB instance or cluster
- An existing AWS KMS key for encrypting RDS DB instances and clusters
- Access to update the KMS key resource policy
- AWS Config enabled in your AWS account (see [Getting Started with AWS Config](https://aws.amazon.com) in the AWS documentation)
Limitations

- You can enable encryption for an RDS DB instance only when you create it, not after it has been created.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- Amazon RDS encryption is available for most DB instance classes. For a list of exceptions, see Encrypting Amazon RDS resources in the Amazon RDS documentation.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.
- The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information, see Envelope encryption in the AWS KMS documentation.
- You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.
- You should delete a KMS key only when you are sure that you don't need to use it any longer. If you aren't sure, consider disabling the KMS key instead of deleting it. You can reenable a disabled KMS key if you need to use it again later, but you cannot recover a deleted KMS key.
- If you don't choose to retain automated backups, your automated backups that are in the same AWS Region as the DB instance are deleted. They can't be recovered after you delete the DB instance.
- Your automated backups are retained for the retention period that is set on the DB instance at the time you delete it. This set retention period occurs whether or not you choose to create a final DB snapshot.
- If automatic remediation is enabled, this solution encrypts all databases that have the same KMS key.

Architecture

The following diagram illustrates the architecture for the AWS CloudFormation implementation. Note that you can also implement this pattern by using the AWS Cloud Development Kit (AWS CDK).
**Tools**

**AWS CloudFormation** – AWS CloudFormation helps you automatically set up your AWS resources. It enables you to use a template file to create and delete a collection of resources together as a single unit (a stack).

**AWS CDK** – The AWS Cloud Development Kit (AWS CDK) is a software development framework for defining your cloud infrastructure in code and provisioning it by using familiar programming languages.

**AWS services and features**

- **AWS Config** – AWS Config keeps track of the configuration of your AWS resources and their relationships to your other resources. It can also evaluate those AWS resources for compliance. This service uses rules that can be configured to evaluate AWS resources against desired configurations. You can use a set of AWS Config managed rules for common compliance scenarios, or you can create your own rules for custom scenarios. When an AWS resource is found to be noncompliant, you can specify a remediation action through an AWS Systems Manager runbook and optionally send an alert through an Amazon Simple Notification Service (Amazon SNS) topic. In other words, you can associate remediation actions with AWS Config rules and choose to run them automatically to address noncompliant resources without manual intervention. If a resource is still noncompliant after automatic remediation, you can set the rule to try automatic remediation again.

- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) makes it easier to set up, operate, and scale a relational database in the cloud. The basic building block of Amazon RDS is the DB
instance, which is an isolated database environment in the AWS Cloud. Amazon RDS provides a selection of instance types that are optimized to fit different relational database use cases. Instance types comprise various combinations of CPU, memory, storage, and networking capacity and give you the flexibility to choose the appropriate mix of resources for your database. Each instance type includes several instance sizes, allowing you to scale your database to the requirements of your target workload.

- **AWS KMS** – AWS Key Management Service (AWS KMS) is a managed service that makes it easy for you to create and control AWS KMS keys, which encrypt your data. A KMS key is a logical representation of a root key. The KMS key includes metadata, such as the key ID, creation date, description, and key state.

- **IAM** – AWS Identity and Access Management (IAM) controls access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

- **SCPs** – Service control policies (SCPs) offer central control over the maximum available permissions for all accounts in your organization. SCPs help you ensure that your accounts stay within your organization’s access control guidelines. SCPs don’t affect users or roles in the management account. They affect only the member accounts in your organization. We strongly recommend that you don’t attach SCPs to the root of your organization without thoroughly testing the impact that the policy has on accounts. Instead, create an organizational unit (OU) that you can move your accounts into one at a time, or at least in small numbers, to ensure that you don’t inadvertently lock users out of key services.

**Code**

The source code and templates for this pattern are available in a GitHub repository. The pattern provides two implementation options: You can deploy an AWS CloudFormation template to create the remediation role that encrypts RDS DB instances and clusters, or use the AWS CDK. The repository has separate folders for these two options.

The *Epics* section provides step-by-step instructions for deploying the CloudFormation template. If you want to use the AWS CDK, follow the instructions in the README.md file in the GitHub repository.

**Epics**

Create the IAM remediation role and AWS Systems Manager runbook

<table>
<thead>
<tr>
<th>Task</th>

</thead>
</table>
| Review CloudFormation parameters and values. | 1. Review stack details and update values based on your environment requirements.  
   2. Choose Create stack to deploy the template.                                                                                                                                                                           | DevOps engineer |
| Review the resources.                        | When the stack has been created, its status changes to CREATE_COMPLETE. Review the created resources (IAM role, AWS Systems Manager runbook) in the CloudFormation console.                                                  | DevOps engineer |

**Update the AWS KMS key policy**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Update your KMS key policy. | 1. Make sure that the key alias `alias/RDSEncryptionAtRestKMSAlias` exists.  
   2. The key policy statement should include the IAM remediation role. (Check the resources created by the CloudFormation template you deployed in the previous epic.)  
   3. In the following key policy, update the portions that are in bold to match your account and the IAM role that was created.                                                                 | DevOps engineer |

```json
{
  "Sid": "Allow access through RDS for all principals in the account that are authorized to use RDS",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::<your-AWS-account-ID>:role/<your-IAM-remediation-role>",
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:List*",
    "kms:Get*",
    "kms:Describe*",
    "kms:MakePublic*",
    "kms:TagResource*",
    "kms:UntagResource*"
  ]
}
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|      | "kms:Decrypt", "kms:ReEncrypt*", "kms:GenerateDataKey*", "kms:CreateGrant", "kms:ListGrants", "kms:DescribeKey"

"Resource": "*

"Condition": {
  "StringEquals": {
    "kms:ViaService": "rds.us-east-1.amazonaws.com",
    "kms:CallerAccount": "<your-AWS-account-ID>"
  }
}

Find and remediate noncompliant resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>View noncompliant resources.</td>
<td>1. To view a list of noncompliant resources, open the AWS Config console at <a href="https://console.aws.amazon.com/config/">https://console.aws.amazon.com/config/</a>. 2. In the navigation pane, choose Rules, and then choose the rds-storage-encrypted rule.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

The noncompliant resources listed in the AWS Config console will be instances, not clusters. The remediation automation encrypts instances and clusters, and creates either a newly encrypted instance or a newly created cluster. However, be sure not to simultaneously remediate multiple instances that belong to the same cluster.

Before you remediate any RDS DB instances or volumes, make sure that the RDS DB instance is not in use. Confirm that there are no write operations occurring while the snapshot is being created, to ensure that the snapshot contains the
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Remediate noncompliant resources.         | 1. When you are ready and the maintenance window is in effect, choose the resource to remediate, and then choose **Remediate**. The **Action status** column should now display **Action execution queued**.  
2. View the progress and status of the remediation in Systems Manager. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/. In the navigation pane, choose **Automation**, and then select the execution ID of the corresponding automation to view further details. | DevOps engineer                  |
| Verify that the RDS DB instance is available. | After the automation completes, the newly encrypted RDS DB instance will become available. The encrypted RDS DB instance will have the prefix `encrypted` followed by the original name. For example, if the unencrypted RDS DB instance name was `database-1`, the newly encrypted RDS DB instance would be `encrypted-database-1`. | DevOps engineer                  |
| Terminate the unencrypted instance.       | After remediation is complete and the newly encrypted resource has been validated, you can terminate the unencrypted instance. Make sure to confirm that the newly encrypted resource matches the unencrypted resource before you terminate any resources. | DevOps engineer                  |
Enforce SCPs

Guides and patterns

- Automatically re-enable AWS CloudTrail by using a custom remediation rule in AWS Config

Additional information

Best practices

- Enable data encryption both at rest and in transit.
- Enable AWS Config in all accounts and AWS Regions.
- Record configuration changes to all resource types.
- Rotate your IAM credentials regularly.
- Leverage tagging for AWS Config, which makes is easier to manage, search for, and filter resources.

FAQ

Q. How does AWS Config work?

A. When you turn on AWS Config, it first discovers the supported AWS resources that exist in your account and generates a configuration item for each resource. AWS Config also generates configuration...
items when the configuration of a resource changes, and it maintains historical records of the configuration items of your resources from the time you start the configuration recorder. By default, AWS Config creates configuration items for every supported resource in the AWS Region. If you don’t want AWS Config to create configuration items for all supported resources, you can specify the resource types that you want it to track.

Q. How are AWS Config and AWS Config rules related to AWS Security Hub?

A. AWS Security Hub is a security and compliance service that provides security and compliance posture management as a service. It uses AWS Config and AWS Config rules as its primary mechanism to evaluate the configuration of AWS resources. AWS Config rules can also be used to evaluate resource configuration directly. Config rules are also used by other AWS services, such as AWS Control Tower and AWS Firewall Manager.

Automatically rotate IAM user access keys at scale with AWS Organizations and AWS Secrets Manager

Created by Tracy Hickey (AWS), Gaurav Verma (AWS), Laura Seletos (AWS), Michael Davie, and Arvind Patel (AWS)

| Environment: PoC or pilot | Technologies: Security, identity, compliance | AWS services: AWS CloudFormation; Amazon CloudWatch Events; AWS Identity and Access Management; AWS Lambda; AWS Organizations; Amazon S3; Amazon SES; AWS Secrets Manager |

Summary

Access keys are long-term credentials for an AWS Identity and Access Management (IAM) user or the AWS account root user. Regularly rotating your IAM credentials helps prevent a compromised set of IAM access keys from accessing components in your AWS account. Rotating IAM credentials is also an important part of security best practices in IAM.

This pattern helps you automatically rotate IAM access keys by using AWS CloudFormation templates, which are provided in the GitHub IAM key rotation repository.

The pattern supports deployment in a single account or multiple accounts. If you’re using AWS Organizations, this solution identifies all AWS account IDs within your organization and dynamically scales as accounts are removed or new accounts are created. The centralized AWS Lambda function uses an assumed IAM role to locally run the rotation functions across multiple accounts that you select.

- New IAM access keys are generated when existing access keys are 90 days old.
- The new access keys are stored as a secret in AWS Secrets Manager. A resource-based policy allows only the specified IAM principal to access and retrieve the secret. If you choose to store keys in the management account, the keys for all accounts are stored in the management account.
- The email address assigned to the owner of the AWS account where the new access keys were created receives a notification.
The previous access keys are deactivated at 100 days old, and then deleted at 110 days old.

A centralized email notification is sent to the AWS account owner.

Lambda functions and Amazon CloudWatch automatically perform these actions. You can then retrieve the new access key pair and replace them in your code or applications. The rotation, deletion, and deactivation periods can be customized.

Prerequisites and limitations

- At least one active AWS account.
- AWS Organizations, configured and set up (see tutorial).
- Permissions to query AWS Organizations from your management account. For more information, see AWS Organizations and service-linked roles in the AWS Organizations documentation.
- An IAM principal that has permissions to launch the AWS CloudFormation template and associated resources. For more information, see Grant self-managed permissions in the AWS CloudFormation documentation.
- An existing Amazon Simple Storage Service (Amazon S3) bucket to deploy the resources.
- Amazon Simple Email Service (Amazon SES) moved out of the sandbox. For more information, see Moving out of the Amazon SES sandbox in the Amazon SES documentation.
- If you choose to run Lambda in a virtual private cloud (VPC), the following resources, which should be created before you run the main CloudFormation template:
  - A VPC.
  - A subnet.
  - Endpoints for Amazon SES, AWS Systems Manager, AWS Security Token Service (AWS STS), Amazon S3, and AWS Secrets Manager. (You can run the endpoint template that's provided in the GitHub IAM key rotation repository to create these endpoints.)
  - The Simple Mail Transfer Protocol (SMTP) user and password stored in AWS Systems Manager parameters (SSM parameters). Parameters must match the main CloudFormation template parameters.

Architecture

Technology stack

- Amazon CloudWatch
- Amazon EventBridge
- IAM
- AWS Lambda
- AWS Organizations
- Amazon S3

Architecture

The following diagrams show the components and workflows for this pattern. The solution supports two scenarios for storing the credentials: in a member account and in the management account.

Option 1: Store the credentials in a member account
Option 2: Store the credentials in the management account

The diagrams show the following workflow:

1. An EventBridge event initiates an account_inventory Lambda function every 24 hours.
2. This Lambda function queries AWS Organizations for a list of all AWS account IDs, account names, and account emails.
3. The account_inventory Lambda function initiates an access_key_auto_rotation Lambda function for each AWS account ID and passes the metadata to it for additional processing.
4. The `access_key_auto_rotation` Lambda function uses an assumed IAM role to access the AWS account ID. The Lambda script runs an audit against all users and their IAM access keys in the account.

5. If the IAM access key's age hasn't exceeded the best practice threshold, the Lambda function takes no further action.

6. If the IAM access key's age has exceeded the best practice threshold, the `access_key_auto_rotation` Lambda function determines which rotation action to perform.

7. When action is required, the `access_key_auto_rotation` Lambda function creates and updates a secret in AWS Secrets Manager if a new key is generated. A resource-based policy is also created that allows only the specified IAM principal to access and retrieve the secret. In the case of option 1, the credentials are stored in Secrets Manager in the respective account. In the case of option 2 (if the `StoreSecretsInCentralAccount` flag is set to `True`), the credentials are stored in Secrets Manager in the management account.

8. A `notifier` Lambda function is initiated to notify the account's owner of the rotation activity. This function receives the AWS account ID, account name, account email, and the rotation actions that were performed.

9. The `notifier` Lambda function queries the deployment S3 bucket for an email template and dynamically updates it with the relevant activity metadata. The email is then sent to the account owner's email address.

**Note:** You can run this solution in audit mode. In audit mode, IAM access keys aren't modified, but an email is sent to notify users. To run the solution in audit mode, set the `DryRunFlag` flag to `True` when you run the key rotation template or in the environment variable for the `access_key_auto_rotation` Lambda function.

**Automation and scale**

The CloudFormation templates that automate this solution are provided in the GitHub IAM key rotation repository and listed in the Code section. In AWS Organizations, you can use CloudFormation StackSets to deploy the `ASA-iam-key-auto-rotation-iam-assumed-roles.yaml` CloudFormation template in multiple accounts instead of deploying the solution individually to each member account.

**Tools**

**AWS services**

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Email Service (Amazon SES) helps you send and receive emails by using your own email addresses and domains.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- **Amazon VPC endpoints** provide an interface to connect to services powered by AWS PrivateLink, including many AWS services. For each subnet that you specify from your VPC, an endpoint network interface is created in the subnet and assigned a private IP address from the subnet address range.

**Code**

The required AWS CloudFormation templates, Python scripts, and runbook documentation are available in the GitHub IAM key rotation repository. The templates are deployed as follows.

Automatically validate and deploy IAM policies and roles in an AWS account by using CodePipeline, IAM Access Analyzer, and AWS CloudFormation macros

*Created by Helton Henrique Ribeiro (AWS) and Guilherme Simoes (AWS)*

<table>

Summary

This pattern describes the steps and provides code to create a deployment pipeline that allows your development teams to create AWS Identity and Access Management (IAM) policies and roles in your Amazon Web Services (AWS) accounts. This approach helps your organization reduce overhead for your operational teams and speed up the deployment process. It also helps your developers to create IAM roles and policies that are compatible with your existing governance and security controls.

This pattern's approach uses AWS Identity and Access Management Access Analyzer to validate the IAM policies that you want to attach to IAM roles and uses AWS CloudFormation to deploy the IAM roles. However, instead of directly editing the AWS CloudFormation template file, your development team creates JSON-formatted IAM policies and roles. An AWS CloudFormation macro transforms these JSON-formatted policy files into AWS CloudFormation IAM resource types before beginning the deployment.

The deployment pipeline (RolesPipeline) has source, validation, and deployment stages. During the source stage, your development team pushes the JSON files that contain the definition of the IAM roles and policies to an AWS CodeCommit repository. AWS CodeBuild then runs a script to validate those files and copies them to an Amazon Simple Storage Service (Amazon S3) bucket. Because your development teams don't have direct access to the AWS CloudFormation template file stored in a separate S3 bucket, they must follow the JSON file creation and validation process.

Finally, during the deployment phase, AWS CodeDeploy uses an AWS CloudFormation stack to update or delete the IAM policies and roles in an account.
Important: This pattern’s workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern’s approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Prerequisites and limitations

Prerequisites

- An active AWS account.

- A new or existing S3 bucket for the RolesPipeline pipeline. Make sure that your IAM user has the required permissions to upload objects to this bucket.

- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.

- AWS Serverless Application Model (AWS SAM) CLI, installed and configured. For more information about this, see Installing the AWS SAM CLI in the AWS SAM documentation.

- Python 3, installed on your local machine. For more information about this, see the Python documentation.

- A Git client, installed and configured.

- The GitHub IAM roles pipeline repository, cloned to your local machine.

- Existing JSON-formatted IAM policies and roles. For more information about this, see the ReadMe file in the Github IAM roles pipeline repository.

- Your developer team must not have permissions to edit this solution’s AWS CodePipeline, CodeBuild, and CodeDeploy resources.

Limitations

- This pattern's workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern's approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Architecture

The following diagram shows you how to automatically validate and deploy IAM roles and policies to an account by using CodePipeline, IAM Access Analyzer, and AWS CloudFormation macros.
The diagram shows the following workflow:

1. A developer writes JSON files that contain the definitions for the IAM policies and roles. The developer pushes the code to a CodeCommit repository and CodePipeline then initiates the RolesPipeline pipeline.
2. CodeBuild validates the JSON files by using IAM Access Analyzer. If there are any security or error-related findings, the deployment process is stopped.
3. If there are no security or error-related findings, the JSON files are sent to the RolesBucket S3 bucket.
4. An AWS CloudFormation macro implemented as an AWS Lambda function then reads the JSON files from the RolesBucket bucket and transforms them into AWS CloudFormation IAM resources types.
5. A predefined AWS CloudFormation stack installs, updates, or deletes the IAM policies and roles in the account.

Automation and scale

AWS CloudFormation templates that automatically deploy this pattern are provided in the GitHub IAM roles pipeline repository.

Tools

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.
- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
- **AWS Identity and Access Management Access Analyzer** – IAM Access Analyzer helps you identify the resources in your organization and accounts, such as S3 buckets or IAM roles, that are shared with an external entity. This helps you to identify unintended access to your resources and data.
**AWS SAM** – AWS Serverless Application Model (AWS SAM) is an open-source framework that you can use to build serverless applications on AWS. AWS SAM provides you with a template specification to define your serverless application, and a CLI tool.

### Code

The source code and templates for this pattern are available in the GitHub IAM roles pipeline repository.

### Epics

#### Clone the repository

<table>
<thead>

<td>Clone the sample repository.</td>
<td>Clone the GitHub IAM roles pipeline repository to your local machine.</td>
<td>App developer, General AWS</td>
</tr>
</tbody>
</table>

#### Deploy the RolesPipeline pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the pipeline.</td>
<td>1. Navigate to the directory that contains the cloned repository.</td>
<td>App developer, General AWS</td>
</tr>
<tr>
<td></td>
<td>2. Run the <code>make deploy bucket=&lt;bucket_name&gt;</code> command. <strong>Important:</strong> you must replace <code>&lt;bucket_name&gt;</code> with the bucket name for your existing S3 bucket.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Run the <code>aws codepipeline get-pipeline --name RolesPipeline</code> command to check if your deployment is successful.</td>
<td></td>
</tr>
<tr>
<td>Clone the pipeline's repository.</td>
<td>1. The RolesPipeline AWS CloudFormation stack creates the roles-pipeline-repo CodeCommit repository.</td>
<td>App developer, General AWS</td>
</tr>
<tr>
<td></td>
<td>2. Sign in to the AWS Management Console, open the AWS CodeCommit console, and then copy the CodeCommit repository's URL to clone it to your local machine. For more information about this, see Connect to an AWS</td>
<td></td>
</tr>
</tbody>
</table>
### Test the RolesPipeline pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test the RolesPipeline pipeline with valid IAM policies and roles.   | 1. Create JSON files for your IAM policies and roles. You can use the samples in the role-example directory from the GitHub IAM roles pipeline repository.  
                          2. Define your IAM policies and roles with the required configurations. **Important:** Make sure that you follow the format described in the ReadMe file from the GitHub IAM roles pipeline repository.  
                          3. Push the modifications into the roles-pipeline-repo CodeCommit repository.  
                          4. Verify the implementation of the RolesPipeline pipeline.  
                          5. Make sure that the IAM policies and roles are correctly deployed in the account.  
                          6. Validate if there is a permissions boundary associated to the IAM policies or roles. For more information about this, see Permissions boundaries for IAM entities in the IAM documentation. | App developer, General AWS |
| Test the RolesPipeline pipeline with invalid IAM policies and roles. | 1. Modify the roles-pipeline-repo CodeCommit repository and include invalid IAM roles or policies. For example, you can use an action that doesn't exist or an invalid IAM policy version.  
                          2. Verify the pipeline implementation. IAM Access Analyzer stops the pipeline during the validation stage if it detects invalid IAM policies or roles. | App developer, General AWS |
Clean up your resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prepare for cleanup.</td>
<td>Empty the S3 buckets and then run the destroy command.</td>
<td>App developer, General AWS</td>
</tr>
</tbody>
</table>
| Delete the RolesStack stack. | 1. The RolesPipeline pipeline creates a RolesStack AWS CloudFormation stack that deploys the IAM policies and roles. You must delete this stack before deleting the RolesPipeline pipeline.  
2. Sign in to the AWS Management Console, open the AWS CloudFormation console, and then choose the RolesStack stack and choose Delete. | App developer, General AWS                   |
| Delete the RolesPipeline stack | To delete the RolesPipeline AWS CloudFormation stack, follow the instructions from the ReadMe file in the Github IAM roles pipeline repository. | App developer, General AWS                   |

Bidirectionally integrate AWS Security Hub with Jira software

*Created by Joaquin Manuel Rinaudo (AWS)*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Security, identity, compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Security Hub to JIRA Integration</td>
<td>AWS services: AWS Lambda; AWS Security Hub; Amazon CloudWatch</td>
<td>Workload: All other workloads</td>
</tr>
</tbody>
</table>
Summary

This solution supports a bidirectional integration between AWS Security Hub and Jira. Using this solution, you can automatically and manually create and update JIRA tickets from Security Hub findings. Security teams can use this integration to notify developer teams of severe security findings that require action.

The solution allows you to:

- Select which Security Hub controls automatically create or update tickets in Jira.
- In the Security Hub console, use Security Hub custom actions to manually escalate tickets in Jira.
- Automatically assign tickets in Jira based on the AWS account tags defined in AWS Organizations. If this tag is not defined, a default assignee is used.
- Automatically suppress Security Hub findings that are marked as false positive or accepted risk in Jira.
- Automatically close a Jira ticket when its related finding is archived in Security Hub.
- Reopen Jira tickets when Security Hub findings reoccur.

Jira workflow

The solution uses a custom Jira workflow that allows developers to manage and document risks. As the issue moves through the workflow, bidirectional integration ensures that the status of the Jira ticket and Security Hub finding is synchronized across the workflows in both services. This workflow is a derivative of SecDevOps Risk Workflow by Dinis Cruz, licensed under CC BY 4.0. We recommend adding a Jira workflow condition so that only members of your security team can change the ticket status.

For an example of a Jira ticket automatically generated by this solution, see the Additional information (p. 2093) section of this pattern.

Prerequisites and limitations

Prerequisites

- If you want to deploy this solution across a multi-account AWS environment:
Your multi-account environment is active and managed by AWS Organizations.

Security Hub is enabled on your AWS accounts.

In AWS Organizations, you have designated a Security Hub administrator account.

You have a cross-account IAM role that has AWSOrganizationsReadOnlyAccess permissions to the AWS Organizations management account.

(Optional) You have tagged your AWS accounts with SecurityContactID. This tag is used to assign Jira tickets to the defined security contacts.

If you want to deploy this solution within a single AWS account:

- You have an active AWS account.
- Security Hub is enabled on your AWS account.
- A Jira Server instance

Important: This solution supports use of Jira Cloud. However, Jira Cloud does not support importing XML workflows, so you need to manually re-create the workflow in Jira.

- Administrator permissions in Jira
- One of the following Jira tokens:
  - For Jira Enterprise, a personal access token (PAT). For more information, see Using Personal Access Tokens (Atlassian support).
  - For Jira Cloud, a Jira API token. For more information, see Manage API tokens (Atlassian support).

Architecture

This section illustrates the architecture of the solution in various scenarios, such as when the developer and security engineer decide to accept the risk or decide to fix the issue.

Scenario 1: Developer addresses the issue

1. Security Hub generates a finding against a specified security control, such as those in the AWS Foundational Security Best Practices standard.
2. An Amazon CloudWatch event associated with the finding and the CreateJIRA action initiates an AWS Lambda function.
3. The Lambda function uses its configuration file and the finding's GeneratorId field to evaluate whether it should escalate the finding.
4. The Lambda function determines the finding should be escalated, it obtains the SecurityContactID account tag from AWS Organizations in the AWS management account. This ID is associated with the developer and is used as the assignee ID for the Jira ticket.
5. The Lambda function uses the credentials stored in AWS Secrets Manager to create a ticket in Jira. Jira notifies the developer.
6. The developer addresses the underlying security finding and, in Jira, changes the status of the ticket to TEST FIX.
7. Security Hub updates the finding as ARCHIVED, and a new event is generated. This event causes the Lambda function to automatically close the Jira ticket.
Scenario 2: Developer decides to accept the risk

1. Security Hub generates a finding against a specified security control, such as those in the AWS Foundational Security Best Practices standard.

2. A CloudWatch event associated with the finding and the CreateJIRA action initiates a Lambda function.

3. The Lambda function uses its configuration file and the finding's GeneratorId field to evaluate whether it should escalate the finding.

4. The Lambda function determines the finding should be escalated, it obtains the SecurityContactID account tag from AWS Organizations in the AWS management account. This ID is associated with the developer and is used as the assignee ID for the Jira ticket.

5. The Lambda function uses the credentials stored in Secrets Manager to create a ticket in Jira. Jira notifies the developer.

6. The developer decides to accept the risk and, in Jira, changes the status of the ticket to AWAITING RISK ACCEPTANCE.

7. The security engineer reviews the request and finds the business justification appropriate. The security engineer changes the status of the Jira ticket to ACCEPTED RISK. This closes the Jira ticket.

8. A CloudWatch daily event initiates the refresh Lambda function, which identifies closed JIRA tickets and updates their related Security Hub findings as SUPPRESSED.
Tools

- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.

- **Amazon CloudWatch Events** helps you monitor system events for your AWS resources by using rules to match events and route them to functions or streams.

- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

- **AWS Organizations** is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

- **AWS Secrets Manager** helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.

- **AWS Security Hub** provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.

**Code repository**

The code for this pattern is available on GitHub, in the [aws-securityhub-jira-software-integration](https://github.com/aws-securityhub-jira-software-integration) repository. It includes the sample code and Jira workflow for this solution.
Epics

Configure Jira

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Import the workflow.</td>
<td>As an administrator in Jira, import the <code>issue-workflow.xml</code> file to your Jira Server instance. This file can be found in the <code>aws-securityhub-jira-software-integration</code> repository in GitHub. For instructions, see Using XML to create a workflow (Jira documentation).</td>
<td>Jira administrator</td>
</tr>
<tr>
<td>Activate and assign the workflow.</td>
<td>Workflows are inactive until you assign them to a workflow scheme. You then assign the workflow scheme to a project.</td>
<td>Jira administrator</td>
</tr>
<tr>
<td></td>
<td>1. For your project, make sure you have identified an issue type scheme for the project. You can create a new issue type or select from an existing one, such as Bug.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Assign the imported workflow to a workflow scheme according to the instructions in Activate a workflow (Jira documentation).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Assign the workflow scheme to a project according to the instructions in Associate a workflow scheme with a project (Jira documentation).</td>
<td></td>
</tr>
</tbody>
</table>

Set up the solution parameters

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the solution parameters.</td>
<td>1. In the <code>conf</code> folder, open <code>params_prod.sh</code> file.</td>
<td>AWS systems administrator</td>
</tr>
<tr>
<td></td>
<td>2. Provide values for the following parameters:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>ORG_ACCOUNT_ID</code> – The account ID for your AWS Organizations management account. The solution reads account tags and assigns tickets to the specific</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td></td>
<td>security contacts defined in those AWS account tags.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• ORG_ROLE – The name of the IAM role used to access the AWS Organization management account. This role must have OrganizationsReadOnlyAccess permissions.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• EXTERNAL_ID – An optional parameter if you are using an external ID to assume the IAM role defined in ORG_ROLE. For more information, see How to use an external ID (IAM documentation).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• JIRA_DEFAULT_ASSIGNEE – This is the Jira ID for default assignee for all Security Issues. This default assigned is used in case account is not tagged properly or role cannot be assumed.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• JIRA_INSTANCE – The HTTPS address for your Jira server in the following format: team-&lt;team-id&gt;.atlassian.net/</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• JIRA_PROJECT_KEY – The name of the Jira project key used to create tickets, such as SEC or TEST. This project must already exist in Jira.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• ISSUE_TYPE – The name of the issue type scheme assigned to the project in Jira, such as Bug or Security Issue.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• REGIONS – List of AWS Region codes where you want to deploy this solution, such as eu-west-1.</td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Save and close the solution parameter file.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Identify the findings you want to automate.</td>
<td>1. Open the Security Hub console at <a href="https://console.aws.amazon.com/securityhub/">https://console.aws.amazon.com/securityhub/</a>&lt;br&gt;2. In the Security Hub navigation pane, choose <strong>Findings</strong>.&lt;br&gt;3. Choose the finding title.&lt;br&gt;4. Choose the finding ID. This displays the complete JSON for the finding.&lt;br&gt;5. In the JSON, copy the string in the <strong>GeneratorId</strong> field. This value is in AWS Security Finding Format (ASFF). For example, <code>aws-foundational-security-best-practices/v/1.0.0/S3.1</code> corresponds to findings from the security control S3.1 <strong>S3 Block Public Access setting should be enabled</strong>.&lt;br&gt;6. Repeat these steps until you have copied all of the <strong>GeneratorId</strong> values for any findings you want to automate.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
</tbody>
</table>
| Add the findings to the configuration file.| 1. In `src/code`, open the `config.json` file.  
2. Paste the `GeneratorID` values you retrieved in the previous story into the default parameter, and use commas to separate each ID.  
3. Save and close the configuration file.  
   The following code example shows automating the `aws-foundational-security-best-practices/v/1.0.0/SNS.1` and `aws-foundational-security-best-practices/v/1.0.0/S3.1` findings.  
   ```json
   {
       "Controls": {
           "eu-west-1": [
               "arn:aws:securityhub:::ruleset/cis-aws-foundations-benchmark/v/1.2.0/rule/1.22",
               "arn:aws:securityhub:::ruleset/aws-foundational-security-benchmark/v/1.0.0/SNS.1",
               "arn:aws:securityhub:::ruleset/aws-foundational-security-benchmark/v/1.0.0/S3.1"
           ],
           "default": ["aws-foundational-security-best-practices/v/1.0.0/SNS.1",
                        "aws-foundational-security-best-practices/v/1.0.0/S3.1"
           ]
       }
   }
   ```  
   **Note:** You can choose to automate different findings for each AWS Region. A good practice to help prevent duplicated findings is to select a single Region to automate creation of IAM-related controls.                                                                 | AWS systems administrator     |

**Deploy the integration**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the integration.</td>
<td>In a command line terminal, enter the following command:</td>
<td>AWS systems administrator</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| Upload Jira credentials to AWS Secrets Manager. | 1. Open the Secrets Manager console at https://console.aws.amazon.com/secretsmanager/.  
2. Under Secrets, choose **Store a new secret**.  
3. For **Secret type**, choose **Other type of secret**.  
4. If you are using Jira Enterprise, for **Key/value pairs**, do the following:  
   • In the first row, enter `auth` in the key box, and then enter `token_auth` in the value box.  
   • Add a second row, enter `token` in the key box, and then enter your personal access token in the value box.  
   If you are using Jira Cloud, for **Key/value pairs**, do the following:  
   • In the first row, enter `auth` in the key box, and then enter `basic_auth` in the value box.  
   • Add a second row, enter `token` in the key box, and then enter your API token in the value box.  
   • Add a third row, enter `email` in the key box, and then enter your email address in the value box.  
5. Choose **Next**.  
6. For **Secret name**, enter Jira-Token, and then at the bottom of the page, choose **Next**.  
7. On the Secret rotation page, keep **Disable automatic rotation**, and then at the bottom of the page, choose **Next**.  
8. On the Review page, review the secret details, and then choose **Store**. | AWS systems administrator |
Task | Description | Skills required
--- | --- | ---
Create the Security Hub custom action. | 1. For each AWS Region, in the AWS Command Line Interface (AWS CLI), use the `create-action-target` command to create a Security Hub custom action named `CreateJiraIssue`.  
```bash
aws securityhub create-action-target --name "CreateJiraIssue" --description "Create ticket in JIRA" --id "CreateJiraIssue" --region $<aws-region>
``` | AWS systems administrator

3. In the Security Hub navigation pane, choose **Findings**.
4. In the list of findings, select the findings you want to escalate.
5. In the **Actions** menu, choose `CreateJiraIssue`.

Additional information

**Example of a Jira ticket**

When a specified Security Hub finding occurs, this solution automatically creates a Jira ticket. The ticket includes the following information:

- **Title** – The title identifies the security issue in the following format:
  
  **AWS Security Issue :: <AWS account ID> :: <Security Hub finding title>**

- **Description** – The description section of the ticket describes the security control associated with the finding, includes a link to the finding in the Security Hub console, and provides a short description of how to handle the security issue in the Jira workflow.

  The following is an example of an automatically generated Jira ticket.
Title
AWS Security Issue :: 012345678912 :: Lambda.1
Lambda function policies should prohibit public access.

What is the problem?
We detected a security finding within the AWS account 012345678912 you are responsible for.

This control checks whether the AWS Lambda function policy attached to the Lambda resource prohibits public access. If the Lambda function policy allows public access, the control fails.

What do I need to do with the ticket?
• Access the account and verify the configuration. Acknowledge working on ticket by moving it to "Allocated for Fix". Once fixed, moved to test fix so Security validates the issue is addressed.
• If you think risk should be accepted, move it to "Awaiting Risk acceptance". This will require review by a Security engineer.
• If you think is a false positive, transition it to "Mark as False Positive". This will get reviewed by a Security engineer and reopened/closed accordingly.

Centralized logging and multiple-account security guardrails

Created by Ankush Verma (AWS) and Tracy (Pierce) Hickey (AWS)

Environment: Production
Technologies: Security, identity, compliance; Management & governance
AWS services: AWS CloudFormation; AWS Config; Amazon CloudWatch; AWS CodePipeline; Amazon GuardDuty; AWS Lambda; Amazon Macie; AWS Security Hub; Amazon S3

Summary
The approach covered in this pattern is suitable for customers who have multiple Amazon Web Services (AWS) accounts with AWS Organizations and are now encountering challenges when using AWS Control
Tower, a landing zone, or account vending machine services to set up baseline guardrails in their accounts.

This pattern demonstrates the use of a streamlined multiple-account architecture to set up centralized logging and standardized security controls in a well-structured manner. With the help of AWS CloudFormation templates, AWS CodePipeline, and automation scripts, this setup is deployed in all accounts that belong to an organization.

The multiple-account architecture includes the following accounts:

- **Centralized logging account** – The account where all the virtual private cloud (VPC) flows logs, AWS CloudTrail logs, the AWS Config log, and all the logs of Amazon CloudWatch Logs (using subscriptions) from all the other accounts are stored.

- **Parent security account** – The account to serve as the parent account for the following security services that manage across multiple accounts.
  - Amazon GuardDuty
  - AWS Security Hub
  - Amazon Macie
  - Amazon Detective

- **Child accounts** – The other accounts in the organization. These accounts store all the useful logs in the centralized logging account. The child accounts join the parent security account as members for the security services.

After you launch the CloudFormation template (attached), it provisions three Amazon Simple Storage Service (Amazon S3) buckets in the centralized logging account. One bucket is used to store all AWS related logs (such as logs from VPC Flow Logs, CloudTrail, and AWS Config) from all the accounts. The second bucket is for storing the CloudFormation templates from all the accounts. The third bucket is for storing Amazon S3 access logs.

A separate CloudFormation template creates the pipeline that uses AWS CodeCommit. After the updated code is pushed to the CodeCommit repository, it takes care of launching resources and setting up security services in all the accounts. For more information about the file structure of the files that will be uploaded to the CodeCommit repository, see the README.md file (attached).

**Prerequisites and limitations**

**Prerequisites**

- An AWS Organizations organization ID, with all accounts joined to the same organization.
- An active email address to receive Amazon Simple Notification Service (Amazon SNS) notifications.
- Confirmed quotas for Amazon Simple Storage Service (Amazon S3) buckets in each of your accounts. By default, each account has 100 S3 buckets. If you require additional buckets, request a quota increase before you deploy this solution.

**Limitations**

All the accounts should be the part of the same organization. If you are not using AWS Organizations, you must modify certain policies, such as the S3 bucket policy, to allow access from the AWS Identity and Access Management (IAM) roles for each account.

**Note:** While the solution is being deployed, you must confirm the Amazon SNS subscription. The confirmation message is sent to the email address that you provide during the deployment process. This will initiate a few email alert messages to this email address, because these alarms are initiated whenever IAM role policies are created or modified in the account. During the deployment process, you can ignore these alert messages.
Architecture

Target technology stack

- Amazon CloudWatch alarms and logs
- AWS CodeCommit repository
- AWS CodePipeline
- AWS Config
- Amazon Detective
- Amazon GuardDuty
- IAM roles and permissions
- Amazon Macie
- S3 buckets
- AWS Security Hub
- Amazon SNS

Target architecture
1. Other accounts registered as child accounts of the parent security account for the security services
2. Security findings from all the child accounts, including the parent account

Resources
The following resources are provisioned automatically when the updated code is pushed to the CodeCommit repository in each account and AWS Region.

CloudFormation stack 1 – Logging parent stack
- Nested stack 1 – Standard IAM roles and policies
- Nested stack 2 – AWS Config setup in the account
- Nested stack 3 – CloudWatch alarms
  - SecurityGroupChangesAlarm
  - UnauthorizedAttemptAlarm
  - RootActivityAlarm
  - NetworkAclChangesAlarm
  - IAMUserManagementAlarm
  - IAMPolicyChangesAlarm
  - CloudTrailChangeAlarm
  - IAMCreateAccessKeyAlarm
  - Metric filters for creating metrics from CloudTrail logs and using them for alarms
  - SNS topic

CloudFormation stack 2 – Parent guardrail stack
- Nested stack 1 – AWS Lambda function for setting up the account password policy
- Nested stack 2 – Basic AWS Config rules
  - CIS-SecurityGroupsMustRestrictSshTraffic
  - OpenSecurityGroupRuleCheck along with the Lambda function for security group rule evaluation
  - check-ec2-for-required-tag
  - check-for-unrestricted-ports

CloudFormation stack 3 – CloudWatch logs export
- Exporting CloudWatch logs from log groups to Amazon S3 using an Amazon Kinesis subscription

Tools
- AWS CloudFormation – AWS CloudFormation uses templates to model and provision, in an automated and secure manner, all the resources needed for your applications across all AWS Regions and accounts.
- Amazon CloudWatch – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.
**AWS CodeCommit** – AWS CodeCommit is a version-control service hosted by AWS. You can use CodeCommit to privately store and manage assets (such as documents, source code, and binary files) in the cloud.

**AWS CodePipeline** – AWS CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software.

**AWS Config** – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.

**Amazon Detective** – Amazon Detective is used to analyze, investigate, and quickly identify the root cause of security findings or suspicious activities. Detective automatically collects log data from your AWS resources. It then uses machine learning, statistical analysis, and graph theory to help you visualize and conduct faster and more efficient security investigations.

**Amazon GuardDuty** – Amazon GuardDuty is a continuous security monitoring service that analyzes and processes the flow logs, CloudTrail management event logs, CloudTrail data event logs, and Domain Name System (DNS) logs. It uses threat intelligence feeds, such as lists of malicious IP addresses and domains, and machine learning to identify unexpected and potentially unauthorized and malicious activity within your AWS environment.

**AWS Identity and Access Management** – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.

**Amazon Macie** – Amazon Macie automates the discovery of sensitive data, such as personally identifiable information (PII) and financial data, to provide you with a better understanding of the data that your organization stores in Amazon S3.

**Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

**AWS Security Hub** – AWS Security Hub provides you with a comprehensive view of your security state in AWS and helps you check your environment against security standards and best practices.

**Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).

## Epics

### Step 1: Set up the IAM roles in all the accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch the Childaccount_IAM_role_All_Accounts.yaml CloudFormation template to create the IAM role in the us-east-1 Region.</td>
<td>To create the required IAM roles and permissions, you must manually launch this template in each account, one by one (centralized logging account, parent security account, and all other AWS accounts in the organization) in the us-east-1 Region. The Childaccount_IAM_role_All_Accounts.yaml template is in the /templates/initial_deployment_templates directory of the package. The IAM role is used when making API calls for provisioning and</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>In the template parameters, provide the name of the IAM role.</td>
<td>Provide the IAM role that CodeBuild, in the parent security account, can assume in all other child accounts. The default role name is <code>security_execute_child_stack_role</code>.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>In the parameters, provide the account ID for the parent security account.</td>
<td>The parent security account is the account where CodeBuild runs.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

### Step 2: Set up S3 buckets in the centralized logging account

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the centralized logging account, in us-east-1, launch the S3Buckets-Centralized-LoggingAccount.yaml CloudFormation template.</td>
<td>To create the S3 buckets in the centralized logging account, launch the S3Buckets-Centralized-LoggingAccount.yaml. The template is in the <code>/templates/initial_deployment_templates</code> directory of the package. The S3 buckets will store all the logs, templates, and Amazon S3 access logs. Make a note of all the S3 bucket names, which you will use to modify the parameter files in the following steps.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>In the template parameters, provide the name of the S3 bucket for AWS logs storage.</td>
<td>Enter a name for the S3 Bucket Name for Centralized Logging in Logging Account parameter. This bucket acts as centralized location to store AWS logs, such as flow logs and CloudTrail logs, from all the accounts. Make a note of both the bucket name and the Amazon Resource Name (ARN).</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Provide the name of the S3 bucket for storing access logs.</td>
<td>Enter an S3 bucket name for the S3 Bucket Name for Access Logs in Logging Account parameter. This S3</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
### Task | Description | Skills required
--- | --- | ---
bucket stores access logs for Amazon S3. | | Cloud architect

**Provide the name of the S3 bucket for storing templates.**

Enter an S3 bucket name in the S3 Bucket Name for CloudFormation Template storage in Logging Account parameter. | Cloud architect

**Provide the organization ID.**

To provide access to S3 buckets within the organization, enter the ID for the organization in the Organization Id for Non-AMS accounts parameter. | Cloud architect

### Step 3: Deploy the CI/CD infrastructure in the parent security account

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Launch the security-guard-rails-codepipeline-Centralized-SecurityAccount.yml CloudFormation template.</strong></td>
<td>To deploy the CI/CD pipeline, manually launch the security-guard-rails-codepipeline-Centralized-SecurityAccount.yml template in the parent security account in us-east-1. The template is in the /templates/initial_deployment_templates directory of the package. This pipeline will deploy all the infrastructure in all the child accounts.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

**Provide a name for the S3 bucket that will store templates in the centralized logging account.**

Enter the name of the S3 bucket that you provided for the S3 Bucket Name for the CloudFormation Template storage in Logging Account parameter in Step 2. | Cloud architect

**Provide the name of the IAM role to be used in the child accounts.**

Enter the name that you provided for the Name of the IAM role parameter in Step 1. | Cloud architect

**Provide an active email address for receiving CodePipeline failure notifications.**

Enter the email address that you want to use for receiving CodePipeline failure notifications and other CloudWatch alarm-related notifications. | Cloud architect
## Step 4: Update files to include account information

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify Accountlist.json.</td>
<td>In the Accountlist.json file, which is at the top level in the package, add the parent security account number and the child account numbers. Note that the ChildAccountList field also includes the parent security account number. See the example in the deployment-instructions.md file in the package.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Modify accounts.csv</td>
<td>In the accounts.csv file, which is at the top level in the package, add all the child accounts along with the email registered with the accounts. See the example in the deployment-instructions.md file.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
| Modify parameters.config. | In the parameters.config file, which is in the /templates folder, update the following six parameters:  
  - pNotifyEmail: The email address that you provided when you set up the pipeline (see Step 3)  
  - pstackNameLogging: The name of the CloudFormation stack for centralized logging  
  - pS3LogsBucket: The name of the S3 bucket where logs from all accounts will be stored (see Step 2)  
  - pBucketName: The ARN for the S3 bucket used to store the logs  
  - pTemplateBucketName: The name of the S3 buckets where templates will be stored (see Step 2)  
  - pAllowedAccounts: Account IDs for the parent and child accounts  

For the other parameters, you can keep the default values. For an example, | Cloud architect |
### Step 5: Access the CodeCommit repository and push the updated files

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Access the CodeCommit repo that you created in Step 3.</strong></td>
<td>From the Outputs section of the CI/CD infrastructure CloudFormation stack (launched in Step 3), note the name of the CodeCommit repository URL. Create access to the repository so that the files can be pushed to it for the infrastructure to be deployed in all the target accounts. For more information, see Setting up for AWS CodeCommit.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td><strong>Push the files to the CodeCommit repository.</strong></td>
<td>Install Git on your machine. Then run the Git commands to clone the empty repository, copy the files from your laptop to the repository folder, and push the artifacts to the repository. Check for the sample Git commands in the deployment-instructions.md file in the package. For basic Git commands, see the Related resources section.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

Check an Amazon CloudFront distribution for access logging, HTTPS, and TLS version

Summary

This pattern checks an Amazon CloudFront distribution to make sure that it uses HTTPS, uses Transport Layer Security (TLS) version 1.2 or later, and has access logging enabled. CloudFront is a service provided by Amazon Web Services (AWS) that speeds up the distribution of your static and dynamic web content, such as .html, .css, .js, and image files, to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations. When a user requests content that you're serving with CloudFront, the request is routed to the edge location that provides the lowest latency (time delay), so that content is delivered with the best possible performance.

This pattern provides an AWS Lambda function that is initiated when Amazon CloudWatch Events detects the CloudFront API call CreateDistribution, CreateDistributionWithTags, or UpdateDistribution. The custom logic in the Lambda function evaluates all CloudFront distributions that were created or updated in the AWS account. It sends a violation notification by using Amazon Simple Notification Service (Amazon SNS) if it detects the following violations:

- Global checks:
  - Custom certificate doesn't use TLS version 1.2
  - Logging is disabled for distribution
- Origin checks:
  - Origin isn't configured with TLS version 1.2
  - Communication with origin is allowed on a protocol other than HTTPS
- Behavior checks:
  - Default behavior communication is allowed on a protocol other than HTTPS
  - Custom behavior communication is allowed on a protocol other than HTTPS
Prerequisites and limitations

Prerequisites

- An active AWS account
- An email address where you want to receive the violation notifications

Limitations

- This security control doesn't check for existing Cloudfront distributions unless an update has been made to the distribution.
- CloudFront is considered a global service and isn't tied to a specific AWS Region. However, Amazon CloudWatch Logs and AWS Cloudtrail API logging for global services occur in the US East (N. Virginia) Region (us-east-1). Therefore, this security control for CloudFront must be deployed and maintained in us-east-1. This single deployment monitors all distributions for CloudFront. Do not deploy the security control in any other AWS Regions. (Deployment in other Regions will result in a failure to initiate CloudWatch Events and the Lambda function, and no SNS notifications.)
- This solution has gone through extensive testing with CloudFront web content distributions. It does not cover real-time messaging protocol (RTMP) streaming distributions.

Architecture

Target technology stack

- Lambda function
- SNS topic
- Amazon EventBridge rule

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy the attached template across multiple accounts that you want to monitor.

Tools

AWS services

- AWS CloudFormation – CloudFormation is a service that helps you model and set up AWS resources by using infrastructure as code.
AWS Prescriptive Guidance Patterns

Epics

• **Amazon EventBridge** – EventBridge delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services, routing that data to targets such as Lambda functions.

• **AWS Lambda** – Lambda supports running code without provisioning or managing servers.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

• **Amazon SNS** – Amazon SNS coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

The attached code includes:

• A .zip file that contains the Lambda code (index.py)

• A CloudFormation template (.yml file) that you run to deploy the Lambda code

Epics

Upload the security control

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the S3 bucket for the Lambda code.</td>
<td>On the Amazon S3 console, create a S3 bucket with an unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. Your S3 bucket must be in the Region where you are planning to deploy the Lambda code.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Upload the Lambda code to the S3 bucket.</td>
<td>Upload the Lambda code (cloudfront_ssl_log_lambda.zip file) that's provided in the Attachments section to the S3 bucket you created in the previous step.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

Deploy the CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the CloudFormation template.</td>
<td>On the AWS CloudFormation console, in the same AWS Region as the S3 bucket, deploy the CloudFormation template.</td>
<td>Cloud architect</td>

<td>For the <strong>S3 Bucket</strong> parameter, specify the name of the S3 bucket that you created in the first epic.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Specify the Amazon S3 key name for the Lambda file.</td>
<td>For the <strong>S3 Key</strong> parameter, specify the Amazon S3 location of the Lambda code .zip file in your S3 bucket. Do not include leading slashes (for example, you can enter lambda.zip or controls/lambda.zip).</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Provide a notification email address.</td>
<td>For the <strong>Notification email</strong> parameter, provide an email address where you would like to receive the violation notifications.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
| Define the logging level. | For the **Lambda Logging level** parameter, define the logging level for your Lambda function. Choose one of the following values:  
  - **INFO** to get detailed informational messages on the application's progress.  
  - **ERROR** to get information about error events that could still allow the application to continue running.  
  - **WARNING** to get information about potentially harmful situations. | Cloud architect |

**Confirm the subscription**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Confirm the subscription.</td>
<td>When the CloudFormation template has been deployed successfully, a new SNS topic is created and a subscription message is sent to the email address you provided. You must confirm this email subscription to receive violation notifications.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
Check for single-host network entries in security group ingress rules for IPv4 and IPv6

Created by SaiJeewan Devireddy (AWS) and John Reynolds (AWS)

| Environment: Production | Technologies: Networking; Security, identity, compliance | AWS services: Amazon SNS; AWS CloudFormation; Amazon CloudWatch; AWS Lambda; Amazon VPC |

Summary

This pattern provides a security control that notifies you when Amazon Web Services (AWS) resources do not meet your specifications. It provides an AWS Lambda function that looks for single-host network entries in both Internet Protocol version 4 (IPv4) and IPv6 security group source address fields. The Lambda function is initiated when Amazon CloudWatch Events detects the Amazon Elastic Compute Cloud (Amazon EC2) AuthorizeSecurityGroupIngress API call. The custom logic in the Lambda function evaluates the subnet mask of the CIDR block of the security group ingress rule. If the subnet mask is determined to be anything other than /32 (IPv4) or /128 (IPv6), the Lambda function sends a violation notification by using Amazon Simple Notification Service (Amazon SNS).

Prerequisites and limitations

Prerequisites

- An active AWS account
- An email address where you want to receive the violation notifications

Limitations

- This security monitoring solution is regional and must be deployed in each AWS Region that you want to monitor.
Architecture

Target technology stack

- Lambda function
- SNS topic
- Amazon EventBridge rule

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template across multiple accounts that you want to monitor.

Tools

AWS services

- **AWS CloudFormation** – CloudFormation is a service that helps you model and set up AWS resources by using infrastructure as code.
- **Amazon EventBridge** – EventBridge delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services, and routes that data to targets such as Lambda functions.

## Deploy the Security Automations for AWS WAF solution by using Terraform
Summary

AWS WAF is a web application firewall that helps protect applications from common exploits by using customizable rules, which you define and deploy in web access control lists (ACLs). Configuring AWS WAF rules can be challenging, especially for organizations that do not have dedicated security teams. To simplify this process, Amazon Web Services (AWS) offers the Security Automations for AWS WAF solution, which automatically deploys a single web ACL with a set of AWS WAF rules that filters web-based attacks. During Terraform deployment, you can specify which protective features to include. After you deploy this solution, AWS WAF inspects web requests to existing Amazon CloudFront distributions or Application Load Balancers, and blocks any requests that don’t match the rules.

The Security Automations for AWS WAF solution can be deployed by using AWS CloudFormation according to the instructions in the Security Automations for AWS WAF Implementation Guide. This pattern provides an alternative deployment option for organizations that use Hashicorp Terraform as their preferred infrastructure as code (IaC) tool to provision and manage their cloud infrastructure. When you deploy this solution, Terraform automatically applies the changes in the cloud and deploys and configures the AWS WAF settings and protective features.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured with necessary permissions. For more information, see Getting started (AWS CLI documentation).
- Terraform installed and configured. For more information, see Install Terraform (Terraform documentation).

Product versions

- AWS CLI version 2.4.25 or later
- Terraform version 1.1.9 or later

Architecture

Target architecture

This pattern deploys the Security Automations for AWS WAF solution. For more information about the target architecture, see Architecture overview in the Security Automations for AWS WAF Implementation Guide. For more information about the AWS Lambda automations in this deployment, the Application log parser, the AWS WAF log parser, the IP lists parser, and the Access handler, see Component details in the Security Automations for AWS WAF Implementation Guide.

Terraform deployment
When you run `terraform apply`, Terraform does the following:

1. Terraform creates IAM roles and Lambda functions based on the inputs from the `testing.tfvars` file.
2. Terraform creates AWS WAF ACL rules and IP sets based on the inputs from the `testing.tfvars` file.
3. Terraform creates the Amazon Simple Storage Service (Amazon S3) buckets, Amazon EventBridge rules, AWS Glue database tables, and Amazon Athena work groups based on the inputs from the `testing.tfvars` file.
4. Terraform deploys the AWS CloudFormation stack to provision the custom resources.
5. Terraform creates the Amazon API Gateway resources based on the given inputs from `testing.tfvars` file.

**Automation and scale**

You can use this pattern to create AWS WAF rules for multiple AWS accounts and AWS Regions to deploy the Security Automations for AWS WAF solution throughout your AWS Cloud environment.

**Tools**

**AWS services**

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS WAF** is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources.

**Other services**

- **Git** is an open-source, distributed version control system.
- **Hashicorp Terraform** is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.

**Code repository**

The code for this pattern is available in the GitHub [AWS WAF Automation Using Terraform](https://github.com/aws-solutions/AWS-WAF-Automation-Using-Terraform) repository.

**Best practices**

- Put static files in separate S3 buckets.
- Avoid hardcoding variables.
- Limit the use of custom scripts.
- Adopt a naming convention.

**Epics**

**Set up your local workstation**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install Git.</td>
<td>Follow the instructions in Getting started (Git website)</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
## Provision the target architecture using Terraform

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initialize the Terraform configuration.</td>
<td>Enter the following command to initialize your working directory that contains the Terraform configuration files.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Preview the Terraform plan.</td>
<td>Enter the following command. Terraform evaluates the configuration files to determine the target state for the declared resources. It then compares the target state against the current state and creates a plan.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Verify the plan.</td>
<td>Review the plan and confirm that it configures the required</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

---

### Tasks

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clone the repository.</td>
<td>On your local workstation, enter the following command to clone the code repository. To copy the full command, including the repo URL, see the Additional information (p. 2115) section of this pattern.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
| Update the variables.    | 1. Navigate into the cloned directory by entering the following command.  
2. In any text editor, open the testing.tfvars file.  
3. Update the values of the variables in the testing.tfvars file.  
4. Save and close the file. | DevOps engineer   |
Deploy the solution.

1. Enter the following command to apply the plan.
   ```bash
terraform apply -var-file="testing.tfvars"
   ```
2. Enter yes to confirm.
   Terraform creates, updates, or destroys infrastructure to achieve the target state declared in the configuration files. For more information about the sequence, see *Terraform deployment* in the *Architecture* (p. 2111) section of this pattern.

Skills required: DevOps engineer

Validate and clean up

Verify the changes.

1. In the Terraform console, verify that the outputs match the expected results.
2. Sign in to the AWS Management Console.
3. Verify the outputs in the Terraform console have been successfully deployed in your AWS account.

Skills required: DevOps engineer

(Optional) Clean up the infrastructure.

If you want to remove all resources and configuration changes made by this solution, do the following:

1. In the Terraform console, enter the following command.
   ```bash
terraform destroy -var-file="testing.tfvars"
   ```
2. Enter yes to confirm.

Skills required: DevOps engineer
Troubleshooting

<table>
<thead>
<tr>
<th>Issue</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>WAFV2 IPSet: WAFOptimisticLockException error</td>
<td>If you receive this error when you run the <code>terraform destroy</code> command, you must manually delete the IP sets. For instructions, see [Deleting an IP set](AWS WAF documentation).</td>
</tr>
</tbody>
</table>

#### Code repository:
- Automated IAM Access Analyzer Role Policy Generator

#### Environment: PoC or pilot

#### Technologies: Security, identity, compliance; Serverless

#### AWS services: AWS IAM Access Analyzer; AWS Lambda; AWS Step Functions; AWS Identity and Access Management
Summary

Least-privilege is the security best practice of granting the minimum permissions required to perform a task. Implementing least-privilege access in an already active Amazon Web Services (AWS) account can be challenging because you don’t to unintentionally block users from performing their job duties by changing their permissions. Before you can implement AWS Identity and Access Management (IAM) policy changes, you need to understand the actions and resources the account users are performing.

This pattern is designed to help you apply the principle of least-privilege access, without blocking or slowing down team productivity. It describes how to use IAM Access Analyzer and AWS Step Functions to dynamically generate an up-to-date IAM policy for your role, based on the actions that are currently being performed in the account. The new policy is designed to permit the current activity but remove any unnecessary, elevated privileges. You can customize the generated policy by defining allow and deny rules, and the solution integrates your custom rules.

This pattern includes options for implementing the solution with AWS Cloud Development Kit (AWS CDK) or Hashicorp CDK for Terraform (CDKTF). You can then associate the new policy to the role by using a continuous integration and continuous delivery (CI/CD) pipeline. If you have a multi-account architecture, you can deploy this solution in any account where you want to generate updated IAM policies for the roles, increasing the security of your entire AWS Cloud environment.

Prerequisites and limitations

Prerequisites

- An active AWS account with a CloudTrail trail enabled.
- IAM permissions for the following:
  - Create and deploy Step Functions workflows. For more information, see Actions, resources, and condition keys for AWS Step Functions (Step Functions documentation).
  - Create AWS Lambda functions. For more information, see Execution role and user permissions (Lambda documentation).
  - Create IAM roles. For more information, see Creating a role to delegate permissions to an IAM user (IAM documentation).
- npm installed. For more information, see Downloading and installing Node.js and npm (npm documentation).
- If you are deploying this solution with AWS CDK (Option 1):
  - AWS CDK Toolkit, installed and configured. For more information, see Install the AWS CDK (AWS CDK documentation).
- If you are deploying this solution with CDKTF (Option 2):
  - CDKTF, installed and configured. For more information, see Install CDK for Terraform (CDKTF documentation).
  - Terraform, installed and configured. For more information, see Get Started (Terraform documentation).
  - AWS Command Line Interface (AWS CLI) locally installed and configured for your AWS account. For more information, see Installing or updating the latest version of the AWS CLI (AWS CLI documentation).

Limitations

- This pattern does not apply the new IAM policy to the role. At the end of this solution, the new IAM policy is stored in a CodeCommit repository. You can use a CI/CD pipeline to apply policies to the roles in your account.
Architecture

Target architecture

1. A regularly scheduled Amazon EventBridge event rule starts a Step Functions workflow. You define this regeneration schedule as part of setting up this solution.

2. In the Step Functions workflow, a Lambda function generates the date ranges to use when analyzing account activity in the CloudTrail logs.

3. The next workflow step calls the IAM Access Analyzer API to start generating the policy.

4. Using the Amazon Resource Name (ARN) of the role you specify during set up, IAM Access Analyzer analyzes the CloudTrail logs for activity within the specified date range. Based on the activity, IAM Access Analyzer generates an IAM policy that permits only the actions and services used by the role during the specified date range. When this step is complete, this step generates a job ID.

5. The next workflow step checks for the job ID every 30 seconds. When the job ID is detected, this step uses the job ID to call the IAM Access Analyzer API and retrieve the new IAM policy. IAM Access Analyzer returns the policy as a JSON file.

6. The next workflow step puts the <IAM role name>/policy.json file in an Amazon Simple Storage Service (Amazon S3) bucket. You define this S3 bucket as part of setting up this solution.

7. An Amazon S3 event notification starts a Lambda function.

8. The Lambda function retrieves the policy from the S3 bucket, integrates the custom rules you define in the allow.json and deny.json files, and then pushes the updated policy to CodeCommit. You define the CodeCommit repository, branch, and folder path as part of setting up this solution.

Tools

AWS services
• **AWS Cloud Development Kit (AWS CDK)** is a software development framework that helps you define and provision AWS Cloud infrastructure in code.

• **AWS CDK Toolkit** is a command line cloud development kit that helps you interact with your AWS Cloud Development Kit (AWS CDK) app.

• **AWS CloudTrail** helps you audit the governance, compliance, and operational and risk of your AWS account.

• **AWS CodeCommit** is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

• **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

• **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them. This pattern uses IAM Access Analyzer, a feature of IAM, to analyze your CloudTrail logs to identify actions and services that have been used by an IAM entity (user or role) and then generate an IAM policy that is based on that activity.

• **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

• **AWS Step Functions** is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications. In this pattern, you use AWS SDK service integrations in Step Functions to call service API actions from your workflow.

**Other tools**

• **CDK for Terraform (CDKTF)** helps you define infrastructure as code (IaC) by using common programming languages, such as Python and Typescript.

• **Lerna** is a build system for managing and publishing multiple JavaScript or TypeScript packages from the same repository.

• **js** is an event-driven JavaScript runtime environment designed for building scalable network applications.

• **npm** is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.

**Code repository**

The code for this pattern is available in the GitHub Automated IAM Access Analyzer Role Policy Generator repository.

Enable Amazon GuardDuty conditionally by using AWS CloudFormation templates

*Created by Ram Kandaswamy (AWS)*

| Environment: Production | Technologies: Security, identity, compliance; DevOps; Operations | AWS services: AWS CloudFormation; Amazon GuardDuty; AWS Lambda; AWS Identity and Access Management |
Summary

You can enable Amazon GuardDuty on an Amazon Web Services (AWS) account by using an AWS CloudFormation template. By default, if GuardDuty is already enabled when you try to use CloudFormation to turn it on, the stack deployment fails. However, you can use conditions in your CloudFormation template to check whether GuardDuty is already enabled. CloudFormation supports the use of conditions that compare static values; it does not support using the output of another resource property within the same template. For more information, see Conditions in the CloudFormation user guide.

In this pattern, you use a CloudFormation custom resource backed by an AWS Lambda function to conditionally enable GuardDuty if it is not already enabled. If GuardDuty is enabled, the stack captures the status and records it in the output section of the stack. If GuardDuty is not enabled, the stack enables it.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Identity and Access Management (IAM) role that has permissions to create, update, and delete CloudFormation stacks

Limitations

- If GuardDuty has been manually disabled for an AWS account or Region, this pattern does not enable GuardDuty for that target account or Region.

Architecture

Target technology stack

The pattern uses CloudFormation for Infrastructure as Code (IaC). You use a CloudFormation custom resource backed by a Lambda function to achieve the dynamic service-enablement capability.

Target architecture

The following high-level architecture diagram shows the process of enabling GuardDuty by deploying a CloudFormation template:

1. You deploy a CloudFormation template to create a CloudFormation stack.
2. The stack creates an IAM role and a Lambda function.
3. The Lambda function assumes the IAM role.
4. If GuardDuty is not already enabled on the target AWS account, the Lambda function enables it.
**Tools**

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **Amazon GuardDuty** – Amazon GuardDuty is a continuous security monitoring service that analyzes and processes logs. It uses threat intelligence feeds, such as lists of malicious IP addresses and domains, and machine learning to identify unexpected and potentially unauthorized and malicious activity within your AWS environment.

- **AWS IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
## Epics

Create the CloudFormation template and deploy the stack

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the CloudFormation template. | 1. Copy the code in *CloudFormation template* in the Additional information (p. 2126) section.  
2. Paste the code in a text editor.  
3. Save the file as `sample.yaml` on your workstation. | AWS DevOps |
| Create the CloudFormation stack. | 1. In AWS CLI, enter the following command. This creates a new CloudFormation stack using the sample.yaml file. For more information, see Creating a stack in the CloudFormation user guide.  
```bash
aws cloudformation create-stack \
  --stack-name guardduty-cf-stack \
  --template-body file://sample.yaml
```
  
2. Confirm the following value appears in the AWS CLI, indicating that the stack has been successfully created. The amount of time required to create the stack can vary.  
```json
"StackStatus": "CREATE_COMPLETE",
```
| | AWS DevOps |
| Validate that GuardDuty is enabled for the AWS account. | 1. Sign in to the AWS Management Console and open the GuardDuty console at [https://console.aws.amazon.com/guardduty/](https://console.aws.amazon.com/guardduty/).  
2. Verify that the GuardDuty service is enabled. | Cloud administrator, AWS administrator |
| Configure additional accounts or AWS Regions. | As needed for your use case, use the AWS CloudFormation StackSet feature to extend this solution to multiple AWS accounts and AWS Regions. For more information, see Working with AWS CloudFormation | Cloud administrator, AWS administrator |

                print("Exception: ", e)
              responseData = {}
              responseData["status"] = enabled
              cfnresponse.send(event, context, cfnresponse.SUCCESS, responseData, "CustomResourcePhysicalID")
          elif event['RequestType'] == "Delete":
            cfn_response=cfn.delete_stack(
              StackName='guardduty-cfn-stack')
            cfnresponse.send(event, context, cfnresponse.SUCCESS, {})
Alternative code option for the Lambda resource

The provided CloudFormation template uses inline code to reference the Lambda resource, for easier reference and guidance. Alternatively, you can place the Lambda code in an Amazon Simple Storage Service (Amazon S3) bucket and reference it in the CloudFormation template. Inline code doesn’t support package dependencies or libraries. You can support these by placing the Lambda code in an S3 bucket and referencing it in the CloudFormation template.

Replace the following lines of code:

```plaintext
Code:
ZipFile: |
```

with the following lines of code:

```plaintext
Code:
S3Bucket: <bucket name>
S3Key: <python file name>
S3ObjectVersion: <version>
```

The S3ObjectVersion property can be omitted if you are not using versioning in your S3 bucket. For more information, see Using versioning in S3 buckets in the Amazon S3 user guide.

Enable transparent data encryption in Amazon RDS for SQL Server

 Created by Ranga Cherukuri (AWS)

<table>
<thead>
<tr>
<th>Created by: AWS</th>

<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to implement Transparent Data Encryption (TDE) in Amazon Relational Database Service (Amazon RDS) for SQL Server to encrypt data at rest.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS for SQL Server DB instance
Amazon RDS currently supports TDE for the following SQL Server versions and editions:

- SQL Server 2012 Enterprise Edition
- SQL Server 2014 Enterprise Edition
- SQL Server 2016 Enterprise Edition
- SQL Server 2017 Enterprise Edition

For the latest information about supported versions and editions, see [Support for Transparent Data Encryption in SQL Server](#) in the Amazon RDS documentation.

**Architecture**

**Technology stack**

- Amazon RDS for SQL Server

**Architecture**

![Architecture Diagram]

**Tools**

**Tools**
SSMS - Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing a SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

**Code**

*Query to get the default certificate name:*

```sql
USE [master]
GO
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'
GO
```

*Query to create a database encryption key (you can specify the AES_256 algorithm instead of AES_128):*

```sql
USE [Databasename]
GO
CREATE DATABASE ENCRYPTION KEY
WITH ALGORITHM = AES_128
ENCRYPTION BY SERVER CERTIFICATE [certificatename]
GO
```

*Query to enable database encryption:*

```sql
ALTER DATABASE [Database Name]
SET ENCRYPTION ON
GO
```

*Query to check the status of encryption:*

```sql
SELECT DB_NAME(database_id) AS DatabaseName, encryption_state, percent_complete FROM sys.dm_database_encryption_keys
```

**Epics**

**Create an option group in the Amazon RDS console**

Ensure that AWS CloudFormation stacks are launched from authorized S3 buckets

*Summary*

You can use AWS CloudFormation templates to set up Amazon Web Services (AWS) resources programmatically, so you spend less time managing those resources and more time focusing on your applications that run in AWS. This pattern provides a way to check that AWS CloudFormation stacks are created only from templates that are stored in specific Amazon Simple Storage Service (Amazon S3) buckets. This check is useful if you have a security or compliance requirement that dictates using templates stored in S3 buckets that are in an allow list.

This security control monitors the AWS CloudFormation CreateStack and UpdateStack API calls, and invokes an AWS Lambda function that checks if the template used in the call is from an authorized S3 bucket. If the template is from a non-authorized bucket, the Lambda function triggers an Amazon Simple Notification Service (Amazon SNS) email notification to the user with the relevant information.

*Prerequisites and limitations*

**Prerequisites**

- An active email address where you would like to receive violation notifications
- An S3 bucket to upload the provided Lambda code
- A list of authorized S3 bucket names

**Limitations**

- UpdateStack API calls that use an existing template in an unauthorized S3 bucket don't generate additional violations, because the URL for the S3 bucket isn't available in the Amazon EventBridge event. We recommend that you delete existing templates from unauthorized S3 buckets after you receive the original CreateStack violation notification.
- This security control doesn't monitor the following AWS CloudFormation events, because they handle updates after the template is initially deployed: CreateChangeSet, CreateStackSet, UpdateStackSet.
You must deploy this security control in every AWS Region you want to monitor.

## Architecture

### Target technology stack

- AWS Lambda
- Amazon SNS
- Amazon EventBridge rule

### Target architecture

![Architecture Diagram]

### Automation and scale

If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts that you want to monitor.

## Tools

- **AWS Cloudformation** – Helps you model and set up AWS resources using an infrastructure-as-code model.
- **Amazon EventBridge** – Delivers a stream of real-time data from your own applications, software-as-a-service (SaaS) applications, and AWS services, and routes that data to targets such as AWS Lambda.
- **AWS Lambda** – Lets you run code without provisioning or managing servers.
- **Amazon SNS** – Provides message delivery from publishers to subscribers. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.
- **Amazon S3** – Lets you store and retrieve any amount of data, at any time, from anywhere on the web.

### Additional information

When you deploy the AWS CloudFormation template provided with this pattern, you'll be prompted for the following information:

- S3 bucket: Specify the bucket where you uploaded the attached Lambda code (.zip file). You can create a new bucket or specify an existing bucket.
- S3 key: Specify the location of the Lambda .zip file in your S3 bucket (for example: `filename.zip` or `controls/filename.zip`). Do not use leading slash marks.
- Notification email: Provide an active email address where violation notifications should be sent.
- Lambda logging level: Specify the logging level for the Lambda function. Use `Info` to log detailed informational messages on progress, `Error` for error events that would still allow the deployment to continue, and `Warning` for potentially harmful situations.
- Authorized buckets: Provide a comma-delimited list of authorized S3 buckets.

Ensure AWS load balancers use secure listener protocols (HTTPS, SSL/TLS)

Created by Chandini Penmetsa (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Security, identity, compliance</td>
</tr>
<tr>
<td>Workload:</td>
<td>All other workloads</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon SNS; AWS CloudFormation; Amazon CloudWatch; AWS Lambda; Elastic Load Balancing (ELB)</td>
</tr>
</tbody>
</table>

Summary

On the Amazon Web Services (AWS) Cloud, Elastic Load Balancing automatically distributes incoming application traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, IP addresses, and AWS Lambda functions. The load balancers use listeners to define the ports and protocols that the load balancer uses to accept traffic from users. Application Load Balancers make routing decisions at the application layer and use the HTTP/HTTPS protocols. Network Load Balancers make routing decisions at the transport layer and use the Transmission Control Protocol (TCP), Transport Layer Security (TLS), User Datagram Protocol (UDP), or TCP_UDP protocols. Classic Load Balancers make routing decisions at either the transport layer, using TCP or Secure Sockets Layer (SSL) protocols, or at the application layer, using HTTP/HTTPS.

Your organization might have a security or compliance requirement that load balancers accept traffic from users only on secure protocols, such as HTTPS or SSL/TLS.

This pattern provides a security control that uses an Amazon EventBridge rule to monitor the CreateListener and ModifyListener API calls for Application Load Balancers and Network Load Balancers, and the CreateLoadBalancerListeners and CreateLoadBalancer API calls for Classic Load Balancers. If HTTP, TCP/UDP, or TCP_UDP is used for the load balancer's listener protocol, the control invokes a Lambda function. The Lambda function publishes a message to an Amazon Simple Notification Service (Amazon SNS) topic to send a notification that contains the load balancer details.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- An email address where you want to receive the violation notification
- An Amazon Simple Storage Service (Amazon S3) bucket to store the Lambda code .zip file

**Limitations**

- This security control does not check for existing load balancers unless an update is made to the load balancer listeners.
- This security control is regional and must be deployed in the AWS Regions that you intend to monitor.
Architecture

Target technology stack

- Lambda function
- Amazon SNS topic
- EventBridge rule

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy this template in multiple accounts that you want this to monitor.

Tools

Tools

**Ensure encryption for Amazon EMR data at rest is enabled at launch**

*Created by Priyanka Chaudhary (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Security, identity, compliance; Analytics</th>
<th>Workload: Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon EMR; Amazon SNS; AWS KMS; AWS CloudFormation; AWS Lambda; Amazon S3</td>
<td></td>
</tr>
</tbody>
</table>
Summary

This pattern provides a security control for monitoring the encryption of Amazon EMR clusters on Amazon Web Services (AWS).

Data encryption helps prevent unauthorized users from reading data on a cluster and associated data storage systems. This includes data that may be intercepted as it travels the network, known as data in transit, and data that is saved to persistent media, known as data at-rest. Data at rest in Amazon Simple Storage Service (Amazon S3) can be encrypted in two ways.

- Server-side encryption with Amazon S3–managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), set up with policies that are suitable for Amazon EMR.

This security control monitors for API calls and initiates an Amazon CloudWatch Events event on RunJobFlow. The trigger invokes AWS Lambda, which runs a Python script. The function retrieves the EMR cluster ID from the event JSON input and determines whether there is a security violation by performing the following checks.

1. Check if an EMR cluster is associated with an Amazon EMR specific security configuration.
2. If an Amazon EMR specific security configuration is associated with the EMR cluster, check if Encryption-at-Rest is turned on.
3. If Encryption-at-Rest is not turned on, send an Amazon Simple Notification Service (Amazon SNS) notification that includes the EMR cluster name, violation details, AWS Region, AWS account, and the Lambda Amazon Resource Name (ARN) that this notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An S3 bucket for the Lambda code .zip file
- An email address where you want to receive the violation notification
- Amazon EMR logging turned off so that all the API logs can be retrieved

Limitations

- This detective control is regional and must be deployed in the AWS Regions you intend to monitor.

Product versions

- Amazon EMR release 4.8.0 and above

Architecture

Target technology stack

- Amazon EMR
Tools

- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up AWS resources using infrastructure as code.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- **Amazon EMR** – Amazon EMR is a managed cluster platform that simplifies running big data frameworks.
- **AWS Lambda** – AWS Lambda supports running code without provisioning or managing servers.
- **Amazon S3** – Amazon S3 is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon SNS coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Ensure that an IAM profile is associated with an EC2 instance**
### Summary

This pattern provides an AWS CloudFormation security control template that sets up automatic notification when an AWS Identity and Access Management (IAM) profile violation occurs for an Amazon Elastic Compute Cloud (Amazon EC2) instance.

An instance profile is a container for an IAM role that you can use to pass role information to an EC2 instance when the instance starts.

Amazon CloudWatch Events initiates this check when AWS CloudTrail logs Amazon EC2 API calls based on the `RunInstances`, `AssociateIamInstanceProfile`, and `ReplaceIamInstanceProfileAssociation` actions. The trigger calls an AWS Lambda function, which uses an Amazon CloudWatch Events event to check for an IAM profile.

If an IAM profile does not exist, the Lambda function initiates an Amazon Simple Notification Service (Amazon SNS) email notification that includes the Amazon Web Services (AWS) account ID and the AWS Region.

If an IAM profile does exist, the Lambda function checks for any wildcard entries in the policy documents. If the wildcards entries exist, initiates an Amazon SNS violation notification, which helps you to implement enhanced security. The notification contains the name of the IAM profile, the event, the EC2 instance ID, the name of the managed policy, the violation, the account ID, and the Region.

### Prerequisites and limitations

#### Prerequisites
- An active account
- An Amazon Simple Storage Service (Amazon S3) bucket for the Lambda code .zip file

#### Limitations
- The AWS CloudFormation template must be deployed for the `RunInstances`, `AssociateIamInstanceProfile`, and `ReplaceIamInstanceProfileAssociation` actions only.
- The security control does not monitor the detachment of IAM profiles.
- The security control does not check for modification of IAM policies that are attached to the EC2 instance IAM profile.
- The security control does not account for unsupported resource-level permissions that require the use of "Resource:*."
- Amazon EC2
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon S3
- Amazon SNS

**Target architecture**

**Automation and scale**

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to launch the template only one time for each account or Region.

**Tools**

- **Amazon EC2** – Amazon EC2 provides scalable computing capacity (virtual servers) in the AWS Cloud.
- **AWS CloudTrail** – AWS CloudTrail helps you enable governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are recorded as events in CloudTrail.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- **AWS Lambda** – AWS Lambda is a compute service that you can use to run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **Amazon S3** – Amazon S3 provides highly scalable object storage that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon SNS enables applications and devices to send and receive notifications from the cloud.

**Code**

- A .zip file of the project is available as an attachment.

**Ensure an Amazon Redshift cluster is encrypted upon creation**

*Created by Mansi Suratwala (AWS)*
Summary

This pattern provides an AWS CloudFormation template that provides you with automatic notification when a new Amazon Redshift cluster is created without encryption.

The AWS CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any Amazon Redshift cluster being created or being restored from a snapshot through AWS CloudTrail. If the cluster is created without AWS Key Management Service (AWS KMS) or cloud hardware security model (HSM) encryption in the AWS account, CloudWatch initiates a Lambda function that sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A virtual private cloud (VPC) with a cluster subnet group, and an associated security group.

Limitations

- The AWS CloudFormation template can be deployed for the CreateCluster and RestoreFromClusterSnapshot actions only.

Architecture

Target technology stack

- Amazon Redshift
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)
- Amazon SNS

Target architecture
Automation and scale

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run it only once in each Region or account.

Tools

Tools

• **Amazon Redshift** – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. Amazon Redshift is integrated with your data lake, which enables you to use your data to acquire new insights for your business and customers.

• **AWS CloudTrail** – AWS CloudTrail is an AWS service that helps you implement governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.

• **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.

• **AWS Lambda** – AWS Lambda supports running code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

• **Amazon S3** – Amazon S3 is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

• **Amazon SNS** – Amazon SNS is a web service that coordinates and manages the delivery or sending of messages to between publishers and clients, including web servers and email addresses.

Monitor and remediate scheduled deletion of AWS KMS keys

Created by Mikesh Khanal (AWS) and Ramya Pulipaka (AWS)

Environment: Production  Technologies: Security, identity, compliance; Operations  AWS services: Amazon SNS; AWS CloudTrail; Amazon CloudWatch

Summary

On the Amazon Web Services (AWS) Cloud, deleting an AWS Key Management Services (AWS KMS) key can result in data loss. Deletion removes the key material and all metadata associated with the AWS KMS...
key, and it is irreversible. After an AWS KMS key is deleted, you can no longer decrypt the data that were encrypted under that AWS KMS key, so that data cannot be recovered.

This pattern sets up monitoring, with notifications when an application or a user schedules an AWS KMS key for deletion. If you receive a notification, you might want to cancel deletion of the AWS KMS key and reconsider your decision to delete it. The pattern uses the AWS Systems Manager automation runbook AWSConfigRemediation-CancelKeyDeletion to facilitate canceling the deletion of an AWS KMS key.

**Note:** The pattern's CloudFormation template must be deployed in all AWS Regions where you want to monitor deletion of AWS KMS keys.

## Prerequisites and limitations

### Prerequisites

- An active AWS account with an AWS Identity and Access Management (IAM) user
- Understanding of the following AWS services:
  - Amazon EventBridge
  - AWS KMS
  - Amazon Simple Notification Service (Amazon SNS)
  - AWS Systems Manager.

### Limitations

- Any customization of the solution requires knowledge of AWS CloudFormation templates and the AWS services used in this pattern.
- Currently, this solution uses the default event bus, and it can be customized according to the requirements. For more information about the custom event bus, see the AWS documentation.

## Architecture

### Target technology stack

- Amazon EventBridge
- AWS KMS
- Amazon SNS
- AWS Systems Manager
- Automation using the following:
  - AWS Command Line Interface (AWS CLI) or AWS SDK
  - AWS CloudFormation stack

### Target architecture
1. Deletion of an AWS KMS key is scheduled.
2. The scheduled-deletion event is evaluated by an EventBridge rule.
3. The EventBridge rule engages the Amazon SNS topic.
4. The EventBridge rule initiates the Systems Manager automation and runbooks.
5. The runbooks cancel the deletion.

Automation and scale

The CloudFormation stack deploys all the necessary resources and services for this solution to work. The pattern can be run independently in a single account or run using AWS CloudFormation StackSets for multiple independent accounts or an organization.

```
aws cloudformation create-stack --stack-name <stack-name> \
  --template-body file://<Full-Path-of-file> \
  --parameters ParameterKey=,ParameterValue= \
  --capabilities CAPABILITY_NAMED_IAM
```

Tools

- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run on AWS. You can use a CloudFormation template to create stacks in an AWS account in an AWS Region. The template describes all the AWS resources that you want, and CloudFormation provisions and configures those resources for you.

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open source tool that you can use to interact with AWS services using commands in your command line shell.

- **Amazon EventBridge** – Amazon EventBridge is a serverless event bus service connecting your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications and AWS services, and it routes that data to targets such as AWS Lambda. EventBridge simplifies the process of building event-driven architectures.

- **AWS KMS** – AWS Key Management Service (AWS KMS) is a managed service for creating and controlling AWS KMS keys, the encryption keys used to encrypt your data.
AWS Prescriptive Guidance Patterns

Epics

- **AWS SDKs** – AWS tools include SDKs so that you can develop and manage applications on AWS in the programming language of your choice.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers). Publishers communicate asynchronously with subscribers by sending messages to a topic, which is a logical access point and communication channel.

- **AWS Systems Manager** – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can automate operational tasks across your AWS resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting on (or taking corrective action on) any policy violations it detects.

**Code**

- The `alerting_ct_logs.yaml` CloudFormation template for the project is attached.

### Epics

#### Prepare the AWS account

<table>

</tr>
</tbody>
</table>

#### Deploy the AWS CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download the CloudFormation template.</td>
<td>Download the attachment to a local path on your computer and extract the <code>alerting_ct_logs.yaml</code> template file.</td>
<td>Developer, Security engineer</td>
</tr>
<tr>
<td>Deploy the template.</td>
<td>In the terminal window where the AWS account profile has been configured, run the following command.</td>
<td>Developer, Security engineer</td>
</tr>
<tr>
<td></td>
<td><code>aws cloudformation create-stack --stack-name &lt;stack_name&gt;</code></td>
<td></td>
</tr>
</tbody>
</table>

## Complete the template parameters

Enter the required values for the parameters.

- **DestinationEmailAddress** – The email address to receive an alert when an AWS KMS key is scheduled for deletion.
- **SNSTopicName** – The name of the Amazon SNS topic.
- **EnableRemediation** – Cancellation of the scheduled key deletion using a Systems Manager runbook. Allowed values are `true` and `false`.
- **AutomationAssumeRole** – The Amazon Resource Name (ARN) of the role that allows Systems Manager automation to perform the actions on your behalf. For more information, see the *Required IAM Permissions* section in the [AWSConfigRemediation-CancelKeyDeletion](https://aws.amazon.com) documentation.
- **Capabilities** – For AWS CloudFormation to *create the stack*, you must explicitly acknowledge that your stack template contains certain capabilities.

### Skills required

*Developer, Security engineer*

## Confirm the subscription

**Task**

Confirm the subscription.

**Description**

Check your email inbox and choose **Confirm subscription** in the email message that

**Skills required**

*Developer, Security engineer*
you receive from Amazon SNS. A web browser window will open and display a subscription confirmation and your subscription ID.

### Manage credentials using AWS Secrets Manager

*Created by Durga Prasad Cheepuri (AWS)*
Summary

This pattern walks you through using AWS Secrets Manager to dynamically fetch database credentials for a Java Spring application.

In the past, when you created a custom application that retrieves information from a database, you typically had to embed the credentials (the secret) for accessing the database directly in the application. When it was time to rotate the credentials, you had to invest time to update the application to use the new credentials, and then distribute the updated application. If you had multiple applications that shared credentials and you missed updating one of them, the application would fail. Because of this risk, many users chose not to regularly rotate their credentials, which effectively substituted one risk for another.

Secrets Manager enables you to replace hard-coded credentials in your code (including passwords) with an API call to retrieve the secret programmatically. This helps ensure that the secret can't be compromised by someone who is examining your code, because the secret simply isn't there. You can also configure Secrets Manager to automatically rotate the secret according to a schedule that you specify. This enables you to replace long-term secrets with short-term ones, which helps significantly reduce the risk of compromise. For more information, see the AWS Secrets Manager documentation.

Prerequisites and limitations

Prerequisites

- An AWS account with access to Secrets Manager
- A Java Spring application

Architecture

Source technology stack

- A Java Spring application with code that accesses a database, with DB credentials managed from the application.properties file.

Target technology stack

- A Java Spring application with code that accesses a database, with DB credentials managed in Secrets Manager. The application.properties file holds the secrets to Secrets Manager.

Secrets Manager integration with an application
Tools

- **Secrets Manager** – AWS Secrets Manager is an AWS service that makes it easier for you to manage secrets. Secrets can be database credentials, passwords, third-party API keys, and even arbitrary text. You can store and control access to these secrets centrally by using the Secrets Manager console, the Secrets Manager command-line interface (CLI), or the Secrets Manager API and SDKs.

Epics

Store secret in Secrets Manager

Additional information

Adding JAR dependencies for using Secrets Manager

*Maven:*

```xml
<groupId>com.amazonaws</groupId>
    <artifactId>aws-java-sdk-secretsmanager</artifactId>
    <version>1.11.355</version>
```

*Gradle:*

```gradle
compile group: 'com.amazonaws', name: 'aws-java-sdk-secretsmanager', version: '1.11.355'
```

Updating the application.properties file with the details of the secret

```properties
spring.aws.secretsmanager.secretName=postgres-local
spring.aws.secretsmanager.endpoint=secretsmanager.us-east-1.amazonaws.com
spring.aws.secretsmanager.region=us-east-1
```

Updating the DB credentials retrieval code in Java

```java
String secretName = env.getProperty("spring.aws.secretsmanager.secretName");
String endpoints = env.getProperty("spring.aws.secretsmanager.endpoint");
```
String AWS Region = env.getProperty("spring.aws.secretsmanager.region");
AwsClientBuilder.EndpointConfiguration config = new
  AwsClientBuilder.EndpointConfiguration(endpoints, AWS Region);
AWSSecretsManagerClientBuilder clientBuilder =
  AWSSecretsManagerClientBuilder.standard();
clientBuilder.setEndpointConfiguration(config);
AWSSecretsManager client = clientBuilder.build();

ObjectMapper objectMapper = new ObjectMapper();
JsonNode secretsJson = null;
ByteBuffer binarySecretData;
GetSecretValueRequest getSecretValueRequest = new
  GetSecretValueRequest().withSecretId(secretName);
GetSecretValueResult getSecretValueResponse = null;
try {
  getSecretValueResponse = client.getSecretValue(getSecretValueRequest);
}
catch (ResourceNotFoundException e) {
  log.error("The requested secret " + secretName + " was not found");
}
catch (InvalidRequestException e) {
  log.error("The request was invalid due to: " + e.getMessage());
}
catch (InvalidParameterException e) {
  log.error("The request had invalid params: " + e.getMessage());
}
if (getSecretValueResponse == null) {
  return null;
} // Decrypted secret using the associated KMS key // Depending on whether the secret
  was a string or binary, one of these fields will be populated

String secret = getSecretValueResponse.getSecretString();
if (secret != null) {
  try {
    secretsJson = objectMapper.readTree(secret);
  }
  catch (IOException e) {
    log.error("Exception while retrieving secret values: " + e.getMessage());
  }
}
else {
  log.error("The Secret String returned is null");
  return null;
}
String host = secretsJson.get("host").textValue();
String port = secretsJson.get("port").textValue();
String dbname = secretsJson.get("dbname").textValue();

String password = secretsJson.get("password").textValue();
Monitor Amazon EMR clusters for in-transit encryption at launch

Created by Susanne Kangnoh (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Analytics; Big data; Cloud-native; Security, identity, compliance</th>
<th>Workload:</th>
<th>Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon EMR; Amazon SNS; AWS CloudTrail; Amazon CloudWatch</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides a security control that monitors Amazon EMR clusters at launch and sends an alert if in-transit encryption hasn't been enabled.

Amazon EMR is a web service that makes it easy for you to run big data frameworks, such as Apache Hadoop, to process and analyze data. Amazon EMR enables you to process vast amounts of data in a cost-effective way by running mapping and reducing steps in parallel.

Data encryption prevents unauthorized users from accessing or reading data at rest or data in transit. Data at rest refers to data that is stored in media such as a local file system on each node, Hadoop Distributed File System (HDFS), or the EMR File System (EMRFS) through Amazon Simple Storage Service (Amazon S3). Data in transit refers to data that travels the network and is in flight between jobs. In-transit encryption supports open-source encryption features for Apache Spark, Apache TEZ, Apache Hadoop, Apache HBase, and Presto. You enable encryption by creating a security configuration from the AWS Command Line Interface (AWS CLI), the console, or AWS SDKs, and specifying the data encryption settings. You can provide the encryption artifacts for in-transit encryption in these two ways:

- By uploading a compressed file of certificates to Amazon S3.
- By referencing a custom Java class that provides encryption artifacts.

The security control that's included with this pattern monitors API calls and generates an Amazon CloudWatch Events event on the RunJobFlow action. The event calls an AWS Lambda function, which runs a Python script. The function gets the EMR cluster ID from the event JSON input, and performs the following checks to determine whether there's a security violation:

- Checks if the EMR cluster has an Amazon EMR-specific security configuration.
- If the cluster does have a security configuration, checks to see if encryption in transit is enabled.
- If the cluster doesn't have a security configuration, sends an alert to an email address that you provide, by using Amazon Simple Notification Service (Amazon SNS). The notification specifies the EMR cluster name, violation details, AWS Region and account information, and the AWS Lambda ARN (Amazon Resource Name) that the notification is sourced from.

Prerequisites and limitations

Prerequisites
• An active AWS account.
• An S3 bucket to upload the Lambda code that's provided with this pattern.
• An email address where you would like to receive violation notifications.
• Amazon EMR logging enabled, for access to all the API logs.

Limitations
• This detective control is regional and must be deployed in each AWS Region that you want to monitor.

Product versions
• Amazon EMR release 4.8.0 or later.

Architecture

Workflow architecture

Automation and scale
• If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy the template in multiple accounts that you want to monitor.

Tools

AWS services
• Amazon EMR – Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data. By using these frameworks and related open-source projects, you can process data for analytics purposes and business intelligence workloads. Additionally, you can use Amazon EMR to transform and move large amounts of data into and out of other AWS data stores and databases, such as Amazon S3 and Amazon DynamoDB.
• AWS Cloudformation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
• AWS Cloudwatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
• **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

• **AWS SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Code**

This pattern includes an attachment with two files:

- **EMRInTransitEncryption.zip** is a compressed file that includes the security control (Lambda code).
- **EMRInTransitEncryption.yml** is a CloudFormation template that deploys the security control.

See the *Epics* section for information about how to use these files.

Monitor Amazon ElastiCache clusters for at-rest encryption

Created by Susanne Kangnoh (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Security, identity, compliance; Databases; Infrastructure; Cloud-native</th>
<th>Workload: Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: Amazon SNS; Amazon CloudWatch; Amazon ElastiCache</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Amazon ElastiCache is an Amazon Web Services (AWS) service that provides a high-performance, scalable, and cost-effective caching solution for distributing an in-memory data store or cache environment in the cloud. It retrieves data from high-throughput and low-latency, in-memory data stores. This functionality makes it a popular choice for real-time use cases such as caching, session stores, gaming, geo-spatial services, real-time analytics, and queuing. ElastiCache offers Redis and Memcached data stores, both of which provide sub-millisecond response times.

Data encryption helps prevent unauthorized users from reading sensitive data available on your Redis clusters and their associated cache storage systems. This includes data saved to persistent media, known as data at rest, and data that can be intercepted as it travels through the network between clients and cache servers, known as data in transit.

You can enable at-rest encryption for ElastiCache for Redis when you create a replication group, by setting the **AtRestEncryptionEnabled** parameter to **true**. When this parameter is enabled, it encrypts the disk during sync, backup, and swap operations, and encrypts backups stored in Amazon Simple Storage Service (Amazon S3). You cannot enable at-rest encryption on an existing replication group.

When you create a replication group, you can enable encryption at rest in these two ways:

- By choosing the **Default** option, which uses service-managed encryption at rest.
- By using a customer managed key and providing the key ID or Amazon Resource Name (ARN) from AWS Key Management Service (AWS KMS).

This pattern provides a security control that monitors for API calls and generates an Amazon CloudWatch Events event on the **CreateReplicationGroup** operation. This event calls an AWS Lambda function, which runs a Python script. The function gets the replication group ID from the event JSON input, and performs the following checks to determine whether there's a security violation:

- Checks if the **AtRestEncryptionEnabled** key exists.
- If **AtRestEncryptionEnabled** exists, checks the value to see if it is **true**.
- If the **AtRestEncryptionEnabled** value is set to **false**, sets a variable that tracks violations and sends a violation message to an email address you provide, by using an Amazon Simple Notification Service (Amazon SNS) notification.
Prerequisites and limitations

Prerequisites

• An active AWS account.
• An S3 bucket to upload the provided Lambda code.
• An email address where you would like to receive violation notifications.
• ElastiCache logging enabled, for access to all the API logs.

Limitations

• This detective control is regional and must be deployed in each AWS Region that you want to monitor.
• The control supports replication groups that are running in a virtual private cloud (VPC).
• The control supports replication groups that are running the following node types:
  • R5, R4, R3
  • M5, M4, M3
  • T3, T2

Product versions

• ElastiCache for Redis version 3.2.6 or later

Architecture

Workflow architecture

Automation and scale

• If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

• Amazon ElastiCache – Amazon ElastiCache makes it easy to set up, manage, and scale distributed in-memory cache environments in the AWS Cloud. It provides a high performance, resizable, and cost-effective in-memory cache, while removing complexity associated with deploying and managing a distributed cache environment. ElastiCache works with both the Redis and Memcached engines.
• AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a
template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **AWS Cloudwatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Code**

This pattern includes an attachment with two files:

- ElasticCache-EncryptionAtRest.zip is a compressed file that includes the security control (Lambda code).

Monitor EC2 instance key pairs using AWS Config

Created by Wassim Benhallam (AWS) and Vikrant Telkar (AWS)

| Environment: Production | Technologies: Security, identity, compliance | AWS services: Amazon SNS; AWS Config; AWS Lambda |

Summary

When launching an Amazon Elastic Compute Cloud (Amazon EC2) instance on the Amazon Web Services (AWS) Cloud, a best practice is to create or use an existing key pair to connect to the instance. The key pair, which consists of a public key stored in the instance and a private key provided to the user, allows secure access through Secure Shell (SSH) to the instance and avoids the use of passwords. However, users can sometimes inadvertently launch instances without attaching a key pair. Because key pairs can be assigned only during the launch of an instance, it's important to quickly identify and flag as noncompliant any instances launched without key pairs. This is particularly useful when working in accounts or environments that mandate the use of key pairs for instance access.

This pattern describes how to create a custom rule in AWS Config to monitor EC2 instance key pairs. When instances are identified as noncompliant, an alert is sent using Amazon Simple Notification Service (Amazon SNS) notifications initiated through an Amazon EventBridge event.

Prerequisites and limitations

Prerequisites

• An active AWS account
• AWS Config enabled for the AWS Region you want to monitor and configured to record all AWS resources

Limitations

• This solution is Region-specific. All resources should be created in the same AWS Region.

Architecture

Target technology stack

• AWS Config
• Amazon EventBridge
• AWS Lambda
• Amazon SNS
1. AWS Config initiates the rule.
2. The rule invokes the Lambda function to evaluate compliance of EC2 instances.
3. The Lambda function sends the updated compliance state to AWS Config.
4. AWS Config sends an event to EventBridge.
5. EventBridge publishes compliance change notifications to an SNS topic.
6. Amazon SNS sends an alert in email.

**Automation and scale**

The solution can monitor any number of EC2 instances within a Region.

**Tools**

**Tools**

- **AWS Config** – AWS Config is a service that enables you to assess, audit, and evaluate the configurations of your AWS resources. AWS Config continuously monitors and records your AWS resource configurations and allows you to automate the evaluation of recorded configurations against desired configurations.

- **Amazon EventBridge** – Amazon EventBridge is a serverless event bus service for connecting your applications with data from a variety of sources.

- **AWS Lambda** – AWS Lambda is a serverless compute service that supports running code without provisioning or managing servers, creating workload-aware cluster scaling logic, maintaining event integrations, or managing runtimes.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a fully managed messaging service for both application-to-application (A2A) and application-to-person (A2P) communication.

**Code**

The code for the Lambda function is attached.
## Epics

### Create a Lambda function to evaluate Amazon EC2 compliance

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an AWS Identity and Access Management (IAM) role for Lambda.</td>
<td>On the AWS Management Console, choose IAM, and then create the role, using Lambda as the trusted entity and adding the AmazonEventBridgeFullAccess and AWSSConfigRulesExecutionRole permissions. For more information, see the AWS documentation.</td>
<td>DevOps</td>
</tr>
</tbody>
</table>
| Create and deploy the Lambda function.                              | 1. On the Lambda console, create a function, using Author from scratch, with Python 3.6 as the runtime and the previously created IAM role. Note the Amazon Resource Name (ARN).  
2. On the Code tab, choose lambda_function.py, and paste the code that is attached to this pattern.  
3. To save your changes, choose Deploy. | DevOps          |

### Create a custom AWS Config rule

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Add a custom AWS Config rule.           | On the AWS Config console, add a custom rule, using the following settings:  
  • ARN – The ARN of the previously created Lambda function  
  • Trigger type – Configuration changes  
  • Scope of changes – Resources  
  • Resource type – Amazon EC2 instance  
  For more information, see the AWS documentation. | DevOps          |
## Configure email notifications when a compliance change event is detected

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the SNS topic and subscription.</td>
<td>On the Amazon SNS console, create a topic using <strong>Standard</strong> as the type, and then create a subscription using <strong>Email</strong> as the protocol. When you receive the confirmation email message, choose the link to confirm the subscription. For more information, see the AWS documentation.</td>
<td>DevOps</td>
</tr>
<tr>
<td>Create an EventBridge rule to initiate Amazon SNS notifications.</td>
<td>On the EventBridge console, create a rule, using the following settings:  - Service name – AWS Config  - Event type – Config Rules Compliance Change  - Message type – Specific message types, ComplianceChangeNotification  - Specific rule name – The name of your previously created AWS Config rule  - Target – SNS topic, your previously created topic  For more information, see the AWS documentation.</td>
<td>DevOps</td>
</tr>
</tbody>
</table>

### Verify the rule and notifications

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create EC2 instances.</td>
<td>Create two EC2 instances of any type and attach a key pair, and create one EC2 instance without a key pair.</td>
<td>DevOps</td>
</tr>
<tr>
<td>Verify the rule.</td>
<td>1. On the AWS Config console, on the Rules page, select your rule. 2. To see compliant and noncompliant EC2 instances, change Resources in scope to All. Verify that two instances are listed as compliant and</td>
<td>DevOps</td>
</tr>

Monitor ElastiCache clusters for security groups

Created by Susanne Kangnoh (AWS)

| Environment: Production | Technologies: Security, identity, compliance; Databases; Infrastructure; Cloud-native | AWS services: Amazon SNS; AWS CloudTrail; Amazon CloudWatch; Amazon ElastiCache |

**Summary**

Amazon ElastiCache is an Amazon Web Services (AWS) service that provides a high-performance, scalable, and cost-effective caching solution for distributing an in-memory data store or cache environment in the cloud. It retrieves data from high-throughput and low-latency, in-memory data stores. This functionality makes it a popular choice for real-time use cases such as caching, session stores, gaming, geo-spatial services, real-time analytics, and queuing. ElastiCache offers Redis and Memcached data stores, both of which provide sub-millisecond response times.

A security group acts as a virtual firewall for your ElastiCache instances by controlling inbound and outbound traffic. Security groups act at the instance level, not at the subnet level. For each security group, you add one set of rules that control the inbound traffic to instances, and a separate set of rules that control the outbound traffic. You can specify allow rules but not deny rules.

This pattern provides a security control that monitors for API calls and generates an Amazon CloudWatch Events event on the `CreateReplicationGroup`, `CreateCacheCluster`, `ModifyCacheCluster`, and
ModifyReplicationGroup operations. This event calls an AWS Lambda function, which runs a Python script. The function gets the replication group ID from the event JSON input, and performs the following checks to determine whether there's a security violation:

- Checks if the security group of the cluster matches the security group that's configured in the Lambda function.

- If the security group of the cluster doesn't match, the function sends a violation message to an email address you provide, by using an Amazon Simple Notification Service (Amazon SNS) notification.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An S3 bucket to upload the provided Lambda code.
- An email address where you would like to receive violation notifications.
- ElastiCache logging enabled, for access to all the API logs.

Limitations

- This detective control is regional and must be deployed in each AWS Region that you want to monitor.
- The control supports replication groups that are running in a virtual private cloud (VPC).

Architecture

Workflow architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- Amazon ElastiCache – Amazon ElastiCache makes it easy to set up, manage, and scale distributed in-memory cache environments in the AWS Cloud. It provides a high performance, resizable, and cost-effective in-memory cache, while removing complexity associated with deploying and managing a distributed cache environment. ElastiCache works with both the Redis and Memcached engines.
• **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

• **AWS Cloudwatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.

• **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Code**

This pattern includes an attachment with two files:

• ElastiCacheAllowedSecurityGroup.zip is a compressed file that includes the security control (Lambda code).

• ElastiCacheAllowedSecurityGroup.yml is a CloudFormation template that deploys the security control.

See the *Epics* section for information about how to use these files.

**Epics**

**Deploy the security control**

<table>
<thead>
<tr>
<th>Task</th>

Monitor IAM root user activity

*Created by Mostefa Brougui (AWS)*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Security, identity, compliance; Management &amp; governance</th>
</tr>
</thead>
<tbody>
<tr>
<td>• aws-iam-root-user-activity-monitor</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

Every Amazon Web Services (AWS) account has a root user. As a [security best practice](https://aws.amazon.com/about-aws/whats-new/) for AWS Identity and Access Management (IAM), we recommend that you use the root user to create an IAM admin user, and then don't use your root user credentials for any other management tasks. Because the root user account has full access to all of your AWS resources and billing information, we recommend that you don't use this account and monitor it for any activity, which might indicate that the account credentials have been compromised.

Using this pattern, you set up an [event-driven architecture](https://aws.amazon.com/about-aws/whats-new/) that monitors the IAM root user. This pattern sets up a hub-and-spoke solution that monitors multiple AWS accounts, the *spoke* accounts, and centralizes management and reporting in a single account, the *hub* account.

When the IAM root user credentials are used, Amazon CloudWatch and AWS CloudTrail record the activity in the log and trail, respectively. In the spoke account, an Amazon EventBridge rule sends the event to the central event bus in the hub account. In the hub account, an EventBridge rule sends the event to an AWS Lambda function. The function uses an Amazon Simple Notification Service (Amazon SNS) topic that notifies you of the root user activity.

In this pattern, you use an AWS CloudFormation template to deploy the monitoring and event-handling services in the spoke accounts. You use a HashiCorp Terraform template to deploy the event-management and notification services in the hub account.

**Prerequisites and limitations**

**Prerequisites**

1. Permissions to deploy AWS resources in your AWS environment.
2. Permissions to deploy CloudFormation stack sets. For more information, see [Prerequisites for stack set operations](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/stack-sets.html) (CloudFormation documentation).
3. Terraform installed and ready to use. For more information, see [Get Started – AWS](https://learn.hashicorp.com/terraform) (Terraform documentation).
4. An existing trail in each spoke account. For more information, see Getting started with AWS CloudTrail (CloudTrail documentation).
5. The trail is configured to send events to CloudWatch Logs. For more information, see Sending events to CloudWatch Logs (CloudTrail documentation).
6. Your hub and spoke accounts must be managed by AWS Organizations.

**Architecture**

The following diagram illustrates the building blocks of the implementation.

1. When the IAM root user credentials are used, CloudWatch and CloudTrail record the activity in the log and trail, respectively.
2. In the spoke account, an EventBridge rule sends the event to the central event bus in the hub account.
3. In the hub account, an EventBridge rule sends the event to a Lambda function.
4. The Lambda function uses an Amazon SNS topic that notifies you of the root user activity.

**Tools**

**AWS services**

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS CloudTrail** helps you audit the governance, compliance, and operational and risk of your AWS account.

- **Amazon CloudWatch Logs** helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.

- **Amazon EventBridge** is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.

- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

- **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

### Other tools and services

- **Terraform** is a CLI application for provisioning and managing cloud infrastructure and resources by using code, in the form of configuration files.

### Code repository

The source code and templates for this pattern are available in a GitHub repository. This pattern provides two templates:

- A Terraform template containing the resources you deploy in the hub account
- A CloudFormation template you deploy as a stack set instance in the spoke accounts

The repository has the following overall structure:

```
|__README.md
|__spoke-stackset.yaml
|__hub.tf
|__root-activity-monitor-module
  |__main.tf  # contains Terraform code to deploy resources in the Hub account
  |__iam    # contains IAM policies JSON files
  |__lambda-assume-policy.json  # contains trust policy of the IAM role
  |__lambda-policy.json   # contains the IAM policy attached to the IAM role used by the Lambda function
  |__outputs  # contains Lambda function zip code
```

The **Epics** section provides step-by-step instructions for deploying the templates.

Send a notification when an IAM user is created

Created by Mansi Suratwala (AWS)

**Summary**

On Amazon Web Services (AWS), you can use this pattern to deploy an AWS CloudFormation template to receive notifications automatically when AWS Identity and Access Management (IAM) users are created.

Using IAM, you can manage access to AWS services and resources securely. You can create and manage AWS users and groups, and use permissions to allow and deny those users and groups access to AWS resources.

The CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event uses AWS CloudTrail to monitor for any IAM user being created in the AWS account. If a user is created, the CloudWatch Events event initiates a Lambda function, which sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the new user creation event.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An AWS CloudTrail trail created and deployed

**Limitations**

- The AWS CloudFormation template must be deployed for `CreateUser` only.
Architecture

Target technology stack

- IAM
- AWS CloudTrail
- Amazon CloudWatch Events
- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)
- Amazon SNS

Target architecture

Automation and scale

You can use the CloudFormation template multiple times for different AWS Regions and accounts. You need to run it only once in each Region or account.

Tools

Tools

- IAM – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- AWS CloudFormation – AWS CloudFormation helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS. You create a template that describes all the AWS resources that you want, and CloudFormation takes care of provisioning and configuring those resources for you.
- AWS CloudTrail – AWS CloudTrail helps you manage governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are recorded as events in CloudTrail. Events include actions taken in the AWS Management Console, AWS Command Line Interface, and AWS SDKs and APIs.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery using Lambda, HTTP, email, mobile push notifications, and mobile text messages (SMS).

Restrict access to AWS APIs for IAM Identity Center and IAM users through trusted source IP ranges
Summary

This pattern provides a service control policy (SCP) that you can attach to the organization root, an organizational unit (OU), or an account in Amazon Web Services (AWS) Organizations. The SCP restricts access to AWS APIs for AWS Identity and Access Management (IAM) users and AWS IAM Identity Center (successor to AWS Single Sign-On) users—either in an IAM Identity Center directory or synchronized from a third-party identity source. Access is restricted to a trusted set of IP ranges that you specify in the SCP. This SCP also prevents an administrator of a member account in the AWS Organizations organization from bypassing the policy by creating a rogue identity provider in IAM.

See the Attachments section for a sample JSON file that you can customize to create the SCP.

Prerequisites and limitations

Prerequisites

• An organization set up with all features enabled in AWS Organizations
• Access to your organization's master account with permissions to run the following actions to deploy the SCP: organizations:CreatePolicy and organizations:AttachPolicy.

Limitations

• The SCP applies only to IAM users and IAM Identity Center users, and doesn't restrict cross-account access.
• You can also use the SCP as a reference to restrict federated access through IAM through a restricted IAM role path. To do this, replace the last condition block in the attached file with the appropriate value (for example, "arn:aws:iam::*:role/human-access/federated-access/*").

Tools

AWS services

• IAM – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
• IAM Identity Center – AWS IAM Identity Center (successor to AWS Single Sign-On) is a cloud-based service that simplifies managing SSO access to AWS accounts and business applications. You can control SSO access and user permissions across all your AWS accounts in AWS Organizations. You can also manage access to applications that support Security Assertion Markup Language (SAML) 2.0.
• AWS Organizations – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.

Code

The attached file provides the JSON contents of the SCP for this pattern. To restrict access to specific IP ranges, replace the variable `${sourceip}` in the JSON file.
Epics

Restrict access to AWS based on trusted source IP ranges

Scan Git repositories for sensitive information and security issues by using git-secrets
Summary

This pattern describes how to use the open-source git-secrets tool from AWS Labs. Git-secrets scans Git source repositories and finds code that may potentially include sensitive information, such as user passwords, or that has other security issues.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Git repository that requires a security scan

Architecture

Target architecture

- Git
- Git-secrets

Tools
- **git-secrets** - Prevents you from committing sensitive information into Git repositories.
- **Git** - An open source distributed version control system.

## Epics

### Connect to an Amazon Elastic Compute Cloud (Amazon EC2) instance

**Send alerts from AWS Network Firewall to a Slack channel**

*Created by Venki Srivatsav (AWS)*

**Code repository:** NfwSlackIntegration

**Environment:** PoC or pilot

**Technologies:** Security, identity, compliance; Networking

**AWS services:** AWS Lambda; AWS Network Firewall; Amazon S3

**Summary**

This pattern describes how to deploy a firewall by using Amazon Web Services (AWS) Network Firewall with the distributed deployment model and how to propagate the alerts generated by AWS Network Firewall to a configurable Slack channel.

Compliance standards such as Payment Card Industry Data Security Standard (PCI DSS) require that you install and maintain a firewall to protect customer data. In the AWS Cloud, a virtual private cloud (VPC) is considered the same as a physical network in the context of these compliance requirements. You can use Network Firewall to monitor network traffic between VPCs and to protect your workloads that run in VPCs governed by a compliance standard. Network Firewall blocks access or generates alerts when it detects unauthorized access from other VPCs in the same account. However, Network Firewall supports a limited number of destinations for delivering the alerts. These destinations include Amazon Simple Storage Service (Amazon S3) buckets, Amazon CloudWatch log groups, and Amazon Kinesis Data Firehose delivery streams. Any further action on these notifications requires offline analysis by using either Amazon Athena or Amazon Kinesis.
This pattern provides a method for propagating alerts that are generated by Network Firewall to a configurable Slack channel for further action in near real time. You can also extend the functionality to other alerting mechanisms such as PagerDuty, Jira, and email. (Those customizations are outside the scope of this pattern.)

Prerequisites and limitations

Prerequisites

- Slack channel (see Getting started in the Slack help center)
- Required privileges to send a message to the channel
- The Slack endpoint URL with an API token (select your app and choose an incoming webhook to see its URL; for more information, see Creating an Incoming Webhook in the Slack API documentation)
- An Amazon Elastic Compute Cloud (Amazon EC2) test instance in the workload subnets
- Test rules in Network Firewall
- Actual or simulated traffic to trigger the test rules
- An S3 bucket to hold the source files to be deployed

Limitations

- Currently this solution supports only a single Classless Inter-Domain Routing (CIDR) range as a filter for source and destination IPs.

Architecture

Target technology stack

- One VPC
- Four subnets (two for the firewall and two for workloads)
- Internet gateway
- Four route tables with rules
- S3 bucket used as an alert destination, configured with a bucket policy and event settings to run a Lambda function
- Lambda function with an execution role, to send Slack notifications
- AWS Secrets Manager secret for storing the Slack URL
- Network firewall with alert configuration
- Slack channel

All components except for the Slack channel are provisioned by the CloudFormation templates and the Lambda function that are provided with this pattern (see the Code (p. 2192)section).

Target architecture

This pattern sets up a decentralized network firewall with Slack integration. This architecture consists of a VPC with two Availability Zones. The VPC includes two protected subnets and two firewall subnets with network firewall endpoints. All traffic going into and out of the protected subnets can be monitored by creating firewall policies and rules. The network firewall is configured to place all alerts in an S3 bucket. This S3 bucket is configured to call a Lambda function when it receives a put event. The Lambda function fetches the configured Slack URL from Secrets Manager and sends the notification message to the Slack workspace.
For more information about this architecture, see the AWS blog post [Deployment models for AWS Network Firewall](https://aws.amazon.com/blogs/security/deployment-models-for-aws-network-firewall/).

**Tools**

**AWS services**

- **AWS Network Firewall** – AWS Network Firewall is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud. You can use Network Firewall to filter traffic at the perimeter of your VPC and protect your workloads on AWS.

- **AWS Secrets Manager** – AWS Secrets Manager is a service for credential storage and retrieval. Using Secrets Manager, you can replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. This pattern uses Secrets Manager to store the Slack URL.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses Amazon S3 to store the CloudFormation templates and Python script for the Lambda function. It also uses an S3 bucket as the network firewall alert destination.

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. This pattern uses AWS CloudFormation to automatically deploy a distributed architecture for Firewall Manager.
Code

The code for this pattern is available on GitHub, in the Network Firewall Slack Integration repository. In the `src` folder of the repository, you’ll find:

- A set of CloudFormation files in YAML format. You use these templates to provision the components for this pattern.
- A Python source file (`slack-lambda.py`) to create the Lambda function.
- A `.zip` archive deployment package (`slack-lambda.py.zip`) to upload your Lambda function code.

To use these files, follow the instructions in the next section.

Epics

Set up the S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an S3 bucket.                      | 1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).  
2. Choose or create an S3 bucket to host the code. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes. We recommend that you use a prefix to organize the code for this pattern.  
For more information, see Creating a bucket in the Amazon S3 documentation. | App developer, App owner, Cloud administrator |
| Upload the CloudFormation templates and Lambda code. | 1. Download the following files from the [GitHub repository](https://github.com/aws-samples/network-firewall-slack-integration) for this pattern:  
   - `base.yml`  
   - `igw-ingress-route.yml`  
   - `slack-lambda.py`  
   - `slackLambda.yml`  
   - `decentralized-deployment.yml`  
   - `protected-subnet-route.yml`  
   - `slack-lambda.py.zip`  
2. Upload the files to the S3 bucket you created. | App developer, App owner, Cloud administrator |
Deploy the CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch the CloudFormation template.</td>
<td>Open the AWS CloudFormation console in the same AWS Region as your S3 bucket and deploy the template base . yml. This template creates the required AWS resources and Lambda functions for the alerts to be transmitted to the Slack channel. For more information about deploying CloudFormation templates, see Creating a stack on the AWS CloudFormation console in the CloudFormation documentation.</td>
<td>App developer, App owner, Cloud administrator</td>
</tr>
<tr>
<td>Complete the parameters in the template.</td>
<td>Specify the stack name and configure the parameter values. For a list of parameters, their descriptions, and default values, see CloudFormation parameters in the Additional information (p. 2197) section.</td>
<td>App developer, App owner, Cloud administrator</td>
</tr>
<tr>
<td>Create the stack.</td>
<td>1. Review stack details and update values based on your environment requirements. 2. Choose Create stack to deploy the template.</td>
<td>App developer, App owner, Cloud administrator</td>
</tr>
</tbody>
</table>

Verify the solution

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test the deployment.</td>
<td>Use the AWS CloudFormation console or the AWS Command Line Interface (AWS CLI) to verify that the resources listed in the Target technology stack (p. 2191) section have been created. If the CloudFormation template fails to deploy successfully, check the values you provided for the pAvailabilityZone1 and pAvailabilityZone2 parameters. These should be appropriate for the AWS Region you're</td>
<td>App developer, App owner, Cloud administrator</td>
</tr>
</tbody>
</table>
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>deploying the solution in. For a list of Availability Zones for each Region, see Regions and Zones in the Amazon EC2 documentation.</td>
<td></td>
</tr>
</tbody>
</table>

For a list of Availability Zones for each Region, see [Regions and Zones](#) in the Amazon EC2 documentation.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Test functionality.  | 1. Open the Amazon EC2 console at [https://console.aws.amazon.com/ec2/](https://console.aws.amazon.com/ec2/).  
2. Create an EC2 instance in one of the protected subnets. Choose an Amazon Linux 2 AMI (HVM) to use as an HTTPS server. For instructions, see [Launch an instance](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/using-an-instance.html) in the Amazon EC2 documentation.  
3. Use the following user data to install a web server on the EC2 instance:  
```
#!/bin/bash
yum install httpd -y
systemctl start httpd
systemctl stop firewalld
cd /var/www/html
echo "Hello!! this is a NFW alert test page, 200 OK" > index.html
```  
4. Create the following network firewall rules:  
**Stateless rule:**  
- Source: 0.0.0.0/0  
- Destination 10.0.3.65/32 (private IP of the EC2 instance)  
- Action: Forward  
**Stateful rule:**  
- Protocol: HTTP  
- Source ip/port: Any / Any  
- Destination ip/port: Any / Any  
5. Get the public IP of the web server you created in step 3.  
6. Access the public IP in a browser. You should see the following message in the browser:  
```
Hello!! this is a NFW alert test page, 200 OK
``` | App developer, App owner, Cloud administrator                                     |
You will also get a notification in the Slack channel. The notification might be delayed, depending on the size of the message. For testing purposes, consider providing a CIDR filter that is not too narrow (for example, a CIDR value with /32 would be considered too narrow, and /8 would be too broad). For more information, see the Filter behavior section in Additional information (p. 2197).

<td>include</td>
</tr>
</tbody>
</table>
Filter behavior

If you haven’t configured any filters in AWS Lambda, all generated alerts are sent to your Slack channel. The source and destination IPs of the generated alerts are matched against the CIDR ranges you configured when you deployed the CloudFormation template. If a match is found, the condition is applied. If either the source or the destination falls within the configured CIDR range and at least one of them is configured with the condition include, an alert is generated. The following tables provide examples of CIDR values, conditions, and results.

<table>
<thead>

Simplify private certificate management by using AWS Private CA and AWS RAM

*Created by Everett Hinckley (AWS) and Vivek Goyal (AWS)*

**Code repository:**
- ACMPCA Hierarchy

**Environment:** Production

**Technologies:** Security, identity, compliance; infrastructure; migration
Summary

You can use AWS Private Certificate Authority (AWS Private CA) to issue private certificates for authenticating internal resources and signing computer code. This pattern provides an AWS CloudFormation template for the rapid deployment of a multi-level CA hierarchy and consistent provisioning experience. Optionally, you can use AWS Resource Access Manager (AWS RAM) to securely share the CA within your organizations or organizational units (OUs) in AWS Organizations, and centralize the CA while using AWS RAM to manage permissions. There is no need for a private CA in every account, so this approach saves you money. Additionally, you can use Amazon Simple Storage Service (Amazon S3) to store the certificate revocation list (CRL) and access logs.

This implementation provides the following features and benefits:

- Centralizes and simplifies the management of the private CA hierarchy by using AWS Private CA.
- Exports certificates and keys to customer-managed devices on AWS and on premises.
- Uses an AWS CloudFormation template for a rapid deployment and consistent provisioning experience.
- Creates a private root CA along with 1, 2, 3, or 4 subordinate CA hierarchy.
- Optionally, uses AWS RAM to share the end-entity subordinate CA with other accounts at the organization or OU level.
- Saves money by removing the need for a private CA in every account by using AWS RAM.
- Creates an optional S3 bucket for the CRL.
- Creates an optional S3 bucket for CRL access logs.

Prerequisites and limitations

Prerequisites

If you want to share the CA within an AWS Organizations structure, identify or set up the following:

- A security account for creating the CA hierarchy and share.
- A separate OU or account for testing.
- Sharing enabled within the AWS Organizations management account. For more information, see Enable resource sharing within AWS Organizations in the AWS RAM documentation.

Limitations

- CAs are regional resources. All CAs reside in a single AWS account and in a single AWS Region.
- User-generated certificates and keys are not supported. For this use case, we recommend that you customize this solution to use an external root CA.
- A public CRL bucket is not supported. We recommend that you keep the CRL private. If internet access to the CRL is required, see the section on using Amazon CloudFront to serve CRLs in Enabling the S3 Block Public Access (BPA) feature in the AWS Private CA documentation.

Architecture

Target technology stack
- AWS Private CA
- AWS RAM
- Amazon S3
- AWS Organizations
- AWS CloudFormation

**Target architecture**

This pattern provides two options for sharing to AWS Organizations:

**Option 1** – Create the share at the organization level. All accounts in the organization can issue the private certificates by using the shared CA, as shown in the following diagram.
**Option 2** — Create the share at the organizational unit (OU) level. Only the accounts in the specified OU can issue the private certificates by using the shared CA. For example, in the following diagram, if the share is created at the Sandbox OU level, both Developer 1 and Developer 2 can issue private certificates by using the shared CA.

### Tools

**AWS services**
- **AWS Private CA** – AWS Private Certificate Authority (AWS Private CA) is a hosted private CA service for issuing and revoking private digital certificates. It helps you create private CA hierarchies, including root and subordinate CAs, without the investment and maintenance costs of operating an on-premises CA.
- **AWS RAM** – AWS Resource Access Manager (AWS RAM) helps you securely share your resources across AWS accounts and within your organization or OUs in AWS Organizations. To reduce operational overhead in a multi-account environment, you can create a resource and use AWS RAM to share that resource across accounts.

- **AWS Organizations** – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses Amazon S3 to store the certificate revocation list (CRL) and access logs.

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. This pattern uses AWS CloudFormation to automatically deploy a multi-level CA hierarchy.

**Code**

The source code for this pattern is available on GitHub, in the **AWS Private CA hierarchy** repository. The repository includes:

- The AWS CloudFormation template `ACMPCA-RootCASubCA.yaml`. You can use this template to deploy the CA hierarchy for this implementation.
- Test files for use cases such as requesting, exporting, describing, and deleting a certificate.

To use these files, follow the instructions in the **Epics** section.

**Epics**

**Architect the CA hierarchy**

#### Additional information

When you export certificates, use a passphrase that is cryptographically strong and aligns with your organization’s data loss prevention strategy.

---

**Turn off security standard controls across all Security Hub member accounts in a multi-account environment**

---

2207
Summary

In the Amazon Web Services (AWS) Cloud, AWS Security Hub standard controls, such as CIS AWS Foundations Benchmark or AWS Foundational Security Best Practices, can only be turned off (disabled) manually from within a single AWS account. In a multi-account environment, you can't turn off the controls across multiple Security Hub member accounts with “one click” (that is, one API call). This pattern demonstrates how to turn off the Security Hub standard controls across all the Security Hub member accounts managed by your Security Hub administrator account with one click.

Prerequisites and limitations

Prerequisites

- A multi-account environment consisting of a Security Hub administrator account that manages multiple member accounts
- AWS Command Line Interface (AWS CLI) version 2, installed
- AWS SAM CLI, installed

Limitations

- This pattern works only in a multi-account environment where a single Security Hub administrator account manages multiple member accounts.
- If you change a lot of controls in a very short timeframe, the event initiation causes multiple parallel invocations, which can lead to API throttling and cause the invocations to fail. For example, this can happen if you programmatically change a lot of controls by using the Security Hub Controls CLI.

Architecture

The following diagram shows an example of an AWS Step Functions workflow that turns off Security Hub standard controls across multiple Security Hub member accounts (as viewed from the Security Hub administrator account).
The diagram includes the following workflow:

1. An Amazon EventBridge rule is initiated on a daily schedule and invokes the state machine. **Note:** You can modify the timing of the rule by updating the **Schedule** parameter in your AWS CloudFormation template.

2. An EventBridge rule is initiated whenever a control is turned on or off in the Security Hub administrator account.

3. A Step Functions state machine propagates the status of the security standard controls (that is, controls that are turned on or off) from the Security Hub administrator account to the member accounts.

4. A cross-account AWS Identity and Access Management (IAM) role is deployed in each member account and assumed by the state machine. The state machine turns the controls on or off in each member account.

5. An Amazon DynamoDB table contains exceptions and information about which controls to turn on or off in a particular account. This information overrides the configurations fetched from the Security Hub administrator account for the specified member account.

**Note:** The purpose of the scheduled EventBridge rule is to ensure that newly added Security Hub member accounts have the same control status as existing accounts.

**Technology stack**

- Amazon DynamoDB
- Amazon EventBridge
- AWS CLI
- AWS Lambda
- AWS SAM CLI
- AWS Security Hub
- AWS Step Functions
Tools

- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

- **Amazon EventBridge** – Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your applications, software as a service (SaaS) applications, and AWS services to targets such as Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- **AWS SAM** – AWS Serverless Application Model (AWS SAM) is an open-source framework that you can use to build serverless applications on AWS. AWS SAM provides you with a template specification to define your serverless application, and a command line interface (CLI) tool.

- **AWS Security Hub** – AWS Security Hub provides you with a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices.

- **AWS Step Functions** – AWS Step Functions is a serverless orchestration service that lets you combine Lambda functions and other AWS services to build business-critical applications. Through the Step Functions graphical console, you see your application’s workflow as a series of event-driven steps.

Code

The code for this pattern is available on the GitHub [AWS Security Hub Cross-Account Controls Disabler](https://github.com/aws-samples/security-hub-cross-account-controls-disabler) repository. The code repository contains the following files and folders, which are applicable to this pattern:

- **UpdateMembers/template.yaml** – This file contains components deployed in the Security Hub administrator account, including the Step Functions state machine and the EventBridge rules.

- **member-iam-role/template.yaml** – This file contains the code to deploy the cross-account IAM role in a member account.

- **StateMachine.json** – This file defines the state machine’s workflow.

- **GetMembers/index.py** – This file contains the code for the `GetMembers` state machine. A script retrieves the status of the security standard controls in all existing Security Hub member accounts.

- **UpdateMember/index.py** – This file contains a script that updates the control status in each member account.

- **CheckResult/index.py** – This file contains a script that checks the status of the workflow invocation (accepted or failed).

### Update AWS CLI credentials from AWS IAM Identity Center by using PowerShell

*Created by Chad Miles (AWS) and Andy Bowen (AWS)*

Summary

If you want to use AWS IAM Identity Center (successor to AWS Single Sign-On) credentials with AWS Command Line Interface (AWS CLI), AWS SDKs, or AWS Cloud Development Kit (AWS CDK), you typically have to copy and paste the credentials from the IAM Identity Center console into the command line interface. This process can take a considerable amount of time and has to be repeated for each account that requires access.

One common solution is to use the AWS CLI `aws sso configure` command. This command adds an IAM Identity Center enabled profile to your AWS CLI or AWS SDK. However, the disadvantage of this solution is that you must run the command `aws sso login` for each AWS CLI profile or account that you have configured this way.

As an alternative solution, this pattern describes how to use AWS CLI named profiles and AWS Tools for PowerShell to store and refresh credentials for multiple accounts from a single IAM Identity Center instance simultaneously. The script also stores IAM Identity Center session data in memory for refreshing credentials without logging into IAM Identity Center again.

Prerequisites and limitations

Prerequisites

- PowerShell, installed and configured. For more information, see [Installing PowerShell](https://github.com) (GitHub repository).
- AWS Tools for PowerShell, installed and configured. For performance reasons, we highly recommend that you install the modularized version of AWS Tools for PowerShell, called AWS.Tools. Each AWS service is supported by its own individual, small module. In the PowerShell prompt, enter the following commands to install the modules needed for this pattern: `AWS.Tools.Installer`, `SSO`, and `SSOIDC`.

```powershell
Install-Module AWS.Tools.Installer
Install-AWSToolsModule SSO, SSOIDC
```

For more information, see [Install AWS.Tools on Windows](https://aws.amazon.com) or [Install AWS.Tools on Linux or macOS](https://aws.amazon.com).
- AWS CLI or the AWS SDK must be previously configured with working credentials by doing one of the following:
  - Use the AWS CLI `aws configure` command. For more information, see [Quick configuration](https://aws.amazon.com) (AWS CLI documentation).
  - Configure AWS CLI or AWS CDK to get temporary access through an IAM role. For more information, see [Getting IAM role credentials for CLI access](https://aws.amazon.com) (IAM Identity Center documentation).

Limitations

- This script can’t be used in a pipeline or fully automated solution. When you deploy this script, you must manually authorize access from IAM Identity Center. The script then continues automatically.

Product versions

- For all operating systems, it is recommended that you use [PowerShell version 7.0](https://aws.amazon.com) or later.
Architecture

You can use the script in this pattern to simultaneously refresh multiple IAM Identity Center credentials, and you can create a credential file for use with AWS CLI, AWS SDKs, or AWS CDK.

Tools

AWS services

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS IAM Identity Center** helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and cloud applications.
- **AWS Tools for PowerShell** are a set of PowerShell modules that help you script operations on your AWS resources from the PowerShell command line.

Other tools

- **PowerShell** is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.

Best practices

Keep one copy of this script for each IAM Identity Center instance. Using one script for multiple instances is not supported.

Epics

Run the SSO script

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Customize the SSO script.</td>
<td>1. Copy the SSO script in the Additional information (p. 2216) section.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>2. In the Param section, for your AWS environment, define the values for the following variables:</td>
<td></td>
</tr>
</tbody>
</table>
### Task | Description | Skills required
--- | --- | ---
- DefaultRoleName – The IAM role or permission set to use by default.  
- Region – The AWS Region in which IAM Identity Center is deployed. For a complete list of Regions and their codes, see [Regional endpoints](#).  
- StartUrl – The URL used to access your IAM Identity Center login page. Use the same format as the example value in the script.  
- EnvironmentName – A short name to reference this copy of the script, to be used when you’re running multiple script copies in the same session.

3. Under line 10, which reads  
```bash  
# Add your Account Information
```

edit the following values in the hash tables to reflect your environment:  
- Profile – The AWS CLI profile name in which to store the temporary credentials.  
- AccountId – The ID of the AWS account for which you are retrieving credentials.  
- RoleName – The name of the IAM Identity Center role or permission set you want to use. You can leave this as $DefaultRoleName if you want to use the same role you defined in the Param section.

Each line in the hash table must end with a comma except the last one.

Use AWS Config to monitor Amazon Redshift security configurations

Created by Lucas Kauffman (AWS)

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>• awslabs/aws-config-rules</td>
<td>AWS Config; Amazon Redshift; AWS Lambda</td>
<td></td>
</tr>
</tbody>
</table>

Summary

Using AWS Config, you can evaluate the security configurations for your AWS resources. AWS Config can monitor the resources, and if configuration settings violate your defined rules, AWS Config flags the resource as noncompliant.

You can use AWS Config to evaluate and monitor your Amazon Redshift clusters and databases. For more information about security recommendations and features, see Security in Amazon Redshift. This pattern includes custom AWS Lambda rules for AWS Config. You can deploy these rules in your account to monitor the security configurations of your Amazon Redshift clusters and databases. The rules in this pattern help you use AWS Config to confirm that:

• Audit logging is enabled for the databases in the Amazon Redshift cluster
• SSL is required to connect to the Amazon Redshift cluster
• Federal Information Processing Standards (FIPS) ciphers are in use
• Databases in the Amazon Redshift cluster are encrypted
• User activity monitoring is enabled

Prerequisites and limitations

Prerequisites

• An active AWS account.
• AWS Config must be enabled in your AWS account. For more information, see Setting Up AWS Config with the Console or Setting Up AWS Config with the AWS CLI.
• Python version 3.9 or later must be used for the AWS Lambda handler. For more information, see Working with Python (AWS Lambda documentation).

```powershell
SessionToken = $SsoAwsAccounts[$i].Credentials.SessionToken } | Set-AWSCredential -StoreAs $SsoAwsAccounts[$i].Profile -ProfileLocation $CredentialFile 
}
Set-Variable -name ""$($EnvironmentName)SsoAwsAccounts"" -Value $SsoAwsAccounts.Clone() -Scope Global
Write-Host "\r$($SsoAwsAccounts.Profile) Profiles registered, $CredsTimeText"
```
Limitations

- For many AWS services, AWS Config publishes an event when it detects a configuration change for a resource within the scope of the rule. AWS Config doesn’t currently support configuration change events for Amazon Redshift. Therefore, the custom AWS Config rules in this pattern use Periodic evaluation as the trigger type. Periodic evaluations occur at the frequency that you specify when you define the rule in AWS Config.

Product versions

- Python version 3.9 or later

Architecture

Target technology stack

- AWS Config

Target architecture

1. AWS Config periodically runs the custom rule.
2. The custom rule invokes the Lambda function.
3. The Lambda function checks the Amazon Redshift clusters for non-compliant configurations.
4. The Lambda function reports the compliance state of each Amazon Redshift cluster to AWS Config.

Automation and scale

The AWS Config custom rules scale to assess all Amazon Redshift clusters in your account. No additional action is required to scale this solution.
Tools

**AWS services**

- **AWS Config** provides a detailed view of the resources in your AWS account and how they’re configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **Amazon Redshift** is a managed petabyte-scale data warehouse service in the AWS Cloud.

**Code repository**

The code for this pattern is available in the GitHub [aws-config-rules](https://github.com/aws-config-rules) repository. The custom rules in this repository are Lambda rules in the Python programming language. This repository contains many custom rules for AWS Config. Only the following rules are used in this pattern:

- **REDSHIFT_AUDIT_ENABLED** – Confirm that audit logging is enabled on the Amazon Redshift cluster. If you also want to confirm that user activity monitoring is enabled, deploy the **REDSHIFT_USER_ACTIVITY_MONITORING_ENABLED** rule instead.
- **REDSHIFT_SSL_REQUIRED** – Confirm that SSL is required to connect to the Amazon Redshift cluster. If you also want to confirm that Federal Information Processing Standards (FIPS) ciphers are in use, deploy the **REDSHIFT_FIPS_REQUIRED** rule instead.
- **REDSHIFT_FIPS_REQUIRED** – Confirm that SSL is required and FIPS ciphers are in use.
- **REDSHIFT_DB_ENCRYPTED** – Confirm that the databases in the Amazon Redshift cluster are encrypted.
- **REDSHIFT_USER_ACTIVITY_MONITORING_ENABLED** – Confirm that audit logging and user activity monitoring is enabled.

**Epics**

Use Network Firewall to capture the DNS domain names from the Server Name Indication (SNI) for outbound traffic

*Created by Kirankumar Chandrashekar (AWS)*

**Environment:** PoC or pilot  
**Technologies:** Security, identity, compliance; Networking; Websites & web apps  
**Workload:** All other workloads  
**AWS services:** AWS Lambda; AWS Network Firewall; Amazon VPC; Amazon CloudWatch Logs

---

**Summary**

This pattern shows you how to use Amazon Web Services (AWS) Network Firewall to collect the DNS domain names that are provided by the Server Name Indication (SNI) in the HTTPS header of your outbound network traffic. Network Firewall is a managed service that makes it easy to deploy critical
network protections for Amazon Virtual Private Cloud (Amazon VPC), including the ability to secure outbound traffic with a firewall that blocks packets that fail to meet certain security requirements. Securing outbound traffic to specific DNS domain names is called egress filtering, which is the practice of monitoring and potentially restricting the flow of outbound information from one network to another.

After you capture the SNI data that passes through Network Firewall, you can use Amazon CloudWatch Logs and AWS Lambda to publish the data to an Amazon Simple Notification Service (Amazon SNS) topic that generates email notifications. The email notifications include the server name and other relevant SNI information. Additionally, you can use the output of this pattern to allow or restrict outbound traffic by domain name in the SNI by using firewall rules. For more information, see Working with stateful rule groups in AWS Network Firewall in the Network Firewall documentation.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows
- Network Firewall, set up and configured in Amazon VPC and in use for inspecting outbound traffic

**Note:** Network Firewall can use any of the following VPC configurations:

- Simple single zone architecture with an internet gateway
- Multi zone architecture with an internet gateway
- Architecture with an internet gateway and a NAT gateway

**Architecture**

The following diagram shows how to use Network Firewall to collect SNI data from outbound network traffic, and then publish that data to an SNS topic by using CloudWatch Logs and Lambda.

The diagram shows the following workflow:

1. Network Firewall collects domain names from the SNI data in the HTTPS header of your outbound network traffic.
2. CloudWatch Logs monitors the SNI data and invokes a Lambda function whenever the outbound network traffic passes through Network Firewall.
3. The Lambda function reads the SNI data captured by CloudWatch Logs and then publishes that data to an SNS topic.
4. The SNS topic sends you an email notification that includes the SNI data.

**Automation and scale**
- You can use AWS CloudFormation to create this pattern by using infrastructure as code.

**Technology stack**
- Amazon CloudWatch Logs
- Amazon SNS
- Amazon VPC
- AWS Lambda
- AWS Network Firewall

**Tools**

**AWS services**
- **Amazon CloudWatch Logs** – You can use Amazon CloudWatch Logs to monitor, store, and access your log files from Amazon Elastic Compute Cloud (Amazon EC2) instances, AWS CloudTrail, Amazon Route 53, and other sources.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).
- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- **AWS Lambda** – AWS Lambda is a compute service that lets you run code without provisioning or managing servers.
- **AWS Network Firewall** – AWS Network Firewall is a managed service that makes it easy to deploy essential network protections for all of your Amazon VPCs.

**Epics**

**Create a CloudWatch log group for Network Firewall**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>

## Set up logging in Network Firewall

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Enable firewall logging.  | 1. Sign in to the AWS Management Console and open the Amazon VPC console.  
2. In the navigation pane, under NETWORK FIREWALL, choose Firewalls.  
3. In the Firewalls section, choose the firewall where you want to capture the server name from the SNI for outbound traffic.  
4. Choose the Firewall details tab, and then choose Edit in the Logging section.  
5. For Log type, select Alert. For Log destination for alerts, select CloudWatch log group.  
6. For CloudWatch log group, search for and choose the log group that you created earlier, and then choose Save. | Cloud administrator      |
For more information about using CloudWatch Logs as a log destination for Network Firewall, see Amazon CloudWatch Logs in the Network Firewall documentation.

Set up a stateful rule in Network Firewall

Create a stateful rule.

1. Sign in to the AWS Management Console and open the Amazon VPC console.
2. In the navigation pane, under NETWORK FIREWALL, choose Network Firewall Rule Groups.
3. Choose Create Network Firewall rule group.
4. On the Create Network Firewall rule group page, for the Rule group type, choose Stateful rule group. **Note:** For more information, see Working with stateful rule groups in AWS Network Firewall.
5. In the Stateful rule group section, enter a name and description for the rule group.
6. For Capacity, set the maximum capacity that you want to allow for the stateful rule group (up to the maximum of 30,000). **Note:** You can't change this setting after you create the rule group. For information about how to calculate capacity, see Setting rule group capacity in AWS Network Firewall. For information about the maximum setting, see AWS Network Firewall quotas.
7. For Stateful rule group options, select 5-tuple.
8. In the Stateful rule order section, choose Default.
9. In the Rule variables section, keep the default values.
### Epics

<table>

<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>11.</td>
<td>Choose Create stateful rule group.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

Associating the stateful rule to Network Firewall:

1. Sign in to the AWS Management Console and open the Amazon VPC console.
2. In the navigation pane, under NETWORK FIREWALL, choose Firewalls.
3. Choose the firewall where you want to capture the server name from the SNI for outbound traffic.
4. In the **Stateful rule groups** section, choose Actions, and then choose Add unmanaged stateful rule groups.
5. On the Add unmanaged stateful rule groups page, select the stateful rule group that you created earlier, and then choose Add stateful rule group.

### Create a Lambda function to read the logs

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the code for the Lambda function.</td>
<td>In an integrated development environment (IDE) that can read the CloudWatch Logs event from Network Firewall for outbound traffic, paste in the following Python 3 code and replace <code>&lt;SNS-topic-ARN&gt;</code> with your value:</td>
<td>App developer</td>
</tr>
</tbody>
</table>

```python
import json
import gzip
import base64
import boto3
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| sns_client = boto3.client('sns') def lambda_handler(event, context): decoded_event = json.loads(gzip.decompress(base64.b64decode(event['awslogs']['data']))).body = '''
{filtermatch}
'''.format(loggroup=decoded_event['logGroup'], logstream=decoded_event['logStream'], filtermatch=decoded_event['logEvents'][0]['message']) print(body) filterMatch = json.loads(body) data = [] if 'http' in filterMatch['event']:

data.append(filterMatch['event']['http']['hostname'])

elif 'tls' in filterMatch['event']:

data.append(filterMatch['event']['tls']['sni'])

result = 'Domain accessed ' + 1*' ' + (data[0]) + 1*' ' via AWS Network Firewall ' + 1*' ' + (filterMatch['firewall_name'])

print(result)

message = {'ServerName': result}

send_to_sns = sns_client.publish(TargetArn='<SNS-topic-ARN>',

#Replace with the SNS topic ARN

Message=json.dumps({'default': json.dumps(message),

'sms': json.dumps(message),

'email': json.dumps(message)}),

Subject='Server Name passed through the Network Firewall',

MessageStructure='json' ) | |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

</tr>
</thead>
</table>
| Add SNS publish permissions. | Add the **sns:Publish** permission to the Lambda execution role, so that Lambda can make API calls to publish messages to SNS.  
1. **Find the execution role** of the Lambda function that you created earlier.  
2. **Add the following policy** to your AWS Identity and Access Management (IAM) role:  
   ```json  
   {  
     "Version": "2012-10-17",  
     "Statement": [  
       {  
         "Sid": "AllowSNSPublish",  
         "Effect": "Allow",  
         "Action": [  
           "sns:GetTopicAttributes",  
           "sns:Subscribe",  
           "sns:Unsubscribe",  
           "sns:Publish"  
         ],  
         "Resource": "*"  
       }  
     ]  
   }  
   ``` | Cloud administrator |

---

**Test the functionality of your SNS notification**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Send traffic through Network Firewall.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
1. Send or wait for HTTPS traffic to pass through Network Firewall.  
2. Check the SNS notification email that you receive from AWS when traffic passes through Network Firewall. The email includes the SNI details for outbound traffic. For example, the email generated from the Lambda code above will have the following content if the accessed domain name is https://aws.amazon.com | Test engineer |
and the subscription protocol is **EMAIL-JSON**:

```json
{
    "Type": "Notification",
    "MessageId": "<messageID>",
    "Subject": "Server Name passed through the Network Firewall",
    "Message": ""\"ServerName\": "Domain 'aws.amazon.com' accessed via AWS Network Firewall 'AWS-Network-Firewall-Multi-AZ-firewall\"",
    "Timestamp": "2022-03-22T04:10:04.217Z",
    "SignatureVersion": "1",
    "Signature": "<Signature>",
    "SigningCertURL": "<SigningCertUrl>",
    "UnsubscribeURL": "<UnsubscribeURL>"
}
```

Then, check the Network Firewall alert log in Amazon CloudWatch by following the instructions in the Amazon CloudWatch documentation. The alert log shows the following output:

```json
{
    "firewall_name": "AWS-Network-Firewall-Multi-AZ-firewall",
    "availability_zone": "us-east-2b",
    "event_timestamp": "<event timestamp>",
    "event": {
        "timestamp": "2021-03-22T04:10:04.214222+0000",
        "flow_id": "<flow ID>",
        "event_type": "alert",
        "src_ip": "10.1.3.76",
        "src_port": 22761,
        "dest_ip": "99.86.59.73",
        "dest_port": 443,
    }
}
```
Use Terraform to automatically enable Amazon GuardDuty for an organization

Created by Aarthi Kannan (AWS)

<table>
<thead>

<tr>
<td>Workload: All other workloads</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Amazon GuardDuty continuously monitors your Amazon Web Services (AWS) accounts and uses threat intelligence to identify unexpected and potentially malicious activity within your AWS environment.
Manually enabling GuardDuty for multiple accounts or organizations, across multiple AWS Regions, or through the AWS Management Console can be cumbersome. You can automate the process by using an infrastructure as code (IaC) tool, such as Terraform, which can provision and manage multi-account, multi-Region services and resources in the cloud.

AWS recommends using AWS Organizations to set up and manage multiple accounts in GuardDuty. This pattern adheres to that recommendation. One benefit of this approach is that, when new accounts are created or added to the organization, GuardDuty will be auto-enabled in these accounts for all supported Regions, without the need for manual intervention.

This pattern demonstrates how to use HashiCorp Terraform to enable Amazon GuardDuty for three or more Amazon Web Services (AWS) accounts in an organization. The sample code provided with this pattern does the following:

- Enables GuardDuty for all AWS accounts that are current members of the target organization in AWS Organizations
- Turns on the Auto-Enable feature in GuardDuty, which automatically enables GuardDuty for any accounts that are added to the target organization in the future
- Allows you select the Regions where you want to enable GuardDuty
- Uses the organization’s security account as the GuardDuty delegated administrator
- Creates an Amazon Simple Storage Service (Amazon S3) bucket in the logging account and configures GuardDuty to publish the aggregated findings from all accounts in this bucket
- Assigns a life-cycle policy that transitions findings from the S3 bucket to Amazon S3 Glacier Flexible Retrieval storage after 365 days, by default

You can manually run this sample code, or you can integrate it into your continuous integration and continuous delivery (CI/CD) pipeline.

Target audience

This pattern is recommended for users who have experience with Terraform, Python, GuardDuty, and AWS Organizations.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An organization is set up in AWS Organizations, and it contains at least the following three accounts:
  - A management account – This is the account from which you deploy the Terraform code, either standalone or as part of the CI/CD pipeline. The Terraform state is also stored in this account.
  - A security account – This account is used as the GuardDuty delegated administrator. For more information, see Important considerations for GuardDuty delegated administrators (GuardDuty documentation).
  - A logging account – This account contains the S3 bucket where GuardDuty publishes the aggregated findings from all member accounts.

For more information about how to set up the organization with the required configuration, see Create an account structure (AWS Well-Architected Labs).

- An Amazon S3 bucket and an Amazon DynamoDB table that serve as a remote backend to store Terraform’s state in the management account. For more information on using remote backends for the Terraform state, see S3 Backends (Terraform documentation). For a code sample that sets up remote state management with an S3 backend, see remote-state-s3-backend (Terraform Registry). Note the following requirements:
• The S3 bucket and DynamoDB table must be in the same Region.
• When creating the DynamoDB table, the partition key must be LockID (case-sensitive), and the partition key type must be String. All other table settings must be at their default values. For more information, see About primary keys and Create a table (DynamoDB documentation).
• An S3 bucket that will be used to store access logs for the S3 bucket in which GuardDuty will publish findings. For more information, see Enabling Amazon S3 server access logging (Amazon S3 documentation).
• Terraform version 0.14.6 or later is installed and configured. For more information, see Get Started – AWS (Terraform documentation).
• Python version 3.9.6 or later is installed and configured. For more information, see Source releases (Python website).
• AWS SDK for Python (Boto3) is installed. For more information, see Installation (Boto3 documentation).
• jq is installed and configured. For more information, see Download jq (jq documentation).

Limitations
• This pattern supports macOS and Amazon Linux 2 operating systems. This pattern has not been tested for use in Windows operating systems.
• GuardDuty must not already be enabled in any of the accounts, in any of the target Regions.
• The IaC solution in this pattern does not deploy the prerequisites.
• This pattern is designed for an AWS landing zone that adheres to the following best practices:
  • The landing zone was created by using AWS Control Tower.
  • Separate AWS accounts are used for security and logging.

Product versions
• Terraform version 0.14.6 or later. The sample code has been tested for version 1.2.8.
• Python version 3.9.6 or later.

Architecture

This section gives a high-level overview of this solution and the architecture established by the sample code. The following diagram shows the resources deployed across the various accounts in the organization, within a single AWS Region.
1. Terraform creates the **GuardDutyTerraformOrgRole** AWS Identity and Access Management (IAM) role in the security account and the logging account.

2. Terraform creates an S3 bucket in the default AWS Region in the logging account. This bucket is used as the publishing destination to aggregate all GuardDuty findings across all Regions and from all accounts in the organization. Terraform also creates an AWS Key Management Service (AWS KMS) key in the security account that is used to encrypt the findings in the S3 bucket and configures automatic archiving of findings from the S3 bucket into S3 Glacier Flexible Retrieval storage.

3. From the management account, Terraform designates the security account as the delegated administrator for GuardDuty. This means that the security account now manages the GuardDuty service for all member accounts, including the management account. Individual member accounts cannot suspend or disable GuardDuty by themselves.

4. Terraform creates the GuardDuty detector in the security account, for the GuardDuty delegated administrator.

5. If it is not already enabled, Terraform enables S3 protection in GuardDuty. For more information, see [Amazon S3 protection in Amazon GuardDuty](GuardDuty documentation).

6. Terraform enrolls all current, active member accounts in the organization as GuardDuty members.

7. Terraform configures the GuardDuty delegated administrator to publish the aggregated findings from all member accounts to the S3 bucket in the logging account.

8. Terraform repeats steps 3 through 7 for each AWS Region you choose.

**Automation and scale**

The sample code provided is modularized so that you can integrate it into your CI/CD pipeline for automated deployment.

**Tools**

**AWS services**
• **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

• **Amazon GuardDuty** is a continuous security monitoring service that analyzes and processes logs to identify unexpected and potentially unauthorized activity in your AWS environment.

• **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

• **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to protect your data.

• **AWS Organizations** is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

• **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

• **AWS SDK for Python (Boto3)** is a software development kit that helps you integrate your Python application, library, or script with AWS services.

Other tools and services

• **Hashicorp Terraform** is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.

• **Python** is a general-purpose programming language.

• **jq** is a command-line processor that helps you work with JSON files.

**Code repository**

The code for this pattern is available on GitHub, in the `amazon-guardduty-for-aws-organizations-with-terraform` repository.

export AWS_SESSION_TOKEN=$(echo $ROLE_CREDENTIALS | jq .Credentials.SessionToken | sed 's/"//g')
```

Verify that new Amazon Redshift clusters have required SSL endpoints

Created by Priyanka Chaudhary (AWS)

| Environment: Production | Technologies: Security, identity, compliance; Analytics; Data lakes | AWS services: AWS CloudTrail; Amazon CloudWatch Events; Amazon Redshift; Amazon SNS; AWS Lambda |

Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that automatically notifies you when a new Amazon Redshift cluster is launched without Secure Sockets Layer (SSL) endpoints.

Amazon Redshift is a fully managed, petabyte-scale, cloud-based data warehouse service. It is designed for large-scale dataset storage and analysis. It is also used to perform large-scale database migrations. For security, Amazon Redshift supports SSL to encrypt the connection between the user's SQL Server client application and the Amazon Redshift cluster. To configure your cluster to require an SSL connection, you set the require_SSL parameter to true in the parameter group that is associated with the cluster during launch.

The security control provided with this pattern monitors Amazon Redshift API calls in AWS CloudTrail logs and initiates an Amazon CloudWatch Events event for the CreateCluster, ModifyCluster, RestoreFromClusterSnapshot, CreateClusterParameterGroup, and ModifyClusterParameterGroup APIs. When the event detects one of these APIs, it calls AWS Lambda, which runs a Python script. The Python function analyzes the CloudWatch event for the listed CloudTrail events. When an Amazon Redshift cluster is created, modified, or restored from an existing snapshot, a new parameter group is created for the cluster, or an existed parameter group is modified, the function checks the require_SSL parameter for the cluster. If the parameter value is false, the function sends an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon Redshift cluster
name, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A virtual private cloud (VPC) with a cluster subnet group, and an associated security group.

Limitations

- This security control is regional. You must deploy it in each AWS Region you want to monitor.

Architecture

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers.
- Amazon Redshift – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud.
• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Code**

This pattern includes the following attachments:

- RedshiftSSLEndpointsRequired.zip – The Lambda code for the security control.
- RedshiftSSLEndpointsRequired.yml – The CloudFormation template that sets up the event and Lambda function.

### Epics

**Set up the S3 bucket**

<table>
<thead>

</thead>
<tbody>
<tr>
<td>Define the S3 bucket.</td>
<td>On the Amazon S3 console, choose or create an S3 bucket to host the Lambda code .zip file. This S3 bucket must be in the same AWS Region as the Amazon Redshift cluster you want to monitor. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Upload the Lambda code.</td>
<td>Upload the Lambda code .zip file provided in the Attachments section to the S3 bucket.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

### Deploy the CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Launch the AWS CloudFormation template.</td>
<td>Open the AWS CloudFormation console in the same AWS Region as your S3 bucket and deploy the attached template RedshiftSSLEndpointsRequired.yml. For more information about deploying AWS CloudFormation templates, see Creating a stack on the AWS CloudFormation console in the CloudFormation documentation.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
Complete the parameters in the template.

When you launch the template, you'll be prompted for the following information:

- **S3 bucket**: Specify the bucket that you created or selected in the first epic. This is where you uploaded the attached Lambda code (.zip file).
- **S3 key**: Specify the location of the Lambda .zip file in your S3 bucket (for example, `filename.zip` or `controls/filename.zip`). Do not include leading slashes.
- **Notification email**: Provide an active email address where you want to receive Amazon SNS notifications.
- **Lamba logging level**: Specify the logging level and frequency for the Lambda function. Use `Info` to log detailed informational messages on progress, `Error` for error events that would still allow the deployment to continue, and `Warning` for potentially harmful situations.

Skills required: Cloud architect

Confirm the subscription.

When the CloudFormation template deploys successfully, it sends a subscription email to the email address you provided. You must confirm this email subscription to start receiving violation notifications.

Skills required: Cloud architect

Verify that new Amazon Redshift clusters launch in a VPC

Created by Priyanka Chaudhary (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Security, identity, compliance; Analytics; Databases</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon CloudWatch; AWS Lambda; Amazon Redshift</td>
</tr>
</tbody>
</table>

Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that automatically notifies you when an Amazon Redshift cluster is launched outside a virtual private cloud (VPC).

Amazon Redshift is a fully managed, petabyte-scale, cloud-based data warehouse product. It is designed for large-scale dataset storage and analysis. It is also used to perform large-scale database migrations. Amazon Virtual Private Cloud (Amazon VPC) lets you provision a logically isolated section of the AWS Cloud where you can launch AWS resources such as Amazon Redshift clusters in a virtual network that you define.

The security control provided with this pattern monitors Amazon Redshift API calls in AWS CloudTrail logs, and initiates an Amazon CloudWatch Events event for the CreateCluster and RestoreFromClusterSnapshot APIs. When the event detects one of these APIs, it calls AWS Lambda, which runs a Python script. The Python function analyzes the CloudWatch event. If an Amazon Redshift cluster is created or restored from a snapshot and appears outside the Amazon VPC network, the function sends an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon Redshift cluster name, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A VPC with a cluster subnet group, and an associated security group.

Limitations

- The AWS CloudFormation template supports the CreateCluster and RestoreFromClusterSnapshot actions (new clusters) only. It does not detect existing Amazon Redshift clusters that were created outside a VPC.
This security control is regional. You must deploy it in each AWS Region you want to monitor.

Architecture

Target architecture

Automation and scale

If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually.
- **AWS CloudTrail** – AWS CloudTrail helps you implement governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **Amazon Redshift** – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. Amazon Redshift is integrated with your data lake, which enables you to use your data to acquire new insights for your business and customers.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses.

Summary

This pattern shows how to create a serverless backend for a React Native mobile app by using AWS Amplify and the following AWS services:

- AWS AppSync
- Amazon Cognito
- Amazon DynamoDB

After you configure and deploy the app’s backend by using Amplify, Amazon Cognito authenticates app users and authorizes them to access the app. AWS AppSync then interacts with the frontend app and a backend DynamoDB table to create and fetch data.
Note: This pattern uses a simple “ToDoList” app as an example, but you can use a similar procedure to create any React Native mobile app.

Prerequisites and limitations

Prerequisites

- An active AWS Account
- Amplify Command Line Interface (Amplify CLI), installed and configured
- XCode (any version)
- Microsoft Visual Studio (any version, any code editor, any text editor)
- Familiarity with Amplify
- Familiarity with Amazon Cognito
- Familiarity with AWS AppSync
- Familiarity with DynamoDB
- Familiarity with Node.js
- Familiarity with npm
- Familiarity with React and React Native
- Familiarity with JavaScript and ECMAScript 6 (ES6)
- Familiarity with GraphQL

Architecture

The following diagram shows an example architecture for running a React Native mobile app’s backend in the AWS Cloud:

The diagram shows the following architecture:
1. Amazon Cognito authenticates app users and authorizes them to access the app.
2. To create and fetch data, AWS AppSync uses a GraphQL API to interact with the frontend app and a backend DynamoDB table.

**Tools**

**AWS services**

- **AWS Amplify** is a set of purpose-built tools and features that helps frontend web and mobile developers quickly build full-stack applications on AWS.
- **AWS AppSync** provides a scalable GraphQL interface that helps application developers combine data from multiple sources, including Amazon DynamoDB, AWS Lambda, and HTTP APIs.
- **Amazon Cognito** provides authentication, authorization, and user management for web and mobile apps.
- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

**Code**

The code for the sample application that's used in this pattern is available in the GitHub [aws-amplify-react-native-ios-todo-app](https://github.com/aws-amplify-react-native-ios-todo-app) repository. To use the sample files, follow the instructions in the [Epics](#) section of this pattern.

**Epics**

**Create and run your React Native app**

| Create and run the ToDoList React Native mobile app in iOS Simulator. | 1. Create a new React Native mobile app project directory in your local environment by running the following command in a new terminal window:  
   ```bash  
npx react-native init ToDoListAmplify  
```  
2. Navigate to the project's root directory by running the following command:  
   ```bash  
cd ToDoListAmplify  
```  
3. Run the app by running the following command:  
   ```bash  
npx react-native run-ios  
``` | App developer |
## Initialize a new backend environment for the app

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the backend services needed to support the app in Amplify. | 1. In your local environment, run the following command from the project's root directory (`ToDoListAmplify`):  
   ```bash
amplify init
```

2. A prompt appears that asks you to provide information about the app. Enter the required information based on your use case. Then, press Enter.

For the ToDoList app setup used in this pattern, apply the following example configuration.

**Example React Native Amplify app configuration settings**

- Name: `ToDoListAmplify`
- Environment: `dev`
- Default editor: Visual Studio Code
- App type: `javascript`
- Javascript framework: `react-native`
- Source Directory Path: `src`
- Distribution Directory Path: `/`
- Build Command: `npm run-script build`
- Start Command: `npm run-script start`

- Select the authentication method you want to use: AWS profile
- Please choose the profile you want to use: `default`

For more information, see [Create a new Amplify backend](#) in the Amplify Dev Center documentation.
### Add Amazon Cognito authentication to your Amplify React Native app

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an Amazon Cognito authentication service. | 1. In your local environment, run the following command from the project's root directory (`ToDoListAmplify`):
```bash
amplify add auth
```
2. A prompt appears that asks you to provide information about the authentication service's configuration settings. Enter the required information based on your use case. Then, press Enter. | App developer |

For the `ToDoList` app setup used in this pattern, apply the following example configuration.

**Example authentication service configuration settings**

<table>
<thead>
<tr>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>? Do you want to use the default authentication and security configuration?</td>
<td>Default configuration</td>
</tr>
<tr>
<td>? How do you want users to be able to sign in?</td>
<td>Username</td>
</tr>
</tbody>
</table>

---

**Note:** The `amplify init` command provisions the following resources by using AWS CloudFormation:

- AWS Identity and Access Management (IAM) roles for authenticated and unauthenticated users (**Auth Role** and **Unauth Role**)
- An Amazon Simple Storage Service (Amazon S3) bucket for deployment (for this pattern's example app, `Amplify-meta.json`)
- A backend environment in Amplify Hosting
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| ? Do you want to configure advanced settings?  
No, I am done | **Note:** The amplify add auth command creates the necessary folders, files, and dependency files in a local folder (amplify) within the project's root directory. For the ToDoList app setup used in this pattern, the `aws-exports.js` is created for this purpose. |  |
| Deploy the Amazon Cognito service to the AWS Cloud. | 1. From the project's root directory, run the following Amplify CLI command:  
   ```  
amplify push  
```
2. A prompt to confirm deployment appears. Enter **Yes.** Then, press **Enter**.  
   **Note:** To see the deployed services in your project, go to the Amplify console by running the following command:  
   ```  
amplify console  
``` | **App developer** |
| Install the required Amplify libraries for React Native and the CocoaPods dependencies for iOS. | 1. Install the required Amplify open-source client libraries by running the following command from the project's root directory:  
   ```  
npm install aws-amplify aws-amplify-react-native \ amazon-cognito-identity-js @react-native-community/netinfo \ @react-native-async-storage/async-storage  
```  
2. Install the required CocoaPods dependencies for iOS by running the following command:  
   ```  
npx pod-install  
``` | **App developer** |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
|  |  | import Amplify from 'aws-amplify'
|  |  | import config from './src/aws-exports'
|  |  | Amplify.configure(config)
<p>|  | <strong>Note:</strong> If you receive an error after importing the Amplify service in the app's entry point file, stop the app. Then, open XCode and select the <code>ToDoListAmplify.xcworkspace</code> from the project's iOS folder and run the app. | App developer |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Update your app's entry point file to use the withAuthenticator Higher-order component (HOC). | **Note:** The withAuthenticator HOC provides sign-in, sign-up, and forgot password workflows in your app by using only a few lines of code. For more information, see Option 1: Use pre-build UI components in the Amplify Dev Center. Also, Higher-order components in the React documentation.  
1. In the app's entry point file (for example, App.js), import the withAuthenticator HOC by entering the following lines of code:  
   ```javascript
   import { withAuthenticator } from 'aws-amplify-react-native'
   ```  
2. Export the withAuthenticator HOC by entering the following code:  
   ```javascript
   export default withAuthenticator(App)
   ```  
   **withAuthenticator HOC code example**
   ```javascript
   import Amplify from 'aws-amplify'
   import config from './src/aws-exports'
   Amplify.configure(config)
   import { withAuthenticator } from 'aws-amplify-react-native';

   const App = () => {
       return null;
   }

   export default withAuthenticator(App);
   ``` | App developer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect the app's frontend to the AWS AppSync API.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

To use the example ToDoList app provided in this pattern, copy the code from the App.js file in the aws-amplify-react-native-ios-todo-app GitHub repository. Then, integrate the example code into your local environment.

The example code provided in the repository's App.js file does the following:

- Shows the form for creating a **ToDo Item** with **Title** and **Description** fields
- Displays the list of to-do items (**Title** and **Description**)
- Posts and fetches data by using aws-amplify methods

### Build an advanced mainframe file viewer in the AWS Cloud

*Created by Boopathy GOPALSAMY (AWS) and Jeremiah O’Connor (AWS)*

**Environment:** PoC or pilot  
**Technologies:** Serverless; Migration  
**Workload:** IBM

**AWS services:** Amazon Athena; AWS Lambda; Amazon OpenSearch Service; AWS Step Functions

### Summary

This pattern provides code samples and steps to help you build an advanced tool for browsing and reviewing your mainframe fixed-format files by using AWS serverless services. The pattern provides
an example of how to convert a mainframe input file to an Amazon OpenSearch Service document for browsing and searching. The file viewer tool can help you achieve the following:

- Retain the same mainframe file structure and layout for consistency in your AWS target migration environment (for example, you can maintain the same layout for files in a batch application that transmits files to external parties)
- Speed up development and testing during your mainframe migration
- Support maintenance activities after the migration

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- A virtual private cloud (VPC) with a subnet that's reachable by your legacy platform
- An input file and its corresponding common business-oriented language (COBOL) copybook (Note: For input file and COBOL copybook examples, see gfs-mainframe-solutions on the GitHub repository. For more information about COBOL copybooks, see the Enterprise COBOL for z/OS 6.3 Programming Guide on the IBM website.)

**Limitations**

- Copybook parsing is limited to no more than two nested levels (OCCURS)

Architecture

**Source technology stack**

- Input files in FB (Fixed Blocked) format
- COBOL copybook layout

**Target technology stack**

- Amazon Athena
- Amazon OpenSearch Service
- Amazon Simple Storage Service (Amazon S3)
- AWS Lambda
- AWS Step Functions

**Target architecture**

The following diagram shows the process of parsing and converting a mainframe input file to an OpenSearch Service document for browsing and searching.
The diagram shows the following workflow:

1. An admin user or application pushes input files to one S3 bucket and COBOL copybooks to another S3 bucket.
2. The S3 bucket with the input files invokes a Lambda function that kicks off a serverless Step Functions workflow. **Note:** The use of an S3 event trigger and Lambda function to drive the Step Functions workflow in this pattern is optional. The GitHub code samples in this pattern don't include the use of these services, but you can use these services based on your requirements.
3. The Step Functions workflow coordinates all the batch processes from the following Lambda functions:
   - The `s3copybookparser.py` function parses the copybook layout and extracts field attributes, data types, and offsets (required for input data processing).
   - The `s3toathena.py` function creates an Athena table layout. Athena parses the input data that's processed by the `s3toathena.py` function and converts the data to a CSV file.
   - The `s3toelasticsearch.py` function ingests the results file from the S3 bucket and pushes the file to OpenSearch Service.
4. Users access OpenSearch Dashboards with OpenSearch Service to retrieve the data in various table and column formats and then run queries against the indexed data.

**Tools**

**AWS services**

- **Amazon Athena** is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, you use Lambda to implement core logic, such as parsing files, converting data, and loading data into OpenSearch Service for interactive file access.
**Epics**

**Prepare the target environment**

Deliver DynamoDB records to Amazon S3 using Kinesis Data Streams and Kinesis Data Firehose with AWS CDK

Created by Shashank Shrivastava (AWS) and Daniel Matuki da Cunha (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Serverless; Data lakes; Databases; Storage &amp; backup</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Amazon DynamoDB ingestion into Amazon S3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

AWS services: AWS CDK; Amazon DynamoDB; Amazon Kinesis Data Firehose; Amazon Kinesis Data Streams; AWS Lambda; Amazon S3

Summary

This pattern provides sample code and an application for delivering records from Amazon DynamoDB to Amazon Simple Storage Service (Amazon S3) by using Amazon Kinesis Data Streams and Amazon Kinesis Data Firehose. The pattern’s approach uses AWS Cloud Development Kit (AWS CDK) L3 constructs and includes an example of how to perform data transformation with AWS Lambda before data is delivered to the target S3 bucket on the Amazon Web Services (AWS) Cloud.

Kinesis Data Streams records item-level modifications in DynamoDB tables and replicates them to the required Kinesis data stream. Your applications can access the Kinesis data stream and view the item-level changes in near-real time. Kinesis Data Streams also provides access to other Amazon Kinesis services, such as Kinesis Data Firehose and Amazon Kinesis Data Analytics. This means that you can build applications that provide real-time dashboards, generate alerts, implement dynamic pricing and advertising, and perform sophisticated data analysis.

You can use this pattern for your data integration use cases. For example, transportation vehicles or industrial equipment can send high volumes of data to a DynamoDB table. This data can then be transformed and stored in a data lake hosted in Amazon S3. You can then query and process the data and predict any potential defects by using serverless services such as Amazon Athena, Amazon Redshift Spectrum, Amazon Rekognition, and AWS Glue.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Getting started with the AWS CLI in the AWS CLI documentation.
- Node.js and npm, installed and configured. For more information about this, see Downloading and installing Node.js and npm in the npm documentation.
- The GitHub Amazon DynamoDB ingestion into Amazon S3 repository, cloned and configured on your local machine.
• Existing sample data for the DynamoDB table. The data must use the "Id": "123", "MessageData": "Hello World" format.

Architecture

The diagram shows the following workflow:

1. Data is ingested using Amazon API Gateway as a proxy for DynamoDB. However, you can use any other source to ingest data into DynamoDB.
2. Item-level changes are generated in near-real time in Kinesis Data Streams for delivery to Amazon S3.
3. Kinesis Data Streams sends the records to Kinesis Data Firehose for transformation and delivery.
4. A Lambda function converts the records from a DynamoDB record format to JSON-format, which contains only the record item attribute names and values.

Tools

• AWS CDK – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.

• AWS CDK Toolkit – The AWS CDK Toolkit, the CLI command cdk, is the primary tool for interacting with your AWS CDK application. It runs your application, interrogates the application model you defined, and produces and deploys the AWS CloudFormation templates generated by the AWS CDK.

• AWS CLI – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

• AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

Code
The code for this pattern is available in the GitHub Amazon DynamoDB ingestion into Amazon S3 repository.

## Epics

### Set up and configure the sample code

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Install the dependencies. | On your local machine, install the dependencies from the package.json files in the pattern/aws-dynamodb-kinesisstreams-s3 and sample-application directories by running the following commands:  
1. `cd <project_root>/pattern/aws-dynamodb-kinesisstreams-s3`  
2. `npm install`  
3. `cd <project_root>/sample-application/`  
4. `npm install` | App developer, General AWS |
| Generate the AWS CloudFormation template. | 1. Run the `cd <project_root>/sample-application/` command.  
2. Run the `cdk synth` command to generate the AWS CloudFormation template.  
3. The `AwsDynamodbKinesisfirehoseS3IngestionStack.template.json` output is stored in the `cdk.out` directory.  
4. Use AWS CDK or the AWS Management Console to process the template in AWS CloudFormation. | App developer, General AWS, AWS DevOps |

## Deploy the resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check and deploy the resources.</td>
<td>1. Run the <code>cdk diff</code> command to identify the resource types that are created by the AWS CDK construct.</td>
<td>App developer, General AWS, AWS DevOps</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>

### Ingest data into the DynamoDB table to test the solution

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Ingest your sample data into the DynamoDB table. | 1. Send a request to your DynamoDB table by running the following command in AWS CLI:  
```bash
aws dynamodb put-item 
  --table-name <your_table_name> 
  --item 
  '{"Id": {"S": "<primary_key_ID>"},"MessageData": {"S": "<data>"}}'
```
By default, the `put-item` doesn't return any value as output if the operation succeeds. If the operation fails, it returns an error. The data is stored in DynamoDB and then sent to Kinesis Data Streams and Kinesis Data Firehose.

**Note:** You use different approaches to add data into a DynamoDB table. For more information about this, see **Load data into tables** in the Amazon DynamoDB documentation. | App developer |
| Verify that a new object is created in the S3 bucket. | Sign in to the AWS Management Console and monitor the S3 bucket to verify that a new object was created with the data that you sent.

For more information about this, see `get-object` in the Amazon S3 API reference documentation. | App developer, General AWS |
Clean up resources

Run AWS Systems Manager automation tasks synchronously from AWS Step Functions

Created by Elie El khoury

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Serverless; DevOps; Operations; End-user computing</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>amazon-stepfunctions-ssm-waitfortasktoken</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Workload: All other workloads</td>
<td>AWS services: AWS Systems Manager; AWS Step Functions</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern explains how to integrate Amazon Web Services (AWS) Step Functions with AWS Systems Manager. It uses AWS SDK service integrations to call the AWS Systems Manager `startAutomationExecution` API with a task token from a state machine workflow, and pauses until the token returns with a success or failure call. To demonstrate the integration, this pattern implements an automation document (runbook) wrapper around the AWS-RunShellScript document and uses `.waitForTaskToken` to synchronously call AWS-RunShellScript. For more information about AWS SDK service integrations in Step Functions, see the AWS Step Functions Developer Guide.

AWS Step Functions is a low-code, visual workflow service that you can use to build distributed applications, automate IT and business processes, and build data and machine learning pipelines by using AWS services. Workflows manage failures, retries, parallelization, service integrations, and observability so you can focus on higher-value business logic.

Automation, a capability of AWS Systems Manager, simplifies common maintenance, deployment, and remediation tasks for AWS services such as Amazon Elastic Compute Cloud (Amazon EC2), Amazon
Relational Database Service (Amazon RDS), Amazon Redshift, and Amazon Simple Storage Service (Amazon S3). Automation gives you granular control over the concurrency of your automations. For example, you can specify how many resources to target concurrently, and how many errors can occur before an automation is stopped.

For implementation details, including runbook steps, parameters, and examples, see the Additional information (p. 2283) section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) permissions to access AWS Step Functions and AWS Systems Manager
- An EC2 instance with AWS Systems Manager Agent (SSM Agent) installed on the instance
- An IAM instance profile for Systems Manager attached to the instance where you plan to run the runbook
- A Step Functions role that has the following IAM permissions (follow the principle of least privilege):

```
{
    "Effect": "Allow",
    "Action": "ssm:StartAutomationExecution",
    "Resource": "*"
}
```

Product versions

- SSM document schema version 0.3 or later
- SSM Agent version 2.3.672.0 or later

Architecture

Target technology stack

- AWS Step Functions
- AWS Systems Manager Automation

Target architecture
Automation and scale

- This pattern provides a CloudFormation template that you can use to deploy the runbooks on multiple instances. (See the GitHub Step Functions and Systems Manager implementation repository.)

Tools

AWS services

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

- **AWS Step Functions** – AWS Step Functions is a serverless orchestration service that lets you combine AWS Lambda functions and other AWS services to build business-critical applications. Through the Step Functions graphical console, you see your application’s workflow as a series of event-driven steps.

- **AWS Systems Manager** – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting on (or taking corrective action on) any policy violations it detects.
The code for this pattern is available in the GitHub Step Functions and Systems Manager implementation repository.

<td>&quot;End&quot;: true</td>
<td></td>
</tr>
<tr>
<td></td>
<td>}</td>
<td></td>
</tr>
<tr>
<td></td>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>

This code calls the runbook to run two commands that demonstrate the waitForTaskToken call to Systems Manager Automation. The task writes "This is a test running automation waitForTaskToken" into the /home/ssm-user/automation.log file, and then sleeps for 100 seconds before it responds back with the task token and releases the next task in the workflow.

If you want to call the SfnRunCommandByTargets runbook

Additional information

Implementation details

This pattern provides an AWS CloudFormation template that deploys two Systems Manager runbooks:

- SfnRunCommandByInstanceIds runs the AWS-RunShellScript command by using instance IDs.
- SfnRunCommandByTargets runs the AWS-RunShellScript command by using targets.

Each runbook implements three steps to achieve a synchronous call when using the .waitForTaskToken option in Step Functions.

<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
<th>Description</th>

<td>Optional</td>
<td>The path to the working directory on your instance.</td>
</tr>
<tr>
<td>Commands</td>
<td>StringList</td>
<td>Required</td>
<td>The shell script or command to run.</td>
</tr>
</tbody>
</table>
| Targets          | MapList  | Required             | An array of search criteria that identifies instances by using key-value pairs that you specify. For example: `[["Key": "InstanceIds", "Values": ["i-02573cafefEXAMPLE", "i-0471e042EXAMPLE"]]

| taskToken        | String   | Required             | The task token to use for callback responses. |

---

**Sample output**

The following table provides sample output from the step function. It shows that the total run time is over 100 seconds between step 5 (TaskSubmitted) and step 6 (TaskSucceeded). This demonstrates that the step function waited for the "sleep 100" command to finish before moving to the next task in the workflow.

**Environment:** Production  
**Technologies:** Serverless; Cloud-native; Software  
**AWS services:** Amazon S3; Amazon SNS; Amazon SQS; AWS Lambda
Summary

This pattern demonstrates a scalable, serverless approach for processing an uploaded file by chaining together Amazon Simple Storage Service (Amazon S3), Amazon Simple Notification Service (Amazon SNS), Amazon Simple Queue Service (Amazon SQS), and AWS Lambda. The uploaded file example is for demonstration purposes. You can use a serverless approach to complete other tasks by chaining together the combination of AWS services that are necessary to meet your business goals. The serverless approach employs an asynchronous workflow that relies on event-driven notifications, resilient storage, and function as a service (FaaS) computing to process requests. You can use the serverless approach to scale to meet demand while minimizing costs.

Prerequisites and limitations

Prerequisites

- An active AWS account with a user who has programmatic access credentials
- AWS Cloud Development Kit (AWS CDK) for deploying a serverless pipeline, installed
- AWS Command Line Interface (AWS CLI), installed and configured
- Python 3.9

Product versions

- AWS CDK 2.x
- Python 3.9

Architecture

The following diagram illustrates how chained AWS services can enable a user to upload a file to an S3 bucket for processing:
The diagram shows the following workflow:

1. A user uploads a file to the S3 bucket.
2. The upload initiates an S3 event that publishes a message to an SNS topic. The message contains the details of the S3 event.
3. The message published to the SNS topic is inserted into an SQS queue, which is subscribed to and receives notifications for that topic.
4. A Lambda function polls the SQS queue (as its event source) and waits for messages to process.
5. When the Lambda function receives messages from the SQS queue, it processes them and acknowledges receipt of those messages.
6. If a message isn’t processed by Lambda, then that message is returned to the SQS queue and is eventually transferred to an SQS dead-letter queue.

Technology stack

- Amazon S3
- Amazon SNS
- Amazon SQS
- AWS Lambda

Tools

AWS services

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **Amazon Simple Notification Service (Amazon SNS)** helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- **Amazon Simple Queue Service (Amazon SQS)** provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Other tools

- **AWS Cloud Development Kit (AWS CDK)** is the primary tool for interacting with your AWS CDK app. It executes your app, interrogates the application model you defined, and produces and deploys the AWS CloudFormation templates generated by the AWS CDK.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **Python** is a high-level, interpreted general purpose programming language.

Code

The code for this pattern is available in the Github Chaining S3 to SNS to SQS to Lambda repository.
# Epics

## Develop your serverless environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clone the repository.</td>
<td>Clone the repository and navigate to the python/s3-sns-sqs-lambda-chain folder.</td>
<td>App developer</td>
</tr>
</tbody>
</table>
| Set up a virtual environment. | 1. In the AWS CDK, run the `python3 -m venv .venv` command.  
2. Run the source `.venv/bin/activate` command on MacOS/Linux or `.venv\Scripts\activate.bat` on Windows. | App developer         |
| Install dependencies.        | Run the `pip install -r requirements.txt` command.                                                             | App developer         |

## Test the CloudFormation stack

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Run unit tests.               | 1. Run the `pip install -r requirements-dev.txt` command.  
2. (Optional) Run the `cdk synth --no-staging > template.yml` command to generate the CloudFormation stack. **Important:** You can inspect the stack, but avoid generating the staged resources and artifacts.  
3. Run the `pytest` command to run all unit tests.  
4. (Optional) Run the `pytest tests/unit/ <test_filename>` command to run tests for a specific file. | App developer, Test engineer |

## Deploy the CloudFormation stack

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>

AWS services: AWS CodeBuild

Summary

This pattern provides sample source code and key unit test components for a Node.js game API. It also includes instructions for running these unit tests from a GitHub repository by using AWS CodeBuild, as part of your continuous integration and continuous delivery (CI/CD) workflow.

Unit testing is a software development process in which different parts of an application, called units, are individually and independently tested for correct operation. Tests validate the quality of the code and confirm that it functions as expected. Other developers can also easily gain familiarity with your code base by consulting the tests. Unit tests reduce future refactoring time, help engineers get up to speed on your code base more quickly, and provide confidence in the expected behavior.

Unit testing involves testing individual functions, including AWS Lambda functions. To create unit tests, you need a testing framework and a way of validating tests (assertions). The code examples in this pattern use the Mocha testing framework and the Chai assertion library.

For more information about unit testing and examples of test components, see the Additional information (p. 2295) section.

Prerequisites and limitations

- An active AWS account with correct CodeBuild permissions
- A GitHub account (see instructions for signing up)
- Git (see installation instructions)
- A code editor to make changes and push your code to GitHub (for example, you can use AWS Cloud9)

Architecture

This pattern implements the architecture that is shown in the following diagram.
Tools

Git

Git is a version control system that you can use for code development.

AWS Cloud9

AWS Cloud9 is an integrated development environment (IDE) that offers a rich code-editing experience with support for several programming languages and runtime debuggers, and a built-in terminal. It contains a collection of tools that you use to code, build, run, test, and debug software, and helps you release software to the cloud. You access the AWS Cloud9 IDE through a web browser.

AWS CodeBuild

AWS CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy. With CodeBuild, you don't need to provision, manage, and scale your own build servers. CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left waiting in a queue. You can get started quickly by using prepackaged build environments, or you can create custom build environments that use your own build tools. With CodeBuild, you are charged by the minute for the compute resources you use.

Code

The source code for this pattern is available on GitHub, in the Sample game unit test application repository. You can create your own GitHub repository from this sample (option 1) or use the sample repository directly (option 2) for this pattern. Follow the instructions for each option in the next section. The option you follow will depend on your use case.

Epics

Option 1 - Run unit tests on your personal GitHub repository with CodeBuild

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create your own GitHub repository based on the sample project.</td>
<td>1. Log in to GitHub. 2. Create a new repository. For instructions, see the GitHub documentation.</td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td><strong>3.</strong> Clone and push the sample repository into the new repository in your account.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| **Create a new CodeBuild project.** | **1.** Sign in to the AWS Management Console and open the CodeBuild console at [https://console.aws.amazon.com/codesuite/codebuild/home](https://console.aws.amazon.com/codesuite/codebuild/home).  
**2.** Choose Create build project.  
**3.** In the Project configuration section, for Project name, type aws-tests-sample-node-js.  
**4.** In the Source section, for Source provider, choose GitHub.  
**5.** For Repository, choose Repository in my GitHub account, and then paste the URL to your newly created GitHub repository.  
**6.** In the Primary source webhook events section, select Rebuild every time a code change is pushed to this repository.  
**7.** For event type, choose PUSH.  
**8.** In the Environment section, choose Managed image, Amazon Linux 2, and the latest image.  
**9.** Leave the default settings for all other options, and then choose Create build project. | App developer, AWS administrator, AWS DevOps |
| **Start the build.** | On the Review page, choose Start build to run the build. | App developer, AWS administrator, AWS DevOps |

**Option 2 - Run unit tests on a public repository with CodeBuild**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Create a new CodeBuild build project.** | **1.** Sign in to the AWS Management Console and open the CodeBuild console at [https://console.aws.amazon.com/codesuite/codebuild/home](https://console.aws.amazon.com/codesuite/codebuild/home).  
**2.** Choose Create build project. | App developer, AWS administrator, AWS DevOps |
### Task Description

3. In the **Project configuration** section, for **Project name**, type `aws-tests-sample-node-js`.
4. In the **Source** section, for **Source provider**, choose **GitHub**.
5. For **Repository**, choose **Public repository**, and then paste the URL: `https://github.com/aws-samples/node-js-tests-sample`.
6. In the **Environment** section, choose **Managed image**, Amazon Linux 2, and the latest image.
7. Leave the default settings for all other options, and then choose **Create build project**.

Start the build. On the **Review** page, choose **Start build** to run the build.

**Skills required**

- App developer, AWS administrator, AWS DevOps

### Analyze the unit tests

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>View test results.</td>
<td>In the CodeBuild console, review the unit test results from the CodeBuild job. They should match the results shown in the Additional information (p. 2295) section. These results validate the GitHub repository integration with CodeBuild.</td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
<tr>
<td>Apply a webhook.</td>
<td>You can now apply a webhook, so you can automatically start a build whenever you push code changes to the main branch of your repository. For instructions, see the CodeBuild documentation.</td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
</tbody>
</table>

Additional information

Unit test results

In the CodeBuild console, you should see the following test results after the project builds successfully.

Example unit test components

This section describes the four types of test components that are used in unit testing: assertions, spies, stubs, and mocks. It includes a brief explanation and code example of each component.

Assertions

An assertion is used to verify an expected result. This is an important test component because it validates the expected response from a given function. The following sample assertion validates that the returned ID is between 0 and 1000 when initializing a new game.

```javascript
const { expect } = require('chai');
const { Game } = require('../src/index');

describe('Game Function Group', () => {
  it('Check that the Game ID is between 0 and 1000', function() {
    const game = new Game();
    expect(game.id).is.above(0).but.below(1000);
  });
});
```

Spies

A spy is used to observe what is happening when a function is running. For example, you might want to validate that the function has been called correctly. The following example shows that start and stop methods are called on a Game class object.

```javascript
const { expect } = require('chai');
const { spy } = require('sinon');
const { Game } = require('../src/index');

describe('Game Function Group', () => {
  const game = new Game();
  const spyStart = spy(game, 'start');
  const spyStop = spy(game, 'stop');

  it('Check that start and stop methods are called', () => {
    spyStart();
    expect(spyStart.calls.count()).to.equal(1);
    spyStop();
    expect(spyStop.calls.count()).to.equal(1);
  });
});
```
it('should verify that the correct function is called', () => {
    const spyStart = spy(Game.prototype, "start");
    const spyStop = spy(Game.prototype, "stop");

    const game = new Game();
    game.start();
    game.stop();

    expect(spyStart.called).to.be.true
    expect(spyStop.called).to.be.true
});

### Stubs

A stub is used to override a function's default response. This is especially useful when the function makes an external request, because you want to avoid making external requests from unit tests. (External requests are better suited for integration tests, which can physically test requests between different components.) In the following example, a stub forces a return ID from the `getId` function.

```javascript
const { expect } = require('chai');
const { stub } = require('sinon');
const { Game } = require('../src/index');
descibe('Game Function Group', () => {
    it('Check that the Game ID is between 0 and 1000', function() {
        let generateIdStub = stub(Game.prototype, 'getId').returns(999999);

        const game = new Game();
        expect(game.getId).is.equal(999999);
        generateIdStub.restore();
    });
});
```

###Mocks

A mock is a fake method that has a pre-programmed behavior for testing different scenarios. A mock can be considered an extended form of a stub and can carry out multiple tasks simultaneously. In the following example, a mock is used to validate three scenarios:

- Function is called
- Function is called with arguments
- Function returns the integer 9

```javascript
const { expect } = require('chai');
const { mock } = require('sinon');
const { Game } = require('../src/index');
descibe('Game Function Group', () => {
    it('Check that the Game ID is between 0 and 1000', function() {
        let mock = mock(Game.prototype).expects('getId').withArgs().returns(9);

        const game = new Game();
        const id = get.getId();
        mock.verify();
    });
});
```

Allow EC2 instances write access to S3 buckets in AMS accounts

Created by Mansi Suratwala (AWS)

<table>

| AWS services: | Amazon S3; AWS Managed Services |

Summary

AWS Managed Services (AMS) helps you to operate your Amazon Web Services (AWS) infrastructure more efficiently and securely. AMS accounts have security guardrails for standardized administration of your AWS resources. One guardrail is that default Amazon Elastic Compute Cloud (Amazon EC2) instance profiles don’t allow Write access to Amazon Simple Storage Service (Amazon S3) buckets. However, your organization might have multiple S3 buckets and require more control over access by EC2 instances. For example, you might want to store database backups from EC2 instances in an S3 bucket.

This pattern explains how to use Requests for Change (RFCs) to allow your EC2 instances Write access to S3 buckets in your AMS account. An RFC is a request created by you or AMS to make a change in your managed environment and that includes a change type (CT) ID for a particular operation.

Prerequisites and limitations

Prerequisites
• An AMS Advanced account. For more information about this, see AMS operations plans in the AWS Managed Services documentation.
• Access to the customer-mc-user-role AWS Identity and Access Management (IAM) role to submit RFCs.
• AWS Command Line Interface (AWS CLI), installed and configured with the EC2 instances in your AMS account.
• An understanding of how to create and submit RFCs in AMS. For more information about this, see What are AMS change types? in the AWS Managed Services documentation.
• An understanding of manual and automated change types (CTs). For more information about this, see Automated and manual CTs in the AWS Managed Services documentation.

Architecture

Technology stack

• AMS
• AWS CLI
• Amazon EC2
• Amazon S3
• IAM

Tools

• AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
• AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
• AWS Managed Services (AMS) helps you operate your AWS infrastructure more efficiently and securely.
• Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
• Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

Epics

Create an S3 bucket with an RFC

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an S3 bucket using an automated RFC.</td>
<td>1. Sign in to your AMS account, choose the <strong>Choose change type</strong> page, choose <strong>RFCs</strong>, and then choose <strong>Create RFC</strong>. 2. Submit the Create S3 Bucket automated RFC.</td>
<td>AWS systems administrator, AWS developer</td>
</tr>
</tbody>
</table>

**Note:** Make sure that you record the S3 bucket's name.
Create an IAM instance profile and associate it with the EC2 instances

<table>

**Automate data stream ingestion into a Snowflake database by using Snowflake Snowpipe, Amazon S3, Amazon SNS, and Amazon Kinesis Data Firehose**

*Created by Bikash Chandra Rout (AWS)*
Summary

This pattern describes how you can use services on the Amazon Web Services (AWS) Cloud to process a continuous stream of data and load it into a Snowflake database. The pattern uses Amazon Kinesis Data Firehose to deliver the data to Amazon Simple Storage Service (Amazon S3), Amazon Simple Notification Service (Amazon SNS) to send notifications when new data is received, and Snowflake Snowpipe to load the data into a Snowflake database.

By following this pattern, you can have continuously generated data available for analysis in seconds, avoid multiple manual COPY commands, and have full support for semi-structured data on load.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A data source that is continuously sending data to a Kinesis Data Firehose delivery stream.
- An existing S3 bucket that is receiving the data from the Kinesis Data Firehose delivery stream.
- An active Snowflake account.

Limitations

- Snowflake Snowpipe doesn't connect directly to Kinesis Data Firehose.

Architecture

Technology stack

- Amazon Kinesis Data Firehose
- Amazon SNS
- Amazon S3
• Snowflake Snowpipe
• Snowflake database

Tools

• **Kinesis Data Firehose** – Amazon Kinesis Data Firehose is a fully managed service for delivering real-time streaming data to destinations such as Amazon S3, Amazon Redshift, Amazon OpenSearch Service, Splunk, and any custom HTTP endpoint or HTTP endpoints owned by supported third-party service providers.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages to subscribing endpoints or clients.

• **Snowflake** – Snowflake is an analytic data warehouse provided as Software-as-a-Service (SaaS).

• **Snowflake Snowpipe** – Snowpipe loads data from files as soon as they’re available in a Snowflake stage.

Epics

Set up a Snowflake Snowpipe

<td></td>
</tr>
<tr>
<td>Create a 30-day lifecycle policy for the S3 bucket.</td>
<td>Sign in to the AWS Management Console and open the Amazon S3 console. Choose the S3 bucket that contains the data from Kinesis Data Firehose. Then choose the “Management” tab in the S3 bucket and choose “Add lifecycle rule.” Enter a name for your rule in the “Lifecycle rule” dialog box and configure a 30-day lifecycle rule for your bucket. For help with this and other stories, see the “Related resources” section.</td>
<td>System Administrator, Developer</td>
</tr>
<tr>
<td>Create an IAM policy for the S3 bucket.</td>
<td>Open the AWS Identity and Access Management (IAM) console and choose “Policies.” Choose “Create policy,” and choose the “JSON” tab. Copy and paste the policy from the “Additional information” section into the JSON field. This policy will grant “PutObject” and “DeleteObject” permissions, as well as “GetObject,” “GetObjectVersion,” and “ListBucket” permissions. Choose “Review policy,” enter a policy name, and then choose “Create policy.”</td>
<td>System Administrator, Developer</td>
</tr>
<tr>
<td>Assign the policy to an IAM role.</td>
<td>Open the IAM console choose “Roles,” and then choose “Create role.” Choose “Another AWS account” as the trusted entity. Enter your AWS account ID, and choose “Require external ID.” Enter a placeholder ID that you will change it later. Choose “Next” and assign the IAM policy you created earlier. Then create the IAM role.</td>
<td>System Administrator, Developer</td>
</tr>
<tr>
<td>Copy the Amazon Resource Name (ARN) for the IAM role.</td>
<td>Open the IAM console and choose “Roles.” Choose the IAM</td>
<td>System Administrator, Developer</td>
</tr>
</tbody>
</table>
## Set up a storage integration in Snowflake

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a storage integration in Snowflake.</td>
<td>Sign in to Snowflake and run the &quot;CREATE STORAGE INTEGRATION&quot; command. This will modify the trusted relationship, grant access to Snowflake, and provide the external ID for your Snowflake stage.</td>
<td>System Administrator, Developer</td>
</tr>
<tr>
<td>Retrieve the IAM role for your Snowflake account.</td>
<td>Run the &quot;DESC INTEGRATION&quot; command to retrieve the ARN for the IAM role. Important: &lt;integration_name&gt; is the name of the Snowflake storage integration you created earlier.</td>
<td>System Administrator, Developer</td>
</tr>
<tr>
<td>Record two column values.</td>
<td>Copy and save the values for the &quot;storage_aws_iam_user_arn&quot; and &quot;storage_aws_external_id&quot; columns.</td>
<td>System Administrator, Developer</td>
</tr>
</tbody>
</table>

## Allow Snowflake Snowpipe to access the S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify the IAM role policy.</td>
<td>Open the IAM console and choose &quot;Roles.&quot; Choose the IAM role you created earlier and choose the &quot;Trust relationships&quot; tab. Choose &quot;Edit trust relationship.&quot; Replace &quot;snowflake_external_id&quot; with the &quot;storage_aws_external_id&quot; value you copied earlier. Replace &quot;snowflake_user_arn&quot; with the &quot;storage_aws_iam_user_arn&quot; value you copied earlier. Then choose &quot;Update trust policy.&quot;</td>
<td>System Administrator, Developer</td>
</tr>
</tbody>
</table>
## Turn on and configure SNS notifications for the S3 bucket

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Turn on event notifications for the S3 bucket.</td>
<td>Open the Amazon S3 console and choose your bucket. Choose “Properties,” and under “Advanced settings” choose “Events.” Choose “Add notification,” and enter a name for this event. If you don’t enter a name, a globally unique identifier (GUID) will be used.</td>
<td>System Administrator, Developer</td>
</tr>
<tr>
<td>Configure Amazon SNS notifications for the S3 bucket.</td>
<td>Under “Events,” choose “ObjectCreate (All)” and then choose “SQS Queue” in the “Send to” dropdown list. In the “SNS” list choose “Add SQS queue ARN,” and paste the “notification_channel” value you copied earlier. Then choose “Save.”</td>
<td>System Administrator, Developer</td>
</tr>
<tr>
<td>Subscribe the Snowflake SQS queue to the SNS topic.</td>
<td>Subscribe the Snowflake SQS queue to the SNS topic you created. For help with this step, see the “Related resources” section.</td>
<td>System Administrator, Developer</td>
</tr>
</tbody>
</table>

## Check the Snowflake stage integration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check and test Snowpipe.</td>
<td>Sign in to Snowflake and open the Snowflake stage. Drop files into your S3 bucket and check if the Snowflake table loads them. Amazon S3 will send SNS notifications to Snowpipe when new objects appear in the S3 bucket.</td>
<td>System Administrator, Developer</td>
</tr>
</tbody>
</table>

## Related resources

- Create lifecycle policy for an S3 bucket
- Subscribe the Snowflake SQS Queue to the Amazon SNS Topic

## Additional information

Create a file format:
CREATE FILE FORMAT <name>
TYPE = 'CSV'
FIELD_DELIMITER = '|
SKIP_HEADER = 1;

Create an external stage:

externalStageParams (for Amazon S3) ::= 
URL = 's3://[['
  [ STORAGE_INTEGRATION = ] | [ CREDENTIALS = ( [ { AWS_KEY_ID = '' AWS_SECRET_KEY = '' [ AWS_TOKEN = '' ] } | AWS_ROLE = '' ] ) ] ]
  [ ENCRYPTION = ( [ TYPE = 'AWS_CSE' ] | [ TYPE = 'AWS_SSE_KMS' ] | [ TYPE = 'AWS_SSE_S3' ] ) ]
] Create a table:

CREATE [ OR REPLACE ] [ { { LOCAL | GLOBAL } TEMPORARY | VOLATILE } | TRANSIENT ] TABLE
[ IF NOT EXISTS ]
<table_name>
( <col_name> <col_type> [ , <col_name> <col_type> ... ]
  [ , outoflineConstraint ]
  [ , ... ]
  [ CLUSTER BY ( <expr> , <...> ) ]
  [ STAGE_FILE_FORMAT = ( { FORMAT_NAME = '<file_format_name>' ]
    [ TYPE = { CSV | JSON | AVRO | ORC | PARQUET | XML } ]
  [ formatTypeOptions ] ]
  [ STAGE_COPY_OPTIONS = ( copyOptions ) ]
  [ DATA_RETENTION_TIME_IN_DAYS = <num> ]
  [ COPY GRANTS ]
  [ COMMENT = '<string_literal>' ]
] Show stages:

SHOW STAGES;

Create a pipe:

CREATE [ OR REPLACE ] PIPE [ IF NOT EXISTS ]
[ AUTO_INGEST = [ TRUE | FALSE ] ]
[ AWS_SNS_TOPIC = ]
[ INTEGRATION = ' ]
[ COMMENT = '' ]
AS

Show pipes:

SHOW PIPES [ LIKE '<pattern>' ]
[ IN [ ACCOUNT | [ DATABASE ] <db_name> | [ SCHEMA ] <schema_name> ] ]
Create a storage integration:

```
CREATE STORAGE INTEGRATION <integration_name>
  TYPE = EXTERNAL_STAGE
  STORAGE_PROVIDER = S3
  ENABLED = TRUE
  STORAGE_AWS_ROLE_ARN = 'arn:aws:iam::001234567890:role/myrole'
  STORAGE_ALLOWED_LOCATIONS = ('s3://<bucket>/<path>/', 's3://<bucket>/<path>/')
  [ STORAGE_BLOCKED_LOCATIONS = ('s3://<bucket>/<path>/', 's3://<bucket>/<path>/') ]
```

Example:

```
CREATE STORAGE INTEGRATION s3_int
  TYPE = EXTERNAL_STAGE
  STORAGE_PROVIDER = S3
  ENABLED = TRUE
  STORAGE_AWS_ROLE_ARN = 'arn:aws:iam::001234567890:role/myrole'
  STORAGE_ALLOWED_LOCATIONS = ('s3://mybucket1/mypath1/', 's3://mybucket2/mypath2/')
  STORAGE_BLOCKED_LOCATIONS = ('s3://mybucket1/mypath1/sensitivedata/', 's3://mybucket2/mypath2/sensitivedata/');
```

For more information about this step, see Configuring a Snowflake storage integration to access Amazon S3 from the Snowflake documentation.

Describe an integration:

```
DESC INTEGRATION <integration_name>;
```

S3 bucket policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObject",
        "s3:GetObjectVersion",
        "s3:DeleteObject",
        "s3:DeleteObjectVersion"
      ],
      "Resource": "arn:aws:s3::://*
    },
    {
      "Effect": "Allow",
      "Action": "s3:ListBucket",
      "Resource": "arn:aws:s3:::",
      "Condition": {
        "StringLike": {
          "s3:prefix": ["/*"],
        }
      }
    }
  ]
}
```
Automatically encrypt existing and new Amazon EBS volumes

Created by Tony DeMarco (AWS) and Josh Joy (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Storage &amp; backup; Security, identity, compliance</th>

<td></td>
</tr>
</tbody>
</table>

AWS services: AWS Config; Amazon EBS; AWS KMS; AWS Systems Manager; AWS Organizations

Summary

Encryption of Amazon Elastic Block Store (Amazon EBS) volumes is important to an organization's data protection strategy. It is an important step in establishing a well-architected environment. Although there is no direct way to encrypt existing unencrypted EBS volumes or snapshots, you can encrypt them by creating a new volume or snapshot. For more information, see Encrypt EBS resources in the Amazon EC2 documentation. This pattern provides preventative and detective controls for encrypting your EBS volumes, both new and existing. In this pattern, you configure account settings, create automated remediation processes, and implement access controls.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- AWS Command Line Interface (AWS CLI), installed and configured on macOS, Linux, or Windows
- jq, installed and configured on macOS, Linux, or Windows
- AWS Identity and Access Management (IAM) permissions are provisioned to have read and write access to AWS CloudFormation, Amazon Elastic Compute Cloud (Amazon EC2), AWS Systems Manager, AWS Config, and AWS Key Management Service (AWS KMS)
- AWS Organizations is configured with all features enabled, a requirement for service control policies
- AWS Config is enabled in the target accounts

Limitations

- In your target AWS account, there must be no AWS Config rules named encrypted-volumes. This solution deploys a rule with this name. Preexisting rules with this name can cause the deployment to fail and result in unnecessary charges related to processing the same rule more than once.
- This solution encrypts all EBS volumes with the same AWS KMS key.
- If you enable encryption of EBS volumes for the account, this setting is Region-specific. If you enable it for an AWS Region, you cannot disable it for individual volumes or snapshots in that Region. For more information, see Encryption by default in the Amazon EC2 documentation.
- When you remediate existing, unencrypted EBS volumes, ensure that the EC2 instance is not in use. This automation shuts down the instance in order to detach the unencrypted volume and
attach the encrypted one. There is downtime while the remediation is in progress. If this is a critical piece of infrastructure for your organization, make sure that manual or automatic high-availability configurations are in place so as to not impact the availability of any applications running on the instance. We recommend that you remediate critical resources only during standard maintenance windows.

**Architecture**

**Automation workflow**

1. AWS Config detects an unencrypted EBS volume.
2. An administrator uses AWS Config to send a remediation command to Systems Manager.
3. The Systems Manager automation takes a snapshot of the unencrypted EBS volume.
4. The Systems Manager automation uses AWS KMS to create an encrypted copy of the snapshot.
5. The Systems Manager automation does the following:
   a. Stops the affected EC2 instance if it is running
   b. Attaches the new, encrypted copy of the volume to the EC2 instance
   c. Returns the EC2 instance to its original state

**Tools**

**AWS services**

- AWS CLI – The AWS Command Line Interface (AWS CLI) provides direct access to the public application programming interfaces (APIs) of AWS services. You can explore a service's capabilities with the AWS CLI and develop shell scripts to manage your resources. In addition to the low-level API-equivalent commands, several AWS services provide customizations for the AWS CLI. Customizations can include higher-level commands that simplify using a service with a complex API.

- AWS CloudFormation – AWS CloudFormation is a service that helps you model and set up your AWS resources. You create a template that describes all the AWS resources that you want (such as Amazon EC2 instances), and CloudFormation provisions and configures those resources for you.
• **AWS Config** – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.

• **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.

• **AWS KMS** – AWS Key Management Service (AWS KMS) is an encryption and key management service scaled for the cloud. AWS KMS keys and functionality are used by other AWS services, and you can use them to protect data in your AWS environment.

• **AWS Organizations** – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.

• **AWS Systems Manager Automation** – Systems Manager Automation simplifies common maintenance and deployment tasks for Amazon EC2 instances and other AWS resources.

### Other services

• **jq** – jq is a lightweight and flexible command-line JSON processor. You use this tool to extract key information from the AWS CLI output.

### Code

• The code for this pattern is available in the GitHub [Automatically remediate unencrypted EBS Volumes using customer KMS keys](https://github.com) repository.

### Epics

#### Automate remediation of unencrypted volumes

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download scripts and CloudFormation templates.</td>
<td>Download the shell script, JSON file, and CloudFormation templates from the GitHub <a href="https://github.com">Automatically remediate unencrypted EBS Volumes using customer KMS keys</a> repository.</td>
<td>AWS administrator, General AWS</td>
</tr>
</tbody>
</table>
| Identify the administrator for the AWS KMS key. | 1. Sign in to the AWS Management Console and open the IAM console at [https://console.aws.amazon.com/iam/](https://console.aws.amazon.com/iam/).  
2. Identify an IAM user or role who will be the AWS KMS key administrator. If a new user or role needs to be created for this purpose, create it now. For more information, see IAM Identities in the IAM documentation. This automation creates a new AWS KMS key. | AWS administrator, General AWS |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Deploy the Stack1 CloudFormation template.** | 1. Open the AWS CloudFormation console at [https://console.aws.amazon.com/cloudformation/](https://console.aws.amazon.com/cloudformation/).  
2. In CloudFormation, deploy the `Stack1.yaml` template. Note the following deployment details:  
   • Give the stack a clear and descriptive name. Note the stack name because you need this value in the next step.  
   • Paste the ARN of the key administrator into the only parameter field in Stack1. This IAM user or role becomes the administrator for the AWS KMS key created by the stack.  

For more information about deploying a CloudFormation template, see [Working with AWS CloudFormation templates](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/) in the CloudFormation documentation. | AWS administrator, General AWS |
| **Deploy the Stack2 CloudFormation template.** | In CloudFormation, deploy the `Stack2.yaml` template. Note the following deployment details:  
   • Give the stack a clear and descriptive name.  
   • For the only parameter of Stack2, enter the name of the stack you created in the previous step. This allows Stack2 to reference the new AWS KMS key and role deployed by the stack in the previous step. | AWS administrator, General AWS |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an unencrypted volume for testing.</td>
<td>Create an EC2 instance with an unencrypted EBS volume. For instructions, see <a href="https://aws.amazon.com/documentation/ec2/create-amazon-ebst/">Create an Amazon EBS volume</a> in the Amazon EC2 documentation. The instance type does not matter, and access to the instance is not needed. You can create a t2.micro instance to stay in the free tier, and you don’t need to create a key pair.</td>
<td>AWS administrator, General AWS</td>
</tr>
</tbody>
</table>
2. Confirm that your new, unencrypted test instance appears in the list of non-compliant resources. If the volume does not appear immediately, wait a few minutes and refresh the results. The AWS Config rule detects the resource changes shortly after the instance and volume are created.  
3. Select the resource, and then choose Remediate.  

You can view the remediation progress and status in Systems Manager as follows:  
2. In the navigation pane, choose Automation.  
3. Choose the Execution ID link to view the steps and the status. | AWS administrator, General AWS |
| Configure additional accounts or AWS Regions. | As needed for your use case, repeat this epic for any additional accounts or AWS Regions. | AWS administrator, General AWS |
# Enable account-level encryption of EBS volumes

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the enable script.</td>
<td>In AWS CLI, run the enable-ebs-encryption-for-account.sh script. You downloaded this script from the GitHub repository in the previous epic.</td>
<td>AWS administrator, General AWS</td>
</tr>
</tbody>
</table>
| Confirm the settings are updated.    | 1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.  
2. On the right side of the screen, choose EBS Encryption.  
3. Confirm that Always encrypt new EBS volumes is turned on and the Default encryption key is set to the ARN that you specified in the previous epic.  
If the Always encrypt new EBS volumes setting is turned off or the key is still set to alias/aws/ebs, confirm that you are logged into the same account and AWS Region where you ran the shell script, and check your shell for error messages. | AWS administrator, General AWS         |
| Configure additional accounts or AWS Regions. | As needed for your use case, repeat this epic for any additional accounts or AWS Regions.                                                                                                                                 | AWS administrator, General AWS         |

# Prevent creation of unencrypted instances

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a service control policy.    | 1. Open the AWS Organizations console at https://console.aws.amazon.com/organizations/v2/.  
2. Create a new service control policy. For more information, see Creating a service control policy in the AWS Organizations documentation.                                                                 | AWS administrator, General AWS         |
3. Add the contents of DenyUnencryptedEC2.json to the policy and save it. You downloaded this JSON file from the GitHub repository in the first epic.

4. Attach this policy to the organization root or any necessary organizational units (OUs). For more information, see Attaching and detaching service control policies in the AWS Organizations documentation.

**AWS services:** Amazon EFS; Amazon S3; AWS Storage Gateway; AWS Systems Manager; Amazon EC2

2315
Summary

This pattern provides four options for backing up your Sun Microsystems SPARC servers after a migration from an on-premises environment to the Amazon Web Services (AWS) Cloud. These backup options help you to implement a backup plan that meets your organization's recovery point objective (RPO) and recovery time objective (RTO), uses automated approaches, and lowers your overall operational costs. The pattern provides an overview of the four backup options and steps to implement them.

If you use a Sun SPARC server hosted as a guest on a Stromasys Charon-SSP emulator, you can use the following three backup options:

- **Backup option 1: Stromasys virtual tape** – Use the Charon-SSP virtual tape feature to set up a backup facility in the Sun SPARC server and archive your backup files to Amazon Simple Storage Service (Amazon S3) and Amazon Simple Storage Service Glacier using AWS Systems Manager Automation.
- **Backup option 2: Stromasys snapshot** – Use the Charon-SSP snapshot feature to set up a backup facility for the Sun SPARC guest servers in Charon-SSP.
- **Backup option 3: Amazon Elastic Block Store (Amazon EBS) volume snapshot** – If you host the Charon-SSP emulator on Amazon Elastic Compute Cloud (Amazon EC2), you can use an Amazon EBS volume snapshot to create backups for a Sun SPARC file system.

If you use a Sun SPARC server hosted as a guest on hardware and Charon-SSP on Amazon EC2, you can use the following backup option:

- **Backup option 4: AWS Storage Gateway virtual tape library (VTL)** – Use a backup application with a Storage Gateway VTL Tape Gateway to back up the Sun SPARC servers.

If you use a Sun SPARC server hosted as a branded zone in a Sun SPARC server, you can use backup options 1, 2, and 4.

Stromasys provides software and services to emulate legacy SPARC, Alpha, VAX, and PA-RISC critical systems. For more information about migrating to the AWS Cloud using Stromasys emulation, see Rehosting SPARC, Alpha, or other legacy systems to AWS with Stromasys on the AWS Blog.

Prerequisites and limitations

**Prerequisites**

- An active AWS account.
- Existing Sun SPARC servers.
- Existing licenses for Charon-SSP. Licenses for Charon-SSP are available from AWS Marketplace and licenses for Stromasys Virtual Environment (VE) are available from Stromasys. For more information, contact Stromasys sales.
- Familiarity with Sun SPARC servers and Linux backups.
- Familiarity with Charon-SSP emulation technology. For more information about this, see Stromasys legacy server emulation in the Stromasys documentation.
- If you want to use the virtual tape facility or backup applications for your Sun SPARC servers file systems, you must create and configure the backup facilities for the Sun SPARC server file system.
- An understanding of RPO and RTO. For more information about this, see Disaster recovery objectives from the Reliability Pillar whitepaper in the AWS Well-Architected Framework documentation.
- To use Backup option 4, you must have the following:
  - A software-based backup application that supports a Storage Gateway VTL Tape Gateway. For more information about this, see Working with VTL devices in the AWS Storage Gateway documentation.
- Bacula Director or a similar backup application, installed and configured. For more information about this, see the Bacula Director documentation.

The following table provides information about the four backup options in this pattern.

<table>
<thead>

<tr>
<td>Option 3 – Amazon EBS volume snapshot</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>Sun SPARC server file systems snapshot</td>
</tr>
</tbody>
</table>

2317
You can use AWS Backup to automate the Amazon EBS snapshot. This backup option requires an automated script to flush in-flight transactions and configure a read-only or temporary stop of the EC2 instance during the Amazon EBS volume snapshot.

**Important**: This backup option might require application downtime or read-only mode to achieve application consistency.

<table>

</thead>
<tbody>
<tr>
<td>You can automatically back up Sun SPARC file system backup data to the VTL by using a backup agent.</td>
<td>Yes</td>
<td>This backup option requires an automated script to flush in-flight transactions and configure a read-only or temporary offline mode during the file system snapshot or application data dump.</td>
<td>A large fleet of Sun SPARC server file system backups</td>
</tr>
</tbody>
</table>

**Application data backup**

**Limitations**

- You can use this pattern's approaches to back up individual Sun SPARC servers, but you can also use these backup options for shared data if you have applications that run in a cluster.

**Architecture**

*Backup option 1: Stromasys virtual tape*
Typically, if you run fewer than ten Sun SPARC servers in your data center, the servers are configured to back up file systems and application data by connecting to tape devices. To reduce change risks during a migration, you should use the same backup mechanism and reuse existing backup scripts. You can use the Charon-SSP emulator’s virtual tape feature to set up a virtual tape device in Charon-SSP Manager and make it available to the Sun SPARC guest server. The following is a typical Sun SPARC server backup process using tape devices:

1. The Sun SPARC server mounts a backup tape device as a small computer system interface (SCSI) device. The Sun SPARC server then uses a backup script that follows a customized runbook to back up the configuration and application data.
2. A schedule is set up to initiate the backup script and save the backup in a tape device.
3. After the backup is complete, the tape is ejected from the tape device and scheduled for offsite storage. Authorized personnel pick up the ejected disk and replace it with a rotation disk.

On the AWS Cloud, operations are automated to simplify this process and meet the shared responsibility model. The following diagram shows the setup for Sun SPARC servers and backups using backup option 1.

The diagram shows the following workflow:

1. Migrate the Sun SPARC servers to Amazon EC2 using the Charon-SSP Amazon Machine Image (AMI).
2. Create and attach the AWS Key Management Service (AWS KMS) encrypted EBS volumes as data volumes to Amazon EC2.
3. Configure SCSI devices using the Physical disk type in Charon-SSP Manager.
4. Create SCSI devices using the Virtual tape type in Charon-SSP Manager and map the SCSI device to the virtual tape file assigned to the Sun SPARC server. Note: Use Charon-SSP Manager to input the virtual tape name, location path for the virtual tape container file, and tape size in megabytes.
5. Map the SCSI devices to the data volumes available in Amazon EC2. Note: Use Charon-SSP Manager to create the SCSI mapping in the Virtual Machine Settings window. Enter the virtual tape device into the SCSI settings. The list of SCSI devices shows the SCSI ID, Device type, LUN ID, and the path to the devices.
6. Provision an AWS KMS encrypted Amazon Elastic File System (Amazon EFS) file share and mount the Amazon EFS file share to Amazon EC2 with Transport Layer Security (TLS) enabled.

7. Create virtual tape container files in the Amazon EFS file share for each guest Sun SPARC guest server.

8. Verify that the virtual tape device is configured in the Sun SPARC guest server and configure the backup script to use the virtual tape device. Note You can run the following command to validate that the virtual tape device is recognized in the Solaris operating system (OS):

   ```bash
   mt -f /dev/rmt/1
   config "Charon Virtual Tape", "Charon Virtual Tape", "CFGCHARONVIRTUALTAPE";
   CFGCHARONVIRTUALTAPE = 2,0x2D,0x10659,4,0x00,0x00,0x00,0x00,0,120,120,3600,3600,3600,3600
   ```

9. Create a Systems Manager Automation runbook to orchestrate the backup process and rotate the tape container file. To initiate the backup, the automation starts by rewinding the tape and then runs the backup command. You can use the following sample backup commands:

   • `mt -f <tape-device-name> rewind`
   • `tar -cvf <tape-device-name> <files-to-backup>`
   • `mt -f <tape-device-name> offline`

### Backup option 2 - Stromasys snapshot

The Charon-SSP emulator provides guest snapshot capability and the emulated SPARC server can be suspended by Charon-SSP Manager. When the guest server is suspended, the system's memory content is saved in a directory. A backup script or application can back up the snapshot file and the guest virtual disk files. Because of a SPARC pause, the Sun SPARC guest server requires downtime when the backup starts. We recommend this backup approach for applications that are deployed in a cluster where temporary reduced capacity is acceptable during the maintenance window.

The following diagram shows the setup of the Sun SPARC servers and backups using backup option 2.

The diagram shows the following workflow:

1. Migrate the Sun SPARC servers to Amazon EC2 using the Charon-SSP AMI.
2. Create and attach the AWS KMS encrypted EBS volumes as data volumes to Amazon EC2.

3. Provision an AWS KMS encrypted Amazon EFS file share and mount it to Amazon EC2 with TLS enabled.

4. Create virtual disks in Charon-SSP Manager and save the virtual disk file in the data volumes. You can use the mkdskcmd command line in the Charon-SSP package to create the virtual disk. **Note:** You can use the `mkdskcmd -o /usr/local/vm/leela/disk0.vdisk -d ST446452W` and `mkdskcmd -o /usr/local/vm/bender/disk0.vdisk -z 4096 -c 16384` commands to create the virtual disk files.

5. Create a snapshot folder in the Amazon EFS file share for each Sun SPARC guest server.

6. Set up the folder path in the **Location snapshot** of the Charon-SSP Manager’s **Preferences** window.

7. Create a Systems Manager Automation runbook to orchestrate the backup process and rotate the tape container file.

**Important:** For **Step 6**, you must configure Charon-SSP Manager to use a snapshot folder. In the **Preferences** window for Charon SSP Manager’s SPARC guest server, enter the full path of the snapshot folder in the Linux system into the **Location** text field in the snapshot configuration group. For example, if Amazon EFS is mounted to `/home/` and a directory called `ssp-snapshot` is created to save snapshots, then you should enter `/home/ssp-snapshot`. If the Sun SPARC guest server is started through the Charon-SSP command line, then you must use `–snapshot=path` to specify the path to store snapshot files.

The following are sample backup Linux commands that you can use to back up a Sun SPARC guest server:

1. In the Linux host, run the following command to suspend the SPARC guest server: `kill -SIGTSTP <SSP-PID>`

2. Upload the Sun SPARC guest server snapshot file and virtual disks files from the Linux host to Amazon S3 with AWS Command Line Interface (AWS CLI): `aws s3 cp <snapshot_file> s3://<bucket-name>/<timestamp>/`

3. Restart the Sun SPARC guest server: `ssp4u -f <sparc-guest-config-file> -a <alias> -S <snapshot-location>`

**Backup option 3: Amazon EBS volume snapshot**

You can also use backup solutions from storage hardware in the data center (for example, taking snapshots of data volumes). If you migrated Solaris instances, you can use a similar approach with EBS volume snapshots.

The following diagram shows the setup of Sun SPARC servers and backups using backup option 3.
The diagram shows the following workflow:

1. Migrate the Sun SPARC servers to Amazon EC2 using the Charon-SSP AMI.
2. Create and attach the AWS KMS encrypted EBS volumes as data volumes to Amazon EC2.
3. Set up the Charon-SSP emulation configuration to use physical disks as virtual SCSI devices.
4. Mount the SCSI storage device in the Solaris guest.
5. Set up AWS Backup to create Amazon EBS multi-volume, crash-consistent backups. For more information about this, see Creating Amazon EBS multi-volume, crash-consistent backups in the AWS Backup documentation.

**Note:** This backup option achieves crash-consistent snapshots but most modern file systems can recover open files without corrupting them. This backup option doesn't always provide the consistency required for mission-critical applications that require in-flight transactions or processing to be fully committed before backing up. To achieve application consistency, we recommend that you use backup scripts with backup option 1 or 4.

**Backup Option 4 – AWS Storage Gateway VTL**

If you need backup continuity when migrating your Sun SPARC servers, then your backup solution cannot have an impact during the migration and you must have options to recover or retrieve backup data when required. This backup approach uses a Storage Gateway Tape Gateway and VTL stored in Amazon S3 to replace your on-premises tape library facilities. By using this approach, you can keep almost all of your existing configuration for some of your enterprise backup solutions.

We tested a SPARC server using Solaris 11 on an EC2 instance running the Charon-SSP emulator. In a typical setup, enterprise backup software must be installed and configured on the Solaris 11 server.

The following diagram shows the setup of Sun SPARC servers and backups using backup option 4.
The diagram shows the following workflow:

1. Set up an Amazon EC2 Linux instance and install Bacula Director.
2. Create a multi-AZ Amazon Relational Database Service (Amazon RDS) for MySQL DB instance for the Bacula Catalog database.
3. Set up an Amazon EC2 Linux instance and install the Charon-SSP emulator.
4. In Charon-SSP Manager, create a Sun SPARC virtual instance by following the Charon-SSP user guide in the Stromasys documentation. Install or restore the SPARC image on the virtual instance.
5. Configure Storage Gateway in a virtual private cloud (VPC) and set it up as a VTL Tape Gateway. For more information about this, see Creating a Tape Gateway in the AWS Storage Gateway documentation.
6. In Bacula Director, configure an Amazon RDS endpoint for the Bacula Catalog database.
7. In Bacula Director, configure the storage pool to use the Storage Gateway VTL.
8. In the Solaris 11 server, configure the Bacula file daemon to use the Bacula Director setup.

**Note:** For a lower risk and faster SPARC migration, you can create a backup pool through the Storage Gateway VTL Tape Gateway, create a backup policy for the backup pool, incrementally add backup targets to use the newly created backup policy, and validate backup results. When you migrate the server, it can be recovered from its backup on Amazon S3 to the emulated Solaris OS. A final delta synchronization is performed during a maintenance window before the cutover.

**Tools**

**Backup option 1: Stromasys virtual tape**

- **Stromasys Charon-SSP emulator** – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including operating systems (OSs) such as SunOS or Solaris, their layered products, and applications.
- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.
• **Amazon EFS** – Amazon Elastic File System (Amazon EFS) provides a simple, serverless, set-and-forget elastic file system for use with AWS Cloud services and on-premises resources.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

• **Amazon S3 Glacier** – Amazon Simple Storage Service Glacier is a secure, durable, and extremely low-cost Amazon S3 storage class for data archiving and long-term backup.

• **AWS Systems Manager Automation** – Automation, a capability of AWS Systems Manager, simplifies common maintenance and deployment tasks of EC2 instances and other AWS resources.

**Backup option 2: Stromasys snapshot**

• **Stromasys Charon-SSP emulator** – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including OSs such as SunOS or Solaris, their layered products, and applications.

• **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.

• **Amazon EFS** – Amazon Elastic File System (Amazon EFS) provides a simple, serverless, set-and-forget elastic file system for use with AWS Cloud services and on-premises resources.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

• **Amazon S3 Glacier** – Amazon Simple Storage Service Glacier is a secure, durable, and extremely low-cost Amazon S3 storage class for data archiving and long-term backup.

• **AWS Systems Manager Automation** – Automation, a capability of AWS Systems Manager, simplifies common maintenance and deployment tasks of EC2 instances and other AWS resources.

**Backup option 3: Amazon EBS volume snapshot**

• **Stromasys Charon-SSP emulator** – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including OSs such as SunOS or Solaris, their layered products, and applications.

• **AWS Backup** – AWS Backup is a fully-managed data protection service that makes it easy to centralize and automate across AWS services, in the cloud, and on premises.

• **Amazon EBS** – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances.

• **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.

**Backup option 4: AWS Storage Gateway VTL**

• **Stromasys Charon-SSP emulator** – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including OSs such as SunOS or Solaris, their layered products, and applications.

• **Bacula** – Bacula is an open-source, enterprise-level computer backup system. For more information about whether your existing backup application supports Tape Gateway, see Supported third-party backup applications for a Tape Gateway in the AWS Storage Gateway documentation.

• **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.
• **Amazon RDS for MySQL** – Amazon Relational Database Service (Amazon RDS) supports DB instances running several versions of MySQL.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

• **Amazon S3 Glacier** – Amazon Simple Storage Service Glacier is a secure, durable, and extremely low-cost Amazon S3 storage class for data archiving and long-term backup.

• **AWS Storage Gateway** – Storage Gateway connects an on-premises software appliance with cloud-based storage to provide seamless integration with data security features between your on-premises IT environment and the AWS storage infrastructure.

## Epics

### Backup option 1 – Create a Stromasys virtual tape backup

<table>

Backup option 4 – Create an AWS Storage Gateway VTL

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a Tape Gateway device.</td>
<td>Sign in to the AWS Management Console, open the AWS Storage Gateway console, and then create a Tape Gateway device in a VPC.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>For more information about this, see Creating a gateway in the AWS Storage Gateway documentation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Create an Amazon RDS DB instance for the Bacula Catalog.</td>
<td>Open the Amazon RDS console and create an Amazon RDS for MySQL DB instance.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>For more information about this, see Creating a MySQL DB instance and connecting to a database on a MySQL DB instance in the Amazon RDS documentation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Deploy the backup application controller in the VPC.</td>
<td>Install Bacula on the EC2 instance, deploy the backup application controller, and then configure the backup storage to connect with the Tape Gateway device. You can use the sample Bacula Director storage daemon configuration in the Bacula-storage-daemon-config.txt file (attached).</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td>For more information about this, see the Bacula documentation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Set up backup application on the Sun SPARC guest servers.</td>
<td>Set up a second client to install and set up the backup application on the Sun SPARC guest servers by using the sample Bacula configuration in the SUN-SPARC-Guest-Bacula-Config.txt file (attached).</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
### Set up the backup configuration and schedule.

**Task:** Set up backup configuration and schedules in the backup application controller by using the sample Bacula Director configuration in the Bacula-Directory-Config.txt file (attached).

For more information about this, see the [Bacula documentation](#).

**Skills required:** DevOps engineer

### Validate that the backup configuration and schedules are correct.

**Task:** Follow the instruction from the [Bacula documentation](#) to perform the validation and backup testing for your setup in the Sun SPARC guest servers.

For example, you can use the following commands to validate the configuration files:

- `bacula-dir -t -c bacula-dir.conf`
- `bacula-fd -t -c bacula-fd.conf`
- `bacula-sd -t -c bacula-sd.conf`

**Skills required:** DevOps engineer

### Additional information

**Backup option 1 – Create a Stromasys virtual tape**

You can use the following sample Systems Manager Automation runbook code to automatically start the backup and then swap the tapes:

```bash
...
#!/usr/bin/bash
mt -f rewind
tar -cvf
mt -f offline
...
```
mainSteps:
  - action: aws:runShellScript
    name:
    inputs:
      onFailure: Abort
      timeoutSeconds: "1200"
      runCommand:
        - |
          # Validate tape backup container file exists
          if [ ! -f {{TapeBackupContainerFile}} ]; then
            logger -s -p local3.warning "Tape backup container file is not exists -
{{TapeBackupContainerFile}}, create a new one"
            touch {{TapeBackupContainerFile}}
          fi
    - action: aws:runShellScript
      name: startBackup
      inputs:
        onFailure: Abort
        timeoutSeconds: "1200"
        runCommand:
          - |
            user={{BACKUP_USER}}
            keypair={{KEYPAIR_PATH}}
            server={{SUN_SPARC_IP}}
            backup_script={{BACKUP_SCRIPT}}
            ssh -i $keypair $user@$server -c "/usr/bin/bash $backup_script"
    - action: aws:runShellScript
      name: swapVirtualDiskContainer
      inputs:
        onFailure: Abort
        timeoutSeconds: "1200"
        runCommand:
          - |
            mv {{TapeBackupContainerFile}} {{TapeBackupContainerFile}}.$(date +%s)
            touch {{TapeBackupContainerFile}}
    - action: aws:runShellScript
      name: uploadBackupArchiveToS3
      inputs:
        onFailure: Abort
        timeoutSeconds: "1200"
        runCommand:
          - |
            aws s3 cp {{TapeBackupContainerFile}} s3://{{BACKUP_BUCKET}}/
{{SUN_SPARC_IP}}/$(date '+%Y-%m-%d')/

Backup option 2 – Stromasys snapshot

You can use the following sample Systems Manager Automation runbook code to automate the backup process:

...
Backup option 4 – AWS Storage Gateway VTL

If you use Solaris non-global zones to run virtualized legacy Sun SPARC servers, the backup application approach can be applied to non-global zones running in the Sun SPARC servers (for example, the backup client can run inside the non-global zones). However, the backup client can also run in the Solaris host and take snapshots of the non-global zones. The snapshots can then be backed up on a tape.

The following sample configuration adds the file system that hosts the Solaris non-global zones into the backup configuration for the Solaris host:

```plaintext
FileSet {
   Name = "Branded Zones"
   Include {
      Options {
         signature = MD5
      }
      File = /zones
   }
}
```

Back up and archive data to Amazon S3 with Veeam Backup & Replication

Created by Jeanna James and Anthony Fiore (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Storage &amp; backup</th>
<th>AWS services:</th>
<th>Amazon EC2; Amazon S3; Amazon S3 Glacier</th>
</tr>
</thead>
</table>

**Summary**

This pattern details the process for sending backups created by Veeam Backup & Replication to supported Amazon Simple Storage Service (Amazon S3) object storage classes by using the Veeam scale-out backup repository capability.

Veeam supports multiple Amazon S3 storage classes to best fit your specific needs. You can choose the type of storage based on the data access, resiliency, and cost requirements of your backup or archive data. For example, you can store data that you don't plan to use for 30 days or longer in Amazon S3 infrequent access (IA) for lower cost. If you're planning to archive data for 90 days or longer, you can use Amazon Simple Storage Service Glacier with Veeam's archive tier. You can also use S3 Object Lock to make backups immutable within Amazon S3.

This pattern doesn't cover how to set up Veeam Backup & Replication with a tape gateway in Amazon Web Services (AWS) Storage Gateway. For information about that topic, see Veeam Backup & Replication using AWS VTL Gateway - Deployment Guide on the Veeam website.

**Prerequisites and limitations**

**Prerequisites**

- Veeam Backup & Replication, including Veeam Availability Suite or Veeam Backup Essentials, installed (you can register for a [free trial](https://veeam.com/en/products/veeam-backup-essentials/free-trial))
- Veeam Backup & Replication license with Enterprise or Enterprise Plus functionality, which includes Veeam Universal License (VUL)
- An active AWS Identity and Access Management (IAM) user account with access to an Amazon S3 bucket
- An active IAM user account with access to Amazon Elastic Compute Cloud (Amazon EC2) and Amazon Virtual Private Cloud (Amazon VPC) (if utilizing archive tier)
- Network connectivity from on premises to AWS services with available bandwidth for backup and restore traffic through a public internet connection or an AWS Direct Connect public virtual interface (VIF)

**Limitations**

- Veeam doesn't support S3 Lifecycle policies on any S3 buckets that are used as Veeam object storage repositories. These include polices with Amazon S3 storage class transitions and S3 Lifecycle expiration rules. Veeam must be the sole entity that manages these objects. Enabling S3 Lifecycle policies might have unexpected results, including data loss.

**Product versions**

2333
• Veeam Backup & Replication v9.5 Update 4 or later (backup only or capacity tier)
• Veeam Backup & Replication v10 or later (backup or capacity tier and S3 Object Lock)
• Veeam Backup & Replication v11 or later (backup or capacity tier, archive or archive tier, and S3 Object Lock)
• S3 Standard
• S3 Standard-IA
• S3 One Zone-IA
• S3 Glacier (v11 only)
• S3 Glacier Deep Archive (v11 only)

Architecture

Source technology stack

• On-premises Veeam Backup & Replication installation with connectivity from a Veeam backup server or a Veeam gateway server to Amazon S3

Target technology stack

• Amazon S3
• Amazon VPC and Amazon EC2 (if using archive tier)

Target architecture

The following diagram shows the scale-out backup repository architecture.

Veeam Backup and Replication software protects data from logical errors such as system failures, application errors, or accidental deletion. In this diagram, backups are run on premises first, and a secondary copy is sent directly to Amazon S3. A backup represents a point-in-time copy of the data.

The workflow consists of three primary components that are required for tiering or copying backups to Amazon S3, and one optional component:

• Veeam Backup & Replication (1) – The backup server that is responsible for coordinating, controlling, and managing backup infrastructure, settings, jobs, recovery tasks, and other processes.
• Veeam gateway server (not shown in the diagram) – An optional on-premises gateway server that is required if the Veeam backup server doesn’t have outbound connectivity to Amazon S3.

• Scale-out backup repository (2) – Repository system with horizontal scaling support for multi-tier storage of data. The scale-out backup repository consists of one or more backup repositories that provide fast access to data and can be expanded with Amazon S3 object storage repositories for long-term storage (capacity tier) and archiving (archive tier). Veeam uses the scale-out backup repository to tier data automatically between local (performance tier) and Amazon S3 object storage (capacity and archive tiers).

• Amazon S3 (3) – AWS object storage service that offers scalability, data availability, security, and performance.

Automation and scale

You can automate the creation of IAM resources and S3 buckets by using the AWS CloudFormation templates provided in the VeeamHub GitHub repository. The templates include both standard and immutable options.

Tools

Tools and AWS services

• Veeam Backup & Replication — Veeam Backup & Replication is a solution from Veeam for protecting, backing up, replicating, and restoring your virtual and physical workloads.

• AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

• Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.

• IAM – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

• Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

• Amazon VPC – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Code

Use the CloudFormation templates provided in the VeeamHub GitHub repository to automatically create the IAM resources and S3 buckets for this pattern. If you prefer to create these resources manually, follow the steps in the Epics section.
# Epics

**Configure Amazon S3 storage in your account**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an IAM user.</td>
<td>Follow the instructions in the <a href="https://docs.aws.amazon.com/IAM/latest/UserGuide/id%E5%87%B6%E6%89%8B.html">IAM documentation</a> to create an IAM user with programmatic access. Veeam uses this entity to authenticate with AWS to read and write to your S3 buckets. You must grant least privilege (that is, grant only the permissions required to perform a task) so the user doesn't have more authority than it needs. For example IAM policies to attach to your Veeam IAM user, see the Additional information (p. 2344) section. Note Alternatively, you can use the CloudFormation templates provided in the <a href="https://github.com/VeeamHub">VeeamHub GitHub repository</a> to create an IAM user and S3 bucket for this pattern.</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
| Create an S3 bucket.  | 1. Sign in to the AWS Management Console and open the Amazon S3 console at [https://console.aws.amazon.com/s3/](https://console.aws.amazon.com/s3/).  
2. If you don't already have an existing S3 bucket to use as the target storage, choose Create bucket, and specify a bucket name, AWS Region, and bucket settings.  
   - We recommend that you enable the Block Public Access option for the S3 bucket and set up the access and user permission policies to meet your organization’s requirements. For an example, see the Amazon S3 documentation.  
   - We recommend that you enable S3 Object Lock, even if you don’t intend to use it right away. This setting can... | AWS administrator         |
Add Amazon S3 and Amazon S3 Glacier (or S3 Glacier Deep Archive) to Veeam Backup & Replication

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Launch the New Object Repository wizard. | Before you set up the object storage and scale-out backup repositories in Veeam, you must add the Amazon S3 and Amazon S3 Glacier storage repositories that you want to use for the capacity and archive tiers. In the next epic, you'll connect these storage repositories to your scale-out backup repository.  
1. On the Veeam console, open the Backup Infrastructure view.  
2. In the inventory pane, choose the Backup Repositories node, and then choose Add Repository.  
3. In the Add Backup Repository dialog box, choose Object Storage, Amazon S3. | AWS administrator, App owner |
| Add Amazon S3 storage for the capacity tier. | 1. In the Amazon Cloud Storage Services dialog box, choose Amazon S3.  
2. At the Name step of the wizard, specify the object storage name and a brief description, such as the creator and creation date.  
3. At the Account step of the wizard, specify the object storage account.  
   a. For Credentials, choose the user credentials that you created in the first epic to access your Amazon S3 object storage. | AWS administrator, App owner |

| Add Amazon S3 Glacier storage for the archive tier. | If you want to create an archive tier, use the IAM permissions detailed in the Additional information (p. 2344) section.  
1. Launch the New Object Repository wizard as described previously.  
2. In the **Amazon Cloud Storage Services** dialog box, choose **Amazon S3 Glacier**.  
3. At the **Name** step of the wizard, specify the object storage name and a brief description, such as the creator and creation date.  
4. At the **Account** step of the wizard, specify the object storage account.  
a. For **Credentials**, choose the user credentials you created in the first epic to access your Amazon S3 Glacier object storage.  
b. For **AWS region**, choose the AWS Region where the Amazon S3 bucket is located.  
5. At the **Bucket** step of the wizard, specify object storage settings.  
a. For **Data center region**, choose the AWS Region.  
b. For **Bucket**, choose an S3 bucket to store your backup data. This can be the same bucket you used for the capacity tier.  
c. For **Folder**, create or select a cloud folder to map your object storage repository to.  
d. If you want to enable immutability, choose **Make recent backups immutable for the entire duration of their retention policy**. Note that enabling immutability results in increased costs because of the increased number of backups. | AWS administrator, App owner |
### Task | Description | Skills required
--- | --- | ---
 | of API calls to Amazon S3 from Veeam.  
e. If you want to use S3 Glacier Deep Archive as your archival storage class, choose **Use the Deep Archive Storage Class**.  
6. At the **Proxy Appliance** step of the wizard, configure the auxiliary instance that is used to transfer the data from Amazon S3 to Amazon S3 Glacier. You can use the default settings or configure each setting manually.  
To configure the settings manually:  
a. Choose **Customize**.  
b. For **EC2 instance type**, choose the instance type for the proxy appliance, based on your speed and cost requirements for transferring the backup files to the archive tier of your scale-out backup repository.  
c. For **Amazon VPC**, choose the VPC for the target instance.  
d. For **Subnet**, choose the subnet for the proxy appliance.  
e. For **Security group**, choose the security group to associate with the proxy appliance.  
f. For **Redirector port**, specify the TCP port for routing requests between the proxy appliance and backup infrastructure components.  
g. Choose **OK** to confirm your settings.  
7. At the **Summary** step of the wizard, review the configuration information, and then choose **Finish**. |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Launch the New Scale-Out Backup Repository wizard. | 1. On the Veeam console, open the **Backup Infrastructure** view.  
2. In the inventory pane, choose **Scale-out Repositories**, and then choose **Add Scale-out Repository**. | App owner, AWS systems administrator          |
| Add a scale-out backup repository and configure capacity and archive tiers. | 1. At the **Name** step of the wizard, specify the name and a brief description of the scale-out backup repository.  
2. If needed, add performance extents. You can also use your existing Veeam local backup repository as your performance tier.  
3. Choose **Advanced**, and specify additional options for the scale-out backup repository.  
   • Choose **Use per-machine backup files** to create a separate backup file for each machine and write these files to the backup repository in multiple streams simultaneously. This option is recommended for better storage and compute resource utilization.  
   • Choose **Perform full backup when required extent is offline** to create a full backup file in case an extent that contains restore points for an incremental backup goes offline. This option requires free space in the scale-out backup repository to host a full backup file.  
4. At the **Policy** step of the wizard, specify the backup placement policy for the repository.  
   • Choose **Data locality** to store full and incremental backup files that belong to the same chain together, | App owner, AWS systems administrator          |
### Task | Description | Skills required
---|---|---
to the same performance extent. You can store files that belong to a new backup chain to the same performance extent or to another one (unless you use a deduplicating storage appliance as a performance extent).

- Choose **Performance** to store full and incremental backup files to different performance extents. This option requires a fast and reliable network connection. If you choose **Performance**, you can restrict the types of backup files to store on each performance extent. For example, you can store full backup files on one extent and incremental backup files on other extents. To choose file types:
  a. Choose **Customize**.
  b. In the **Backup Placement Settings** dialog box, choose a performance extent, and then choose **Edit**.
  c. Choose the type of backup files you want to store on the extent.

5. At the **Capacity Tier** step of the wizard, configure the long-term storage tier that you want to attach to the scale-out backup repository.

  a. Choose **Extend scale-out backup repository capacity with object storage**. For the object storage repository, choose the Amazon S3 storage for the capacity tier that you added in the previous epic.
  b. Choose **Window** to select a time window for moving or copying data.
  c. Choose **Copy backups to object storage as soon as they are created** to copy
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>all or only recently created backup files to the capacity extent.</td>
<td></td>
</tr>
<tr>
<td>d.</td>
<td>Choose <strong>Move backups to object storage as they age out of the operational restores window</strong> to transfer inactive backup chains to the capacity extent. In the <strong>Move backup files older than X days</strong> field, specify a duration after which backup files should be offloaded. (To offload inactive backup chains on the day they were created, specify 0 days.) You can also choose <strong>Override</strong> to move backup files sooner if the scale-out backup repository has reached a threshold that you specify.</td>
<td></td>
</tr>
<tr>
<td>e.</td>
<td>Choose <strong>Encrypt data uploaded to object storage</strong> and specify a password to encrypt all data and their metadata for offloading. Choose <strong>Add</strong> or <strong>Manage passwords</strong> to specify a new password.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>At the <strong>Archive Tier</strong> step of the wizard, configure the archive storage tier that you want to attach to the scale-out backup repository. (This step doesn't appear if you skipped adding Amazon S3 Glacier storage.)</td>
<td></td>
</tr>
<tr>
<td>a.</td>
<td>Choose <strong>Archive GFS full backups to object storage</strong>. For the object storage repository, choose the Amazon S3 Glacier storage you added in the previous epic.</td>
<td></td>
</tr>
<tr>
<td>b.</td>
<td>For <strong>Archive GFS backups older than N days</strong>, choose a time window for moving files to the archive extent. (To archive inactive backup chains on the day they were created, specify 0 days.)</td>
<td></td>
</tr>
</tbody>
</table>
7. At the **Summary** step of the wizard, review the configuration of the scale-out backup repository, and then choose **Finish**.

### Additional information

The following sections provide sample IAM policies you can use when you create an IAM user in the **Epics** section of this pattern.

**IAM policy for capacity tier**

**Note**  Change the name of the S3 buckets in the example policy from `<yourbucketname>` to the name of the S3 bucket that you want to use for Veeam capacity tier backups.

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "s3:GetObjectVersion",
                "s3:ListBucketVersions",
                "s3:ListBucket",
                "s3:PutObjectLegalHold",
                "s3:GetBucketVersioning",
                "s3:GetObjectLegalHold",
                "s3:GetBucketObjectLockConfiguration",
                "s3:GetObjectLockStatus",
                "s3:GetObject*",
                "s3:GetEncryptionConfiguration",
                "s3:PutObjectRetention",
                "s3:PutBucketObjectLockConfiguration",
                "s3:DeleteObject*",
                "s3:DeleteObjectVersion",
                "s3:GetBucketLocation"
            ],
            "Resource": [
                "arn:aws:s3:::<yourbucketname>/*",
                "arn:aws:s3:::<yourbucketname>"
            ]
        }
    ]
}
```
IAM policy for archive tier

**Note**  Change the name of the S3 buckets in the example policy from `<yourbucketname>` to the name of the S3 bucket that you want to use for Veeam archive tier backups.

To use your existing VPC, subnet, and security groups:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": [
                "s3:DeleteObject",
                "s3:PutObject",
                "s3:GetObject",
                "s3:RestoreObject",
                "s3:ListBucket",
                "s3:AbortMultipartUpload",
                "s3:GetBucketVersioning",
                "s3:ListAllMyBuckets",
                "s3:GetBucketLocation",
                "s3:GetBucketObjectLockConfiguration",
                "s3:GetObjectRetention",
                "s3:GetObjectVersion",
                "s3:PutObjectLegalHold",
                "s3:GetObjectRetention",
                "s3:DeleteObjectVersion",
                "s3:ListBucketVersions",
                "ec2:DescribeInstances",
                "ec2:CreateKeyPair",
                "ec2:DescribeKeyPairs",
                "ec2:RunInstances",
                "ec2:DeleteKeyPair",
                "ec2:DescribeVpcAttribute",
                "ec2:CreateTags",
                "ec2:DescribeSubnets",
                "ec2:TerminateInstances",
                "ec2:DescribeSecurityGroups",
                "ec2:DescribeImages",
                "ec2:DescribeVpcs"
            ],
            "Resource": "*"
        }
    ]
}
```

To create new VPC, subnet, and security groups:

```json
{
    "Version": "2012-10-17",
```
Back up and archive mainframe data to Amazon S3 using Model9 Manager

*Created by Santosh Kumar Singh (AWS), Mikhael Liberman (Model9 Mainframe Software), Gilberto Biondo (AWS), and Maggie Li (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Mainframe</th>
<th>Target:</th>
<th>Amazon S3</th>
</tr>
</thead>
</table>
Summary

This pattern shows you how to back up and archive mainframe data directly to Amazon Simple Storage Service (Amazon S3), and then recall and restore that data to the mainframe by using Model9 Manager. If you're looking for a way to modernize your backup and archive solution as part of your mainframe modernization journey or to meet compliance requirements, then this pattern can help you meet your goals.

Typically, organizations running core business applications on mainframes use a virtual tape library (VTL) to back up data stores such as files and logs, but this method can be expensive because it consumes billable MIPS. Also, you can't access data stored on tapes outside the mainframe. To avoid these issues, you can use Model9 Manager to quickly and cost-effectively transfer operational and historical mainframe data directly to Amazon S3. Model9 Manager enables you to back up and archive data over TCP/IP directly to the cloud, while taking advantage of IBM z Integrated Information Processor (zIIP) engines to reduce cost, parallelism, and transfer times.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Model9 Manager with a valid license key
- TCP/IP connectivity between the mainframe and AWS
- An AWS Identity and Access Management (IAM) user with read/write access to an S3 bucket
- S3 bucket policies defined to read/write data
- Mainframe security product (RACF) access in place to run Model9 processes
- A Model9 z/OS agent (Java version 8 64-bit SR5 FP16 or above) that has available network ports, firewall rules permitting access to S3 buckets, and a dedicated z/FS file system
- Meeting the requirements for the Model9 management server

Limitations

- Model9 Manager stores its operational data in a PostgreSQL database that runs as a Docker container on the same Amazon Elastic Compute Cloud (Amazon EC2) instance as the management server. Model9 Manager doesn't yet run as an Amazon Relational Database Service (Amazon RDS) service. For more information on the latest Model9 product updates, see What's New? in the Model9 documentation.
- This pattern can help you back up and archive z/OS mainframe data only. Model9 Manager backs up and archives only mainframe files.
- This pattern can't help you convert data into standard open formats, such as JSON or CSV. You must use an additional Model9 transformation service, such as Model9 Gravity, to convert the data into standard open formats. Cloud-native applications and data analytics tools can access the data after that data is written to the cloud.

Product versions
Model9 Manager v2.X

Architecture

Source technology stack

- Mainframe running z/OS
- Mainframe files such as data sets and z/OS UNIX System Services (USS) files
- Mainframe disk, such as a direct-access storage device (DASD)
- Mainframe tape (virtual or physical tape library)

Target technology stack

- Amazon S3
- Amazon EC2 instance in a virtual private cloud (VPC)
- AWS Direct Connect
- Amazon Elastic File System (Amazon EFS)

Target architecture

The following diagram shows a reference architecture where Model9 software agents on a mainframe drive the legacy data backup and archive processes that store the data in Amazon S3.

The diagram shows the following workflow:

1. Model9 software agents run on mainframe local partitions (LPARs). The software agents read/write mainframe data from DASD or tape directly to Amazon S3 over TCP/IP.
2. Direct Connect enables a physical, isolated connection between the on-premises network and AWS. For enhanced security, you can run a site-to-site VPN on top of Direct Connect to encrypt data in transit.
3. S3 buckets store mainframe files as block storage data, and Model9 agents directly communicate with the S3 buckets.

4. Model9 management servers run as Docker containers on EC2 instances. The instances communicate with agents running on mainframe LPARs and S3 buckets.

5. Amazon EFS is mounted on both active and passive EC2 instances to share the Network File System (NFS) storage. This is to make sure that metadata related to a policy created on the management server is not lost in the event of a failover. In the event of a failover by the active server, you can access the passive server without any data loss. If the passive server fails, you can also access the active server without any data loss.

Tools

AWS services

- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

- **Amazon Elastic File System (Amazon EFS)** helps you create and configure shared file systems in the AWS Cloud.

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve nearly any amount of data.

- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

- **AWS Direct Connect** links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.

- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Other tools

- **Model9 management server** is a GUI application that runs as a Docker container on an Amazon Linux Amazon Machine Image (AMI) for Amazon EC2. The management server provides the functionality to manage Model9 activities, such as reporting, creating and managing policies, running archives, and performing backups, recalls, and restores.

- **Model9 z/OS agent** runs on an on-premises mainframe LPAR that reads and writes files directly to object storage by using TCP/IP. A started task runs on a mainframe LPAR and is responsible for reading/writing backup and archive data to and from Amazon S3.

- **Model9 Mainframe Command Line Interface (M9CLI)** provides you with a set of commands to perform Model9 actions directly from TSO/E or in batch operations, without the dependency on the Model9 management server.

- **Model9 server API (M9SAPI)** gives you the ability to run Model9 policies directly from the mainframe by using the Job Control Language (JCL).

<tr>
<td>2. Choose the policy that you want to run your restore process on. Now, you can see lists of all the backup or archive activities that ran in the past for that specific policy.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. To select the backups that you want to restore, choose the <strong>Date-time</strong> column. The file/Volume/Storage group name shows the run details of the policy.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. On the right of the table, choose the three-dot menu, and then choose <strong>RESTORE</strong>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. In the pop-up window, enter your target name, volume, and storage group, and then choose <strong>RESTORE</strong>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6. Enter your mainframe credentials, and then choose <strong>RESTORE</strong> again.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>7. To verify that the restore is successful, check the logs or the mainframe.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Run the backup or archive policy from the mainframe

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the backup or archive policy using M9CLI.</td>
<td>You can use the M9CLI to perform backup and restore processes from TSO/E, REXX, or through JCLs without setting up rules on the Model9 management server. <strong>Using TSO/E</strong> If you use TSO/E, make sure that M9CLI REXX is concatenated to TSO. To back up a data set through TSO/E, use the</td>
<td>Mainframe Storage Admin/Developer</td>
</tr>
</tbody>
</table>
### AWS Prescriptive Guidance Patterns

**Epics**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>example TSO M9CLI BACKDSN &lt;DSNAME&gt; command.</td>
</tr>
</tbody>
</table>

**Note:** For more information on M9CLI commands, see CLI Overview in the Model9 documentation.

**Using JCLs**

To run the backup and archive policy by using JCLs, run the M9CLI command.

**Using batch operations**

The following example shows you how to archive a data set by running the M9CLI command through batch:

```plaintext
//JOBNAME JOB ...
//M9CLI EXEC PGM=IKJEFT01
//STEPLIB DD DISP=SHR,DSN=<MODEL9 LOADLIB>
//SYSEXEC DD DISP=SHR,DSN=<MODEL9 EXEC LIB>
//SYSTSPRT DD SYSOUT=* 
//SYSPRINT DD SYSOUT=* 
//SYSTSIN DD TSO M9CLI ARCHIVE M9CLI ARCHIVE <DSNNAME OR DSN PATTERN> /
```
### Task: Run the backup or archive policy in JCL batch.

**Description:** Model9 provides a sample JCL routine called **M9SAPIJ**. You can customize **M9SAPIJ** to run a specific policy created on the management server with a JCL. This job can also be part of a batch scheduler for running backup and restore processes automatically.

The batch job expects the following mandatory values:

- Management server IP address/host name
- Port number
- Policy ID or policy name (which is created on the management server)

**Note:** You can also change other values as per the instructions on the sample job.

**Skills required:** Mainframe Storage Admin/Developer

### Configure Veritas NetBackup for VMware Cloud on AWS

*Created by Shubham Salani*

**Environment:** Production  
**Technologies:** Storage & backup; Cloud-native  
**Workload:** All other workloads  
**AWS services:** Amazon S3; AWS Transit Gateway; Amazon VPC; Amazon EBS
Many enterprises use Veritas NetBackup as a backup and recovery solution for their on-premises VMware vSphere-based workloads. Once enterprises migrate their workloads to software-defined data centers (SDDCs) in the VMware Cloud on Amazon Web Services (AWS) infrastructure, there is no clear lift-and-shift procedure to integrate NetBackup. This pattern describes how you can set up Veritas NetBackup in your AWS account and configure it to back up the workloads in your VMware SDDCs.

This pattern does not include instructions for migrating your workloads. For more information, see Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX. When setting up your workloads to VMware Cloud on AWS, use a stretched cluster (VMware documentation). In this configuration, your cluster spans two AWS Availability Zones within a single Region. This provides high availability and resiliency in the event that one of the Availability Zones becomes unavailable. Elastic DRS and a vSAN witness host (VMware documentation) seamlessly copy the data to a third Availability Zone, known as a fault domain. This parity solution can help you recover the data in the event of a failure. Because this approach requires three Availability Zones, when selecting an AWS Region for your VMware Cloud environment, make sure that it has three or more Availability Zones. For more information, see Regions and Availability Zones.

In this pattern, each SDDC has a backup host, which is a proxy server. Using Amazon Elastic Compute Cloud (Amazon EC2) instances, you set up the NetBackup master and media servers in a separate virtual private cloud (VPC), one for each SDDC. Because elastic network interfaces provide high bandwidth and low latency, you use them to configure connectivity between the backup hosts and their corresponding NetBackup master and media servers. The EC2 instances direct the backups to Amazon Elastic Block Store (Amazon EBS) volumes, which is the first point of backup. You can use AWS DataSync to keep your EBS volumes for the SDDCs synchronized.

You can also use AWS Transit Gateway and an interface VPC endpoint to connect the EBS volumes to another storage service, such as Amazon Simple Storage Service (Amazon S3). According to your retention policy, you can use S3 Intelligent-Tiering S3 Glacier storage classes to optimize your storage costs. For more information, see Using Amazon S3 storage classes (Amazon S3 documentation).

Prerequisites and limitations

Prerequisites

- Your VMware Cloud on AWS environment uses a stretched cluster that spans two Availability Zones.
- The backup host must reside on the VMware Cloud on AWS SDDC that has access to the datastore where the VMware Virtual Machine Disk File (VMDK) files are deployed.
- HotAdd transport mode must be enabled on the NetBackup client to back up and restore virtual machines (VMs), and it must permit restores from user-directed files and folders.

Limitations

- The NetBackup master server must use DNS resolution to a private IP address for the vCenter backup host in the SDDC.
- The hosts files on the NetBackup master server and backup host should contain the following:
  - The private IP address and private DNS name of the master server
  - The private IP address and private DNS name of the backup host
- If you are configuring interface VPC endpoints to an S3 bucket, the SDDC Compute Gateway firewall must be configured to allow HTTPS from a Classless Inter-Domain Routing (CIDR) block source. For more information, see Access an S3 Bucket Using an S3 Endpoint (VMware documentation).
- VMware Cloud on AWS does not support the following features of NetBackup:
  - Backing up or restoring VM templates
• Using NetBackup vSphere Client (HTML5 plug-in)
• Locking and unlocking VMs for backups or restores
• Backups cannot be stored in a vSAN datastore
• Network block device (NBD), NBDSSL, and SAN transport modes

Product versions
• VMware Cloud on AWS SDDC version 1.0 or later
• Veritas NetBackup version 8.1.2 or later
• Linux version 6.8 or later
• VMware vSphere version 6.0 or later

Architecture
The following diagram shows the configuration of NetBackup for VMware Cloud on AWS. The NetBackup master and media servers are deployed in a separate VPC and are connected to the backup hosts in the SDDCs by elastic network interfaces. The NetBackup master and media servers store the backups in Amazon EBS volumes. You can optionally configure additional storage in Amazon S3 buckets by using AWS Transit Gateway and an AWS PrivateLink interface VPC endpoint.

Tools
AWS services and tools
• Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
• AWS PrivateLink helps you create unidirectional, private connections from your virtual private clouds (VPCs) to services outside of the VPC.
AWS Prescriptive Guidance Patterns

Epics

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other services
- **VMware Cloud on AWS** is an integrated cloud offering jointly developed by Amazon Web Services (AWS) and VMware.
- **NetBackup for VMware** backs up and restores the VMware virtual machines that run on VMware ESXi hosts.

Summary

This pattern demonstrates how to migrate nearly any amount of data from an on-premises Apache Hadoop environment to the Amazon Web Services (AWS) Cloud by using the Apache open-source tool DistCp with AWS PrivateLink for Amazon Simple Storage Service (Amazon S3). Instead of using the public internet or a proxy solution to migrate data, you can use AWS PrivateLink for Amazon S3 to
migrate data to Amazon S3 over a private network connection between your on-premises data center and an Amazon Virtual Private Cloud (Amazon VPC). If you use DNS entries in Amazon Route 53 or add entries in the `/etc/hosts` file in all nodes of your on-premises Hadoop cluster, then you are automatically directed to the correct interface endpoint.

This guide provides instructions for using DistCp for migrating data to the AWS Cloud. DistCp is the most commonly used tool, but other migration tools are available. For example, you can use offline AWS tools like AWS Snowball or AWS Snowmobile, or online AWS tools like AWS Storage Gateway or AWS DataSync. Additionally, you can use other open-source tools like Apache NiFi.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account with a private network connection between your on-premises data center and the AWS Cloud
- Hadoop, installed on premises with DistCp
- A Hadoop user with access to the migration data in the Hadoop Distributed File System (HDFS)
- AWS Command Line Interface (AWS CLI), installed and configured
- An AWS Identity and Access Management (IAM) user or role with permissions to put objects into an S3 bucket

**Limitations**

Virtual private cloud (VPC) limitations apply to AWS PrivateLink for Amazon S3. For more information, see Interface endpoint properties and limitations and AWS PrivateLink quotas (AWS PrivateLink documentation).

AWS PrivateLink for Amazon S3 doesn't support the following:

- Federal Information Processing Standard (FIPS) endpoints
- Website endpoints
- Legacy global endpoints

**Architecture**

**Source technology stack**

- Hadoop cluster with DistCp installed

**Target technology stack**

- Amazon S3
- Amazon VPC
The diagram shows how the Hadoop administrator uses DistCp to copy data from an on-premises environment through a private network connection, such as AWS Direct Connect, to Amazon S3 through an Amazon S3 interface endpoint.

**Tools**

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
- **Apache Hadoop DistCp** – DistCp (distributed copy) is a tool used for copying large inter-clusters and intra-clusters. DistCp uses Apache MapReduce for distribution, error handling and recovery, and reporting.

</thead>
</table>
| Configure the name resolution.| You must configure the name resolution to allow Hadoop to access the Amazon S3 interface endpoint. You can't use the endpoint name itself. Instead, you must resolve `<your-bucket-name>.s3.<your-aws-region>.amazonaws.com` or `*.s3.<your-aws-region>.amazonaws.com`. For more information on this naming limitation, see [Introducing the Hadoop S3A client](https://hadoop.apache.org/docs/current/hadoop-project-dist/hadoop-common/IntroducingTheHadoopS3A.html) (Hadoop website). Choose one of the following configuration options:  
  * Use on-premises DNS to resolve the private IP address of the endpoint. You can override behavior for all buckets or selected buckets. For more information, see “Option 2: Access Amazon S3 using Domain Name System Response Policy Zones (DNS RPZ)” in [Secure hybrid access to Amazon S3 using AWS PrivateLink](https://aws.amazon.com/privatelink/).  
  * Configure on-premises DNS to conditionally forward traffic to the resolver inbound endpoints in the VPC. Traffic is forwarded to Route 53. For more information, see “Option 3: Forwarding DNS requests from on premises using Amazon Route 53 Resolver Inbound Endpoints” in [Secure hybrid access to Amazon S3 using AWS PrivateLink](https://aws.amazon.com/privatelink/).  
  * Edit the `/etc/hosts` file on all the nodes in your Hadoop cluster. This is a temporary solution for testing and isn't recommended for production. To edit the `/etc/hosts` file, add an entry for either `<your-bucket-name>.s3.<your-aws-region>.amazonaws.com` or `*.s3.<your-aws-region>.amazonaws.com`. | AWS administrator   |

<tr>
<td></td>
<td>hadoop distcp -Dfs.s3a.aws.credentials.provider=&quot;org.apache.hadoop.fs.s3a.TemporaryAWSCredentialsProvider&quot; \Dfs.s3a.access.key=&quot;${AWS_ACCESS_KEY_ID}&quot; \Dfs.s3a.secret.key=&quot;${AWS_SECRET_ACCESS_KEY}&quot; \Dfs.s3a.session.token=&quot;${AWS_SESSION_TOKEN}&quot; \Dfs.s3a.path.style.access=true \Dfs.s3a.connection.ssl.enabled=true -Dfs.s3a.endpoint=s3.&lt;your-aws-region&gt;.amazonaws.com \hdfs:///user/root/ s3a:///&lt;your-bucket-name&gt;</td>
<td>Migration engineer, AWS administrator</td>
</tr>
</tbody>
</table>

**Note:** The AWS Region of the endpoint isn’t automatically discovered when you use the DistCp command with AWS PrivateLink for Amazon S3. Hadoop 3.3.2 and later versions resolve this issue by enabling the option to explicitly set the AWS Region of the S3 bucket. For more information, see [S3A to add option fs.s3a.endpoint.region to set AWS region](Hadoop website). For more information on additional S3A providers, see [General S3A Client configuration](Hadoop website). For example, if you use encryption, you can add the following option to the series of commands above depending on your type of encryption:

-Dfs.s3a.server-side-encryption-algorithm=AES-256 [or SSE-C or SSE-KMS]
### Task Description

**Note:** To use the interface endpoint with S3A, you must create a DNS alias entry for the S3 Regional name (for example, s3.<your-aws-region>.amazonaws.com) to the interface endpoint. See the *Configure authentication for Amazon S3 section* for instructions. This workaround is required for Hadoop 3.3.2 and earlier versions. Future versions of S3A won’t require this workaround.

If you have signature issues with Amazon S3, add an option to use Signature Version 4 (SigV4) signing:

```bash
-Dmapreduce.map.java.opts="-Dcom.amazonaws.services.s3.enableV4=true"
```

<table>

### Use CloudEndure for disaster recovery of an on-premises database

*Created by Anuraag Deekonda (AWS)*

<table>
<thead>
<tr>
<th>Created by: AWS</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Modernization; Databases; Storage &amp; backup</th>
</tr>
</thead>
</table>

### Summary

This pattern uses CloudEndure Disaster Recovery and the CloudEndure Failback Client for disaster recovery (DR). It sets up DR for an on-premises data center host, using an Amazon Elastic Compute Cloud (Amazon EC2) instance.

You must use the CloudEndure Failback Client for replicating from a non-cloud or other cloud infrastructure to the Amazon Web Services (AWS) Cloud. After your disaster event is over, you will want to fail back your machines. CloudEndure prepares you for failback by reversing the direction of data replication from the target machine back to the source machine. The CloudEndure User Console treats the currently launched target machines as source machines. Replication is reversed from your selected target machines back to your original source infrastructure.

### Prerequisites and limitations

**Prerequisites**

...
• An active AWS account
• An on-premises database

Architecture

Source technology stack
• A database in an on-premises data center

Target technology stack
• A database on an EC2 instance (for a complete list of supported operating system versions, see Amazon EC2 FAQs)

Source and target network architecture

Tools
• CloudEndure Disaster Recovery – CloudEndure Disaster Recovery reduces downtime and data loss by providing fast, reliable recovery of physical, virtual, and cloud-based servers into AWS. CloudEndure Disaster Recovery continuously replicates your machines (including operating system, system state configuration, databases, applications, and files) into a low-cost staging area in your target AWS account and preferred Region. If there is a disaster, you can instruct CloudEndure Disaster Recovery to automatically launch thousands of machines in their fully provisioned state in minutes.

Deploy a React-based single-page application to Amazon S3 and CloudFront

Created by Jean-Baptiste Guillois (AWS)

Code repository: React-based CORS single-page application

Environment: Production

Technologies: Websites & web apps; Cloud-native; Serverless

Workload: All other workloads

AWS services: Amazon CloudFront; Amazon S3; Amazon API Gateway

Summary

A single-page application (SPA) is a web application implementation that loads a web document and updates it by using JavaScript APIs. Your customers can then use your website without loading entire pages from the server, which helps improve your website's performance and provides a more dynamic user experience.

This pattern provides a step-by-step approach and code to host a single-page application (SPA) written in React on Amazon Simple Storage Service (Amazon S3) and Amazon CloudFront. The pattern's sample SPA uses a REST API exposed by Amazon API Gateway to demonstrate cross-origin resource sharing (CORS) best practices.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• An integrated development environment (IDE), such as AWS Cloud9.
• Node.js and npm, installed and configured. For more information, see the Downloads section of the Node.js documentation.
• Yarn, installed and configured. For more information, see the Yarn documentation.
Architecture

Technology stack
- Amazon API Gateway
- Amazon CloudFront
- Amazon Route 53
- Amazon Simple Storage Service (Amazon S3)
- Amazon Identity and Access Management (IAM)
- Amazon CloudWatch
- AWS CloudTrail
- AWS CloudFormation

Tools
- **AWS Cloud9** – AWS Cloud9 is an IDE that offers a rich code-editing experience with support for several programming languages and runtime debuggers, and a built-in terminal. AWS Cloud9 contains a collection of tools that you use to code, build, run, test, and debug software, and helps you release software to the cloud.
- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- **Amazon CloudFront** – Amazon CloudFront is a web service that speeds up distribution of your static and dynamic web content, such as .html, .css, .js, and image files, to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations for lower latency and improved performance.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
• **Amazon Route 53** – Amazon Route 53 is a highly available and scalable cloud Domain Name System (DNS) web service that you can use to perform three main functions in any combination: domain registration, DNS routing, and health checking.

• **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

• **AWS CloudTrail** – AWS CloudTrail is an AWS service that helps you enable governance, compliance, and operational and risk auditing of your AWS account.

• **Amazon CloudWatch** – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables that you can measure for your resources and applications.

• **Amazon API Gateway** – Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.

**Code**

This pattern's sample application code is available in the GitHub [React-based CORS single-page application repository](https://github.com/aws-samples/react-cors-spa).

**Epics**

**Locally build and deploy your application**

| Deploy the AWS CloudFormation template. | 1. Sign in to the AWS Management Console, and then open the AWS CloudFormation console.  
2. Choose **Create Stack**, and then choose **With new resources (standard)**.  
3. Choose **Upload a template file**.  
4. Choose **Choose file**, choose the `react-cors-spa-stack.yaml` file from the cloned repository, and then choose **Next**.  
5. Enter a name for your stack, and then choose **Next**.  
6. Keep all default options, and then choose **Next**.  
7. Review the final settings for your stack, and then choose **Create stack**. | App developer, AWS DevOps   |
| Customize your application source files. | 1. After your stack is deployed, open the **Output** tab and identify the APIEndpoint URL and Bucket name.  
2. Copy the API endpoint URL.  
3. Navigate to `<project_root>/src/App.js`, and then paste the URL into the APIEndPoint variable value on line 26 of the `App.js` file. | App developer              |
| Build the application package. | In your project directory, run the `yarn build` command to build the application package.                                                                                                                  | App developer              |
| Deploy the application package. | 1. Open the Amazon S3 console.  
2. Identify and choose the S3 bucket that you created earlier.  
3. Choose **Upload**, and then choose **Add files**.  
4. Choose the content of your build folder.  
5. Choose **Add folder**, and then choose the static directory.  
**Important:** Don't choose | App developer, AWS DevOps   |
Embed an Amazon QuickSight dashboard in a local Angular application

### Task 1: Embed an Amazon QuickSight dashboard in a local Angular application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Task Description
Choose the contents; choose the directory. 6. Choose **Upload** to upload the files and directory to your S3 bucket.

#### Test the application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Test Task Description
Access and test the application.

1. Open the Amazon CloudFront console, and then choose **Distributions**.
2. Choose the relevant distribution ID, choose the **Distribution domain name**, and then copy the URL.
3. Open a browser window, and then paste the URL to access the application.

#### Clean up the resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Clean up Task Description
Delete the S3 bucket contents.

1. Open the Amazon S3 console and choose the bucket that you created earlier.
2. Choose **Empty** to delete the bucket's contents.

Delete the AWS CloudFormation stack.

1. Open the AWS CloudFormation console and choose the stack that you created earlier.
2. Choose **Delete** to delete the stack and all related resources.

---

**Created by Sean Griffin (AWS)**
Summary

This pattern provides guidance for embedding an Amazon QuickSight dashboard into a locally hosted Angular application for development or testing. The embedded analytics feature in Amazon QuickSight doesn't support this functionality natively. It requires an Amazon QuickSight account with an existing dashboard and knowledge of Angular.

When you work with embedded Amazon QuickSight dashboards, you would typically have to host your application on a web server to view the dashboard. This makes development more difficult, because you have to continuously push your changes to the web server to make sure everything is behaving correctly. This pattern shows how to run a locally hosted server and use Amazon QuickSight embedded analytics to make the development process easier and more streamlined.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- An active QuickSight account with session capacity pricing
- QuickSight Embedding SDK installed
- Angular CLI installed
- Familiarity with Angular
- mkcert installed

Limitations

- This pattern provides guidance on embedding a QuickSight dashboard by using the ANONYMOUS (publicly accessible) authentication type. If you are using AWS Identity and Access Management (IAM) or QuickSight authentication with your embedded dashboards, the provided code won't apply. However, the steps for hosting the Angular application in the Epics section are still valid.

Architecture

Technology stack

- Angular frontend
- AWS Lambda and Amazon API Gateway backend

Architecture

In this architecture, the HTTP APIs in API Gateway enable the local Angular application to call the Lambda function. The Lambda function returns the URL for embedding the Quicksight dashboard.
Automation and scale

You can automate the backend deployment by using AWS CloudFormation or AWS Serverless Application Model (AWS SAM).

Tools

- **Angular CLI** – The Angular CLI is a command-line interface tool that you use to initialize, develop, scaffold, and maintain Angular applications directly from a command shell.
- **QuickSight Embedding SDK** – You use this SDK to embed QuickSight dashboards into your HTML.
- **mkcert** – mkcert is a simple tool for creating locally trusted development certificates. It requires no configuration. mkcert is required because QuickSight allows only HTTPS requests for embedding dashboards.

AWS services

- **Amazon API Gateway** – Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- **Amazon QuickSight** – Amazon QuickSight is a business analytics service for building visualizations, performing ad hoc analyses, and getting business insights from your data.

Code

See the *Attachments* section to get the Lambda code for this pattern.

<th>Skills required</th>
</tr>
</thead>
</table>
| Create the Lambda function. | 1. On the Lambda console, open the [Functions page](#).  
2. Choose Create Function.  
3. Under Basic information, do the following:  
   a. Choose Author from Scratch.  
   b. For Function name, enter get-qs-embed-url.  
   c. For Runtime, choose Python 3.9.  
4. Choose Create Function.  
5. Copy the code from the attached get-qs-embed-url.py file into the Lambda function Code source tab.  
6. Deploy your function.  
7. Add DASHBOARD_ID as an environment variable to your Lambda function:  
   a. On the Configuration tab, choose Environment variables, Edit, Add environment variable.  
   b. Add an environment variable with the key DASHBOARD_ID.  
   c. To get the value of your DASHBOARD_ID, navigate to your dashboard in QuickSight and copy the UUID at the end of the URL in your browser. For example, if the URL is https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/<dashboard-id>, specify the <dashboard-id> part of the URL as the key value.  
   d. Choose Save.  
8. Modify the execution role of the Lambda function and add the QuicksightGetDashboardEmbedUrl policy to it.  
   a. On the Configuration tab, choose Permissions, and then choose your role name.                                                                 | App developer   |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>b.</td>
<td>Choose <strong>Attach policies</strong>, search for QuicksightGetDashboardEmbedUrl, select its checkbox, and then choose <strong>Attach policy</strong>.</td>
<td></td>
</tr>
<tr>
<td>9.</td>
<td>Create and run a test event. You can use the &quot;Hello World&quot; template, because the function won't use any of the data in the test event.</td>
<td></td>
</tr>
<tr>
<td>a.</td>
<td>Choose the <strong>Test</strong> tab.</td>
<td></td>
</tr>
<tr>
<td>b.</td>
<td>Give your test event a name, and then choose <strong>Save changes</strong>.</td>
<td></td>
</tr>
<tr>
<td>c.</td>
<td>To test your Lambda function, choose <strong>Test</strong>. The response should look similar to this:</td>
<td></td>
</tr>
</tbody>
</table>

```json
{
  "statusCode": 200,
  "body": "https://us-east-1.quicksight.aws.amazon.com/embed/f1acc07866783b9a4543a05ba929b3a/dashboards/8a123480-8d77-4f71-92a0-0e736968b99b1?code=AYABeNod..."
}
```
Create an API in API Gateway.

1. On the API Gateway console, choose Create API, and then choose HTTP API, Build.
   a. Choose Add integration, and then choose the Lambda function you just created.
   b. For API name, enter qs-embed-api.
   c. Choose Next, and then change ANY to GET for the /get-qs-embed-url route.
   d. Choose Next, Next, and then Create.

2. Navigate to the CORS section of your API and choose Configure. Configure the following:
   - Access Control Allow Origin: https://my-qs-app.net:4200
   - Access Control Allow Headers: *
   - Access Control Allow Methods: *
   - Access Control Allow Credentials: YES

3. From the upper-left corner of the screen, navigate to the API qs-embed-api. Note the Invoke URL of the $default stage under Stages for qs-embed-api.

   **Note:** my-qs-app.net can be any domain. If you want to use a different domain name, make sure to update the Allow Origin information in the second step, and change my-qs-app.net in the following steps.

Create the Angular application

1. Create the application with the Angular CLI.
   **Note:** The following commands are for Unix or MacOS machines.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>To create the application, use the following commands:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ng new quicksight-app --defaults</td>
<td></td>
</tr>
<tr>
<td></td>
<td>cd quicksight-app/src/app</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ng g c dashboard</td>
<td></td>
</tr>
<tr>
<td></td>
<td>npm i amazon-quicksight-embedding-sdk</td>
<td></td>
</tr>
<tr>
<td></td>
<td>echo &quot;declare module 'amazon-quicksight-embedding-sdk';&quot; &gt;&gt; types.d.ts</td>
<td></td>
</tr>
<tr>
<td>2.</td>
<td>Navigate to your src/environments/environment.ts file, and add apiUrl and the URL of your API Gateway to it:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>export environment = { production: false, apiUrl: &quot;&lt;Invoke URL from previous steps&gt;&quot; };</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Add code to your dashboard.component.ts file.</td>
<td>Add the following code to the src/app/dashboard/dashboard.component.ts file:</td>
<td>App developer</td>
</tr>
</tbody>
</table>

```typescript
import { Component, OnInit } from '@angular/core';
import { HttpClient } from '@angular/common/http';
import * as QuicksightEmbedding from 'amazon-quicksight-embedding-sdk';
import { environment } from '../../environments/environment';

@Component({
  selector: 'app-dashboard',
  templateUrl: './dashboard.component.html',
  styleUrls: ['./dashboard.component.css']
})
export class DashboardComponent implements OnInit {
  constructor(private http: HttpClient) { }
  dashboard: any;
  ngOnInit() {
    this.GetDashboardURL();
  }
  public async GetDashboardURL() {
    const url = await this.http.get(environment.apiUrl + 'get-qs-embed-url').toPromise()
    this.Dashboard(url);
  }
  public Dashboard(embeddedURL: any) {
    var containerDiv = document.getElementById('dashboardContainer');
    var options = {
      url: embeddedURL,
      container: containerDiv,
      scrolling: "yes",
      height: "850px",
      width: "100%"
    };
    this.dashboard = QuicksightEmbedding.embedDashboard(options);
  }
}
### Host the Angular application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure mkcert.         | **Note:** The following commands are for Unix or MacOS machines. If you're using Windows, see the *Additional information (p. 2403)* section for the equivalent echo command.  
1. To create a local certificate authority (CA) on your machine:  
   ```bash  
mkcert -install  
``` | App developer |
| Modify your app.component.html file to load your dashboard component. | 1. Delete all the existing code in the `src/app/app.component.html` file.  
2. Add the following:  
   ```html  
   <app-dashboard></app-dashboard>  
   ``` | App developer |
| Import HttpClientModule into your app.module.ts file. | 1. At the top of the `src/app/app.module.ts` file, add:  
   ```typescript  
   import { HttpClientModule } from '@angular/common/http';  
   ```  
2. Add HttpClientModule as an import after BrowserModule. | App developer |

AWS Prescriptive Guidance Patterns  
Epics
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.</td>
<td>Configure my-qs-app.net to always redirect to your local PC:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>echo &quot;127.0.0.1 my-qs-app.net&quot;</td>
<td>AWS administrator</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Make sure you're in the src/ directory of the Angular project:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>mkcert my-qs-app.net 127.0.0.1</td>
<td></td>
</tr>
</tbody>
</table>

**Configure QuickSight to allow your domain.**

1. In QuickSight, choose your name in the upper-right corner, and then choose **Manage Quicksight**.
2. Navigate to **Domains and Embedding**.
3. Add https://my-qs-app.net:4200 as an allowed domain.

**Start a local Angular development server.**

Run the following command:

```
ng serve --host my-qs-app.net --port 4200 --ssl --ssl-key ./src/my-qs-app.net-key.pem --ssl-cert ./src/my-qs-app.net.pem -o
```

This enables Secure Sockets Layer (SSL) with the custom certificate you created earlier.

When the build is complete, it opens a browser window and you can view your embedded Amazon QuickSight dashboard hosted locally in Angular.

**Additional information**

If you're using Windows, run the Command Prompt window as an administrator, and configure my-qs-app.net to always redirect to your local PC by using the following command:

```
echo 127.0.0.1 my-qs-app.net >> %WINDIR%\System32\Drivers\Etc\Hosts
```
