- Attachments 128
- Build a cold start forecasting model using SageMaker AI DeepAR 129
  - Summary 129
  - Prerequisites and limitations 129
  - Architecture 130
  - Tools 132
  - Best practices 132
  - Epics 133
  - Related resources 135
- Build an MLOps workflow using SageMaker AI and Azure DevOps 136
  - Summary 136
  - Prerequisites and limitations 136
  - Architecture 137
  - Tools 140
  - Best practices 141
  - Epics 141
  - Troubleshooting 150
  - Related resources 151
- Configure logging in Amazon Bedrock using CloudFormation 153
  - Summary 153
  - Prerequisites and limitations 153
  - Architecture 154
  - Tools 156
  - Epics 157
  - Related resources 159
- Create Docker containers in SageMaker for model training in Step Functions 161
  - Summary 161
  - Prerequisites and limitations 161
  - Architecture 162
  - Tools 162
  - Epics 163
  - Related resources 175
- Create access controls in Amazon EKS with Amazon Bedrock agents 176
  - Summary 176
  - Prerequisites and limitations 176
  - Architecture 177

- Tools 179
- Best practices 180
- Epics 180
- Troubleshooting 197
- Related resources 198

Deploy a RAG use case on AWS 199
- Summary 199
- Prerequisites and limitations 199
- Architecture 200
- Tools 202
- Best practices 204
- Epics 204
- Related resources 208
- Additional information 208

Deploy multiple pipeline model objects in a single SageMaker endpoint 210
- Summary 210
- Prerequisites and limitations 210
- Architecture 211
- Tools 212
- Epics 213
- Related resources 223

Develop AI chat-based assistants by using RAG and ReAct prompting 224
- Summary 224
- Prerequisites and limitations 225
- Architecture 226
- Tools 230
- Best practices 232
- Epics 232
- Troubleshooting 238
- Related resources 238
- Additional information 239

Develop a chat-based assistant using Amazon Bedrock 240
- Summary 240
- Prerequisites and limitations 240
- Architecture 241
- Tools 244

- Best practices ... 245
- Epics ... 246
- Related resources ... 249
- Additional information ... 250
- Document institutional knowledge from voice inputs ... 253
  - Summary ... 253
  - Prerequisites and limitations ... 253
  - Architecture ... 254
  - Tools ... 256
  - Best practices ... 257
  - Epics ... 258
  - Related resources ... 263
- Generate personalized recommendations using Amazon Personalize ... 265
  - Summary ... 265
  - Prerequisites and limitations ... 265
  - Architecture ... 265
  - Tools ... 267
  - Epics ... 268
  - Related resources ... 271
  - Additional information ... 272
- Streamline ML workflows using SageMaker AI and Hydra ... 276
  - Summary ... 276
  - Prerequisites and limitations ... 276
  - Architecture ... 277
  - Tools ... 279
  - Best practices ... 280
  - Epics ... 280
  - Troubleshooting ... 287
  - Related resources ... 287
  - Additional information ... 287
- Train and deploy a custom GPU-supported ML model ... 289
  - Summary ... 289
  - Prerequisites and limitations ... 289
  - Architecture ... 290
  - Tools ... 290
  - Epics ... 291

Related resources ... 306
Additional information ... 306
... 309

.... 383
Summary 383
Prerequisites and limitations 383
Architecture 383
Tools 384
Epics 385
Related resources 390
Automate data ingestion from AWS Data Exchange into Amazon S3 391
Summary 391
Prerequisites and limitations 391
Architecture 391
Tools 392
Epics 393
Related resources 395
Attachments 395
Automate encryption enforcement in AWS Glue 396
Summary 396
Prerequisites and limitations 396
Architecture 396
Tools 398
Best practices 398
Epics 399
Related resources 401
Build a data pipeline to process Google Analytics data using the AWS DataOps Development Kit 402
Summary 402
Prerequisites and limitations 402

- Architecture ... 402
- Tools ... 404
- Epics ... 405
- Troubleshooting ... 407
- Related resources ... 407
- Additional information ... 407

Build a video processing pipeline ... 410
- Summary ... 410
- Prerequisites and limitations ... 410
- Architecture ... 411
- Tools ... 412
- Epics ... 412
- Related resources ... 420
- Additional information ... 420
- Attachments ... 421

Build an ETL pipeline from Amazon S3 to Amazon Redshift using AWS Glue ... 422
- Summary ... 422
- Prerequisites and limitations ... 422
- Architecture ... 423
- Tools ... 424
- Epics ... 425
- Related resources ... 431
- Additional information ... 432

Build an enterprise data mesh with Amazon DataZone ... 433
- Summary ... 433
- Prerequisites and limitations ... 433
- Architecture ... 434
- Tools ... 436
- Epics ... 437
- Related resources ... 449
- Additional information ... 450

Calculate value at risk (VaR) by using AWS services ... 452
- Summary ... 452
- Prerequisites and limitations ... 452
- Architecture ... 453
- Tools ... 455

Best practices 456
Epics 456
Related resources 459
Configure cross-account access to a shared AWS Glue Data Catalog 460
Summary 460
Prerequisites and limitations 460
Architecture 460
Tools 462
Epics 462
Related resources 475
Additional information 475
Convert NORMALIZE to Amazon Redshift SQL 476
Summary 476
Prerequisites and limitations 476
Architecture 476
Tools 477
Epics 482
Related resources 482
Convert RESET WHEN to Amazon Redshift SQL 483
Summary 483
Prerequisites and limitations 483
Architecture 483
Tools 484
Epics 488
Related resources 488
Deploy and manage a serverless data lake on AWS 490
Summary 490
Prerequisites and limitations 490
Architecture 491
Tools 493
Epics 494
Related resources 496
..... 498
Summary 498
Prerequisites and limitations 498

Tools ... 499
Epics ... 500
Related resources ... 503
Attachments ... 503
Ensure Amazon EMR logging to Amazon S3 ... 504
Summary ... 504
Prerequisites and limitations ... 504
Architecture ... 505
Tools ... 506
Epics ... 506
Related resources ... 509
Attachments ... 509
Generate test data using AWS Glue ... 510
Summary ... 510
Prerequisites and limitations ... 510
Architecture ... 511
Tools ... 511
Best practices ... 512
Epics ... 512
Related resources ... 523
Additional information ... 524
Ingest IoT data directly into Amazon S3 ... 528
Summary ... 528
Prerequisites and limitations ... 528
Architecture ... 529
Tools ... 530
Best practices ... 530
Epics ... 531
Troubleshooting ... 538
Related resources ... 539
Additional information ... 539
Launch a Spark job in Amazon EMR using a Lambda function ... 544
Summary ... 544
Prerequisites and limitations ... 544
Architecture ... 545
Tools ... 545

Epics ... 546
Related resources ... 549
Additional information ... 550
Attachments ... 552
Migrate Apache Cassandra workloads to Amazon Keyspaces ... 553
Summary ... 553
Prerequisites and limitations ... 553
Architecture ... 553
Tools ... 554
Best practices ... 555
Epics ... 555
Troubleshooting ... 568
Related resources ... 568
Additional information ... 568
Migrate Hadoop data to Amazon S3 by using WANdisco LiveData Migrator ... 570
Summary ... 570
Prerequisites and limitations ... 570
Architecture ... 571
Epics ... 572
Related resources ... 577
Additional information ... 577
Migrate Oracle Business Intelligence 12C to the AWS Cloud ... 579
Summary ... 579
Prerequisites and limitations ... 579
Architecture ... 580
Tools ... 582
Epics ... 583
Related resources ... 596
Additional information ... 596
Migrate an ELK Stack to the AWS Cloud ... 601
Summary ... 601
Prerequisites and limitations ... 601
Architecture ... 603
Tools ... 606
Epics ... 607
Related resources ... 614

Additional information ... 616
Migrate data to AWS using Starburst ... 617
Summary ... 617
Prerequisites and limitations ... 617
Architecture ... 617
Tools ... 621
Epics ... 622
Related resources ... 625
Optimize the ETL ingestion of input file size ... 626
Summary ... 626
Prerequisites and limitations ... 626
Architecture ... 626
Tools ... 628
Epics ... 628
Related resources ... 631
Additional information ... 631
Orchestrate an ETL pipeline with Step Functions ... 632
Summary ... 632
Prerequisites and limitations ... 632
Architecture ... 633
Tools ... 634
Epics ... 635
Troubleshooting ... 642
Related resources ... 643
Additional information ... 643
Perform ML analytics using Amazon Redshift ML ... 646
Summary ... 646
Prerequisites and limitations ... 646
Architecture ... 647
Tools ... 648
Epics ... 649
Related resources ... 653
Query Amazon DynamoDB by using Amazon Athena ... 654
Summary ... 654
Prerequisites and limitations ... 654
Architecture ... 655

- Tools ... 656
- Epics ... 657
- Troubleshooting ... 660
- Related resources ... 661

Query DynamoDB tables using Athena ... 662
- Summary ... 662
- Prerequisites and limitations ... 662
- Architecture ... 663
- Tools ... 664
- Epics ... 664
- Related resources ... 673
- Additional information ... 673

Set up a minimum viable data space ... 675
- Summary ... 675
- Prerequisites and limitations ... 676
- Architecture ... 677
- Tools ... 679
- Best practices ... 680
- Epics ... 681
- Troubleshooting ... 735
- Related resources ... 735
- Additional information ... 735

Set up language-specific sorting for Amazon Redshift query results ... 740
- Summary ... 740
- Prerequisites and limitations ... 740
- Architecture ... 740
- Tools ... 741
- Epics ... 741
- Related resources ... 745
- Additional information ... 746

Subscribe a Lambda function to event notifications from cross-Region S3 buckets ... 750
- Summary ... 750
- Prerequisites and limitations ... 750
- Architecture ... 750
- Tools ... 752
- Epics ... 752

Related resources ... 756
Three AWS Glue job types for converting data ... 758
Summary ... 758
Prerequisites and limitations ... 758
Architecture ... 758
Tools ... 759
Epics ... 760
Related resources ... 763
Additional information ... 763
Attachments ... 769
Visualize Amazon Redshift audit logs using Athena and QuickSight ... 770
Summary ... 770
Prerequisites and limitations ... 770
Architecture ... 771
Tools ... 771
Epics ... 772
Related resources ... 775
Attachments ... 775
Visualize IAM credential reports using Amazon QuickSight ... 776
Summary ... 776
Prerequisites and limitations ... 776
Architecture ... 777
Tools ... 778
Epics ... 779
Additional information ... 785
More patterns ... 787
Compute ... 789
Containers & microservices ... 790
Access Amazon Neptune from Amazon EKS ... 792
Access container applications on Amazon ECS ... 804
Access container applications on Amazon ECS with an AWS Fargate launch type ... 822
Access container applications privately on Amazon EKS ... 838
Activate mTLS in App Mesh on Amazon EKS ... 846
Automate backups for Amazon RDS for PostgreSQL DB instances ... 854
Automate deployment of Node Termination Handler ... 867
Automatically build and deploy a Java application to Amazon EKS ... 882

Create an Amazon ECS task definition on EC2 instances using Amazon EFS 906
Deploy Lambda functions with container images 912
Deploy Java microservices on Amazon ECS using AWS Fargate 921
Deploy Kubernetes packages using Amazon EKS and Helm 928
Deploy a Java microservice on Amazon EKS and expose it with an Application Load Balancer 939
Deploy a clustered application to Amazon ECS by using AWS Copilot 952
Deploy a gRPC-based application on Amazon EKS 963
Deploy and debug Amazon EKS clusters 977
Deploy containers by using Elastic Beanstalk 1006
Generate a static outbound IP address using Lambda and Amazon VPC 1013
Identify duplicate container images automatically 1028
Install SSM Agent on Amazon EKS worker nodes 1058
Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands 1064
Migrate NGINX Ingress Controllers for EKS Auto Mode 1071
Migrate container workloads from ARO to ROSA 1091
Place Kubernetes Pods on compatible nodes in Amazon EKS 1109
Replicate filtered Amazon ECR container images across accounts or Regions 1127
Rotate credentials without restarting containers 1144
Run Amazon ECS tasks on Amazon WorkSpaces 1151
Run an ASP.NET web API Docker container on AWS 1162
Run message-driven workloads using AWS Fargate 1175
Run stateful workloads with persistent data storage 1185
Set up auto scaling using Amazon EKS Pod Identity and KEDA 1209
.... 1233
Use mutual TLS in Amazon ECS with ALB 1255
More patterns 1285
Serverless 1287
Build a React Native app using AWS Amplify 1288
Centrally manage tenants across multiple SaaS products 1307
Consolidate Amazon S3 presigned URL generation and object downloads 1320
Create a cross-account Amazon EventBridge connection 1337
Deliver DynamoDB records to Amazon S3 1352
Implement path-based API versioning by using API Gateway 1359
Import the psycopg2 library to AWS Lambda 1371

Integrate API Gateway with Amazon SQS 1380
Process APIs asynchronously with AWS Lambda 1396
Process APIs asynchronously with Amazon DynamoDB Streams 1406
Process APIs asynchronously with Amazon SQS 1416
Run Systems Manager Automation tasks synchronously from Step Functions 1427
Run parallel reads of S3 objects with AWS Lambda 1442
Send telemetry data from Lambda to OpenSearch 1457
Set up a serverless cell router 1474
Set up private access to an Amazon S3 bucket 1493
Troubleshoot Step Functions states 1500
Use a serverless approach to chain AWS services together 1510
More patterns 1516
Networking 1518
Automate peering for AWS Transit Gateway 1519
Centralize network connectivity using AWS Transit Gateway 1526
Configure HTTPS encryption for Oracle JD Edwards EnterpriseOne by using an Application Load Balancer 1533
Connect to Application Migration Service data and control planes over a private network 1544
Create Infoblox objects using AWS CloudFormation custom resources 1559
Customize CloudWatch alerts for Network Firewall 1573
Deploy resources in a Wavelength Zone using Terraform 1593
Migrate DNS records in bulk to a Route 53 private hosted zone 1603
Modify HTTP headers when you migrate from F5 to an Application Load Balancer on AWS 1613
Report Network Access Analyzer findings in multiple AWS accounts 1619
Set up DNS resolution for hybrid networks in a multi-account AWS environment 1651
..... 1669
View AWS Network Firewall logs and metrics using Splunk 1675
More patterns 1686
Content delivery 1687
Send AWS WAF logs to Splunk using Firehose 1688
Serve static content in an S3 bucket through a VPC by using CloudFront 1697
More patterns 1707
Databases & storage 1708
Databases 1709

Access on-premises SQL Server data using linked servers ... 1711
Add HA to Oracle PeopleSoft on AWS ... 1717
Assess query performance for migrating SQL Server databases to MongoDB Atlas on AWS ... 1741
Automate blue/green deployments of Aurora global databases with IaC ... 1752
Automate cross-account replication of Amazon RDS instances ... 1786
Automate database tasks with AWS Lambda and Task Scheduler ... 1801
Automate failover and failback with DR Orchestrator Framework ... 1813
Automatically back up SAP HANA databases ... 1842
Automatically generate PynamoDB models and CRUD functions for DynamoDB ... 1850
Block public access to Amazon RDS ... 1859
Configure cross-account Amazon DynamoDB access ... 1867
Configure read-only routing in an Always On availability group ... 1882
Connect by using an SSH tunnel in pgAdmin ... 1892
Convert JSON Oracle queries into PostgreSQL database SQL ... 1897
Copy Amazon DynamoDB tables across accounts ... 1928
Copy Amazon DynamoDB tables across accounts ... 1935
Create cost and usage reports for Amazon RDS and Amazon Aurora ... 1948
Deploy SQL Server FCIs on Amazon EC2 and Amazon FSx ... 1956
Emulate Oracle PL/SQL associative arrays in Amazon Aurora and Amazon RDS ... 1973
Enable encrypted connections for PostgreSQL DB instances ... 1984
Encrypt an existing Amazon RDS for PostgreSQL DB instance ... 1993
Enforce automatic tagging of Amazon RDS databases at launch ... 2001
Estimate DynamoDB costs ... 2007
Estimate storage costs for an Amazon DynamoDB table ... 2019
Estimate the Amazon RDS engine size for an Oracle database using AWR reports ... 2024
Export Amazon RDS for SQL Server tables to an S3 bucket ... 2054
Handle anonymous blocks in Dynamic SQL statements ... 2066
Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible ... 2074
Help enforce DynamoDB tagging ... 2081
Implement cross-Region DR ... 2087
Migrate 100+ argument Oracle functions to PostgreSQL ... 2104
Migrate SAP HANA to AWS using HSR ... 2110
Migrate SQL Server Always On availability group using AWS MGN ... 2124
Migrate SQL Server to AWS using distributed availability groups ... 2135
Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS ... 2146

Monitor Amazon Aurora for encryption ... 2155
Monitor GoldenGate logs by using Amazon CloudWatch ... 2161
Replatform Oracle Database EE to Amazon RDS for Oracle SE2 ... 2174
Replicate mainframe databases to AWS by using Precisely Connect ... 2185
Schedule jobs for Amazon RDS and Aurora PostgreSQL ... 2207
Send notifications for RDS for SQL Server using an SMTP server ... 2213
Set up DR for SAP on IBM Db2 on AWS ... 2226
Set up a CI/CD pipeline for database migration by using Terraform ... 2248
Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom ... 2258
Set up data replication between RDS for MySQL and MySQL on Amazon EC2 ... 2267
Transition roles for an Oracle PeopleSoft application ... 2273
Unload data from Amazon Redshift across accounts ... 2307
Database migration patterns by workload ... 2337
More patterns ... 2348
Storage & backup ... 2353
Allow EC2 instances write access to S3 buckets in AMS ... 2354
Automate data stream ingestion into a Snowflake database ... 2360
Automatically encrypt EBS volumes ... 2371
Back up Sun SPARC servers in the Charon-SSP emulator on AWS ... 2383
Back up and archive data to Amazon S3 with Veeam ... 2405
Configure NetBackup for VMware Cloud on AWS ... 2431
Copy S3 objects between accounts and Regions by using AWS CLI ... 2439
Copy S3 objects between accounts and Regions by using S3 Batch Replication ... 2454
Migrate Hadoop data to Amazon S3 using DistCp and AWS PrivateLink for Amazon S3 .. 2467
More patterns ... 2482
Developer tools ... 2484
DevOps ... 2485
Automate AWS infrastructure operations ... 2488
Automate CloudFront updates for changes in load balancer endpoints ... 2498
Automate CodeGuru reviews for AWS CDK Python applications ... 2508
Automate AWS resource assessment ... 2520
Automate SAP systems installation ... 2535
Automate Service Catalog portfolio and product deployment using AWS CDK ... 2547
Automate deletion of CloudFormation stacks ... 2567
Automate dynamic pipeline management to deploy hotfix solutions ... 2580
Automate ingestion of Amazon MWAA custom metrics ... 2609

Automate management of Amazon Lex resources using the AWS CDK and CloudFormation 2626
Automate stack set deployment by using AWS CodePipeline and AWS CodeBuild 2646
Automatically attach a managed policy for Systems Manager to EC2 instance profiles 2677
Automatically build CI/CD pipelines and Amazon ECS clusters for microservices 2693
Build a loosely coupled architecture with microservices 2706
Build and push Docker images to Amazon ECR 2718
Build and test iOS apps with AWS services 2724
Check AWS CDK applications or CloudFormation templates for best practices by using rule packs 2731
Configure mutual TLS for applications on Amazon EKS 2736
Create AppStream 2.0 resources using AWS CloudFormation 2748
Create a custom log parser for Amazon ECS using Firelens 2754
Create a pipeline and AMI using CodePipeline and HashiCorp Packer 2764
Create dynamic CI pipelines for Java and Python projects 2771
Deploy CloudWatch Synthetics canaries 2787
Deploy a CI/CD pipeline for Java microservices on Amazon ECS 2794
Deploy a ChatOps solution to manage SAST scan results 2804
Deploy agentic systems on Amazon Bedrock with CrewAI 2823
.... 2841
Deploy an Amazon EKS cluster from AWS Cloud9 using an EC2 instance profile 2846
Deploy code in multiple AWS Regions 2858
Deploy updates to on-premises EC2 instances using CodePipeline 2870
Deploy workloads from Azure DevOps pipelines to private Amazon EKS clusters 2879
Execute Amazon Redshift SQL queries 2912
Export AWS Backup reports as a CSV file 2925
Export Amazon EC2 instance tags to a CSV file 2934
Generate an AWS CloudFormation template containing AWS Config managed rules 2941
Give SageMaker notebook instances cross-account access to a CodeCommit repository 2948
Implement a GitHub Flow branching strategy 2959
Implement a Gitflow branching strategy 2969
Implement a Trunk branching strategy 2983
Implement centralized custom Checkov scanning 2990
Implement diagnostics with K8sGPT and Amazon Bedrock 3001
Initiate different CI/CD pipelines after detecting changes in a monorepo 3016
Integrate a Bitbucket repository with AWS Amplify 3034

Launch a CodeBuild project across AWS accounts using Lambda 3043
Manage Multi-AZ failover for EMR clusters by using Application Recovery Controller 3058
Manage blue/green deployments of microservices to multiple accounts and Regions 3073
Monitor Amazon ECR repositories for wildcard permissions 3108
Optimize multi-account serverless deployments 3113
Provision AWS Service Catalog products using GitHub Actions 3133
Provision least-privilege IAM roles 3145
Publish Amazon CloudWatch metrics to a CSV file 3159
Remove Amazon EC2 entries across AWS accounts from AWS Managed Microsoft AD 3165
Remove Amazon EC2 entries in same AWS account from AWS Managed Microsoft AD 3183
Run unit tests for Python ETL jobs in AWS Glue 3194
Set up Helm v3 charts in Amazon S3 3204
Set up a CI/CD pipeline with CodePipeline 3213
Set up centralized logging at scale using Terraform 3228
Set up end-to-end encryption for applications on Amazon EKS 3253
Simplify Amazon EKS multi-tenant application deployment 3267
Subscribe multiple email endpoints to an SNS topic 3289
Use the AWS Fargate WaitCondition hook construct 3294
Use third-party Git repos in AWS CodePipeline 3306
Validate Terraform configurations by using AWS CodePipeline 3316
More patterns 3333
Infrastructure 3336
Access a bastion host using Session Manager and Instance Connect 3338
Centralize DNS resolution by using AWS Managed Microsoft AD 3355
Centralize monitoring by using Observability Access Manager 3367
Check EC2 instances for mandatory tags at launch 3382
Clean up AFT resources safely after state file loss 3388
Connect to an EC2 instance using Session Manager 3402
Create a pipeline in AWS Regions that don't support AWS CodePipeline 3411
Customize default role names by using AWS CDK aspects and escape hatches 3419
Deploy a Cassandra cluster on Amazon EC2 with private static IPs 3428
Extend VRFs to AWS using Transit Gateway Connect 3436
Get Amazon SNS notifications for state changes to AWS KMS keys 3454
Preserve routable IP space in multi-account VPC designs for non-workload subnets 3461
Provision a Terraform product in Service Catalog from a repo 3467
Register multiple AWS accounts with a single email address 3487

Set up DNS resolution for hybrid networks in a single-account AWS environment 3505
Set up UiPath RPA bots automatically on Amazon EC2 3511
Set up a highly available PeopleSoft architecture on AWS 3529
Set up disaster recovery for Oracle JD Edwards EnterpriseOne 3558
Set up drift detection and reporting 3585
Successfully import an S3 bucket as a CloudFormation stack 3591
Synchronize Amazon EFS file systems in different Regions 3602
Test AWS infrastructure using LocalStack and Terraform Tests 3610
Upgrade SAP Pacemaker clusters from ENSA1 to ENSA2 3619
Use consistent Availability Zones in VPCs across different accounts 3642
Use user IDs in IAM policies 3649
Validate Account Factory for Terraform code locally 3660
More patterns 3680
Web & mobile apps 3684
Authenticate React web application users 3685
Continuously deploy an Amplify web application 3696
Create a React app by using AWS Amplify and Amazon Cognito 3705
Create a portal for micro-frontends 3721
Deploy a React-based SPA to Amazon S3 and CloudFront 3753
Deploy an Amazon API Gateway API using private endpoints 3761
Embed an Amazon QuickSight dashboard in a local Angular application 3769
Explore web app development with Green Boost 3790
Run unit tests by using AWS CodeBuild 3818
Structure a Python project in hexagonal architecture 3827
More patterns 3853
IoT 3855
Extract and query AWS IoT SiteWise metadata attributes 3856

Modernization 5220
Analyze and visualize software architecture in CAST Imaging 5221
Assess application readiness before migrating to AWS by using CAST Highlight 5233
Automatically archive expired DynamoDB data to Amazon S3 5257
Build a multi-tenant serverless architecture in Amazon OpenSearch Service 5274
Deploy multiple-stack applications 5327
Deploy nested applications using AWS SAM 5338

- Implement the serverless saga pattern by using AWS Step Functions ... 5348
- Manage on-premises container applications with Amazon ECS Anywhere ... 5364
- Modernize ASP.NET Web Forms applications on AWS ... 5375
- Run event-driven workloads with AWS Fargate ... 5391
- Tenant onboarding in SaaS architecture ... 5401
- Use CQRS and event sourcing ... 5426
- More patterns ... 5455

Mainframes ... 5457

- Access AWS services from IBM z/OS by installing the AWS CLI ... 5459
- Back up and archive mainframe data to Amazon S3 ... 5480
- Build COBOL Db2 programs by using AWS Mainframe Modernization and AWS CodeBuild ... 5506
- Build a Micro Focus Enterprise Server PAC ... 5530
- Build a mainframe file viewer in the AWS Cloud ... 5551
- Containerize modernized Blu Age applications ... 5568
- Convert EBCDIC data to ASCII on AWS ... 5578
- Convert mainframe EBCDIC files to ASCII files using AWS Lambda ... 5597
- Convert mainframe data files with complex record layouts ... 5618
- Deploy an environment for containerized apps ... 5635
- Generate Db2 z/OS data insights ... 5646
- Generate insights by using AWS Mainframe Modernization and Amazon Q in QuickSight 5701
- Implement Microsoft Entra ID authentication for AWS Blu Age ... 5723
- Integrate Stonebranch Universal Controller with AWS ... 5741
- Migrate and replicate VSAM files to the AWS Cloud using Precisely ... 5777
- Modernize a mainframe application using AWS Transform ... 5796
- Modernize mainframe output management on AWS ... 5815
- Modernize your mainframe batch printing workloads on AWS ... 5866
- Modernize your mainframe environment with Rocket Software Enterprise Suite ... 5897
- Modernize your mainframe online printing workloads on AWS ... 5918
- Move mainframe files to Amazon S3 using Transfer Family ... 5952
- Secure user access in a Db2 federation database ... 5966
- Transfer Db2 z/OS data to AWS ... 5975
- More patterns ... 6003

Management ... 6004

Cost management ... 6005

- Create detailed cost and usage reports for AWS Glue jobs ... 6006

Create detailed cost and usage reports for Amazon EMR clusters 6012
More patterns 6017
End-user computing 6018
Implement SAML 2.0 authentication for Amazon WorkSpaces 6019
More patterns 6029
High-performance computing 6030
Deploy a Lustre file system by using Terraform and DRA 6031
Set up a Grafana monitoring dashboard for AWS ParallelCluster 6040
More patterns 6055
Hybrid cloud 6056
Configure a data center extension to VMware Cloud on AWS 6057
Configure vRealize Automation to provision VMs on VMware Cloud on AWS 6063
Integrate VMware vRealize Network Insight with VMware Cloud on AWS 6074
Migrate VMs to VMware Cloud on AWS by using HCX OSAM 6080
Send logs from VMware Cloud on AWS to Splunk 6086
Set up a pipeline for hybrid workloads on Amazon ECS Anywhere 6093
More patterns 6112
Management & governance 6113
Alert when Amazon Data Firehose resources are not encrypted 6114
Automate adding or updating Windows registry entries 6119
Automatically create an RFC using Python 6124
Automatically stop and start an Amazon RDS DB instance 6131
Centralize software package distribution in AWS Organizations by using Terraform 6146
Configure logging for .NET applications in CloudWatch Logs 6159
Copy AWS Service Catalog products across AWS accounts and Regions 6168
Create a RACI matrix for cloud operations 6179
Create alarms for custom metrics using CloudWatch 6185
Create an AWS Cloud9 IDE with default encrypted EBS volumes 6192
Create tag-based CloudWatch dashboards automatically 6198
Document your landing zone design 6208
Enable Amazon DevOps Guru across an organization with the AWS CDK 6211
Govern permission sets for multiple accounts using AFT 6238
Implement AFT by using a bootstrap pipeline 6250
Manage AWS Service Catalog products in multiple AWS accounts and Regions 6275
Migrate an AWS account from AWS Organizations to AWS Control Tower 6283
Monitor SAP RHEL Pacemaker clusters 6298

Monitor application activity using CloudWatch Logs Insights ... 6317
Monitor use of an AMI across AWS accounts ... 6327
Set up alerts for programmatic account closures in AWS Organizations ... 6345
View EBS snapshot details for your AWS account or organization ... 6355

AWS Prescriptive Guidance Patterns

Amazon Web Services (AWS) Prescriptive Guidance patterns provide step-by-step instructions, architecture, tools, and code for implementing specific cloud migration, modernization, and deployment scenarios. These patterns, which are vetted by subject matter experts at AWS, are meant for builders and hands-on users who are planning to, or are in the process of, migrating to AWS. They also support users who are already on AWS and are looking for ways to optimize or modernize their cloud operations.

You can use these patterns to move your on-premises or cloud workloads of varying complexity to AWS and to accelerate your cloud adoption, optimization, and modernization efforts, regardless of whether you're in the proof of concept, planning, or implementation phase of your project. For example, for a cloud migration project:

- In the planning phase, you can evaluate the different options available to migrate to AWS. You can choose the right pattern that fits your needs, depending on whether you want to relocate, rehost, replatform, or rearchitect. You can also understand the different tools available for migration, and start planning to procure licenses or start initial conversations with vendors.
- In the proof of concept and implementation phases, you can follow the step-by-step instructions provided in the pattern to migrate your workload to AWS. Each pattern includes details such as prerequisites, target reference architectures, tools, step-by-step tasks, best practices, troubleshooting, and code.
- If you're already using the AWS Cloud, you can find patterns that will help you modernize, optimize, scale, and secure your use of cloud resources.

To view lists of patterns by technical domain, use the following links or the filtering and search options on the AWS Prescriptive Guidance home page.

- Cloud foundations
- AI & machine learning
- Analytics
- Compute
- Databases & storage
- Developer tools
- IoT

- Migration & modernization
- Management
- Security, identity & compliance

To view all publications, including guides, strategies, and patterns, see the AWS Prescriptive Guidance home page.

Automate account creation by using the Landing Zone Accelerator on AWS

Justin Kuskowski, Joe Behrens, and Nathan Scott, Amazon Web Services

Summary

This pattern explains how to use the Landing Zone Accelerator on AWS solution to automatically deploy a new AWS account when an authorized user submits a request. It uses AWS Step Functions to orchestrate a number of AWS Lambda functions. The Lambda functions add the account information to a Git repository, initiate an AWS CodePipeline pipeline, and validate that the necessary AWS resources are provisioned. When the process is complete, the user receives a notification that the account has been created.

Optionally, you can integrate Microsoft Entra ID groups and assign AWS IAM Identity Center permission sets during the account creation process. If your organization is using Microsoft Entra ID as an identity source, this optional feature helps you automatically manage and configure access to the new account.

Prerequisites and limitations

Prerequisites

- Access to the management account in AWS Organizations
- AWS Cloud Development Kit (AWS CDK) version 2.118.0 or later, installed and configured
- Python version 3.9 or later, installed
- AWS Command Line Interface (AWS CLI) version 2.13.19 or later, installed
- Docker version 24.0.6 or later, installed
- Landing Zone Accelerator on AWS solution, deployed in the management account
- (Optional) Microsoft Entra ID and IAM Identity Center, integrated

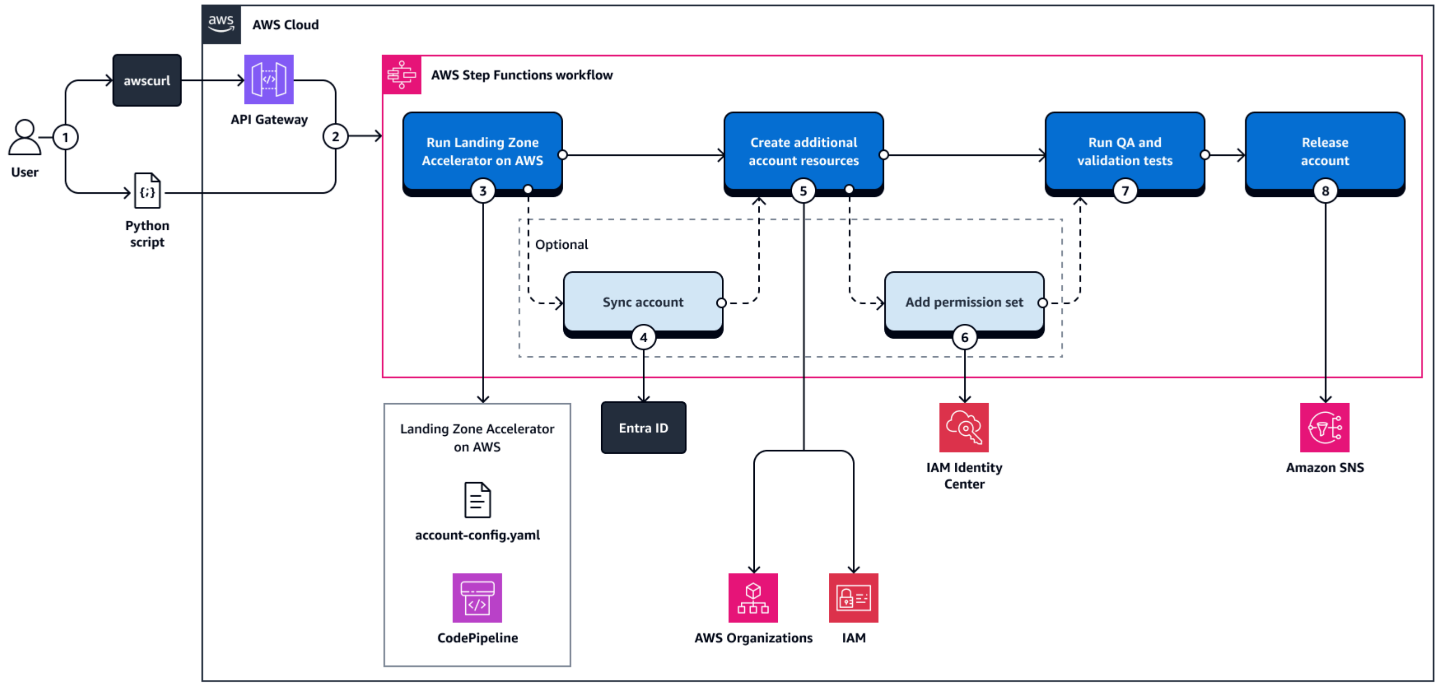
Limitations

The account creation workflow supports sequential executions to deploy a single AWS account. This limitation makes sure that the account creation workflow has successfully completed without having to compete for resources during a parallel run.

Architecture

Target architecture

The following image shows the high-level architecture of automating creation of a new AWS account by using the Landing Zone Accelerator on AWS. AWS Step Functions orchestrates the automation. Each task in the Step Functions workflow is performed by one or more AWS Lambda functions.



The diagram shows the following workflow:

1. The user requests an account by either running a Python script or by using Amazon API Gateway.
2. The Account Creation Orchestrator workflow starts in AWS Step Functions.
3. The workflow updates the `account-config.yaml` file in the source code repository. It also initiates the Landing Zone Accelerator on AWS pipeline and checks the status of the pipeline. This pipeline creates and sets up the new account. For more information about how this works, see the [Architecture overview](#) for the Landing Zone Accelerator on AWS.
4. (Optional) When the pipeline is complete, the workflow checks whether the group exists in Microsoft Entra ID. If the group doesn't exist in Microsoft Entra ID, the workflow adds the group to Microsoft Entra ID.
5. The workflow performs additional steps that the Landing Zone Accelerator on AWS solution can't do. The default steps include:

- Creating an account alias in AWS Identity and Access Management (IAM)
- Attaching tags to the account in AWS Organizations
- Creating parameters in AWS Systems Manager Parameter Store based on the tags assigned to the account

6. (Optional) The workflow assigns one or more permission sets to the Microsoft Entra ID group that you previously specified. The permission sets allow users in the group to access the new account and allow them to perform the actions you configure.
7. An AWS Lambda function runs QA and validation tests. It validates resource creation, checks that tags have been created, and validates that security resources have been deployed.
8. The workflow releases the account and uses Amazon Simple Email Service (Amazon SES) to notify the user that the process has completed successfully.

For more information about the Step Functions workflow, see *Step Functions workflow diagram* in the Additional information section of this pattern.

Microsoft Entra ID applications

If you choose to integrate with Microsoft Entra ID, you create the following two applications when you deploy this pattern:

- An application that is linked to IAM Identity Center and makes sure that Microsoft Entra ID groups are available in IAM Identity Center. In this example, this Microsoft Entra ID application is named `LZA2`.
- An application that allows a Lambda function to communicate with Microsoft Entra ID and call the Microsoft Graph APIs. In this pattern, this application is named `create_aws_account`.

These applications collect data that is used to sync the Microsoft Entra ID group and assign permission sets.

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale. In this pattern, you use API Gateway to check the availability of AWS account names, initiate the AWS Step Functions workflow, and check the status of the Step Functions execution.

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts. This solution uses an EventBridge rule that starts a Lambda function if the Step Functions workflow state changes to `Failed`, `Timed-out`, or `Aborted`.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and cloud applications.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data. In this pattern, AWS KMS keys are used to encrypt data, such as data stored in Amazon Simple Storage Service (Amazon S3), Lambda environment variables, and data in Step Functions.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon Simple Email Service (Amazon SES) helps you send and receive emails by using your own email addresses and domains. After a new account is successfully created, you receive a notification through Amazon SES.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses. If an error occurs during the account creation process, Amazon SNS sends a notification to the email addresses that you configure.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- AWS Systems Manager Parameter Store provides secure, hierarchical storage for configuration data management and secrets management.

Other tools

- awscurl automates the process of signing AWS API requests and helps you make requests as a standard curl command.
- Microsoft Entra ID, formerly known as *Azure Active Directory*, is a cloud-based identity and access management service.
- Microsoft Graph APIs help you access data and intelligence in Microsoft cloud services, such as Microsoft Entra and Microsoft 365.

Code repository

The code for this pattern is available in the GitHub lza-account-creation-workflow repository.

The lambda_layer directory contains the following layers, which are referenced in more than one Lambda function:

- account_creation_helper – This layer includes the modules for assuming roles and checking the progress in AWS Service Catalog.
- boto3 – This layer includes the AWS SDK for Python (Boto3) module to make sure that AWS Lambda has the latest version.
- identity_center_helper – This layer supports calls to IAM Identity Center.

The lambda_src directory contains the following Lambda functions:

- AccountTagToSsmParameter – This function uses the tags attached to the account in AWS Organizations in order to create parameters in Parameter Store. Each parameter starts with an `/account/tags/` prefix.
- AttachPermissionSet – This function adds a permission set to an IAM Identity Center group.
- AzureADGroupSync – This function syncs the target Microsoft Entra ID group to IAM Identity Center.
- CheckForRunningProcesses – This function checks whether the `AWSAccelerator-Pipeline` pipeline is currently running. If the pipeline is running, the function delays the AWS Step Functions workflow.
- CreateAccount – This function uses AWS Service Catalog and AWS Control Tower to create the new AWS account.

- CreateAdditionalResources – This function creates the AWS resources that aren't managed by Landing Zone Accelerator or AWS CloudFormation, such as the account alias and AWS Service Catalog tags.
- GetAccountStatus – This function scans for the provisioned product in AWS Service Catalog to determine if the account creation process has completed.
- GetExecutionStatus – This function retrieves the status of a running or completed AWS Step Functions execution.
- NameAvailability – This function checks if an AWS account name already exists in AWS Organizations.
- ReturnResponse – If the account creation was successful, this function returns the ID of the new account. If the account creation was not successful, it returns an error message.
- RunStepFunction – This function runs the AWS Step Functions workflow that creates the account.
- SendEmailWithSES – This function sends emails to the users who are waiting for the account creation to finish.
- ValidateADGroupSyncToSSO – This function checks if the specified Microsoft Entra ID groups are synced with IAM Identity Center.
- ValidateResources – This function validates that all AWS Control Tower customizations have run successfully.

Best practices

We recommend the following naming conventions for the AWS CDK:

- Start all parameters with a `p` prefix.
- Start all conditions with a `c` prefix.
- Start all resources with an `r` prefix.
- Start all outputs with an `o` prefix.

Epics

Deploy the IAM roles for validation and tagging

Task	Description	Skills required
Prepare the Landing Zone Accelerator on AWS for customization.	1. In the Landing Zone Accelerator on AWS code repository, create a file named `customizations-config.yaml`. You use this file to define customizations for the core solution. For more information, see [Customizing the solution](). 2. In the `customizations-config.yaml` file, create a section called `cloudFormationStacks`.	AWS DevOps
Prepare to deploy the `lza-account-creation-validation` role.	Now, you customize the solution to deploy the `lza-account-creation-validation` IAM role in all accounts other than the management account. This role provides the `ValidateResources` Lambda function with read-only access to the new accounts. 1. Download the [account-creation-validation-role.yaml]() file from GitHub.	AWS DevOps

Task	Description	Skills required

	2. Save the file to the location that is indicated in the templates section of the `customizations-config.yaml` file.
	3. Open the `customizations-config.yaml` file.
	4. In the `cloudFormationStacks` section, add the following code. Update the target AWS Region as needed for your landing zone:
	<pre> - deploymentTargets:
	        organizationalUnits:
	          - Root
	        excludedAccounts:
	          - Management
	
	      description: IAM Role to allow Account Validation
	      name: lza-account-creation-validation
	      regions:
	        - us-east-1
	      template: cloudformation/account-creation-validation-role.yaml</pre>	

Task	Description	Skills required

	``
	          runOrder: 1
	          terminati
	onProtection: true
	          parameters:
	            - name:
	 pManagementAccount
	Id
	              value:
	 "{{ account Managemen
	t }}"
	``
	5. Save and close the `customizations-con fig.yaml` file.	

Task	Description	Skills required

Prepare to deploy the `account-tagging-to-ssm-parameter-role` role.	Now, you customize the solution to deploy the `account-tagging-to-ssm-parameter-role` IAM role in all accounts other than the management account. This role is used to create the parameters in AWS Systems Manager Parameter Store.
	
	1. Download the account-tagging-to-ssm-parameter-role.yaml file from GitHub.
	2. Save the file to the location that is indicated in the templates section of the `customizations-config.yaml` file.
	3. Open the `customizations-config.yaml` file.
	4. In the `cloudFormationStacks` section, add the following code. Update the target AWS Region as needed for your landing zone:
	
	`      - deploymentTargets:`
	`          organizationalUnits:`
	`            - Root`
		AWS DevOps

Task	Description	Skills required

	``
	            excludedA
	ccounts:
	              -
	 Management
	          descripti
	on: IAM Role to
	 create SSM Parameter
	s based on Account
	 Tagging
	          name: lza-
	account-tagging-to-
	ssm-parameter
	          regions:
	            - us-
	east-1
	          template:
	 cloudformation/acc
	ount-tagging-to-ss
	m-parameter-role.y
	aml
	          runOrder: 1
	          terminati
	onProtection: true
	
	          parameters:
	            - name:
	 pManagementAccount
	Id
	              value:
	 "{{ account Managemen
	t }}"
	``
	5. Save and close the `customizations-config.yaml` file.	

Task	Description	Skills required

Prepare to deploy the `config-log-validation-role` role.	Now, you customize the solution to deploy the `config-log-validation-role` IAM role in the log archive account. This role allows the `ValidateResources` Lambda function to access the Amazon S3 bucket for logging and access AWS Config rules.
	
	1. Download the config-log-validation-role.yaml file from GitHub.
	2. Save the file to the location that is indicated in the templates section of the `customizations-config.yaml` file.
	3. Open the `customizations-config.yaml` file.
	4. In the `cloudFormationStacks` section, add the following code. Update the target AWS Region as needed for your landing zone:
	
	`- deploymentTargets:`
	`accounts:`
	`- LogArchive`
		AWS DevOps

Task	Description	Skills required

	``
	          descripti
	on: IAM Role to
	 validate Config and
	 Logs
	          name:
	 lza-config-log-val
	idation-role
	          regions:
	            - us-
	east-1
	          template:
	 cloudformation/con
	fig-log-validation-
	role.yaml
	          runOrder: 1
	          terminati
	onProtection: true
	
	          parameters:
	            - name:
	 pManagementAccount
	Id
	              value:
	 "{{ account Managemen
	t }}"
	``
	5. Save, close, and commit the changes made to the `customizations-config.yaml` file.	

(Optional) Get data from Microsoft Entra ID

Task	Description	Skills required
Create the application that that allows a Lambda function to communicate with Microsoft Entra ID.	1. In the Microsoft Entra ID admin center, register the `create_aws_account` application. For instructi	Microsoft Entra ID

Task	Description	Skills required

	ons, see Register an application in the Microsoft documentation.
	2. Follow the instructions in Update an app's requested permissions in the Microsoft documentation to configure the following Microsoft Graph permissions for the `create_aws_account` application:
	• Application.Read.All
	  • Type: Application
	  • Admin consent required: Yes
	• AppRoleAssignment.ReadWrite.All
	  • Type: Application
	  • Admin consent required: Yes
	• Group.ReadWrite.All
	  • Type: Application
	  • Admin consent required: Yes
	• ServicePrincipalEndpoint.Read.All
	  • Type: Application
	  • Admin consent required: Yes
	• Synchronization.ReadWrite.All	

Task	Description	Skills required

	• Type: Application
	• Admin consent required: Yes
	• User.Read
	  • Type: Delegated
	  • Admin consent required: No	

Task	Description	Skills required
Retrieve values for the `create_aws_account` application.	Now, you retrieve the values that you need for the `create_aws_account` application. 1. In the Microsoft Entra ID admin center, navigate to **App registrations**, and then choose `create_aws_account` . 2. In the left pane, choose **Overview**. 3. On the **Overview** page, make note of the following values: • Application (client) ID • Directory (tenant) ID 4. In the left pane, under **Manage**, choose **Certificates & secrets**. 5. On the **Certificates & secrets** page, choose the **Client secrets** tab, and then make note of the following values: • Client secret value • Client secret ID	Microsoft Entra ID

Task	Description	Skills required
Create the application that integrates Microsoft Entra ID with IAM Identity Center.	In the Microsoft Entra ID admin center, register the `LZA2` application. For instructions, see [Register an application](#) in the Microsoft documentation.	Microsoft Entra ID
Retrieve values for the `LZA2` application.	Now, you retrieve the values that you need for the `LZA2` application. 1. In the Microsoft Entra ID admin center, navigate to **Enterprise applications**, and then choose `LZA2`. 2. In the left pane, choose **Overview**. 3. On the **Overview** page, make note of the following values: • Name • Object ID 4. In the left pane, under **Manage**, choose **Manifest**. 5. In the JSON file, in the `appRoles` section, locate the app role named `User`. 6. Make note of the `id` value for this app role.	Microsoft Entra ID

Task	Description	Skills required

Create a secret.	1. In the AWS CLI, enter the following command to create the variables . Use the values that you retrieved for the `create_aws_account` and LZA2 applications:
	`# Variables for create_aws_account app TENANT_ID='<Directory ID>' CLIENT_ID='<Application ID>' SECRET_ID='<Client secret ID>' SECRET_VALUE='<Client secret value>'`
	`# Variables for LZA2 app OBJECT_ID='<Object ID>' APP_ROLE_ID='<App role ID>' ENTERPRISE_APP_NAME='<Name>'`
	2. Enter the following command to create a secret named `GraphApiSecret` in AWS Secrets Manager:
	`aws secretsmanager create-secret \ --name GraphApiSecret \`
		AWS DevOps

Task	Description	Skills required
	``` --secret-string "{\"client_id\": \"${CLIENT_ID}\", \"tenant_id\": \"${TENANT_ID}\", \"object_id\": \"${OBJECT_ID}\", \"app_role_id\": \"${APP_ROLE_ID}\" , \"secret_value\": \"${SECRET_VALUE}\ ", \"secret_id\": \"${SECRET_ID}\"}" ``` If you need to update the secret in the future, you can update the variables and run the following command: ``` aws secretsmanager update-secret \ --secret-id GraphApiSecret \ --secret-string "{\"client_id\": \"${CLIENT_ID}\", \"tenant_id\": \"${TENANT_ID}\", \"object_id\": \"${OBJECT_ID}\", \"app_role_id\": \"${APP_ROLE_ID}\" , \"secret_value\": \"${SECRET_VALUE}\ ", \"secret_id\": \"${SECRET_ID}\"}" ```	

Deploy the solution

Task	Description	Skills required

Clone the source code.	1. Enter the following command to clone the [lza-account-creation-workflow](https://github.com/aws-samples/lza-account-creation-workflow) repository:
	`git clone https://github.com/aws-samples/lza-account-creation-workflow`
	2. Enter the following command to navigate into the `config` directory of the cloned repository:
	`cd lza-account-creation-workflow/config`
		DevOps engineer

Update the `deploy-config.yaml` file.	1. Open the `deploy-config.yaml` file. 2. Review the template and update the values as needed for deployment in your AWS environment. For example, update values for the following: • `accountCreationFailure` • `accountCompletionFromEmail` • `ssoLoginUrl` • `rootEmailPrefix`	AWS DevOps

Task	Description	Skills required
	• `rootEmailDomain` 3. If you're integrating with Microsoft Entra ID, do the following: • Set `enableAzureADIntegration` to `true`. • For `graphApiSecretName` value, enter the secret that you created previously (`GraphApiSecret`). 4. Save and close the `deploy-config.yaml` file.	

Task	Description	Skills required

Deploy the solution in your AWS environment.	1. Enter the following command:
	`cdk bootstrap <account-number>/<Region>`
	For more information, see [Bootstrapping](#) in the AWS CDK documentation.
	2. Enter the following command to synthesize the CloudFormation template:
	`cdk synth`
	For more information, see [Configure and perform AWS CDK stack synthesis](#) in the AWS CDK documenta tion.
	3. Enter the following command to deploy the solution.
	`cdk deploy`
	For more information, see [Deploy AWS CDK applications](#) in the AWS CDK documentation.
		AWS DevOps

Task	Description	Skills required
	Note This solution uses an Amazon S3 bucket to store the source code for this solution. You can use the upload_to_source_bucket.py script to create an archive of the source code and upload an updated version.	

Option 1 – Create an account using Python

Task	Description	Skills required
Identify which arguments to use.	Choose which arguments to use when you run the Python script that initiates the Step Functions workflow. For a complete list of arguments, see the [Additional information](#additional-information) section of this pattern.	AWS DevOps, Python
Start the Python script.	1. Enter the following command to navigate into the cloned repository: `cd lza-account-creation-workflow` 2. Run the Python script that initiates the Step Functions workflow. The following is	DevOps engineer, Python

Task	Description	Skills required
	an example command that includes sample arguments and values: `python ./run-stepfunction.py \ --account-name "lza-test-01" \ --support-dl "johnsmith@example.com" \ --managed-org-unit "Workloads/Workload-1" \ --purpose "Testing new micro service" \ --force-update true \ --ad-integration "{\"CustomerAccountAdmin\": \"platform-admin\", \"CustomerAccountDev\": \"workload1-app1\"}" \ --bypass-creation true \ --tags APPLICATION=TestingMicroService` 3. Wait until you receive a notification that the account has been successfully created. **Note** If the account creation process	

Task	Description	Skills required
	fails, Amazon SNS sends a notification to the email addresses that you define in `accountCreationFailure` in the `deploy-config.yaml` file. The account requester is not notified.	

Option 2 – Create an account using API Gateway and awscurl

Task	Description	Skills required
Set up the variables for awscurl.	1. Enter the following command to navigate into the source code directory: `cd lza-account-creation-workflow` 2. Enter the following command to set the AWS access key variables. You can copy the variables from the [AWS access portal](#) and then paste them into a shell. The following is an example:	AWS DevOps

Task	Description	Skills required

```
export AWS_ACCESS_KEY_ID="<id>"
export AWS_SECRET_ACCESS_KEY="<key>"
export AWS_SESSION_TOKEN="<token>"
```

3. Enter the following command to set the AWS Region for API calls:

```
export AWS_REGION=$(aws configure get region)
```

4. Enter the following command to retrieve the API Gateway endpoint from the `lza-account-creation-workflow-application` CloudFormation output:

```
export API_GATEWAY_ENDPOINT=$(aws cloudformation describe-stacks --stack-name "lza-account-creation-workflow-application" --query 'Stacks[*].Outputs[?OutputKey==`oApiGatewayCreateAccountEndpoint`].OutputValue' --output text)
```

Task	Description	Skills required
Check name availability.	Enter the following command to verify that the name is available for the AWS account. Replace <AWS_ACCOUNT_NAME> with the name of the target account:	AWS DevOps

```
awscurl --service execute-api \
    --region ${AWS_REGION} \
    --access_key ${AWS_ACCESS_KEY_ID} \
    --secret_key ${AWS_SECRET_ACCESS_KEY} \
    --security_token ${AWS_SESSION_TOKEN} \
    -X POST ${API_GATEWAY_ENDPOINT}check_name?account_name=<AWS_ACCOUNT_NAME>
```

Task	Description	Skills required

Run the account creation workflow.	1. In the root folder of the cloned repository, open the `api_example.json` file.
	2. Update the parameters with your configuration values:
	<pre>{
	    "account_name":
	 "lza-test-01",
	    "account_email":
	 "johnsmith+lzatest
	01@example.com",
	    "support_dl":
	 "johnsmith@example
	.com",
	    "managed_
	org_unit": "Workload
	s/Workload-1",
	    "ad_integration":
	 [
	        {
	            "Permissi
	onSetName":
	 "CustomerAccountAd
	min",
	            "ActiveDi
	rectoryGroupName":
	 "platform-admin"
	        },
	        {
	            "Permissi
	onSetName":
	 "CustomerAccountDe
	v",
	            "ActiveDi
	rectoryGroupName":
	 "workload1-app1"
	        }
	    ],</pre>
		AWS DevOps

Task	Description	Skills required

	``
	    "force_update": "true",
	    "bypass_creation": "false",
	    "account_tags": [
	        {
	            "Key": "Environment",
	            "Value": "Dev"
	        }, {
	            "Key": "DeploymentMethod",
	            "Value": "ApiGateway"
	        }
	    ]
	}
	``
	3. Save and close the `api_example.json` file.
	4. Enter the following command to initiate the Step Functions workflow:
	``
	awscurl --service execute-api \
	    --data @api-example.json \
	    --region ${AWS_REGION} \
	    --access_key ${AWS_ACCESS_KEY_ID} \
	    --secret_key ${AWS_SECRET_ACCESS_KEY} \
	    --security_token ${AWS_SESSION_TOKEN} \
	``	

Task	Description	Skills required

	``` -X POST ${API_GATEWAY_ENDPOINT}execute ```
	5. In the output from the previous command, make note of the Step Functions execution Amazon Resource Name (ARN).
	6. If you want to check the status of the Step Functions workflow, enter the following command. Replace `<STEP_FUNCTION_EXECUTION_NAME>` with the Step Functions execution ARN or name:
	``` awscurl --service execute-api \ --region ${AWS_REGION} \ --access_key ${AWS_ACCESS_KEY_ID} \ --secret_key ${AWS_SECRET_ACCESS_KEY} \ --security_token ${AWS_SESSION_TOKEN} \ -X GET ${API_GATEWAY_ENDPOINT}get_execution_status?execution=<STEP_FUN ```	

Task	Description	Skills required
	`CTION_EXECUTION_NAME>` 7. Wait until you receive a notification that the account has been successfully created. **Note** If the account creation process fails, Amazon SNS sends a notification to the email addresses that you define in `accountCreationFailure` in the `deploy-config.yaml` file. The account requester is not notified.	

(Optional) Clean up the solution

Task	Description	Skills required
Remove objects from the Amazon S3 buckets.	Remove any objects in the following Amazon S3 buckets: • `lza-account-creation-work-<CDK_UNIQUE_ID>`	AWS DevOps

Task	Description	Skills required
	• `lza-account-creation-workflow-src-<AWS_REGION>-<AWS_ACCOUNT>` • `lza-account-creation-workflow-<AWS_REGION>-<AWS_ACCOUNT>`	

Delete the CloudFormation stack.	Enter the following command to delete the CloudFormation stack:
	`aws cloudformation delete-stack \ --stack-name lza-account-creation-workflow-application`
	`aws cloudformation wait stack-delete-complete \ --stack-name lza-account-creation-workflow-application`
		AWS DevOps

Delete the pipeline.	Enter the following command to delete the `lza-account-creation-workflow-pipeline` pipeline: `cdk destroy lza-account-creation-workflow-pipeline --force`	AWS DevOps

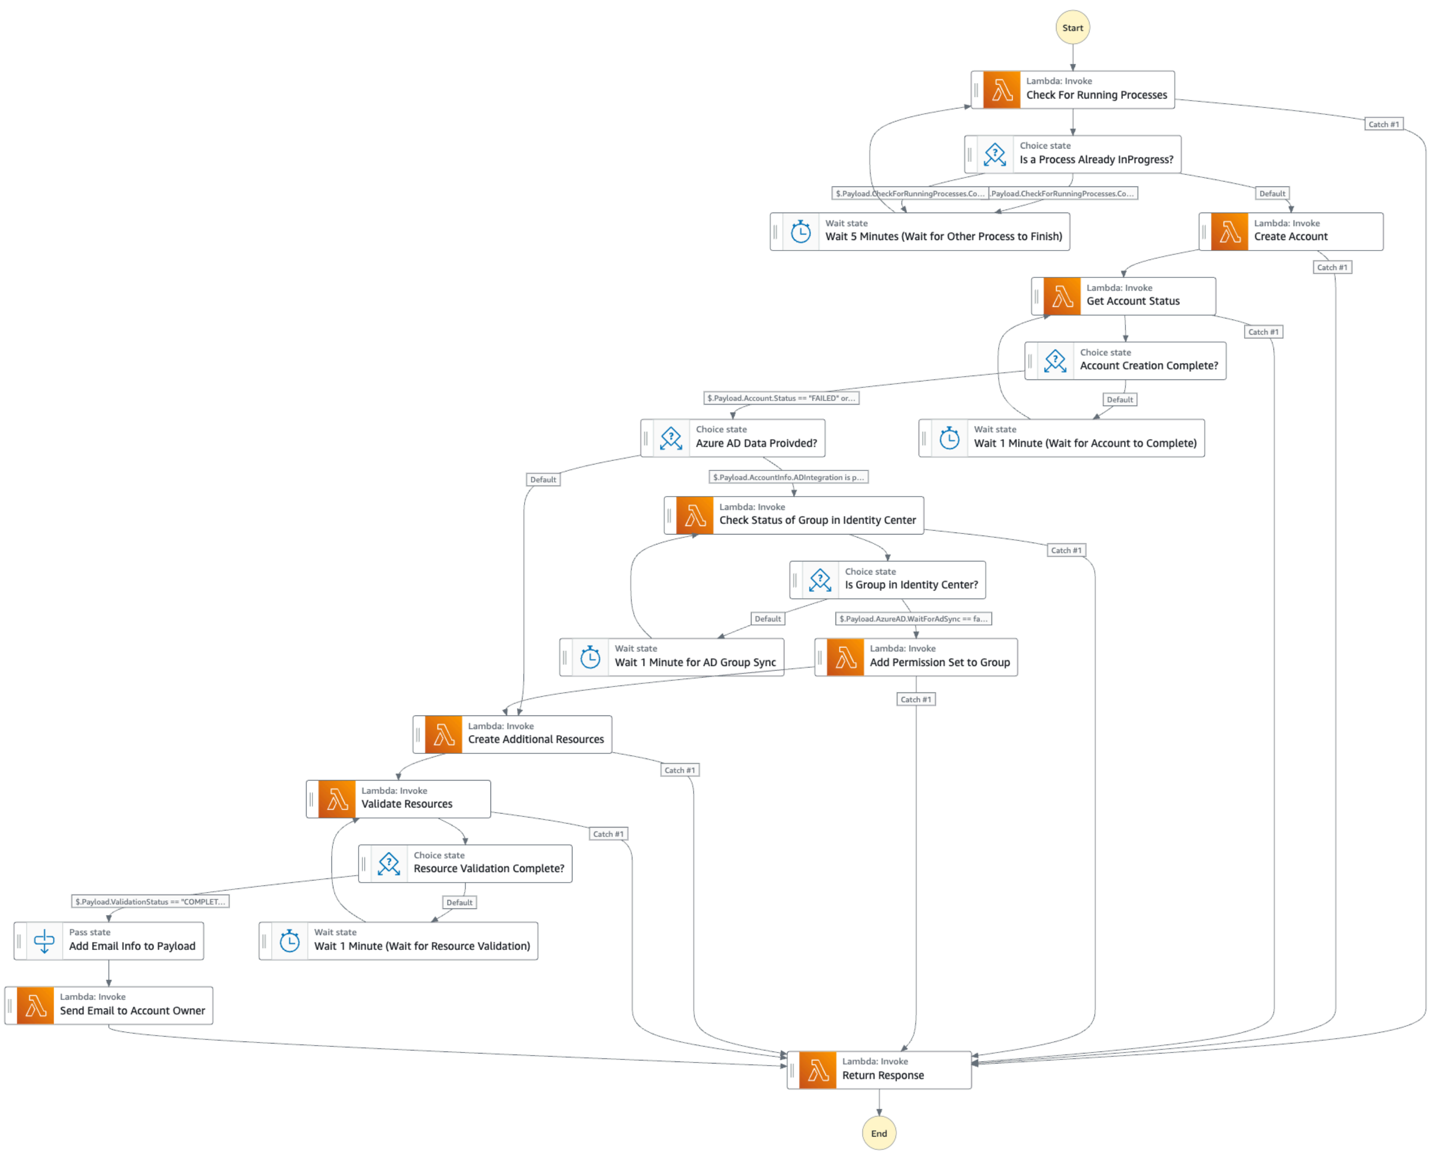
Additional information

Step Functions workflow diagram

The following image shows the states in the Step Functions workflow.



Arguments

The following are the arguments that you can use when you run the Python script that initiates the Step Functions workflow.

The following arguments are required:

- `account-name (-a)` (string) – The name of the new AWS account.
- `support-dl (-s)` (string) – The email address that receives notification when the account creation process is complete.
- `managed-org-unit (-m)` (string) – The managed organizational unit (OU) that will contain the new account.

The following arguments are optional:

- `ad-integration (-ad)` (string dictionary) – The Microsoft Entra ID group and assigned permission set. The following is an example of how to use this argument:

```
--ad-integration "{\"<PermissionSetName>\": \"<EntraIdGroupName>\"}"
```

- `account-email (-e)` (string) – The email address for the root user of the new AWS account.

> **Note**
>
> If this argument isn't used, an email address will be generated by using the values `rootEmailPrefix` and `rootEmailDomain` from the `configs/deploy-config.yaml` file. If an email address isn't provided, an email address is generated by using the following format: `rootEmailPrefix+accountName@rootEmailDomain`.

- `region (-r)` (string) – The AWS Region where the Step Functions workflow was deployed. The default value is `us-east-1`.
- `force-update (-f)` (string Boolean) – Enter `true` to force AWS Service Catalog to update the provisioned product.
- `bypass-creation (-b)` (string Boolean) – Enter `true` to bypass adding the account to the `accounts-config.yaml` file and bypass running the `AWSAccelerator-Pipeline` pipeline. This argument is typically used to test the account creation workflow process or to run the rest of the Step Functions steps if an error occurs in the `Landing Zone Accelerator` pipeline.

- `tags (-t)` (string) – Additional tags that you want to add to the AWS account. By default, the following tags are added: `account-name`, `support-dl`, and `purpose`. The following is an example of how to use this argument:

```
--tags TEST1=VALUE1 TEST2=VALUE2
```

Automatically inventory AWS resources across multiple accounts and Regions

Matej Macek, Amazon Web Services

Summary

This pattern outlines an automated approach to maintaining a comprehensive inventory of AWS resources across multiple accounts and AWS Regions. It is designed to help infrastructure and security engineers improve their resource management practices. It uses AWS Config to track resource changes, Amazon Athena for querying, and Amazon QuickSight for interactive dashboards. You implement this solution by deploying an AWS CloudFormation stack.

This solution is similar to the one presented in Visualizing AWS Config data using Amazon Athena and Amazon QuickSight (AWS blog post). This pattern expands on that solution to address the following common requirements and provide the following key benefits:

- **Compliance-focused –** This approach can help you meet regulatory requirements such as PCI DSS, NIST SP 800-53, ISO/IEC 27001, HIPAA, GDPR, and others that mandate accurate asset inventories.
- **Customization framework –** It provides a foundation for creating QuickSight dashboards for various AWS resources, so that you can customize the solution to your specific requirements.
- **User-driven enhancements –** This approach incorporates feedback from real-world use cases and addresses requests for a more comprehensive solution.

Infrastructure, security, and finance teams often face visibility and collaboration challenges in dynamic, multi-account or multi-Region environments. This solution is designed to address those challenges and significantly reduce the time and effort required to create and maintain a resource inventory. The result is a centralized view of resources that helps you improve resource allocation decisions, identify and mitigate risks, optimize costs, and improve overall visibility and collaboration. This approach bridges the gap between conceptual solutions and real-world implementation needs for security, compliance, and operational purposes.

Prerequisites and limitations

Prerequisites

- The following active AWS accounts:

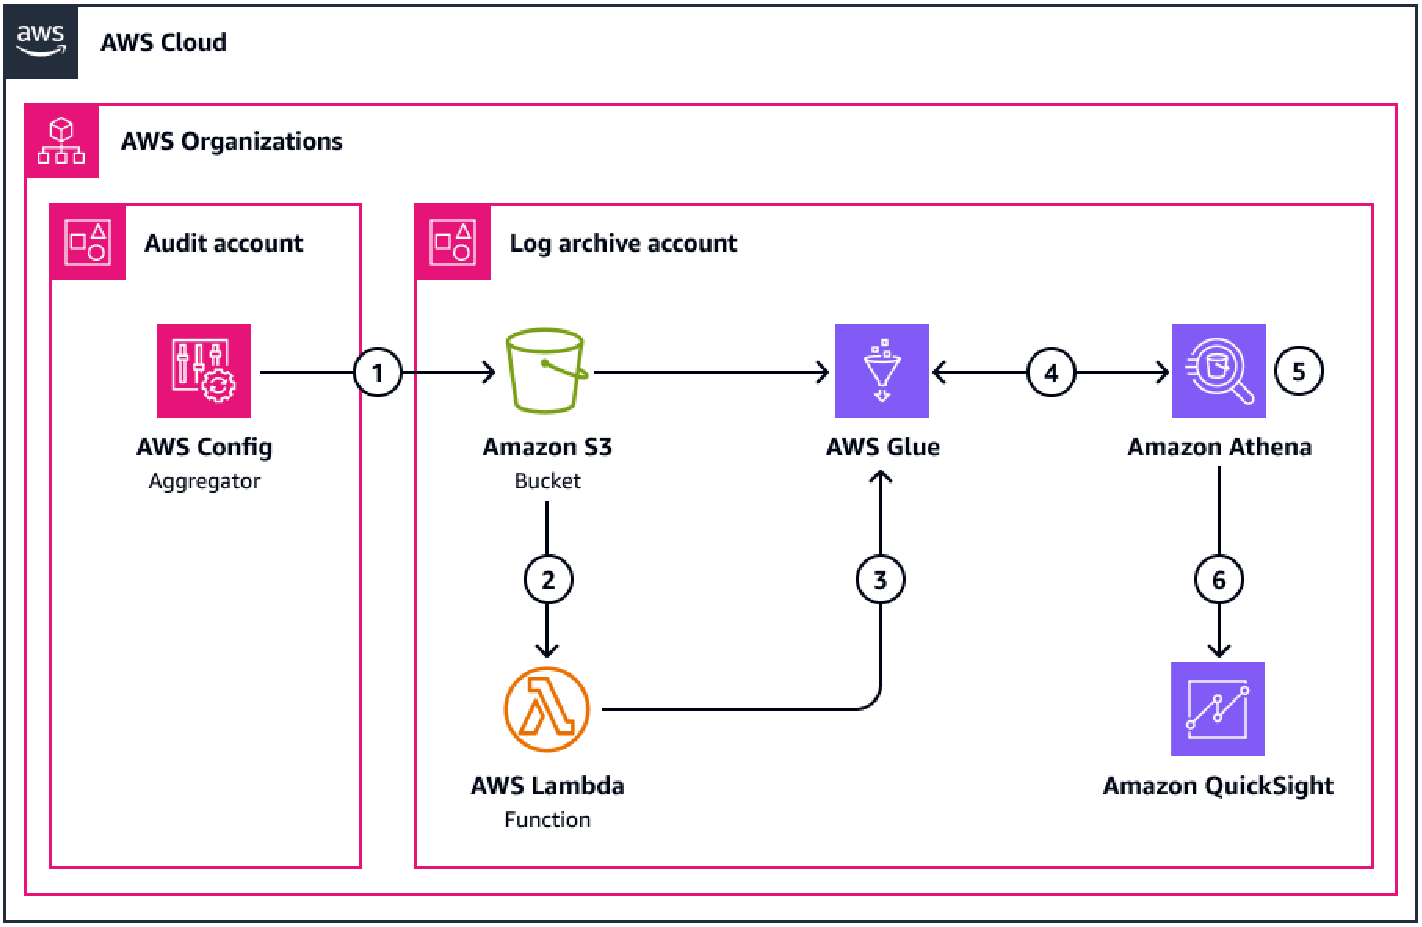
  - *Management account* - A centralized account for billing, creating accounts, and controlling access across the organization
  - *Audit account* – A centralized hub for security monitoring, compliance checks, and drift notifications
  - *Log archive account* – A centralized account for storing and analyzing the collected data
- In the audit account, an AWS Config aggregator that collects and aggregates configuration data from your target accounts and Regions
- In the log archive account, set up the following:
  - An Amazon Simple Storage Service (Amazon S3) bucket where you store the data from the AWS Config aggregator
  - An Amazon QuickSight subscription
  - An authorized connection between QuickSight and Amazon Athena
  - Permissions to access the Amazon S3 bucket through an Athena query
- AWS Command Line Interface (AWS CLI), installed and configured
- Permissions to deploy a CloudFormation stack that provisions the following resources:
  - An AWS Lambda function
  - An Amazon S3 notification configuration
  - Athena database, tables, and views
  - QuickSight datasets and data sources
- Permissions to run automations in AWS Systems Manager
- Permissions to access QuickSight

Limitations

- The solution relies on AWS Config. AWS Config usually records configuration changes to your resources right after a change is detected, or at the frequency that you specify. However, this is on a best-effort basis and can take longer at times.
- This solution tracks only resource types that AWS Config supports.
- The solution does not track resource inventory across other cloud providers or on-premises environments.
- Some AWS services aren't available in all AWS Regions. For Region availability, see the Service endpoints and quotas page in the AWS documentation, and choose the link for the service.

Architecture

The following diagram shows a streamlined process for collecting, organizing, analyzing, and visualizing configuration and compliance data across multiple accounts in an AWS organization.



The diagram shows the following workflow:

1. On a periodic schedule, the AWS Config aggregator collects configuration and compliance data about the resources in the target accounts and Regions and then delivers the data to the Amazon S3 bucket in the log archive account.
2. Adding new AWS Config data to the Amazon S3 bucket invokes an AWS Lambda function.
3. The Lambda function partitions the data by configuring keys with values that correspond to the Region and date of each snapshot file. This helps AWS Glue efficiently query and process the configuration and compliance data.
4. Amazon Athena uses an AWS Glue schema to run SQL queries against the data stored in the Amazon S3 bucket. It utilizes the schema metadata from AWS Glue to understand the structure of the data.

5. Views in Athena define and extract the target datasets.
6. Dashboards in Amazon QuickSight help you to visualize and analyze the datasets.

Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time. An AWS Config aggregator collects AWS Config configuration and compliance data from multiple AWS accounts and Regions.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams. This pattern uses an AWS Glue Data Catalog and Schema registry.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. AWS Systems Manager Automation simplifies common maintenance, deployment, and remediation tasks for many AWS services.

Code repository

The AWS CloudFormation template for this pattern is available in the AWS Config visualization GitHub repository. This CloudFormation template deploys an AWS Systems Manager automation runbook that sets up AWS Config for use with Amazon Athena. This automation prepares AWS Glue to connect with the designated Amazon S3 bucket, creates views in Amazon Athena, and configures Amazon QuickSight for dashboard visualization.

Best practices

- We recommend that you follow the best practices in Set up and govern a secure, multi-account AWS environment with AWS Control Tower on AWS Prescriptive Guidance.
- We recommend that you create an AWS Config aggregator that collects configuration and compliance data for the entire AWS organization. For more information, see Multi-Account Multi-Region Data Aggregation in the AWS Config documentation.
- Before deploying this solution, we recommend that you review the current pricing information for Amazon S3, AWS Config, Athena, and QuickSight.

Epics

Deploy the CloudFormation stack

Task	Description	Skills required
Download the CloudFormation template.	Download the Config-QuickSight-Visualization-SSM-Automation.yaml CloudFormation template.	AWS administrator, Cloud administrator, DevOps engineer
Modify the CloudFormation template.	Complete this step only if you're using AWS Control Tower and AWS Config is managed by AWS Control Tower. You need to modify the CloudFormation template. 1. Sign in to the management account.	DevOps engineer, AWS administrator

Task	Description	Skills required
	2. Open the [AWS Organizations console](#). 3. Navigate to the **Settings** page. This page displays details about the organization, including the organization ID. 4. Copy the organization ID. 5. In your preferred text editor, open the **Config-QuickSight-Visualization-SSM-Automation.yaml** file. 6. Find the following line: `return re.match( '^AWSLogs/(\d+)/Config/([\w-]+)/(\d+)/(\d+)/(\d+)/ConfigSnapshot/[^\\\]+$', object_key)` 7. Replace this line with the following, where `<ORGANIZATION_ID>` is the ID that you previously copied: `return re.match( '^<ORGANIZATION_ID>/AWSLogs/(\d+)/Config/([\w-]+)/(\d+)/(\d+)/(\d+)/ConfigSnapshot/[^\\\]+$', object_key)`	

Task	Description	Skills required
	8. Save and close the **Config-QuickSight-Visualization-SSM-Automation.yaml** file.	
Create a CloudFormation stack.	Follow the instructions in [Create a stack from the CloudFormation console](). Note the following: 1. Choose **Upload a template file**, and then choose the YAML file you downloaded. 2. For **Stack name**, enter `Config-QuickSight-Visualization-SSM-Automation` . 3. Choose **Submit**.	AWS administrator, Cloud administrator, DevOps engineer

Run the automation in Systems Manager

Task	Description	Skills required
Find your QuickSight user name.	1. Open the [QuickSight console](). 2. Open the profile menu. 3. Make note of the user name. You need this value later.	AWS administrator, Cloud administrator, DevOps engineer
Find the delivery channel name and Amazon S3 bucket name.	1. In the AWS CLI, enter the following command:	AWS administrator, Cloud administrator, DevOps engineer

Task	Description	Skills required

	<pre>aws configservice
	 describe-delivery-
	channels</pre>2. Make note of the Amazon S3 bucket name and the name of your the AWS Config delivery channel. You need these values later.	

Task	Description	Skills required
Run the automation in Systems Manager.	1. Open the AWS Systems Manager console. 2. In the navigation pane, choose **Documents**. 3. Choose **Owned by me**. 4. Choose **Config-QuickSight-Visualization**. 5. Choose **Execute automation**. 6. In the **Input parameters** section, enter your values for the following parameters: • `ConfigDeliveryChannelName` – Enter the name of your AWS Config delivery channel. This parameter is required. • `ConfigS3BucketLocation` – Enter the name of the Amazon S3 bucket where you store AWS Config configuration data. This parameter is required. • `QuickSightUserName` – Enter a user name that has administrative access to QuickSight. This parameter is required.	AWS administrator, Cloud administrator, DevOps engineer

Task	Description	Skills required
	• `AutomationAssumeRole` – The Amazon Resource Name (ARN) of the AWS Identity and Access Management (IAM) role that allows Systems Manager Automation to perform the actions on your behalf. This parameter is optional. Leave this parameter blank. • `DeleteConfigVisualization` – Choose `false`. 7. Choose **Execute**.	

Visualize data in Amazon QuickSight

Task	Description	Skills required
Refresh data.	To schedule dataset refreshes according to your specific requirements, follow the instructions in [Refreshing SPICE data]().	AWS administrator, DevOps engineer, Cloud administrator
Create an analysis.	To create a dashboard in QuickSight that helps you visualize the resources, follow the instructions in [Starting an analysis in Amazon QuickSight]().	QuickSight administrator

Task	Description	Skills required
Create a dashboard.	1. After you finish modifying your QuickSight analysis, follow the instructions in Publishing dashboards to create a dashboard. A *dashboard* is an analysis that you can share with other QuickSight users. 2. Follow the instructions in Granting access to a dashboard to share the dashboard with your target QuickSight users.	QuickSight administrator

(Optional) Clean up

Task	Description	Skills required
Delete the resources created by the Systems Manager automation.	1. Open the AWS Systems Manager console. 2. In the navigation pane, choose **Documents**. 3. Choose **Owned by me**. 4. Choose **Config-QuickSight-Visualization**. 5. Choose **Execute automation**. 6. In the **Input parameters** section, for the `DeleteConfigVisualization` parameter, enter `true`. 7. Choose **Execute**.	AWS administrator, Cloud administrator, DevOps engineer

Task	Description	Skills required
Delete the CloudFormation stack.	To delete the resources in the `Config-QuickSight-Visualization-SSM-Automation` stack, follow the instructions in [Delete a stack from the CloudFormation console]().	AWS administrator, Cloud administrator, DevOps engineer

Troubleshooting

Issue	Solution

Amazon QuickSight is attempting to connect to the `us-east-1` AWS Region, but the creation of resources in that Region is not permitted.	A service control policy is restricting your subscription to Amazon QuickSight in this Region. In the service control policy, manually specify the target AWS Region. Replace `<REGION_ID>` with the appropriate Region identifier:
	`https://<REGION_ID>.quicksight.aws.amazon.com/sn/start/dashboards`
	The following is an example:
	`https://eu-central-1.quicksight.aws.amazon.com/sn/start/dashboards`

In Amazon Athena, you encounter the following message: `Before you run your first query, you need to set up a query result location in Amazon S3.`	Make sure that you have prepared an Amazon S3 bucket where you will store the query results from Amazon Athena. Then follow the instructions in [Specify a query result location using the Amazon Athena console]().

Configure VPC Flow Logs for centralization across AWS accounts

Benjamin Morris and Aman Kaur Gandhi, Amazon Web Services

Summary

In an Amazon Web Services (AWS) virtual private cloud (VPC), the VPC Flow Logs feature can provide useful data for operational and security troubleshooting. However, there are limitations on using VPC Flow Logs in a multi-account environment. Specifically, cross-account flow logs from Amazon CloudWatch Logs are not supported. Instead, you can centralize the logs by configuring an Amazon Simple Storage Service (Amazon S3) bucket with the appropriate bucket policy.

Note

This pattern discusses the requirements for sending flow logs to a centralized location. However, if you also want logs to be available locally in member accounts, you can create multiple flow logs for each VPC. Users without access to the Log Archive account can see traffic logs for troubleshooting. Alternatively, you can configure a single flow log for each VPC that sends logs to CloudWatch Logs. You can then use an Amazon Data Firehose subscription filter to forward the logs to an S3 bucket. For more information, see the Related resources section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Organizations organization with an account that is used to centralize logs (for example, Log Archive)

Limitations

If you use the AWS Key Management Service (AWS KMS) managed key `aws/s3` to encrypt your central bucket, it won't receive logs from a different account. Instead, you will see an

`Unsuccessful` error code 400 with a message such as "`LogDestination: <bucketName> is undeliverable`" for your given `ResourceId`.

This is because an account's AWS managed keys can't be shared across accounts.

The solution is to use either Amazon S3 managed encryption (SSE-S3) or an AWS KMS customer managed key that you can share with member accounts.

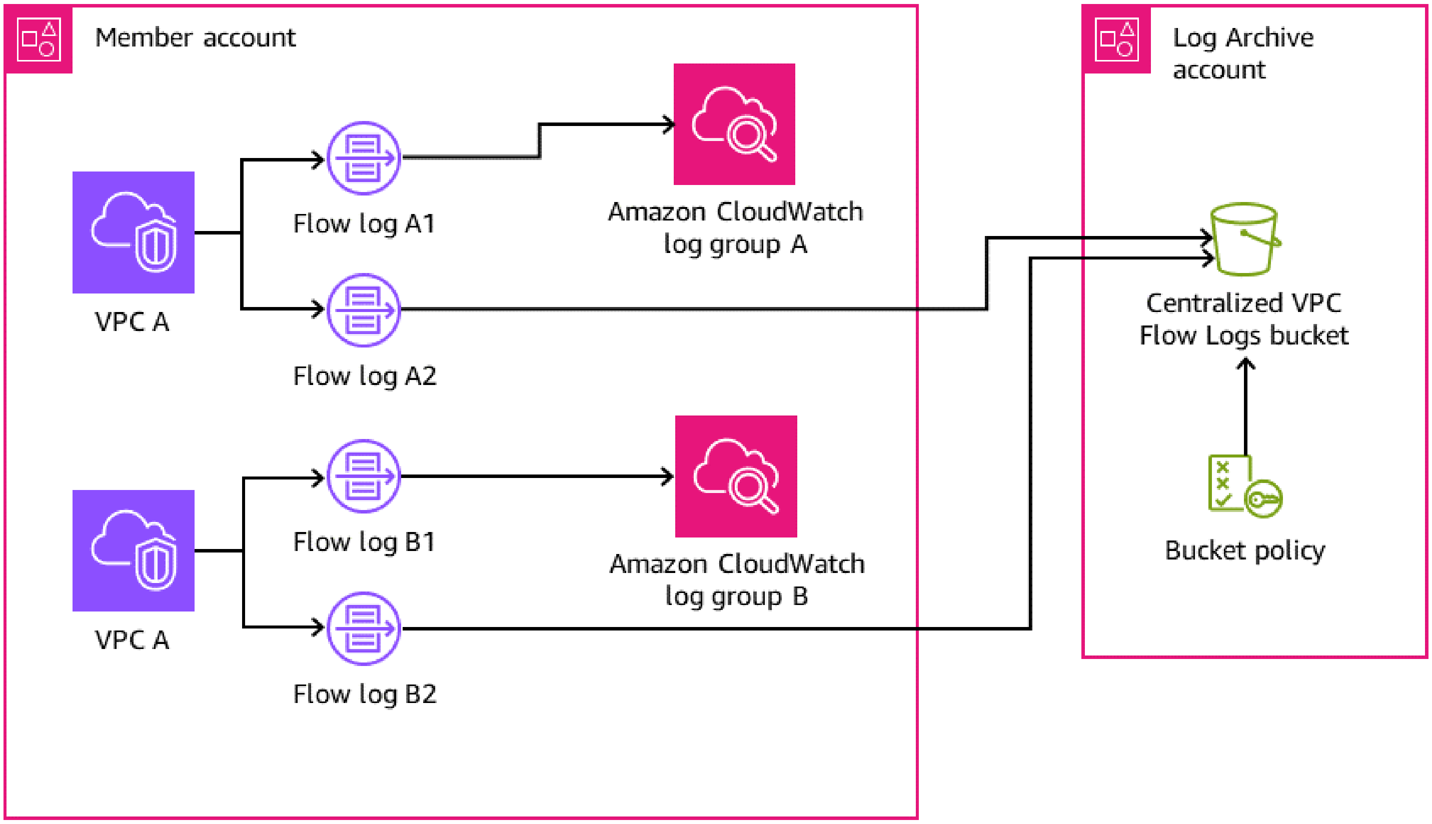
Architecture

Target technology stack

In the following diagram, two flow logs are deployed for each VPC. One sends logs to a local CloudWatch Logs group. The other sends logs to an S3 bucket in a centralized logging account. The bucket policy permits the log delivery service to write logs to the bucket.

> **Note**
>
> As of November 2023, AWS now supports the aws:SourceOrgID condition key. This condition allows you to deny writing to the centralized bucket for accounts outside of your AWS Organizations organization.

Target architecture



Automation and scale

Each VPC is configured to send logs to the S3 bucket in the central logging account. Use one of the following automation solutions to help ensure that flow logs are configured appropriately:

- [AWS CloudFormation StackSets]
- [AWS Control Tower Account Factory for Terraform (AFT)]
- [An AWS Config rule with remediation]

Tools

Tools

- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

- [Amazon Virtual Private Cloud (Amazon VPC)] helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses the VPC Flow Logs feature to capture information about the IP traffic going to and from network interfaces in your VPC.

Best practices

Using infrastructure as code (IaC) can greatly simplify the VPC Flow Logs deployment process. Abstracting your VPC deployment definitions to include a flow log resource construct will deploy your VPCs with flow logs automatically. This is demonstrated in the next section.

Centralized flow logs

Example syntax for adding centralized flow logs to a VPC module in HashiCorp Terraform

This code creates a flow log that sends logs from a VPC to a centralized S3 bucket. Note that this pattern doesn't cover creation of the S3 bucket.

For recommended bucket policy statements, see the Additional information section.

```
variable "vpc_id" { type = string }
locals { custom_log_format_v5 = "$${version} $${account-id} $${interface-id} $
${srcaddr} $${dstaddr} $${srcport} $${dstport} $${protocol} $${packets} $${bytes}
 $${start} $${end} $${action} $${log-status} $${vpc-id} $${subnet-id} $${instance-
id} $${tcp-flags} $${type} $${pkt-srcaddr} $${pkt-dstaddr} $${region} $${az-id} $
${sublocation-type} $${sublocation-id} $${pkt-src-aws-service} $${pkt-dst-aws-service}
 $${flow-direction} $${traffic-path}" }
resource "aws_flow_log" "centralized_flow_log" {
  log_destination      = "arn:aws:s3:::centralized-vpc-flow-logs-
<log_archive_account_id>" # Optionally, a prefix can be added after the ARN.
  log_destination_type = "s3"
  traffic_type         = "ALL"
  vpc_id               = var.vpc_id
  log_format           = local.custom_log_format_v5 # If you want fields from VPC Flow
 Logs v3+, you will need to create a custom log format.
}
```

For more information about the custom log format, see the AWS documentation.

Local flow logs

Example syntax for adding local flow logs to a VPC module in Terraform with required permissions

This code creates a flow log that sends logs from a VPC to a local CloudWatch Logs group.

```
data "aws_region" "current" {}
variable "vpc_id" { type = string }
resource "aws_iam_role" "local_flow_log_role" {
  name = "flow-logs-policy-${var.vpc_id}"
  assume_role_policy = <<EOF
{
  "Version": "2012-10-17",
  "Statement": [{
      "Effect": "Allow",
      "Principal": {"Service": "vpc-flow-logs.amazonaws.com"},
      "Action": "sts:AssumeRole"
  }]
}
EOF
}
resource "aws_iam_role_policy" "logs_permissions" {
  name = "flow-logs-policy-${var.vpc_id}"
  role = aws_iam_role.local_flow_log_role.id
  policy = <<EOF
{
  "Version": "2012-10-17",
  "Statement": [{
      "Action": ["logs:CreateLog*", "logs:PutLogEvents", "logs:DescribeLog*",
 "logs:DeleteLogDelivery"],
      "Effect": "Allow",
      "Resource": "arn:aws:logs:${data.aws_region.current.name}:*:log-group:vpc-flow-
logs*"
  }]
}
EOF
}
resource "aws_cloudwatch_log_group" "local_flow_logs" {
  name              = "vpc-flow-logs/${var.vpc_id}"
  retention_in_days = 30
}
resource "aws_flow_log" "local_flow_log" {
  iam_role_arn    = aws_iam_role.local_flow_log_role.arn
  log_destination = aws_cloudwatch_log_group.local_flow_logs.arn
  traffic_type    = "ALL"
  vpc_id          = var.vpc_id
```

```
}
```

Epics

Deploy VPC Flow Logs infrastructure

Task	Description	Skills required
Determine the encryption strategy and create the policy for the central S3 bucket.	The central bucket does not support the `aws/s3` AWS KMS key, so you must use either SSE-S3 or an AWS KMS customer managed key. If you use an AWS KMS key, the key policy must allow member accounts to use the key.	Compliance
Create the central flow log bucket.	Create the central bucket to which flow logs will be sent, and apply the encryption strategy that you chose in the previous step. This should be in a Log Archive or similarly purposed account. Obtain the bucket policy from the [Additional information](#) section, and apply it to your central bucket after updating placeholders with your environment specific values.	General AWS
Configure VPC Flow Logs to send logs to the central flow log bucket.	Add flow logs to each VPC that you want to gather data from. The most scalable way to do this is to use IaC tools such as AFT or AWS Cloud	Network administrator

Task	Description	Skills required
	Development Kit (AWS CDK). For example, you can create a Terraform module that deploys a VPC alongside a flow log. If necessary, you add the flow logs manually.	
Configure VPC Flow Logs to send to local CloudWatch Logs.	(Optional) If you want flow logs to be visible in the accounts where the logs are being generated, create another flow log to send data to CloudWatch Logs in the local account. Alternatively, you can send the data to an account-specific S3 bucket in the local account.	General AWS

    ]
}
```

Manage AWS permission sets dynamically by using Terraform

Vinicius Elias and Marcos Vinicius Pinto Jordao, Amazon Web Services

Summary

AWS IAM Identity Center enhances AWS Identity and Access Management (IAM) by providing a centralized hub for managing single sign-on access to AWS accounts and cloud applications. However, manual management of IAM Identity Center permission sets can become increasingly complex and error-prone as your organization grows. This complexity can lead to potential security gaps and administrative overhead.

This solution enables you to manage permission sets through infrastructure as code (IaC) using a continuous integration and continuous delivery (CI/CD) pipeline built with native AWS services. It enables a seamless integration of the permission set assignment mechanism with AWS Control Tower lifecycle events or an Account Factory for Terraform (AFT) environment. This approach provides dynamic identity configurations for both new and existing AWS accounts.

Amazon EventBridge rules monitor AWS account creation and updates, which helps your identity configurations to remain synchronized with your organizational structure. After creating or updating accounts in AWS Control Tower or AFT, the pipeline is triggered. It evaluates a set of JSON files with permission set definitions and assignment rules. Then the pipeline applies and synchronizes the settings across all accounts.

This approach provides the following benefits:

- **Consistency** – Eliminates manual configuration drift across your AWS organization
- **Auditability** – Maintains a complete history of all identity management changes
- **Scalability** – Automatically applies configurations as your AWS environment grows
- **Security** – Reduces human error in permission assignments
- **Compliance** – Facilitates meeting regulatory requirements through documented changes and assignment rules

Prerequisites and limitations

- A multi-account environment with AWS Control Tower and AWS Organizations set up. Optionally, you can use AFT with AWS Control Tower.

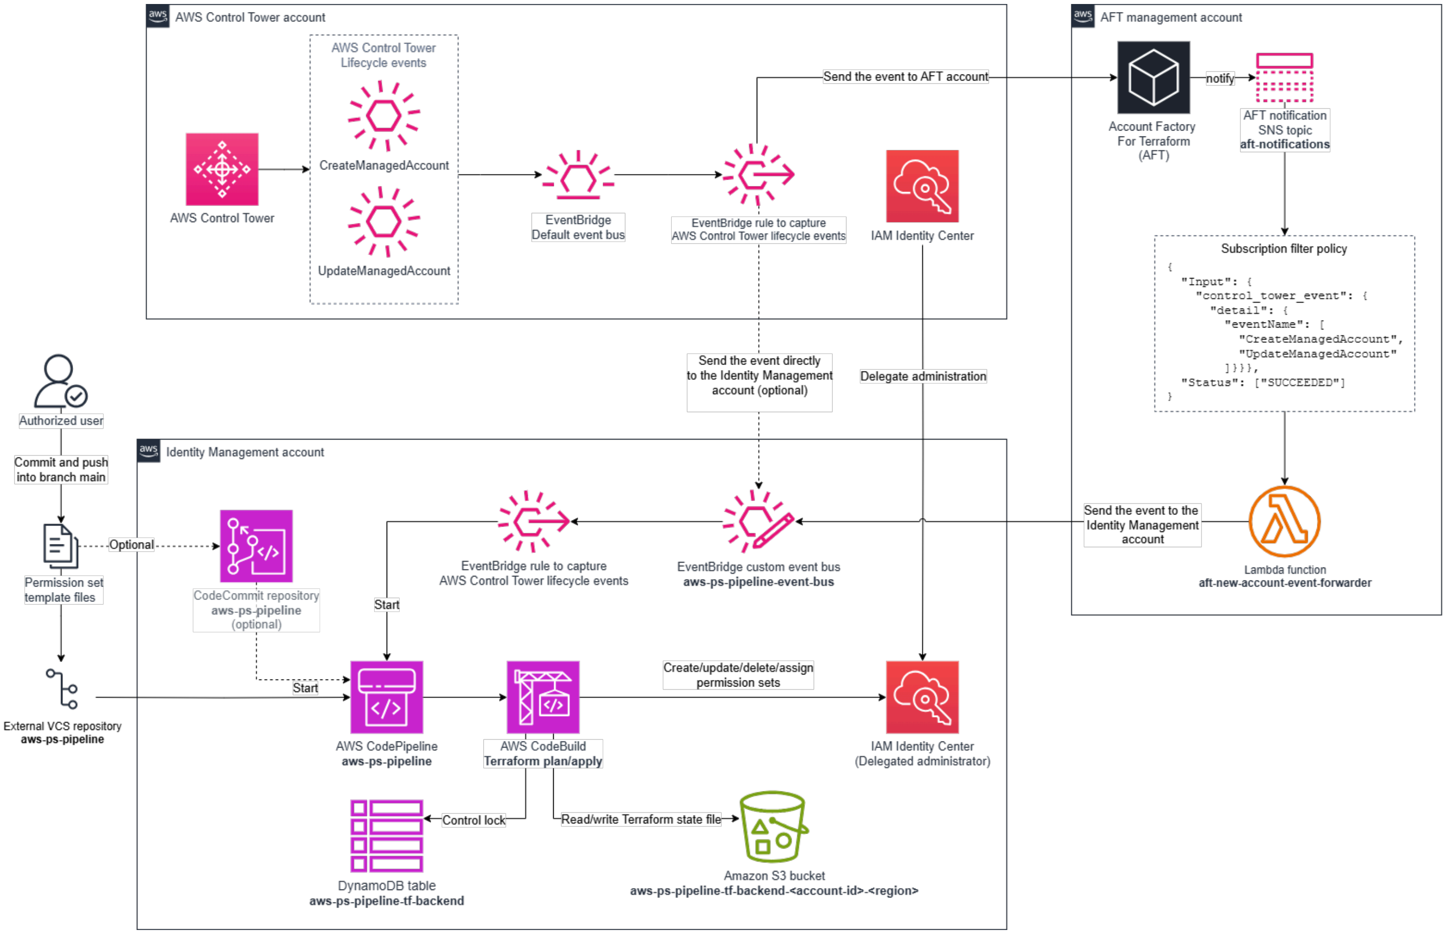
- An IAM Identity Center delegated administrator AWS account to receive the solution. For more information, see Delegated administration in the IAM Identity Center documentation.
- A version control system (VCS) repository to handle the main code. For a sample, see the solution's GitHub repository.
- Necessary AWS resources for the Terraform backend management, such as an Amazon Simple Storage Service (Amazon S3) bucket and Amazon DynamoDB table.

Limitations

- The pipeline uses AWS native resources and open source Terraform. The pipeline is not prepared to make calls to third-party ecosystems.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

The following diagram shows the components and workflow for this pattern.



AWS Control Tower events flow

The solution begins with the integration of events coming from either AWS Control Tower or AFT. The choice between one or the other service is made at the implementation time through variable definition. Regardless of the method used, the pipeline is triggered whenever an account is created or updated. The pipeline reconciles the policies stored in the permission sets management repository.

Following are the AWS Control Tower lifecycle events:

- `CreateManagedAccount` – When a new account is created
- `UpdateManagedAccount` – When an existing account is updated

Event routing

EventBridge serves as the central event processing service, capturing events generated in the AWS Control Tower account. When events occur, EventBridge intelligently routes them to a centralized event bus in the solution account. AWS Control Tower lifecycle events follow distinct routing patterns. If AFT is defined as the event source, the AFT management account handles the events instead of the AWS Control Tower account. This event-driven architecture enables automated responses to organizational changes without manual intervention.

AFT integration process

When AWS Control Tower lifecycle events reach the AFT management account, they automatically trigger multiple downstream processes that are intrinsic to AFT. After the AFT account customization workflow completes, it publishes a message to the dedicated `aft-notifications` Amazon Simple Notification Service (Amazon SNS) topic. That topic triggers the `aft-new-account-forward-event` AWS Lambda function that's implemented by this solution. The Lambda function sends the event to the solution account event bus, where it's used to start the pipeline.

Infrastructure as code pipeline

The solution pipeline operates as a fully automated deployment mechanism. The AWS CodePipeline service continuously monitors the repository for changes. Upon detecting new commits, it automatically initiates the deployment workflow and initiates a sequential process that includes validation and execution phases. The system runs Terraform `plan` operations to identify proposed changes, followed by Terraform `apply` commands to implement those changes in the AWS environment. Notably, the pipeline runs without any manual approval gates. This approach enables rapid deployment of infrastructure changes while maintaining auditability through pipeline logs and Terraform state files.

The pipeline leverages AWS CodeBuild to run Terraform operations in a controlled environment with appropriate permissions. Through this IaC approach, the pipeline can perform comprehensive permission management operations including:

- Create new permission sets.
- Update existing permission sets.
- Remove unnecessary permission sets.
- Manage the assignment of these permissions across accounts and groups within the AWS organizations.

To maintain infrastructure consistency and prevent conflicting changes, the solution implements the Terraform backend state management system using an Amazon S3 bucket and dedicated

Amazon DynamoDB table. This approach provides persistent storage location for Terraform state files and state locking mechanisms to prevent concurrent modifications to the same resources.

The main Terraform code uses the official AWS `permission-sets` Terraform module. This module can dynamically manage permission sets in IAM Identity Center, based on permission set templates.

Source control management

The permission set templates (JSON files) reside in an external version control system, such as GitHub, that provides a centralized repository for identity management configurations. This approach establishes a single source of truth for permission set definitions, while enabling collaborative development through standard code review practices. Authorized users can commit changes to these templates following organizational change management processes. These commits serve as the primary trigger for the automated deployment pipeline, initiating the infrastructure update process.

For an example of how to configure the permission sets using the JSON file in the repository, see Additional information.

Tools

AWS services

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeConnections enables AWS resources and services, such as CodePipeline, to connect to external code repositories, such as GitHub.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command line shell.
- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and cloud applications.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses. It enables push notifications for account management events, ensuring that relevant parties are informed of important changes or actions within the system.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the AWS Samples organization on GitHub in the sample-terraform-aws-permission-sets-pipeline repository.

Best practices

- Always pin the versions of the Terraform modules and providers used to run code in production.
- Use a static code analysis tool, such as Checkov, to scan your code and then solve the security issues.

- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see [Grant least privilege] and [Security best practices] in the IAM documentation.

Epics

Create the prerequisites (optional)

Task	Description	Skills required

Create Terraform backend resources.	If you haven't created your Terraform backend AWS resources yet, use the following steps to create an Amazon S3 bucket (`s3-tf-backend-{ACCOUNT_ID}`) and a DynamoDB table (`ddb-tf-backend`).
	
	1. Sign in to the AWS account where you will deploy the solution, and open AWS CloudShell in the AWS Control Tower home AWS Region.
	2. Run the following commands, replacing the placeholder `{ACCOUNT_ID}` with your AWS account ID:
	
	`aws s3api create-bucket --bucket s3-tf-backend-{ACCOUNT_ID}`
	`aws s3api put-bucket-versioning --bucket s3-tf-backend-{ACC`
		AWS administrator

Task	Description	Skills required
	```OUNT_ID} --versioning-configuration Status=Enabled aws dynamodb create-table --table-name ddb-tf-backend --attribute-definitions AttributeName=LockID,AttributeType=S --key-schema AttributeName=LockID,KeyType=HASH --provisioned-throughput ReadCapacityUnits=1,WriteCapacityUnits=1```	

Task	Description	Skills required
Create a cross-account role.	You must provide a cross-account IAM role in the `event-source-account` Terraform AWS provider configuration. If you haven't created this role yet, use the following steps to create it: 1. Sign in to the AWS account that will be your event source (AWS Control Tower management account or AFT account), and open AWS CloudShell. 2. Run the following command, replacing the placeholder `{ACCOUNT_ID}` with the AWS account ID that you're using for this solution, not your current AWS account ID: `aws iam create-role \ --role-name CrossAccountRole \ --assume-role-policy-document '{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Principal": {`	AWS administrator

Task	Description	Skills required

	``
	 "AWS": "arn:aws:iam::{ACCOUNT_ID}:root"
	                 },
	
	 "Action": "sts:AssumeRole"
	             }
	         ]
	     }'
	``
	1. Check the command output and copy the role Amazon Resource Name (ARN) (for example, `arn:aws:iam::111122223333:role/CrossAccountRole`).
	2. To attach an IAM policy to the role, run the following command:
	``
	aws iam attach-role-policy \\
	    --role-name CrossAccountRole \\
	    --policy-arn arn:aws:iam::aws:policy/AdministratorAccess
	``
	This example uses the AWS managed IAM policy [AdministratorAccess](). If you prefer, you can use a more specific policy.	

Prepare the permission set repository

Task	Description	Skills required
Create a dedicated repository.	This task assumes that you're using GitHub. Create a dedicated repository to store the main Terraform code and the permission set template JSON files.	DevOps engineer
Prepare the permission set code.	For information about how you can structure the following files, see the sample code on the solution repository: ├── main.tf ├── outputs.tf ├── providers.jinja └── templates Copy the content, keep the `providers.jinja` values, and make the necessary adjustments to the other files. For example, add permission set template files into `templates` or pin the `aws-ia/permission-sets/aws` module version in the `main.tf` file.	DevOps engineer
Commit your changes.	Commit and push the changes to the repository that you created earlier. Save	DevOps engineer

Task	Description	Skills required
	the repository name and its GitHub organization, for example, `myorg/aws-ps-pipeline` .	

Prepare the deployment code

Task	Description	Skills required
Download the content.	Download (clone) the content from the solution [repository]().	DevOps engineer
Fulfill the variables.	Create a `terraform .tfvars` file and add the following necessary variables: • `repository_name` – Name of permission set repository that you created earlier • `branch_name` – Name of the permission set repository branch • `vcs_provider` – Your VCS provider • `account_lifecycle_events_source` – The source of events to trigger the pipeline (AWS Control Tower or AFT) `repository_name = "myorg/aws-ps-pipeline"`	DevOps engineer

Task	Description	Skills required

	<pre>branch_name
	         = "main"
	vcs_provider
	          = "github"
	account_lifecycle_
	events_source = "CT"</pre> For information about additional variable options, see the variables.tf file in this pattern's GitHub repository.	

Task	Description	Skills required

Adjust the Terraform backend configuration.	In the `backend.tf` file, replace the placeholders with your own values. Use the AWS Control Tower home AWS Region, and provide the names of the previously created Amazon S3 bucket and DynamoDB table.
	<pre>terraform {
	  required_version =
	 ">=1.6"
	  backend "s3" {
	    region =
	 "{region}"
	    bucket =
	 "{bucket_name}"
	    key =
	 "terraform.tfstate"
	    dynamodb_table =
	 "{table_name}"
	    encrypt =
	 "true"
	  }
	}</pre>If you prefer, you can use your own Terraform backend configuration.
		DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Adjust the Terraform provider configuration.</td><td>

In the `providers.tf` file, replace the placeholders with your own information. Use the AWS Control Tower home Region, and provide the ARN of the previously created cross-account IAM role for the `event-source-account` provider.

```
provider "aws" {
  region = "{region}"
}

provider "aws" {
  alias  = "event-source-account"
  region = "{region}"
  assume_role {
    role_arn = "{role_arn}"
  }
}
```

</td><td>DevOps engineer</td></tr>
</table>

Deploy the solution manually

Task	Description	Skills required
Select the AWS account.	We recommend that you deploy the solution in the IAM Identity Center delegated administrator account. However, you can also deploy it in the AWS Organizations management account.	AWS administrator

Task	Description	Skills required
	To sign in to the selected account in the same Region as the IAM Identity Center instance, use the AWS CLI. Make sure that the IAM role you're using has permission to assume the role that's specified for the `event-source-account` provider in the previous steps. Also, this role must have access to the AWS resources that are used in the Terraform backend configuration.	
Run Terraform manually.	To initialize, plan and apply the configurations, run the following Terraform commands in the order shown: 1. `terraform init` 2. `terraform plan` 3. `terraform apply`	DevOps engineer
Check the deployment results.	In the IAM Identity Center delegated administrator account, check that the `aws-ps-pipeline` pipeline has been created. Also check that there is a AWS CodeConnections connection with **Pending** status.	AWS DevOps

Task	Description	Skills required
Finish the CodeConnections configuration.	To finish the CodeConnections configuration, use the following steps: 1. Go to CodeConnections, select the connection that was created, and choose **Update pending connection**. 2. Provide your GitHub credentials, install a new GitHub App or select an existing one that has access to the permission set repository, and choose **Connect**. The pipeline should now have access to the permission set repository. For detailed instructions, see [Update a pending connection]() in the Developer Tools console documentation.	AWS DevOps

Choose a pipeline execution flow to test the solution

Task	Description	Skills required
Run the pipeline by AWS Control Tower or AFT updates.	After an account is created or changed by using AWS Control Tower or AFT (depending on the type of	AWS administrator

Task	Description	Skills required
	lifecycle events that you chose), the pipeline starts.	
Run the pipeline by changing the code.	After you change the code and commit it to the `main` branch, the pipeline starts.	AWS DevOps
Run the pipeline manually.	To start the pipeline manually, use the Release change feature in AWS CodePipeline.	AWS DevOps

Troubleshooting

Issue	Solution
Access denied	Verify that you have the permissions required to deploy the solution.
CodeConnections issues	• Check that the connection status is **Available** rather than **Pending**. • Verify that the CodeConnections configura tion is properly completed with GitHub credentials. For more information, see Update a pending connection in the Developer Tools console documentation. • Make sure that the GitHub app has proper access permissions to the permission set repository.
Pipeline execution problems	• Check Amazon CloudWatch logs for pipeline execution errors. • Make sure that the IAM Identity Center delegation is set up correctly. Otherwise,

Issue	Solution
	it can cause pipeline failures when reading AWS account metadata.
Permission sets deployment issues	• Validate that the JSON syntax in the permission set template files is correct. • Verify that the IAM managed policies referenced in templates exist. • Check if the specified groups and users in assignments exist in IAM Identity Center.

Additional information

JSON file with sample permission set

The following example shows how to configure a permission set by using the JSON file in the repository:

```
{
  "Name": "ps-billing", // Permission set identifier
  "Comment": "Sample permission set for billing access", // Comment to document the
 purpose of the permission set
  "Description": "Billing access in AWS", // Detailed description
  "SessionDuration": "PT4H", // Session duration = 4 hours (ISO 8601 format)
  "ManagedPolicies": [ // List of AWS IAM managed policies
    "arn:aws:iam::aws:policy/job-function/Billing",
```

```
    "arn:aws:iam::aws:policy/job-function/SupportUser",
    "arn:aws:iam::aws:policy/AWSSupportAccess",
    "arn:aws:iam::aws:policy/job-function/ViewOnlyAccess"
  ],
  "CustomerPolicies": [], // References to IAM policies previously created
  "CustomPolicy": {}, // Inline IAM policy defined directly in the permission set
  "PermissionBoundary": {  // AWS or customer managed IAM policy to be used as boundary
    "ManagedPolicy": "",
    "CustomerPolicy": ""
  },
  "Assignments": [ // Define the assignment rules
    {
      "all_accounts": true, // Apply to ALL active AWS accounts in organization
      "principal": "G_BILLING_USERS", // Group/user name in Identity Center
      "type": "GROUP", // Can be "GROUP" or "USER"
      "account_id": [], // List of AWS account ID (empty since all_accounts=true)
      "account_ou": [], // List of AWS Organizational Unit IDs with target AWS accounts
      "account_tag": [] // List of tags (key:value) to match AWS Organization accounts
 tags
    }
  ]
}
```

For more information, see the JSON schema in the AWS Permission Sets module documentation on the Terraform website.

Tips

- You can use Terraform import blocks to import an existing permission set to the solution.
- You can use AFT to implement the AWS permission set pipeline in a delegated account. For more information, see AFT Blueprints.

Tag Transit Gateway attachments automatically using AWS Organizations

Richard Milner-Watts, Haris Bin Ayub, and John Capps, Amazon Web Services

Summary

On Amazon Web Services (AWS), you can use AWS Resource Access Manager to share AWS Transit Gateway across AWS account boundaries. When you create Transit Gateway attachments across account boundaries, however, the attachments are created without a Name tag. That can make identifying attachments time consuming.

This solution provides an automated mechanism to gather information about each Transit Gateway attachment for accounts within an organization that is managed by AWS Organizations. The process includes looking up the Classless Inter-Domain Routing (CIDR) range from the Transit Gateway route table. The solution then applies a Name tag in the form of `<CIDR-range>-<AccountName>` to the attachment within the account that holds the transit gateway.

This solution can be used alongside a solution such as the Serverless Transit Network Orchestrator from the AWS Solutions Library. Serverless Transit Network Orchestrator enables the automated creation of Transit Gateway Gateway attachments at scale.

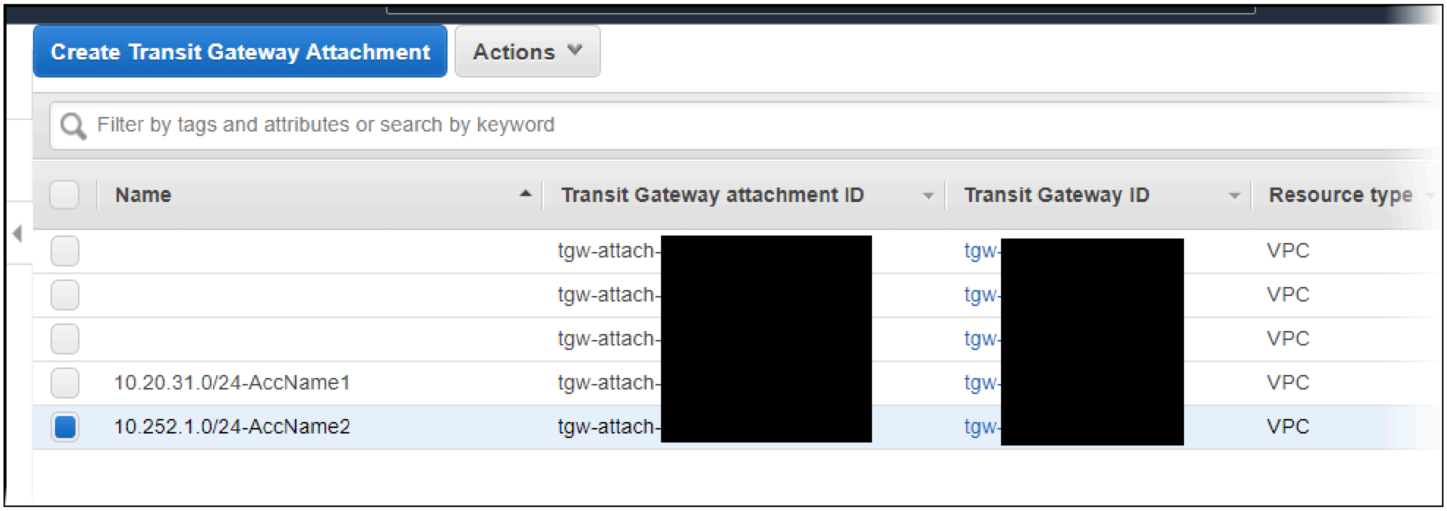
Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Organizations organization that contains all related accounts
- Access to the organization management account, under the organization's root, to create the required AWS Identity and Access Management (IAM) role
- A Shared Networking member account containing one or more transit gateways that are shared with the organization and have attachments

Architecture

The following screenshot of the AWS Management Console shows examples of Transit Gateway attachments with no associated Name tag and two Transit Gateway attachments with Name tags generated by this solution. The structure of the generated Name tag is `<CIDR-range>-<AccountName>`.



This solution uses AWS CloudFormation to deploy an AWS Step Functions workflow that manages the creation of Transit Gateway Name tags across all configured AWS Regions. The workflow invokes AWS Lambda functions, which perform the underlying tasks.

After the solution has obtained the account names from AWS Organizations, the Step Functions state machine gets all Transit Gateway attachment IDs. These are processed in parallel by Region. This processing includes looking up the CIDR range for each attachment. The CIDR range is obtained by searching the Transit Gateway route tables within the Region for a matching Transit Gateway attachment ID. If all the required information is available, the solution applies a Name tag to the attachment. The solution will not overwrite any existing Name tags.

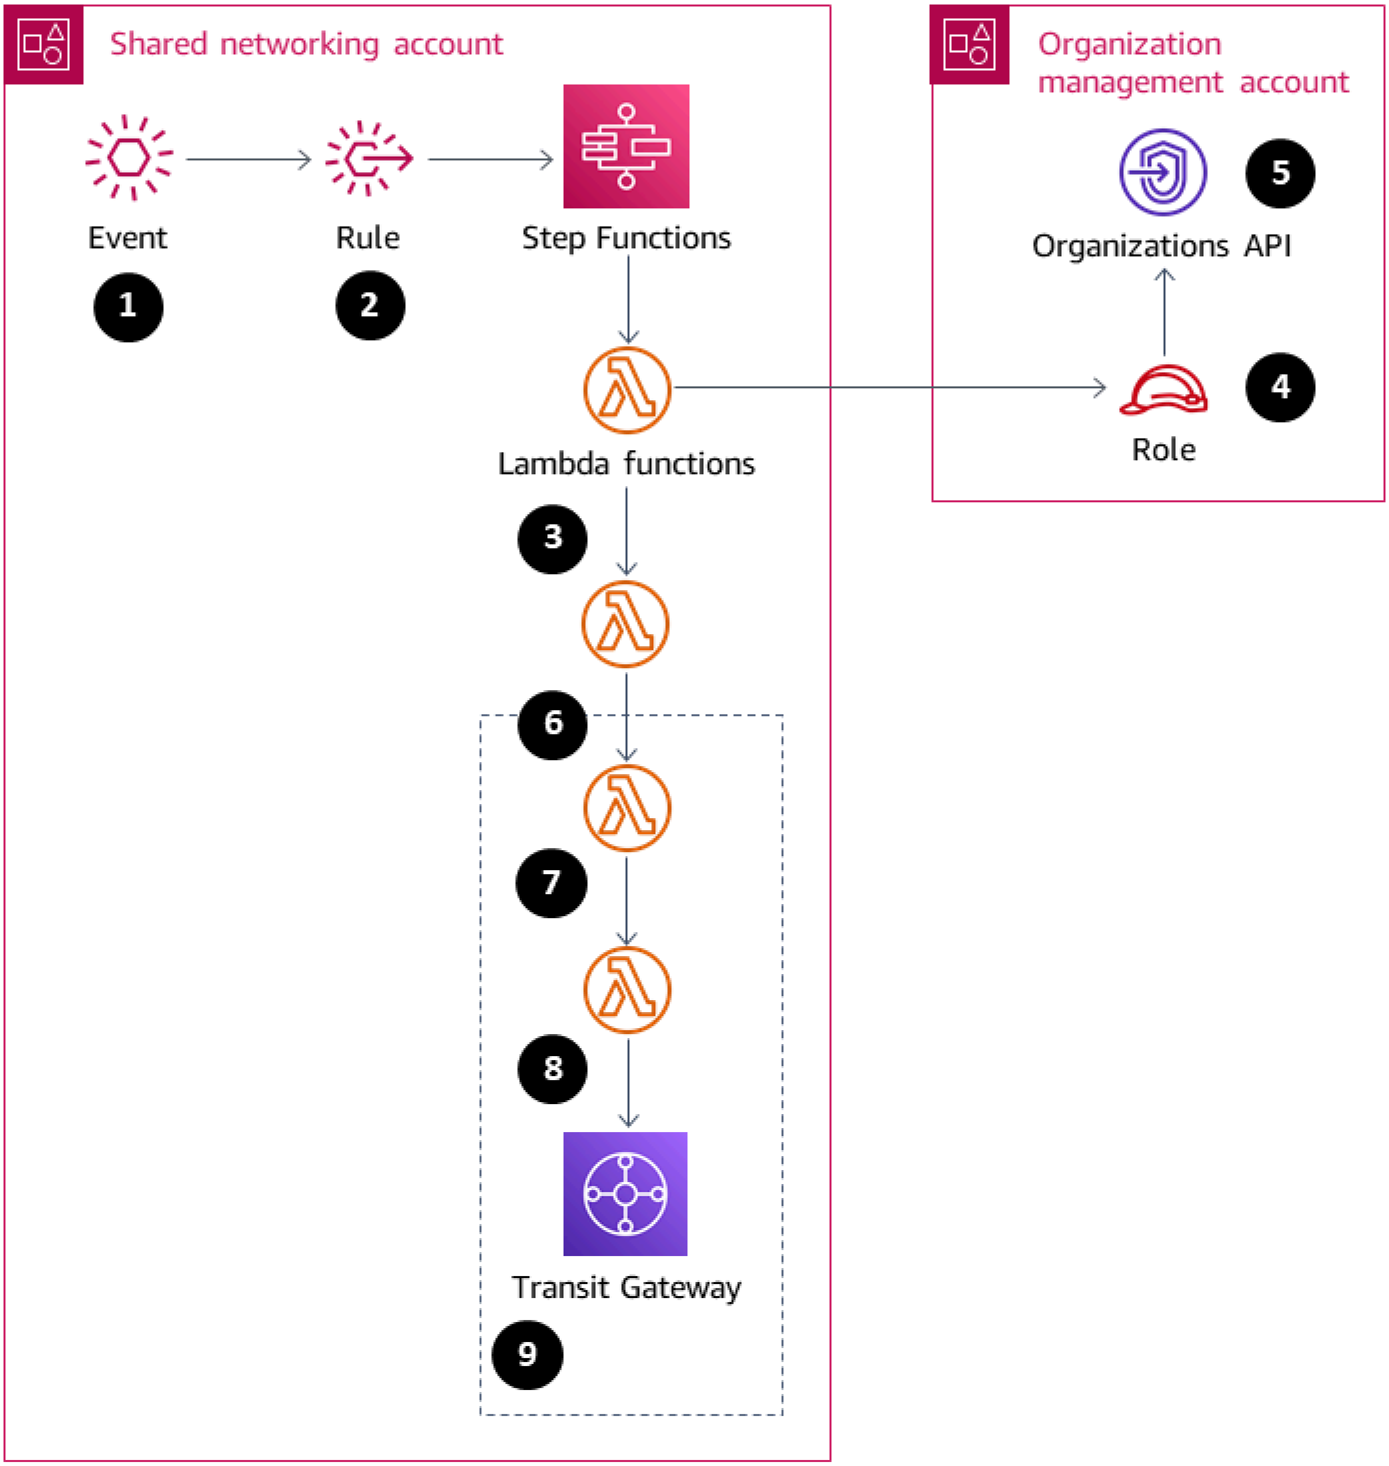
The solution runs on a schedule controlled by an Amazon EventBridge event. The event initiates the solution each day at 6:00 AM UTC.

Target technology stack

- Amazon EventBridge
- AWS Lambda
- AWS Organizations
- AWS Transit Gateway
- Amazon Virtual Private Cloud (Amazon VPC)
- AWS X-Ray

Target architecture

The solution architecture and workflow are shown in the following diagram.



1. The scheduled event initiates the rule.

2. The EventBridge rule starts the Step Functions state machine.
3. The state machine invokes the `tgw-tagger-organizations-account-query` Lambda function.
4. The `tgw-tagger-organizations-account-query` Lambda function assumes the role in the organization management account.
5. The `tgw-tagger-organizations-account-query` Lambda function calls the Organizations API to return AWS account metadata.
6. The state machine invokes the `tgw-tagger-attachment-query` Lambda function.
7. For each Region, in parallel, the state machine invokes `tgw-tagger-rtb-query` Lambda function to read the CIDR range for each attachment.
8. For each Region, in parallel, the state machine invokes `tgw-tagger-attachment-tagger` Lambda function.
9. Name tags are created for Transit Gateway attachments in the Shared Networking account.

Automation and scale

The solution processes each Region in parallel to reduce the total duration of the run.

Tools

AWS services

- [AWS CloudFormation](#) provides a way to model a collection of related AWS and third-party resources, provision them quickly and consistently, and manage them throughout their lifecycles, by treating infrastructure as code.
- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [Amazon EventBridge](#) is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge receives an event, an indicator of a change in environment, and applies a rule to route the event to a target. Rules match events to targets based on either the structure of the event, called an event pattern, or on a schedule.
- [AWS Lambda](#) is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests each day to thousands each second. You pay only for the compute time that you consume. There is no charge when your code is not running.

- AWS Organizations helps you centrally manage and govern your environment as you grow and scale your AWS resources. Using Organizations, you can programmatically create new AWS accounts and allocate resources, group accounts to organize your workflows, apply policies to accounts or groups for governance, and simplify billing by using a single payment method for all of your accounts.
- AWS Step Functions is a low-code visual workflow service used to orchestrate AWS services, automate business processes, and build serverless applications. Workflows manage failures, retries, parallelization, service integrations, and observability so developers can focus on higher-value business logic.
- AWS Transit Gateway connects VPCs and on-premises networks through a central hub. This simplifies your network and puts an end to complex peering relationships. It acts as a cloud router, so that each new connection is made only one time.
- Amazon Virtual Private Cloud (Amazon VPC) is a service for launching AWS resources in a logically isolated virtual network that you define.
- AWS X-Ray collects data about requests that your application serves, and provides tools that you can use to view, filter, and gain insights into that data to identify issues and opportunities for optimization.

Code

The source code for this solution is available in the Transit Gateway Attachment Tagger GitHub repository. The repository includes the following files:

- `tgw-attachment-tagger-main-stack.yaml` creates all the resources to support this solution within the Shared Networking account.
- `tgw-attachment-tagger-organizations-stack.yaml` creates a role in the management account of the organization.

Epics

Deploy the main solution stack

Task	Description	Skills required
Gather required prerequisite information.	To configure cross-acc ount access from the	DevOps engineer

Task	Description	Skills required
	Lambda function to the AWS Organizations API, you need the account ID for the organization's management account. **Note** The order in which the two AWS CloudFormation stacks are created matters. You must deploy resources into the Shared Networking account first. The role in the Shared Networking account must already exist before deploying resources into the organization's management account. For more information, see the [AWS documentation]().	

Task	Description	Skills required
Launch the AWS CloudFormation template for the main solution stack.	The template for the main solution stack will deploy the IAM roles, Step Functions workflow, Lambda functions, and the Amazon CloudWatch event. Open the AWS Management Console for the Shared Networking account, and then open the :&CFN console. Create the stack by using the `tgw-attachment-tagger-main-stack.yaml` template and the following values: • **Stack name – tgw-attachment-tagger-main-stack** • **awsOrganizationsRootAccountId** – Account ID for the organization's management account • **TGWRegions** parameter – AWS Regions for the solution, entered as a comma-delimited string • **TGWList** parameter – Transit gateway IDs to be excluded from the solution, entered in a comma-delimited string	DevOps engineer

Task	Description	Skills required
	For more information about launching a AWS CloudFormation stack, see the AWS documentation.	
Verify that the solution has launched successfully.	Wait for the CloudFormation stack to reach a status of **CREATE_COMPLETE**. This should take less than one minute. Open the Step Functions console, and verify that a new state machine has been created with the name **tgw-attachment-tagger-state-machine**.	DevOps engineer

Deploy the AWS Organizations stack

Task	Description	Skills required
Gather required prerequisite information.	To configure cross-account access from the Lambda function to the AWS Organizations API, you need the account ID for the Shared Networking account.	DevOps engineer
Launch the CloudFormation template for the Organizations stack	The template for the AWS Organizations stack will deploy the IAM role in the organization's management account.	DevOps engineer

Task	Description	Skills required
	Access the AWS console for the organization's management account. and then open the CloudFormation console. Create the stack by using the `tgw-attachment-tagger-organizations-stack.yaml` template and the following values: • **Stack name – tgw-attachment-tagger-organizations-stack** • **NetworkingAccountId** parameter – Account ID for the Shared Networking account For the other stack creation options, use the defaults.	
Verify that the solution has launched successfully.	Wait for the AWS CloudFormation stack to reach a status of **CREATE_COMPLETE**. This should take less than one minute. Open the AWS Identity and Access Management (IAM) console, and verify that a new role has been created with the name **tgw-attachment-tagger-organization-query-role**.	DevOps engineer

Verify the solution

Task	Description	Skills required
Run the state machine.	Open the Step Functions console for the Shared Networking account, and choose **State machines** in the navigation pane. Select the state machine **tgw-attachment-tagger-state-machine**, and choose **Start Execution**. Because the input to this state machine is not used by the solution, you can use the default value. `{ "Comment": "Insert your JSON here" }` Choose **Start Execution**.	DevOps engineer
Watch the state machine until completion.	On the new page that opens, you can watch the state machine run. The duration will depend on the number of Transit Gateway attachments to process. On this page, you can examine each step of the state machine. You can view the various tasks within the	DevOps engineer

Task	Description	Skills required
	state machine and follow links to the CloudWatch logs for the Lambda functions. For the tasks that run in parallel within the map, you can use the **Index** dropdown list to view the specific implement ations for each Region.	
Verify the Transit Gateway attachment tags.	Open the VPC console for the Shared Networking account, and choose **Transit Gateway Attachments**. On the console, a Name tag is provided for attachments that met the criteria (the attachment is propagated to a Transit Gateway route table, and the resource owner is a member of the organization).	DevOps engineer
Verify the CloudWatch event initiation.	Wait for the CloudWatc h event to initiate. This is scheduled for 06:00 UTC. Then open the Step Functions console for the Shared Networking account, and choose **State machines** in the navigation pane. Select the state machine **tgw-attachment-tagger-state -machine**. Verify that the solution ran at 06:00 UTC.	DevOps engineer

Aggregate data in Amazon DynamoDB for ML forecasting in Athena

Sachin Doshi and Peter Molnar, Amazon Web Services

Summary

This pattern shows you how to build complex aggregations of Internet of Things (IoT) data in an Amazon DynamoDB table by using Amazon Athena. You also learn how to enrich the data with machine learning (ML) inference by using Amazon SageMaker AI and how to query geospatial data by using Athena. You can use this pattern as the basis for creating an ML forecasting solution that meets your organization's requirements.

For demonstration purposes, this pattern uses an example scenario of a business that's operating a scooter rideshare and wants to predict the optimal number of scooters that must be deployed for customers in different urban neighborhoods. The business uses a pre-trained ML model that predicts customer demand for the next hour based on the past four hours. The scenario uses a public dataset from the Office of Civic Innovation & Technology for the Louisville Metro government. The resources for this scenario are available in a GitHub repository.

Prerequisites and limitations

- An active AWS account
- Permissions to create an AWS CloudFormation stack with AWS Identity and Access Management (IAM) roles for the following:
  - Amazon Simple Storage Service (Amazon S3) bucket
  - Athena
  - DynamoDB
  - SageMaker AI
  - AWS Lambda

Architecture

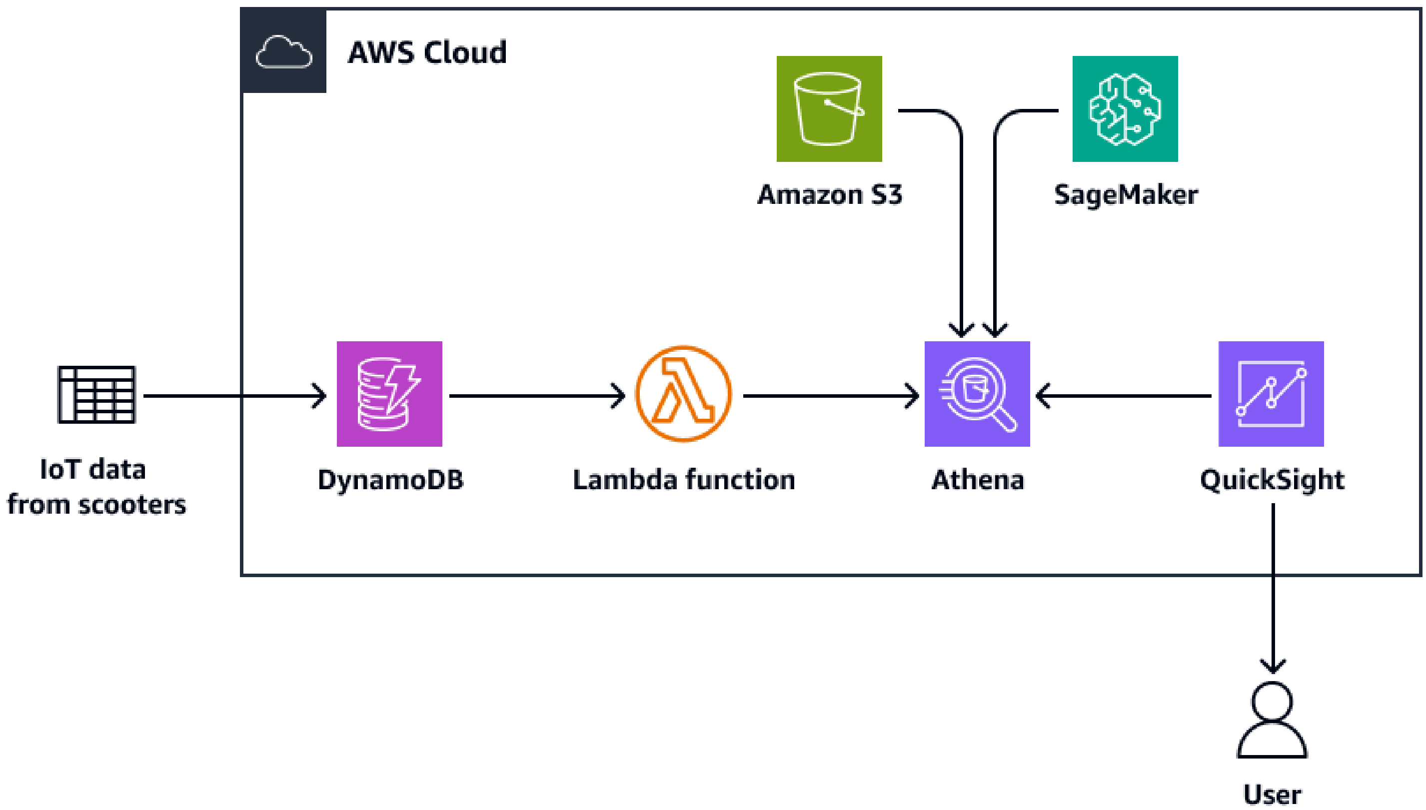
Technology stack

- Amazon QuickSight

- Amazon S3
- Athena
- DynamoDB
- Lambda
- SageMaker AI

Target architecture

The following diagram shows an architecture for building complex aggregations of data in DynamoDB by using the querying capabilities of Athena, a Lambda function, Amazon S3 storage, a SageMaker AI endpoint, and a QuickSight dashboard.



The diagram shows the following workflow:

1. A DynamoDB table ingests IoT data that's transmitted from a fleet of scooters.
2. A Lambda function loads the DynamoDB table with the ingested data.
3. An Athena query creates a new DynamoDB table for the geospatial data that represents the urban neighborhoods.

4. The query location is saved in an S3 bucket.
5. An Athena function queries the ML inference from the SageMaker AI endpoint that hosts the pre-trained ML model.
6. Athena queries data directly from the DynamoDB tables and aggregates the data for analysis.
7. A user views the output of the analyzed data in a QuickSight dashboard.

Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- Amazon SageMaker AI is a managed ML service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Code repository

The code for this pattern is available in the GitHub Use ML predictions over Amazon DynamoDB data with Amazon Athena ML repository. You can use the CloudFormation template from the repository to create the following resources used in the example scenario:

- A DynamoDB table
- A Lambda function to load the table with relevant data
- A SageMaker AI endpoint for inference requests, with the pre-trained XGBoost model that's stored in Amazon S3
- An Athena workgroup named `V2EngineWorkGroup`

- Named Athena queries to look up the geospatial shapefiles and predict scooter demand
- A prebuilt Amazon Athena DynamoDB connector that enables Athena to communicate with DynamoDB and uses AWS Serverless Application Model (AWS SAM) to build the application in reference to the DynamoDB connector

Epics

Get the example dataset

Task	Description	Skills required
Download the dataset and resources.	1. Download a public dataset of dockless vehicle rentals. For demo purposes, this data is prepopulated in DynamoDB as part of the use case, but in a production environment you send this data to DynamoDB through various mechanisms such as IoT devices or Amazon Kinesis consumers. These mechanisms use Lambda to insert data into DynamoDB. 2. Download the GIS shapefiles that represent the boundaries of historical and cultural neighborhoods within the city of Louisville, KY. The public dataset is provided by the Louisville and Jefferson County, KY Information Consortium. The original	App developer, Data scientist

Task	Description	Skills required
	shapefiles are already converted into a text file that you can query with Athena, but you can find the Python code for transforming shapefiles in the Jupyter notebook at [Geo-Spatial processing of GIS shapefiles with Amazon Athena](#) in GitHub. 3. Download the pretrained [Python code](#) that trains the ML model for hourly forecasts by using SageMaker AI and Athena. 4. Get the SQL query in Athena that brings everything together for live predictions from the data stored in DynamoDB. 5. (Optionally) Use QuickSight to [visualize geospatial data over a map of Louisville, Kentucky](#).	

Use a CloudFormation template to deploy the required resources

Task	Description	Skills required
Create a CloudFormation stack.	1. Download the CloudFormation template from the GitHub [repository](#).	AWS DevOps

Task	Description	Skills required
	2. **Note** Sign in to the AWS Management Console, and then choose `us-east-1` . : The ML model is stored in the Amazon Elastic Container Registry (Amazon ECR) for the `us-east-1` AWS Region, but the pattern is Region agnostic. You can replicate the pattern in any Region where the AWS services used in this pattern are supported. 3. Open the [CloudFormation console](), and then choose **Stacks** on the navigation pane. 4. Choose **Create stack**, and then choose **With existing resources (import resources)**. 5. On the **Identify resources** page, choose **Next**. 6. In the **Specify template** section, for **Template**	

Task	Description	Skills required
	source, select **Upload a template file**. 7. Choose **File**, and then choose the CloudFormation template that you downloaded earlier. 8. Choose **Next**, accept the default parameter values, and choose **Next** to step through the rest of the setup wizard. 9. Select the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box. 10. Choose **Create stack**. **Note** It can take 15–20 minutes for the CloudFormation stack to create these resources.	

Task	Description	Skills required
Verify the CloudFormation deployment.	To verify that the sample data from the CloudFormation template is loaded into DynamoDB, do the following: 1. Open the DynamoDB console, and then choose **Tables** from the navigation pane. 2. In the **Tables** section, check for the `DynamoDBTableDocklessVehicles` table. 3. After resource creation is complete, open the Athena console, and then choose **Workgroups** from the navigation pane. 4. Choose the `V2EngineWorkGroup` workgroup, and then choose **Switch workgroup**. 5. If you get a prompt to save the query result location, choose an Amazon S3 location where you have write permissions. 6. Choose **Save**. 7. In the navigation pane, choose **Query editor**, and then select the `athena-ml-db-<your-AWS-account-number>` database.	App developer

Load geolocation files into Athena

Task	Description	Skills required
Create an Athena table with geospatial data.	To load the geolocation files into Athena, do the following: 1. Open the [Athena console](), and then choose **Query editor** from the navigation pane. 2. Choose the **Saved queries** tab. 3. Search for and select **Q1: Neighborhoods**. 4. To return to the query editor, choose the **Editor** tab. 5. Choose **Run**. This creates a table named `louisville_ky_neighborhoods` in your database. Make sure the table is created in the `athena-ml-db-<your-AWS-account-number>` database. The query creates a new table for the geospatial data that represents the urban neighborhoods. The data table is created from GIS shapefiles. The `CREATE EXTERNAL TABLE` statement defines the schema of the table and the location and	Data engineer

Task	Description	Skills required
	format of the underlying data file. For the Python code to process shapefiles and produce this table, see Geo-Spatial processing of GIS shapefiles with Amazon Athena in AWS Samples. For detailed SQL code, see create_neighborhood_table.sql on GitHub.	

Predict demand for scooters by neighborhood from the aggregated DynamoDB data

Task	Description	Skills required
Declare a function in Athena to query SageMaker AI.	1. Open the Athena console, choose **Query editor** from the navigation pane, and then choose the **Editor** tab. 2. Copy and paste the following SQL statement into the query editor. `USING EXTERNAL FUNCTION predict_demand ( location_id BIGINT, hr BIGINT , dow BIGINT, n_pickup_1 BIGINT, n_pickup_2 BIGINT, n_pickup_3 BIGINT, n_pickup_4 BIGINT,`	Data scientist, Data engineer

Task	Description	Skills required
	``` n_dropoff_1 BIGINT, n_dropoff_2 BIGINT, n_dropoff_3 BIGINT, n_dropoff_4 BIGINT) RETURNS DOUBLE SAGEMAKER '<Your SageMaker endpoint>' ``` The first part of the SQL statement declares the external function to query ML inferences from the SageMaker AI endpoint that hosts the pre-trained model. 3. Define the order and type of the input parameters and the type of the return values. 4. Choose **Run**.	

Task	Description	Skills required
Predict demand for scooters by neighborhood from the aggregated DynamoDB data.	Now you can use Athena to query transactional data directly from DynamoDB, and then aggregate the data for analysis and forecasting. This isn't easily achieved by directly querying a DynamoDB NoSQL database. 1. Open the [Athena console,](https://console.aws.amazon.com/athena/) and then choose the **Query editor** from the navigation pane. 2. Choose the **Saved queries** tab. 3. Search for and select **Q2: DynamoDBAthenaMLScooterPredict**. 4. To return to the query editor, choose the **Editor** tab. 5. Choose **Run**. The SQL statement does the following: • Uses an [Athena Federated Query](https://docs.aws.amazon.com/athena/latest/ug/connect-to-a-data-source.html) to query the DynamoDB table with the raw trip data • Places geographic coordinates into neighborhoods by using the geospatial functions of Athena	App developer, Data scientist

Task	Description	Skills required
	• Enriches data with ML inference by using SageMaker AI For information about using SQL to aggregate DynamoDB data and SageMaker AI inference data in Athena, see [athena_long.sql](#) in GitHub.	
Verify the output.	The output table includes the neighborhood, longitude, and latitude of the centroid of the neighborhood. It also includes the number of vehicles that are predicted for the next hour. The query produces the predictions for a selected point in time. You can make predictions for any other time by changing the expression `TIMESTAMP '2019-09-07 15:00'` everywhere in the statement. If you have a real-time data feed in your DynamoDB table, change the timestamp to `NOW()`.	App developer, Data scientist

Clean up the environment

Task	Description	Skills required
Delete resources.	1. Open the Athena console and empty the bucket that you created as part of the CloudFormation stack. 2. Open the CloudFormation console, and then delete the stack named `bdb-1462-athena-dynamodb-ml-stack` . 3. Open the Amazon CloudWatch console, and then delete the log group named `/aws/sagemaker/Endpoints/Sg-athena-ml-dynamodb-model-endpoint` .	App developer, AWS DevOps

Associate an AWS CodeCommit repository in one AWS account with Amazon SageMaker AI Studio Classic in another account

Laurens van der Maas and Aubrey Oosthuizen, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern provides instructions and code on how to associate an AWS CodeCommit repository in one AWS account (Account A) with Amazon SageMaker AI Studio Classic in another AWS account (Account B). To set up the association, you must create an AWS Identity and Access Management (IAM) policy and role in Account A and an IAM inline policy in Account B. Then, you use a shell script to clone the CodeCommit repository from Account A to Amazon SageMaker AI Classic in Account B.

Prerequisites and limitations

Prerequisites

- Two AWS accounts, one containing the CodeCommit repository and the other containing a SageMaker AI Domain with a user
- Provisioned SageMaker AI Domain and user, with internet access or access to CodeCommit and AWS Security Token Service (AWS STS) through virtual private network (VPC) endpoints
- A basic understanding of IAM
- A basic understanding of SageMaker AI Studio Classic
- A basic understanding of Git and CodeCommit

Limitations

This pattern applies to SageMaker AI Studio Classic only, not to RStudio on Amazon SageMaker AI.

Architecture

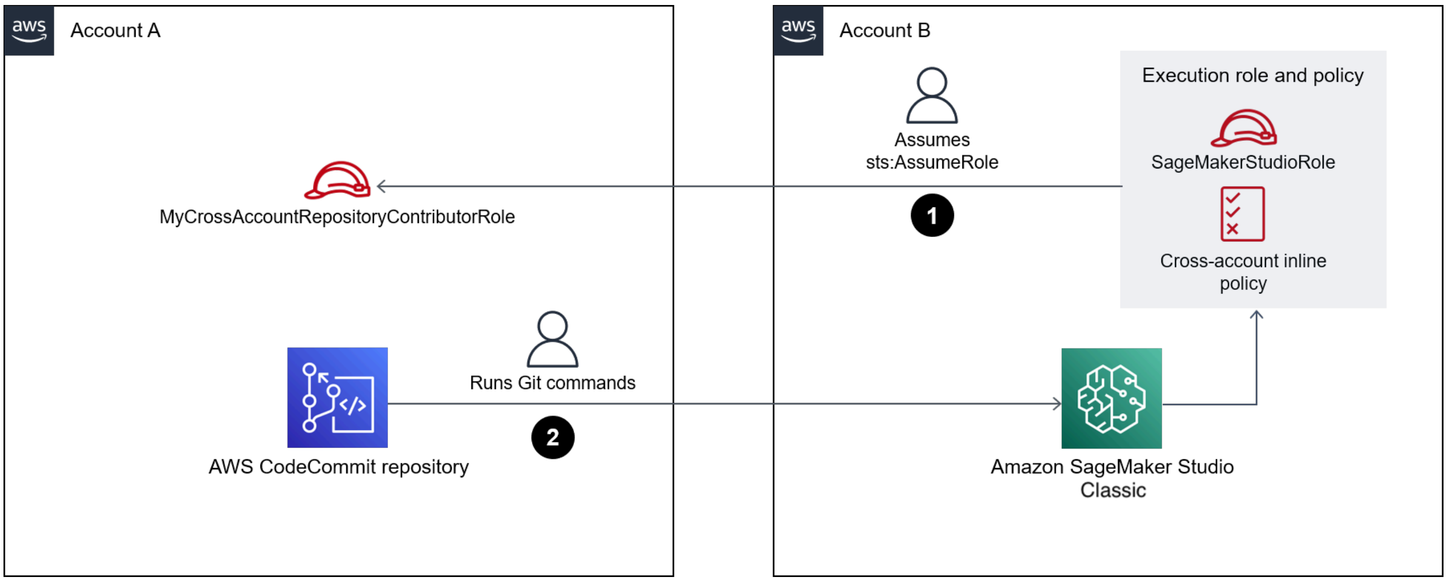
Technology stack

- Amazon SageMaker AI
- Amazon SageMaker AI Studio Classic

- AWS CodeCommit
- AWS Identity and Access Management (IAM)
- Git

Target architecture

The following diagram shows an architecture that associates a CodeCommit repository from Account A to SageMaker AI Studio Classic in Account B.



The diagram shows the following workflow:

1. A user assumes the `MyCrossAccountRepositoryContributorRole` role in Account A through the `sts:AssumeRole` role, while using the SageMaker AI execution role in SageMaker AI Studio Classic in Account B. The assumed role includes the CodeCommit permissions to clone and interact with the specified repository.
2. The user performs Git commands from the system terminal in SageMaker AI Studio Classic.

Automation and scale

This pattern consists of manual steps that can be automated by using the AWS Cloud Development Kit (AWS CDK), AWS CloudFormation, or Terraform.

Tools

AWS tools

- Amazon SageMaker AI is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- Amazon SageMaker AI Studio Classic is a web-based, integrated development environment (IDE) for machine learning that lets you build, train, debug, deploy, and monitor your machine learning models.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

  Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Other tools

- Git is a distributed version-control system for tracking changes in source code during software development.

Epics

Create an IAM policy and IAM role in Account A

Task	Description	Skills required
Create an IAM policy for repository access in Account A.	1. Sign in to the AWS Management Console and open the IAM console. 2. In the navigation pane, choose **Policies**, and then choose **Create policy**. 3. Choose the **JSON** tab. 4. Copy the policy statement from *Example IAM policy* in the Additional information section of this pattern, and then paste the statement	AWS DevOps

Task	Description	Skills required
	into the JSON editor. Make sure to replace all placeholder values in the policy. 5. Choose **Next:Tags**, and then choose **Next:Review**. 6. For **Name**, enter a name for the policy. **Note**: In this pattern, the IAM policy is referred to as `CrossAccountAccessForMySharedDemoRepo` , but you can choose whatever policy name that you prefer. 7. Choose **Create policy**. **Tip** It's a best practice to restrict the scope of your IAM policies to the minimum required permissions for your use case.	

Task	Description	Skills required
Create an IAM role for repository access in Account A.	1. In the navigation pane of the [IAM console](https://console.aws.amazon.com/iam/), choose **Roles**, and then choose **Create role**. 2. For **Trusted entity type**, select **AWS account**. 3. In the **AWS account** section, select **Another AWS account**. 4. For **Account ID**, enter the account ID for Account B. 5. On the **Add permissions** page, search for and choose the `CrossAccountAccessForMySharedDemoRepo` policy that you created earlier. 6. Choose **Next**. 7. For **Role name**, enter a name. **Note**: In this pattern, the IAM role name is referred to as `MyCrossAccountRepositoryContributorRole`, but you can choose whatever role name that you prefer. 8. Choose **Create role**, and then copy the Amazon Resource Name (ARN) of the new role.	AWS DevOps

Create an IAM inline policy in Account B

Task	Description	Skills required
Attach an inline policy to the execution role that's attached to your SageMaker Domain user in Account B.	1. In the navigation pane of the IAM console, choose **Roles**. 2. Search for and choose the execution role that's attached to your SageMaker AI Domain user in Account B. 3. Choose **Add permissions**, and then choose **Create inline policy**. 4. Choose the **JSON** tab. 5. Copy the following policy statement, and then paste it into the JSON editor. `{ "Version": "2012-10-17", "Statement": [ { "Sid": "VisualEditor0", "Effect": "Allow", "Action": "sts:AssumeRole", "Resource": "arn:aws:iam::<Account_A_ID>:role/<Account_A_Role_Name>" } ] }`	AWS DevOps

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::<Account_A_ID>:role/<Account_A_Role_Name>"
        }
    ]
}
```

Task	Description	Skills required
	6. Replace `<Account_A_ID>` with the account ID for Account A. Replace `<Account_A_Role_Name>` with the name of the IAM role that you created earlier. 7. Choose **Review policy**. 8. For **Name**, enter a name for your inline policy. 9. Choose **Create policy**.	

Clone the repository in SageMaker AI Studio Classic for Account B

Task	Description	Skills required
Create the shell script in SageMaker AI Studio Classic in Account B.	1. In the navigation pane of the [SageMaker console](https://console.aws.amazon.com/sagemaker/), choose **Studio**. 2. Select your user profile and then choose **Open Studio**. 3. In the **Home** section, choose **Open Launcher**. 4. In the **Utilities and files** section, choose **Text file**. 5. Copy the script from *Example SageMaker shell script* in the [Additional information](#additional-information) section of this pattern, and then paste the statement into the new file. Make sure to replace	AWS DevOps

Task	Description	Skills required
	all placeholder values in the script. 6. Right-click the **untitled.txt** tab of your new file, and then choose **Rename Text**. For **New Name**, enter **cross_account_git_clone.sh**, and then choose **Rename**.	
Invoke the shell script from the system terminal.	1. In the **Home** section of the [SageMaker console](https://console.aws.amazon.com/sagemaker/), choose **Open Launcher**. 2. In the **Utilities and files** section, choose **System terminal**. 3. In the terminal, run the following command: `chmod u+x ./cross_account_git_clone.sh && ./cross_account_git_clone.sh` You have cloned your CodeCommit repository in a SageMaker AI Studio cross-account. You can now perform all Git commands from the system terminal.	AWS DevOps

Additional information

Example IAM policy

If you use this example policy, do the following:

- Replace <CodeCommit_Repository_Region> with the AWS Region for the repository.
- Replace <Account_A_ID> with the account ID for Account A.
- Replace <CodeCommit_Repository_Name> with the name of your CodeCommit repository in Account A.

```
{
"Version": "2012-10-17",
"Statement": [
    {
        "Effect": "Allow",
        "Action": [
            "codecommit:BatchGet*",
            "codecommit:Create*",
            "codecommit:DeleteBranch",
            "codecommit:Get*",
            "codecommit:List*",
            "codecommit:Describe*",
            "codecommit:Put*",
            "codecommit:Post*",
            "codecommit:Merge*",
            "codecommit:Test*",
            "codecommit:Update*",
            "codecommit:GitPull",
            "codecommit:GitPush"
        ],
        "Resource": [

 "arn:aws:codecommit:<CodeCommit_Repository_Region>:<Account_A_ID>:<CodeCommit_Repository_Name>
        ]
    }
]
}
```

Example SageMaker AI shell script

If you use this example script, do the following:

- Replace <Account_A_ID> with the account ID for Account A.
- Replace <Account_A_Role_Name> with the name of the IAM role that you created earlier.

- Replace <CodeCommit_Repository_Region> with the AWS Region for the repository.
- Replace <CodeCommit_Repository_Name> with the name of your CodeCommit repository in Account A.

```
#!/usr/bin/env bash
#Launch from system terminal
pip install --quiet git-remote-codecommit

mkdir -p ~/.aws
touch ~/.aws/config

echo "[profile CrossAccountAccessProfile]
region = <CodeCommit_Repository_Region>
credential_source=EcsContainer
role_arn = arn:aws:iam::<Account_A_ID>:role/<Account_A_Role_Name>
output = json" > ~/.aws/config

echo '[credential "https://git-
codecommit.<CodeCommit_Repository_Region>.amazonaws.com"]
        helper = !aws codecommit credential-helper $@ --profile
 CrossAccountAccessProfile
        UseHttpPath = true' > ~/.gitconfig

git clone codecommit::<CodeCommit_Repository_Region>://
CrossAccountAccessProfile@<CodeCommit_Repository_Name>
```

Automatically extract content from PDF files using Amazon Textract

Tianxia Jia, Amazon Web Services

Summary

Many organizations need to extract information from PDF files that are uploaded to their business applications. For example, an organization could need to accurately extract information from tax or medical PDF files for tax analysis or medical claim processing.

On the Amazon Web Services (AWS) Cloud, Amazon Textract automatically extracts information (for example, printed text, forms, and tables) from PDF files and produces a JSON-formatted file that contains information from the original PDF file. You can use Amazon Textract in the AWS Management Console or by implementing API calls. We recommend that you use programmatic API calls to scale and automatically process large numbers of PDF files.

When Amazon Textract processes a file, it creates the following list of `Block` objects: pages, lines and words of text, forms (key-value pairs), tables and cells, and selection elements. Other object information is also included, for example, bounding boxes, confidence intervals, IDs, and relationships. Amazon Textract extracts the content information as strings. Correctly identified and transformed data values are required because they can be more easily used by your downstream applications.

This pattern describes a step-by-step workflow for using Amazon Textract to automatically extract content from PDF files and process it into a clean output. The pattern uses a template matching technique to correctly identify the required field, key name, and tables, and then applies post-processing corrections to each data type. You can use this pattern to process different types of PDF files and you can then scale and automate this workflow to process PDF files that have an identical format.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon Simple Storage Service (Amazon S3) bucket to store the PDF files after they are converted to JPEG format for processing by Amazon Textract. For more information about S3 buckets, see Buckets overview in the Amazon S3 documentation.

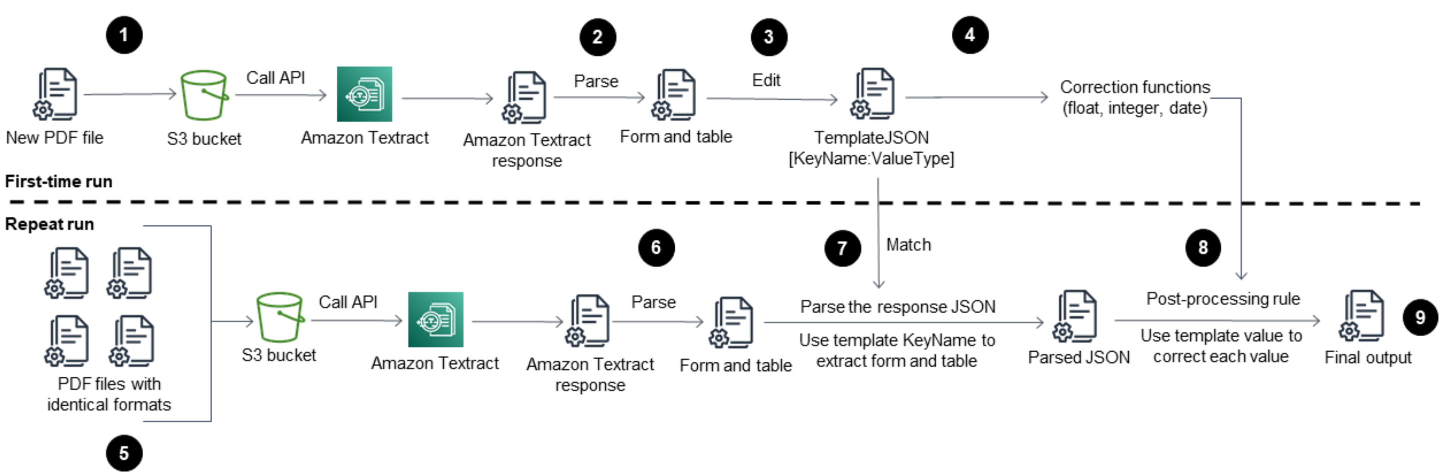
- The `Textract_PostProcessing.ipynb` Jupyter notebook (attached), installed and configured. For more information about Jupyter notebooks, see [Create a Jupyter notebook] in the Amazon SageMaker documentation.
- Existing PDF files that have an identical format.
- An understanding of Python.

Limitations

- Your PDF files must be of good quality and clearly readable. Native PDF files are recommended, but you can use scanned documents that are converted to a PDF format if all the individual words are clear. For more information about this, see PDF document preprocessing with Amazon Textract: Visuals detection and removal on the AWS Machine Learning Blog.
- For multipage files, you can use an asynchronous operation or split the PDF files into a single page and use a synchronous operation. For more information about these two options, see Detecting and analyzing text in multipage documents and Detecting and analyzing text in single-page documents in the Amazon Textract documentation.

Architecture

This pattern's workflow first runs Amazon Textract on a sample PDF file (*First-time run*) and then runs it on PDF files that have an identical format to the first PDF (*Repeat run*). The following diagram shows the combined *First-time run* and *Repeat run* workflow that automatically and repeatedly extracts content from PDF files with identical formats.



The diagram shows the following workflow for this pattern:

1. Convert a PDF file into JPEG format and store it in an S3 bucket.
2. Call the Amazon Textract API and parse the Amazon Textract response JSON file.
3. Edit the JSON file by adding the correct `KeyName:DataType` pair for each required field. Create a `TemplateJSON` file for the *Repeat run* stage.
4. Define the post-processing correction functions for each data type (for example, float, integer, and date).
5. Prepare the PDF files that have an identical format to your first PDF file.
6. Call the Amazon Textract API and parse the Amazon Textract response JSON.
7. Match the parsed JSON file with the `TemplateJSON` file.
8. Implement post-processing corrections.

The final JSON output file has the correct `KeyName` and `Value` for each required field.

Target technology stack

- Amazon SageMaker
- Amazon S3
- Amazon Textract

Automation and scale

You can automate the *Repeat run* workflow by using an AWS Lambda function that initiates Amazon Textract when a new PDF file is added to Amazon S3. Amazon Textract then runs the processing scripts and the final output can be saved to a storage location. For more information about this, see Using an Amazon S3 trigger to invoke a Lambda function in the Lambda documentation.

Tools

- Amazon SageMaker is a fully managed ML service that helps you to quickly and easily build and train ML models, and then directly deploy them into a production-ready hosted environment.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Textract makes it easy to add document text detection and analysis to your applications.

Epics

First-time run

Task	Description	Skills required
Convert the PDF file.	Prepare the PDF file for your first-time run by splitting it into a single page and converting it into JPEG format for the Amazon Textract [synchronous operation](#) (`Syn API`). **Note** You can also use the Amazon Textract [asynchronous operation](#) (`Asyn API`) for multipage PDF files.	Data scientist, Developer

Parse the Amazon Textract response JSON.	Open the `Textract_PostProcessing.ipynb` Jupyter notebook (attached) and call the Amazon Textract API by using the following code:
	
	`response = textract.analyze_document(`
	`Document={`
	`'S3Object': {`
	`'Bucket': BUCKET,`
	`'Name': '{}'.format(filename)`
		Data scientist, Developer

Task	Description	Skills required

	``
	                    }
	                },
	        FeatureTy
	pes=["TABLES",
	 "FORMS"])
	``
	Parse the response JSON into a form and table by using the following code:
	``
	parseformKV=form_k
	v_from_JSON(response)
	parseformTable
	s=get_tables_fromJ
	SON(response)
	``	

Edit the TemplateJSON file.	Edit the parsed JSON for each `KeyName` and correspon ding `DataType` (for example, string, float, integer, or date), and table headers (for example, `ColumnNames` and `RowNames`). This template is used for each individual PDF file type, which means that the template can be reused for PDF files that have an identical format.	Data scientist, Developer

Task	Description	Skills required
Define the post-processing correction functions.	The values in Amazon Textract's response for the `TemplateJSON` file are strings. There is no differentiation for date, float, integer, or currency. These values must be converted to the correct data type for your downstream use case. Correct each data type according to the `TemplateJSON` file by using the following code: `finalJSON=postprocessingCorrection(parsedJSON,templateJSON)`	Data scientist, Developer

Repeat run

Task	Description	Skills required
Prepare the PDF files.	Prepare the PDF files by splitting them into a single page and converting them into JPEG format for the Amazon Textract [synchronous operation](https://docs.aws.amazon.com/textract/latest/dg/sync.html) (`Syn API`). **Note** You can also use the Amazon Textract	Data scientist, Developer

Task	Description	Skills required
	asynchronous operation (Asyn API) for multipage PDF files.	
Call the Amazon Textract API.	Call the Amazon Textract API by using the following code: ```response = textract.analyze_document(Document={ 'S3Object': { 'Bucket': BUCKET, 'Name': '{}'.format(filename) } }, FeatureTypes=["TABLES", "FORMS"])```	Data scientist, Developer
Parse the Amazon Textract response JSON.	Parse the response JSON into a form and table by using the following code: ```parseformKV=form_kv_from_JSON(response) parseformTables=get_tables_fromJSON(response)```	Data scientist, Developer

Task	Description	Skills required
Load the TemplateJSON file and match it with the parsed JSON.	Use the `TemplateJSON` file to extract the correct key-value pairs and table by using the following commands: `form_kv_corrected=form_kv_correction(parseformKV,templateJSON) form_table_corrected=form_Table_correction(parseformTables, templateJSON) form_kv_table_corrected_final={**form_kv_corrected , **form_table_corrected}`	Data scientist, Developer
Post-processing corrections.	Use `DataType` in the `TemplateJSON` file and post-processing functions to correct data by using the following code: `finalJSON=postprocessingCorrection(form_kv_table_corrected_final,templateJSON)`	Data scientist, Developer

Build a cold start forecasting model by using DeepAR for time series in Amazon SageMaker AI Studio Lab

Ivan Cui and Eyal Shacham, Amazon Web Services

Summary

Whether you're allocating resources more efficiently for web traffic, forecasting patient demand for staffing needs, or anticipating sales of a company's products, forecasting is an essential tool. Cold start forecasting builds forecasts for a time series that has little historical data, such as a new product that just entered the retail market. This pattern uses the Amazon SageMaker AI DeepAR forecasting algorithm to train a cold start forecasting model and demonstrates how to perform forecasting on cold start items.

DeepAR is a supervised learning algorithm for forecasting scalar (one-dimensional) time series using recurrent neural networks (RNN). DeepAR takes the approach of training a single model jointly over all of the time series of related products' time series.

Traditional time series forecasting methods such as autoregressive integrated moving average (ARIMA) or exponential smoothing (ETS) rely heavily on historical time series of each individual product. Therefore, those methods aren't effective for cold start forecasting. When your dataset contains hundreds of related time series, DeepAR outperforms the standard ARIMA and ETS methods. You can also use the trained model to generate forecasts for new time series that are similar to the time series that it has been trained on.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Amazon SageMaker AI domain.
- An Amazon SageMaker AI Studio Lab or Jupiter lab application.
- An Amazon Simple Storage Service (Amazon S3) bucket with read and write permissions.
- Knowledge of programming in Python.
- Knowledge of using a Jupyter notebook.

Limitations

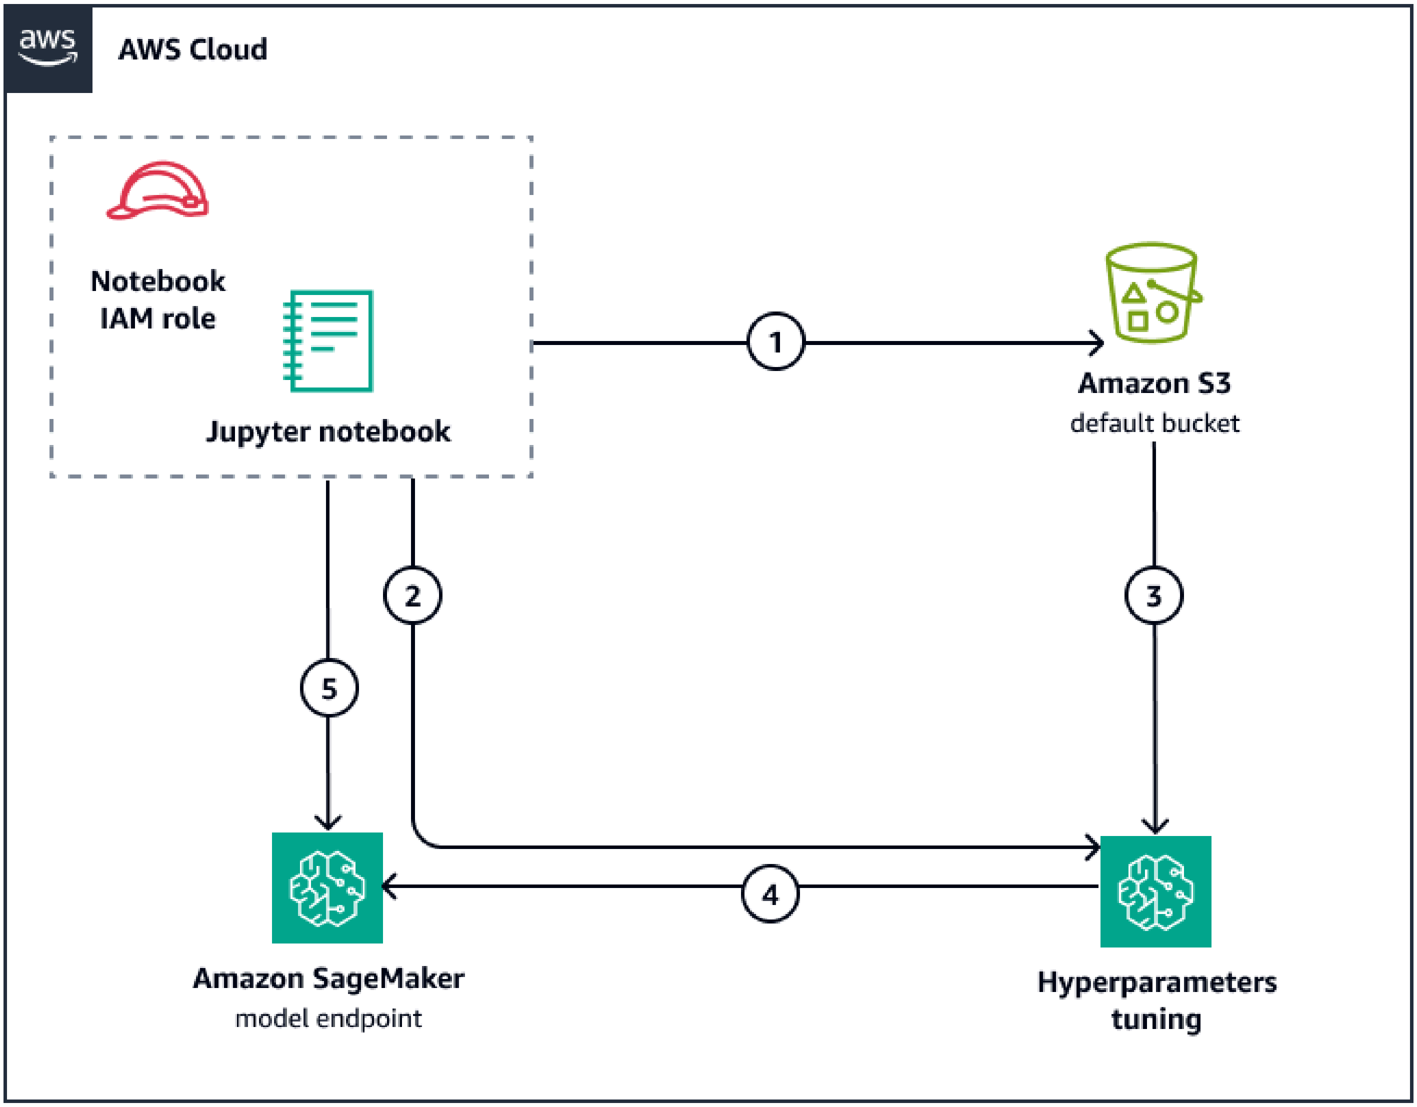
- Invoking the forecast model without any historical data points will return an error. Invoking the model with minimal historical data points will return inaccurate predictions with high confidence. This pattern suggests an approach to resolving these known limitations of cold start forecasting.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- Python version 3.10 or later.
- The pattern's notebook was tested in Amazon SageMaker AI Studio on an ml.t3.medium instance with the Python 3 (Data Science) kernel.

Architecture

The following diagram shows the workflow and architecture components for this pattern.



The workflow performs the following tasks:

1. Input files of training and testing data are synthesized and then uploaded to an Amazon S3 bucket. This data includes multiple time series with categorical and dynamic features, along with target values (to be predicted). The Jupyter notebook visualizes the data to better understand the requirements of the training data and the expected predicted values.
2. A hyperparameters tuner job is created to train the model and find the best model based on predefined metrics.
3. The input files are downloaded from the Amazon S3 bucket to each instance of the hyperparameters tuning jobs.
4. After the tuner job selects the best model based on the tuner's predefined threshold, the model is deployed as a SageMaker AI endpoint.

5. The deployed model is then ready to be invoked where its predictions are validated against the test data.

The notebook demonstrates how well the model predicts the target values when an adequate number of historical data points are available. However, when we invoke the model with fewer historical data points (which represent a cold product), the model's predictions do not match the original testing data even within the model's confidence levels. In the pattern, a new model is built for cold products where its initial context length (predicted points) is defined as the amount of available historical points, and a new model is trained iteratively as new data points are acquired. The notebook shows that the model will have accurate predictions as long as the amount of historical data points is close to its context length.

Tools

AWS services

- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon SageMaker AI is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- Amazon SageMaker AI Studio is a web-based, integrated development environment (IDE) for ML that lets you build, train, debug, deploy, and monitor your ML models.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub DeepAR-ColdProduct-Pattern repository.

Best practices

- Train your model in a virtual environment, and always use version control for the highest reproducibility effort.

- Include as many high-quality categorical features as you can to get the highest predictive model.
- Make sure that the metadata contains similar categorical items in order for the model to infer cold start products predictions adequately.
- Run a hyperparameter tuning job to get the highest predictive model.
- In this pattern, the model you build has a context length of 24 hours, which means that it will predict the next 24 hours. If you try to predict the next 24 hours when you have less than 24 hours of data historically, the model's prediction accuracy degrades linearly based on the amount of historical data points. To mitigate this issue, create a new model for each set of historical data points until this number reaches the desired prediction (context) length. For example, start with a context length model of 2 hours, then increase the model progressively to 4 hours, 8 hours, 16 hours, and 24 hours.

Epics

Start your SageMaker AI Studio Classic application

Task	Description	Skills required
Start your notebook environment.	1. Sign in to the AWS Management Console, and open the SageMaker AI Studio home page. Then choose **Open Studio**. 2. In the left navigation pane, choose the **Studio Classic** icon in **Applications**. Then, choose the **Open** button on the **Application** list. For more information, see Launch Amazon SageMaker AI Studio in the SageMaker AI documentation.	Data scientist

Create and activate the notebook

Task	Description	Skills required
Set up your virtual environment for model training.	To set up your virtual environment for model training, do the following: 1. Download the `deepar_synthetic.ipynb` notebook from this pattern's GitHub repository to your local machine. 2. In Amazon SageMaker AI Studio Classic, choose the **Upload Files** icon from the **Studio Classic** menu bar and select the downloaded notebook. 3. Choose the notebook in the **File Browser** in the left navigation pane. Follow the prompts to set up a notebook environment. Select the Data Science 3.0 Image and Python 3 Kernel. For more information, see Upload Files to SageMaker AI Studio Classic in the SageMaker AI documentation.	Data scientist
Create and validate a forecasting model.	• Follow the instructions in the notebook to create the training and testing data,	Data scientist

Task	Description	Skills required
	train the model, and then invoke the model. • Observe how accurate the model's predictions are when it's provided with adequate historical data points.

Build an MLOps workflow by using Amazon SageMaker AI and Azure DevOps

Deepika Kumar, Sara van de Moosdijk, and Philips Kokoh Prasetyo, Amazon Web Services

Summary

Machine learning operations (MLOps) is a set of practices that automate and simplify machine learning (ML) workflows and deployments. MLOps focuses on automating the ML lifecycle. It helps ensure that models are not just developed but also deployed, monitored, and retrained systematically and repeatedly. It brings DevOps principles to ML. MLOps results in faster deployment of ML models, better accuracy over time, and stronger assurance that they provide real business value.

Organizations often have existing DevOps tools and data storage solutions before starting their MLOps journey. This pattern showcases how to harness the strengths of both Microsoft Azure and AWS. It helps you integrate Azure DevOps with Amazon SageMaker AI to create an MLOps workflow.

The solution simplifies working between Azure and AWS. You can use Azure for development and AWS for machine learning. It promotes an effective process for making machine learning models from start to finish, including data handling, training, and deployment on AWS. For efficiency, you manage these processes through Azure DevOps pipelines. The solution is applicable to foundation model operations (FMOps) and large language model operations (LLMOps) in generative AI, which includes fine-tuning, vector databases, and prompt management.

Prerequisites and limitations

Prerequisites

- **Azure subscription –** Access to Azure services, such as Azure DevOps, for setting up the continuous integration and continuous deployment (CI/CD) pipelines.
- **Active AWS account –** Permissions to use the AWS services used in this pattern.
- **Data –** Access to historical data for training the machine learning model.
- **Familiarity with ML concepts –** Understanding of Python, Jupyter Notebooks, and machine learning model development.
- **Security configuration –** Proper configuration of roles, policies, and permissions across both Azure and AWS to ensure secure data transfer and access.

- **(Optional) Vector database –** If you're using a Retrieval Augmented Generation (RAG) approach and a third-party service for the vector database, you need access to the external vector database.

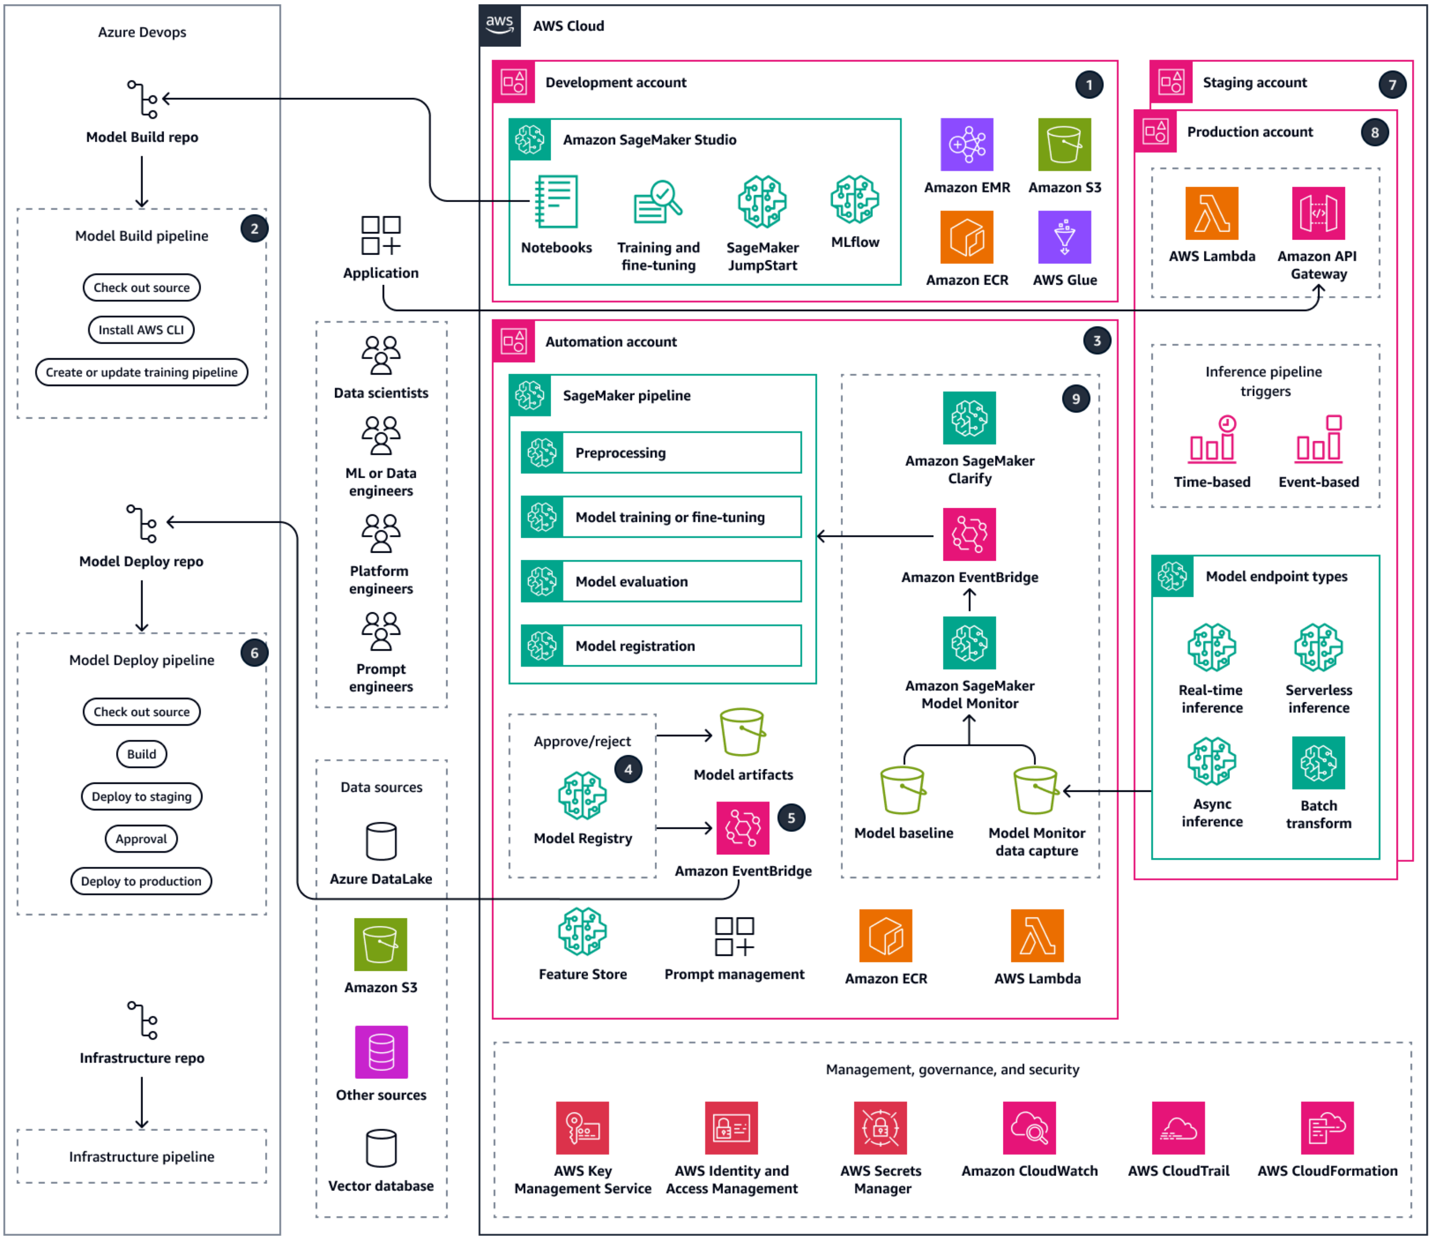
Limitations

- This guidance does not discuss secure cross-cloud data transfers. For more information about cross-cloud data transfers, see AWS Solutions for Hybrid and Multicloud.
- Multicloud solutions may increase latency for real-time data processing and model inference.
- This guidance provides one example of a multi-account MLOps architecture. Adjustments are necessary based on your machine learning and AWS strategy.
- This guidance does not describe the use of AI/ML services other than Amazon SageMaker AI.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

Target architecture

The target architecture integrates Azure DevOps with Amazon SageMaker AI, creating a cross-cloud ML workflow. It uses Azure for CI/CD processes and SageMaker AI for ML model training and deployment. It outlines the process of obtaining data (from sources such as Amazon S3, Snowflake, and Azure Data Lake) through model building and deployment. Key components include CI/CD pipelines for model building and deployment, data preparation, infrastructure management, and Amazon SageMaker AI for training and fine-tuning, evaluation, and deployment of ML models. This architecture is designed to provide efficient, automated, and scalable ML workflows across cloud platforms.



The architecture consists of the following components:

1. Data scientists perform ML experiments in the development account to explore different approaches for ML use cases by using various data sources. Data scientists perform unit tests and trials, and to track their experiments, they can use [Amazon SageMaker AI with MLflow](). In generative AI model development, data scientists fine-tune foundation models from Amazon SageMaker AI JumpStart model hub. Following model evaluation, data scientists push and merge the code to the Model Build repository, which is hosted on Azure DevOps. This repository contains code for a multi-step model building pipeline.

2. On Azure DevOps, the Model Build pipeline, which provides continuous integration (CI), can be activated automatically or manually upon code merge to the main branch. In the Automation account, this activates the SageMaker AI pipeline for data preprocessing, model training and fine-tuning, model evaluation, and conditional model registration based on accuracy.
3. The Automation account is a central account across ML platforms that hosts ML environments (Amazon ECR), models (Amazon S3), model metadata (SageMaker AI Model Registry), features (SageMaker AI Feature Store), automated pipelines (SageMaker AI Pipelines), and ML log insights (CloudWatch). For a generative AI workload, you might require additional evaluations for prompts in the downstream applications. A prompt management application helps to streamline and automate the process. This account allows reusability of ML assets and enforces best practices accelerate delivery of ML use cases.
4. The latest model version is added to SageMaker AI Model Registry for review. It tracks model versions and respective artifacts (lineage and metadata). It also manages the status of the model (approve, reject, or pending), and it manages the version for downstream deployment.
5. After a trained model in Model Registry is approved through the studio interface or an API call, an event can be dispatched to Amazon EventBridge. EventBridge starts the Model Deploy pipeline on Azure DevOps.
6. The Model Deploy pipeline, which provides continuous deployment (CD), checks out the source from the Model Deploy repository. The source contains code, the configuration for the model deployment, and test scripts for quality benchmarks. The Model Deploy pipeline can be tailored to your inference type.
7. After quality control checks, the Model Deploy pipeline deploys the model to the Staging account. The Staging account is a copy of the Production account, and it is used for integration testing and evaluation. For a batch transformation, the Model Deploy pipeline can automatically update the batch inference process to use the latest approved model version. For a real-time, serverless, or asynchronous inference, it sets up or updates the respective model endpoint.
8. After successful testing in the Staging account, a model can be deployed to the Production account by manual approval through the Model Deploy pipeline. This pipeline provisions a production endpoint in the **Deploy to production** step, including model monitoring and a data feedback mechanism.
9. After the model is in production, use tools such as SageMaker AI Model Monitor and SageMaker AI Clarify to identify bias, detect drift, and continuously monitor the model's performance.

Automation and scale

Use infrastructure as code (IaC) to automatically deploy to multiple accounts and environments. By automating the process of setting up an MLOps workflow, it is possible to separate the environments used by ML teams working on different projects. AWS CloudFormation helps you model, provision, and manage AWS resources by treating infrastructure as code.

Tools

AWS services

- Amazon SageMaker AI is a managed ML service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. In this pattern, Amazon S3 is used for data storage and integrated with SageMaker AI for model training and model objects.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, Lambda is used for data pre-processing and post-processing tasks.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable. In this pattern, it stores Docker containers that SageMaker AI uses as training and deployment environments.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. In this pattern, EventBridge orchestrates event-driven or time-based workflows that initiate automatic model retraining or deployment.
- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale. In this pattern, it is used to create an external-facing, single point of entry for SageMaker AI endpoints.
- For RAG applications, you can use AWS services, such as Amazon OpenSearch Service and Amazon RDS for PostgreSQL, to store the vector embeddings that provide the LLM with your internal data.

Other tools

- Azure DevOps helps you manage CI/CD pipelines and facilitate code builds, tests, and deployment.
- Azure Data Lake Storage or Snowflake are possible third-party sources of training data for ML models.
- Pinecone, Milvus, or ChromaDB are possible third-party vector databases to store vector embeddings.

Best practices

Before implementing any component of this multicloud MLOps workflow, complete the following activities:

- Define and understand the machine learning workflow and the tools required to support it. Different use cases require different workflows and components. For example, a feature store might be required for feature reuse and low latency inference in a personalization use case, but it may not be required for other use cases. Understanding the target workflow, use case requirements, and preferred collaboration methods of the data science team is needed to successfully customize the architecture.
- Create a clear separation of responsibility for each component of the architecture. Spreading data storage across Azure Data Lake Storage, Snowflake, and Amazon S3 can increase complexity and cost. If possible, choose a consistent storage mechanism. Similarly, avoid using a combination of Azure and AWS DevOps services, or a combination of Azure and AWS ML services.
- Choose one or more existing models and datasets to perform end-to-end testing of the MLOps workflow. The test artifacts should reflect real use cases that the data science teams develop when the platform enters production.

Epics

Design your MLOps architecture

Task	Description	Skills required
Identify data sources.	Based on current and future use cases, available data sources, and types of data (such as confidential data),	Data engineer, Data scientist, Cloud architect

Task	Description	Skills required
	document the data sources that need to be integrated with the MLOps platform. Data can be stored in Amazon S3, Azure Data Lake Storage, Snowflake, or other sources. For generative AI workloads , data might also include a knowledge base that grounds the generated response. This data is stored as vector embeddings in vector databases. Create a plan for integrating these sources with your platform and securing access to the correct resources.	
Choose applicable services.	Customize the architect ure by adding or removing services based on the desired workflow of the data science team, applicable data sources, and existing cloud architect ure. For example, data engineers and data scientists may perform data preproces sing and feature engineering in SageMaker AI, AWS Glue, or Amazon EMR. It is unlikely that all three services would be required.	AWS administrator, Data engineer, Data scientist, ML engineer

Task	Description	Skills required
Analyze security requireme nts.	Gather and document security requirements. This includes determining: • Which teams or engineers can access specific data sources • Which teams or engineers can access pre-trained foundation models • Whether teams are allowed to access the code and models of other teams • Which permissions (if any) team members should have for non-development accounts • Which security measures need to be implement ed for cross-cloud data transfer For more information about securing generative AI workloads, see [Securing generative AI: An introduction to the Generative AI Security Scoping Matrix]() (AWS blog post).	AWS administrator, Cloud architect

Set up AWS Organizations

Task	Description	Skills required
Set up AWS Organizations.	Set up AWS Organizations on the root AWS account. This helps you manage the subsequent accounts that you create as part of a multi-account MLOps strategy. For more information, see the AWS Organizations documentation.	AWS administrator

Set up the development environment and versioning

Task	Description	Skills required
Create an AWS development account.	Create an AWS account where data engineers and data scientists have permissions to experiment and create ML models. For instructions, see Creating a member account in your organization in the AWS Organizations documentation.	AWS administrator
Create a Model Build repository.	Create a Git repository in Azure where data scientists can push their model build and deployment code after the experimentation phase is complete. For instructions, see Set up a Git repository in	DevOps engineer, ML engineer

Task	Description	Skills required
	the Azure DevOps documenta tion.	
Create a Model Deploy repository.	Create a Git repository in Azure that stores standard deployment code and templates. It should include code for every deploymen t option that the organizat ion uses, as identified in the design phase. For example, it should include real-time endpoints, asynchron ous endpoints, serverless inference, or batch transform s. For instructions, see Set up a Git repository in the Azure DevOps documentation.	DevOps engineer, ML engineer
Create an Amazon ECR repository.	Set up an Amazon ECR repository that stores the approved ML environments as Docker images. Allow data scientists and ML engineers to define new environments. For instructions, see Creating a private repository in the Amazon ECR documentation.	ML engineer

Task	Description	Skills required
Set up SageMaker AI Studio.	Set up SageMaker AI Studio on the development account according to the previously defined security requireme nts, preferred data science tools (such as MLflow), and preferred integrated development environment (IDE). Use lifecycle configura tions to automate the installation of key functiona lity and create a uniform development environment for data scientists. For more information, see Amazon SageMaker AI Studio and MLflow tracking server in the SageMaker AI documentation.	Data scientist, ML engineer, Prompt engineer

Integrate CI/CD pipelines

Task	Description	Skills required
Create an Automation account.	Create an AWS account where automated pipelines and jobs run. You can give data science teams read access to this account. For instructions, see Creating a member account in your organization in the AWS Organizations documenta tion.	AWS administrator

Task	Description	Skills required
Set up a model registry.	Set up SageMaker AI Model Registry in the Automation account. This registry stores the metadata for ML models and helps certain data scientists or team leads to approve or reject models. For more information, see Register and deploy models with Model Registry in the SageMaker AI documentation.	ML engineer
Create a Model Build pipeline.	Create a CI/CD pipeline in Azure that starts manually or automatically when code is pushed to the Model Build repository. The pipeline should check out the source code and create or update a SageMaker AI pipeline in the Automation account. The pipeline should add a new model to the model registry. For more information about creating a pipeline, see the Azure Pipelines documentation.	DevOps engineer, ML engineer

Build the deployment stack

Task	Description	Skills required
Create AWS staging and deployment accounts.	Create AWS accounts for staging and deployment of	AWS administrator

Task	Description	Skills required
	ML models. These accounts should be identical to allow for accurate testing of the models in staging before moving to production. You can give data science teams read access to the staging account. For instructions, see [Creating a member account in your organization] in the AWS Organizations documentation.	
Set up S3 buckets for model monitoring.	Complete this step if you want to enable model monitoring for the deployed models that are created by the Model Deploy pipeline. Create Amazon S3 buckets for storing the input and output data. For more information about creating S3 buckets, see [Creating a bucket] in the Amazon S3 documentation. Set up cross-account permissions so that the automated model monitoring jobs run in the Automation account. For more information, see [Monitor data and model quality] in the SageMaker AI documentation.	ML engineer

Task	Description	Skills required
Create a Model Deploy pipeline.	Create a CI/CD pipeline in Azure that starts when a model is approved in the model registry. The pipeline should check out the source code and model artifact, build the infrastructure templates for deploying the model in the staging and production accounts, deploy the model in the staging account, run automated tests, wait for manual approval, and deploy the approved model into the production account. For more information about creating a pipeline, see the [Azure Pipelines documentation].	DevOps engineer, ML engineer

(Optional) Automate ML environment infrastructure

Task	Description	Skills required
Build AWS CDK or CloudForm ation templates.	Define AWS Cloud Developme nt Kit (AWS CDK) or AWS CloudFormation templates for all environments that need to be deployed automatically. This might include the development environment, automation environment, and staging and deployment environments. For more information, see	AWS DevOps

Task	Description	Skills required
	the [AWS CDK](#) and [CloudFormation](#) documentation.	
Create an Infrastructure pipeline.	Create a CI/CD pipeline in Azure for infrastructure deployment. An administrator can initiate this pipeline to create new AWS accounts and set up the environments that the ML team requires.	DevOps engineer

Troubleshooting

Issue	Solution
**Insufficient monitoring and drift detection – **Inadequate monitoring can lead to missed detection of model performance issues or data drift.	Strengthen monitoring frameworks with tools such as Amazon CloudWatch, SageMaker AI Model Monitor, and SageMaker AI Clarify. Configure alerts for immediate action on identified issues.
CI pipeline trigger errors – The CI pipeline in Azure DevOps might not be triggered upon code merge due to misconfiguration.	Check the Azure DevOps project settings to ensure that the webhooks are properly set up and pointing to the correct SageMaker AI endpoints.
Governance – The central Automation account might not enforce best practices across ML platforms, leading to inconsistent workflows.	Audit the Automation account settings, ensuring that all ML environments and models conform to predefined best practices and policies.
Model registry approval delays – This happens when there's a delay in checking and approving the model, either because people	Implement a notification system to alert stakeholders of models that are pending approval, and streamline the review process.

Issue	Solution
take time to review it or because of technical issues.	
Model deployment event failures – Events dispatched to start model deployment pipelines might fail, causing deployment delays.	Confirm that Amazon EventBridge has the correct permissions and event patterns to invoke Azure DevOps pipelines successfully.
Production deployment bottlenecks – Manual approval processes can create bottlenecks, delaying the production deployment of models.	Optimize the approval workflow within the model deploy pipeline, promoting timely reviews and clear communication channels.

Configure model invocation logging in Amazon Bedrock by using AWS CloudFormation

Vikramaditya Bhatnagar, Amazon Web Services

Summary

You can configure Amazon Bedrock to collect invocation logs, model input data, and model output data for all model invocations in your AWS account. This is a best practice for building robust generative AI applications with Amazon Bedrock. You can store model invocation logs in an Amazon CloudWatch Logs log group, in an Amazon Simple Storage Service (Amazon S3) bucket, or in both. Having log data in CloudWatch Logs helps you create custom metric filters, alarms, and dashboards. Amazon S3 is ideal for replicating data across AWS Regions or for long-term storage, as governed by your organization's policies.

This pattern provides a sample AWS CloudFormation template that uses an infrastructure as code (IaC) approach to configure model invocation logging for Amazon Bedrock. The template configures log storage in both CloudWatch Logs and Amazon S3.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The following permissions:
  - Permissions to create CloudFormation stacks
  - Permissions to access Amazon Bedrock
  - Permissions to create and access Amazon S3 buckets
  - Permissions to create and access CloudWatch Logs log groups
  - Permissions to create and access AWS Lambda functions
  - Permissions to create and access AWS Key Management Service (AWS KMS) keys

Limitations

This pattern logs model invocations to both CloudWatch Logs and Amazon S3. It does not support choosing only one of these two services.

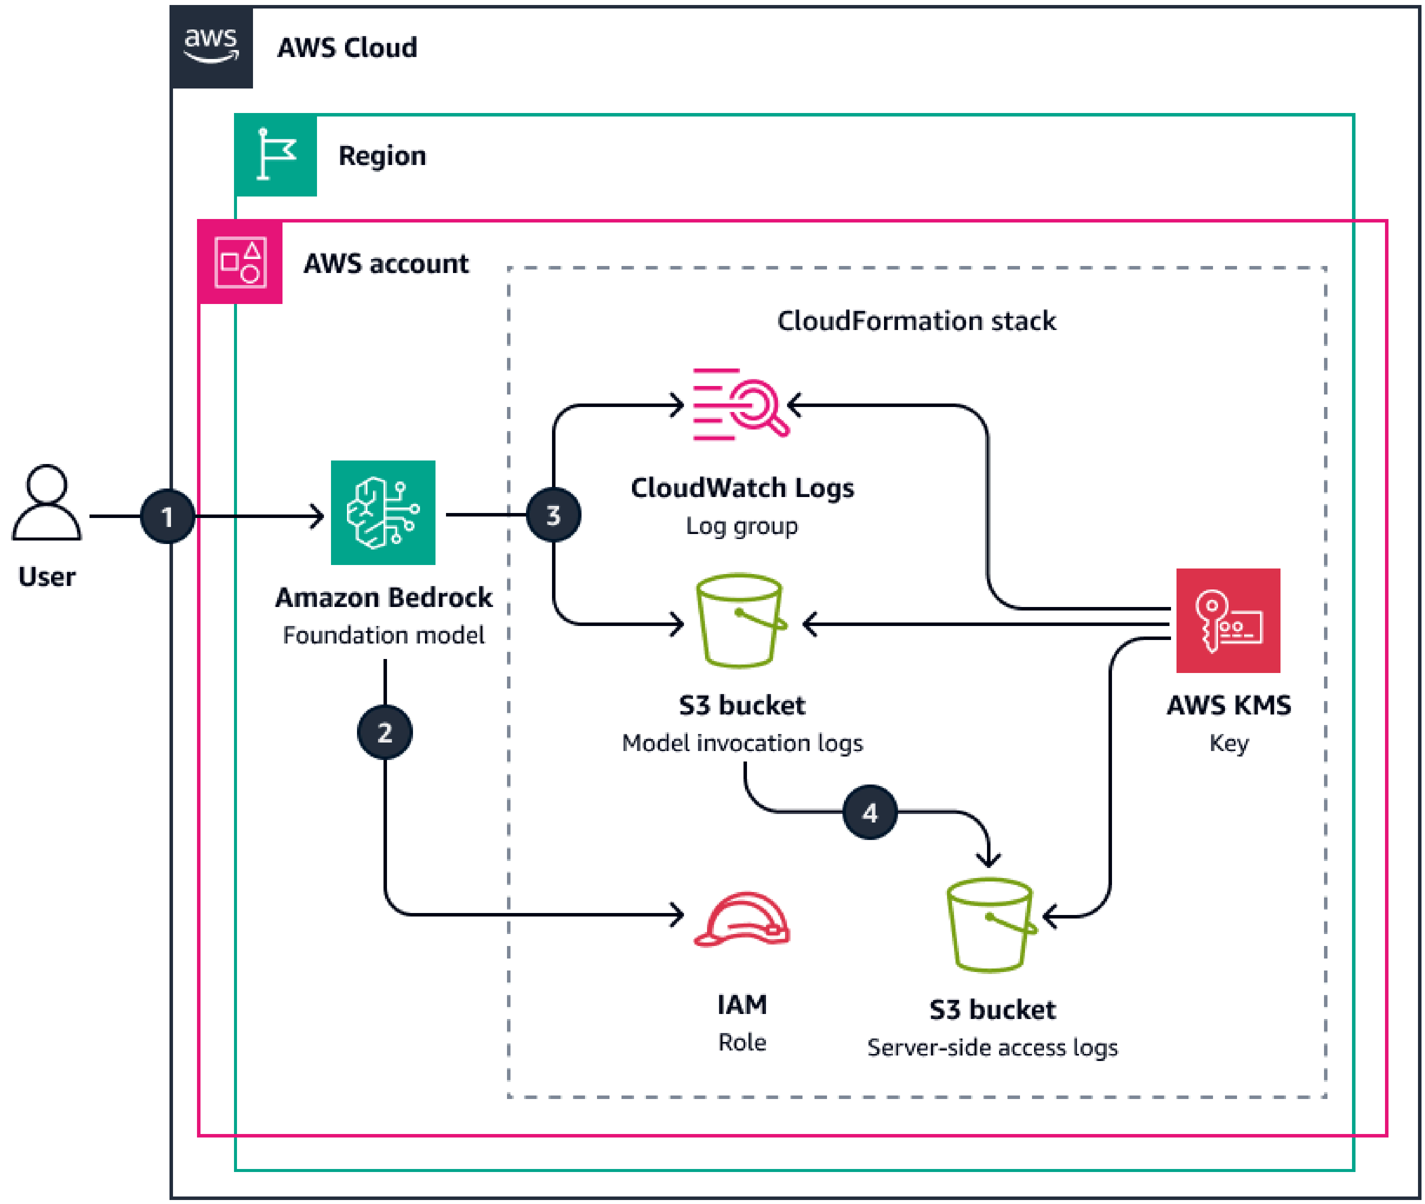
Architecture

Target architecture

The CloudFormation template provisions the following resources in your target AWS account:

- A CloudWatch Logs log group for storing model invocation logs
- An Amazon S3 bucket for storing model invocation logs and a corresponding bucket policy
- An Amazon S3 bucket for storing server-side access logs and a corresponding bucket policy
- An AWS Lambda function that configures logging settings in Amazon Bedrock
- An AWS KMS key and a corresponding key alias
- An AWS Identity and Access Management (IAM) service role for Amazon Bedrock

The following diagram shows how invocation logs are stored after you deploy the CloudFormation stack associated with this pattern. Amazon Bedrock publishes log data when the foundation model delivers text, an image, a video, or embedding data. As shown in the diagram, the Amazon S3 buckets and the CloudWatch Logs log group are encrypted with an AWS KMS key.



The diagram shows the following workflow:

1. A user submits a query to a foundation model in Amazon Bedrock.
2. Amazon Bedrock assumes the IAM service role.
3. Amazon Bedrock generates log data and stores it in an CloudWatch Logs log group and in an Amazon S3 bucket.
4. If a user reads, uploads, or deletes any files in the Amazon S3 bucket that contains the model invocation logs, those activities are logged in another Amazon S3 bucket for server-side access logs.

Automation and scale

To scale this solution, you can deploy the CloudFormation template as a stack set to multiple AWS Regions and AWS accounts. For more information, see Managing stacks across accounts and Regions with StackSets in the CloudFormation documentation.

Tools

AWS services

- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI companies and Amazon available for your use through a unified API.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- Amazon CloudWatch Logs helps you centralize the logs from all of your systems, applications, and AWS services so you can monitor them and archive them securely.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance.

Other tools

- Git is an open source, distributed version control system.

Code repository

The code for this pattern is available in the GitHub enable-bedrock-logging-using-cloudformation repository.

Epics

Create the CloudFormation stack

Task	Description	Skills required
Download the CloudForm ation template.	Download the [CloudForm ation template](#) from the GitHub repository.	Cloud architect
Deploy the template.	Create a stack in your target account and Region. In the **Parameters** section, specify values for the parameter s that are defined in the template. For instructions, see [Creating a stack](#) in the CloudFormation documenta tion.	Cloud architect

Test the solution

Task	Description	Skills required
Enable model access.	In Amazon Bedrock, add access to the foundation model. For instructions, see [Add or remove access to Amazon Bedrock foundatio n models](#) in the Amazon Bedrock documentation.	Cloud architect
Run a sample prompt.	In Amazon Bedrock playgroun ds, run a sample prompt. For instructions, see [Generate responses in the console using playgrounds](#) in the	Cloud architect

Task	Description	Skills required
	Amazon Bedrock documenta tion.	
Review the logging configura tion.	1. Sign into the [Amazon Bedrock console](). 2. In the navigation bar, choose the AWS Region where you deployed the CloudFormation stack. 3. In the left navigation pane, under **Bedrock configura tions**, choose **Settings**. 4. Confirm the following: • Model invocation logging is enabled. • All data types are selected. • For logging destinations, **Both S3 and CloudWatc h Logs** is selected.	Cloud architect
Review the Amazon S3 bucket.	1. In the **S3 configurations** section, choose **Browse S3**. This opens the target bucket in the Amazon S3 console. 2. Confirm that logging data is present for the sample prompt that you previously ran.	Cloud architect

Task	Description	Skills required
Review the log group.	1. Navigate back to the **Settings** page in the Amazon Bedrock console. 2. In the **CloudWatch Logs configurations** section, review the settings for the CloudWatch Logs log group. Make note of the log group name. 3. Open the CloudWatch console. 4. In the navigation pane, under **Logs**, choose **Log groups**. 5. Choose the name of the log group where Amazon Bedrock publishes log data. 6. Confirm that logging data is present for the sample prompt that you previously ran.	Cloud architect

Create a custom Docker container image for SageMaker and use it for model training in AWS Step Functions

Julia Bluszcz, Aubrey Oosthuizen, Mohan Gowda Purushothama, Neha Sharma, and Mateusz Zaremba, Amazon Web Services

Summary

This pattern shows how to create a Docker container image for Amazon SageMaker and use it for a training model in AWS Step Functions. By packaging custom algorithms in a container, you can run almost any code in the SageMaker environment, regardless of programming language, framework, or dependencies.

In the example SageMaker notebook provided, the custom Docker container image is stored in Amazon Elastic Container Registry (Amazon ECR). Step Functions then uses the container that's stored in Amazon ECR to run a Python processing script for SageMaker. Then, the container exports the model to Amazon Simple Storage Service (Amazon S3).

Prerequisites and limitations

Prerequisites

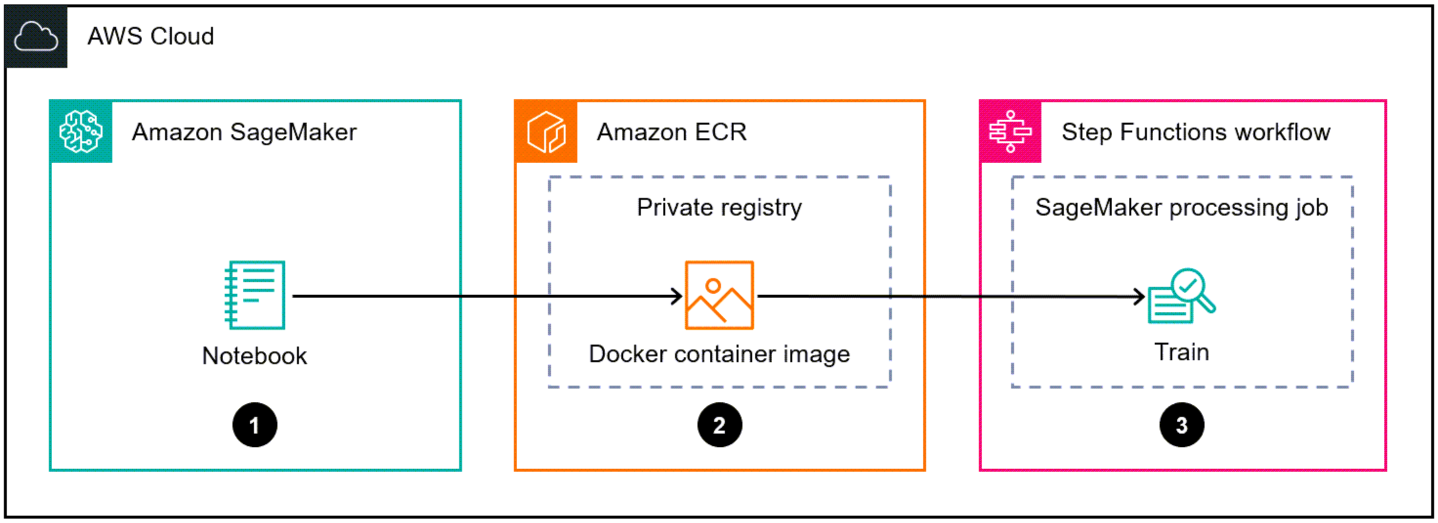
- An active AWS account
- An AWS Identity and Access Management (IAM) role for SageMaker with Amazon S3 permissions
- An IAM role for Step Functions
- Familiarity with Python
- Familiarity with the Amazon SageMaker Python SDK
- Familiarity with the AWS Command Line Interface (AWS CLI)
- Familiarity with AWS SDK for Python (Boto3)
- Familiarity with Amazon ECR
- Familiarity with Docker

Product versions

- AWS Step Functions Data Science SDK version 2.3.0
- Amazon SageMaker Python SDK version 2.78.0

Architecture

The following diagram shows an example workflow for creating a Docker container image for SageMaker, then using it for a training model in Step Functions:



The diagram shows the following workflow:

1. A data scientist or DevOps engineer uses a Amazon SageMaker notebook to create a custom Docker container image.
2. A data scientist or DevOps engineer stores the Docker container image in an Amazon ECR private repository that's in a private registry.
3. A data scientist or DevOps engineer uses the Docker container to run a Python SageMaker processing job in a Step Functions workflow.

Automation and scale

The example SageMaker notebook in this pattern uses an `ml.m5.xlarge` notebook instance type. You can change the instance type to fit your use case. For more information about SageMaker notebook instance types, see [Amazon SageMaker Pricing].

Tools

- [Amazon Elastic Container Registry (Amazon ECR)] is a managed container image registry service that's secure, scalable, and reliable.
- [Amazon SageMaker] is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.

- Amazon SageMaker Python SDK is an open source library for training and deploying machine-learning models on SageMaker.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- AWS Step Functions Data Science Python SDK is an open source library that helps you create Step Functions workflows that process and publish machine learning models.

Epics

Create a custom Docker container image and store it in Amazon ECR

Task	Description	Skills required
Setup Amazon ECR and create a new private registry.	If you haven't already, set up Amazon ECR by following the instructions in Setting up with Amazon ECR in the *Amazon ECR User Guide*. Each AWS account is provided with a default private Amazon ECR registry.	DevOps engineer
Create an Amazon ECR private repository.	Follow the instructions in Creating a private repository in the *Amazon ECR User Guide*. **Note** The repository that you create is where you'll store your custom Docker container images.	DevOps engineer

Use Amazon Bedrock agents to automate creation of access entry controls in Amazon EKS through text-based prompts

Keshav Ganesh and Sudhanshu Saurav, Amazon Web Services

Summary

Organizations face challenges in managing access controls and resource provisioning when multiple teams need to work with a shared Amazon Elastic Kubernetes Service (Amazon EKS) cluster. A managed Kubernetes service such as Amazon EKS has simplified cluster operations. However, the administrative overhead of managing team access and resource permissions remains complex and time-consuming.

This pattern shows how Amazon Bedrock agents can help you automate Amazon EKS cluster access management. This automation allows development teams to focus on their core application development rather than dealing with access control setup and management. You can customize an Amazon Bedrock agent to perform actions for a wide variety of tasks through simple natural language prompts.

By using AWS Lambda functions as action groups, an Amazon Bedrock agent can handle tasks such as creating user access entries and managing access policies. In addition, an Amazon Bedrock agent can configure pod identity associations that allow access to AWS Identity and Access Management (IAM) resources for the pods running in the cluster. Using this solution, organizations can streamline their Amazon EKS cluster administration with simple text-based prompts, reduce manual overhead, and improve overall development efficiency.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Established IAM roles and permissions for the deployment process. This includes permissions to access Amazon Bedrock foundation models (FM), create Lambda functions, and any other required resources across the target AWS accounts.
- Access enabled in the active AWS account to these Amazon Bedrock FMs: Amazon Titan Text Embeddings V2 and Anthropic Claude 3 Haiku.
- AWS Command Line Interface (AWS CLI) version 2.9.11 or later, installed and configured.

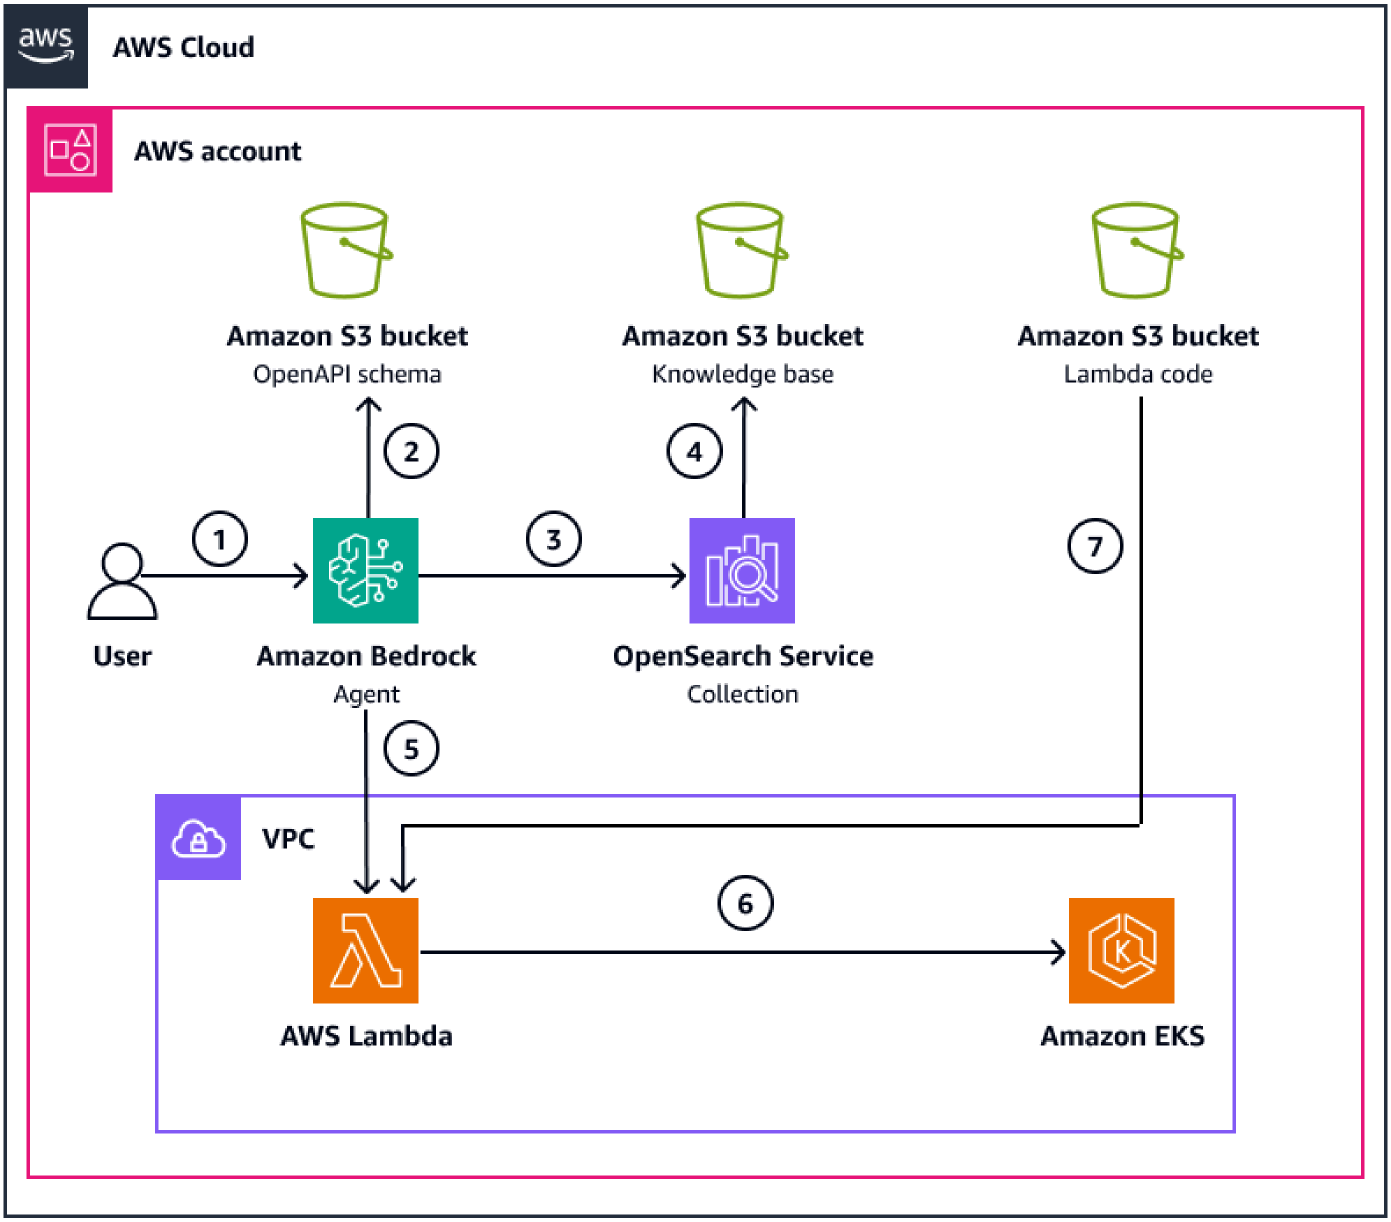
- eksctl 0.194.0 or later, installed.

Limitations

- Training and documentation might be required to help ensure smooth adoption and effective use of these techniques. Using Amazon Bedrock, Amazon EKS, Lambda, Amazon OpenSearch Service, and OpenAPI involve a significant learning curve for developers and DevOps teams.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

The following diagram shows the workflow and architecture components for this pattern.



This solution performs the following steps:

1. The user interacts with the Amazon Bedrock agent by submitting a prompt or query that serves as input for the agent to process and take action.
2. Based on the prompt, the Amazon Bedrock agent checks the OpenAPI schema to identify the correct API to target. If the Amazon Bedrock agent finds the correct API call, the request goes to the action group that is associated with the Lambda function that implements these actions.

3. If a relevant API isn't found, the Amazon Bedrock agent queries the OpenSearch collection. The OpenSearch collection uses indexed knowledge base content that is sourced from the Amazon S3 bucket that contains the *Amazon EKS User Guide*.
4. The OpenSearch collection returns relevant contextual information to the Amazon Bedrock agent.
5. For actionable requests (those that match an API operation), the Amazon Bedrock agent executes within a virtual private cloud (VPC) and triggers the Lambda function.
6. The Lambda function performs an action that's based on the user's input inside the Amazon EKS cluster.
7. The Amazon S3 bucket for the Lambda code stores the artifact that has the code and logic written for the Lambda function.

Tools

AWS services

- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon OpenSearch Service is a managed service that helps you deploy, operate, and scale OpenSearch clusters in the AWS Cloud. Its collections feature helps you to organize your data and build comprehensive knowledge bases that AI assistants such as Amazon Bedrock agents can use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- eksctl is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.

Code repository

The code for this pattern is available in the GitHub eks-access-controls-bedrock-agent repository.

Best practices

- Maintain the highest possible security when implementing this pattern. Make sure that the Amazon EKS cluster is private, has limited access permissions, and all the resources are inside a virtual private cloud (VPC). For additional information, see Best practices for security in the Amazon EKS documentation.
- Use AWS KMS customer managed keys wherever possible, and grant limited access permissions to them.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Set up the environment

Task	Description	Skills required
Clone the repository.	To clone this pattern's repository, run the following command in your local workstation: `git clone https://github.com/aws-samples/eks-access-controls-bedrock-agent.git`	AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Get the AWS account ID.</td><td>To get the AWS account ID, use the following steps:

1. Open a shell in the root folder of the cloned repo, <code>eks-access-controls-bedrock-agent</code> .
2. To get your AWS account ID, navigate to the cloned directory and run the following command:

<pre>AWS_ACCOUNT=$(aws sts
 get-caller-identity
 --query "Account" --
output text)</pre>
This command stores your AWS account ID in the <code>AWS_ACCOUNT</code> variable.</td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required

Create the S3 bucket for Lambda code.	To implement this solution, you must create three Amazon S3 buckets that serve different purposes, as shown in the [architecture](#) diagram. The S3 buckets are for Lambda code, a knowledge base, and OpenAPI schema.
	
	To create the Lambda code bucket, use the following steps:
	
	1. To create an S3 bucket for Lambda code, run the following command:
	`aws s3 mb s3://bedrock-agent-lambda-artifacts-${AWS_ACCOUNT} --region us-east-1`
	2. To install the Lambda code dependency, run the following command:
	`cd eks-lambda`
	`npm install`
	`tsc`
	`cd .. && cd opensearch-lambda`
	`npm install`
	`tsc`
	`cd ..`
	3. To package the code and upload it to the S3
		AWS DevOps

Task	Description	Skills required
	bucket for Lambda, run the following command: `aws cloudformation package \ --template-file eks-access-controls.yaml \ --s3-bucket bedrock-agent-lambda-artifacts-${AWS_ACCOUNT} \ --output-template-file eks-access-controls-template.yaml \ --region us-east-1` The package command creates a new CloudFormation template (`eks-access-controls-template.yaml`) that contains: • References to the Lambda function code stored in your S3 bucket. • Definitions for all required AWS infrastructure including VPC, subnets, Amazon Bedrock agent, and OpenSearch collection. You can use this template to deploy the complete solution by using CloudFormation.	

Task	Description	Skills required

Create the S3 bucket for the knowledge base.	To create the Amazon S3 bucket for the knowledge base, use the following steps:
	1. To create the Amazon S3 bucket for the knowledge base, run the following command:
	`aws s3 mb s3://eks-knowledge-base-${AWS_ACCOUNT} --region us-east-1`
	2. To download the *Amazon EKS User Guide* and store it in a directory, run the following commands:
	`mkdir dataSource`
	`cd dataSource`
	`curl https://docs.aws.amazon.com/pdfs/eks/latest/userguide/eks-ug.pdf -o eks-user-guide.pdf`
	3. To upload the user guide to the S3 bucket that you created in step 1, run the following command:
	`aws s3 cp eks-user-guide.pdf s3://eks-knowledge-base-${AWS_ACCOUNT} \`
	`--region us-east-1 \`
		AWS DevOps

Task	Description	Skills required
	4. To return to the root directory, run the following command: `cd ..`	

Create the S3 bucket for the OpenAPI schema.	To create the Amazon S3 bucket for the OpenAPI schema, use the following steps:
	1. To create the S3 bucket, run the following command:
	`aws s3 mb s3://eks-openapi-schema-${AWS_ACCOUNT} --region us-east-1`
	2. To upload the OpenAPI schema to the S3 bucket, run the following command:
	`aws s3 cp openapi-schema.yaml s3://eks-openapi-schema-${AWS_ACCOUNT} --region us-east-1`
		AWS DevOps

Deploy the CloudFormation stack

Task	Description	Skills required
Deploy the CloudFormation stack.	To deploy the CloudFormation stack, use the CloudFormation template file `eks-access-controls-template.yaml` that you created earlier. For more detailed instructions, see [Create a stack from the CloudFormation console](#) in the CloudFormation documentation. **Note** Provisioning the OpenSearch index with the CloudFormation template takes about 10 minutes. After the stack is created, make a note of the `VPC_ID` and `PRIVATE_SUBNET ID` s.	AWS DevOps
Create the Amazon EKS cluster.	To create the Amazon EKS cluster inside the VPC, use the following steps: 1. Create a copy of the `eks-config.yaml` configuration file, and name the copy as `eks-deploy.yaml` .	AWS DevOps

Task	Description	Skills required

	2. Open `eks-deploy.yaml` in a text editor. Then, replace the following placeholder values with values from the deployed stack: `VPC_ID`, `PRIVATE_SUBNET1`, and `PRIVATE_SUBNET2`
	3. To create the cluster by using the eksctl utility, run the following command:
	`eksctl create cluster -f eks-deploy.yaml`
	Note
	This cluster creation process can take up to 15-20 minutes to complete.
	4. To verify that the cluster was created successfully, run the following commands:
	`aws eks describe-cluster --name --query "cluster.status"`
	`aws eks update-kubeconfig --name --region`
	`kubectl get nodes`	

Task	Description	Skills required
	The expected results are as follows: • The cluster status is `ACTIVE`. • The command `kubectl get nodes` shows that all nodes are in `Ready` state.	

Connect the Lambda function and the Amazon EKS cluster

Task	Description	Skills required
Create a connection between the Amazon EKS cluster and the Lambda function.	To set up network and IAM permissions to allow the Lambda function to communicate with the Amazon EKS cluster, use the following steps: 1. To identify the IAM role that's attached to the Lambda function, open the AWS Management Console and locate the Lambda function named `bedrock-agent-eks-access-control` . Make a note of the Amazon Resource Name (ARN) of the IAM role. 2. To create an access entry in the Amazon EKS cluster for the Lambda function's	AWS DevOps

Task	Description	Skills required

	IAM role, run the following command:
	`aws eks create-access-entry --cluster-name eks-testing-cluster --principal-arn <principal-Role-ARN>`
	3. To assign `AmazonEKSClusterAdminPolicy` permissions to this role, run the following command:
	`aws eks associate-access-policy --cluster-name eks-testing-cluster --principal-arn <principal-Role-ARN> --policy-arn arn:aws:eks::aws:cluster-access-policy/AmazonEKSClusterAdminPolicy --access-scope type=cluster`
	For more information, see [Associate access policies with access entries] and [AmazonEKSClusterAdminPolicy] in the Amazon EKS documentation.
	4. Locate the Amazon EKS cluster's security group.	

Task	Description	Skills required
	Add an inbound rule to allow incoming network traffic from the Lambda function to the Amazon EKS cluster. Use the following values for the inbound rule: • **Type** – HTTPS • **Port range** – 443 • **Source** – Lambda security group For more information, see Configure security group rules in the Amazon VPC documentation.	

Test the solution

Task	Description	Skills required
Test the Amazon Bedrock agent.	Before testing the Amazon Bedrock agent, make sure that you do the following: • Test with non-production roles first. • Document any changes made to cluster access. • Have a plan to revert changes if needed.	AWS DevOps

Task	Description	Skills required
	To access the Amazon Bedrock agent, use the following steps: 1. Sign in to the AWS Management Console using an [IAM role with Amazon Bedrock permissions](), and open the Amazon Bedrock console at [https://console.aws.amazon.com/bedrock/](). 2. Select **Agents** from the left navigation pane. Then, choose your configured agent in the **Agents** section. 3. To test the agent, try the following sample prompts in which you replace `Principal-ARN-OF-ROLE` with an actual IAM role ARN: • To create an access entry for any IAM role that you wanted to provide access to the EKS cluster, use the following prompt: `Create an access entry in cluster eks-testing-new for a role whose principal arn is <Principal-ARN-`	

Task	Description	Skills required
	OF-ROLE> with access policy as AmazonEKSAdminPolicy *Expected result*: • The agent should confirm the access entry creation. • To verify, check using the AWS Management Console or use the Amazon EKS API and run the following command: aws eks list-access-entries --cluster-name ekscluster • To describe the access entry that you created, use the following prompt: Describe an access entry in cluster eks-testing-new whose principal arn is <Principal-ARN-OF-ROLE> *Expected result*: • The agent should return details about the access entry. • The details should match what you configured earlier for the access entry.	

Task	Description	Skills required
	• To delete the access entry that you created, use the following prompt: `Delete the access entry in cluster eks-testing-new whose principal arn is <Principal-ARN-OF-ROLE>` *Expected result*: • The agent should confirm the deletion of the access entry. • To verify, check using the AWS Management Console or use the Amazon EKS API and run the following command: `aws eks list-access-entries --cluster-name ekscluster` You can also ask the agent to perform actions for EKS Pod Identity associations. For more details, see [Learn how EKS Pod Identity grants pods access to AWS services]() in the Amazon EKS documentation.	

Clean up

Task	Description	Skills required
Clean up resources.	To clean up the resources that this pattern created, use the following procedure. Wait for each deletion step to complete before proceeding to the next step. **Warning** This procedure will permanently delete all resources created by these stacks. Make sure that you've backed up any important data before proceeding. 1. To delete the Amazon EKS cluster, run the following command: `eksctl delete cluster -f eks-deploy.yaml` **Note** This operation can take 15-20 minutes to complete.	AWS DevOps

Task	Description	Skills required

	2. To delete the Amazon S3 buckets, run the following commands:
	• To empty the Lambda bucket:
	`aws s3 rm s3://bedrock-agent-lambda-artifacts-${AWS_ACCOUNT} --recursive`
	• To empty the knowledge base bucket:
	`aws s3 rm s3://eks-knowledge-base-${AWS_ACCOUNT} –recursive`
	• To empty the OpenAPI schema bucket:
	`aws s3 rm s3://bedrock-agent-openapi-schema-${AWS_ACCOUNT} –recursive`
	• To delete the empty buckets:
	`aws s3 rb s3://bedrock-agent-lambda-artifacts-${AWS_ACCOUNT}`
	`aws s3 rb s3://eks-knowledge-base-${AWS_ACCOUNT}`
	`aws s3 rb s3://bedrock-agent-openapi-`	

Task	Description	Skills required

	```schema-${AWS_ACCOUNT}```
	3. To delete the CloudFormation stack, run the following command:
	```aws cloudformation delete-stack \ --stack-name```
	4. To verify deletion of the Amazon EKS cluster, run the following command:
	```eksctl get clusters```
	5. To verify deletion of the Amazon S3 buckets, run the following commands:
	• To verify deletion of the Lambda bucket:
	```aws s3 ls | grep "bedrock-agent-lambda-artifacts"```
	• To verify deletion of the knowledge base bucket:
	```aws s3 ls | grep "eks-knowledge-base"```
	• To verify deletion of the OpenAPI schema bucket:	

Task	Description	Skills required

	`aws s3 ls | grep "bedrock-agent-openapi-schema"`
	6. To verify stack deletion, run the following command:
	`aws cloudformation list-stacks \--query 'StackSummaries[?StackName==``]'`
	If the stack fails to delete, see Troubleshooting.	

Troubleshooting

Issue	Solution
A non-zero error code is returned during environment setup.	Verify that you're using the correct folder when running any command to deploy this solution. For more information, see the FIRST_DEPLOY.md file in this pattern's repository.
The Lambda function isn't able to do the task.	Make sure that connectivity is set up correctly from the Lambda function to the Amazon EKS cluster.
The agent prompts don't recognize the APIs.	Redeploy the solution. For more information, see the RE_DEPLOY.md file in this pattern's repository.

Issue	Solution
The stack fails to delete.	An initial attempt to delete the stack might fail. This failure can occur because of dependency issues with the custom resource that was created for the OpenSearch collectio n which does the indexing for the knowledge base. To delete the stack, retry the delete operation by retaining the custom resource.

Deploy a RAG use case on AWS by using Terraform and Amazon Bedrock

Martin Maritsch, Nicolas Jacob Baer, Olivier Brique, Julian Ferdinand Grueber, Alice Morano, and Nicola D Orazio, Amazon Web Services

Summary

AWS provides various options to build your Retrieval Augmented Generation (RAG)-enabled generative AI use cases. This pattern provides you with a solution for a RAG-based application based on LangChain and Amazon Aurora PostgreSQL-Compatible as a vector store. You can directly deploy this solution with Terraform into your AWS account and implement the following simple RAG use case:

1. The user manually uploads a file to an Amazon Simple Storage Service (Amazon S3) bucket, such as a Microsoft Excel file or a PDF document. (For more information about supported file types, see the Unstructured documentation.)
2. The content of the file is extracted and embedded into a knowledge database that's based on serverless Aurora PostgreSQL-Compatible, which supports near real-time ingestion of documents into the vector store. This approach enables the RAG model to access and retrieve relevant information for use cases where low latencies matter.
3. When the user engages with the text generation model, it enhances the interaction through retrieval augmentation of relevant content from the previously uploaded files.

The pattern uses Amazon Titan Text Embeddings v2 as the embedding model and Anthropic Claude 3 Sonnet as the text generation model, both available on Amazon Bedrock.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured with your AWS account. For installation instructions, see Install or update to the latest version of the AWS CLI in the AWS CLI documentation. To review your AWS credentials and your access to your account, see Configuration and credential file settings in the AWS CLI documentation.

- Model access that's enabled for the required large language models (LLMs) in the Amazon Bedrock console of your AWS account. This pattern requires the following LLMs:
  - `amazon.titan-embed-text-v2:0`
  - `anthropic.claude-3-sonnet-20240229-v1:0`

Limitations

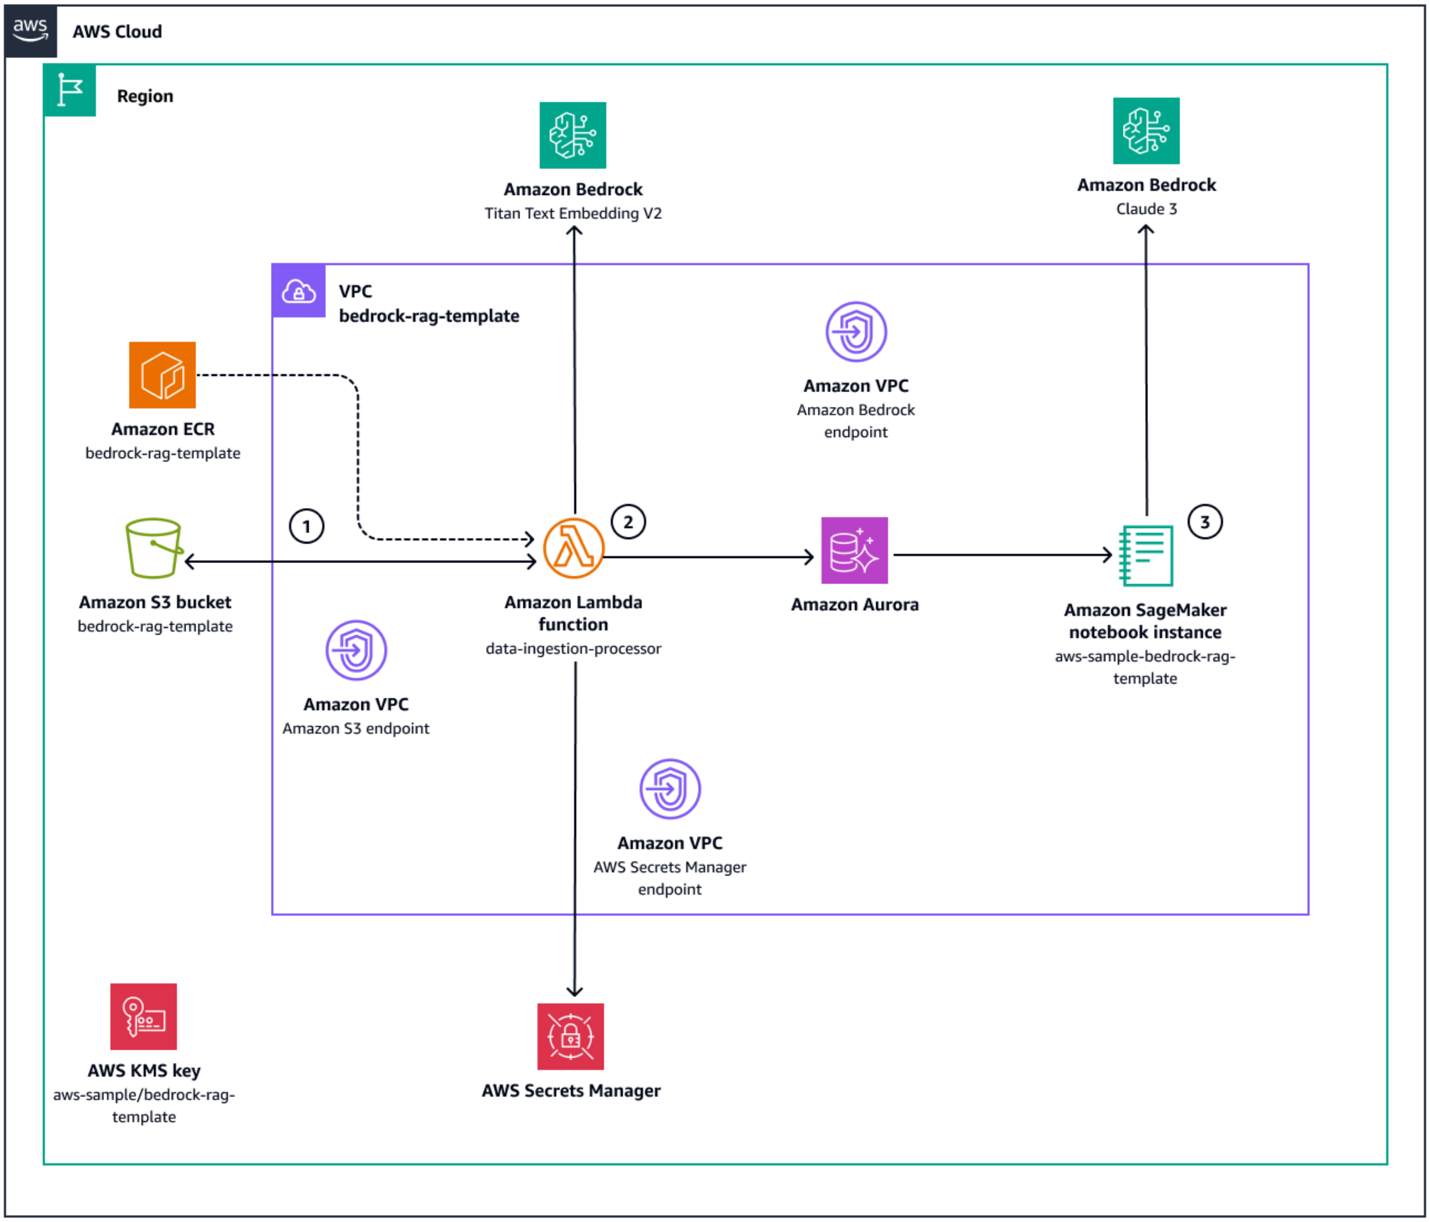
- This sample architecture doesn't include an interface for programmatic question answering with the vector database. If your use case requires an API, consider adding Amazon API Gateway with an AWS Lambda function that runs retrieval and question-answering tasks.
- This sample architecture doesn't include monitoring features for the deployed infrastructure. If your use case requires monitoring, consider adding AWS monitoring services.
- If you upload a lot of documents in a short time frame to the Amazon S3 bucket, the Lambda function might encounter rate limits. As a solution, you can decouple the Lambda function with an Amazon Simple Queue Service (Amazon SQS) queue where you can control the rate of Lambda invocations.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- AWS CLI version 2 or later
- Docker version 26.0.0 or later
- Poetry version 1.7.1 or later
- Python version 3.10 or later
- Terraform version 1.8.4 or later

Architecture

The following diagram shows the workflow and architecture components for this pattern.



This diagram illustrates the following:

1. When an object is created in the Amazon S3 bucket `bedrock-rag-template-<account_id>`, an [Amazon S3 notification](#) invokes the Lambda function `data-ingestion-processor`.
2. The Lambda function `data-ingestion-processor` is based on a Docker image stored in the Amazon Elastic Container Registry (Amazon ECR) repository `bedrock-rag-template`.

   The function uses the LangChain S3FileLoader to read the file as a LangChain Document. Then, the LangChain RecursiveCharacterTextSplitter chunks each document, given a `CHUNK_SIZE` and a `CHUNK_OVERLAP` that depends on the maximum token size of the Amazon Titan Text

Embedding V2 embedding model. Next, the Lambda function invokes the embedding model on Amazon Bedrock to embed the chunks into numerical vector representations. Lastly, these vectors are stored in the Aurora PostgreSQL database. To access the database, the Lambda function first retrieves the username and password from AWS Secrets Manager.

3. On the Amazon SageMaker AI [notebook instance](#) `aws-sample-bedrock-rag-template`, the user can write a question prompt. The code invokes Claude 3 on Amazon Bedrock and adds the knowledge base information to the context of the prompt. As a result, Claude 3 provides responses using the information in the documents.

This pattern's approach to networking and security is as follows:

- The Lambda function `data-ingestion-processor` is in a private subnet within the virtual private cloud (VPC). The Lambda function isn't allowed to send traffic to the public internet because of its security group. As a result, the traffic to Amazon S3 and Amazon Bedrock is routed through the VPC endpoints only. Consequently, the traffic doesn't traverse the public internet, which reduces latency and adds an additional layer of security at the networking level.
- All the resources and data are encrypted whenever applicable by using the AWS Key Management Service (AWS KMS) key with the alias `aws-sample/bedrock-rag-template`.

Automation and scale

This pattern uses Terraform to deploy the infrastructure from the code repository into an AWS account.

Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments. In this pattern, Aurora PostgreSQL-Compatible uses the pgvector plugin as the vector database.
- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command line shell.

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable. In this pattern, Amazon ECR hosts the Docker image for the `data-ingestion-processor` Lambda function.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, Lambda ingests data into the vector store.
- Amazon SageMaker AI is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. The VPC includes subnets and routing tables to control traffic flow.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.
- Poetry is a tool for dependency management and packaging in Python.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub terraform-rag-template-using-amazon-bedrock repository.

Best practices

- Although this code sample can be deployed into any AWS Region, we recommend that you use US East (N. Virginia) – `us-east-1` or US West (N. California) – `us-west-1`. This recommendation is based on the availability of foundation and embedding models in Amazon Bedrock at the time of this pattern's publication. For an up-to-date list of Amazon Bedrock foundation model support in AWS Regions, see Model support by AWS Region in the Amazon Bedrock documentation. For information about deploying this code sample to other Regions, see Additional information.
- This pattern provides a proof-of-concept (PoC) or pilot demo only. If you want to take the code to production, be sure to use the following best practices:
  - Enable server access logging for Amazon S3.
  - Set up monitoring and alerting for the Lambda function.
  - If your use case requires an API, consider adding Amazon API Gateway with a Lambda function that runs retrieval and question-answering tasks.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Deploy the solution in an AWS account

Task	Description	Skills required
Clone the repository.	To clone the GitHub repository provided with this pattern, use the following command: `git clone https://github.com/aws-samples/terraform-rag-template-using-amazon-bedrock`	AWS DevOps

Task	Description	Skills required
Configure the variables.	To configure the parameters for this pattern, do the following: 1. On your computer, in the GitHub repository, use the following command to open the `terraform` folder: `cd terraform` 2. Open the `commons.tfvars` file, and customize the parameters according to your needs.	AWS DevOps

Task	Description	Skills required

Deploy the solution.	To deploy the solution, do the following:
	
	1. In the `terraform` folder, use the following command to run Terraform and pass in the variables that you customized:
	`terraform init`
	`terraform apply -var-file=commons.tfvars`
	2. Confirm that the resources shown in the architecture diagram were deployed successfully.
	
	The infrastructure deployment provisions an SageMaker AI instance inside the VPC and with the permissions to access the Aurora PostgreSQL database.
		AWS DevOps

Test the solution

Task	Description	Skills required
Run the demo.	After the previous infrastructure deployment has succeeded, use the following steps to run the demo in a Jupyter notebook:	General AWS

Task	Description	Skills required
	1. Sign in to the AWS Management Console of the AWS account where the infrastructure is deployed. 2. Open the SageMaker AI notebook instance `aws-sample-bedrock-rag-template` . 3. Move the `rag_demo.ipynb` Jupyter notebook onto the SageMaker AI notebook instance by using drag and drop. 4. Open the `rag_demo.ipynb` on the SageMaker AI notebook instance, and choose the `conda_python3` kernel. 5. To run the demo, run the cells of the notebook. The Jupyter notebook guides you through the following process: • Installing requirements • Embedding definition • Database connection • Data ingestion • Retrieval augmented text generation • Relevant document queries	

Clean up infrastucture

Task	Description	Skills required
Clean up the infrastructure.	To remove all the resources that you created when they are no longer required, use the following command: `terraform destroy -var-file=commons.tfvars`	AWS DevOps

- Working with Amazon Aurora PostgreSQL

Other resources

- pgvector documentation

Additional information

Implementing a vector database

This pattern uses Aurora PostgreSQL-Compatible to implement a vector database for RAG. As alternatives to Aurora PostgreSQL, AWS provides other capabilities and services for RAG, such as Amazon Bedrock Knowledge Bases and Amazon OpenSearch Service. You can choose the solution that best fits your specific requirements:

- Amazon OpenSearch Service provides distributed search and analytics engines that you can use to store and query large volumes of data.
- Amazon Bedrock Knowledge Bases is designed for building and deploying knowledge bases as an additional abstraction to simplify the RAG ingestion and retrieval process. Amazon Bedrock Knowledge Bases can work with both Aurora PostgreSQL and Amazon OpenSearch Service.

Deploying to other AWS Regions

As described in Architecture, we recommend that you use either the Region US East (N. Virginia) – `us-east-1` or US West (N. California) – `us-west-1` to deploy this code sample. However, there are two possible ways to deploy this code sample to Regions other than `us-east-1` and `us-west-1`. You can configure the deployment Region in the `commons.tfvars` file. For cross-Region foundation model access, consider the following options:

- **Traversing the public internet** – If the traffic can traverse the public internet, add internet gateways to the VPC. Then, adjust the security group assigned to the Lambda function `data-ingestion-processor` and the SageMaker AI notebook instance to allow outbound traffic to the public internet.
- **Not traversing the public internet** – To deploy this sample to any Region other than `us-east-1` or `us-west-1`, do the following:

1. In either the `us-east-1` or `us-west-1` Region, create an additional VPC including a VPC endpoint for `bedrock-runtime`.
2. Create a peering connection by using VPC peering or a transit gateway to the application VPC.
3. When configuring the `bedrock-runtime` boto3 client in any Lambda function outside of `us-east-1` or `us-west-1`, pass the private DNS name of the VPC endpoint for `bedrock-runtime` in `us-east-1` or us-west-1 as the `endpoint_url` to the boto3 client.

Deploy preprocessing logic into an ML model in a single endpoint using an inference pipeline in Amazon SageMaker

Mohan Gowda Purushothama, Gabriel Rodriguez Garcia, and Mateusz Zaremba, Amazon Web Services

Summary

This pattern explains how to deploy multiple pipeline model objects in a single endpoint by using an inference pipeline in Amazon SageMaker. The pipeline model object represents different machine learning (ML) workflow stages, such as preprocessing, model inference, and postprocessing. To illustrate the deployment of serially connected pipeline model objects, this pattern shows you how to deploy a preprocessing Scikit-learn container and a regression model based on the linear learner algorithm built into SageMaker. The deployment is hosted behind a single endpoint in SageMaker.

Note

The deployment in this pattern uses the ml.m4.2xlarge instance type. We recommend using an instance type that aligns with your data size requirements and the complexity of your workflow. For more information, see Amazon SageMaker Pricing. This pattern uses prebuilt Docker images for Scikit-learn, but you can use your own Docker containers and integrate them into your workflow.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Python 3.9
- Amazon SageMaker Python SDK and Boto3 library
- AWS Identity and Access Management (AWS IAM) role with basic SageMaker permissions and Amazon Simple Storage Service (Amazon S3) permissions

Product versions

- Amazon SageMaker Python SDK 2.49.2

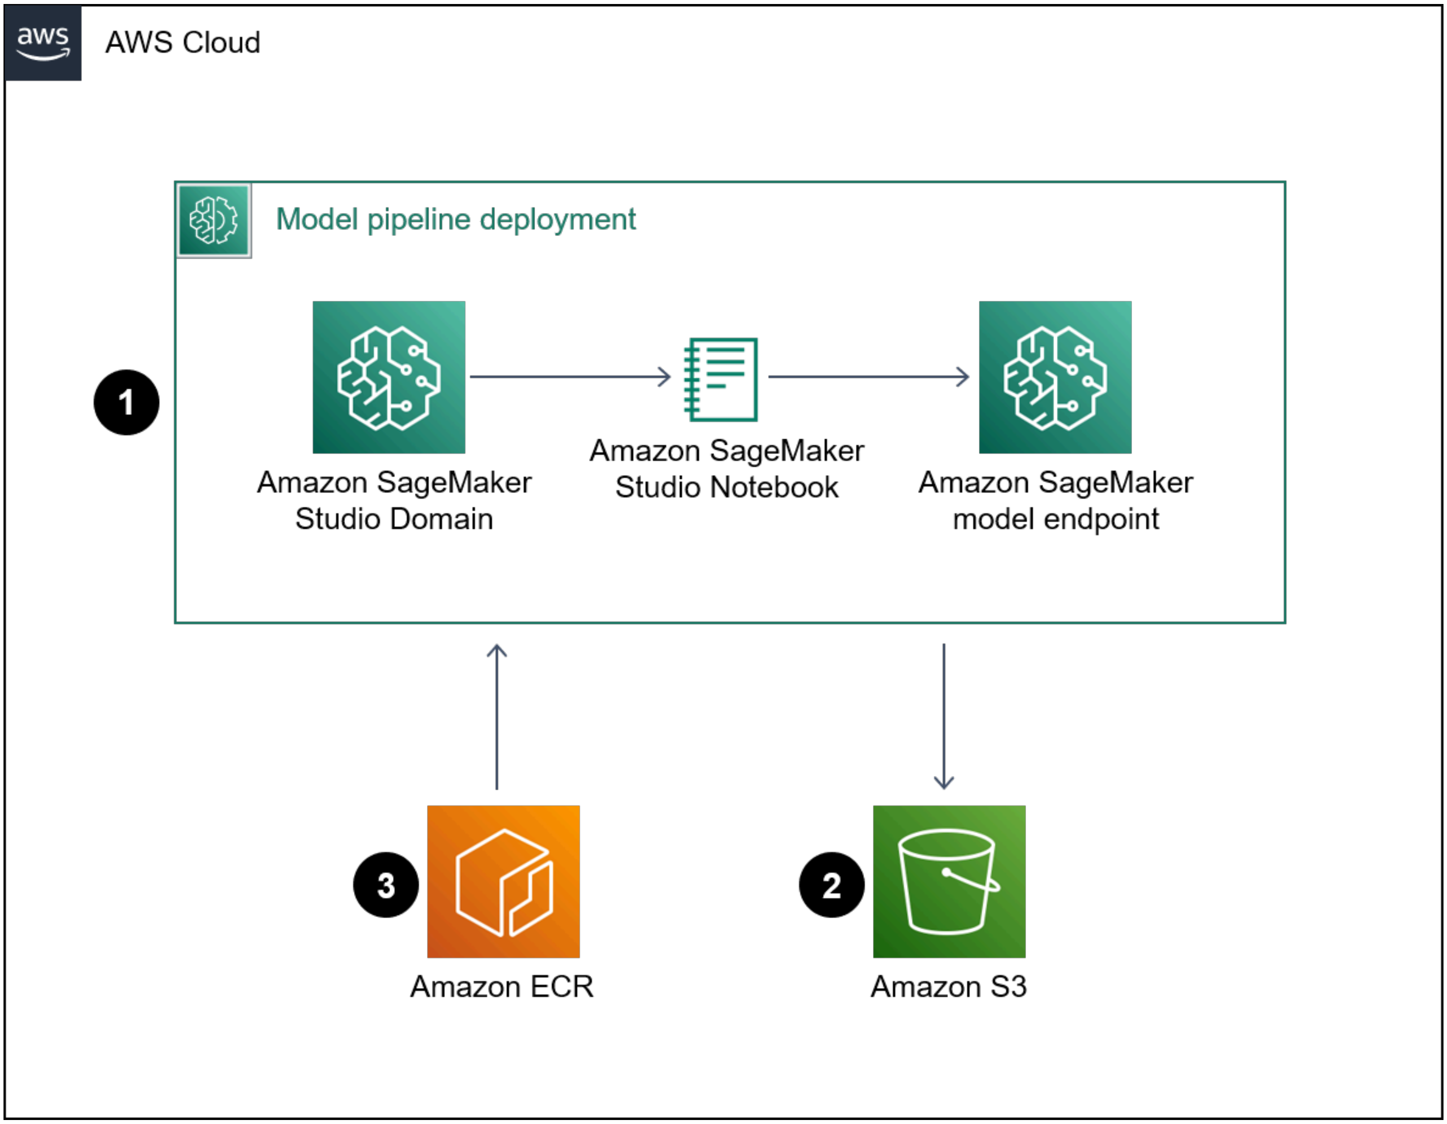
Architecture

Target technology stack

- Amazon Elastic Container Registry (Amazon ECR)
- Amazon SageMaker
- Amazon SageMaker Studio
- Amazon Simple Storage Service (Amazon S3)
- Real-time inference endpoint for Amazon SageMaker

Target architecture

The following diagram shows the architecture for the deployment of an Amazon SageMaker pipeline model object.



The diagram shows the following workflow:

1. A SageMaker notebook deploys a pipeline model.
2. An S3 bucket stores the model artifacts.
3. Amazon ECR gets the source container images from the S3 bucket.

Tools

AWS tools

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.

- Amazon SageMaker is a managed ML service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- Amazon SageMaker Studio is a web-based, integrated development environment (IDE) for ML that lets you build, train, debug, deploy, and monitor your ML models.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code

The code for this pattern is available in the GitHub Inference Pipeline with Scikit-learn and Linear Learner repository.

Epics

Prepare the dataset

Task	Description	Skills required

Prepare the dataset for your regression task.	Open a notebook in Amazon SageMaker Studio.
	
	To import all necessary libraries and initialize your working environment, use the following example code in your notebook:
	
	`import sagemaker`
	`from sagemaker import get_execution_role`
	
	`sagemaker_session = sagemaker.Session()`
	
	`# Get a SageMaker-compatible role used by this Notebook Instance.`
		Data scientist

Task	Description	Skills required

	``
	role = get_execu
	tion_role()
	
	# S3 prefix
	bucket = sagemaker
	_session.default_b
	ucket()
	prefix = "Scikit-L
	inearLearner-pipel
	ine-abalone-example"
	``
	
	To download a sample dataset, add the following code to your notebook:
	
	``
	! mkdir abalone_data
	! aws s3 cp s3://sage
	maker-sample-files
	/datasets/tabular/
	uci_abalone/abalon
	e.csv ./abalone_data
	``
	
	Note
	
	The example in this pattern uses the Abalone Data Set from the UCI Machine Learning Repository.	

Task	Description	Skills required

Upload the dataset to an S3 bucket.	In the notebook where you prepared your dataset earlier, add the following code to upload your sample data to an S3 bucket:
	`WORK_DIRECTORY = "abalone_data"`
	
	`train_input = sagemaker_session.upload_data(`
	`    path="{}/{}".format(WORK_DIRECTORY, "abalone.csv"),`
	`    bucket=bucket,`
	`    key_prefix="{}/{}".format(prefix, "train"),`
	`)`
		Data scientist

Create the data preprocessor using SKLearn

Task	Description	Skills required
Prepare the preprocessor.py script.	1. Copy the preprocessing logic from the Python file in the GitHub sklearn_abalone_featurizer.py repository, and then paste the code into a separate Python file called `sklearn_abalone_featurizer.py` . You can modify the code to fit your custom dataset and custom workflow.	Data scientist

Task	Description	Skills required
	2. Save the `sklearn_abalone_featurizer.py` file in the root directory of your project (that is, in the same location where you run your SageMaker notebook).	

Task	Description	Skills required

Create the SKLearn preproces sor object.	To create an SKLearn preprocessor object (called SKLearn Estimator) that you can incorporate into your final inference pipeline, run the following code in your SageMaker notebook:
	
	`from sagemaker.sklearn.estimator import SKLearn`
	
	`FRAMEWORK_VERSION = "0.23-1"`
	`script_path = "sklearn_abalone_featurizer.py"`
	
	`sklearn_preprocessor = SKLearn(`
	`    entry_point=script_path,`
	`    role=role,`
	`    framework_version=FRAMEWORK_VERSION,`
	`    instance_type="ml.c4.xlarge",`
	`    sagemaker_session=sagemaker_session,`
	`)`
	`sklearn_preprocessor.fit({"train": train_input})`
		Data scientist

Task	Description	Skills required

Test the preprocessor's inference.	To confirm that your preprocessor is defined correctly, launch a [batch transform job](https://docs.aws.amazon.com/sagemaker/latest/dg/batch-transform.html) by entering the following code in your SageMaker notebook:
	
	`# Define a SKLearn Transformer from the trained SKLearn Estimator`
	`transformer = sklearn_preprocessor.transformer(`
	`    instance_count=1, instance_type="ml.m5.xlarge", assemble_with="Line", accept="text/csv"`
	`)`
	
	`# Preprocess training input`
	`transformer.transform(train_input, content_type="text/csv")`
	`print("Waiting for transform job: " + transformer.latest_transform_job.job_name)`
	`transformer.wait()`
	`preprocessed_train = transformer.output_path`	

Create a machine learning model

Task	Description	Skills required

Create a model object.	To create a model object based on the linear learner algorithm, enter the following code in your SageMaker notebook:
	
	`import boto3`
	`from sagemaker`
	`.image_uris import`
	` retrieve`
	
	`ll_image = retrieve(`
	`"linear-learner",`
	` boto3.Session().re`
	`gion_name)`
	`s3_ll_output_key`
	`_prefix = "ll_train`
	`ing_output"`
	`s3_ll_output_location`
	` = "s3://{}/{}/{}/{}"`
	`.format(`
	`    bucket, prefix,`
	` s3_ll_output_key_p`
	`refix, "ll_model"`
	`)`
	
	`ll_estimator =`
	` sagemaker.estimato`
	`r.Estimator(`
	`    ll_image,`
	`    role,`
	`    instance_count=1,`
	`    instance_type="ml.`
	`m4.2xlarge",`
	`    volume_size=20,`
	`    max_run=3600,`
	`    input_mode="File",`
		Data scientist

Task	Description	Skills required

	``
	    output_path=s3_ll_
	output_location,
	    sagemaker_session=
	sagemaker_session,
	)
	
	ll_estimator.s
	et_hyperparameters
	(feature_dim=10,
	 predictor_type="re
	gressor", mini_batc
	h_size=32)
	
	ll_train_data =
	 sagemaker.inputs.T
	rainingInput(
	    preprocessed_train
	,
	    distribution="Full
	yReplicated",
	    content_type="text
	/csv",
	    s3_data_type="S3Pr
	efix",
	)
	
	data_channels =
	 {"train": ll_train_
	data}
	ll_estimator.fit(inpu
	ts=data_channels,
	 logs=True)
	``
	
	The preceding code retrieves the relevant Amazon ECR Docker image from the public Amazon ECR Registry for the model, creates an estimator object, and then uses that	

Task	Description	Skills required
	object to train the regression model.	

Deploy the final pipeline

Task	Description	Skills required

Deploy the pipeline model.	To create a pipeline model object (that is, a preprocessor object) and deploy the object, enter the following code in your SageMaker notebook:
	
	`from sagemaker.model import Model`
	`from sagemaker.pipeline import PipelineModel`
	`import boto3`
	`from time import gmtime, strftime`
	
	`timestamp_prefix = strftime("%Y-%m-%d-%H-%M-%S", gmtime())`
	
	`scikit_learn_inferencee_model = sklearn_preprocessor.create_model()`
	`linear_learner_model = ll_estimator.create_model()`
	
	`model_name = "inference-pipeline-" + timestamp_prefix`
		Data scientist

Task	Description	Skills required
	``` endpoint_name = "inference-pipeline- ep-" + timestamp_prefix sm_model = PipelineM odel(name=model_name, role=role, models= [scikit_learn_infe rencee_model, linear_learner_model]) sm_model.deploy(init ial_instance_count =1, instance_type="ml. c4.xlarge", endpoint_ name=endpoint_name) ``` **Note** You can adjust the instance type used in the model object to meet your needs.	

Task	Description	Skills required

Test the inference.	To confirm the endpoint is working correctly, run the following sample inference code in your SageMaker notebook:
	`from sagemaker.predictor import Predictor`
	`from sagemaker.serializers import CSVSerializer`
	
	`payload = "M, 0.44, 0.365, 0.125, 0.516, 0.2155, 0.114, 0.155"`
	`actual_rings = 10`
	`predictor = Predictor(`
	`    endpoint_name=endpoint_name, sagemaker_session=sagemaker_session, serializer=CSVSerializer()`
	`)`
	
	`print(predictor.predict(payload))`
		Data scientist

Develop advanced generative AI chat-based assistants by using RAG and ReAct prompting

Praveen Kumar Jeyarajan, Shuai Cao, Noah Hamilton, Kiowa Jackson, Jundong Qiao, and Kara Yang, Amazon Web Services

Summary

A typical corporation has 70 percent of its data trapped in siloed systems. You can use generative AI-powered chat-based assistants to unlock insights and relationships between these data silos through natural language interactions. To get the most out of generative AI, the outputs must be trustworthy, accurate, and inclusive of the available corporate data. Successful chat-based assistants depend on the following:

- Generative AI models (such as Anthropic Claude 2)
- Data source vectorization
- Advanced reasoning techniques, such as the ReAct framework, for prompting the model

This pattern provides data-retrieval approaches from data sources such as Amazon Simple Storage Service (Amazon S3) buckets, AWS Glue, and Amazon Relational Database Service (Amazon RDS). Value is gained from that data by interleaving Retrieval Augmented Generation (RAG) with chain-of-thought methods. The results support complex chat-based assistant conversations that draw on the entirety of your corporation's stored data.

This pattern uses Amazon SageMaker manuals and pricing data tables as an example to explore the capabilities of a generative AI chat-based assistant. You will build a chat-based assistant that helps customers evaluate the SageMaker service by answering questions about pricing and the service's capabilities. The solution uses a Streamlit library for building the frontend application and the LangChain framework for developing the application backend powered by a large language model (LLM).

Inquiries to the chat-based assistant are met with an initial intent classification for routing to one of three possible workflows. The most sophisticated workflow combines general advisory guidance with complex pricing analysis. You can adapt the pattern to suit enterprise, corporate, and industrial use cases.

Prerequisites and limitations

Prerequisites

- AWS Command Line Interface (AWS CLI) installed and configured
- AWS Cloud Development Kit (AWS CDK) Toolkit 2.114.1 or later installed and configured
- Basic familiarity with Python and AWS CDK
- Git installed
- Docker installed
- Python 3.11 or later installed and configured (for more information, see the Tools section)
- An active AWS account bootstrapped by using AWS CDK
- Amazon Titan and Anthropic Claude model access enabled in the Amazon Bedrock service
- AWS security credentials, including `AWS_ACCESS_KEY_ID`, correctly configured in your terminal environment

Limitations

- LangChain doesn't support every LLM for streaming. The Anthropic Claude models are supported, but models from AI21 Labs are not.
- This solution is deployed to a single AWS account.
- This solution can be deployed only in AWS Regions where Amazon Bedrock and Amazon Kendra are available. For information about availability, see the documentation for Amazon Bedrock and Amazon Kendra.

Product versions

- Python version 3.11 or later
- Streamlit version 1.30.0 or later
- Streamlit-chat version 0.1.1 or later
- LangChain version 0.1.12 or later
- AWS CDK version 2.132.1 or later

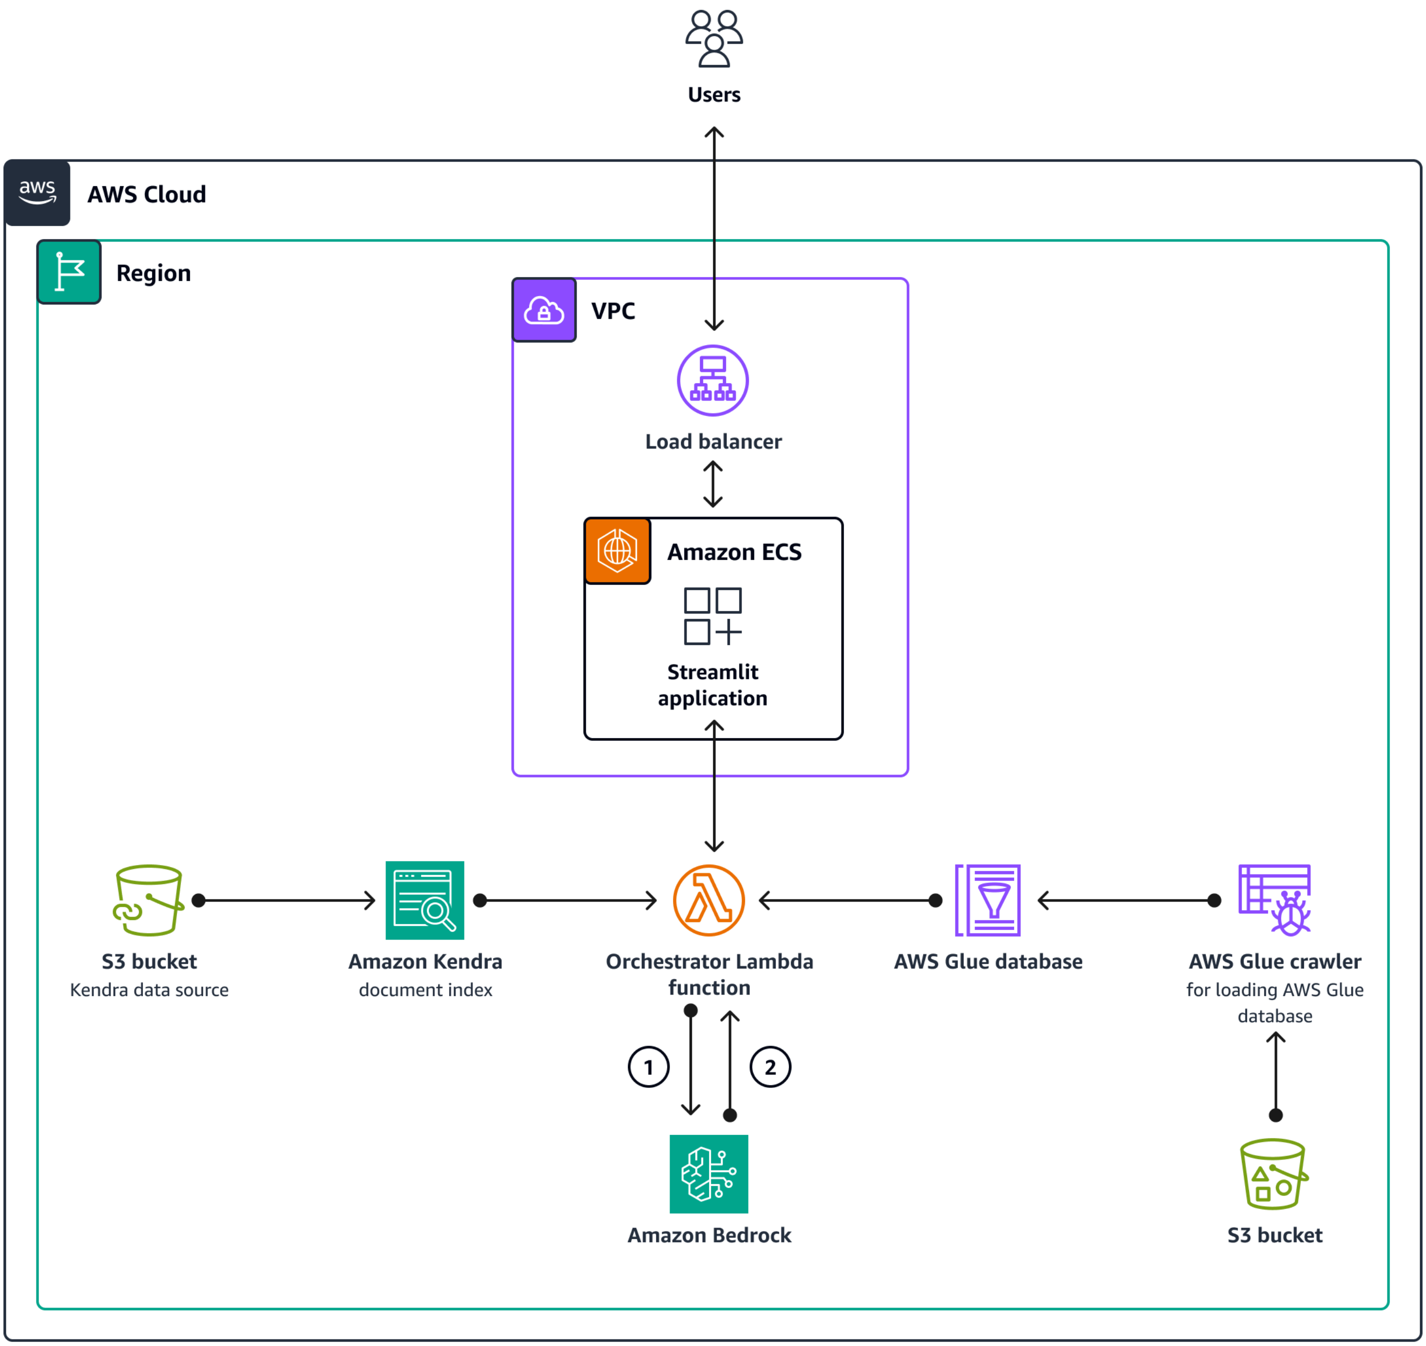
Architecture

Target technology stack

- Amazon Athena
- Amazon Bedrock
- Amazon Elastic Container Service (Amazon ECS)
- AWS Glue
- AWS Lambda
- Amazon S3
- Amazon Kendra
- Elastic Load Balancing

Target architecture

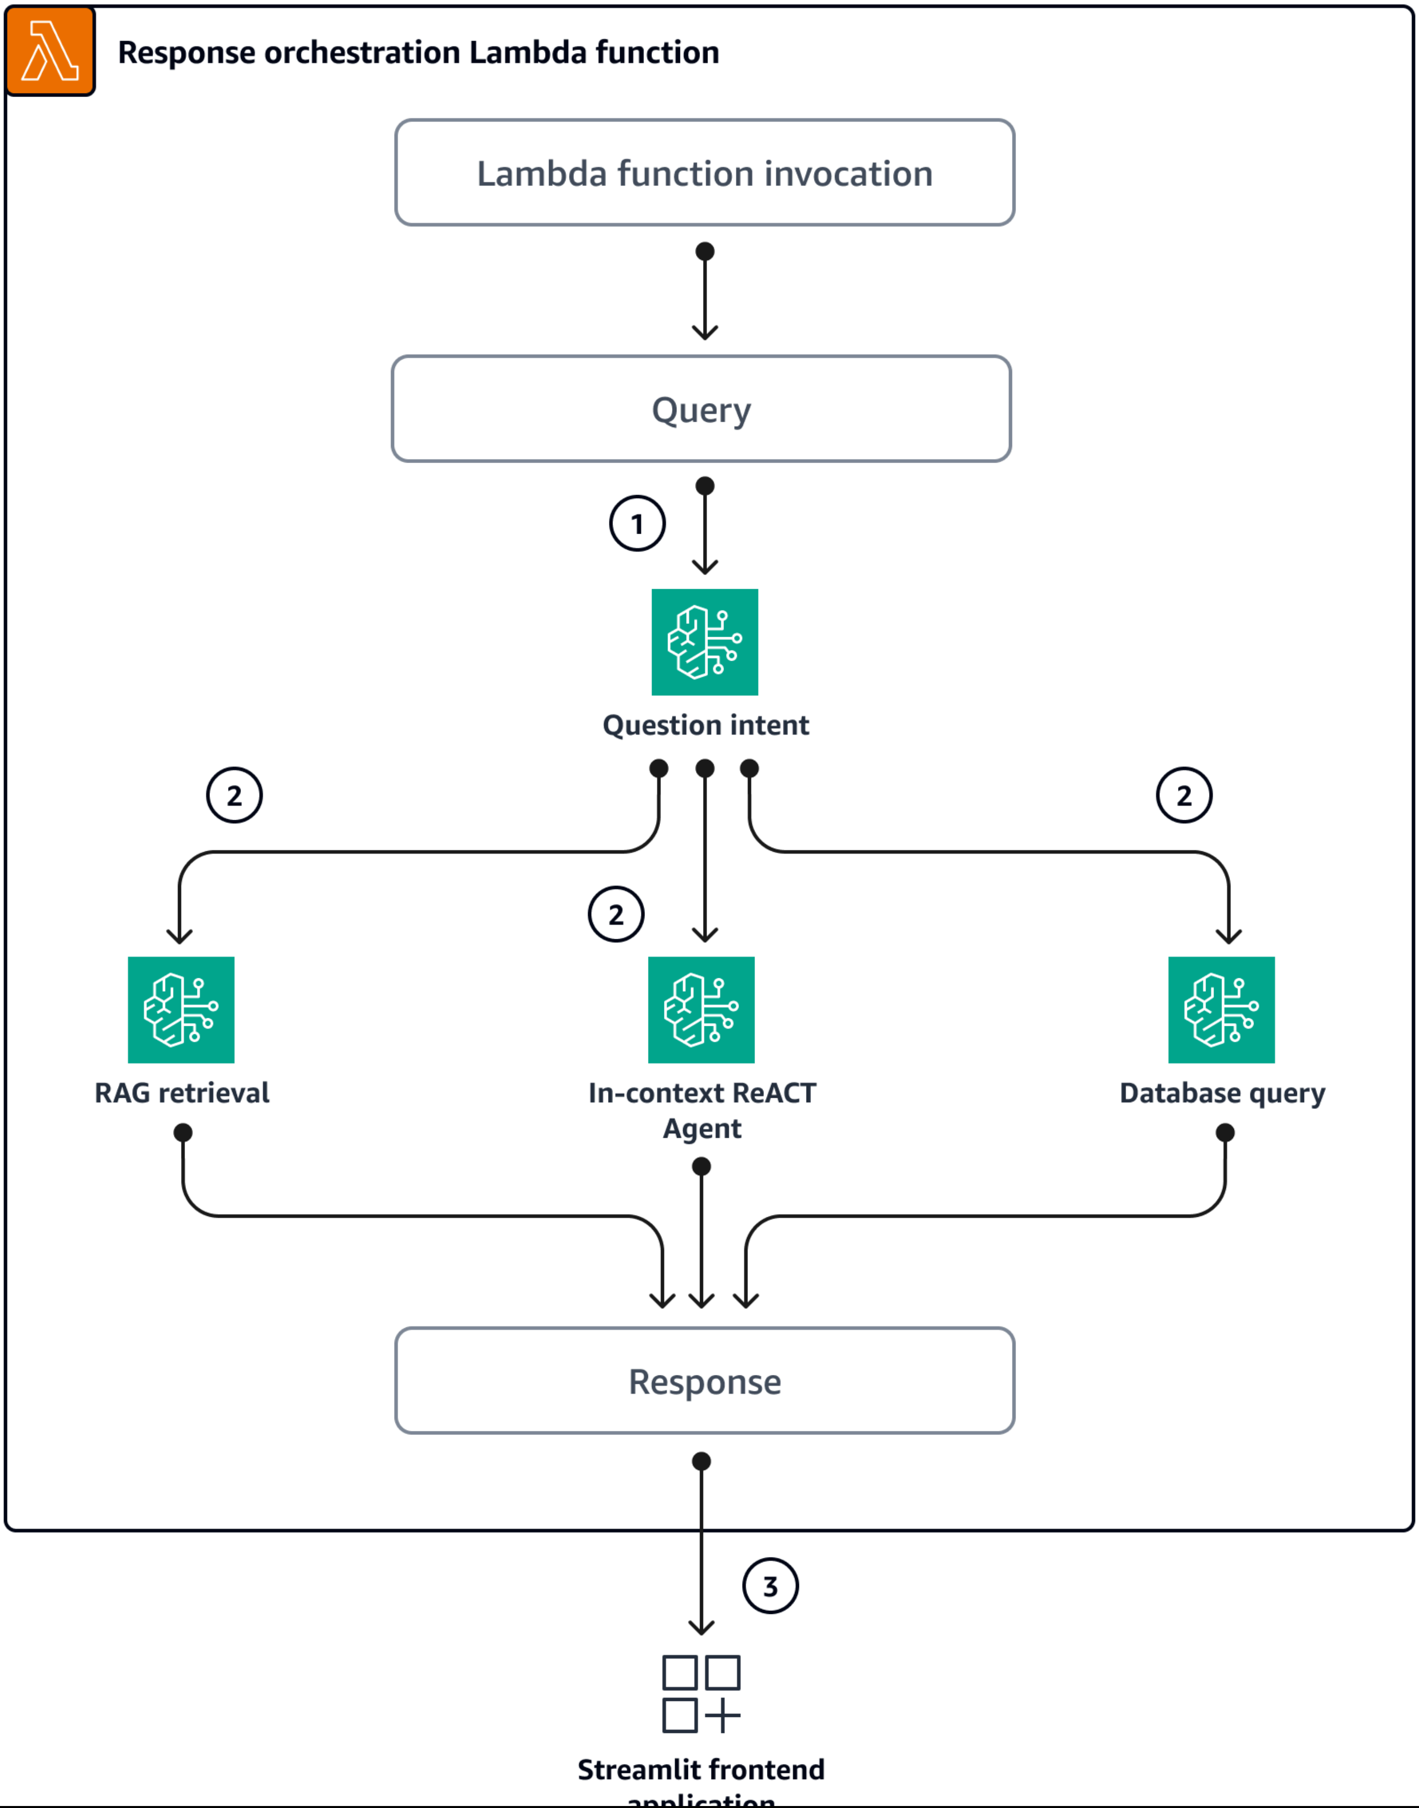
The AWS CDK code will deploy all the resources that are required to set up the chat-based assistant application in an AWS account. The chat-based assistant application shown in the following diagram is designed to answer SageMaker related queries from users. Users connect through an Application Load Balancer to a VPC that contains an Amazon ECS cluster hosting the Streamlit application. An orchestration Lambda function connects to the application. S3 bucket data sources provide data to the Lambda function through Amazon Kendra and AWS Glue. The Lambda function connects to Amazon Bedrock for answering queries (questions) from chat-based assistant users.



1. The orchestration Lambda function sends the LLM prompt request to the Amazon Bedrock model (Claude 2).
2. Amazon Bedrock sends the LLM response back to the orchestration Lambda function.

Logic flow within the orchestration Lambda function

When users ask a question through the Streamlit application, it invokes the orchestration Lambda function directly. The following diagram shows the logic flow when the Lambda function is invoked.



Response orchestration Lambda function
Lambda function invocation
Query
1
Question intent
2
2
2
RAG retrieval
In-context ReACT Agent
Database query
Response
3
Streamlit frontend application

- Step 1 – The input `query` (question) is classified into one of the three intents:
  - General SageMaker guidance questions
  - General SageMaker pricing (training/inference) questions
  - Complex questions related to SageMaker and pricing
- Step 2 – The input `query` initiates one of the three services:
  - `RAG Retrieval service`, which retrieves relevant context from the [Amazon Kendra](#) vector database and calls the LLM through [Amazon Bedrock](#) to summarize the retrieved context as the response.
  - `Database Query service`, which uses- the LLM, database metadata, and sample rows from relevant tables to convert the input `query` into a SQL query. Database Query service runs the SQL query against the SageMaker pricing database through [Amazon Athena](#) and summarizes the query results as the response.
  - `In-context ReACT Agent service`, which breaks down the input `query` into multiple steps before providing a response. The agent uses `RAG Retrieval service` and `Database Query service` as tools to retrieve relevant information during the reasoning process. After the reasoning and actions processes are complete, the agent generates the final answer as the response.
- Step 3 – The response from the orchestration Lambda function is sent to the Streamlit application as output.

Tools

AWS services

- [Amazon Athena](#) is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- [Amazon Bedrock](#) is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- [AWS Cloud Development Kit (AWS CDK)](#) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS Command Line Interface (AWS CLI)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [Amazon Elastic Container Service (Amazon ECS)](#) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.

- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams. This pattern uses an AWS Glue crawler and an AWS Glue Data Catalog table.
- Amazon Kendra is an intelligent search service that uses natural language processing and advanced machine learning algorithms to return specific answers to search questions from your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.

Code repository

The code for this pattern is available in the GitHub genai-bedrock-chatbot repository.

The code repository contains the following files and folders:

- `assets` folder – The static assets the architecture diagram and the public dataset
- `code/lambda-container` folder – The Python code that is run in the Lambda function
- `code/streamlit-app` folder – The Python code that is run as the container image in Amazon ECS
- `tests` folder – The Python files that are run to unit test the AWS CDK constructs
- `code/code_stack.py` – The AWS CDK construct Python files used to create AWS resources
- `app.py` – The AWS CDK stack Python files used to deploy AWS resources in the target AWS account
- `requirements.txt` – The list of all Python dependencies that must be installed for AWS CDK
- `requirements-dev.txt` – The list of all Python dependencies that must be installed for AWS CDK to run the unit-test suite
- `cdk.json` – The input file to provide values required to spin up resources

Note: The AWS CDK code uses L3 (layer 3) constructs and AWS Identity and Access Management (IAM) policies managed by AWS for deploying the solution.

Best practices

- The code example provided here is for a proof-of-concept (PoC) or pilot demo only. If you want to take the code to Production, be sure to use the following best practices:
  - Amazon S3 access logging is enabled.
  - VPC Flow Logs is enabled.
  - The Amazon Kendra Enterprise Edition index is enabled.
- Set up monitoring and alerting for the Lambda function. For more information, see Monitoring and troubleshooting Lambda functions. For general best practices when working with Lambda functions, see the AWS documentation.

Epics

Set up AWS credentials on your local machine

Task	Description	Skills required

Export variables for the account and AWS Region where the stack will be deployed.	To provide AWS credentials for AWS CDK by using environment variables, run the following commands.
	`export CDK_DEFAULT_ACCOUNT=<12 Digit AWS Account Number>`
	`export CDK_DEFAULT_REGION=<region>`
		DevOps engineer, AWS DevOps

Set up the AWS CLI profile.	To set up the AWS CLI profile for the account, follow the instructions in the AWS documentation.	DevOps engineer, AWS DevOps

Set up your environment

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Clone the repo on your local machine.</td><td>To clone the repository, run the following command in your terminal.
<pre>git clone https://github.com/awslabs/genai-bedrock-chatbot.git</pre></td><td>DevOps engineer, AWS DevOps</td></tr>
<tr><td>Set up the Python virtual environment and install required dependencies.</td><td>To set up the Python virtual environment, run the following commands.

source .venv/bin/activate</pre>To set up the required dependencies, run the following command.
<pre>pip3 install -r requirements.txt</pre></td><td>DevOps engineer, AWS DevOps</td></tr>
<tr><td>Set up the AWS CDK environment and synthesize the AWS CDK code.</td><td>1. To set up the AWS CDK environment in your AWS account, run the following command.
<pre>cdk bootstrap aws://ACCOUNT-NUMBER/REGION</pre></td><td>DevOps engineer, AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	2. To convert the code to an AWS CloudFormation stack configuration, run the command `cdk synth`.	

Configure and deploy the chat-based assistant application

Task	Description	Skills required
Provision Claude model access.	To enable Anthropic Claude model access for your AWS account, follow the instructions in the Amazon Bedrock documentation.	AWS DevOps
Deploy resources in the account.	To deploy resources in the AWS account by using the AWS CDK, do the following: 1. In the root of the cloned repository, in the `cdk.json` file, provide inputs for the `logging` parameters. Example values are `INFO`, `DEBUG`, `WARN`, and `ERROR`. These values define log-level messages for the Lambda function and the Streamlit application. 2. The `app.py` file in the root of the cloned repository contains the AWS CloudFormation stack	AWS DevOps, DevOps engineer

Task	Description	Skills required
	name used for deploymen t. The default stack name is `chatbot-stack` . 3. To deploy resources, run the command `cdk deploy`. The `cdk deploy` command uses L3 constructs to create multiple Lambda functions for copying documents and CSV dataset files to S3 buckets. 4. After the command is complete, sign in to the AWS Management Console, open the CloudForm ation console, and [review that the stack deployed successfully](#). Upon successful deploymen t, you can access the chat-based assistant application by using the URL provided in the CloudFormation **Outputs** section.	

Task	Description	Skills required
Run the AWS Glue crawler and create the Data Catalog table.	An [AWS Glue crawler](#) is used to keep the data schema dynamic. The solution creates and updates partitions in the [AWS Glue Data Catalog table](#) by running the crawler on demand. After the CSV dataset files are copied into the S3 bucket, run the AWS Glue crawler and create the Data Catalog table schema for testing: 1. Navigate to the AWS Glue console. 2. In the navigation pane, under **Data Catalog**, choose **Crawlers**. 3. Select the crawler with suffix `sagemaker-pricing-crawler` . 4. Run the crawler. 5. After the crawler runs successfully, it creates an AWS Glue Data Catalog table. **Note** The AWS CDK code configures the AWS Glue crawler to run on demand, but you can	DevOps engineer, AWS DevOps

Task	Description	Skills required
	also [schedule](#) it to run periodically.	
Initiate document indexing.	After the files are copied into the S3 bucket, use Amazon Kendra to crawl and index them: 1. Navigate to the Amazon Kendra console. 2. Select the index with the suffix `chatbot-index` . 3. In the navigation pane, choose **Data sources**, and select the data source connector with the suffix `chatbot-index` . 4. Choose **Sync Now** to initiate the indexing process. **Note** The AWS CDK code configures the Amazon Kendra index sync to run on demand, but you can also run periodically by using the [Schedule parameter](#).	AWS DevOps, DevOps engineer

Clean up all AWS resources in the solution

Task	Description	Skills required
Remove the AWS resources.	After you test the solution, clean up the resources: 1. To remove AWS resources deployed by the solution, run the command `cdk destroy`. 2. Delete all objects from the two S3 buckets, and then remove the buckets. For more information, see Deleting a bucket.	DevOps engineer, AWS DevOps

Troubleshooting

Develop a fully automated chat-based assistant by using Amazon Bedrock agents and knowledge bases

Jundong Qiao, Shuai Cao, Noah Hamilton, Kiowa Jackson, Praveen Kumar Jeyarajan, and Kara Yang, Amazon Web Services

Summary

Many organizations face challenges when creating a chat-based assistant that is capable of orchestrating diverse data sources to offer comprehensive answers. This pattern presents a solution for developing a chat-based assistant that is capable of answering queries from both documentation and databases, with a straightforward deployment.

Starting with Amazon Bedrock, this fully managed generative artificial intelligence (AI) service provides a wide array of advanced foundation models (FMs). This facilitates the efficient creation of generative AI applications with a strong focus on privacy and security. In the context of documentation retrieval, the Retrieval Augmented Generation (RAG) is a pivotal feature. It uses knowledge bases to augment FM prompts with contextually relevant information from external sources. An Amazon OpenSearch Serverless index serves as the vector database behind the knowledge bases for Amazon Bedrock. This integration is enhanced through careful prompt engineering to minimize inaccuracies and make sure that responses are anchored in factual documentation. For database queries, the FMs of Amazon Bedrock transform textual inquiries into structured SQL queries, incorporating specific parameters. This enables the precise retrieval of data from databases managed by AWS Glue databases. Amazon Athena is used for these queries.

For handling more intricate queries, achieving comprehensive answers demands information sourced from both documentation and databases. Agents for Amazon Bedrock is a generative AI feature that helps you build autonomous agents that can understand complex tasks and break them down into simpler tasks for orchestration. The combination of insights retrieved from the simplified tasks, facilitated by Amazon Bedrock autonomous agents, enhances the synthesis of information, leading to more thorough and exhaustive answers. This pattern demonstrates how to build a chat-based assistant by using Amazon Bedrock and the related generative AI services and features within an automated solution.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Docker, installed
- AWS Cloud Development Kit (AWS CDK), installed and bootstrapped to the `us-east-1` or `us-west-2` AWS Regions
- AWS CDK Toolkit version 2.114.1 or later, installed
- AWS Command Line Interface (AWS CLI), installed and configured
- Python version 3.11 or later, installed
- In Amazon Bedrock, enable access to Claude 2, Claude 2.1, Claude Instant, and Titan Embeddings G1 – Text

Limitations

- This solution is deployed to a single AWS account.
- This solution can be deployed only in AWS Regions where Amazon Bedrock and Amazon OpenSearch Serverless are supported. For more information, see the documentation for Amazon Bedrock and Amazon OpenSearch Serverless.

Product versions

- Llama-index version 0.10.6 or later
- Sqlalchemy version 2.0.23 or later
- Opensearch-py version 2.4.2 or later
- Requests_aws4auth version 1.2.3 or later
- AWS SDK for Python (Boto3) version 1.34.57 or later

Architecture

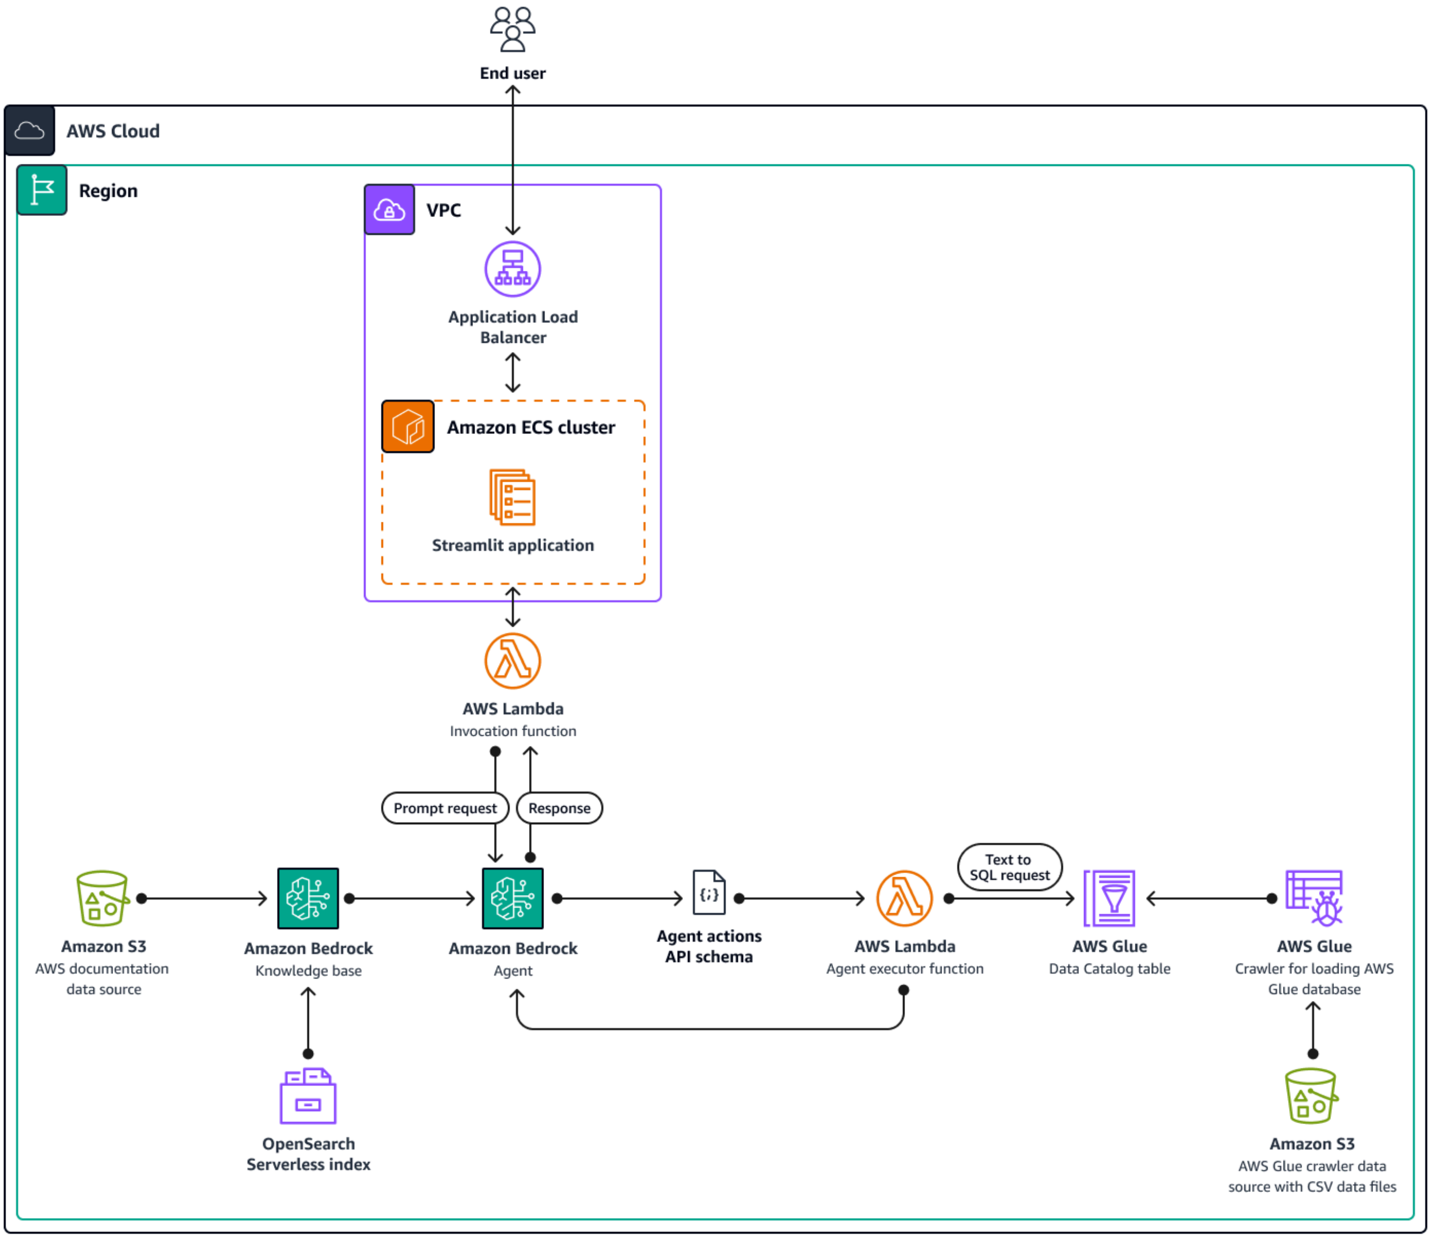
Target technology stack

The AWS Cloud Development Kit (AWS CDK) is an open source software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation. The AWS CDK stack used in this pattern deploys the following AWS resources:

- AWS Key Management Service (AWS KMS)

- Amazon Simple Storage Service (Amazon S3)
- AWS Glue Data Catalog, for the AWS Glue database component
- AWS Lambda
- AWS Identity and Access Management (IAM)
- Amazon OpenSearch Serverless
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon Elastic Container Service (Amazon ECS)
- AWS Fargate
- Amazon Virtual Private Cloud (Amazon VPC)
- Application Load Balancer

Target architecture



The diagram shows a comprehensive AWS cloud-native setup within a single AWS Region, using multiple AWS services. The primary interface for the chat-based assistant is a [Streamlit](https://streamlit.io/) application hosted on an Amazon ECS cluster. An [Application Load Balancer](https://docs.aws.amazon.com/elasticloadbalancing/latest/application/introduction.html) manages accessibility. Queries made through this interface activate the `Invocation` Lambda function, which then interfaces with agents for Amazon Bedrock. This agent responds to user inquiries by either consulting the knowledge bases for Amazon Bedrock or by invoking an `Agent executor` Lambda function. This function triggers a set of actions associated with the agent, following a predefined API schema. The knowledge bases for Amazon Bedrock use an OpenSearch Serverless index as their vector database foundation. Additionally, the `Agent executor` function generates SQL queries that are executed against the AWS Glue database through Amazon Athena.

Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams. This pattern uses an AWS Glue crawler and an AWS Glue Data Catalog table.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon OpenSearch Serverless is an on-demand serverless configuration for Amazon OpenSearch Service. In this pattern, an OpenSearch Serverless index serves as a vector database for the knowledge bases for Amazon Bedrock.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Streamlit is an open source Python framework to create data applications.

Code repository

The code for this pattern is available in the GitHub genai-bedrock-agent-chatbot repository. The code repository contains the following files and folders:

- `assets` folder – The static assets, such as the architecture diagram and the public dataset.
- `code/lambdas/action-lambda` folder – The Python code for the Lambda function that acts as an action for the Amazon Bedrock agent.
- `code/lambdas/create-index-lambda` folder – The Python code for the Lambda function that creates the OpenSearch Serverless index.
- `code/lambdas/invoke-lambda` folder – The Python code for the Lambda function that invokes the Amazon Bedrock agent, which is called directly from the Streamlit application.
- `code/lambdas/update-lambda` folder – The Python code for the Lambda function that updates or deletes resources after the AWS resources are deployed through the AWS CDK.
- `code/layers/boto3_layer` folder – The AWS CDK stack that creates a Boto3 layer that is shared across all Lambda functions.
- `code/layers/opensearch_layer` folder – The AWS CDK stack that creates an OpenSearch Serverless layer that installs all dependencies to create the index.
- `code/streamlit-app` folder – The Python code that is run as the container image in Amazon ECS
- `code/code_stack.py` – The AWS CDK construct Python files that create AWS resources.
- `app.py` – The AWS CDK stack Python files that deploy AWS resources in the target AWS account.
- `requirements.txt` – The list of all Python dependencies that must be installed for the AWS CDK.
- `cdk.json` – The input file to provide the values that are required to create resources. Also, in the `context/config` fields, you can customize the solution accordingly. For more information about customization, see the Additional information section.

Best practices

- The code example provided here is for proof-of-concept (PoC) or pilot purposes only. If you want to take the code to production, be sure to use the following best practices:
  - Enable Amazon S3 access logging
  - Enable VPC Flow Logs

- Set up monitoring and alerting for the Lambda functions. For more information, see Monitoring and troubleshooting Lambda functions. For best practices, see the Best practices for working with AWS Lambda functions.

Epics

Set up AWS credentials on your local workstation

Task	Description	Skills required

Export variables for the account and Region.	To provide AWS credentials for the AWS CDK by using environment variables, run the following commands.
	`export CDK_DEFAULT_ACCOUNT=<12-digit AWS account number>`
	`export CDK_DEFAULT_REGION=<Region>`
		AWS DevOps, DevOps engineer

Set up the AWS CLI named profile.	To set up the AWS CLI named profile for the account, follow the instructions in Configuration and credential file settings.	AWS DevOps, DevOps engineer

Set up your environment

Task	Description	Skills required
Clone the repo to your local workstation.	To clone the repository, run the following command in your terminal. `git clone https://github.com/awslabs/`	DevOps engineer, AWS DevOps

Task	Description	Skills required
	`genai-bedrock-agent-chatbot.git`	

Set up the Python virtual environment.	To set up the Python virtual environment, run the following commands.
	`cd genai-bedrock-agent-chatbot`
	`python3 -m venv .venv`
	`source .venv/bin/activate`
	To set up the required dependencies, run the following command.
	`pip3 install -r requirements.txt`
		DevOps engineer, AWS DevOps

Set up the AWS CDK environment.	To convert the code to an AWS CloudFormation template, run the command `cdk synth`.	AWS DevOps, DevOps engineer

Configure and deploy the application

Task	Description	Skills required
Deploy resources in the account.	To deploy resources in the AWS account by using the AWS CDK, do the following: 1. In the root of the cloned repository, in the `cdk.json` file, provide	DevOps engineer, AWS DevOps

Task	Description	Skills required
	inputs for the logging parameters. Example values are `INFO`, `DEBUG`, `WARN`, and `ERROR`. These values define log-level messages for the Lambda functions and the Streamlit application. 2. The `cdk.json` file in the root of the cloned repository contains the AWS CloudFormation stack name used for deploymen t. The default stack name is `chatbot-stack` . The default Amazon Bedrock agent name is `ChatbotBedrockAgent` , and the default Amazon Bedrock agent alias is `Chatbot_Agent` . 3. To deploy resources, run the command `cdk deploy`. The `cdk deploy` command uses layer-3 constructs to create multiple Lambda functions for copying documents and CSV dataset files to S3 buckets. It also deploys the Amazon Bedrock agent, knowledge bases, and	

Task	Description	Skills required
	`Action group` Lambda function for the Amazon Bedrock agent. 4. Sign in to the AWS Management Console, and then open the CloudFormation console at https://console.aws.amazon.com/cloudformation/. 5. Confirm that the stack deployed successfully. For instructions, see Reviewing your stack on the AWS CloudFormation console. After successful deployment, you can access the chat-based assistant application by using the URL provided on the **Outputs** tab in the CloudFormation console.	

Clean up all AWS resources in the solution

Task	Description	Skills required
Remove the AWS resources.	After you test the solution, to clean up the resources, run the command `cdk destroy`.	AWS DevOps, DevOps engineer

Additional information

Customize the chat-based assistant with your own data

To integrate your custom data for deploying the solution, follow these structured guidelines. These steps are designed to ensure a seamless and efficient integration process, enabling you to deploy the solution effectively with your bespoke data.

For knowledge base data integration

Data preparation

1. Locate the `assets/knowledgebase_data_source/` directory.
2. Place your dataset within this folder.

Configuration adjustments

1. Open the `cdk.json` file.
2. Navigate to the `context/configure/paths/knowledgebase_file_name` field, and then update it accordingly.
3. Navigate to the `bedrock_instructions/knowledgebase_instruction` field, and then update it to accurately reflect the nuances and context of your new dataset.

For structural data integration

Data organization

1. Within the `assets/data_query_data_source/` directory, create a subdirectory, such as `tabular_data`.
2. Put your structured dataset (acceptable formats include CSV, JSON, ORC, and Parquet) into this newly created subfolder.
3. If you are connecting to an existing database, update the function `create_sql_engine()` in `code/lambda/action-lambda/build_query_engine.py` to connect to your database.

Configuration and code updates

1. In the `cdk.json` file, update the `context/configure/paths/athena_table_data_prefix` field to align with the new data path.
2. Revise `code/lambda/action-lambda/dynamic_examples.csv` by incorporating new text-to-SQL examples that correspond with your dataset.
3. Revise `code/lambda/action-lambda/prompt_templates.py` to mirror the attributes of your structured dataset.
4. In the `cdk.json` file, update the `context/configure/bedrock_instructions/action_group_description` field to explain the purpose and functionality of the `Action group` Lambda function.
5. In the `assets/agent_api_schema/artifacts_schema.json` file, explain the new functionalities of your `Action group` Lambda function.

General update

In the `cdk.json` file, in the `context/configure/bedrock_instructions/agent_instruction` section, provide a comprehensive description of the Amazon Bedrock agent's intended functionality and design purpose, taking into account the newly integrated data.

Document institutional knowledge from voice inputs by using Amazon Bedrock and Amazon Transcribe

Praveen Kumar Jeyarajan, Jundong Qiao, Rajiv Upadhyay, and Megan Wu, Amazon Web Services

Summary

Capturing institutional knowledge is paramount for ensuring organizational success and resilience. Institutional knowledge represents the collective wisdom, insights, and experiences accumulated by employees over time, often tacit in nature and passed down informally. This wealth of information encompasses unique approaches, best practices, and solutions to intricate problems that might not be documented elsewhere. By formalizing and documenting this knowledge, companies can preserve institutional memory, foster innovation, enhance decision-making processes, and accelerate learning curves for new employees. Additionally, it promotes collaboration, empowers individuals, and cultivates a culture of continuous improvement. Ultimately, harnessing institutional knowledge helps companies use their most valuable asset—the collective intelligence of their workforce—to navigate challenges, drive growth, and maintain competitive advantage in dynamic business environments.

This pattern explains how to capture institutional knowledge through voice recordings from senior employees. It uses Amazon Transcribe and Amazon Bedrock for systematic documentation and verification. By documenting this informal knowledge, you can preserve it and share it with subsequent cohorts of employees. This endeavor supports operational excellence and improves the effectiveness of training programs through the incorporation of practical knowledge acquired through direct experience.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Docker, installed
- AWS Cloud Development Kit (AWS CDK) version 2.114.1 or later, installed and bootstrapped to the `us-east-1` or `us-west-2` AWS Regions
- AWS CDK Toolkit version 2.114.1 or later, installed
- AWS Command Line Interface (AWS CLI), installed and configured

- Python version 3.12 or later, installed
- Permissions to create Amazon Transcribe, Amazon Bedrock, Amazon Simple Storage Service (Amazon S3), and AWS Lambda resources

Limitations

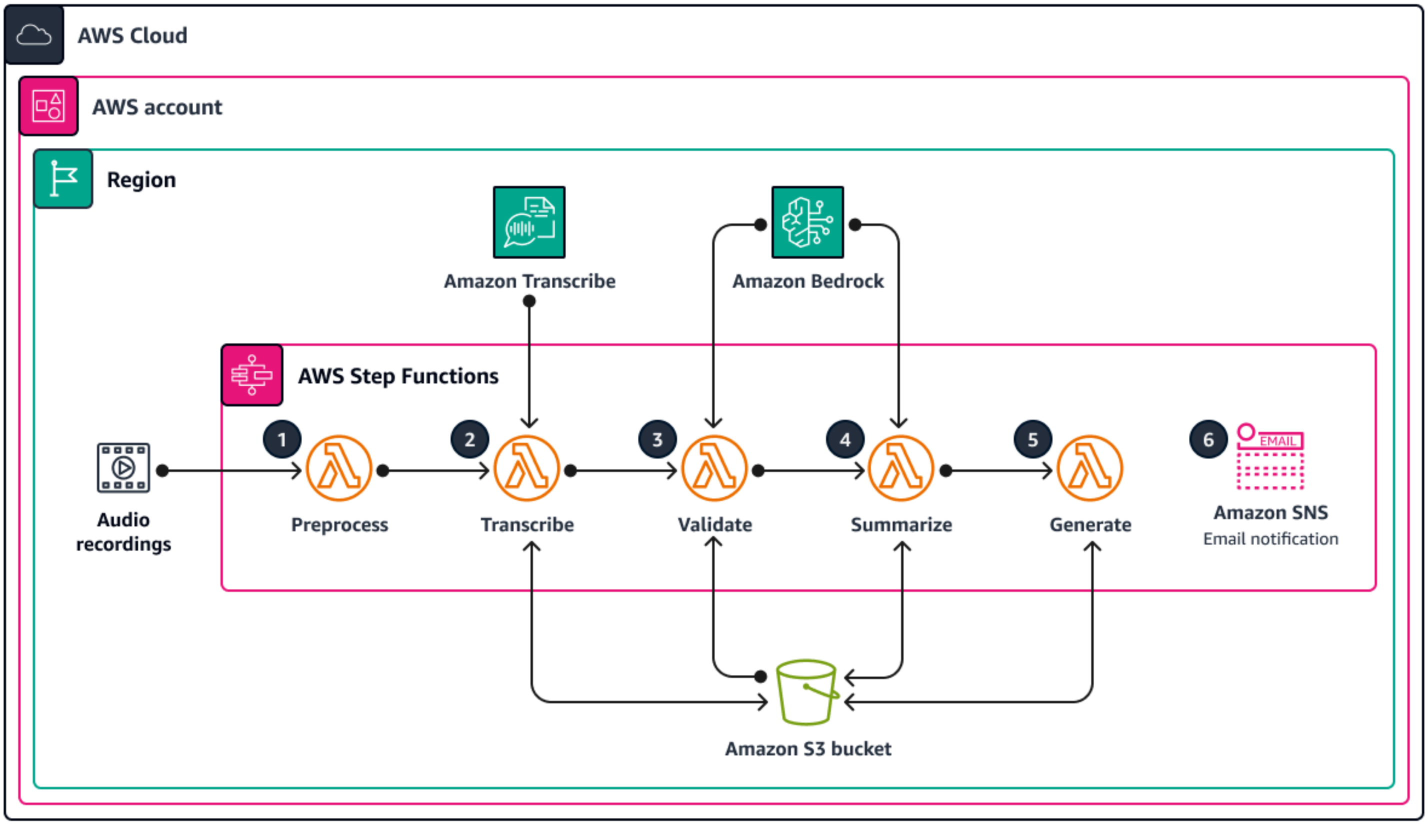
- This solution is deployed to a single AWS account.
- This solution can be deployed only in AWS Regions where Amazon Bedrock and Amazon Transcribe are available. For information about availability, see the documentation for Amazon Bedrock and Amazon Transcribe.
- The audio files must be in a format that Amazon Transcribe supports. For a list of supported formats, see Media formats in the Transcribe documentation.

Product versions

- AWS SDK for Python (Boto3) version 1.34.57 or later
- LangChain version 0.1.12 or later

Architecture

The architecture represents a serverless workflow on AWS. AWS Step Functions orchestrates Lambda functions for audio processing, text analysis, and document generation. The following diagram shows the Step Functions workflow, also known as a *state machine*.



Each step in the state machine is handled by a distinct Lambda function. The following are the steps in the document generation process:

1. The `preprocess` Lambda function validates the input passed to Step Functions and lists all of the audio files present in the provided Amazon S3 URI folder path. Downstream Lambda functions in the workflow use the file list to validate, summarize, and generate the document.
2. The `transcribe` Lambda function uses Amazon Transcribe to convert audio files into text transcripts. This Lambda function is responsible for initiating the transcription process and accurately transforming speech into text, which is then stored for subsequent processing.
3. The `validate` Lambda function analyzes the text transcripts, determining the relevance of the responses to the initial questions. By using a large language model (LLM) through Amazon Bedrock, it identifies and separates on-topic answers from off-topic responses.
4. The `summarize` Lambda function uses Amazon Bedrock to generate a coherent and concise summary of the on-topic answers.
5. The `generate` Lambda function assembles the summaries into a well-structured document. It can format the document according to predefined templates and include any additional necessary content or data.

6. If any of the Lambda functions fail, you receive an email notification through Amazon Simple Notification Service (Amazon SNS).

Throughout this process, AWS Step Functions makes sure that each Lambda function is initiated in the correct sequence. This state machine has the capacity for parallel processing to enhance efficiency. An Amazon S3 bucket acts as the central storage repository, supporting the workflow by managing the various media and document formats involved.

Tools

AWS services

- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- Amazon Transcribe is an automatic speech recognition service that uses machine learning models to convert audio to text.

Other tools

- LangChain is a framework for developing applications that are powered by large language models (LLMs).

Code repository

The code for this pattern is available in the GitHub genai-knowledge-capture repository.

The code repository contains the following files and folders:

- `assets` folder – The static assets for the solution, such as the architecture diagram and the public dataset
- `code/lambdas` folder – The Python code for all Lambda functions
  - `code/lambdas/generate` folder - The Python code that generates a document from the summarized data in the S3 bucket
  - `code/lambdas/preprocess` folder - The Python code that processes the inputs for the Step Functions state machine
  - `code/lambdas/summarize` folder - The Python code that summarizes the transcribed data by using Amazon Bedrock service
  - `code/lambdas/transcribe` folder - The Python code that converts speech data (audio file) into text by using Amazon Transcribe
  - `code/lambdas/validate` folder - The Python code that validates whether all answers pertain to the same topic
- `code/code_stack.py` – The AWS CDK construct Python file that is used to create AWS resources
- `app.py` – The AWS CDK app Python file that is used to deploy AWS resources in the target AWS account
- `requirements.txt` – The list of all Python dependencies that must be installed for the AWS CDK
- `cdk.json` – The input file to provide values that are required to create resources

Best practices

The code example provided is for proof-of-concept (PoC) or pilot purposes only. If you want to take the solution to production, use the following best practices:

- Enable [Amazon S3 access logging](#)
- Enable [VPC Flow Logs](#)

Epics

Set up AWS credentials on your local workstation

Task	Description	Skills required

Export variables for the account and AWS Region.	To provide AWS credentials for the AWS CDK by using environment variables, run the following commands.
	`export CDK_DEFAULT_ACCOUNT=<12-digit AWS account number>`
	`export CDK_DEFAULT_REGION=<Region>`
		AWS DevOps, DevOps engineer

Set up the AWS CLI named profile.	To set up the AWS CLI named profile for the account, follow the instructions in Configuration and credential file settings.	AWS DevOps, DevOps engineer

Set up your environment

Task	Description	Skills required
Clone the repo to your local workstation.	To clone the genai-knowledge-capture repository, run the following command in your terminal. `git clone https://github.com/aws-samples/genai-knowledge-capture`	AWS DevOps, DevOps engineer

Task	Description	Skills required
(Optional) Replace the audio files.	To customize the sample application to incorpora te your own data, do the following: 1. Navigate to the `assets/audio_samples` folder in the cloned repository. 2. Delete the folders containing the sample audio files. 3. Create a folder for each topic you want to analyze. 4. Transfer your audio files to their respective folders.	AWS DevOps, DevOps engineer

Set up the Python virtual environment.	To set up the Python virtual environment, run the following commands.
	
	`cd genai-knowledge-capture`
	`python3 -m venv .venv`
	`source .venv/bin/activate`
	`pip install -r requirements.txt`
		AWS DevOps, DevOps engineer

Synthesize the AWS CDK code.	To convert the code to an AWS CloudFormation stack configuration, run the following command. `cdk synth`	AWS DevOps, DevOps engineer

Configure and deploy the solution

Task	Description	Skills required
Provision foundation model access.	Enable access to the Anthropic Claude 3 Sonnet model for your AWS account. For instructions, see Add model access in the Bedrock documentation.	AWS DevOps
Deploy resources in the account.	To deploy resources in the AWS account by using the AWS CDK, do the following: 1. (Optional) In the root of the cloned repository, in the `app.py` file, update the AWS CloudFormation stack name. The default stack name is `genai-knowledge-capture-stack` . 2. To deploy resources, run the command `cdk deploy`. The `cdk deploy` command uses layer-3 constructs to create a set of Lambda functions, an S3 bucket, an Amazon SNS topic, and a Step Functions state machine. Audio files in the `assets/audio_samples` folder are	AWS DevOps, DevOps engineer

Task	Description	Skills required
	copied into the S3 bucket during deployment. 3. Sign in to the AWS Management Console, and then open the CloudFormation console at https://console.aws.amazon.com/cloudformation/. 4. Confirm that the stack deployed successfully. For instructions, see Reviewing your stack on the AWS CloudFormation console.	
Subscribe to the Amazon SNS topic.	To subscribe to the Amazon SNS topic for notification, do the following: 1. In the CloudFormation console, in the navigate pane, choose **Stacks**. 2. Choose the `genai-knowledge-capture-stack` stack. 3. Choose the **Outputs** tab. 4. Find the Amazon SNS topic name with the key `SNSTopicName` . 5. Configure an email address to receive notifications by following the instructions in Subscribe an email address to an Amazon SNS topic.	General AWS

Test the solution

Task	Description	Skills required
Run the state machine.	1. Open the [Step Functions console](). 2. On the **State machines** page, choose **genai-knowledge-capture-stack-state-machine**. 3. Choose **Start execution**. 4. (Optional) In the **Name** box, enter a name for the execution. 5. In the **Input** area, enter the following JSON object by replacing the placeholder text, where: • `<Name>` is what you want to name the document. • `<S3 bucket name>` is the name of the Amazon S3 bucket that contains the audio files. • `<Folder path>` is the directory that contains the audio files. `{ "documentName": "<Name>", "audioFileFolderUri": "s3://<S3 bucket name>/<Folder path>" }`	App developer, General AWS

Task	Description	Skills required
	6. Choose **Start Execution**. 7. On the execution details page, review the results and wait for the execution to complete.	

Clean up all AWS resources in the solution

Task	Description	Skills required
Remove the AWS resources.	After you test the solution, clean up the resources: 1. Delete all objects from the S3 bucket, and then delete the bucket. For more information, see [Deleting a bucket](#). 2. From the cloned repository, run the command `cdk destroy`.	AWS DevOps, DevOps engineer

Generate personalized and re-ranked recommendations using Amazon Personalize

Mason Cahill, Matthew Chasse, and Tayo Olajide, Amazon Web Services

Summary

This pattern shows you how to use Amazon Personalize to generate personalized recommendations—including re-ranked recommendations—for your users based on the ingestion of real-time user-interaction data from those users. The example scenario used in this pattern is based on a pet adoption website that generates recommendations for its users based on their interactions (for example, what pets a user visits). By following the example scenario, you learn to use Amazon Kinesis Data Streams to ingest interaction data, AWS Lambda to generate recommendations and re-rank the recommendations, and Amazon Data Firehose to store the data in an Amazon Simple Storage Service (Amazon S3) bucket. You also learn to use AWS Step Functions to build a state machine that manages the solution version (that is, a trained model) that generates your recommendations.

Prerequisites and limitations

Prerequisites

- An active AWS account with a bootstrapped AWS Cloud Development Kit (AWS CDK)
- AWS Command Line Interface (AWS CLI) with configured credentials
- Python 3.9

Product versions

- Python 3.9
- AWS CDK 2.23.0 or later
- AWS CLI 2.7.27 or later

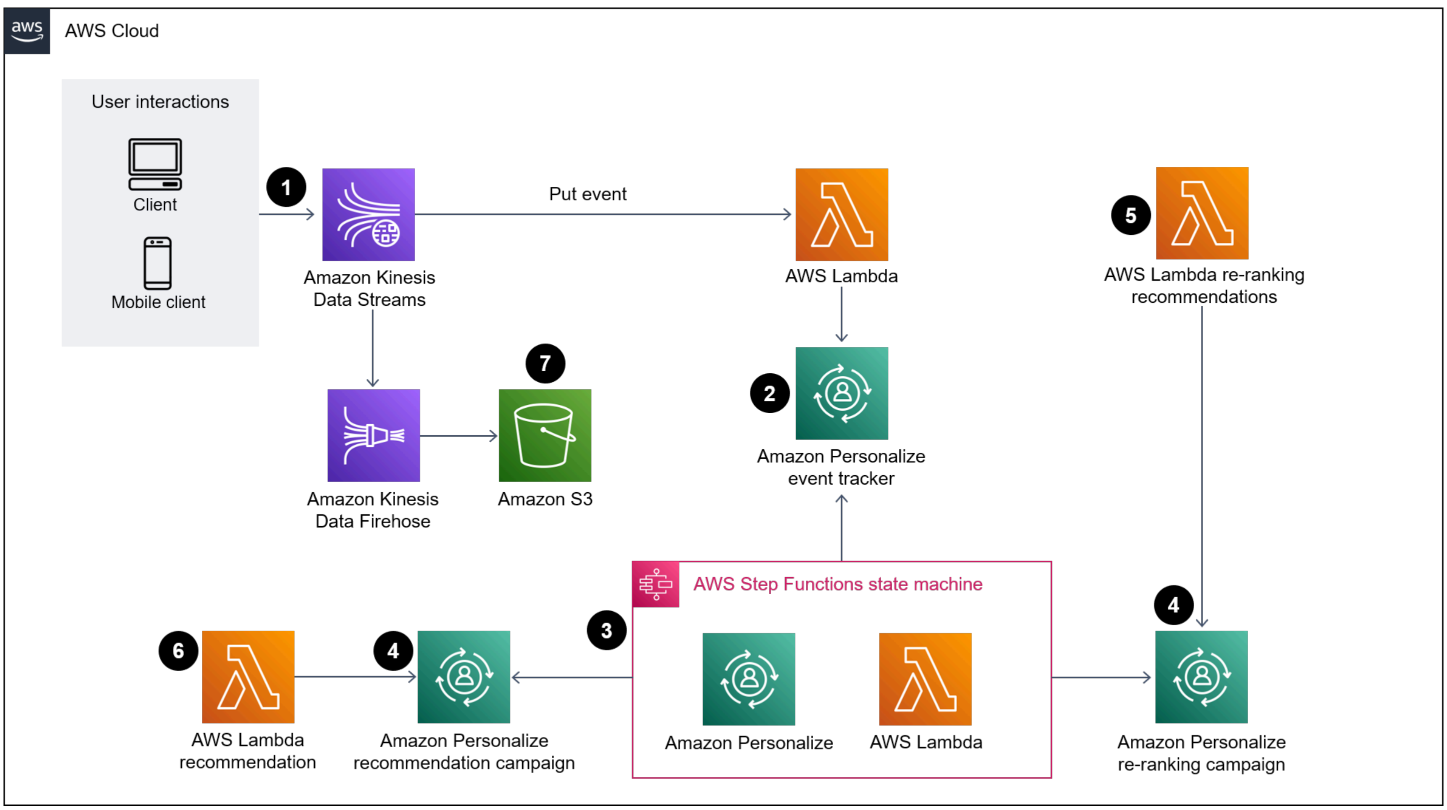
Architecture

Technology stack

- Amazon Data Firehose
- Amazon Kinesis Data Streams
- Amazon Personalize
- Amazon Simple Storage Service (Amazon S3)
- AWS Cloud Development Kit (AWS CDK)
- AWS Command Line Interface (AWS CLI)
- AWS Lambda
- AWS Step Functions

Target architecture

The following diagram illustrates a pipeline for ingesting real-time data into Amazon Personalize. The pipeline then uses that data to generate personalized and re-ranked recommendations for users.



The diagram shows the following workflow:

1. Kinesis Data Streams ingests real-time user data (for example, events like visited pets) for processing by Lambda and Firehose.

2. A Lambda function processes the records from Kinesis Data Streams and makes an API call to add the user-interaction in the record to an event tracker in Amazon Personalize.
3. A time-based rule invokes a Step Functions state machine and generates new solution versions for the recommendation and re-ranking models by using the events from the event tracker in Amazon Personalize.
4. Amazon Personalize campaigns are updated by the state machine to use the new solution version.
5. Lambda re-ranks the list of recommended items by calling the Amazon Personalize re-ranking campaign.
6. Lambda retrieves the list of recommended items by calling the Amazon Personalize recommendations campaign.
7. Firehose saves the events to an S3 bucket where they can be accessed as historical data.

Tools

AWS tools

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon Data Firehose helps you deliver real-time streaming data to other AWS services, custom HTTP endpoints, and HTTP endpoints owned by supported third-party service providers.
- Amazon Kinesis Data Streams helps you collect and process large streams of data records in real time.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Personalize is a fully managed machine learning (ML) service that helps you generate item recommendations for your users based on your data.
- AWS Step Functions is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications.

Other tools

- pytest is a Python framework for writing small, readable tests.
- Python is a general-purpose computer programming language.

Code

The code for this pattern is available in the GitHub Animal Recommender repository. You can use the AWS CloudFormation template from this repository to deploy the resources for the example solution.

> **Note**
>
> The Amazon Personalize solution versions, event tracker, and campaigns are backed by custom resources (within the infrastructure) that expand on native CloudFormation resources.

Epics

Create the infrastructure

Task	Description	Skills required
Create an isolated Python environment.	**Mac/Linux setup** 1. To manually create a virtual environment, run the `$ python3 -m venv .venv` command from your terminal. 2. After the init process completes, run the `$ source .venv/bin/activate` command to activate the virtual environment. **Windows setup**	DevOps engineer

Task	Description	Skills required
	To manually create a virtual environment, run the `% .venv\Scripts\activate.bat` command from your terminal.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Synthesize the CloudFormation template.</td><td>1. To install the required dependencies, run the <code>$ pip install -r requirements.txt</code> command from your terminal.
2. In the AWS CLI, set the following environment variables:
• <code>export ACCOUNT_ID=123456789</code>
• <code>export CDK_DEPLOY_REGION=us-east-1</code>
• <code>export CDK_ENVIRONMENT=dev</code>
3. In the <code>config/{env}.yml</code> file, update <code>vpcId</code> to match your virtual private cloud (VPC) ID.
4. To synthesize the CloudFormation template for this code, run the <code>$ cdk synth</code> command.

Note
In step 2, <code>CDK_ENVIRONMENT</code> refers to the <code>config/{env}.yml</code> file.</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
Deploy resources and create infrastructure.	To deploy the solution resources, run the `./deploy.sh` command from your terminal. This command installs the required Python dependencies. A Python script creates an S3 bucket and an AWS Key Management Service (AWS KMS) key, and then adds the seed data for the initial model creations. Finally, the script runs `cdk deploy` to create the remaining infrastructure. **Note** The initial model training happens during stack creation. It can take up to two hours for the stack to finish getting created.	DevOps engineer

Additional information

Example payloads and responses

Recommendation Lambda function

To retrieve recommendations, submit a request to the recommendation Lambda function with a payload in the following format:

```
{
  "userId": "3578196281679609099",
  "limit": 6
}
```

The following example response contains a list of animal groups:

```
[{"id": "1-domestic short hair-1-1"},
{"id": "1-domestic short hair-3-3"},
{"id": "1-domestic short hair-3-2"},
{"id": "1-domestic short hair-1-2"},
{"id": "1-domestic short hair-3-1"},
{"id": "2-beagle-3-3"},
```

If you leave out the `userId` field, the function returns general recommendations.

Re-ranking Lambda function

To use re-ranking, submit a request to the re-ranking Lambda function. The payload contains the `userId` of all the item IDs to be re-ranked and their metadata. The following example data uses the Oxford Pets classes for `animal_species_id` (1=cat, 2=dog) and integers 1-5 for `animal_age_id` and `animal_size_id`:

```
{
   "userId":"12345",
   "itemMetadataList":[
      {
         "itemId":"1",
         "animalMetadata":{
            "animal_species_id":"2",
            "animal_primary_breed_id":"Saint_Bernard",
            "animal_size_id":"3",
```

```
                "animal_age_id":"2"
            }
        },
        {
            "itemId":"2",
            "animalMetadata":{
                "animal_species_id":"1",
                "animal_primary_breed_id":"Egyptian_Mau",
                "animal_size_id":"1",
                "animal_age_id":"1"
            }
        },
        {
            "itemId":"3",
            "animalMetadata":{
                "animal_species_id":"2",
                "animal_primary_breed_id":"Saint_Bernard",
                "animal_size_id":"3",
                "animal_age_id":"2"
            }
        }
    ]
}
```

The Lambda function re-ranks these items, and then returns an ordered list that includes the item IDs and the direct response from Amazon Personalize. This is a ranked list of the animal groups that the items are in and their score. Amazon Personalize uses [User-Personalization](#) and [Personalized-Ranking](#) recipes to include a score for each item in the recommendations. These scores represent the relative certainty that Amazon Personalize has about which item the user will choose next. Higher scores represent greater certainty.

```
{
    "ranking":[
        "1",
        "3",
        "2"
    ],

   }
}
```

Amazon Kinesis payload

The payload to send to Amazon Kinesis has the following format:

```
{
    "Partitionkey": "randomstring",
    "Data": {
        "userId": "12345",
        "sessionId": "sessionId4545454",
        "eventType": "DetailView",
        "animalMetadata": {
            "animal_species_id": "1",
            "animal_primary_breed_id": "Russian_Blue",
            "animal_size_id": "1",
            "animal_age_id": "2"
        },
        "animal_id": "98765"

    }
}
```

Note

The `userId` field is removed for an unauthenticated user.

Streamline machine learning workflows from local development to scalable experiments by using SageMaker AI and Hydra

David Sauerwein, Marco Geiger, and Julian Ferdinand Grueber, Amazon Web Services

Summary

This pattern provides a unified approach to configuring and running machine learning (ML) algorithms from local testing to production on Amazon SageMaker AI. ML algorithms are the focus of this pattern, but its approach extends to feature engineering, inference, and whole ML pipelines. This pattern demonstrates the transition from local script development to SageMaker AI training jobs through a sample use case.

A typical ML workflow is to develop and test solutions on a local machine, run large scale experiments (for example, with different parameters) in the cloud, and deploy the approved solution in the cloud. Then, the deployed solution must be monitored and maintained. Without a unified approach to this workflow, developers often need to refactor their code at each stage. If the solution depends on a large number of parameters that might change at any stage of this workflow, it can become increasingly difficult to remain organized and consistent.

This pattern addresses these challenges. First, it eliminates the need for code refactoring between environments by providing a unified workflow that remains consistent whether running on local machines, in containers, or on SageMaker AI. Second, it simplifies parameter management through Hydra's configuration system, where parameters are defined in separate configuration files that can be easily modified and combined, with automatic logging of each run's configuration. For more details about how this pattern addresses these challenges, see [Additional information](#).

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Identity and Access Management (IAM) [user role](#) for deploying and starting the SageMaker AI training jobs
- AWS Command Line Interface (AWS CLI) version 2.0 or later [installed](#) and [configured](#)

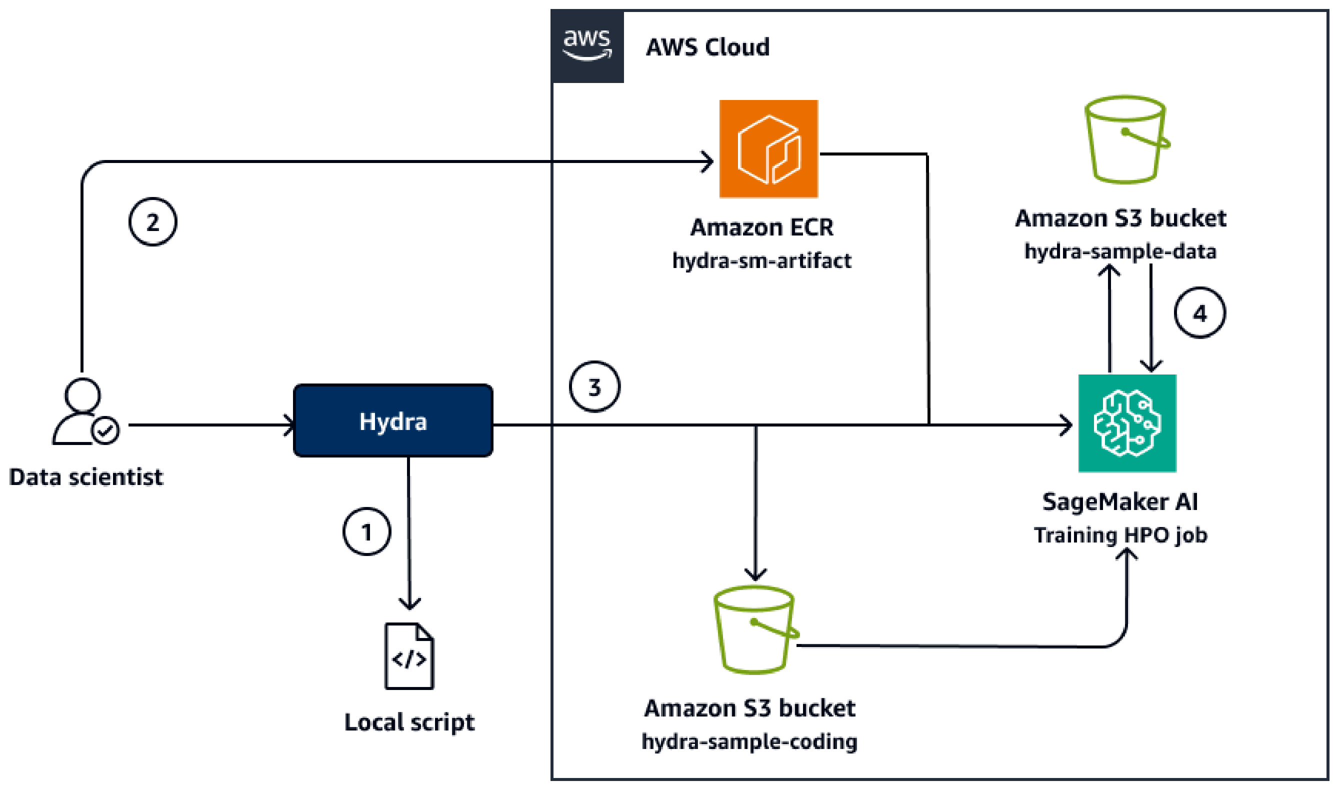
- Poetry version 1.8 or later, but earlier than 2.0, installed
- Docker installed
- Python version 3.10.x

Limitations

- The code currently only targets SageMaker AI training jobs. Extending it to processing jobs and whole SageMaker AI pipelines is straightforward.
- For a fully productionized SageMaker AI setup, additional details need to be in place. Examples could be custom AWS Key Management Service (AWS KMS) keys for compute and storage, or networking configurations. You can also configure these additional options by using Hydra in a dedicated subfolder of the `config` folder.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

The following diagram depicts the architecture of the solution.



The diagram shows the following workflow:

1. The data scientist can iterate over the algorithm at small scale in a local environment, adjust parameters, and test the training script rapidly without the need for Docker or SageMaker AI. (For more details, see the "Run locally for quick testing" task in Epics.)
2. Once satisfied with the algorithm, the data scientist builds and pushes the Docker image to the Amazon Elastic Container Registry (Amazon ECR) repository named `hydra-sm-artifact`. (For more details, see "Run workflows on SageMaker AI" in Epics.)
3. The data scientist initiates either SageMaker AI training jobs or hyperparameter optimization (HPO) jobs by using Python scripts. For regular training jobs, the adjusted configuration is written to the Amazon Simple Storage Service (Amazon S3) bucket named `hydra-sample-config`. For HPO jobs, the default configuration set located in the `config` folder is applied.
4. The SageMaker AI training job pulls the Docker image, reads the input data from the Amazon S3 bucket `hydra-sample-data`, and either fetches the configuration from the Amazon S3 bucket `hydra-sample-config` or uses the default configuration. After training, the job saves the output data to the Amazon S3 bucket `hydra-sample-data`.

Automation and scale

- For automated training, retraining, or inference, you can integrate the AWS CLI code with services like AWS Lambda, AWS CodePipeline, or Amazon EventBridge.
- Scaling can be achieved by changing configurations for instance sizes or by adding configurations for distributed training.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell. For this pattern, the AWS CLI is useful for both initial resource configuration and testing.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon SageMaker AI is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment. SageMaker AI Training is a fully managed ML service within SageMaker AI that enables the training of ML models at scale. The tool can handle the computational demands of training models efficiently, making use of built-in scalability and integration with other AWS services. SageMaker AI Training also supports custom algorithms and containers, making it flexible for a wide range of ML workflows.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers. It was used in this pattern to ensure consistent environments across various stages, from development to deployment, and to package dependencies and code reliably. Docker's containerization allowed for easy scaling and version control across the workflow.

- Hydra is a configuration management tool that provides flexibility for handling multiple configurations and dynamic resource management. It is instrumental in managing environment configurations, allowing seamless deployment across different environments. For more details about Hydra, see Additional information.
- Python is a general-purpose computer programming language. Python was used to write the ML code and the deployment workflow.
- Poetry is a tool for dependency management and packaging in Python.

Code repository

The code for this pattern is available in the GitHub configuring-sagemaker-training-jobs-with-hydra repository.

Best practices

- Choose an IAM role for deploying and starting the SageMaker AI training jobs that follows the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.
- Use temporary credentials to access the IAM role in the terminal.

Epics

Set up the environment

Task	Description	Skills required

Create and activate the virtual environment.	To create and activate the virtual environment, run the following commands in the root of the repository:
	`poetry install`
	`poetry shell`
		General AWS

Task	Description	Skills required
Deploy the infrastructure.	To deploy the infrastructure using CloudFormation, run the following command: `aws cloudformation deploy --template-file infra/hydra-sagemaker-setup.yaml --stack-name hydra-sagemaker-setup  --capabilities CAPABILITY_NAMED_IAM`	General AWS, DevOps engineer
Download the sample data.	To download the input data from openml to your local machine, run the following command: `python scripts/download_data.py`	General AWS

Task	Description	Skills required
Run locally for quick testing.	To run the training code locally for testing, run the following command: `python mypackage/train.py data.train_data_path=data/train.csv evaluation.base_dir_path=data` The logs of all executions are stored by execution time in a folder called `outputs`. For more information, see the "Output" section in the GitHub repository. You can also perform multiple trainings in parallel, with different parameters, by using the `--multirun` functionality. For more details, see the Hydra documentation.	Data scientist

Run workflows on SageMaker AI

Task	Description	Skills required
Set the environment variables.	To run your job on SageMaker AI, set the following environment variables, providing your AWS Region and your AWS account ID:	General AWS

Task	Description	Skills required
	```export ECR_REPO_NAME=hydra-sm-artifact export image_tag=latest export AWS_REGION="<your_aws_region>" # for instance, us-east-1 export ACCOUNT_ID="<your_account_id>" export BUCKET_NAME_DATA=hydra-sample-data-$ACCOUNT_ID export BUCKET_NAME_CONFIG=hydra-sample-config-$ACCOUNT_ID export AWS_DEFAULT_REGION=$AWS_REGION export ROLE_ARN=arn:aws:iam::${ACCOUNT_ID}:role/hydra-sample-sagemaker export INPUT_DATA_S3_PATH=s3://$BUCKET_NAME_DATA/hydra-on-sm/input/ export OUTPUT_DATA_S3_PATH=s3://$BUCKET_NAME_DATA/hydra-on-sm/output/```	

Task	Description	Skills required
Create and push Docker image.	To create the Docker image and push it to the Amazon ECR repository, run the following command: `chmod +x scripts/create_and_push_image.sh scripts/create_and_push_image.sh $ECR_REPO_NAME $image_tag $AWS_REGION $ACCOUNT_ID` This task assumes that you have valid credentials in your environment. The Docker image is pushed to the Amazon ECR repository specified in the environment variable in the previous task and is used to activate the SageMaker AI container in which the training job will run.	ML engineer, General AWS

Task	Description	Skills required
Copy input data to Amazon S3.	The SageMaker AI training job needs to pick up the input data. To copy the input data to the Amazon S3 bucket for data, run the following command: `aws s3 cp data/train.csv "${INPUT_DATA_S3_PATH}train.csv"`	Data engineer, General AWS
Submit SageMaker AI training jobs.	To simplify the execution of your scripts, specify default configuration parameters in the `default.yaml` file. In addition to ensuring consistency across runs, this approach also offers the flexibility to easily override default settings as needed. See the following example: `python scripts/start_sagemaker_training_job.py sagemaker.role_arn=$ROLE_ARN sagemaker.config_s3_bucket=$BUCKET_NAME_CONFIG sagemaker.input_data_s3_path=$INPUT_DATA_S3_PATH sagemaker.output_data_s3_path=$OUTPUT_DATA_S3_PATH`	General AWS, ML engineer, Data scientist

Task	Description	Skills required
Run SageMaker AI hyperparameter tuning.	Running SageMaker AI hyperparameter tuning is similar to submitting a SageMaker AI training job. However, the execution script differs in some important ways as you can see in the start_sagemaker_hpo_job.py file. The hyperparameters to be tuned must be passed through the boto3 payload, not a channel to the training job. To start the hyperparameter optimization (HPO) job, run the following commands: `python scripts/start_sagemaker_hpo_job.py sagemaker.role_arn=$ROLE_ARN sagemaker.config_s3_bucket=$BUCKET_NAME_CONFIG sagemaker.input_data_s3_path=$INPUT_DATA_S3_PATH sagemaker.output_data_s3_path=$OUTPUT_DATA_S3_PATH`	Data scientist

Troubleshooting

Issue	Solution
Expired token	Export fresh AWS credentials.
Lack of IAM permissions	Make sure that you export the credentia ls of an IAM role that has all the required IAM permissions to deploy the CloudForm ation template and to start the SageMaker AI training jobs.

Additional information

This pattern addresses the following challenges:

Consistency from local development to at-scale deployment – With this pattern, developers can use the same workflow, regardless of whether they're using local Python scripts, running local Docker containers, conducting large experiments on SageMaker AI, or deploying in production on SageMaker AI. This consistency is important for the following reasons:

- **Faster iteration** – It allows for fast, local experimentation without the need for major adjustments when scaling up.
- **No refactoring** – Transitioning to larger experiments on SageMaker AI is seamless, requiring no overhaul of the existing setup.
- **Continuous improvement** – Developing new features and continuously improving the algorithm is straightforward because the code remains the same across environments.

Configuration management – This pattern makes use of Hydra, a configuration management tool, to provide the following benefits:

- Parameters are defined in configuration files, separate from the code.
- Different parameter sets can be swapped or combined easily.
- Experiment tracking is simplified because each run's configuration is logged automatically.
- Cloud experiments can use the same configuration structure as local runs, ensuring consistency.

With Hydra, you can manage configuration effectively, enabling the following features:

- **Divide configurations** – Break your project configurations into smaller, manageable pieces that can be independently modified. This approach makes it easier to handle complex projects.
- **Adjust defaults easily** – Change your baseline configurations quickly, making it simpler to test new ideas.
- **Align CLI inputs and config files** – Combine command line inputs with your configuration files smoothly. This approach reduces clutter and confusion, making your project more manageable over time.

Train and deploy a custom GPU-supported ML model on Amazon SageMaker

Ankur Shukla, Amazon Web Services

Summary

Training and deploying a graphics processing unit (GPU)-supported machine learning (ML) model requires an initial setup and initialization of certain environment variables to fully unlock the benefits of NVIDIA GPUs. However, it can be time-consuming to set up the environment and make it compatible with Amazon SageMaker architecture on the Amazon Web Services (AWS) Cloud.

This pattern helps you train and build a custom GPU-supported ML model using Amazon SageMaker. It provides steps to train and deploy a custom CatBoost model built on an open-source Amazon reviews dataset. You can then benchmark its performance on a `p3.16xlarge` Amazon Elastic Compute Cloud (Amazon EC2) instance.

This pattern is useful if your organization wants to deploy existing GPU-supported ML models on SageMaker. Your data scientists can follow the steps in this pattern to create NVIDIA GPU-supported containers and deploy ML models on those containers.

Prerequisites and limitations

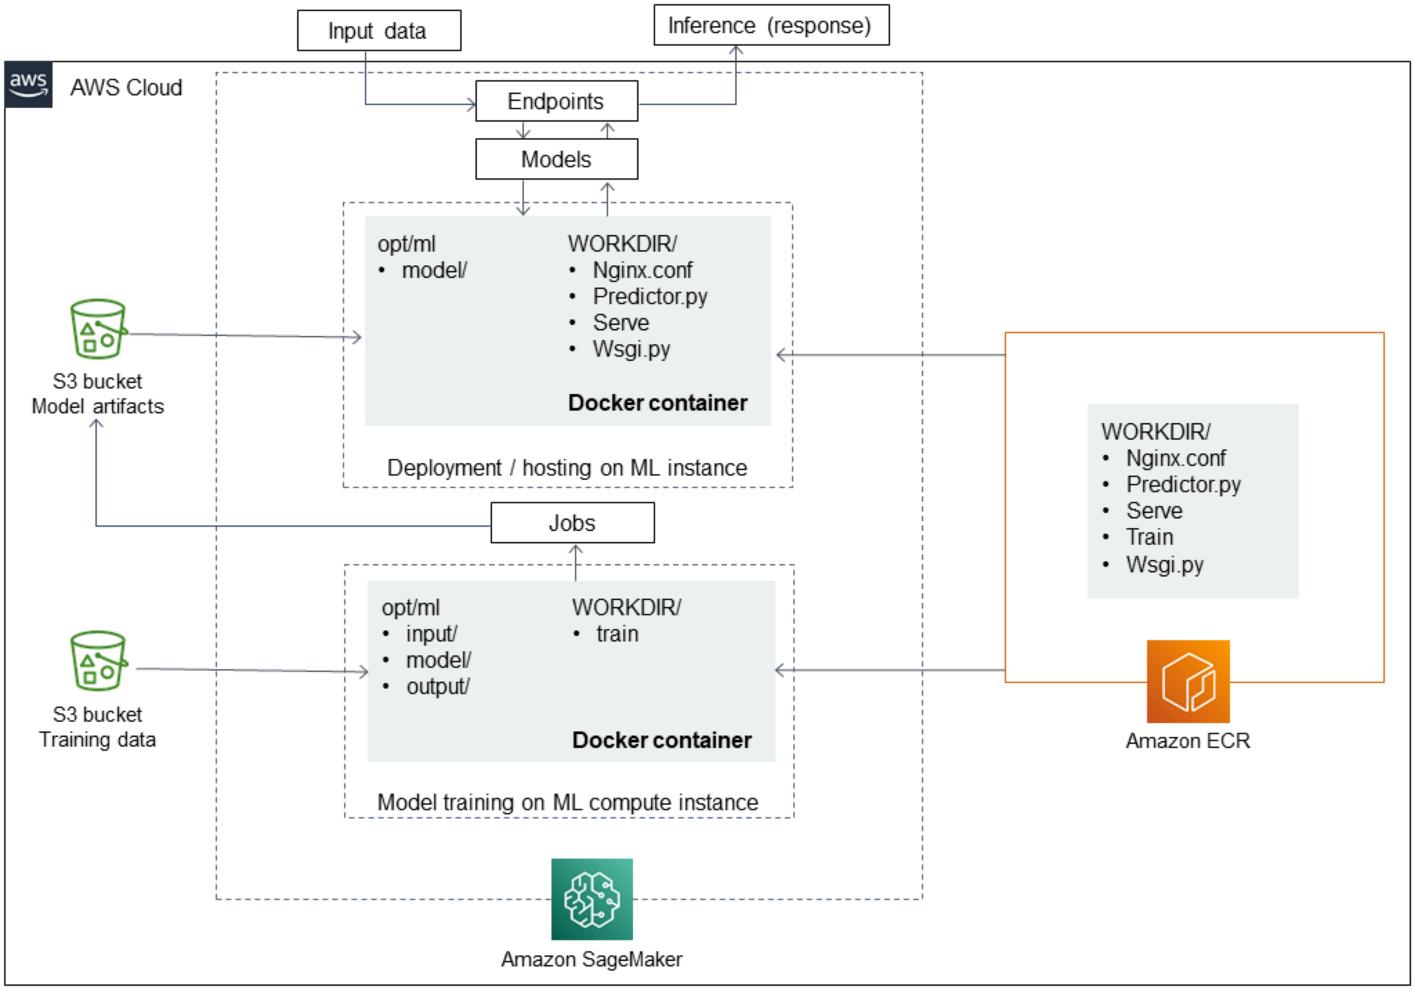
Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) source bucket to store the model artifacts and predictions.
- An understanding of SageMaker notebook instances and Jupyter notebooks.
- An understanding of how to create an AWS Identity and Access Management (IAM) role with basic SageMaker role permissions, S3 bucket access and update permissions, and additional permissions for Amazon Elastic Container Registry (Amazon ECR).

Limitations

- This pattern is intended for supervised ML workloads with a train and deploy code written in Python.

Architecture



Technology stack

- SageMaker
- Amazon ECR

Tools

Tools

- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- Amazon SageMaker – SageMaker is a fully managed ML service.

- Docker – Docker is a software platform for building, testing, and deploying applications quickly.
- Python – Python is a programming language.

Code

The code for this pattern is available on the GitHub Implementing a review classification model with Catboost and SageMaker repository.

Epics

Prepare the data

Task	Description	Skills required
Create an IAM role and attach the required policies.	Sign in to the AWS Management Console, open the IAM console, and create a new IAM role. Attach the following policies to the IAM role: • `AmazonEC2ContainerRegistryFullAccess` • `AmazonS3FullAccess` • `AmazonSageMakerFullAccess` For more information about this, see Create a notebook instance in the Amazon SageMaker documentation.	Data scientist
Create the SageMaker notebook instance.	Open the SageMaker console, choose **Notebook instances**, and then choose **Create notebook instance**. For **IAM role**, choose the IAM role that	Data scientist

Task	Description	Skills required
	you created earlier. Configure the notebook instance according to your requirements and then choose **Create notebook instance**. For detailed steps and instructions, see [Create a notebook instance](#) in the Amazon SageMaker documentation.	
Clone the repository.	Open the terminal in the SageMaker notebook instance and clone the GitHub [Implementing a review classification model with Catboost and SageMaker](#) repository by running the following command: `git clone https://github.com/aws-samples/review-classification-using-catboost-sagemaker.git`	
Start the Jupyter notebook.	Start the `Review classification model with Catboost and SageMaker.ipynb` Jupyter notebook, which contains the predefined steps.	Data scientist

Feature engineering

Task	Description	Skills required
Run commands in Jupyter notebook.	Open the Jupyter notebook and run the commands from the following stories to prepare the data to train your ML model.	Data scientist

Read the data from the S3 bucket.	<pre>import pandas as pd
	import csv
	fname = 's3://ama
	zon-reviews-pds/ts
	v/amazon_reviews_u
	s_Digital_Video_Do
	wnload_v1_00.tsv.gz'
	df = pd.read_csv(fname,
	sep='\t',delimiter
	='\t',error_bad_li
	nes=False)</pre>
		Data scientist

Preprocess the data.	<pre>import numpy as np
	def pre_process(df):
	
	   df.fillna(value={'
	review_body': '',
	 'review_headline':
	 ''}, inplace=True)
	  df.fillna(value={'v
	erified_purchase':
	 'Unk'}, inplace=True)
	
	  df.fillna(0,
	 inplace=True)
	 return df
	df = pre_process(df)
	df.review_date =
	 pd.to_datetime(df.
	review_date)</pre>
		Data scientist

Task	Description	Skills required
	`df['target'] = np.where(df['star_rating']>=4,1,0)` **Note** This code replaces null values in the `'review_body'` with an empty string and replaces the `'verified_purchase'` column with `'Unk'`, which means "unknown."	

Task	Description	Skills required

Split the data into training, validation, and test datasets.	To keep the distribution of the target label identical across the split sets, you must stratify the sampling by using the [scikit-learn library](https://scikit-learn.org/).
	`from sklearn.model_selection import StratifiedShuffleSplit`
	`sss = StratifiedShuffleSplit(n_splits=2, test_size=0.10, random_state=0)`
	`sss.get_n_splits(df, df['target'])`
	`for train_index, test_index in sss.split(df, df['target']):`
	`    X_train_vallid , X_test = df.iloc[train_index], df.iloc[test_index]`
	
	`sss.get_n_splits(X_train_vallid, X_train_vallid['target'])`
	`for train_index, test_index in sss.split(X_train_vallid, X_train_vallid['target']):`
	`    X_train , X_valid = X_train_vallid.iloc[train_index], X_train_vallid.iloc[test_index]`
		Data scientist

Build, run, and push the Docker image to Amazon ECR

Task	Description	Skills required
Prepare and push the Docker image.	In the Jupyter notebook, run the commands from the following stories to prepare the Docker image and push it to Amazon ECR.	ML engineer

Create a repository in Amazon ECR.	<pre>%%sh
	
	algorithm_name=s
	agemaker-catboost-
	github-gpu-img
	
	chmod +x code/train
	chmod +x code/serve
	
	account=$(aws sts get-
	caller-identity --
	query Account --output
	 text)
	
	# Get the region
	 defined in the current
	 configuration (default
	 to us-west-2 if none
	 defined)
	region=$(aws configure
	 get region)
	region=${region:-us-
	east-1}
	
	fullname="${accou
	nt}.dkr.ecr.${regi
	on}.amazonaws.com/
	${algorithm_name}:
	latest"
	
	aws ecr create-re
	pository --repository-</pre>
		ML engineer

Task	Description	Skills required
	`name "${algorithm_name}" > /dev/nul`	
Build a Docker image locally.	```docker build -t "${algorithm_name}" .``` ```docker tag ${algorithm_name} ${fullname}```	ML engineer
Run the Docker image and push it to Amazon ECR.	`docker push ${fullname}`	ML engineer

Training

Task	Description	Skills required
Create a SageMaker hyperparameter tuning job.	In the Jupyter notebook, run the commands from the following stories to create a SageMaker hyperparameter tuning job using your Docker image.	Data scientist

Create a SageMaker estimator .	Create a [SageMaker estimator](https://docs.aws.amazon.com/sagemaker/latest/dg/ex1-train-model.html) by using the Docker image's name.
	`import sagemaker as sage`
	`from time import gmtime, strftime`
	`sess = sage.Session()`
	`from sagemaker.tuner import IntegerParameter, CategoricalParameter, ContinuousParameter, HyperparameterTuner`
		Data scientist

Task	Description	Skills required
	```account = sess.boto_session.client('sts').get_caller_identity()['Account'] region = sess.boto_session.region_name image = '{}.dkr.ecr.{}.amazonaws.com/sagemaker-catboost-github-gpu-img:latest'.format(account, region) tree_hpo = sage.estimator.Estimator(image, role, 1, 'ml.p3.16xlarge', train_volume_size = 100, output_path="s3://{}/sagemaker/DEMO-GPU-Catboost/output".format(bucket), sagemaker_session=sess)```	

Task	Description	Skills required

Create an HPO job.	Create a hyperparameter optimization (HPO) tuning job with parameter ranges and pass the train and validation sets as parameters to the function.
	``
	hyperparameter_ranges = {'iterations': IntegerParameter(80000, 130000),
	
	 'max_depth': IntegerParameter(6, 10),
	
	 'max_ctr_complexity': IntegerParameter(4, 10),
	
	    'learning_rate': ContinuousParameter(0.01, 0.5)}
	
	objective_metric_name = 'auc'
	metric_definitions = [{'Name': 'auc',
	
	 'Regex': 'auc: ([0-9\\.]+)'}]
	
	tuner = HyperparameterTuner(tree_hpo,
	
	    objective_metric_name,
	
	    hyperparameter_ranges,
	``
		Data scientist

	``
	    metric_definitions
	,
	
	    objective_type='Ma
	ximize',
	
	    max_jobs=50,
	
	    max_parallel_jobs=
	2)
	``	

Run the HPO job.	```
	train_location =
	 's3://'+bucket+'/s
	agemaker/DEMO-GPU-
	Catboost/data/train/'
	valid_location =
	 's3://'+bucket+'/s
	agemaker/DEMO-GPU-
	Catboost/data/valid/'
	
	tuner.fit({'train':
	 train_location,
	           'validati
	on': valid_location
	   })
	``
		Data scientist

Receive the best performing training job.	``` import sagemaker as sage from time import gmtime, strftime sess = sage.Session() best_job =tuner.be st_training_job() ```	Data scientist

Batch transform

Task	Description	Skills required
Create a SageMaker batch transform job on test data for model prediction.	In the Jupyter notebook, run the commands from the following stories to create the model from your SageMaker hyperparameter tuning job and submit a SageMaker batch transform job on the test data for model predictio n.	Data scientist

Create the SageMaker model.	Create a model in SageMaker model using the best training job.
	
	`attached_estimator = sage.estimator.Estimator.attach(best_job)`
	
	`output_path ='s3://'+bucket+'/sagemaker/DEMO-GPU-Catboost/data/test-predictions/'`
	`input_path  ='s3://'+bucket+'/sagemaker/DEMO-GPU-Catboost/data/test/'`
	
	`transformer = attached_estimator.transformer(instance_count=1,`
	
	`   instance_type='ml.p3.16xlarge',`
		Data scientist

Task	Description	Skills required

	``
	   assemble_with='Lin
	e',
	
	 accept='text/csv',
	
	 max_payload=1,
	
	   output_path=output
	_path,
	                    env
	 = {'SAGEMAKER_MODEL_
	SERVER_TIMEOUT' :
	 '3600' })
	``	

Create batch transform job.	Create batch transform job on the test data set. ``` transformer.transf orm(input_path, content_type='text/ csv', split_type='Line') ```	Data scientist

Analyze the results

Task	Description	Skills required
Read the results and evaluate the model's performance.	In the Jupyter notebook, run the commands from the following stories to read	Data scientist

Task	Description	Skills required
	the results and evaluate the performance of the model on Area Under the ROC Curve (ROC-AUC) and Area Under the Precision Recall Curve (PR-AUC) model metrics. For more information about this, see Amazon Machine Learning key concepts in the Amazon Machine Learning (Amazon ML) documentation.	

Read the batch transform job results.	Read the batch transform job results into a data frame.
	
	`file_name = 's3://'+bucket+'/sagemaker/DEMO-GPU-Catboost/data/test-predictions/file_1.out'`
	
	`results = pd.read_csv(file_name, names=['review_id','target','score'] ,sep='\t',escapechar ='\\' , quoting=csv.QUOTE_NONE, lineterminator='\n',quotechar='"').dropna()`
		Data scientist

Task	Description	Skills required

Evaluate the performance metrics.	Evaluate the performance of the model on ROC-AUC and PR-AUC.
	
	``
	from sklearn import
	 metrics
	import matplotlib
	import pandas as pd
	matplotlib.use('agg',
	 warn=False, force=Tru
	e)

	    print('Neural-
	Nets: ROC auc=%.3f' %
	 (roc_auc_score))
	
	    plt.plot(fpr, tpr,
	 label="data 1, auc=" +
	 str(roc_auc_score))
	``
		Data scientist

Task	Description	Skills required

	<pre> plt.xlabel('1-Spec
	ificity')
	    plt.ylabel('Sensit
	ivity')
	    plt.legend(loc=4)
	    plt.show()
	
	    lr_precision,
	 lr_recall, _ =
	 metrics.precision_
	recall_curve(labels,
	 predictions)
	    lr_auc = metrics.a
	uc(lr_recall,
	 lr_precision)
	    # summarize scores
	    print('Neural-
	Nets: PR auc=%.3f' %
	 (lr_auc))
	    # plot the precision
	-recall curves
	    no_skill = len(label
	s[labels==1.0]) /
	 len(labels)
	    plt.plot([0, 1],
	 [no_skill, no_skill]
	, linestyle='--',
	 label='No Skill')
	
	    plt.plot(lr_recall
	, lr_precision,
	 marker='.', label='Ne
	ural-Nets')
	    # axis labels
	    plt.xlabel('Recall
	')
	    plt.ylabel('Precis
	ion')
	    # show the legend
	    plt.legend()
	    # show the plot</pre>	

Task	Description	Skills required

	`plt.show()`
	
	`return auc`
	
	`analyze_results(results['target'].values,results['score'].values)`

Additional information

The following list shows the different elements of the Dockerfile that is run in the *Build, run, and push the Docker image into Amazon ECR* epic.

Install Python with aws-cli.

```
FROM amazonlinux:1

 RUN yum update -y && yum install -y python36 python36-devel python36-libs python36-
tools python36-pip && \
 yum install gcc tar make wget util-linux kmod man sudo git -y && \
 yum install wget -y && \
 yum install aws-cli -y && \
 yum install nginx -y && \
yum install gcc-c++.noarch -y && yum clean all
```

Install the Python packages

```
RUN pip-3.6 install --no-cache-dir --upgrade pip && \pip3 install --no-cache-dir --
upgrade setuptools && \
pip3 install Cython && \
```

```
pip3 install --no-cache-dir numpy==1.16.0 scipy==1.4.1 scikit-learn==0.20.3
 pandas==0.24.2 \
flask gevent gunicorn boto3 s3fs  matplotlib joblib catboost==0.20.2
```

Install CUDA and CuDNN

```
RUN wget https://developer.nvidia.com/compute/cuda/9.0/Prod/local_installers/
cuda_9.0.176_384.81_linux-run \
&& chmod u+x cuda_9.0.176_384.81_linux-run \
&& ./cuda_9.0.176_384.81_linux-run --tmpdir=/data --silent --toolkit --override \
&& wget https://custom-gpu-sagemaker-image.s3.amazonaws.com/installation/cudnn-9.0-
linux-x64-v7.tgz \
&& tar -xvzf cudnn-9.0-linux-x64-v7.tgz \
&& cp /data/cuda/include/cudnn.h /usr/local/cuda/include \
&& cp /data/cuda/lib64/libcudnn* /usr/local/cuda/lib64 \

&& chmod a+r /usr/local/cuda/include/cudnn.h /usr/local/cuda/lib64/libcudnn* \
&&  rm -rf /data/*
```

Create the required directory structure for SageMaker

```
RUN mkdir /opt/ml /opt/ml/input /opt/ml/input/config /opt/ml/input/data /opt/ml/input/
data/training /opt/ml/model /opt/ml/output /opt/program
```

Set the NVIDIA environment variables

```
ENV PYTHONPATH=/opt/program
ENV PYTHONUNBUFFERED=TRUE
ENV PYTHONDONTWRITEBYTECODE=TRUE
ENV PATH="/opt/program:${PATH}"

# Set NVIDIA mount environments
ENV LD_LIBRARY_PATH=/usr/local/nvidia/lib:/usr/local/nvidia/lib64:$LD_LIBRARY_PATH
ENV NVIDIA_VISIBLE_DEVICES="all"
ENV NVIDIA_DRIVER_CAPABILITIES="compute,utility"
ENV NVIDIA_REQUIRE_CUDA "cuda>=9.0"
```

Copy training and inference files into the Docker image

```
COPY code/* /opt/program/
WORKDIR /opt/program
```

Translate natural language into query DSL for OpenSearch and Elasticsearch queries

Tabby Ward, Nicholas Switzer, and Breanne Warner, Amazon Web Services

Summary

This pattern demonstrates how to use large language models (LLMs) to convert natural language queries into query domain-specific language (query DSL), which makes it easier for users to interact with search services such as OpenSearch and Elasticsearch without extensive knowledge of the query language. This resource is particularly valuable for developers and data scientists who want to enhance search-based applications with natural language querying capabilities, ultimately improving user experience and search functionality.

The pattern illustrates techniques for prompt engineering, iterative refinement, and incorporation of specialized knowledge, all of which are crucial in synthetic data generation. Although this approach focuses primarily on query conversion, it implicitly demonstrates the potential for data augmentation and scalable synthetic data production. This foundation could be extended to more comprehensive synthetic data generation tasks, to highlight the power of LLMs in bridging unstructured natural language inputs with structured, application-specific outputs.

This solution doesn't involve migration or deployment tools in the traditional sense. Instead, it focuses on demonstrating a proof of concept (PoC) for converting natural language queries to query DSL by using LLMs.

- The pattern uses a Jupyter notebook as a step-by-step guide for setting up the environment and implementing the text-to-query conversion.
- It uses Amazon Bedrock to access LLMs, which are crucial for interpreting natural language and generating appropriate queries.
- The solution is designed to work with Amazon OpenSearch Service. You can follow a similar process for Elasticsearch, and the generated queries could potentially be adapted for similar search engines.

[Query DSL](#) is a flexible, JSON-based search language that's used to construct complex queries in both Elasticsearch and OpenSearch. It enables you to specify queries in the query parameter of search operations, and supports various query types. A DSL query includes leaf queries and compound queries. Leaf queries search for specific values in certain fields and encompass full-text, term-level, geographic, joining, span, and specialized queries. Compound queries act as wrappers for multiple leaf or compound clauses, and combine their results or modify their behavior. Query DSL supports the creation of sophisticated searches, ranging from simple, match-all queries to complex, multi-clause queries that produce highly specific results. Query DSL is particularly valuable for projects that require advanced search capabilities, flexible query construction, and JSON-based query structures.

This pattern uses techniques such as few-shot prompting, system prompts, structured output, prompt chaining, context provision, and task-specific prompts for text-to-query DSL conversion. For definitions and examples of these techniques, see the Additional information section.

Prerequisites and limitations

Prerequisites

To effectively use the Jupyter notebook for converting natural language queries into query DSL queries, you need:

- **Familiarity with Jupyter notebooks**. Basic understanding of how to navigate and run code in a Jupyter notebook environment.
- **Python environment**. A working Python environment, preferably Python 3.x, with the necessary libraries installed.
- **Elasticsearch or OpenSearch knowledge**. Basic knowledge of Elasticsearch or OpenSearch, including its architecture and how to perform queries.
- **AWS account**. An active AWS account to access Amazon Bedrock and other related services.
- **Libraries and dependencies**. Installation of specific libraries mentioned in the notebook, such as `boto3` for AWS interaction, and any other dependencies required for LLM integration.
- **Model access within Amazon Bedrock**. This pattern uses three Claude LLMs from Anthropic. Open the Amazon Bedrock console and choose **Model access**. On the next screen, choose **Enable specific models** and select these three models:
  - Claude 3 Sonnet
  - Claude 3.5 Sonnet
  - Claude 3 Haiku
- **Proper IAM policies and IAM role**. To run the notebook in an AWS account, your AWS Identity and Access Management (IAM) role requires the `SagemakerFullAccess` policy as well

as the policy that's provided in the Additional information section, which you can name `APGtext2querydslpolicy`. This policy includes subscribing to the three Claude models listed.

Having these prerequisites in place ensures a smooth experience when you work with the notebook and implement the text-to-query functionality.

Limitations

- **Proof of concept status**. This project is primarily intended as a proof of concept (PoC). It demonstrates the potential of using LLMs to convert natural language queries into query DSL, but it might not be fully optimized or production-ready.
- **Model limitations**:

  Context window constraints. When using the LLMs that are available on Amazon Bedrock, be aware of the context window limitations:

  Claude models (as of September 2024):

  - Claude 3 Opus: 200,000 tokens
  - Claude 3 Sonnet: 200,000 tokens
  - Claude 3 Haiku: 200,000 tokens

  Other models on Amazon Bedrock might have different context window sizes. Always check the latest documentation for the latest information.

  Model availability. The availability of specific models on Amazon Bedrock can vary. Make sure that you have access to the required models before you implement this solution.
- **Additional limitations**
  - **Query complexity**. The effectiveness of the natural language to query DSL conversion might vary depending on the complexity of the input query.
  - **Version compatibility**. The generated query DSL might need adjustments based on the specific version of Elasticsearch or OpenSearch that you use.
  - **Performance**. This pattern provides a PoC implementation, so query generation speed and accuracy might not be optimal for large-scale production use.
  - **Cost**. Using LLMs in Amazon Bedrock incurs costs. Be aware of the pricing structure for your chosen model. For more information, see Amazon Bedrock pricing.

- **Maintenance**. Regular updates to the prompts and model selection might be necessary to keep up with advancements in LLM technology and changes in query DSL syntax.

Product versions

This solution was tested in Amazon OpenSearch Service. If you want to use Elasticsearch, you might have to make some changes to replicate the exact functionality of this pattern.

- **OpenSearch version compatibility**. OpenSearch maintains backward compatibility within major versions. For example:
  - OpenSearch 1.x clients are generally compatible with OpenSearch 1.x clusters.
  - OpenSearch 2.x clients are generally compatible with OpenSearch 2.x clusters.

  However, it's always best to use the same minor version for both client and cluster when possible.
- **OpenSearch API compatibility**. OpenSearch maintains API compatibility with Elasticsearch OSS 7.10.2 for most operations. However, some differences exist, especially in newer versions.
- **OpenSearch upgrade considerations**:
  - Direct downgrades are not supported. Use snapshots for rollback if needed.
  - When you upgrade, check the compatibility matrix and release notes for any breaking changes.

Elasticsearch considerations

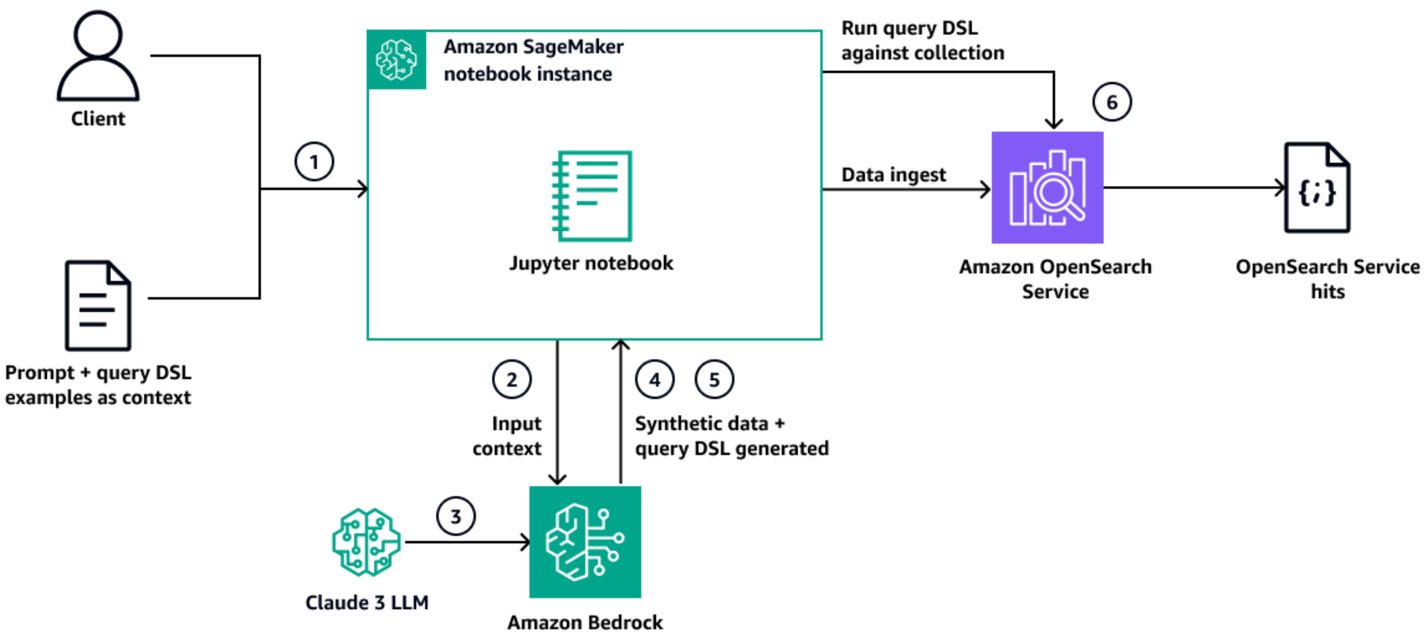
- **Elasticsearch version**. The major version of Elasticsearch you're using is crucial, because query syntax and features can change between major versions. Currently, the latest stable version is Elasticsearch 8.x. Make sure that your queries are compatible with your specific Elasticsearch version.
- **Elasticsearch query DSL library version**. If you're using the Elasticsearch query DSL Python library, make sure that its version matches your Elasticsearch version. For example:
  - For Elasticsearch 8.x, use an `elasticsearch-dsl` version that's greater or equal to 8.0.0 but smaller than 9.0.0.
  - For Elasticsearch 7.x, use an `elasticsearch-dsl` version that's greater or equal to 7.0.0 but smaller than 8.0.0.
- **Client library version**. Whether you're using the official Elasticsearch client or a language-specific client, make sure that it's compatible with your Elasticsearch version.

- **Query DSL version**. Query DSL evolves with Elasticsearch versions. Some query types or parameters might be deprecated or introduced in different versions.
- **Mapping version**. The way you define mappings for your indexes and change between versions. Always check the mapping documentation for your specific Elasticsearch version.
- **Analysis tools versions**. If you're using analyzers, tokenizers, or other text analysis tools, their behavior or availability might change between versions.

Architecture

Target architecture

The following diagram illustrates the architecture for this pattern.



where:

1. User input and system prompt with few-shot prompting examples. The process begins with a user who provides a natural language query or a request for schema generation.
2. Amazon Bedrock. The input is sent to Amazon Bedrock, which serves as the interface to access the Claude LLM.
3. Claude 3 Sonnet LLM. Amazon Bedrock uses Claude 3 Sonnet from the Claude 3 family of LLMs to process the input. It interprets and generates the appropriate Elasticsearch or OpenSearch query DSL. For schema requests, it generates synthetic Elasticsearch or OpenSearch mappings.

4. Query DSL generation. For natural language queries, the application takes the LLM's output and formats it into a valid Elasticsearch or OpenSearch Service query DSL.
5. Synthetic data generation. The application also takes schemas to create synthetic Elasticsearch or OpenSearch data to be loaded into an OpenSearch Serverless collection for testing.
6. OpenSearch or Elasticsearch. The generated Query DSL is queried against an OpenSearch Serverless collection on all indexes. JSON output contains the relevant data and number of *hits* from the data that resides in the OpenSearch Serverless collection.

Automation and scale

The code that's provided with this pattern is built strictly for PoC purposes. The following list provides a few suggestions for automating and scaling the solution further and moving the code to production. These enhancements are outside the scope of this pattern.

- Containerization:
  - Dockerize the application to ensure consistency across different environments.
  - Use container orchestration platforms such as Amazon Elastic Container Service (Amazon ECS) or Kubernetes for scalable deployments.
- Serverless architecture:
  - Convert the core functionality into AWS Lambda functions.
  - Use Amazon API Gateway to create RESTful endpoints for the natural language query input.
- Asynchronous processing:
  - Implement Amazon Simple Queue Service (Amazon SQS) to queue incoming queries.
  - Use AWS Step Functions to orchestrate the workflow of processing queries and generating query DSL.
- Caching:
  - Implement a mechanism to cache the prompts.
- Monitoring and logging:
  - Use Amazon CloudWatch for monitoring and alerting.
  - Implement centralized logging with Amazon CloudWatch Logs or Amazon OpenSearch Service for log analytics.
- Security enhancements:
  - Implement IAM roles for fine-grained access control.

  - Use AWS Secrets Manager to securely store and manage API keys and credentials.
- Multi-Region deployment:
  - Consider deploying the solution across multiple AWS Regions for improved latency and disaster recovery.
  - Use Amazon Route 53 for intelligent request routing.

By implementing these suggestions, you can transform this PoC into a robust, scalable, and production-ready solution. We recommend that you thoroughly test each component and the entire system before full deployment.

Tools

Tools

- Amazon SageMaker AI notebooks are fully managed Jupyter notebooks for machine learning development. This pattern uses notebooks as an interactive environment for data exploration, model development, and experimentation in Amazon SageMaker AI. Notebooks provide seamless integration with other SageMaker AI features and AWS services.
- Python is a general-purpose computer programming language. This pattern uses Python as the core language to implement the solution.
- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API. Amazon Bedrock provides access to LLMs for natural language processing. This pattern uses Anthropic Claude 3 models.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services, including Amazon Bedrock.
- Amazon OpenSearch Service is a managed service that helps you deploy, operate, and scale OpenSearch Service clusters in the AWS Cloud. This pattern uses OpenSearch Service as the target system for generating query DSL.

Code repository

The code for this pattern is available in the GitHub Prompt Engineering Text-to-QueryDSL Using Claude 3 Models repository. The example uses a health social media app that creates posts for users and user profiles associated with the health application.

Best practices

When working with this solution, consider the following:

- The need for proper AWS credentials and permissions to access Amazon Bedrock
- Potential costs associated with using AWS services and LLMs
- The importance of understanding query DSL to validate and potentially modify the generated queries

Epics

Set up the environment and prepare data

Task	Description	Skills required
Set up the development environment.	**Note** For detailed instructions and code for this and the other steps in this pattern, see the comprehensive walkthrough in the GitHub repository. 1. Install the required Python packages, including `boto3`, `numpy`, `awscli`, `opensearch-py` , and `requests-aws4auth` by using **pip**. 2. Import the necessary modules such as `boto3`, `json`, `os`, `opensearch` from `opensearchpy` ,	Python, pip, AWS SDK

Task	Description	Skills required
	`RequestsHttpConnection` from `Opensearchpy`, `bulk` from `opensearchpy.helpers`, `sagemaker`, `time`, `random`, `re`, and `AWS4Auth` from `requests_aws4auth`.	
Set up AWS access.	Set up the Amazon Bedrock client and SageMaker AI session. Retrieve the Amazon Resource Name (ARN) for the SageMaker AI execution role for later use in creating the OpenSearch Serverless collection.	IAM, AWS CLI, Amazon Bedrock, Amazon SageMaker
Load health app schemas.	Read and parse JSON schemas for health posts and user profiles from predefined files. Convert schemas to strings for later use in prompts.	DevOps engineer, General AWS, Python, JSON

Generate synthetic data

Task	Description	Skills required
Create an LLM-based data generator.	Implement the **generate_data()** function to call the Amazon Bedrock Converse API with Claude 3 models. Set up model IDs for Sonnet, Sonnet 3.5, and Haiku:	Python, Amazon Bedrock API, LLM prompting

Task	Description	Skills required
	```model_id_sonnet3_5 = "anthropic.claude-3-5-sonnet-20240620-v1:0" model_id_sonnet = "anthropic.claude-3-sonnet-20240229-v1:0" model_id_haiku = "anthropic.claude-3-haiku-20240307-v1:0"```	
Create synthetic health posts.	Use the **generate_data()** function with a specific message prompt to create synthetic health post entries based on the provided schema. The function call looks like this: ```health_post_data = generate_data(bedrock_rt, model_id_sonnet, system_prompt, message_healthpost, inference_config)```	Python, JSON
Create synthetic user profiles.	Use the **generate_data()** function with a specific message prompt to create synthetic user profile entries based on the provided schema. This is similar to health posts generation, but uses a different prompt.	Python, JSON

Set up OpenSearch and ingest data

Task	Description	Skills required
Set up an OpenSearch Serverless collection.	Use Boto3 to create an OpenSearch Serverless collection with appropriate encryption, network, and access policies. The collection creation looks like this: `collection = aoss_client.create_collection(name=es_name, type='SEARCH')` For more information about OpenSearch Serverless, see the [AWS documentation]().	OpenSearch Serverless, IAM
Define OpenSearch indexes.	Create indiexes for health posts and user profiles by using the OpenSearch client, based on the predefined schema mappings. The index creation looks like this: `response_health = oss_client.indices.create(healthpost_index, body=healthpost_body)`	OpenSearch, JSON
Load data into OpenSearch.	Run the **ingest_data()** function to bulk insert the synthetic health posts and user profiles into their respective OpenSearch	Python, OpenSearch API, bulk data operations

Task	Description	Skills required
	indexes. The function uses the bulk helper from `opensearch-py` : `success, failed = bulk(oss_client, actions)`	

Generate and run queries

Task	Description	Skills required
Design few-shot prompt examples.	Generate example queries and corresponding natural language questions by using Claude 3 models to serve as few-shot examples for query generation. The system prompt includes these examples: `system_prompt_query_generation = [{"text": f"""You are an expert query dsl generator. ... Examples: {example_prompt} ..."""}]`	LLM prompting, query DSL
Create a text-to-query DSL converter.	Implement the system prompt, which includes schemas, data, and few-shot examples, for query generation. Use the system prompt to convert natural language	Python, Amazon Bedrock API, LLM prompting

Task	Description	Skills required
	queries to query DSL. The function call looks like this: ```query_response = generate_data(bedrock_rt, model_id, system_prompt_query_generation, query, inference_config)```	
Test query DSL on OpenSearch.	Run the **query_oss()** function to run the generated query DSL against the OpenSearch Serverless collection and return results. The function uses the OpenSearch client's search method: ```response = oss_client.search(index="_all", body=temp)```	Python, OpenSearch API, query DSL

Test and evaluate

Task	Description	Skills required
Create a test query set.	Use Claude 3 to generate a diverse set of test questions based on the synthetic data and schemas: ```test_queries = generate_data(bedrock_rt, model_id_sonnet, query_sys```	LLM prompting

Task	Description	Skills required
	`tem_prompt, query_prompt, inference_config)`	
Assess the accuracy of the query DSL conversion.	Test the generated query DSL by running queries against OpenSearch and analyzing the returned results for relevance and accuracy. This involves running the query and inspecting the hits: `output = query_oss(response1) print("Response after running query against Opensearch") print(output)`	Python, data analysis, query DSL
Benchmark Claude 3 models.	Compare the performance of different Claude 3 models (Haiku, Sonnet, Sonnet 3.5) for query generation in terms of accuracy and latency. To compare, change the `model_id` when you call **generate_data()** and measure execution time.	Python, performance benchmarking

Clean up and document

Task	Description	Skills required
Develop a cleanup process.	Delete all indexes from the OpenSearch Serverless collection after use.	Python, AWS SDK, OpenSearch API

}
```

Prompt techniques with Anthropic Claude 3 models

This pattern demonstrates the following prompting techniques for text-to-query DSL conversion using Claude 3 models.

- **Few-shot prompting:** Few-shot prompting is a powerful technique for improving the performance of Claude 3 models on Amazon Bedrock. This approach involves providing the model with a small number of examples that demonstrate the desired input/output behavior before asking it to perform a similar task. When you use Claude 3 models on Amazon Bedrock, few-shot prompting can be particularly effective for tasks that require specific formatting, reasoning patterns, or domain knowledge. To implement this technique, you typically structure your prompt with two main components: the example section and the actual query. The example section contains one or more input/output pairs that illustrate the task, and the query section presents the new input for which you want a response. This method helps Claude 3 understand the context and expected output format, and often results in a more accurate and consistent response.

Example:

```
"query": {
  "bool": {
    "must": [
      {"match": {"post_type": "recipe"}},
      {"range": {"likes_count": {"gte": 100}}},
      {"exists": {"field": "media_urls"}}
    ]
  }
}
Question: Find all recipe posts that have at least 100 likes and include media URLs.
```

- **System prompts:** In addition to few-shot prompting, Claude 3 models on Amazon Bedrock also support the use of system prompts. System prompts are a way to provide overall context, instructions, or guidelines to the model before presenting it with specific user inputs. They are particularly useful for setting the tone, defining the model's role, or establishing constraints for the entire conversation. To use a system prompt with Claude 3 on Amazon Bedrock, you include it in the `system` parameter of your API request. This is separate from the user messages and applies to the entire interaction. Detailed system prompts are used to set context and provide guidelines for the model.

  Example:

```
You are an expert query dsl generator. Your task is to take an input question and
 generate a query dsl to answer the question. Use the schemas and data below to
 generate the query.

Schemas: [schema details]
Data: [sample data]
Guidelines:
- Ensure the generated query adheres to DSL query syntax
- Do not create new mappings or other items that aren't included in the provided
 schemas.
```

- **Structured output**: You can instruct the model to provide output in specific formats, such as JSON or within XML tags.

Example:

```
Put the query in json tags
```

- **Prompt chaining**: The notebook uses the output of one LLM call as input for another, such as using generated synthetic data to create example questions.
- **Context provision**: Relevant context, including schemas and sample data, is provided in the prompts.

  Example:

```
Schemas: [schema details]
Data: [sample data]
```

- **Task-specific prompts**: Different prompts are crafted for specific tasks, such as generating synthetic data, creating example questions, and converting natural language queries to query DSL.

  Example for generating test questions:

```
Your task is to generate 5 example questions users can ask the health app based on
 provided schemas and data. Only include the questions generated in the response.
```

Use Amazon Q Developer as a coding assistant to increase your productivity

Ram Kandaswamy, Amazon Web Services

Summary

This pattern uses a tic-tac-toe game to demonstrate how you can apply Amazon Q Developer across a range of development tasks. It generates code for a tic-tac-toe game as a single-page application (SPA), enhances its UI, and creates scripts to deploy the application on AWS.

Amazon Q Developer functions as a coding assistant to help accelerate software development workflows and enhance productivity for both developers and non-developers. Regardless of your technical expertise, it helps you create architectures and design solutions for business problems, bootstraps your working environment, helps you implement new features, and generates test cases for validation. It uses natural language instructions and AI capabilities to ensure consistent, high-quality code and to mitigate coding challenges regardless of your programming skills.

The key advantage of Amazon Q Developer is its ability to liberate you from repetitive coding tasks. When you use the `@workspace` annotation, Amazon Q Developer ingests and indexes all code files, configurations, and project structure in your integrated development environment (IDE), and provides tailored responses to help you focus on creative problem-solving. You can dedicate more time to designing innovative solutions and enhancing the user experience. If you aren't technical, you can use Amazon Q Developer to streamline workflows and collaborate more effectively with the development team. The Amazon Q Developer **Explain code** feature offers detailed instructions and summaries, so you can navigate complex code bases.

Furthermore, Amazon Q Developer provides a language-agnostic approach that helps junior and mid-level developers expand their skill sets. You can concentrate on core concepts and business logic instead of language-specific syntax. This reduces the learning curve when you switch technologies.

Prerequisites and limitations

Prerequisites

- IDE (for example, WebStorm or Visual Studio Code) with the Amazon Q Developer plugin installed. For instructions, see [Installing the Amazon Q Developer extension or plugin in your IDE] in the Amazon Q Developer documentation.

- An active AWS account set up with Amazon Q Developer. For instructions, see Getting started in the Amazon Q Developer documentation.
- **npm** installed. For instructions, see the npm documentation. This pattern was tested with npm version 10.8.
- AWS Command Line Interface (AWS CLI) installed. For instructions, see the AWS CLI documentation.

Limitations

- Amazon Q Developer can perform only one development task at a time.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Tools

- This pattern requires an IDE such as Visual Studio Code or WebStorm. For a list of supported IDEs, see the Amazon Q Developer documentation.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.

Best practices

See Best coding practices with Amazon Q Developer in AWS Prescriptive Guidance. In addition:

- When you provide prompts to Amazon Q Developer, make sure that your instructions are clear and unambiguous. Add code snippets and annotations such as `@workspace` to the prompt to provide more context for your prompts.
- Include relevant libraries and import them to avoid conflicts or incorrect guesses by the system.
- If the code generated isn't accurate or as expected, use the **Provide feedback & regenerate** option. Try breaking the prompts into smaller instructions.

Epics

Set up the working environment

Task	Description	Skills required
Create a new project.	To create a new project in your working environment, run the following command and accept the default settings for all questions: `npx create-next-app@latest`	App developer, Programmer, Software developer
Test the base application.	Run the following command and confirm that the base application loads successfully in the browser: `npm run dev`	App developer, Programmer, Software developer

Clean up the base code.	Navigate to the `page.tsx` file in the `src/app` folder and delete the default content to get a blank page. After deletion, the file should look like this:
	`export default function Home() {`
	`  return (<div></div>`
	`      );`
	`}`
		App developer, Programmer, Software developer

Use Amazon Q Developer to design a tic-tac-toe game project

Task	Description	Skills required
Get an overview of steps.	1. In your IDE, open your project, and choose the Amazon Q icon to open the chat panel. 2. In the Amazon Q Developer chat panel, ask for an overview of creating a single-page application (SPA). For example: `I would like to create a single-page application involving Next.js React framework for tic-tac-toe game. What are the steps?`	App developer, Programmer, Software developer
Generate code for tic-tac-toe.	In the chat panel, start a development task by using the `/dev` command followed by the description of the task. For example: `/dev Create a React-based single-page application written in TypeScript for a tic-tac-toe game with the following specifications: 1. Design an aesthetically pleasing interface with the game grid`	App developer, Programmer, Software developer

Task	Description	Skills required
	``` centered vertically and horizontally on the page. 2. Include a heading and clear instructions on how to play the game. 3. Implement color-cod ing for X and O marks to distinguish them easily. ``` Amazon Q Developer generates code based on your instructions.	
Inspect and accept the generated code.	Visually inspect the code, and choose **Accept code** to automatically replace the `page.tsx` file. If you run into issues, choose **Provide feedback & regenerate** and describe the issue you encountered.	App developer, Programmer, Software developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Fix lint errors.</td><td>The example tic-tac-toe game includes a grid. The code that Amazon Q Developer generates might use the default type <code>any</code>. You can add type safety by prompting Amazon Q Developer as follows:<pre><code>/dev Ensure proper
 TypeScript typing
 for the onSquare Click
 event handler
to resolve any 'any'
 type issues.</code></pre></td><td>App developer, Programmer, Software developer</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add visual appeal.</td><td>You can break the original requirement into smaller fragments. For example, you can improve the game UI with the following prompts in the dev tasks. This prompt enhances Cascading Style Sheets (CSS) styles and exports the app for deployment.<pre><code>/dev Debug and fix any
 CSS issues to correctly
 display the game grid
 and overall layout.

Simplify the code by
 removing game history
 functionality and
 related components.

Implement static file
 export to an 'out'
 directory for easy
 deployment. The
 solution
should be fully
 functional, visually
 appealing, and free of
 typing errors or layout
 issues.</code></pre></td><td>App developer, Programmer, Software developer</td></tr>
</table>

Task	Description	Skills required

Test again.	1. Now that you have completed the development lifecycle, test the code to confirm that it works as expected. To run the application locally, use the command:
	`npm run dev`
	2. If the application works as expected, use the `build` command to export the entire application to the output folder in preparation for deployment:
	`npm run build`
		App developer, Programmer, Software developer

Deploy the application to the AWS Cloud

Task	Description	Skills required

Create folders and files for deployment.	In the project in your working environment, create a deployment folder and two files inside it: `pushtos3.sh` and `cloudformation.yml` :
	`mkdir deployment && cd deployment`
	`touch pushtos3.sh && chmod +x pushtos3.sh`
		App developer, Programmer, Software developer

Task	Description	Skills required
	`touch cloudformation.yml`	

Task	Description	Skills required
Generate automation code.	1. In the chat panel for Amazon Q Developer, provide the following prompt: ```/dev Generate a Cloudformation template that creates two resources: tictactoe artifact bucket and CloudFront. CloudFront should be configured with this bucket as origin. Add cache policy appropriate for Amazon S3 and default root object as index.html. Ensure that origin access control is used and no public bucket is created. Output all the resources and their ARNs.``` 2. Review and accept the generated code. The `cloudformation.yml` file that you created previously should now be populated with an AWS CloudFormation script that creates the resources for the AWS Cloud.	AWS administrator, AWS DevOps, App developer

Task	Description	Skills required
Generate script content.	To create a deployment script, use the following prompt: `/dev Modify the pushtos3 shell script so that it can use AWS CLI commands to create a CloudFormation stack named tictactoe-stack if it does not exist already, and use cloudformation.yml as the source template. Wait for the stack to complete and sync the contents from the out folder to the S3 bucket. Perform invalidation of the CloudFront origin.`	App developer, Programmer, Software developer
Deploy the application to the AWS Cloud.	1. Configure the working environment with valid AWS credentials. 2. Run the shell script to deploy the fully functiona l tic-tac-toe game to the AWS Cloud.	AWS administrator, AWS DevOps, Cloud architect, App developer

Troubleshooting

Issue	Solution
The build doesn't create a single-page application or export it to the output folder.	Look at the contents of the `next.conf ig.mjs` file.

Issue	Solution

	If the code has the following default configuration:
	 `const nextConfig = {};`
	 modify it as follows:
	 `const nextConfig = {`
	 `  output: 'export',`
	 `  distDir: 'out',`
	 `};`

Use SageMaker Processing for distributed feature engineering of terabyte-scale ML datasets

Chris Boomhower, Amazon Web Services

Summary

Many terabyte-scale or larger datasets often consist of a hierarchical folder structure, and the files in the dataset sometimes share interdependencies. For this reason, machine learning (ML) engineers and data scientists must make thoughtful design decisions to prepare such data for model training and inference. This pattern demonstrates how you can use manual macrosharding and microsharding techniques in combination with Amazon SageMaker Processing and virtual CPU (vCPU) parallelization to efficiently scale feature engineering processes for complicated big data ML datasets.

This pattern defines *macrosharding* as the splitting of data directories across multiple machines for processing, and *microsharding* as the splitting of data on each machine across multiple processing threads. The pattern demonstrates these techniques by using Amazon SageMaker with sample time-series waveform records from the PhysioNet MIMIC-III dataset. By implementing the techniques in this pattern, you can minimize the processing time and costs for feature engineering while maximizing resource utilization and throughput efficiency. These optimizations rely on distributed SageMaker Processing on Amazon Elastic Compute Cloud (Amazon EC2) instances and vCPUs for similar, large datasets, regardless of data type.

Prerequisites and limitations

Prerequisites

- Access to SageMaker notebook instances or SageMaker Studio, if you want to implement this pattern for your own dataset. If you are using Amazon SageMaker for the first time, see Get started with Amazon SageMaker in the AWS documentation.
- SageMaker Studio, if you want to implement this pattern with the PhysioNet MIMIC-III sample data.
- The pattern uses SageMaker Processing, but doesn't require any experience running SageMaker Processing jobs.

Limitations

- This pattern is well suited to ML datasets that include interdependent files. These interdependencies benefit the most from manual macrosharding and running multiple, single-instance SageMaker Processing jobs in parallel. For datasets where such interdependencies do not exist, the `ShardedByS3Key` feature in SageMaker Processing might be a better alternative to macrosharding, because it sends sharded data to multiple instances that are managed by the same Processing job. However, you can implement this pattern's microsharding strategy in both scenarios to best utilize instance vCPUs.

Product versions

- Amazon SageMaker Python SDK version 2

Architecture

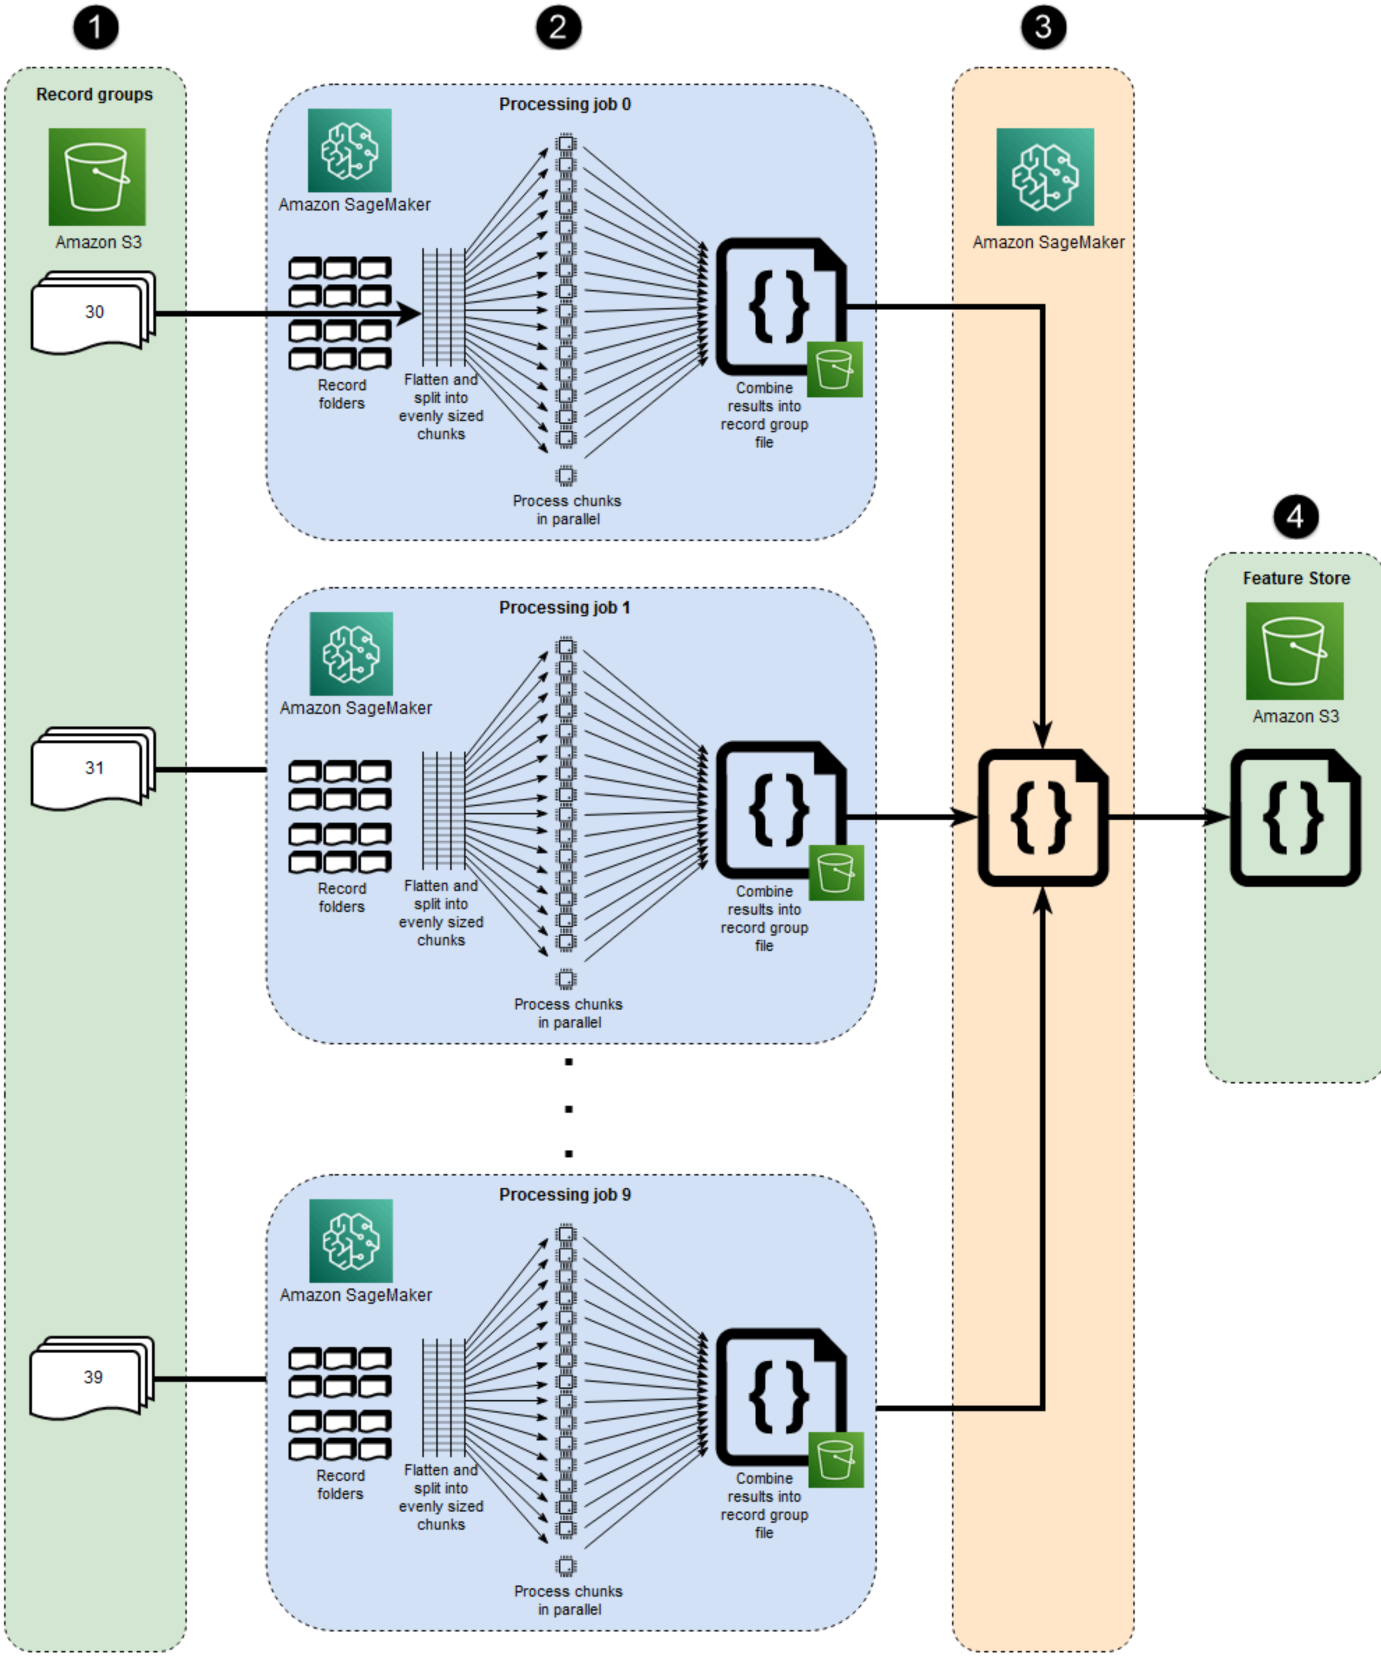
Target technology stack

- Amazon Simple Storage Service (Amazon S3)
- Amazon SageMaker

Target architecture

Macrosharding and distributed EC2 instances

The 10 parallel processes represented in this architecture reflect the structure of the MIMIC-III dataset. (Processes are represented by ellipses for diagram simplification.) A similar architecture applies to any dataset when you use manual macrosharding. In the case of MIMIC-III, you can use the dataset's raw structure to your advantage by processing each patient group folder separately, with minimal effort. In the following diagram, the record groups block appears on the left (1). Given the distributed nature of the data, it makes sense to shard by patient group.



1

Processing job 0
Processing job 1
Processing job 9
Amazon SageMaker
Record folders
Flatten and split into evenly sized chunks
Process chunks in parallel
Combine results into record group file
Amazon SageMaker
Feature Store
Amazon S3

However, manually sharding by patient group means that a separate Processing job is required for each patient group folder, as you can see in the middle section of the diagram (2), instead of a single Processing job with multiple EC2 instances. Because MIMIC-III's data includes both binary waveform files and matching text-based header files, and there is a required dependency on the wfdb library for binary data extraction, all the records for a specific patient must be made available on the same instance. The only way to be certain that each binary waveform file's associated header file is also present is to implement manual sharding to run each shard within its own Processing job, and to specify `s3_data_distribution_type='FullyReplicated'` when you define the Processing job input. Alternatively, if all data were available in a single directory and no dependencies existed between files, a more suitable option might be to launch a single Processing job with multiple EC2 instances and `s3_data_distribution_type='ShardedByS3Key'` specified. Specifying `ShardedByS3Key` as the Amazon S3 data distribution type directs SageMaker to manage data sharding automatically across instances.

Launching a Processing job for each folder is a cost-efficient way to preprocess the data, because running multiple instances concurrently saves time. For additional cost and time savings, you can use microsharding within each Processing job.

Microsharding and parallel vCPUs

Within each Processing job, the grouped data is further divided to maximize use of all available vCPUs on the SageMaker fully managed EC2 instance. The blocks in the middle section of the diagram (2) depict what happens within each primary Processing job. The contents of the patient record folders are flattened and divided evenly based on the number of available vCPUs on the instance. After the folder contents are divided, the evenly sized set of files are distributed across all vCPUs for processing. When processing is complete, the results from each vCPU are combined into a single data file for each Processing job.

In the attached code, these concepts are represented in the following section of the `src/feature-engineering-pass1/preprocessing.py` file.

```
def chunks(lst, n):
    """
    Yield successive n-sized chunks from lst.

    :param lst: list of elements to be divided
    :param n: number of elements per chunk
    :type lst: list
    :type n: int
```

```
    :return: generator comprising evenly sized chunks
    :rtype: class 'generator'
    """
    for i in range(0, len(lst), n):
        yield lst[i:i + n]

# Generate list of data files on machine
data_dir = input_dir
d_subs = next(os.walk(os.path.join(data_dir, '.')))[1]
file_list = []
for ds in d_subs:
    file_list.extend(os.listdir(os.path.join(data_dir, ds, '.')))
dat_list = [os.path.join(re.split('_|\.', f)[0].replace('n', ''), f[:-4]) for f in
 file_list if f[-4:] == '.dat']

# Split list of files into sub-lists
cpu_count = multiprocessing.cpu_count()
splits = int(len(dat_list) / cpu_count)
if splits == 0: splits = 1
dat_chunks = list(chunks(dat_list, splits))

# Parallelize processing of sub-lists across CPUs
ws_df_list = Parallel(n_jobs=-1, verbose=0)(delayed(run_process)(dc) for dc in
 dat_chunks)

# Compile and pickle patient group dataframe
ws_df_group = pd.concat(ws_df_list)
ws_df_group = ws_df_group.reset_index().rename(columns={'index': 'signal'})
ws_df_group.to_json(os.path.join(output_dir, group_data_out))
```

A function, `chunks`, is first defined to consume a given list by dividing it into evenly sized chunks of length `n` and by returning these results as a generator. Next, the data is flattened across patient folders by compiling a list of all binary waveform files that are present. After this is done, the number of vCPUs available on the EC2 instance is obtained. The list of binary waveform files is evenly divided across these vCPUs by calling `chunks`, and then each waveform sublist is processed on its own vCPU by using [joblib's Parallel class](). Results are automatically combined into a single list of dataframes by the Processing job, which SageMaker then processes further before writing it to Amazon S3 upon job completion. In this example, there are 10 files written to Amazon S3 by the Processing jobs (one for each job).

When all the initial Processing jobs are complete, a secondary Processing job, which is shown in the block to the right of the diagram (3) combines the output files produced by each primary Processing job and writes the combined output to Amazon S3 (4).

Tools

Tools

- Python – The sample code used for this pattern is Python (version 3).
- SageMaker Studio – Amazon SageMaker Studio is a web-based, integrated development environment (IDE) for machine learning that lets you build, train, debug, deploy, and monitor your machine learning models. You run SageMaker Processing jobs by using Jupyter notebooks inside SageMaker Studio.
- SageMaker Processing – Amazon SageMaker Processing provides a simplified way to run your data processing workloads. In this pattern, the feature engineering code is implemented at scale by using SageMaker Processing jobs.

Code

The attached .zip file provides the complete code for this pattern. The following section describes the steps to build the architecture for this pattern. Each step is illustrated by sample code from the attachment.

Epics

Set up your SageMaker Studio environment

Task	Description	Skills required
Access Amazon SageMaker Studio.	Onboard to SageMaker Studio in your AWS account by following the direction s provided in the Amazon SageMaker documentation.	Data scientist, ML engineer
Install the wget utility.	Install *wget* if you onboarded with a new SageMaker Studio configuration or if you've	Data scientist, ML engineer

Task	Description	Skills required
	never used these utilities in SageMaker Studio before. To install, open a terminal window in the SageMaker Studio console and run the following command: `sudo yum install wget`	

Download and unzip the sample code.	Download the `attachments.zip` file in the *Attachments* section. In a terminal window, navigate to the folder where you downloaded the file and extract its contents:
	
	`unzip attachment.zip`
	
	Navigate to the folder where you extracted the .zip file, and extract the contents of the `Scaled-Processing.zip` file.
	
	`unzip Scaled-Processing.zip`
		Data scientist, ML engineer

Task	Description	Skills required
Download the sample dataset from physionet.org and upload it to Amazon S3.	Run the `get_data.ipynb` Jupyter notebook within the folder that contains the `Scaled-Processing` files. This notebook downloads a sample MIMIC-III dataset from physionet.org and uploads it to your SageMaker Studio session bucket in Amazon S3.	Data scientist, ML engineer

Configure the first preprocessing script

Task	Description	Skills required

Flatten the file hierarchy across all subdirectories.	In large datasets such as MIMIC-III, files are often distributed across multiple subdirectories even within a logical parent group. Your script should be configure d to flatten all group files across all subdirectories, as the following code demonstra tes.
	`# Generate list of .dat files on machine`
	`data_dir = input_dir`
	`d_subs = next(os.walk(os.path.join(data_dir, '.')))[1]`
	`file_list = []`
	`for ds in d_subs:`
	`    file_list.extend(os.listdir(os.path.`
		Data scientist, ML engineer

Task	Description	Skills required
	``` join(data_dir, ds, '.'))) dat_list = [os.path. join(re.split('_|\\ .', f)[0].replace('n', ''), f[:-4]) for f in file_list if f[-4:] == '.dat'] ``` **Note** The example code snippets in this epic are from the `src/feature-engineering-pass1/preprocessing.py` file, which is provided in the attachment.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Divide files into subgroups based on vCPU count.</td><td>Files should be divided into evenly sized subgroups, or chunks, depending on the number of vCPUs present on the instance that runs the script. For this step, you can implement code similar to the following.
<pre><code># Split list of files
 into sub-lists
cpu_count = multiproc
essing.cpu_count()
splits = int(len(d
at_list) / cpu_count)
if splits == 0: splits =
 1
dat_chunks = list(chun
ks(dat_list, splits))</code></pre></td><td>Data scientist, ML engineer</td></tr>
<tr><td>Parallelize processing of subgroups across vCPUs.</td><td>Script logic should be configured to process all subgroups in parallel. To do this, use the Joblib library's <code>Parallel</code> class and <code>delayed</code> method as follows.
<pre><code># Parallelize processin
g of sub-lists across
 CPUs
ws_df_list = Parallel(
n_jobs=-1, verbose=0)
(delayed(run_process)
(dc) for dc in dat_chunk
s)</code></pre></td><td>Data scientist, ML engineer</td></tr>
</table>

Task	Description	Skills required

Save single file group output to Amazon S3.	When parallel vCPU processing is complete, the results from each vCPU should be combined and uploaded to the file group's S3 bucket path. For this step, you can use code similar to the following.
	`# Compile and pickle patient group dataframe`
	`ws_df_group = pd.concat(ws_df_list)`
	`ws_df_group = ws_df_group.reset_index().rename(columns={'index': 'signal'})`
	`ws_df_group.to_json(os.path.join(output_dir, group_data_out))`
		Data scientist, ML engineer

Configure the second preprocessing script

Task	Description	Skills required
Combine data files produced across all Processing jobs that ran the first script.	The previous script outputs a single file for each SageMaker Processing job that processes a group of files from the dataset. Next, you need to combine these output files into a single object and write a single output dataset to Amazon S3. This is demonstra	Data scientist, ML engineer

Task	Description	Skills required

	ted in the `src/feature-engineering-pass1p5/preprocessing.py` file, which is provided in the attachment, as follows.
	``
	def write_parquet(wavs_df, path):
	    """
	    Write waveform summary dataframe to S3 in parquet format.
	
	    :param wavs_df: waveform summary dataframe
	    :param path: S3 directory prefix
	    :type wavs_df: pandas dataframe
	    :type path: str
	    :return: None
	    """
	    extra_args = {"ServerSideEncryption": "aws:kms"}
	    wr.s3.to_parquet(
	        df=wavs_df,
	        path=path,
	        compression='snappy',
	        s3_additional_kwargs=extra_args)
	
	def combine_data():
	    """
	    Get combined data and write to parquet.
	``	

Task	Description	Skills required

	``
	    :return: waveform
	 summary dataframe
	    :rtype: pandas
	 dataframe
	    """
	    wavs_df = get_data(
	)
	    wavs_df = normalize
	_signal_names(wavs
	_df)
	    write_parquet(wavs
	_df, "s3://{}/{}/
	{}".format(buck
	et_xform, dataset_p
	refix, pass1p5ou
	t_data))
	
	    return wavs_df
	
	wavs_df = combine_d
	ata()
	``	

Run Processing jobs

Task	Description	Skills required
Run the first Processing job.	To perform macrosharding, run a separate Processing job for each file group. Microsharding is performed inside each Processing job, because each job runs your first script. The following code demonstrates how to launch a Processing job for each file group directory in the	Data scientist, ML engineer

Task	Description	Skills required
	following snippet (included in `notebooks/FeatExtract_Pass1.ipynb`).	

```
pat_groups = list(range(30,40))
ts = str(int(time.time()))

for group in pat_groups:
    sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
                                         role=role,
                                          instance_type='ml.m5.4xlarge',
                                          instance_count=1,
                                          volume_size_in_gb=5)
    sklearn_processor.run(
        code='../src/feature-engineering-pass1/preprocessing.py',
        job_name='-'.join(['scaled-processing-p1', str(group), ts]),
        arguments=[
            "input_path", "/opt/ml/processing/input",
```

Task	Description	Skills required

	``
	            "output_p
	ath", "/opt/ml/
	processing/output",
	            "group_da
	ta_out", "ws_df_gr
	oup.json"
	        ],
	        inputs=
	        [
	            Processin
	gInput(
	
	 source=f's3://{ses
	s.default_bucket()}/
	data_inputs/{group}',
	
	 destination='/opt/ml/
	processing/input',
	
	 s3_data_distributi
	on_type='FullyRepl
	icated'
	            )
	        ],
	        outputs=
	        [
	            Processin
	gOutput(
	
	 source='/opt/ml/pr
	ocessing/output',
	
	 destination=f's3:/
	/{sess.default_buc
	ket()}/data_outputs/
	{group}'
	            )
	        ],
	        wait=False
	    )
	``	

Task	Description	Skills required

Run the second Processing job.	To combine the outputs generated by the first set of processing jobs and perform any additional computations for preprocessing, you run your second script by using a single SageMaker Processing job. The following code demonstrates this (included in `notebooks/FeatExtract_Pass1p5.ipynb`).
	``
	ts = str(int(time.time()))
	bucket = sess.default_bucket()
	
	sklearn_processor = SKLearnProcessor(framework_version='0.20.0',
	         role=role,
	            instance_type='ml.t3.2xlarge',
	            instance_count=1,
	            volume_size_in_gb=5)
	sklearn_processor.run(
	    code='../src/feature-engineering-pass1p5/preprocessing.py',
	``
		Data scientist, ML engineer

Task	Description	Skills required

	``
	    job_name='-'.join(
	['scaled-processing',
	 'p1p5', ts]),
	    arguments=['bucket
	', bucket,
	                'pass1out
	_prefix', 'data_out
	puts',
	                'pass1out
	_data', 'ws_df_gr
	oup.json',
	                'pass1p5o
	ut_data', 'waveform
	_summary.parquet',
	                'statsdat
	a_name', 'signal_s
	tats.csv'],
	    wait=True
	)
	``

Visualize AI/ML model results using Flask and AWS Elastic Beanstalk

Chris Caudill and Durga Sury, Amazon Web Services

Summary

Visualizing output from artificial intelligence and machine learning (AI/ML) services often requires complex API calls that must be customized by your developers and engineers. This can be a drawback if your analysts want to quickly explore a new dataset.

You can enhance the accessibility of your services and provide a more interactive form of data analysis by using a web-based user interface (UI) that enables users to upload their own data and visualize the model results in a dashboard.

This pattern uses [Flask] and [Plotly] to integrate Amazon Comprehend with a custom web application and visualize sentiments and entities from user-provided data. The pattern also provides the steps to deploy an application by using AWS Elastic Beanstalk. You can adapt the application by using [Amazon Web Services (AWS) AI services] or with a custom trained model hosted on an endpoint (for example, an [Amazon SageMaker endpoint]).

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured on your local machine. For more information about this, see Configuration basics in the AWS CLI documentation. You can also use an AWS Cloud9 integrated development environment (IDE); for more information about this, see Python tutorial for AWS Cloud9 and Previewing running applications in the AWS Cloud9 IDE in the AWS Cloud9 documentation.

  Notice: AWS Cloud9 is no longer available to new customers. Existing customers of AWS Cloud9 can continue to use the service as normal. Learn more
- An understanding of Flask's web application framework. For more information about Flask, see the Quickstart in the Flask documentation.

- Python version 3.6 or later, installed and configured. You can install Python by following the instructions from [Setting up your Python development environment]() in the AWS Elastic Beanstalk documentation.
- Elastic Beanstalk Command Line Interface (EB CLI), installed and configured. For more information about this, see [Install the EB CLI]() and [Configure the EB CLI]() from the AWS Elastic Beanstalk documentation.

Limitations

- This pattern's Flask application is designed to work with .csv files that use a single text column and are restricted to 200 rows. The application code can be adapted to handle other file types and data volumes.
- The application doesn't consider data retention and continues to aggregate uploaded user files until they are manually deleted. You can integrate the application with Amazon Simple Storage Service (Amazon S3) for persistent object storage or use a database such as Amazon DynamoDB for serverless key-value storage.
- The application only considers documents in the English language. However, you can use Amazon Comprehend to detect a document's primary language. For more information about the supported languages for each action, see [API reference]() in the Amazon Comprehend documentation.
- A troubleshooting list that contains common errors and their solutions is available in the *Additional information* section.

Architecture

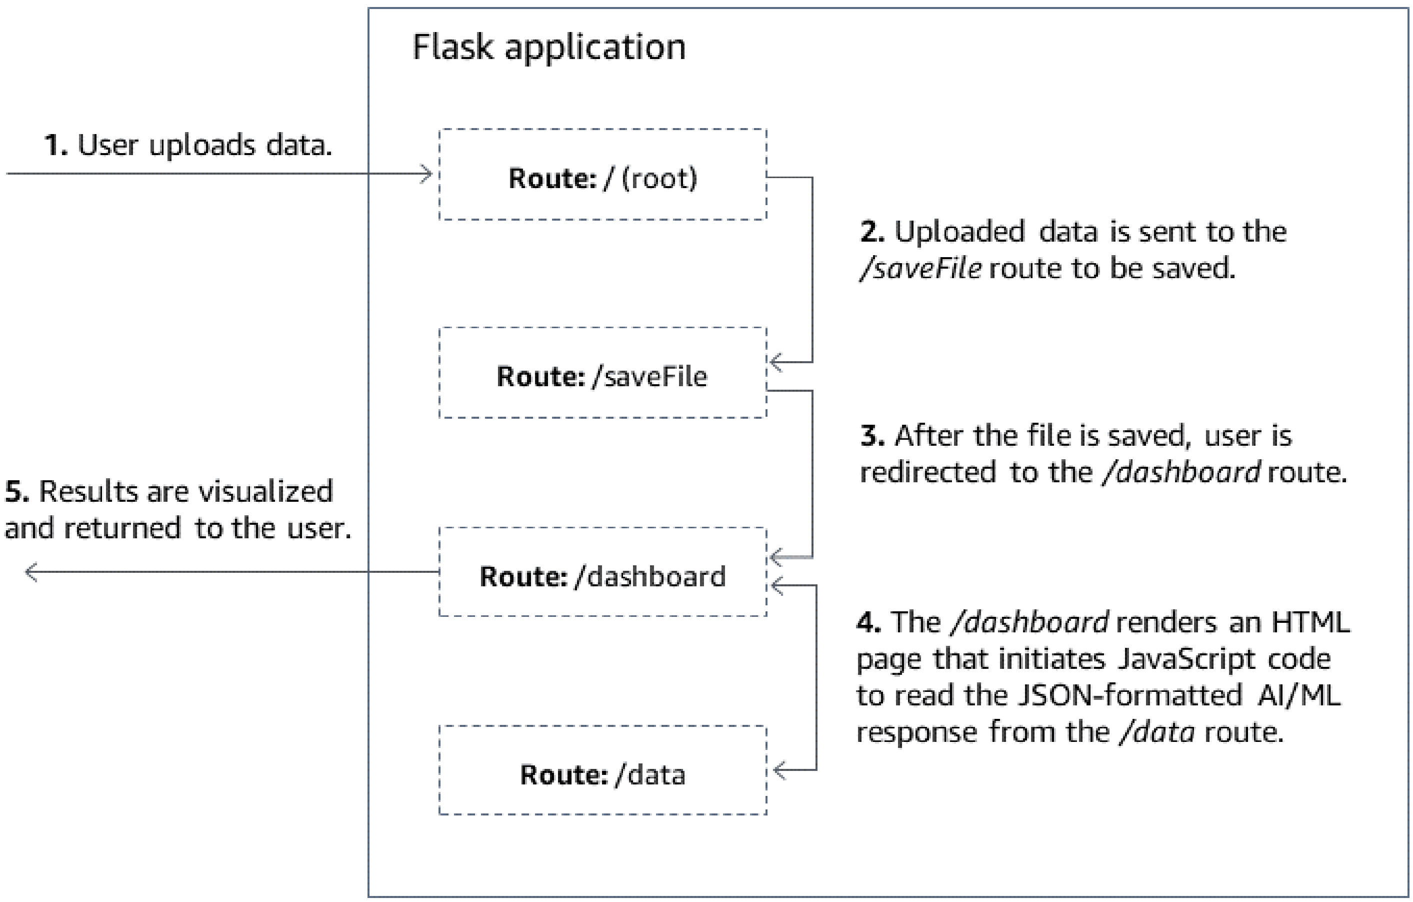
Flask application architecture

Flask is a lightweight framework for developing web applications in Python. It is designed to combine Python's powerful data processing with a rich web UI. The pattern's Flask application shows you how to build a web application that enables users to upload data, sends the data to Amazon Comprehend for inference, and then visualizes the results. The application has the following structure:

- `static` – Contains all the static files that support the web UI (for example, JavaScript, CSS, and images)
- `templates` – Contains all of the application's HTML pages

- `userData` – Stores uploaded user data
- `application.py` – The Flask application file
- `comprehend_helper.py` – Functions to make API calls to Amazon Comprehend
- `config.py` – The application configuration file
- `requirements.txt` – The Python dependencies required by the application

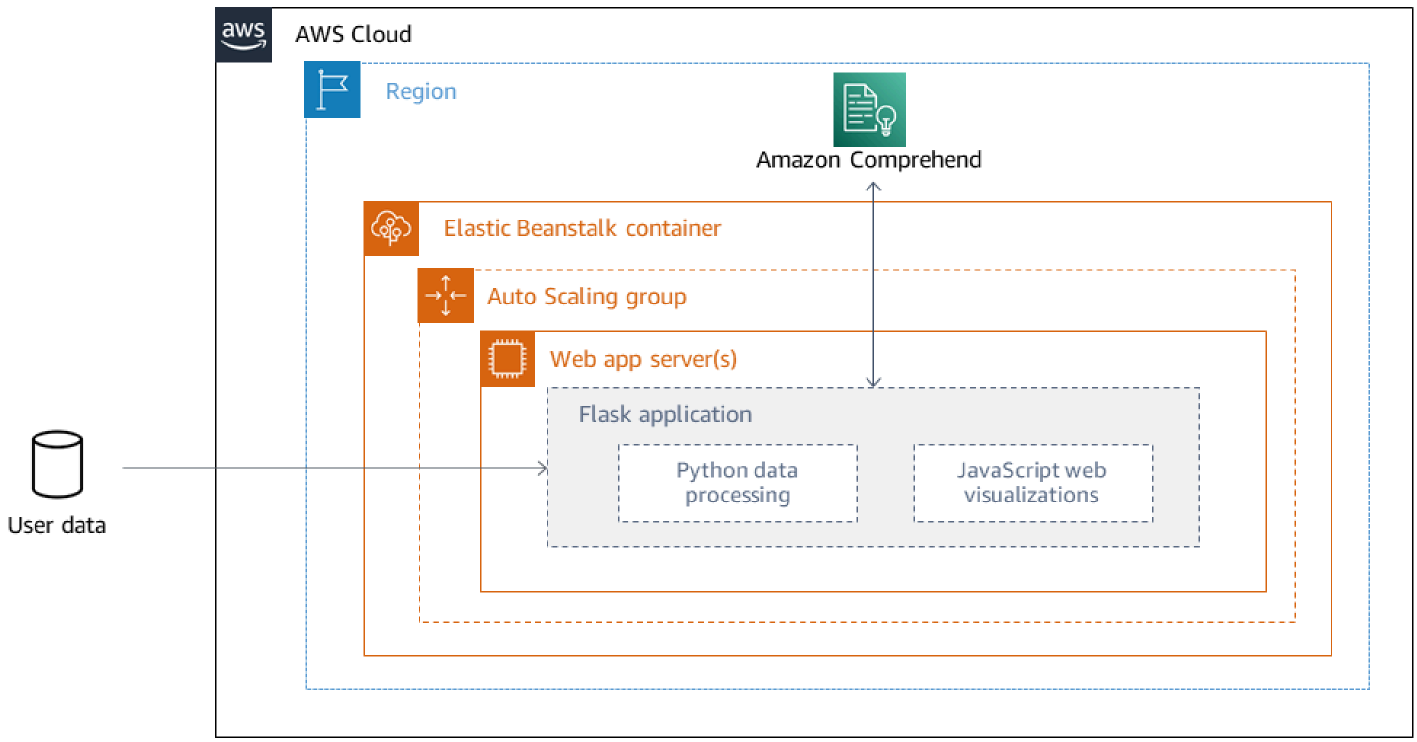
The `application.py` script contains the web application's core functionality, which consists of four Flask routes. The following diagram shows these Flask routes.



- / is the application's root and directs users to the `upload.html` page (stored in the `templates` directory).
- `/saveFile` is a route that is invoked after a user uploads a file. This route receives a `POST` request via an HTML form, which contains the file uploaded by the user. The file is saved in the `userData` directory and the route redirects users to the `/dashboard` route.

- `/dashboard` sends users to the `dashboard.html` page. Within this page's HTML, it runs the JavaScript code in `static/js/core.js` that reads data from the `/data` route and then builds visualizations for the page.
- `/data` is a JSON API that presents the data to be visualized in the dashboard. This route reads the user-provided data and uses the functions in `comprehend_helper.py` to send the user data to Amazon Comprehend for sentiment analysis and named entity recognition (NER). Amazon Comprehend's response is formatted and returned as a JSON object.

Deployment architecture



Design considerations

For more information about design considerations for applications deployed using Elastic Beanstalk on the AWS Cloud, see in the AWS Elastic Beanstalk documentation.

Technology stack

- Amazon Comprehend
- Elastic Beanstalk
- Flask

Automation and scale

Elastic Beanstalk deployments are automatically set up with load balancers and auto scaling groups. For more configuration options, see Configuring Elastic Beanstalk environments in the AWS Elastic Beanstalk documentation.

Tools

- AWS Command Line Interface (AWS CLI) is a unified tool that provides a consistent interface for interacting with all parts of AWS.
- Amazon Comprehend uses natural language processing (NLP) to extract insights about the content of documents without requiring special preprocessing.
- AWS Elastic Beanstalk helps you quickly deploy and manage applications in the AWS Cloud without having to learn about the infrastructure that runs those applications.
- Elastic Beanstalk CLI (EB CLI) is a command line interface for AWS Elastic Beanstalk that provides interactive commands to simplify creating, updating, and monitoring environments from a local repository.
- The Flask framework performs data processing and API calls using Python and offers interactive web visualization with Plotly.

Code

The code for this pattern is available in the GitHub Visualize AI/ML model results using Flask and AWS Elastic Beanstalk repository.

Epics

Set up the Flask application

Task	Description	Skills required
Clone the GitHub repository.	Pull the application code from the GitHub Visualize AI/ML model results using Flask and AWS Elastic Beanstalk repository by running the following command:	Developer

Task	Description	Skills required
	`git clone git@github.com:aws-samples/aws-comprehend-elasticbeanstalk-for-flask.git` **Note** Make sure that you configure your SSH keys with GitHub.	

Install the Python modules.	After you clone the repository, a new local `aws-comprehend-elasticbeanstalk-for-flask` directory is created. In that directory, the `requirements.txt` file contains the Python modules and versions that run the application. Use the following commands to install the modules:
	
	`cd aws-comprehend-elasticbeanstalk-for-flask`
	
	`pip install -r requirements.txt`
		Python developer

Task	Description	Skills required

Test the application locally.	Start the Flask server by running the following command:
	`python application.py`
	This returns information about the running server. You should be able to access the application by opening a browser and visiting http://localhost:5000
	Note
	If you're running the application in an AWS Cloud9 IDE, you need to replace the `application.run()` command in the `application.py` file with the following line:
	`application.run(host=os.getenv('IP', '0.0.0.0'),port=int(os.getenv('PORT', 8080)))`
	You must revert this change before deployment.
		Python developer

Deploy the application to Elastic Beanstalk

Task	Description	Skills required
Launch the Elastic Beanstalk application.	To launch your project as an Elastic Beanstalk application, run the following command from your application's root directory: `eb init -p python-3.6 comprehend_flask --region us-east-1` **Important** • `comprehend_flask` is the name of the Elastic Beanstalk application and can be changed according to your requirements. • You can replace the AWS Region with a Region of your choice. The default Region in AWS CLI is used if you don't specify a Region. • The application was built with Python version 3.6. You might encounter errors if you use other Python versions. Run the `eb init -i` command for more	Architect, Developer

Task	Description	Skills required
	deployment configuration options.	
Deploy the Elastic Beanstalk environment.	Run the following command from the application's root directory: `eb create comprehend-flask-env` **Note** `comprehend-flask-env` is the name of the Elastic Beanstalk environment and can be changed according to your requirements. The name can only contain letters, numbers, and dashes.	Architect, Developer

Task	Description	Skills required

Authorize your deployment to use Amazon Comprehend.	Although your application might be successfully deployed, you should also provide your deployment with access to Amazon Comprehend. `ComprehendFullAccess` is an AWS managed policy that provides the deployed application with permissions to make API calls to Amazon Comprehend.
	
	Attach the `ComprehendFullAccess` policy to `aws-elasticbeanstalk-ec2-role` (this role is automatically created for your deployment's Amazon Elastic Compute Cloud (Amazon EC2) instances) by running the following command:
	
	`aws iam attach-role-policy --policy-arn arn:aws:iam::aws:policy/ComprehendFullAccess --role-name aws-elasticbeanstalk-ec2-role`
	
	Important
	
	`aws-elasticbeanstalk-`
		Developer, Security architect

Task	Description	Skills required
	`ec2-role` is created when your applicati on deploys. You must complete the deployment process before you can attach the AWS Identity and Access Management (IAM) policy.	
Visit your deployed applicati on.	After your application successfully deploys, you can visit it by running the `eb open` command. You can also run the `eb status` command to receive details about your deploymen t. The deployment URL is listed under `CNAME`.	Architect, Developer

(Optional) Customize the application to your ML model

Task	Description	Skills required
Authorize Elastic Beanstalk to access the new model.	Make sure that Elastic Beanstalk has the required access permissions for your new model endpoint. For example, if you use an Amazon SageMaker endpoint, your deployment needs to have permission to invoke the endpoint.	Developer, Security architect

Task	Description	Skills required
	For more information about this, see InvokeEndpoint in the Amazon SageMaker documentation.	
Send the user data to a new model.	To change the underlying ML model in this application, you must change the following files: • `comprehend_helper.py` – This is the Python script that connects with Amazon Comprehend, processes the response, and returns the final result to the application. In this script, you can either route the data to another AI service on the AWS Cloud or you can send the data to a custom model endpoint. We recommend that you also format the results in this script for logical separation and the reusability of this pattern. • `application.py` – If you change the name of the `comprehend_helper.py` script or functions, you need to update the application `application.py` script to reflect those changes.	Data scientist

Task	Description	Skills required
Update the dashboard visualizations.	Typically, incorporating a new ML model means that visualizations must be updated to reflect the new results. These changes are made in the following files: • `templates/dashboard.html` – The prebuilt application only accounts for two basic visualizations. The entire layout of the page can be adjusted in this file. • `static/js/core.js` – This script captures the formatted output of the Flask server's `/data` route and uses Plotly to create visualizations. You can add or update the page's charts.	Web developer

(Optional) Deploy the updated application

Task	Description	Skills required
Update your application's requirements file.	Before sending changes to Elastic Beanstalk, update the `requirements.txt` file to reflect any new Python modules by running the following command in your application's root directory:	Python developer

Task	Description	Skills required
	`pip freeze > requirements.txt`	
Redeploy the Elastic Beanstalk environment.	To ensure that your application changes are reflected in your Elastic Beanstalk deployment, navigate to your application's root directory and run the following command: `eb deploy` This sends the most recent version of the application's code to your existing Elastic Beanstalk deployment.	Systems administrator, Architect

Additional information

Troubleshooting list

The following are six common errors and their solutions.

Error 1

```
Unable to assume role "arn:aws:iam::xxxxxxxxxx:role/aws-elasticbeanstalk-ec2-role".
 Verify that the role exists and is configured correctly.
```

Solution: If this error occurs when you run `eb create`, create a sample application on the Elastic Beanstalk console to create the default instance profile. For more information about this, see [Creating an Elastic Beanstalk environment](#) in the AWS Elastic Beanstalk documentation.

Error 2

```
Your WSGIPath refers to a file that does not exist.
```

Solution: This error occurs in deployment logs because Elastic Beanstalk expects the Flask code to be named `application.py`. If you chose a different name, run `eb config` and edit the WSGIPath as shown in the following code sample:

```
aws:elasticbeanstalk:container:python:
     NumProcesses: '1'
     NumThreads: '15'
     StaticFiles: /static/=static/
     WSGIPath: application.py
```

Make sure that you replace `application.py` with your file name.

You can also leverage Gunicorn and a Procfile. For more information about this approach, see [Configuring the WSGI server with a Procfile](#) in the AWS Elastic Beanstalk documentation.

Error 3

```
Target WSGI script '/opt/python/current/app/application.py' does not contain WSGI
 application 'application'.
```

Solution: Elastic Beanstalk expects the variable that represents your Flask application to be named `application`. Make sure that the `application.py` file uses `application` as the variable name:

```
application = Flask(__name__)
```

Error 4

```
The EB CLI cannot find your SSH key file for keyname
```

Solution: Use the EB CLI to specify which key pair to use or to create a key pair for your deployment's EC2 instances. To resolve the error, run `eb init -i` and one of the options will ask:

```
Do you want to set up SSH for your instances?
```

Respond with Y to either create a key pair or specify an existing key pair.

Error 5

I've updated my code and redeployed but my deployment is not reflecting my changes.

Solution: If you're using a Git repository with your deployment, make sure that you add and commit your changes before redeploying.

Error 6

You are previewing the Flask application from an AWS Cloud9 IDE and run into errors.

Solution: For more information about this, see Previewing running applications in the AWS Cloud9 IDE in the AWS Cloud9 documentation.

Natural language processing using Amazon Comprehend

By choosing to use Amazon Comprehend, you can detect custom entities in individual text documents by running real-time analysis or asynchronous batch jobs. Amazon Comprehend also enables you to train custom entity recognition and text classification models that can be used in real time by creating an endpoint.

This pattern uses asynchronous batch jobs to detect sentiments and entities from an input file that contains multiple documents. The sample application provided by this pattern is designed for users to upload a .csv file containing a single column with one text document per row. The `comprehend_helper.py` file in the GitHub Visualize AI/ML model results using Flask and AWS Elastic Beanstalk repository reads the input file and sends the input to Amazon Comprehend for processing.

BatchDetectEntities

Amazon Comprehend inspects the text of a batch of documents for named entities and returns the detected entity, location, type of entity, and a score that indicates Amazon Comprehend's level of confidence. A maximum of 25 documents can be sent in one API call, with each document smaller than 5,000 bytes in size. You can filter the results to show only certain entities based on the use case. For example, you could skip the `'quantity'` entity type and set a threshold score for the detected entity (for example, 0.75). We recommend that you explore the results for your specific use case before choosing a threshold value. For more information about this, see BatchDetectEntities in the Amazon Comprehend documentation.

BatchDetectSentiment

Amazon Comprehend inspects a batch of incoming documents and returns the prevailing sentiment for each document (`POSITIVE`, `NEUTRAL`, `MIXED`, or `NEGATIVE`). A maximum of 25 documents can be sent in one API call, with each document smaller than 5,000 bytes in size. Analyzing the sentiment is straightforward and you choose the sentiment with the highest score to be displayed in the final results. For more information about this, see BatchDetectSentiment in the Amazon Comprehend documentation.

Flask configuration handling

Flask servers use a series of configuration variables to control how the server runs. These variables can contain debug output, session tokens, or other application settings. You can also define custom variables that can be accessed while the application is running. There are multiple approaches for setting configuration variables.

In this pattern, the configuration is defined in `config.py` and inherited within `application.py`.

- **Note**

  `config.py` contains the configuration variables that are set up on the application's startup. In this application, a `DEBUG` variable is defined to tell the application to run the server in debug mode. : Debug mode should not be used when running an application in a production environment. `UPLOAD_FOLDER` is a custom variable that is defined to be referenced later in the application and inform it where uploaded user data should be stored.
- `application.py` initiates the Flask application and inherits the configuration settings defined in `config.py`. This is performed by the following code:

```
application = Flask(__name__)
application.config.from_pyfile('config.py')
```

Analyze Amazon Redshift data in Microsoft SQL Server Analysis Services

Sunil Vora, Amazon Web Services

Summary

This pattern describes how to connect and analyze Amazon Redshift data in Microsoft SQL Server Analysis Services, by using the Intellisoft OLE DB Provider or CData ADO.NET Provider for database access.

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. SQL Server Analysis Services is an online analytical processing (OLAP) tool that you can use to analyze data from data marts and data warehouses such as Amazon Redshift. You can use SQL Server Analysis Services to create OLAP cubes from your data for rapid, advanced data analysis.

Prerequisites and limitations

Assumptions

- This pattern describes how to set up SQL Server Analysis Services and Intellisoft OLE DB Provider or CData ADO.NET Provider for Amazon Redshift on an Amazon Elastic Compute Cloud (Amazon EC2) instance. Alternatively, you can install both on a host in your corporate data center.

Prerequisites

- An active AWS account
- An Amazon Redshift cluster with credentials

Architecture

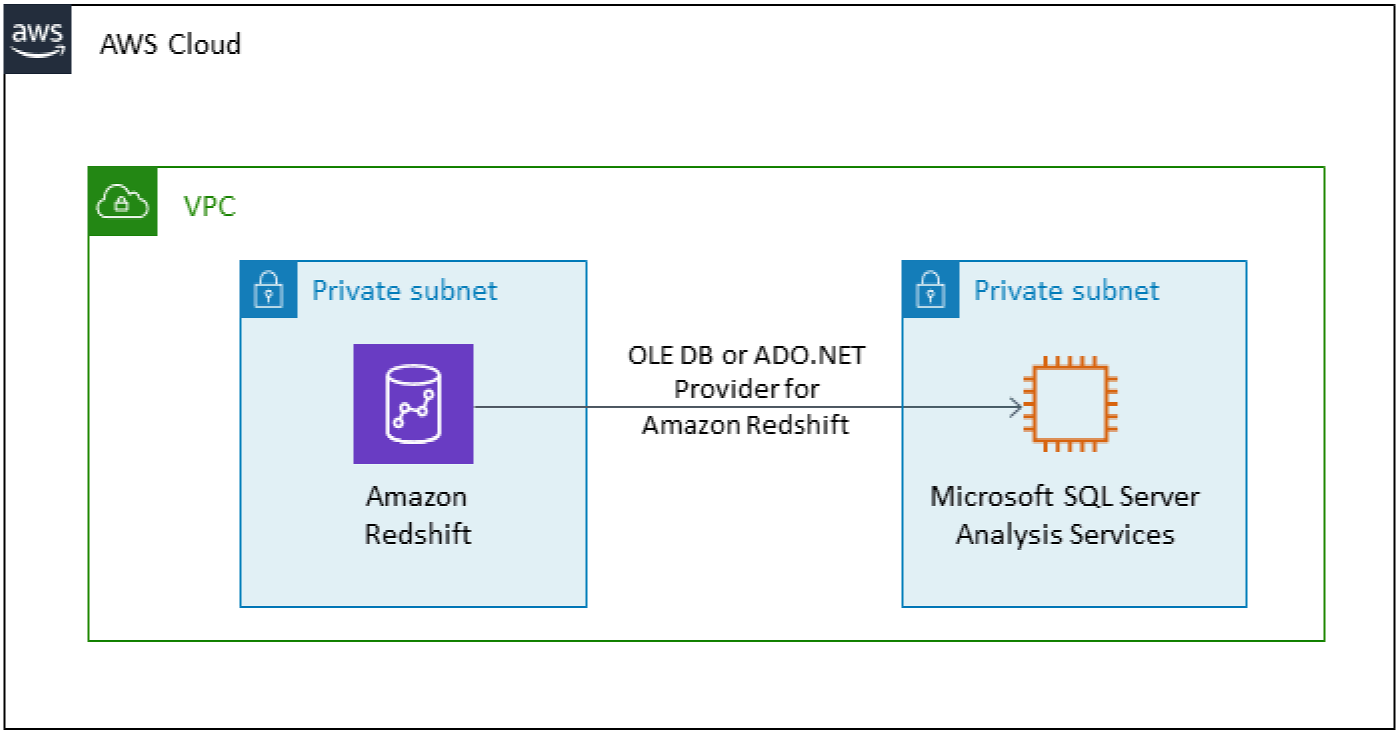
Source technology stack

- An Amazon Redshift cluster

Target technology stack

- Microsoft SQL Server Analysis Services

Source and target architecture



Tools

- Microsoft Visual Studio 2019 (Community Edition)
- Intellisoft OLE DB Provider for Amazon Redshift (Trial) or CData ADO.NET Provider for Amazon Redshift (Trial)

Epics

Analyze tables

Task	Description	Skills required
Analyze the tables and data to be imported.	Identify the Amazon Redshift tables to be imported and their sizes.	DBA

Set up EC2 instance and install tools

Task	Description	Skills required
Set up an EC2 instance.	In your AWS account, create an EC2 instance in a private or public subnet.	Systems administrator
Install tools for database access.	Download and install the Intellisoft OLE DB Provider for Amazon Redshift (or CData ADO.NET Provider for Amazon Redshift).	Systems administrator
Install Visual Studio.	Download and install Visual Studio 2019 (Community Edition).	Systems administrator
Install extensions.	Install the **Microsoft Analysis Services Projects** extension in Visual Studio.	Systems administrator
Create a project.	Create a new tabular model project in Visual Studio to store your Amazon Redshift data. In Visual Studio, choose the **Analysis Services Tabular Project** option when creating your project.	DBA

Create data source and import tables

Task	Description	Skills required
Create an Amazon Redshift data source.	Create an Amazon Redshift data source by using the Intellisoft OLE DB Provider	Amazon Redshift, DBA

Task	Description	Skills required
	for Amazon Redshift (or CData ADO.NET Provider for Amazon Redshift) and your Amazon Redshift credentials.	
Import tables.	Select and import tables and views from Amazon Redshift into your SQL Server Analysis Services project.	Amazon Redshift, DBA

Clean up after migration

Task	Description	Skills required
Delete the EC2 instance.	Delete the EC2 instance you launched previously.	Systems administrator

Analyze and visualize nested JSON data with Amazon Athena and Amazon QuickSight

Anoop Singh, Amazon Web Services

Summary

This pattern explains how to translate a nested, JSON-formatted data structure into a tabular view by using Amazon Athena, and then visualize the data in Amazon QuickSight.

You can use JSON-formatted data for API-powered data feeds from operational systems to create data products. This data can also help you understand your customers and their interactions with your products better, so you can tailor user experiences and predict outcomes.

Prerequisites and limitations

Prerequisites

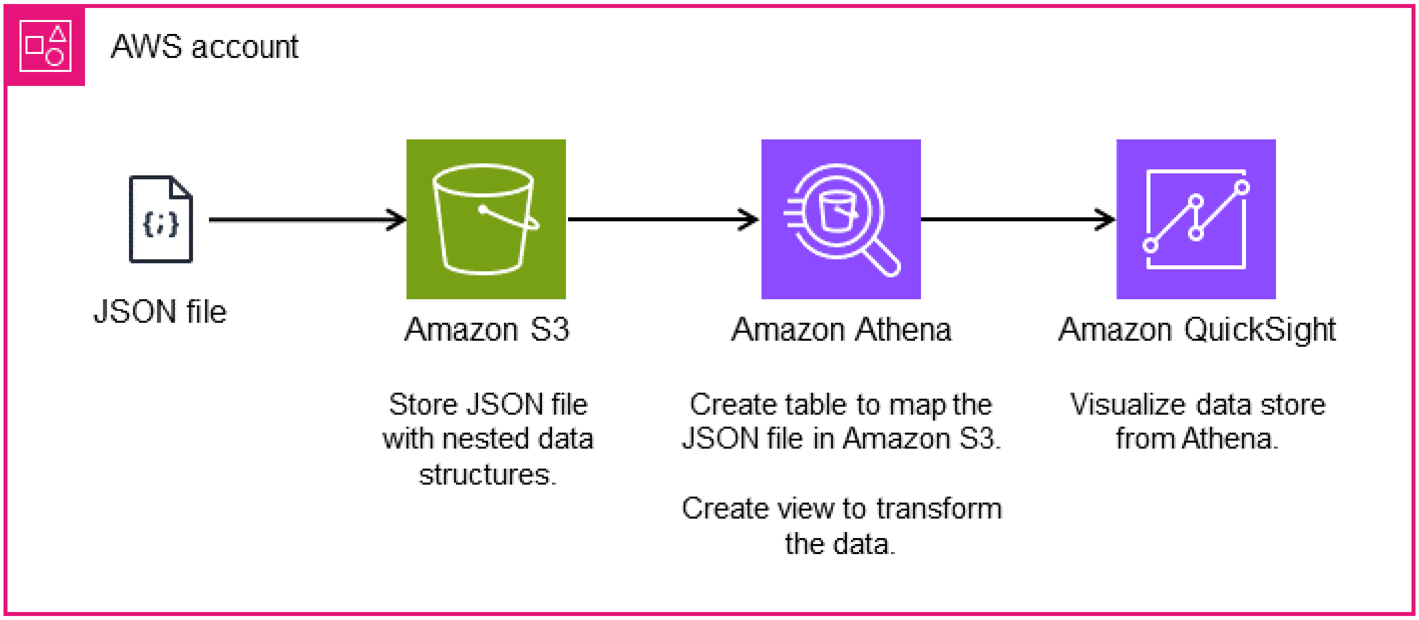
- An active AWS account
- A JSON file that represents a nested data structure (this pattern provides a sample file)

Limitations:

- JSON features integrate well with existing SQL-oriented functions in Athena. However, they aren't ANSI SQL compatible, and the JSON file is expected to carry each record on a separate line. You might need to use the `ignore.malformed.json` property in Athena to indicate if malformed JSON records should be turned into null characters or generate errors. For more information, see Best practices for reading JSON data in the Athena documentation.
- This pattern considers only simple and small amounts of JSON-formatted data. If you want to use these concepts at scale, consider applying data partitioning and consolidate your data into larger files.

Architecture

The following diagram shows the architecture and workflow for this pattern. The nested data structures are stored in Amazon Simple Storage Service (Amazon S3) in JSON format. In Athena, the JSON data is mapped to an Athena data structure. You then create a view to analyze the data, and visualize the data structure in QuickSight.



Tools

AWS services

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. This pattern uses Amazon S3 to store the JSON file.
- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL. This pattern uses Athena to query and transform the JSON data. With a few actions in the AWS Management Console, you can point Athena at your data in Amazon S3 and use standard SQL to run one-time queries. Athena is serverless, so there is no infrastructure to set up or manage, and you pay only for the queries that you run. Athena scales automatically and runs queries in parallel, so results are fast, even with large datasets and complex queries.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data on a single dashboard. QuickSight lets you easily create and publish interactive dashboards that include machine learning (ML) insights. You can access these dashboards from any device, and embed them into your applications, portals, and websites.

Example code

The following JSON file provides a nested data structure that you can use in this pattern.

```
{
  "symbol": "AAPL",
  "financials": [
    {
      "reportDate": "2017-03-31",
      "grossProfit": 20591000000,
      "costOfRevenue": 32305000000,
      "operatingRevenue": 52896000000,
      "totalRevenue": 52896000000,
      "operatingIncome": 14097000000,
      "netIncome": 11029000000,
      "researchAndDevelopment": 2776000000,
      "operatingExpense": 6494000000,
      "currentAssets": 101990000000,
      "totalAssets": 334532000000,
      "totalLiabilities": 200450000000,
      "currentCash": 15157000000,
      "currentDebt": 13991000000,
      "totalCash": 67101000000,
      "totalDebt": 98522000000,
      "shareholderEquity": 134082000000,
      "cashChange": -1214000000,
      "cashFlow": 12523000000,
      "operatingGainsLosses": null
    }
  ]
}
```

Epics

Set up an S3 bucket

Task	Description	Skills required
Create an S3 bucket.	To create a bucket to store the JSON file, sign in to the AWS Management Console, open the [Amazon S3 console](https://console.aws.amazon.com/s3/), and then choose **Create**	Systems administrator

Task	Description	Skills required
	bucket. For more information, see Creating a bucket in the Amazon S3 documentation.	
Add the nested JSON data.	Upload your JSON file to the S3 bucket. For a sample JSON file, see the previous section. For instructions, see Uploading objects in the Amazon S3 documentation.	Systems administrator

Analyze data in Athena

Task	Description	Skills required

Create a table for mapping the JSON data.	1. Open the Athena console.
	2. Create a database by following the instructions in the Athena documentation.
	3. From the **Database** menu, choose the database that you created.
	4. In the query editor, enter a `CREATE TABLE` statement such as the following:
	
	`CREATE EXTERNAL TABLE financials_json (`
	`symbol string,`
	`financials array<`
	`struct<reportdate: string,`
	`grossprofit: bigint,`
		Developer

Task	Description	Skills required

	``
	                totalreve
	nue: bigint,
	                totalcash
	: bigint,
	                totaldebt
	: bigint,
	                researcha
	nddevelopment:
	 bigint>>
	)
	ROW FORMAT SERDE
	 'org.openx.data.js
	onserde.JsonSerDe'
	 LOCATION 's3://s3b
	ucket-for-athena/'
	``
	where `LOCATION` specifies the location of the S3 bucket that contains the JSON file.
	5. Choose **Run** to create the table.
	
	For more information about creating tables, see the [Athena documentation].	

Task	Description	Skills required
Create a view for data analysis.	1. Open the [Athena console](). 2. Create a database by following the instructions in the [Athena documentation](). 3. From the **Database** menu, choose the database that you created. 4. In the query editor, enter a `CREATE VIEW` statement such as the following: `CREATE OR REPLACE VIEW financial_json_view AS SELECT symbol, financials[1].reportdate one_report_date, -- indexes start with 1 financials[1].totalrevenue one_total_revenue, financials[1].reportdate another_report_date, financials[1].totalrevenue another_total_revenue FROM financials_json where symbol='AAPL' ORDER BY 1` 5. Choose **Run** to create the view.	Developer

Task	Description	Skills required
	For more information about creating views, see the Athena documentation.	
Analyze and validate the data.	1. Open the Athena console. 2. In the query editor, run queries by using the view that you created in the previous step. 3. Validate the data against the JSON file, to confirm that column names and data types are mapped correctly.	Developer

Visualize data in QuickSight

Task	Description	Skills required
Set up Athena as a data source in QuickSight.	1. Open the QuickSight console. 2. Choose **Datasets**, **New dataset**. 3. Choose Athena as a data source. 4. Choose the database that includes the view that you created. 5. Choose the view that you want to create a dataset for.	Systems administrator

Task	Description	Skills required
	6. On the **Finish data set creation** page, choose **Directly query your data**. 7. Choose **Visualize**.	
Visualize data in QuickSight.	1. After you visualize the dataset, choose the visuals from the left pane, and choose fields for the dataset. For more informati on, see the tutorial in the QuickSight documentation. 2. Save the changes to the analysis. 3. Choose **Publish dashboard** to publish the visuals that you created.	Data analyst

Automate data ingestion from AWS Data Exchange into Amazon S3

Adnan Alvee and Manikanta Gona, Amazon Web Services

Summary

This pattern provides an AWS CloudFormation template that enables you to automatically ingest data from AWS Data Exchange into your data lake in Amazon Simple Storage Service (Amazon S3).

AWS Data Exchange is a service that makes it easy to securely exchange file-based data sets in the AWS Cloud. AWS Data Exchange data sets are subscription-based. As a subscriber, you can also access data set revisions as providers publish new data.

The AWS CloudFormation template creates an event in Amazon CloudWatch Events and an AWS Lambda function. The event watches for any updates to the data set you have subscribed to. If there is an update, CloudWatch initiates a Lambda function, which copies the data over to the S3 bucket you specify. When the data has been copied successfully, Lambda sends you an Amazon Simple Notification Service (Amazon SNS) notification.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Subscription to a data set in AWS Data Exchange

Limitations

- The AWS CloudFormation template must be deployed separately for each subscribed data set in AWS Data Exchange.

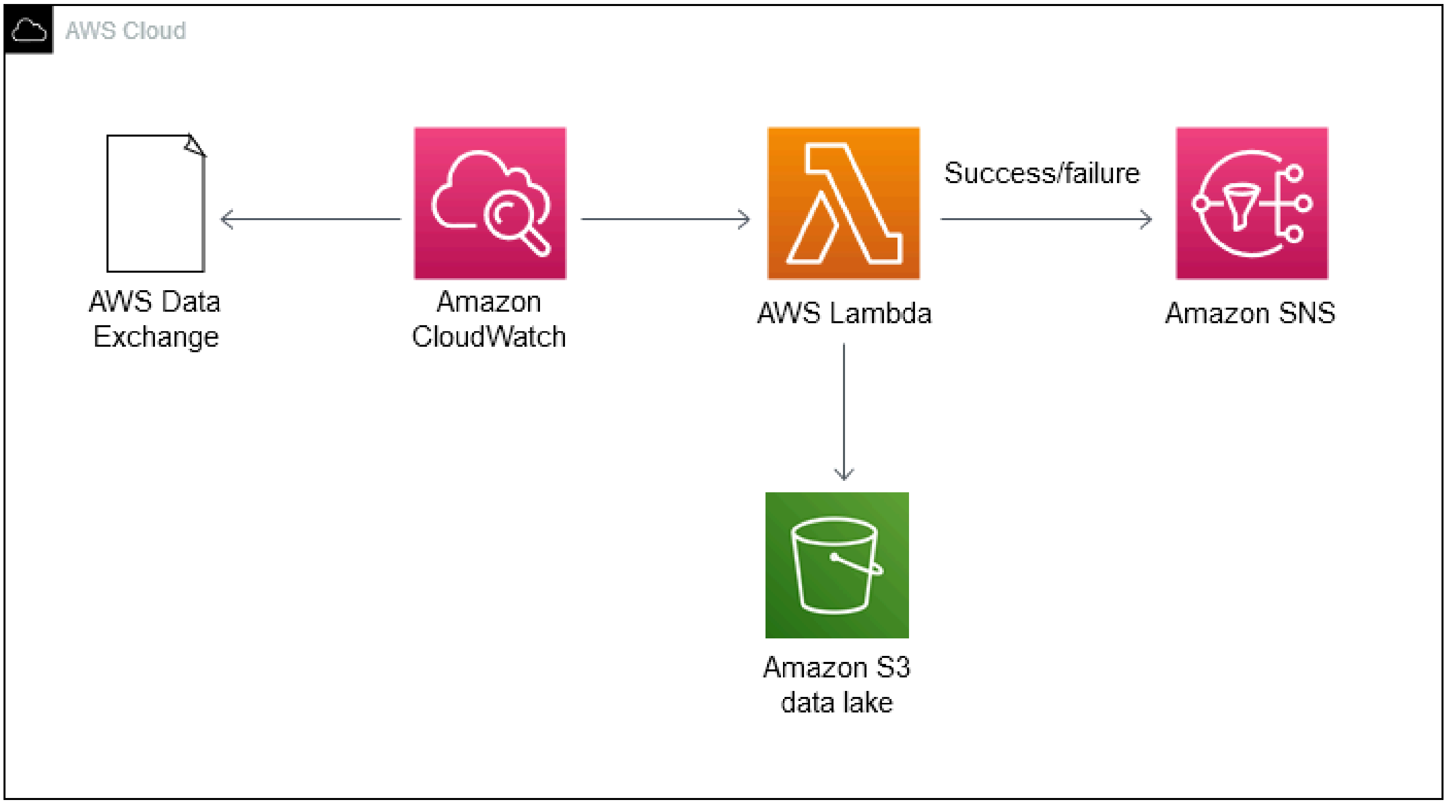
Architecture

Target technology stack

- AWS Lambda
- Amazon S3

- AWS Data Exchange
- Amazon CloudWatch
- Amazon SNS

Target architecture



Automation and scale

You can use the AWS CloudFormation template multiple times for the data sets you want to ingest into the data lake.

Tools

- AWS Data Exchange makes it easy for AWS customers to securely exchange file-based data sets in the AWS Cloud. As a subscriber, you can find and subscribe to hundreds of products from qualified data providers. Then, you can quickly download the data set or copy it to Amazon S3 for use across a variety of AWS analytics and machine learning services. Anyone with an AWS account can be an AWS Data Exchange subscriber.
- AWS Lambda lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per

second. You pay only for the compute time you consume; there is no charge when your code isn't running. With Lambda, you can run code for virtually any type of application or backend service with zero administration. Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging.

- Amazon S3 provides storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using **cron** or **rate** expressions.
- Amazon Simple Notification Service (Amazon SNS) enables applications, end-users, and devices to instantly send and receive notifications from the cloud. Amazon SNS provides topics (communication channels) for high-throughput, push-based, many-to-many messaging. Using Amazon SNS topics, publishers can distribute messages to a large number of subscribers for parallel processing, including Amazon Simple Queue Service (Amazon SQS) queues, Lambda functions, and HTTP/S webhooks. You can also use Amazon SNS to send notifications to end users using mobile push, SMS, and email.

Epics

Subscribe to a data set

Task	Description	Skills required
Subscribe to a data set.	In the AWS Data Exchange console, subscribe to a dataset. For instructions, see Subscribing to data products on AWS Data Exchange in the AWS documentation.	General AWS

Task	Description	Skills required
Note the data set attributes.	Note the AWS Region, ID, and revision ID for the data set. You will need this for the AWS CloudFormation template in the next step.	General AWS

Deploy the AWS CloudFormation template

Task	Description	Skills required
Create an S3 bucket and folder.	If you already have a data lake in Amazon S3, create a folder to store the data to ingest from AWS Data Exchange. If you are deploying the template for testing purposes, create a new S3 bucket, and note the bucket name and folder prefix for the next step.	General AWS
Deploy the AWS CloudForm ation template.	Deploy the AWS CloudForm ation template that's provided as an attachment to this pattern. For instructions, see the AWS CloudFormation documentation. Configure the following parameters to correspond to your AWS account, data set, and S3 bucket settings: **Dataset AWS Region**, **Dataset ID**, **Revision ID**, **S3 Bucket Name** (for example, `DOC-`	General AWS

Task	Description	Skills required
	`EXAMPLE-BUCKET`), **Folder Prefix** (for example, `myfolder/`), and **Email for SNS Notification**. You can set the **Dataset Name** parameter to any name. When you deploy the template, it runs a Lambda function to automatically ingest the first set of data available in the data set. Subsequent ingestion then takes place automatically, as new data arrives in the data set.

Automate encryption enforcement in AWS Glue using an AWS CloudFormation template

Diogo Guedes, Amazon Web Services

Summary

This pattern shows you how to set up and automate encryption enforcement in AWS Glue by using an AWS CloudFormation template. The template creates all the required configurations and resources for enforcing encryption. These resources include an initial configuration, a preventive control created by an Amazon EventBridge rule, and an AWS Lambda function.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Permissions to deploy the CloudFormation template and its resources

Limitations

This security control is regional. You must deploy the security control in each AWS Region where you want to set up encryption enforcement in AWS Glue.

Architecture

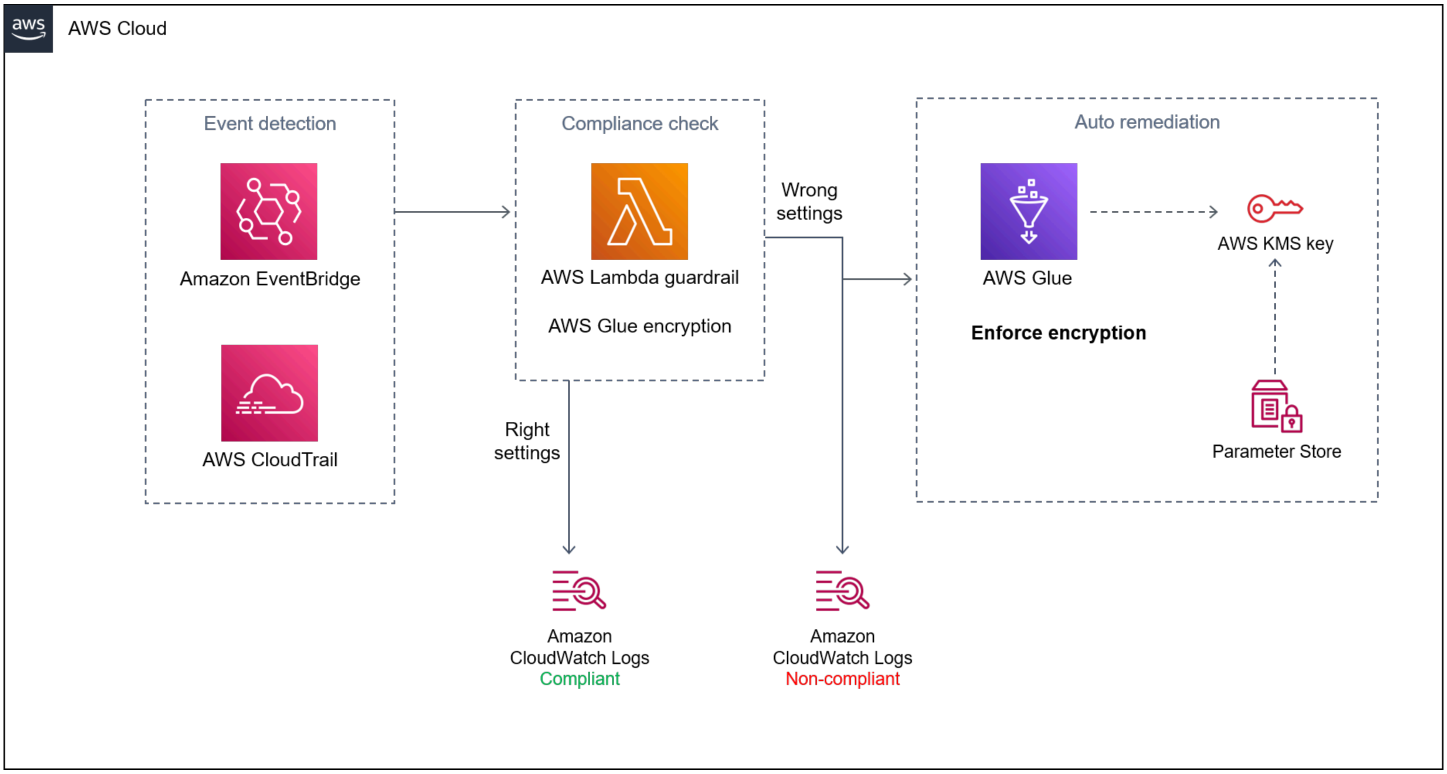
Target technology stack

- Amazon CloudWatch Logs (from AWS Lambda)
- Amazon EventBridge rule
- AWS CloudFormation stack
- AWS CloudTrail
- AWS Identity and Access Management (IAM) managed role and policy
- AWS Key Management Service (AWS KMS)
- AWS KMS alias

- AWS Lambda function
- AWS Systems Manager Parameter Store

Target architecture

The following diagram shows how to automate encryption enforcement in AWS Glue.



The diagram shows the following workflow:

1. A CloudFormation template creates all the resources, including the initial configuration and detective control for encryption enforcement in AWS Glue.
2. An EventBridge rule detects a state change in the encryption configuration.
3. A Lambda function is invoked for evaluation and logging through CloudWatch Logs. For non-compliant detection, the Parameter Store is recovered with an Amazon Resource Name (ARN) for an AWS KMS key. The service is remediated to compliant status with encryption enabled.

Automation and scale

If you're using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts where you want to enable encryption enforcement in AWS Glue.

Tools

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CloudTrail helps you enable operational and risk auditing, governance, and compliance of your AWS account.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

Code

The code for this pattern is available in the GitHub aws-custom-guardrail-event-driven repository.

Best practices

AWS Glue supports data encryption at rest for authoring jobs in AWS Glue and developing scripts using development endpoints.

Consider the following best practices:

- Configure ETL jobs and development endpoints to use AWS KMS keys to write encrypted data at rest.

- Encrypt the metadata stored in the AWS Glue Data Catalog by using keys that you manage through AWS KMS.
- Use AWS KMS keys to encrypt job bookmarks and the logs generated by crawlers and ETL jobs.

Epics

Launch the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	Download the `aws-custom-guardrail-event-driven.yaml` template from the GitHub repository, and then deploy the template. The `CREATE_COMPLETE` status indicates that your template was successfully deployed. **Note** The template requires no input parameters.	Cloud architect

Verify the encryption settings in AWS Glue

Task	Description	Skills required
Check the AWS KMS key configurations.	1. Sign in to the AWS Management Console and then open the AWS Glue console.	Cloud architect

Task	Description	Skills required
	2. In the navigation pane, under **Data Catalog**, choose **Catalog settings**. 3. Verify that the **Metadata encryption** and **Encrypt connection passwords** settings are flagged and configured to use `KMSKeyGlue` .	

Test the encryption enforcement

Task	Description	Skills required
Identify the encryption setting in CloudFormation.	1. Sign in to the AWS Management Console and then open the [CloudFormation console](https://console.aws.amazon.com/cloudformation/). 2. In the navigation pane, choose **Stacks**, and then choose your stack. 3. Choose the **Resources** tab. 4. In the **Resources** table, find the encryption setting by **Logical ID**.	Cloud architect
Switch the provisioned infrastructure to an uncompliant state.	1. Sign in to the AWS Management Console and then open the [AWS Glue console](https://console.aws.amazon.com/glue/). 2. In the navigation pane, under **Data Catalog**, choose **Catalog settings**.	Cloud architect

Task	Description	Skills required
	3. Clear the **Metadata encryption** check box. 4. Clear the **Encrypt connection passwords** check box. 5. Choose **Save**. 6. Refresh the AWS Glue console. The guardrail detects the uncompliant state in AWS Glue after you clear the check boxes, and then enforces compliance by automatically remediating the encryption misconfiguration. As a result, the encryption check boxes should again be selected after you refresh the page.

Build a data pipeline to ingest, transform, and analyze Google Analytics data using the AWS DataOps Development Kit

Anton Kukushkin and Rudy Puig, Amazon Web Services

Summary

This pattern describes how to build a data pipeline to ingest, transform, and analyze Google Analytics data by using the AWS DataOps Development Kit (AWS DDK) and other AWS services. The AWS DDK is an open-source development framework that helps you build data workflows and modern data architecture on AWS. One of the main objectives of the AWS DDK is to save you the time and effort that's typically devoted to labor-intensive data pipeline tasks, such as orchestrating pipelines, building infrastructure, and creating the DevOps behind that infrastructure. You can offload these labor-intensive tasks to AWS DDK so that you can focus on writing code and other high-value activities.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon AppFlow connector for Google Analytics, configured
- Python and pip (Python's package manager)
- Git, installed and configured
- AWS Command Line Interface (AWS CLI), installed and configured
- AWS Cloud Development Kit (AWS CDK), installed

Product versions

- Python 3.7 or later
- pip 9.0.3 or later

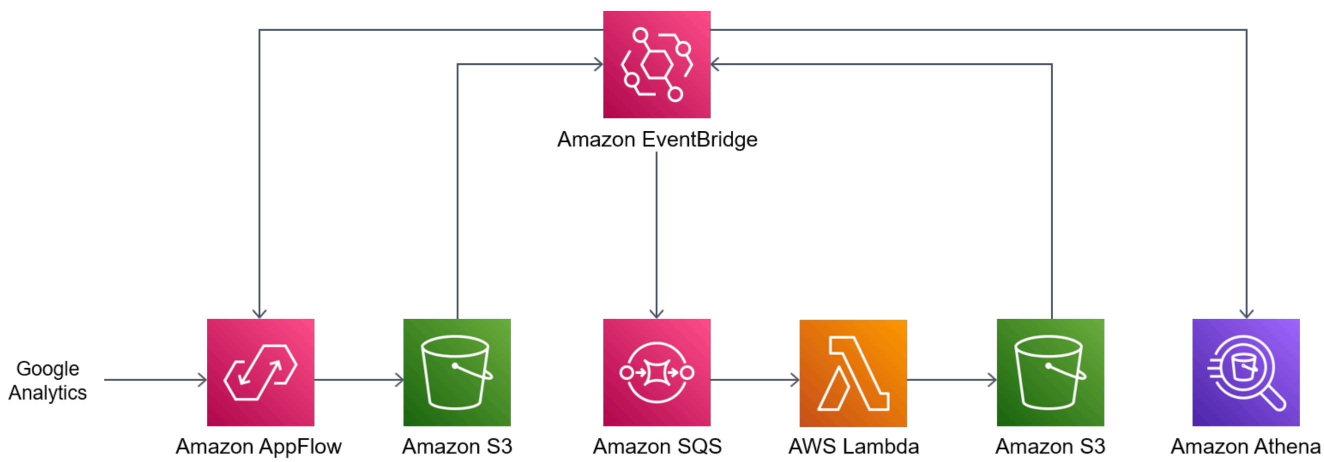
Architecture

Technology stack

- Amazon AppFlow
- Amazon Athena
- Amazon CloudWatch
- Amazon EventBridge
- Amazon Simple Storage Service (Amazon S3)
- Amazon Simple Queue Service (Amazon SQS)
- AWS DataOps Development Kit (AWS DDK)
- AWS Lambda

Target architecture

The following diagram shows the event-driven process that ingests, transforms, and analyzes Google Analytics data.



The diagram shows the following workflow:

1. An Amazon CloudWatch scheduled event rule invokes Amazon AppFlow.
2. Amazon AppFlow ingests Google Analytics data into an S3 bucket.
3. After the data is ingested by the S3 bucket, event notifications in EventBridge are generated, captured by a CloudWatch Events rule, and then put into an Amazon SQS queue.
4. A Lambda function consumes events from the Amazon SQS queue, reads the respective S3 objects, transforms the objects to Apache Parquet format, writes the transformed objects to the S3 bucket, and then creates or updates the AWS Glue Data Catalog table definition.
5. An Athena query runs against the table.

Tools

AWS tools

- Amazon AppFlow is a fully-managed integration service that enables you to securely exchange data between software as a service (SaaS) applications.
- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Cloud Development Kit (AWS CDK) is a framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- AWS DataOps Development Kit (AWS DDK) is an open-source development framework to help you build data workflows and modern data architecture on AWS.

Code

The code for this pattern is available in the GitHub AWS DataOps Development Kit (AWS DDK) and Analyzing Google Analytics data with Amazon AppFlow, Amazon Athena, and AWS DataOps Development Kit repositories.

Epics

Prepare the environment

Task	Description	Skills required
Clone the source code.	To clone the source code, run the following command: `git clone https://github.com/aws-samples/aws-ddk-examples.git`	DevOps engineer
Create a virtual environment.	Navigate to the source code directory, and then run the following command to create a virtual environment: `cd google-analytics-data-using-appflow/python && python3 -m venv .venv`	DevOps engineer
Install the dependencies.	To activate the virtual environment and install the dependencies, run the following command: `source .venv/bin/activate && pip install -r requirements.txt`	DevOps engineer

Deploy the application that uses your data pipeline

Task	Description	Skills required
Bootstrap the environment.	1. Confirm that the AWS CLI is set up with valid credentials for your AWS account. For more information, see [Using named profiles](#) in the AWS CLI documentation. 2. Run the `cdk bootstrap --profile [AWS_PROFILE]` command.	DevOps engineer
Deploy the data.	To deploy the data pipeline, run the `cdk deploy --profile [AWS_PROFILE]` command.	DevOps engineer

Test the deployment

Task	Description	Skills required
Validate stack status.	1. Open the [AWS CloudFormation console](#). 2. On the **Stacks** page, confirm that the status of the stack `DdkAppflowAthenaStack` is `CREATE_COMPLETE`.	DevOps engineer

Troubleshooting

Issue	Solution
Deployment fails during the creation of an `AWS::AppFlow::Flow` resource and you receive the following error: `Connector Profile with name ga-connection does not exist`	Confirm that you created an Amazon AppFlow connector for Google Analytics and named it `ga-connection`. For instructions, see Google Analytics in the Amazon AppFlow documentation.

Related resources

- AWS DataOps Development Kit (AWS DDK) (GitHub)
- AWS DDK Examples (GitHub)

Additional information

AWS DDK data pipelines are composed of one or many stages. In the following code examples, you use `AppFlowIngestionStage` to ingest data from Google Analytics, `SqsToLambdaStage` to handle data transformation, and `AthenaSQLStage` to run the Athena query.

First, the data transformation and ingestion stages are created, as the following code example shows:

```
        appflow_stage = AppFlowIngestionStage(
            self,
            id="appflow-stage",
            flow_name=flow.flow_name,
        )
        sqs_lambda_stage = SqsToLambdaStage(
            self,
            id="lambda-stage",
            lambda_function_props={
                "code": Code.from_asset("./ddk_app/lambda_handlers"),
                "handler": "handler.lambda_handler",
                "layers": [
                    LayerVersion.from_layer_version_arn(
```

```
                         self,
                         id="layer",
                         layer_version_arn=f"arn:aws:lambda:
{self.region}:336392948345:layer:AWSDataWrangler-Python39:1",
                     )
                 ],
                 "runtime": Runtime.PYTHON_3_9,
             },
         )
         # Grant lambda function S3 read & write permissions
         bucket.grant_read_write(sqs_lambda_stage.function)
         # Grant Glue database & table permissions
         sqs_lambda_stage.function.add_to_role_policy(
             self._get_glue_db_iam_policy(database_name=database.database_name)
         )
         athena_stage = AthenaSQLStage(
             self,
             id="athena-sql",
             query_string=[
                 (
                     "SELECT year, month, day, device, count(user_count) as cnt "
                     f"FROM {database.database_name}.ga_sample "
                     "GROUP BY year, month, day, device "
                     "ORDER BY cnt DESC "
                     "LIMIT 10; "
                 )
             ],
             output_location=Location(
                 bucket_name=bucket.bucket_name, object_key="query-results/"
             ),
             additional_role_policy_statements=[
                 self._get_glue_db_iam_policy(database_name=database.database_name)
             ],
         )
```

Next, the `DataPipeline` construct is used to "wire" the stages together by using EventBridge rules, as the following code example shows:

```
         (
             DataPipeline(self, id="ingestion-pipeline")
             .add_stage(
                 stage=appflow_stage,
                 override_rule=Rule(
```

```
                    self,
                    "schedule-rule",
                    schedule=Schedule.rate(Duration.hours(1)),
                    targets=appflow_stage.targets,
                ),
            )
            .add_stage(
                stage=sqs_lambda_stage,
                # By default, AppFlowIngestionStage stage emits an event after the flow
 run finishes successfully
                # Override rule below changes that behavior to call the the stage when
 data lands in the bucket instead
                override_rule=Rule(
                    self,
                    "s3-object-created-rule",
                    event_pattern=EventPattern(
                        source=["aws.s3"],
                        detail={
                            "bucket": {"name": [bucket.bucket_name]},
                            "object": {"key": [{"prefix": "ga-data"}]},
                        },
                        detail_type=["Object Created"],
                    ),
                    targets=sqs_lambda_stage.targets,
                ),
            )
            .add_stage(stage=athena_stage)
        )
```

For more code examples, see the GitHub Analyzing Google Analytics data with Amazon AppFlow, Amazon Athena, and AWS DataOps Development Kit repository.

Build a video processing pipeline by using Amazon Kinesis Video Streams and AWS Fargate

Piotr Chotkowski and Pushparaju Thangavel, Amazon Web Services

Summary

This pattern demonstrates how to use Amazon Kinesis Video Streams and AWS Fargate to extract frames from a video stream and store them as image files for further processing in Amazon Simple Storage Service (Amazon S3).

The pattern provides a sample application in the form of a Java Maven project. This application defines the AWS infrastructure by using the AWS Cloud Development Kit (AWS CDK). Both the frame processing logic and the infrastructure definitions are written in the Java programming language. You can use this sample application as a basis for developing your own real-time video processing pipeline or to build the video preprocessing step of a machine learning pipeline.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Java SE Development Kit (JDK) 11, installed
- Apache Maven, installed
- AWS Cloud Development Kit (AWS CDK), installed
- AWS Command Line Interface (AWS CLI) version 2, installed
- Docker (required for building Docker images to use in AWS Fargate task definitions), installed

Limitations

This pattern is intended as a proof of concept, or as a basis for further development. It should not be used in its current form in production deployments.

Product versions

- This pattern was tested with the AWS CDK version 1.77.0 (see AWS CDK versions)

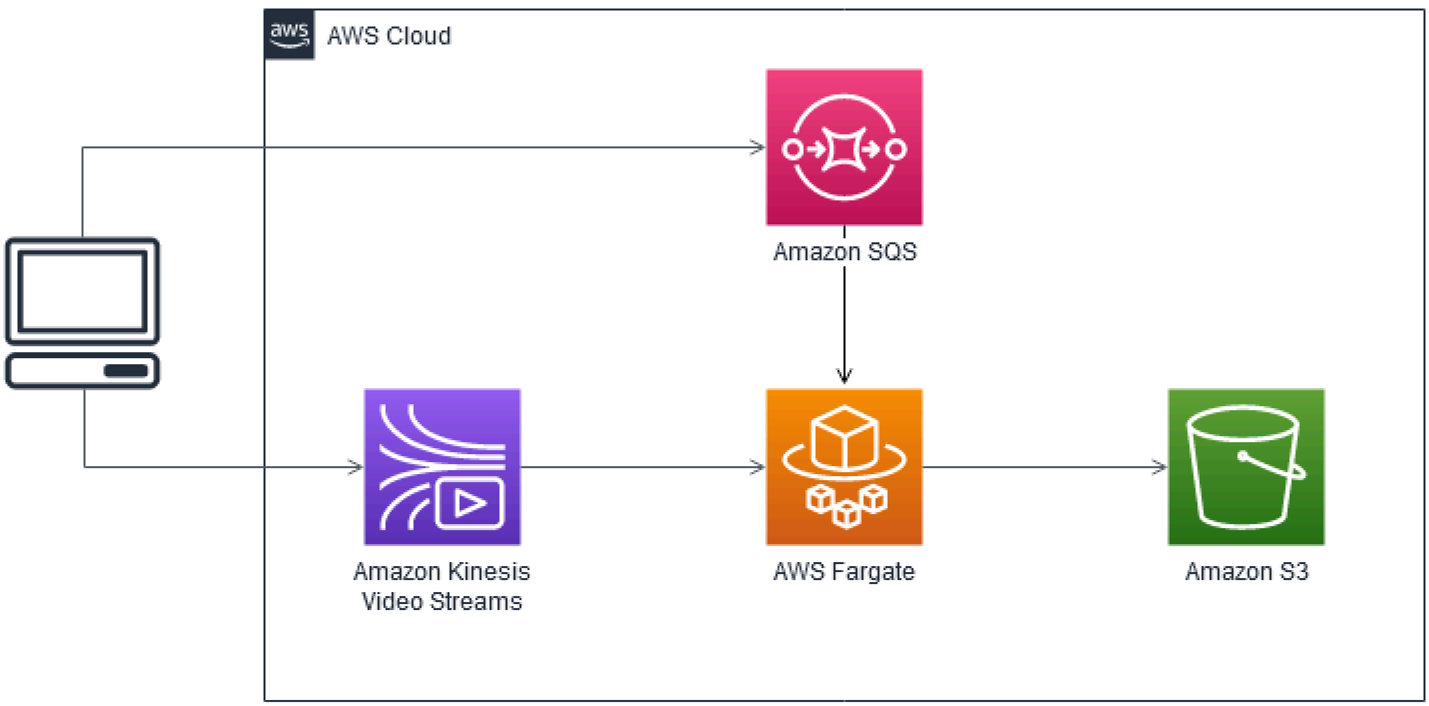
- JDK 11
- AWS CLI version 2

Architecture

Target technology stack

- Amazon Kinesis Video Streams
- AWS Fargate task
- Amazon Simple Queue Service (Amazon SQS) queue
- Amazon S3 bucket

Target architecture



The user creates a Kinesis video stream, uploads a video, and sends a JSON message that contains details about the input Kinesis video stream and the output S3 bucket to an SQS queue. AWS Fargate, which is running the main application in a container, pulls the message from the SQS queue and starts extracting frames. Each frame is saved in an image file and stored in the target S3 bucket.

Automation and scale

The sample application can scale both horizontally and vertically within a single AWS Region. Horizontal scaling can be achieved by increasing the number of deployed AWS Fargate tasks that read from the SQS queue. Vertical scaling can be achieved by increasing the number of frame-splitting and image-publishing threads in the application. These settings are passed as environment variables to the application in the definition of the QueueProcessingFargateService resource in the AWS CDK. Due to the nature of AWS CDK stack deployment, you can deploy this application in multiple AWS Regions and accounts with no additional effort.

Tools

Tools

- AWS CDK is a software development framework for defining your cloud infrastructure and resources by using programming languages such as TypeScript, JavaScript, Python, Java, and C#/.Net.
- Amazon Kinesis Video Streams is a fully managed AWS service that you can use to stream live video from devices to the AWS Cloud, or build applications for real-time video processing or batch-oriented video analytics.
- AWS Fargate is a serverless compute engine for containers. Fargate removes the need to provision and manage servers, and lets you focus on developing your applications.
- Amazon S3 is an object storage service that offers scalability, data availability, security, and performance.
- Amazon SQS is a fully managed message queuing service that enables you to decouple and scale microservices, distributed systems, and serverless applications.

Code

- A .zip file of the sample application project (`frame-splitter-code.zip`) is attached.

Epics

Deploy the infrastructure

Task	Description	Skills required
Start the Docker daemon.	Start the Docker daemon on your local system. The AWS	Developer, DevOps engineer

Task	Description	Skills required
	CDK uses Docker to build the image that is used in the AWS Fargate task. You must run Docker before you proceed to the next step.	
Build the project.	Download the `frame-splitter-code` sample application (attached) and extract its contents into a folder on your local machine. Before you can deploy the infrastructure, you have to build the [Java Maven](https://maven.apache.org/) project. At a command prompt, navigate to the root directory of the project, and build the project by running the command: `mvn clean install`	Developer, DevOps engineer

Task	Description	Skills required
Bootstrap the AWS CDK.	(First-time AWS CDK users only) If this is the first time you're using the AWS CDK, you might have to bootstrap the environment by running the AWS CLI command: `cdk bootstrap --profile "$AWS_PROFILE_NAME"` where `$AWS_PROFILE_NAME` holds the name of the AWS profile from your AWS credentials. Or, you can remove this parameter to use the default profile. For more information, see the AWS CDK documentation.	Developer, DevOps engineer

Task	Description	Skills required
Deploy the AWS CDK stack.	In this step, you create the required infrastructure resources (SQS queue, S3 bucket, AWS Fargate task definition) in your AWS account, build the Docker image that is required for the AWS Fargate task, and deploy the application. At a command prompt, navigate to the root directory of the project, and run the command: `cdk deploy --profile "$AWS_PROFILE_NAME" --all` where `$AWS_PROFILE_NAME` holds the name of the AWS profile from your AWS credentials. Or, you can remove this parameter to use the default profile. Confirm the deployment. Note the **QueueUrl** and **Bucket** values from the CDK deployment output; you will need these in later steps. The AWS CDK creates the assets, uploads them to your AWS account, and creates all infrastructure resources. You can observe the resource creation process in the [AWS CloudFormation](https://console.aws.amazon.com/cloudformation)	Developer, DevOps engineer

Task	Description	Skills required
	console. For more information, see the AWS CloudFormation documentation and the AWS CDK documentation.	

Task	Description	Skills required
Create a video stream.	In this step, you create a Kinesis video stream that will serve as an input stream for video processing. Make sure that you have the AWS CLI installed and configured. In the AWS CLI, run: `aws kinesisvideo --profile "$AWS_PROFILE_NAME" create-stream --stream-name "$STREAM_NAME" --data-retention-in-hours "24"` where `$AWS_PROFILE_NAME` holds the name of the AWS profile from your AWS credentials (or remove this parameter to use the default profile) and `$STREAM_NAME` is any valid stream name. Alternatively, you can create a video stream by using the Kinesis console by following the steps in the [Kinesis Video Streams documentation](). Note the AWS Resource Name (ARN) of the created stream; you will need it later.	Developer, DevOps engineer

Run an example

Task	Description	Skills required
Upload the video to the stream.	In the project folder for the sample `frame-splitter-code` application, open the `ProcessingTaskTest.java` file in the `src/test/java/amazon/awscdk/examples/splitter` folder. Replace the `profileName` and `streamName` variables with the values you used in the previous steps. To upload the example video to the Kinesis video stream you created in the previous step, run: `amazon.awscdk.examples.splitter.ProcessingTaskTest#testExample test` Alternatively, you can upload your video by using one of the methods described in the [Kinesis Video Streams documentation].	Developer, DevOps engineer
Initiate video processing.	Now that you have uploaded a video to the Kinesis video stream, you can start processing it. To initiate the processing logic, you have to send a message with	Developer, DevOps engineer

Task	Description	Skills required

	details to the SQS queue that the AWS CDK created during deployment. To send a message by using the AWS CLI, run:
	`aws sqs --profile "$AWS_PROFILE_NAME" send-message --queue-url QUEUE_URL --message-body MESSAGE`
	where `$AWS_PROFILE_NAME` holds the name of the AWS profile from your AWS credentials (remove this parameter to use the default profile), `QUEUE_URL` is the **QueueUrl** value from the AWS CDK output, and `MESSAGE` is a JSON string in the following format:
	`{ "streamARN": "STREAM_ARN", "bucket": "BUCKET_NAME", "s3Directory": "test-output" }`
	where `STREAM_ARN` is the ARN of of the video stream you created in an earlier step and `BUCKET_NAME` is the **Bucket** value from the AWS CDK output.	

Task	Description	Skills required
	Sending this message initiates video processing. Alternatively, you can send a message by using the Amazon SQS console, as described in the Amazon SQS documentation.	
View images of the video frames.	You can see the resulting images in the S3 output bucket `s3://BUCKET_NAME/test-output` where `BUCKET_NAME` is the **Bucket** value from the AWS CDK output.	Developer, DevOps engineer

Related resources

Additional information

Choosing an IDE

We recommend that you use your favorite Java IDE to build and explore this project.

Cleaning up

After you finish running this example, remove all deployed resources to avoid incurring additional AWS infrastructure costs.

To remove the infrastructure and the video stream, use these two commands in the AWS CLI:

```
cdk destroy --profile "$AWS_PROFILE_NAME" --all
```

```
aws kinesisvideo --profile "$AWS_PROFILE_NAME" delete-stream --stream-arn "$STREAM_ARN"
```

Alternatively, you can remove the resources manually by using the AWS CloudFormation console to remove the AWS CloudFormation stack, and the Kinesis console to remove the Kinesis video stream. Note that `cdk destroy` doesn't remove the output S3 bucket or the images in Amazon Elastic Container Registry (Amazon ECR) repositories (`aws-cdk/assets`). You have to remove them manually.

Build an ETL service pipeline to load data incrementally from Amazon S3 to Amazon Redshift using AWS Glue

Rohan Jamadagni and Arunabha Datta, Amazon Web Services

Summary

This pattern provides guidance on how to configure Amazon Simple Storage Service (Amazon S3) for optimal data lake performance, and then load incremental data changes from Amazon S3 into Amazon Redshift by using AWS Glue, performing extract, transform, and load (ETL) operations.

The source files in Amazon S3 can have different formats, including comma-separated values (CSV), XML, and JSON files. This pattern describes how you can use AWS Glue to convert the source files into a cost-optimized and performance-optimized format like Apache Parquet. You can query Parquet files directly from Amazon Athena and Amazon Redshift Spectrum. You can also load Parquet files into Amazon Redshift, aggregate them, and share the aggregated data with consumers, or visualize the data by using Amazon QuickSight.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An S3 source bucket that has the right privileges and contains CSV, XML, or JSON files.

Assumptions

- The CSV, XML, or JSON source files are already loaded into Amazon S3 and are accessible from the account where AWS Glue and Amazon Redshift are configured.
- Best practices for loading the files, splitting the files, compression, and using a manifest are followed, as discussed in the [Amazon Redshift documentation](https://docs.aws.amazon.com/redshift/latest/dg/t_Loading-data-from-S3.html).
- The source file structure is unaltered.
- The source system is able to ingest data into Amazon S3 by following the folder structure defined in Amazon S3.
- The Amazon Redshift cluster spans a single Availability Zone. (This architecture is appropriate because AWS Lambda, AWS Glue, and Amazon Athena are serverless.) For high availability, cluster snapshots are taken at a regular frequency.

Limitations

- The file formats are limited to those that are currently supported by AWS Glue.
- Real-time downstream reporting isn't supported.

Architecture

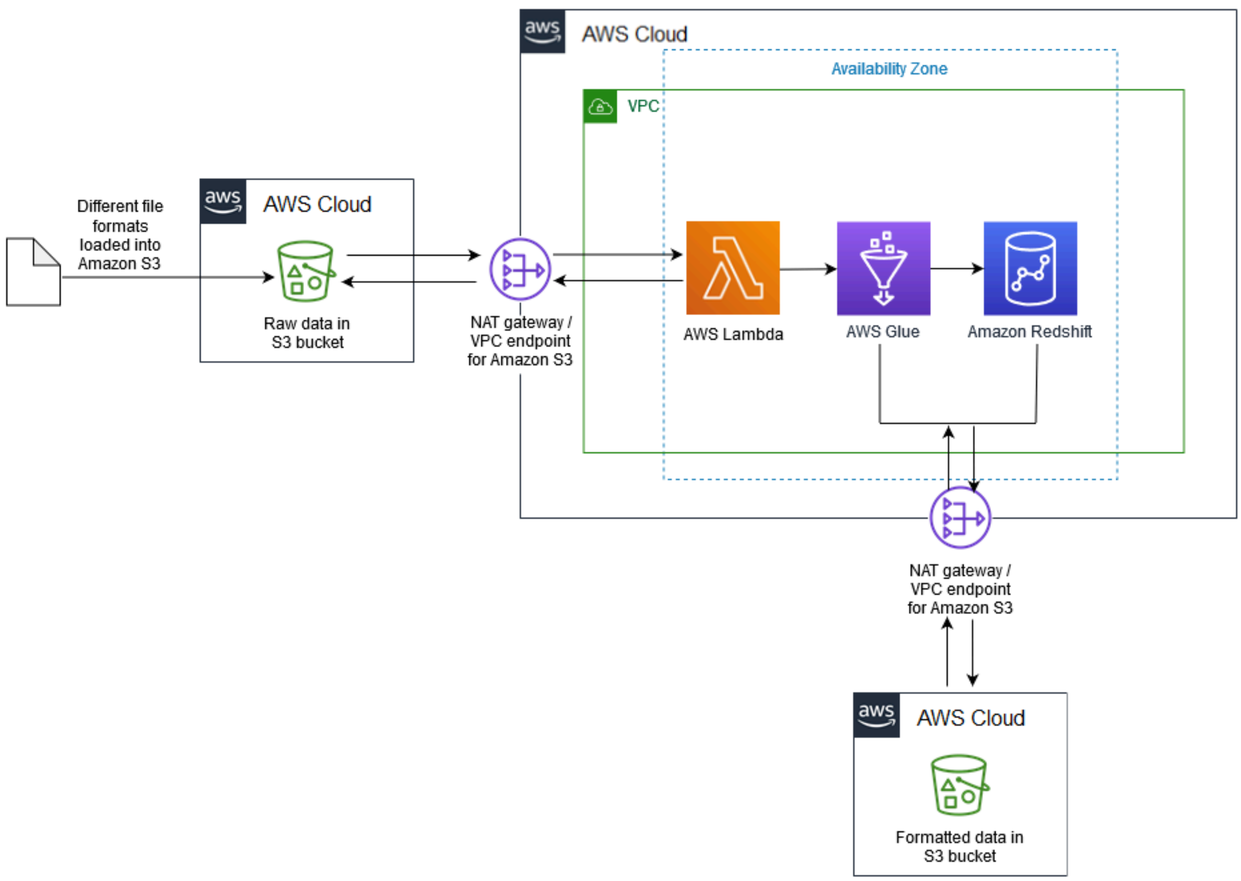
Source technology stack

- S3 bucket with CSV, XML, or JSON files

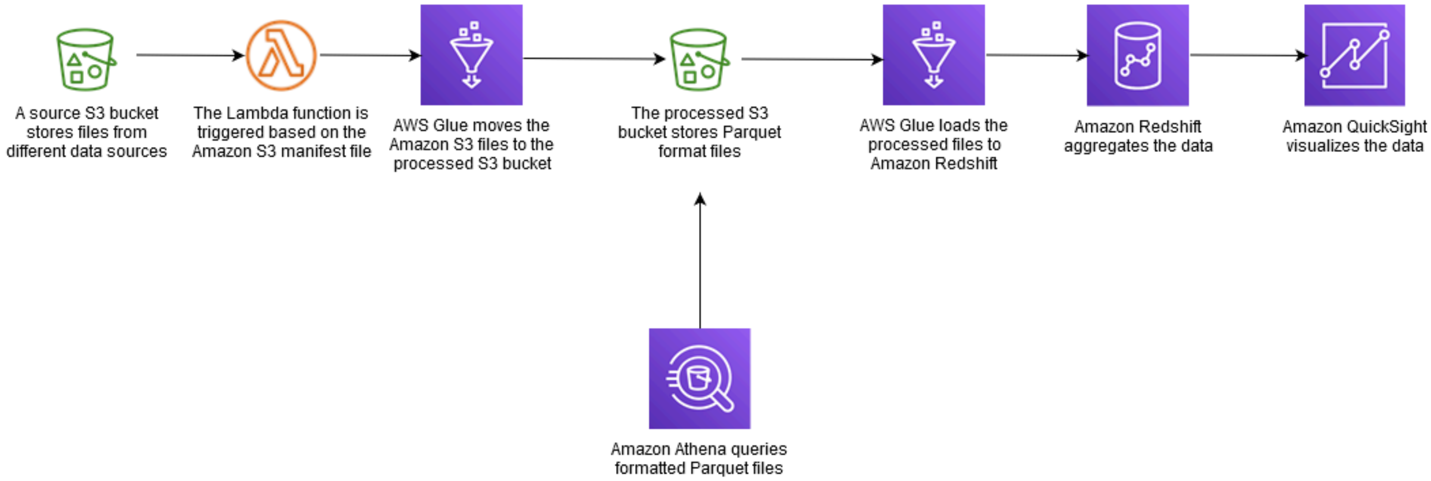
Target technology stack

- S3 data lake (with partitioned Parquet file storage)
- Amazon Redshift

Target architecture



Data flow



Tools

- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- AWS Lambda – AWS Lambda lets you run code without provisioning or managing servers. AWS Lambda is an event-driven service; you can set up your code to automatically initiate from other AWS services.
- Amazon Redshift – Amazon Redshift is a fully managed, petabyte-scale data warehouse service. With Amazon Redshift, you can query petabytes of structured and semi-structured data across your data warehouse and your data lake using standard SQL.
- AWS Glue – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics. AWS Glue discovers your data and stores the associated metadata (for example, table definitions and schema) in the AWS Glue Data Catalog. Your cataloged data is immediately searchable, can be queried, and is available for ETL.
- AWS Secrets Manager – AWS Secrets Manager facilitates protection and central management of secrets needed for application or service access. The service stores database credentials, API keys, and other secrets, and eliminates the need to hardcode sensitive information in plaintext format. Secrets Manager also offers key rotation to meet security and compliance needs. It has built-in integration for Amazon Redshift, Amazon Relational Database Service (Amazon RDS), and Amazon DocumentDB. You can store and centrally manage secrets by using the Secrets Manager console, the command-line interface (CLI), or Secrets Manager API and SDKs.

- [Amazon Athena](#) – Amazon Athena is an interactive query service that makes it easy to analyze data that's stored in Amazon S3. Athena is serverless and integrated with AWS Glue, so it can directly query the data that's cataloged using AWS Glue. Athena is elastically scaled to deliver interactive query performance.

Epics

Create the S3 buckets and folder structure

Task	Description	Skills required
Analyze source systems for data structure and attributes.	Perform this task for each data source that contributes to the Amazon S3 data lake.	Data engineer
Define the partition and access strategy.	This strategy should be based on the frequency of data captures, delta processin g, and consumption needs. Make sure that S3 buckets are not open to the public and that access is controlle d by specific service role-based policies only. For more information, see the [Amazon S3 documentation](#).	Data engineer
Create separate S3 buckets for each data source type and a separate S3 bucket per source for the processed (Parquet) data.	Create a separate bucket for each source, and then create a folder structure that's based on the source system's data ingestion frequency ; for example, `s3://source-system-name/date/hour` . For the processed (converted to Parquet format) files, create a similar structure	Data engineer

Task	Description	Skills required
	; for example, `s3://source-processed-bucket/date/hour` . For more information about creating S3 buckets, see the [Amazon S3 documentation]().	

Create a data warehouse in Amazon Redshift

Task	Description	Skills required
Launch the Amazon Redshift cluster with the appropriate parameter groups and maintenance and backup strategy.	Use the Secrets Manager database secret for admin user credentials while creating the Amazon Redshift cluster. For information about creating and sizing an Amazon Redshift cluster, see the [Amazon Redshift documentation]() and the [Sizing Cloud Data Warehouses]() whitepaper.	Data engineer
Create and attach the IAM service role to the Amazon Redshift cluster.	The AWS Identity and Access Management (IAM) service role ensures access to Secrets Manager and the source S3 buckets. For more information, see the AWS documentation on [authorization]() and [adding a role]().	Data engineer
Create the database schema.	Follow Amazon Redshift best practices for table design. Based on the use case, choose	Data engineer

Task	Description	Skills required
	the appropriate sort and distribution keys, and the best possible compression encoding. For best practices, see the AWS documentation.	
Configure workload management.	Configure workload management (WLM) queues, short query acceleration (SQA), or concurrency scaling, depending on your requirements. For more information, see Implementing workload management in the Amazon Redshift documentation.	Data engineer

Create a secret in Secrets Manager

Task	Description	Skills required
Create a new secret to store the Amazon Redshift sign-in credentials in Secrets Manager.	This secret stores the credentials for the admin user as well as individual database service users. For instructions, see the Secrets Manager documentation. Choose **Amazon Redshift Cluster** as the secret type. Additionally, on the **Secret rotation** page, turn on the rotation. This will create the appropriate user in the Amazon Redshift cluster and will rotate the key secrets at defined intervals.	Data engineer

Task	Description	Skills required
Create an IAM policy to restrict Secrets Manager access.	Restrict Secrets Manager access to only Amazon Redshift administrators and AWS Glue.	Data engineer

Configure AWS Glue

Task	Description	Skills required
In the AWS Glue Data Catalog, add a connection for Amazon Redshift.	For instructions, see the [AWS Glue documentation].	Data engineer
Create and attach an IAM service role for AWS Glue to access Secrets Manager, Amazon Redshift, and S3 buckets.	For more information, see the [AWS Glue documentation].	Data engineer
Define the AWS Glue Data Catalog for the source.	This step involves creating a database and required tables in the AWS Glue Data Catalog. You can either use a crawler to catalog the tables in the AWS Glue database, or define them as Amazon Athena external tables. You can also access the external tables defined in Athena through the AWS Glue Data Catalog. See the AWS documentation for more information about [defining the Data Catalog] and	Data engineer

Task	Description	Skills required
	creating an external table in Athena.	
Create an AWS Glue job to process source data.	The AWS Glue job can be a Python shell or PySpark to standardize, deduplicate, and cleanse the source data files. To optimize performance and avoid having to query the entire S3 source bucket, partition the S3 bucket by date, broken down by year, month, day, and hour as a pushdown predicate for the AWS Glue job. For more information, see the AWS Glue documentation. Load the processed and transformed data to the processed S3 bucket partitions in Parquet format. You can query the Parquet files from Athena.	Data engineer
Create an AWS Glue job to load data into Amazon Redshift.	The AWS Glue job can be a Python shell or PySpark to load the data by upserting the data, followed by a complete refresh. For details, see the AWS Glue documentation and the *Additional information* section.	Data engineer

Task	Description	Skills required
(Optional) Schedule AWS Glue jobs by using triggers as necessary.	The incremental data load is primarily driven by an Amazon S3 event that causes an AWS Lambda function to call the AWS Glue job. Use AWS Glue trigger-based scheduling for any data loads that demand time-based instead of event-based scheduling.	Data engineer

Create a Lambda function

Task	Description	Skills required
Create and attach an IAM service-linked role for AWS Lambda to access S3 buckets and the AWS Glue job.	Create an IAM service-linked role for AWS Lambda with a policy to read Amazon S3 objects and buckets, and a policy to access the AWS Glue API to start an AWS Glue job. For more information, see the [Knowledge Center]().	Data engineer
Create a Lambda function to run the AWS Glue job based on the defined Amazon S3 event.	The Lambda function should be initiated by the creation of the Amazon S3 manifest file. The Lambda function should pass the Amazon S3 folder location (for example, source_bucket/year/month/date/hour) to the AWS Glue job as a parameter. The AWS Glue job will use this	Data engineer

Task	Description	Skills required
	parameter as a pushdown predicate to optimize file access and job processin g performance. For more information, see the AWS Glue documentation.	
Create an Amazon S3 PUT object event to detect object creation, and call the respective Lambda function.	The Amazon S3 PUT object event should be initiated only by the creation of the manifest file. The manifest file controls the Lambda function and the AWS Glue job concurrency, and processes the load as a batch instead of processin g individual files that arrive in a specific partition of the S3 source bucket. For more information, see the Lambda documentation.	Data engineer

Additional information

Detailed approach for upsert and complete refresh

Upsert: This is for datasets that require historical aggregation, depending on the business use case. Follow one of the approaches described in Updating and inserting new data (Amazon Redshift documentation) based on your business needs.

Complete refresh: This is for small datasets that don't need historical aggregations. Follow one of these approaches:

1. Truncate the Amazon Redshift table.
2. Load the current partition from the staging area

or:

1. Create a temporary table with current partition data.
2. Drop the target Amazon Redshift table.
3. Rename the temporary table to the target table.

Build an enterprise data mesh with Amazon DataZone, AWS CDK, and AWS CloudFormation

Dhrubajyoti Mukherjee, Ravi Kumar, Weizhou Sun, and Adjoa Taylor, Amazon Web Services

Summary

On Amazon Web Services (AWS), customers understand that data is the key to accelerating innovation and driving business value for their enterprise. To manage this massive data, you can adopt a decentralized architecture such as data mesh. A data mesh architecture facilitates product thinking, a mindset that takes customers, goals, and the market into account. Data mesh also helps to establish a federated governance model that provides fast, secure access to your data.

Strategies for building a data mesh-based enterprise solution on AWS discusses how you can use the Data Mesh Strategy Framework to formulate and implement a data mesh strategy for your organization. By using the Data Mesh Strategy Framework, you can optimize the organization of teams and their interactions to accelerate your data mesh journey.

This document provides guidance on how to build an enterprise data mesh with Amazon DataZone. Amazon DataZone is a data management service for cataloging, discovering, sharing, and governing data stored across AWS, on premises, and third-party sources. The pattern includes code artifacts that help you deploy the data mesh–based data solution infrastructure using AWS Cloud Development Kit (AWS CDK) and AWS CloudFormation. This pattern is intended for cloud architects and DevOps engineers.

For information about the objectives of this pattern and the solution scope, see the Additional information section.

Prerequisites and limitations

Prerequisites

- A minimum of two active AWS accounts: one for the central governance account and another for the member account
- AWS administrator credentials for the central governance account in your development environment
- AWS Command Line Interface (AWS CLI) installed to manage your AWS services from the command line

- Node.js and Node Package Manager (npm) installed to manage AWS CDK applications
- AWS CDK Toolkit installed globally in your development environment by using npm, to synthesize and deploy AWS CDK applications

```
npm install -g aws-cdk
```

- Python version 3.12 installed in your development environment
- TypeScript installed in your development environment or installed globally by using npm compiler:

```
npm install -g typescript
```

- Docker installed in your development environment
- A version control system such as Git to maintain the source code of the solution (recommended)
- An integrated development environment (IDE) or text editor with support for Python and TypeScript (strongly recommended)

Limitations

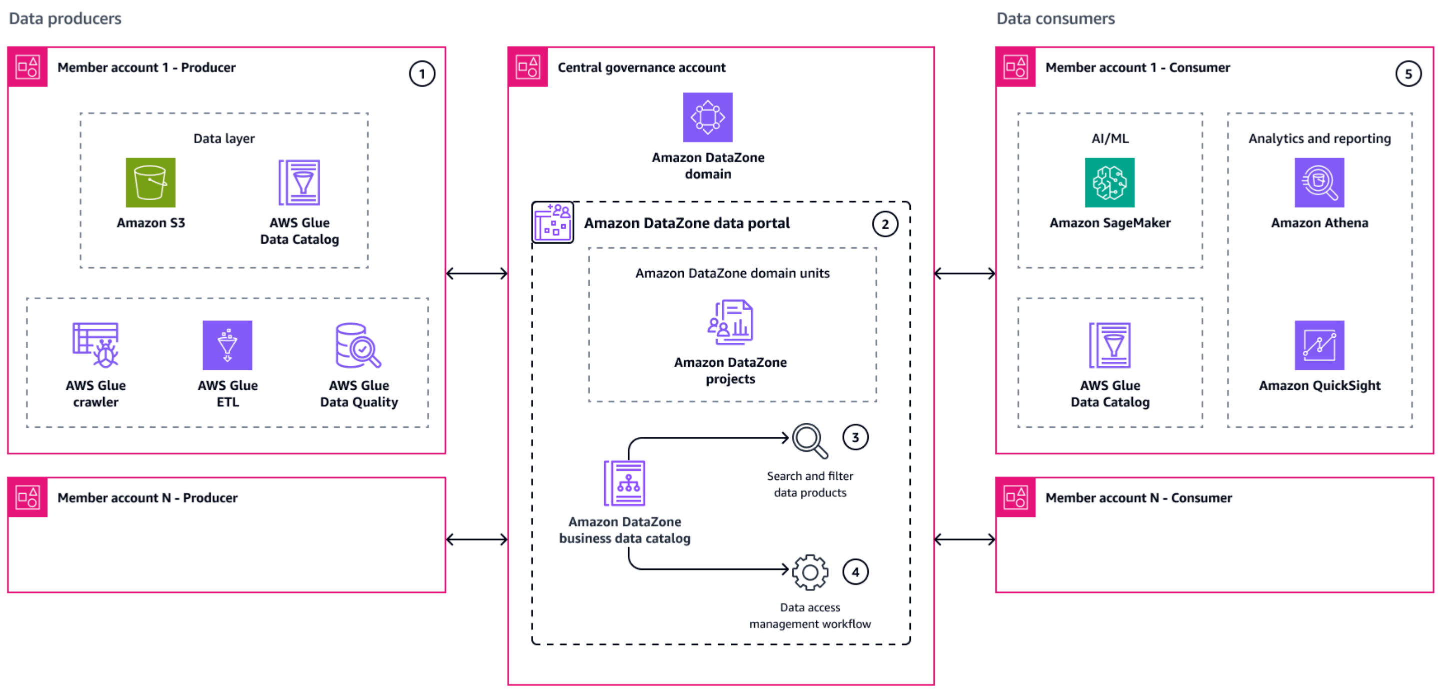
- The solution has been tested only on machines that are running Linux or macOS.
- In the current version, the solution doesn't support the integration of Amazon DataZone and AWS IAM Identity Center by default. However, you can configure it to support this integration.

Product versions

- Python version 3.12

Architecture

The following diagram shows a data mesh reference architecture. The architecture is based on Amazon DataZone and uses Amazon Simple Storage Service (Amazon S3) and AWS Glue Data Catalog as data sources. The AWS services that you use with Amazon DataZone in your data mesh implementation might differ, based on your organization's requirements.



1. In the producer accounts, raw data is either fit for consumption in its current form or it's transformed for consumption by using AWS Glue. The technical metadata for the data is stored in Amazon S3 and is evaluated using a AWS Glue data crawler. The data quality is measured by using AWS Glue Data Quality. The source database in the Data Catalog is registered as an asset in the Amazon DataZone catalog. The Amazon DataZone catalog is hosted in the central governance account using Amazon DataZone data source jobs.
2. The central governance account hosts the Amazon DataZone domain and the Amazon DataZone data portal. The AWS accounts of the data producers and consumers are associated with the Amazon DataZone domain. The Amazon DataZone projects of the data producers and consumers are organized under the corresponding Amazon DataZone domain units.
3. End users of the data assets log into the Amazon DataZone data portal by using their AWS Identity and Access Management (IAM) credentials or single sign-on (with integration through IAM Identity Center). They search, filter, and view asset information (for example, data quality information or business and technical metadata) in the Amazon DataZone data catalog.
4. After an end user finds the data asset that they want, they use the Amazon DataZone subscription feature to request access. The data owner on the producer team receives a notification and evaluates the subscription request in the Amazon DataZone data portal. The data owner approves or rejects the subscription request based on its validity.
5. After the subscription request is granted and fulfilled, the asset is accessed in the consumer account for the following activities:

- AI/ML model development by using Amazon SageMaker AI
- Analytics and reporting by using Amazon Athena and Amazon QuickSight

Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- Amazon DataZone is a data management service that helps you catalog, discover, share, and govern data stored across AWS, on premises, and in third-party sources.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- Amazon SageMaker AI is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code repository

The solution is available in the GitHub data-mesh-datazone-cdk-cloudformation repository.

Epics

Set up the environment

Task	Description	Skills required
Clone the repository.	To clone the repository, run the following command in your local development environment (Linux or macOS): `git clone https://github.com/aws-samples/data-mesh-datazone-cdk-cloudformation`	Cloud architect, DevOps engineer

Create the environment.	To create the Python virtual environment, run the following commands:
	`python3 -m venv .venv`
	`source .venv/bin/activate`
	`pip install -r requirements.txt`
		Cloud architect, DevOps engineer

Bootstrap the account.	To bootstrap the central governance account by using AWS CDK, run the following command: `cdk bootstrap aws://<GOVERNANCE_ACCOUNT_ID>/<AWS_REGION>`	Cloud architect, DevOps engineer

Task	Description	Skills required
	Sign in to the AWS Management Console, open the central governance account console, and get the Amazon Resource Name (ARN) of the AWS CDK execution role.	
Construct the `DzDataMeshMemberStackSet.yaml` file.	To construct the `DzDataMeshMemberStackSet.yaml` file, from the root directory of the repository, initiate the following bash script: `./lib/scripts/create_dz_data_mesh_member_stack_set.sh`	Cloud architect, DevOps engineer
Confirm template creation.	Ensure that the AWS CloudFormation template file is created at the `lib/cfn-templates/DzDataMeshMemberStackSet.yaml` location.	Cloud architect, DevOps engineer

Deploy resources in the central governance account

Task	Description	Skills required
Modify the configuration.	In the `config/Config.ts` file, modify the following parameters:	Cloud architect, DevOps engineer

Task	Description	Skills required

	`DZ_APPLICATION_NAME - Name of the application.`
	`DZ_STAGE_NAME - Name of the stage.`
	`DZ_DOMAIN_NAME - Name of the Amazon DataZone domain`
	`DZ_DOMAIN_DESCRIPTION - Description of the Amazon DataZone domain`
	`DZ_DOMAIN_TAG - Tag of the Amazon DataZone domain`
	`DZ_ADMIN_PROJECT_NAME - Name of the Amazon DataZone project for administrators`
	`DZ_ADMIN_PROJECT_DESCRIPTION - Description of the Amazon DataZone project for administrators`
	`CDK_EXEC_ROLE_ARN - ARN of the cdk execution role`
	`DZ_ADMIN_ROLE_ARN - ARN of the administrator role`
	
	Keep the remaining parameters empty.	

Task	Description	Skills required
Update the Amazon DataZone glossary configuration.	To update the Amazon DataZone glossary configuration in the `lib/utils/glossary_config.json` file, use the following example configuration: `{ "GlossaryName": "PII Data", "GlossaryDescription": "If data source contains PII attributes", "GlossaryTerms": [{ "Name": "Yes", "ShortDescription": "Yes", "LongDescription": "Yes Glossary Term" }, { "Name": "No", "ShortDescription": "No", "LongDescription": "No Glossary Term" } ] }`	Cloud architect, DevOps engineer

```
{
    "GlossaryName":
 "PII Data",
    "GlossaryDescripti
on": "If data source
 contains PII attribute
s",
    "GlossaryTerms": [{
            "Name":
 "Yes",
            "ShortDes
cription": "Yes",
            "LongDesc
ription": "Yes Glossary
 Term"
        },
        {
            "Name":
 "No",
            "ShortDes
cription": "No",
            "LongDesc
ription": "No Glossary
 Term"
        }
    ]
}
```

Task	Description	Skills required
Update the Amazon DataZone metadata form configuration.	To update the Amazon DataZone metadata form configuration in the `lib/utils/metadata_form_config.json` file, use the following example configuration: `{ "FormName": "ScheduleDataRefresh", "FormDescription": "Form for data refresh schedule", "FormSmithyModel": "@amazon.datazone#displayname(defaultName: \"Data Refresh Schedule\")\nstructure ScheduleDataRefresh {\n @documentation(\"Schedule of Data Refresh\")\n @required\n @amazon.datazone#searchable\n @amazon.datazone#displayname(defaultName: \"Data Refresh Schedule\")\n data_refresh_schedule: String\n}" }`	Cloud architect, DevOps engineer

Task	Description	Skills required

Export the AWS credentials.	To export AWS credentials to your development environment for the IAM role with administrative permissions, use the following format:
	`export AWS_ACCESS_KEY_ID=`
	`export AWS_SECRET_ACCESS_KEY=`
	`export AWS_SESSION_TOKEN=`
		Cloud architect, DevOps engineer

Synthesize the template.	To synthesize the AWS CloudFormation template, run the following command: `npx cdk synth`	Cloud architect, DevOps engineer
Deploy the solution.	To deploy the solution, run the following command: `npx cdk deploy --all`	Cloud architect, DevOps engineer

Configure new member accounts

Task	Description	Skills required
Deploy the template.	Deploy the AWS CloudFormation template located at `lib/cfn-templates/DzDataMeshCfnStackSetExecutionRole.yaml` in the member account	Cloud architect, DevOps engineer

Task	Description	Skills required
	with the following input parameters: • `GovernanceAccountID` – Account ID of the governance account • `DataZoneKMSKeyID` – ID of the AWS Key Management Service (AWS KMS) key that encrypts the Amazon DataZone metadata • `NotificationQueueName` – Name of the Amazon SQS notification queue in the governance account	
Update the ARNs.	To update the list of AWS CloudFormation StackSet execution role ARNs for the member accounts, use the following code: `DZ_MEMBER_STACK_SET_EXEC_ROLE_LIST - List of Stack set execution role arns for the member accounts.`	Cloud architect, DevOps engineer

Task	Description	Skills required

Synthesize and deploy.	To synthesize the AWS CloudFormation template and deploy the solution, run the following commands:
	`npx cdk synth`
	`npx cdk deploy --all`
		Cloud architect, DevOps engineer

Task	Description	Skills required
Associate the member account.	To associate the member account with the central governance account, do the following: 1. Sign in to the console of the central governance account, and open the Amazon DataZone console at https://console.aws.amazon.com/datazone/. 2. Choose the domain that you created. 3. Scroll to the **Associated accounts** tab, and choose **Request Association**. 4. Provide the AWS account ID, and choose **AWSRAMPermissionDataZonePortalReadWrite** as **RAM policy**. 5. Choose **Request Association**. 6. Wait until you receive an email notification that your account is successfully bootstrapped.	Cloud architect, DevOps engineer

Task	Description	Skills required
Update the parameters.	To update the member account–specific parameters in the config file at `config/Config.ts` , use the following format: `export const DZ_MEMBER_ACCOUNT_CONFIG: memberAccountConfig = { '123456789012' : { PROJECT_NAME: 'TEST-PROJECT-123456789012', PROJECT_DESCRIPTION: 'TEST-PROJECT-123456789012', PROJECT_EMAIL: 'user@xyz.com' } }`	Cloud architect, DevOps engineer

Synthesize and deploy the template.	To synthesize the AWS CloudFormation template and deploy the solution, run the following commands:
	`npx cdk synth`
	`npx cdk deploy --all`
		Cloud architect, DevOps engineer

Task	Description	Skills required
Add member accounts.	To create and configure additional member accounts in the data solution, repeat the previous steps for each member account. This solution doesn't different iate between data producers and consumers.	Cloud architect, DevOps engineer

Clean up

Task	Description	Skills required
Disassociate the member accounts.	To disassociate the accounts, do the following: 1. Sign in to the console and open the Amazon DataZone console. 2. Choose **View Domains**. 3. Select the domain that you created. 4. Choose the **Account associations** tab. 5. Select the member account that you want to disassoci ate. 6. Choose **Disassociate**, and enter `disassociate` to confirm. 7. Repeat steps 3-6 for all member accounts.	Cloud architect, DevOps engineer

Task	Description	Skills required
Delete the stack instances.	To delete the AWS CloudFormation stack instances, do the following: 1. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation/. 2. In the navigation pane, choose **StackSets**. 3. Choose the stack set named **StackSet-DataZone-DataMesh-Member**, and choose the **Stack instances** tab. 4. Copy the AWS account ID of the member account that you want to remove from membership. 5. Choose **Actions**, choose **Delete stacks from StackSet**, and keep the default options. 6. In the **Account numbers** field, enter the account ID. 7. In the **Specify regions** dropdown list, choose the AWS Region. 8. Choose **Next**, and then choose **Submit**. 9. On the **Operations** tab, confirm that the operation has succeeded. The stack	Cloud architect, DevOps engineer

Task	Description	Skills required
	deletion might take some time. 10. Repeat steps 2-9 for all member accounts.	
Destroy all resources.	To destroy resources, implement the following steps in your local development environment (Linux or macOS): 1. Navigate to the root directory of your repository. 2. Export the AWS credentials for the IAM role that you used to create the AWS CDK stack. 3. To destroy the cloud resources, run the following command: `npx cdk destroy --all`	Cloud architect, DevOps engineer

Additional information

Objectives

Implementing this pattern achieves the following:

- **Decentralized ownership of data** – Shift data ownership from a central team to teams that represent the source systems, business units, or use cases of your organization.
- **Product thinking** – Introduce a product-based mindset that includes customers, the market, and other factors when considering the data assets in your organization.
- **Federated governance** – Improve security guardrails, controls, and compliance across your organization's data products.
- **Multi-account and multiple-project support** – Support efficient, secure data sharing and collaboration across the business units or projects of your organization.
- **Centralized monitoring and notifications** – Monitor the cloud resources of your data mesh by using Amazon CloudWatch, and notify users when a new member account is associated.
- **Scalability and extensibility** – Add new use cases into the data mesh as your organization evolves.

Solution scope

When you use this solution, you can start small and scale as you progress in your data mesh journey. Often, when a member account adopts the data solution, it contains account configurations specific to the organization, project, or business unit. This solution accommodates these diverse AWS account configurations by supporting the following features:

- AWS Glue Data Catalog as the data source for Amazon DataZone
- Management of the Amazon DataZone data domain and the related data portal
- Management of adding member accounts in the data mesh–based data solution
- Management of Amazon DataZone projects and environments
- Management of Amazon DataZone glossaries and metadata forms
- Management of IAM roles that correspond to the data mesh–based data solution users
- Notification of data mesh–based data solution users
- Monitoring of the provisioned cloud infrastructure

This solution uses AWS CDK and AWS CloudFormation to deploy the cloud infrastructure. It uses AWS CloudFormation to do the following:

- Define and deploy cloud resources at a lower level of abstraction.
- Deploy cloud resources from the AWS Management Console. By using this approach, you can deploy infrastructure without a development environment.

The data mesh solution uses AWS CDK to define resources at higher abstraction level. As a result, the solution provides a decoupled, modular, and scalable approach by choosing the relevant tool to deploy the cloud resources.

Next steps

You can reach out to AWS experts for guidance on building data mesh with Amazon DataZone.

The modular nature of this solution supports building data management solutions with different architectures, such as data fabric and data lakes. In addition, based on the requirements of your organization, you can extend the solution to other Amazon DataZone data sources.

Calculate value at risk (VaR) by using AWS services

Sumon Samanta, Amazon Web Services

Summary

This pattern describes how to implement a value at risk (VaR) calculation system by using AWS services. In an on-premises environment, most VaR systems use a large, dedicated infrastructure and in-house or commercial grid scheduling software to run batch processes. This pattern presents a simple, reliable, and scalable architecture to handle VaR processing in the AWS Cloud. It builds a serverless architecture that uses Amazon Kinesis Data Streams as a streaming service, Amazon Simple Queue Service (Amazon SQS) as a managed queue service, Amazon ElastiCache as a caching service, and AWS Lambda to process orders and calculate risk.

VaR is a statistical measure that traders and risk managers use to estimate potential loss in their portfolio beyond a certain confidence level. Most VaR systems involve running a large number of mathematical and statistical calculations and storing the results. These calculations require significant compute resources, so VaR batch processes have to be broken into smaller sets of compute tasks. Splitting a large batch into smaller tasks is possible because these tasks are mostly independent (that is, calculations for one task don't depend other tasks).

Another important requirement for a VaR architecture is compute scalability. This pattern uses a serverless architecture that automatically scales in or out based on compute load. Because the batch or online compute demand is difficult to predict, dynamic scaling is required to complete the process within the timeline imposed by a service-level agreement (SLA). Also, a cost-optimized architecture should be able to scale down each compute resource as soon as the tasks on that resource are complete.

AWS services are well-suited for VaR calculations because they offer scalable compute and storage capacity, analytics services for processing in a cost-optimized way, and different types of schedulers to run your risk management workflows. Also, you pay only for the compute and storage resources that you use on AWS.

Prerequisites and limitations

Prerequisites

- An active AWS account.

- Input files, which depend on your business requirements. A typical use case involves the following input files:
  - Market data file (input to the VaR calculation engine)
  - Trade data file (unless trade data comes through a stream).
  - Configuration data file (model and other static configuration data)
  - Calculation engine model files (quantitative libraries)
  - Time series data file (for historical data such as the stock price for the last five years)
- If the market data or other input comes in through a stream, Amazon Kinesis Data Streams set up, and Amazon Identity and Access Management (IAM) permissions configured to write to the stream.

This pattern builds an architecture in which trade data is written from a trading system to a Kinesis data stream. Instead of using a streaming service, you can save your trade data in small batch files, store them in an Amazon Simple Storage Service (Amazon S3) bucket, and invoke an event to start processing the data.

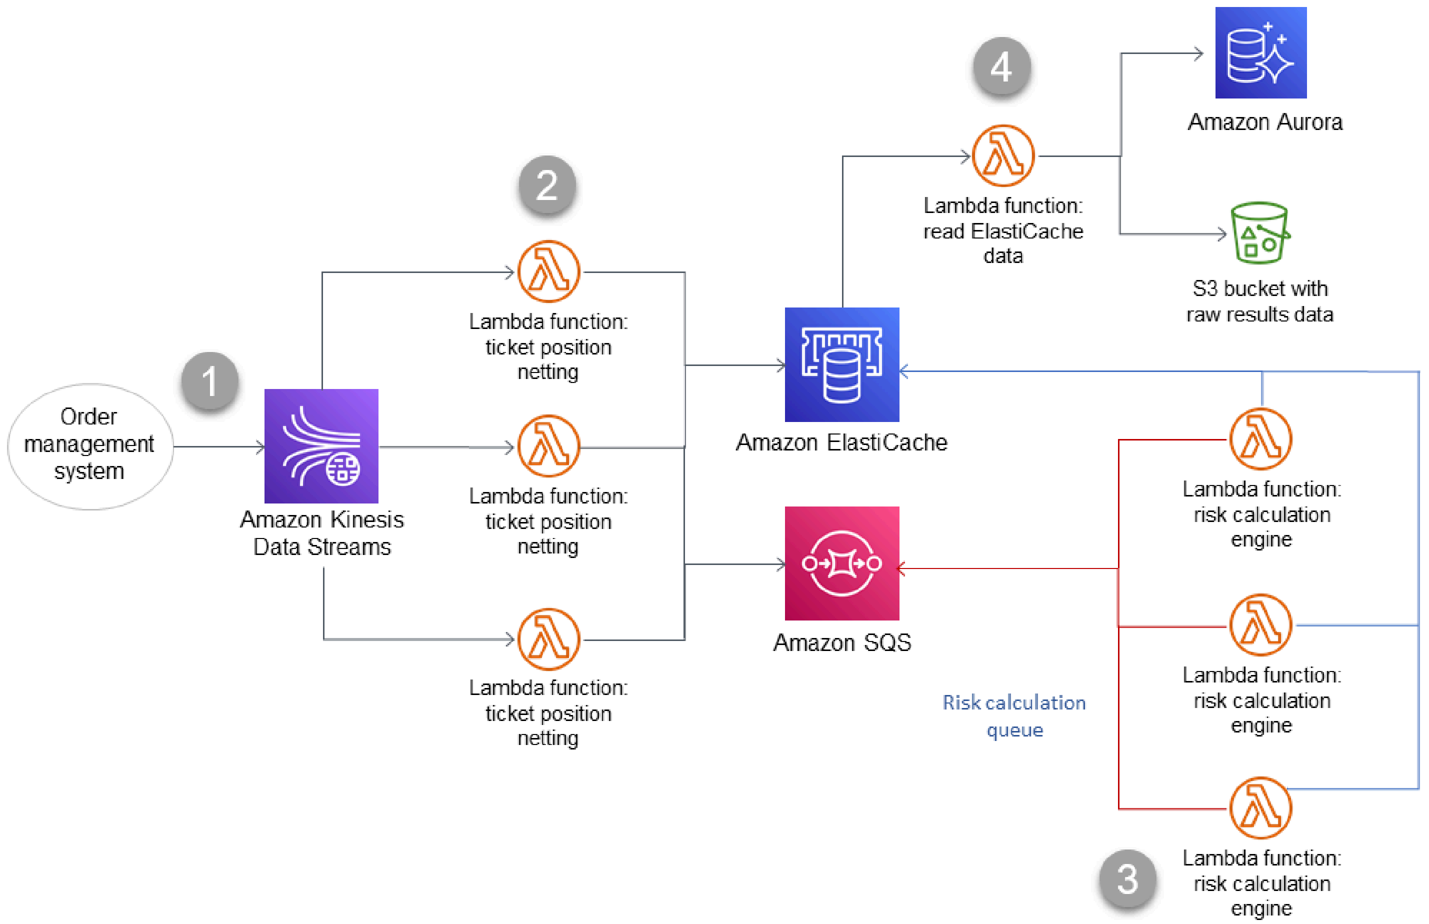
Limitations

- Kinesis data stream sequencing is guaranteed on each shard, so trade orders that are written to multiple shards are not guaranteed to be delivered in the same order as write operations.
- The AWS Lambda runtime limit is currently 15 minutes. (For more information, see the Lambda FAQ.)

Architecture

Target architecture

The following architecture diagram displays the AWS services and workflows for the risk assessment system.



The diagram illustrates the following:

1. Trades stream in from the order management system.
2. The *ticket position netting* Lambda function processes the orders and writes consolidated messages for each ticker to a risk queue in Amazon SQS.
3. The *risk calculation engine* Lambda function processes the messages from Amazon SQS, performs risk calculations, and updates the VaR profit and loss (PnL) information in the risk cache in Amazon ElastiCache.
4. The *read ElastiCache data* Lambda function retrieves the risk results from ElastiCache and stores them in a database and S3 bucket.

For more information about these services and steps, see the *Epics* section.

Automation and scale

You can deploy the entire architecture by using the AWS Cloud Development Kit (AWS CDK) or AWS CloudFormation templates. The architecture can support both batch processing and intraday (real-time) processing.

Scaling is built into the architecture. As more trades are written into the Kinesis data stream and are waiting to be processed, additional Lambda functions can be invoked to process those trades and can then scale down after processing is complete. Processing through multiple Amazon SQS risk calculation queues is also an option. If strict ordering or consolidation is required across queues, processing cannot be parallelized. However, for an end-of-the-day batch or a mini intraday batch, the Lambda functions can process in parallel and store the final results in ElastiCache.

Tools

AWS services

- Amazon Aurora MySQL-Compatible Edition is a fully managed, MySQL-compatible relational database engine that helps you set up, operate, and scale MySQL deployments. This pattern uses MySQL as an example, but you can use any RDBMS system to store data.
- Amazon ElastiCache helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud.
- Amazon Kinesis Data Streams helps you collect and process large streams of data records in real time.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code

This pattern provides an example architecture for a VaR system in the AWS Cloud and describes how you can use Lambda functions for VaR calculations. To create your Lambda functions, see the code examples in the Lambda documentation. For assistance, contact AWS Professional Services.

Best practices

- Keep each VaR compute task as small and lightweight as possible. Experiment with different numbers of trades in each compute task to see which one is most optimized for compute time and cost.
- Store reusable objects in Amazon ElastiCache. Use a framework such as Apache Arrow to reduce serialization and deserialization.
- Consider Lambda's time limitation. If you think your compute tasks might exceed 15 minutes, try to break them down into smaller tasks to avoid the Lambda timeout. If this is not possible, you might consider a container orchestration solution with AWS Fargate, Amazon Elastic Container Service (Amazon ECS), and Amazon Elastic Kubernetes Service (Amazon EKS).

Epics

Trade flow to risk system

Task	Description	Skills required
Start writing trades.	New, settled, or partially settled trades are written from the order management system to a risk stream. This pattern uses Amazon Kinesis as the managed streaming service. The trade order ticker's hash is used to put trade orders across multiple shards.	Amazon Kinesis

Run Lambda functions for order processing

Task	Description	Skills required
Start risk processing with Lambda.	Run an AWS Lambda function for the new orders. Based	Amazon Kinesis, AWS Lambda, Amazon ElastiCache

Task	Description	Skills required
	on the number of pending trade orders, Lambda will automatically scale. Each Lambda instance has one or more orders and retrieves the latest position for each ticker from Amazon ElastiCache. (You can use a CUSIP ID, a Curve name, or an index name for other financial derivative products as a key to store and retrieve data from ElasticCache.) In ElastiCache, the total position (quantity) and the key-value pair <*ticker*, *net position*>, where *net position* is the scaling factor, are updated once for each ticker.	

Write messages for each ticker into queue

Task	Description	Skills required
Write consolidated messages to the risk queue.	Write the message to a queue. This pattern uses Amazon SQS as a managed queue service. A single Lambda instance might get a mini batch of trade orders at any given time, but will write only a single message for each ticker to Amazon SQS. A scaling factor is calculate	Amazon SQS, AWS Lambda

Task	Description	Skills required
	d: (*old net position* + *current position*) / *old net position*.	

Invoke risk engine

Task	Description	Skills required
Start risk calculations.	The Lambda function for the risk engine lambda is invoked. Each position is processed by a single Lambda function. However, for optimization purposes, each Lambda function can process multiple messages from Amazon SQS.	Amazon SQS, AWS Lambda

Retrieve risk results from cache

Task	Description	Skills required
Retrieve and update risk cache.	Lambda retrieves the current net position for each ticker from ElastiCache. It also retrieves a VaR profit and loss (PnL) array for each ticker from ElastiCache. If the PnL array already exists, the Lambda function updates the array and VaR with a scale, which comes from the Amazon SQS message written by the netting Lambda function. If the PnL array isn't	Amazon SQS, AWS Lambda, Amazon ElastiCache

Task	Description	Skills required
	in ElasticCache, a new PnL and VaR are calculated by using simulated ticker price series data.	

Update data in Elastic Cache and store in database

Task	Description	Skills required
Store risk results.	After the VaR and PnL numbers are updated in ElastiCache, a new Lambda function is invoked every five minutes. This function reads all stored data from ElastiCac he and stores it in an Aurora MySQL-Compatible database and in an S3 bucket.	AWS Lambda, Amazon ElastiCache

Configure cross-account access to a shared AWS Glue Data Catalog using Amazon Athena

Denis Avdonin, Amazon Web Services

Summary

This pattern provides step-by-step instructions, including AWS Identity and Access Management (IAM) policy samples, to configure cross-account sharing of a dataset stored in an Amazon Simple Storage Service (Amazon S3) bucket by using the AWS Glue Data Catalog. You can store the dataset in an S3 bucket. The metadata is collected by an AWS Glue crawler and put into the AWS Glue Data Catalog. The S3 bucket and the AWS Glue Data Catalog reside in an AWS account referred to as the *data account*. You can provide access to IAM principals in another AWS account referred to as the *consumer account*. Users can query the data in the consumer account by using the Amazon Athena serverless query engine.

Prerequisites and limitations

Prerequisites

- Two active AWS accounts
- An S3 bucket in one of the AWS accounts
- Athena engine version 2
- AWS Command Line Interface (AWS CLI), installed and configured (or AWS CloudShell for running AWS CLI commands)

Product versions

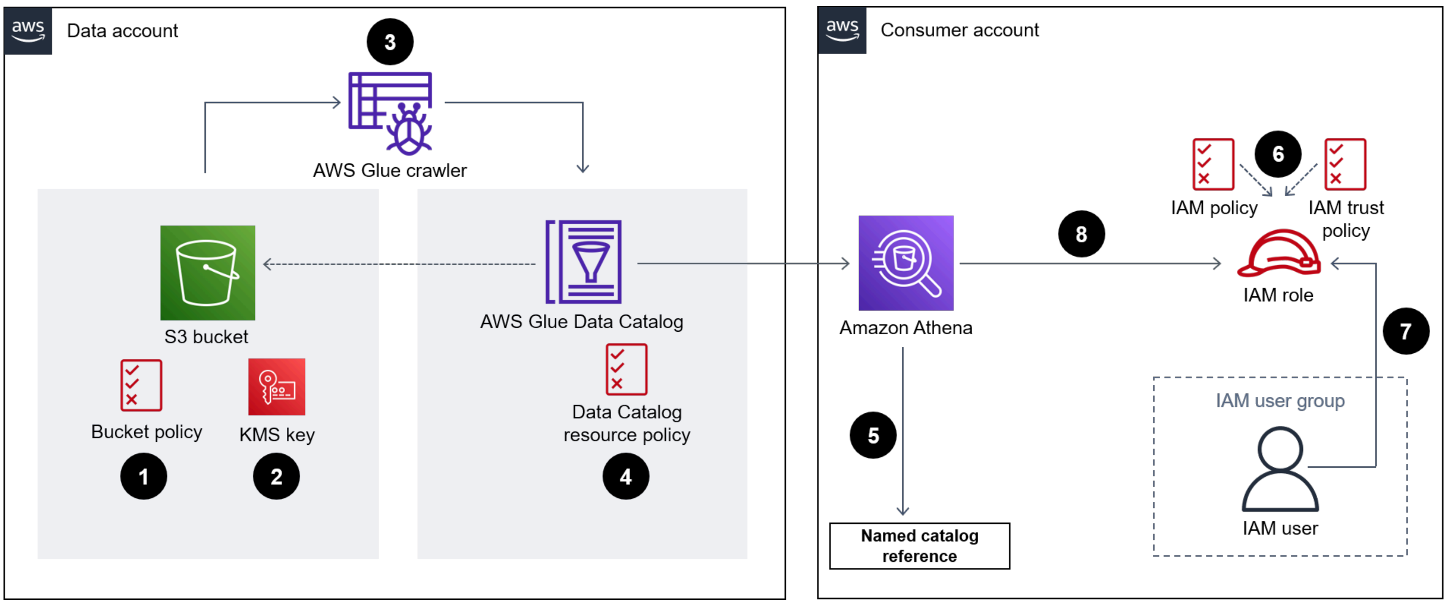
This pattern works with Athena engine version 2 and Athena engine version 3 only. We recommend that you upgrade to Athena engine version 3. If you can't upgrade from Athena engine version 1 to Athena engine version 3, follow the approach discussed in Cross-account AWS Glue Data Catalog access with Amazon Athena in the AWS Big Data Blog.

Architecture

Target technology stack

- Amazon Athena
- Amazon Simple Storage Service (Amazon S3)
- AWS Glue
- AWS Identity and Access Management (IAM)
- AWS Key Management Service (AWS KMS)

The following diagram shows an architecture that uses IAM permissions to share data in an S3 bucket in one AWS account (data account) with another AWS account (consumer account) through the AWS Glue Data Catalog.



The diagram shows the following workflow:

1. The S3 bucket policy in the data account grants permissions to an IAM role in the consumer account and to the AWS Glue crawler service role in the data account.
2. The AWS KMS key policy in the data account grants permissions to the IAM role in the consumer account and to the AWS Glue crawler service role in the data account.
3. The AWS Glue crawler in the data account discovers the schema of the data that's stored in the S3 bucket.
4. The resource policy of the AWS Glue Data Catalog in the data account grants access to the IAM role in the consumer account.
5. A user creates a named catalog reference in the consumer account by using an AWS CLI command.

6. An IAM policy grants an IAM role in the consumer account access to resources in the data account. The IAM role's trust policy allows users in the consumer account to assume the IAM role.
7. A user in the consumer account assumes the IAM role and accesses objects in the data catalog by using SQL queries.
8. The Athena serverless engine runs the SQL queries.

> **Note**
>
> IAM best practices recommend that you grant permissions to an IAM role and use identity federation.

Tools

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to protect your data.

Epics

Set up permissions in the data account

	bucket"
	        }
	    ]
	}
	``
	The bucket policy grants permissions to the IAM role in the consumer account and to the AWS Glue crawler service role in the data account.	

Task	Description	Skills required

(If required) Grant access to the data encryption key.	If the S3 bucket is encrypted by an AWS KMS key, grant `kms:Decrypt` permission on the key to the IAM role in the consumer account and to the AWS Glue crawler service role in the data account.
	
	Update the [key policy](https://docs.aws.amazon.com/kms/latest/developerguide/key-policies.html) with the following statement:
	
	`{`
	`    "Effect": "Allow",`
	`    "Principal": {`
	`        "AWS": [`
	`            "arn:aws:iam::<consumer account id>:role/<role name>",`
	`            "arn:aws:iam::<data account id>:role/service-role/AWSGlueServiceRole-data-bucket-crawler"`
	`        ]`
	`    },`
	`    "Action": "kms:Decrypt",`
	`    "Resource": "arn:aws:kms:<region>:<data account id>:key/<key id>"`
	`}`
		Cloud administrator

Task	Description	Skills required
Grant the crawler access to the data.	Attach the following IAM policy to the crawler's service role: ```{ "Version": "2012-10-17", "Statement": [{ "Effect": "Allow", "Action": "s3:GetObject", "Resource": "arn:aws:s3:::data-bucket/*" }, { "Effect": "Allow", "Action": "s3:ListBucket", "Resource": "arn:aws:s3:::data-bucket" }] }```	Cloud administrator

```
{
    "Version":
 "2012-10-17",
    "Statement": [
        {
            "Effect":
 "Allow",
            "Action":
 "s3:GetObject",
            "Resource":
 "arn:aws:s3:::data-
bucket/*"
        },
        {
            "Effect":
 "Allow",
            "Action":
 "s3:ListBucket",
            "Resource":
 "arn:aws:s3:::data-
bucket"
        }
    ]
}
```

Task	Description	Skills required
(If required) Grant the crawler access to the data encryption key.	If the S3 bucket is encrypted by an AWS KMS key, grant `kms:Decrypt` permission on the key to the crawler's service role by attaching the following policy to it:	Cloud administrator

```
{
    "Effect": "Allow",
    "Action": "kms:Decrypt",
    "Resource":
 "arn:aws:kms:<region>:<data account
 id>:key/<key id>"
}
```

Task	Description	Skills required

Grant the IAM role in the consumer account and the crawler access to the data catalog.	1. Sign in to the AWS Management Console and open the [AWS Glue console](#).
	2. In the navigation pane, under **Data Catalog**, choose **Settings**.
	3. In the **Permissions** section, add the following statement, and then choose **Save**.
	
	`{`
	`    "Version" : "2012-10-17",`
	`    "Statement" : [`
	`        {`
	`            "Effect" : "Allow",`
	`            "Principal" : {`
	`                "AWS" : [`
	`                    "arn:aws:iam::<consumer account id>:role/<role name>",`
	`                    "arn:aws:iam::<data account id>:role/service-role/AWSGlueServiceRole-data-bucket-crawler"`
	`                ]`
	`            },`
	`            "Action" : "glue:*",`
		Cloud administrator

Task	Description	Skills required

	`"Resource`
	`" : [`
	
	`"arn:aws:glue:<reg`
	`ion>:<data account`
	`id>:catalog",`
	
	`"arn:aws:glue:<reg`
	`ion>:<data account`
	`id>:database/*",`
	
	`"arn:aws:glue:<reg`
	`ion>:<data account`
	`id>:table/*"`
	`]`
	`}`
	`]`
	`}`
	
	This policy allows all AWS Glue actions on all databases and tables in the data account. You can customize the policy to grant only required permissions to the consumer principals. For example, you can provide read-only access to specific tables or views in a database.	

Access data from the consumer account

Task	Description	Skills required
Create a named reference for the data catalog.	To create a named data catalog reference, use CloudShell or a locally	Cloud administrator

Task	Description	Skills required
	installed AWS CLI to run the following command: `aws athena create-data-catalog --name <shared catalog name> --type GLUE --parameters catalog-id=<data account id>`	

Task	Description	Skills required
Grant the IAM role in the consumer account access to the data.	Attach the following policy to the IAM role in the consumer account to grant the role cross-account access to the data: `{ "Version": "2012-10-17", "Statement": [{ "Effect": "Allow", "Action": "s3:GetObject", "Resource": "arn:aws:s3:::data-bucket/*" }, { "Effect": "Allow", "Action": "s3:ListBucket", "Resource": "arn:aws:s3:::data-bucket" }, { "Effect": "Allow", "Action": "glue:*", "Resource": ["arn:aws:glue:<region>:<data account id>:catalog",`	Cloud administrator

Task	Description	Skills required

	``` "arn:aws:glue:<reg ion>:<data account id>:database/*", "arn:aws:glue:<reg ion>:<data account id>:table/*"] }] } ```
	Next, use the following template to specify what users can accept the IAM role in its trust policy:
	``` { "Version": "2012-10-17", "Statement": [{ "Effect": "Allow", "Principal": { "AWS": "arn:aws:iam::<consumer account id>:user/<IAM user>" }, "Action": "sts:AssumeRole" }] } ```
	Finally, grant user permissions to assume the IAM role by	

Task	Description	Skills required
	attaching the same policy to the user group they belong to.	

(If required) Grant the IAM role in the consumer account access to the data encryption key.	If the S3 bucket is encrypted by an AWS KMS key, grant `kms:Decrypt` permission on the key to the IAM role in the consumer account by attaching the following policy to it:
	`{`
	`    "Effect": "Allow",`
	`    "Action": "kms:Decrypt",`
	`    "Resource": "arn:aws:kms:<region>:<data account id>:key/<key id>"`
	`}`
		Cloud administrator

Switch to the IAM role in the consumer account to access data.	As a data consumer, [switch to the IAM role](#) to access data in the data account.	Data consumer

Task	Description	Skills required

Access the data.	Query data using Athena. For example, open the Athena query editor and run the following query:
	`SELECT * FROM <shared catalog name>.<database name>.<table name>`
	Instead of using a named catalog reference, you can also refer to the catalog by its Amazon Resource Name (ARN).
	Note
	If you use a dynamic catalog reference in a query or view, surround the reference with escaped double quotation marks (\"). For example:
	`SELECT * FROM \"glue:arn:aws:glue:<region>:<data account id>:catalog\".<database name>.<table name>`
		Data consumer

Task	Description	Skills required
	For more information, see Cross-account access to AWS Glue data catalogs in the Amazon Athena User Guide.	

Related resources

- Cross-account access to AWS Glue data catalogs (Athena documentation)
- (AWS CLI) create-data-catalog (AWS CLI Command Reference)
- Cross-account AWS Glue Data Catalog access with Amazon Athena (AWS Big Data Blog)
- Security best practices in IAM (IAM documentation)

Additional information

Using Lake Formation as an alternative for cross-account sharing

You can also use AWS Lake Formation to share access to AWS Glue catalog objects across accounts. Lake Formation provides fine-grained access control at the column and row level, tag-based access control, governed tables for ACID transactions, and other functionality. Although Lake Formation is well-integrated with Athena, it does require additional configuration compared to this pattern's IAM-only approach. We recommend that you consider the decision to use Lake Formation or IAM-only access controls within the wider context of your overall solution architecture. Considerations include what other services are involved and how they integrate with both approaches.

Convert the Teradata NORMALIZE temporal feature to Amazon Redshift SQL

Po Hong, Amazon Web Services

Summary

NORMALIZE is a Teradata extension to the ANSI SQL standard. When a SQL table includes a column that has a **PERIOD** data type, **NORMALIZE** combines values that meet or overlap in that column, to form a single period that consolidates multiple, individual period values. To use **NORMALIZE**, at least one column in the SQL **SELECT** list must be of Teradata's temporal **PERIOD** data type. For more information about **NORMALIZE**, see the Teradata documentation.

Amazon Redshift doesn't support **NORMALIZE**, but you can implement this functionality by using native SQL syntax and the **LAG** window function in Amazon Redshift. This pattern focuses on using the Teradata **NORMALIZE** extension with the **ON MEETS OR OVERLAPS** condition, which is the most popular format. It explains how this feature works in Teradata and how it can be converted into Amazon Redshift native SQL syntax.

Prerequisites and limitations

Prerequisites

- Basic Teradata SQL knowledge and experience
- Amazon Redshift knowledge and experience

Architecture

Source technology stack

- Teradata data warehouse

Target technology stack

- Amazon Redshift

Target architecture

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents. The migration doesn't automatically convert the Teradata **NORMALIZE** phrase to Amazon Redshift SQL. You can convert this Teradata extension by following the guidelines in this pattern.

Tools

Code

To illustrate the concept and functionality of **NORMALIZE**, consider the following table definition in Teradata:

```
CREATE TABLE systest.project
     (    emp_id        INTEGER,
          project_name  VARCHAR(20),
          dept_id       INTEGER,
          duration      PERIOD(DATE)
     );
```

Run the following SQL code to insert sample data into the table:

```
BEGIN TRANSACTION;

INSERT INTO systest.project VALUES (10, 'First Phase', 1000,  PERIOD(DATE '2010-01-10',
 DATE '2010-03-20') );
INSERT INTO systest.project VALUES (10, 'First Phase', 2000,  PERIOD(DATE '2010-03-20',
 DATE '2010-07-15') );

INSERT INTO systest.project VALUES (10, 'Second Phase', 2000,  PERIOD(DATE
 '2010-06-15', DATE '2010-08-18') );
INSERT INTO systest.project VALUES (20, 'First Phase', 2000,  PERIOD(DATE '2010-03-10',
 DATE '2010-07-20') );

INSERT INTO systest.project VALUES (20, 'Second Phase', 1000,  PERIOD(DATE
 '2020-05-10', DATE '2020-09-20') );

END TRANSACTION;
```

Results:

```
select * from systest.project order by 1,2,3;
```

```
 *** Query completed. 4 rows found. 4 columns returned.
 *** Total elapsed time was 1 second.

     emp_id  project_name              dept_id  duration
-----------  --------------------  -----------  ------------------------
         10  First Phase                  1000  ('10/01/10', '10/03/20')
         10  First Phase                  2000  ('10/03/20', '10/07/15')
         10  Second Phase                 2000  ('10/06/15', '10/08/18')
         20  First Phase                  2000  ('10/03/10', '10/07/20')
         20  Second Phase                 1000  ('20/05/10', '20/09/20')
```

Teradata NORMALIZE use case

Now add the Teradata **NORMALIZE** SQL clause to the **SELECT** statement:

```
SELECT NORMALIZE ON MEETS OR OVERLAPS emp_id, duration
FROM systest.project
ORDER BY 1,2;
```

This **NORMALIZE** operation is performed on a single column (emp_id). For emp_id=10, the three overlapping period values in duration coalesce into a single period value, as follows:

```
     emp_id  duration
-----------  ------------------------
         10  ('10/01/10', '10/08/18')
         20  ('10/03/10', '10/07/20')
         20  ('20/05/10', '20/09/20')
```

The following **SELECT** statement performs a **NORMALIZE** operation on project_name and dept_id. Note that the **SELECT** list contains only one **PERIOD** column, duration.

```
SELECT NORMALIZE project_name, dept_id, duration
FROM systest.project;
```

Output:

```
project_name              dept_id  duration
--------------------  -----------  ------------------------
First Phase                  1000  ('10/01/10', '10/03/20')
Second Phase                 1000  ('20/05/10', '20/09/20')
First Phase                  2000  ('10/03/10', '10/07/20')
```

```
Second Phase                2000  ('10/06/15', '10/08/18')
```

Amazon Redshift equivalent SQL

Amazon Redshift currently doesn't support the **PERIOD** data type in a table. Instead, you need to divide a Teradata **PERIOD** data field into two parts: start_date, end_date, as follows:

```
CREATE TABLE systest.project
     (    emp_id        INTEGER,
          project_name  VARCHAR(20),
          dept_id       INTEGER,
          start_date  DATE,
          end_date    DATE
     );
```

Insert sample data into the table:

```
BEGIN TRANSACTION;

INSERT INTO systest.project VALUES (10, 'First Phase', 1000,  DATE '2010-01-10', DATE
 '2010-03-20' );
INSERT INTO systest.project VALUES (10, 'First Phase', 2000,  DATE '2010-03-20', DATE
 '2010-07-15');

INSERT INTO systest.project VALUES (10, 'Second Phase', 2000,  DATE '2010-06-15', DATE
 '2010-08-18' );
INSERT INTO systest.project VALUES (20, 'First Phase', 2000,  DATE '2010-03-10', DATE
 '2010-07-20' );

INSERT INTO systest.project VALUES (20, 'Second Phase', 1000,  DATE '2020-05-10', DATE
 '2020-09-20' );

END TRANSACTION;
```

Output:

```
 emp_id | project_name | dept_id | start_date |  end_date
--------+--------------+---------+------------+------------
     10 | First Phase  |    1000 | 2010-01-10 | 2010-03-20
     10 | First Phase  |    2000 | 2010-03-20 | 2010-07-15
     10 | Second Phase |    2000 | 2010-06-15 | 2010-08-18
     20 | First Phase  |    2000 | 2010-03-10 | 2010-07-20
```

```
     20 | Second Phase |    1000 | 2020-05-10 | 2020-09-20
(5 rows)
```

To rewrite Teradata's **NORMALIZE** clause, you can use the [LAG window function] in Amazon Redshift. This function returns the values for a row at a given offset above (before) the current row in the partition.

You can use the **LAG** function to identify each row that begins a new period by determining if a period meets or overlaps with the previous period (0 if yes and 1 if no). When this flag is cumulatively summed up, it provides a group identifier that can be used in the outer **Group By** clause to arrive at the desired result in Amazon Redshift.

Here's a sample Amazon Redshift SQL statement that uses **LAG()**:

```
SELECT emp_id, start_date, end_date,
            (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY
 start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
FROM systest.project
ORDER BY 1,2;
```

Output:

```
 emp_id | start_date |  end_date  | groupstartflag
--------+------------+------------+----------------
     10 | 2010-01-10 | 2010-03-20 |              1
     10 | 2010-03-20 | 2010-07-15 |              0
     10 | 2010-06-15 | 2010-08-18 |              0
     20 | 2010-03-10 | 2010-07-20 |              1
     20 | 2020-05-10 | 2020-09-20 |              1
(5 rows)
```

The following Amazon Redshift SQL statement normalizes only on the emp_id column:

```
SELECT T2.emp_id, MIN(T2.start_date) as new_start_date, MAX(T2.end_date) as
 new_end_date
FROM
( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY emp_id ORDER BY start_date ROWS
 UNBOUNDED PRECEDING) As GroupID
FROM ( SELECT emp_id, start_date, end_date,
            (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY
 start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
```

```
FROM systest.project ) T1
) T2
GROUP BY T2.emp_id, T2.GroupID
ORDER BY 1,2;
```

Output:

```
 emp_id | new_start_date | new_end_date
--------+----------------+------------------------------------
     10 | 2010-01-10     | 2010-08-18
     20 | 2010-03-10     | 2010-07-20
     20 | 2020-05-10     | 2020-09-20
(3 rows)
```

The following Amazon Redshift SQL statement normalizes on both the project_name and dept_id columns:

```
SELECT T2.project_name, T2.dept_id, MIN(T2.start_date) as new_start_date,
 MAX(T2.end_date) as new_end_date
FROM
( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY project_name, dept_id ORDER BY
 start_date ROWS UNBOUNDED PRECEDING) As GroupID
FROM ( SELECT project_name, dept_id, start_date, end_date,
            (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY project_name,
 dept_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
FROM systest.project ) T1
) T2
GROUP BY T2.project_name, T2.dept_id, T2.GroupID
ORDER BY 1,2,3;
```

Output:

```
 project_name | dept_id | new_start_date | new_end_date
--------------+---------+----------------+--------------
 First Phase  |    1000 | 2010-01-10     | 2010-03-20
 First Phase  |    2000 | 2010-03-10     | 2010-07-20
 Second Phase |    1000 | 2020-05-10     | 2020-09-20
 Second Phase |    2000 | 2010-06-15     | 2010-08-18

Convert the Teradata RESET WHEN feature to Amazon Redshift SQL

Po Hong, Amazon Web Services

Summary

RESET WHEN is a Teradata feature used in SQL analytical window functions. It is an extension to the ANSI SQL standard. **RESET WHEN** determines the partition over which an SQL window function operates based on some specified condition. If the condition evaluates to **TRUE**, a new, dynamic sub-partition is created inside the existing window partition. For more information about **RESET WHEN**, see the Teradata documentation.

Amazon Redshift doesn't support **RESET WHEN** in SQL window functions. To implement this functionality, you have to convert **RESET WHEN** to the native SQL syntax in Amazon Redshift, and use multiple, nested functions. This pattern demonstrates how you can use the Teradata **RESET WHEN** feature and how you can convert it to Amazon Redshift SQL syntax.

Prerequisites and limitations

Prerequisites

- Basic knowledge of the Teradata data warehouse and its SQL syntax
- Good understanding of Amazon Redshift and its SQL syntax

Architecture

Source technology stack

- Teradata data warehouse

Target technology stack

- Amazon Redshift

Architecture

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents. The migration doesn't automatically convert the Teradata **RESET WHEN** phrase to Amazon Redshift SQL. You can convert this Teradata extension by following the guidelines in the next section.

Tools

Code

To illustrate the concept of **RESET WHEN**, consider the following table definition in Teradata:

```
create table systest.f_account_balance
( account_id integer NOT NULL,
  month_id integer,
  balance integer )
unique primary index (account_id, month_id);
```

Run the following SQL code to insert sample data into the table:

```
BEGIN TRANSACTION;
Insert Into systest.f_account_balance values (1,1,60);
Insert Into systest.f_account_balance values (1,2,99);
Insert Into systest.f_account_balance values (1,3,94);
Insert Into systest.f_account_balance values (1,4,90);
Insert Into systest.f_account_balance values (1,5,80);
Insert Into systest.f_account_balance values (1,6,88);
Insert Into systest.f_account_balance values (1,7,90);
Insert Into systest.f_account_balance values (1,8,92);
Insert Into systest.f_account_balance values (1,9,10);
Insert Into systest.f_account_balance values (1,10,60);
Insert Into systest.f_account_balance values (1,11,80);
Insert Into systest.f_account_balance values (1,12,10);
END TRANSACTION;
```

The sample table has the following data:

account_id	month_id	balance
1	1	60

1	2	99
1	3	94
1	4	90
1	5	80
1	6	88
1	7	90
1	8	92
1	9	10
1	10	60
1	11	80
1	12	10

For each account, let's say that you want to analyze the sequence of consecutive monthly balance increases. When one month's balance is less than, or equal to, the previous month's balance, the requirement is to reset the counter to zero and restart.

Teradata RESET WHEN use case

To analyze this data, Teradata SQL uses a window function with a nested aggregate and a **RESET WHEN** phrase, as follows:

```
SELECT account_id, month_id, balance,
 ( ROW_NUMBER() OVER (PARTITION BY account_id ORDER BY month_id
RESET WHEN balance <= SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS
 BETWEEN 1 PRECEDING AND 1 PRECEDING) ) -1 ) as balance_increase
FROM systest.f_account_balance
ORDER BY 1,2;
```

Output:

account_id	month_id	balance	balance_increase
1	1	60	0
1	2	99	1
1	3	94	0
1	4	90	0
1	5	80	0
1	6	88	1
1	7	90	2
1	8	92	3
1	9	10	0
1	10	60	1
1	11	80	2
1	12	10	0

The query is processed as follows in Teradata:

1. The **SUM(balance)** aggregate function calculates the sum of all balances for a given account in a given month.
2. We check to see if a balance in a given month (for a given account) is greater than the balance of the previous month.
3. If the balance increased, we track a cumulative count value. If the **RESET WHEN** condition evaluates to **false**, which means that the balance has increased over successive months, we continue to increase the count.
4. The **ROW_NUMBER()** ordered analytical function calculates the count value. When we reach a month whose balance is less than, or equal to, the balance of the previous month, the **RESET WHEN** condition evaluates to **true**. If so, we start a new partition and **ROW_NUMBER()** restarts

the count from 1. We use **ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING** to access the value of the previous row.

5. We subtract 1 to ensure that the count value starts with 0.

Amazon Redshift equivalent SQL

Amazon Redshift doesn't support the **RESET WHEN** phrase in an SQL analytical window function. To produce the same result, you must rewrite the Teradata SQL using Amazon Redshift native SQL syntax and nested sub-queries, as follows:

```
SELECT account_id, month_id, balance,
   (ROW_NUMBER() OVER(PARTITION BY account_id, new_dynamic_part ORDER BY month_id) -1)
 as balance_increase
FROM
( SELECT account_id, month_id, balance, prev_balance,
SUM(dynamic_part) OVER (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN
 UNBOUNDED PRECEDING AND CURRENT ROW) As new_dynamic_part
FROM ( SELECT account_id, month_id, balance,
SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN 1 PRECEDING
 AND 1 PRECEDING) as prev_balance,
(CASE When balance <= prev_balance Then 1 Else 0 END) as dynamic_part
FROM systest.f_account_balance ) A
) B
ORDER BY 1,2;
```

Because Amazon Redshift doesn't support nested window functions in the **SELECT** clause of a single SQL statement, you must use two nested sub-queries.

- In the inner sub-query (alias A), a dynamic partition indicator (**dynamic_part**) is created and populated. **dynamic_part** is set to 1 if one month's balance is less than or equal to the preceding month's balance; otherwise, it's set to 0.
- In the next layer (alias B), a **new_dynamic_part** attribute is generated as the result of a **SUM** window function.
- Finally, you add **new_dynamic_part** as a new partition attribute (**dynamic partition**) to the existing partition attribute (**account_id**) and apply the same **ROW_NUMBER()** window function as in Teradata (and minus one).

After these changes, Amazon Redshift SQL generates the same output as Teradata.

Deploy and manage a serverless data lake on the AWS Cloud by using infrastructure as code

Kirankumar Chandrashekar and Abdel Jaidi, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern describes how to use serverless computing and infrastructure as code (IaC) to implement and administer a data lake on the Amazon Web Services (AWS) Cloud. This pattern is based on the serverless data lake framework (SDLF) workshop developed by AWS.

SDLF is a collection of reusable resources that accelerate the delivery of enterprise data lakes on the AWS Cloud and helps with faster deployment to production. It is used to implement the foundational structure of a data lake by following best practices.

SDLF implements a continuous integration / continuous deployment (CI/CD) process throughout the code and infrastructure deployment by using AWS services such as AWS CodePipeline, AWS CodeBuild, and AWS CodeCommit.

This pattern uses multiple AWS serverless services to simplify data lake management. These include Amazon Simple Storage Service (Amazon S3) and Amazon DynamoDB for storage, AWS Lambda and AWS Glue for computing, and Amazon CloudWatch Events, Amazon Simple Queue Service (Amazon SQS), and AWS Step Functions for orchestration.

AWS CloudFormation and AWS code services act as the IaC layer to provide reproducible and fast deployments with easy operations and administration.

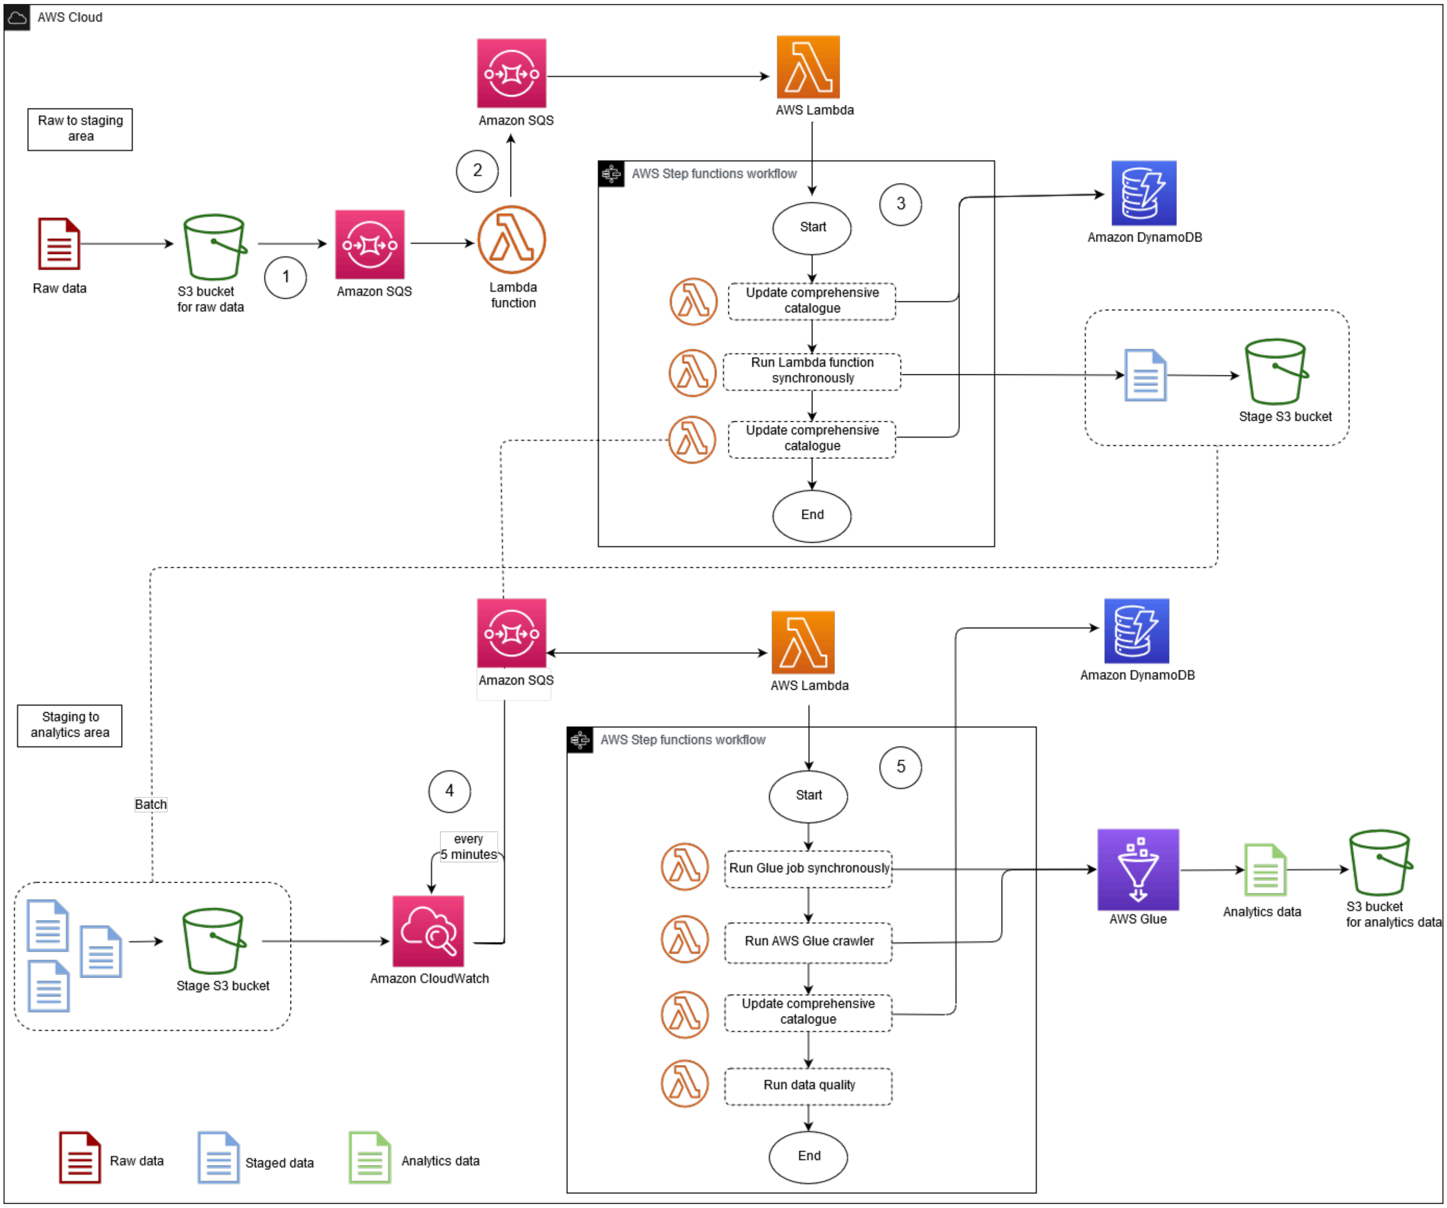
Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured.
- A Git client, installed and configured.

- The SDLF workshop, open in a web browser window and ready to use.

Architecture



The architecture diagram illustrates an event-driven process with the following steps.

1. After a file is added to the raw data S3 bucket, an Amazon S3 event notification is placed in an SQS queue. Each notification is delivered as a JSON file, which contains metadata such as the S3 bucket name, object key, or timestamp.
2. This notification is consumed by a Lambda function that routes the event to the correct extraction, transformation, and loading (ETL) process based on the metadata. The Lambda

function can also use contextual configurations stored in an Amazon DynamoDB table. This step enables decoupling and scaling to multiple applications in the data lake.

3. The event is routed to the first Lambda function in the ETL process, which transforms and moves data from the raw data area to the staging area for the data lake. The first step is to update the comprehensive catalog. This is a DynamoDB table that contains all the file metadata of the data lake. Each row in this table holds operational metadata about a single object stored in Amazon S3. A synchronous call is made to a Lambda function that performs a light transformation, which is a computationally inexpensive operation (such as converting a file from one format to another), on the S3 object. Because a new object has been added to the staging S3 bucket, the comprehensive catalog is updated and a message is sent to the SQS queue waiting for the next phase in the ETL.
4. A CloudWatch Events rule triggers a Lambda function every 5 minutes. This function checks if messages were delivered to the SQS queue from the previous ETL phase. If a message was delivered, the Lambda function begins the second function from AWS Step Functions in the ETL process.
5. A heavy transformation is then applied on a batch of files. This heavy transformation is a computationally expensive operation, such as a synchronous call to an AWS Glue job, AWS Fargate task, Amazon EMR step, or Amazon SageMaker notebook. Table metadata is extracted from the output files by using an AWS Glue crawler, which updates the AWS Glue catalog. File metadata is also added to the comprehensive catalog table in DynamoDB. Finally, a data quality step leveraging Deequ is also run.

Technology stack

- Amazon CloudWatch Events
- AWS CloudFormation
- AWS CodePipeline
- AWS CodeBuild
- AWS CodeCommit
- Amazon DynamoDB
- AWS Glue
- AWS Lambda
- Amazon S3
- Amazon SQS

- AWS Step Functions

Tools

- Amazon CloudWatch Events – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS CloudFormation – CloudFormation helps create and provision AWS infrastructure deployments predictably and repeatedly.
- AWS CodeBuild – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- AWS CodeCommit – CodeCommit is a version control service hosted by AWS that you can use to privately store and manage assets (such as source code and binary files).
- AWS CodePipeline – CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software changes continuously.
- Amazon DynamoDB – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.
- AWS Glue – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics.
- AWS Lambda – Lambda supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- AWS Step Functions - AWS Step Functions is a serverless function orchestrator that makes it easy to sequence AWS Lambda functions and multiple AWS services into business-critical applications.
- Amazon SQS – Amazon Simple Queue Service (Amazon SQS) is a fully managed message queuing service that helps you decouple and scale microservices, distributed systems, and serverless applications.
- Deequ – Deequ is a tool that helps you compute data quality metrics for large datasets, define and verify data quality constraints, and stay informed about changes in the data distribution.

Code repository

The source code and resources for the SDLF are available in the AWS Labs GitHub repository.

Epics

Set up the CI/CD pipeline to provision IaC

Task	Description	Skills required
Set up the CI/CD pipeline to manage IaC for the data lake.	Sign in to the AWS Management Console and follow the steps from the Initial setup section of the SDLF workshop. This creates the initial CI/CD resources , such as CodeCommit repositories, CodeBuild environments, and CodePipeline pipelines that provision and manage IaC for the data lake.	DevOps engineer

Version-control the IaC

Task	Description	Skills required
Clone the CodeCommit repository on your local machine.	Follow the steps from the Deploying the foundations section of the SDLF workshop. This helps you clone the Git repository that hosts IaC into your local environment. For more information, see Connecting to CodeCommit repositories from the CodeCommit documentation.	DevOps engineer

Task	Description	Skills required
Modify the CloudFormation templates.	Use your local workstation and a code editor to modify the CloudFormation templates according to your use cases or requirements. Commit them to the locally cloned Git repository. For more information, see [Working with AWS CloudFormation templates]() from the AWS CloudFormation documentation.	DevOps engineer

Task	Description	Skills required
Push the changes to the CodeCommit repository.	Your infrastructure code is now under version control and modifications to your code base are tracked. When you push a change to the CodeCommit repository, CodePipeline automatically applies it to your infrastru cture and delivers it to CodeBuild. **Important** If you use the AWS SAM CLI in CodeBuild, run the `sam package` and `sam deploy` commands. If you use AWS CLI, run the `aws cloudformation package` and `aws cloudformation deploy` commands.	DevOps engineer

Enforce tagging of Amazon EMR clusters at launch

Priyanka Chaudhary, Amazon Web Services

Summary

This pattern provides a security control that ensures that Amazon EMR clusters are tagged when they are created.

Amazon EMR is an Amazon Web Services (AWS) service for processing and analyzing vast amounts of data. Amazon EMR offers an expandable, low-configuration service as an easier alternative to running in-house cluster computing. You can use tagging to categorize AWS resources in different ways, such as by purpose, owner, or environment . For example, you can tag your Amazon EMR clusters by assigning custom metadata to each cluster. A tag consists of a key and value that you define. We recommend that you create a consistent set of tags to meet your organization's requirements. When you add a tag to an Amazon EMR cluster, the tag is also propagated to each active Amazon Elastic Compute Cloud (Amazon EC2) instance that is associated with the cluster. Similarly, when you remove a tag from an Amazon EMR cluster, that tag is removed from each associated, active EC2 instance as well.

The detective control monitors API calls and initiates an Amazon CloudWatch Events event for the RunJobFlow, AddTags, RemoveTags, and CreateTags APIs. The event calls AWS Lambda, which runs a Python script. The Python function gets the Amazon EMR cluster ID from the JSON input from the event and performs the following checks:

- Check if the Amazon EMR cluster is configured with tag names that you specify.
- If not, send an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon EMR cluster name, violation details, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code. Or, you can create an S3 bucket for this purpose, as described in the *Epics* section.

- An active email address where you would like to receive violation notifications.
- A list of mandatory tags you want to check for.

Limitations

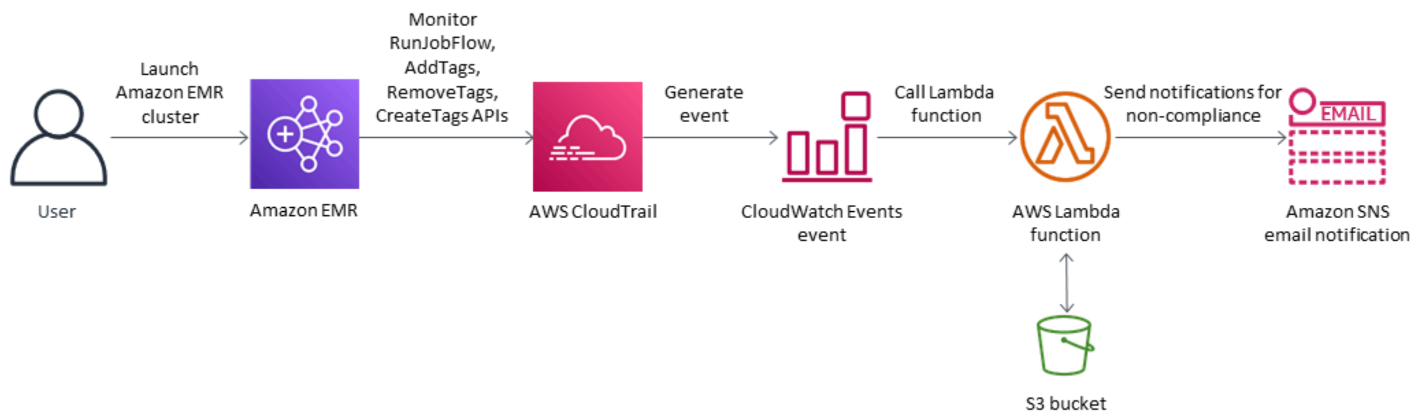
- This security control is regional. You must deploy it in each AWS Region that you want to monitor.

Product versions

- Amazon EMR release 4.8.0 and later.

Architecture

Workflow architecture



Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- Amazon CloudWatch Events - Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- Amazon EMR - Amazon EMR is web service that simplifies running big data frameworks and processing vast amounts of data efficiently.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

This pattern includes the following attachments:

- `EMRTagValidation.zip` – The Lambda code for the security control.
- `EMRTagValidation.yml` – The CloudFormation template that sets up the event and Lambda function.

Epics

Set up the S3 bucket

Ensure Amazon EMR logging to Amazon S3 is enabled at launch

Priyanka Chaudhary, Amazon Web Services

Summary

This pattern provides a security control that monitors logging configuration for Amazon EMR clusters running on Amazon Web Services (AWS).

Amazon EMR is an AWS tool for big data processing and analysis. Amazon EMR offers the expandable low-configuration service as an alternative to running in-house cluster computing. Amazon EMR provides two types of EMR clusters.

- **Transient Amazon EMR clusters**: Transient Amazon EMR clusters automatically shut down and stop incurring costs when processing is finished.
- **Persistent Amazon EMR clusters**: Persistent Amazon EMR clusters continue to run after the data processing job is complete.

Amazon EMR and Hadoop both produce log files that report status on the cluster. By default, these are written to the master node in the **/mnt/var/log/** directory. Depending on how you configure the cluster when you launch it, you can also save these logs to Amazon Simple Storage Service (Amazon S3) and view them through the graphical debugging tool. Note that Amazon S3 logging can be specified only when the cluster is launched. With this configuration, logs are sent from the primary node to the Amazon S3 location every 5 minutes. For transient clusters, Amazon S3 logging is important because the clusters disappear when processing is complete, and these log files can be use to debug any failed jobs.

The pattern uses an AWS CloudFormation template to deploy a security control that monitors for API calls and starts Amazon CloudWatch Events on "RunJobFlow." The trigger invokes AWS Lambda, which runs a Python script. The Lambda function retrieves the EMR cluster ID from the event JSON input and also checks for an Amazon S3 log URI. If an Amazon S3 URI is not found, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification detailing the EMR cluster name, violation details, AWS Region, AWS account, and the Lambda Amazon Resource Name (ARN) that the notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An S3 bucket for the Lambda code .zip file
- An email address where you want to receive the violation notification

Limitations

- This detective control is regional and must be deployed in the AWS Regions you intend to monitor.

Product versions

- Amazon EMR release 4.8.0 and later

Generate test data using an AWS Glue job and Python

Moinul Al-Mamun, Amazon Web Services

Summary

This pattern shows you how to quickly and easily generate millions of sample files concurrently by creating an AWS Glue job written in Python. The sample files are stored in an Amazon Simple Storage Service (Amazon S3) bucket. The ability to quickly generate a large number of sample files is important for testing or evaluating services in the AWS Cloud. For example, you can test the performance of AWS Glue Studio or AWS Glue DataBrew jobs by performing data analysis on millions of small files in an Amazon S3 prefix.

Although you can use other AWS services to generate sample datasets, we recommend that you use AWS Glue. You don't need to manage any infrastructure because AWS Glue is a serverless data processing service. You can just bring your code and run it in an AWS Glue cluster. Additionally, AWS Glue provisions, configures, and scales the resources required to run your jobs. You pay only for the resources that your jobs use while running.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), installed and configured to work with the AWS account

Product versions

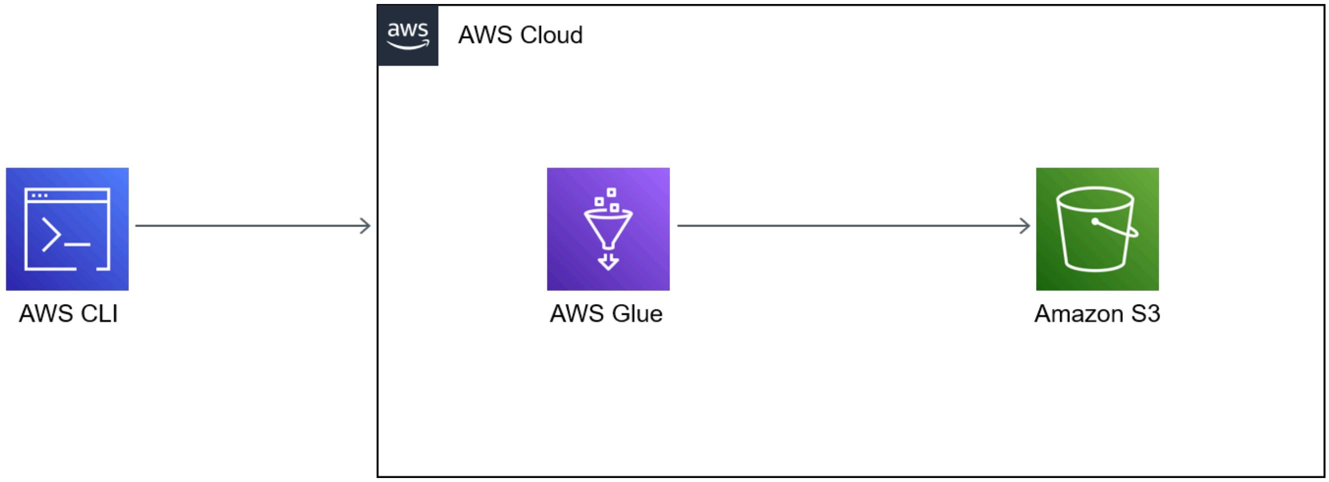
- Python 3.9
- AWS CLI version 2

Limitations

The maximum number of AWS Glue jobs per trigger is 50. For more information, see AWS Glue endpoints and quotas.

Architecture

The following diagram depicts an example architecture centered around an AWS Glue job that writes its output (that is, sample files) to an S3 bucket.



The diagram includes the following workflow:

1. You use the AWS CLI, AWS Management Console, or an API to initiate the AWS Glue job. The AWS CLI or API enables you to automate the parallelization of the invoked job and reduce the runtime for generating sample files.
2. The AWS Glue job generates file content randomly, converts the content into CSV format, and then stores the content as an Amazon S3 object under a common prefix. Each file is less than a kilobyte. The AWS Glue job accepts two user-defined job parameters: `START_RANGE` and `END_RANGE`. You can use these parameters to set file names and the number of files generated in Amazon S3 by each job run. You can run multiple instances of this job in parallel (for example, 100 instances).

Tools

- [Amazon Simple Storage Service (Amazon S3)] is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Command Line Interface (AWS CLI)] is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Glue] is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.

- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Best practices

Consider the following AWS Glue best practices as you implement this pattern:

- **Use the right AWS Glue worker type to reduce cost.** We recommend that you understand the different properties of worker types, and then choose the right worker type for your workload based on CPU and memory requirements. For this pattern, we recommend that you use a Python shell job as your job type to minimize DPU and reduce cost. For more information, see Adding jobs in AWS Glue in the AWS Glue Developer Guide.
- **Use the right concurrency limit to scale your job.** We recommend that you base the maximum concurrency of your AWS Glue job on your time requirement and required number of files.
- **Start generating a small number of files at first.** To reduce cost and save time when you build your AWS Glue jobs, start with a small number of files (such as 1,000). This can make troubleshooting easier. If generating a small number of files is successful, then you can scale to a larger number of files.
- **Run locally first.** To reduce cost and save time when you build your AWS Glue jobs, start the development locally and test your code. For instructions on setting up a Docker container that can help you write AWS Glue extract, transform, and load (ETL) jobs both in a shell and in an integrated development environment (IDE), see the Developing AWS Glue ETL jobs locally using a container post on the AWS Big Data Blog.

For more AWS Glue best practices, see Best practices in the AWS Glue documentation.

Epics

Create a destination S3 bucket and IAM role

Task	Description	Skills required
Create an S3 bucket for storing the files.	Create an S3 bucket and a prefix within it.	App developer

Task	Description	Skills required
	Note This pattern uses the `s3://{your-s3-bucket-name}/small-files/` location for demonstration purposes.	

Task	Description	Skills required

Create and configure an IAM role.	You must create an IAM role that your AWS Glue job can use to write to your S3 bucket.
	
	1. Create an IAM role (for example, called `"AWSGlueServiceRole-smallfiles"`).
	2. Choose AWS Glue as the policy's trusted entity.
	3. Attach an AWS managed policy called `"AWSGlueServiceRole"` to the role.
	4. Create an inline policy or customer managed policy called `"s3-small-file-access"` based on the following configuration. Replace `"{bucket}"` with your bucket name.
	
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Effect": "Allow",`
	`            "Action": [`
	`                "s3:GetObject",`
	`                "s3:PutObject"`
		App developer

Task	Description	Skills required

	``
	            ],
	            "Resource
	": [
	
	 "arn:aws:s3:::{buc
	ket}/small-files/i
	nput/*"
	            ]
	        }
	    ]
	}
	``
	5. Attach the `"s3-small-file-access"` policy to your role.	

Create and configure an AWS Glue job to handle concurrent runs

Task	Description	Skills required
Create an AWS Glue job.	You must create an AWS Glue job that generates your content and stores it in an S3 bucket. Create an AWS Glue job, and then configure your job by completing the following steps: 1. Sign in to the AWS Management Console and open the AWS Glue console. 2. In the navigation pane, under **Data Integration and ETL**, choose **Jobs**.	App developer

Task	Description	Skills required
	3. In the **Create job** section, choose **Python Shell script editor**. 4. In the **Options** section, select **Create a new script with boilerplate code**, and then choose **Create**. 5. Choose **Job details**. 6. For **Name**, enter **create_small_files**. 7. For **IAM Role**, select the IAM role that you created earlier. 8. In the **This job runs** section, choose **A new script to be authored by you**. 9. Expand **Advanced properties**. 10. For **Maximum concurrency**, enter **100** for demonstration purposes. **Note**: Maximum concurrency defines how many instances of the job that you can run in parallel. 11. Choose **Save**.	

Task	Description	Skills required

Update the job code.	1. Open the [AWS Glue console](). 2. In the navigation pane, choose **Jobs**. 3. In the **Your jobs** section, choose the job that you created earlier. 4. Choose the **Script** tab, and then update the script based on the following code. Update the `BUCKET_NAME` , `PREFIX`, and `text_str` variables with your values.
	 `from awsglue.utils import getResolvedOptions`
	`import sys`
	`import boto3`
	`from random import randrange`
	
	`# Two arguments`
	`args = getResolvedOptions(sys.argv, ['START_RANGE', 'END_RANGE'])`
	
	`START_RANGE = int(args['START_RANGE'])`
	`END_RANGE = int(args['END_RANGE'])`
	
	`BUCKET_NAME = '{BUCKET_NAME}'`
		App developer

Task	Description	Skills required

	``
	PREFIX = 'small-files/input/'
	s3 = boto3.resource('s3')
	for x in range(START_RANGE, END_RANGE):
	    # generate file name
	    file_name = f"input_{x}.txt"
	    # generate text
	    text_str = str(randrange(100000))+","+str(randrange(100000))+", " + str(randrange(10000000)) + "," + str(randrange(10000))
	    # write in s3
	    s3.Object(BUCKET_NAME, PREFIX + file_name).put(Body=text_str)
	``
	5. Choose **Save**.	

Run the AWS Glue job from the command line or console

Task	Description	Skills required
Run the AWS Glue job from the command line.	To run your AWS Glue job from the AWS CLI , run the following command using your values: ``` cmd:~$ aws glue start-job-run --job-name ```	App developer

Task	Description	Skills required
	``` create_small_files --arguments '{"--STAR T_RANGE":"0","--EN D_RANGE":"1000000"}' cmd:~$ aws glue start-job-run --job-name create_small_files --arguments '{"--STAR T_RANGE":"1000000" ,"--END_RANGE":"20 00000"}' ``` **Note** For instructions on running the AWS Glue job from the AWS Management Console, see the *Run the AWS Glue job in the AWS Management Console* story in this pattern. **Tip** We recommend using the AWS CLI to run AWS Glue jobs if you want to run multiple executions at a time with different parameters, as shown in the example above.	

Task	Description	Skills required

	To generate all AWS CLI commands that are required to generate a defined number of files using a certain parallelization factor, run the following bash code (using your values):
	
	``
	# define parameters
	NUMBER_OF_FILES=
	10000000;
	PARALLELIZATION=50;
	
	# initialize
	_SB=0;
	
	# generate commands
	for i in $(seq 1
	 $PARALLELIZATION);
	do
	      echo aws glue
	 start-job-run --
	job-name create_sm
	all_files --argumen
	ts "'"'{"--START_RANG
	E":"'$(((NUMBER_OF
	_FILES/PARALLELIZA
	TION) * (i-1) +
	 _SB))'","--END_RAN
	GE":"'$(((NUMBER_O
	F_FILES/PARALLELIZ
	ATION) * (i)))'"}'"'";
	      _SB=1;
	done
	``
	
	If you use the script above, consider the following:	

Task	Description	Skills required
	• The script simplifies the invocation and generation of small files at scale. • Update `NUMBER_OF_FILES` and `PARALLELIZATION` with your values. • The script above prints a list of commands that you must run. Copy those output commands, and then run them in your terminal. • If you want to run the commands directly from within the script, remove the `echo` statement in line 11. **Note** To see an example of output from the above script, see *Shell script output* in the *Additional information* section of this pattern.	

Task	Description	Skills required
Run the AWS Glue job in the AWS Management Console.	1. Sign in to the AWS Management Console and open the [AWS Glue console](https://console.aws.amazon.com/glue/). 2. In the navigation pane, under **Data Integration and ETL**, choose **Jobs**. 3. In the **Your jobs** section, choose your job. 4. In the **Parameters (optional)** section, update your parameters. 5. Choose **Action**, and then choose **Run job**. 6. Repeat steps 3-5 as many times as you require. For example, to create 10 million files, repeat this process 10 times.	App developer

Task	Description	Skills required
Check the status of your AWS Glue job.	1. Open the AWS Glue console. 2. In the navigation pane, choose **Jobs**. 3. In the **Your jobs** section, choose the job that you created earlier (that is, `create_small_files`). 4. For insight into the progress and generation of your files, review the **Run ID**, **Run Status**, and other columns.	App developer

Additional information

Benchmarking test

This pattern was used to generate 10 million files using different parallelization parameters as part of a benchmarking test. The following table shows the output of the test:

Parallelization	Number of files generated by a job run	Job duration	Speed
10	1,000,000	6 hours, 40 minutes	Very slow
50	200,000	80 minutes	Moderate
100	100,000	40 minutes	Fast

If you want to make the process faster, you can configure more concurrent runs in your job configuration. You can easily adjust the job configuration based on your requirements, but keep in mind that there is an AWS Glue service quota limit. For more information, see [AWS Glue endpoints and quotas](#).

Shell script output

The following example shows the output of the shell script from the *Run the AWS Glue job from the command line* story in this pattern.

```
user@MUC-1234567890 MINGW64 ~
  $ # define parameters
  NUMBER_OF_FILES=10000000;
  PARALLELIZATION=50;
  # initialize
  _SB=0;

  # generate commands
  for i in $(seq 1 $PARALLELIZATION);
   do
         echo aws glue start-job-run --job-name create_small_files --arguments
 "'"'{"--START_RANGE":"'$(((NUMBER_OF_FILES/PARALLELIZATION)  (i-1) + SB))'","--
ENDRANGE":"'$(((NUMBER_OF_FILES/PARALLELIZATION)  (i)))'"}'"'";
         _SB=1;
```

```
    done

  aws glue start-job-run --job-name create_small_files --arguments '{"--
START_RANGE":"0","--END_RANGE":"200000"}'

START_RANGE":"9800001","--END_RANGE":"10000000"}'

  user@MUC-1234567890 MINGW64 ~
```

FAQ

How many concurrent runs or parallel jobs should I use?

The number of concurrent runs and parallel jobs depend on your time requirement and desired number of test files. We recommend that you check the size of the files that you're creating. First, check how much time an AWS Glue job takes to generate your desired number of files. Then, use the right number of concurrent runs to meet your goals. For example, if you assume that 100,000 files takes 40 minutes to complete the run but your target time is 30 minutes, then you must increase the concurrency setting for your AWS Glue job.

What type of content can I create using this pattern?

You can create any type of content, such as text files with different delimiters (for example, PIPE, JSON, or CSV). This pattern uses Boto3 to write to a file and then saves the file in an S3 bucket.

What level of IAM permission do I need in the S3 bucket?

You must have an identity-based policy that allows `Write` access to objects in your S3 bucket. For more information, see [Amazon S3: Allows read and write access to objects in an S3 bucket]() in the Amazon S3 documentation.

Cost-effectively ingest IoT data directly into Amazon S3 using AWS IoT Greengrass

Sebastian Viviani and Rizwan Syed, Amazon Web Services

Summary

This pattern shows you how to cost-effectively ingest Internet of Things (IoT) data directly into an Amazon Simple Storage Service (Amazon S3) bucket by using an AWS IoT Greengrass Version 2 device. The device runs a custom component that reads the IoT data and saves the data in persistent storage (that is, a local disk or volume). Then, the device compresses the IoT data into an Apache Parquet file and uploads the data periodically to an S3 bucket.

The amount and speed of IoT data that you ingest is limited only by your edge hardware capabilities and network bandwidth. You can use Amazon Athena to cost-effectively analyze your ingested data. Athena supports compressed Apache Parquet files and data visualization by using Amazon Managed Grafana.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An edge gateway that runs on AWS IoT Greengrass Version 2 and collects data from sensors (The data sources and the data collection process are beyond the scope of this pattern, but you can use nearly any type of sensor data. This pattern uses a local MQTT broker with sensors or gateways that publish data locally.)
- AWS IoT Greengrass component, roles, and SDK dependencies
- A stream manager component to upload the data to the S3 bucket
- AWS SDK for Java, AWS SDK for JavaScript, or AWS SDK for Python (Boto3) to run the APIs

Limitations

- The data in this pattern isn't uploaded in real time to the S3 bucket. There is a delay period, and you can configure the delay period. Data is buffered temporarily in the edge device and then uploaded once the period expires.
- The SDK is available only in Java, Node.js, and Python.

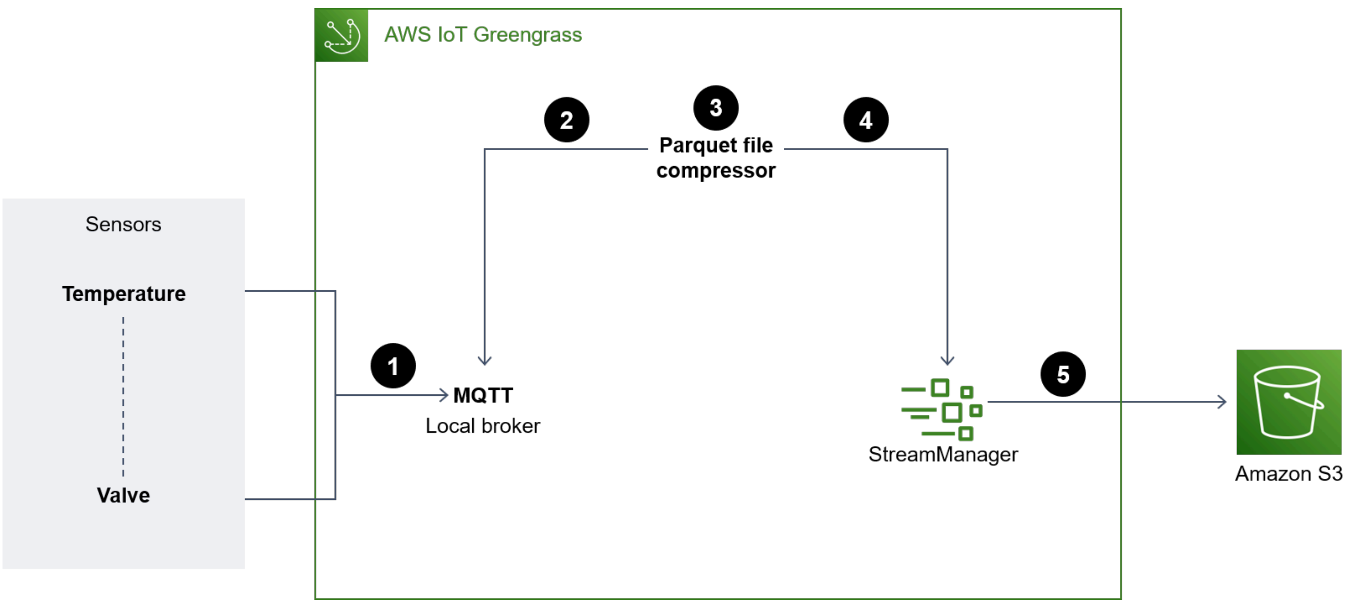
Architecture

Target technology stack

- Amazon S3
- AWS IoT Greengrass
- MQTT broker
- Stream manager component

Target architecture

The following diagram shows an architecture designed to ingest IoT sensor data and store that data in an S3 bucket.



The diagram shows the following workflow:

1. Multiple sensors (for example, temperature and valve) updates are published to a local MQTT broker.
2. The Parquet file compressor that's subscribed to these sensors updates topics and receives these updates.
3. The Parquet file compressor stores the updates locally.
4. After the period lapses, the stored files are compressed into Parquet files and passed on to the stream manager to get uploaded to the specified S3 bucket.

5. The stream manager uploads the Parquet files to the S3 bucket.

> **Note**
>
> The stream manager (`StreamManager`) is a managed component. For examples of how to export data to Amazon S3, see Stream manager in the AWS IoT Greengrass documentation. You can use a local MQTT broker as a component or another broker like Eclipse Mosquitto.

Tools

AWS tools

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS IoT Greengrass is an open source IoT edge runtime and cloud service that helps you build, deploy, and manage IoT applications on your devices.

Other tools

- Apache Parquet is an open-source column-oriented data file format designed for storage and retrieval.
- MQTT (Message Queuing Telemetry Transport) is a lightweight messaging protocol that's designed for constrained devices.

Best practices

Use the right partition format for uploaded data

There are no specific requirements for the root prefix names in the S3 bucket (for example, `"myAwesomeDataSet/"` or `"dataFromSource"`), but we recommend that you use a meaningful partition and prefix so that it's easy to understand the purpose of the dataset.

We also recommend that you use the right partitioning in Amazon S3 so that the queries run optimally on the dataset. In the following example, the data is partitioned in HIVE format so that the amount of data scanned by each Athena query is optimized. This improves performance and reduces cost.

```
s3://<ingestionBucket>/<rootPrefix>/year=YY/month=MM/day=DD/
HHMM_<suffix>.parquet
```

Epics

Set up your environment

Task	Description	Skills required
Create an S3 bucket.	1. Create an S3 bucket or use an existing bucket. 2. Create a meaningful prefix for the S3 bucket where you want to ingest the IoT data (for example, `s3:\\<bucket>\<prefix>`). 3. Record your prefix for later use.	App developer

Add IAM permissions to the S3 bucket.	To grant users write access to the S3 bucket and prefix that you created earlier, add the following IAM policy to your AWS IoT Greengrass role:
	`{`
	`"Version": "2012-10-17",`
	`"Statement": [`
	`{`
	`"Sid": "S3DataUpload",`
	`"Effect": "Allow",`
	`"Action": [`
		App developer

Task	Description	Skills required

	``
	 "s3:List*",
	
	 "s3:Put*"
	            ],
	            "Resource":
	 [
	
	 "arn:aws:s3:::<ing
	estionBucket>",
	
	 "arn:aws:s3:::<ing
	estionBucket>/<pre
	fix>/*"
	            ]
	        }
	    ]
	}
	``
	
	For more information, see [Creating an IAM policy to access Amazon S3 resources](#) in the Aurora documentation.
	
	Next, update the resource policy (if needed) for the S3 bucket to allow write access with the correct AWS [principals](#).	

Build and deploy the AWS IoT Greengrass component

Task	Description	Skills required
Update the recipe of the component.	[Update the component configuration](#) when you	App developer

Task	Description	Skills required

	create a deployment based on the following example:
	
	``
	{
	  "region": "<region>",
	  "parquet_period": <period>,
	  "s3_bucket": "<s3Bucket>",
	  "s3_key_prefix": "<s3prefix>"
	}
	``
	
	Replace `<region>` with your AWS Region, `<period>` with your periodic interval, `<s3Bucket>` with your S3 bucket, and `<s3prefix>` with your prefix.	

Task	Description	Skills required
Create the component.	Do one of the following: • Create the component. • Add the component to the CI/CD pipeline (if one exists). Be sure to copy the artifact from the artifact repository to the AWS IoT Greengrass artifact bucket. Then, create or update your AWS IoT Greengrass component. • **Note** Add the MQTT broker as a component or add it manually later. : This decision affects the authentication scheme that you can use with the broker. Manually adding a broker decouples the broker from AWS IoT Greengras s and enables any supported authentication scheme of the broker. The AWS provided broker components	App developer

Task	Description	Skills required
	have predefine d authentication schemes. For more information, see [MQTT 3.1.1 broker (Moquette)]() and [MQTT 5 broker (EMQX)]().	
Update the MQTT client.	The sample code doesn't use authentication because the component connects locally to the broker. If your scenario differs, update the MQTT client section as needed. Additionally, do the following: 1. Update the MQTT topics in the subscription. 2. Update the MQTT message parser as needed as messages from each source may differ.	App developer

Add the component to the AWS IoT Greengrass Version 2 core device

Task	Description	Skills required
Update the deployment of the core device.	If the deployment of the AWS IoT Greengrass Version 2 core device already exists, [revise the deployment](). If the deployment doesn't exist, [create a new deployment]().	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

To give the component the correct name, update the log manager configuration for the new component (if needed) based on the following:

```
{
  "logsUploaderConfiguration": {
    "systemLogsConfiguration": {
    ...
    },
    "componentLogsConfigurationMap": {
      "<com.iot.ingest.parquet>": {
        "minimumLogLevel": "INFO",
        "diskSpaceLimit": "20",
        "diskSpaceLimitUnit": "MB",
        "deleteLogFileAfterCloudUpload": "false"
      }
      ...
    }
  },
  "periodicUploadIntervalSec": "300"
}
```

Finally, complete the revision of the deployment for your AWS IoT Greengrass core device.

</td><td></td></tr>
</table>

Verify data ingestion into the S3 bucket

Task	Description	Skills required
Check the logs for the AWS IoT Greengrass volume.	Check for the following: • The MQTT client is successfully connected to the local MQTT broker. • The MQTT client is subscribed to the correct topics. • Sensor update messages are coming to the broker on the MQTT topics. • Parquet compression happens at every periodic interval.	App developer
Check the S3 bucket.	Verify if the data is being uploaded to the S3 bucket. You can see the files being uploaded at every period. You can also verify if the data is uploaded to the S3 bucket by querying the data in the next section.	App developer

Set up querying from Athena

Task	Description	Skills required
Create a database and table.	1. Create an AWS Glue database (if needed).	App developer

Task	Description	Skills required
	2. Create a table in AWS Glue manually or by running a crawler in AWS Glue.	
Grant Athena access to the data.	1. Update permissions to allow Athena to access the S3 bucket. For more information, see Fine-grained access to databases and tables in the AWS Glue Data Catalog in the Athena documentation. 2. Query the table in your database.	App developer

Troubleshooting

Issue	Solution
MQTT client fails to connect	• Validate the permissions on the MQTT broker. If you have an MQTT broker from AWS, see MQTT 3.1.1 broker (Moquette) and MQTT 5 broker (EMQX). • Validate the credentials on the MQTT client. If you have an MQTT broker from AWS, see MQTT 3.1.1 broker (Moquette) and MQTT 5 broker (EMQX).
MQTT client fails to subscribe	Validate the permissions on the MQTT broker. If you have an MQTT broker from AWS, see MQTT 3.1.1 broker (Moquette) and MQTT 5 broker (EMQX).
Parquet files don't get created	• Verify that the MQTT topics are correct.

Issue	Solution
	• Verify that the MQTT messages from the sensors are in the correct format.
Objects are not uploaded to the S3 bucket	• Verify that you have internet connectivity and endpoint connectivity. • Verify that the resource policy for your S3 bucket is correct. • Verify the permissions for the AWS IoT Greengrass Version 2 core device role.

Additional information

Cost analysis

The following cost analysis scenario demonstrates how the data ingestion approach covered in this pattern can impact data ingestion costs in the AWS Cloud. The pricing examples in this scenario are based on prices at the time of publication. Prices are subject to change. Additionally, your costs may vary depending on your AWS Region, AWS service quotas, and other factors related to your cloud environment.

Input signal set

This analysis uses the following set of input signals as the basis for comparing IoT ingestion costs with other available alternatives.

Number of signals	Frequency	Data per signal
125	25 Hz	8 bytes

In this scenario, the system receives 125 signals. Each signal is 8 bytes and occurs every 40 milliseconds (25 Hz). These signals could come individually or grouped in a common payload. You have the option to split and pack these signals based on your needs. You can also determine the latency. Latency consists of the time period for receiving, accumulating, and ingesting the data.

For comparison purposes, the ingestion operation for this scenario is based in the `us-east-1` AWS Region. The cost comparison applies to AWS services only. Other costs, like hardware or connectivity, are not factored into the analysis.

Cost comparisons

The following table shows the monthly cost in US dollars (USD) for each ingestion method.

Method	Monthly cost
AWS IoT SiteWise*	331.77 USD
AWS IoT SiteWise Edge with data processing pack (keeping all data at the edge)	200 USD
AWS IoT Core and Amazon S3 rules for accessing raw data	84.54 USD
Parquet file compression at the edge and uploading to Amazon S3	0.5 USD

*Data must be downsampled to comply with service quotas. This means there is some data loss with this method.

Alternative methods

This section shows the equivalent costs for the following alternative methods:

- **AWS IoT SiteWise –** Each signal must be uploaded in an individual message. Therefore, the total number of messages per month is 125×25×3600×24×30, or 8.1 billion messages per month. However, AWS IoT SiteWise can handle only 10 data points per second per property. Assuming the data is downsampled to 10 Hz, the number of messages per month is reduced to 125×10×3600×24×30, or 3.24 billion. If you use the publisher component that packs measurements in groups of 10 (at 1 USD per million messages), then you get a monthly cost of 324 USD per month. Assuming that each message is 8 bytes (1 Kb/125), that's 25.92 Gb of data storage. This adds a monthly cost of 7.77 USD per month. The total cost for the first month is 331.77 USD and increases by 7.77 USD every month.
- **AWS IoT SiteWise Edge with data processing pack, including all models and signals fully processed at the edge (that is, no cloud ingestion) –** You can use the data processing pack as an alternative to reduce costs and to configure all the models that get calculated at the edge. This can work just for storage and visualization, even if no real calculation is performed. In this case, it's necessary to use powerful hardware for the edge gateway. There is a fixed cost of 200 USD per month.
- **Direct ingestion to AWS IoT Core by MQTT and an IoT rule to store the raw data in Amazon S3 –** Assuming all the signals are published in a common payload, the total number of messages published to AWS IoT Core is 25×3600×24×30, or 64.8 million per month. At 1 USD per million messages, that's a monthly cost of 64.8 USD per month. At 0.15 USD per million rule activations and with one rule per message, that adds a monthly cost of 19.44 USD per month. At a cost of 0.023 USD per Gb of storage in Amazon S3, that adds another 1.5 USD per month (increasing every month to reflect the new data). The total cost for the first month is 84.54 USD and increases by 1.5 USD every month.
- **Compressing data at the edge in a Parquet file and uploading to Amazon S3 (proposed method) –** The compression ratio depends on the type of data. With the same industrial data tested for MQTT, the total output data for a full month is 1.2 Gb. This costs 0.03 USD per month. Compression ratios (using random data) described in other benchmarks are on the order of 66 percent (closer to a worst-case scenario). The total data is 21 Gb and costs 0.5 USD per month.

Parquet file generator

The following code example shows the structure of a Parquet file generator that's written in Python. The code example is for illustration purposes only and won't work if pasted into your environment.

```
import queue
```

```
import paho.mqtt.client as mqtt
import pandas as pd

#queue for decoupling the MQTT thread
messageQueue = queue.Queue()
client = mqtt.Client()
streammanager = StreamManagerClient()

def feederListener(topic, message):
    payload = {
        "topic" : topic,
        "payload" : message,
    }
    messageQueue.put_nowait(payload)

def on_connect(client_instance, userdata, flags, rc):
    client.subscribe("#",qos=0)

def on_message(client, userdata, message):
    feederListener(topic=str(message.topic),
 message=str(message.payload.decode("utf-8")))

filename = "tempfile.parquet"
streamname = "mystream"
destination_bucket= "amzn-s3-demo-bucket"
keyname="mykey"
period= 60

client.on_connect = on_connect
client.on_message = on_message
streammanager.create_message_stream(
            MessageStreamDefinition(name=streamname,
 strategy_on_full=StrategyOnFull.OverwriteOldestData)
        )

while True:
   try:
       message = messageQueue.get(timeout=myArgs.mqtt_timeout)
   except (queue.Empty):
       logger.warning("MQTT message reception timed out")

   currentTimestamp = getCurrentTime()
```

```
  if currentTimestamp >= nextUploadTimestamp:
      df = pd.DataFrame.from_dict(accumulator)
      df.to_parquet(filename)
      s3_export_task_definition = S3ExportTaskDefinition(input_url=filename,
bucket=destination_bucket, key=key_name)
      streammanager.append_message(streamname,
Util.validate_and_serialize_to_json_bytes(s3_export_task_definition))
      accumulator = {}
      nextUploadTimestamp += period
  else:
       accumulator.append(message)
```

Launch a Spark job in a transient EMR cluster using a Lambda function

Dhrubajyoti Mukherjee, Amazon Web Services

Summary

This pattern uses the Amazon EMR RunJobFlow API action to launch a transient cluster to run a Spark job from a Lambda function. A transient EMR cluster is designed to terminate as soon as the job is complete or if any error occurs. A transient cluster provides cost savings because it runs only during the computation time, and it provides scalability and flexibility in a cloud environment.

The transient EMR cluster is launched using the Boto3 API and the Python programming language in a Lambda function. The Lambda function, which is written in Python, provides the added flexibility of initiating the cluster when it is needed.

To demonstrate a sample batch computation and output, this pattern will launch a Spark job in an EMR cluster from a Lambda function and run a batch computation against the example sales data of a fictional company. The output of the Spark job will be a comma-separated values (CSV) file in Amazon Simple Storage Service (Amazon S3). The input data file, Spark .jar file, a code snippet, and an AWS CloudFormation template for a virtual private cloud (VPC) and AWS Identity and Access Management (IAM) roles to run the computation are provided as an attachment.

Prerequisites and limitations

Prerequisites

- An active AWS account

Limitations

- Only one Spark job can be initiated from the code at a time.

Product versions

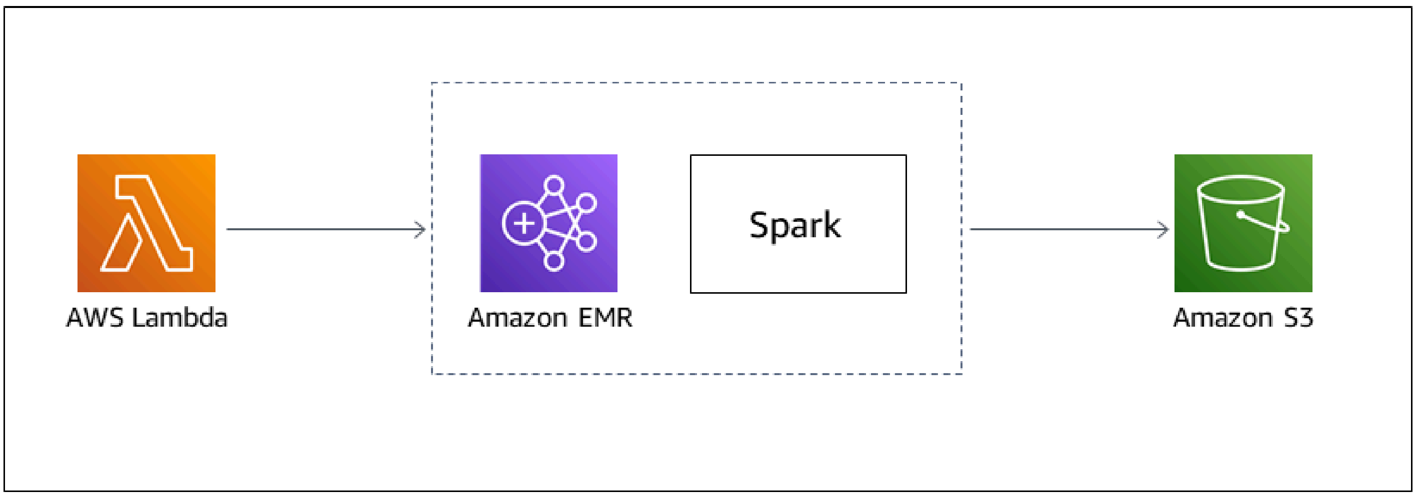
- Tested on Amazon EMR 6.0.0

Architecture

Target technology stack

- Amazon EMR
- AWS Lambda
- Amazon S3
- Apache Spark

Target architecture



Automation and scale

To automate the Spark-EMR batch computation, you can use either of the following options.

- Implement an Amazon EventBridge rule that can initiate the Lambda function in a cron schedule. For more information, see [Tutorial: Schedule AWS Lambda functions using EventBridge].
- Configure [Amazon S3 event notifications] to initiate the Lambda function on file arrival.
- Pass the input parameters to the AWS Lambda function through the event body and Lambda environment variables.

Tools

AWS services

- Amazon EMR is a managed cluster platform that simplifies running big data frameworks on AWS to process and analyze large amounts of data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Apache Spark is a multiple-language analytics engine for large-scale data processing.

Epics

Create the Amazon EMR and Lambda IAM roles and the VPC

Task	Description	Skills required
Create the IAM roles and the VPC.	If you already have the AWS Lambda and Amazon EMR IAM roles and a VPC, you can skip this step. To run the code, both the EMR cluster and the Lambda function require IAM roles. The EMR cluster also requires a VPC with a public subnet or a private subnet with a NAT gateway. To automatically create all the IAM roles and a VPC, deploy the attached AWS CloudForm ation template as is, or you can create the roles and the VPC manually as specified in	Cloud architect

Task	Description	Skills required
	the *Additional information* section.	
Note the AWS CloudFormation template output keys.	After the CloudFormation template has successfully deployed, navigate to the **Outputs** tab in the AWS CloudFormation console. Note the five output keys: • `S3Bucket` • `LambdaExecutionRole` • `ServiceRole` • `JobFlowRole` • `Ec2SubnetId` You will use the values from these keys when you create the Lambda function.	Cloud architect

Upload the Spark .jar file

Task	Description	Skills required
Upload the Spark .jar file.	Upload the Spark .jar file to the S3 bucket that the AWS CloudFormation stack created. The bucket name is the same as the output key `S3Bucket`.	General AWS

Create the Lambda function to launch the EMR cluster

Task	Description	Skills required
Create a Lambda function.	On the Lambda console, create a Python 3.9+ Lambda function with an execution role. The execution role policy must allow Lambda to launch an EMR cluster. (See the attached AWS CloudForm ation template.)	Data engineer, Cloud engineer
Copy and paste the code.	Replace the code in the `lambda_function.py` file with the code from the *Additional information* section of this pattern.	Data engineer, Cloud engineer
Change the parameters in the code.	Follow the comments in the code to change the parameter values to match your AWS account.	Data engineer, Cloud engineer
Launch the function to initiate the cluster.	Launch the function to initiate the creation of a transient EMR cluster with the Spark .jar file provided. It will run the Spark job and terminate automatically when the job is complete.	Data engineer, Cloud engineer
Check the EMR cluster status.	After the EMR cluster is initiated, it appears in the Amazon EMR console under the **Clusters** tab. Any errors while launching the cluster	Data engineer, Cloud engineer

Task	Description	Skills required
	or running the job can be be checked accordingly.	

Set up and run the sample demo

Task	Description	Skills required
Upload the Spark .jar file.	Download the Spark .jar file from the *Attachments* section and upload it to the S3 bucket.	Data engineer, Cloud engineer
Upload the input dataset.	Upload the attached `fake_sales_data.csv` file to the S3 bucket.	Data engineer, Cloud engineer
Paste the Lambda code and change the parameters.	Copy the code from the **Tools** section, and paste the code in a Lambda function, replacing the code `lambda_function.py` file. Change the parameter values to match your account.	Data engineer, Cloud engineer
Launch the function and verify the output.	After the Lambda function initiates the cluster with the provided Spark job, it generates a .csv file in the S3 bucket.	Data engineer, Cloud engineer

                }
            }
        ]
    )
```

IAM roles and VPC creation

To launch the EMR cluster in a Lambda function, a VPC and IAM roles are needed. You can set up the VPC and IAM roles by using the AWS CloudFormation template in the Attachments section of this pattern, or you can manually create them by using the following links.

The following IAM roles are required to run Lambda and Amazon EMR.

Lambda execution role

A Lambda function's execution role grants it permission to access AWS services and resources.

Service role for Amazon EMR

The Amazon EMR role defines the allowable actions for Amazon EMR when provisioning resources and performing service-level tasks that are not performed in the context of an Amazon Elastic Compute Cloud (Amazon EC2) instance running within a cluster. For example, the service role is used to provision EC2 instances when a cluster launches.

Service role for EC2 instances

The service role for cluster EC2 instances (also called the EC2 instance profile for Amazon EMR) is a special type of service role that is assigned to every EC2 instance in an Amazon EMR cluster when the instance launches. Application processes that run on top of Apache Hadoop assume this role for permissions to interact with other AWS services.

VPC and subnet creation

You can create a VPC from the VPC console.

Migrate Apache Cassandra workloads to Amazon Keyspaces by using AWS Glue

Nikolai Kolesnikov, Karthiga Priya Chandran, and Samir Patel, Amazon Web Services

Summary

This pattern shows you how to migrate your existing Apache Cassandra workloads to Amazon Keyspaces (for Apache Cassandra) by using CQLReplicator on AWS Glue. You can use CQLReplicator on AWS Glue to minimize the replication lag of migrating your workloads down to a matter of minutes. You also learn how to use an Amazon Simple Storage Service (Amazon S3) bucket to store data required for the migration, including Apache Parquet files, configuration files, and scripts. This pattern assumes that your Cassandra workloads are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances in a virtual private cloud (VPC).

Prerequisites and limitations

Prerequisites

- Cassandra cluster with a source table
- Target table in Amazon Keyspaces to replicate the workload
- S3 bucket to store intermediate Parquet files that contain incremental data changes
- S3 bucket to store job configuration files and scripts

Limitations

- CQLReplicator on AWS Glue requires some time to provision Data Processing Units (DPUs) for the Cassandra workloads. The replication lag between the Cassandra cluster and the target keyspace and table in Amazon Keyspaces is likely to last for only a matter of minutes.

Architecture

Source technology stack

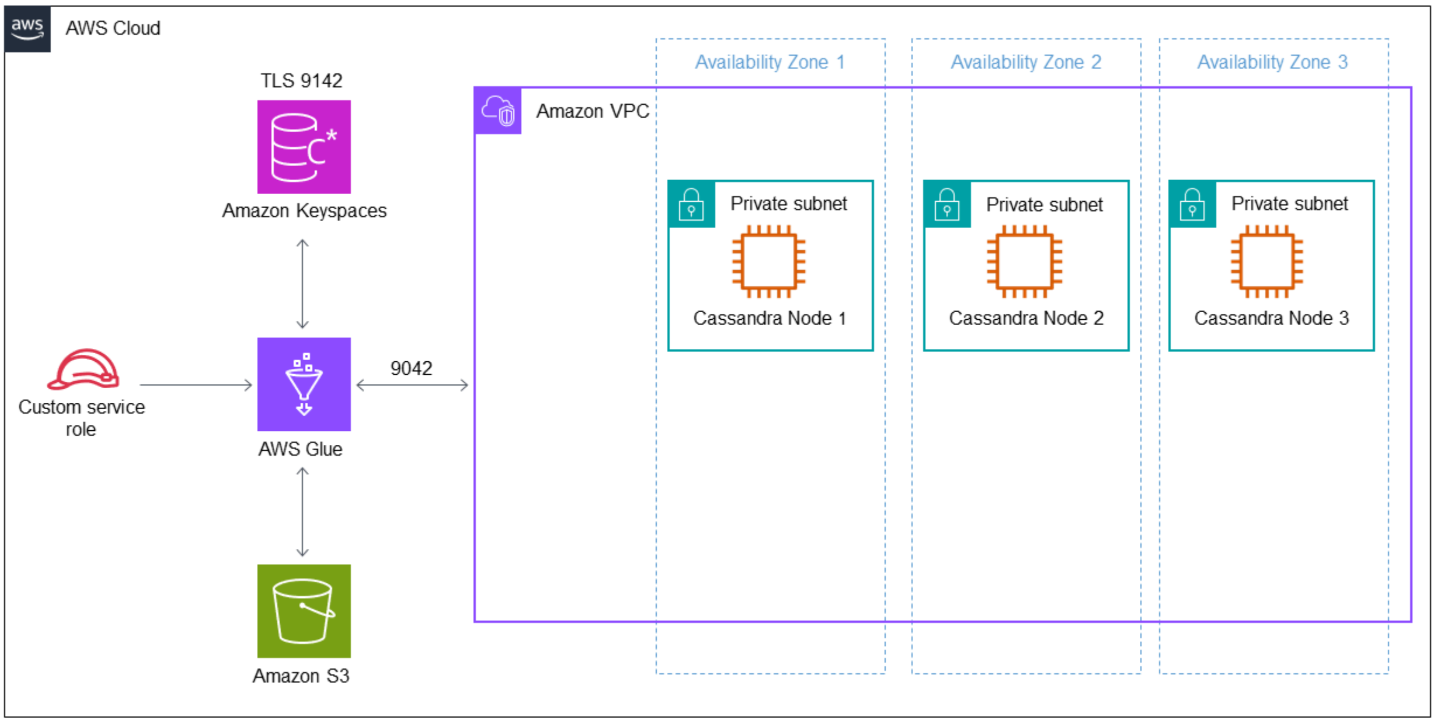
- Apache Cassandra
- DataStax Server
- ScyllaDB

Target technology stack

- Amazon Keyspaces

Migration architecture

The following diagram shows an example architecture where a Cassandra cluster is hosted on EC2 instances and spread across three Availability Zones. The Cassandra nodes are hosted in private subnets.



The diagram shows the following workflow:

1. A custom service role provides access to Amazon Keyspaces and the S3 bucket.
2. An AWS Glue job reads the job configuration and scripts in the S3 bucket.
3. The AWS Glue job connects through port 9042 to read data from the Cassandra cluster.
4. The AWS Glue job connects through port 9142 to write data to Amazon Keyspaces.

Tools

AWS services and tools

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS CloudShell is a browser-based shell that you can use to manage AWS services by using the AWS Command Line Interface (AWS CLI) and a range of preinstalled development tools.
- AWS Glue is a fully managed ETL service that helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- Amazon Keyspaces (for Apache Cassandra) is a managed database service that helps you migrate, run, and scale your Cassandra workloads in the AWS Cloud.

Code

The code for this pattern is available in the GitHub CQLReplicator repository.

Best practices

- To determine the necessary AWS Glue resources for the migration, estimate the number of rows in the source Cassandra table. For example, 250 K rows per 0.25 DPU (2 vCPUs, 4 GB of memory) with 84 GB disk.
- Pre-warm Amazon Keyspaces tables before running CQLReplicator. For example, eight CQLReplicator tiles (AWS Glue jobs) can write up to 22 K WCUs per second, so the target should be pre-warmed up to 25-30 K WCUs per second.
- To enable communication between AWS Glue components, use a self-referencing inbound rule for all TCP ports in your security group.
- Use the incremental traffic strategy to distribute the migration workload over time.

Epics

Deploy CQLReplicator

Task	Description	Skills required
Create a target keyspace and table.	1. Create a keyspace and table in Amazon Keyspaces. For more information on write capacity, see *Write*	App owner, AWS administr ator, DBA, App developer

Task	Description	Skills required
	unit calculations in the Additional information section of this pattern. You can also create a keyspace by using the Cassandra Query Language (CQL). For more informati on, see *Create a keyspace by using CQL* in the Additional information section of this pattern. **Note** After you create the table, consider switching the table to on-demand capacity mode to avoid unnecessary charges. 2. To update to throughput mode, run the following script: `ALTER TABLE target_keyspace.target_table WITH CUSTOM_PROPERTIES = { 'capacity_mode': { 'throughput_mode': 'PAY_PER_REQUEST'} }`	

Task	Description	Skills required

Configure the Cassandra driver to connect to Cassandra.	Use the following configuration script:
	<pre>Datastax-java-driver {
	  basic.request.consistency = "LOCAL_QUORUM"
	  basic.contact-points = ["127.0.0.1:9042"]
	   advanced.reconnect-on-init = true
	   basic.load-balancing-policy {
	        local-datacenter = "datacenter1"
	}
	advanced.auth-provider = {
	       class = PlainTextAuthProvider
	       username = "user-at-sample"
	       password = "S@MPLE=PASSWORD="
	}
	}</pre>
	Note
	The preceding script uses the Spark Cassandra Connector. For more information, see the reference configuration for Cassandra.
		DBA

Task	Description	Skills required

Configure the Cassandra driver to connect to Amazon Keyspaces.	Use the following configura tion script:
	
	`datastax-java-driver {`
	`basic {`
	`  load-balancing-pol`
	`icy {`
	`    local-datacenter =`
	` us-west-2`
	`        }`
	`  contact-points = [`
	`            "cassandr`
	`a.us-west-2.amazon`
	`aws.com:9142"`
	`        ]`
	`  request {`
	`  page-size = 2500`
	`  timeout = 360 seconds`
	`  consistency =`
	` LOCAL_QUORUM`
	`        }`
	`    }`
	`advanced {`
	` control-connection {`
	`  timeout = 360 seconds`
	`        }`
	` session-leak.thres`
	`hold = 6`
	` connection {`
	` connect-timeout = 360`
	` seconds`
	` init-query-timeout =`
	` 360 seconds`
	` warn-on-init-error =`
	` false`
	`        }`
	` auth-provider = {`
	`  class = software.`
	`aws.mcs.auth.SigV4`
	`AuthProvider`
		DBA

Task	Description	Skills required

	``
	  aws-region = us-
	west-2
	 }
	
	 ssl-engine-factory {
	  class = DefaultSs
	lEngineFactory
	        }
	    }
	}
	``
	
	Note
	
	The preceding script uses the Spark Cassandra Connector. For more information, see the reference configuration for [Cassandra]().	

Task	Description	Skills required
Create an IAM role for the AWS Glue job.	Create a new AWS service role named `glue-cassandra-migration` with AWS Glue as a trusted entity. **Note** The `glue-cassandra-migration` should provide read and write access to the S3 bucket and Amazon Keyspaces. The S3 bucket contains the .jar files, configuration files for Amazon Keyspaces and Cassandra, and the intermediate Parquet files. For example, it contains the `AWSGlueServiceRole`, `AmazonS3FullAccess`, and `AmazonKeyspacesFullAccess` managed policies.	AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Download CQLReplicator in AWS CloudShell.</td><td>Download the project to your home folder by running the following command:<pre><code>git clone https://github.com/aws-samples/cql-replicator.git
cd cql-replicator/glue
# Only for AWS CloudShell, the bc package includes bc and dc. Bc is an arbitrary precision numeric processing arithmetic language
sudo yum install bc -y</code></pre></td><td></td></tr>
<tr><td>Modify the reference configuration files.</td><td>Copy <code>CassandraConnector.conf</code> and <code>KeyspacesConnector.conf</code> to the <code>../glue/conf</code> directory in the project folder.</td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required

Initiate the migration process.	The following command initializes the CQLReplicator environment. Initializaition involves copying .jar artifacts, and creating an AWS Glue connector, an S3 bucket, an AWS Glue job, the `migration` keyspace, and the `ledger` table:
	`cd cql-replicator/glue/bin`
	`./cqlreplicator --state init --sg '"sg-1","sg-2"' \ --subnet "subnet-XXXXXXXXXXX" \ --az us-west-2a --region us-west-2 \ --glue-iam-role glue-cassandra-migration \ --landing-zone s3://cql-replicator-1234567890-us-west-2`
	The script includes the following parameters:
	• `--sg` – The security groups that allow access to the Cassandra cluster from AWS Glue and include the self-referencing inbound rule for all traffic
		AWS DevOps

Task	Description	Skills required
	• `--subnet` – The subnet to which the Cassandra cluster belongs • `--az` – The Availability Zone of the subnet • `--region` – The AWS Region where the Cassandra cluster is deployed • `--glue-iam-role` – The IAM role permissions that AWS Glue can assume when calling Amazon Keyspaces and Amazon S3 on your behalf • `--landing zone` – An optional parameter for reusing an S3 bucket (If you don't supply a value for the `--landing zone` parameter, the `init` process will try to create a new bucket to store the configuration files, .jar artifacts, and intermediate files.)	

Task	Description	Skills required
Validate the deployment.	After you run the previous command, the AWS account should contain the following: • The CQLReplicator AWS Glue job and the AWS Glue connector in AWS Glue • The S3 bucket that stores the artifacts • The target keyspace `migration` and the `ledger` table in Amazon Keyspaces	AWS DevOps

Run CQLReplicator

Task	Description	Skills required
Start the migration process.	To operate CQLReplicator on AWS Glue, you need to use the `--state run` command, followed by a series of parameters. The precise configuration of these parameters is primarily determined by your unique migration requirements. For example, these settings might vary if you choose to replicate time to live (TTL) values and updates, or you offload objects exceeding 1 MB to Amazon S3.	AWS DevOps

Task	Description	Skills required
	To replicate the workload from the Cassandra cluster to Amazon Keyspaces, run the following command: `./cqlreplicator --state run --tiles 8 \ --landing-zone s3://cql-replicator-1234567890-us-west-2 \ --region us-west-2 \ --src-keyspace source_keyspace \ --src-table source_table \ --trg-keyspace taget_keyspace \ --writetime-column column_name \ --trg-table target_table --inc-traffic` Your source keyspace and table are `source_keyspace.source_table` in the Cassandra cluster. Your target keyspace and table are `target_keyspace.target_table` in Amazon Keyspaces. The parameter `--inc-traffic`	

Task	Description	Skills required
	helps prevent incremental traffic from overloading the Cassandra cluster and Amazon Keyspaces with a high number of requests. To replicate updates, add `--writetime-column regular_column_name` to your command line. The regular column is going to be used as the source of the write timestamp.	

Monitor the migration process

Task	Description	Skills required
Validate migrated Cassandra rows during the historical migration phase.	To obtain the number of rows replicated during the backfilling phase, run the following command: `./cqlreplicator --state stats \ --landing-zone s3://cql-replicator-1234567890-us-west-2 \ --src-keyspace source_keyspace --src-table source_table --region us-west-2`	AWS DevOps

Stop the migration process

Task	Description	Skills required
Use the `cqlreplicator` command or the AWS Glue console.	To stop the migration process gracefully, run the following command: `./cqlreplicator --state request-stop --tiles 8 \ --landing-zone s3://cql-replicator-1234567890-us-west-2 \ --region us-west-2 \ --src-keyspace source_keyspace --src-table source_table` To stop the migration process immediately, use the AWS Glue console.	AWS DevOps

Clean up

Task	Description	Skills required
Delete the deployed resources .	The following command will delete the AWS Glue job, connector, S3 bucket, and Keyspaces table `ledger`: `./cqlreplicator --state cleanup --landing-zone`	AWS DevOps

Task	Description	Skills required
	`s3://cql-replicator-1234567890-us-west-2`	

Troubleshooting

Issue	Solution
AWS Glue jobs failed and returned an Out of Memory (OOM) error.	1. Change the worker type (scale up). For example, change `G0.25X` to `G.1X` or `G.1X` to `G.2X`. Alternatively, increase the number of DPUs per AWS Glue job (scale out) in CQLReplicator. 2. Start the migration process from the point where it was interrupted. To restart failed CQLReplicator jobs, rerun the `--state run` command with the same parameters.

- CQLReplicator with AWS Glue README.MD
- AWS Glue documentation
- Amazon Keyspaces documentation
- Apache Cassandra

Additional information

Migration considerations

You can use AWS Glue to migrate your Cassandra workload to Amazon Keyspaces, while keeping your Cassandra source databases completely functional during the migration process. After the replication is complete, you can choose to cut over your applications to Amazon Keyspaces with minimal replication lag (less than minutes) between the Cassandra cluster and Amazon Keyspaces.

To maintain data consistency, you can also use a similar pipeline to replicate the data back to the Cassandra cluster from Amazon Keyspaces.

Write unit calculations

As an example, consider that you intend to write 500,000,000 with the row size 1 KiB during one hour. The total number of Amazon Keyspaces write units (WCUs) that you require is based on this calculation:

`(number of rows/60 mins 60s) 1 WCU per row = (500,000,000/(60*60s) * 1 WCU) = 69,444 WCUs required`

69,444 WCUs per second is the rate for 1 hour, but you could add some cushion for overhead. For example, `69,444 * 1.10 = 76,388` WCUs has 10 percent overhead.

Create a keyspace by using CQL

To create a keyspace by using CQL, run the following commands:

```
CREATE KEYSPACE target_keyspace WITH replication = {'class': 'SingleRegionStrategy'}
CREATE TABLE target_keyspace.target_table ( userid uuid, level text, gameid int,
 description text, nickname text, zip text, email text, updatetime text, PRIMARY KEY
 (userid, level, gameid) ) WITH default_time_to_live = 0 AND CUSTOM_PROPERTIES =
 {'capacity_mode':{ 'throughput_mode':'PROVISIONED', 'write_capacity_units':76388,
 'read_capacity_units':3612 }} AND CLUSTERING ORDER BY (level ASC, gameid ASC)
```

Migrate Hadoop data to Amazon S3 by using WANdisco LiveData Migrator

Tony Velcich, Amazon Web Services

Summary

This pattern describes the process for migrating Apache Hadoop data from a Hadoop Distributed File System (HDFS) to Amazon Simple Storage Service (Amazon S3). It uses WANdisco LiveData Migrator to automate the data migration process.

Prerequisites and limitations

Prerequisites

- Hadoop cluster edge node where LiveData Migrator will be installed. The node should meet the following requirements:
  - Minimum specification: 4 CPUs, 16 GB RAM, 100 GB storage.
  - 2 Gbps minimum network.
  - Port 8081 accessible on your edge node to access the WANdisco UI.
  - Java 1.8 64-bit.
  - Hadoop client libraries installed on the edge node.
  - Ability to authenticate as the HDFS superuser (for example, "hdfs").
  - If Kerberos is enabled on your Hadoop cluster, a valid keytab that contains a suitable principal for the HDFS superuser must be available on the edge node.
- An active AWS account with access to an S3 bucket.
- An AWS Direct Connect link established between your on-premises Hadoop cluster (specifically the edge node) and AWS.

Product versions

- LiveData Migrator 1.8.6
- WANdisco UI (OneUI) 5.8.0

Architecture

Source technology stack

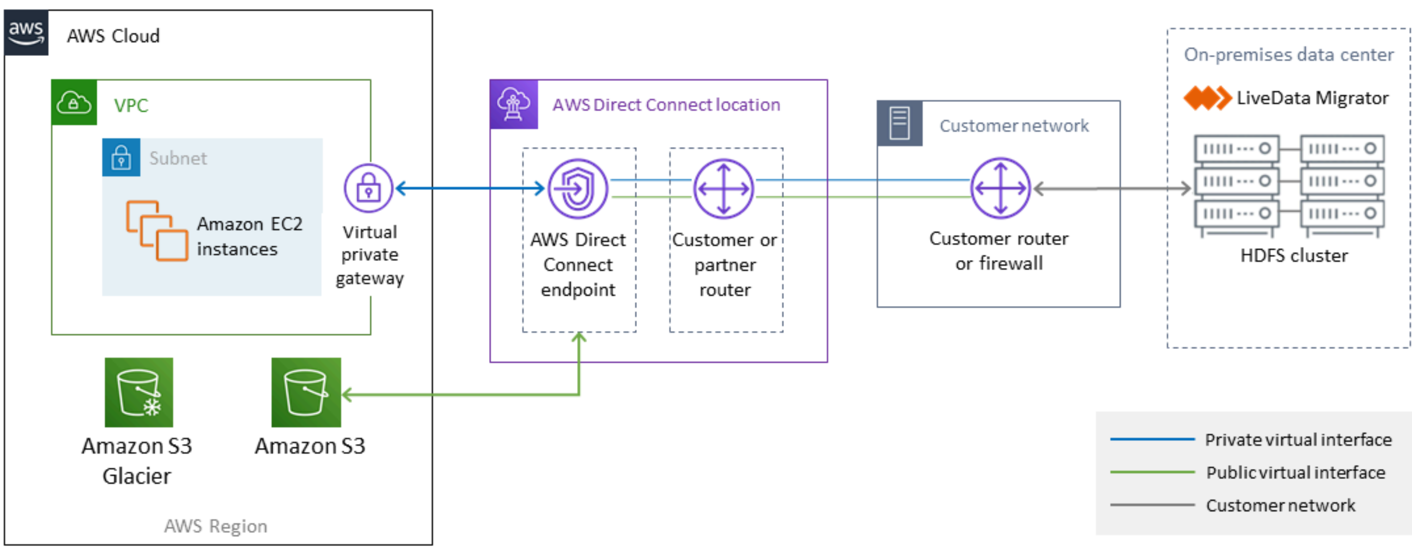
- On-premises Hadoop cluster

Target technology stack

- Amazon S3

Architecture

The following diagram shows the LiveData Migrator solution architecture.



The workflow consists of four primary components for data migration from on-premises HDFS to Amazon S3.

- LiveData Migrator – Automates the migration of data from HDFS to Amazon S3, and resides on an edge node of the Hadoop cluster.
- HDFS – A distributed file system that provides high-throughput access to application data.
- Amazon S3 – An object storage service that offers scalability, data availability, security, and performance.
- AWS Direct Connect – A service that establishes a dedicated network connection from your on-premises data centers to AWS.

Automation and scale

You will typically create multiple migrations so that you can select specific content from your source file system by path or directory. You can also migrate data to multiple, independent file systems at the same time by defining multiple migration resources.

Epics

Configure Amazon S3 storage in your AWS account

Task	Description	Skills required
Sign in to your AWS account.	Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.	AWS experience
Create an S3 bucket.	If you don't already have an existing S3 bucket to use as the target storage, choose the "Create bucket" option on the Amazon S3 console, and specify a bucket name, AWS Region, and bucket settings for block public access. AWS and WANdisco recommend that you enable the block public access options for the S3 bucket, and set up the bucket access and user permission policies to meet your organization's requirements. An AWS example is provided at https://docs.aws.amazon.com/AmazonS3/latest/dev/	AWS experience

Task	Description	Skills required
	example-walkthroughs-managing-access-example1.html.	

Install LiveData Migrator

Task	Description	Skills required
Download the LiveData Migrator installer.	Download the LiveData Migrator installer and upload it to the Hadoop edge node. You can download a free trial of LiveData Migrator at https://www2.wandisco.com/ldm-trial. You can also obtain access to LiveData Migrator from AWS Marketplace, at https://aws.amazon.com/marketplace/pp/B07B8SZND9.	Hadoop administrator, Application owner
Install LiveData Migrator.	Use the downloaded installer and install LiveData Migrator as the HDFS superuser on an edge node in your Hadoop cluster. See the "Additional information" section for the installation commands.	Hadoop administrator, Application owner
Check the status of LiveData Migrator and other services.	Check the status of LiveData Migrator, Hive migrator, and WANdisco UI by using the commands provided in the "Additional information" section.	Hadoop administrator, Application owner

Configure storage through the WANdisco UI

Task	Description	Skills required
Register your LiveData Migrator account.	Log in to the WANdisco UI through a web browser on port 8081 (on the Hadoop edge node) and provide your details for registration. For example, if you are running LiveData Migrator on a host named myldmhost.example.com, the URL would be: http://myldmhost.example.com:8081	Application owner
Configure your source HDFS storage.	Provide the configuration details needed for your source HDFS storage. This will include the "fs.defaultFS" value and a user-defined storage name. If Kerberos is enabled, provide the principal and keytab location for LiveData Migrator to use. If NameNode HA is enabled on the cluster, provide a path to the core-site.xml and hdfs-site.xml files on the edge node.	Hadoop administrator, Application owner
Configure your target Amazon S3 storage.	Add your target storage as the S3a type. Provide the user-defined storage name and the S3 bucket name. Enter "org.apache.hadoop.fs.s3a.SimpleAWSCredential	AWS, Application owner

Task	Description	Skills required
	sProvider" for the Credentials Provider option, and provide the AWS access and secret keys for the S3 bucket. Additional S3a propertie s will also be needed. For details, see the "S3a Propertie s" section in the LiveData Migrator documentation at https://docs.wandisco.com/ live-data-migrator/docs/ command-reference/#fil esystem-add-s3a.	

Prepare for the migration

Task	Description	Skills required
Add exclusions (if needed).	If you want to exclude specific datasets from migration , add exclusions for the source HDFS storage. These exclusions can be based on file size, file names (based on regex patterns), and modificat ion date.	Hadoop administrator, Application owner

Create and start the migration

Task	Description	Skills required
Create and configure the migration.	Create a migration in the dashboard of the WANdisco UI. Choose your source (HDFS)	Hadoop administrator, Application owner

Task	Description	Skills required
	and target (the S3 bucket). Add new exclusions that you have defined in the previous step. Select either the "Overwrite" or the "Skip if Size Match" option. Create the migration when all fields are complete.	
Start the migration.	On the dashboard, select the migration you created. Click to start the migration. You can also start a migration automatically by choosing the auto-start option when you create the migration.	Application owner

Manage bandwidth (optional)

Task	Description	Skills required
Set a network bandwidth limit between the source and target.	In the Storages list on the dashboard, select your source storage and select "Bandwidth Management" in the Grouping list. Clear the unlimited option, and define the maximum bandwidth limit and unit. Choose "Apply."	Application owner, Networking

Monitor and manage migrations

Task	Description	Skills required
View migration information using the WANdisco UI.	Use the WANdisco UI to view license, bandwidth, storage and migration informati on. The UI also provides a notification system so you can receive notifications about errors, warnings, or important milestones in your usage.	Hadoop administrator, Application owner
Stop, resume, and delete migrations.	You can stop a migration from transferring content to its target by placing it in the STOPPED state. Stopped migrations can be resumed. Migrations in the STOPPED state can also be deleted.	Hadoop administrator, Application owner

Additional information

Installing LiveData Migrator

You can use the following commands to install LiveData Migrator, assuming that the installer is inside your working directory:

```
su – hdfs
chmod +x livedata-migrator.sh && sudo ./livedata-migrator.sh
```

Checking the status of LiveData Migrator and other services after installation

Use the following commands to check the status of LiveData Migrator, Hive migrator, and WANdisco UI:

```
service livedata-migrator status
service hivemigrator status
service livedata-ui status
```

Migrate Oracle Business Intelligence 12c to the AWS Cloud from on-premises servers

Lanre (Lan-Ray) showunmi and Patrick Huang, Amazon Web Services

Summary

This pattern shows how to migrate Oracle Business Intelligence Enterprise Edition 12c from on-premises servers to the AWS Cloud by using AWS CloudFormation. It also describes how you can use other AWS services to implement Oracle BI 12c components that deliver high availability, security, flexibility, and the ability to dynamically scale.

For a list of best practices related to migrating Oracle BI 12c to the AWS Cloud, see the **Additional information** section of this pattern.

Note

It's a best practice to run multiple test migrations before transferring your existing Oracle BI 12c data to the cloud. These tests help you fine tune your migration approach, identify and fix potential issues, and estimate downtime requirements more accurately.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Secure network connectivity between your on-premises servers and AWS through either AWS Virtual Private Network (AWS VPN) services or AWS Direct Connect
- Software licenses for your Oracle operating system, Oracle BI 12c, Oracle Database, Oracle WebLogic Server, and Oracle HTTP Server

Limitations

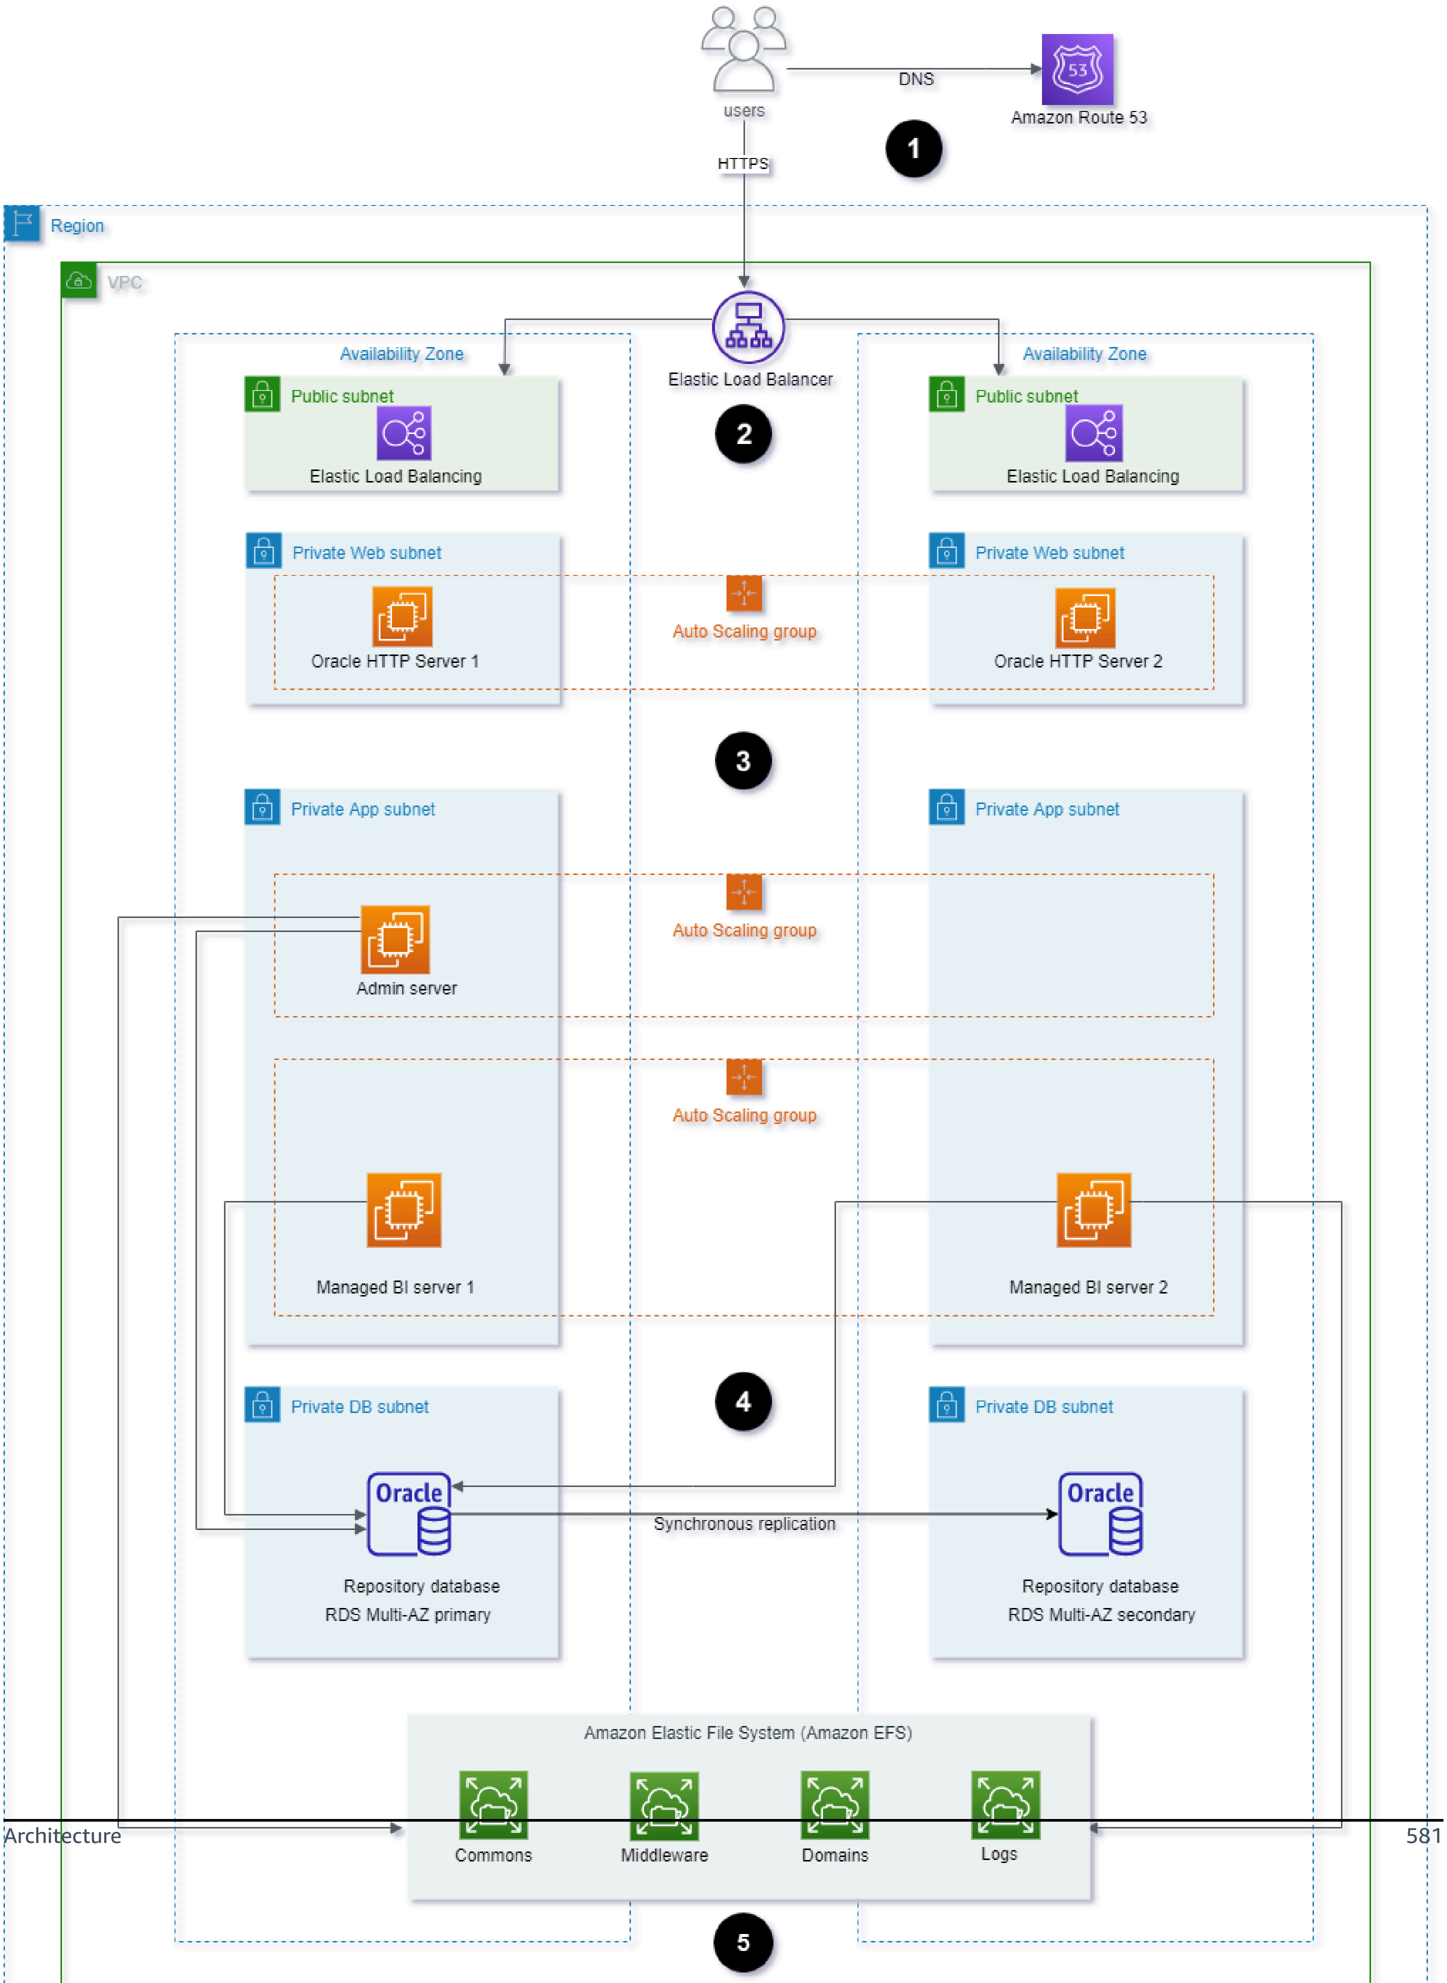
For information about storage size limits, see the Amazon Relational Database Service (Amazon RDS) for Oracle documentation.

Product versions

- Oracle Business Intelligence Enterprise Edition 12c
- Oracle WebLogic Server 12c
- Oracle HTTP Server 12c
- Oracle Database 12c (or newer)
- Oracle Java SE 8

Architecture

The following diagram shows an example architecture for running Oracle BI 12c components in the AWS Cloud:



users

This diagram shows the following architecture:

1. Amazon Route 53 provides domain name service (DNS) configuration.
2. Elastic Load Balancing (ELB) distributes network traffic to improve the scalability and availability of the Oracle BI 12c components across multiple Availability Zones.
3. Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling groups host the Oracle HTTP Servers, Weblogic Admin server, and managed BI servers across multiple Availability Zones.
4. Amazon Relational Database Service (Amazon RDS) for Oracle database store BI Server metadata across multiple Availability Zones.
5. Amazon Elastic File System (Amazon EFS) is mounted to every Oracle BI 12c component for shared file storage.

Technology stack

- Amazon Elastic Block Store (Amazon EBS)
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Elastic File System (Amazon EFS)
- Amazon RDS for Oracle
- AWS Certificate Manager (ACM)
- Elastic Load Balancing (ELB)
- Oracle BI 12c
- Oracle WebLogic Server 12c
- Oracle HTTP Server (OHS)

Tools

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Certificate Manager (ACM) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- Amazon EC2 Auto Scaling helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.
- Elastic Load Balancing distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- Oracle Data Pump helps you move data and metadata from one database to another at high speeds.
- Oracle Fusion Middleware is a suite of application development tools and integration solutions to identity management, collaboration, and business intelligence reporting.
- Oracle GoldenGate helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.
- Oracle WebLogic Scripting Tool (WLST) provides a command line interface that helps you horizontally scale out your WebLogic clusters.

Epics

Assess the source environment

Task	Description	Skills required
Gather software inventory information.	Identify versions and patch levels for each of your source technology stack's software	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
	components, including the following: • Oracle operating system • Oracle Database • Oracle BI 12c • Oracle WebLogic Server • Oracle HTTP Server • Java	
Gather compute and storage inventory information.	In your source environment, review current and historica l utilization metrics for the following: • CPU usage • Memory usage • Storage usage **Important** Make sure that you account for historical spikes in usage.	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator, System Administrator

Task	Description	Skills required
Gather information about the source environment's architecture and its requireme nts.	Obtain a full understanding of your source environment's architecture and its requireme nts, including knowledge of the following: • Oracle WebLogic Server domain configuration • Clustering • Load balancing • Connectivity • Availability • Disaster recovery requireme nts	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator
Identify Java Database Connectivity (JDBC) data sources.	Gather information about your source environment's JDBC data sources and drivers for each database engine that it uses.	Migration Architect, Applicati on Owner, Oracle BI Administr ator, Database Engineer or Administrator
Gather information about environment-specific settings.	Collect information about settings and configurations that are specific to your source environment, including the following: • Custom startup and shutdown scripts • Java and other environme nt variables • Certificates	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
Identify any dependencies on other applications.	Collect information about integrations in your source environment that create dependencies with other applications. **Important** Make sure that you identify any Lightweight Directory Access Protocol (LDAP) integrations and other networking requirements.	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Design your target environment

Task	Description	Skills required
Create a high-level design document.	Create a target architecture design document. Make sure that you use the information that you collected when assessing your source environment to inform the design document.	Solutions Architect, Application Architect, Database Engineer, Migration Architect
Obtain approval for the design document.	Review the design document with stakeholders and obtain the required approvals.	Application or Service Owner, Solutions Architect, Application Architect

Deploy the infrastructure

Task	Description	Skills required
Prepare the infrastructure code in CloudFormation.	Create CloudFormation templates to provision your Oracle BI 12c infrastructure in the AWS Cloud. For more information, see [Working with AWS CloudFormation templates]() in the *AWS CloudFormation User Guide*. **Note** It's a best practice to create modular CloudFormation templates for each Oracle BI 12c tier, rather than one large template for all of your resources. For more information about CloudFormation best practices, see [8 best practices when automating your deployments with AWS CloudFormation]() on the AWS Blog.	Cloud Infrastructure Achitect, Solutions Architect, Application Architect
Download the required software.	DDownload the following software along with the	Migration Architect, Database Engineer, Application Architect

Task	Description	Skills required
	required versions and patches from the Oracle website: • Java JDK8 • Oracle WebLogic Server 12c • Oracle BI 12c	
Prepare the installation scripts.	Create software installation scripts that run a silent install. These scripts simplify the deployment automation. For more information, see OBIEE 12c: How to Perform Silent Installation? on the Oracle Support site. You need an Oracle Support account to view the documentation.	Migration Architect, Database Engineer, Application Architect

Task	Description	Skills required
Create an Amazon EBS-backed Linux AMI for your web and application tiers.	1. Deploy and configure Amazon EC2 instances for your web and application tiers. Make sure that the instances meet the prerequisites for running the following: • Oracle operating system environment setup • Oracle operating system user account set up • Java software installation 2. Create Amazon Machine Images (AMIs) of the instances and save copies for future use. For instructions, see Create an Amazon EBS-backed Linux AMI in the *Amazon EC2 User Guide for Linux Instances*.	Migration Architect, Database Engineer, Application Architect
Launch your AWS infrastructure by using CloudFormation.	Deploy your Oracle BI 12c web and application tiers in modules by using the CloudFormation templates that you created. For instructions, see Getting started with AWS CloudFormation in the *AWS CloudFormation User Guide*.	Cloud Infrastructure Architect, Solutions Architect, Application Architect

Migrate Oracle BI 12c to AWS by using a fresh installation

Task	Description	Skills required
Stage the required software.	Stage the required software in a location that is accessible to the Amazon EC2 instances. For example, you could stage the software in Amazon S3 or another Amazon EC2 instance that would be accessible to your web and application servers.	Migration Architect, Oracle BI Architect, Cloud Infrastructure Achitect, Solutions Architect, Application Architect
Prepare your repository database for Oracle BI 12c installation.	Create Oracle BI 12c schemas by running the Oracle Repository Creation Utility (RCU) against a new Amazon RDS for Oracle database instance.	Cloud Infrastructure Achitect, Solutions Architect, Applicati on Architect, Migration Architect, Oracle BI Architect
Install Oracle Fusion Middleware 12c and Oracle BI 12c.	1. Starting with one Amazon EC2 instance, install Oracle Fusion Middleware 12c infrastructure and OBIEE 12c. For more informati on, see the following sections of the *Oracle Fusion Middleware Enterpris e Deployment Guide for Oracle Business Intellige nce*: • Starting the infrastru cture installer on BIHOST1 • Installing Oracle Business Intelligence	Migration Architect, Oracle BI Architect

Task	Description	Skills required
	[in preparation for an enterprise deployment](#) **Note** Use Amazon EFS to host directories that will be shared among Oracle BI 12c cluster nodes. 2. Apply any required patches to the installation. 3. Create AMIs of the instances and save copies for future use.	
Configure your Oracle WebLogic Server domain for Oracle BI 12c.	Configure your Oracle BI 12c domain as a non-clustered deployment. For more information, see [Configuring the BI Domain](#) in the *Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intellige nce*.	Migration Architect, Oracle BI Architect

Task	Description	Skills required
Perform horizontal scale out of the Oracle BI 12c.	Horizontally scale out the single node to the desired number of nodes. For more information, see Scaling out Oracle Business Intelligence in the *Oracle Fusion Middleware Enterprise Deployment Guide for Oracle Business Intelligence*.	Migration Architect, Oracle BI Architect
Install Oracle HTTP Server 12c.	1. Install Oracle HTTP Server 12c on the Oracle web tier Amazon EC2 instances. For instructions see Install Oracle HTTP Server 12c in *Install and configure Oracle HTTP Server for Oracle Access Management 12c*. 2. Apply any required patches to the installation. 3. Create AMIs of the instances and save copies for future use.	Migration Architect, Oracle BI Architect
Configure load balancers for SSL termination.	1. Create or import SSL certificates in ACM. 2. Associate the SSL certificates with ELB.	Cloud Infrastructure Architect , Migration Architect

Task	Description	Skills required
Migrate business intelligence metadata artifacts to AWS.	1. Export Oracle Business Intelligence Application Archive (BAR) files from the on-premises Oracle BI 12c installation. To export the BAR files, use the WebLogic Scripting Tool (WLST) to run the exportServiceInstance command. 2. Import the on-premises BAR files into the AWS Oracle BI 12c installation. To import the BAR files, run the **importServiceInstance** WLST command.	Migration Architect, Oracle BI Architect

Task	Description	Skills required
Perform post-migration tasks.	After importing the BAR files, do the following: • Configure any additional JDBC data sources. • Install drivers for other data sources like PostgreSQL, or Amazon Redshift. • Configure Oracle LDAP, SSL, single sign-on (SSO), and WebLogic security store. • Configure AWS Identity and Access Management (IAM) policies. • Activate usage tracking. • Set up integrations to other systems. • Migrate any custom scripts.	Migration Architect, Oracle BI Architect

Test the new environment

Task	Description	Skills required
Test the new Oracle BI 12c environment.	Conduct end-to-end testing on the new Oracle BI 12c environment. Use automation as much as possible. Example of testing activities include the following: • Validating dashboards, reports, and URLs	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
	• User acceptance testing (UAT) • Operational acceptance testing (OAT) **Note** Conduct additional testing and validation as required.	

Cut over to the new environment

Task	Description	Skills required
Disconnect traffic to the on-premises Oracle BI 12c environment.	At the appointed cutover window, stop all traffic to the on-premises Oracle BI 12c environment.	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator
Resynchronize the new Oracle BI 12c repository database with the source database.	Resynchronize the Amazon RDS Oracle Oracle BI 12c repository database with the on-premises database. To synchronize the databases , you can either use an Oracle Data Pump refresh or an AWS DMS change data capture (CDC).	Oracle BI Administrator, Database Engineer/Administr ator
Switch your Oracle BI 12c URLs to point to the new AWS environment.	Update the Oracle BI 12c URLs on your internal DNS	Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

Task	Description	Skills required
	servers so that they point to the new AWS installation.	
Monitor the new environme nt.	Monitor the new Oracle BI 12c environment by using any of the following tools: • Amazon CloudWatch • Amazon RDS Performance Insights • Oracle Enterprise Manager	Oracle BI Administrator, Database Engineer/Administr ator, Application Administr ator
Get sign-off on the project.	Review the testing results with stakeholders and obtain the required approvals to wrap up the migration.	Application Owner, Service Owner, Cloud Infrastructure Architect, Migration Architect, Oracle BI Architect

- Oracle Business Intelligence Application Archive (BAR) Files (Oracle Help Center)
- How to migrate OBI 12c between environments (Oracle Support)

Additional information

The following is a list of best practices related to migrating Oracle BI 12c to the AWS Cloud.

Repository databases

It's a best practice to host Oracle BI 12c database schemas on an Amazon RDS for Oracle instance. This instance type provides cost-efficient and resizable capacity while automating administration tasks, such as hardware provisioning, database setup, patching, and backups.

For more information, see Using the Oracle Repository Creation Utility on RDS for Oracle in the *Amazon RDS User Guide*.

Web and application tiers

Memory optimized Amazon EC2 instances are often well suited for Oracle BI 12c servers. Whatever instance type you choose, make sure that the instances that you provision meet your system's memory usage requirements. Also, make sure that you configure a sufficient WebLogic Java Virtual Machine (JVM) heap size based on your Amazon EC2 instance's available memory.

Local storage

I/O plays an important part in the overall performance of your Oracle BI 12c application. Amazon Elastic Block Store (Amazon EBS) offers different storage classes that are optimized for different workload patterns. Make sure that you choose an Amazon EBS volume type that fits your use case.

For more information about EBS volume types, see Amazon EBS features in the Amazon EBS documentation.

Shared storage

A clustered Oracle BI 12c domain requires shared storage for the following resources:

- Configuration files
- Oracle BI 12c singleton data directory (SDD)
- Oracle global cache
- Oracle BI Scheduler scripts
- Oracle WebLogic Server binaries

You can meet this shared storage requirement by using Amazon EFS, which provides a scalable, fully managed elastic Network File System (NFS) file system.

Fine tuning shared storage performance

Amazon EFS has two throughput modes: **Provisioned** and **Bursting**. The service also has two performance modes: **General Purpose** and **Max I/O**.

To fine tune performance, start by testing your workloads in the **General Purpose** performance mode and **Provisioned** throughput mode. Doing these tests will help you determine if those baseline modes are sufficient to meet your desired service levels.

For more information, see Amazon EFS performance in the *Amazon EFS User Guide*.

Availability and disaster recovery

It's a best practice to deploy Oracle BI 12c components across multiple Availability Zones to protect those resources in the event of an Availability Zone failure. The following is a list of availability and disaster recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:

- **Oracle BI 12c repository databases**: Deploy a multi-AZ Amazon RDS database instance to your Oracle BI 12crepository database. In a multi-AZ deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different AZ. Running an Oracle BI 12c repository database instance across Availability Zones can enhance availability during planned system maintenance and help protect your databases against instance and Availability Zone failures.
- **Oracle BI 12c Managed Servers**: To achieve fault tolerance, it's a best practice to deploy Oracle BI 12c system components on Managed Servers in an Amazon EC2 Auto Scaling Group configured to span multiple Availability Zones. Auto Scaling replaces faulty instances based on Amazon EC2 health checks. In the event of an Availability Zone failure, Oracle HTTP Servers continue to direct traffic to Managed Servers in the functioning Availability Zone. Then, Auto Scaling launches instances to keep up with your host count requirements. Activating HTTP session state replication is recommended to help make sure that there's a smooth failover of the existing sessions to the functioning Managed Servers.
- **Oracle BI 12c Administration Servers:** To make sure that your Administration Server has high availability, host it in an Amazon EC2 Auto Scaling group configured to span multiple Availability Zones. Then, set the minimum and maximum size of the group set to **1**. If an Availability Zone failure occurs, Amazon EC2 Auto Scaling starts up a replacement Administration Server in an alternate Availability Zone. To recover any failed underlying hosts within the same Availability Zone, you can activate Amazon EC2 Auto Recovery.
- **Oracle Web Tier servers:** It's a best practice to associate your Oracle HTTP Server with your Oracle WebLogic Server domain. For high availability, deploy your Oracle HTTP Server in an Amazon EC2 Auto Scaling group configured to aspen multiple Availability Zoness. Then, place the server behind an ELB elastic load balancer. To provide additional protection against host failure, you can activate Amazon EC2 Auto Recovery.

Scalability

The elasticity of the AWS Cloud helps you scale applications either horizontally or vertically in response to workload requirements.

Vertical scaling

To vertically scale your application, you can change the size and type of the Amazon EC2 instances that are running your Oracle BI 12c components. You don't need to over-provision instances at the start of your deployment and incur unnecessary cost.

Horizontal scaling

Amazon EC2 Auto Scaling helps you horizontally scale your application by automatically adding or removing Managed Servers based on workload requirements.

> **Note**
>
> Horizontal scaling with Amazon EC2 Auto Scaling requires scripting skills and thorough testing to implement.

Backup and recovery

The following is a list of backup and recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:

- **Oracle Business Intelligence metadata repositories:** Amazon RDS automatically creates and saves backups of your database instances. These backups are retained for a period of time that you specify. Make sure that you configure your Amazon RDS backup duration and retention settings based on your data protection requirements. For more information, see Amazon RDS backup and restore.
- **Managed Servers, Administration Servers, and Web Tier servers:** Make sure that you configure Amazon EBS snapshots based on your data protection and retention requirements.
- **Shared storage:** You can manage backup and recovery for files stored in Amazon EFS by using AWS Backup. The AWS Backup service can also be deployed to centrally manage backup and recovery of other services, including Amazon EC2, Amazon EBS, and Amazon RDS. For more information, see What is AWS Backup? In the *AWS Backup Developer Guide*.

Security and compliance

The following is a list of security best practices and AWS services that can help you protect your Oracle BI 12c applications in the AWS Cloud:

- **Encryption at rest:** Amazon RDS, Amazon EFS, and Amazon EBS all support industry standard encryption algorithms. You can use AWS Key Management Service (AWS KMS) to create and manage cryptographic keys and control their use across AWS services and in your applications. You can also configure Oracle Transparent Data Encryption (TDE) on the Amazon RDS for Oracle database instance that's hosting your Oracle BI 12c repository database.
- **Encryption in transit:** It's a best practice to activate either SSL or TLS protocols to protect data in transit between the various layers of your Oracle BI 12c installation. You can use AWS Certificate Manager (ACM) to provision, manage, and deploy public and private SSL and TLS certificates for your Oracle BI 12c resources.
- **Network security**: Make sure that you deploy your Oracle BI 12c resources in an Amazon VPC that has the appropriate access controls configured for your use case. Configure your security groups to filter inbound and outbound traffic from the Amazon EC2 instances that are running your installation. Also, make sure that you configure Network Access Control Lists (NACLs) that allow or deny traffic based on defined rules.
- **Monitoring and logging**: You can use AWS CloudTrail to track API calls to your AWS infrastructure, including your Oracle BI 12c resources. This functionality is useful when tracking changes to infrastructure or when conducting a security analysis. You can also use Amazon CloudWatch to view operational data that can provide you with actionable insight into the performance and health of your Oracle BI 12c application. You can configure alarms and take automated actions based on those alarms, too. Amazon RDS provides additional monitoring tools, including Enhanced Monitoring and Performance Insights.

Migrate an ELK Stack to Elastic Cloud on AWS

Battulga Purevragchaa and Antony Prasad Thevaraj, Amazon Web Services

uday reddy, None

Summary

Elastic has provided services for many years, with their users and customers typically managing Elastic themselves on premises. Elastic Cloud, the managed Elasticsearch service, provides a way to consume the Elastic Stack (ELK Stack) and solutions for enterprise search, observability, and security. You can access Elastic solutions with apps such as Logs, Metrics, APM (application performance monitoring), and SIEM (security information and event management). You can use integrated features such as machine learning, index lifecycle management, Kibana Lens (for drag-and drop visualizations).

When you move from self-managed Elasticsearch to Elastic Cloud, the Elasticsearch service takes care of the following:

- Provisioning and managing the underlying infrastructure
- Creating and managing Elasticsearch clusters
- Scaling clusters up and down
- Upgrades, patching, and taking snapshots

This gives you more time to focus on solving other challenges.

This pattern defines how to migrate on-premises Elasticsearch 7.13 to Elasticsearch on Elastic Cloud on Amazon Web Services (AWS). Other versions might require slight modifications to the processes described in thie pattern. For more information, contact your Elastic representative.

Prerequisites and limitations

Prerequisites

- An active AWS account with access to Amazon Simple Storage Service (Amazon S3) for snapshots
- A secure, sufficiently high-bandwidth private link for copying snapshot data files to Amazon S3
- Amazon S3 Transfer Acceleration

- Elastic Snapshot policies to ensure that data ingestion is archived regularly, either to a sufficiently large local data store or to remote storage (Amazon S3)

You must understand how large your snapshots and the lifecyle policies for accompanying indexes are on premises before initiating your migration. For more information, contact Elastic.

Roles and skills

The migration process also requires the roles and expertise described in the following table.

Role	Expertise	Responsibilities
App support	Familiarity with Elastic Cloud and Elastic on premises	All Elastic related tasks
Systems administrator or DBA	In-depth knowledge of the on-premises Elastic environment and its configura tion	The ability to provision storage, install and use the AWS Command Line Interface (AWS CLI), and identify all data sources feeding Elastic on premises
Network administrator	Knowledge of on-premises to AWS network connectivity, security, and performance	Establishment of network links from on premises to Amazon S3, with an understanding of connectivity bandwidth

Limitations

- Elasticsearch on Elastic Cloud is available only in supported AWS Regions (September 2021).

Product versions

- Elasticsearch 7.13

Architecture

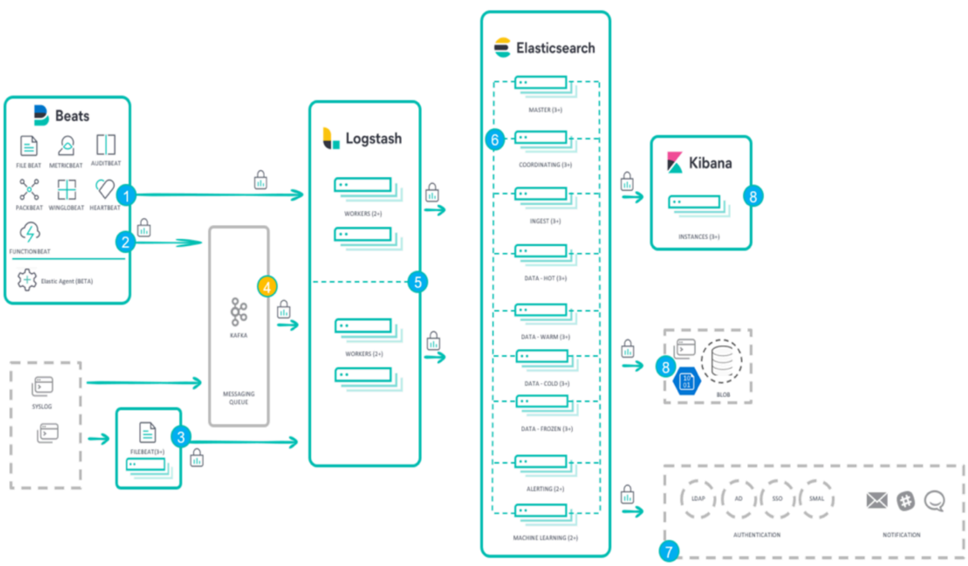
Source technology stack

On-premises Elasticsearch 7.13 or later:

- Cluster snapshots
- Index snapshots
- Beats configuration

Source technology architecture

The following diagram shows a typical on-premises architecture with different ingestion methods, node types, and Kibana. The different node types reflect the Elasticsearch cluster, authentication, and visualization roles.



1. Ingestion from Beats to Logstash
2. Ingestion from Beats to Apache Kafka messaging queue
3. Ingestion from Filebeat to Logstash
4. Ingestion from Apache Kafka messaging queue to Logstash
5. Ingestion from Logstash to an Elasticsearch cluster
6. Elasticsearch cluster

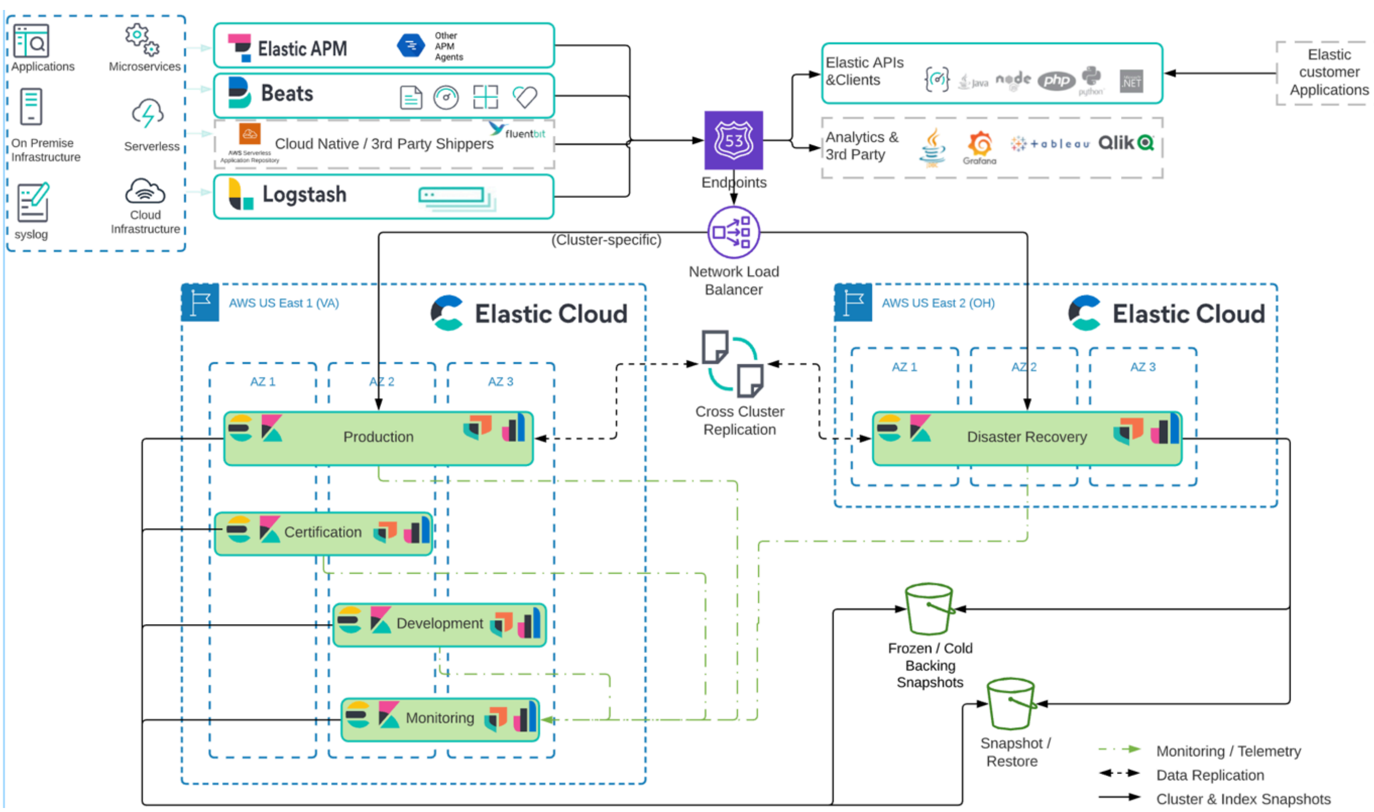
7. Authentication and notification node
8. Kibana and blob nodes

Target technology stack

Elastic Cloud is deployed to your software as a service (SaaS) account in multiple AWS Regions with cross-cluster replication.

- Cluster snapshots
- Index snapshots
- Beats configurations
- Elastic Cloud
- Network Load Balancer
- Amazon Route 53
- Amazon S3

Target architecture



The managed Elastic Cloud infrastructure is:

- Highly available, being present in multiple Availability Zones and multiple AWS Regions.
- Region failure tolerant because data (indexes and snapshots) is replicated using Elastic Cloud cross-cluster replication (CCR)
- Archival, because snapshots are archived in Amazon S3
- Network partition tolerant through a combination of Network Load Balancers and Route 53
- Data ingestion originating from (but not limited to) Elastic APM, Beats, Logstash

High-level migration steps

Elastic has developed its own prescriptive methodology for migrating on-premises Elastic Cluster to Elastic Cloud. The Elastic methodology is directly aligned and complementary to the AWS migration guidance and best practices, including Well-Architected Framework and AWS Migration Acceleration Program (MAP). Typically, the three AWS migration phases are the following:

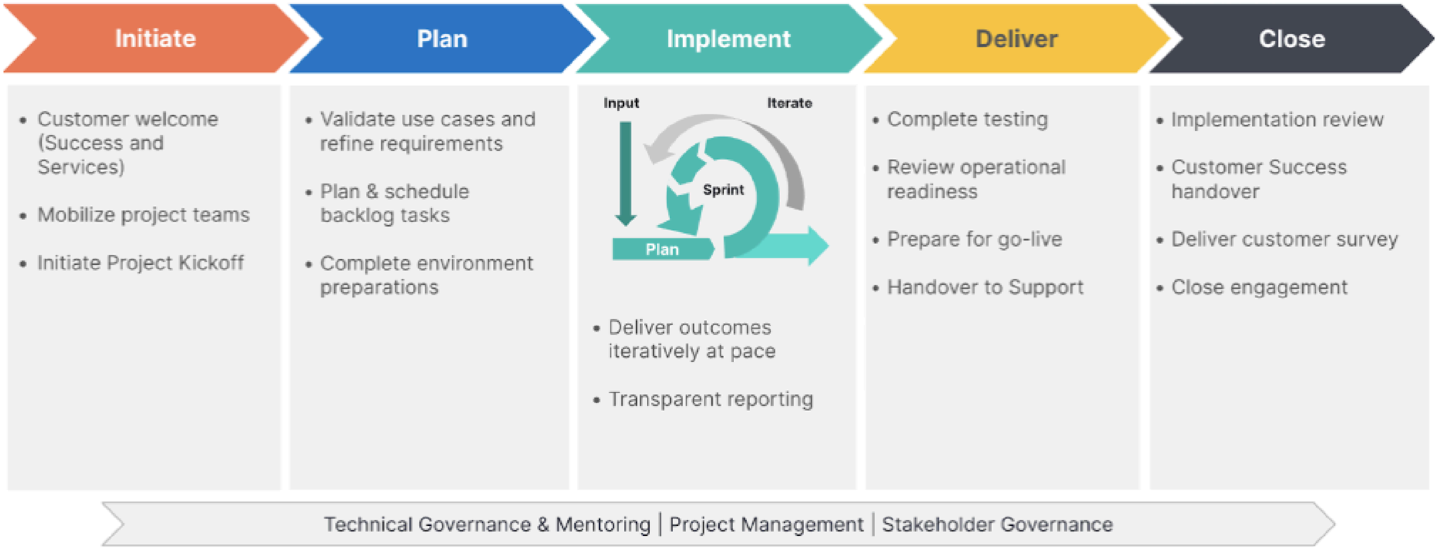
- Assess
- Mobilize
- Migrate and modernize

Elastic follows similar migration phases with complementary terminology:

- Initiate
- Plan
- Implement
- Deliver
- Close

Elastic uses the Elastic Implementation Methodology to facilitate the delivery of project outcomes. This is inclusive by design to ensure that the Elastic, consulting teams, and customer teams work together with clarity to jointly deliver intended outcomes.

The Elastic methodology combines traditional waterfall phasing with Scrum within the implementation phase. Configurations of technical requirements are delivered iteratively in a collaborative manner while minimizing risk.



Tools

AWS services

- Amazon Route 53 – Amazon Route 53 is a highly available and scalable Domain Name System (DNS) web service. You can use Route 53 to perform three main functions in any combination: domain registration, DNS routing, and health checking.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses an S3 bucket and Amazon S3 Transfer Acceleration.
- Elastic Load Balancing – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones.

Other tools

- Beats – Beats ship data from Logstash or Elasticsearch
- Elastic Cloud – Elastic Cloud is a managed service for hosting Elasticsearch.
- Elasticsearch – Elasticsearch is a search and analytics engine that uses the Elastic Stack to centrally store your data for search and analytics that scale. This pattern also uses snapshot creation and cross-cluster replication.
- Logstash – Logstash is a server-side data processing pipeline that ingests data from multiple sources, transforms it, and then sends it to your data storage.

Epics

Prepare the migration

Task	Description	Skills required
Identify servers running the on-premises Elastic solution.	Confirm that Elastic migration is supported.	App owner
Understand the on-premises server configuration.	To understand the server configuration needed to drive workloads successfu lly on premises, find the server hardware footprint, network configuration, and storage characteristics that are currently in use	App Support
Gather user and app account information.	Identify the user names and app names that are used by the on-premises Elastic environment.	Systems administrator, App support
Document Beats and data shipper configuration.	To document the configura tions, look at existing data sources and sinks. For more information, see the Elastic documentation.	App support
Determine the velocity and volume of data.	Establish a baseline for how much data the cluster is handling.	Systems administrator, App support
Document RPO and RTO scenarios.	Document recovery point objective (RPO) and recovery time objective (RTO) scenarios in terms of outages and	App owner, Systems administr ator, App support

Task	Description	Skills required
	service level agreements (SLAs).	
Determine the optimal snapshot lifecycle settings.	Define how often data needs to be secured by using Elastic snapshots *during and after* the migration.	App owner, Systems administr ator, App support
Define post-migration performance expectations.	Generate metrics on current and expected screen refresh, query runtimes, and user interface behaviors.	Systems administrator, App support
Document internet access transport, bandwidth, and availability requirements.	Ascertain speed, latency, and resiliency of internet connections for copying snapshots to Amazon S3.	Network administrator
Document current costs of on-premises runtime for Elastic.	Ensure that the sizing of the AWS targeted environment is designed to be both high performing and cost effective.	DBA, Systems administrator, App support
Identify the authentication and authorization needs.	The Elastic Stack security features provide built-in realms such as Lightweight Directory Access Protocol (LDAP), Security Assertion Markup Language (SAML), and OpenID Connect (OIDC).	DBA, Systems administrator, App support
Understand the specific regulatory requirements based on the geographic location.	Ensure that data is exported and encrypted according to your requirements and to any relevant national requireme nts.	DBA, Systems administrator, App support

Implement the migration

Task	Description	Skills required
Prepare the staging area on Amazon S3.	To receive snapshots on Amazon S3, create an S3 bucket and a temporary AWS Identity and Access Management (IAM) role with full access to your newly created bucket. For more information, see Creating a role to delegate permissions to an IAM user. Use the AWS Security Token Service to request temporary security credentials. Keep the access key ID, secret access key, and session token secured. Enable Amazon S3 Transfer Acceleration on the bucket.	AWS administrator
Install AWS CLI and the Amazon S3 plugin on premises.	On each Elasticsearch node, run the following command. `sudo bin/elasticsearch-plugin install repository-s3` Then reboot the node.	AWS administrator
Configure Amazon S3 client access.	Add the keys created previously by running the following commands.	AWS administrator

Task	Description	Skills required

	`elasticsearch-keystore add s3.client.default.access_key`
	`elasticsearch-keystore add s3.client.default.secret_key`
	`elasticsearch-keystore add s3.client.default.session_token`	

Register a snapshot repository for Elastic data	Use the Kibana Dev Tools to tell the on-premises local cluster which remote S3 bucket to write to.	AWS administrator
Configure snapshot policy.	To configure snapshot lifecycle management, on the Kibana **Policies** tab, choose **SLM policy**, and define which times, data streams, or indexes should be included, and what names to use. Configure a policy that takes frequent snapshots. Snapshots are incremental and make efficient use of storage. Match your readiness assessment decision. A policy can also specify a retention policy and automatically delete snapshots when they are no longer needed.	App support

Task	Description	Skills required
Verify that snapshots work.	In Kibana Dev Tools, run the following command. `GET _snapshot/<your_repo_name>/_all`	AWS administrator, App support,
Deploy a new cluster on Elastic Cloud.	Log in to Elastic, and choose a cluster for "observability, search or security" derived from your business findings in the readiness assessment.	AWS administrator, App support
Set up cluster key store access.	The new cluster needs access to the S3 bucket that will store the snapshots. On the Elasticsearch Service Console, choose **Security**, and enter the access and secret IAM keys that you created earlier.	AWS administrator

Task	Description	Skills required
Configure the Elastic Cloud hosted cluster to access Amazon S3.	Set up new cluster access to the previously created snapshot repository in Amazon S3. Using Kibana, do the following: 1. Choose **Stack Managemen t**, **Snapshot Settings**, **RegisterRepo**. 2. In the **Alias** field, enter the name of the repository. 3. For **S3 Client name**, choose **secondary**. 4. Add the S3 bucket that you created earlier to the repository. 5. Choose **Compress snapshot**. 6. For the **Encryption** settings, keep the default values.	AWS administrator, App Support
Verify the new Amazon S3 repository.	Ensure that you can access your new repository hosted in the Elastic Cloud cluster.	AWS administrator

Task	Description	Skills required

Initilaize the Elasticsearch service cluster.	On the Elasticsearch Service Console, initialize the Elasticsearch service cluster from the S3 snapshot.
	
	Run the following commands as POST.
	
	`*/_close?expand_wildcards=all`
	
	`/_snapshot/<your-repo-name>/ <your-snapshot-name>/_restore`
	
	`*/_open?expand_wildcards=all`
		App Support

Complete the migration

Task	Description	Skills required
Verify that the snapshot restore was successful.	Using Kibana Dev Tools, run the following command. `GET _cat/indices`	App support
Redploy ingestion services.	Connect the endpoints for Beats and Logstash to the new Elasticsearch service endpoint.	App support

Test the cluster environment and clean up

Task	Description	Skills required
Validate the cluster environment.	After the on-premises Elastic cluster environment is migrated to AWS, you can connect to it and use your own user acceptance testing (UAT) tools to validate the new environment.	App support
Clean-up the resources.	After you validate that the cluster migrated successfu lly, remove the S3 bucket and the IAM role used for the migration.	AWS administrator

Migrate data to the AWS Cloud by using Starburst

Antony Prasad Thevaraj and Suresh Veeragoni, Amazon Web Services

Shaun Van Staden, None

Summary

Starburst helps accelerate your data migration journey to Amazon Web Services (AWS) by providing an enterprise query engine that brings existing data sources together in a single access point. You can run analytics across multiple data sources to get valuable insights, before finalizing any migration plans. Without disrupting business-as-usual analytics, you can migrate the data by using the Starburst engine or a dedicated extract, transform, and load (ETL) application.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC)
- An Amazon Elastic Kubernetes Service (Amazon EKS) cluster
- An Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group
- A list of current system workloads that need to be migrated
- Network connectivity from AWS to your on-premises environment

Architecture

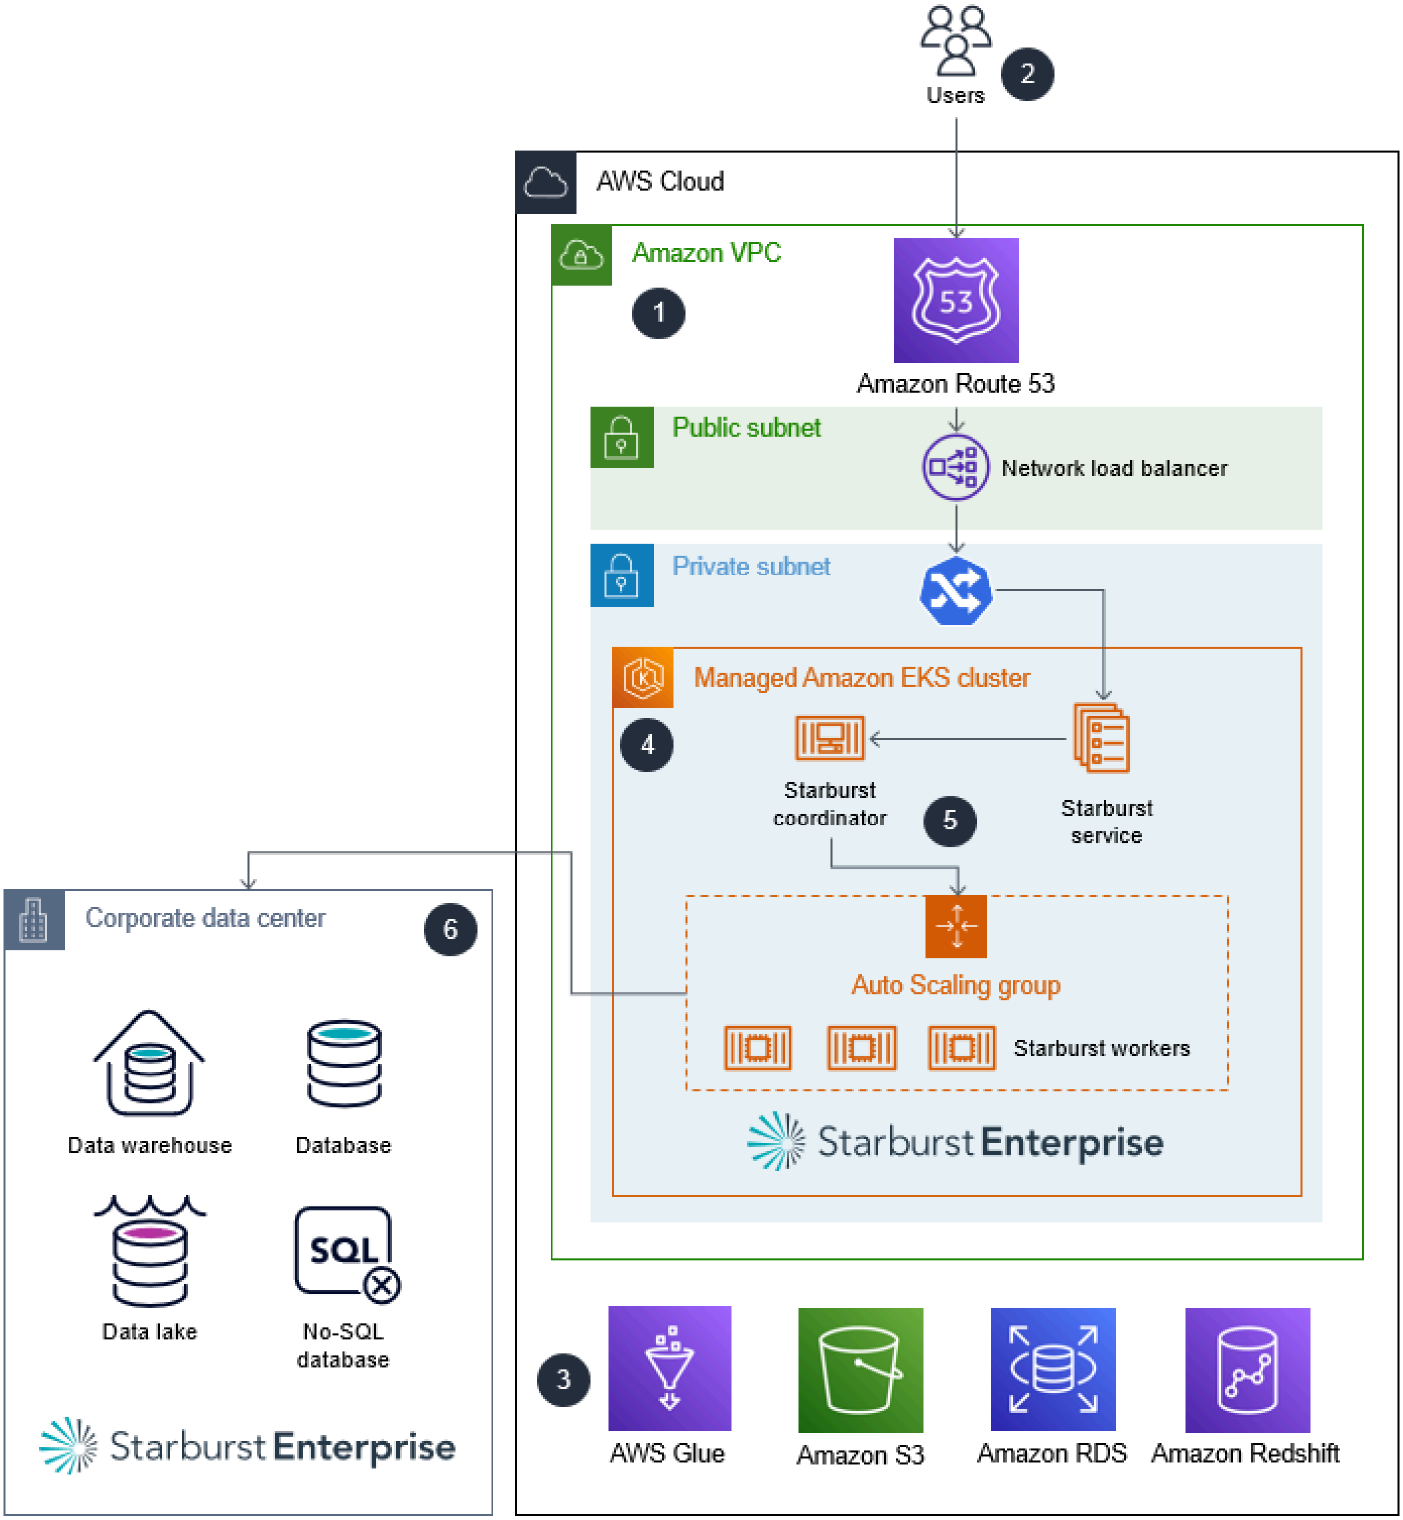
Reference architecture

The following high-level architecture diagram shows the typical deployment of Starburst Enterprise in the AWS Cloud:

1. The Starburst Enterprise cluster runs inside your AWS account.
2. A user authenticates by using Lightweight Directory Access Protocol (LDAP) or Open Authorization (OAuth) and interacts directly with the Starburst cluster.
3. Starburst can connect to several AWS data sources, such as AWS Glue, Amazon Simple Storage Service (Amazon S3), Amazon Relational Database Service (Amazon RDS), and Amazon Redshift.

Starburst provides federated query capabilities across data sources in the AWS Cloud, on premises, or in other cloud environments.

4. You launch Starburst Enterprise in an Amazon EKS cluster by using Helm charts.
5. Starburst Enterprise uses Amazon EC2 Auto Scaling groups and Amazon EC2 Spot Instances to optimize infrastructure.
6. Starburst Enterprise connects directly to your existing on-premises data sources to read data real-time. In addition, if you have an existing Starburst Enterprise deployment in this environment, you can directly connect your new Starburst cluster in the AWS Cloud to this existing cluster.

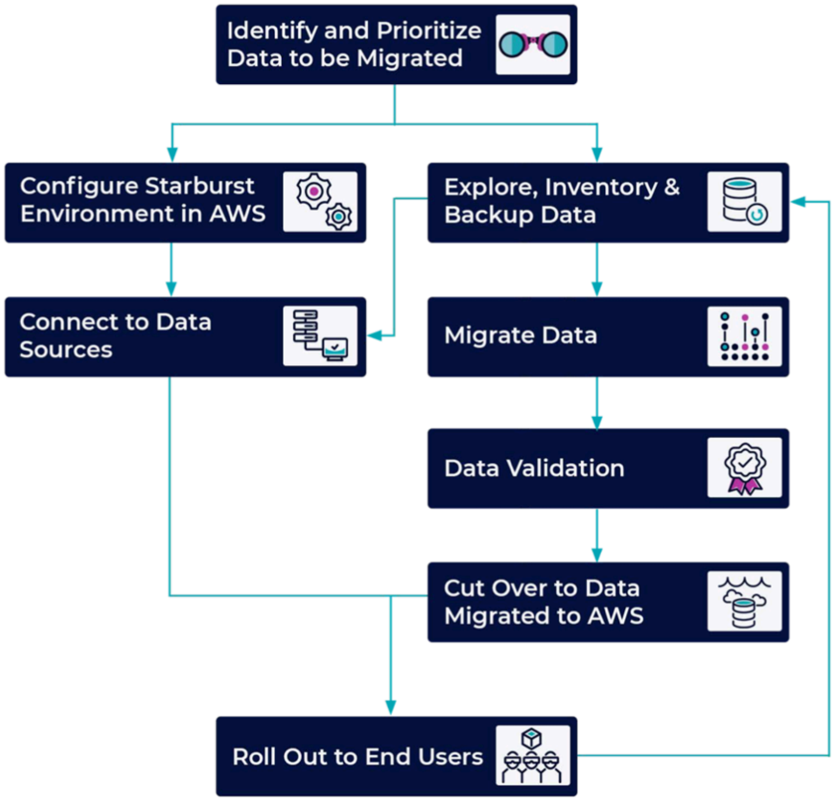


Please note the following:

- Starburst is not a data virtualization platform. It is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.
- When Starburst is deployed as part of a migration, it has direct connectivity to the existing on-premises infrastructure.
- Starburst provides several built-in enterprise and open-source connectors that facilitate connectivity to a variety of legacy systems. For a full list of connectors and their capabilities, see Connectors in the *Starburst Enterprise user guide*.
- Starburst can query data in real-time from on-premises data sources. This prevents interruptions of regular business operations while data is being migrated.
- If you are migrating from an existing on-premises Starburst Enterprise deployment, you can use a special connector, *Starburst Stargate*, to connect your Starburst Enterprise cluster in AWS directly to your on-premises cluster. This provides additional performance benefits when business users and data analysts are federating queries from the AWS Cloud to your on-premises environment.

High-level process overview

You can accelerate data migration projects by using Starburst because Starburst enables insights across all of your data, prior to migrating it. The following image shows the typical process for migrating data by using Starburst.



Roles

The following roles are typically required to complete a migration using Starburst:

- **Cloud administrator** – Responsible for making cloud resources available to run the Starburst Enterprise application
- **Starburst administrator** – Responsible for installing, configuring, managing, and supporting the Starburst application
- **Data engineer**– Responsible for:
  - Migrating the legacy data to the cloud
  - Building semantic views to support analytics
- **Solution or system owner** – Responsible for the overall solution implementation

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.

Other tools

- Helm – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- Starburst Enterprise – Starburst Enterprise is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.
- Starburst Stargate – Starburst Stargate links catalogs and data sources in one Starburst Enterprise environment, such as a cluster in an on-premises data center, to the catalogs and data sources in another Starburst Enterprise environment, such as a cluster in the AWS Cloud.

Epics

Assess the data

Task	Description	Skills required
Identify and prioritize your data.	Identify the data you want to move. Large, on-premises legacy systems can include core data that you want to migrate alongside data that you don't want to move or can't be moved because of compliance reasons. Starting with a data inventory helps you prioritize which data you should target first. For more information, see Get started with automated portfolio discovery.	Data engineer, DBA

Task	Description	Skills required
Explore, inventory, and back up your data.	Validate the quality, quantity, and relevance of the data for your use case. Back up or create a snapshot of the data as needed, and finalize the target environment for the data.	Data engineer, DBA

Set up the Starburst Enterprise environment

Task	Description	Skills required
Configure Starburst Enterprise in the AWS Cloud.	While data is being catalogued, set up Starburst Enterprise in a managed Amazon EKS cluster. For more information see, Deploying with Kubernetes in the *Starburst Enterprise reference documentation*. This allows business-as-usual analytics while data migration is in process.	AWS administrator, App developer
Connect Starburst to the data sources.	After you have identified the data and set up Starburst Enterprise, connect Starburst to the data sources. Starburst reads data directly from the data source as a SQL query. For more information, see the Starburst Enterprise reference documentation.	AWS administrator, App developer

Migrate the data

Task	Description	Skills required
Build and run the ETL pipelines.	Begin the data migration process. This activity can occur at the same time as business-as-usual analytics . For the migration, you can use a third-party product or Starburst. Starburst has the capability to both read and write data across different sources. For more information, see the Starburst Enterprise reference documentation.	Data engineer
Validate the data.	After the data has been migrated, validate the data to ensure all required data has been moved and is intact.	Data engineer, DevOps engineer

Cut over

Task	Description	Skills required
Cut over the data.	After data migration and validation is complete, you can cut over the data. This involves changing the data connection links in Starburst. Instead of pointing at the on-premises sources, you point to the new cloud sources and update the semantic	Data engineer, Cutover lead

Task	Description	Skills required
	views. For more informati on, see Connectors in the *Starburst Enterprise reference documentation*.	
Roll out to users.	Data consumers begin working off the migrated data sources. This process is invisible to the analytics end users.	Cutover lead, Data engineer

Optimize the ETL ingestion of input file size on AWS

Apoorva Patrikar, Amazon Web Services

Summary

This pattern shows you how to optimize the ingestion step of the extract, transform, and load (ETL) process for big data and Apache Spark workloads on AWS Glue by optimizing file size before processing your data. Use this pattern to prevent or resolve the *small files problem*. That is, when a large number of small files slows down data processing due to the aggregate size of the files. For example, hundreds of files that are only a few hundred kilobytes each can significantly slow down data processing speeds for your AWS Glue jobs. This is because AWS Glue must perform internal list functions on Amazon Simple Storage Service (Amazon S3) and YARN (Yet Another Resource Negotiator) must store a large amount of metadata. To improve data processing speeds, you can use grouping to enable your ETL tasks to read a group of input files into a single in-memory partition. The partition automatically groups smaller files together. Alternatively, you can use custom code to add batch logic to your existing files.

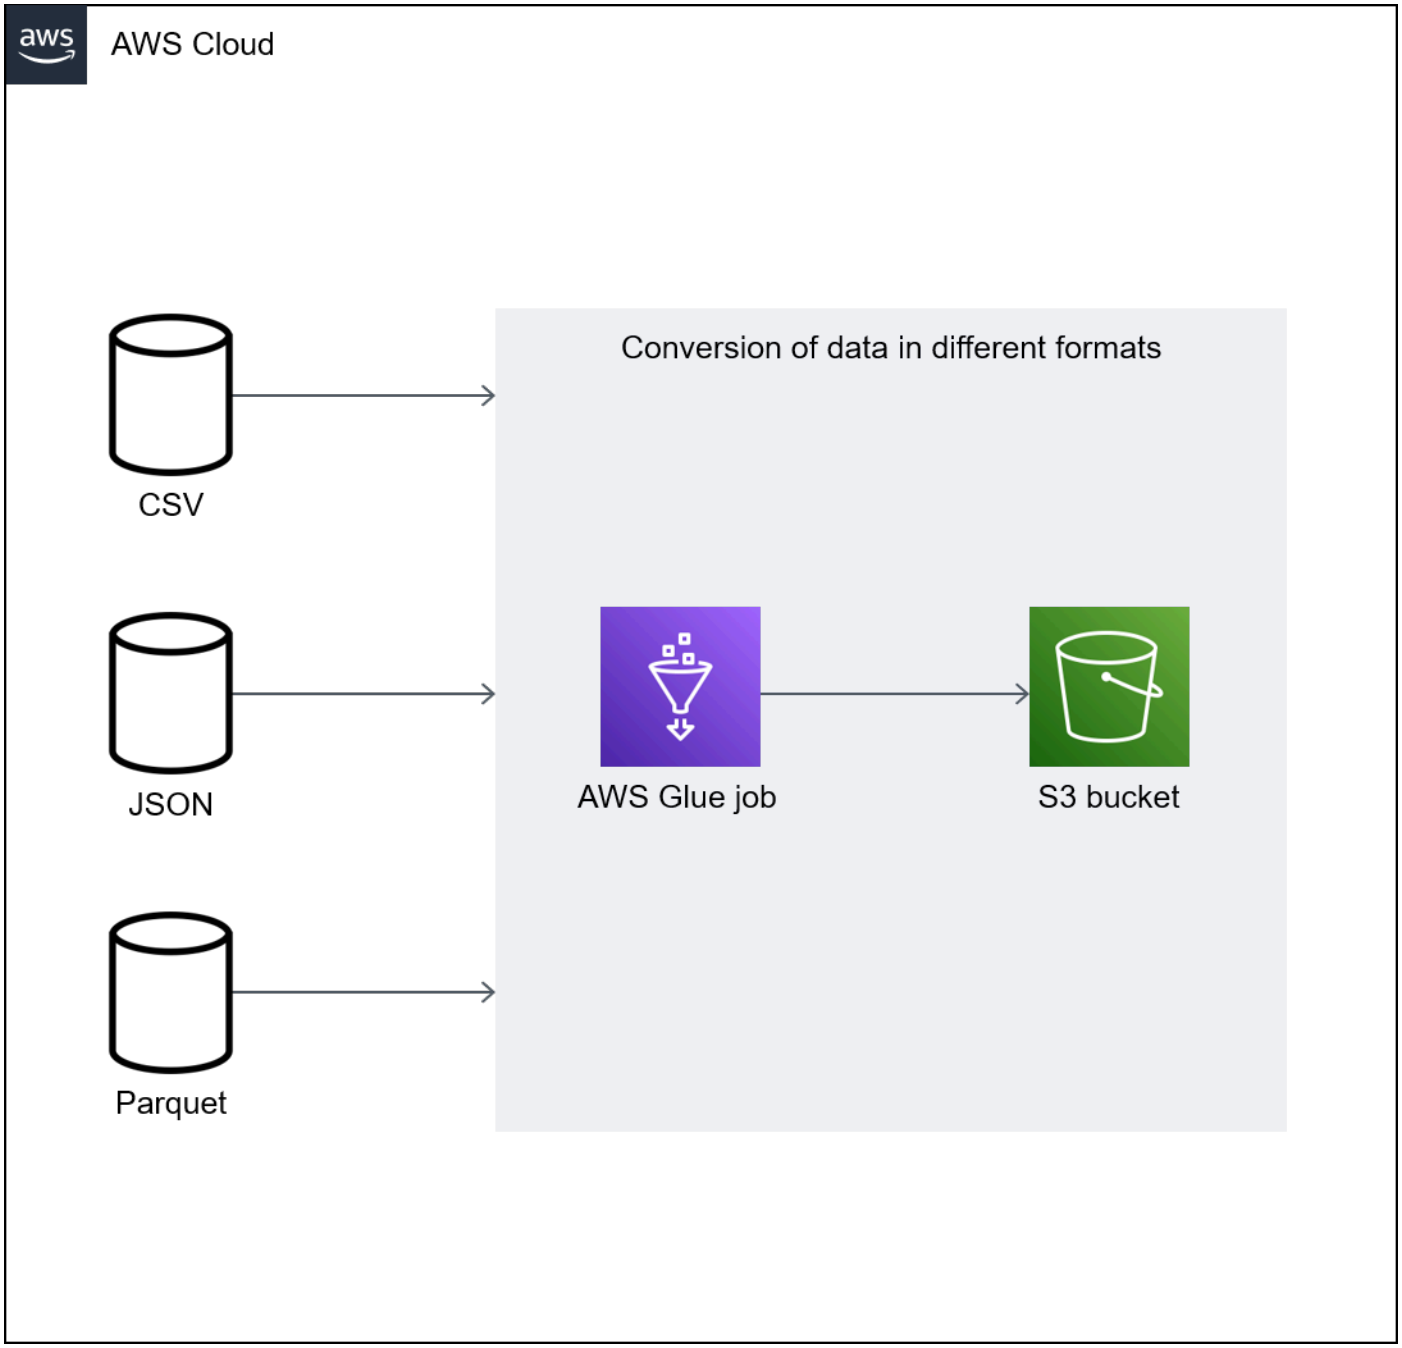
Prerequisites and limitations

Prerequisites

- An active AWS account
- One or more AWS glue jobs
- One or more big data or Apache Spark workloads
- An S3 bucket

Architecture

The following pattern shows how data in different formats is processed by an AWS Glue job and then stored in an S3 bucket to get visibility into performance.



The diagram shows the following workflow:

1. **Note**

   An AWS Glue job converts small files in CSV, JSON, and Parquet format to dynamic frames. : The size of the input file has the most significant impact on the performance of the AWS Glue job.

2. The AWS Glue job performs internal list functions in an S3 bucket.

Tools

- AWS Glue is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Epics

Use grouping to optimize ETL ingestion during reading

Task	Description	Skills required
Specify the group size.	If you have more than 50,000 files, grouping is done by default. However, you can also use grouping for less than 50,000 files by specifying the group size in the `connectionOptions` parameter. The `connectionOptions` parameter is in the `create_dynamic_frame.from_options` method.	Data engineer
Write the grouping code.	Use the `create_dynamic_frame` method to create a dynamic frame. For example: `S3bucket_node1 = glueContext.create_dynamic_frame.from_options(`	Data engineer

Task	Description	Skills required

	`format_options={"multiline": False},`
	`connection_type="s3",`
	`format="json",`
	`connection_options={`
	`"paths": ["s3://bucket/prefix/file.json"],`
	`"recurse": True,`
	`"groupFiles": 'inPartition',`
	`"groupSize": 1048576`
	`},`
	`transformation_ctx="S3bucket_node1",`
	`)`
	
	Note
	Use `groupFiles` to group files in an Amazon S3 partition group. Use `groupSize` to set the target size of the group to be read in memory. Specify `groupSize` in bytes (1048576 = 1 MB).	

Add the code to the workflow.	Add the grouping code to your job workflow in AWS Glue.	Data engineer

Use custom logic to optimize ETL ingestion

Task	Description	Skills required
Choose the language and processing platform.	Choose the scripting language and processing platform tailored to your use case.	Cloud architect
Write the code.	Write the custom logic to batch your files together.	Cloud architect
Add the code to the workflow.	Add the code to your job workflow in AWS Glue. This enables your custom logic to be applied every time the job is run.	Data engineer

Repartition when writing data after transformation

Task	Description	Skills required
Analyze consumption patterns.	Find out how downstream applications will use the data you write. For example, if they query data each day and you only partition data per Region or have very small output files, such as 2.5 KB per file, then this is not optimal for consumption.	DBA
Repartition data before writing.	Repartition based on joins or queries during processin g (based on processing logic) and after processing (based on consumption). For	Data engineer

Task	Description	Skills required
	example, repartition based on byte size, such as `.repartition(100000)`, or repartition based on columns, such as `.repartition("column_name")`.	

Related resources

- Reading input files in larger groups
- Monitoring AWS Glue
- Monitoring AWS Glue using Amazon CloudWatch metrics
- Job monitoring and debugging
- Getting started with serverless ETL on AWS Glue

Additional information

Determining file size

There is no straightforward way to determine if a file size is too big or too small. The impact of file size on processing performance depends on the configuration of your cluster. In core Hadoop, we recommend that you use files that are 128 MB or 256 MB to make the most of the block size.

For most text file workloads on AWS Glue, we recommended a file size between 100 MB and 1 GB for a 5-10 DPU cluster. To figure out the best size of input files, monitor the preprocessing section of your AWS Glue job, and then check the CPU utilization and memory utilization of the job.

Additional considerations

If performance in the early ETL stages is a bottleneck, consider grouping or merging the data files before processing. If you have complete control on the file generation process, it can be even more efficient to aggregate data points on the source system itself before the raw data is sent to AWS.

Orchestrate an ETL pipeline with validation, transformation, and partitioning using AWS Step Functions

Sandip Gangapadhyay, Amazon Web Services

Summary

This pattern describes how to build a serverless extract, transform, and load (ETL) pipeline to validate, transform, compress, and partition a large CSV dataset for performance and cost optimization. The pipeline is orchestrated by AWS Step Functions and includes error handling, automated retry, and user notification features.

When a CSV file is uploaded to an Amazon Simple Storage Service (Amazon S3) bucket source folder, the ETL pipeline starts to run. The pipeline validates the content and the schema of the source CSV file, transforms the CSV file to a compressed Apache Parquet format, partitions the dataset by year, month, and day, and stores it in a separate folder for analytics tools to process.

The code that automates this pattern is available on GitHub, in the ETL Pipeline with AWS Step Functions repository.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured with your AWS account, so that you can create AWS resources by deploying an AWS CloudFormation stack. We recommend using AWS CLI version 2. For instructions, see Installing or updating to the latest version of the AWS CLI in the AWS CLI documentation. For configuration instructions, see Configuration and credential file settings in the AWS CLI documentation.
- An Amazon S3 bucket.
- A CSV dataset with the correct schema. (The code repository included with this pattern provides a sample CSV file with the correct schema and data type that you can use.)
- A web browser that supports the AWS Management Console. (See the list of supported browsers.)
- AWS Glue console access.

- AWS Step Functions console access.

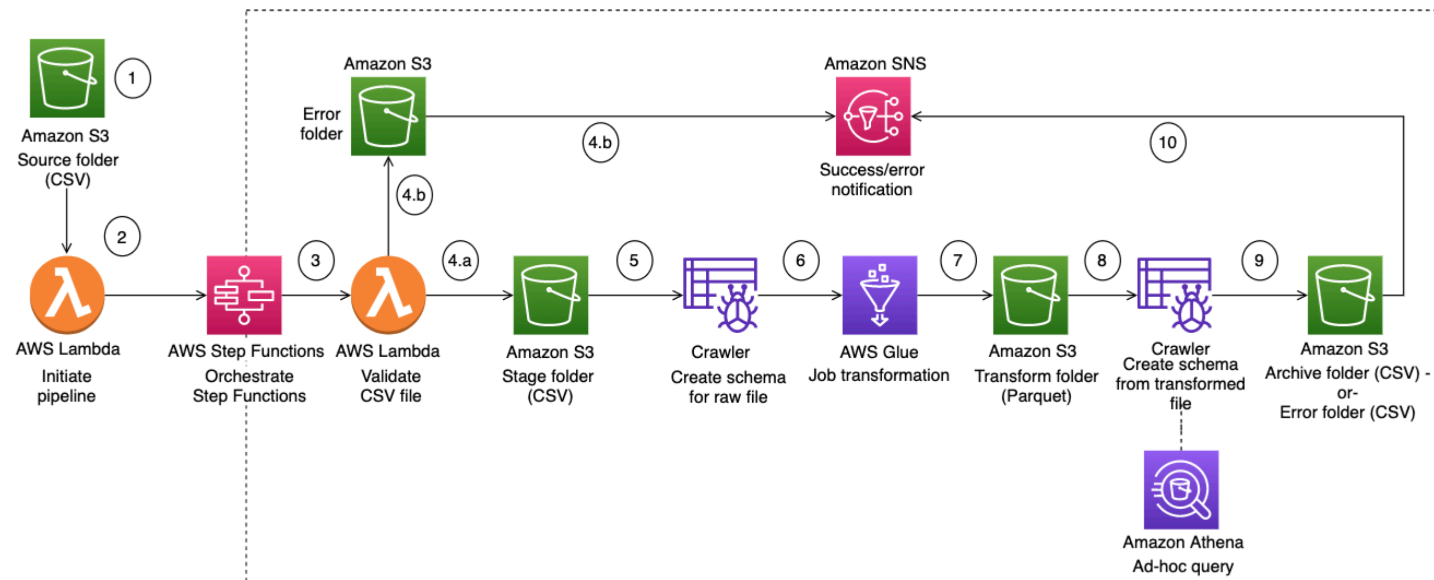
Limitations

- In AWS Step Functions, the maximum limit for keeping history logs is 90 days. For more information, see Step Functions service quotas in the AWS Step Functions documentation.

Product versions

- Python 3.13 for AWS Lambda
- AWS Glue version 4.0

Architecture



The workflow illustrated in the diagram consists of these high-level steps:

1. The user uploads a CSV file into the source folder in Amazon S3.
2. An Amazon S3 notification event initiates an AWS Lambda function that starts the AWS Step Functions state machine.
3. The Lambda function validates the schema and data type of the raw CSV file.
4. Depending on the validation results:
    a. If validation of the source file succeeds, the file moves to the stage folder for further processing.

   b. If validation fails, the file moves to the error folder, and an error notification is sent through Amazon Simple Notification Service (Amazon SNS).

5. An AWS Glue crawler creates the schema of the raw file from the stage folder in Amazon S3.
6. An AWS Glue job transforms, compresses, and partitions the raw file into Parquet format.
7. The AWS Glue job also moves the file to the transform folder in Amazon S3.
8. The AWS Glue crawler creates the schema from the transformed file. The resulting schema can be used by any analytics job. You can also use Amazon Athena to run ad-hoc queries.
9. If the pipeline completes without errors, the schema file is moved to the archive folder. If any errors are encountered, the file is moved to the error folder instead.
10. Amazon SNS sends a notification that indicates success or failure based on the pipeline completion status.

All the AWS resources used in this pattern are serverless. There are no servers to manage.

Tools

AWS services

- AWS Glue – AWS Glue is a fully managed ETL service that makes it easy for customers to prepare and load their data for analytics.
- AWS Step Functions – AWS Step Functions is a serverless orchestration service that lets you combine AWS Lambda functions and other AWS services to build business-critical applications. Through the AWS Step Functions graphical console, you see your application's workflow as a series of event-driven steps.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a highly available, durable, secure, fully managed pub/sub messaging service that enables you to decouple microservices, distributed systems, and serverless applications.
- AWS Lambda – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

Code

The code for this pattern is available on GitHub, in the [ETL Pipeline with AWS Step Functions] repository. The code repository contains the following files and folders:

- `template.yml` – AWS CloudFormation template for creating the ETL pipeline with AWS Step Functions.
- `parameter.json` – Contains all parameters and parameter values. You update this file to change parameter values, as described in the *Epics* section.
- `myLayer/python` folder – Contains Python packages needed to create the required AWS Lambda layer for this project.
- `lambda` folder – Contains the following Lambda functions:
  - `move_file.py` – Moves the source dataset to the archive, transform, or error folder.
  - `check_crawler.py` – Checks the status of the AWS Glue crawler as many times as configured by the `RETRYLIMIT` environment variable before it sends a failure message.
  - `start_crawler.py` – Starts the AWS Glue crawler.
  - `start_step_function.py` – Starts AWS Step Functions.
  - `start_codebuild.py` – Starts the AWS CodeBuild project.
  - `validation.py` – Validates the input raw dataset.
  - `s3object.py` – Creates the required directory structure inside the Amazon S3 bucket.
  - `notification.py` – Sends success or error notifications at the end of the pipeline.

To use the sample code, follow the instructions in the *Epics* section.

Epics

Prepare the source files

Task	Description	Skills required
Clone the sample code repository.	1. Open the ETL Pipeline with AWS Step Functions repository. 2. Choose **Code** on the main repository page, above the file list, and copy the URL	Developer

Task	Description	Skills required
	listed under **Clone with HTTPS**. 3. Change your working directory to the location where you want to store the sample files. 4. At a terminal or command prompt, type the command: `git clone <repoURL>` where `<repoURL>` refers to the URL you copied in step 2.	

Task	Description	Skills required
Update parameter values.	In your local copy of the repository, edit the `parameter.json` file and update the default parameter values as follows: • `pS3BucketName` — The name of the Amazon S3 bucket for storing the datasets. The template will create this bucket for you. The bucket name must be globally unique. • `pSourceFolder` — The name of the folder inside the Amazon S3 bucket that will be used to upload the source CSV file. • `pStageFolder` — The name of the folder inside the Amazon S3 bucket that will be used as the staging area during the process. • `pTransformFolder` — The name of the folder inside the Amazon S3 bucket that will be used to store transformed and partitioned datasets. • `pErrorFolder` — The folder inside the Amazon S3 bucket that the source CSV file will be moved to if it can't be validated.	Developer

Task	Description	Skills required
	• `pArchiveFolder` – The name of the folder inside the Amazon S3 bucket that will be used to archive the source CSV file. • `pEmailforNotification` – A valid email address for receiving success/error notifications. • `pPrefix` – A prefix string that will be used in the AWS Glue crawler name. • `pDatasetSchema` – The dataset schema that the source file will be validated against. The Cerberus Python package is used for source dataset validation. For more information, see the Cerberus website.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Upload the source code to the Amazon S3 bucket.</td><td>Before you deploy the AWS CloudFormation template that automates the ETL pipeline, you must package the source files for the template and upload them to an Amazon S3 bucket. To do this, run the following AWS CLI command with your preconfigured profile:

<pre><code>aws cloudformation
 package --template-
file template.yml --s3-
bucket <bucket_name>
 --output-template-
file packaged.template
 --profile <profile_
name></code></pre>
where:
<code><bucket_name></code> is the name of an existing Amazon S3 bucket in the AWS Region where you want to deploy the stack. This bucket is used to store the source code package for the CloudFormation template.
<code><profile_name></code> is a valid AWS CLI profile that you preconfigured when you set up AWS CLI.</td><td>Developer</td></tr>
</table>

Create the stack

Task	Description	Skills required
Deploy the CloudFormation template.	To deploy the AWS CloudFormation template, run the following AWS CLI command: `aws cloudformation deploy --stack-name <stack_name> --template-file packaged.template --parameter-overrides file://parameter.json --capabilities CAPABILITY_IAM --profile <profile_name>` where: • `<stack_name>` is a unique identifier for the CloudFormation stack. • `<profile-name>` is your preconfigured AWS CLI profile.	Developer
Check progress.	On the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/), check the progress of stack development. When the status is `CREATE_COMPLETE`, the stack has been deployed successfully.	Developer
Note the AWS Glue database name.	The **Outputs** tab for the stack displays the name of the AWS	Developer

Task	Description	Skills required
	Glue database. The key name is `GlueDBOutput` .	

Test the pipeline

Task	Description	Skills required
Start the ETL pipeline.	1. Navigate to the source folder (`source`, or the folder name you set in the `parameter.json` file) inside the Amazon S3 bucket. 2. Upload a sample CSV file to this folder. (The code repository provides a sample file called `Sample_Bank_Transaction_Raw_Dataset.csv` that you can use.) Uploading the file will start the ETL pipeline through Step Functions. 3. On the [Step Functions console](https://console.aws.amazon.com/states/), check the ETL pipeline status.	Developer
Check for the partitioned dataset.	When the ETL pipeline completes, verify that the partitioned dataset is available in the Amazon S3 transform folder (`transform` , or the folder name you set	Developer

Task	Description	Skills required
	in the `parameter.json` file).	
Check for the partitioned AWS Glue database.	1. On the AWS Glue console, select the AWS Glue database created by the stack (this is the database that you noted in the previous epic). 2. Verify that the partitioned table is available in the AWS Glue Data Catalog.	Developer
Run queries.	(Optional) Use Amazon Athena to run ad-hoc queries on the partitioned and transformed database. For instructions, see Run SQL queries in Amazon Athena in the AWS documentation.	Database analyst

Troubleshooting

Issue	Solution
AWS Identity and Access Management (IAM) permissions for the AWS Glue job and crawler	If you further customize the AWS Glue job or the crawler, be sure to grant the appropriate IAM permissions in the IAM role used by the AWS Glue job, or provide data permissions to AWS Lake Formation. For more information, see the AWS documentation.

Perform advanced analytics using Amazon Redshift ML

Po Hong and Chyanna Antonio, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, you can use Amazon Redshift machine learning (Amazon Redshift ML) to perform ML analytics on data stored in either an Amazon Redshift cluster or on Amazon Simple Storage Service (Amazon S3). Amazon Redshift ML supports supervised learning, which is typically used for advanced analytics. Use cases for Amazon Redshift ML include revenue forecasting, credit card fraud detection, and customer lifetime value (CLV) or customer churn predictions.

Amazon Redshift ML makes it easy for database users to create, train, and deploy ML models by using standard SQL commands. Amazon Redshift ML uses Amazon SageMaker Autopilot to automatically train and tune the best ML models for classification or regression based on your data, while you retain control and visibility.

All interactions between Amazon Redshift, Amazon S3, and Amazon SageMaker are abstracted away and automated. After the ML model is trained and deployed, it becomes available as a user-defined function (UDF) in Amazon Redshift and can be used in SQL queries.

This pattern complements the Create, train, and deploy ML models in Amazon Redshift using SQL with Amazon Redshift ML from the AWS Blog, and the Build, train, and deploy an ML model with Amazon SageMaker tutorial from the Getting Started Resource Center.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Existing data in an Amazon Redshift table

Skills

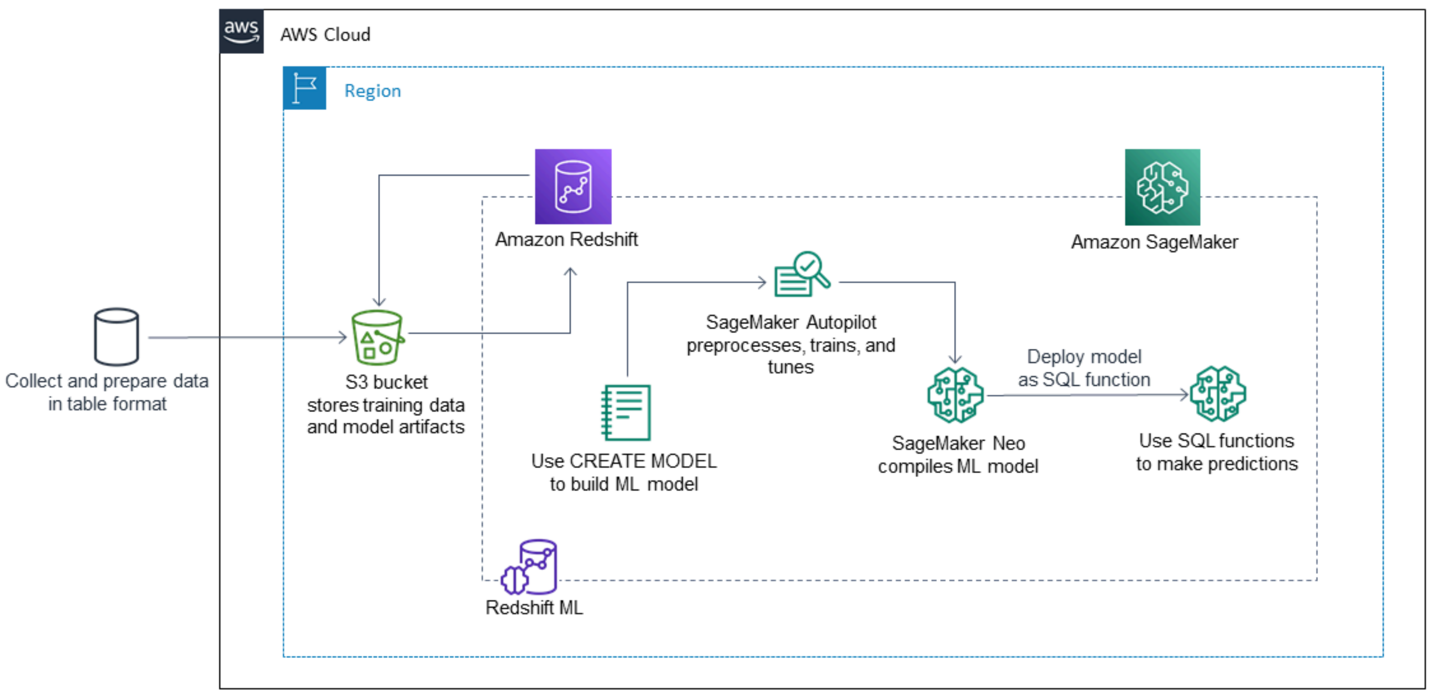
- Familiarity with terms and concepts used by Amazon Redshift ML, including *machine learning*, *training*, and *prediction*. For more information about this, see Training ML models in the Amazon Machine Learning (Amazon ML) documentation.

- Experience with Amazon Redshift user setup, access management, and standard SQL syntax. For more information about this, see Getting started with Amazon Redshift in the Amazon Redshift documentation.
- Knowledge and experience with Amazon S3 and AWS Identity and Access Management (IAM).
- Experience running commands in AWS Command Line Interface (AWS CLI) is also beneficial but not required.

Limitations

- The Amazon Redshift cluster and S3 bucket must be located in the same AWS Region.
- This pattern's approach only supports supervised learning models such as regression, binary classification, and multiclass classification.

Architecture



The following steps explain how Amazon Redshift ML works with SageMaker to build, train, and deploy an ML model:

1. Amazon Redshift exports training data to an S3 bucket.
2. SageMaker Autopilot automatically preprocesses the training data.

3. After the `CREATE MODEL` statement is invoked, Amazon Redshift ML uses SageMaker for training.
4. SageMaker Autopilot searches for and recommends the ML algorithm and optimal hyper-parameters that optimize the evaluation metrics.
5. Amazon Redshift ML registers the output ML model as a SQL function in the Amazon Redshift cluster.
6. The ML model's function can be used in a SQL statement.

Technology stack

- Amazon Redshift
- SageMaker
- Amazon S3

Tools

- Amazon Redshift – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- Amazon Redshift ML – Amazon Redshift machine learning (Amazon Redshift ML) is a robust, cloud-based service that makes it easy for analysts and data scientists of all skill levels to use ML technology.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- Amazon SageMaker – SageMaker is a fully managed ML service.
- Amazon SageMaker Autopilot – SageMaker Autopilot is a feature-set that automates key tasks of an automatic machine learning (AutoML) process.

Code

You can create a supervised ML model in Amazon Redshift by using the following code:

```
"CREATE MODEL customer_churn_auto_model
FROM (SELECT state,
             account_length,
             area_code,
             total_charge/account_length AS average_daily_spend,
```

```
            cust_serv_calls/account_length AS average_daily_cases,
            churn
      FROM customer_activity
      WHERE  record_date < '2020-01-01'
     )
TARGET churn
FUNCTION ml_fn_customer_churn_auto
IAM_ROLE 'arn:aws:iam::XXXXXXXXXXXX:role/Redshift-ML'
SETTINGS (
  S3_BUCKET 'your-bucket'
);")
```

Note

The SELECT state can refer to Amazon Redshift regular tables, Amazon Redshift Spectrum external tables, or both.

Epics

Prepare a training and test dataset

Task	Description	Skills required
Prepare a training and test dataset.	Sign in to the AWS Management Console and open the Amazon SageMaker console. Follow the instructi ons from the Build, train, and deploy a machine learning model tutorial to create a .csv or Apache Parquet file that has a label column (*supervised training*) and no header. **Note** We recommend that you shuffle and split	Data scientist

Task	Description	Skills required
	the raw dataset into a training set for the model's training (70 percent) and a test set for the model's performance evaluation (30 percent).	

Prepare and configure the technology stack

Task	Description	Skills required
Create and configure an Amazon Redshift cluster.	On the Amazon Redshift console, create a cluster according to your requirements. For more information about this, see [Create a cluster](#) in the Amazon Redshift documentation. **Important** Amazon Redshift clusters must be created with the `SQL_PREVIEW` maintenance track. For more information about preview tracks, see [Choosing cluster maintenance tracks](#) in	DBA, Cloud architect

Task	Description	Skills required
	the Amazon Redshift documentation.	
Create an S3 bucket to store training data and model artifacts.	On the Amazon S3 console, create an S3 bucket for the training and test data. For more information about creating an S3 bucket, see [Create an S3 bucket](#) from AWS Quick Starts. **Important** Make sure that your Amazon Redshift cluster and S3 bucket are in the same Region.	DBA, Cloud architect
Create and attach an IAM policy to the Amazon Redshift cluster.	Create an IAM policy to allow the Amazon Redshift cluster to access SageMaker and Amazon S3. For instructions and steps, see [Cluster setup for using Amazon Redshift ML](#) in the Amazon Redshift documentation.	DBA, Cloud architect

Task	Description	Skills required
Allow Amazon Redshift users and groups to access schemas and tables.	Grant permissions to allow users and groups in Amazon Redshift to access internal and external schemas and tables. For steps and instructions, see Managing permissions and ownership in the Amazon Redshift documentation.	DBA

Create and train the ML model in Amazon Redshift

Task	Description	Skills required
Create and train the ML model in Amazon Redshift.	Create and train your ML model in Amazon Redshift ML. For more information, see the `CREATE MODEL` statement in the Amazon Redshift documentation.	Developer, Data scientist

Perform batch inference and prediction in Amazon Redshift

Task	Description	Skills required
Perform inference using the generated ML model function.	For more information about performing inference by using the generated ML model function, see Prediction in the Amazon Redshift documentation.	Data scientist, Business intelligence user

Query Amazon DynamoDB tables with SQL by using Amazon Athena

Gavin Perrie, Ajit Ambike, and Brad Yates, Amazon Web Services

Summary

If your data includes sources other than Amazon Simple Storage Service (Amazon S3), you can use federated queries to access those relational, non-relational, object, or custom data sources. This pattern shows how to configure federated query access through Amazon Athena to Amazon DynamoDB by using an SQL data source connector.

Using this pattern you can do the following:

- Query DynamoDB tables by using SQL.
- Run federated SQL queries in Athena and join DynamoDB tables with other supported data sources.

Prerequisites and limitations

Prerequisites

- A DynamoDB table.
- An Athena workgroup set to use Athena engine version 2. For instructions, see the Athena documentation.
- An S3 bucket where the `AthenaDynamoDBConnector` AWS Lambda function can spill the data. The S3 bucket and the Lambda function must be in the same AWS Region.

If this is your first time accessing Athena, you will need an additional S3 bucket to use as the query result location. For instructions, see the Athena documentation.

Limitations

- Write operations such as INSERT INTO are not supported.

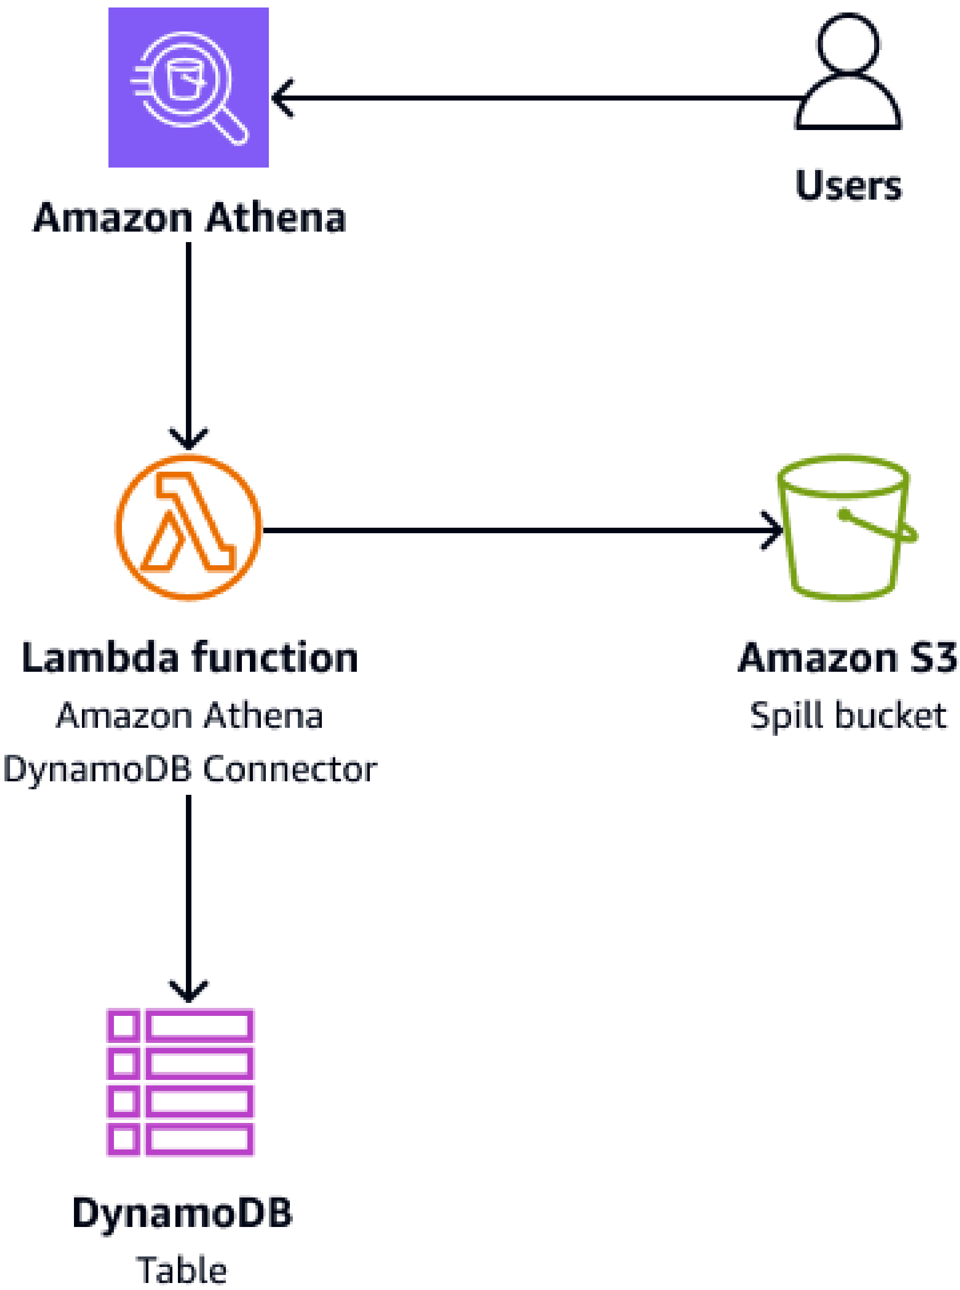
Product versions

- Athena Query Federation releases on GitHub

Architecture

Target architecture

The following diagram shows the connection flow after the pattern is established. The user connects to Amazon Athena to provide the query. Athena passes the query and target to the DynamoDB data source connector Lambda function, which retrieves and returns the data to Athena. If large amounts of data are returned, Athena stores the temporary results in the spill bucket before packaging and returning the complete dataset.



Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL. This pattern uses Amazon Athena

DynamoDB Connector, a tool built using the Amazon Athena Query Federation SDK and installed as an AWS Lambda application through the AWS Serverless Application Repository.

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code repository

The code for this pattern is available in the GitHub Athena Query Federation repository.

Epics

Set up and test the DynamoDB data source connector

Task	Description	Skills required
Deploy the AthenaDynamoDBConnector application.	To deploy AthenaDynamoDBConnecter, do the following: 1. Sign in to the AWS Management Console, and choose the AWS Region that you're using for the DynamoDB table and the spill bucket. 2. Open the **Serverless Application Repository** at https://console.aws.amazon.com/serverlessrepo/.	AWS DevOps

Task	Description	Skills required
	3. In the navigation pane, choose **Available Applications**. 4. For AWS Identity and Access Management (IAM) access, under the search bar, select the **Show apps that create custom IAM roles or resource policies** check box. 5. Search for and select **AthenaDynamoDBConnector**, and ensure that the author listed is **Amazon Athena Federation**. 6. In **Application Settings**, enter the following values: • **SpillBucket** – Location that the function can spill data to. • **AthenaCatalogName** – The name of the Lambda function that will be created. The name will also be used as the **Data Source Name** in Athena. 7. Select the check box to acknowledge the creation of IAM roles and policies. 8. Choose **Deploy**.	

Task	Description	Skills required
Create a data source for Athena.	To create the data source, do the following: 1. Open the Athena console at https://console.aws.amazon.com/athena/. 2. Expand the navigation pane, and choose **Data sources**. 3. Choose **Create data source**. 4. Choose **Amazon DynamoDB**. 5. Enter the **Data Source Name**. 6. Select the Lambda function that you created. 7. Review the details, and choose **Create data source**.	AWS DevOps

Task	Description	Skills required
Use Athena to query the DynamoDB table.	To query the DynamoDB table, do the following: 1. On the Athena console, expand the navigation pane, and choose **Query editor**. 2. On the **Data source** dropdown list, choose the data source that you created. 3. Confirm that the DynamoDB tables are listed under **Tables**. 4. Run the query.	App developer

Troubleshooting

Issue	Solution
Query fails with `GENERIC_INTERNAL_ERROR: The bucket is in this region: <region>`.	Make sure that the Athena spill bucket and Lambda function are created in the same AWS Region.
The newly created data source isn't visible on the Athena console.	Athena data catalogs are regional. Ensure the `AthenaDynamoDBConnector` has been deployed in the Region where you are trying to use Athena.
You're unable to run the query against the newly created data source.	Check that the **Query Result Location** has been set.

Access, query, and join Amazon DynamoDB tables using Athena

Moinul Al-Mamun, Amazon Web Services

Summary

This pattern shows you how to set up a connection between Amazon Athena and Amazon DynamoDB by using the Amazon Athena DynamoDB connector. The connector uses an AWS Lambda function to query the data in DynamoDB. You don't need to write any code to set up the connection. After the connection is established, you can quickly access and analyze DynamoDB tables by using Athena Federated Query to run SQL commands from Athena. You can also join one or more DynamoDB tables to each other or to other data sources, such as Amazon Redshift or Amazon Aurora.

Prerequisites and limitations

Prerequisites

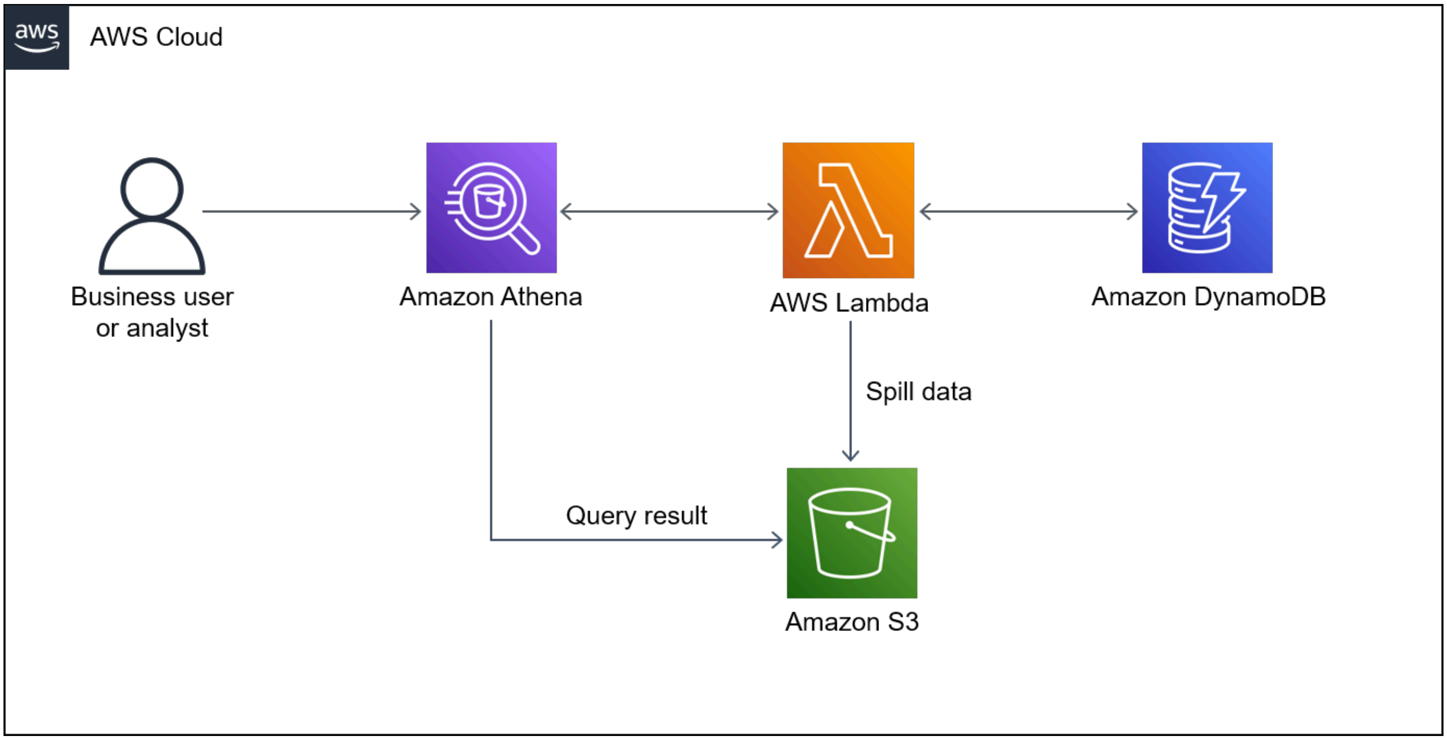
- An active AWS account with permissions to manage DynamoDB tables, Athena Data sources, Lambda, and AWS Identity and Access Management (IAM) roles
- An Amazon Simple Storage Service (Amazon S3) bucket where Athena can store query results
- An S3 bucket where the Athena DynamoDB Connector can save the data in the short term
- An AWS Region that supports Athena engine version 2
- IAM permissions to access Athena and the required S3 buckets
- Amazon Athena DynamoDB Connector, installed

Limitations

There is a cost for querying DynamoDB tables. Table sizes exceeding a few gigabytes (GBs) can incur a high cost. We recommend that you consider cost before performing any full table SCAN operation. For more information, see Amazon DynamoDB pricing. To reduce costs and achieve high performance, we recommend that you always use LIMIT in your query (for example, `SELECT * FROM table1 LIMIT 10`). Also, before you perform a JOIN or GROUP BY query in a production environment, consider the size of your tables. If your tables are too large, consider alternative options such as migrating the table to Amazon S3.

Architecture

The following diagram shows how a user can run a SQL query on a DynamoDB table from Athena.



The diagram shows the following workflow:

1. To query a DynamoDB table, a user runs a SQL query from Athena.
2. Athena initiates a Lambda function.
3. The Lambda function queries the requested data in the DynamoDB table.
4. DynamoDB returns the requested data to the Lambda function. Then, the function transfers the query results to the user through Athena.
5. The Lambda function stores data in the S3 bucket.

Technology stack

- Amazon Athena
- Amazon DynamoDB
- Amazon S3
- AWS Lambda

Tools

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- Amazon Athena DynamoDB Connector is an AWS tool that enables Athena to connect with DynamoDB and access your tables by using SQL queries.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Epics

Create sample DynamoDB tables

Task	Description	Skills required
Create the first sample table.	1. Sign in to the AWS Management Console and open the DynamoDB console. 2. Choose **Create table**. 3. For **Table name**, enter **dydbtable1**. 4. For **Partition key**, enter **PK1**. 5. For **Sort key**, enter **SK1**. 6. In the **Table settings** section, choose **Customize settings**. 7. In the **Table class** section, choose **DynamoDB Standard**.	Developer

Task	Description	Skills required
	8. In the **Read/write capacity settings** section, for **Capacity mode**, choose **On-demand**. 9. In the **Encryption at rest** section, choose **Owned by Amazon DynamoDB**. 10. Choose **Create table**.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Insert sample data into the first table.</td><td>
1. Open the DynamoDB console.
2. In the navigation pane, choose Table, and then choose your table in the Name column.
3. Choose Actions, and then choose Create item.
4. Choose JSON view.
5. In the title bar of the Attributes editor, turn off View DynamoDB JSON.
6. In the Attributes editor, enter the following sample data one by one:
<pre>{
  "PK1": "1234",
  "SK1": "info",
  "Salary": "5000"
 }</pre>
<pre>{
  "PK1": "1235",
  "SK1": "info",
  "Salary": "5200"
 }</pre>
</td><td>Developer</td></tr>
</table>

Task	Description	Skills required
Create the second sample table.	1. Open the [DynamoDB console](). 2. Choose **Create table**. 3. For **Table name**, enter **dydbtable2**. 4. For **Partition key**, enter **PK2**. 5. For **Sort key**, enter **SK2**. 6. In the **Table settings** section, choose **Customize settings**. 7. In the **Table class** section, choose **DynamoDB Standard**. 8. In the **Read/write capacity settings** section, for **Capacity mode**, choose **On-demand**. 9. In the **Encryption at rest** section, choose **Owned by Amazon DynamoDB**. 10. Choose **Create table**.	Developer

Task	Description	Skills required
Insert sample data into the second table.	1. Open the [DynamoDB console](). 2. In the navigation pane, choose **Table**, and then choose your table in the **Name** column. 3. Choose **Actions**, and then choose **Create item**. 4. In the title bar of the **Attributes** editor, turn off **View DynamoDB JSON**. 5. In the **Attributes** editor, enter the following sample data one by one: `{ "PK2": "1234", "SK2": "bonus", "Bonus": "500" }` `{ "PK2": "1235", "SK2": "bonus", "Bonus": "1000" }`	Developer

Create a data source in Athena for DynamoDB

Task	Description	Skills required
Set up the data source connector.	Create a data source for DynamoDB, and then create a	Developer

Task	Description	Skills required
	Lambda function to connect to that data source. 1. Sign in to the AWS Management Console and open the [Athena console](#). 2. In the navigation pane, choose **Data sources**, and then choose **Create data source**. 3. Choose the **Amazon DynamoDB** data source, and then choose **Next**. 4. In the **Data source details** section, for **Data source name**, enter **testDynamoDB**. 5. In the **Connection details** section, select a Lambda function that's already deployed or choose **Create Lambda function** if you don't have a Lambda function to use for this pattern. **Note**: For more information on creating a Lambda function, see [Getting started with Lambda](#) in the Lambda Developer Guide. 6. (Optional) If you choose **Create Lambda function**, then you must configure the AWS CloudFormation	

Task	Description	Skills required
	template that's included by the Java application before deploying that stack. The template includes ApplicationName, SpillBucket, AthenaCatalogName, and other application settings. **Note**: After you deploy this Java-based application, the stack creates a Lambda function that enables Athena to communicate with DynamoDB. This makes your tables accessible through SQL commands. 7. Deploy your Lambda function. 8. Choose **Next**.	

Task	Description	Skills required
Verify that the Lambda function can access the S3 spill bucket.	1. Open the [Lambda console](https://console.aws.amazon.com/lambda/). 2. In the navigation pane, choose **Functions**, and then choose the function that you created earlier. 3. Choose the **Configuration** tab. 4. In the left pane, choose **Environment variables**, and then confirm that the value for the key is `spill_bucket` . 5. In the left pane, choose **Permissions**, and then in the **Execution role** section, choose the attached IAM role. **Note**: You are directed to the IAM role that's attached to your Lambda function in the IAM console. 6. Confirm that you have write permission on `spill_bucket` bucket. If you experience errors, see the *Additional information* section in this pattern for guidance.	Developer

Access DynamoDB tables from Athena

Task	Description	Skills required
Query the DynamoDB tables.	1. Sign in to the AWS Management Console and open the [Athena console](). 2. In the navigation pane, choose **Data sources**, and then choose **Create data source**. 3. In the navigation pane, choose **Query editor**. 4. On the **Editor** tab, in the **Data** section, for **Data source**, choose your data source for **Data source**. 5. For **Database**, choose your database. 6. For Query 1, enter the following query: `SELECT * FROM dydbtable1 t1;` 7. Choose **Run**, and then verify the output in the table. 8. For Query 2, enter the following query: `SELECT * FROM dydbtable2 t2;` 9. Choose **Run**, and then verify the output in the table.	Developer
Join the two DynamoDB tables.	DynamoDB is a NoSQL data store and doesn't support the SQL join operation.	Developer

Task	Description	Skills required
	Consequently, you must perform a join operation on two DynamoDB tables: 1. Choose the plus icon to create another query. 2. For Query 3, enter the following query: `SELECT pk1, salary, bonus FROM dydbtable1 t1 JOIN dydbtable2 t2 ON t1.pk1 = t2.pk2;`

Additional information

If you run a query in Athena with `spill_bucket` in the `{bucket_name}/folder_name/` format, then you can receive the following error message:

```
"GENERIC_USER_ERROR: Encountered an exception[java.lang.RuntimeException] from your
 LambdaFunction[arn:aws:lambda:us-east-1:xxxxxx:function:testdynamodb] executed in
 context[retrieving meta-data] with message[You do NOT own the spill bucket with the
 name: s3://amzn-s3-demo-bucket/athena_dynamodb_spill_data/]
```

```
This query ran against the "default" database, unless qualified by the query. Please
 post the error message on our forum  or contact customer support with Query Id:
 [query-id]"
```

To resolve this error, update the Lambda function's environment variable `spill_bucket` to `{bucket_name_only}`, and then update the following Lambda IAM policy for bucket write access:

```
{
             "Action": [
                 "s3:GetObject",
                 "s3:ListBucket",
                 "s3:GetBucketLocation",
                 "s3:GetObjectVersion",
                 "s3:PutObject",
                 "s3:PutObjectAcl",
                 "s3:GetLifecycleConfiguration",
                 "s3:PutLifecycleConfiguration",
                 "s3:DeleteObject"
            ],
             "Resource": [
                 "arn:aws:s3:::spill_bucket",
                 "arn:aws:s3:::spill_bucket/*"
            ],
             "Effect": "Allow"
        }
```

Alternatively, you can remove the Athena data source connector that you created earlier, and recreate it by using only `{bucket_name}` for `spill_bucket`.

Set up a minimum viable data space to share data between organizations

Ramy Hcini, Michael Miller, and Jorge Hernandez Suarez, Amazon Web Services

Ismail Abdellaoui and Malte Gasseling, Think-it

Summary

Data spaces are federated networks for data exchange with trust and control over one's data as core principles. They enable organizations to share, exchange, and collaborate on data at scale by offering a cost-effective and technology-agnostic solution.

Data spaces have the potential to significantly drive efforts for a sustainable future by using data-driven problem solving with an end-to-end approach that involves all relevant stakeholders.

This pattern guides you through the example of how two companies can use data space technology on Amazon Web Services (AWS) to drive their carbon emissions–reduction strategy forward. In this scenario, company X provides carbon-emissions data, which company Y consumes. See the [Additional information](#) section for the following data space specification details:

- Participants
- Business case
- Data space authority
- Data space components
- Data space services
- Data to be exchanged
- Data model
- Tractus-X EDC connector

The pattern includes steps for the following:

- Deploying the infrastructure needed for a basic data space with two participants running on AWS.
- Exchanging carbon emissions–intensity data by using the connectors in a secure way.

This pattern deploys a Kubernetes cluster that will host data space connectors and their services through Amazon Elastic Kubernetes Service (Amazon EKS).

The Eclipse Dataspace Components (EDC) control plane and data plane are both deployed on Amazon EKS. The official Tractus-X Helm chart deploys PostgreSQL and HashiCorp Vault services as dependencies.

In addition, the identity service is deployed on Amazon Elastic Compute Cloud (Amazon EC2) to replicate a real-life scenario of a minimum viable data space (MVDS).

Prerequisites and limitations

Prerequisites

- An active AWS account to deploy the infrastructure in your chosen AWS Region
- An AWS Identity and Access Management (IAM) user with access to Amazon S3 that will be used temporarily as a technical user (The EDC connector currently doesn't support the use of roles. We recommend that you create one IAM user specifically for this demo and that this user will have limited permissions associated with it.)
- AWS Command Line Interface (AWS CLI) installed and configured in your chosen AWS Region
- AWS security credentials
- eksctl on your workstation
- Git on your workstation
- kubectl
- Helm
- Postman
- An AWS Certificate Manager (ACM) SSL/TLS certificate
- A DNS name that will point to an Application Load Balancer (the DNS name must be covered by the ACM certificate)
- HashiCorp Vault (For information about using AWS Secrets Manager to manage secrets, see the Additional information section.)

Product versions

- AWS CLI version 2+

- Postman Collection v2.1

Limitations

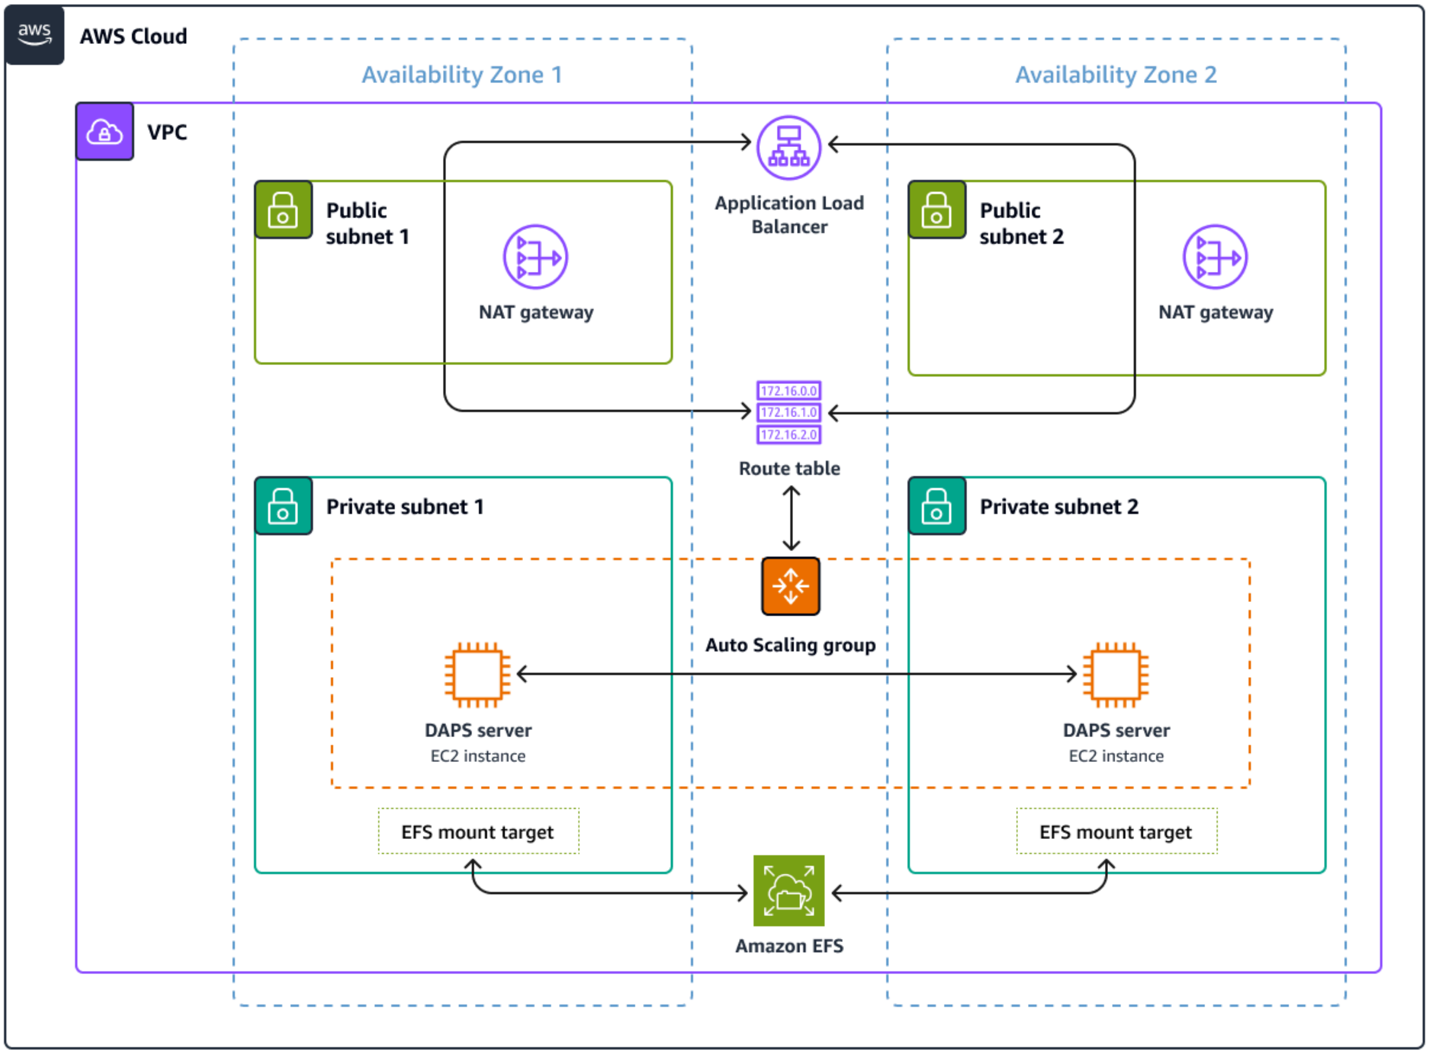
- **Connector selection** – This deployment uses an EDC-based connector. However, be sure to consider the strengths and functionalities of both the EDC and FIWARE True connectors to make an informed decision that aligns with the specific needs of the deployment.
- **EDC connector build** – The chosen deployment solution relies on the Tractus-X EDC Connector Helm chart, a well-established and extensively tested deployment option. The decision to use this chart is driven by its common usage and the inclusion of essential extensions in the provided build. While PostgreSQL and HashiCorp Vault are default components, you have the flexibility to customize your own connector build if needed.
- **Private cluster access** – Access to the deployed EKS cluster is restricted to private channels. Interaction with the cluster is performed exclusively through the use of `kubectl` and IAM. Public access to the cluster resources can be enabled by using load balancers and domain names, which must be implemented selectively to expose specific services to a broader network. However, we do not recommend providing public access.
- **Security focus** – Emphasis is placed on abstracting security configurations to default specifications so that you can concentrate on the steps involved in EDC connector data exchange. Although default security settings are maintained, it's imperative to enable secure communications before you expose the cluster to the public network. This precaution ensures a robust foundation for secure data handling.
- **Infrastructure cost** – An estimation of the infrastructure's cost can be found by using the AWS Pricing Calculator. A simple calculation shows that costs can be up to 162.92 USD per month for the deployed infrastructure.

Architecture

The MVDS architecture comprises two virtual private clouds (VPCs), one for the Dynamic Attribute Provisioning System (DAPS) identity service and one for Amazon EKS.

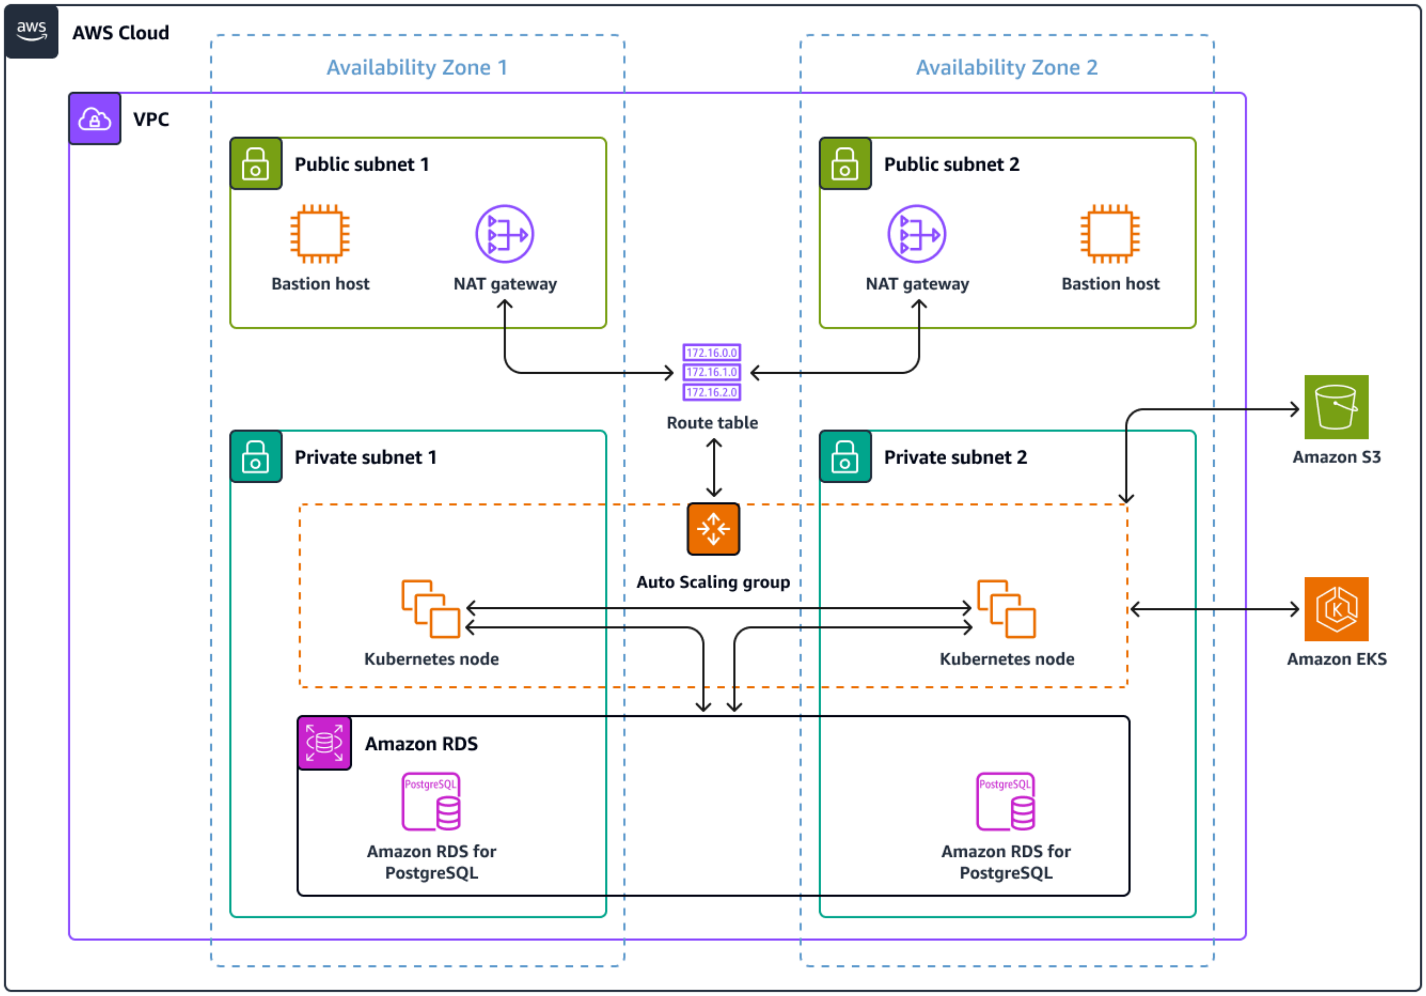
DAPS architecture

The following diagram shows DAPS running on EC2 instances controlled by an Auto Scaling group. An Application Load Balancer and route table expose the DAPS servers. Amazon Elastic File System (Amazon EFS) synchronizes the data among the DAPS instances.



Amazon EKS architecture

Data spaces are designed to be technology-agnostic solutions, and multiple implementations exist. This pattern uses an Amazon EKS cluster to deploy the data space technical components. The following diagram shows the deployment of the EKS cluster. Worker nodes are installed in private subnets. The Kubernetes pods access the Amazon Relational Database Service (Amazon RDS) for PostgreSQL instance that is also in the private subnets. The Kubernetes pods store shared data in Amazon S3.



Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across EC2 instances, containers, and IP addresses in one or more Availability Zones.

Other tools

- eksctl is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- Git is an open source, distributed version control system.
- HashiCorp Vault provides secure storage with controlled access for credentials and other sensitive information.
- Helm is an open source package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- kubectl is a command-line interface that helps you run commands against Kubernetes clusters.
- Postman is an API platform.

Code repository

The Kubernetes configuration YAML files and Python scripts for this pattern are available in the GitHub aws-patterns-edc repository. The pattern also uses the Tractus-X EDC repository.

Best practices

Amazon EKS and isolation of participants’ infrastructures

Namespaces in Kubernetes will separate the company X provider’s infrastructure from the company Y consumer’s infrastructure in this pattern. For more information, see EKS Best Practices Guides.

In a more realistic situation, each participant would have a separate Kubernetes cluster running within their own AWS account. The shared infrastructure (DAPS in this pattern) would be accessible by data space participants while being completely separated from participants' infrastructures.

Epics

Set up the environment, and provision an EKS cluster and EC2 instances

Task	Description	Skills required
Clone the repository.	To clone the repository to your workstation, run the following command: `git clone https://github.com/Think-iT-Labs/aws-patterns-edc` The workstation must have access to your AWS account.	DevOps engineer
Provision the Kubernetes cluster and set up namespaces.	To deploy a simplified default EKS cluster in your account, run the following `eksctl` command on the workstation where you cloned the repo: `eksctl create cluster` The command creates the VPC and private and public subnets that span three different Availability Zones. After the network layer is created, the command creates two `m5.large` EC2 instances within an Auto Scaling group. For more information and example output, see the eksctl guide.	DevOps engineer

Task	Description	Skills required

	After you provision the private cluster, add the new EKS cluster to your local Kubernetes configuration by running the following command:
	`aws eks update-kubeconfig --name <EKS CLUSTER NAME> --region <AWS REGION>`
	This pattern uses the `eu-west-1` AWS Region to run all commands. However, you can run the same commands in your preferred AWS Region.
	To confirm that your EKS nodes are running and are in the ready state, run the following command:
	`kubectl get nodes`	

Task	Description	Skills required

Set up the namespaces.	To create namespaces for the provider and the consumer, run the following commands:
	`kubectl create ns provider`
	`kubectl create ns consumer`
	In this pattern, it's important to use `provider` and `consumer` as the namespaces to fit the configurations in the next steps.
		DevOps engineer

Deploy the identity service

Task	Description	Skills required
Deploy DAPS by using AWS CloudFormation.	For ease of managing DAPS operations, the DAPS server is installed on EC2 instances. To install DAPS, use the [AWS CloudFormation template](). You will need the ACM certificate and DNS name from the *Prerequisites* section. The template deploys and configures the following: • Application Load Balancer • Auto Scaling group	DevOps engineer

Task	Description	Skills required
	• EC2 instances configured with user data to install all necessary packages • IAM roles • DAPS You can deploy the AWS CloudFormation template by signing in to the AWS Management Console and using the [AWS CloudFormation console](). You can also deploy the template by using an AWS CLI command such as the following: `aws cloudformation create-stack --stack-name daps \ --template-body file://aws-patterns-edc/cloudformation.yml --parameters \ ParameterKey=CertificateARN,ParameterValue=<ACM Certificate ARN> \ ParameterKey=DNSName,ParameterValue=<DNS name> \ ParameterKey=InstanceType,ParameterValue=<EC2 instance type> \ ParameterKey=EnvironmentName,ParameterValue=<Environment Name> --capabil`	

Task	Description	Skills required
	`ities CAPABILIT Y_NAMED_IAM` The environment name is your own choice. We recommend using a meaningful term, such as `DapsInfrastructure` , because it will be reflected in the AWS resource tags. For this pattern, `t3.small` is large enough to run the DAPS workflow, which has three Docker containers. The template deploys the EC2 instances in private subnets. This means that the instances are not directly accessibl e through SSH (Secure Shell) from the internet. The instances are provisioned with the necessary IAM role and AWS Systems Manager Agent to enable access to the running instances through [Session Manager](), a capability of AWS Systems Manager. We recommend using Session Manager for access. Alternati vely, you could provision a bastion host to allow SSH access from the internet. When using the bastion host	

Task	Description	Skills required

	approach, the EC2 instance might take a few more minutes to start running.
	
	After the AWS CloudFormation template is successfully deployed, point the DNS name to your Application Load Balancer DNS name. To confirm, run the following command:
	
	`dig <DNS NAME>`
	
	The output should be similar to the following:
	
	`; <<>> DiG 9.16.1-Ubuntu <<>> edc-pattern.think-it.io`
	`;; global options: +cmd`
	`;; Got answer:`
	`;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 42344`
	`;; flags: qr rd ra; QUERY: 1, ANSWER: 3, AUTHORITY: 0, ADDITIONAL: 1`
	
	`;; OPT PSEUDOSECTION:`
	`; EDNS: version: 0, flags:; udp: 65494`
	`;; QUESTION SECTION:`
	`;edc-pattern.think-it.io.           IN      A`
	
	`;; ANSWER SECTION:`

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Register the participants’ connectors to the DAPS service.</td><td>From within any of the EC2 instances provisioned for DAPS, register participants:

1. Run the available script on the EC2 instance by using the root user:
<code>cd /srv/mvds/omejdn-daps</code>
2. Register the provider:
<code>bash scripts/register_connector.sh <provider_name></code>
3. Register the consumer:
<code>bash scripts/register_connector.sh <consumer_name></code>

The choice of the names doesn't impact the next steps. We recommend using either <code>provider</code> and <code>consumer</code> or <code>companyx</code> and <code>companyy</code>.

The registration commands will also automatically configure the DAPS service with the needed informati on fetched from the created certificates and keys.</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	While you are logged in to a DAPS server, gather information needed for later steps in the installation: 1. From `omejdn-daps/config/clients.yml` get the `client id` for the provider and the consumer. The `client id` values are long strings of hexadecimal digits. 2. From the `omejdn-daps/keys` directory, copy the contents of the `consumer.cert` , `consumer.key` , `provider.cert` , and `provider.key` files. We recommend copying and pasting the text into similarly named files prefixed with `daps-` on your workstation. You should have the client IDs for the provider and consumer and should have four files in your working directory on your workstation: • Source file name `consumer.cert` becomes workstation file name `daps-consumer.cert` .	

Task	Description	Skills required
	• Source file name `consumer.key` becomes workstation file name `daps-consumer.key` . • Source file name `provider.cert` becomes workstation file name `daps-provider.cert` . • Source file name `provider.key` becomes workstation file name `daps-provider.key` .	

Deploy the participants' connectors

Task	Description	Skills required
Clone the Tractus-X EDC repository and use the 0.4.1 version.	The Tractus-X EDC connector 's build requires PostgreSQ L (assets database) and HashiCorp Vault (secrets management) services to be deployed and available. There are many different versions of Tractus-X EDC Helm charts. This pattern specifies version 0.4.1 because it uses the DAPS server. The latest versions use Managed Identity Wallet (MIW) with a distributed	DevOps engineer

Task	Description	Skills required

	implementation of the identity service.
	
	On the workstation where you created the two Kubernetes namespaces, clone the [tractusx-edc repository](), and check out the `release/0.4.1` branch.
	
	`git clone https://github.com/eclipse-tractusx/tractusx-edc`
	
	`cd tractusx-edc`
	
	`git checkout release/0.4.1`	

Task	Description	Skills required

Configure the Tractus-X EDC Helm chart.	Modify the Tractus-X Helm chart template configuration to enable both connectors to interact together.
	
	To do this, you would add the namespace to the DNS name of the service so that it could be resolved by other services in the cluster. These modifications should be made to the `charts/tractusx-connector/templates/_helpers.tpl` file. This pattern provides a [final modified version of this file](#) for you to use. Copy it and put it in the daps section of the file `charts/tractusx-connector/templates/_helpers.tpl` .
	
	Make sure to comment all DAPS dependencies in `charts/tractusx-connector/Chart.yaml` :
	
	`dependencies:`
	`  # IDS Dynamic Attribute Provisioning Service (IAM)`
	`  #  - name: daps`
	`  # version: 0.0.1`
	`  # repository: "file://./subcharts/omejdn"`
	`  # alias: daps`
		DevOps engineer

Task	Description	Skills required
	``` # condition: install.daps```	

Task	Description	Skills required

Configure the connectors to use PostgreSQL on Amazon RDS.	(Optional) Amazon Relational Database Service (Amazon RDS) instance is not required in this pattern. However, we highly recommend using Amazon RDS or Amazon Aurora because they provide features such as high availability and backup and recovery.
	
	To replace PostgreSQL on Kubernetes with Amazon RDS, do the following:
	
	1. Provision the [Amazon RDS for PostgreSQL instance](#).
	2. In `Chart.yaml`, comment the `PostgreSQL` section.
	3. In `provider_values.yml` and `consumer_values.yml`, configure the `postgresql` section as follows:
	
	`postgresql:`
	`  auth:`
	`    database: edc`
	`    password: <RDS PASSWORD>`
	`    username: <RDS Username>`
		DevOps engineer

Task	Description	Skills required

	``
	  jdbcUrl: jdbc:post
	gresql://<RDS DNS
	 NAME>:5432/edc
	  username: <RDS
	 Username>
	  password: <RDS
	 PASSWORD>
	  primary:
	    persistence:
	      enabled: false
	  readReplicas:
	    persistence:
	      enabled: false
	``	

Task	Description	Skills required
Configure and deploy the provider connector and its services.	To configure the provider connector and its services, do the following: 1. To download the `provider_edc.yaml` file from the `edc_helm_configs` directory to the current Helm chart folder, run the following command: `wget -q https://raw.githubusercontent.com/Think-iT-Labs/aws-patterns-edc/main/edc_helm_configs/provider_edc.yaml> -P charts/tractusx-connector/` 2. Replace the following variables (also marked in the file) with their values: • `CLIENT_ID` – The ID generated by the DAPS. The `CLIENT_ID` should be in `/srv/mvds/omejdn-daps/config/clients.yml/config/clients.yml` on the DAPS server. It should a string of hexadecimal characters.	DevOps engineer

Task	Description	Skills required

	`DAPS_URL` – The URL of the DAPS server. It should be `https://{DNS name}` using the DNS name that you set up when you ran the AWS CloudFormation template. `VAULT_TOKEN` – The token to be used for Vault authorization. Choose any value. `vault.fullnameOverride` – `vault-provider`. `vault.hashicorp.url` – `http://vault-provider:8200/`. The previous values assume that the deployment name and the namespace name are provider.
	3. To run the Helm chart from your workstation, use the following commands:
	`cd charts/tractusx-connector`
	
	`helm dependency build`	

Task	Description	Skills required
	```helm upgrade --install provider ./ -f provider_edc.yaml -n provider```	

Task	Description	Skills required

Add the certificate and keys to the provider vault.	To avoid confusion, produce the following certificates outside of the `tractusx-edc/charts` directory.
	
	For example, run the following command to change to your home directory:
	
	`cd ~`
	
	You now need to add the secrets that are needed by the provider into the vault.
	
	The names of the secrets within the vault are the values of the keys in the `secretNames:` section of the `provider_edc.yml` file. By default, they are configured as follows:
	
	`secretNames:`
	`transferProxyTokenSignerPrivateKey: transfer-proxy-token-signer-private-key`
	`transferProxyTokenSignerPublicKey: transfer-proxy-token-signer-public-key`
	`transferProxyTokenEncryptio`
		DevOps engineer

Task	Description	Skills required

	`nAesKey: transfer-proxy-token-encryption-aes-key`
	`dapsPrivateKey: daps-private-key`
	`dapsPublicKey: daps-public-key`
	
	An Advanced Encryption Standard (AES) key, private key, public key, and self-signed certificate are generated initially. These are subsequently added as secrets to the vault.
	
	Furthermore, this directory should contain the `daps-provider.cert` and `daps-provider.key` files that you copied from the DAPS server.
	
	1. Run the following commands:
	
	`# generate a private key`
	`openssl ecparam -name prime256v1 -genkey -noout -out provider-private-key.pem`
	`# generate corresponding public key`
	`openssl ec -in provider-private-key.pem -pubout -out`	

Task	Description	Skills required
	``` provider-public-ke y.pem # create a self-sign ed certificate openssl req -new - x509 -key provider- private-key.pem -out provider-cert.pem - days 360 # generate aes key openssl rand -base64 32 > provider- aes.key ``` 2. Before adding the secrets to the vault, convert them from multiple lines to single lines by replacing line breaks with \n: ``` cat provider-private- key.pem | sed 's/$/\ \\\n/'\|tr -d '\\n' > provider-private-k ey.pem.line cat provider-public- key.pem \| sed 's/$/\ \\\n/'|tr -d '\\n' > provider-public-ke y.pem.line cat provider-cert.pem | sed 's/$/\\\\ n/'\|tr -d '\\n' > provider-cert.pem. line cat provider-aes.key \| sed 's/$/\\\\ n/'|tr -d '\\n' > provider-aes.key.l ine ```	

Task	Description	Skills required

	<pre>## The following block is for daps certificate and key
	openssl x509 -in daps-provider.cert -outform PEM | sed 's/$/\\\\n/'|tr -d '\\n' > daps-provider.cert.line
	cat daps-provider.key | sed 's/$/\\\\n/'| tr -d '\\n' > daps-provider.key.line</pre> 3. To format the secrets that will be added to Vault, run the following commands: <pre>JSONFORMAT='{"content": "%s"}'
	#create a single line in JSON format
	printf "${JSONFORMAT}\\n" "`cat provider-private-key.pem.line`" > provider-private-key.json
	printf "${JSONFORMAT}\\n" "`cat provider-public-key.pem.line`" > provider-public-key.json
	printf "${JSONFORMAT}\\n" "`cat provider-cert.pem.line`" > provider-cert.json
	printf "${JSONFORMAT}\\n" "`cat</pre>	

Task	Description	Skills required
	``` provider-aes.key.l ine`" > provider- aes.json  printf "${JSONFO RMAT}\\n" "`cat daps- provider.key.line`"  > daps-provider.key. json printf "${JSONFO RMAT}\\n" "`cat daps- provider.cert.line`" > daps-provider.cert .json ``` The secrets are now in JSON format and are ready to be added to the vault. 4. To get the pod name for the vault, run the following command: ``` kubectl get pods - n provider|egrep "vault|NAME" ``` The pod name will be similar to `"vault-provider-0"`. This name is used when creating a port forward to the vault. The port forward gives you to access the vault to add the secret. You should run this from a workstation that has AWS credentials configured.	

Task	Description	Skills required
	5. To access the vault, use `kubectl` to configure a port forward: `kubectl port-forward <VAULT_POD_NAME> 8200:8200 -n provider` You should now be able to access the vault through your browser or the CLI. **Browser** 1. Using the browser, navigate to http://127.0.0.1:8200, which will use the port forward that you configured. 2. Log in using the token you that configured previously in `provider_edc.yml` . In the secrets engine, create three secrets. Each secret will have a `Path for this secret` value, which is the secret name shown in the following list. Within the `secret data` section, the name of the key will be `content` and the value will be the single line of text from the respective file named `.line`.	

Task	Description	Skills required
	3. The secret names are sourced from the `secretNames` section in the `provider_edc.yml` file. 4. Create the following secrets: • Secret `transfer-proxy-token-signer-private-key` with file name `provider-private-key.pem.line` • Secret `transfer-proxy-token-signer-public-key` with file name `provider-cert.pem.line` • Secret `transfer-proxy-token-encryption-aes-key` with file name `provider-aes.key.line` • Secret `daps-private-key` with file name `daps-provider.key.line` • Secret `daps-public-key` with file name `daps-provider.cert.line`	

Task	Description	Skills required

	Vault CLI
	
	The CLI will also use the port forward that you configured.
	
	1. On your workstation, install Vault CLI by following the instructions in the [HashiCorp Vault documentation]().
	2. To log in to the vault by using the token that you set up in `provider_edc.yml`, run the following command:
	`vault login -address=http://127.0.0.1:8200`
	With the correct token, you should see the message `"Success! You are now authenticated."`
	3. To create the secrets by using the JSON formatted files that you created previously, run the following code:
	`vault kv put -address=http://127.0.0.1:8200 secret/transfer-proxy-token-signer-private-key @provider-private-key.json`	

Task	Description	Skills required
	```vault kv put -address=http://127.0.0.1:8200 secret/transfer-proxy-token-signer-public-key @provider-cert.json vault kv put -address=http://127.0.0.1:8200 secret/transfer-proxy-token-encryption-aes-key @provider-aes.json vault kv put -address=http://127.0.0.1:8200 secret/daps-private-key @daps-provider.key.json vault kv put -address=http://127.0.0.1:8200 secret/daps-public-key @daps-provider.cert.json```	

Task	Description	Skills required

Configure and deploy the consumer connector and its services.	The steps for configuring and deploying the consumer are similar to those you completed for the provider:
	
	1. To copy the `consumer_edc.yaml` from the [aws-patterns-edc](https://github.com/Think-iT-Labs/aws-patterns-edc) repo into the `tractusx-edc/charts/tractusx-connector` folder, run the following commands:
	
	`cd tractusx-edc`
	
	`wget -q https://raw.githubusercontent.com/Think-iT-Labs/aws-patterns-edc/main/edc_helm_configs/consumer_edc.yaml -P charts/tractusx-connector/`
	
	2. Update the following variables with their actual values:
	
	• `CONSUMER_CLIENT_ID` – The ID generated by DAPS. The `CONSUMER_CLIENT_ID` should be in `config/clients.yml` on the DAPS server.	

Task	Description	Skills required

	• `DAPS_URL` – The same DAPS URL that you used for the provider.
	• `VAULT_TOKEN` – The token to be used for Vault authorization. Choose any value.
	• `vault.fullnameOverride` – `vault-consumer`
	• `vault.hashicorp.url` – `http://vault-provider:8200/`
	
	The previous values assume that the deployment name and the namespace name are `consumer`.
	
	3. To run the Helm chart, use the following commands:
	
	`cd charts/tractusx-connector`
	
	`helm upgrade --install consumer ./ -f consumer_edc.yaml -n consumer`	

Task	Description	Skills required

Add the certificate and keys to the consumer vault.	From a security standpoint, we recommend regenerating the certificates and keys for each data space participant. This pattern regenerates certificates and keys for the consumer.
	
	The steps are very similar to those for the provider. You can verify the secret names in the `consumer_edc.yml` file.
	
	The names of the secrets within the vault are the values of the keys in the `secretNames:` section of the `consumer_edc.yml file`. By default, they are configured as follows:
	
	`secretNames:`
	`    transferProxyTokenSignerPrivateKey: transfer-proxy-token-signer-private-key`
	`    transferProxyTokenSignerPublicKey: transfer-proxy-token-signer-public-key`
	`    transferProxyTokenEncryptionAesKey: transfer-proxy-token-encryption-aes-key`
		DevOps engineer

	cKey: daps-public-key
	``
	
	The `daps-consumer.cert` and `daps-consumer.key` files that you copied from the DAPS server should already exist in this directory.
	
	1. Run the following commands:
	
	``
	# generate a private key
	openssl ecparam -name prime256v1 -genkey -noout -out consumer-private-key.pem
	# generate corresponding public key
	openssl ec -in consumer-private-key.pem -pubout -out consumer-public-key.pem
	# create a self-signed certificate
	openssl req -new -x509 -key consumer-private-key.pem -out consumer-cert.pem -days 360
	# generate aes key
	openssl rand -base64 32 > consumer-aes.key
	``	

Task	Description	Skills required

	2. Manually edit the files to replace line breaks with \n, or use three commands similar to the following:
	
	`cat consumer-private-key.pem | sed 's/$/\\\\n/'|tr -d '\\n' > consumer-private-key.pem.line`
	`cat consumer-public-key.pem | sed 's/$/\\\\n/'|tr -d '\\n' > consumer-public-key.pem.line`
	`cat consumer-cert.pem | sed 's/$/\\\\n/'|tr -d '\\n' > consumer-cert.pem.line`
	`cat consumer-aes.key | sed 's/$/\\\\n/'|tr -d '\\n' > consumer-aes.key.line`
	`cat daps-consumer.cert | sed 's/$/\\\\n/'|tr -d '\\n' > daps-consumer.cert.line`
	`cat daps-consumer.key | sed 's/$/\\\\n/'|tr -d '\\n' > daps-consumer.key.line`
	
	3. To format the secrets that will be added to Vault, run the following commands:	

Task	Description	Skills required
	```JSONFORMAT='{"content": "%s"}' #create a single line in JSON format printf "${JSONFORMAT}\\n" "`cat consumer-private-key.pem.line`" > consumer-private-key.json printf "${JSONFORMAT}\\n" "`cat consumer-public-key.pem.line`" > consumer-public-key.json printf "${JSONFORMAT}\\n" "`cat consumer-cert.pem.line`" > consumer-cert.json printf "${JSONFORMAT}\\n" "`cat consumer-aes.key.line`" > consumer-aes.json printf "${JSONFORMAT}\\n" "`cat daps-consumer.key.line`" > daps-consumer.key.json printf "${JSONFORMAT}\\n" "`cat daps-consumer.cert.line`" > daps-consumer.cert.json```	

Task	Description	Skills required

	The secrets are now in JSON format and are ready to be added to the vault.
	4. To get the pod name for the consumer vault, run the following command:
	`kubectl get pods -n consumer | egrep "vault|NAME"`
	The pod name will be similar to `"vault-consumer-0"` . This name is used when creating a port forward to the vault. The port forward gives you to access the vault to add the secret. You should run this from a workstation that has AWS credentials configured.
	5. To access the vault, use `kubectl` to configure a port forward:
	`kubectl port-forward <VAULT_POD_NAME> 8201:8200 -n consumer`
	The local port is 8201 this time so that you can have port forwards in place for	

Task	Description	Skills required
	both the producer and consumer. **Browser** You can use your browser to connect to http://localhost:8201/ to access the consumer vault and create the secrets with names and content as outlined. The secrets and files that contain the content are the following: • Secret `transfer-proxy-token-signer-private-key` with file name `consumer-private-key.pem.line` • Secret `transfer-proxy-token-signer-public-key` with file name `consumer-cert.pem.line` • Secret `transfer-proxy-token-encryption-aes-key` with file name `consumer-aes.key.line` **Vault CLI**	

Task	Description	Skills required

	Using Vault CLI, you can run the following commands to log in to the vault and create the secrets:
	
	1. Log in to the vault by using the token that you configured within `consumer_edc.yml` :
	
	`vault login -address=http://127.0.0.1:8201`
	
	With the correct token, you should see the message `"Success! You are now authenticated."`
	2. To create the secrets using the JSON formatted files that you created previously, run the following code:
	
	`vault kv put -address=http://127.0.0.1:8201 secret/transfer-proxy-token-signer-private-key @consumer-private-key.json`
	`vault kv put -address=http://127.0.0.1:8201 secret/transfer-proxy-token-signer-public-key @consumer-cert.json`
	`vault kv put -address=http://127.0.0.1:8201 secret/transfer-`	

Task	Description	Skills required
	```proxy-token-encryption-aes-key @consumer-aes.json vault kv put -address=http://127.0.0.1:8201 secret/daps-private-key @daps-consumer.key.json vault kv put -address=http://127.0.0.1:8201 secret/daps-public-key @daps-consumer.cert.json```	

Set up an HTTP client to interact with the management API of the connectors

Task	Description	Skills required
Set up port forwarding.	1. To check the status of the pods, run the following commands: ```kubectl get pods -n provider kubectl get pods -n consumer``` 2. To make sure that the Kubernetes deployments were successful, look at the logs of the provider and consumer Kubernetes pods by running the following commands:	DevOps engineer

Task	Description	Skills required

	`kubectl logs -n provider <producer control plane pod name>`
	`kubectl logs -n consumer <consumer control plane pod name>`
	
	The cluster is private and is not accessible publicly. To interact with the connector s, use the Kubernetes port-forwarding feature to forward traffic generated by your machine to the connector control plane.
	
	1. On the first terminal, forward the consumer' s requests to the management API through port 8300:
	`kubectl port-forward deployment/consumer-tractusx-connector-controlplane 8300:8081 -n consumer`
	2. On the second terminal, forward the provider' s requests to the management API through port 8400:	

Task	Description	Skills required
	```kubectl port-forward deployment/provider-tractusx-connector-controlplane 8400:8081 -n provider```	

Task	Description	Skills required

Create S3 buckets for the provider and the consumer.	The EDC connector currently doesn't use temporary AWS credentials, such as those provided by assuming a role. The EDC supports only the use of an [IAM access key ID and secret access key combination]().
	
	 Two S3 buckets are required for later steps. One S3 bucket is used for storing data made available by the provider. The other S3 bucket is for data received by the consumer.
	
	 The IAM user should have permission to read and write objects only in the two named buckets.
	
	 An access key ID and secret access key pair needs to be created and kept safe. After this MVDS has been decommissioned, the IAM user should be deleted.
	
	 The following code is an example IAM policy for the user:
	
	 `{`
	 `  "Version": "2012-10-17",`
	 `  "Statement": [`
	 `    {`
		DevOps engineer

Task	Description	Skills required

```
      "Sid": "Stmt1708
699805237",

        "arn:aws:
s3:::<S3 Provider
 Bucket>/*",
        "arn:aws:
s3:::<S3 Consumer
 Bucket>/*"
        ]    }
  ]
}
```

Task	Description	Skills required
Set up Postman to interact with the connector.	You can now interact with the connectors through your EC2 instance. Use Postman as an HTTP client, and provide Postman Collections for both the provider and the consumer connectors. Import the collections from the `aws-pattern-edc` repository into your Postman instance. This pattern uses Postman collection variables to provide input to your requests.	App developer, Data engineer

Provide company X carbon-emissions footprint data through the connector

Task	Description	Skills required
Prepare the carbon-emissions intensity data to be shared.	First you need to decide on the data asset to be shared. The data of company X represents the carbon-em issions footprint of its vehicle fleet. Weight is Gross Vehicle Weight (GVW) in tonnes, and emissions are in grams of CO2 per tonne-kilometer (g CO2 e/t-km) according to the Wheel-to-Well (WTW) measurement:	Data engineer, App developer

Task	Description	Skills required
	- Vehicle type: Van; weight: < 3.5; emissions: 800 - Vehicle type: Urban truck; weight: 3.5–7.5; emissions: 315 - Vehicle type: Medium goods vehicle (MGV); weight: 7.5–20; emissions: 195 - Vehicle type: Heavy goods vehicle (HGV); weight: > 20; emissions: 115 The example data is in the `carbon_emissions_data.json` file in the `aws-patterns-edc` repository. Company X uses Amazon S3 to store objects. Create the S3 bucket and store the example data object there. The following commands create an S3 bucket with default security settings. We highly recommend consulting [Security best practices for Amazon S3](). `aws s3api create-bucket <BUCKET_NAME> --region <AWS_REGION>`	

Task	Description	Skills required
	``` # You need to add '--create-bucket-configuration # LocationConstraint=<AWS_REGION>' if you want to create # the bucket outside of us-east-1 region aws s3api put-object --bucket <BUCKET_NAME> \ --key <S3 OBJECT NAME> \ --body <PATH OF THE FILE TO UPLOAD> ``` The S3 bucket name should be globally unique. For more information about naming rules, see the AWS documentation.	

Task	Description	Skills required

Register the data asset to the provider's connector by using Postman.	An EDC connector data asset holds the name of the data and its location. In this case, the EDC connector data asset will point to the created object in the S3 bucket:
	
	• **Connector:** Provider
	• **Request:** Create Asset
	• **Collection Variables:** Update `ASSET_NAME` . Choose a meaningful name that represents the asset.
	• **Request Body:** Update the request body with the S3 bucket that you created for the provider.
	
	`"dataAddress": {`
	`    "edc:type": "AmazonS3",`
	`    "name": "Vehicle Carbon Footprint",`
	`    "bucketName": "<REPLACE WITH THE SOURCE BUCKET NAME>",`
	`    "keyName": "<REPLACE WITH YOUR OBJECT NAME>",`
	`    "region": "<REPLACE WITH THE BUCKET REGION>",`
	`    "accessKeyId": "<REPLACE WITH YOUR ACCESS KEY ID>",`
	`    "secretAccessKey": "<REPLACE`
		App developer, Data engineer

Task	Description	Skills required

	``
	 WITH SECRET ACCESS
	 KEY>"
	}
	``
	- **Response:** A successful request returns the created time and the asset ID of the newly created asset.
	``
	{
	 "@id": "c89aa31c-ec4c-44ed-9e8c-1647f19d7583"
	}
	``
	- **Collection variable ASSET_ID:** Update the Postman collection variable `ASSET_ID` with the ID that was generated automatically by the EDC connector after creation.	

Task	Description	Skills required

Define the usage policy of the asset.	An EDC data asset must be associated with clear usage policies. First, create the Policy Definition in the provider connector.
	
	The policy of company X is to allow participants of the data space to use the carbon-emissions footprint data.
	
	• **Request Body:**
	  ◦ **Connector:** Provider
	  ◦ **Request:** Create Policy
	  ◦ **Collection Variables:** Update the `Policy Name` variable with the name of the policy.
	• **Response:** A successful request returns the created time and the policy ID of the newly created policy. Update the collection variable `POLICY_ID` with the ID of the policy generated by the EDC connector after creation.
		App developer, Data engineer

Task	Description	Skills required
Define an EDC Contract Offer for the asset and its usage policy.	To allow other participants to request access to your data, offer it in a contract that specifies the usage conditions and permissions: • **Connector:** Provider • **Request:** Create Contract Definition • **Collection Variables:** Update the `Contract Name` variable with a name for the contract offer or definition.	App developer, Data engineer

Discover the assets and reach agreement on the defined contracts

Task	Description	Skills required
Request the data catalog shared by company X.	As a data consumer in the data space, company Y first needs to discover the data that is being shared by other participants. In this basic setup, you can do this by asking the consumer connector to request the catalog of available assets from the provider connector directly. • **Connector:** Consumer • **Request:** Request Catalog	App developer, Data engineer

Task	Description	Skills required

	• **Response:** All available data assets from the provider together with their attached usage policies. As a data consumer, look for the contract of your interest and update the following collection variables accordingly.
	  • `CONTRACT_OFFER_ID` – The ID of the contract offer the consumer wants to negotiate
	  • `ASSET_ID` – The ID of the asset the consumer wants to negotiate
	  • `PROVIDER_CLIENT_ID` – The ID of the provider connector to negotiate with	

Task	Description	Skills required
Initiate a contract negotiation for the carbon-emissions intensity data from company X.	Now that you have identified the asset that you want to consume, initiate a contract negotiation process between the consumer and provider connectors. • **Connector:** Consumer • **Request:** Contract Negotiation • **Collection Variables:** Update the `CONSUMER_CLIENT_ID` variable with the ID of the consumer connector to negotiate with. The process might take some time before reaching the VERIFIED state. You can check the state of the Contract Negotiation and the corresponding Agreement ID by using the `Get Negotiation` request.	App developer, Data engineer

Consume the data by using the contract agreement

Task	Description	Skills required
Consume data from HTTP endpoints.	(Option 1) To use HTTP data plane to consume data in the data space, you can use	App developer, Data engineer

Task	Description	Skills required
	webhook.site to emulate an HTTP server, and initiate the transfer process in the consumer connector: • **Connector:** Consumer • **Request:** Contract Negotiation • **Collection Variables:** Update the `Contract Agreement ID` variable with the ID of the contract agreement generated by the EDC connector. • **Request Body:** Update the request body to specify HTTP as a `dataDestination` alongside the webhook URL: `{ "dataDestination": { "type": "HttpProxy" }, "privateProperties": { "receiverHttpEndpoint": "<WEBHOOK URL>" } }` The connector will send the information necessary to	

Task	Description	Skills required
	download the file directly to the webhook URL. The received payload is similar to the following: `{ "id": "dcc90391-3819-4b54-b401-1a005a029b78", "endpoint": "http://consumer-tractusx-connector-dataplane.consumer:8081/api/public", "authKey": "Authorization", "authCode": "<AUTH CODE YOU RECEIVE IN THE ENDPOINT>", "properties": { "https://w3id.org/edc/v0.0.1/ns/cid": "vehicle-carbon-footprint-contract:4563abf7-5dc7-4c28-bc3d-97f45e32edac:b073669b-db20-4c83-82df-46b583c4c062" } }` Use the received credentials to get the S3 asset that was shared by the provider.	
	In this last step, you must send the request to the	

Task	Description	Skills required
	consumer data plane (forward ports properly), as stated in the payload (`endpoint`).	

Task	Description	Skills required
Consume data from S3 buckets directly.	(Option 2) Use Amazon S3 integration with the EDC connector, and directly point to the S3 bucket in the consumer infrastructure as a destination: • **Request Body:** Update the request body to specify the S3 bucket as a dataDesti nation. This should be the S3 bucket that you previousl y created for storing data received by the consumer. `{ "dataDestination": { "type": "AmazonS3", "bucketName": "{{ REPLACE WITH THE DESTINATION BUCKET NAME }}", "keyName": "{{ REPLACE WITH YOUR OBJECT NAME }}", "region": "{{ REPLACE WITH THE BUCKET REGION }}", "accessKeyId": "{{ REPLACE WITH YOUR ACCESS KEY ID }}", "secretAccessKey": "{{ REPLACE WITH SECRET ACCESS KEY }}"`	Data engineer, App developer

Task	Description	Skills required

	``
	    }
	  }
	}
	``	

Troubleshooting

Issue	Solution
The connector might raise an issue about the certificate PEM format.	Concatenate the contents of each file to a single line by adding \n.

Additional information

Data space specifications

Participants

Participant	Description of the company	Focus of the company
Company X	Operates a fleet of vehicles across Europe and South America to transport various goods.	Aims to make data-driv en decisions to reduce its carbon-emissions footprint intensity.

Company Y	An environmental regulatory authority	Enforces environmental regulations and policies designed to monitor and mitigate the environmental impact of businesses and industries, including carbon-emissions intensity.

Business case

Company X uses data space technology to share carbon footprint data with a compliance auditor, company Y, to evaluate and address the environmental impact of company X's logistics operations.

Data space authority

The data space authority is a consortium of the organizations governing the data space. In this pattern, both company X and company Y form the governance body and represent a federated data space authority.

Data space components

Component	Chosen implementation	Additional information
Dataset exchange protocol	Dataspace Protocol version 0.8	• JSON-LD • Data Catalog Vocabulary (DCAT)
Data space connector	Tractus-X EDC Connector version 0.4.1	• EDC extensions
Data exchange policies	Default USE Policy	• Open Digital Rights Language (ODRL)

Data space services

Service	Implementation	Additional information

Identity service	[Dynamic Attribute Provisioning System (DAPS)]()	"A Dynamic Attribute Provisioning System (DAPS) has the intent to ascertain certain attributes to organizations and connectors. Hence, third parties do not need to trust the latter **provided they trust the DAPS assertions**." — DAPS To focus on the connector's logic, the data space is deployed on an Amazon EC2 machine using Docker Compose.
Discovery service	[Gaia-X Federated Catalogue]()	"The Federated Catalogue constitutes an indexed repository of Gaia-X Self-Descriptions to enable the discovery and selection of Providers and their service offerings. The Self-Descriptions are the information given by Participants about themselves and about their services in the form of properties and claims." — Gaia-X Ecosystem Kickstarter

Data to be exchanged

Data assets	Description	Format
Carbon emissions data	Intensity values for different vehicle types in the specified	JSON file

	region (Europe and South America) from the entire fleet of vehicles

Data model

```
{
  "region": "string",

	• **observability** – Port: 8085 Path: `/observability`
Data plane	**default** – Port: 8080 Path: `/api` **public** – Port: 8081 Path: `/api/dataplane/control` **proxy** – Port: 8186 Path: `/proxy` **metrics** – Port: 9090 Path: `/metrics` **observability** – Port: 8085 Path: `/observability`
Vault	Port: 8200
PostgreSQL	Port: 5432

Using AWS Secrets Manager Manager

It's possible to use Secrets Manager instead of HashiCorp Vault as the secrets manager. To do so you, must use or build the AWS Secrets Manager EDC extension.

You will be responsible for creating and maintaining your own image, because Tractus-X doesn't provide support for Secrets Manager.

To accomplish that, you need to modify the build Gradle files of both the control plane and the data plane of the connector by introducing your AWS Secrets Manager EDC extension (see this maven artifact for an example), then build, maintain, and reference the Docker image.

For more insights on refactoring the Tractus-X connector Docker image, see Refactor Tractus-X EDC Helm charts.

For simplicity purposes, we avoid to rebuilding the connector image in this pattern and use HashiCorp Vault.

Set up language-specific sorting for Amazon Redshift query results using a scalar Python UDF

Ethan Stark, Amazon Web Services

Summary

This pattern provides steps and sample code for using a scalar Python UDF (user-defined function) to set up case insensitive linguistic sorting for Amazon Redshift query results. It's necessary to use a scalar Python UDF because Amazon Redshift returns results based on binary UTF-8 ordering and doesn't support language-specific sorting. A Python UDF is non-SQL processing code that's based on a Python 2.7 program and runs in a data warehouse. You can run Python UDF code with a SQL statement in a single query. For more information, see the Introduction to Python UDFs in Amazon Redshift AWS Big Data Blog post.

The sample data in this pattern is based on the Turkish alphabet for demonstration purposes. The scalar Python UDF in this pattern is built to make the default query results of Amazon Redshift conform to the linguistic ordering of characters in the Turkish language. For more information, see *Turkish language example* in the *Additional information* section of this pattern. You can modify the scalar Python UDF in this pattern for other languages.

Prerequisites and limitations

Prerequisites

- Amazon Redshift cluster with a database, schema, and tables
- Amazon Redshift user with CREATE TABLE and CREATE FUNCTION permissions
- Python 2.7 or later

Limitations

The linguistic sorting used by the queries in this pattern is case insensitive.

Architecture

Technology stack

- Amazon Redshift

- Python UDF

Tools

AWS services

- Amazon Redshift is a managed petabyte-scale data warehouse service in the AWS Cloud. Amazon Redshift is integrated with your data lake, which enables you to use your data to acquire new insights for your business and customers.

Other tools

- Python (UDFs) user-defined functions are functions that you can write in Python and then call in SQL statements.

Epics

Develop code to sort query results in linguistic order

Task	Description	Skills required

Create a table for your sample data.	To create a table in Amazon Redshift and insert your sample data into the table, use the following SQL statements:
	``
	CREATE TABLE my_table
	 (first_name varchar(30));
	
	INSERT INTO my_table
	 (first_name)
	VALUES
	    ('ali'),
	    ('Ali'),
	    ('ırmak'),
	    ('IRMAK'),
	    ('irem'),
	``
		Data engineer

Task	Description	Skills required

	``
	    ('İREM'),
	    ('oğuz'),
	    ('OĞUZ'),
	    ('ömer'),
	    ('ÖMER'),
	    ('sedat'),
	    ('SEDAT'),
	    ('şule'),
	``
	
	Note
	
	The first names in the sample data include special character s from the Turkish alphabet. For more information about Turkish language considerations for this example, see *Turkish language example* in the *Additional information* section of this pattern.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Check the default sorting of the sample data.</td><td>To see the default sorting of your sample data in Amazon Redshift, run the following query:
<pre>SELECT first_name
 FROM my_table ORDER BY
 first_name;</pre>The query returns the list of first names from the table that you created earlier:
<pre>first_name

Ali
IRMAK
OĞUZ
SEDAT
ali
irem
oğuz
sedat
ÖMER
ömer
İREM
ırmak
ŞULE
şule</pre>The query results aren’t in the correct order because the default binary UTF-8 ordering doesn’t accommodate the linguistic ordering of the Turkish special characters.</td><td>Data engineer</td></tr>
</table>

Task	Description	Skills required

Create a scalar Python UDF.	To create a scalar Python UDF, use the following SQL code:
	<pre>CREATE OR REPLACE
	 FUNCTION collate_sort
	 (value varchar)
	RETURNS varchar
	IMMUTABLE
	AS
	$$
	    def sort_str(val):
	        import string
	
	        dictionary = {
	            'I': 'ı',
	            'ı': 'h~',
	            'İ': 'i',
	            'Ş': 's~',
	            'ş': 's~',
	            'Ğ': 'g~',
	            'ğ': 'g~',
	            'Ü': 'u~',
	            'ü': 'u~',
	            'Ö': 'o~',
	            'ö': 'o~',
	            'Ç': 'c~',
	            'ç': 'c~'
	        }
	
	        for key, value
	 in dictionary.items()
	:
	            val =
	 val.replace(key,
	 value)
	
	        return val.lower
	()
	
	    return sort_str(
	value)</pre>
		Data engineer

Task	Description	Skills required
	``` $$ LANGUAGE plpythonu; ```	

Query the sample data.	To query the sample data by using the Python UDF, run the following SQL query:
	`SELECT first_name FROM my_table ORDER BY collate_order(first_name);`
	The query now returns the sample data in Turkish linguistic order:
	`first_name`
	`---------------`
	`ali`
	`Ali`
	`ırmak`
	`IRMAK`
	`irem`
	`İREM`
	`oğuz`
	`OĞUZ`
	`ömer`
	`Ömer`
	`sedat`
	`SEDAT`
	`şule`
	`ŞULE`
		Data engineer

Related resources

- ORDER BY clause (Amazon Redshift documentation)
- Creating a scalar Python UDF (Amazon Redshift documentation)

Additional information

Turkish language example

Amazon Redshift returns query results based on binary UTF-8 sort ordering, not language-specific sort ordering. This means that if you query an Amazon Redshift table containing Turkish characters, then the query results aren't sorted according to the linguistic ordering of the Turkish language. The Turkish language contains six special characters (ç, ı, ğ, ö, ş, and ü) that don't appear in the Latin alphabet. These special characters are placed at the end of a sorted result set based on binary UTF-8 ordering, as the following table shows.

Binary UTF-8 ordering	Turkish linguistic ordering
a	a
b	b
c	c
d	**ç (*)**
e	d
f	e
g	f
h	g
i	**ğ (*)**
j	h
k	**ı (*)**
l	i
m	j
n	k
o	l

p	m
r	n
s	o
t	**ö (*)**
u	p
v	r
y	s
z	**ş (*)**
ç (*)	t
ğ (*)	u
ı (*)	**ü (*)**
ö (*)	v
ş (*)	y
ü (*)	z

Note

The asterisk (*) indicates a special character in the Turkish language.

As the table above illustrates, special character **ç** is between **c** and **d** in Turkish linguistic ordering, but appears after **z** in binary UTF-8 ordering. The scalar Python UDF in this pattern uses the following character replacement dictionary to replace the Turkish special characters with corresponding Latin-equivalent characters.

Turkish special character	Latin-equivalent character

ç	c~
ı	h~
ğ	g~
ö	o~
ş	s~
ü	u~

Note

A tilde (~) character is appended to the end of the Latin characters that replace their corresponding Turkish special characters.

Modify a scalar Python UDF function

To modify the scalar Python UDF function from this pattern so that the function accepts a locate parameter and supports a multiple transaction dictionary, use the following SQL code:

```
CREATE OR REPLACE FUNCTION collate_sort (value varchar, locale varchar)
RETURNS varchar
IMMUTABLE
AS
$$
    def sort_str(val):
       import string
       # Turkish Dictionary
       if locale == 'tr-TR':
            dictionary = {
               'I': 'ı',
               'ı': 'h~',
               'İ': 'i',
               'Ş': 's~',
               'ş': 's~',
               'Ğ': 'g~',
               'ğ': 'g~',
               'Ü': 'u~',
```

```
                'ü': 'u~',
                'Ö': 'o~',
                'ö': 'o~',
                'Ç': 'c~',
                'ç': 'c~'
        }
        # German Dictionary
        if locale == 'de-DE':
            dictionary = {
                ....
                ....
        }

        for key, value in dictionary.items():
            val = val.replace(key, value)

        return val.lower()

    return sort_str(value)

$$ LANGUAGE plpythonu;
```

The following example code shows how to query the modified Python UDF:

```
SELECT first_name FROM my_table ORDER BY collate_order(first_name, 'tr-TR');
```

Subscribe a Lambda function to event notifications from S3 buckets in different AWS Regions

Suresh Konathala, Amazon Web Services

Andrew Preston and Arindom Sarkar, None

Summary

Amazon Simple Storage Service (Amazon S3) Event Notifications publishes notifications for certain events in your S3 bucket (for example, object created events, object removal events, or restore object events). You can use an AWS Lambda function to process these notifications according to your application's requirements. However, the Lambda function can't directly subscribe to notifications from S3 buckets that are hosted in different AWS Regions.

This pattern's approach deploys a fanout scenario to process Amazon S3 notifications from cross-Region S3 buckets by using an Amazon Simple Notification Service (Amazon SNS) topic for each Region. These Regional SNS topics send the Amazon S3 event notifications to an Amazon Simple Queue Service (Amazon SQS) queue in a central Region that also contains your Lambda function. The Lambda function subscribes to this SQS queue and processes the event notifications according to your organization's requirements.

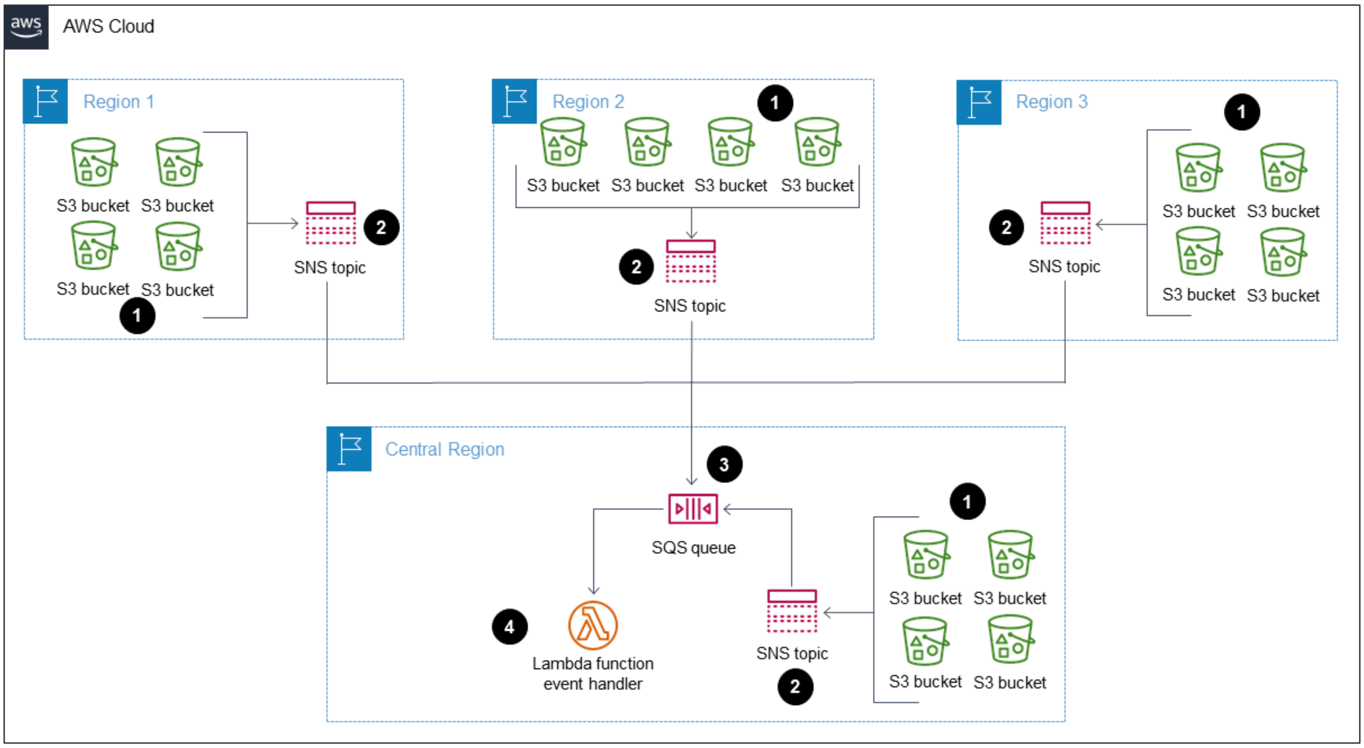
Prerequisites and limitations

Prerequisites

- An active AWS account.
- Existing S3 buckets in multiple Regions, including a central Region to host the Amazon SQS queue and Lambda function.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- Familiarity with the fanout scenario in Amazon SNS. For more information about this, see Common Amazon SNS scenarios in the Amazon SNS documentation.

Architecture

The following diagram shows the architecture for this pattern's approach.



The diagram shows the following workflow:

1. Amazon S3 sends event notifications about S3 buckets (for example, object created, object removed, or object restored) to an SNS topic in the same Region.
2. The SNS topic publishes the event to an SQS queue in the central Region.
3. The SQS queue is configured as the event source for your Lambda function and buffers the event messages for the Lambda function.
4. The Lambda function polls the SQS queue for messages and processes the Amazon S3 event notifications according to your application's requirements.

Technology stack

- Lambda
- Amazon SNS
- Amazon SQS
- Amazon S3

Tools

- AWS CLI – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.
- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.
- Amazon SQS – Amazon Simple Queue Service (Amazon SQS) offers a secure, durable, and available hosted queue that lets you integrate and decouple distributed software systems and components. Amazon SQS supports both standard and FIFO queues.

Epics

Create the SQS queue and Lambda function in your central Region

Task	Description	Skills required
Create an SQS queue with a Lambda trigger.	Sign in to the AWS Management Console and use the instructions from the tutorial Using Lambda with Amazon SQS in the AWS Lambda documentation to	AWS DevOps, Cloud architect

Task	Description	Skills required
	create the following resources in your central Region: • A Lambda execution role • A Lambda function to process the Amazon S3 events • An SQS queue **Note** Make sure that you configure the SQS queue as the event source for your Lambda function.	

Create an SNS topic and set up event notifications for the S3 buckets in each required Region

Task	Description	Skills required
Create an SNS topic to receive Amazon S3 event notificat ions.	Create an SNS topic in a Region that you want to receive Amazon S3 event notifications from. For more information about this, see [Creating an SNS topic]() in the Amazon SNS documentation. **Important** Make sure that you record your SNS topic's Amazon	AWS DevOps, Cloud architect

Task	Description	Skills required
	Resource Name (ARN).	
Subscribe the SNS topic to the central SQS queue.	Subscribe your SNS topic to the SQS queue hosted by your central Region. For more information about this, see Subscribing to an SNS topic in the Amazon SNS documentation.	AWS DevOps, Cloud architect

Task	Description	Skills required

Update the SNS topic's access policy.	1. Open the Amazon SNS console, choose **Topics**, and then choose the SNS topic that you created earlier.
	2. Choose **Edit** and then expand the **Access policy - optional** section.
	3. Attach the following access policy to your SNS topic to allow `sns:publish` permission for Amazon S3 and then choose **Save**:
	<pre>{
	  "Version": "2012-10-17",
	  "Statement": [
	    {
	      "Sid": "0",
	      "Effect": "Allow",
	      "Principal": {
	        "Service": "s3.amazonaws.com"
	      },
	      "Action": "sns:Publish",
	      "Resource": "arn:aws:sns:us-west-2::s3Events-SNSTopic-us-west-2"
	    }
	  ]
	}</pre>
		AWS DevOps, Cloud architect

Task	Description	Skills required
Set up notifications for each S3 bucket in the Region.	Set up event notifications for each S3 bucket in the Region. For more information about this, see Enabling and configuring event notifications using the Amazon S3 console in the Amazon S3 documentation. **Note** In the **Destination** section, choose **SNS topic** and specify the ARN of the SNS topic that you created earlier.	AWS DevOps, Cloud architect
Repeat this epic for all required Regions.	**Important** Repeat the tasks in this epic for each Region that you want to receive Amazon S3 event notifications from, including your central Region.	AWS DevOps, Cloud architect

Three AWS Glue ETL job types for converting data to Apache Parquet

Adnan Alvee, Nith Govindasivan, and Karthikeyan Ramachandran, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, AWS Glue is a fully managed extract, transform, and load (ETL) service. AWS Glue makes it cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.

This pattern provides different job types in AWS Glue and uses three different scripts to demonstrate authoring ETL jobs.

You can use AWS Glue to write ETL jobs in a Python shell environment. You can also create both batch and streaming ETL jobs by using Python (PySpark) or Scala in a managed Apache Spark environment. To get you started with authoring ETL jobs, this pattern focuses on batch ETL jobs using Python shell, PySpark, and Scala. Python shell jobs are meant for workloads requiring lesser compute power. The managed Apache Spark environment is meant for workloads requiring high compute power.

Apache Parquet is built to support efficient compression and encoding schemes. It can speed up your analytics workloads because it stores data in a columnar fashion. Converting data to Parquet can save you storage space, cost, and time in the longer run. To learn more about Parquet, see the blog post Apache Parquet: How to be a hero with the open-source columnar data format.

Prerequisites and limitations

Prerequisites

- AWS Identity and Access Management (IAM) role (If you don't have a role, see the Additional information section.)

Architecture

Target technology stack

- AWS Glue
- Amazon Simple Storage Service (Amazon S3)

- Apache Parquet

Automation and scale

- AWS Glue workflows support full automation of an ETL pipeline.
- You can change the number of data processing units (DPUs), or worker types, to scale horizontally and vertically.

Tools

AWS services

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Glue is a fully managed ETL service for categorizing, cleaning, enriching, and moving your data between various data stores and data streams.

Other tools

- Apache Parquet is an open-source column-oriented data file format designed for storage and retrieval.

Configuration

Use the following settings for configuring the compute power of AWS Glue ETL. To reduce costs, use the minimal settings when you run the workload that is provided in this pattern.

- **Python shell –** You can use 1 DPU to utilize 16 GB of memory or 0.0625 DPU to utilize 1 GB of memory. This pattern uses 0.0625 DPU, which is the default in the AWS Glue console.
- **Python or Scala for Spark –** If you choose the Spark-related job types in the console, AWS Glue by default uses 10 workers and the G.1X worker type. This pattern uses two workers, which is the minimum number allowed, with the standard worker type, which is sufficient and cost effective.

The following table displays the different AWS Glue worker types for the Apache Spark environment. Because a Python shell job does not use the Apache Spark environment to run Python, it is not included in the table.

	Standard	G.1X	G.2X
vCPU	4	4	8
Memory	16 GB	16 GB	32 GB
Disk space	50 GB	64 GB	128 GB
Executor per worker	2	1	1

Code

For the code that is used in this pattern, including the IAM role and parameter configuration, see the Additional information section.

Epics

Upload the data

Task	Description	Skills required
Upload the data into a new or existing S3 bucket.	Create or use an existing S3 bucket in your account. Upload the sample_data.csv file from the Attachments section, and note the S3 bucket and prefix location.	General AWS

Create and run the AWS Glue job

Task	Description	Skills required
Create the AWS Glue job.	Under the ETL section of the AWS Glue console, add an AWS Glue job. Select the appropriate job type, AWS Glue version, and the	Developer, cloud or data

Task	Description	Skills required
	corresponding DPU/Worker type and number of workers. For details, see the *Configura tion* section.	
Change the input and output locations.	Copy the code corresponding to your AWS Glue job, and change the input and output location that you noted in the **Upload the data** epic.	Developer, cloud or data

Task	Description	Skills required
Configure the parameters.	You can use the snippets provided in the [Additional information](#) section to set parameters for your ETL job. AWS Glue uses four argument names internally: • `--conf` • `--debug` • `--mode` • `--JOB_NAME` The `--JOB_NAME` parameter must be explicitly entered on the AWS Glue console. Choose **Jobs**, **Edit Job**, **Security configuration, script libraries, and job parameters (optional)**. Enter `--JOB_NAME` as the key and provide a value. You can also use the AWS Command Line Interface (AWS CLI) or the AWS Glue API to set this parameter. The `--JOB_NAME` parameter is used by Spark and is not needed in a Python shell environment job. You must add `--` before every parameter name; otherwise, the code will not work. For example, for the code snippets, the location	Developer, cloud or data

Task	Description	Skills required
	parameters must be invoked by `--input_loc` and `--output_loc` .	
Run the ETL job.	Run your job and check the output. Note how much space was reduced from the original file.	Developer, cloud or data

Additional information

IAM role

When you create the AWS Glue jobs, you can use either an existing IAM role that has the permissions shown in the following code snippet or a new role.

To create a new role, use the following YAML code.

```
# (c) 2022 Amazon Web Services, Inc. or its affiliates. All Rights Reserved. This AWS
 Content is provided subject to the terms of the AWS Customer
# Agreement available at https://aws.amazon.com/agreement/ or other written agreement
 between Customer and Amazon Web Services, Inc.

AWSTemplateFormatVersion: "2010-09-09"
```

```
Description: This template will setup IAM role for AWS Glue service.

Resources:
  rGlueRole:
    Type: AWS::IAM::Role
    Properties:
      AssumeRolePolicyDocument:
        Version: "2012-10-17"
        Statement:
          - Effect: "Allow"
            Principal:
              Service:
                - "glue.amazonaws.com"
            Action:
              - "sts:AssumeRole"
      ManagedPolicyArns:
        - arn:aws:iam::aws:policy/service-role/AWSGlueServiceRole
      Policies:
        - PolicyName: !Sub "${AWS::StackName}-s3-limited-read-write-inline-policy"
          PolicyDocument:
            Version: "2012-10-17"
            Statement:
              - Effect: Allow
                Action:
                  - "s3:PutObject"
                  - "s3:GetObject"
                Resource: "arn:aws:s3:::*/*"
      Tags:
        - Key  : "Name"
          Value : !Sub "${AWS::StackName}"

Outputs:
  oGlueRoleName:
    Description: AWS Glue IAM role
    Value:
      Ref: rGlueRole
    Export:
      Name: !Join [ ":", [ !Ref "AWS::StackName", rGlueRole ] ]
```

AWS Glue Python Shell

The Python code uses the Pandas and PyArrow libraries to convert data to Parquet. The Pandas library is already available. The PyArrow library is downloaded when you run the pattern, because it is a one-time run. You can use wheel files to convert PyArrow to a library and provide the file as a library package. For more information about packaging wheel files, see [Providing your own Python library](#).

AWS Glue Python shell parameters

```
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["input_loc", "output_loc"])
```

AWS Glue Python shell code

```
from io import BytesIO
import pandas as pd
import boto3
import os
import io
import site
from importlib import reload
from setuptools.command import easy_install
install_path = os.environ['GLUE_INSTALLATION']
easy_install.main( ["--install-dir", install_path, "pyarrow"] )
reload(site)
import pyarrow

input_loc = "s3://bucket-name/prefix/sample_data.csv"
output_loc = "s3://bucket-name/prefix/"

input_bucket = input_loc.split('/', 1)[0]
object_key = input_loc.split('/', 1)[1]

output_loc_bucket = output_loc.split('/', 1)[0]
output_loc_prefix = output_loc.split('/', 1)[1]

s3 = boto3.client('s3')
obj = s3.get_object(Bucket=input_bucket, Key=object_key)
```

```
df = pd.read_csv(io.BytesIO(obj['Body'].read()))

parquet_buffer = BytesIO()
s3_resource = boto3.resource('s3')
df.to_parquet(parquet_buffer, index=False)
s3_resource.Object(output_loc_bucket, output_loc_prefix +  'data' +
 '.parquet').put(Body=parquet_buffer.getvalue())
```

AWS Glue Spark job with Python

To use an AWS Glue Spark job type with Python, choose **Spark** as the job type. Choose **Spark 3.1, Python 3 with improved job startup time (Glue Version 3.0)** as the AWS Glue version.

AWS Glue Python parameters

```
from awsglue.utils import getResolvedOptions

args = getResolvedOptions(sys.argv, ["JOB_NAME", "input_loc", "output_loc"])
```

AWS Glue Spark job with Python code

```
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import *
from awsglue.dynamicframe import DynamicFrame
from awsglue.utils import getResolvedOptions
from awsglue.job import Job

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)

input_loc = "s3://bucket-name/prefix/sample_data.csv"
output_loc = "s3://bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(\
    connection_type = "s3", \
    connection_options = {
        "paths": [input_loc]}, \
```

```
    format = "csv",
    format_options={
        "withHeader": True,
        "separator": ","
    })

outputDF = glueContext.write_dynamic_frame.from_options(\
    frame = inputDyf, \
    connection_type = "s3", \
    connection_options = {"path": output_loc \
        }, format = "parquet")
```

For a large number of compressed big files (for example, 1,000 files that are each about 3 MB), use the `compressionType` parameter with the `recurse` parameter to read all the files that are available within the prefix, as shown in the following code.

```
input_loc = "bucket-name/prefix/"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
                    connection_type = "s3",
                    connection_options = {"paths": [input_loc],
                                            "compressionType":"gzip","recurse" :"True",
                                            },
                    format = "csv",
                    format_options={"withHeader": True,"separator": ","}
                    )
```

For a large number of compressed small files (for example, 1,000 files that are each about 133 KB), use the `groupFiles` parameter, along with both the `compressionType` and the `recurse` parameters. The `groupFiles` parameter groups small files into multiple big files, and the `groupSize` parameter controls the grouping to the specified size in bytes (for example, 1 MB). The following code snippet provides an example of using these parameters within the code.

```
input_loc = "bucket-name/prefix/"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
                    connection_type = "s3",
                    connection_options = {"paths": [input_loc],
                                            "compressionType":"gzip","recurse" :"True",
```

```
                                                "groupFiles" :"inPartition",
 "groupSize" :"1048576",
                                               },
                    format = "csv",
                    format_options={"withHeader": True,"separator": ","}
                    )
```

Without any change in the worker nodes, these settings enable the AWS Glue job to read multiple files (large or small, with or without compression) and write them to the target in Parquet format.

AWS Glue Spark job with Scala

To use an AWS Glue Spark job type with Scala, choose **Spark** as the job type and **Language** as **Scala**. Choose **Spark 3.1, Scala 2 with improved job startup time (Glue Version 3.0)** as the AWS Glue version. To save on storage space, the following AWS Glue with Scala sample also uses the `applyMapping` feature to convert data types.

AWS Glue Scala parameters

```
import com.amazonaws.services.glue.util.GlueArgParser val args =
 GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME", "inputLoc",
 "outputLoc").toArray)
```

AWS Glue Spark job with Scala code

```
import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.DynamicFrame
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.Job
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters._

object GlueScalaApp {
  def main(sysArgs: Array[String]) {

    @transient val spark: SparkContext = SparkContext.getOrCreate()
    val glueContext: GlueContext = new GlueContext(spark)
```

```
    val inputLoc = "s3://bucket-name/prefix/sample_data.csv"
    val outputLoc = "s3://bucket-name/prefix/"

    val readCSV = glueContext.getSource("csv", JsonOptions(Map("paths" ->
 Set(inputLoc)))).getDynamicFrame()

    val applyMapping = readCSV.applyMapping(mappings = Seq(("_c0", "string", "date",
 "string"), ("_c1", "string", "sales", "long"),
    ("_c2", "string", "profit", "double")), caseSensitive = false)

    val formatPartition = applyMapping.toDF().coalesce(1)

    val dynamicFrame = DynamicFrame(formatPartition, glueContext)

    val dataSink = glueContext.getSinkWithFormat(
        connectionType = "s3",
        options = JsonOptions(Map("path" -> outputLoc )),
        transformationContext = "dataSink", format =
 "parquet").writeDynamicFrame(dynamicFrame)
  }
}
```

Visualize Amazon Redshift audit logs using Amazon Athena and Amazon QuickSight

Sanket Sirsikar and Gopal Krishna Bhatia, Amazon Web Services

Summary

Security is an integral part of database operations on the Amazon Web Services (AWS) Cloud. Your organization should ensure that it monitors database user activities and connections to detect potential security incidents and risks. This pattern helps you monitor your databases for security and troubleshooting purposes, which is a process known as database auditing.

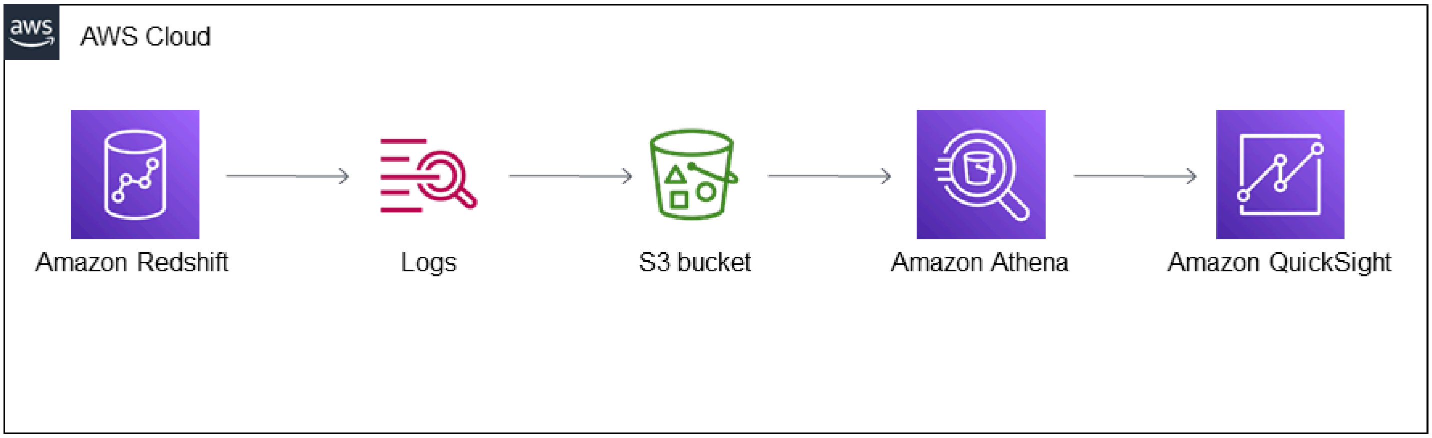
This pattern provides a SQL script that automates the creation of an Amazon Athena table and views for a reporting dashboard in Amazon QuickSight that helps you audit Amazon Redshift logs. This ensures that users responsible for monitoring database activities have convenient access to data security features.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon Redshift cluster. For more information about this, see Create an Amazon Redshift cluster in the Amazon Redshift documentation.
- Access to an existing Athena workgroup. For more information, see How workgroups work in the Amazon Athena documentation.
- An existing Amazon Simple Storage Service (Amazon S3) source bucket with the required AWS Identity and Access Management (IAM) permissions. For more information, see Bucket permissions for Amazon Redshift audit logging from Database audit logging in the Amazon Redshift documentation.

Architecture



Technology stack

- Athena
- Amazon Redshift
- Amazon S3
- QuickSight

Tools

- Amazon Athena – Athena is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- Amazon QuickSight – QuickSight is a scalable, serverless, embeddable, machine learning-powered business intelligence (BI) service.
- Amazon Redshift – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

Epics

Configure the Amazon Redshift cluster

Task	Description	Skills required
Enable audit logging for the Amazon Redshift cluster.	1. Sign in to the AWS Management Console, open the Amazon Redshift console, choose **CLUSTERS**, and then choose the cluster that you want to enable logging for. 2. Choose the **Properties** tab and then enable auditing by following the instructi ons from [Configuring auditing using the console](#) in the Amazon Redshift documentation.	DBA, Data engineer
Enable logging in the Amazon Redshift cluster parameter group.	You can enable auditing of connection logs, user logs, and user activity logs at the same time by using the AWS Management Console, the Amazon Redshift API reference, or AWS Command Line Interface (AWS CLI). For auditing of user activity logs, you must enable the `enable_user_activi ty_logging` database parameter. If you only enable the audit logging feature but not the associated parameter	DBA, Data engineer

Task	Description	Skills required
	, the database audit logs the logging information for the connection and user logs but not for the user activity logs. The `enable_user_activity_logging` parameter is not enabled by default, but you can enable it by changing it from `false` to `true`. **Important** You need to create a new cluster parameter group with the `user_activity_logging` parameter enabled and attach it to your Amazon Redshift cluster. For more information about this, see [Modifying a cluster](#) in the Amazon Redshift documentation. For more information about this task, see [Amazon Redshift parameter groups](#) and [Configuring auditing using the console](#) in the Amazon Redshift documentation.	

Task	Description	Skills required
Configure S3 bucket permissions for Amazon Redshift cluster logging.	When you enable logging, Amazon Redshift collects logging information and uploads it to log files stored in an S3 bucket. You can use an existing S3 bucket or create a new bucket. **Important** Make sure that Amazon Redshift has the required IAM permissions to access the S3 bucket. For more information about this, see [Bucket permissions for Amazon Redshift audit logging] from [Database audit logging] in the Amazon Redshift documentation.	DBA, Data engineer

Create the Athena table and views

Task	Description	Skills required
Create the Athena table and views to query Amazon Redshift audit log data from the S3 bucket.	Open the Amazon Athena console and use the data definition language (DDL) query from the `AuditLogging.sql` SQL script	Data engineer

Task	Description	Skills required
	(attached) to create the table and views for user activity logs, user logs, and connectio n logs. For more information and instructions, see the Create tables and run queries tutorial from the Amazon Athena Workshop.	

Set up log monitoring in the QuickSight dashboard

Task	Description	Skills required
Create a QuickSight dashboard using Athena as the data source.	Open the Amazon QuickSigh t console and create a QuickSight dashboard by following the instructions in the Visualize with QuickSigh t using Athena tutorial from the Amazon Athena Workshop.	DBA, Data engineer

Related resources

- Create tables and run queries in Athena
- Visualize with QuickSight using Athena

Visualize IAM credential reports for all AWS accounts using Amazon QuickSight

Parag Nagwekar and Arun Chandapillai, Amazon Web Services

Summary

Warning: IAM users have long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

You can use AWS Identity and Access Management (IAM) credential reports to help you meet the security, auditing, and compliance requirements of your organization. Credential reports provide a list of all the users in your AWS accounts and show the status of their credentials, such as passwords, access keys, and multi-factor authentication (MFA) devices. You can use credential reports for multiple AWS accounts managed by AWS Organizations.

This pattern includes steps and code to help you create and share IAM credential reports for all the AWS accounts in your organization by using Amazon QuickSight dashboards. You can share the dashboards with stakeholders in your organization. The reports can help your organization achieve the following targeted business outcomes:

- Identify security incidents related to IAM users
- Track real-time migration of IAM users to single sign-on (SSO) authentication
- Track AWS Regions accessed by IAM users
- Stay compliant
- Share information with other stakeholders

Prerequisites and limitations

Prerequisites

- An active AWS account
- An organization with member accounts

- An [IAM role] with permissions to access accounts in Organizations
- AWS Command Line Interface (AWS CLI) version 2, [installed] and [configured]
- A [subscription] to [Amazon QuickSight Enterprise edition]

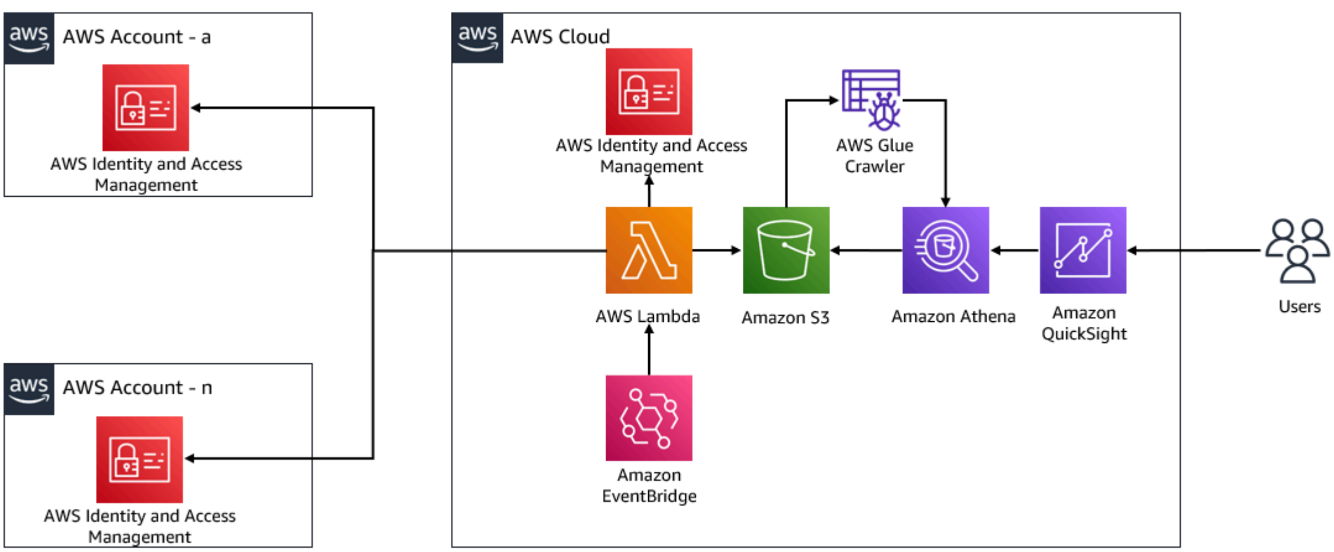
Architecture

Technology stack

- Amazon Athena
- Amazon EventBridge
- Amazon QuickSight
- Amazon Simple Storage Service (Amazon S3)
- AWS Glue
- AWS Identity and Access Management (IAM)
- AWS Lambda
- AWS Organizations

Target architecture

The following diagram shows an architecture for setting up a workflow that captures IAM credential report data from multiple AWS accounts.



1. EventBridge invokes a Lambda function daily.

2. The Lambda function assumes an IAM role in every AWS account across the organization. Then, the function creates the IAM credentials report and stores the report data in a centralized S3 bucket. You must enable encryption and deactivate public access on the S3 bucket.
3. An AWS Glue crawler crawls the S3 bucket daily and updates the Athena table accordingly.
4. QuickSight imports and analyzes the data from the credential report and builds a dashboard that can be visualized by and shared with stakeholders.

Tools

AWS services

- Amazon Athena is an interactive query service that makes it easy to analyze data in Amazon S3 by using standard SQL.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Code

The code for this pattern is available in the GitHub getiamcredsreport-allaccounts-org repository. You can use the code from this repository to create IAM credential reports across AWS accounts in Organizations and store them in a central location.

Epics

Set up the infrastructure

Task	Description	Skills required
Set up Amazon QuickSight Enterprise edition.	1. Activate the Amazon QuickSight Enterprise edition in your AWS account. For more information, see Managing user access inside Amazon QuickSight in the QuickSight documentation. 2. To grant dashboard permissions, get the Amazon Resource Name (ARN) of the QuickSight users.	AWS administrator, AWS DevOps, Cloud administrator, Cloud architect
Integrate Amazon QuickSight with Amazon S3 and Athena.	You must authorize QuickSight to use Amazon S3 and Athena before you deploy the AWS CloudFormation stack.	AWS administrator, AWS DevOps, Cloud administrator, Cloud architect

Deploy the infrastructure

Task	Description	Skills required
Clone the GitHub repository.	1. Clone the GitHub getiamcredsreport-allaccounts-org repository to your local machine by running the following command: `git clone https://github.com`	AWS administrator

Task	Description	Skills required
	`/aws-samples/getiamcredsreport-allaccounts-org`	

Task	Description	Skills required
Deploy the infrastructure.	1. Sign in to the AWS Management Console and open the [CloudFormation console](https://console.aws.amazon.com/cloudformation/). 2. In the navigation pane, choose **Create stack**, and then choose **With new resources (standard)**. 3. On the **Identify resources** page, choose **Next**. 4. On the **Specify template** page, for **Template source**, select **Upload a template file**. 5. Choose **Choose file**, select the `Cloudformation-createcredrepo.yaml` file from your cloned GitHub repository, and then choose **Next**. 6. In **Parameters**, update `IAMRoleName` with your IAM role. This should be the IAM role that you want Lambda to assume in every account of the organization. This role creates the credential report. **Note**: The role doesn't have to be present in all accounts at this step of stack creation. 7. In **Parameters**, update `S3BucketName` with the	AWS administrator

Task	Description	Skills required
	name of the S3 bucket where Lambda can store the credentials for all accounts. 8. For **Stack name**, enter your stack name. 9. Choose **Submit**. 10Note the Lambda function's role name.	

Create an IAM permission policy.	[Create an IAM policy](#) for every AWS account across your organization with the following permissions:
	<pre>{
	  "Version": "2012-10-
	17",
	  "Statement": [
	    {
	      "Effect": "Allow",
	      "Action": [
	        "iam:Gene
	rateCredentialRepo
	rt",
	        "iam:GetC
	redentialReport"
	      ],
	      "Resource": "*"
	    }
	  ]
	}</pre>
		AWS DevOps, Cloud administrator, Cloud architect, Data engineer

Task	Description	Skills required
Create an IAM role with a trust policy.	1. [Create an IAM role](#) for the AWS accounts and attach the permission policy that you created in the previous step. 2. Attach the following trust policy to the IAM role: `{ "Version":"2012-10-17", "Statement":[ { "Effect": "Allow", "Principal":{ "AWS":[ "arn:aws:iam::<MasterAccountID>:role/<LambdaRole>" ] }, "Action": "sts:AssumeRole" } ] }` **Important** Replace `arn:aws:iam::<MasterAccountID>:role/<LambdaRole>` with the ARN of the	Cloud administrator, Cloud architect, AWS administrator

Task	Description	Skills required
	Lambda role that you noted previously. **Note** Organizations typically use automation to create IAM roles for their AWS accounts. We recommend that you use this automation, if available. Alternatively, you can use the `CreateRoleforOrg.py` script from the code repository. The script requires an existing administrative role or any other IAM role that has permission to create an IAM policy and role in every AWS account.	

Task	Description	Skills required
Configure Amazon QuickSight to visualize the data.	1. Sign in to QuickSight with your credentials. 2. Create a dataset by using Athena (using the `iamcredreportdb` database and `"cfn_iamcredreport"` table), and then automatically refresh the dataset. 3. Create an analysis in QuickSight. 4. Create a QuickSight dashboard.	AWS DevOps, Cloud administrator, Cloud architect, Data engineer

Additional information

Additional considerations

Consider the following:

- After you use CloudFormation to deploy the infrastructure, you can wait to get the reports created in Amazon S3 and analyzed by Athena until Lambda and AWS Glue run as per their schedules. Alternatively, you can run Lambda manually to get the reports in Amazon S3, and then run the AWS Glue crawler to get the Athena table that's created from the data.
- QuickSight is a powerful tool for analyzing and visualizing data based on your business requirements. You can use parameters in QuickSight to control widget data based on data fields that you choose. Also, you can use a QuickSight analysis to create parameters (for example, Account, Date, and User fields such as `partition_0`, `partition_1`, and `user` respectively) from your dataset to add controls for the parameters for Account, Date, and User.
- To build your own QuickSight dashboards, see QuickSight Workshops from the AWS Workshop Studio website.
- To see sample QuickSight dashboards, see the GitHub getiamcredsreport-allaccounts-org code repository.

Targeted business outcomes

You can use this pattern to achieve the following targeted business outcomes:

- **Identify security incidents related to IAM users –** Investigate every user across every AWS account in your organization by using a single pane of glass. You can track the trend of an IAM user's most recently accessed individual AWS Regions and the services they used.
- **Track real-time migration of IAM users to SSO authentication –** By using SSO, users can sign in once with a single credential and access multiple AWS accounts and applications. If you're planning to migrate your IAM users to SSO, this pattern can help you transition to SSO and track all IAM user credential usage (such as access to the AWS Management Console or usage of access keys) across all AWS accounts.
- **Track AWS Regions accessed by IAM users –** You can control IAM user access to Regions for various purposes, such as data sovereignty and cost control. You can also track use of Regions by any IAM user.
- **Stay compliant –** By following the principle of least privilege, you can grant only the specific IAM permissions that are required to perform a specific task. Also, you can track access to AWS services, the AWS Management Console, and long-term credentials usage.
- **Share information with other stakeholders –** You can share curated dashboards with other stakeholders, without granting them access to IAM credential reports or AWS accounts.

More patterns

- Authenticate existing React application users by using Amazon Cognito and AWS Amplify UI
- Automatically extract content from PDF files using Amazon Textract
- Build a cold start forecasting model by using DeepAR for time series in Amazon SageMaker AI Studio Lab
- Create detailed cost and usage reports for Amazon EMR clusters by using AWS Cost Explorer
- Create detailed cost and usage reports for Amazon RDS and Amazon Aurora
- Create detailed cost and usage reports for AWS Glue jobs by using AWS Cost Explorer
- Deliver DynamoDB records to Amazon S3 using Kinesis Data Streams and Firehose with AWS CDK
- Deploy an AWS Glue job with an AWS CodePipeline CI/CD pipeline
- Embed an Amazon QuickSight dashboard in a local Angular application
- Ensure an Amazon Redshift cluster is encrypted upon creation
- Ensure encryption for Amazon EMR data at rest is enabled at launch
- Estimate storage costs for an Amazon DynamoDB table
- Execute Amazon Redshift SQL queries by using Terraform
- Extract and query AWS IoT SiteWise metadata attributes in a data lake
- Generate data insights by using AWS Mainframe Modernization and Amazon Q in QuickSight
- Generate Db2 z/OS data insights by using AWS Mainframe Modernization and Amazon Q in QuickSight
- Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account
- Identify and alert when Amazon Data Firehose resources are not encrypted with an AWS KMS key
- Import the psycopg2 library to AWS Lambda to interact with your PostgreSQL database
- Ingest and analyze AWS security logs in Microsoft Sentinel
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL in SSL mode by using AWS DMS
- Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters
- Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT
- Migrate data from an on-premises Hadoop environment to Amazon S3 using DistCp with AWS PrivateLink for Amazon S3
- Migrate from Couchbase Server to Couchbase Capella on AWS

- Migrate on-premises Cloudera workloads to Cloudera Data Platform on AWS
- Monitor Amazon EMR clusters for in-transit encryption at launch
- Manage Multi-AZ failover for EMR clusters by using Application Recovery Controller
- Automate blue/green deployments of Amazon Aurora global databases by using IaC principles
- Provision AWS Service Catalog products based on AWS CloudFormation templates by using GitHub Actions
- Run unit tests for Python ETL jobs in AWS Glue using the pytest framework
- Set up a Grafana monitoring dashboard for AWS ParallelCluster
- Unload data from an Amazon Redshift cluster across accounts to Amazon S3
- Verify that new Amazon Redshift clusters have required SSL endpoints
- Verify that new Amazon Redshift clusters launch in a VPC
- Visualize AI/ML model results using Flask and AWS Elastic Beanstalk

Containers & microservices

Topics

- Access an Amazon Neptune database from an Amazon EKS container
- Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer
- Access container applications privately on Amazon ECS by using AWS Fargate, AWS PrivateLink, and a Network Load Balancer
- Access container applications privately on Amazon EKS using AWS PrivateLink and a Network Load Balancer
- Activate mTLS in AWS App Mesh using AWS Private CA on Amazon EKS
- Automate backups for Amazon RDS for PostgreSQL DB instances by using AWS Batch
- Automate deployment of Node Termination Handler in Amazon EKS by using a CI/CD pipeline
- Automatically build and deploy a Java application to Amazon EKS using a CI/CD pipeline
- Create an Amazon ECS task definition and mount a file system on EC2 instances using Amazon EFS
- Deploy Lambda functions with container images
- Deploy Java microservices on Amazon ECS using AWS Fargate
- Deploy Kubernetes resources and packages using Amazon EKS and a Helm chart repository in Amazon S3
- Deploy a sample Java microservice on Amazon EKS and expose the microservice using an Application Load Balancer
- Deploy a clustered application to Amazon ECS by using AWS Copilot
- Deploy a gRPC-based application on an Amazon EKS cluster and access it with an Application Load Balancer
- Deploy and debug Amazon EKS clusters
- Deploy containers by using Elastic Beanstalk
- Generate a static outbound IP address using a Lambda function, Amazon VPC, and a serverless architecture
- Identify duplicate container images automatically when migrating to an Amazon ECR repository
- Install SSM Agent on Amazon EKS worker nodes by using Kubernetes DaemonSet

- Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands
- Migrate NGINX Ingress Controllers when enabling Amazon EKS Auto Mode
- Migrate your container workloads from Azure Red Hat OpenShift (ARO) to Red Hat OpenShift Service on AWS (ROSA)
- Place Kubernetes Pods on Amazon EKS by using node affinity, taints, and tolerations
- Replicate filtered Amazon ECR container images across accounts or Regions
- Rotate database credentials without restarting containers
- Run Amazon ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere
- Run an ASP.NET Core web API Docker container on an Amazon EC2 Linux instance
- Run message-driven workloads at scale by using AWS Fargate
- Run stateful workloads with persistent data storage by using Amazon EFS on Amazon EKS with AWS Fargate
- Set up event-driven auto scaling in Amazon EKS by using Amazon EKS Pod Identity and KEDA
- Streamline PostgreSQL deployments on Amazon EKS by using PGO
- Simplify application authentication with mutual TLS in Amazon ECS by using Application Load Balancer
- More patterns

Access an Amazon Neptune database from an Amazon EKS container

Ramakrishnan Palaninathan, Amazon Web Services

Summary

This pattern establishes a connection between Amazon Neptune, which is a fully managed graph database, and Amazon Elastic Kubernetes Service (Amazon EKS), a container orchestration service, to access a Neptune database. Neptune DB clusters are confined within a virtual private cloud (VPC) on AWS. For this reason, accessing Neptune requires careful configuration of the VPC to enable connectivity.

Unlike Amazon Relational Database Service (Amazon RDS) for PostgreSQL, Neptune doesn't rely on typical database access credentials. Instead, it uses AWS Identity and Access Management (IAM) roles for authentication. Therefore, connecting to Neptune from Amazon EKS involves setting up an IAM role with the necessary permissions to access Neptune.

Furthermore, Neptune endpoints are accessible only within the VPC where the cluster resides. This means that you have to configure network settings to facilitate communication between Amazon EKS and Neptune. Depending on your specific requirements and networking preferences, there are various approaches to configuring the VPC to enable seamless connectivity between Neptune and Amazon EKS. Each method offers distinct advantages and considerations, which provide flexibility in designing your database architecture to suit your application's needs.

Prerequisites and limitations

Prerequisites

- Install the latest version of **kubectl** (see instructions). To check your version, run:

```
kubectl version --short
```

- Install the latest version of **eksctl** (see instructions). To check your version, run:

```
eksctl info
```

- Install the latest version of the AWS Command Line Interface (AWS CLI) version 2 (see instructions). To check your version, run:

```
aws --version
```

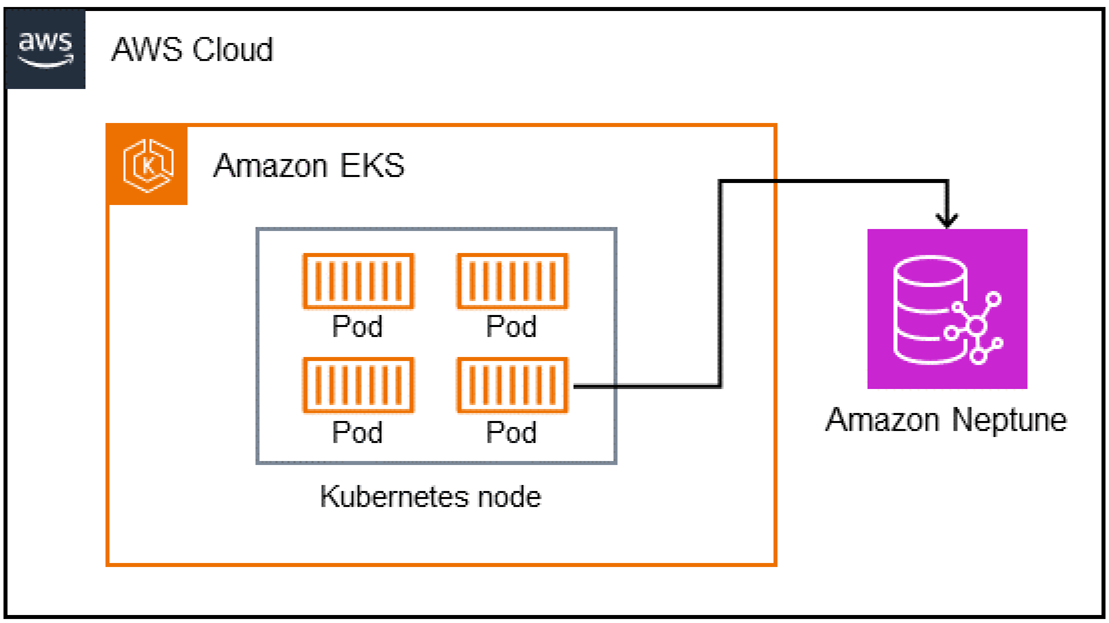
- Create a Neptune DB cluster (see instructions). Make sure to establish communications between the cluster's VPC and Amazon EKS through VPC peering, AWS Transit Gateway, or another method. Also make sure that the status of the cluster is "available" and that it has an inbound rule on port 8182 for the security group.
- Configure an IAM OpenID Connect (OIDC) provider on an existing Amazon EKS cluster (see instructions).

Product versions

- Amazon EKS 1.27
- Amazon Neptune engine version 1.3.0.0 (2023-11-15)

Architecture

The following diagram shows the connection between Kubernetes pods in an Amazon EKS cluster and Neptune to provide access to a Neptune database.



Automation and scale

You can use the Amazon EKS Horizontal Pod Autoscaler to scale this solution.

Tools

Services

- [Amazon Elastic Kubernetes Service (Amazon EKS)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Amazon Neptune](#) is a graph database service that helps you build and run applications that work with highly connected datasets.

Best practices

For best practices, see [Identity and Access Management](#) in the *Amazon EKS Best Practices Guides*.

Epics

Set environment variables

Task	Description	Skills required
Verify the cluster context.	Before you interact with your Amazon EKS cluster by using Helm or other command-line tools, you must define environment variables that encapsulate your cluster's details. These variables are used in subsequent commands to ensure that they target the correct cluster and resources. First, confirm that you are operating within the correct cluster context. This ensures that any subsequent commands are sent to the intended Kubernetes cluster. To verify the current context, run the following command.	AWS administrator, Cloud administrator

Task	Description	Skills required
	`kubectl config current-context`	
Define the `CLUSTER_NAME` variable.	Define the `CLUSTER_NAME` environment variable for your Amazon EKS cluster. In the following command, replace the sample value `us-west-2` with the correct AWS Region for your cluster. Replace the sample value `eks-workshop` with your existing cluster name. `export CLUSTER_NAME=$(aws eks describe-cluster --region us-west-2 --name eks-workshop --query "cluster.name" --output text)`	AWS administrator, Cloud administrator
Validate output.	To validate that the variables have been set properly, run the following command. `echo $CLUSTER_NAME` Verify that the output of this command matches the input you specified in the previous step.	AWS administrator, Cloud administrator

Create IAM role and associate it with Kubernetes

Task	Description	Skills required
Create a service account.	You use IAM roles for service accounts to map your Kubernetes service accounts to IAM roles, to enable fine-grained permissions management for your applications that run on Amazon EKS. You can use eksctl to create and associate an IAM role with a specific Kubernetes service account within your Amazon EKS cluster. The AWS managed policy `NeptuneFullAccess` allows write and read access to your specified Neptune cluster. **Important** You must have an OIDC endpoint associated with your cluster before you run these commands. Create a service account that you want to associate with an AWS managed policy named `NeptuneFullAccess` .	AWS administrator, Cloud administrator

Task	Description	Skills required

	<pre>eksctl create iamservic
	eaccount --name eks-
	neptune-sa --namespa
	ce default --cluster
	 $CLUSTER_NAME --
	attach-policy-arn
	 arn:aws:iam::aws:p
	olicy/NeptuneFullA
	ccess --approve --
	override-existing-
	serviceaccounts</pre>
	where `eks-neptune-sa` is the name of the service account that you want to create.
	
	Upon completion, this command displays the following response:
	<pre>2024-02-07 01:12:39 [#]
	 created serviceaccount
	 "default/eks-neptune-
	sa"</pre>	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Verify that the account is set up properly.</td><td>Make sure that the <code>eks-neptune-sa</code> service account is set up correctly in the default namespace in your cluster.
<pre>kubectl get sa eks-neptu
ne-sa -o yaml</pre>The output should look like this:
<pre>apiVersion: v1
kind: ServiceAccount
metadata:
  annotations:
    eks.amazonaws.com/
role-arn: arn:aws:i
am::123456789123:r
ole/eksctl-eks-wor
kshop-addon-iamser
viceaccount-d-Role1-
Q35yKgdQOlmM
  creationTimestamp:
 "2024-02-07T01:12:
39Z"
  labels:
    app.kubernetes.io/
managed-by: eksctl
  name: eks-neptune-sa
  namespace: default
  resourceVersion:
 "5174750"
  uid: cd6ba2f7-
a0f5-40e1-a6f4-408
1e0042316</pre></td><td>AWS administrator, Cloud administrator</td></tr>
</table>

Task	Description	Skills required

Check connectivity.	Deploy a sample pod called `pod-util` and check connectivity with Neptune.
	``
	apiVersion: v1
	kind: Pod
	metadata:
	  name: pod-util
	  namespace: default
	spec:
	  serviceAccountName: eks-neptune-sa
	  containers:
	  - name: pod-util
	    image: public.ecr.aws/patrickc/troubleshoot-util
	    command:
	      - sleep
	      - "3600"
	    imagePullPolicy: IfNotPresent
	``
	``
	kubectl apply -f pod-util.yaml
	``
	``
	kubectl exec --stdin --tty pod-util -- /bin/bash
	bash-5.1# curl -X POST -d '{"gremlin":"g.V().limit(1)"}' https://db-neptune-1.cluster-xxxxxxxxxxxx.us-west-2.neptune.amazonaws.com:8182/gremlin
	{"requestId":"a4964f2d-12b1-4ed3-8a14-e
	``
		AWS administrator, Cloud administrator

Task	Description	Skills required

	`ff511431a0e","status":{"message":"","code":200,"attributes":{"@type":"g:Map","@value":[]}},"result":{"data":{"@type":"g:List","@value":[]},"meta":{"@type":"g:Map","@value":[]}}}`
	`bash-5.1# exit`
	`exit`	

Validate connection activity

Task	Description	Skills required
Enable IAM database authentication.	By default, IAM database authentication is disabled when you create a Neptune DB cluster. You can enable or disable IAM database authentication by using the AWS Management Console. Follow the steps in the AWS documentation to enable IAM database authentication in Neptune.	AWS administrator, Cloud administrator
Verify connections.	In this step, you interact with the `pod-util` container, which is already in running status, to install **awscurl** and verify the connection.	AWS administrator, Cloud administrator

Task	Description	Skills required

	1. Run the following command to find the pod.
	`kubectl get pods`
	The output should look like this:
	`NAME READY STATUS RESTARTS AGE pod-util 1/1 Running 0 50m`
	2. Run the following command to install **awscurl**.
	`kubectl exec --stdin --tty pod-util -- /bin/bash bash-5.1# pip3 install awscurl Installing collected packages: idna, configparser, configargparse, charset-normalizer, certifi, requests, awscurl Successfully installed awscurl-0.32 certifi-2024.2.2 charset-normalizer-3.3.2 configargparse-1.7 configparser-6.0.0 idna-3.6 requests-2.31.0 bash-5.1# awscurl https://db-neptune-1.cluster-xxxxxxxxxxxx.us-west-2.neptune.amazonaws.co`	

Task	Description	Skills required
	`m:8182/status --region us-west-2 --service neptune-db {"status":"healthy","startTime":"Thu Feb 08 01:22:14 UTC 2024","dbEngineVersion":"1.3.0.0.R1","role":"writer","dfeQueryEngine":"viaQueryHint","gremlin":{"version":"tinkerpop-3.6.4"},"sparql":{"version":"sparql-1.1"},"opencypher":{"version":"Neptune-9.0.20190305-1.0"},"labMode":{"ObjectIndex":"disabled","ReadWriteConflictDetection":"enabled"},"features":{"SlowQueryLogs":"disabled","ResultCache":{"status":"disabled"},"IAMAuthentication":"enabled","Streams":"disabled","AuditLog":"disabled"},"settings":{"clusterQueryTimeoutInMs":"120000","SlowQueryLogsThreshold":"5000"}}`	

Troubleshooting

Issue	Solution
Can't access the Neptune database.	Review the IAM policy that's attached to the service account. Make sure that it allows the necessary actions (for example, `neptune:Connec,neptune:DescribeDBInstances`) for the operations you want to run.

Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer

Kirankumar Chandrashekar, Amazon Web Services

Summary

This pattern describes how to privately host a Docker container application on Amazon Elastic Container Service (Amazon ECS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). Amazon Elastic File System (Amazon EFS) is used if the application requires persistent storage.

The Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

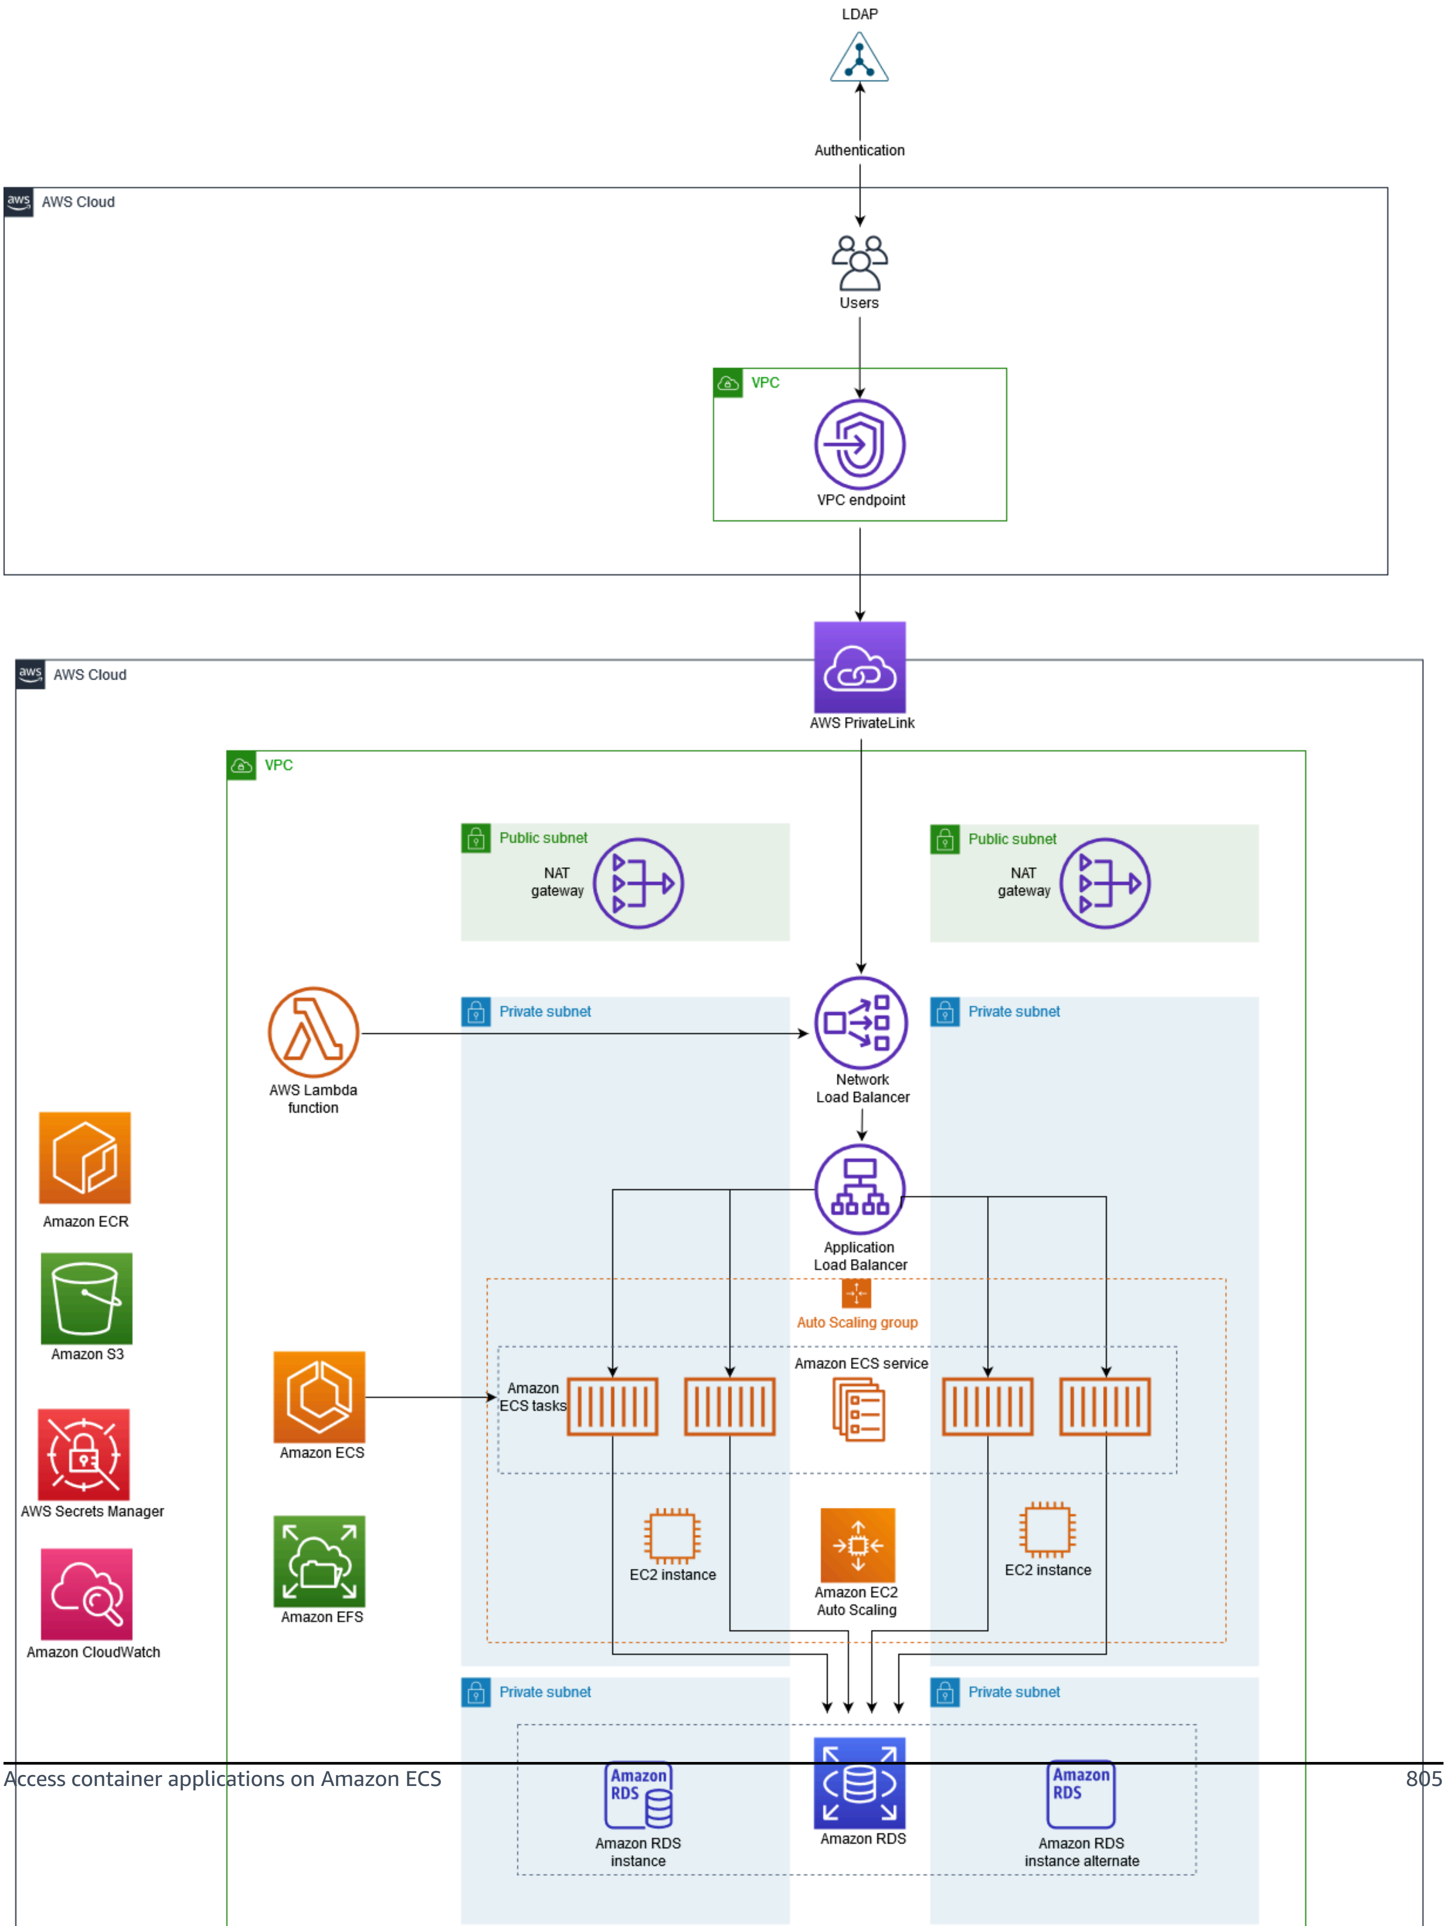
You can also use AWS Fargate instead of an Amazon EC2 Auto Scaling group. For more information, see Access container applications privately on Amazon ECS by using AWS Fargate, AWS PrivateLink, and a Network Load Balancer.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows
- Docker, installed and configured on Linux, macOS, or Windows
- An application running on Docker

Architecture



Technology stack

- Amazon CloudWatch
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon EC2 Auto Scaling
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Lambda
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

Automation and scale

- You can use AWS CloudFormation to create this pattern by using Infrastructure as Code.

Tools

- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- Amazon EC2 Auto Scaling – Amazon EC2 Auto Scaling helps you ensure that you have the correct number of Amazon EC2 instances available to handle the load for your application.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- Amazon EFS – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.

- [AWS Lambda](#) – Lambda is a compute service for running code without provisioning or managing servers.
- [Amazon RDS](#) – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- [AWS Secrets Manager](#) – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, by providing an API call to Secrets Manager to retrieve the secret programmatically.
- [Amazon VPC](#) – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- [Elastic Load Balancing](#) – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon EC2 instances, containers, and IP addresses, in multiple Availability Zones.
- [Docker](#) – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Epics

Create networking components

Task	Description	Skills required
Create a VPC.	1. Sign in to the AWS Management Console and open the Amazon VPC console. Choose **Create VPC**, and choose **VPC and more**. 2. Enter a name for your VPC, and choose an appropriate CIDR block range. 3. Specify two Availability Zones, two public subnets, four private subnets. Two	Cloud administrator

Task	Description	Skills required
	private subnets are for Amazon ECS tasks, and two private subnets are for Amazon RDS databases. 4. Specify one NAT gateway for each Availability Zone. 5. Choose **Create VPC**.	

Create the load balancers

Task	Description	Skills required
Create a Network Load Balancer.	1. Open the Amazon EC2 console and choose the AWS Region that contains your VPC. 2. Under **Load balancing**, choose **Load balancers**, and choose **Create load balancer**. 3. Choose **Network Load Balancer**, and choose **Create**. 4. On the **Configure load balancer** page, configure your Network Load Balancer and listener. **Important:** Make sure you choose your Network Load Balancer's scheme as **Internal**. 5. Choose the applicabl e security settings,	Cloud administrator

Task	Description	Skills required
	configure a security group and a target group. Choose **Instance** or **IP** as the **Target type** in the **Configure routing** section. Make sure you do not register a target. 6. When you have configure d all the settings, choose **Next: Review**, and then choose **Create**.	

Task	Description	Skills required
Create an Application Load Balancer.	1. On the Amazon EC2 console, choose the same Region that contains your VPC. 2. Under **Load balancing**, choose **Load balancers**, and choose **Create load balancer**. 3. Choose **Application Load Balancer**, and choose **Create**. 4. **Important** Configure your Application Load Balancer and its listener. Make sure you choose your Application Load Balancer's scheme as **Internal**. 5. Choose the applicabl e security settings, configure a security group and a target group. Choose **Instance** or **IP** as the **Target type** in the **Configure routing** section. Make sure you do not register a target. 6. When you have configure d all the settings, choose	Cloud administrator

Task	Description	Skills required
	Next: Review, and then choose **Create**.	

Create an Amazon EFS file system

Task	Description	Skills required
Create an Amazon EFS file system.	1. Open the Amazon EFS console, and choose **Create file system**. 2. In the **Create file system** dialog box, enter a name for your file system, and choose your VPC. 3. Choose **Create** to create the file system. 4. Set up and configure your Amazon EFS file system.	Cloud administrator
Mount targets for the subnets.	1. Return to the Amazon EFS console, and choose **File systems**. The **File systems** page shows the Amazon EFS file systems in your account. 2. Choose the file system that you created, and choose **Manage** to display the **Availability Zones**. To add a mount target, choose **Add mount target**, and add the four private subnets that you created.	Cloud administrator

Task	Description	Skills required
Verify that the subnets are mounted as targets.	1. On the Amazon EFS console, choose **File systems**. 2. Choose **Network** to display the list of existing mount targets. Make sure that these include the four subnets that you created.	Cloud administrator

Create an S3 bucket

Task	Description	Skills required
Create an S3 bucket.	Open the Amazon S3 console and create an S3 bucket to store your application's static assets, if required.	Cloud administrator

Create a Secrets Manager secret

Task	Description	Skills required
Create an AWS KMS key to encrypt the Secrets Manager secret.	Open the AWS Key Management Service (AWS KMS) console and create a KMS key.	Cloud administrator
Create a Secrets Manager secret to store the Amazon RDS password.	1. Open the AWS Secrets Manager console, and create a new secret by choosing **Store a new secret**.	Cloud Administrator

Task	Description	Skills required
	2. Choose the KMS key that you created, and store your new secret.	

Create an Amazon RDS instance

Task	Description	Skills required
Create a DB subnet group.	1. Open the Amazon RDS console and choose **Subnet groups**. 2. Choose **Create DB subnet group**, and enter a name and description for your DB subnet group. 3. Choose the VPC that you created earlier, and choose the Availability Zones and subnets. Then choose **Create**.	Cloud administrator
Create an Amazon RDS instance.	Create and configure an Amazon RDS instance within the private subnets. Make sure that **Multi-AZ** is turned on for HA.	Cloud administrator
Load data to the Amazon RDS instance.	Load the relational data required by your applicati on into your Amazon RDS instance. This process will vary depending on your application's needs, as well as	Cloud administrator, DBA

Task	Description	Skills required
	how your database schema is defined and designed.	

Create the Amazon ECS components

Task	Description	Skills required
Create an ECS cluster.	1. Open the Amazon ECS console, and choose **Clusters**. 2. Choose **Create clusters**, and set up an ECS cluster according to your required specifications.	Cloud administrator
Create the Docker images.	Create the Docker images by following the instructions in the *Related resources* section.	Cloud administrator
Create Amazon ECR repositor ies.	1. On the Amazon ECR console, choose **Repositor ies**. 2. Choose **Create repository**, and enter a unique name for your repository. 3. Configure the repository according to your specifica tions, including AWS KMS encryption if required.	Cloud administrator, DevOps engineer
Authenticate your Docker client for the Amazon ECR repository.	To authenticate your Docker client for the Amazon ECR repository, run the "`aws ecr`	Cloud administrator

Task	Description	Skills required
	`get-login-password` command in the AWS CLI.	
Push the Docker images to the Amazon ECR repository.	1. Identify the Docker image you want to push, and run the `docker images` command in the AWS CLI. 2. Tag your image with the Amazon ECR registry, repository, and optional image tag name combinati on. 3. Push the Docker image by running the `docker push` command. 4. Repeat these steps for all required images.	Cloud administrator

Task	Description	Skills required
Create an Amazon ECS task definition.	A task definition is required to run Docker containers in Amazon ECS. 1. Return to the Amazon ECS console, choose **Task definitions**, and then choose **Create new task definition**. 2. On the **Select compatibilities** page, select the launch type that your task should use, and choose **Next step**. **Important** For help with setting up your task definition, see "Creating a task definition" in the *Related resources* section. Make sure you provide the Docker images that you pushed to Amazon ECR.	Cloud administrator

Task	Description	Skills required
Create an Amazon ECS service.	Create an Amazon ECS service by using the ECS cluster you created earlier. Make sure you choose Amazon EC2 as the launch type, and choose the task definition created in the previous step, as well as the target group of the Applicati on Load Balancer.	Cloud administrator

Create an Amazon EC2 Auto Scaling group

Task	Description	Skills required
Create a launch configuration.	Open the Amazon EC2 console, and create a launch configuration. Make sure that the user data has the code to allow the EC2 instances to join the desired ECS cluster. For an example of the code required, see the *Related resources* section.	Cloud administrator
Create an Amazon EC2 Auto Scaling group.	Return to the Amazon EC2 console and under **Auto Scaling**, choose **Auto Scaling groups**. Set up an Amazon EC2 Auto Scaling group. Make sure you choose the private subnets and launch configura tion that you created earlier.	Cloud administrator

Set up AWS PrivateLink

Task	Description	Skills required
Set up the AWS PrivateLink endpoint.	1. On the Amazon VPC console, create an AWS PrivateLink endpoint. 2. Associate this endpoint with the Network Load Balancer, which makes the application hosted on Amazon ECS available privately to customers. For more information, see the *Related resources* section.	Cloud administrator

Create a VPC endpoint

Task	Description	Skills required
Create a VPC endpoint.	Create a VPC endpoint for the AWS PrivateLink endpoint that you created earlier. The VPC endpoint Fully Qualified Domain Name (FQDN) will point to the AWS PrivateLink endpoint FQDN. This creates an elastic network interface to the VPC endpoint service that the DNS endpoints can access.	Cloud administrator

Create the Lambda function

Task	Description	Skills required
Create the Lambda function.	On the AWS Lambda console, create a Lambda function to update the Application Load Balancer IP addresses as targets for the Network Load Balancer. For more informati on on this, see the Using AWS Lambda to enable static IP addresses for Application Load Balancers blog post.	App developer

Access container applications privately on Amazon ECS by using AWS Fargate, AWS PrivateLink, and a Network Load Balancer

Kirankumar Chandrashekar, Amazon Web Services

Summary

This pattern describes how to privately host a Docker container application on the Amazon Web Services (AWS) Cloud by using Amazon Elastic Container Service (Amazon ECS) with an AWS Fargate launch type, behind a Network Load Balancer, and access the application by using AWS PrivateLink. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). You can use Amazon Elastic File System (Amazon EFS) if the application requires persistent storage.

This pattern uses a Fargate launch type for the Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end. It can then be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

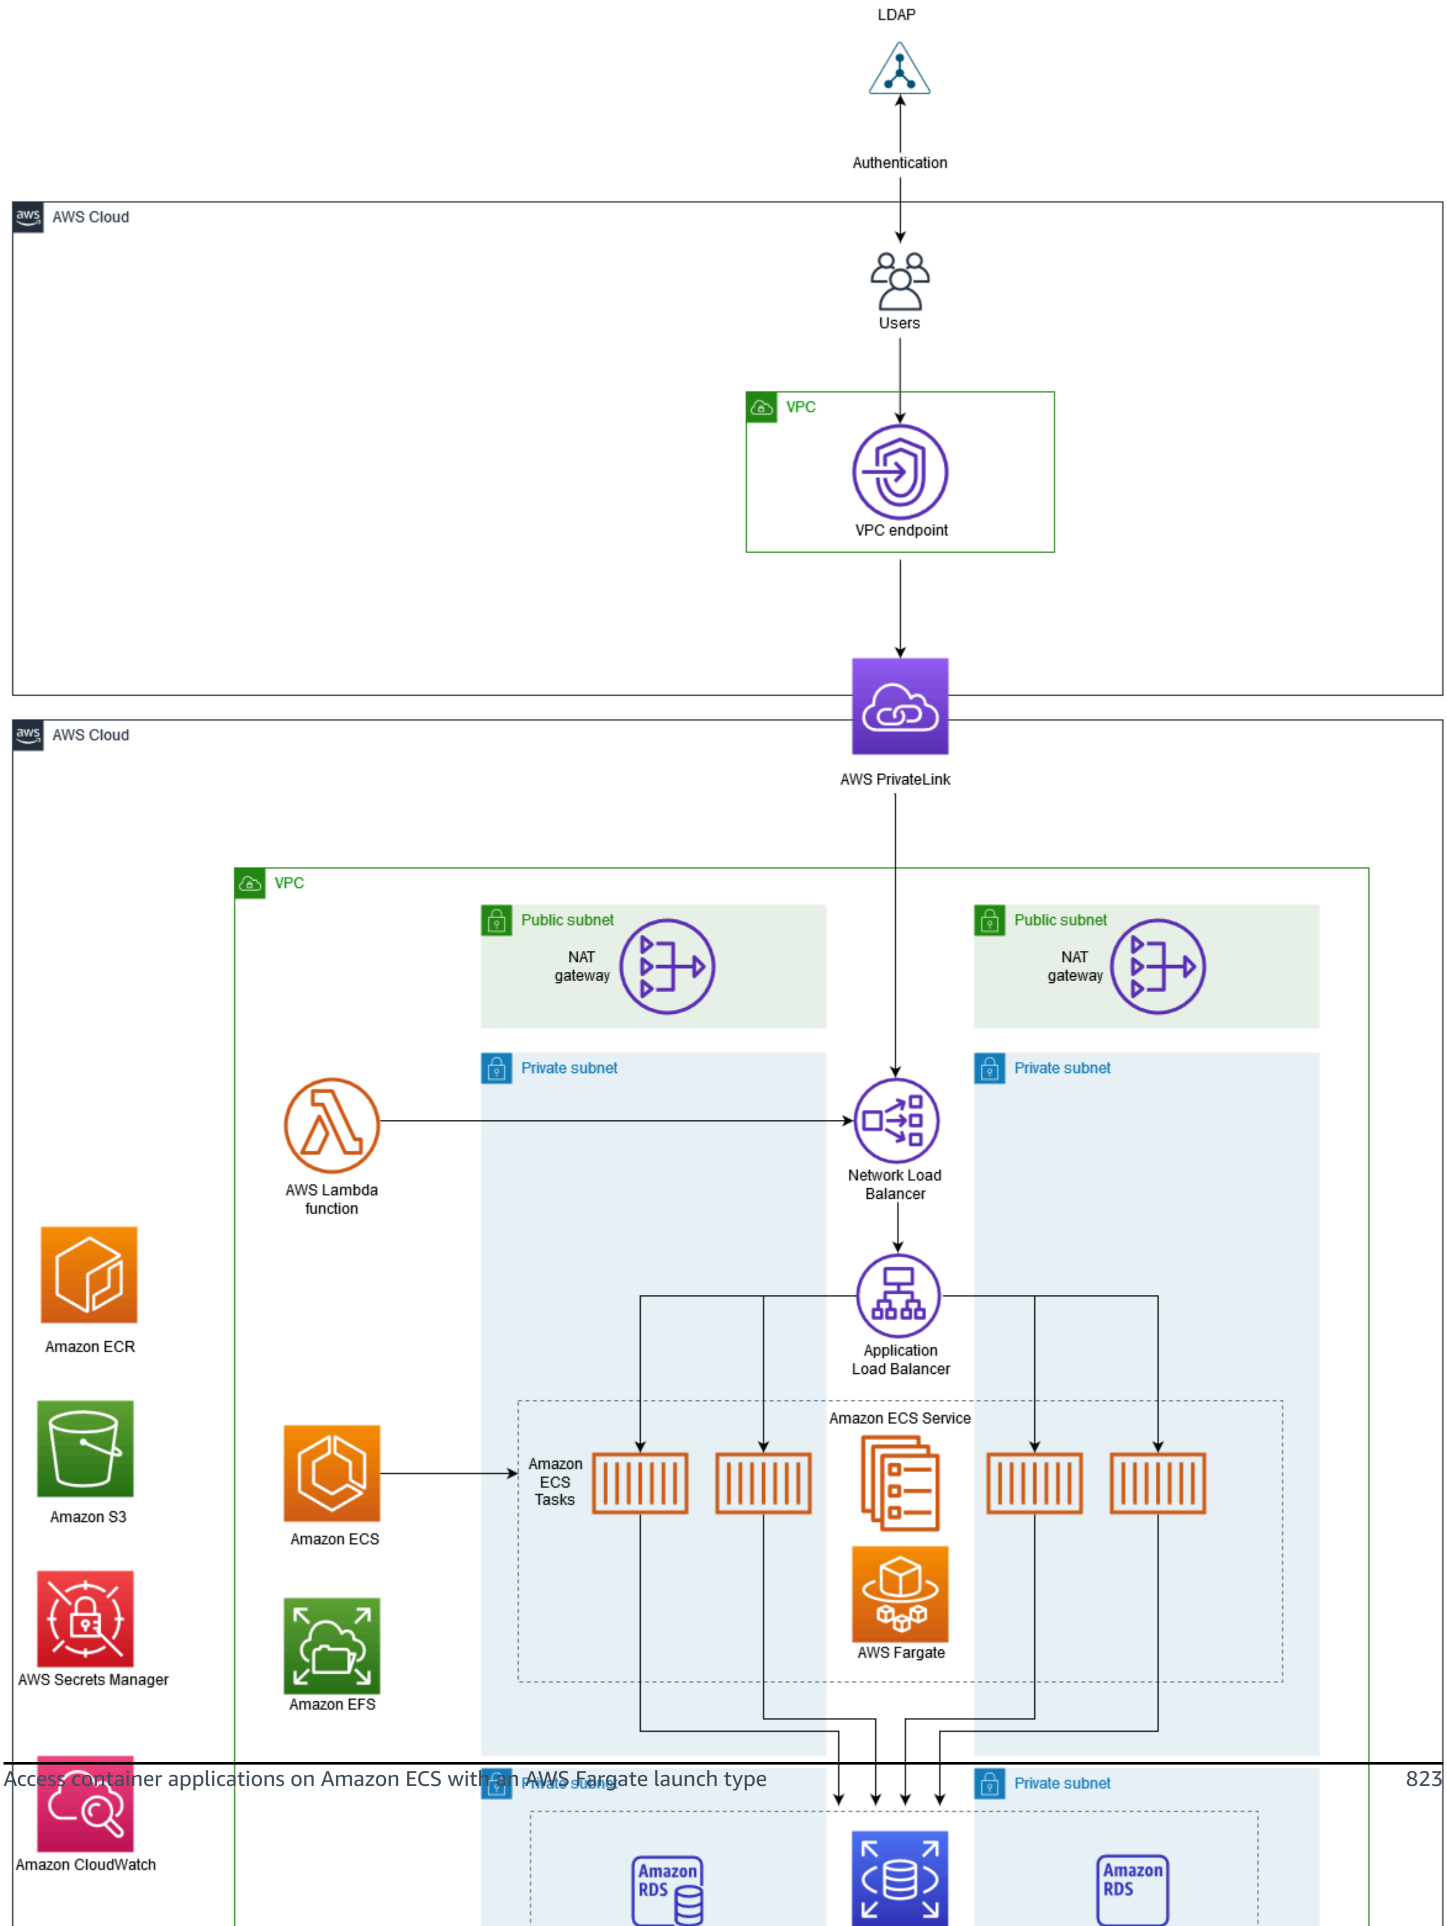
You can use Fargate with Amazon ECS to run containers without having to manage servers or clusters of Amazon Elastic Compute Cloud (Amazon EC2) instances. You can also use an Amazon EC2 Auto Scaling group instead of Fargate. For more information, see Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows
- Docker, installed and configured on Linux, macOS, or Windows
- An application running on Docker

Architecture



Technology stack

- Amazon CloudWatch
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon EFS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Fargate
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

Automation and scale

- You can use AWS CloudFormation to create this pattern by using Infrastructure as Code.

Tools

AWS services

- Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon EC2 instances.
- Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.

- Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in multiple Availability Zones.

Other tools

- Docker helps developers to easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Epics

Create networking components

Task	Description	Skills required
Create a VPC.	1. Sign in to the AWS Management Console, and open the Amazon VPC console. Choose **Create VPC**, and choose **VPC and more**. 2. Enter a name for your VPC, and choose an appropriate CIDR block range. 3. Specify two Availability Zones, two public subnets, four private subnets. Two private subnets are for Amazon ECS tasks, and two private subnets are for Amazon RDS databases.	Cloud administrator

Task	Description	Skills required
	4. Specify one NAT gateway for each Availability Zone. 5. Choose Create **VPC**.	

Create the load balancers

Task	Description	Skills required
Create a Network Load Balancer.	1. Open the Amazon EC2 console, and choose the AWS Region that contains your VPC. 2. Under **Load balancing**, choose **Load balancers**, and choose **Create load balancer**. 3. Choose **Network Load Balancer**, and choose **Create**. 4. On the **Configure load balancer** page, configure your Network Load Balancer and listener. **Important:** Make sure you choose your Network Load Balancer's scheme as **Internal**. 5. Choose the applicable security settings, configure a security group and a target group. Choose **IP** as the **Target type** in the **Configure routing** section.	Cloud administrator

Task	Description	Skills required
	Make sure you do not register a target. 6. When you have configure d all the settings, choose **Next: Review**, and then choose **Create**. For help with this and other stories, see the *Related resources* section.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create an Application Load Balancer.</td><td>1. On the Amazon EC2 console, choose the same Region that contains your VPC.
2. Under Load balancing, choose Load balancers, and choose Create load balancer.
3. Choose Application Load Balancer, and choose Create.
4. Important
Configure your Application Load Balancer and its listener. Make sure you choose your Application Load Balancer's scheme as Internal.
5. Choose the applicable security settings, configure a security group and a target group. Choose IP as the Target type in the Configure routing section. Make sure you do not register a target.
6. When you have configure d all the settings, choose</td><td>Cloud administrator</td></tr>
</table>

Task	Description	Skills required
	Next: Review, and then choose **Create**.	

Create an Amazon EFS file system

Task	Description	Skills required
Create an Amazon EFS file system.	1. Open the Amazon EFS console, and choose **Create file system**. 2. In the **Create file system** dialog box, enter a name for your file system, and choose your VPC. 3. Choose **Create** to create the file system. 4. Set up and configure your Amazon EFS file system.	Cloud administrator
Mount targets for the subnets.	1. Return to the Amazon EFS console, and choose **File systems**. The **File systems** page shows the Amazon EFS file systems in your account. 2. Choose the file system that you created, and choose **Manage** to display the **Availability Zone**. 3. To add a mount target, choose **Add mount target**, and add the four private subnets that you created.	Cloud administrator

Task	Description	Skills required
Verify that the subnets are mounted as targets.	1. On the Amazon EFS console, choose **File systems**. 2. Choose **Network** to display the list of existing mount targets. Make sure that these include the four subnets that you created.	Cloud administrator

Create an S3 bucket

Task	Description	Skills required
Create an S3 bucket.	Open the Amazon S3 console and create an S3 bucket to store your application's static assets, if required.	Cloud administrator

Create a Secrets Manager secret

Task	Description	Skills required
Create an AWS KMS key to encrypt the Secrets Manager secret.	Open the AWS Key Management Service (AWS KMS) console and create a KMS key.	Cloud administrator
Create a Secrets Manager secret to store the Amazon RDS password.	1. Open the AWS Secrets Manager console, and create a new secret by choosing **Store a new secret**.	Cloud administrator

Task	Description	Skills required
	2. Choose the KMS key that you created, and store your new secret.	

Create an Amazon RDS instance

Task	Description	Skills required
Create a DB subnet group.	1. Open the Amazon RDS console, and choose **Subnet groups**. 2. Choose **Create DB subnet group**, and enter a name and description for your DB subnet group. 3. Choose the VPC that you created earlier, and choose the Availability Zones and subnets. Then choose **Create**.	Cloud administrator
Create an Amazon RDS instance.	Create and configure an Amazon RDS instance within the private subnets. Make sure that **Multi-AZ** is turned on for high availability (HA).	Cloud administrator
Load data to the Amazon RDS instance.	Load the relational data required by your applicati on into your Amazon RDS instance. This process will vary depending on your application's needs, as well as	DBA

Task	Description	Skills required
	how your database schema is defined and designed.	

Create the Amazon ECS components

Task	Description	Skills required
Create an ECS cluster.	1. Open the Amazon ECS console, and choose **Clusters**. 2. Choose **Create clusters**, and set up an ECS cluster according to your required specifications.	Cloud administrator
Create the Docker images.	Create the Docker images by following the instructions in the AWS documentation.	Cloud administrator
Create an Amazon ECR repository.	1. Open the Amazon ECR console, and choose **Repositories**. 2. Choose **Create repository**, and enter a unique name for your repository. 3. Configure the repository according to your specifica tions, including AWS KMS encryption if required.	Cloud administrator, DevOps engineer
Push the Docker images to the Amazon ECR repository.	1. Identify the Docker image you want to push, and run the `docker images` command in AWS CLI.	Cloud administrator

Task	Description	Skills required
	2. Tag your image with the Amazon ECR registry, repository, and optional image tag name combinati on. 3. Push the Docker image by running the `docker push` command. 4. Repeat these steps for all required images.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create an Amazon ECS task definition.</td><td>A task definition is required to run Docker containers in Amazon ECS.

1. Return to the Amazon ECS console, choose Task definitions, and then choose Create new task definition.
2. On the Select compatibi lities page, select the launch type that your task should use, and choose Next step.

Important
For help with setting up your task definitio n, see "Creating a task definition" in the Related resources section. Make sure you provide the Docker images that you pushed to Amazon ECR.</td><td>Cloud administrator</td></tr>
</table>

Task	Description	Skills required
Create an ECS service and choose Fargate as the launch type.	1. Create an Amazon ECS service by using the ECS cluster you created earlier. Make sure you choose **Fargate** as the launch type. 2. Choose the task definitio n created in the previous step, and choose the target group of the Application Load Balancer.	Cloud administrator

Set up AWS PrivateLink

Task	Description	Skills required
Set up the AWS PrivateLink endpoint.	1. Open the Amazon VPC console, and create an AWS PrivateLink endpoint. 2. Associate this endpoint with the Network Load Balancer, which makes the application hosted on Amazon ECS available privately to customers.	Cloud administrator

Create a VPC endpoint

Task	Description	Skills required
Create a VPC endpoint.	Create a VPC endpoint for the AWS PrivateLink endpoint that you created earlier. The VPC endpoint Fully Qualified	Cloud administrator

Task	Description	Skills required
	Domain Name (FQDN) will point to the AWS PrivateLink endpoint FQDN. This creates an elastic network interface to the VPC endpoint service that the Domain Name Service endpoints can access.	

Set the target

Task	Description	Skills required
Add the Application Load Balancer as a target.	To add the Application Load Balancer as a target for the Network Load Balancer, follow the instructions in the AWS documentation.	App developer

Access container applications privately on Amazon EKS using AWS PrivateLink and a Network Load Balancer

Kirankumar Chandrashekar, Amazon Web Services

Summary

This pattern describes how to privately host a Docker container application on Amazon Elastic Kubernetes Service (Amazon EKS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud.

The Amazon EKS cluster running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

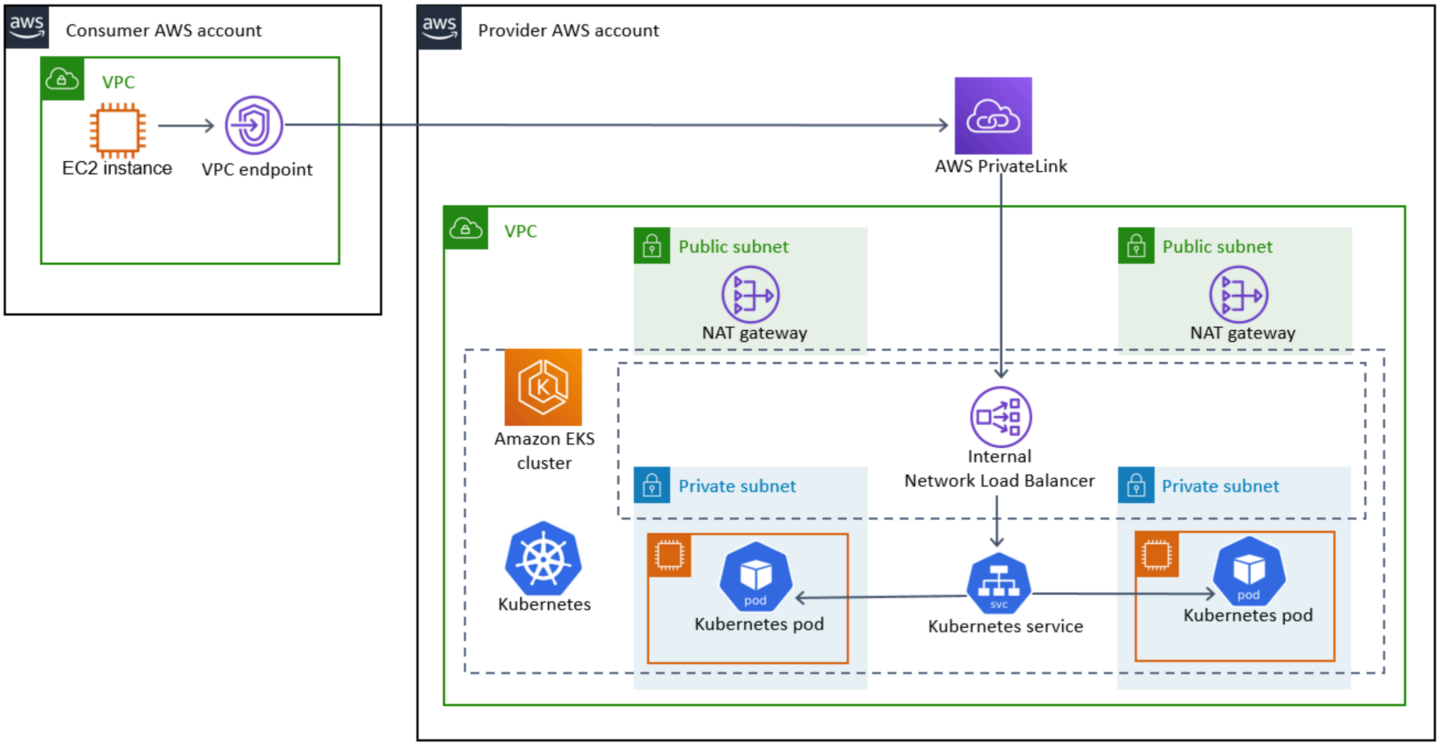
The setup described by this pattern is a secure way to share application access among VPCs and AWS accounts. It requires no special connectivity or routing configurations, because the connection between the consumer and provider accounts is on the global AWS backbone and doesn't traverse the public internet.

Prerequisites and limitations

Prerequisites

- Docker, installed and configured on Linux, macOS, or Windows.
- An application running on Docker.
- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows.
- An existing Amazon EKS cluster with tagged private subnets and configured to host applications. For more information, see Subnet tagging in the Amazon EKS documentation.
- Kubectl, installed and configured to access resources on your Amazon EKS cluster. For more information, see Installing kubectl in the Amazon EKS documentation.

Architecture



Technology stack

- Amazon EKS
- AWS PrivateLink
- Network Load Balancer

Automation and scale

- Kubernetes manifests can be tracked and managed on a Git-based repository, and deployed by using continuous integration and continuous delivery (CI/CD) in AWS CodePipeline.
- You can use AWS CloudFormation to create this pattern by using infrastructure as code (IaC).

Tools

- AWS CLI – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.

- [Elastic Load Balancing](#) – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.

- [Amazon EKS](#) – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.
- [Amazon VPC](#) – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- [Kubectl](#) – Kubectl is a command line utility for running commands against Kubernetes clusters.

Epics

Deploy the Kubernetes deployment and service manifest files

Task	Description	Skills required

Create the Kubernetes deployment manifest file.	Create a deployment manifest file by modifying the following sample file according to your requireme nts.
	```apiVersion: apps/v1```
	```kind: Deployment```
	```metadata:```
	``` name: sample-app```
	```spec:```
	``` replicas: 3```
	``` selector:```
	``` matchLabels:```
	``` app: nginx```
	``` template:```
	``` metadata:```
	``` labels:```
	``` app: nginx```
	``` spec:```
	``` containers:```
	``` - name: nginx```
		DevOps engineer

Task	Description	Skills required

	``
	            image:
	 public.ecr.aws/z9d
	2n7e1/nginx:1.19.5
	            ports:
	              - name: http
	                container
	Port: 80
	``
	
	Note
	
	This is a NGINX sample configuration file that is deployed by using the NGINX Docker image. For more information, see [How to use the official NGINX Docker image](#) in the Docker documentation.	

Deploy the Kubernetes deployment manifest file.	Run the following command to apply the deployment manifest file to your Amazon EKS cluster: `kubectl apply -f <your_deployment_f ile_name>`	DevOps engineer

Task	Description	Skills required

Create the Kubernetes service manifest file.	Create a service manifest file by modifying the following sample file according to your requirements.
	
	`apiVersion: v1`
	`kind: Service`
	`metadata:`
	`  name: sample-service`
	`  annotations:`
	`    service.beta.kubernetes.io/aws-load-balancer-type: nlb`
	`    service.beta.kubernetes.io/aws-load-balancer-internal: "true"`
	`spec:`
	`  ports:`
	`    - port: 80`
	`      targetPort: 80`
	`      protocol: TCP`
	`  type: LoadBalancer`
	`  selector:`
	`    app: nginx`
	
	Important
	Make sure that you included the following `annotations` to define an internal Network Load Balancer:
		DevOps engineer

Task	Description	Skills required
	`service.beta.kubernetes.io/aws-load-balancer-type: nlb service.beta.kubernetes.io/aws-load-balancer-internal: "true"`	
Deploy the Kubernetes service manifest file.	Run the following command to apply the service manifest file to your Amazon EKS cluster: `kubectl apply -f <your_service_file_name>`	DevOps engineer

Create the endpoints

Task	Description	Skills required
Record the Network Load Balancer's name.	Run the following command to retrieve the name of the Network Load Balancer: `kubectl get svc sample-service -o wide` Record the Network Load Balancer's name, which is required to create an AWS PrivateLink endpoint.	DevOps engineer
Create an AWS PrivateLink endpoint.	Sign in to the AWS Management Console, open	Cloud administrator

Task	Description	Skills required
	the Amazon VPC console, and then create an AWS PrivateLink endpoint. Associate this endpoint with the Network Load Balancer, this makes the application privately available to customers. For more information, see [VPC endpoint services (AWS PrivateLink)]() in the Amazon VPC documentation. **Important** If the consumer account requires access to the application, the consumer account's [AWS account ID]() must be added to the allowed principals list for the AWS PrivateLink endpoint configuration. For more information, see [Adding and removing permissions for your endpoint service]() in the Amazon VPC documentation.	

Task	Description	Skills required
Create a VPC endpoint.	On the Amazon VPC console, choose **Endpoint Services**, and then choose **Create Endpoint Service**. Create a VPC endpoint for the AWS PrivateLink endpoint. The VPC endpoint's fully qualified domain name (FQDN) points to the FQDN for the AWS PrivateLink endpoint. This creates an elastic network interface to the VPC endpoint service that the DNS endpoints can access.	Cloud administrator

Activate mTLS in AWS App Mesh using AWS Private CA on Amazon EKS

Omar Kahil, Emmanuel Saliu, Muhammad Shahzad, and Andy Wong, Amazon Web Services

Summary

This pattern shows how to implement Mutual Transport Layer Security (mTLS) on Amazon Web Services (AWS) using certificates from AWS Private Certificate Authority (AWS Private CA) in AWS App Mesh. It uses the Envoy secret discovery service (SDS) API through the Secure Production Identity Framework for Everyone (SPIFFE). SPIFFE is a Cloud Native Computing Foundation (CNCF) open-source project with wide community support that provides fine-grained and dynamic workload identity management. To implement SPIFFE standards, use the SPIRE SPIFFE runtime environment.

Using mTLS in App Mesh offers two-way peer authentication, because it adds a layer of security over TLS and allows services in the mesh to verify the client that's making the connection. The client in the client-server relationship also provides an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client. This helps to verify if the certificate is issued by a trusted certificate authority (CA) and if the certificate is a valid one.

Prerequisites and limitations

Prerequisites

- An Amazon Elastic Kubernetes Service (Amazon EKS) cluster with self-managed or managed node groups
- App Mesh controller deployed on the cluster with SDS activated
- A private certificate from AWS Certificate Manager (ACM) that is issued by AWS Private CA

Limitations

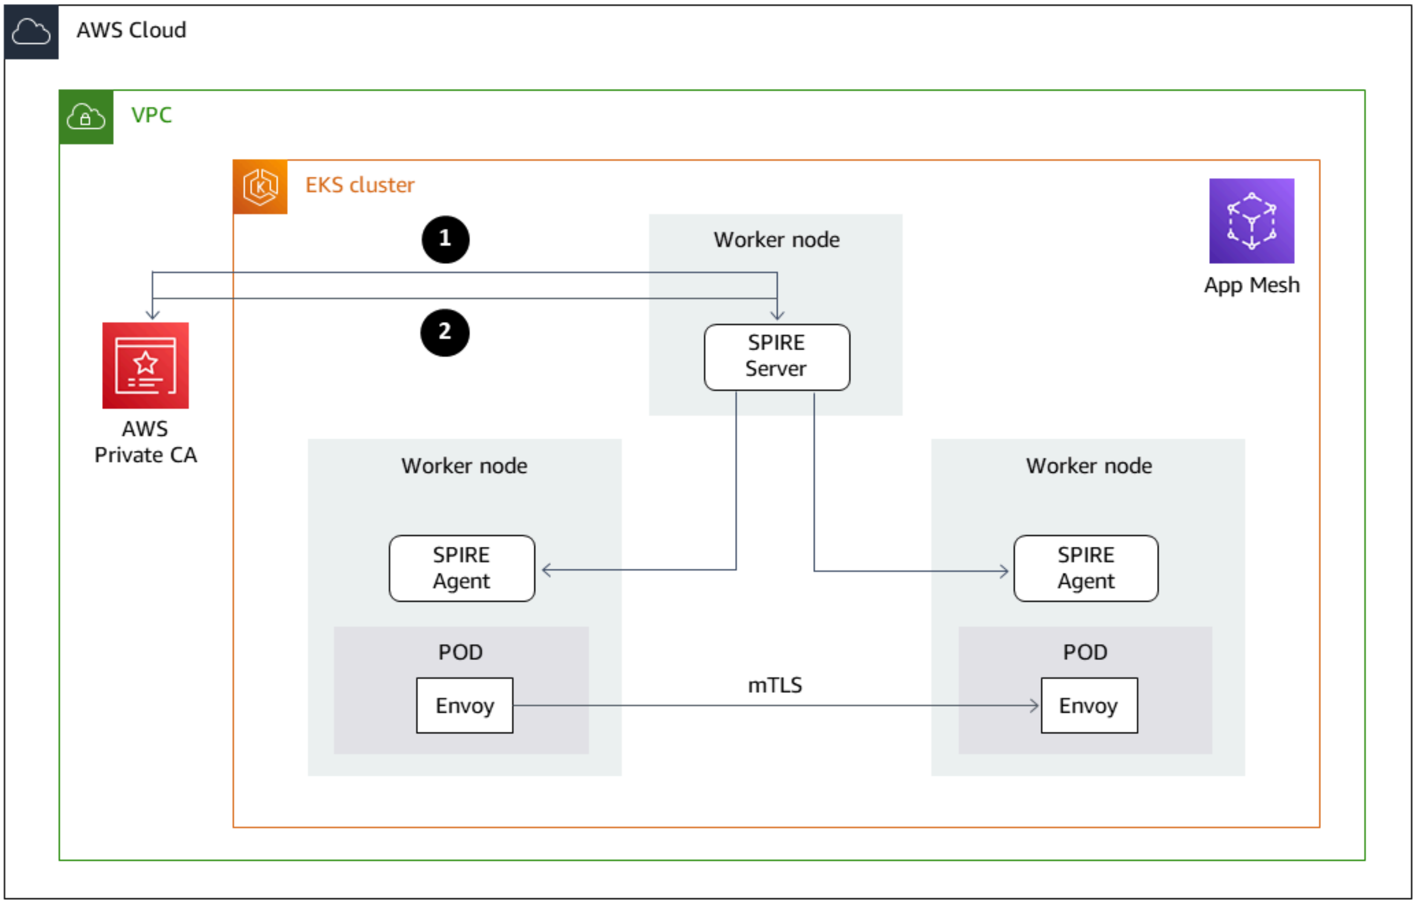
- SPIRE cannot be installed on AWS Fargate because the SPIRE Agent must be run as a Kubernetes DaemonSet.

Product versions

- AWS App Mesh Controller chart 1.3.0 or later

Architecture

The following diagram shows the EKS cluster with App Mesh in the VPC. The SPIRE server in one worker node communicates with the SPIRE Agents in other worker nodes, and with AWS Private CA. Envoy is used for mTLS communication between the SPIRE Agent worker nodes.



The diagram illustrates the following steps:

1. Certificate is issued.
2. Request cert signing and certificate.

Tools

AWS services

- [AWS Private CA](#) – AWS Private Certificate Authority (AWS Private CA) enables creation of private certificate authority (CA) hierarchies, including root and subordinate CAs, without the investment and maintenance costs of operating an on-premises CA.

- AWS App Mesh – AWS App Mesh is a service mesh that makes it easier to monitor and control services. App Mesh standardizes how your services communicate, giving you consistent visibility and network traffic controls for every service in an application.
- Amazon EKS – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

Other tools

- Helm – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster. This pattern uses Helm to deploy AWS App Mesh Controller.
- AWS App Mesh Controller chart – AWS App Mesh Controller chart is used by this pattern to enable AWS App Mesh on Amazon EKS.

Epics

Set up the environment

Task	Description	Skills required
Set up App Mesh with Amazon EKS.	Follow base deployment steps that are provided in the repository.	DevOps engineer
Install SPIRE.	Install SPIRE on the EKS cluster by using spire_set up.yaml.	DevOps engineer
Install the AWS Private CA certificate.	Create and install a certifica te for your private root CA by following the instructions in the AWS documentation.	DevOps engineer
Grant permissions to the cluster node instance role.	To attach policies to the cluster node instance role, use the code that's in the	DevOps engineer

Task	Description	Skills required
	Additional information section.	
Add the SPIRE plugin for AWS Private CA.	To add the plugin to the SPIRE server configuration, use the code that's in the Additional information section. Replace the `certificate_authority_arn` Amazon Resource Name (ARN) to your private CA ARN. The signing algorithm used must be the same as the signing algorithm on the private CA. Replace `your_region` with your AWS Region. For more information about the plugin, see Server plugin: UpstreamAuthority "aws_pca".	DevOps engineer
Update bundle.cert.	After you create the SPIRE server, a `spire-bundle.yaml` file will be created. Change the `bundle.crt` value in the `spire-bundle.yaml` file from the private CA to the public certificate.	DevOps engineer

Deploy and register the workloads

Task	Description	Skills required
Register node and workload entries with SPIRE.	To register node and workload (services) with SPIRE Server, use the code in the [repository]().	DevOps engineer
Create a mesh in App Mesh with mTLS activated.	Create a new mesh in App Mesh with all the component s for your microservices application (for example, virtual service, virtual router, and virtual nodes).	DevOps engineer
Inspect the registered entries.	You can inspect the registere d entries for your nodes and workloads by running the following command. `kubectl exec -n spire spire-server-0 -- /opt/spire/bin/spire-server entry show` This will show the entries for the SPIRE Agents.	DevOps engineer

Verify mTLS traffic

Task	Description	Skills required
Verify mTLS traffic.	1. From the frontend service, send an HTTP header to the backend service, and verify a successful response	DevOps engineer

Task	Description	Skills required

	with the services that are registered in SPIRE.
	2. For mutual TLS authentication, you can inspect the `ssl.handshake` statistic by running the following command.
	`kubectl exec -it $POD -n $NAMESPACE -c envoy -- curl http://localhost:9901/stats | grep ssl.handshake`
	After running the previous command, you should see the listener `ssl.handshake` count, which will look similar to the following example:
	`listener.0.0.0.0_15000.ssl.handshake: 2`	

Task	Description	Skills required
Verify that certificates are being issued from AWS Private CA.	You can check that the plugins have been configure d correctly and certificates are being issued from your upstream private CA by viewing the logs in your SPIRE server. Run the following command. `kubectl logs spire-server-0 -n spire` Then view the logs that are produced. This code assumes that your server is named `spire-server-0` and is hosted in your spire namespace. You should see successful loading of the plugins and a connection being made to your upstream private CA.	DevOps engineer

Automate backups for Amazon RDS for PostgreSQL DB instances by using AWS Batch

Kirankumar Chandrashekar, Amazon Web Services

Summary

Backing up your PostgreSQL databases is an important task and can typically be completed with the pg_dump utility, which uses the COPY command by default to create a schema and data dump of a PostgreSQL database. However, this process can become repetitive if you require regular backups for multiple PostgreSQL databases. If your PostgreSQL databases are hosted in the cloud, you can also take advantage of the automated backup feature provided by Amazon Relational Database Service (Amazon RDS) for PostgreSQL as well. This pattern describes how to automate regular backups for Amazon RDS for PostgreSQL DB instances using the pg_dump utility.

Note: The instructions assume that you're using Amazon RDS. However, you can also use this approach for PostgreSQL databases that are hosted outside Amazon RDS. To take backups, the AWS Lambda function must be able to access your databases.

A time-based Amazon CloudWatch Events event initiates a Lambda function that searches for specific backup tags applied to the metadata of the PostgreSQL DB instances on Amazon RDS. If the PostgreSQL DB instances have the **bkp:AutomatedDBDump = Active** tag and other required backup tags, the Lambda function submits individual jobs for each database backup to AWS Batch.

AWS Batch processes these jobs and uploads the backup data to an Amazon Simple Storage Service (Amazon S3) bucket. This pattern uses a Dockerfile and an entrypoint.sh file to build a Docker container image that is used to make backups in the AWS Batch job. After the backup process is complete, AWS Batch records the backup details to an inventory table on Amazon DynamoDB. As an additional safeguard, a CloudWatch Events event initiates an Amazon Simple Notification Service (Amazon SNS) notification if a job fails in AWS Batch.

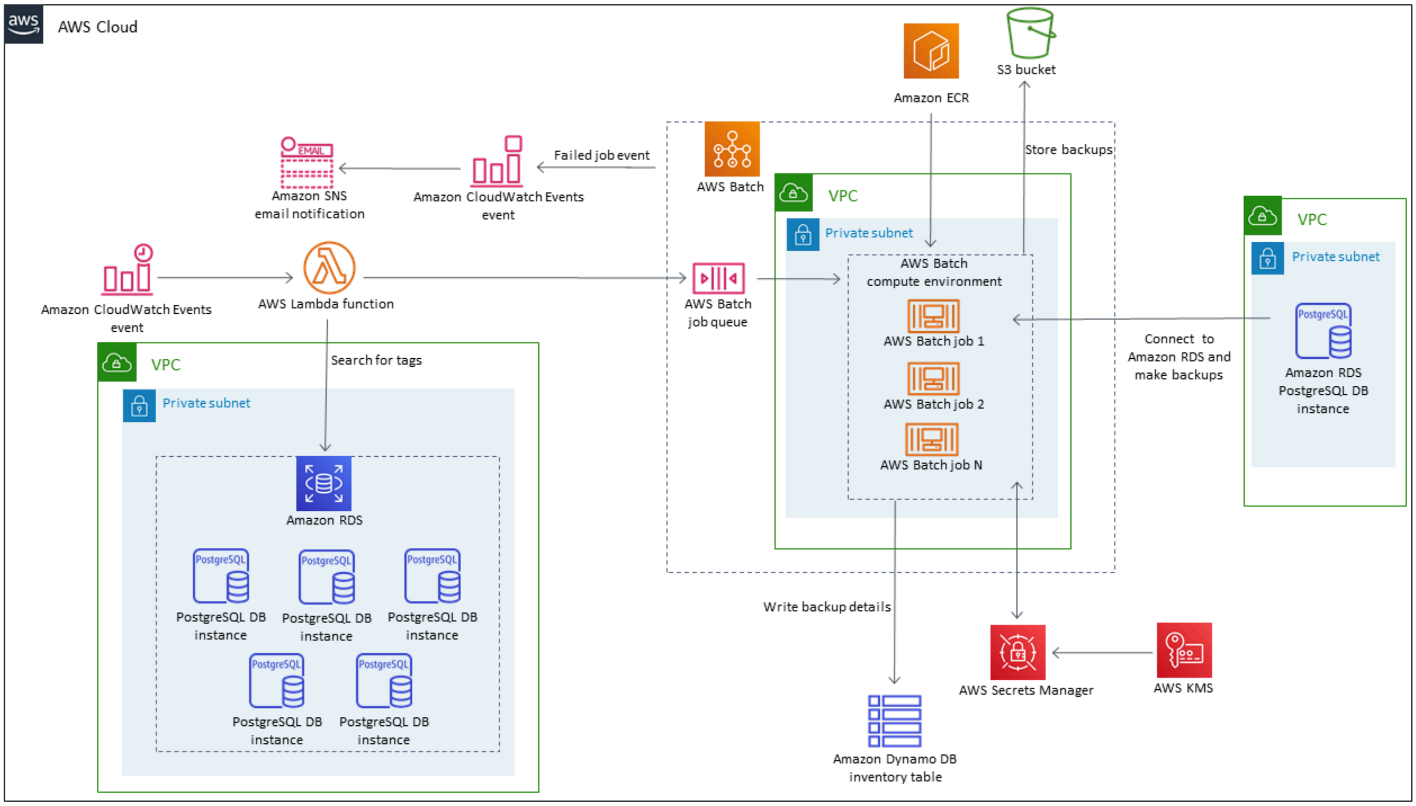
Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing managed or unmanaged compute environment. For more information, see Managed and unmanaged compute environments in the AWS Batch documentation.

- [AWS Command Line Interface (CLI) version 2 Docker image](), installed and configured.
- Existing Amazon RDS for PostgreSQL DB instances.
- An existing S3 bucket.
- [Docker](), installed and configured on Linux, macOS, or Windows.
- Familiarity with coding in Lambda.

Architecture



Technology stack

- Amazon CloudWatch Events
- Amazon DynamoDB
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon RDS
- Amazon SNS
- Amazon S3

- AWS Batch
- AWS Key Management Service (AWS KMS)
- AWS Lambda
- AWS Secrets Manager
- Docker

Tools

- Amazon CloudWatch Events – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- Amazon DynamoDB – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- Amazon RDS – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- AWS Batch – AWS Batch helps you run batch computing workloads on the AWS Cloud.
- AWS KMS – AWS Key Management Service (AWS KMS) is a managed service that makes it easy for you to create and control the encryption keys used to encrypt your data.
- AWS Lambda – Lambda is a compute service that helps you run code without provisioning or managing servers.
- AWS Secrets Manager – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Docker – Docker helps developers easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Your PostgreSQL DB instances on Amazon RDS must have tags applied to their metadata. The Lambda function searches for tags to identify DB instances that should be backed up, and the following tags are typically used.

Tag	Description
bkp:AutomatedDBDump = Active	Identifies an Amazon RDS DB instance as a candidate for backups.
bkp:AutomatedBackupSecret = <secret_name >	Identifies the Secrets Manager secret that contains the Amazon RDS login credentials.
bkp:AutomatedDBDumpS3Bucket = <s3_bucket_name>	Identifies the S3 bucket to send backups to.
bkp:AutomatedDBDumpFrequency bkp:AutomatedDBDumpTime	Identify the frequency and times when databases should be backed up.
bkp:pgdumpcommand = <pgdump_command>	Identifies the databases for which the backups need to be taken.

Epics

Create an inventory table in DynamoDB

Task	Description	Skills required
Create a table in DynamoDB.	Sign in to the AWS Management Console, open the Amazon DynamoDB console, and create a table. For help with this and other stories, see the *Related resources* section.	Cloud administrator, Database administrator
Confirm that the table was created.	Run the `aws dynamodb describe-table --table-name <table-name> | grep TableStatus` command. If the table exists, the command will	Cloud administrator, Database administrator

Task	Description	Skills required
	return the `"TableSta tus": "ACTIVE",` result.	

Create an SNS topic for failed job events in AWS Batch

Task	Description	Skills required
Create an SNS topic.	Open the Amazon SNS console, choose **Topics**, and create an SNS topic with the name `JobFailedAlert` . Subscribe an active email address to the topic, and check your email inbox to confirm the SNS subscription email from AWS Notifications.	Cloud administrator
Create a failed job event rule for AWS Batch.	Open the Amazon CloudWatc h console, choose **Events**, and then choose **Create rule**. Choose **Show advanced options**, and choose **Edit**. For **Build a pattern that selects events for processin g by your targets**, replace the existing text with the "Failed job event" code from the *Additional information* section. This code defines a CloudWatch Events rule that initiates when AWS Batch has a `Failed` event.	Cloud administrator
Add event rule target.	In **Targets**, choose **Add targets**, and choose the	Cloud administrator

Task	Description	Skills required
	`JobFailedAlert` SNS topic. Configure the remaining details and create the Cloudwatch Events rule.	

Build a Docker image and push it to an Amazon ECR repository

Task	Description	Skills required
Create an Amazon ECR repository.	Open the Amazon ECR console and choose the AWS Region in which you want to create your repository. Choose **Repositories**, and then choose **Create repository**. Configure the repository according to your requirements.	Cloud administrator
Write a Dockerfile.	Sign in to Docker and use the "Sample Dockerfile" and "Sample entrypoint.sh file" from the *Additional information* section to build a Dockerfile.	DevOps engineer
Create a Docker image and push it to the Amazon ECR repository.	Build the Dockerfile into a Docker image and push it to the Amazon ECR repository. For help with this story, see the *Related resources* section.	DevOps engineer

Create the AWS Batch components

Task	Description	Skills required
Create an AWS Batch job definition.	Open the AWS Batch console and create a job definition that includes the Amazon ECR repository's Uniform Resource Identifier (URI) as the property `Image`.	Cloud administrator
Configure the AWS Batch job queue.	On the AWS Batch console, choose **Job queues**, and then choose **Create queue**. Create a job queue that will store jobs until AWS Batch runs them on the resources within your compute environment. Important: Make sure you write logic for AWS Batch to record the backup details to the DynamoDB inventory table.	Cloud administrator

Create and schedule a Lambda function

Task	Description	Skills required
Create a Lambda function to search for tags.	Create a Lambda function that searches for tags on your PostgreSQL DB instances and identifies backup candidate s. Make sure your Lambda function can identify the `bkp:AutomatedDBDump = Active` tag and all other	DevOps engineer

Task	Description	Skills required
	required tags. Important: The Lambda function must also be able to add jobs to the AWS Batch job queue.	
Create a time-based CloudWatch Events event.	Open the Amazon CloudWatch console and create a CloudWatch Events event that uses a cron expression to run your Lambda function on a regular schedule. Important: All scheduled events use the UTC time zone.	Cloud administrator

Test the backup automation

Task	Description	Skills required
Create an Amazon KMS key.	Open the Amazon KMS console and create a KMS key that can be used to encrypt the Amazon RDS credentials stored in AWS Secrets Manager.	Cloud administrator
Create an AWS Secrets Manager secret.	Open the AWS Secrets Manager console and store your Amazon RDS for PostgreSQL database credentials as a secret.	Cloud administrator
Add the required tags to the PostgreSQL DB instances.	**Important** Open the Amazon RDS console and	Cloud administrator

Task	Description	Skills required
	add tags to the PostgreSQL DB instances that you want to automatically back up. You can use the tags from the table in the *Tools* section. If you require backups from multiple PostgreSQL databases within the same Amazon RDS instance, then use `-d test:-d test1` as the value for the `bkp:pgdumpcommand` tag. `test` and `test1` are database names. Make sure that there is no space after the colon (:).	

Task	Description	Skills required
Verify the backup automation.	To verify the backup automation, you can either invoke the Lambda function or wait for the backup schedule to begin. After the backup process is complete, check that the DynamoDB inventory table has a valid backup entry for your PostgreSQL DB instances. If they match, then the backup automation process is successful.	Cloud administrator

Automate deployment of Node Termination Handler in Amazon EKS by using a CI/CD pipeline

Sandip Gangapadhyay, Sandeep Gawande, Viyoma Sachdeva, Pragtideep Singh, and John Vargas, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

On the Amazon Web Services (AWS) Cloud, you can use AWS Node Termination Handler, an open-source project, to handle Amazon Elastic Compute Cloud (Amazon EC2) instance shutdown within Kubernetes gracefully. AWS Node Termination Handler helps to ensure that the Kubernetes control plane responds appropriately to events that can cause your EC2 instance to become unavailable. Such events include the following:

- EC2 instance scheduled maintenance
- Amazon EC2 Spot Instance interruptions
- Auto Scaling group scale in
- Auto Scaling group rebalancing across Availability Zones
- EC2 instance termination through the API or the AWS Management Console

If an event isn't handled, your application code might not stop gracefully. It also might take longer to recover full availability, or it might accidentally schedule work to nodes that are going down. The `aws-node-termination-handler` (NTH) can operate in two different modes: Instance Metadata Service (IMDS) or Queue Processor. For more information about the two modes, see the Readme file.

This pattern uses AWS CodeCommit, and it automates the deployment of NTH by using Queue Processor through a continuous integration and continuous delivery (CI/CD) pipeline.

> **Note**
>
> If you're using EKS managed node groups, you don't need the `aws-node-termination-handler`.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A web browser that is supported for use with the AWS Management Console. See the list of supported browsers.
- AWS Cloud Development Kit (AWS CDK) installed.
- `kubectl`, the Kubernetes command line tool, installed.
- `eksctl`, the AWS Command Line Interface (AWS CLI) for Amazon Elastic Kubernetes Service (Amazon EKS), installed.
- A running EKS cluster with version 1.20 or later.
- A self-managed node group attached to the EKS cluster. To create an Amazon EKS cluster with a self-managed node group, run the following command.

```
eksctl create cluster --managed=false --region <region> --name <cluster_name>
```

  For more information on `eksctl`, see the eksctl documentation.
- AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. For more information, see Creating an IAM OIDC provider for your cluster.

Limitations

- You must use an AWS Region that supports the Amazon EKS service.

Product versions

- Kubernetes version 1.20 or later
- `eksctl` version 0.107.0 or later
- AWS CDK version 2.27.0 or later

Architecture

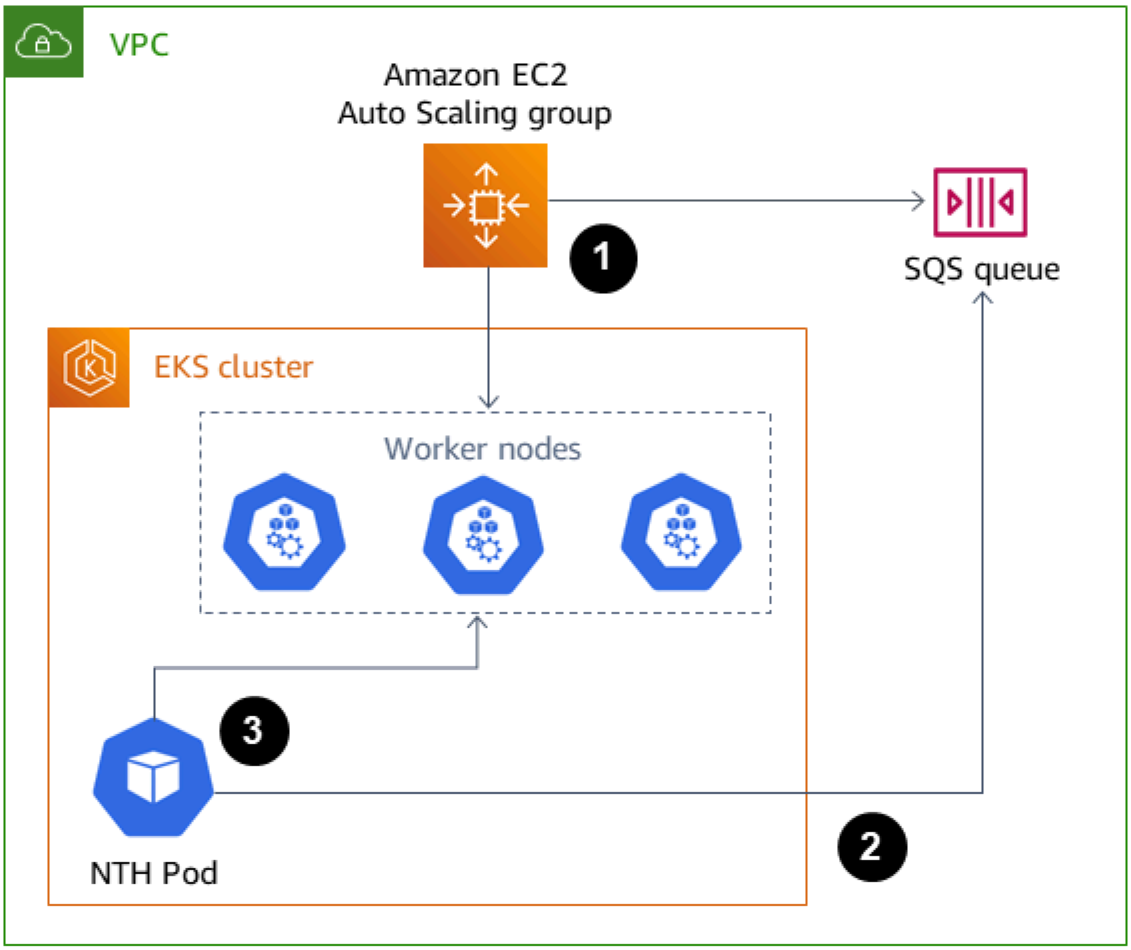
Target technology stack

- A virtual private cloud (VPC)

- An EKS cluster
- Amazon Simple Queue Service (Amazon SQS)
- IAM
- Kubernetes

Target architecture

The following diagram shows the high-level view of the end-to-end steps when the node termination is started.



The workflow shown in the diagram consists of the following high-level steps:

1. The automatic scaling EC2 instance terminate event is sent to the SQS queue.
2. The NTH Pod monitors for new messages in the SQS queue.
3. The NTH Pod receives the new message and does the following:

- Cordons the node so that new pod does not run on the node.
- Drains the node, so that the existing pod is evacuated
- Sends a lifecycle hook signal to the Auto Scaling group so that the node can be terminated.

Automation and scale

- Code is managed and deployed by AWS CDK, backed by AWS CloudFormation nested stacks.
- The Amazon EKS control plane runs across multiple Availability Zones to ensure high availability.
- For automatic scaling, Amazon EKS supports the Kubernetes Cluster Autoscaler and Karpenter.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- Amazon EC2 Auto Scaling helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

Other tools

- kubectl is a Kubernetes command line tool for running commands against Kubernetes clusters. You can use kubectl to deploy applications, inspect and manage cluster resources, and view logs.

Code

The code for this pattern is available in the deploy-nth-to-eks repo on GitHub.com. The code repo contains the following files and folders.

- `nth folder` – The Helm chart, values files, and the scripts to scan and deploy the AWS CloudFormation template for Node Termination Handler.
- `config/config.json` – The configuration parameter file for the application. This file contains all the parameters needed for CDK to be deployed.
- `cdk` – AWS CDK source code.
- `setup.sh` – The script used to deploy the AWS CDK application to create the required CI/CD pipeline and other required resources.
- `uninstall.sh` – The script used to clean up the resources.

To use the example code, follow the instructions in the *Epics* section.

Best practices

For best practices when automating AWS Node Termination Handler, see the following:

- EKS Best Practices Guides
- Node Termination Handler - Configuration

Epics

Set up your environment

Task	Description	Skills required
Clone the repo.	To clone the repo by using SSH (Secure Shell), run the following the command. `git clone git@github.com:aws-samples/deploy-nth-to-eks.git`	App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required

	To clone the repo by using HTTPS, run the following the command.
	
	`git clone https://github.com/aws-samples/deploy-nth-to-eks.git`
	
	Cloning the repo creates a folder named `deploy-nth-to-eks`.
	
	Change to that directory.
	
	`cd deploy-nth-to-eks`	

Set the kubeconfig file.	Set your AWS credentials in your terminal and confirm that you have rights to assume the cluster role. You can use the following example code. `aws eks update-kubeconfig --name <Cluster_Name> --region <region>--role-arn <Role_ARN>`	AWS DevOps, DevOps engineer, App developer

Deploy the CI/CD pipeline

Task	Description	Skills required
Set up the parameters.	In the `config/config.json` file, set up the following required parameters. • `pipelineName` : The name of the CI/CD pipeline to be created by AWS CDK (for example, `deploy-nth-to-eks-pipeline`). AWS CodePipeline will create a pipeline that has this name. • `repositoryName` : The AWS CodeCommit repo to be created (for example, `deploy-nth-to-eks-repo`). AWS CDK will create this repo and set it as the source for the CI/CD pipeline. **Note** This solution will create this CodeCommit repo and the branch (provided in the following branch parameter).	App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required
	• `branch`: The branch name in the repo (for example, `main`). A commit to this branch will initiate the CI/CD pipeline. • `cfn_scan_script` : The path of the script that will be used to scan the AWS CloudFormation template for NTH (`scan.sh`). This script exists in `nth` folder that will be part of the AWS CodeCommit repo. • `cfn_deploy_scrip t`: The path of the script that will be used to deploy the AWS CloudFormation template for NTH (`installApp.sh`). • `stackName` : The name of the CloudFormation stack to be deployed. • `eksClusterName` : The name of the existing EKS cluster. • `eksClusterRole` : The IAM role that will be used to access the EKS cluster for all Kubernetes API calls (for example, `clusteradmin`). Usually, this role is added in `aws-auth` `ConfigMap` .	

Task	Description	Skills required
	• `create_cluster_role` : To create the `eksClusterRole` IAM role, enter **yes**. If you want to provide an existing cluster role in the `eksClusterRole` parameter, enter **no**. • `create_iam_oidc_provider` : To create the IAM OIDC provider for your cluster, enter **yes**. If an IAM OIDC provider already exists, enter **no**. For more information, see [Creating an IAM OIDC provider for your cluster](#). • `AsgGroupName` : A comma-separated list of Auto Scaling group names that are part of the EKS cluster (for example, `ASG_Group_1,ASG_Group_2`). • `region`: The name of the AWS Region where the cluster is located (for example, `us-east-2`). • `install_cdk` : If AWS CDK isn't currently installed on the machine, enter **yes**. Run the `cdk --version` command to check whether the installed AWS CDK	

Task	Description	Skills required
	version is 2.27.0 or later. In that case, enter **no**. If you enter **yes**, the setup.sh script will run the `sudo npm install -g cdk@2.27.0` command to install AWS CDK on the machine. The script requires sudo permissio ns, so provide the account password when prompted.	
Create the CI/CD pipeline to deploy NTH.	Run the setup.sh script. `./setup.sh` The script will deploy the AWS CDK application that will create the CodeCommi t repo with example code, the pipeline, and CodeBuild projects based on the user input parameters in `config/config.json` file. This script will ask for the password as it installs npm packages with the sudo command.	App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required
Review the CI/CD pipeline.	Open the AWS Managemen t Console, and review the following resources created in the stack. • CodeCommit repo with the contents of the `nth` folder • AWS CodeBuild project `cfn-scan`, which will scan the CloudFormation template for vulnerabilities. • CodeBuild project `Nth-Deploy` , which will deploy the AWS CloudFormation template and the correspon ding NTH Helm charts through the AWS CodePipel ine pipeline. • A CodePipeline pipeline to deploy NTH. After the pipeline runs successfully, Helm release `aws-node-terminati on-handler` is installed in the EKS cluster. Also, a Pod named `aws-node-termination-handler` is running in the `kube-syst em` namespace in the cluster.	App developer, AWS DevOps, DevOps engineer

Test NTH deployment

Task	Description	Skills required
Simulate an Auto Scaling group scale-in event.	To simulate an automatic scaling scale-in event, do the following: 1. On the AWS console, open the **EC2 console, and choose Auto Scaling Groups.** 2. Select the Auto Scaling group that has same name as the one provided in `config/config.json` , and choose **Edit**. 3. Decrease **Desired and Minimum Capacity** by 1. 4. Choose **Update**.	
Review the logs.	During the scale-in event, the NTH Pod will cordon and drain the correspon ding worker node (the EC2 instance that will be terminated as part of the scale-in event). To check the logs, use the code in the *Additional information* section.	App developer, AWS DevOps, DevOps engineer

Clean up

Task	Description	Skills required
Clean up all AWS resources.	To clean up the resources created by this pattern, run the following command. `./uninstall.sh` This will clean up all the resources created in this pattern by deleting the CloudFormation stack.	DevOps engineer

Troubleshooting

Issue	Solution

The npm registry isn't set correctly.	During the installation of this solution, the script installs npm install to download all the required packages. If, during the installation, you see a message that says "Cannot find module," the npm registry might not be set correctly. To see the current registry setting, run the following command.
	`npm config get registry`
	To set the registry with `https://registry.npmjs.org/` , run the following command.
	`npm config set registry https://registry.npmjs.org`

Issue	Solution
Delay SQS message delivery.	As part of your troubleshooting, if you want to delay the SQS message delivery to NTH Pod, you can adjust the SQS delivery delay parameter. For more information, see Amazon SQS delay queues.

Related resources

- AWS Node Termination Handler source code
- EC2 workshop
- AWS CodePipeline
- Amazon Elastic Kubernetes Service (Amazon EKS)
- AWS Cloud Development Kit
- AWS CloudFormation

Additional information

1. Find the NTH Pod name.

```
kubectl get pods -n kube-system |grep aws-node-termination-handler
aws-node-termination-handler-65445555-kbqc7   1/1     Running   0          26m
kubectl get pods -n kube-system |grep aws-node-termination-handler
aws-node-termination-handler-65445555-kbqc7   1/1     Running   0          26m
```

2. Check the logs. An example log looks like the following. It shows that the node has been cordoned and drained before sending the Auto Scaling group lifecycle hook completion signal.

```
kubectl -n kube-system logs aws-node-termination-handler-65445555-kbqc7
022/07/17 20:20:43 INF Adding new event to the event store

Automatically build and deploy a Java application to Amazon EKS using a CI/CD pipeline

MAHESH RAGHUNANDANAN, Jomcy Pappachen, and James Radtke, Amazon Web Services

Summary

This pattern describes how to create a continuous integration and continuous delivery (CI/CD) pipeline that automatically builds and deploys a Java application with recommended DevSecOps practices to an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the AWS Cloud. This pattern uses a greeting application developed with a Spring Boot Java framework and that uses Apache Maven.

You can use this pattern's approach to build the code for a Java application, package the application artifacts as a Docker image, security scan the image, and upload the image as a workload container on Amazon EKS. This pattern's approach is useful if you want to migrate from a tightly coupled monolithic architecture to a microservices architecture. The approach also helps you to monitor and manage the entire lifecycle of a Java application, which ensures a higher level of automation and helps avoid errors or bugs.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured. For more information about this, see [Installing or updating to the latest version of the AWS CLI] in the AWS CLI documentation.

  AWS CLI version 2 must be configured with the same AWS Identity and Access Management (IAM) role that creates the Amazon EKS cluster, because only that role is authorized to add other IAM roles to the `aws-auth` `ConfigMap`. For information and steps to configure AWS CLI, see [Configuring settings] in the AWS CLI documentation.
- IAM roles and permissions with full access to AWS CloudFormation. For more information about this, see [Controlling access with IAM] in the AWS CloudFormation documentation.
- An existing Amazon EKS cluster, with details of the IAM role name and the Amazon Resource Name (ARN) of the IAM role for worker nodes in the EKS cluster.

- Kubernetes Cluster Autoscaler, installed and configured in your Amazon EKS cluster. For more information, see Scale cluster compute with Karpenter and Cluster Autoscaler in the Amazon EKS documentation.
- Access to code in the GitHub repository.

> **Important**
>
> AWS Security Hub is enabled as part of the AWS CloudFormation templates that are included in the code for this pattern. By default, after Security Hub is enabled, it comes with a 30–day free trial. After the trial, there is a cost associated with this AWS service. For more information about pricing, see AWS Security Hub pricing.

Product versions

- Helm version 3.4.2 or later
- Apache Maven version 3.6.3 or later
- BridgeCrew Checkov version 2.2 or later
- Aqua Security Trivy version 0.37 or later

Architecture

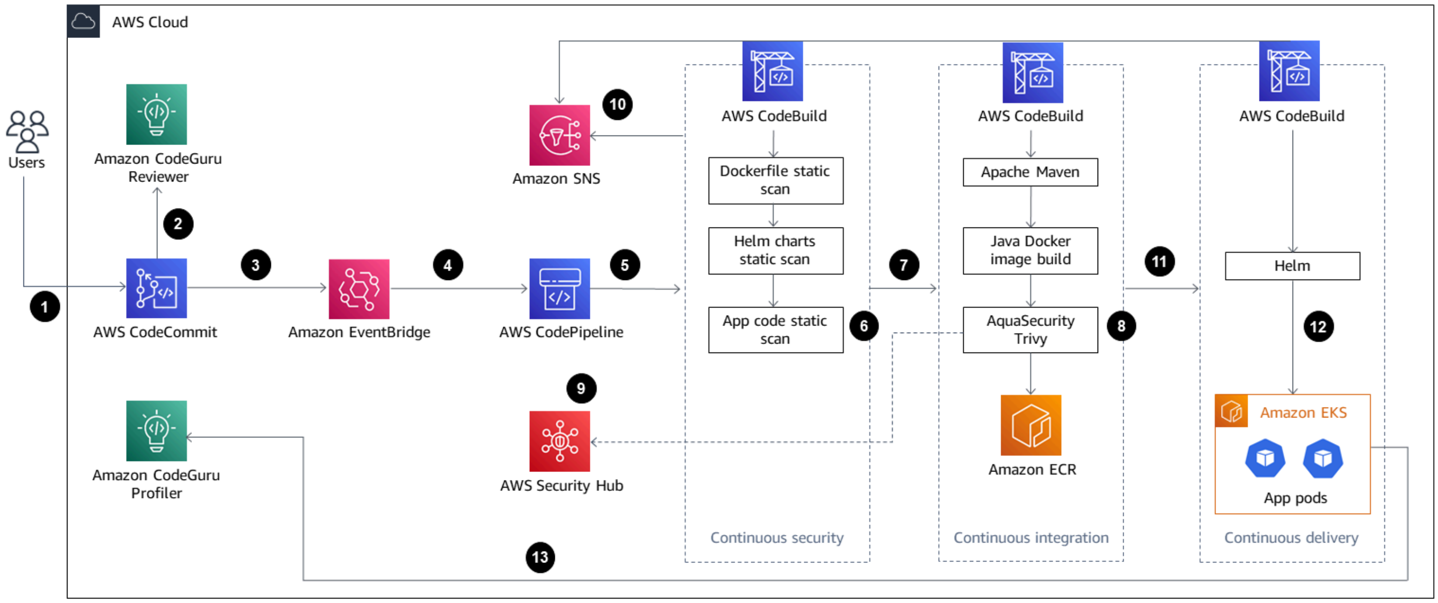
Technology stack

- AWS CodeBuild
- AWS CodeCommit

  Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more. However, this solution will work with any version control system (VCS) Git provider such as GitHub or GitLab with minimal changes.
- Amazon CodeGuru
- AWS CodePipeline
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon EKS

- Amazon EventBridge
- AWS Security Hub
- Amazon Simple Notification Service (Amazon SNS)

Target architecture



The diagram shows the following workflow:

1. The developer updates the Java application code in the base branch of the CodeCommit repository, which creates a pull request (PR).
2. As soon as the PR is submitted, Amazon CodeGuru Reviewer automatically reviews the code, analyzes it based on best practices for Java, and gives recommendations to the developer.
3. After the PR is merged to the base branch, an Amazon EventBridge event is created.
4. The EventBridge event initiates the CodePipeline pipeline, which starts.
5. CodePipeline runs the CodeSecurity Scan stage (continuous security).
6. AWS CodeBuild starts the security scan process in which the Dockerfile and Kubernetes deployment Helm files are scanned by using Checkov, and application source code is scanned based on incremental code changes. The application source code scan is performed by the CodeGuru Reviewer Command Line Interface (CLI) wrapper.
7. If the security scan stage is successful, the Build stage (continuous integration) is initiated.

8. In the Build stage, CodeBuild builds the artifact, packages the artifact to a Docker image, scans the image for security vulnerabilities by using Aqua Security Trivy, and stores the image in Amazon ECR.
9. The vulnerabilities detected from step 8 are uploaded to Security Hub for further analysis by developers or engineers. Security Hub provides an overview and recommendations for remediating the vulnerabilities.
10. Email notifications of sequential phases within the CodePipeline pipeline are sent through Amazon SNS.
11. After the continuous integration phases are complete, CodePipeline enters the Deploy stage (continuous delivery).
12. The Docker image is deployed to Amazon EKS as a container workload (pod) by using Helm charts.
13. The application pod is configured with Amazon CodeGuru Profiler agent, which sends the profiling data of the application (CPU, heap usage, and latency) to CodeGuru Profiler, which helps developers understand the behavior of the application.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

  Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more
- Amazon CodeGuru Profiler collects runtime performance data from your live applications, and provides recommendations that can help you fine-tune your application performance.
- Amazon CodeGuru Reviewer uses program analysis and machine learning to detect potential defects that are difficult for developers to find and offers suggestions for improving your Java and Python code.

- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources, including AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Security Hub provides a comprehensive view of your security state on AWS. It also helps you check your AWS environment against security industry standards and best practices.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other services

- Helm is an open-source package manager for Kubernetes.
- Apache Maven is a software project management and comprehension tool.
- BridgeCrew Checkov is a static code analysis tool for scanning infrastructure as code (IaC) files for misconfigurations that might lead to security or compliance problems.
- Aqua Security Trivy is a comprehensive scanner for vulnerabilities in container images, file systems, and Git repositories, in addition to configuration issues.

Code

The code for this pattern is available in the GitHub aws-codepipeline-devsecops-amazoneks repository.

Best practices

- This pattern follows IAM security best practices to apply the principle of least privilege for IAM entities across all phases of the solution. If you want to extend the solution with additional AWS services or third-party tools, we recommend that you review the section on applying least-privilege permissions in the IAM documentation.
- If you have multiple Java applications, we recommend that you create separate CI/CD pipelines for each application.
- If you have a monolith application, we recommend that you break the application into microservices where possible. Microservices are more flexible, they make it easier to deploy applications as containers, and they provide better visibility into the overall build and deployment of the application.

Epics

Set up the environment

Task	Description	Skills required
Clone the GitHub repository.	To clone the repository, run the following command. `git clone https://github.com/aws-samples/aws-codepipeline-devsecops-amazoneks`	App developer, DevOps engineer
Create an S3 bucket and upload the code.	1. Sign in to the AWS Management Console, open the Amazon S3 console, and then create an S3 bucket in the AWS Region where you plan to deploy this solution. For more information, see Creating a bucket in the	AWS DevOps, Cloud administrator, DevOps engineer

Task	Description	Skills required

	Amazon S3 documentation.
	2. In the S3 bucket, create a folder named `code`.
	3. Navigate to where you cloned the repository. To create a compressed version of the entire code with the .zip extension (`cicdstack.zip`) and validate the .zip file, run the following commands in order.
	`cd aws-codepipeline-devsecops-amazoneks`
	`python -m zipfile -c cicdstack.zip *`
	`python -m zipfile -t cicdstack.zip`
	Note
	If the `python` command fails and states that Python was not found, use `python3` instead.
	4. Upload the `cicdstack.zip` file to the code folder that you previously created in the S3 bucket.	

Task	Description	Skills required
Create an AWS CloudFormation stack.	1. Open the [AWS CloudFormation console](#) and choose **Create stack**. 2. In **Specify template**, choose **Upload a template file**, upload the `cf_templates/codecommit_ecr.yaml` file, and then choose **Next**. 3. In **Specify stack details**, enter the stack name, and then provide the following input parameter values: • `CodeCommitRepositoryBranchName` : The name of the branch where your code will reside (the default is `main`) • `CodeCommitRepositoryName` : The name of the CodeCommitrepository to create • `CodeCommitRepositoryS3Bucket` : The name of the S3 bucket where you created the code folder • `CodeCommitRepositoryS3BucketObjKey` : `code/cicdstack.zip`	AWS DevOps, DevOps engineer

Task	Description	Skills required
	• `ECRRepositoryName` : The name of the Amazon ECR repository to create 4. Choose **Next**, use the default settings for the **Configure stack options**, and then choose **Next**. 5. In the **Review** section, verify the template and stack details, and then choose **Create stack**. The stack is then created, including the CodeCommit and Amazon ECR repositories. 6. Note the names of the CodeCommit and Amazon ECR repositories, which will be required to set up the Java CI/CD pipeline.	
Validate the CloudFormation stack deployment.	1. Under **Stacks** on the CloudFormation console, verify the status of the CloudFormation stack that you deployed. The status of the stack should be **CREATE COMPLETE**. 2. From the console, validate that the CloudFormation and Amazon ECR repositories have been provisioned and are ready.	AWS DevOps, DevOps engineer

Task	Description	Skills required
Delete the S3 bucket.	Empty and delete the S3 bucket that you created earlier. For more information, see [Deleting a bucket](#) in the Amazon S3 documentation.	AWS DevOps, DevOps engineer

Configure the Helm charts

Task	Description	Skills required

Configure the Helm charts of your Java application.	1. In the location where you cloned the GitHub repository, navigate to the folder `helm_charts/aws-proserve-java-greeting` . In this folder, the `values.dev.yaml` file contains information about Kubernetes resources configuration that you can modify for your container deployments to Amazon EKS. Update the Docker repository parameter by providing your AWS account ID, AWS Region, and Amazon ECR repository name.
	`image:`
	`  repository: <account-id>.dkr.ecr.<region>.amazon`
		DevOps engineer

Task	Description	Skills required

	`aws.com/<app-ecr-repo-name>`
	2. The Java pod's service type is set to `LoadBalancer` .
	`service:`
	`  type: LoadBalancer`
	`  port: 80`
	`  targetPort: 8080`
	`  path: /hello`
	`  initialDelaySeconds: 60`
	`  periodSeconds: 30`
	To use a different service (for example, `NodePort`), you can change this parameter. For more information, see the [Kubernetes documentation](#).
	3. You can activate the [Kubernetes Horizontal Pod Autoscaler](#) by changing the `autoscaling` parameter to `enabled: true`.
	`autoscaling:`
	`  enabled: true`
	`  minReplicas: 1`
	`  maxReplicas: 100`
	`  targetCPUUtilizationPercentage: 80`
	`  # targetMemoryUtilizationPercentage: 80`	

Task	Description	Skills required
	4. You can enable different features for the Kubernetes workloads by changing the values in the `values.<ENV>.yaml` file, where <ENV> is your development, production, UAT, or QA environment.	

Validate Helm charts for syntax errors.	1. From the terminal, verify that Helm v3 is installed in your local workstation by running the following command.
	`helm --version`
	If Helm v3 isn't installed, install it.
	2. In the terminal, navigate to the Helm charts directory (`helm_charts/aws-proserve-java-greeting`), and run the following command.
	`helm lint . -f values.dev.yaml`
	This will check the Helm charts for any syntax errors.
		DevOps engineer

Set up the Java CI/CD pipeline

Task	Description	Skills required
Create the CI/CD pipeline.	1. Open the [AWS CloudFormation console](), and choose **Create stack**. 2. In **Specify template**, choose **Upload a template file**, upload the `cf_templates/build_deployment.yaml` template, and then choose **Next**. 3. In **Specify stack details**, specify the **Stack name**, and then provide the following values for the input parameters: • `CodeBranchName` : Branch name of the CodeCommit repository where your code resides • `EKSClusterName` : Name of your EKS cluster (not the `EKSCluster` ID) • `EKSCodeBuildAppName` : Name of the app Helm chart (`aws-proserve-java-greeting`) • `EKSWorkerNodeRoleARN` : ARN of the IAM role	AWS DevOps

Task	Description	Skills required
	assigned to the Amazon EKS worker nodes • `EKSWorkerNodeRoleName` : Name of the IAM role assigned to the Amazon EKS worker nodes • `EcrDockerRepository` : Name of the Amazon ECR repository where the Docker images of your code will be stored • `EmailRecipient` : Email address where build notifications should be sent • `EnvType`: Environment (for example, dev, test, or prod) • `SourceRepoName` : Name of the CodeCommit repository where your code resides 4. Choose **Next**. Use the default settings in **Configure stack options**, and then choose **Next**. 5. In the **Review** section, verify the CloudFormation template and stack details, and then choose **Next**. 6. Choose **Create stack**.	

Task	Description	Skills required
	7. During the CloudFormation stack deployment, the owner of the email address that you provided in the parameters will receive a message to subscribe to an SNS topic. To subscribe to Amazon SNS, the owner must choose the link in the message. 8. After the stack is created, open the **Outputs** tab of the stack, and then record the ARN value for the `EksCodeBuildkubeRoleARN` output key. This IAM ARN value will be required later when you provide permissions for the CodeBuild IAM role to deploy workloads in the Amazon EKS cluster.	

Activate integration between Security Hub and Aqua Security

Task	Description	Skills required
Turn on Aqua Security integration.	This step is required for uploading the Docker image vulnerability findings reported by Trivy to Security Hub. Because AWS CloudFormation doesn't support Security	AWS administrator, DevOps engineer

Task	Description	Skills required
	Hub integrations, this process must be done manually. 1. Open the [AWS Security Hub console](), and navigate to **Integrations**. 2. Search for Aqua Security, and select **Aqua Security: Aqua Security**. 3. Choose **Accept findings**.	

Configure CodeBuild to run Helm or kubectl commands

Task	Description	Skills required
Allow CodeBuild to run Helm or kubectl commands in the Amazon EKS cluster.	For CodeBuild to be authenticated to use Helm or `kubectl` commands with the Amazon EKS cluster, you must add the IAM roles to the `aws-auth ConfigMap` . In this case, add the ARN of the IAM role `EksCodeBuildkubeRoleARN` , which is the IAM role created for the CodeBuild service to access the Amazon EKS cluster and deploy workloads on it. This is a one-time activity. **Important** The following procedure must be	DevOps

Task	Description	Skills required

	completed before the deployment approval stage in CodePipeline.
	
	1. Open the `cf_templates/kube_aws_auth_configmap_patch.sh` shell script in your Amazon Linux or macOS environment.
	2. Authenticate to the Amazon EKS cluster by running the following command.
	`aws eks --region <aws-region> update-kubeconfig --name <eks-cluster-name>`
	3. Run the shell script by using the following command, replacing `<rolearn-eks-codebuild-kubectl>` with the ARN value of `EksCodeBuildkubeRoleARN` that you recorded earlier.
	`bash cf_templates/kube_aws_auth_configmap_patch.sh <rolearn-eks-codebuild-kubectl>`	

Task	Description	Skills required
	The `aws_auth ConfigMap` is configured, and access is granted.	

Validate the CI/CD pipeline

Task	Description	Skills required

Verify that the CI/CD pipeline automatically initiates.	1. The CodeSecurity Scan stage in the pipeline will usually fail if Checkov detects vulnerabilities in the Dockerfile or Helm charts. However, the purpose of this example is to establish a process of identifying potential security vulnerabilities rather than fixing it through the CI/CD pipeline, typically a DevSecOps process. In the file `buildspec/buildspec_secscan.yaml`, the `checkov` command uses the `--soft-fail` flag to avoid pipeline failure.
	`- echo -e "\n Running Dockerfile Scan"`
	`- checkov -f code/app/Dockerfile --framework dockerfile --soft-fail --summary-position bottom`
		DevOps

Task	Description	Skills required
	``` - echo -e "\n Running Scan of Helm Chart files" - cp -pv helm_charts/$EKS_CODEBUILD_APP_NAME/values.dev.yaml helm_charts/$EKS_CODEBUILD_APP_NAME/values.yaml - checkov -d helm_charts/$EKS_CODEBUILD_APP_NAME --framework helm --soft-fail --summary-position bottom - rm -rfv helm_charts/$EKS_CODEBUILD_APP_NAME/values.yaml ``` For the pipeline to fail when vulnerabilities are reported for the Dockerfile and Helm charts, the `--soft-fail` option must be removed from the `checkov` command. Developers or engineers can then fix the vulnerabilities and commit the changes to the CodeCommit source code repository. 2. Similar to CodeSecurity Scan, the Build stage uses Aqua Security Trivy to identify `HIGH` and `CRITICAL` Docker image	

Task	Description	Skills required
	vulnerabilities before pushing the application to Amazon ECR. `- AWS_REGION=$AWS_DEFAULT_REGION AWS_ACCOUNT_ID=$AWS_ACCOUNT_ID trivy -d image --no-progress --ignore-unfixed --exit-code 0 --severity HIGH,CRITICAL --format template --template "@securityhub/asff.tpl" -o securityhub/report.asff $AWS_ACCOUNT_ID.dkr.ecr.$AWS_DEFAULT_REGION.amazonaws.com/$IMAGE_REPO_NAME:$CODEBUILD_RESOLVED_SOURCE_VERSION` In this example, the pipeline doesn't fail when Docker image vulnerabilities are reported, because the `trivy` command in the `buildspec/buildspec.yml` file includes the flag `--exit-code` with a value of`0`. For the pipeline to fail when `HIGH` and `CRTICAL` vulnerabilities are reported, change the value of `--exit-code` to 1. Developers or engineers	

Task	Description	Skills required
	can then fix the vulnerabilities and commit the changes to the CodeCommit source code repository. 3. Docker image vulnerabilities reported by Aqua Security Trivy are uploaded to Security Hub. On the Security Hub console, navigate to **Findings**. Filter the findings with **Record State = Active** and **Product = Aqua Security**. This lists the Docker image vulnerabilities in Security Hub. It can take 15 minutes to an hour for vulnerabilities to appear in Security Hub. For more information about starting the pipeline by using CodePipeline, see [Start a pipeline in]CodePipeline, [Start a pipeline manually], and [Start a pipeline on a schedule] in the CodePipeline documentation.	

Task	Description	Skills required
Approve the deployment.	1. After the build phase is complete, there is a deployment approval gate. The reviewer or a release manager should inspect the build, and, if all requirements are met, approve it. This is the recommended approach for teams that use continuous delivery for application deployment. 2. After approval, the pipeline initiates the Deploy stage. 3. After the Deploy stage is successful, the CodeBuild log for this stage provides the URL of the application. Use the URL to validate the readiness of the applicati on.	DevOps

Task	Description	Skills required
Validate application profiling.	After the deployment is complete and the application pod is deployed in Amazon EKS, the Amazon CodeGuru Profiler agent that is configured in the application will try to send profiling data of the application (CPU, heap summary, latency, and bottlenecks) to CodeGuru Profiler. For the initial deployment of an application, CodeGuru Profiler takes about 15 minutes to visualize the profiling data.	AWS DevOps

Related resources

- AWS CodePipeline documentation
- Scanning images with Trivy in an AWS CodePipeline (AWS blog post)
- Improving your Java applications using Amazon CodeGuru Profiler (AWS blog post)
- AWS Security Finding Format (ASFF) syntax
- Amazon EventBridge event patterns
- Helm upgrade

Additional information

- AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more. This solution will also work with any version control system (VCS) Git provider such as GitHub or GitLab with minimal changes.

- CodeGuru Profiler should not be confused with the AWS X-Ray service in terms of functionality. We recommend that you use CodeGuru Profiler to identify the most expensive lines of codes that might cause bottlenecks or security issues, and fix them before they become a potential risk. The X-Ray service is for application performance monitoring.
- In this pattern, event rules are associated with the default event bus. If needed, you can extend the pattern to use a custom event bus.
- This pattern uses CodeGuru Reviewer as a static application security testing (SAST) tool for application code. You can also use this pipeline for other tools, such as SonarQube or Checkmarx. You can add the scan setup instructions for any of these tools to `buildspec/buildspec_secscan.yaml` to replace the CodeGuru scan instructions.

Create an Amazon ECS task definition and mount a file system on EC2 instances using Amazon EFS

Durga Prasad Cheepuri, Amazon Web Services

Summary

This pattern provides code samples and steps to create an Amazon Elastic Container Service (Amazon ECS) task definition that runs on Amazon Elastic Compute Cloud (Amazon EC2) instances in the Amazon Web Services (AWS) Cloud, while using Amazon Elastic File System (Amazon EFS) to mount a file system on those EC2 instances. Amazon ECS tasks that use Amazon EFS automatically mount the file systems that you specify in the task definition and make these file systems available to the task's containers across all Availability Zones in an AWS Region.

To meet your persistent storage and shared storage requirements, you can use Amazon ECS and Amazon EFS together. For example, you can use Amazon EFS to store persistent user data and application data for your applications with active and standby ECS container pairs running in different Availability Zones for high availability. You can also use Amazon EFS to store shared data that can be accessed in parallel by ECS containers and distributed job workloads.

To use Amazon EFS with Amazon ECS, you can add one or more volume definitions to a task definition. A volume definition includes an Amazon EFS file system ID, access point ID, and a configuration for AWS Identity and Access Management (IAM) authorization or Transport Layer Security (TLS) encryption in transit. You can use container definitions within task definitions to specify the task definition volumes that get mounted when the container runs. When a task that uses an Amazon EFS file system runs, Amazon ECS ensures that the file system is mounted and available to the containers that need access to it.

Prerequisites and limitations

Prerequisites

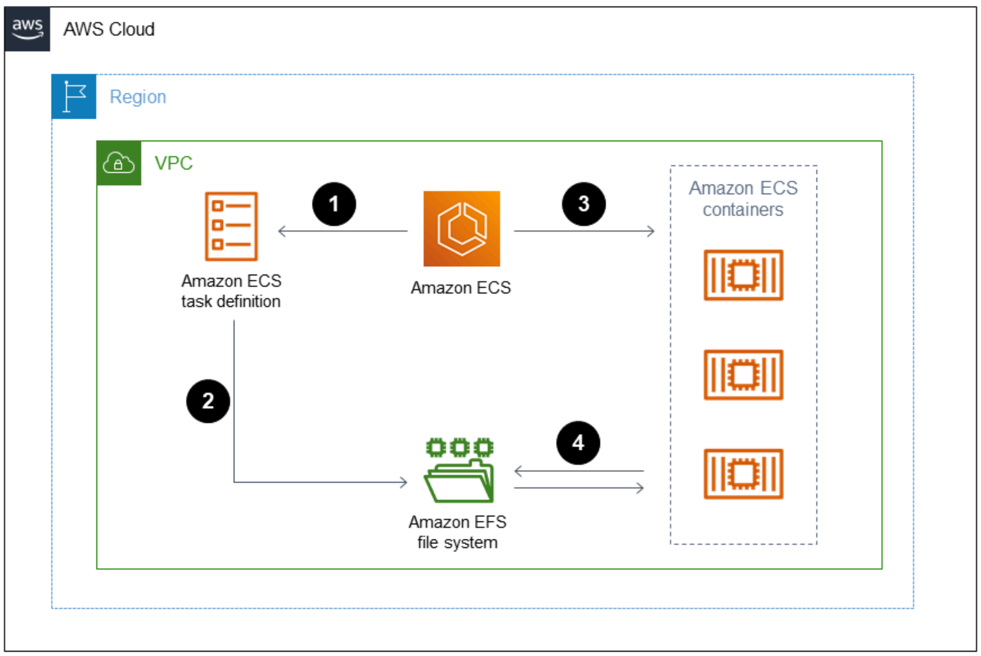
- An active AWS account
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router
- (Recommended) Amazon ECS container agent 1.38.0 or later for compatibility with Amazon EFS access points and IAM authorization features (For more information, see the AWS blog post New for Amazon EFS – IAM Authorization and Access Points.)

Limitations

- Amazon ECS container agent versions earlier than 1.35.0 don't support Amazon EFS file systems for tasks that use the EC2 launch type.

Architecture

The following diagram shows an example of an application that uses Amazon ECS to create a task definition and mount an Amazon EFS file system on EC2 instances in ECS containers.



The diagram shows the following workflow:

1. Create an Amazon EFS file system.
2. Create a task definition with a container.
3. Configure the container instances to mount the Amazon EFS file system. The task definition references the volume mounts, so the container instance can use the Amazon EFS file system. ECS tasks have access to the same Amazon EFS file system, regardless of which container instance those tasks are created on.
4. Create an Amazon ECS service with three instances of the task definition.

Technology stack

- Amazon EC2
- Amazon ECS
- Amazon EFS

Tools

- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of EC2 instances that you manage.
- Amazon EFS – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- AWS CLI – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

Epics

Create an Amazon EFS file system

Task	Description	Skills required
Create an Amazon EFS file system by using the AWS Management Console.	1. **Note** Create an Amazon EFS file system and choose the VPC that includes	AWS DevOps

Task	Description	Skills required
	your containers. : If you use a different VPC, set up a VPC peering connection. 2. Note the file system ID.	

Create an Amazon ECS task definition by using either an Amazon EFS file system or the AWS CLI

Task	Description	Skills required
Create a task definition using an Amazon EFS file system.	Create a task definition by using the new Amazon ECS console or classic Amazon ECS console with the following configurations: • If you use the new console, choose **Amazon EC2 instances** for **App environment**. If you use the classic console, choose **EC2** as the launch type. • Add a volume. Enter a name for the volume, choose **EFS** for volume type, and then choose the file system ID that you noted earlier. For the root directory, choose the Amazon EFS file system path that you want to host on the Amazon ECS container host.	AWS DevOps

Task	Description	Skills required

Create a task definition using the AWS CLI.	1. To create a JSON template with input parameter placeholders for your task definition, run the following command:
	`aws ecs register-task-definition --generate-cli-skeleton`
	2. To create the task definition with the JSON template, run the following command:
	`aws ecs register-task-definition --cli-input-json file://<path_to_your_json_file>`
	3. **Note** Enter the input parameters in your JSON template based on the `task_definition_parameters.json` file (attached). : For more information on input parameters, see [Task definition parameters](#) (Amazon ECS
		AWS DevOps

Deploy Lambda functions with container images

Ram Kandaswamy, Amazon Web Services

Summary

AWS Lambda supports containers images as a deployment model. This pattern shows how to deploy Lambda functions through container images.

Lambda is a serverless, event-driven compute service that you can use to run code for virtually any type of application or backend service without provisioning or managing servers. With container image support for Lambda functions, you get the benefits of up to 10 GB of storage for your application artifact and the ability to use familiar container image development tools.

The example in this pattern uses Python as the underlying programming language, but you can use other languages, such as Java, Node.js, or Go. For the source, consider a Git-based system such as GitHub, GitLab, or Bitbucket, or use Amazon Simple Storage Service (Amazon S3).

Prerequisites and limitations

Prerequisites

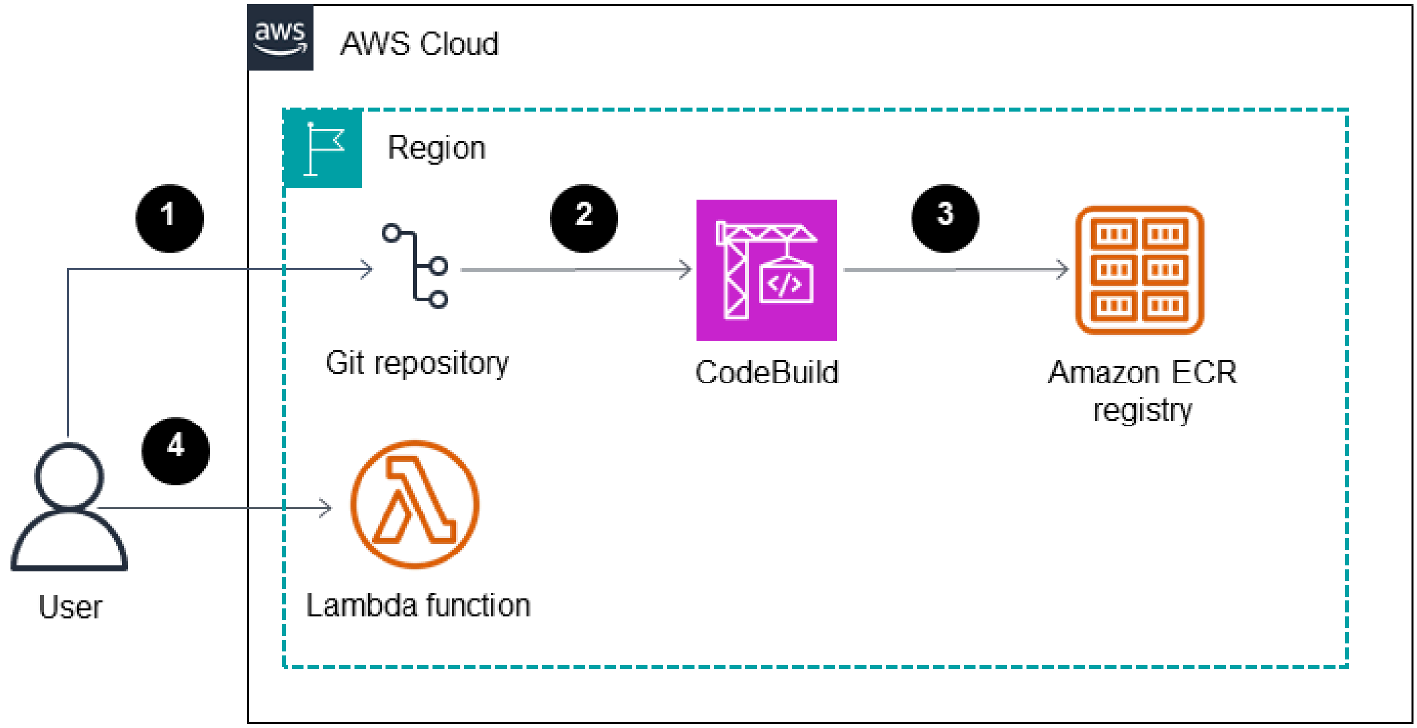
- Amazon Elastic Container Registry (Amazon ECR) activated
- Application code
- Docker images with the runtime interface client and the latest version of Python
- Working knowledge of Git

Limitations

- Maximum image size supported is 10 GB.
- Maximum runtime for a Lambda based container deployment is 15 minutes.

Architecture

Target architecture



1. You create a Git repository and commit the application code to the repository.
2. The AWS CodeBuild project is triggered by commit changes.
3. The CodeBuild project creates the Docker image and publishes the built image to Amazon ECR.
4. You create the Lambda function using the image in Amazon ECR.

Automation and scale

This pattern can be automated by using AWS CloudFormation, AWS Cloud Development Kit (AWS CDK), or API operations from an SDK. Lambda can automatically scale based on the number of requests, and you can tune it by using the concurrency parameters. For more information, see the Lambda documentation.

Tools

AWS services

- AWS CloudFormation AWS CloudFormationhelps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions. This pattern uses AWS CloudFormation Application Composer, which helps you visually view and edit AWS CloudFormation templates.

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- GitHub, GitLab, and Bitbucket are some of the commonly used Git-based source control system to keep track of source code changes.

Best practices

- Make your function as efficient and small as possible to avoid loading unnecessary files.
- Strive to have static layers higher up in your Docker file list, and place layers that change more often lower down. This improves caching, which improves performance.
- The image owner is responsible for updating and patching the image. Add that update cadence to your operational processes. For more information, see the AWS Lambda documentation.

Epics

Create a project in CodeBuild

Task	Description	Skills required
Create a Git repository.	Create a Git repository that will contain the application source code, the Dockerfile, and the `buildspec.yaml` file.	Developer

Task	Description	Skills required
Create a CodeBuild project.	To use a CodeBuild project to create the custom Lambda image, do the following: 1. Sign in to the AWS Management Console, and open the CodeBuild console at https://console.aws.amazon.com/codesuite/codebuild/. 2. Create a new project. For source, choose the Git repository that you created. For information about different kinds of Git repository integration, see the [Working with connections](#) documentation. 3. Confirm that privileged mode is enabled. To build Docker images, this is necessary. Otherwise, the image will not build successfully. 4. Provide values for the project name and description.	Developer

Task	Description	Skills required
Edit the Dockerfile.	The Dockerfile should be located in the top-level directory where you're developing the application. The Python code should be in the `src` folder. When you create the image, use the official Lambda supported images. Otherwise , a bootstrap error will occur, making the packing process more difficult. For details, see the Additional information section.	Developer
Create a repository in Amazon ECR.	Create a container repositor y in Amazon ECR. In the following example command, the name of the repository created is `cf-demo`: `aws ecr create-re pository --cf-demo` The repository will be referenced in the `buildspec .yaml` file.	AWS administrator, Developer

Task	Description	Skills required
Push the image to Amazon ECR.	You can use CodeBuild to perform the image-build process. CodeBuild needs permission to interact with Amazon ECR and to work with S3. As part of the process, the Docker image is built and pushed to the Amazon ECR registry. For details on the template and the code, see the Additional information section.	Developer
Verify that the image is in the repository.	To verify that the image is in the repository, on the Amazon ECR console, choose **Repositories**. The image should be listed, with tags and with the results of a vulnerability scan report if that feature was turned on in the Amazon ECR settings. For more information, see the AWS documentation.	Developer

Create the Lambda function to run the image

Task	Description	Skills required
Create the Lambda function.	On the Lambda console, choose **Create function**, and then choose **Container image**. Enter the function name and the URI for the	App developer

Task	Description	Skills required
	image that is in the Amazon ECR repository, and then choose **Create function**. For more information, see the [AWS Lambda documentation]().	
Test the Lambda function.	To invoke and test the function, choose **Test**. For more information, see the [AWS Lambda documentation]().	App developer

Troubleshooting

Issue	Solution
Build is not succeeding.	1. Check if the privileged mode is turned on for the CodeBuild project. 2. Ensure that the Docker related commands have the necessary permissions. Trying adding `sudo` to the commands. 3. Verify that the IAM role associated with CodeBuild has a policy with appropria te actions to interact with Amazon ECR, Amazon S3, and CloudWatch logs.

Related resources

- [Pass temporary credentials]()

Additional information

Edit the Dockerfile

The following code shows the commands that you edit in the Dockerfile:

```
FROM public.ecr.aws/lambda/python:3.xx

# Copy function code
COPY app.py ${LAMBDA_TASK_ROOT}
COPY requirements.txt  ${LAMBDA_TASK_ROOT}

# install dependencies
RUN pip3 install --user -r requirements.txt

# Set the CMD to your handler (could also be done as a parameter override outside of
 the Dockerfile)
CMD [ "app.lambda_handler" ]
```

In the `FROM` command, use appropriate value for the Python version that is supported by Lambda (for example, `3.12`). This will be the base image that is available in the public Amazon ECR image repository.

The `COPY app.py ${LAMBDA_TASK_ROOT}` command copies the code to the task root directory, which the Lambda function will use. This command uses the environment variable so we don't have to worry about the actual path. The function to be run is passed as an argument to the `CMD [ "app.lambda_handler" ]` command.

The `COPY requirements.txt` command captures the dependencies necessary for the code.

The `RUN pip install --user -r requirements.txt` command installs the dependencies to the local user directory.

To build your image, run the following command.

```
docker build -t <image name> .
```

Add the image in Amazon ECR

In the following code, replace `aws_account_id` with the account number, and replace `us-east-1` if you are using a different Region. The `buildspec` file uses the CodeBuild build number to uniquely identify image versions as a tag value. You can change this to fit your requirements.

The buildspec custom code

```
phases:
  install:
    runtime-versions:
       python: 3.xx
  pre_build:
    commands:
      - python3 --version
      - pip3 install --upgrade pip
      - pip3 install --upgrade awscli
      - sudo docker info
  build:
    commands:
      - echo Build started on `date`
      - echo Building the Docker image...
      - ls
      - cd app
      - docker build -t cf-demo:$CODEBUILD_BUILD_NUMBER .
      - docker container ls
  post_build:
    commands:
      - echo Build completed on `date`
      - echo Pushing the Docker image...
      - aws ecr get-login-password --region us-east-1 | docker login --username AWS --
password-stdin aws_account_id.dkr.ecr.us-east-1.amazonaws.com
      - docker tag cf-demo:$CODEBUILD_BUILD_NUMBER aws_account_id.dkr.ecr.us-
east-1.amazonaws.com/cf-demo:$CODEBUILD_BUILD_NUMBER
      - docker push aws_account_id.dkr.ecr.us-east-1.amazonaws.com/cf-demo:
$CODEBUILD_BUILD_NUMBER
```

Deploy Java microservices on Amazon ECS using AWS Fargate

Vijay Thompson and Sandeep Bondugula, Amazon Web Services

Summary

This pattern provides guidance for deploying containerized Java microservices on Amazon Elastic Container Service (Amazon ECS) by using AWS Fargate. The pattern doesn't use Amazon Elastic Container Registry (Amazon ECR) for container management; instead, Docker images are pulled in from a Docker hub.

Prerequisites and limitations

Prerequisites

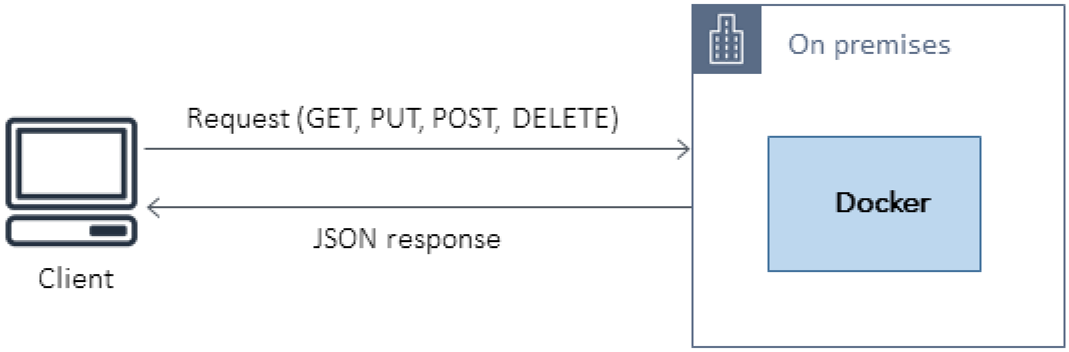
- An existing Java microservices application on a Docker hub
- A public Docker repository
- An active AWS account
- Familiarity with AWS services, including Amazon ECS and Fargate
- Docker, Java, and Spring Boot framework
- Amazon Relational Database Service (Amazon RDS) up and running (optional)
- A virtual private cloud (VPC) if the application requires Amazon RDS (optional)

Architecture

Source technology stack

- Java microservices (for example, implemented in Spring Boot) and deployed on Docker

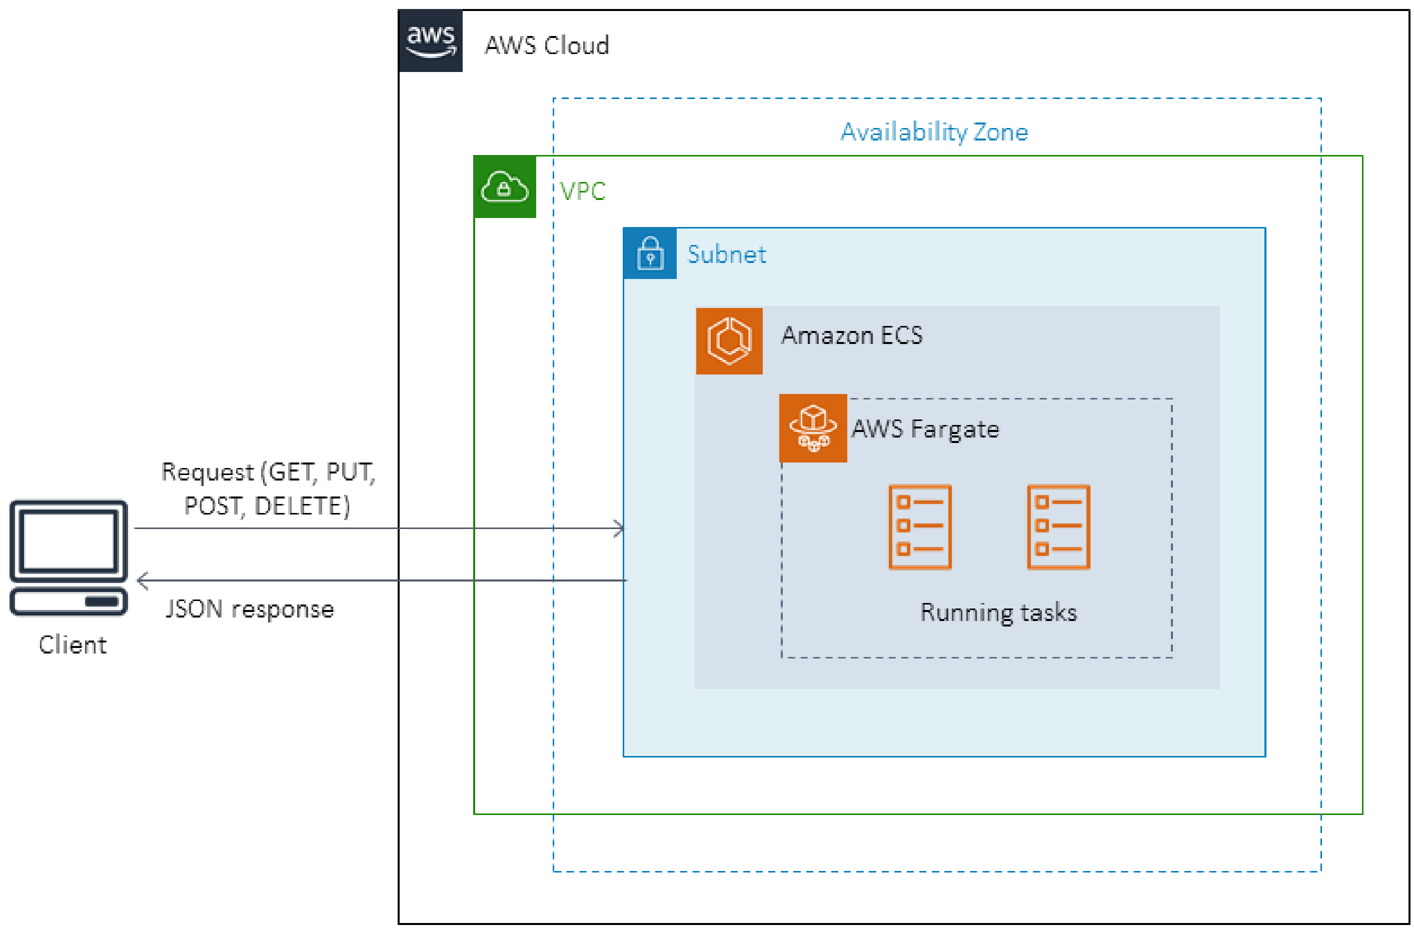
Source architecture



Target technology stack

- An Amazon ECS cluster that hosts each microservice by using Fargate
- A VPC network to host the Amazon ECS cluster and associated security groups
- A cluster/task definition for each microservice that spins up containers by using Fargate

Target architecture



Tools

Tools

- [Amazon ECS](#) eliminates the need to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.
- [AWS Fargate](#) helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It’s used in conjunction with Amazon Elastic Container Service (Amazon ECS).
- [Docker](#) is a software platform that allows you to build, test, and deploy applications quickly. Docker packages software into standardized units called *containers* that have everything the software needs to run, including libraries, system tools, code, and runtime.

Docker code

The following Dockerfile specifies the Java Development Kit (JDK) version that is used, where the Java archive (JAR) file exists, the port number that is exposed, and the entry point for the application.

```
FROM openjdk:11
ADD target/Spring-docker.jar Spring-docker.jar
EXPOSE 8080
ENTRYPOINT ["java","-jar","Spring-docker.jar"]
```

Epics

Create new task definitions

Task	Description	Skills required
Create a task definition.	Running a Docker container in Amazon ECS requires a task definition. Open the Amazon ECS console at https://console.aws.amazon.com/ecs/, choose **Task definitions**, and then create a new	AWS systems administrator, App developer

Task	Description	Skills required
	task definition. For more information, see the [Amazon ECS documentation]().	
Choose launch type.	Choose **Fargate** as the launch type.	AWS systems administrator, App developer
Configure the task.	Define a task name and configure the application with the appropriate amount of task memory and CPU.	AWS systems administrator, App developer
Define the container.	Specify the container name. For the image, enter the Docker site name, the repository name, and the tag name of the Docker image (`docker.io/sample-repo/sample-application:sample-tag-name`). Set memory limits for the application, and set port mappings (`8080, 80`) for the allowed ports.	AWS systems administrator, App developer
Create the task.	When the task and container configurations are in place, create the task. For detailed instructions, see the links in the *Related resources* section.	AWS systems administrator, App developer

Configure the cluster

Task	Description	Skills required
Create and configure a cluster.	Choose **Networking only** as the cluster type, configure the name, and then create the cluster or use an existing cluster if available. For more information, see the Amazon ECS documentation.	AWS systems administrator, App developer

Configure Task

Task	Description	Skills required
Create a task.	Inside the cluster, choose **Run new task**.	AWS systems administrator, App developer
Choose launch type.	Choose **Fargate** as the launch type.	AWS systems administrator, App developer
Choose task definition, revision, and platform version.	Choose the task that you want to run, the revision of the task definition, and the platform version.	AWS systems administrator, App developer
Select the cluster.	Choose the cluster where you want to run the task from.	AWS systems administrator, App developer
Specify the number of tasks.	Configure the number of tasks that should run. If you're launching with two or more tasks, a load balancer is required to distribute the traffic among the tasks.	AWS systems administrator, App developer

Task	Description	Skills required
Specify the task group.	(Optional) Specify a task group name to identify a set of related tasks as a task group.	AWS systems administrator, App developer
Configure the cluster VPC, subnets, and security groups.	Configure the cluster VPC and the subnets on which you want to deploy the applicati on. Create or update security groups (HTTP, HTTPS, and port 8080) to provide access to inbound and outbound connections.	AWS systems administrator, App developer
Configure public IP settings.	Enable or disable the public IP, depending on whether you want to use a public IP address for Fargate tasks. The default, recommended option is **Enabled**.	AWS systems administrator, App developer
Review settings and create the task	Review your settings, and then choose **Run Task**.	AWS systems administrator, App developer

Cut over

Task	Description	Skills required
Copy the application URL.	When the task status has been updated to *Running*, select the task. In the Networking section, copy the public IP.	AWS systems administrator, App developer

Task	Description	Skills required
Test your application.	In your browser, enter the public IP to test the applicati on.	AWS systems administrator, App developer

Deploy Kubernetes resources and packages using Amazon EKS and a Helm chart repository in Amazon S3

Sagar Panigrahi, Amazon Web Services

Summary

This pattern helps you to manage Kubernetes applications efficiently, regardless of their complexity. The pattern integrates Helm into your existing continuous integration and continuous delivery (CI/CD) pipelines to deploy applications into a Kubernetes cluster. Helm is a Kubernetes package manager that helps you manage Kubernetes applications. Helm charts help to define, install, and upgrade complex Kubernetes applications. Charts can be versioned and stored in Helm repositories, which improves mean time to restore (MTTR) during outages.

This pattern uses Amazon Elastic Kubernetes Service (Amazon EKS) for the Kubernetes cluster. It uses Amazon Simple Storage Service (Amazon S3) as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account with a virtual private cloud (VPC)
- An Amazon EKS cluster
- Worker nodes set up within the Amazon EKS cluster and ready to take workloads
- Kubectl for configuring the Amazon EKS kubeconfig file for the target cluster in the client machine
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmatic or role) access to Amazon S3 from the client machine
- Source code management and a CI/CD pipeline

Limitations

- There is no support at this time for upgrading, deleting, or managing custom resource definitions (CRDs).
- If you are using a resource that refers to a CRD, the CRD must be installed separately (outside of the chart).

Product versions

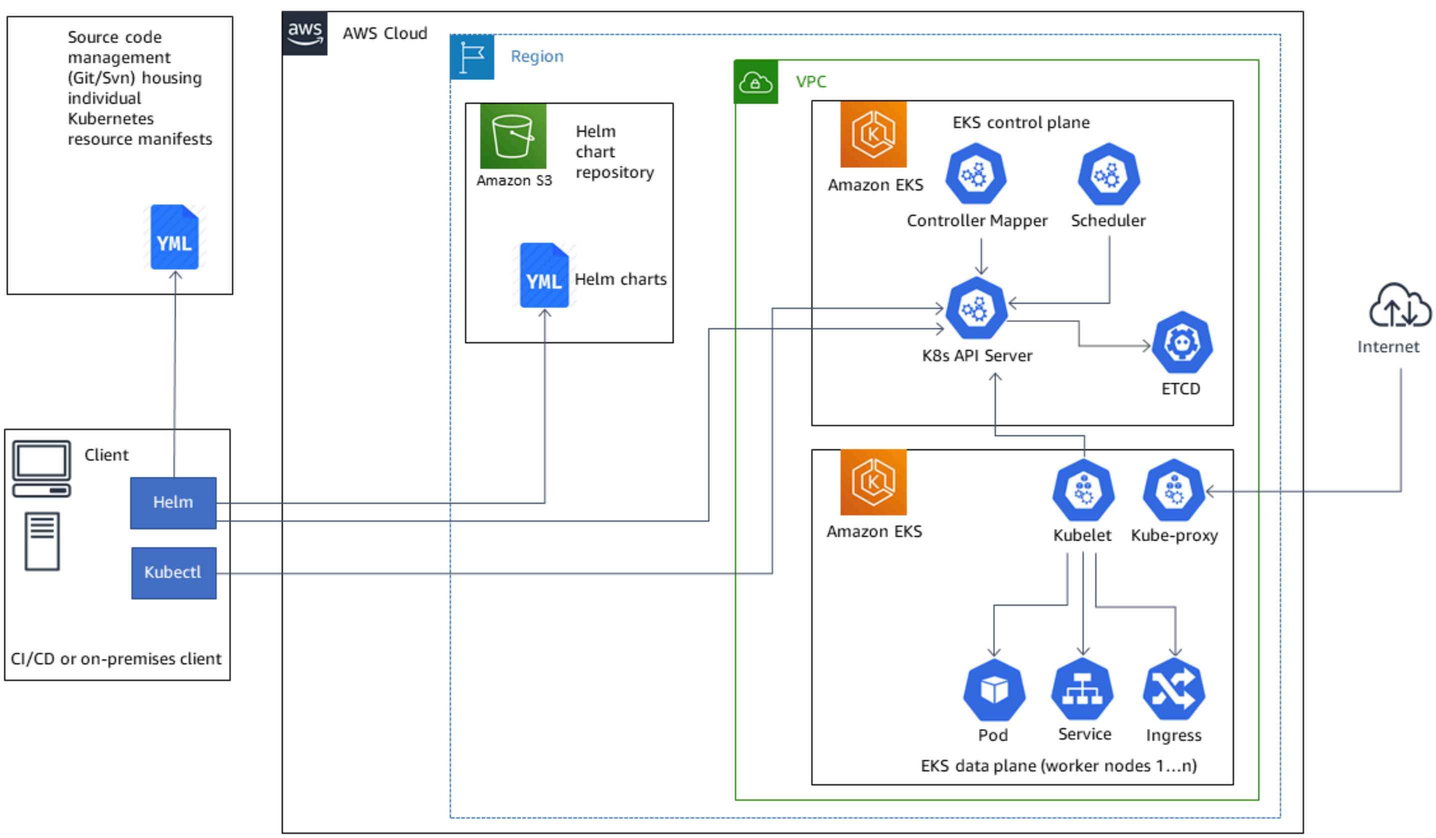
- Helm v3.6.3

Architecture

Target technology stack

- Amazon EKS
- Amazon VPC
- Amazon S3
- Source code management
- Helm
- Kubectl

Target architecture



Automation and scale

- AWS CloudFormation can be used to automate the infrastructure creation. For more information, see Creating Amazon EKS resources with AWS CloudFormation in the Amazon EKS documentation.
- Helm is to be incorporated into your existing CI/CD automation tool to automate the packaging and versioning of Helm charts (out of scope for this pattern).
- GitVersion or Jenkins build numbers can be used to automate the versioning of charts.

Tools

Tools

- Amazon EKS – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service for running Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.
- Helm – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- Kubectl – Kubectl is a command line utility for running commands against Kubernetes clusters.

Code

The example code is attached.

Epics

Configure and initialize Helm

Task	Description	Skills required
Install the Helm client.	To download and install the Helm client on your local system, use the following command.	DevOps engineer

Task	Description	Skills required
	`sudo curl https://raw.githubusercontent.com/helm/helm/master/scripts/get-helm-3 | bash`	
Validate the Helm installation.	To validate that Helm is able to communicate with the Kubernetes API server within the Amazon EKS cluster, run `helm version`.	DevOps engineer

Create and install a Helm chart in the Amazon EKS cluster

Task	Description	Skills required
Create a Helm chart for NGINX.	To create a helm chart named `my-nginx` on the client machine, run `helm create my-nginx`.	DevOps engineer
Review the structure of the chart.	To review the structure of the chart, run the tree command `tree my-nginx/` .	DevOps engineer
Deactivate service account creation in the chart.	In `values.yaml` , under the `serviceAccount` section, set the `create` key to `false`. This is turned off because there is no requirement to create a service account for this pattern.	DevOps engineer
Validate (lint) the modified chart for syntactical errors.	To validate the chart for any syntactical error before	DevOps engineer

Task	Description	Skills required
	installing it in the target cluster, run `helm lint my-nginx/` .	
Install the chart to deploy Kubernetes resources.	To run the Helm chart installation, use the following command. `helm install --name my-nginx-release --debug my-nginx/ --namespace helm-space` The optional `debug` flag outputs all debug messages during the installation. The `namespace` flag specifies the namespace in which the resources part of this chart will be created.	DevOps engineer
Review the resources in the Amazon EKS cluster.	To review the resources that were created as part of the Helm chart in the `helm-space` namespace, use the following command. `kubectl get all -n helm-space`	DevOps engineer

Roll back to a previous version of a Kubernetes application

Task	Description	Skills required
Modify and upgrade the release.	To modify the chart, in `values.yaml` , change the `replicaCount` value to 2. Then upgrade the already installed release by running the following command. `helm upgrade my-nginx-release my-nginx/ --namespace helm-space`	DevOps engineer
Review the history of the Helm release.	To list all the revisions for a specific release that have been installed using Helm, run the following command. `helm history my-nginx-release`	DevOps engineer
Review the details for a specific revision.	Before switching or rolling back to a working version, and for an additional layer of validation before installin g a revision, view which values were passed to each of the revisions by using the following command. `helm get --revision=2 my-nginx-release`	DevOps engineer

Task	Description	Skills required
Roll back to a previous version.	To roll back to a previous revision, use the following command. `helm rollback my-nginx-release 1` This example is rolling back to revision number 1.	DevOps engineer

Initialize an S3 bucket as a Helm repository

Task	Description	Skills required
Create an S3 bucket for Helm charts.	Create a unique S3 bucket. In the bucket, create a folder called `charts`. The example in this pattern uses `s3://my-helm-charts/charts` as the target chart repository.	Cloud administrator
Install the Helm plugin for Amazon S3.	To install the helm-s3 plugin on your client machine, use the following command. `helm plugin install https://github.com/hypnoglow/helm-s3.git --version 0.10.0` Note: Helm V3 support is available with plugin version 0.9.0 and above.	DevOps engineer

Task	Description	Skills required
Initialize the Amazon S3 Helm repository.	To initialize the target folder as a Helm repository, use the following command. `helm S3 init s3://my-helm-charts/charts` The command creates an `index.yaml` file in the target to track all the chart information that is stored at that location.	DevOps engineer
Add the Amazon S3 repository to Helm.	To add the repository in the client machine, use the following command. `helm repo add my-helm-charts s3://my-helm-charts/charts` This command adds an alias to the target repository in the Helm client machine.	DevOps engineer
Review the repository list.	To view the list of repositories in the Helm client machine, run `helm repo list`.	DevOps engineer

Package and store charts in the Amazon S3 Helm repository

Task	Description	Skills required
Package the chart.	To package the `my-nginx` chart that you created, run	DevOps engineer

Task	Description	Skills required
	`helm package ./my-nginx/` . The command packages all the contents of the `my-nginx` chart folder into an archive file, which is named using the version number that is mentioned in the `Chart.yaml` file.	
Store the package in the Amazon S3 Helm repository.	To upload the package to the Helm repository in Amazon S3, run the following command, using the correct name of the `.tgz` file. `helm s3 push ./my-nginx-0.1.0.tgz my-helm-charts`	DevOps engineer
Search for the Helm chart.	To confirm that the chart appears both locally and in the Helm repository in Amazon S3, run the following command. `helm search repo my-nginx`	DevOps engineer

Modify, version, and package a chart

Task	Description	Skills required
Modify and package the chart.	In `values.yaml` , set the `replicaCount` value to 1. Then package the chart by	DevOps engineer

Task	Description	Skills required
	running `helm package ./my-nginx/`, this time changing the version in `Chart.yaml` to `0.1.1`. The versioning is ideally updated through automation using tools such as GitVersion or Jenkins build numbers in a CI/CD pipeline. Automating the version number is out of scope for this pattern.	
Push the new version to the Helm repository in Amazon S3.	To push the new package with version of 0.1.1 to the `my-helm-charts` Helm repository in Amazon S3, run the following command. `helm s3 push ./my-nginx-0.1.1.tgz my-helm-charts`	DevOps engineer

Search for and install a chart from the Amazon S3 Helm repository

Task	Description	Skills required
Search for all versions of the my-nginx chart.	To view all the available versions of a chart, run the following command with the `--versions` flag. `helm search repo my-nginx --versions`	DevOps engineer

Task	Description	Skills required
	Without the flag, Helm by default displays the latest uploaded version of a chart.	
Install a chart from the Amazon S3 Helm repository.	The search results from the previous task show the multiple versions of the `my-nginx` chart. To install the new version (0.1.1) from the Amazon S3 Helm repository, use the following command. `helm upgrade my-nginx-release my-helm-charts/my-nginx --version 0.1.1 --namespace helm-space`	DevOps engineer

Deploy a sample Java microservice on Amazon EKS and expose the microservice using an Application Load Balancer

Vijay Thompson and Akkamahadevi Hiremath, Amazon Web Services

Summary

This pattern describes how to deploy a sample Java microservice as a containerized application on Amazon Elastic Kubernetes Service (Amazon EKS) by using the `eksctl` command line utility and Amazon Elastic Container Registry (Amazon ECR). You can use an Application Load Balancer to load balance the application traffic.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows
- A running Docker daemon
- The `eksctl` command line utility, installed and configured on macOS, Linux, or Windows (For more information, see Getting started with Amazon EKS – eksctl in the Amazon EKS documentation.)
- The `kubectl` command line utility, installed and configured on macOS, Linux, or Windows (For more information, see Installing or updating kubectl in the Amazon EKS documentation.)

Limitations

- This pattern doesn't cover the installation of an SSL certificate for the Application Load Balancer.

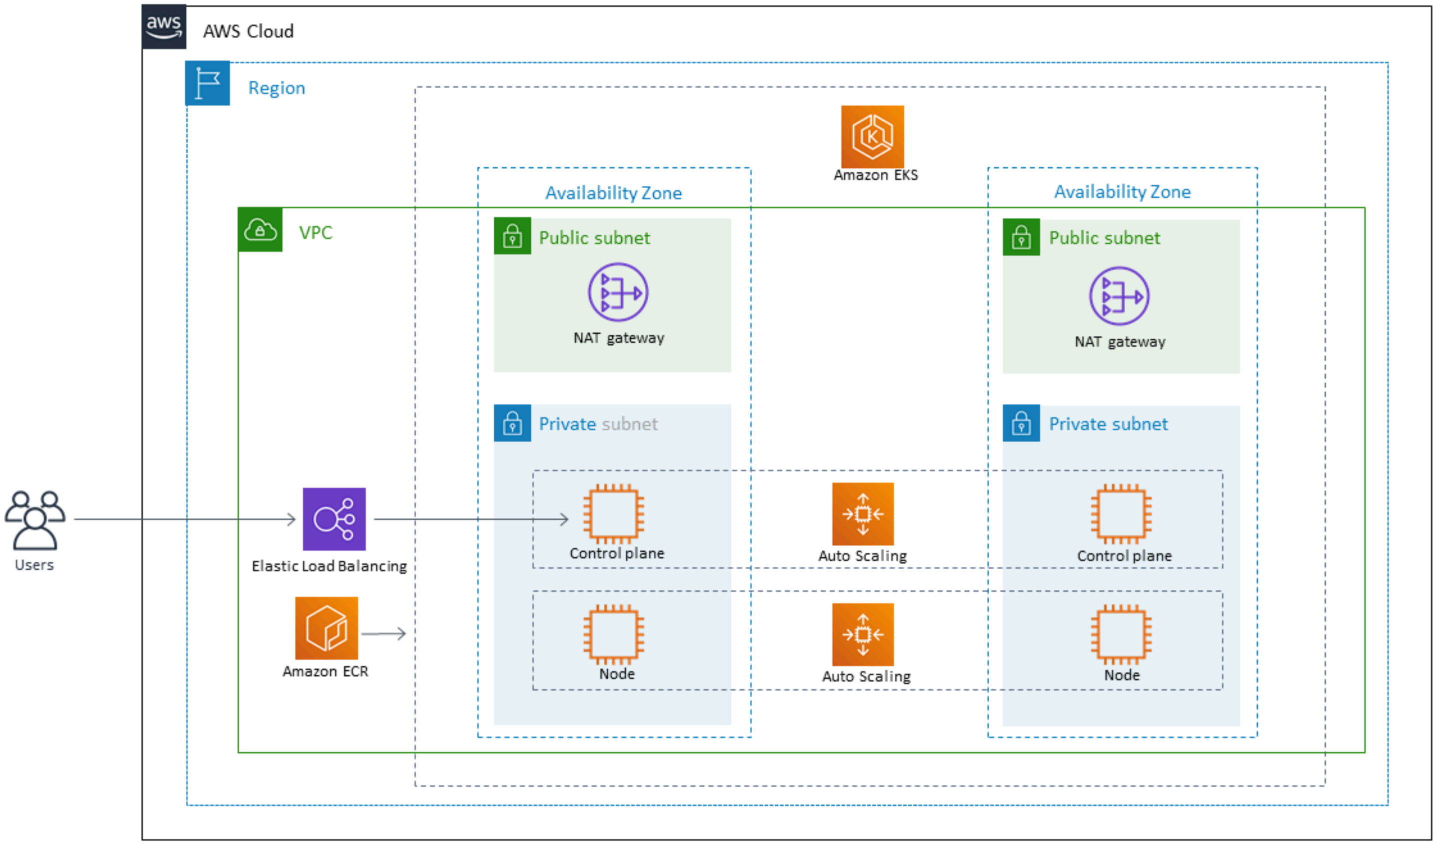
Architecture

Target technology stack

- Amazon ECR
- Amazon EKS
- Elastic Load Balancing

Target architecture

The following diagram shows an architecture for containerizing a Java microservice on Amazon EKS.



Tools

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.
- eksctl helps you create clusters on Amazon EKS.
- kubectl makes it possible to run commands against Kubernetes clusters.

- Docker helps you build, test, and deliver applications in packages called containers.

Epics

Create an Amazon EKS cluster by using eksctl

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create an Amazon EKS cluster.</td><td>To create an Amazon EKS cluster that uses two t2.small Amazon EC2 instances as nodes, run the following command:
<pre>eksctl create cluster --name <your-cluster-name> --version <version-number> --nodes=1 --node-type=t2.small</pre>
Note
The process can take between 15 to 20 minutes. After the cluster is created, the appropriate Kubernetes configuration is added to your kubeconfig file. You can use the <code>kubeconfig</code> file with <code>kubectl</code> to deploy the application in later steps.</td><td>Developer, System Admin</td></tr>
</table>

Task	Description	Skills required
Verify the Amazon EKS cluster.	To verify that the cluster is created and that you can connect to it, run the `kubectl get nodes` command.	Developer, System Admin

Create an Amazon ECR repository and push the Docker image.

Task	Description	Skills required
Create an Amazon ECR repository.	Follow the instructions from [Creating a private repository]() in the Amazon ECR documentation.	Developer, System Admin
Create a POM XML file.	Create a `pom.xml` file based on the *Example POM file* code in the [Additional information]() section of this pattern.	Developer, System Admin

Create a source file.	Create a source file called `HelloWorld.java` in the `src/main/java/eksExample` path based on the following example:
	`package eksExample;`
	`import static spark.Spark.get;`
	
	`public class HelloWorld {`
	`    public static void main(String[] args) {`
	`        get("/", (req, res) -> {`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>
<pre>
            return
 "Hello World!";
        });
    }
}
</pre>
Be sure to use the following directory structure:
<pre>
Dockerfile
deployment.yaml
ingress.yaml
pom.xml
service.yaml
src
    ### main
        ### java
            ###
 eksExample
                ###
 HelloWorld.java
</pre>
</td><td></td></tr>
<tr><td>Create a Dockerfile.</td><td>Create a <code>Dockerfile</code> based on the Example Dockerfile code in the Additional information section of this pattern.</td><td>Developer, System Admin</td></tr>
</table>

Task	Description	Skills required

Build and push the Docker image.	In the directory where you want your `Dockerfile` to build, tag, and push the image to Amazon ECR, run the following commands:
	`aws ecr get-login -password --region <region>| docker login --username <username > --password-stdin <account_number>.dkr.ecr.<region>.amazonaws.com`
	`docker buildx build --platform linux/amd64 -t hello-world-java:v1 .`
	`docker tag hello-world-java:v1 <account_number>.dkr.ecr.<region>.amazonaws.com/<repository_name>:v1`
	`docker push <account_number>.dkr.ecr.<region>.amazonaws.com/<repository_name>:v1`
	
	Note
	Modify the AWS Region, account number, and repository details in the preceding commands. Be sure to note the	

Task	Description	Skills required
	image URL for later use. **Important** A macOS system with an M1 chip has a problem building an image that's compatible with Amazon EKS running on an AMD64 platform. To resolve this issue, use [docker buildx](https://docs.docker.com/engine/reference/commandline/buildx/) to build a Docker image that works on Amazon EKS.	

Deploy the Java microservices

Task	Description	Skills required
Create a deployment file.	Create a YAML file called `deployment.yaml` based on the *Example deployment file* code in the [Additional information](#additional-information) section of this pattern.	Developer, System Admin

Task	Description	Skills required
	Note Use the image URL that you copied earlier as the path of the image file for the Amazon ECR repository.	
Deploy the Java microservices on the Amazon EKS cluster.	To create a deployment in your Amazon EKS cluster, run the `kubectl apply -f deployment.yaml` command.	Developer, System Admin
Verify the status of the pods.	1. To verify the status of the pods, run the `kubectl get pods` command. 2. Wait for the status to change to **Ready**.	Developer, System Admin
Create a service.	1. Create a file called `service.yaml` based on the *Example service file* code in the [Additional information](#) section of this pattern. 2. Run the `kubectl apply -f service.yaml` command.	Developer, System Admin

Task	Description	Skills required
Install the AWS Load Balancer Controller add-on.	Follow the instructions from [Installing the AWS Load Balancer Controller add-on]() in the Amazon EKS documenta tion. **Note** You must have the add-on installed to create an Applicati on Load Balancer or Network Load Balancer for a Kubernetes service.	Devloper, System Admin
Create an ingress resource.	Create a YAML file called `ingress.yaml` based on the *Example ingress resource file* code in the [Additional information]() section of this pattern.	Developer, System Admin
Create an Application Load Balancer.	To deploy the ingress resource and create an Application Load Balancer, run the `kubectl apply -f ingress.yaml` command.	Developer, System Admin

Test the application

Task	Description	Skills required
Test and verify the application.	1. To get the load balancer's DNS name from the ADDRESS field, run the `kubectl get ingress.networking.k8s.io/java-microservice-ingress` command. 2. On an EC2 instance in the same VPC as your Amazon EKS nodes, run the `curl -v <DNS address from previous command>` command.	Developer, System Admin

                  number: 80
```

Deploy a clustered application to Amazon ECS by using AWS Copilot

Jean-Baptiste Guillois, Mathew George, and Thomas Scott, Amazon Web Services

Summary

This pattern shows how to deploy containers in an Amazon Elastic Container Service (Amazon ECS) cluster in two ways—by using the Amazon Web Services (AWS) Management Console, and by using AWS Copilot—to demonstrate how AWS Copilot simplifies deployment tasks.

Amazon ECS is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster. Your containers are defined in a task definition that you use to run individual tasks or tasks within a service. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.

The AWS Copilot command line interface (CLI) commands simplify building, releasing, and operating production-ready containerized applications on Amazon ECS from a local development environment. The AWS Copilot CLI aligns with developer workflows that support modern application best practices: from using infrastructure as code to creating a continuous integration and continuous delivery (CI/CD) pipeline provisioned on behalf of a user. You can use the AWS Copilot CLI as part of your everyday development and testing cycle as an alternative to the AWS Management Console.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) locally installed and configured to use your AWS account (see the installation instructions and the configuration instructions in the AWS CLI documentation)
- AWS Copilot locally installed (see the installation instructions in the Amazon ECS documentation)
- Docker installed on your local machine (see the Docker documentation)

Limitations

- Docker enforces pull limits of 100 container images per 6 hours per IP address on the free plan.

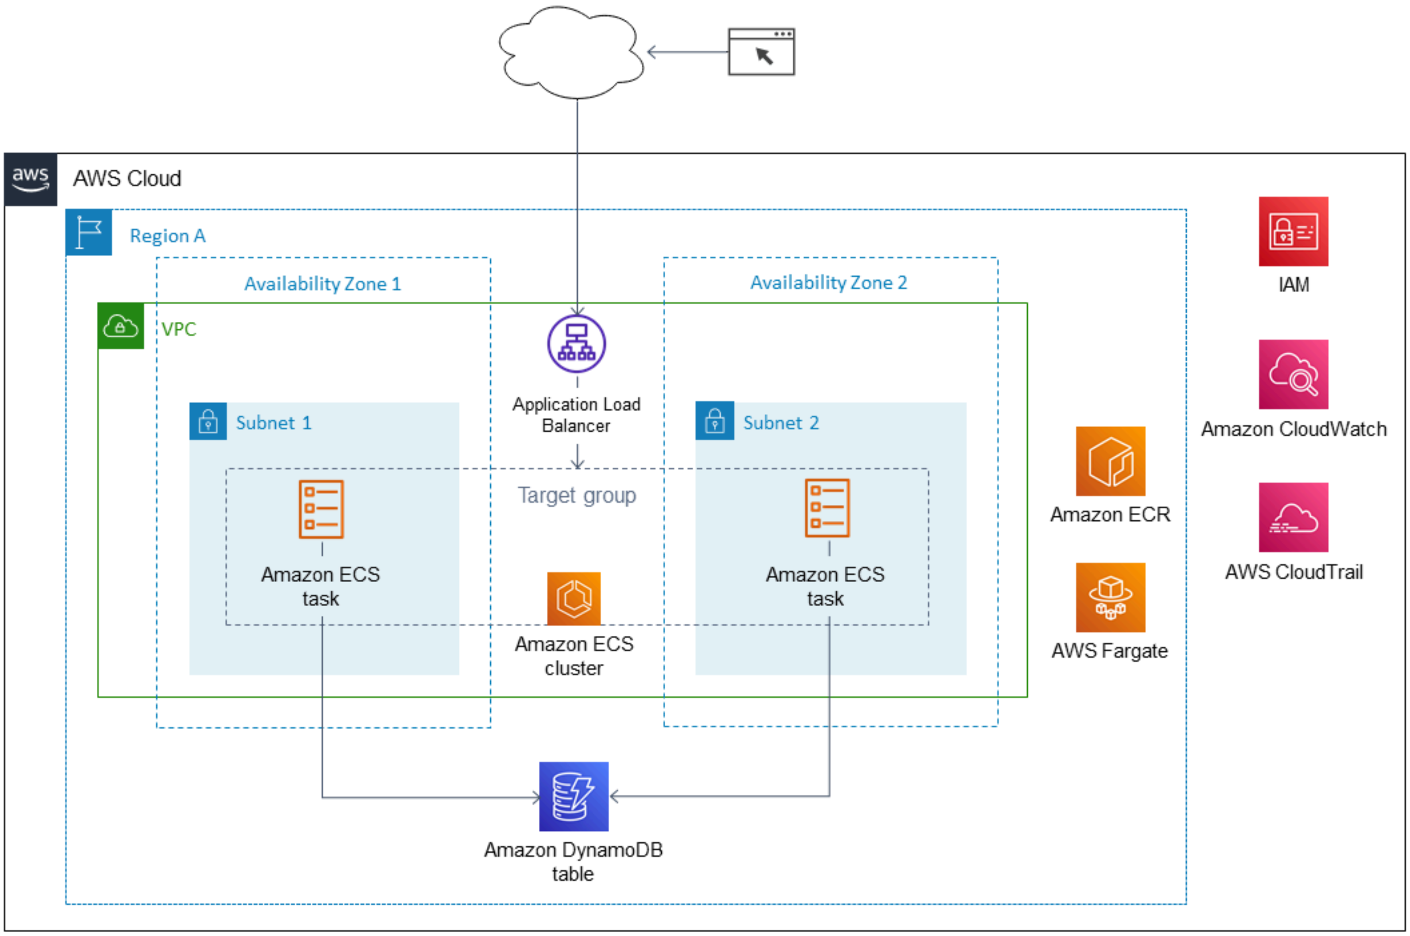
Architecture

Target technology stack

- AWS environment set up with a virtual private cloud (VPC), public and private subnets, and security groups
- Amazon ECS cluster
- Amazon ECS service and task definition
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon DynamoDB
- Application Load Balancer
- AWS Fargate
- Amazon Identity and Access Management (IAM)
- Amazon CloudWatch
- AWS CloudTrail

Target architecture

When you deploy the sample application for this pattern, multiple tasks are created and deployed in separate Availability Zones. Each task stores data in Amazon DynamoDB. When you access the webpage for a task, you can view the data from all other tasks.



Tools

AWS services

- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.
- AWS Copilot – AWS Copilot provides a command line interface that helps you launch and manage containerized applications on AWS, including pushing to a registry, creating a task definition, and creating a cluster.

- AWS Fargate – AWS Fargate is a serverless, pay-as-you-go compute engine that lets you focus on building applications without managing servers. AWS Fargate is compatible with both Amazon ECS and Amazon Elastic Kubernetes Service (Amazon EKS). When you run your Amazon ECS tasks and services with the Fargate launch type or a Fargate capacity provider, you package your application in containers, specify the CPU and memory requirements, define networking and IAM policies, and launch the application. Each Fargate task has its own isolation boundary and doesn't share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task.
- Amazon DynamoDB – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- Elastic Load Balancing (ELB) – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones. It monitors the health of its registered targets, and routes traffic only to the healthy targets. Elastic Load Balancing scales your load balancer as your incoming traffic changes over time. It can automatically scale to the vast majority of workloads.

Tools

- Docker Command Line Interface
- AWS Command Line Interface (AWS CLI)
- AWS Copilot command line interface

Code

The code for the sample application used in this pattern is available on GitHub, in the Cluster Sample Application repository. Follow the instructions in the next section to use the sample files.

Epics

Deploy the application stack - option 1 (AWS Management Console)

Task	Description	Skills required
Clone the GitHub repository.	Clone the sample code repository by using the command:	App developer, AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>git clone https://github.com/aws-samples/cluster-sample-app cluster-sample-app
 && cd cluster-sample-app</code></pre></td><td></td></tr>
<tr><td>Create your Amazon ECR repository.</td><td>1. Sign in to the AWS Management Console and open the Amazon ECR console at https://console.aws.amazon.com/ecr/repositories.
2. Choose Create repository.
3. For the repository name, enter cluster-sample-app.
4. For all other settings, keep the default values.
5. Choose Create repository.

For more information, see Creating a private repository in the Amazon ECR documentation.</td><td>App developer, AWS DevOps</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Build, tag, and push your Docker image to your Amazon ECR repository.</td><td>

1. Select the repository you just created and choose **View push commands**.
2. Copy the commands that are displayed and run them locally to build, tag, and push your docker image. These commands will be similar to the following.

To authenticate your Docker client to the registry:

```
aws ecr get-login
-password --region
 <YOUR_AWS_REGION> |
 docker login --usernam
e AWS --password-stdin
 <YOUR_AWS_ACCOUNT>
.dkr.ecr.<YOUR_AWS
_REGION>.amazonaws
.com
```

To build your Docker image:

```
docker build -t cluster-
sample-app .
```

To tag your Docker image:

```
docker tag cluster-
sample-app:latest
 <YOUR_AWS_ACCOUNT>
.dkr.ecr.<YOUR_AWS
_REGION>.amazonaws
```

</td><td>App developer, AWS DevOps</td></tr>
</table>

Task	Description	Skills required

	`.com/cluster-sample-app:latest`
	
	To push the Docker image to your repository:
	
	`docker push <YOUR_AWS_ACCOUNT>.dkr.ecr.<YOUR_AWS_REGION>.amazonaws.com/cluster-sample-app:latest`	

Task	Description	Skills required
Deploy the application stack.	1. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation/. 2. Choose **Create stack**. 3. In the **Prepare template** section, choose **Template is ready**. 4. In the **Specify template** section, choose **Upload a template file**. 5. Choose the local file `cluster-sample-app-stack.yml` that you cloned from the GitHub repository as the CloudFormation template, and then choose **Next**. 6. Enter a name for your stack, and then choose **Next**. 7. Keep all default options, and then choose **Next**. 8. Review all options, acknowledge the creation of IAM resources, and then choose **Create stack**. 9. When your application stack has been deployed, choose the **Output** tab, copy the URL, and open it in your browser to access the application.	AWS DevOps, App developer

Task	Description	Skills required
	For more information about deploying CloudFormation templates, see Creating a stack in the AWS CloudFormation documentation.	

Deploy the application stack – option 2 (AWS Copilot CLI)

Task	Description	Skills required
Clone the GitHub repository.	Clone the sample code repository by using the command: `git clone https://github.com/aws-samples/cluster-sample-app cluster-sample-app && cd cluster-sample-app`	App developer, AWS DevOps
Deploy your container image to AWS by using the AWS Copilot CLI.	Deploy the application in one step by using the following command in the root directory of your project: `copilot init --app cluster-sample-app --name demo --type "Load Balanced Web Service" --dockerfile ./Dockerfile --port 8080 --deploy` You should then be able to access the application by	App developer, AWS DevOps

Task	Description	Skills required
	using the DNS name provided as output.	

Delete the created resources

Task	Description	Skills required
Delete the resources created through the AWS Managemen t Console.	If you used option 1 (the AWS Management Console) to deploy the application stack, follow these steps when you're ready to delete the resources you created: 1. Open the CloudForm ation console at https://console.aws.amazon.com/cloudformation/. 2. Select the stack you created, and then choose **Delete**. 3. Open the Amazon ECR console at https://console.aws.amazon.com/ecr/repositories. 4. Select the repository you created, and then choose **Delete**.	App developer, AWS DevOps
Delete the resources created by AWS Copilot.	If you used option 2 (the AWS Copilot CLI) to deploy the application stack, run the following command from the root directory of your project	App developer, AWS DevOps

Task	Description	Skills required
	when you're ready to delete the resources you created: `copilot app delete`

Deploy a gRPC-based application on an Amazon EKS cluster and access it with an Application Load Balancer

Kirankumar Chandrashekar and Huy Nguyen, Amazon Web Services

Summary

This pattern describes how to host a gRPC-based application on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster and securely access it through an Application Load Balancer.

gRPC is an open-source remote procedure call (RPC) framework that can run in any environment. You can use it for microservice integrations and client-server communications. For more information about gRPC, see the AWS blog post Application Load Balancer support for end-to-end HTTP/2 and gRPC.

This pattern shows you how to host a gRPC-based application that runs on Kubernetes pods on Amazon EKS. The gRPC client connects to an Application Load Balancer through the HTTP/2 protocol with an SSL/TLS encrypted connection. The Application Load Balancer forwards traffic to the gRPC application that runs on Amazon EKS pods. The number of gRPC pods can be automatically scaled based on traffic by using the Kubernetes Horizontal Pod Autoscaler. The Application Load Balancer's target group performs health checks on the Amazon EKS nodes, evaluates if the target is healthy, and forwards traffic only to healthy nodes.

Prerequisites and limitations

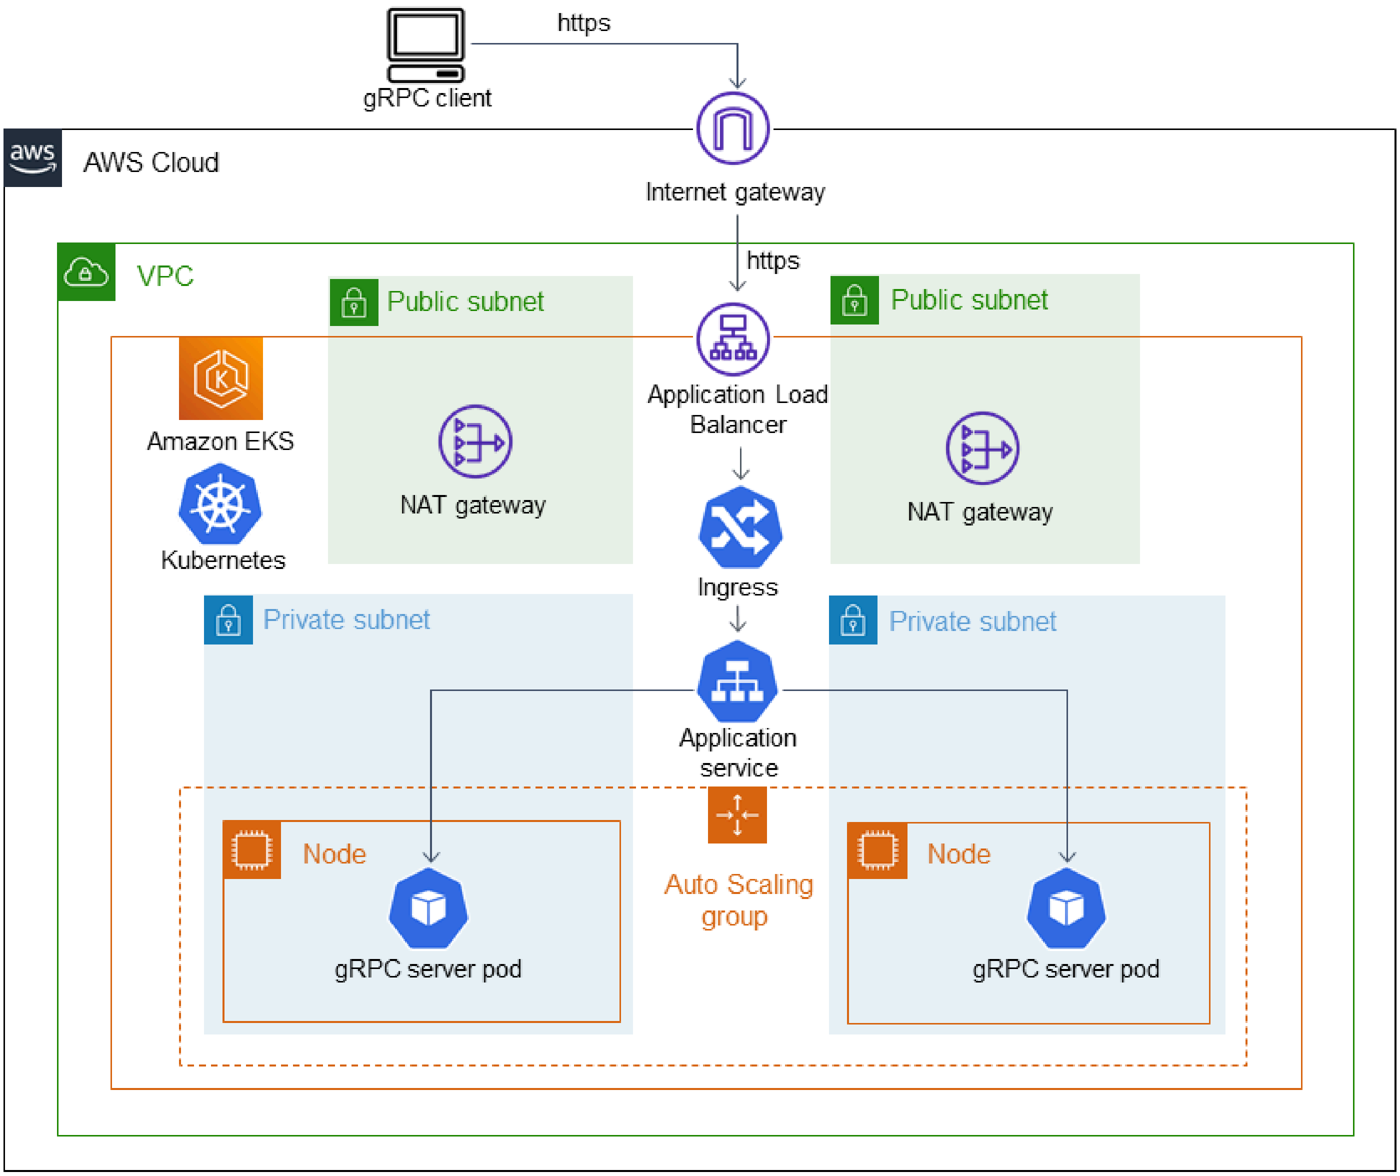
Prerequisites

- An active AWS account.
- Docker, installed and configured on Linux, macOS, or Windows.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows.
- eksctl, installed and configured on Linux, macOS, or Windows.
- `kubectl`, installed and configured to access resources on your Amazon EKS cluster. For more information, see Installing or updating kubectl in the Amazon EKS documentation.
- gRPCurl, installed and configured.
- A new or existing Amazon EKS cluster. For more information, see Getting started with Amazon EKS.

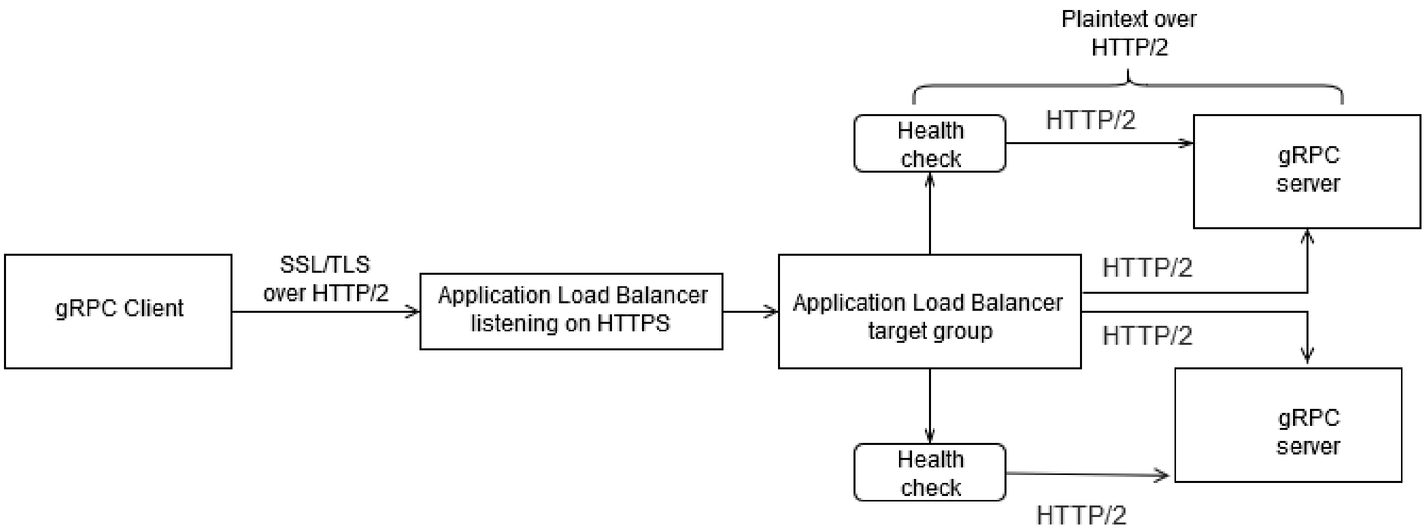
- Your computer terminal configured to access the Amazon EKS cluster. For more information, see Configure your computer to communicate with your cluster in the Amazon EKS documentation.
- AWS Load Balancer Controller, provisioned in the Amazon EKS cluster.
- An existing DNS host name with a valid SSL or SSL/TLS certificate. You can obtain a certificate for your domain by using AWS Certificate Manager (ACM) or uploading an existing certificate to ACM. For more information about these two options, see Requesting a public certificate and Importing certificates into AWS Certificate Manager in the ACM documentation.

Architecture

The following diagram shows the architecture implemented by this pattern.



The following diagram shows a workflow where SSL/TLS traffic is received from a gRPC client that offloads to an Application Load Balancer. Traffic is forwarded in plaintext to the gRPC server because it comes from a virtual private cloud (VPC).



Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command line shell.
- Elastic Load Balancing distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.

Tools

- eksctl is a simple CLI tool for creating clusters on Amazon EKS.
- kubectl is a command line utility for running commands against Kubernetes clusters.
- AWS Load Balancer Controller helps you manage AWS Elastic Load Balancers for a Kubernetes cluster.
- gRPCurl is a command line tool that helps you interact with gRPC services.

Code repository

The code for this pattern is available in the GitHub grpc-traffic-on-alb-to-eks repository.

Epics

Build and push the gRPC server's Docker image to Amazon ECR

Task	Description	Skills required
Create an Amazon ECR repository.	Sign in to the AWS Management Console, open the Amazon ECR console, and then create an Amazon ECR repository. For more information, see Creating a repository in the Amazon ECR documentation. Make sure that you record the Amazon ECR repository's URL. You can also create an Amazon ECR repository with AWS CLI by running the following command: `aws ecr create-repository --repository-name helloworld-grpc`	Cloud administrator
Build the Docker image.	1. Clone the GitHub grpc-traffic-on-alb-to-eks repository. `git clone https://github.com/aws-samples/grpc-traffic-on-alb-to-eks.git` 2. From the root directory of the repository, make sure	DevOps engineer

Task	Description	Skills required
	that the Dockerfile exists and then run the following command to build the Docker image: `docker build -t <amazon_ecr_repository_url>:<Tag> .` **Important** Make sure that you replace `<amazon_ecr_repository_url>` with the URL of the Amazon ECR repository that you created earlier.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Push the Docker image to Amazon ECR.</td><td>

1. Run the following command to log in to the Amazon ECR repository:

```
aws ecr get-login-password --region us-east-1 --no-cli-auto-prompt | docker login --username AWS --password-stdin <your_aws_account_id>.dkr.ecr.us-east-1.amazonaws.com
```

2. Push the Docker image to the Amazon ECR repository by running the following command:

```
docker push <your_aws_account_id>.dkr.ecr.us-east-1.amazonaws.com/helloworld-grpc:1.0
```

Important

Make sure that you replace `<your_aws_account_id>` with your AWS account ID.

</td><td>DevOps engineer</td></tr>
</table>

Deploy the Kubernetes manifests to the Amazon EKS cluster

Task	Description	Skills required
Modify the values in the Kubernetes manifest file.	1. Modify the `grpc-sample.yaml` Kubernetes manifest file in the Kubernetes folder of the repository according to your requirements. You must modify the annotations and host name in the ingress resource. For a sample ingress resource, see the Additional information section. For more information about ingress annotations, see Ingress annotations in the Kubernetes documentation. 2. In the Kubernetes deployment resource, change the deployment resource's `image` to the uniform resource identifier (URI) for the Amazon ECR repository that you pushed the Docker image to. For a sample deployment resource, see the Additional information section.	DevOps engineer
Deploy the Kubernetes manifest file.	Deploy the `grpc-sample.yaml` file to the Amazon EKS cluster by running	DevOps engineer

Task	Description	Skills required
	the following `kubectl` command: `kubectl apply -f ./kubernetes/grpc-sample.yaml`	

Create the DNS record for the Application Load Balancer's FQDN

Task	Description	Skills required
Record the FQDN for the Application Load Balancer.	1. Run the following `kubectl` command to describe the Kubernetes ingress resource that manages the Application Load Balancer: `kubectl get ingress -n grpcserver` Sample output is provided in the [Additional information](#) section. In the output, the `HOSTS` field displays the DNS host name that the SSL certificates were created for. 2. Record the Application Load Balancer’s fully qualified domain name (FQDN) from the `Address` field of the output.	DevOps engineer

Task	Description	Skills required
	3. Create a DNS record that points to the Application Load Balancer's FQDN. If your DNS provider is Amazon Route 53, you can create an alias record that points to the Application Load Balancer's FQDN. For more information about this option, see [Choosing between alias and non-alias records](#) in the Route 53 documentation.	

Test the solution

Task	Description	Skills required
Test the gRPC server.	Use gRPCurl to test the endpoint by running the following command: `grpcurl grpc.example.com:443 list grpc.reflection.v1alpha.ServerReflection helloworld.helloworld` **Note** Replace `grpc.example.com` with your DNS name.	DevOps engineer

Task	Description	Skills required
Test the gRPC server using a gRPC client.	In the `helloworld_client_ssl.py` sample gRPC client, replace the host name from `grpc.example.com` with the host name used for the gRPC server. The following code sample shows the response from the gRPC server for the client's request: `python ./app/helloworld_client_ssl.py message: "Hello to gRPC server from Client" message: "Thanks for talking to gRPC server!! Welcome to hello world. Received message is \"Hello to gRPC server from Client\"" received: true` This shows that the client can talk to the server and that the connection is successful.	DevOps engineer

Clean up

Task	Description	Skills required
Remove the DNS record.	Remove the DNS record that points to the Application Load Balancer's FQDN that you created earlier.	Cloud administrator
Remove the load balancer.	On the [Amazon EC2 console](https://console.aws.amazon.com/ec2/), choose **Load Balancers**, and then remove the load balancer that the Kubernetes controller created for your ingress resource.	Cloud administrator
Delete the Amazon EKS cluster.	Delete the Amazon EKS cluster by using `eksctl`: `eksctl delete cluster -f ./eks.yaml`	AWS DevOps

Related resources

- [Network load balancing on Amazon EKS]()
- [Target groups for your Application Load Balancers]()

Additional information

Sample ingress resource:

```
---
apiVersion: networking.k8s.io/v1

            fieldRef:
              fieldPath: status.podIP
      restartPolicy: Always
```

Sample output:

```
NAME              CLASS           HOSTS                          Address
 PORTS          AGE
 grpcserver      <none>      <DNS-HostName>                  <ELB-address>
 80            27d
```

Deploy and debug Amazon EKS clusters

Svenja Raether and Mathew George, Amazon Web Services

Summary

Containers are becoming an essential part of cloud native application development. Kubernetes provides an efficient way to manage and orchestrate containers. Amazon Elastic Kubernetes Service (Amazon EKS) is a fully-managed, certified Kubernetes conformant service for building, securing, operating, and maintaining Kubernetes clusters on Amazon Web Services (AWS). It supports running pods on AWS Fargate to provide on-demand, right-sized compute capacity.

It's important for developers and administrators to know debugging options when running containerized workloads. This pattern walks you through deploying and debugging containers on Amazon EKS with AWS Fargate. It includes creating, deploying, accessing, debugging, and cleaning up the Amazon EKS workloads.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) role configured with sufficient permissions to create and interact with Amazon EKS, IAM roles, and service linked roles
- AWS Command Line Interface (AWS CLI) installed on the local machine
- eksctl
- kubectl
- Helm

Limitations

- This pattern provides developers with useful debugging practices for development environments. It does not state best practices for production environments.
- If you are running Windows, use your operating system–specific commands for setting the environment variables.

Product versions used

- AWS CLI version 2
- kubectl version within one minor version difference of the Amazon EKS control plane that you're using
- eksctl latest version
- Helm v3

Architecture

Technology stack

- Application Load Balancer
- Amazon EKS
- AWS Fargate

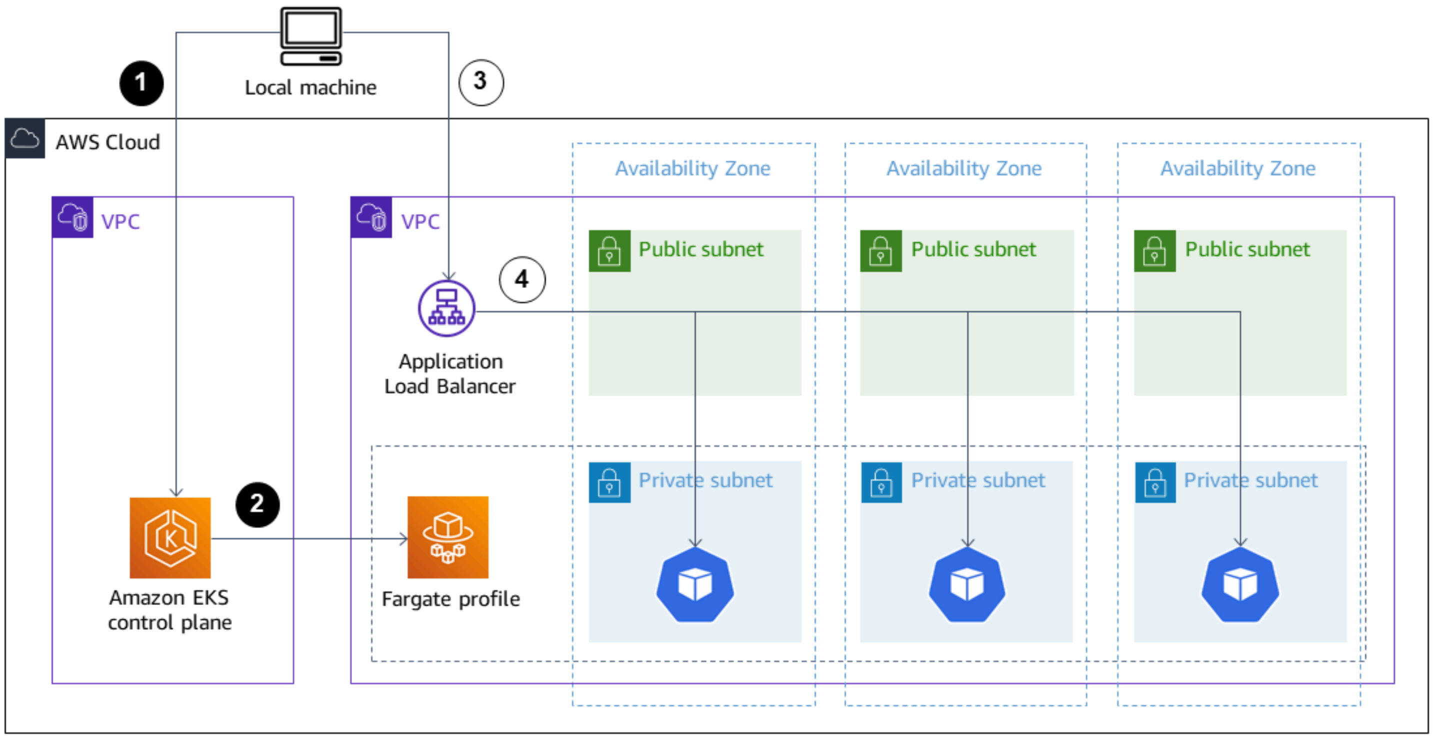
Target architecture

All resources shown in the diagram are provisioned by using `eksctl` and `kubectl` commands issued from a local machine. Private clusters must be run from an instance that is inside the private VPC.

The target architecture consists of an EKS cluster using the Fargate launch type. This provides on-demand, right-sized compute capacity without the need to specify server types. The EKS cluster has a control plane, which is used to manage the cluster nodes and workloads. The pods are provisioned into private VPC subnets spanning multiple Availability Zones. The Amazon ECR Public Gallery is referenced to retrieve and deploy an NGINX web server image to the cluster's pods.

The diagram shows how to access the Amazon EKS control plane using by `kubectl` commands and how to access the application by using the Application Load Balancer.

.



1. A local machine outside the AWS Cloud sends commands to the Kubernetes control plane inside an Amazon EKS managed VPC.
2. Amazon EKS schedules pods based on the selectors in the Fargate profile.
3. The local machine opens the Application Load Balancer URL in the browser.
4. The Application Load Balancer divides traffic between the Kubernetes pods in Fargate cluster nodes deployed in private subnets spanning multiple Availability Zones.

Tools

AWS services

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes. This pattern also uses the eksctl command-line tool to work with Kubernetes clusters on Amazon EKS.
- AWS Fargate helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).

- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones. This pattern uses the AWS Load Balancer Controller controlling component to create the Application Load Balancer when a Kubernetes ingress is provisioned. The Application Load Balancer distributes incoming traffic among multiple targets.

Other tools

- Helm is an open-source package manager for Kubernetes. In this pattern, Helm is used to install the AWS Load Balancer Controller.
- Kubernetes is an open-source system for automating deployment, scaling, and management of containerized applications.
- NGINX is a high-performance web and reverse proxy server.

Epics

Create an EKS cluster

Task	Description	Skills required
Create the files.	Using the code in the *Additional information* section, create the following files: • `clusterconfig-fargate.yaml` • `nginx-deployment.yaml` • `nginx-service.yaml` • `nginx-ingress.yaml` • `index.html`	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required

Set environment variables.	**Note** If a command fails because of previous unfinished tasks, wait a few seconds, and then run the command again.
	
	This pattern uses the AWS Region and cluster name that are defined in the file `clusterconfig-fargate.yaml` . Set the same values as environment variables to reference them in further commands.
	
	`export AWS_REGION="us-east-1"`
	`export CLUSTER_NAME="my-fargate"`
		App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Create an EKS cluster.	To create an EKS cluster that uses the specifications from the `clusterconfig-fargate.yaml` file, run the following command. `eksctl create cluster -f clusterconfig-fargate.yaml` The file contains the `ClusterConfig` , which provisions a new EKS cluster named `my-fargate-cluster` in the `us-east-1` Region and one default Fargate profile (`fp-default`). The default Fargate profile is configured with two selectors (`default` and `kube-system`).	App developer, AWS DevOps, AWS administrator

Task	Description	Skills required

Check the created cluster.	To check the created cluster, run the following command.
	`eksctl get cluster --output yaml`
	The output should be the following.
	`- Name: my-fargate`
	`  Owned: "True"`
	`  Region: us-east-1`
	Check the created Fargate profile by using the `CLUSTER_NAME` .
	`eksctl get fargateprofile --cluster $CLUSTER_NAME --output yaml`
	This command displays information about the resources. You can use the information to verify the created cluster. The output should be the following.
	`- name: fp-default`
	`  podExecutionRoleARN: arn:aws:iam::<YOUR-ACCOUNT-ID>:role/eksctl-my-fargate-cluster-FargatePodExecutionRole-xxx`
	`  selectors:`
		App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required

	``
	  - namespace: default
	  - namespace: kube-

	  - subnet-ccc
	``	

Deploy a container

Task	Description	Skills required

Deploy the NGINX web server.	To apply the NGINX web server deployment on the cluster, run the following command.
	`kubectl apply -f ./nginx-deployment.yaml`
	The output should be the following.
	`deployment.apps/nginx-deployment created`
	The deployment includes three replicas of the NGINX image taken from the Amazon ECR Public Gallery. The image is deployed to the default namespace and exposed on port 80 on the running pods.
		App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required

Check the deployment and pods.	(Optional) Check the deployment. You can verify the status of your deployment with the following command.
	`kubectl get deployment`
	The output should be the following.
	`NAME READY UP-TO-DATE AVAILABLE AGE`
	`nginx-deployment 3/3 3 3 7m14s`
	A pod is a deployable object in Kubernetes, containing one or more containers. To list all pods, run the following command.
	`kubectl get pods`
	The output should be the following.
	`NAME READY STATUS RESTARTS AGE`
	`nginx-deployment-xxxx-aaa 1/1 Running 0 94s`
		App developer, AWS DevOps, AWS administrator

Task	Description	Skills required
	``` nginx-deployment-xxxx- bbb 1/1 Running 0 94s nginx-deployment-xxxx- ccc 1/1 Running 0 94s ```	

Scale the deployment.	To scale the deployment from the three replicas that were specified in `deployment.yaml` to four replicas, use the following command.
	`kubectl scale deployment nginx-deployment --replicas 4`
	The output should be the following.
	`deployment.apps/nginx-deployment scaled`
		App developer, AWS DevOps, AWS systems administrator

Deploy an AWS Load Balancer Controller

Task	Description	Skills required
Set environment variables.	Describe the cluster's CloudFormation stack to retrieve information about its VPC. `aws cloudformation describe-stacks --stack-name eksctl-$CLUSTER_NAME-cluste`	App developer, AWS DevOps, AWS systems administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

```
r --query "Stacks[0
].Outputs[?OutputK
ey==\`VPC\`].Outpu
tValue"
```

The output should be the following.

```
[
    "vpc-<YOUR-VPC-ID>
"
]
```

Copy the VPC ID and export it as an environment variable.

```
export VPC_ID="vpc-
<YOUR-VPC-ID>"
```

</td><td></td></tr>
<tr><td>Configure IAM for the cluster service account.</td><td>

Use the `AWS_REGION` and `CLUSTER_NAME` from the earlier epic to create an IAM Open ID Connect provider for the cluster.

```
eksctl utils associate-
iam-oidc-provider \
--region $AWS_REGION \
--cluster $CLUSTER_
NAME \
--approve
```

</td><td>App developer, AWS DevOps, AWS systems administrator</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr>
<td>Download and create the IAM policy.</td>
<td>

Download the IAM policy for the AWS Load Balancer Controller that allows it to make calls to AWS APIs on your behalf.

```
curl -o iam-policy.json https://raw.githubusercontent.com/kubernetes-sigs/aws-load-balancer-controller/main/docs/install/iam_policy.json
```

Create the policy in your AWS account by using the AWS CLI.

```
aws iam create-policy \
--policy-name AWSLoadBalancerControllerIAMPolicy \
--policy-document file://iam-policy.json
```

You should see the following output.

```
{
"Policy": {
       "PolicyName": "AWSLoadBalancerControllerIAMPolicy",
       "PolicyId": "<YOUR_POLICY_ID>",
       "Arn": "arn:aws:iam::<YOUR-ACCOUNT
```

</td>
<td>App developer, AWS DevOps, AWS systems administrator</td>
</tr>
</table>

nginx-ingress   <none>
   *   k8s-defau
lt-nginxing-xxx.us
-east-1.elb.amazon
aws.com   80   80s</pre>
Copy the <code>ADDRESS</code> (for example, <code>k8s-default-nginxing-xxx.us-east-1.elb.amazonaws.com</code>) from the output, and paste it into your browser to access the <code>index.html</code> file.</td><td>App developer, AWS DevOps, AWS systems administrator</td></tr>
</table>

Debug running containers

Task	Description	Skills required
Select a pod.	List all pods, and copy the desired pod's name.	App developer, AWS DevOps, AWS systems administrator

Task	Description	Skills required

	`kubectl get pods`
	
	The output should be the following.
	
	`NAME READY STATUS RESTARTS AGE`
	`nginx-deployment-xxxx-aaa 1/1 Running 0 55m`
	`nginx-deployment-xxxx-bbb 1/1 Running 0 55m`
	`nginx-deployment-xxxx-ccc 1/1 Running 0 55m`
	`nginx-deployment-xxxx-ddd 1/1 Running 0 42m`
	
	This command lists the existing pods and additional information.
	
	If you are interested in a specific pod, fill in the name of the pod you are interested in for the `POD_NAME` variable or set it as an environment variable. Otherwise, omit this parameter to look up all resources.	

Task	Description	Skills required
	`export POD_NAME="nginx-deployment-<YOUR-POD-NAME>"`	
Access the logs.	Get the logs from the pod that you want to debug. `kubectl logs $POD_NAME`	App developer, AWS systems administrator, AWS DevOps

Forward the NGINX port.	Use port-forwarding to map the pod's port for accessing the NGINX web server to a port on your local machine.
	
	`kubectl port-forward deployment/nginx-deployment 8080:80`
	
	In your browser, open the following URL.
	
	`http://localhost:8080`
	
	The `port-forward` command provides access to the `index.html` file without making it publicly available over a load balancer. This is useful for accessing the running application while debugging it. You can stop the port-forwarding by pressing the keyboard command **Ctrl+C**.
		App developer, AWS DevOps, AWS systems administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>

<tr><td>Delete the IAM policy.</td><td>Delete the previously created policy by using the AWS CLI.
<pre>aws iam delete-policy --policy-arn $POLICY_ARN</pre></td><td>App developer, AWS administrator, AWS DevOps</td></tr>
</table>

Troubleshooting

Issue	Solution
You receive an error message upon cluster creation stating that your targeted Availability Zone doesn't have sufficient capacity to support the cluster. You should see a message similar to the following. `Cannot create cluster 'my-fargate' because us-east-1e, the targeted availability zone, does not currently have sufficient capacity to support the cluster. Retry and choose from these availability zones: us-east-1a, us-east-1b, us-east-1c, us-east-1d, us-east-1f`	Create the cluster again using the recommended Availability Zones from the error message. Specify a list of Availability Zones in the last line of your `clusterconfig-fargate.yaml` file (for example, `availabilityZones: ["us-east-1a", "us-east-1b", "us-east-1c"]`).

Deploy containers by using Elastic Beanstalk

Thomas Scott and Jean-Baptiste Guillois, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, AWS Elastic Beanstalk supports Docker as an available platform, so that containers can run with the created environment. This pattern shows how to deploy containers using the Elastic Beanstalk service. The deployment of this pattern will use the web server environment based on the Docker platform.

To use Elastic Beanstalk for deploying and scaling web applications and services, you upload your code and the deployment is automatically handled. Capacity provisioning, load balancing, automatic scaling, and application health monitoring are also included. When you use Elastic Beanstalk, you can take full control over the AWS resources that it creates on your behalf. There is no additional charge for Elastic Beanstalk. You pay only for the AWS resources that are used to store and run your applications.

This pattern includes instructions for deployment using the [AWS Elastic Beanstalk Command Line Interface (EB CLI)] and the AWS Management Console.

Use cases

Use cases for Elastic Beanstalk include the following:

- Deploy a prototype environment to demo a frontend application. (This pattern uses a Dockerfile as the example.)
- Deploy an API to handle API requests for a given domain.
- Deploy an orchestration solution using Docker-Compose (`docker-compose.yml` is not used as the practical example in this pattern).

Prerequisites and limitations

Prerequisites

- An AWS account
- AWS EB CLI locally installed
- Docker installed on a local machine

Limitations

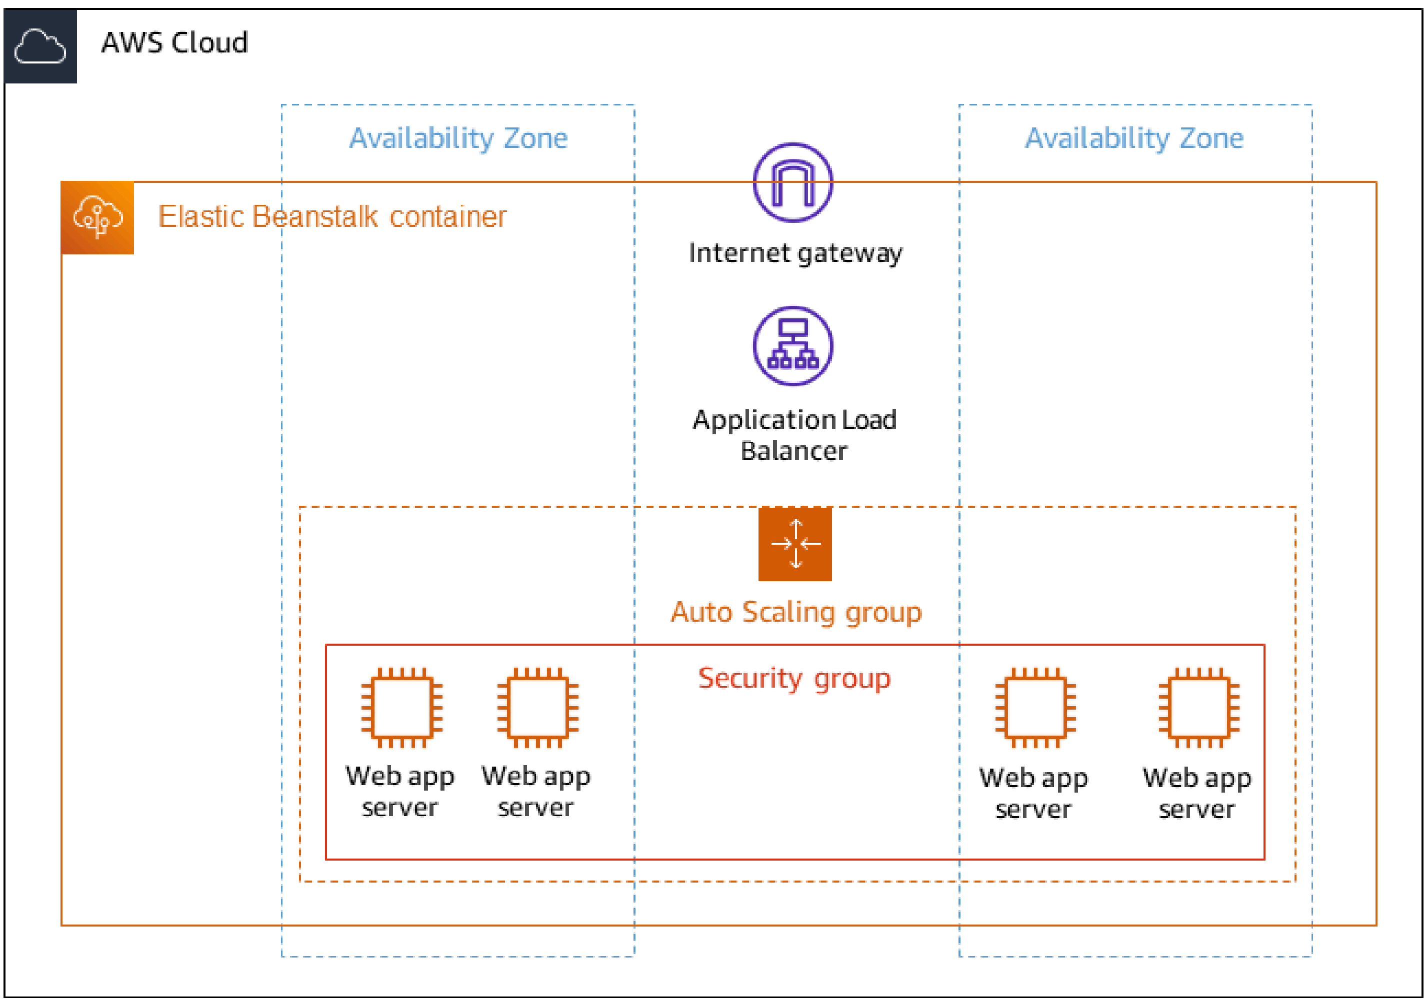
- There is a Docker pull limit of 100 pulls per 6 hours per IP address on the free plan.

Architecture

Target technology stack

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Security group
- Application Load Balancer
- Auto Scaling group

Target architecture



Automation and scale

AWS Elastic Beanstalk can automatically scale based on the number of requests made. AWS resources created for an environment include one Application Load Balancer, an Auto Scaling group, and one or more Amazon EC2 instances.

The load balancer sits in front of the Amazon EC2 instances, which are part of the Auto Scaling group. Amazon EC2 Auto Scaling automatically starts additional Amazon EC2 instances to accommodate increasing load on your application. If the load on your application decreases, Amazon EC2 Auto Scaling stops instances, but it keeps at least one instance running.

Automatic scaling triggers

The Auto Scaling group in your Elastic Beanstalk environment uses two Amazon CloudWatch alarms to initiate scaling operations. The default triggers scale when the average outbound network traffic from each instance is higher than 6 MB or lower than 2 MB over a period of five minutes. To use Amazon EC2 Auto Scaling effectively, configure triggers that are appropriate for your application, instance type, and service requirements. You can scale based on several statistics including latency, disk I/O, CPU utilization, and request count. For more information, see Auto Scaling triggers.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS EB Command Line Interface (EB CLI) is a command-line client that you can use to create, configure, and manage Elastic Beanstalk environments.
- Elastic Load Balancing distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.

Other services

- Docker packages software into standardized units called containers that include libraries, system tools, code, and runtime.

Code

The code for this pattern is available in the GitHub Cluster Sample Application repository.

Epics

Build with a Dockerfile

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Clone the remote repository.</td><td>

- To clone the repository, run the command `git clone https://github.com/aws-samples/cluster-sample-app.git`.< /p>

</td><td>App developer, AWS administrator, AWS DevOps</td></tr>
<tr><td>Initialize the Elastic Beanstalk Docker project.</td><td>

1. Create a file called `aws.json` at the root.
2. In the `aws.json` file, add the following code.

```
{
         "AWSEBDockerrunVersion":"1",
         "Image":{
            "Name":"cluster-sample-app"
         },
         "Ports":[
            {
               "ContainerPort":80,
               "HostPort":8080
            }
         ]
      }
```

</td><td>App developer, AWS administrator, AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	3. Run the command `eb init -p docker` at the root of the project.	
Test the project locally.	1. Run the command `eb local run` at the root of the project. 2. Test the application by navigating to `http://localhost`.	App developer, AWS administrator, AWS DevOps

Deploy using EB CLI

Task	Description	Skills required
Run deployment command	1. Run the command `eb create docker-sample-cluster-app` at the root of the project.	App developer, AWS administrator, AWS DevOps
Access the deployed version.	After the deployment command has finished, access the project using the `eb open` command.	App developer, AWS administrator, AWS DevOps

Deploy using the console

Task	Description	Skills required
Deploy the application by using the browser.	1. Open the console. 2. Navigate to the Elastic Beanstalk console. 3. Choose **Create Application.**	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	4. For the **Application Name**, enter **Cluster-Sample-App**. 5. Choose **Docker** as the platform. 6. Choose **Upload your code.** 7. Choose your local .zip file (in the root of the cloned project) or a public Amazon Simple Storage Service (Amazon S3) URL.	
Access the deployed version.	After deployment, access the deployed application, and choose the URL provided.	App developer, AWS administrator, AWS DevOps

Related resources

- Web server environments
- Install the EB CLI on macOS
- Manually install the EB CLI

Additional information

Advantages of using Elastic Beanstalk

- Automatic infrastructure provisioning
- Automatic management of the underlying platform
- Automatic patching and updates to support the application
- Automatic scaling of the application
- Ability to customize the number of nodes
- Ability to access the infrastructure components if needed
- Ease of deployment over other container deployment solutions

Generate a static outbound IP address using a Lambda function, Amazon VPC, and a serverless architecture

Thomas Scott, Amazon Web Services

Summary

This pattern describes how to generate a static outbound IP address in the Amazon Web Services (AWS) Cloud by using a serverless architecture. Your organization can benefit from this approach if it wants to send files to a separate business entity by using Secure File Transfer Protocol (SFTP). This means that the business entity must have access to an IP address that allows files through its firewall.

The pattern's approach helps you create an AWS Lambda function that uses an [Elastic IP address](#) as the outbound IP address. By following the steps in this pattern, you can create a Lambda function and a virtual private cloud (VPC) that routes outbound traffic through an internet gateway with a static IP address. To use the static IP address, you attach the Lambda function to the VPC and its subnets.

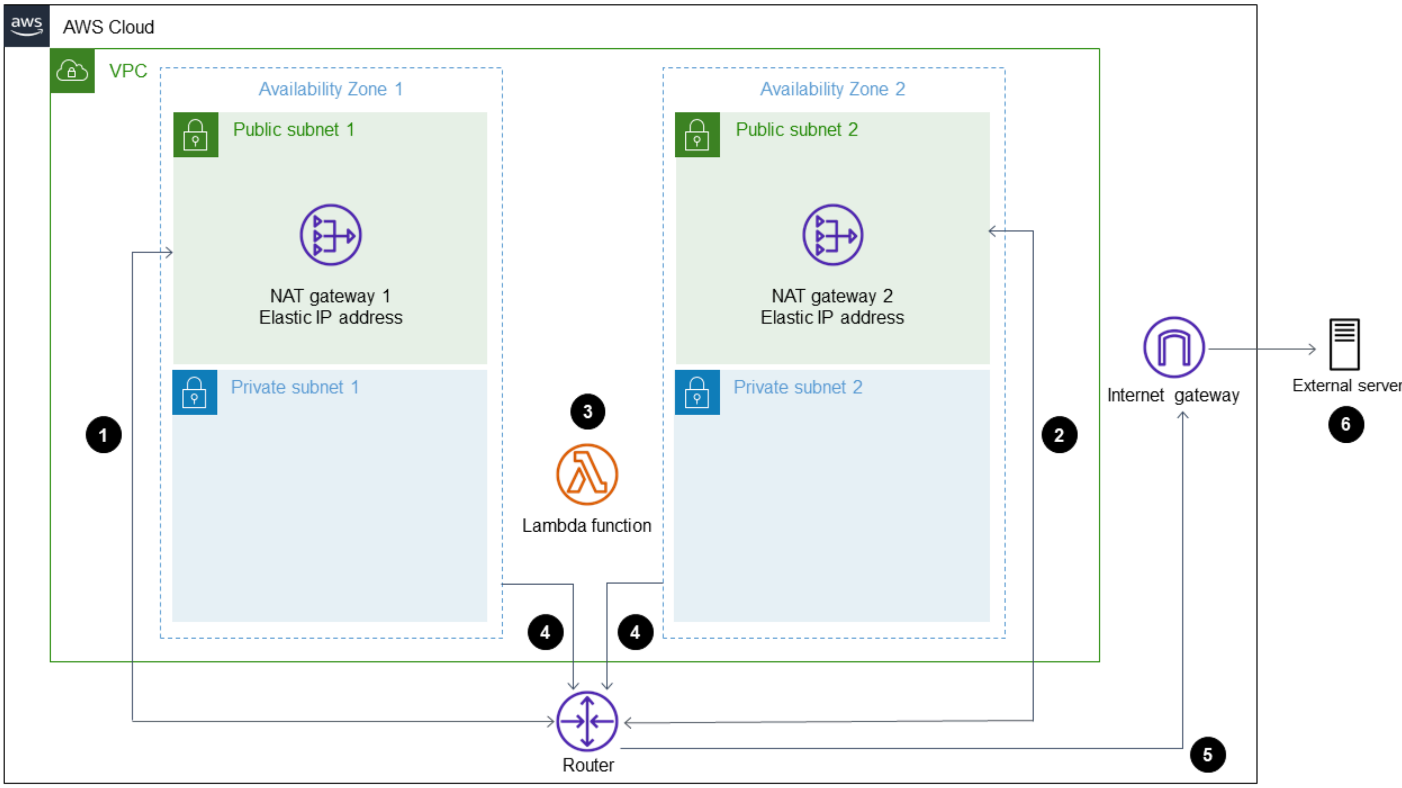
Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Identity and Access Management (IAM) permissions to create and deploy a Lambda function, and to create a VPC and its subnets. For more information about this, see Execution role and user permissions in the AWS Lambda documentation.
- If you plan to use infrastructure as code (IaC) to implement this pattern's approach, you need an integrated development environment (IDE) such as AWS Cloud9. For more information about this, see What is AWS Cloud9? in the AWS Cloud9 documentation.

Architecture

The following diagram shows the serverless architecture for this pattern.



The diagram shows the following workflow:

1. Outbound traffic leaves `NAT gateway 1` in `Public subnet 1`.
2. Outbound traffic leaves `NAT gateway 2` in `Public subnet 2`.
3. The Lambda function can run in `Private subnet 1` or `Private subnet 2`.
4. `Private subnet 1` and `Private subnet 2` route traffic to the NAT gateways in the public subnets.
5. The NAT gateways send outbound traffic to the internet gateway from the public subnets.
6. Outbound data is transferred from the internet gateway to the external server.

Technology stack

- Lambda
- Amazon Virtual Private Cloud (Amazon VPC)

Automation and scale

You can ensure high availability (HA) by using two public and two private subnets in different Availability Zones. Even if one Availability Zone becomes unavailable, the pattern’s solution continues to work.

Tools

- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- Amazon VPC – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Create a new VPC

Task	Description	Skills required
Create a new VPC.	Sign in to the AWS Management Console, open the Amazon VPC console, and then create a VPC named `Lambda VPC` that has `10.0.0.0/25` as the IPv4 CIDR range. For more information about creating a VPC, see Getting started with Amazon VPC in the Amazon VPC documentation.	AWS administrator

Create two public subnets

Task	Description	Skills required
Create the first public subnet.	1. On the Amazon VPC console, choose **Subnets** and then choose **Create Subnet**. 2. For **Name tag**, enter `public-one` . 3. For **VPC**, choose `Lambda VPC`. 4. Choose an Availability Zone and record it. 5. For **IPv4 CIDR block**, enter `10.0.0.0/28` and then choose **Create subnet**.	AWS administrator
Create the second public subnet.	1. On the Amazon VPC console, choose **Subnets** and then choose **Create Subnet**. 2. For **Name tag**, enter `public-two` . 3. For **VPC**, choose `Lambda VPC`. 4. **Important** Choose an Availability Zone and record it. : You cannot use the Availability Zone that contains the `public-one` subnet.	AWS administrator

Task	Description	Skills required
	5. For **IPv4 CIDR block**, enter `10.0.0.16/28` and then choose **Create subnet**.	

Create two private subnets

Task	Description	Skills required
Create the first private subnet.	1. On the Amazon VPC console, choose **Subnets** and then choose **Create Subnet**. 2. For **Name tag**, enter `private-one` . 3. For **VPC**, choose `Lambda VPC`. 4. Choose the Availability Zone that contains the `public-one` subnet that you created earlier. 5. For **IPv4 CIDR block**, enter `10.0.0.32/28` and then choose **Create subnet**.	AWS administrator
Create the second private subnet.	1. On the Amazon VPC console, choose **Subnets** and then choose **Create Subnet**. 2. For **Name tag**, enter `private-two` . 3. For **VPC**, choose `Lambda VPC`.	AWS administrator

Task	Description	Skills required
	4. Choose the same Availability Zone that contains the `public-two` subnet that you created earlier. 5. For **IPv4 CIDR block**, enter `10.0.0.64/28` and then choose **Create subnet**.	

Create two Elastic IP addresses for your NAT gateways

Task	Description	Skills required
Create the first Elastic IP address.	1. On the Amazon VPC console, choose **Elastic IPs** and then choose **Allocate new address**. 2. Choose **Allocate** and record the **Allocation ID** for your newly created Elastic IP address. **Note** This Elastic IP address is used for your first NAT gateway.	AWS administrator
Create the second Elastic IP address.	1. On the Amazon VPC console, choose **Elastic IPs** and then choose **Allocate new address**. 2. Choose **Allocate** and record the **Allocatio**	AWS administrator

Task	Description	Skills required
	n ID for this second Elastic IP address. **Note** This Elastic IP address is used for your second NAT gateway.	

Create an internet gateway

Task	Description	Skills required
Create an internet gateway.	1. On the Amazon VPC console, choose **Internet Gateways** and then choose **Create internet gateway**. 2. Enter `Lambda internet gateway` as the name and then choose **Create internet gateway**. Make sure that you record the internet gateway ID.	AWS administrator
Attach the internet gateway to the VPC.	Select the internet gateway that you just created, and then choose **Actions, Attach to VPC**.	AWS administrator

Create two NAT gateways

Task	Description	Skills required
Create the first NAT gateway.	1. On the Amazon VPC console, choose **NAT Gateways** and then choose **Create NAT Gateway**. 2. Enter `nat-one` as the NAT gateway name. 3. Choose `public-one` as the subnet to create the NAT gateway in. 4. For **Connectivity type**, choose **Public**. 5. For **Elastic IP allocation ID**, choose the first Elastic IP address that you created earlier and associate it with the NAT gateway. 6. Choose **Create NAT gateway**.	AWS administrator
Create the second NAT gateway.	1. On the Amazon VPC console, choose **NAT Gateways** and then choose **Create NAT Gateway**. 2. Enter `nat-two` as the NAT gateway name. 3. Choose `public-two` as the subnet to create the NAT gateway in.	AWS administrator

Task	Description	Skills required
	4. For **Connectivity type**, choose **Public**. 5. For **Elastic IP allocation ID**, choose the second Elastic IP address that you created earlier and associate it with the NAT gateway. 6. Choose **Create NAT gateway**.	

Create route tables for your public and private subnets

Task	Description	Skills required
Create the route table for the public-one subnet.	1. On the Amazon VPC console, choose **Route Tables** and then choose **Create route table**. 2. Enter `public-one-subnet` as the route table name and then choose **Create route table**. 3. Choose the `public-one-subnet` route table, choose **Edit routes**, and then choose **Add route**. 4. Specify `0.0.0.0` in the **Destination** box and then choose the internet gateway ID in the **Target** list. 5. On the **Subnet associations** tab, choose **Edit**	AWS administrator

Task	Description	Skills required
	subnet associations, choose the `public-one` subnet with the `10.0.0.0/28` CIDR range, and then choose **Save associations**. 6. Choose **Save Changes**.	

Task	Description	Skills required
Create the route table for the public-two subnet.	1. On the Amazon VPC console, choose **Route Tables** and then choose **Create route table**. 2. Enter `public-two-subnet` as the route table name and then choose **Create route table**. 3. Choose the `public-two-subnet` route table, choose **Edit routes**, and then choose **Add route**. 4. Specify `0.0.0.0` in the **Destination** box and then choose the internet gateway ID in the **Target** list. 5. On the **Subnet associations** tab, choose **Edit subnet associations**, choose the `public-two` subnet with the `10.0.0.16/28` CIDR range, and then choose **Save associations**. 6. Choose **Save Changes**.	AWS administrator

Task	Description	Skills required
Create the route table for the private-one subnet.	1. On the Amazon VPC console, choose **Route Tables** and then choose **Create route table**. 2. Enter `private-one-subnet` as the route table name and then choose **Create route table**. 3. Choose the `private-one-subnet` route table, choose **Edit routes**, and then choose **Add route**. 4. Specify `0.0.0.0` in the **Destination** box and then choose the NAT gateway in the `public-one` subnet in the **Target** list. 5. On the **Subnet associations** tab, choose **Edit subnet associations**, choose the `private-one` subnet with the `10.0.0.32/28` CIDR range, and then choose **Save associations**. 6. Choose **Save Changes**.	AWS administrator

Task	Description	Skills required
Create the route table for the private-two subnet.	1. On the Amazon VPC console, choose **Route Tables** and then choose **Create route table**. 2. Enter `private-two-subnet` as the route table name and then choose **Create route table**. 3. Choose the `private-two-subnet` route table, choose **Edit routes**, and then choose **Add route**. 4. Specify `0.0.0.0` in the **Destination** box and then choose the NAT gateway in the `public-two` subnet in the **Target** list. 5. On the **Subnet associations** tab, choose **Edit subnet associations**, choose the `private-two` subnet with the `10.0.0.64/28` CIDR range, and then choose **Save associations**. 6. Choose **Save Changes**.	AWS administrator

Create the Lambda function, add it to the VPC, and test the solution

Task	Description	Skills required
Create a new Lambda function.	1. Open the AWS Lambda console and choose **Create function**. 2. Under **Basic information**, enter `Lambda test` under **Function name** and then choose the language of your choice under **Runtime**. 3. Choose **Create function**.	AWS administrator
Add the Lambda function to your VPC.	1. On the AWS Lambda console, choose **Functions** and then choose the function that you created earlier. 2. Choose **Configuration** and then choose **VPC**. 3. Choose **Edit** and then choose `Lambda VPC` and both private subnets. 4. Choose **Default security group** for testing purposes and then choose **Save**.	AWS administrator
Write code to call an external service.	1. In the programming language of your choice, write code to call an external service that returns your IP address.	AWS administrator

Task	Description	Skills required
	2. Verify that the returned IP address matches one of your Elastic IP addresses.

Identify duplicate container images automatically when migrating to an Amazon ECR repository

Rishabh Yadav and Rishi Singla, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

The pattern provides an automated solution to identify whether images that are stored in different container repositories are duplicates. This check is useful when you plan to migrate images from other container repositories to Amazon Elastic Container Registry (Amazon ECR).

For foundational information, the pattern also describes the components of a container image, such as the image digest, manifest, and tags. When you plan a migration to Amazon ECR, you might decide to synchronize your container images across container registries by comparing the digests of the images. Before you migrate your container images, you need to check whether these images already exist in the Amazon ECR repository to prevent duplication. However, it can be difficult to detect duplication by comparing image digests, and this might lead to issues in the initial migration phase. This pattern compares the digests of two similar images that are stored in different container registries and explains why the digests vary, to help you compare images accurately.

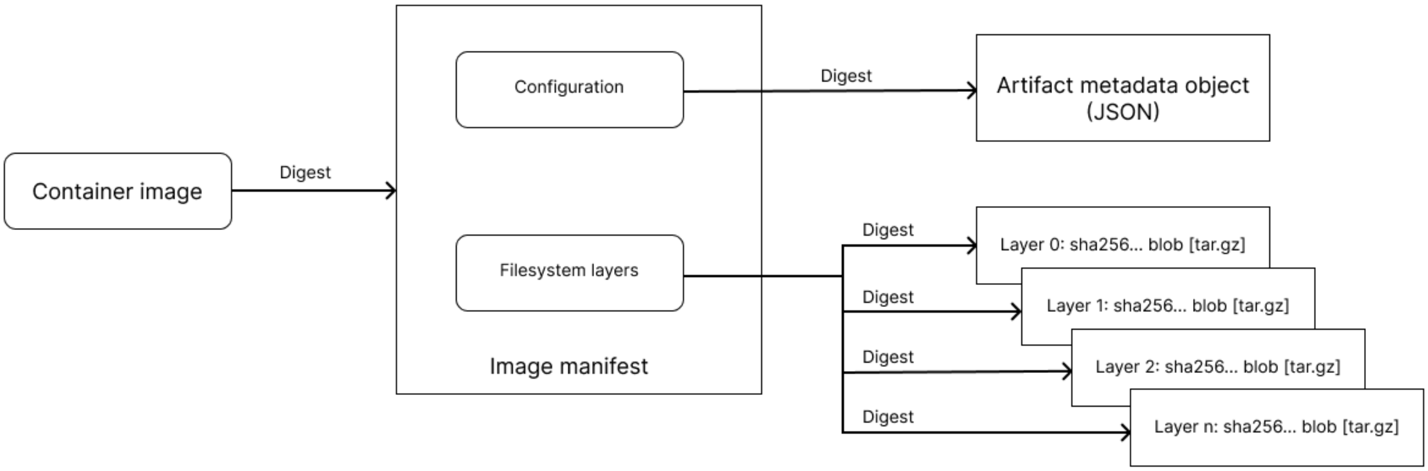
Prerequisites and limitations

- An active AWS account
- Access to the Amazon ECR public registry
- Familiarity with the following AWS services:
  - AWS CodeCommit
  - AWS CodePipeline
  - AWS CodeBuild
  - AWS Identity and Access Management (IAM)
  - Amazon Simple Storage Service (Amazon S3)
- Configured CodeCommit credentials (see instructions)

Architecture

Container image components

The following diagram illustrates some of the components of a container image. These components are described after the diagram.



Terms and definitions

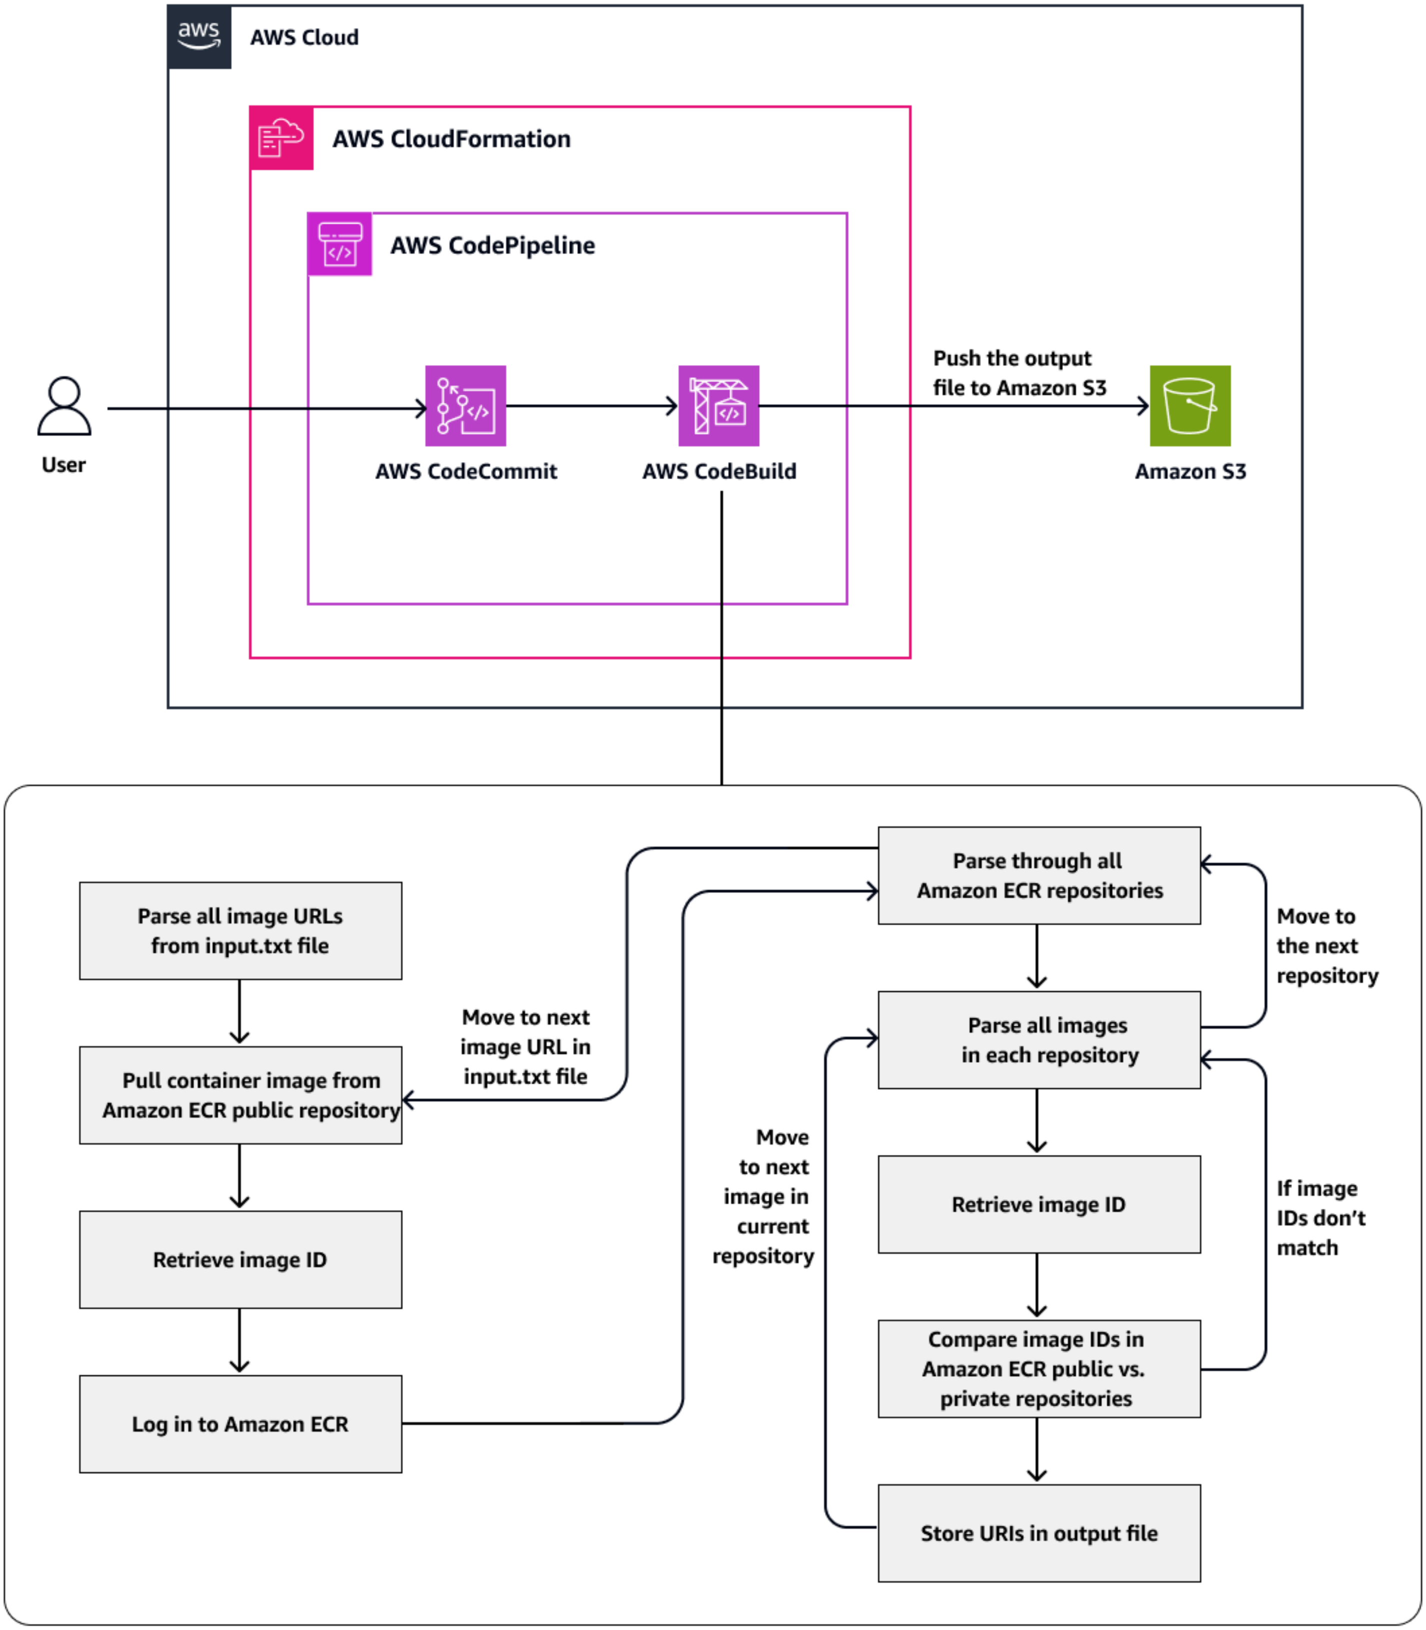
The following terms are defined in the Open Container Initiative (OCI) Image Specification.

- **Registry:** A service for image storage and management.
- **Client:** A tool that communicates with registries and works with local images.
- **Push:** The process for uploading images to a registry.
- **Pull:** The process for downloading images from a registry.
- **Blob:** The binary form of content that is stored by a registry and can be addressed by a digest.
- **Index:** A construct that identifies multiple image manifests for different computer platforms (such as x86-64 or ARM 64-bit) or media types. For more information, see the OCI Image Index Specification.
- **Manifest:** A JSON document that defines an image or artifact that is uploaded through the manifest's endpoint. A manifest can reference other blobs in a repository by using descriptors. For more information, see the OCI Image Manifest Specification.
- **Filesystem layer:** System libraries and other dependencies for an image.
- **Configuration:** A blob that contains artifact metadata and is referenced in the manifest. For more information, see the OCI Image Configuration Specification.

- **Object or artifact:** A conceptual content item that's stored as a blob and associated with an accompanying manifest with a configuration.
- **Digest:** A unique identifier that's created from a cryptographic hash of the contents of a manifest. The image digest helps uniquely identify an immutable container image. When you pull an image by using its digest, you will download the same image every time on any operating system or architecture. For more information, see the OCI Image Specification.
- **Tag:** A human-readable manifest identifier. Compared with image digests, which are immutable, tags are dynamic. A tag that points to an image can change and move from one image to another, although the underlying image digest remains the same.

Target architecture

The following diagram displays the high-level architecture of the solution provided by this pattern to identify duplicate container images by comparing images that are stored in Amazon ECR and private repositories.



AWS Cloud
AWS CloudFormation
AWS CodePipeline
User
AWS CodeCommit
AWS CodeBuild
Push the output file to Amazon S3
Amazon S3
Parse all image URLs from input.txt file
Pull container image from Amazon ECR public repository
Retrieve image ID
Log in to Amazon ECR
Move to next image URL in input.txt file
Parse through all Amazon ECR repositories
Parse all images in each repository
Retrieve image ID
Compare image IDs in Amazon ECR public vs. private repositories
Store URIs in output file
Move to the next repository
If image IDs don't match
Move to next image in current repository

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CodeBuildis a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.

Code

The code for this pattern is available in the GitHub repository Automated solution to identify duplicate container images between repositories.

Best practices

- AWS CloudFormation best practices
- AWS CodePipeline best practices

Epics

Pull container images from Amazon ECR public and private repositories

Task	Description	Skills required
Pull an image from the Amazon ECR public repository.	From the terminal, run the following command to pull the image `amazonlinux` from the Amazon ECR public repository.	App developer, AWS DevOps, AWS administrator

Task	Description	Skills required

	`$~ % docker pull public.ecr.aws/amazonlinux/amazonlinux:2018.03`
	
	When the image has been pulled to your local machine, you'll see the following pull digest, which represents the image index.
	
	`2018.03: Pulling from amazonlinux/amazonlinux`
	`4ddc0f8d367f: Pull complete`
	
	`Digest: sha256:f972d24199508c52de7ad37a298bda35d8a1bd7df158149b381c03f6c6e363b5`
	
	`Status: Downloaded newer image for public.ecr.aws/amazonlinux/amazonlinux:2018.03`
	`public.ecr.aws/amazonlinux/amazonlinux:2018.03`	

Task	Description	Skills required

Push the image to an Amazon ECR private repository.	1. Create a private Amazon ECR repository named `test_ecr_repository` in the US East (N. Virginia) Region (`us-east-1`).
	`$~ % aws ecr get-login-password --region us-east-1 | docker login --username AWS --password-stdin <account-id>.dkr.ecr.us-east-1.amazonaws.com`
	`Login Succeeded`
	where `<account-id>` refers to your AWS account.
	2. Tag the local image that you pulled previously. Use the value `public.ecr.aws/amazonlinux/amazonlinux:2018.03` and push it to the Amazon ECR private repository.
	`$~ % docker tag public.ecr.aws/amazonlinux/amazonlinux:2018.03 <account-id>.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest`
		AWS administrator, AWS DevOps, App developer

Task	Description	Skills required

	`$~ % docker push <account-id>.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest`
	
	When you push the image to the Amazon ECR repository, Docker will push the underlying image and not the image index.
	
	`The push refers to repository [<account-id>.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository] d5655967c2c4: Pushed latest: digest: sha256:52db9000073d93b9bdee6a7246a68c35a741aaade05a8f4febba0bf795cdac02 size: 529`	

Task	Description	Skills required

Pull the same image from the Amazon ECR private repositor y.	1. From the terminal, run the following command to pull the image that you previously pushed to the Amazon ECR private repository.
	<pre>$~ % docker pull
	 <account-id>.dkr.e
	cr.us-east-1.amazo
	naws.com/test_ecr_
	repository:latest
	latest: Pulling from
	 test_ecr_repository
	Digest: sha256:52
	db9000073d93b9bdee
	6a7246a68c35a741aa
	ade05a8f4febba0bf7
	95cdac02
	Status: Image is up
	 to date for <account-
	id>.dkr.ecr.us-eas
	t-1.amazonaws.com/
	test_ecr_repositor
	y:latest
	<account-id>.dkr.e
	cr.us-east-1.amazo
	naws.com/test_ecr_
	repository:latest</pre>The digest for this image matches the digest of the image that you pushed to the Amazon ECR private repository, and represent s the underlying image. This value doesn't match the image index that you
		App developer, AWS DevOps, AWS administrator

Task	Description	Skills required
	pulled from the public repository. 2. To verify, retrieve the image index by digest. `curl -k -H "Authorization: Bearer $TOKEN" https://public.ecr.aws/v2/amazonlinux/amazonlinux/manifests/sha256:f972d24199508c52de7ad37a298bda35d8a1bd7df158149b381c03f6c6e363b55 { "schemaVersion": 2, "mediaType": "application/vnd.docker.distribution.manifest.list.v2+json", "manifests": [{ "mediaType": "application/vnd.docker.distribution.manifest.v2+json", "size": 529, "digest": "sha256:52db9000073d93b9bdee6a7246a68c35a741aaade05a8f4febba0bf795cdac02", "platform": { "architecture": "amd64",`	

Task	Description	Skills required
	```"os": "linux" } }] }```	

Compare the image manifests

Task	Description	Skills required
Find the manifest of the image stored in the Amazon ECR public repository.	From the terminal, run the following command to pull the manifest of the image `public.ecr.aws/amazonlinux/amazonlinux:2018.03` from the Amazon ECR public repository. ```$~ % docker manifest inspect public.ecr.aws/amazonlinux/amazonlinux:2018.03 { "schemaVersion": 2, "mediaType": "application/vnd.docker.distribution.manifest.list.v2+json", "manifests": [{ "mediaType": "application/vnd.docker.distribution.manifest.v2+json", "size": 529,```	AWS administrator, AWS DevOps, App developer

Task	Description	Skills required
	"digest": "sha256:52db9000073d93b9bdee6a7246a68c35a741aaade05a8f4febba0bf795cdac02", "platform": { "architecture": "amd64", "os": "linux" } }] }	

Task	Description	Skills required

Find the manifest of the image stored in the Amazon ECR private repository.	From the terminal, run the following command to pull the manifest of the image `<account-id>.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest` from the Amazon ECR private repository.
	`$~ % docker manifest inspect <account-id>.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest`
	
	`{ "schemaVersion": 2, "mediaType": "application/vnd.docker.distribution.manifest.v2+json", "config": { "mediaType": "application/vnd.docker.container.image.v1+json", "size": 1477, "digest": "sha256:f7cee5e1af28ad4e147589c474d399b12d9b551ef4c3e11e02d982fce5eebc68" }, "layers": [ {`
		AWS DevOps, AWS systems administrator, App developer

Task	Description	Skills required
	"mediaType": "application/vnd.docker.image.rootfs.diff.tar.gzip", "size": 62267075, "digest": "sha256:4ddc0f8d367f424871a060e2067749f32bd36a91085e714dcb159952f2d71453" }] }	

Task	Description	Skills required
Compare the digest pulled by Docker with the manifest digest for the image in the Amazon ECR private repository.	Another question is why the digest provided by the **docker pull** command differs from the manifest's digest for the image `<account-id>.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest` . The digest used for **docker pull** represents the digest of the image manifest, which is stored in a registry. This digest is considered the root of a hash chain, because the manifest contains the hash of the content that will be downloaded and imported into Docker. The image ID used within Docker can be found in this manifest as `config.digest` . This represents the image configuration that Docker uses. So you could say that the manifest is the envelope, and the image is the content of the envelope. The manifest digest is always different from the image ID. However, a specific manifest should always produce the same image ID. Because the	AWS DevOps, AWS systems administrator, App developer

Task	Description	Skills required
	manifest digest is a hash chain, we cannot guarantee that it will always be the same for a given image ID. In most cases, it produces the same digest, although Docker cannot guarantee that. The possible difference in the manifest digest stems from Docker not storing the blobs that are compressed with gzip locally. Therefore , exporting layers might produce a different digest, although the uncompressed content remains the same. The image ID verifies that uncompressed content is the same; that is, the image ID is now a content addressable identifier (`chainID`). To confirm this informati on, you can compare the output of the **docker inspect** command on the Amazon ECR public and private repositor ies: 1. Run the following command from your terminal for the image stored in the Amazon ECR public repository.	

Task	Description	Skills required

	`$~ % docker inspect public.ecr.aws/amazonlinux/amazonlinux:2018.03`
	
	For the output from the command, see the [Additional information](#) section.
	
	2. Run the following command from your terminal for the image stored in the Amazon ECR private repository.
	
	`$~ % docker inspect <account-id>.dkr.ecr.us-east-1.amazonaws.com/test_ecr_repository:latest`
	
	For the output from the command, see the [Additional information](#) section.
	
	The results verify that both images have the same image ID digest and layer digest.
	
	ID: `f7cee5e1af28ad4e147589c474d399b12d9b551ef4c3e11e02d982fce5eebc68`	

Task	Description	Skills required
	Layers: d5655967c `2c4e8d68f8ec7cf753` `218938669e6c16ac13` `24303c073c736a2e2a2` Additionally, the digests are based on the bytes of the object that's managed locally (the local file is a tar of the container image layer) or the blob that's pushed to the registry server. However, when you push the blob to a registry, the tar is compresse d and the digest is computed in the compressed tar file. Therefore, the difference in the **docker pull** digest value arises from compressi on that is applied at the registry (Amazon ECR private or public) level. **Note** This explanation is specific to using a Docker client. You won’t see this behavior with other clients such as **nerdctl** or **Finch**, because they don’t automatically compress the image	

Task	Description	Skills required
	during push and pull operations.	

Automatically identify duplicate images between Amazon ECR public and private repositories

Task	Description	Skills required
Clone the repository.	Clone the Github repository for this pattern into a local folder: `$git clone https://github.com/aws-samples/automated-solution-to-identify-duplicate-container-images-between-repositories`	AWS administrator, AWS DevOps
Set up a CI/CD pipeline.	The GitHub repository includes a `.yaml` file that creates an AWS CloudFormation stack to set up a pipeline in AWS CodePipeline. 1. Sign in to the AWS Management Console and open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/). 2. Create a stack by using the template `pipeline.yaml` file, which is in the code folder in the cloned repository.	AWS administrator, AWS DevOps

Task	Description	Skills required
	3. Accept or change the default values of parameters. Specify values for the following: • Stack name • `ArtifactStoreBucketName` – An existing S3 bucket that will be used to store AWS CodePipeline artifacts • `OutputBucket` – An existing S3 bucket that will be used to store the URIs for the duplicate images • `SourceImageFile` – An existing text file named `input.txt` that contains the image URIs from the public repository that will be checked against the Amazon ECR private repository to detect duplication 4. Review and adjust stack options, and then choose **Submit** to run the template. The pipeline will be set up with two stages (CodeCommit and CodeBuild, as shown in	

Task	Description	Skills required
	the architecture diagram) to identify images in the private repository that also exist in the public repository. The pipeline is configured with the following resources: • CodePipeline for the orchestration of the deployment pipeline. • A CodeCommit repository to store the bash script and input file. The bash script is used to compare the container image IDs in the public and private repositories to find duplications. This check is performed across all the repositories in the specified AWS account in a single AWS Region. • A CodeBuild project to invoke the bash script to identify images that are already present in the Amazon ECR repository. • Necessary IAM roles to allow access. • An S3 bucket to store the output file that contains image URIs. • Another S3 bucket to store CodePipeline artifacts.	

Task	Description	Skills required
Populate the CodeCommit repository.	To populate the CodeCommi t repository, perform these steps: 1. Open the [CodeCommit console](#) and navigate to the AWS Region where you created the CloudForm ation stack. 2. Find the repository that you provisioned by using the CloudFormation script from the list, choose **Clone URL,** and then copy the **HTTPS URL** protocol to connect to the repository. 3. Open a command prompt and run the **git clone** command with the HTTPS URL that you copied in the previous step. 4. Navigate to the root directory. Create a file named `input.txt` and populate this file with the Amazon ECR public image registry URIs that you would like to search for in the private Amazon ECR repository. 5. Copy the files `script.sh` , `buildspec.yml` , and `input.txt` from your local copy of the GitHub	AWS administrator, AWS DevOps

Task	Description	Skills required

	repository [Automated solution to identify duplicate container images between repositories](#) to the cloned CodeCommit repository.
	6. Upload the files to CodeCommit by using these commands:
	`git add .`
	`git commit -m "added input files"`
	`git push`	

Clean up.	To avoid incurring future charges, delete the resources by following these steps: 1. Navigate to the S3 bucket that stores the CodePipeline artifacts, and empty the bucket. 2. Navigate to the S3 bucket that stores the duplicate image URIs, and empty the bucket. 3. Navigate to the CloudFormation console and delete the stack that you created to set up the pipeline.	AWS administrator

Troubleshooting

Issue	Solution
When you try to push, pull, or otherwise interact with a CodeCommit repository from the terminal or command line, you are prompted to provide a user name and password, and you must supply the Git credentials for your IAM user.	The most common causes for this error are the following: • Your local computer is running an operating system that doesn't support credential management, or it doesn't have a credential management utility installed. • The Git credentials for your IAM user haven't been saved to one of these credential management systems. Depending on your operating system and local environment, you might need to install a credential manager, configure the credentia l manager that is included in your operating system, or customize your local environment to use credential storage. For example, if your computer is running macOS, you can use the Keychain Access utility to store your credentia ls. If your computer is running Windows, you can use the Git Credential Manager that is installed with Git for Windows. For more information, see Setup for HTTPS users using Git credentials in the CodeCommit documentation and Credential Storage in the Git documentation.
You encounter HTTP 403 or "no basic auth credentials" errors when you push an image to the Amazon ECR repository.	You might encounter these error messages from the **docker push** or **docker pull** command, even if you have successfully authenticated to Docker by using the **aws ecr get-login-password** command. Known causes are:

Issue	Solution
	• You have authenticated to a different Region. For more information, see Private registry authentication in the Amazon ECR documentation. • You have authenticated to push to a repository that you don't have permissio ns for. For more information, see Private repository policies in the Amazon ECR documentation. • Your token has expired. The default expiration period for tokens obtained by using the `GetAuthorizationToken` operation is 12 hours.

Install SSM Agent on Amazon EKS worker nodes by using Kubernetes DaemonSet

Mahendra Revanasiddappa, Amazon Web Services

Summary

Note, September 2021: The latest Amazon EKS optimized AMIs install SSM Agent automatically. For more information, see the release notes for the June 2021 AMIs.

In Amazon Elastic Kubernetes Service (Amazon EKS), because of security guidelines, worker nodes don't have Secure Shell (SSH) key pairs attached to them. This pattern shows how you can use the Kubernetes DaemonSet resource type to install AWS Systems Manager Agent (SSM Agent) on all worker nodes, instead of installing it manually or replacing the Amazon Machine Image (AMI) for the nodes. DaemonSet uses a cron job on the worker node to schedule the installation of SSM Agent. You can also use this pattern to install other packages on worker nodes.

When you're troubleshooting issues in the cluster, installing SSM Agent on demand enables you to establish an SSH session with the worker node, to collect logs or to look into instance configuration, without SSH key pairs.

Prerequisites and limitations

Prerequisites

- An existing Amazon EKS cluster with Amazon Elastic Compute Cloud (Amazon EC2) worker nodes.
- Container instances should have the required permissions to communicate with the SSM service. The AWS Identity and Access Management (IAM) managed role **AmazonSSMManagedInstanceCore** provides the required permissions for SSM Agent to run on EC2 instances. For more information, see the AWS Systems Manager documentation.

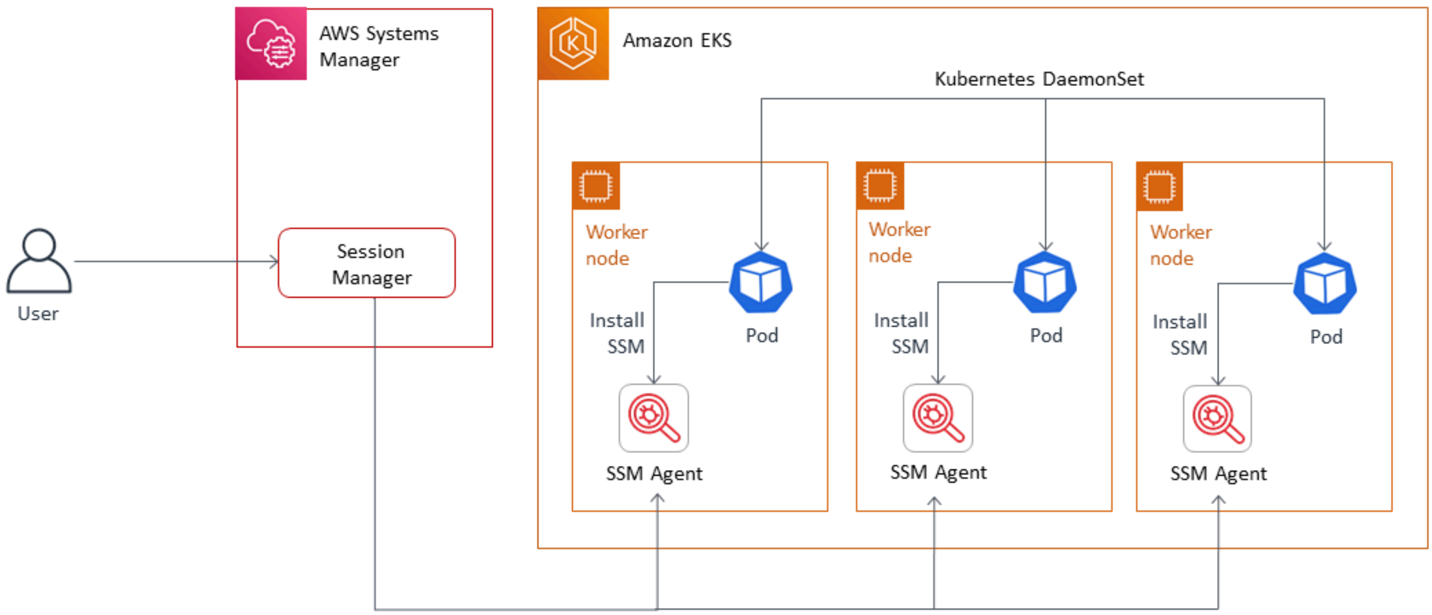
Limitations

- This pattern isn't applicable to AWS Fargate, because DaemonSets aren't supported on the Fargate platform.
- This pattern applies only to Linux-based worker nodes.

- The DaemonSet pods run in privileged mode. If the Amazon EKS cluster has a webhook that blocks pods in privileged mode, the SSM Agent will not be installed.

Architecture

The following diagram illustrates the architecture for this pattern.



Tools

Tools

- kubectl is a command-line utility that is used to interact with an Amazon EKS cluster. This pattern uses `kubectl` to deploy a DaemonSet on the Amazon EKS cluster, which will install SSM Agent on all worker nodes.
- Amazon EKS makes it easy for you to run Kubernetes on AWS without having to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.
- AWS Systems Manager Session Manager lets you manage your EC2 instances, on-premises instances, and virtual machines (VMs) through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).

Code

Use the following code to create a DaemonSet configuration file that will install SSM Agent on the Amazon EKS cluster. Follow the instructions in the Epics section.

```
cat << EOF > ssm_daemonset.yaml
apiVersion: apps/v1
kind: DaemonSet
metadata:
  labels:
    k8s-app: ssm-installer
  name: ssm-installer
  namespace: kube-system
spec:
  selector:
    matchLabels:
      k8s-app: ssm-installer
  template:
    metadata:
      labels:
        k8s-app: ssm-installer
    spec:
      containers:
      - name: sleeper
        image: busybox
        command: ['sh', '-c', 'echo I keep things running! && sleep 3600']
      initContainers:
      - image: amazonlinux
        imagePullPolicy: Always
        name: ssm
        command: ["/bin/bash"]
        args: ["-c","echo '* * * * * root yum install -y https://s3.amazonaws.com/
ec2-downloads-windows/SSMAgent/latest/linux_amd64/amazon-ssm-agent.rpm & rm -rf /etc/
cron.d/ssmstart' > /etc/cron.d/ssmstart"]
        securityContext:
          allowPrivilegeEscalation: true
        volumeMounts:
        - mountPath: /etc/cron.d
          name: cronfile
        terminationMessagePath: /dev/termination-log
        terminationMessagePolicy: File
      volumes:
      - name: cronfile
        hostPath:
          path: /etc/cron.d
```

```
          type: Directory
      dnsPolicy: ClusterFirst
      restartPolicy: Always
      schedulerName: default-scheduler
      terminationGracePeriodSeconds: 30
EOF
```

Epics

Set up kubectl

Task	Description	Skills required
Install and configure kubectl to access the EKS cluster.	If `kubectl` isn't already installed and configured to access the Amazon EKS cluster, see [Installing kubectl](#) in the Amazon EKS documentation.	DevOps

Deploy the DaemonSet

Task	Description	Skills required
Create the DaemonSet configuration file.	Use the code in the [Code](#) section earlier in this pattern to create a DaemonSet configuration file called `ssm_daemonset.yaml` , which will be deployed to the Amazon EKS cluster. The pod launched by DaemonSet has a main container and an `init` container. The main container has a `sleep` command. The	DevOps

Task	Description	Skills required
	`init` container includes a `command` section that creates a cron job file to install SSM Agent at the path `/etc/cron.d/` . The cron job runs only once, and the file it creates is automatically deleted after the job is complete. When the init container has finished, the main container waits for 60 minutes before exiting. After 60 minutes, a new pod is launched. This pod installs SSM Agent, if it's missing, or updates SSM Agent to the latest version. If required, you can modify the `sleep` command to restart the pod once a day or to run more often.	
Deploy the DaemonSet on the Amazon EKS cluster.	To deploy the DaemonSet configuration file you created in the previous step on the Amazon EKS cluster, use the following command: `kubectl apply -f ssm_daemonset.yaml` This command creates a DaemonSet to run the pods on worker nodes to install SSM Agent.	DevOps

Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands

Akkamahadevi Hiremath, Amazon Web Services

Summary

This pattern provides code samples and steps to install the AWS Systems Manager Agent (SSM Agent) and Amazon CloudWatch agent on Amazon Elastic Kubernetes Service (Amazon EKS) worker nodes in the Amazon Web Services (AWS) Cloud during Amazon EKS cluster creation. You can install the SSM Agent and CloudWatch agent by using the `preBootstrapCommands` property from the `eksctl` config file schema (Weaveworks documentation). Then, you can use the SSM Agent to connect to your worker nodes without using an Amazon Elastic Compute Cloud (Amazon EC2) key pair. Additionally, you can use the CloudWatch agent to monitor memory and disk utilization on your Amazon EKS worker nodes.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The eksctl command line utility, installed and configured on macOS, Linux, or Windows
- The kubectl command line utility, installed and configured on macOS, Linux, or Windows

Limitations

- We recommend that you avoid adding long-running scripts to the `preBootstrapCommands` property, because this delays the node from joining the Amazon EKS cluster during scaling activities. We recommend that you create a custom Amazon Machine Image (AMI) instead.
- This pattern applies to Amazon EC2 Linux instances only.

Architecture

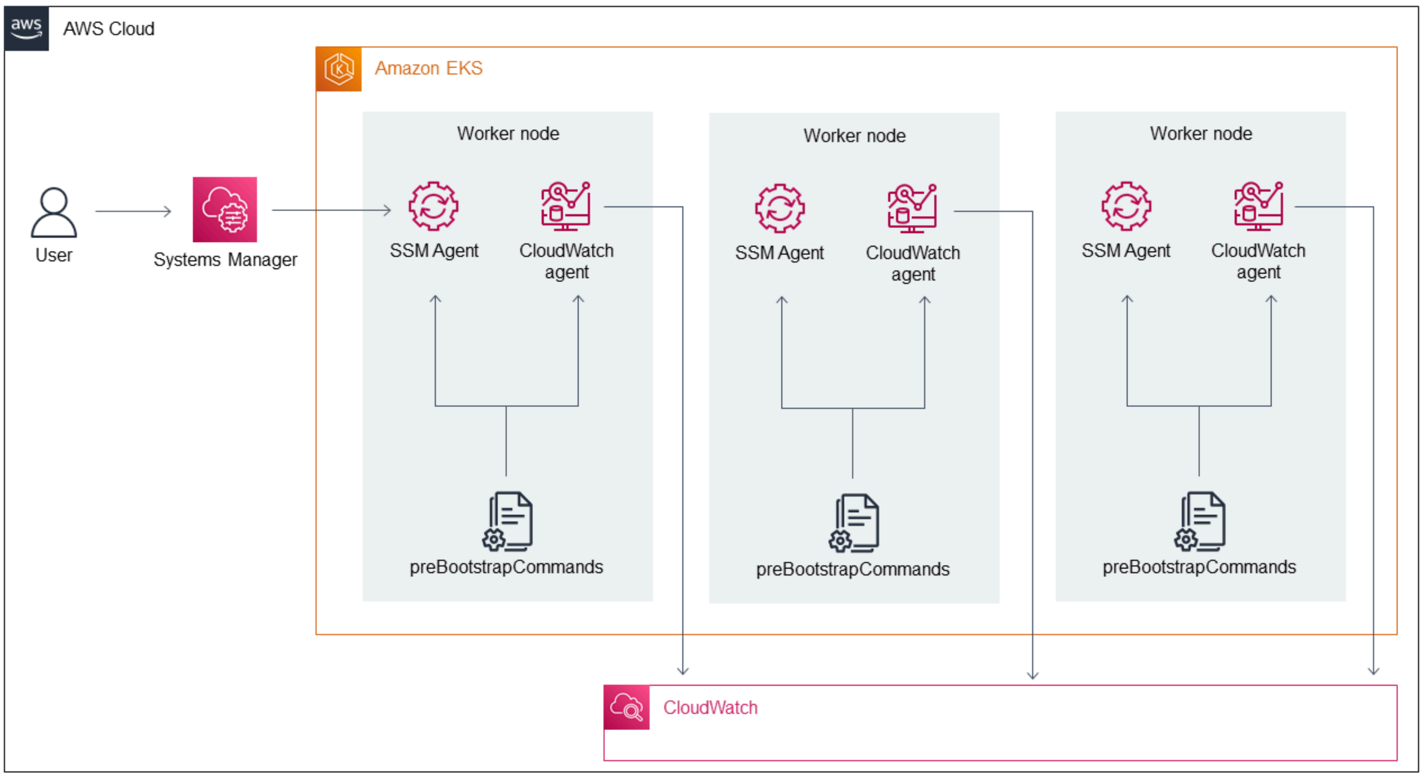
Technology stack

- Amazon CloudWatch

- Amazon Elastic Kubernetes Service (Amazon EKS)
- AWS Systems Manager Parameter Store

Target architecture

The following diagram shows an example of a user connecting to Amazon EKS worker nodes using SSM Agent which was installed using the `preBootstrapCommands`.



The diagram shows the following workflow:

1. The user creates an Amazon EKS cluster by using the `eksctl` configuration file with the `preBootstrapCommands` property, which installs the SSM Agent and CloudWatch agent.
2. Any new instances that join the cluster later due to scaling activities get created with the pre-installed SSM Agent and CloudWatch agent.
3. The user connects to Amazon EC2 by using the SSM Agent and then monitors memory and disk utilization by using the CloudWatch agent.

Tools

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Systems Manager Parameter Store provides secure, hierarchical storage for configuration data management and secrets management.
- AWS Systems Manager Session Manager helps you manage your EC2 instances, on-premises instances, and virtual machines through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).
- eksctl is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- kubectl is a command-line utility for communicating with the cluster API server.

Epics

Create an Amazon EKS cluster

Task	Description	Skills required
Store the CloudWatch agent configuration file.	Store the CloudWatch agent configuration file in the AWS Systems Manager Parameter Store in the AWS Region where you want to create your Amazon EKS cluster. To do this, create a parameter in AWS Systems Manager Parameter Store and note the name of the parameter (for example, `AmazonCloudwatch-linux`). For more information, see the *Example CloudWatch agent configuration file* code	DevOps engineer

Task	Description	Skills required
	in the [Additional information](#) section of this pattern.	
Create the eksctl configura tion file and cluster.	1. Create an `eksctl` configuration file that includes the CloudWatc h agent and SSM Agent installation steps. For more information, see the *Example eksctl configura tion file* code in the [Additional information](#) section of this pattern. 2. Create a cluster by running the `eksctl create cluster -f cluster.y aml` command.	AWS DevOps

Verify that the SSM Agent and CloudWatch agent work

Task	Description	Skills required
Test the SSM Agent.	Use SSH to connect to your Amazon EKS cluster nodes by using any of the methods covered in [Start a session](#) from the AWS Systems Manager documentation.	AWS DevOps
Test the CloudWatch agent.	Use the CloudWatch console to validate the CloudWatch agent: 1. Sign in to the AWS Management Console	AWS DevOps

Task	Description	Skills required
	and open the CloudWatch console. 2. On the navigation pane, expand **Metrics** and then choose **All metrics**. 3. In the search box on the **Browse** tab, enter and then choose **CWAgent metrics** to see the memory and disk metrics.	

Related resources

- Starting a session (AWS CLI) (AWS Systems Manager documentation)
- Starting a session (Amazon EC2 console) (AWS Systems Manager documentation)

Additional information

Example CloudWatch agent configuration file

In the following example, the CloudWatch agent is configured to monitor disk and memory utilization on Amazon Linux instances:

```
{
    "agent": {
        "metrics_collection_interval": 60,
        "run_as_user": "cwagent"
    },
    "metrics": {
        "append_dimensions": {
            "AutoScalingGroupName": "${aws:AutoScalingGroupName}",
```

```
            "ImageId": "${aws:ImageId}",
            "InstanceId": "${aws:InstanceId}",
            "InstanceType": "${aws:InstanceType}"
        },
        "metrics_collected": {
            "disk": {
                "measurement": [
                    "used_percent"
                ],
                "metrics_collection_interval": 60,
                "resources": [
                    "*"
                ]
            },
            "mem": {
                "measurement": [
                    "mem_used_percent"
                ],
                "metrics_collection_interval": 60
            }
        }
    }
}
```

Example eksctl configuration file

```
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: test
  region: us-east-2
  version: "1.24"
managedNodeGroups:
  - name: test
    minSize: 2
    maxSize: 4
    desiredCapacity: 2
    volumeSize: 20
    instanceType: t3.medium
    preBootstrapCommands:
    - sudo yum install amazon-ssm-agent -y
    - sudo systemctl enable amazon-ssm-agent
    - sudo systemctl start amazon-ssm-agent
```

```
    - sudo yum install amazon-cloudwatch-agent -y
    - sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-
config -m ec2 -s -c ssm:AmazonCloudwatch-linux
    iam:
      attachPolicyARNs:
        - arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
        - arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
        - arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
        - arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
        - arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore
```

Additional code details

- In the last line of the `preBootstrapCommands` property, `AmazonCloudwatch-linux` is the name of the parameter created in AWS System Manager Parameter Store. You must include `AmazonCloudwatch-linux` in Parameter Store in the same AWS Region where you created the Amazon EKS cluster. You can also specify a file path, but we recommend using Systems Manager for easier automation and reusability.
- If you use `preBootstrapCommands` in the `eksctl` configuration file, you see two launch templates in the AWS Management Console. The first launch template includes the commands specified in `preBootstrapCommands`. The second template includes the commands specified in `preBootstrapCommands` and default Amazon EKS user data. This data is required to get the nodes to join the cluster. The node group's Auto Scaling group uses this user data to spin up new instances.
- If you use the `iam` attribute in the `eksctl` configuration file, you must list the default Amazon EKS policies with any additional policies required in your attached AWS Identity and Access Management (IAM) policies. In the code snippet from the *Create the eksctl configuration file and cluster* step, `CloudWatchAgentServerPolicy` and `AmazonSSMMangedInstanceCore` are additional policies added to make sure that the CloudWatch agent and SSM Agent work as expected. The `AmazonEKSWorkerNodePolicy`, `AmazonEKS_CNI_Policy`, `AmazonEC2ContainerRegistryReadOnly` policies are mandatory policies required for the Amazon EKS cluster to function correctly.

Migrate NGINX Ingress Controllers when enabling Amazon EKS Auto Mode

Olawale Olaleye and Shamanth Devagari, Amazon Web Services

Summary

EKS Auto Mode for Amazon Elastic Kubernetes Service (Amazon EKS) can reduce the operational overhead of running your workloads on Kubernetes clusters. This mode allows AWS to also set up and manage the infrastructure on your behalf. When you enable EKS Auto Mode on an existing cluster, you must carefully plan the migration of NGINX Ingress Controller configurations. This is because the direct transfer of Network Load Balancers isn't possible.

You can use a blue/green deployment strategy to migrate an NGINX Ingress Controller instance when you enable EKS Auto Mode in an existing Amazon EKS cluster.

Prerequisites and limitations

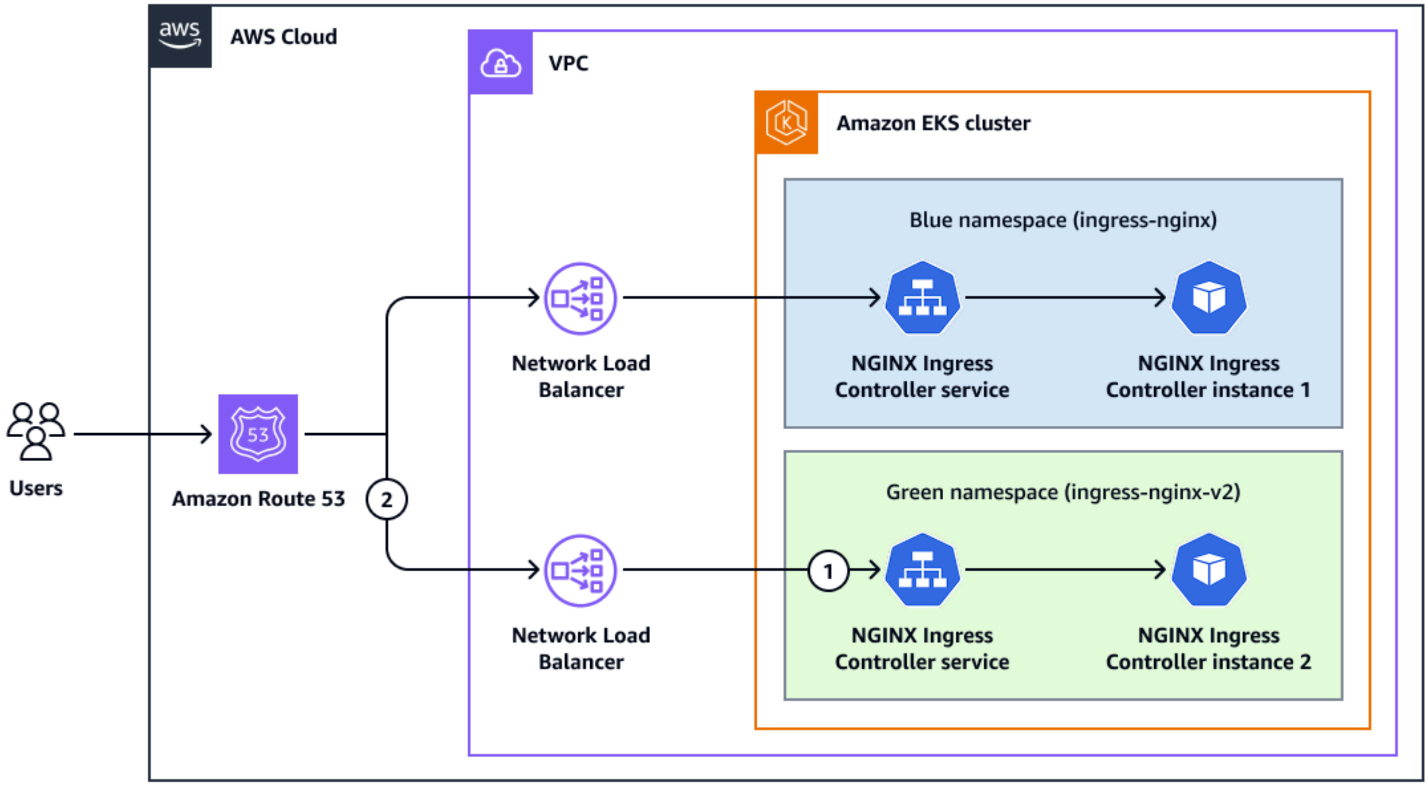
Prerequisites

- An active AWS account
- An Amazon EKS cluster running Kubernetes version 1.29 or later
- Amazon EKS add-ons running minimum versions
- Latest version of kubectl
- An existing NGINX Ingress Controller instance
- (Optional) A hosted zone in Amazon Route 53 for DNS-based traffic shifting

Architecture

A *blue/green deployment* is a deployment strategy in which you create two separate but identical environments. Blue/green deployments provide near-zero downtime release and rollback capabilities. The fundamental idea is to shift traffic between two identical environments that are running different versions of your application.

The following image shows the migration of Network Load Balancers from two different NGINX Ingress Controller instances when enabling EKS Auto Mode. You use a blue/green deployment to shift traffic between the two Network Load Balancers.



The original namespace is the *blue* namespace. This is where the original NGINX Ingress Controller service and instance run, before you enable EKS Auto Mode. The original service and instance connect to a Network Load Balancer that has a DNS name that is configured in Route 53. The [AWS Load Balancer Controller] deployed this Network Load Balancer in the target virtual private cloud (VPC).

The diagram shows the following workflow to set up an environment for a blue/green deployment:

1. Install and configure another NGINX Ingress Controller instance in a different namespace, a *green* namespace.
2. In Route 53, configure a DNS name for a new Network Load Balancer.

Tools

AWS services

- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.

- Elastic Load Balancing distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- Amazon Route 53 is a highly available and scalable DNS web service.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- Helm is an open source package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- kubectl is a command-line interface that helps you run commands against Kubernetes clusters.
- NGINX Ingress Controller connects Kubernetes apps and services with request handling, auth, self-service custom resources, and debugging.

Epics

Review the existing environment

Task	Description	Skills required
Confirm that the original NGINX Ingress Controller instance is operational.	Enter the following command to verify that the resources in the `ingress-nginx` namespace are operational. If you have deployed NGINX Ingress Controller in another namespace, update the namespace name in this command. `kubectl get all -n ingress-nginx`	DevOps engineer

Task	Description	Skills required

	In the output, confirm that NGINX Ingress Controller pods are in running state. The following is an example output:
	``
	NAME
	
	   READY STATUS
	 RESTARTS AGE
	pod/ingress-nginx-
	admission-create-xqn9d
	       0/1 Completed
	   0 88m

Task	Description	Skills required
	``` ADDRESS PORTS AGE ingress.networking.k8s.io/demo nginx nginxautomode.local.dev k8s-ingressn-ingressn-abcdefg-12345.elb.eu-west-1.amazonaws.com 80 56m ```	

Confirm the service is reachable.	Enter the following command to confirm that the service is reachable through the DNS name of the Network Load Balancer:
	`curl -H "Host: nginxautomode.local.dev" http://k8s-ingressn-ingressn-abcdefg-12345.elb.eu-west-1.amazonaws.com`
	The following is the expected output:
	`<html><body><h1>It works!</h1></body></html>`
		DevOps engineer

Task	Description	Skills required

(Optional) Create a DNS record.	1. Follow the instructions in [Creating records by using the Amazon Route 53 console](#) (Route 53 documentation) to create a DNS record for the configured domain.
	2. Enter the following command to confirm that the service is reachable through the configured domain name:
	`curl "http://nginxautomode.local.dev/?[1-5]"`
	The following is the expected output:
	`<html><body><h1>It works!</h1></body></html>`
	`<html><body><h1>It works!</h1></body></html>`
	`<html><body><h1>It works!</h1></body></html>`
	`<html><body><h1>It works!</h1></body></html>`
	`<html><body><h1>It works!</h1></body></html>`
		DevOps engineer, AWS DevOps

Enable EKS Auto Mode on the existing cluster

Task	Description	Skills required
Enable EKS Auto Mode.	Follow the instructions in [Enable EKS Auto Mode on an existing cluster](#) (Amazon EKS documentation).	AWS DevOps

Install a new NGINX Ingress Controller

Task	Description	Skills required

Configure a new NGINX Ingress Controller instance.	1. Download the [deploy.yaml](#) template.
	2. Open the **deploy.yaml** template in your preferred editor.
	3. In the `kind: Namespace` section, enter a unique name for the namespace, such as `ingress-nginx-v2` :
	<pre>apiVersion: v1
	kind: Namespace
	metadata:
	  labels:
	    app.kubernetes.io/instance: ingress-nginx
	    app.kubernetes.io/name: ingress-nginx
	  name: ingress-nginx-v2</pre>
		DevOps engineer

Task	Description	Skills required

	4. For each section, update the `namespace` value to the new name.
	5. In the `kind: Deployment` section, do the following:
	a. Enter a unique value for `--controller-class`, such as `k8s.io/ingress-nginx-v2`.
	b. Enter a unique value for `--ingress-class`, such as `nginx-v2`.
	<pre>apiVersion: apps/v1
	kind: Deployment
	  name: ingress-nginx-controller
	  namespace: ingress-nginx-v2
	...
	    spec:
	      containers:
	      - args:
	        - /nginx-ingress-controller
	        - --publish-service=$(POD_NAMESPACE)/ingress-nginx-controller
	        - --election-id=ingress-nginx-leader
	        - --controller-class=k8s.io/ingress-nginx-v2</pre>	

Task	Description	Skills required

	``
	      - --ingress-
	class=nginx-v2
	``
	6. In the `kind: IngressClass` section, enter the same values for `--controller-class` and `--ingress-class` that you used in the previous section:
	``
	apiVersion: networking.k8s.io/v1
	kind: IngressClass
	metadata:
	  labels:
	    app.kubernetes.io/component: controller
	    app.kubernetes.io/instance: ingress-nginx
	    app.kubernetes.io/name: ingress-nginx
	    app.kubernetes.io/part-of: ingress-nginx
	    app.kubernetes.io/version: 1.12.0
	  name: nginx-v2
	spec:
	  controller: k8s.io/ingress-nginx-v2
	``
	7. In the following section, add `loadBalancerClass: eks.amazonaws.com/nlb` to	

Task	Description	Skills required

	provision a Network Load Balancer for the NGINX Ingress Controller instance:
	
	`apiVersion: v1`
	`kind: Service`
	`metadata:`
	`  name: ingress-nginx-controller`
	`  namespace: ingress-nginx-v2`
	`spec:`
	`...`
	`  selector:`
	`    app.kubernetes.io/component: controller`
	`    app.kubernetes.io/instance: ingress-nginx`
	`    app.kubernetes.io/name: ingress-nginx`
	`  type: LoadBalancer`
	`  loadBalancerClass: eks.amazonaws.com/nlb`
	
	8. Save and close the **deploy.yaml** template.	

Deploy the new NGINX Instance Controller instance.	Enter the following command to apply the modified manifest file: `kubectl apply -f deploy.yaml`	DevOps engineer

Task	Description	Skills required

Confirm successful deployment.	Enter the following command to verify that the resources in the `ingress-nginx-v2` namespace are operational:
	`kubectl get all -n ingress-nginx-v2`
	In the output, confirm that NGINX Ingress Controller pods are in a running state. The following is an example output:
	`NAME READY STATUS RESTARTS AGE`
	`pod/ingress-nginx-admission-create-7shrj 0/1 Completed 0 24s`
	`pod/ingress-nginx-admission-patch-vkxr5 0/1 Completed 1 24s`
	`pod/ingress-nginx-controller-757bfcbc6d-4fw52 1/1 Running 0 24s`
	
	`NAME TYPE CLUSTER-IP EXTERNAL-IP`
		DevOps engineer

Migrate your container workloads from Azure Red Hat OpenShift (ARO) to Red Hat OpenShift Service on AWS (ROSA)

Naveen Ramasamy, Srikanth Rangavajhala, and Gireesh Sreekantan, Amazon Web Services

Summary

This pattern provides step-by-step instructions for migrating container workloads from Azure Red Hat OpenShift (ARO) to Red Hat OpenShift Service on AWS (ROSA). ROSA is a managed Kubernetes service provided by Red Hat in collaboration with AWS. It helps you deploy, manage, and scale your containerized applications by using the Kubernetes platform, and benefits from both Red Hat's expertise in Kubernetes and the AWS Cloud infrastructure.

Migrating container workloads from ARO, from other clouds, or from on premises to ROSA involves transferring applications, configurations, and data from one platform to another. This pattern helps ensure a smooth transition while optimizing for AWS Cloud services, security, and cost efficiency. It covers two methods for migrating your workloads to ROSA clusters: CI/CD and Migration Toolkit for Containers (MTC).

This pattern covers both methods. The method you choose depends on the complexity and certainty of your migration process. If you have full control over your application's state and can guarantee a consistent setup through a pipeline, we recommend that you use the CI/CD method. However, if your application state involves uncertainties, unforeseen changes, or a complex ecosystem, we recommend that you use MTC as a reliable and controlled path to migrate your application and its data to a new cluster. For a detailed comparison of the two methods, see the Additional information section.

Benefits of migrating to ROSA:

- ROSA seamlessly integrates with AWS as a native service. It is easily accessible through the AWS Management Console and billed through a single AWS account. It offers full compatibility with other AWS services and provides collaborative support from both AWS and Red Hat.
- ROSA supports hybrid and multi-cloud deployments. It enables applications to run consistently across on-premises data centers and multiple cloud environments.
- ROSA benefits from Red Hat's security focus, and provides features such as role-based access control (RBAC), image scanning, and vulnerability assessments to ensure a secure container environment.

- ROSA is designed to scale applications easily and provides high availability options. It allows applications to grow as needed while maintaining reliability.
- ROSA automates and simplifies the deployment of a Kubernetes cluster compared with manual setup and management methods. This accelerates the development and deployment process.
- ROSA benefits from AWS Cloud services, and provides seamless integration with AWS offerings such as database services, storage solutions, and security services.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Permissions configured for AWS services that ROSA relies on to deliver functionality. For more information, see Prerequisites in the ROSA documentation.
- ROSA enabled on the ROSA console. For instructions, see the ROSA documentation.
- The ROSA cluster installed and configured. For more information, see Get started with ROSA in the ROSA documentation. To understand the different methods for setting up a ROSA cluster, see the AWS Prescriptive Guidance guide ROSA implementation strategies.
- Network connectivity established from the on-premises network to AWS through AWS Direct Connect (preferred) or AWS Virtual Private Network (AWS VPN).
- An Amazon Elastic Compute Cloud (Amazon EC2) instance or another virtual server to install tools such as `aws client`, OpenShift CLI (`oc`) client, ROSA client, and Git binary.

Additional prerequisites for the CI/CD method:

- Access to the on-premises Jenkins server with permissions to create a new pipeline, add stages, add OpenShift clusters, and perform builds.
- Access to the Git repository where application source code is maintained, with permissions to create a new Git branch and perform commits to the new branch.

Additional prerequisites for the MTC method:

- An Amazon Simple Storage Service (Amazon S3) bucket, which will be used as a replication repository.
- Administrative access to the source ARO cluster. This is required to set up the MTC connection.

Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

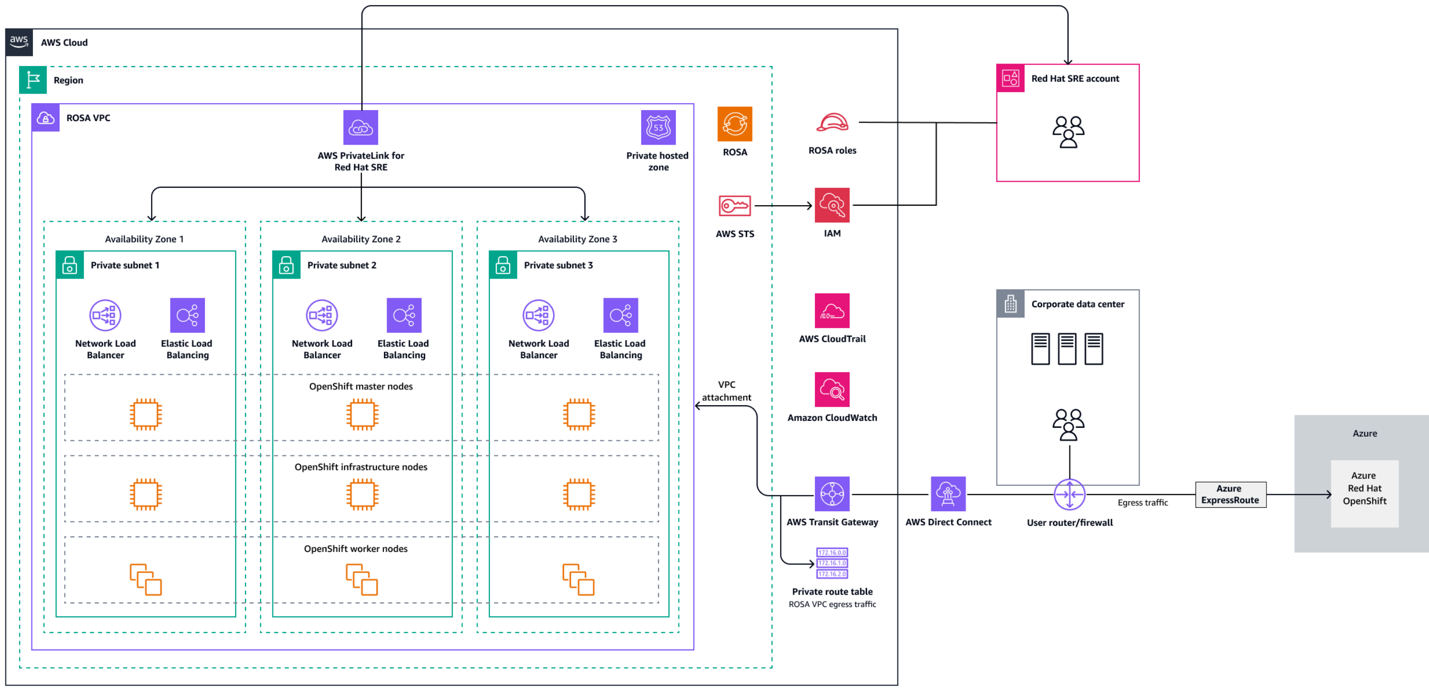
ROSA provides three network deployment patterns: public, private, and AWS PrivateLink. PrivateLink enables Red Hat site reliability engineering (SRE) teams to manage the cluster by using a private subnet connected to the cluster's PrivateLink endpoint in an existing VPC.

Choosing the PrivateLink option provides the most secure configuration. For that reason, we recommend it for sensitive workloads or strict compliance requirements. For information about the public and private network deployment options, see the Red Hat OpenShift documentation.

Important

You can create a PrivateLink cluster only at installation time. You cannot change a cluster to use PrivateLink after installation.

The following diagram illustrates the PrivateLink architecture for a ROSA cluster that uses AWS Direct Connect to connect to the on-premises and ARO environments.



AWS permissions to ROSA

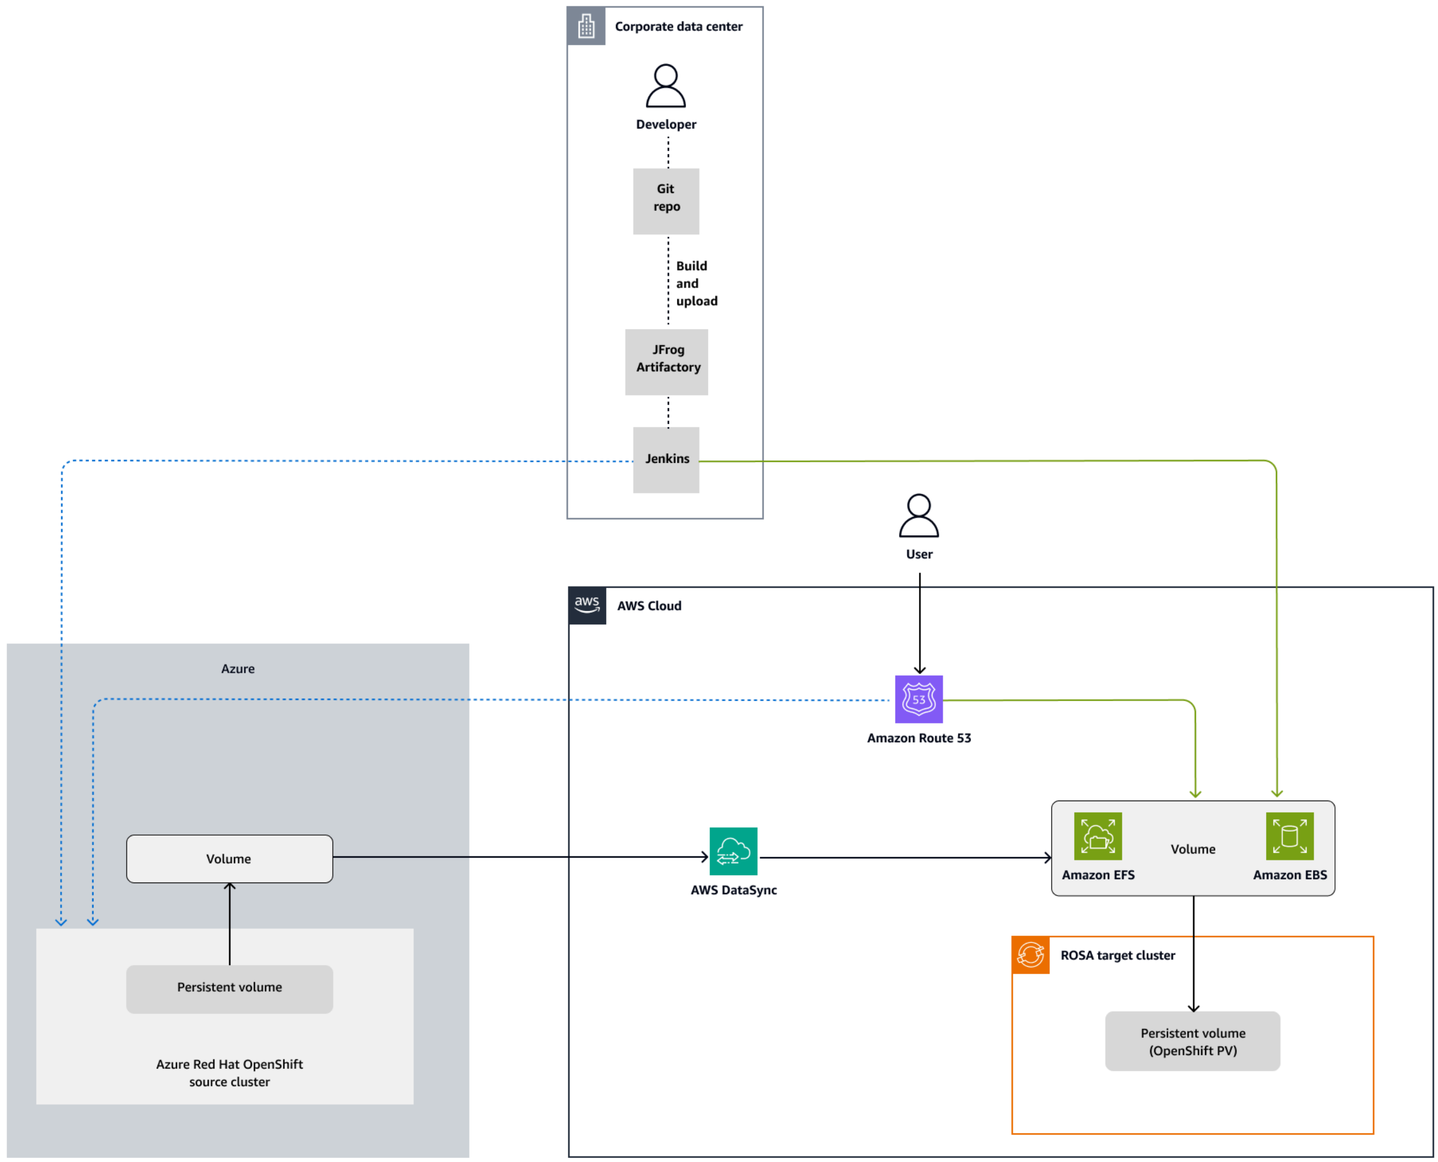
For AWS permissions to ROSA, we recommend that you use AWS Security Token Service (AWS STS) with short-lived, dynamic tokens. This method uses least-privilege predefined roles and policies to grant ROSA minimal permissions to operate in the AWS account, and supports ROSA installation, control plane, and compute functionality.

CI/CD pipeline redeployment

CI/CD pipeline redeployment is the recommended method for users who have a mature CI/CD pipeline. When you choose this option, you can use any DevOps deployment strategy to gradually shift your application load to deployments on ROSA.

> **Note**
>
> This pattern assumes a common use case where you have an on-premises Git, JFrog Artifactory, and Jenkins pipeline. This approach requires that you establish network connectivity from your on-premises network to AWS through AWS Direct Connect, and that you set up the ROSA cluster before you follow the instructions in the Epics section. See the Prerequisites section for details.

The following diagram shows the workflow for this method.



MTC method

You can use the [Migration Toolkit for Containers (MTC)]() to migrate your containerized workloads between different Kubernetes environments, such as from ARO to ROSA. MTC simplifies the migration process by automating several key tasks and providing a comprehensive framework for managing the migration lifecycle.

The following diagram shows the workflow for this method.

Tools

AWS services

- AWS DataSync is an online data transfer and discovery service that helps you move files or object data to, from, and between AWS storage services.
- AWS Direct Connect links your internal network to a AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- AWS PrivateLink helps you create unidirectional, private connections from your virtual private clouds (VPCs) to services outside of the VPC.
- Red Hat OpenShift Service on AWS (ROSA) is a managed service that helps Red Hat OpenShift users to build, scale, and manage containerized applications on AWS.
- AWS Security Token Service (AWS STS) helps you request temporary, limited-privilege credentials for users.

Other tools

- Migration Toolkit for Containers (MTC) provides a console and API for migrating containerized applications from ARO to ROSA.

Best practices

- For resilience and if you have security compliance workloads, set up a Multi-AZ ROSA cluster that uses PrivateLink. For more information, see the ROSA documentation.

> **Note**
>
> PrivateLink cannot be configured after installation.

- The S3 bucket that you use for replication repository should not be public. Use the appropriate S3 bucket policies to restrict access.
- If you choose the MTC method, use the **Stage** migration option to reduce the downtime window during cutover.
- Review your service quotas before and after you provision the ROSA cluster. If necessary, request a quota increase according to your requirements. For more information, see the Service Quotas documentation.
- Review the ROSA security guidelines and implement security best practices.
- We recommend that you remove the default cluster administrator after installation. For more information, see the Red Hat OpenShift documentation.
- Use machine pool automatic scaling to scale down unused worker nodes in the ROSA cluster to optimize costs. For more information, see the ROSA Workshop.
- Use the Red Hat Cost Management service for OpenShift Container Platform to better understand and track costs for clouds and containers. For more information, see the ROSA Workshop.
- Monitor and audit ROSA cluster infrastructure services and applications by using AWS services. For more information, see the ROSA Workshop.

Epics

Option 1: Use a CI/CD pipeline

Task	Description	Skills required
Add the new ROSA cluster to Jenkins.	1. On the Jenkins console, choose **Manage Jenkins**, **Configure System**.	AWS administrator, AWS systems administrator, AWS DevOps

Task	Description	Skills required
	2. On the **Manage Jenkins** page, in the **OpenShift Plug-in** section, choose **Add a new cluster**. 3. Provide required information such as the cluster name, API server URL, and token information to authenticate with ROSA.	
Add the `oc` client to your Jenkins nodes.	1. On the Jenkins console, choose **Manage Jenkins**, **Global Tool Configuration**. 2. In the **OpenShift Client Tools** section, install the OpenShift CLI (`oc`) client version that is the same as your ROSA cluster version.	AWS administrator, AWS systems administrator, AWS DevOps
Create a new Git branch.	Create a new branch in your Git repository for `rosa-dev`. This branch separates the code or configuration parameter changes for ROSA from your existing pipeline.	AWS DevOps
Tag images for ROSA.	In your build stage, use a different tag to identify the images that are built from the ROSA pipeline.	AWS administrator, AWS systems administrator, AWS DevOps

Task	Description	Skills required
Create a pipeline.	Create a new Jenkins pipeline that's similar to your existing pipeline. For this pipeline, use the `rosa-dev` Git branch that you created earlier, and make sure to include the Git checkout, code scan, and build stages that are identical to your existing pipeline.	AWS administrator, AWS systems administrator, AWS DevOps
Add a ROSA deployment stage.	In the new pipeline, add a stage to deploy to the ROSA cluster and reference the ROSA cluster that you added to the Jenkins global configuration.	AWS administrator, AWS DevOps, AWS systems administrator
Start a new build.	In Jenkins, select your pipeline and choose **Build now**, or start a new build by committing a change to the `rosa-dev` branch in Git.	AWS administrator, AWS DevOps, AWS systems administrator
Verify the deployment.	Use the **oc** command or the [ROSA console](https://console.redhat.com/openshift) to verify that the application has been deployed on your target ROSA cluster.	AWS administrator, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Copy data to the target cluster.	For stateful workloads, copy the data from the source cluster to the target cluster by using AWS DataSync or open source utilities such as **rsync**, or you can use the MTC method. For more informati on, see the [AWS DataSync documentation]().	AWS administrator, AWS DevOps, AWS systems administrator
Test your application.	1. Retrieve the route URL for your application by using the **oc route** command or the [ROSA console](). 2. Test your application by using the route URL.	AWS administrator, AWS DevOps, AWS systems administrator
Cut over.	If your testing is successful, use the appropriate Amazon Route 53 policy to move the traffic from the ARO-hoste d application to the ROSA-hosted application. When you complete this step, your application's workload will fully transition to the ROSA cluster.	AWS administrator, AWS systems administrator

Option 2: Use MTC

Task	Description	Skills required
Install the MTC operator.	Install the MTC operator on both ARO and ROSA clusters: 1. In the ARO or ROSA console, navigate to the **Operators**, **OperatorHub** page. 2. In the **Filter by** keyword box, find or type **MTC**. 3. Select the MTC operator to display additional informati on. 4. After you read the information about the operator, choose **Install**.	AWS administrator, AWS DevOps, AWS systems administrator
Configure network traffic to the replication repository.	If you're using a proxy server, configure it to allow network traffic between the replication repository and the clusters. The replication repository is an intermedi ate storage object that MTC uses to migrate data. The source and target clusters must have network access to the replication repository during migration.	AWS administrator, AWS DevOps, AWS systems administrator
Add the source cluster to MTC.	On the MTC web console, add the ARO source cluster.	AWS administrator, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Add Amazon S3 as your replication repository.	On the MTC web console, add the Amazon S3 bucket (see Prerequisites) as the replicati on repository.	AWS administrator, AWS DevOps, AWS systems administrator
Create a migration plan.	On the MTC web console, create a migration plan and specify the data transfer type as **Copy**. This will instruct MTC to copy the data from the source (ARO) cluster to the S3 bucket, and from the bucket to the target (ROSA) cluster.	AWS administrator, AWS DevOps, AWS systems administrator

Task	Description	Skills required
Run the migration plan.	Run the migration plan by using the **Stage** or **Cutover** option: • Choose **Stage** to copy data to the target cluster without stopping your application. You can run multiple stage migrations to copy most of your data before cutover migration. This shortens the duration of cutover migration. • Choose **Cutover** to stop your application on the source cluster while moving the resources to the target cluster. To prevent stopping the application, you can clear the **Halt transactions on the source cluster during migration** check box.	AWS administrator, AWS DevOps, AWS systems administrator

Troubleshooting

Issue	Solution
Connectivity issues	When you migrate your container workloads from ARO to ROSA, you might encounter connectivity issues that should be resolved to ensure a successful migration. To address these connectivity issues (listed in this table)

Issue	Solution
	during migration, meticulous planning, coordination with your network and security teams, and thorough testing are vital. Implementing a gradual migration strategy and verifying connectivity at each step will help minimize potential disruptions and ensure a smooth transition from ARO to ROSA.
Network configuration differences	ARO and ROSA might have variations in their network configurations, such as virtual network (VNet) settings, subnets, and network policies. For proper communication between services, make sure that the network settings align between the two platforms.
Security group and firewall rules	ROSA and ARO might have different default security group and firewall settings. Make sure to adjust and update these rules to permit necessary traffic to maintain connectiv ity among containers and services during migration.
IP address and DNS changes	When you migrate workloads, IP addresses and DNS names might change. Reconfigure applications that rely on static IPs or specific DNS names.
External service access	If your application depends on external services such as databases or APIs, you might have to update their connection settings to make sure they can communicate with the new services from ROSA.

Issue	Solution
Azure Private Link configuration	If you use Azure Private Link or private endpoint services in ARO, you will need to set up the equivalent functionality in ROSA to ensure private connectivity between resources.
AWS VPN or AWS Direct Connect setup	If there are existing AWS VPN or AWS Direct Connect connections between your on-premises network and ARO, you will need to establish similar connections with ROSA for uninterrupted communication with your local resources.
Ingress and load balancer settings	Configurations for ingress controllers and load balancers might differ between ARO and ROSA. Reconfigure these settings to maintain external access to your services.
Certificate and TLS handling	If your applications use SSL certificates or TLS, make sure that the certificates are valid and configured correctly in ROSA.
Container registry access	If your containers are hosted in an external container registry, set up the proper authentic ation and access permissions for ROSA.
Monitoring and logging	Update monitoring and logging configurations to reflect the new infrastructure on ROSA so you can continue to monitor the health and performance of your containers effectively.

Additional information

Choosing between MTC and CI/CD pipeline redeployment options

Migrating applications from one OpenShift cluster to another requires careful consideration. Ideally, you would want a smooth transition by using a CI/CD pipeline to redeploy the application and handle the migration of persistent volume data. However, in practice, a running application on a cluster is susceptible to unforeseen changes over time. These changes can cause the application to gradually deviate from its original deployment state. MTC offers a solution for scenarios where the exact contents of a namespace are uncertain and a seamless migration of all application components to a new cluster is important.

Making the right choice requires evaluating your specific scenario and weighing the benefits of each approach. By doing so, you can ensure a successful and seamless migration that aligns with your needs and priorities. Here are additional guidelines for choosing between the two options.

CI/CD pipeline redeployment

The CI/CD pipeline method is the recommended approach if your application can be confidently redeployed by using a pipeline. This ensures that the migration is controlled, predictable, and aligned with your existing deployment practices. When you choose this method, you can use blue/green deployment or canary deployment strategies to gradually shift the load to deployments on ROSA. For this scenario, this pattern assumes that Jenkins is orchestrating application deployments from the on-premises environment.

Advantages:

- You do not require administrative access to the source ARO cluster or need to deploy any operators on the source or destination cluster.
- This approach helps you switch traffic gradually by using a DevOps strategy.

Disadvantages:

- It requires more effort to test the functionality of your application.
- If your application contains persistent data, it requires additional steps to copy the data by using AWS DataSync or other tools.

MTC migration

In the real world, running applications can undergo unanticipated changes that cause them to drift away from the initial deployment. Choose the MTC option when you're unsure about the current state of your application on the source cluster. For example, if your application ecosystem spans various components, configurations, and data storage volumes, we recommend that you choose MTC to ensure a complete migration that covers the application and its entire environment.

Advantages:

- MTC provides complete backup and restore of the workload.
- It will copy the persistent data from source to target while migrating the workload.
- It does not require access to the source code repository.

Disadvantages:

- You need administrative privileges to install the MTC operator on the source and destination clusters.

- The DevOps team requires training to use the MTC tool and perform migrations.

Place Kubernetes Pods on Amazon EKS by using node affinity, taints, and tolerations

Hitesh Parikh and Raghu Bhamidimarri, Amazon Web Services

Summary

This pattern demonstrates the use of Kubernetes *node affinity*, node *taints*, and Pod *tolerations* to intentionally schedule application Pods on specific worker nodes in an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the Amazon Web Services (AWS) Cloud.

A *taint* is a node property that enables nodes to reject a set of pods. A *toleration* is a Pod property that enables the Kubernetes scheduler to schedule Pods on nodes that have matching taints.

However, tolerations alone can’t prevent a scheduler from placing a Pod on a worker node that doesn’t have any taints. For example, a compute intensive Pod with a toleration can unintentionally get scheduled on a general-purpose untainted node. In that scenario, the *node affinity* property of a Pod instructs the scheduler to place the Pod on a node that meets the node selection criteria specified in the node affinity.

Taints, tolerations, and node affinity together instruct the scheduler to schedule Pods consistently on the nodes with matching taints and the node labels that match the node affinity node-selection criteria specified on the Pod.

This pattern provides an example Kubernetes deployment manifest file, and the steps to create an EKS cluster, deploy an application, and validate Pod placement.

Prerequisites and limitations

Prerequisites

- An AWS account with credentials configured to create resources on your AWS account
- AWS Command Line Interface (AWS CLI)
- eksctl
- kubectl
- Docker installed (for the operating system being used), and the engine started (for information about Docker licensing requirements, see the Docker site)

- Java version 11 or later
- A Java microservice running on your favorite integrated development environment (IDE); for example, IntelliJ IDEA Community Edition or Eclipse (if you don't have a Java microservice, see the Deploy a sample Java microservice on Amazon EKS pattern and Microservices with Spring for help with creating the microservice)

Limitations

- This pattern doesn't provide the Java code, and it assumes that you are already familiar with Java. To create a basic Java microservice, see Deploy a sample Java microservice on Amazon EKS.
- The steps in this article create AWS resources that can accrue cost. Make sure that you clean up the AWS resources after you have completed the steps to implement and validate the pattern.

Architecture

Target technology stack

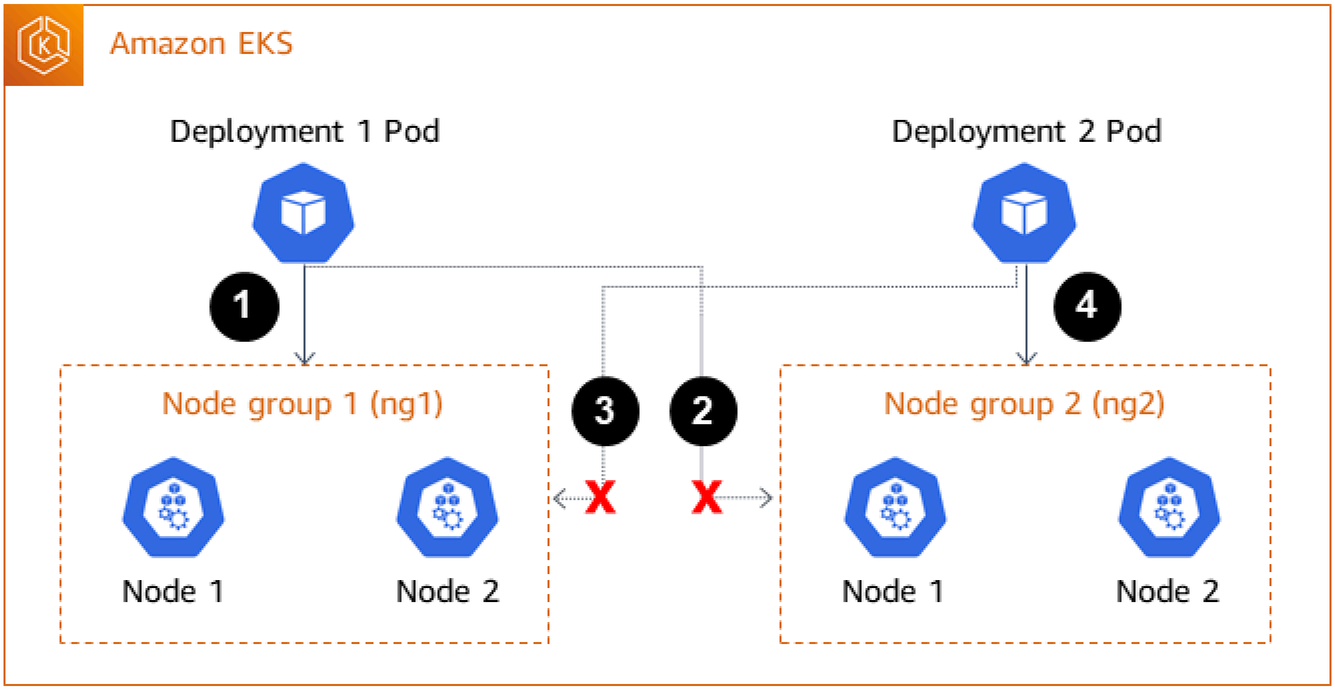
- Amazon EKS
- Java
- Docker
- Amazon Elastic Container Registry (Amazon ECR)

Target architecture

The solution architecture diagram shows Amazon EKS with two Pods (Deployment 1 and Deployment 2) and two node groups (ng1 and ng2) with two nodes each. The Pods and nodes have the following properties.

	Deployment 1 Pod	Deployment 2 Pod	Node group 1 (ng1)	Node group 2 (ng2)
Toleration	key: classified_workload, value: true, effect: NoSchedule	None		

	key: machine_learning_workload, value: true, effect: NoSchedule			
Node affinity	key: alpha.eksctl.io/nodegroup-name = ng1;	None	nodeGroups.name = ng1	
Taint			key: classified_workload, value: true, effect: NoSchedule key: machine_learning_workload, value: true, effect: NoSchedule	None



1. The Deployment 1 Pod has tolerations and node affinity defined, which instructs the Kubernetes scheduler to place the deployment Pods on the Node group 1 (ng1) nodes.
2. Node group 2 (ng2) doesn't have a node label that matches the node affinity node selector expression for Deployment 1, so the Pods will not be scheduled on ng2 nodes.
3. The Deployment 2 Pod doesn't have any tolerations or node affinity defined in the deployment manifest. The scheduler will reject scheduling Deployment 2 Pods on Node group 1 because of the taints on the nodes.
4. The Deployment 2 Pods will be placed on Node group 2 instead, because the nodes don't have any taints.

This pattern demonstrates that by using taints and tolerations, combined with node affinity, you can control placement of Pods on specific sets of worker nodes.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.

- [Amazon Elastic Kubernetes Service (Amazon EKS)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [eksctl](#) is AWS equivalent of kubectl and helps with creating EKS.

Other tools

- [Docker](#) is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- [kubectl](#) is a command-line interface that helps you run commands against Kubernetes clusters.

Epics

Create the EKS cluster

Task	Description	Skills required
Create the cluster.yaml file.	Create a file called `cluster.yaml` with the following code. ```apiVersion: eksctl.io/v1alpha5 kind: ClusterConfig metadata: name: eks-taint-demo region: us-west-1 # Unmanaged nodegroups with and without taints. nodeGroups: - name: ng1 instanceType: m5.xlarge minSize: 2 maxSize: 3 taints:```	App owner, AWS DevOps, Cloud administrator, DevOps engineer

```
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig

metadata:
  name: eks-taint-demo
  region: us-west-1

# Unmanaged nodegroups with and without taints.
nodeGroups:
  - name: ng1
    instanceType: m5.xlarge
    minSize: 2
    maxSize: 3
    taints:
```

Task	Description	Skills required

	``
	      - key: classifie
	d_workload
	        value: "true"
	        effect:
	 NoSchedule
	      - key: machine_l
	earning_workload
	        value: "true"
	        effect:
	 NoSchedule
	
	  - name: ng2
	    instanceType:
	 m5.xlarge
	    minSize: 2
	    maxSize: 3
	``	

Create the cluster by using eksctl.	Run the `cluster.yaml` file to create the EKS cluster. Creating the cluster might take a few minutes. `eksctl create cluster -f cluster.yaml`	AWS DevOps, AWS systems administrator, App developer

Create an image and upload it to Amazon ECR

Task	Description	Skills required
Create an Amazon ECR private repository.	To create an Amazon ECR repository, see [Creating a private repository](). Note the URI of the repo.	AWS DevOps, DevOps engineer, App developer
Create the Dockerfile.	If you have an existing Docker container image that you want to use to test the	AWS DevOps, DevOps engineer

Task	Description	Skills required

	pattern, you can skip this step.
	
	To create a Dockerfile, use the following snippet as a reference. If you encounter errors, see the [Troubleshooting](#) section.
	
	`FROM adoptopenjdk/openjdk11:jdk-11.0.14.1_1-alpine`
	
	`RUN apk add maven`
	`WORKDIR /code`
	
	`# Prepare by downloading dependencies`
	`ADD pom.xml /code/pom.xml`
	`RUN ["mvn", "dependency:resolve"]`
	`RUN ["mvn", "verify"]`
	
	`# Adding source, compile and package into a fat jar`
	`ADD src /code/src`
	`RUN ["mvn", "package"]`
	
	`EXPOSE 4567`
	`CMD ["java", "-jar", "target/eksExample-jar-with-dependencies.jar"]`	

Task	Description	Skills required
Create the pom.xml and source files, and build and push the Docker image.	To create the `pom.xml` file and the Java source file, see [Deploy a sample Java microservice on Amazon EKS](#) pattern. Use the instructions in that pattern to build and push the Docker image.	AWS DevOps, DevOps engineer, App developer

Deploy to Amazon EKS

Task	Description	Skills required
Create the deployment.yaml file.	To create the `deploymen t.yaml` file, use the code in the [*Additional information*](#) section. In the code, the key for node affinity is any label that you create while creating node groups. This pattern uses the default label created by eksctl. For information about customizing labels, see [Assigning Pods to Nodes](#) in the Kubernetes documenta tion. The value for the node affinity key is the name of the node group that was created by `cluster.yaml` .	AWS DevOps, DevOps engineer, App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>To get the key and value for the taint, run the following command.
<pre>kubectl get nodes -o
 json | jq '.items[]
.spec.taints'</pre>The image is the URI of the Amazon ECR repository that you created in an earlier step.</td><td></td></tr>
<tr><td>Deploy the file.</td><td>To deploy to Amazon EKS, run the following command.
<pre>kubectl apply -f
 deployment.yaml</pre></td><td>App developer, DevOps engineer, AWS DevOps</td></tr>
</table>

Task	Description	Skills required

Check the deployment.	1. To check if the pods are READY, run the following command.
	`kubectl get pods -o wide`
	If the POD is ready, the output should look similar to the following, with the STATUS as Running.
	`NAME READY STATUS RESTARTS AGE IP NODE NOMINATED NODE READINESS GATES`
	`<pod_name> 1/1 Running 0 12d 192.168.18.50 ip-192-168-20-110.us-west-1.compute.internal <none> <none>`
	Note the name of the Pod and the name of the node. You can skip the next step.
	2. (Optional) To get additional details about the Pod and check the tolerations on the Pod, run the following command.
		App developer, DevOps engineer, AWS DevOps

Task	Description	Skills required

	`kubectl describe pod <pod_name>`
	
	An example of the output is in the *Additional information* section.
	
	3. To validate that the Pod placement on the node is correct, run the following command.
	
	`kubectl describe node <node name> | grep -A 1 "Taints"`
	
	Confirm that the taint on the node matches toleration, and the label on the node matches the node affinity defined in `deployment.yaml` .
	
	The Pod with tolerations and node affinity should be placed on a node with the matching taints and the node affinity labels. The previous command gives you the taints on the node. The following is an example output.
	
	`kubectl describe node ip-192-168-29-181.us-west-1.compute.`	

Task	Description	Skills required

	<pre>internal | grep -A 1
	 "Taints"
	Taints:
	 classifled_workloa
	d=true:NoSchedule
	
	 machine_learning_w
	orkload=true:NoSch
	edule</pre>Additionally, run the following command to check that the node on which the Pod is placed has a label matching the node affinity node label.<pre>kubectl get node <node
	 name> --show-labels</pre>4. To verify that the applicati on is doing what it is intended to do, check the Pod logs by running the following command.<pre>kubectl logs -f <name-
	of-the-pod></pre>	

Task	Description	Skills required

Create a second deploymen t .yaml file without toleration and node affinity.	This additional step is to validate that when no node affinity or tolerations are specified in the deploymen t manifest file, the resulting Pod is not scheduled on a node with taints. (It should be scheduled on a node that doesn't have any taints). Use the following code to create a new deployment file called `deploy_no_taint.yaml` .
	`apiVersion: apps/v1`
	`kind: Deployment`
	`metadata:`
	`  name: microservice-deployment-non-tainted`
	`spec:`
	`  replicas: 1`
	`  selector:`
	`    matchLabels:`
	`      app.kubernetes.io/name: java-microservice-no-taint`
	`  template:`
	`    metadata:`
	`      labels:`
	`        app.kubernetes.io/name: java-microservice-no-taint`
	`    spec:`
	`      containers:`
	`        - name: java-microservice-container-2`
	`          image: <account_number>.dkr.ecr<region>.ama`
		App developer, AWS DevOps, DevOps engineer

Task	Description	Skills required
	```zonaws.com/<repository_name>:latest ports: - containerPort: 4567```	
Deploy the second deployment .yaml file, and validate Pod placement	1. Run the following command. ```kubectl apply -f deploy_no_taint.yaml``` 2. After the deployment is successful, run the same commands that you ran previously to check the Pod placement in a node group with no taint. ```kubectl describe node <node_name> | grep "Taints"``` The output should be the following. ```Taints: <none>``` This completes the testing.	App developer, AWS DevOps, DevOps engineer

Clean up resources

Task	Description	Skills required
Clean up the resources.	To avoid incurring AWS charges for resources that are left running, use the following command. `eksctl delete cluster --name <Name of the cluster> --region <region-code>`	AWS DevOps, App developer

Troubleshooting

Issue	Solution
Some of these commands might not run if your system uses arm64 architecture (especially if you are running this on an M1 Mac). The following line might error out. `FROM adoptopenjdk/openjdk11:jdk-11.0.14.1_1-alpine`	If you have errors when running the Dockerfile, replace the `FROM` line with the following line. `FROM bellsoft/liberica-openjdk-alpine-musl:17`

Replicate filtered Amazon ECR container images across accounts or Regions

Abdal Garuba, Amazon Web Services

Summary

Amazon Elastic Container Registry (Amazon ECR) can replicate all container images in an image repository across Amazon Web Services (AWS) Regions and AWS accounts natively, by using the cross-Region and cross-account replication features. (For more information, see the AWS blog post Cross region replication in Amazon ECR has landed.) However, there is no way to filter the images that are copied across AWS Regions or accounts based on any criteria.

This pattern describes how to replicate container images that are stored in Amazon ECR across AWS accounts and Regions, based on image tag patterns. The pattern uses Amazon CloudWatch Events to listen for push events for images that have a predefined, custom tag. A push event starts an AWS CodeBuild project and passes the image details to it. The CodeBuild project copies the images from the source Amazon ECR registry to the destination registry based on the details provided.

This pattern copies images that have specific tags across accounts. For example, you can use this pattern to copy only production-ready, secure images to the production AWS account. In the development account, after images are thoroughly tested, you can add a predefined tag to the secure images and use the steps in this pattern to copy the marked images to the production account.

Prerequisites and limitations

Prerequisites

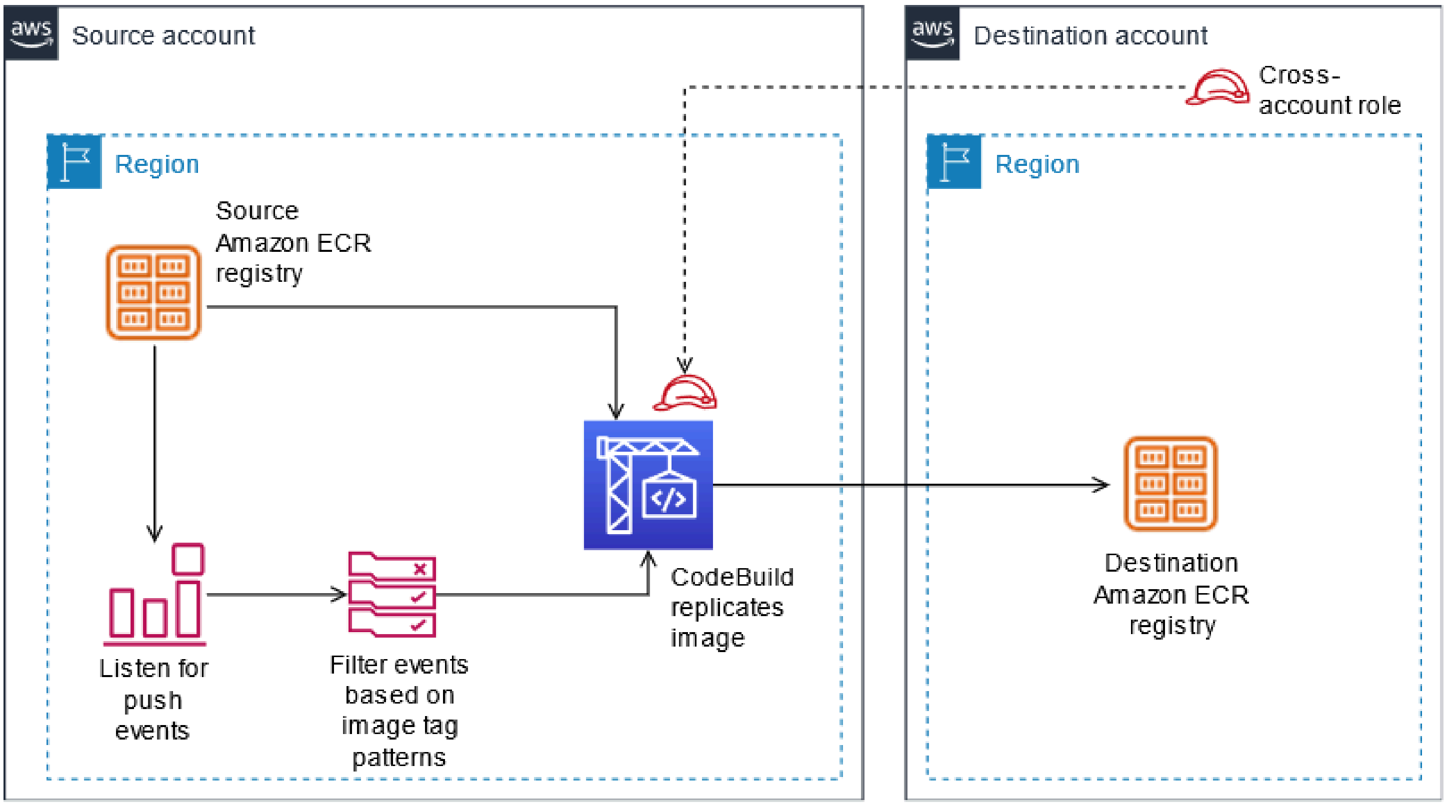
- An active AWS account for source and destination Amazon ECR registries
- Administrative permissions for the tools used in this pattern
- Docker installed on your local machine for testing
- AWS Command Line Interface (AWS CLI), for authenticating into Amazon ECR

Limitations

- This pattern watches the push events of the source registry in only one AWS Region. You can deploy this pattern to other Regions to watch registries in those Regions.
- In this pattern, one Amazon CloudWatch Events rule listens for a single image tag pattern. If you want to check for multiple patterns, you can add events to listen for additional image tag patterns.

Architecture

Target architecture



Automation and scale

This pattern can be automated with an infrastructure as code (IaC) script and deployed at scale. To use AWS CloudFormation templates to deploy this pattern, download the attachment and follow the instructions in the [Additional information](#) section.

You can point multiple Amazon CloudWatch Events events (with different custom event patterns) to the same AWS CodeBuild project to replicate multiple image tag patterns, but you will need to update the secondary validation in the `buildspec.yaml` file (which is included in the attachment and in the [Tools](#) section) as follows to support multiple patterns.

```
...
if [[ ${IMAGE_TAG} != release-* ]]; then
...
```

Tools

Amazon services

- IAM – AWS Identity and Access Management (IAM) enables you to manage access to AWS services and resources securely. In this pattern, you would need to create the cross-account IAM role that AWS CodeBuild will assume when pushing container images to the destination registry.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is a fully managed container registry that makes it easy to store, manage, share, and deploy your container images and artifacts anywhere. Image push actions to the source registry send system event details to the event bus that is picked up by Amazon CloudWatch Events.
- AWS CodeBuild – AWS CodeBuild is a fully managed continuous integration service that provides compute power to perform jobs such as compiling source code, running tests, and producing artifacts that are ready to be deployed. This pattern uses AWS CodeBuild to perform the copy action from the source Amazon ECR registry to the destination registry.
- CloudWatch Events – Amazon CloudWatch Events delivers a stream of system events that describe changes in AWS resources. This pattern uses rules to match Amazon ECR push actions with a specific image tag pattern.

Tools

- Docker CLI – Docker is a tool that makes it easier to create and manage containers. Containers pack an application and all its dependencies into one unit or package that can easily be deployed on any platform that supports the container runtime.

Code

You can implement this pattern in two ways:

- Automated setup: Deploy the two AWS CloudFormation templates provided in the attachment. For instructions, see the Additional information section.
- Manual setup: Follow the steps in the Epics section.

Sample buildspec.yaml

If you're using the CloudFormation templates that are provided with this pattern, the `buildspec.yaml` file is included in the CodeBuild resources.

```
  version: 0.2
  env:
    shell: bash
  phases:
    install:
      commands:
        - export CURRENT_ACCOUNT=$(echo ${CODEBUILD_BUILD_ARN} | cut -d':' -f5)
        - export CURRENT_ECR_REGISTRY=${CURRENT_ACCOUNT}.dkr.ecr.
${AWS_REGION}.amazonaws.com
        - export DESTINATION_ECR_REGISTRY=${DESTINATION_ACCOUNT}.dkr.ecr.
${DESTINATION_REGION}.amazonaws.com
    pre_build:
      on-failure: ABORT
      commands:
        - echo "Validating Image Tag ${IMAGE_TAG}"
        - |
          if [[ ${IMAGE_TAG} != release-* ]]; then
            aws codebuild stop-build --id ${CODEBUILD_BUILD_ID}
            sleep 60
            exit 1
          fi
        - aws ecr get-login-password --region ${AWS_REGION} | docker login -u AWS --

Epics

Create IAM roles

Task	Description	Skills required
Create a CloudWatch Events role.	In the source AWS account, create an IAM role for Amazon CloudWatch Events to assume. The role should have permissions to start a AWS CodeBuild project. To create the role by using the AWS CLI, follow the instructions in the IAM documentation. Example trust policy (`trustpolicy.json`): `{ "Version": "2012-10-17", "Statement": { "Effect": "Allow", "Principal": {"Service": "events.amazonaws.com"},`	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Task	Description	Skills required

	``
	    "Action": "sts:AssumeRole"
	  }
	}
	``
	Example permission policy (`permissionpolicy.json`):
	``
	{
	  "Version": "2012-10-17",
	  "Statement": {
	    "Effect": "Allow",
	    "Action": "codebuild:StartBuild",
	    "Resource": "<CodeBuild Project ARN>"
	  }
	}
	``	

Task	Description	Skills required

Create a CodeBuild role.	Create an IAM role for AWS CodeBuild to assume, by following the [instructions in the IAM documentation](#). The role should have the following permissions:
	
	• Permission to assume the destination cross-account role
	• Permission to create log groups and log streams, and to put log events
	• Read-only permissions to all Amazon ECR repositories, by adding the [AmazonEC2ContainerRegistryReadOnly](#) managed policy to the role
	• Permission to stop CodeBuild
	
	Example trust policy (`trustpolicy.json`):
	
	`{`
	`  "Version": "2012-10-17",`
	`  "Statement": [`
	`    {`
	`      "Effect": "Allow",`
	`      "Principal": {`
	`        "Service": "codebuild.amazonaws.com"`
	`      },`
		AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer

Task	Description	Skills required
	``` "Action": "sts:AssumeRole" }] } ``` Example permission policy (`permissionpolicy.json`): ``` { "Version": "2012-10-17", "Statement": [{ "Action": ["codebuild:StartBuild", "codebuild:StopBuild", "codebuild:Get*", "codebuild:List*", "codebuild:BatchGet*"], "Resource": "*", "Effect": "Allow" }, { "Action": ["logs:CreateLogGroup", ```	

Task	Description	Skills required

	``
	 "logs:CreateLogStr
	eam",
	
	 "logs:PutLogEvents"
	            ],
	            "Resource":
	 "*",
	            "Effect":
	 "Allow"
	        },
	        {
	            "Action":
	 "sts:AssumeRole",
	            "Resource":
	 "<ARN of destination
	 role>",
	            "Effect":
	 "Allow",
	            "Sid":
	 "AssumeCrossAccoun
	tArn"
	        }
	    ]
	}
	``
	Attach the managed policy `AmazonEC2ContainerRegistryReadOnly` to the CLI command as follows:
	``
	~$ aws iam attach-role-
	policy \
	--policy-arn arn:aws:i
	am::aws:policy/Ama
	zonEC2ContainerReg
	istryReadOnly \
	--role-name <name of
	 CodeBuild Role>
	``	

Task	Description	Skills required
Create a cross-account role.	In the destination AWS account, create an IAM role for the AWS CodeBuild role for the source account to assume. The cross-account role should allow container images to create a new repository and upload container images to Amazon ECR. To create the IAM role by using the AWS CLI, follow the [instructions in the IAM documentation](#). To allow the AWS CodeBuild project from the previous step, use the following trust policy: `{ "Version": "2012-10-17", "Statement": { "Effect": "Allow", "Principal": { "AWS": "<ARN of source codebuild role>" }, "Action": "sts:AssumeRole" } }` To allow the AWS CodeBuild project from the previous	AWS administrator, AWS DevOps, Cloud administrator, Cloud architect, DevOps engineer, AWS systems administrator

Task	Description	Skills required

	step to save images in the destination registry, use the following permission policy:
	
	`{`
	`    "Version":`
	` "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Action": [`
	
	` "ecr:GetDownloadUr`
	`lForLayer",`
	
	` "ecr:BatchCheckLay`
	`erAvailability",`
	
	` "ecr:PutImage",`
	
	` "ecr:InitiateLayer`
	`Upload",`
	
	` "ecr:UploadLayerPa`
	`rt",`
	
	` "ecr:CompleteLayer`
	`Upload",`
	
	` "ecr:GetRepository`
	`Policy",`
	
	` "ecr:DescribeRepos`
	`itories",`
	
	` "ecr:GetAuthorizat`
	`ionToken",`
	
	` "ecr:CreateReposit`
	`ory"`
	`            ],`	

Task	Description	Skills required

	``
	            "Resource":
	 "*",
	            "Effect":
	 "Allow"
	        }
	    ]
	}
	``	

Create the CodeBuild project

Task	Description	Skills required
Create a CodeBuild project.	Create a AWS CodeBuild project in the source account by following the [instructions in the AWS CodeBuild documentation](). The project should be in the same Region as the source registry. Configure the project as follows: • Environment type: `LINUX CONTAINER` • Service role: `CodeBuild Role` • Privileged mode: `true` • Environment image: `aws/codebuild/standard:x.x` (use the latest image available) • Environment variables: • `CROSS_ACCOUNT_ROLE_ARN` : The Amazon	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer

Task	Description	Skills required
	Resource Name (ARN) of the cross-account role • `DESTINATION_REGION` : The name of the cross-account Region • `DESTINATION_ACCOUNT` : The number of the destination account • Build specifications: Use the `buildspec.yaml` file listed in the Tools section.	

Create the event

Task	Description	Skills required
Create an events rule.	Because the pattern uses the content filtering feature, you need to create the event by using Amazon EventBridge. Create the event and target by following the instructions in the EventBridge documentation, with a few modifications: • For **Define pattern**, choose **Event Pattern**, and then choose **Custom pattern.** • Copy the following custom events pattern sample code into the text box provided: `{`	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer

Task	Description	Skills required

	``
	  "source": ["aws.ecr
	"],
	  "detail-type":
	 ["ECR Image
	 Action"],
	  "detail": {
	    "action-type":
	 ["PUSH"],
	    "result":
	 ["SUCCESS"],
	    "image-ta
	g": [{ "prefix":
	 "release-"}]
	  }
	}
	``
	• For **Select targets**, choose the AWS CodeBuild project, and paste the ARN for the AWS CodeBuild project that you created in the previous epic.
	• For **Configure Input**, choose **Input Transformer**.
	  • In the **Input Path** text box, paste:
	``
	{"IMAGE_TAG":"$.de
	tail.image-tag","R
	EPO_NAME":"$.detai
	l.repository-name"
	}
	``
	  • In the **Input Template** text box, paste:
	``
	{"environmentVaria
	blesOverride":
	 [{"name":
	``	

Task	Description	Skills required
	`"IMAGE_TAG", "value":<IMAGE_TAG>},{"name":"REPO_NAME","value":<REPO_NAME>}]}` • Choose **Use existing role**, and choose the name of the CloudWatch Events role you created previously in the *Create IAM roles* epic.	

Validate

Task	Description	Skills required
Authenticate with Amazon ECR.	Authenticate to both source and destination registries by following the steps in the [Amazon ECR documentation]().	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, DevOps engineer, Cloud architect
Test image replication.	In your source account, push a container image to a new or existing Amazon ECR source repository with an image tag prefixed with `release-`. To push the image, follow the steps in the [Amazon ECR documentation](). You can monitor the progress of the CodeBuild project in the [CodeBuild console]().	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Task	Description	Skills required
	After the CodeBuild project has completed successfully, sign in to the destination AWS account, open the Amazon ECR console, and confirm that the image exists in the destination Amazon ECR registry.	
Test image exclusion.	In your source account, push a container image to a new or existing Amazon ECR source repository with an image tag that doesn't have the custom prefix. Confirm that the CodeBuild project isn't started, and that no container images appear in the destination registry.	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Related resources

- Getting started with CodeBuild
- Getting started with Amazon EventBridge
- Content-based filtering in Amazon EventBridge event patterns
- Delegate access across AWS accounts using IAM roles
- Private image replication

Additional information

To automatically deploy the resources for this pattern, follow these steps:

1. Download the attachment and extract the two CloudFormation templates: `part-1-copy-tagged-images.yaml` and `part-2-destination-account-role.yaml`.
2. Log in to the [AWS CloudFormation console](), and deploy `part-1-copy-tagged-images.yaml` in the same AWS account and Region as the source Amazon ECR registries. Update the parameters as needed. The template deploys the following resources:
   - Amazon CloudWatch Events IAM role
   - AWS CodeBuild project IAM role
   - AWS CodeBuild project
   - AWS CloudWatch Events rule
3. Take note of the value of `SourceRoleName` in the **Outputs** tab. You will need this value in the next step.
4. Deploy the second CloudFormation template, `part-2-destination-account-role.yaml`, in the AWS account that you want to copy the Amazon ECR container images to. Update the parameters as needed. For the `SourceRoleName` parameter, specify the value from step 3. This template deploys the cross-account IAM role.
5. Validate image replication and exclusion, as described in the last step of the Epics section.

Rotate database credentials without restarting containers

Josh Joy, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, you can use AWS Secrets Manager to rotate, manage, and retrieve database credentials throughout their lifecycle. Users and applications retrieve secrets with a call to the Secrets Manager API, removing the need to hardcode sensitive information in plaintext.

If you're using containers for microservice workloads, you can securely store credentials in AWS Secrets Manager. To separate out configuration from code, these credentials are commonly injected into the container. However, it's important to rotate your credentials periodically and automatically. It's also important to support the ability to refresh credentials after revocation. At the same time, applications require the ability to rotate credentials while reducing any potential downstream availability impact.

This pattern describes how to rotate your secrets that are secured with AWS Secrets Manager within your containers without requiring your containers to restart. In addition, this pattern reduces the number of credential lookups to Secrets Manager by using the Secrets Manager client-side caching component. When you use the client-side caching component to refresh the credentials within the application, the container doesn't need to be restarted to fetch a rotated credential.

This approach works for Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS).

Two scenarios are covered. In the single-user scenario, the database credential is refreshed on secret rotation by detecting the expired credential. The credential cache is instructed to refresh the secret, and then the application re-establishes the database connection. The client-side caching component caches the credential within the application and helps avoid reaching out to Secrets Manager for each credential lookup. The credential is rotated within the application without the need to force the credential refresh by restarting the container.

The second scenario rotates the secret by alternating between two users. Having two active users reduces the potential for downtime, because one user's credentials are always active. Two-user credential rotation is helpful when you have a large deployment with clusters in which there might be a small propagation delay of credential updates.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An application running in a container in Amazon EKS or Amazon ECS.
- Credentials stored in Secrets Manager, with rotation enabled.
- A second set of credentials stored in Secrets Manager, if deploying the two-user solution. Code examples can be found in the GitHub repo aws-secrets-manager-rotation-lambdas.
- An Amazon Aurora database.

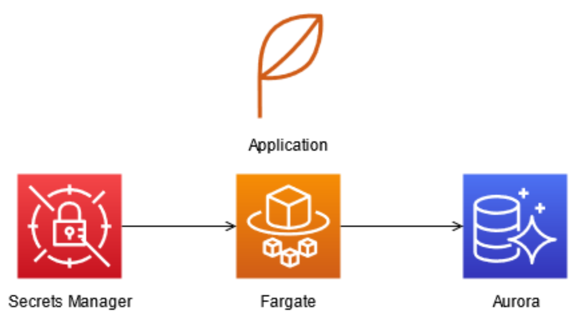
Limitations

- This example is targeted for Python applications. For Java applications, you can use the Java client-side caching component or the JDBC client-side caching library for Secrets Manager.

Architecture

Target architecture

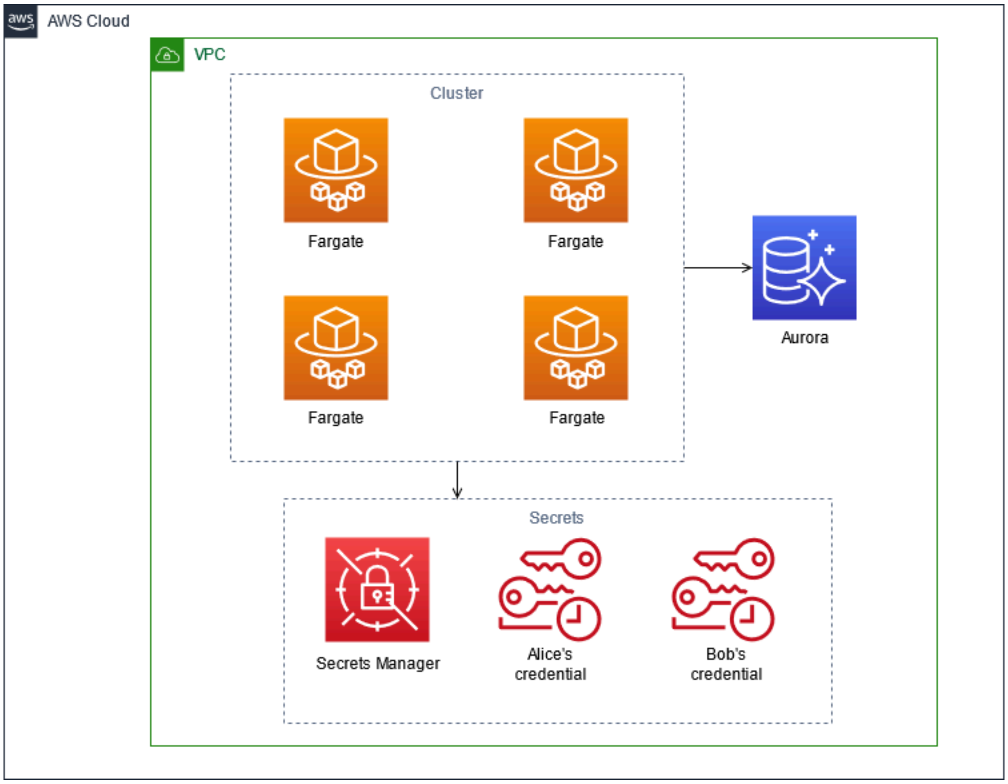
Scenario 1 – Rotation of a credential for a single user



In the first scenario, a single database credential is periodically rotated by Secrets Manager. The application container runs in Fargate. When the first database connection is established, the application container fetches the database credential for Aurora. The Secrets Manager caching component then caches the credential for future connection establishment. When rotation period has elapsed, the credential expires and the database returns an authentication error. The application then fetches the rotated credential, invalidates the cache, and updates the credential cache via the Secrets Manager client-side caching component.

In this scenario, there might be a minimal disruption while the credential is being rotated and stale connections are using the outdated credential. This concern can be addressed by using the two-user scenario.

Scenario 2 – Rotation of credentials for two users



In the second scenario, two database user credentials (Alice's and Bob's) are periodically rotated by Secrets Manager. The application container runs in a Fargate cluster. When the first database connection is established, the application container fetches the Aurora database credential for the first user (Alice). The Secrets Manager caching component then caches the credential for future connection establishment.

Although there are two users and credentials, one only active credential is managed by Secrets Manager. In this case, the caching component periodically expires and fetches the latest credential. If the Secrets Manager rotation period is longer than the cache timeout, the caching component picks up the rotated credential for the second user (Bob). For example, if the cache expiration is measured in minutes and the rotation period is measured in days, the caching component fetches the new credential as part of its periodic cache refresh. In this way, the downtime is minimized because each user's credential is active for one Secrets Manager rotation.

Automation and scale

You can use AWS CloudFormation to deploy this pattern by using infrastructure as code. This builds and creates the application container, creates the Fargate task, deploys the container into Fargate, and sets up and configure Secrets Manager with Aurora. For step-by-step deployment instructions, see the readme file.

Tools

Tools

- AWS Secrets Manager enables the replacement of hardcoded credentials, including passwords, with an API call to Secrets Manager to retrieve the secret. Because Secrets Manager can automatically rotate the secret according to a schedule, you can replace long-term secrets with short-term ones, reducing the risk of compromise.
- Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Code

Example Python code

This pattern uses the Python client-side caching component for Secrets Manager to retrieve the authentication credentials when establishing the database connection. The client-side caching component helps avoid reaching out to Secrets Manager each time.

Now, when the rotation period elapses, the cached credential will be expired, and connecting to the database will result in an authentication error. For MySQL, the authentication error code is 1045. This example uses Amazon Aurora for MySQL, though you could use another engine such as PostgreSQL. Upon the authentication error, the database connection exception handling code catches the error. It then informs the Secrets Manager client-side caching component to refresh the secret, then to reauthenticate and re-establish the database connection. If you are using PostgreSQL or another engine, you must look up the corresponding authentication error code.

The container application can now update the database password with the rotated password without restarting the container.

Place the following code in your application code that handles database connections. This example uses Django, and it subclasses the database backend with a database wrapper for connections. If you are using a different programming language or database connection library, see your database connection library to review how to subclass database connection retrieval.

```
    def get_new_connection(self, conn_params):
        try:
            logger.info("get connection")
            databasecredentials.get_conn_params_from_secrets_manager(conn_params)
            conn =super(DatabaseWrapper,self).get_new_connection(conn_params)
            return conn
        except MySQLdb.OperationalError as e:
            error_code=e.args[0]
            if error_code!=1045:
                raise e

            logger.info("Authentication error. Going to refresh secret and try again.")
            databasecredentials.refresh_now()
            databasecredentials.get_conn_params_from_secrets_manager(conn_params)
            conn=super(DatabaseWrapper,self).get_new_connection(conn_params)
            logger.info("Successfully refreshed secret and established new database
 connection.")
            return conn
```

Run Amazon ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere

Akash Kumar, Amazon Web Services

Summary

Amazon Elastic Container Service (Amazon ECS) Anywhere supports the deployment of Amazon ECS tasks in any environment, including Amazon Web Services (AWS) managed infrastructure and customer managed infrastructure. You can do this while using a fully AWS managed control plane that's running in the cloud and always up to date.

Enterprises often use Amazon WorkSpaces for developing container-based applications. This has required Amazon Elastic Compute Cloud (Amazon EC2) or AWS Fargate with an Amazon ECS cluster to test and run ECS tasks. Now, by using Amazon ECS Anywhere, you can add Amazon WorkSpaces as external instances directly to an ECS cluster, and you can run your tasks directly. This reduces your development time, because you can test your container with an ECS cluster locally on Amazon WorkSpaces. You can also save the cost of using EC2 or Fargate instances for testing your container applications.

This pattern showcases how to deploy ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere. It sets up the ECS cluster and uses AWS Directory Service Simple AD to launch the WorkSpaces. Then the example ECS task launches NGINX in the WorkSpaces.

Prerequisites and limitations

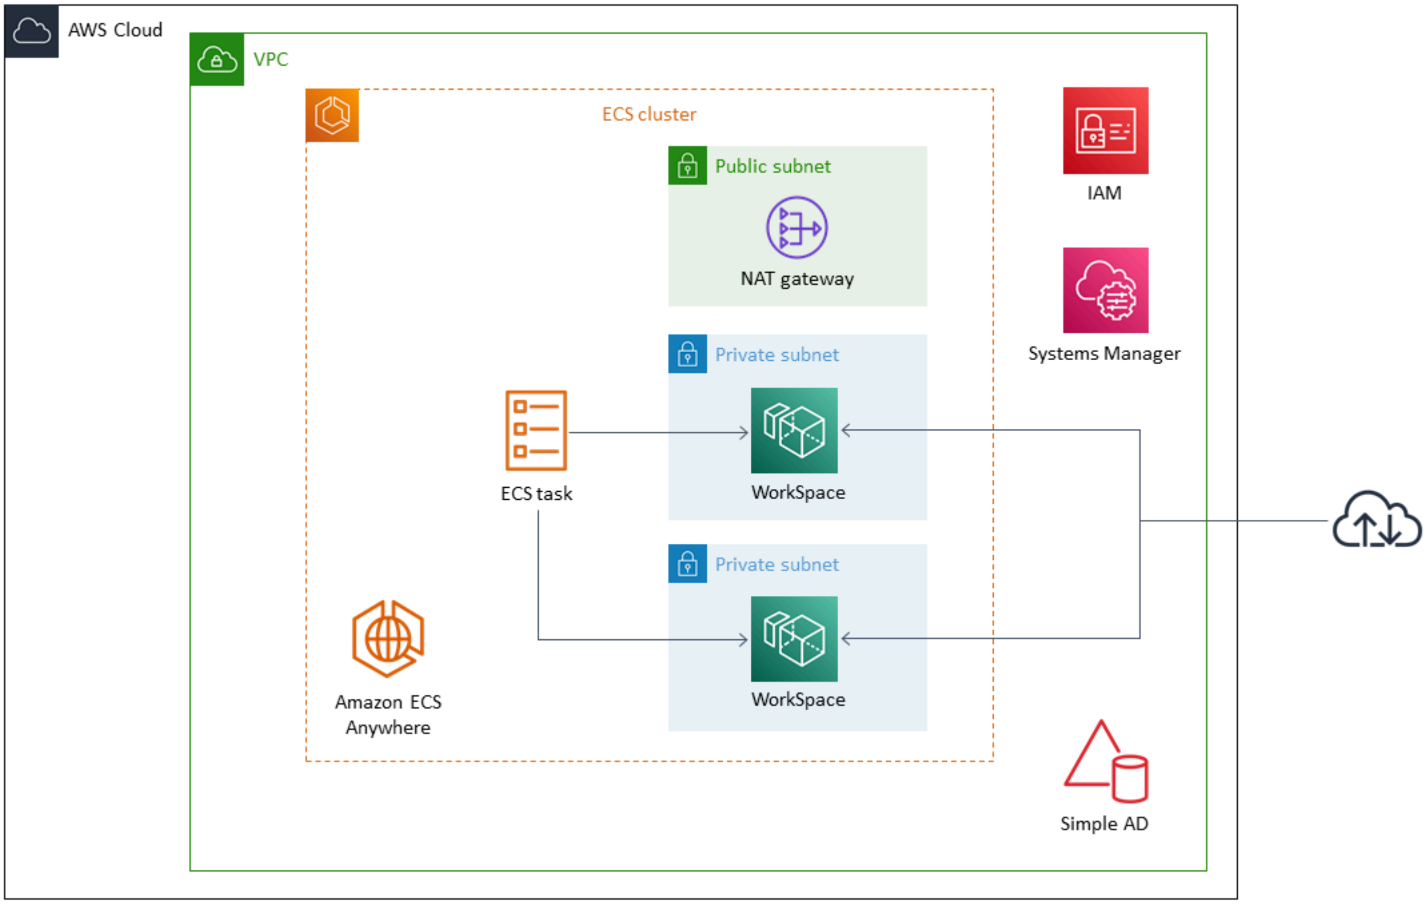
- An active AWS account
- AWS Command Line Interface (AWS CLI)
- AWS credentials configured on your machine

Architecture

Target technology stack

- A virtual private cloud (VPC)
- An Amazon ECS cluster
- Amazon WorkSpaces
- AWS Directory Service with Simple AD

Target architecture



The architecture includes the following services and resources:

- An ECS cluster with public and private subnets in a custom VPC
- Simple AD in the VPC to provide user access to Amazon WorkSpaces
- Amazon WorkSpaces provisioned in the VPC using Simple AD
- AWS Systems Manager activated for adding Amazon WorkSpaces as managed instances
- Using Amazon ECS and AWS Systems Manager Agent (SSM Agent), Amazon WorkSpaces added to Systems Manager and the ECS cluster
- An example ECS task to run in the WorkSpaces in the ECS cluster

Tools

- [AWS Directory Service Simple Active Directory (Simple AD)](#) is a standalone managed directory powered by a Samba 4 Active Directory Compatible Server. Simple AD provides a subset of the features offered by AWS Managed Microsoft AD, including the ability to manage users and to securely connect to Amazon EC2 instances.

- [Amazon Elastic Container Service (Amazon ECS)] is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- [AWS Identity and Access Management (IAM)] helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Systems Manager] helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.
- [Amazon WorkSpaces] helps you provision virtual, cloud-based Microsoft Windows or Amazon Linux desktops for your users, known as *WorkSpaces*. WorkSpaces eliminates the need to procure and deploy hardware or install complex software.

Epics

Set up the ECS cluster

Task	Description	Skills required
Create and configure the ECS cluster.	To create the ECS cluster, follow the instructions in the [AWS documentation], including the following steps: • For **Select cluster compatibility**, choose **Networking only**, which will support an Amazon WorkSpace as an external instance to the ECS cluster. • Choose to create a new VPC.	Cloud architect

Launch Amazon WorkSpaces

Task	Description	Skills required
Set up Simple AD and launch Amazon WorkSpaces.	To provision a Simple AD directory for your newly created VPC and launch Amazon WorkSpaces, follow the instructions in the [AWS documentation]().	Cloud architect

Set up AWS Systems Manager for a hybrid environment

Task	Description	Skills required
Download the attached scripts.	On your local machine, download the `ssm-trust-policy.json` and `ssm-activation.json` files that are in the *Attachments* section.	Cloud architect

Add the IAM role.	Add environment variables based on your business requirements.
	`export AWS_DEFAULT_REGION=${AWS_REGION_ID}`
	`export ROLE_NAME=${ECS_TASK_ROLE}`
	`export CLUSTER_NAME=${ECS_CLUSTER_NAME}`
	`export SERVICE_NAME=${ECS_CLUSTER_SERVICE_NAME}`
	Run the following command.
		Cloud architect

Task	Description	Skills required
	`aws iam create-role --role-name $ROLE_NAME --assume-role-policy-document file://ssm-trust-policy.json`	
Add the AmazonSSM ManagedInstanceCore policy to the IAM role.	Run the following command. `aws iam attach-role-policy --role-name $ROLE_NAME --policy-arn arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore`	Cloud architect
Add the AmazonEC2Container ServiceforEC2Role policy to IAM role.	Run the following command. `aws iam attach-role-policy --role-name $ROLE_NAME --policy-arn arn:aws:iam::aws:policy/service-role/AmazonEC2ContainerServiceforEC2Role`	Cloud architect
Verify the IAM role.	To verify the IAM role, run the following command. `aws iam list-attached-role-policies --role-name $ROLE_NAME`	Cloud architect

Task	Description	Skills required
Activate Systems Manager.	Run the following command. `aws ssm create-activation --iam-role $ROLE_NAME | tee ssm-activation.json`	Cloud architect

Add WorkSpaces to the ECS cluster

Task	Description	Skills required
Connect to your WorkSpaces.	To connect to and set up your Workspaces, follow the instructions in the [AWS documentation]().	App developer
Download the ecs-anywhere install script.	At the command prompt, run the following command. `curl -o "ecs-anywhere-install.sh" "https://amazon-ecs-agent-packages-preview.s3.us-east-1.amazonaws.com/ecs-anywhere-install.sh" && sudo chmod +x ecs-anywhere-install.sh`	App developer
Check integrity of the shell script.	(Optional) Run the following command. `curl -o "ecs-anywhere-install.sh.sha256" "https://amazon-ecs-agent-packages-preview.s3.us-east-`	App developer

Task	Description	Skills required
	`1.amazonaws.com/ecs-anywhere-install.sh.sha256" && sha256sum -c ecs-anywhere-install.sh.sha256`	
Add an EPEL repository on Amazon Linux.	To add an Extra Packages for Enterprise Linux (EPEL) repository, run the command `sudo amazon-linux-extras install epel -y`.	App developer
Install Amazon ECS Anywhere.	To run the install script, use the following command. `sudo ./ecs-anywhere-install.sh --cluster $CLUSTER_NAME --activation-id $ACTIVATION_ID --activation-code $ACTIVATION_CODE --region $AWS_REGION`	

Task	Description	Skills required
Check instance information from the ECS cluster.	To check the Systems Manager and ECS cluster instance information and validate that WorkSpaces were added on the cluster, run the following command from your local machine. `aws ssm describe-instance-informati on" && "aws ecs list-container-instances --cluster $CLUSTER_NAME`	App developer

Add an ECS task for the WorkSpaces

Task	Description	Skills required
Create a task execution IAM role.	Download `task-execution-assume-role.json` and `external-task-definition.json` from the *Attachments* section. On your local machine, run the following command. `aws iam --region $AWS_DEFAULT_REGIO N create-role --role-name $ECS_TASK _EXECUTION_ROLE --assume-role-policy-document file://ta`	Cloud architect

Task	Description	Skills required
	```sk-execution-assume-role.json```	
Add the policy to the execution role.	Run the following command. ```aws iam --region $AWS_DEFAULT_REGION attach-role-policy --role-name $ECS_TASK_EXECUTION_ROLE --policy-arn arn:aws:iam::aws:policy/service-role/AmazonECSTaskExecutionRolePolicy```	Cloud architect
Create a task role.	Run the following command. ```aws iam --region $AWS_DEFAULT_REGION create-role --role-name $ECS_TASK_EXECUTION_ROLE --assume-role-policy-document file://task-execution-assume-role.json```	Cloud architect
Register the task definition to the cluster.	On your local machine, run the following command. ```aws ecs register-task-definition --cli-input-json file://external-task-definition.json```	Cloud architect

Task	Description	Skills required
Run the task.	On your local machine, run the following command. `aws ecs run-task --cluster $CLUSTER_NAME --launch-type EXTERNAL --task-definition nginx`	Cloud architect

Validate the task running state.	To fetch the task ID, run the following command.
	`export TEST_TASKID=$(aws ecs list-tasks --cluster $CLUSTER_NAME | jq -r '.taskArns[0]')`
	With the task ID, run the following command.
	`aws ecs describe-tasks --cluster $CLUSTER_NAME --tasks ${TEST_TASKID}`
		Cloud architect

Verify the task on the WorkSpace.	To check that NGINX is running on the WorkSpace, run the command `curl http://localhost:8080`.	App developer

Run an ASP.NET Core web API Docker container on an Amazon EC2 Linux instance

Vijai Anand Ramalingam and Sreelaxmi Pai, Amazon Web Services

Summary

This pattern is for people who are starting to containerize their applications on the Amazon Web Services (AWS) Cloud. When you begin to containerize apps on cloud, usually there are no container orchestrating platforms set up. This pattern helps you quickly set up infrastructure on AWS to test your containerized applications without needing an elaborate container orchestrating infrastructure.

The first step in the modernization journey is to transform the application. If it's a legacy .NET Framework application, you must first change the runtime to ASP.NET Core. Then do the following:

- Create the Docker container image
- Run the Docker container using the built image
- Validate the application before deploying it on any container orchestration platform, such as Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic Kubernetes Service (Amazon EKS).

This pattern covers the build, run, and validate aspects of modern application development on an Amazon Elastic Compute Cloud (Amazon EC2) Linux instance.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- An AWS Identity and Access Management (IAM) role with sufficient access to create AWS resources for this pattern
- Visual Studio Community 2022 or later downloaded and installed
- A .NET Framework project modernized to ASP.NET Core
- A GitHub repository

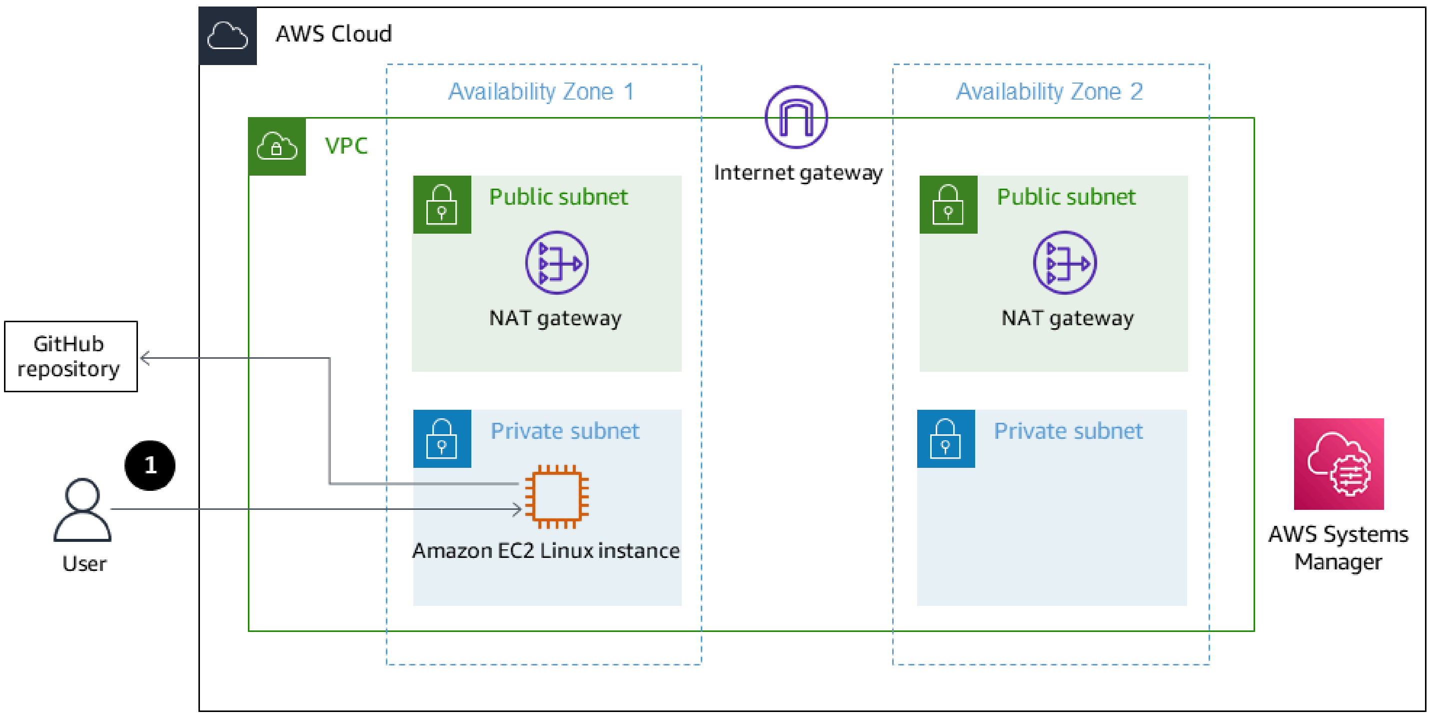
Product versions

- Visual Studio Community 2022 or later

Architecture

Target architecture

This pattern uses an [AWS CloudFormation template](#) to create the highly available architecture shown in the following diagram. An Amazon EC2 Linux instance is launched in a private subnet. AWS Systems Manager Session Manager is used to access the private Amazon EC2 Linux instance and to test the API running in the Docker container.



1. Access to the Linux instance through Session Manager

Tools

AWS services

- [AWS Command Line Interface](#) – AWS Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services through commands in your command line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console.

- AWS Management Console – The AWS Management Console is a web application that comprises and refers to a broad collection of service consoles for managing AWS resources. When you first sign in, you see the console home page. The home page provides access to each service console and offers a single place to access the information you need to perform your AWS related tasks.
- AWS Systems Manager Session Manager – Session Manager is a fully managed AWS Systems Manager capability. With Session Manager, you can manage your Amazon Elastic Compute Cloud (Amazon EC2) instances. Session Manager provides secure and auditable node management without the need to open inbound ports, maintain bastion hosts, or manage SSH keys.

Other tools

- Visual Studio 2022 – Visual Studio 2022 is an integrated development environment (IDE).
- Docker – Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.

Code

```
FROM mcr.microsoft.com/dotnet/aspnet:5.0 AS base
 WORKDIR /app
EXPOSE 80
EXPOSE 443

FROM mcr.microsoft.com/dotnet/sdk:5.0 AS build
WORKDIR /src

```

Epics

Develop the ASP.NET Core web API

Task	Description	Skills required
Create an example ASP.NET Core web API using Visual Studio.	To create an example ASP.NET Core web API, do the following: 1. Open Visual Studio 2022. 2. Choose **Create a new project**. 3. Select the **ASP.NET Core Web API** project template, and choose **Next**. 4. For the project name, enter **DemoNetCoreWebAPI**, and choose **Next**. 5. Choose **Create**. 6. To run the project locally, press F5. 7. Verify that the default **WeatherForecast** API endpoint is returning the results using [Swagger](https://swagger.io/). 8. Open the command prompt, navigate to the .csproj project folder, and run the following commands to push the new web API to your GitHub repository. `git add --all`	App developer

Task	Description	Skills required
	```git commit -m "Initial Version"``` ```git push```	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a Dockerfile.</td><td>To create a Dockerfile, do one of the following:
Create the Dockerfile manually using the sample Dockerfile in the Code section. Based on the requirements, select the appropriate .NET base image. For information about .NET and ASP.NET Core related images, see Docker hub.
Create the Dockerfile using Visual Studio and Docker Desktop. In the solution explorer, right click on the project, choose Add->Docker Support. For Target OS, select Linux. Ensure that the new Dockerfile is in the same path as the solution file (.sln).
To push the changes to your GitHub repository, run the following command.<pre>git add --all
git commit -m "Dockerfile added"
git push</pre></td><td>App developer</td></tr>
</table>

Set up the Amazon EC2 Linux instance

Task	Description	Skills required
Set up the infrastructure.	Launch the AWS CloudFormation template to create the infrastructure, which includes the following: • A virtual private cloud (VPC), using the AWS VPC Quick Start, with two public and two private subnets spanning two Availability Zones. • The required IAM role to enable AWS Systems Manager. • In one of the private subnets, an Amazon Linux 2 demo instance with the latest SSM Agent. Although this instance doesn't have any direct connectivity from the internet, it can be accessed securely by using AWS Systems Manager Session Manager without requiring a bastion host. **Note** Amazon Linux 2 is nearing end of support. For more information, see	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	the Amazon Linux 2 FAQs. To learn more about accessing a private Amazon EC2 instance using Session Manager without requiring a bastion host, see the Toward a bastion-less world blog post.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Log in to the Amazon EC2 Linux instance.</td><td>To connect to the Amazon EC2 Linux instance in the private subnet, do the following:

1. Open the Amazon EC2 console.
2. In the navigation pane, choose Instances.
3. Select the Amazon Linux 2 demo instance, and choose Connect.

Note
Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs.

4. Choose Session Manager.
5. Choose Connect to open a new terminal window.
6. Run the following command.

<code>sudo su</code></td><td>App developer</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install and start Docker.</td><td>To install and start Docker in the Amazon EC2 Linux instance, do the following:

1. To install Docker, run the following command.
<pre><code>yum install -y docker</code></pre>2. To start the Docker service, run the following command.
<pre><code>service docker start</code></pre>3. To verify Docker installat ion, run the following command.
<pre><code>docker info</code></pre></td><td>App developer, AWS administrator, AWS DevOps</td></tr>
</table>

Task	Description	Skills required

Install Git and clone the repository.	To install Git on the Amazon EC2 Linux instance and clone the repository from GitHub, do the following.
	
	1. To install Git, run the following command.
	
	`yum install git -y`
	
	2. To clone the repository, run the following command.
	
	`git clone https://github.com/<username>/<repo-name>.git`
	
	3. To navigate to the Dockerfile, run the following command.
	
	`cd <repo-name>/DemoNetCoreWebAPI/`
		App developer, AWS administrator, AWS DevOps

Task	Description	Skills required

Build and run the Docker container.	To build the Docker image and run the container inside the Amazon EC2 Linux instance, do the following:
	
	1. To create the Docker image, run the following command.
	`docker build -t aspnetcorewebapiimage -f Dockerfile .`
	2. To view all the Docker images, run the following command.
	`docker images`
	3. To create and run the container, run the following command.
	`docker run -d -p 80:80 --name aspnetcorewebapicontainer aspnetcorewebapiimage`
		App developer, AWS administrator, AWS DevOps

Test the web API

Task	Description	Skills required
Test the web API using the curl command.	To test the web API, run the following command.	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

```
curl -X GET "http://l
ocalhost/WeatherFo
recast" -H  "accept:
 text/plain"
```

Verify the API response.

Note

You can get the curl commands for each endpoint from Swagger when you are running it locally.
</td><td></td></tr>
</table>

Clean up resources

Task	Description	Skills required
Delete all resources.	Delete the stack to remove all the resources. This ensures that you aren’t charged for any services that you aren’t using.	AWS administrator, AWS DevOps

Run message-driven workloads at scale by using AWS Fargate

Stan Zubarev, Amazon Web Services

Summary

This pattern shows how to run message-driven workloads at scale in the AWS Cloud by using containers and AWS Fargate.

Using containers to process data can be helpful when the amount of data an application processes exceeds the limitations of function-based serverless compute services. For example, if an application requires more compute capacity or processing time than what AWS Lambda offers, using Fargate can improve performance.

The following example setup uses the [AWS Cloud Development Kit (AWS CDK) in TypeScript] to configure and deploy the following resources in the AWS Cloud:

- A Fargate service
- An Amazon Simple Queue Service (Amazon SQS) queue
- An Amazon DynamoDB table.
- An Amazon CloudWatch dashboard

The Fargate service receives and processes messages from the Amazon SQS queue, then stores them in the Amazon DynamoDB table. You can monitor how many Amazon SQS messages are processed and how many DynamoDB items are created by Fargate by using the CloudWatch dashboard.

Note

You can also use this pattern's example code to build more complex data processing workloads in event-driven serverless architectures. For more information, see [Run event-driven and scheduled workloads at scale with AWS Fargate].

Prerequisites and limitations

Prerequisites

- An active AWS account

- The latest version of the [AWS Command Line Interface (AWS CLI)](), installed and configured on your local machine
- [Git](), installed and configured on your local machine
- The [AWS CDK](), installed and configured on your local machine
- [Go](), installed and configured on your local machine
- [Docker](), installed and configured on your local machine

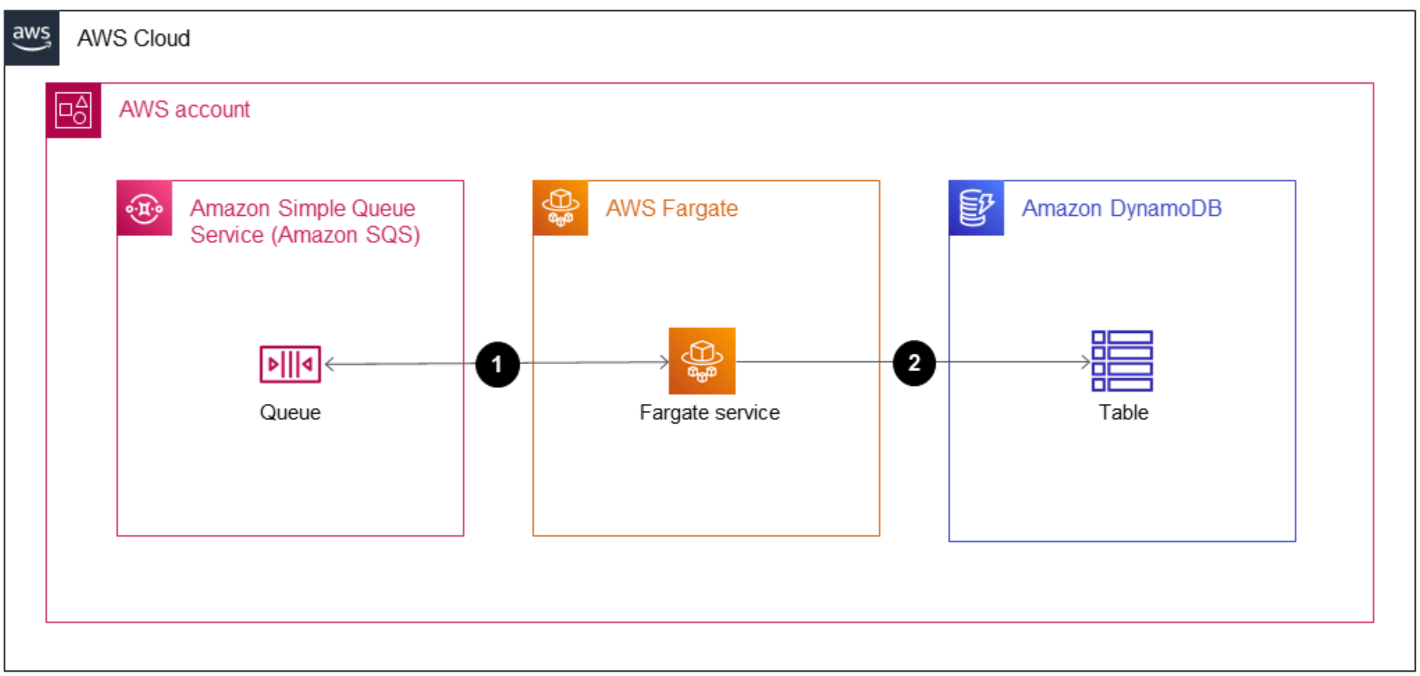
Architecture

Target technology stack

- Amazon SQS
- AWS Fargate
- Amazon DynamoDB

Target architecture

The following diagram shows an example workflow for running message-driven workloads at scale in the AWS Cloud by using Fargate:



The diagram shows the following workflow:

1. The Fargate service uses Amazon SQS long polling to receive messages from an Amazon SQS queue.
2. The Fargate service then processes the Amazon SQS messages and stores them in a DynamoDB table.

Automation and scale

To automate scaling your Fargate task count, you can configure Amazon Elastic Container Service (Amazon ECS) Service Auto Scaling. It's a best practice to configure the scaling policy based on the number of visible messages in your application's Amazon SQS queue.

For more information, see Scaling based on Amazon SQS in the *Amazon EC2 Auto Scaling User Guide*.

Tools

AWS services

- AWS Fargate helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.

Code

The code for this pattern is available in the GitHub sqs-fargate-ddb-cdk-go repository.

Epics

Create and deploy the resources by using the AWS CDK

Task	Description	Skills required
Clone the GitHub repository.	Clone the GitHub [sqs-fargate-ddb-cdk-go](https://github.com/aws-samples/sqs-fargate-ddb-cdk-go) repository to your local machine by running the following command: `git clone https://github.com/aws-samples/sqs-fargate-ddb-cdk-go.git`	App developer
Verify that the AWS CLI is configured to the correct AWS account and that the AWS CDK has the required permissions.	To check if your AWS CLI configuration settings are correct, you can run the following Amazon Simple Storage Service (Amazon S3) ls command: `aws s3 ls` This procedure also requires the AWS CDK to have permissions to provision infrastructure within your AWS account. To grant the required permissions, you must create named AWS profile in AWS CLI and export it as an **AWS_PROFILE** environment variable.	App developer

Task	Description	Skills required
	Note If you haven't used the AWS CDK in your AWS account before, you must first provision the required AWS CDK resources . For more informati on, see [Bootstrapping](#) in the *AWS CDK v2 Developer Guide*.	

Task	Description	Skills required

Deploy the AWS CDK stack to your AWS account.	1. Build a container image by running the following AWS CLI command:
	`docker build -t go-fargate .`
	2. Open the AWS CDK directory by running the following command:
	`cd cdk`
	3. Install the required npm modules by running the following command:
	`npm i`
	4. Deploy the AWS CDK pattern to your AWS account by running the following command:
	`cdk deploy --profile ${AWS_PROFILE}`
		App developer

Test the setup

Task	Description	Skills required
Send a test message to the Amazon SQS queue.	For instructions, see Sending messages to a queue (console) in the *Amazon SQS Developer Guide*. **Test Amazon SQS message example**	App developer

Task	Description	Skills required

	``
	{
	    "message": "hello,
	 Fargate"
	}
	``	

Verify that the test message appears in the Fargate service's CloudWatch logs.	Follow the instructions in Viewing CloudWatch Logs in the *Amazon ECS Developer Guide*. Make sure that you review the logs for the **go-fargate-service** log group in the **go-service-cluster** ECS cluster.	App developer
Verify that the test message appears in the DynamoDB table.	1. Open the DynamoDB console. 2. In the left navigation pane, choose Tables. Then, select the following table from the list: **sqs-fargate-ddb-table**. 3. Choose **Explore table items**. 4. Verify that the test message appears in the **Items returned** list.	App developer

Task	Description	Skills required
Verify that the Fargate service is sending messages to CloudWatch Logs.	1. Open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/). 2. In the left navigation pane, choose **Dashboards**. 3. In the Custom Dashboard s list, select the dashboard named **go-service-dashboard**. 4. Verify that the test message appears in the logs. **Note** The AWS CDK creates the CloudWatc h dashboard in your AWS account automatically.	App developer

Clean up

Task	Description	Skills required
Delete the AWS CDK stack.	1. Open your AWS CDK directory in the AWS CLI by running the following command: `cd cdk`	App developer

Task	Description	Skills required
	2. Delete the AWS CDK stack by running the following command: `cdk destroy --profile ${AWS_PROFILE}`	
Verify that the AWS CDK stack is deleted.	To make sure that the stack was deleted, run the following command: `aws cloudformation list-stacks --query \ "StackSummaries[?contains(StackName,'SqsFargate')].StackStatus" \ --profile ${AWS_PROFILE}` The `StackStatus` value returned in the command output is `DELETE_COMPLETE` if the stack is deleted. For more information, see [Examples of CloudFormation stack operation commands for the AWS CLI and PowerShell]() in the *AWS CloudFormation User Guide*.	App developer

Run stateful workloads with persistent data storage by using Amazon EFS on Amazon EKS with AWS Fargate

Ricardo Morais, Rodrigo Bersa, and Lucio Pereira, Amazon Web Services

Summary

This pattern provides guidance for enabling Amazon Elastic File System (Amazon EFS) as a storage device for containers that are running on Amazon Elastic Kubernetes Service (Amazon EKS) by using AWS Fargate to provision your compute resources.

The setup described in this pattern follows security best practices and provides security at rest and security in transit by default. To encrypt your Amazon EFS file system, it uses an AWS Key Management Service (AWS KMS) key, but you can also specify a key alias that dispatches the process of creating a KMS key.

You can follow the steps in this pattern to create a namespace and Fargate profile for a proof-of-concept (PoC) application, install the Amazon EFS Container Storage Interface (CSI) driver that is used to integrate the Kubernetes cluster with Amazon EFS, configure the storage class, and deploy the PoC application. These steps result in an Amazon EFS file system that is shared among multiple Kubernetes workloads, running over Fargate. The pattern is accompanied by scripts that automate these steps.

You can use this pattern if you want data persistence in your containerized applications and want to avoid data loss during scaling operations. For example:

- **DevOps tools** – A common scenario is to develop a continuous integration and continuous delivery (CI/CD) strategy. In this case, you can use Amazon EFS as a shared file system to store configurations among different instances of the CI/CD tool or to store a cache (for example, an Apache Maven repository) for pipeline stages among different instances of the CI/CD tool.
- **Web servers** – A common scenario is to use Apache as an HTTP web server. You can use Amazon EFS as a shared file system to store static files that are shared among different instances of the web server. In this example scenario, modifications are applied directly to the file system instead of static files being baked into a Docker image.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An existing Amazon EKS cluster with Kubernetes version 1.17 or later (tested up to version 1.27)
- An existing Amazon EFS file system to bind a Kubernetes StorageClass and provision file systems dynamically
- Cluster administration permissions
- Context configured to point to the desired Amazon EKS cluster

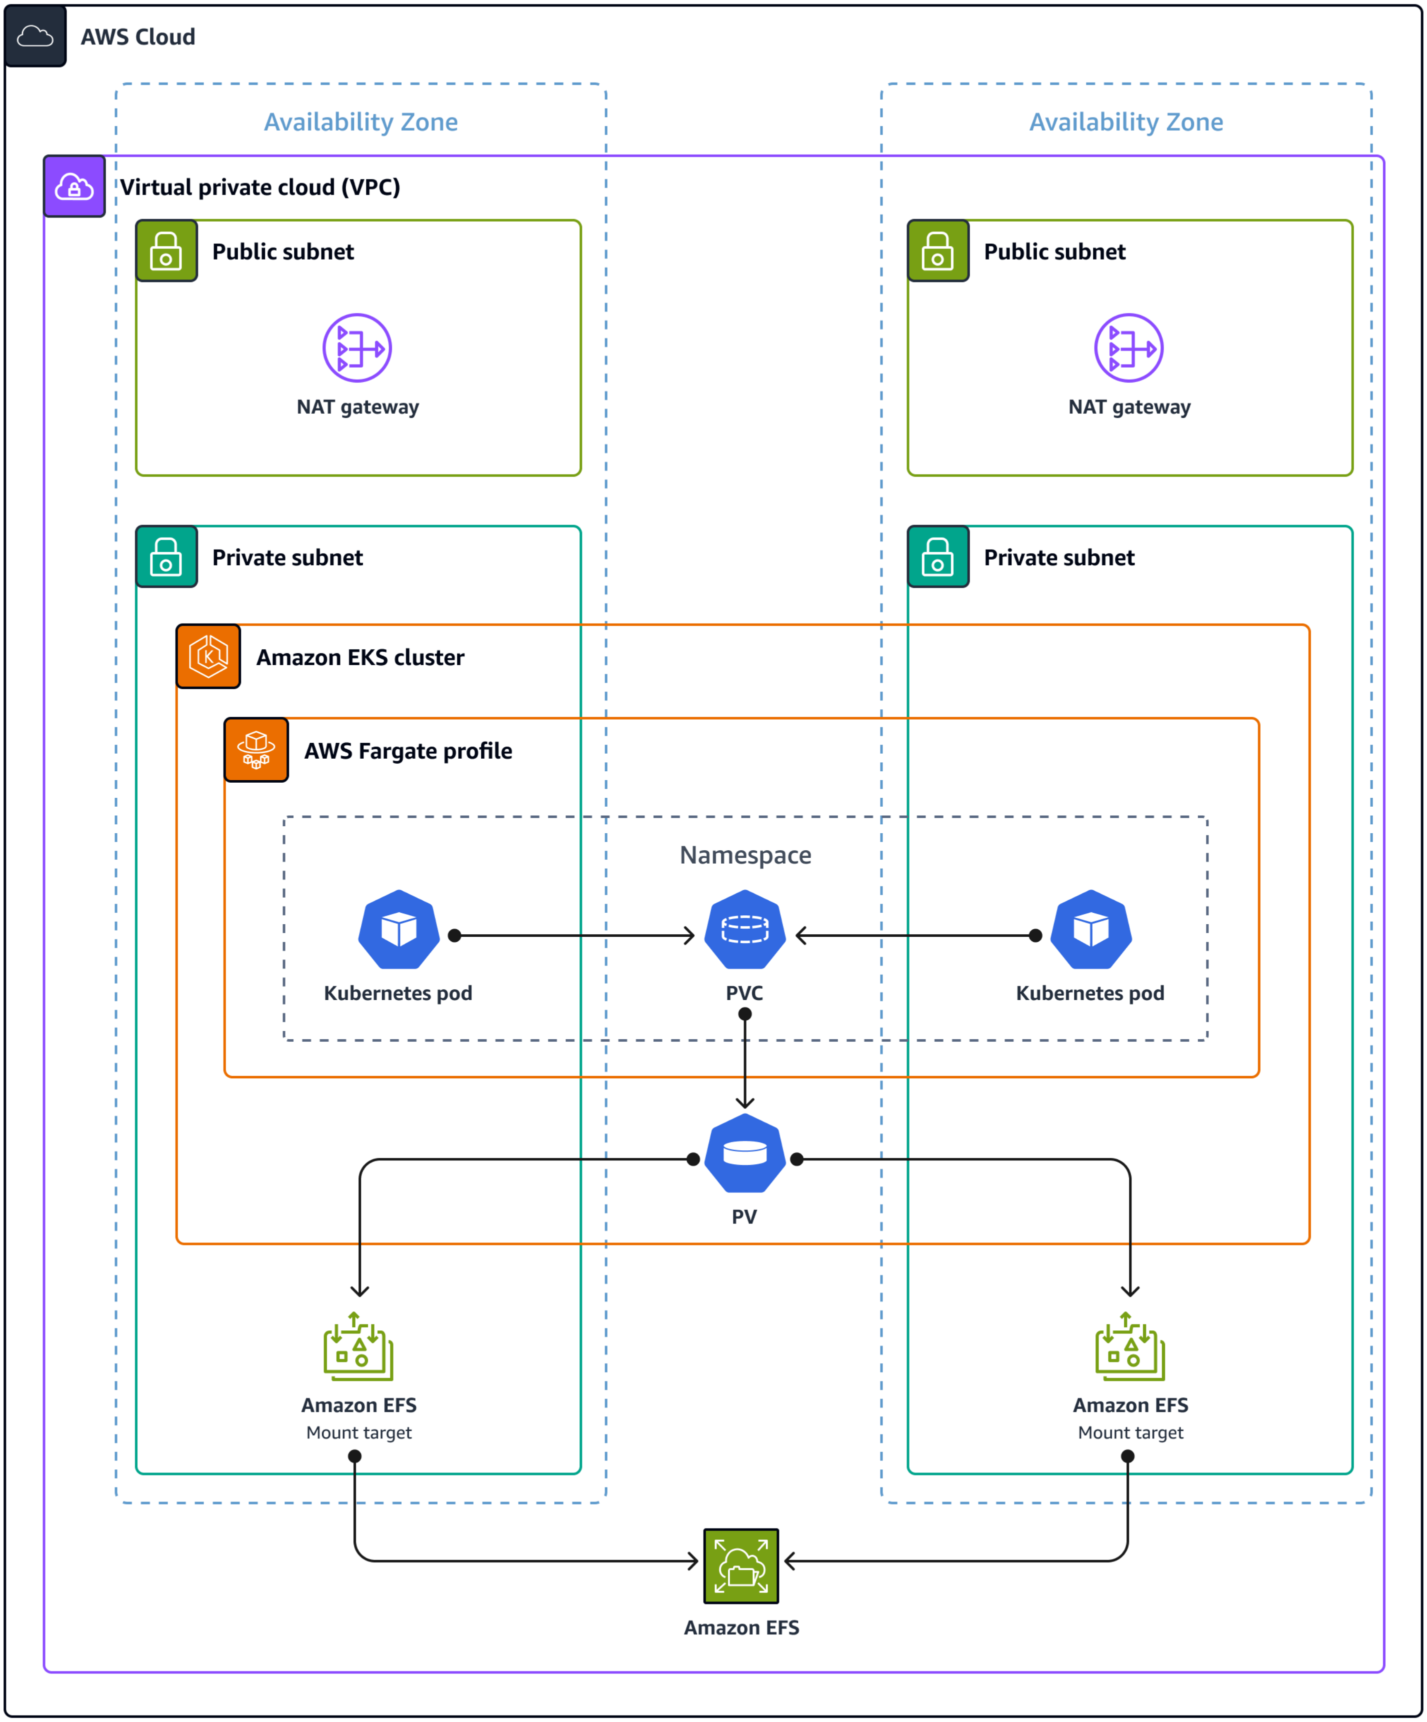
Limitations

- There are some limitations to consider when you're using Amazon EKS with Fargate. For example, the use of some Kubernetes constructs, such as DaemonSets and privileged containers, aren't supported. For more information, about Fargate limitations, see the AWS Fargate considerations in the Amazon EKS documentation.
- The code provided with this pattern supports workstations that are running Linux or macOS.

Product versions

- AWS Command Line Interface (AWS CLI) version 2 or later
- Amazon EFS CSI driver version 1.0 or later (tested up to version 2.4.8)
- eksctl version 0.24.0 or later (tested up to version 0.158.0)
- jq version 1.6 or later
- kubectl version 1.17 or later (tested up to version 1.27)
- Kubernetes version 1.17 or later (tested up to version 1.27)

Architecture



The target architecture is comprised of the following infrastructure:

- A virtual private cloud (VPC)
- Two Availability Zones
- A public subnet with a NAT gateway that provides internet access
- A private subnet with an Amazon EKS cluster and Amazon EFS mount targets (also known as *mount points*)
- Amazon EFS at the VPC level

The following is the environment infrastructure for the Amazon EKS cluster:

- AWS Fargate profiles that accommodate the Kubernetes constructs at the namespace level
- A Kubernetes namespace with:
  - Two application pods distributed across Availability Zones
  - One persistent volume claim (PVC) bound to a persistent volume (PV) at the cluster level
- A cluster-wide PV that is bound to the PVC in the namespace and that points to the Amazon EFS mount targets in the private subnet, outside of the cluster

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that you can use to interact with AWS services from the command line.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud. In this pattern, it provides a simple, scalable, fully managed, and shared file system for use with Amazon EKS.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or operate your own clusters.
- AWS Fargate is a serverless compute engine for Amazon EKS. It creates and manages compute resources for your Kubernetes applications.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- eksctl is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- kubectl is a command-line interface that helps you run commands against Kubernetes clusters.
- jq is a command-line tool for parsing JSON.

Code

The code for this pattern is provided in the GitHub Persistence Configuration with Amazon EFS on Amazon EKS using AWS Fargate repo. The scripts are organized by epic, in the folders `epic01` through `epic06`, corresponding to the order in the Epics section in this pattern.

Best practices

The target architecture includes the following services and components, and it follows AWS Well-Architected Framework best practices:

- Amazon EFS, which provides a simple, scalable, fully managed elastic NFS file system. This is used as a shared file system among all replications of the PoC application that are running in pods, which are distributed in the private subnets of the chosen Amazon EKS cluster.
- An Amazon EFS mount target for each private subnet. This provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.
- Amazon EKS, which runs the Kubernetes workloads. You must provision an Amazon EKS cluster before you use this pattern, as described in the Prerequisites section.
- AWS KMS, which provides encryption at rest for the content that's stored in the Amazon EFS file system.
- Fargate, which manages the compute resources for the containers so that you can focus on business requirements instead of infrastructure burden. The Fargate profile is created for all private subnets. It provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.
- Kubernetes Pods, for validating that content can be shared, consumed, and written by different instances of an application.

Epics

Provision an Amazon EKS cluster (optional)

Task	Description	Skills required
Create an Amazon EKS cluster.	**Note** If you already have a cluster deployed, skip to the next epic. Create an Amazon EKS cluster in your existing AWS account. In the [GitHub directory](), use one of the patterns to deploy an Amazon EKS cluster by using Terraform or eksctl. For more information, see [Creating an Amazon EKS cluster]() in the Amazon EKS documentation. In the Terraform pattern, there are also examples showing how to: link Fargate profiles to your Amazon EKS cluster, create an Amazon EFS file system, and deploy Amazon EFS CSI driver in your Amazon EKS cluster.	AWS administrator, Terraform or eksctl administrator, Kubernetes administrator

Task	Description	Skills required

Export environment variables.	Run the env.sh script. This provides the information required in the next steps.
	
	`source ./scripts/env.sh`
	`Inform the AWS Account ID:`
	`<13-digit-account-id>`
	`Inform your AWS Region:`
	`<aws-Region-code>`
	`Inform your Amazon EKS Cluster Name:`
	`<amazon-eks-cluster-name>`
	`Inform the Amazon EFS Creation Token:`
	`<self-genereated-uuid>`
	
	If not noted yet, you can get all the information requested above with the following CLI commands.
	
	`# ACCOUNT ID`
	`aws sts get-caller-identity --query "Account" --output text`
	
	`# REGION CODE`
	`aws configure get region`
	
	`# CLUSTER EKS NAME`
	`aws eks list-clusters --query "clusters" --output text`
		AWS systems administrator

Task	Description	Skills required
	``` # GENERATE EFS TOKEN uuidgen ```	

Create a Kubernetes namespace and a linked Fargate profile

Task	Description	Skills required

Create a Kubernetes namespace and Fargate profile for application workloads.	Create a namespace for receiving the application workloads that interact with Amazon EFS. Run the `create-k8s-ns-and-linked-fargate-profile.sh` script. You can choose to use a custom namespace name or the default provided namespace `poc-efs-eks-fargate` .
	
	With a custom application namespace name:
	
	`export $APP_NAMESPACE=<CUSTOM_NAME>`
	`./scripts/epic01/create-k8s-ns-and-linked-fargate-profile.sh \`
	`-c "$CLUSTER_NAME" -n "$APP_NAMESPACE"`
	
	Without a custom application namespace name:
		Kubernetes user with granted permissions

Task	Description	Skills required
	`./scripts/epic01/create-k8s-ns-and-linked-fargate-profile.sh \ -c "$CLUSTER_NAME"` where `$CLUSTER_NAME` is the name of your Amazon EKS cluster. The `-n <NAMESPACE>` parameter is optional; if not informed, a default generated namespace name will be provided.	

Create an Amazon EFS file system

Task	Description	Skills required
Generate a unique token.	Amazon EFS requires a creation token to ensure idempotent operation (calling the operation with the same creation token has no effect). To meet this requirement, you must generate a unique token through an available technique. For example, you can generate a universally unique identifier (UUID) to use as a creation token.	AWS systems administrator
Create an Amazon EFS file system.	Create the file system for receiving the data files that are read and written by the application workloads. You	AWS systems administrator

Task	Description	Skills required
	can create an encrypted or non-encrypted file system. (As a best practice, the code for this pattern creates an encrypted system to enable encryption at rest by default.) You can use a unique, symmetric AWS KMS key to encrypt your file system. If a custom key is not specified, an AWS managed key is used. Use the create-efs.sh script to create an encrypted or non-encrypted Amazon EFS file system, after you generate a unique token for Amazon EFS. **With encryption at rest, without a KMS key:** `./scripts/epic02/create-efs.sh \ -c "$CLUSTER_NAME" \ -t "$EFS_CREATION_TOKEN"` where `$CLUSTER_NAME` is the name of your Amazon EKS cluster and `$EFS_CREATION_TOKEN` is a unique creation token for the file system.	

Task	Description	Skills required

	With encryption at rest, with a KMS key:
	`./scripts/epic02/create-efs.sh \ -c "$CLUSTER_NAME" \ -t "$EFS_CREATION_TOKEN" \ -k "$KMS_KEY_ALIAS"`
	where `$CLUSTER_NAME` is the name of your Amazon EKS cluster, `$EFS_CREATION_TOKEN` is a unique creation token for the file system, and `$KMS_KEY_ALIAS` is the alias for the KMS key.
	Without encryption:
	`./scripts/epic02/create-efs.sh -d \ -c "$CLUSTER_NAME" \ -t "$EFS_CREATION_TOKEN"`
	where `$CLUSTER_NAME` is the name of your Amazon EKS cluster, `$EFS_CREATION_TOKEN` is a unique creation token for the file system, and –d disables encryption at rest.	

Task	Description	Skills required
Create a security group.	Create a security group to allow the Amazon EKS cluster to access the Amazon EFS file system.	AWS systems administrator
Update the inbound rule for the security group.	Update the inbound rules of the security group to allow incoming traffic for the following settings: • **TCP protocol** – port 2049 • **Source** – CIDR block ranges for the private subnets in the VPC that contains the Kubernetes cluster	AWS systems administrator
Add a mount target for each private subnet.	For each private subnet of the Kubernetes cluster, create a mount target for the file system and the security group.	AWS systems administrator

Install Amazon EFS components into the Kubernetes cluster

Task	Description	Skills required
Deploy the Amazon EFS CSI driver.	Deploy the Amazon EFS CSI driver into the cluster. The driver provisions storage according to persisten t volume claims created by applications. Run the `create-k8s-efs-csi-sc.sh` script to deploy the Amazon EFS CSI driver and	Kubernetes user with granted permissions

Task	Description	Skills required
	the storage class into the cluster. `./scripts/epic03/create-k8s-efs-csi-sc.sh` This script uses the `kubectl` utility, so make sure that the context has been configured and point to the desired Amazon EKS cluster.	
Deploy the storage class.	Deploy the storage class into the cluster for the Amazon EFS provisioner (efs.csi.aws.com).	Kubernetes user with granted permissions

Install the PoC application into the Kubernetes cluster

Task	Description	Skills required
Deploy the persistent volume.	Deploy the persistent volume, and link it to the created storage class and to the ID of the Amazon EFS file system. The application uses the persistent volume to read and write content. You can specify any size for the persistent volume in the storage field. Kubernetes requires this field, but because Amazon EFS is an elastic file system, it does not enforce any file	Kubernetes user with granted permissions

Task	Description	Skills required

	system capacity. You can deploy the persistent volume with or without encryption. (The Amazon EFS CSI driver enables encryption by default, as a best practice.) Run the `deploy-poc-app.sh` script to deploy the persistent volume, the persistent volume claim, and the two workloads.
	
	With encryption in transit:
	
	`./scripts/epic04/deploy-poc-app.sh \ -t "$EFS_CREATION_TOKEN"`
	
	where `$EFS_CREATION_TOKEN` is the unique creation token for the file system.
	
	Without encryption in transit:
	
	`./scripts/epic04/deploy-poc-app.sh -d \ -t "$EFS_CREATION_TOKEN"`
	
	where `$EFS_CREATION_TOKEN` is the unique creation token for the file	

Task	Description	Skills required
	system, and `-d` disables encryption in transit.	
Deploy the persistent volume claim requested by the application.	Deploy the persistent volume claim requested by the application, and link it to the storage class. Use the same access mode as the persistent volume you created previousl y. You can specify any size for the persistent volume claim in the storage field. Kubernetes requires this field, but because Amazon EFS is an elastic file system, it does not enforce any file system capacity.	Kubernetes user with granted permissions
Deploy workload 1.	Deploy the pod that represent s workload 1 of the applicati on. This workload writes content to the file `/data/out1.txt` .	Kubernetes user with granted permissions
Deploy workload 2.	Deploy the pod that represent s workload 2 of the applicati on. This workload writes content to the file `/data/out2.txt` .	Kubernetes user with granted permissions

Validate file system persistence, durability, and shareability

Task	Description	Skills required
Check the status of the `PersistentVolume` .	Enter the following command to check the status of the `PersistentVolume` . `kubectl get pv` For an example output, see the Additional information section.	Kubernetes user with granted permissions
Check the status of the `PersistentVolumeClaim` .	Enter the following command to check the status of the `PersistentVolumeClaim` . `kubectl -n poc-efs-eks-fargate get pvc` For an example output, see the Additional information section.	Kubernetes user with granted permissions
Validate that workload 1 can write to the file system.	Enter the following command to validate that workload 1 is writing to `/data/out1.txt` . `kubectl exec -ti poc-app1 -n poc-efs-eks-fargate -- tail -f /data/out1.txt` The results are similar to the following:	Kubernetes user with granted permissions

Task	Description	Skills required

	`...`
	`Thu Sep  3 15:25:07 UTC 2023 - PoC APP 1`
	`Thu Sep  3 15:25:12 UTC 2023 - PoC APP 1`
	`Thu Sep  3 15:25:17 UTC 2023 - PoC APP 1`
	`...`	

Validate that workload 2 can write to the file system.	Enter the following command to validate that workload 2 is writing to `/data/out2.txt` .
	`kubectl -n $APP_NAMESPACE exec -ti poc-app2 -- tail -f /data/out2.txt`
	The results are similar to the following:
	`...`
	`Thu Sep  3 15:26:48 UTC 2023 - PoC APP 2`
	`Thu Sep  3 15:26:53 UTC 2023 - PoC APP 2`
	`Thu Sep  3 15:26:58 UTC 2023 - PoC APP 2`
	`...`
		Kubernetes user with granted permissions

Task	Description	Skills required

Validate that workload 1 can read the file written by workload 2.	Enter the following command to validate that workload 1 can read the `/data/out2.txt` file written by workload 2.
	`kubectl exec -ti poc-app1 -n poc-efs-eks-fargate -- tail -n 3 /data/out2.txt`
	The results are similar to the following:
	`...`
	`Thu Sep  3 15:26:48 UTC 2023 - PoC APP 2`
	`Thu Sep  3 15:26:53 UTC 2023 - PoC APP 2`
	`Thu Sep  3 15:26:58 UTC 2023 - PoC APP 2`
	`...`
		Kubernetes user with granted permissions

Task	Description	Skills required

Validate that workload 2 can read the file written by workload 1.	Enter the following command to validate that workload 2 can read the `/data/out1.txt` file written by workload 1.
	
	`kubectl -n $APP_NAMESPACE exec -ti poc-app2 -- tail -n 3 /data/out1.txt`
	
	The results are similar to the following:
	
	`...`
	`Thu Sep  3 15:29:22 UTC 2023 - PoC APP 1`
	`Thu Sep  3 15:29:27 UTC 2023 - PoC APP 1`
	`Thu Sep  3 15:29:32 UTC 2023 - PoC APP 1`
	`...`
		Kubernetes user with granted permissions

Task	Description	Skills required

Validate that files are retained after you remove application components.	Next, you use a script to remove the application components (persistent volume, persistent volume claim, and pods), and validate that the files `/data/out1.txt` and `/data/out2.txt` are retained in the file system. Run the `validate-efs-content.sh` script by using the following command.
	`./scripts/epic05/validate-efs-content.sh \ -t "$EFS_CREATION_TOKEN"`
	where `$EFS_CREATION_TOKEN` is the unique creation token for the file system.
	The results are similar to the following:
	`pod/poc-app-validation created`
	`Waiting for pod get Running state...`
	`Waiting for pod get Running state...`
	`Waiting for pod get Running state...`
	`Results from execution of 'find /data' on`
		Kubernetes user with granted permissions, System administrator

Task	Description	Skills required

	`validation process pod:`
	`/data`
	`/data/out2.txt`
	`/data/out1.txt`	

Monitor operations

Task	Description	Skills required
Monitor application logs.	As part of a day-two operation, ship the applicati on logs to Amazon CloudWatc h for monitoring.	AWS systems administrator, Kubernetes user with granted permissions
Monitor Amazon EKS and Kubernetes containers with Container Insights.	As part of a day-two operation, monitor the Amazon EKS and Kubernete s systems by using Amazon CloudWatch Container Insights. This tool collects, aggregates, and summarize s metrics from containerized applications at different levels and dimensions. For more information, see the Related resources section.	AWS systems administrator, Kubernetes user with granted permissions
Monitor Amazon EFS with CloudWatch.	As part of a day-two operation, monitor the file systems using Amazon CloudWatch, which collects and processes raw data from Amazon EFS into readable, near real-time metrics. For	AWS systems administrator

Task	Description	Skills required
	more information, see the Related resources section.	

Clean up resources

Task	Description	Skills required
Clean up all created resources for the pattern.	After you complete this pattern, clean up all resources , to avoid incurring AWS charges. Run the `clean-up-resources.sh` script to remove all resources after you have finished using the PoC application. Complete one of the following options. **With encryption at rest, with a KMS key:** `./scripts/epic06/clean-up-resources.sh \ -c "$CLUSTER_NAME" \ -t "$EFS_CREATION_TOKEN" \ -k "$KMS_KEY_ALIAS"` where `$CLUSTER_NAME` is the name of your Amazon EKS cluster, `$EFS_CREATION_TOKEN` is the creation token for the file system, and `$KMS_KEY_`	Kubernetes user with granted permissions, System administrator

Task	Description	Skills required
	`ALIAS` is the alias for the KMS key. **Without encryption at rest:** `./scripts/epic06/clean-up-resources.sh \ -c "$CLUSTER_NAME" \ -t "$EFS_CREATION_TOKEN"` where `$CLUSTER_NAME` is the name of your Amazon EKS cluster and `$EFS_CREATION_TOKEN` is the creation token for the file system.

The following is an example output of the `kubectl get pv` command.

```
NAME          CAPACITY   ACCESS MODES   RECLAIM POLICY   STATUS   CLAIM
            STORAGECLASS   REASON   AGE
poc-app-pv   1Mi         RWX            Retain           Bound    poc-efs-eks-fargate/
poc-app-pvc   efs-sc                   3m56s
```

The following is an example output of the `kubectl -n poc-efs-eks-fargate get pvc` command.

```
NAME          STATUS   VOLUME        CAPACITY   ACCESS MODES   STORAGECLASS   AGE
poc-app-pvc   Bound    poc-app-pv    1Mi        RWX            efs-sc         4m34s
```

Set up event-driven auto scaling in Amazon EKS by using Amazon EKS Pod Identity and KEDA

Dipen Desai, Abhay Diwan, Kamal Joshi, and Mahendra Revanasiddappa, Amazon Web Services

Summary

Orchestration platforms, such as Amazon Elastic Kubernetes Service (Amazon EKS), have streamlined the lifecycle management of container-based applications. This helps organizations focus on building, securing, operating, and maintaining container-based applications. As event-driven deployments become more common, organizations are more frequently scaling Kubernetes deployments based on various event sources. This method, combined with auto scaling, can result in significant cost savings by providing on-demand compute resources and efficient scaling that is tailored to application logic.

KEDA is a Kubernetes-based event-driven autoscaler. KEDA helps you scale any container in Kubernetes based on the number of events that need to be processed. It is lightweight and integrates with any Kubernetes cluster. It also works with standard Kubernetes components, such as Horizontal Pod Autoscaling (HPA). KEDA also offers TriggerAuthentication, which is a feature that helps you delegate authentication. It allows you to describe authentication parameters that are separate from the ScaledObject and the deployment containers.

AWS provides AWS Identity and Access Management (IAM) roles that support diverse Kubernetes deployment options, including Amazon EKS, Amazon EKS Anywhere, Red Hat OpenShift Service on AWS (ROSA), and self-managed Kubernetes clusters on Amazon Elastic Compute Cloud (Amazon EC2). These roles use IAM constructs, such as OpenID Connect (OIDC) identity providers and IAM trust policies, to operate across different environments without relying directly on Amazon EKS services or APIs. For more information, see IAM roles for service accounts in the Amazon EKS documentation.

Amazon EKS Pod Identity simplifies the process for Kubernetes service accounts to assume IAM roles without requiring OIDC providers. It provides the ability to manage credentials for your applications. Instead of creating and distributing your AWS credentials to the containers or using the Amazon EC2 instance’s role, you associate an IAM role with a Kubernetes service account and configure your Pods to use the service account. This helps you use an IAM role across multiple clusters and simplifies policy management by enabling the reuse of permission policies across IAM roles.

By implementing KEDA with Amazon EKS Pod Identity, businesses can achieve efficient event-driven auto scaling and simplified credential management. Applications scale based on demand, which optimizes resource utilization and reduces costs.

This pattern helps you integrate Amazon EKS Pod Identity with KEDA. It showcases how you can use the `keda-operator` service account and delegate authentication with `TriggerAuthentication`. It also describes how to set up a trust relationship between an IAM role for the KEDA operator and an IAM role for the application. This trust relationship allows KEDA to monitor messages in the event queues and adjust scaling for the destination Kubernetes objects.

Prerequisites and limitations

Prerequisites

- AWS Command Line Interface (AWS CLI) version 2.13.17 or later, installed
- Python version 3.11.5 or later, installed
- AWS SDK for Python (Boto3) version 1.34.135 or later, installed
- Helm version 3.12.3 or later, installed
- kubectl version 1.25.1 or later, installed
- Docker Engine version 26.1.1 or later, installed
- An Amazon EKS cluster version 1.24 or later, created
- Prerequisites for creating the Amazon EKS Pod Identity agent, met

Limitations

- It is required that you establish a trust relationship between the `keda-operator` role and the `keda-identity` role. Instructions are provided in the Epics section of this pattern.

Architecture

In this pattern, you create the following AWS resources:

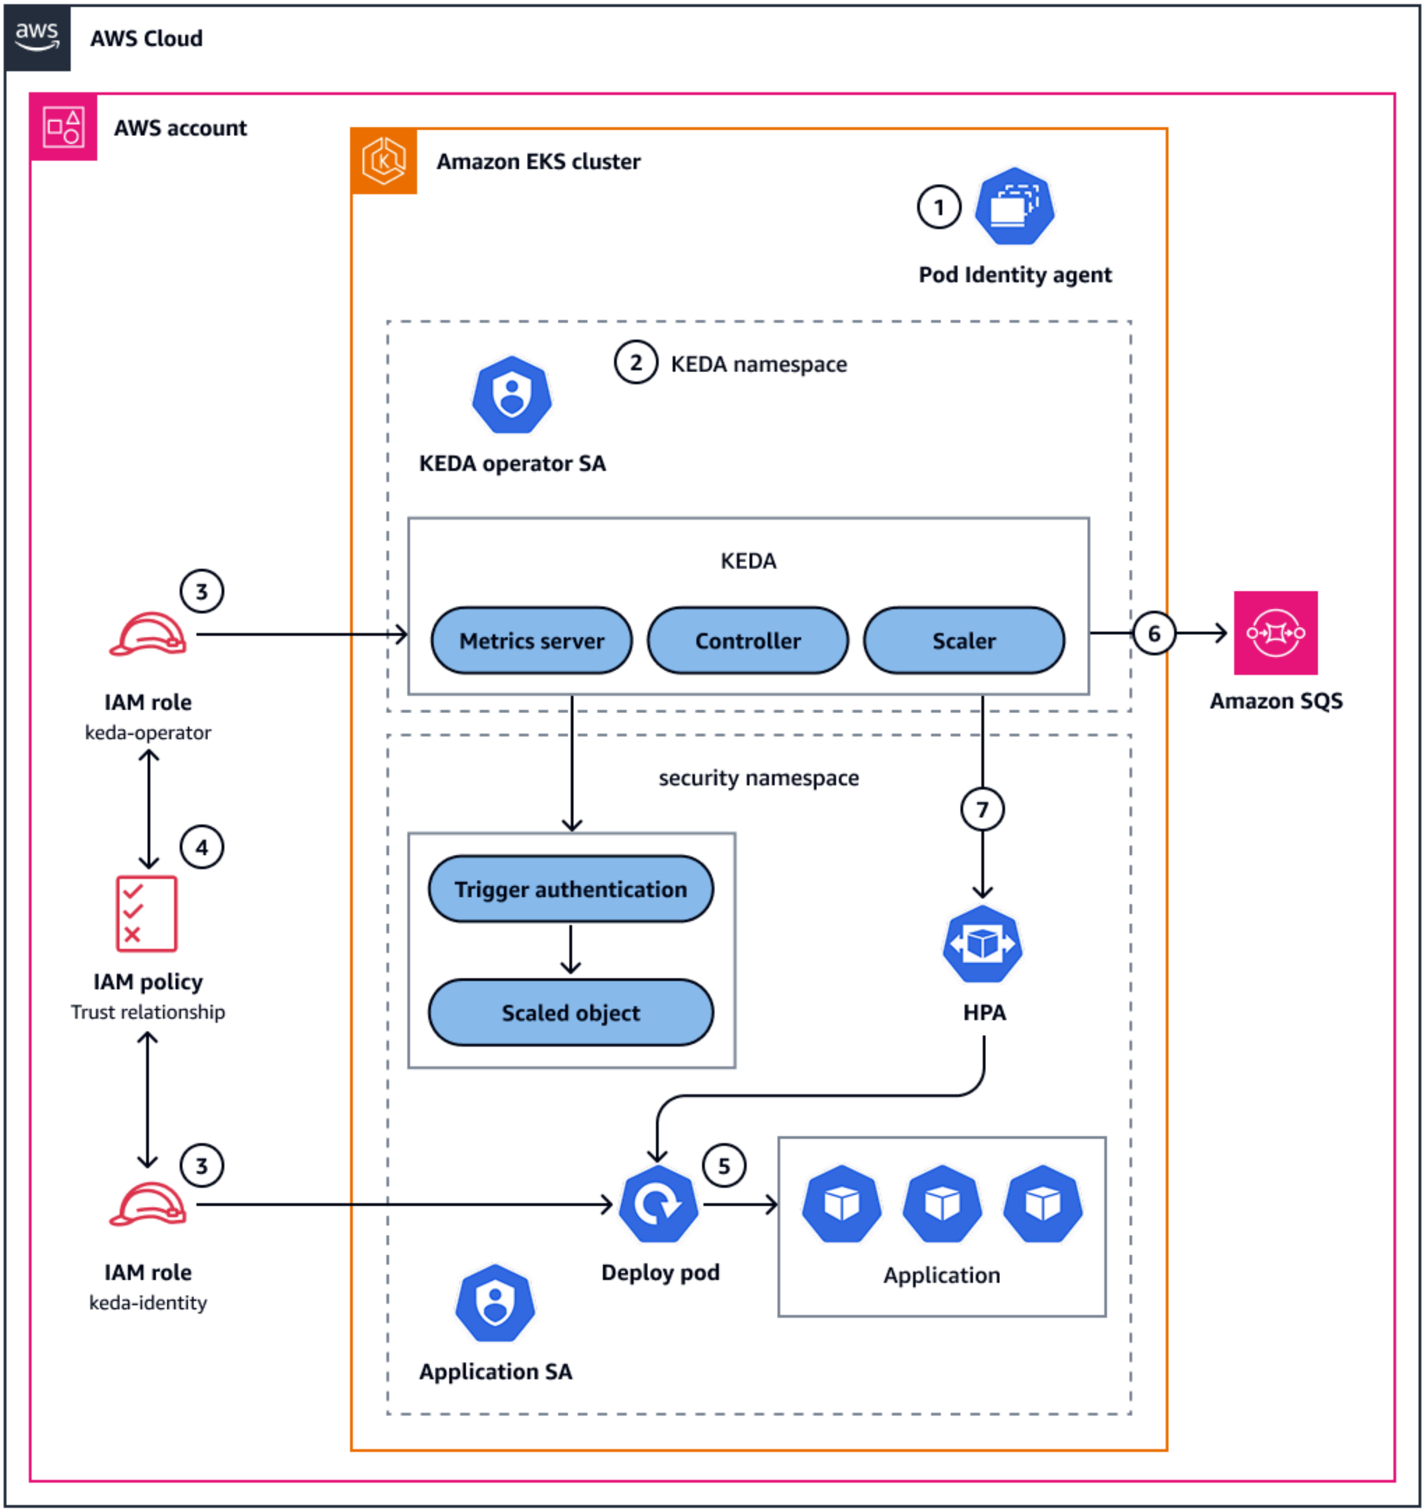
- **Amazon Elastic Container Registry (Amazon ECR) repository** – In this pattern, this repo is named `keda-pod-identity-registry`. This private repo is used to store Docker images of the sample application.
- **Amazon Simple Queue Service (Amazon SQS) queue** – In this pattern, this queue is named `event-messages-queue`. The queue acts as a message buffer that collects and stores incoming

messages. KEDA monitors the queue metrics, such as message count or queue length, and it automatically scales the application based on these metrics.

- **IAM role for the application** – In this pattern, this role is named `keda-identity`. The `keda-operator` role assumes this role. This role allows access to the Amazon SQS queue.
- **IAM role for the KEDA operator** – In this pattern, this role is named `keda-operator`. The KEDA operator uses this role to make the required AWS API calls. This role has permissions to assume the `keda-identity` role. Because of the trust relationship between the `keda-operator` and the `keda-identity` roles, the `keda-operator` role has Amazon SQS permissions.

Through the `TriggerAuthentication` and `ScaledObject` Kubernetes custom resources, the operator uses the `keda-identity` role to connect with an Amazon SQS queue. Based on the queue size, KEDA automatically scales the application deployment. It adds 1 pod for every 5 unread messages in the queue. In the default configuration, if there are no unread messages in the Amazon SQS queue, the application scales down to 0 pods. The KEDA operator monitors the queue at an interval that you specify.

The following image shows how you use Amazon EKS Pod Identity to provide the `keda-operator` role with secure access to the Amazon SQS queue.



The diagram shows the following workflow:

1. You install the Amazon EKS Pod Identity agent in the Amazon EKS cluster.
2. You deploy KEDA operator in the KEDA namespace in the Amazon EKS cluster.

3. You create the `keda-operator` and `keda-identity` IAM roles in the target AWS account.
4. You establish a trust relationship between the IAM roles.
5. You deploy the application in the `security` namespace.
6. The KEDA operator polls messages in an Amazon SQS queue.
7. KEDA initiates HPA, which automatically scales the application based on the queue size.

Tools

AWS services

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

Other tools

- KEDA is a Kubernetes-based event-driven autoscaler.

Code repository

The code for this pattern is available in the GitHub Event-driven auto scaling using EKS Pod Identity and KEDA repository.

Best practices

We recommend that you adhere to the following best practices:

- Amazon EKS best practices
- Security best practices in IAM
- Amazon SQS best practices

Epics

Create AWS resources

Task	Description	Skills required
Create the IAM role for the KEDA operator.	1. Sign in to the AWS Management Console, and then open the [IAM console](). 2. In the navigation pane, choose **Roles**. 3. Choose **Create role**. 4. Choose the **Custom trust policy** role type. 5. In the **Custom trust policy** section, enter the following custom trust policy for this role: `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Principal": { "Service": "pods.eks.amazonaws.com" }, "Action": [ "sts:AssumeRole", "sts:TagSession" ] }`	AWS administrator

Task	Description	Skills required

	``
	    ]
	}
	``
	6. On the **Add permissions** page, choose **Next**. You do not add any policies to this role.
	7. For **Role name**, enter `keda-operator` .
	8. Choose **Create role**.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create the IAM role for the sample application.</td><td>

In the IAM console, in the navigation pane, choose Roles.
Choose Create role.
Choose the Custom trust policy role type.
In the Custom trust policy section, enter the following custom trust policy for this role. Replace <code><account number></code> with your target account number:

<pre><code>{
    "Version":
 "2012-10-17",
    "Statement": [
        {
            "Effect":
 "Allow",
            "Principa
l": {

 "Service": "pods.eks
.amazonaws.com",
                "AWS":
 "arn:aws:iam::<acc
ount number>:role/
keda-operator"
            },
            "Action":
 [

 "sts:AssumeRole",

 "sts:TagSession"
            ]
        }</code></pre>
</td><td>AWS administrator</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>
<pre><code>   ]
}</code></pre>
<ol start="5">
On the Add permissions page, add the following AWS managed polices to the role:

<code>AmazonSQSReadOnlyAccess</code>
<code>AWSLambdaSQSQueueExecutionRole</code>

Choose Next.
For Role name, enter <code>keda-identity</code> .
Choose Create role.

</td><td></td></tr>
<tr><td>Create an Amazon SQS queue.</td><td>

Open the Amazon SQS console.
Choose Create queue.
For Type, choose Standard.
On Create queue page, for Name, enter <code>event-messages-queue</code> .
Choose Create queue. You do not change any of the default settings for this queue.

</td><td>General AWS</td></tr>
</table>

Task	Description	Skills required
Create an Amazon ECR repository.	1. Open the [Amazon ECR console](). 2. Choose **Create repository**. 3. For **Repository name**, enter `keda-pod-identity-registry` . 4. Choose **Create repository**. You do not change any of the default settings for this repository.	General AWS

Set up the Amazon EKS cluster

Task	Description	Skills required
Deploy the Amazon EKS Pod Identity agent.	For the target Amazon EKS cluster, set up the Amazon EKS Pod Identity agent. Follow the instructions in [Set up the Amazon EKS Pod Identity Agent]() in the Amazon EKS documentation.	AWS DevOps

Deploy KEDA.	1. Enter the following commands to deploy KEDA on the target Amazon EKS cluster:
	```# Add Helm Repo for Keda```
	```helm repo add kedacore https://kedacore.github.io/charts```
	```# Update Helm repo```
	```helm repo update```
		DevOps engineer

Task	Description	Skills required

	<pre># Install Keda
	helm install keda
	 kedacore/keda --
	namespace keda --
	create-namespace</pre> For more information, see [Deploying with Helm](#) in the KEDA documentation.
	2. After successful deploymen t, in the output, validate that three deployments are created for the KEDA operator. The following is a sample output:<pre>NAME
	               READY
	   UP-TO-DATE
	 AVAILABLE AGE
	keda-admission-
	webhooks 1/1
	     1 1
	        89s
	keda-operator
	             1/1 1
	            1
	  89s
	keda-operator-
	metrics-apiserver
	 1/1 1
	 1 89s</pre>	

Task	Description	Skills required
Assign the IAM role to the Kubernetes service account.	Follow the instructions in [Assign an IAM role to a Kubernetes service account](#) in the Amazon EKS documentation. Use the following values: • For **IAM role**, enter `keda-operator` . • For **Kubernetes namespace** , enter `keda`. • For **Kubernetes service account**, enter `keda-operator` .	AWS DevOps
Create a namespace.	Enter the following command to create a `security` namespace in the target Amazon EKS cluster: `kubectl create ns security`	DevOps engineer

Deploy the sample application

Task	Description	Skills required
Clone the application files.	Enter the following command to clone the [Event-driven auto scaling using EKS Pod Identity and KEDA repository](#) from GitHub: `git clone https://github.com/aws-samp`	DevOps engineer

Task	Description	Skills required
	```les/event-driven-autoscaling-using-podidentity-and-keda.git```	
Build the Docker image.	1. Enter the following command to navigate into the cloned repository: ```cd event-driven-autoscaling-using-podidentity-and-keda``` 2. Enter the following command to build the Docker image for the sample application: ```docker build -t keda-pod-identity-registry .```	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Push the Docker image to Amazon ECR.</td><td>

1. In the terminal where you built the Docker image, enter the following command to log in to Amazon ECR. Replace `<AWS_REGION>` and `<AWS_ACCOUNT_ID>` with values from your AWS environment:

```
aws ecr get-login-password \
   --region <AWS_REGION> | docker login \
   --username AWS \
   --password-stdin <AWS_ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com
```

2. Enter the following command to tag the image. Replace `<AWS_REGION>` and `<AWS_ACCOUNT_ID>` with values from your AWS environment:

```
docker tag keda-pod-identity-registry:latest <AWS_ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com/keda-pod-identity-registry:latest
```

</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	3. Enter the following command to push the image to Amazon ECR. Replace `<AWS_REGION>` and `<AWS_ACCOUNT_ID>` with values from your AWS environment: `docker push <AWS_ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com/keda-pod-identity-registry:latest` **Note** You can find push commands by navigating to the Amazon ECR repository page and then choosing **View push commands**.	

Task	Description	Skills required
Deploy the sample application.	1. In the cloned repository, open the **deploy.yaml** file. 2. Replace `<AWS_ACCOUNT_ID>` and `<AWS_REGION>` with values from your environment. 3. Save and close the **deploy.yaml** file. 4. Enter the following command to deploy the sample application on the target Amazon EKS cluster: `kubectl apply -f deploy.yaml` This command creates a deployment and service account in the cluster.	DevOps engineer

Task	Description	Skills required

Assign the IAM role to the application service account.	Do one of the following to associate the `keda-identity` IAM role with the service account for the sample application:
	
	• Follow the instructions in Assign an IAM role to a Kubernetes service account in the Amazon EKS documentation. Use the following values:
	  ◦ For **IAM role**, enter `keda-identity` .
	  ◦ For **Kubernetes namespace**, enter `security`.
	  ◦ For **Kubernetes service account**, enter `my-sqs-read-msgs` .
	• Enter the following AWS CLI command. Replace `<cluster-name>` with the name of the target Amazon EKS cluster, and replace `<role-ARN>` with the Amazon Resource Name (ARN) of the `keda-identity` role:
	
	`aws eks create-pod-identity-association \`
	`  --cluster-name <cluster-name> \`
		DevOps engineer

Task	Description	Skills required

	``
	  --role-arn <role-ARN> \
	  --namespace security \
	  --service-account my-sqs-read-msgs
	``	

Task	Description	Skills required
Deploy `ScaledObject` and `TriggerAuthentication` .	1. In the cloned repository, open the **keda.yaml** file. 2. Replace `{{AWS_ACCOUNT_ID}}` with the ID of your target AWS account. 3. Replace `{{AWS_REGION}}` with your target AWS Region. 4. (Optional) In lines 21–24, update the parameters for the `ScaledObject` scaling policy. See the following for more information about these parameters: • pollingInterval • cooldownPeriod • idleReplicaCount • minReplicaCount 5. Save and close the **keda.yaml** file. 6. Enter the following command to deploy the `ScaledObject` and `TriggerAuthentication` resources: `kubectl -n security apply -f keda.yaml`	DevOps engineer

Test auto scaling

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Send messages to the Amazon SQS queue.</td><td>1. Enter the following command to navigate into the cloned repository:
<pre>cd event-driven-autoscaling-using-podidentity-and-keda</pre>2. Enter the following command to send test messages to the Amazon SQS queue:
<pre>python sqs_send_msg.py</pre>The sqs_send_msg.py script acts as an application that generates messages for testing auto scaling.

Note
If you're running Python 3, enter <code>python3 sqs_send_msg.py</code> .</td><td>DevOps engineer</td></tr>
<tr><td>Monitor the application pods.</td><td>1. In different terminal, enter the following command to monitor the pods:</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required

	`kubectl -n security get po`
	2. For every 5 unread messages in the Amazon SQS queue, KEDA adds one pod. In the output of the previous command, confirm that new pods are being added. The following is a sample output:
	`kubectl -n security get po`
	`NAME READY STATUS RESTARTS AGE`
	`q-read-797f4c7589-2bj76 1/1 Running 0 2s`
	`q-read-797f4c7589-4zxph 1/1 Running 0 49s`
	`q-read-797f4c7589-cg9dt 1/1 Running 0 18s`
	`q-read-797f4c7589-slc69 1/1 Running 0 33s`
	3. When you are finished testing, in the original terminal, enter CTRL + C (Windows) or CMD + C	

Task	Description	Skills required
	(macOS). This stops the **python sqs_send_msg.py** script.	

Troubleshooting

Issue	Solution

The KEDA operator cannot scale the applicati on.	Enter the following command to check the logs of the `keda-operator` IAM role:
	`kubectl logs -n keda -l app=keda-operator -c keda-operator`
	
	If there is an HTTP `403` response code, then the application and the KEDA scaler do not have sufficient permissions to access the Amazon SQS queue. Complete the following steps:
	1. Check the IAM policies and statements for the `keda-identity` role to confirm that that queue read access is granted.
	2. Validate the trust relationship between the IAM roles. The following is an example:
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Effect": "Allow",`
	`            "Principal": {`
	`                "Service": "pods.eks.amazonaws.com"`

Issue	Solution

	``
	            },
	            "Action": [
	                "sts:AssumeRole",
	                "sts:TagSession"
	            ]
	        }
	    ]
	}
	``
	
	If there is an `Assume-Role` error, then an [Amazon EKS node IAM role](#) is unable to assume the IAM role that is defined for `TriggerAuthentication`. Complete the following steps:
	
	1. Enter the following command to delete the `keda-operator` pod and create a new one:
	
	``
	kubectl delete pod keda-operator-<alphenumeric-value> --namespace keda
	``
	
	2. Enter the following command to check the identity that the pod assumes:
	
	``
	kubectl describe pod <keda-operator-pod-name> --namespace keda
	``
	
	3. When the pod successfully restarts, confirm that the following two variables are added to the pod description:
	
	• `AWS_CONTAINER_CREDENTIALS_FULL_URI`
	• `AWS_CONTAINER_AUTHORIZATION_TOKEN_FILE`

Streamline PostgreSQL deployments on Amazon EKS by using PGO

Shalaka Dengale, Amazon Web Services

Summary

This pattern integrates the Postgres Operator from Crunchy Data (PGO) with Amazon Elastic Kubernetes Service (Amazon EKS) to streamline PostgreSQL deployments in cloud-native environments. PGO provides automation and scalability for managing PostgreSQL databases in Kubernetes. When you combine PGO with Amazon EKS, it forms a robust platform for deploying, managing, and scaling PostgreSQL databases efficiently.

This integration provides the following key benefits:

- Automated deployment: Simplifies PostgreSQL cluster deployment and management.
- Custom resource definitions (CRDs): Uses Kubernetes primitives for PostgreSQL management.
- High availability: Supports automatic failover and synchronous replication.
- Automated backups and restores: Streamlines backup and restore processes.
- Horizontal scaling: Enables dynamic scaling of PostgreSQL clusters.
- Version upgrades: Facilitates rolling upgrades with minimal downtime.
- Security: Enforces encryption, access controls, and authentication mechanisms.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows.
- AWS CLI Config, to connect AWS resources from the command line.
- eksctl, installed and configured on Linux, macOS, or Windows.
- `kubectl`, installed and configured to access resources on your Amazon EKS cluster. For more information, see Set up kubectl and eksctl in the Amazon EKS documentation.
- Your computer terminal configured to access the Amazon EKS cluster. For more information, see Configure your computer to communicate with your cluster in the Amazon EKS documentation.

Product versions

- Kubernetes versions 1.21–1.24 or later (see the PGO documentation).
- PostgreSQL version 10 or later. This pattern uses PostgreSQL version 16.

Limitations

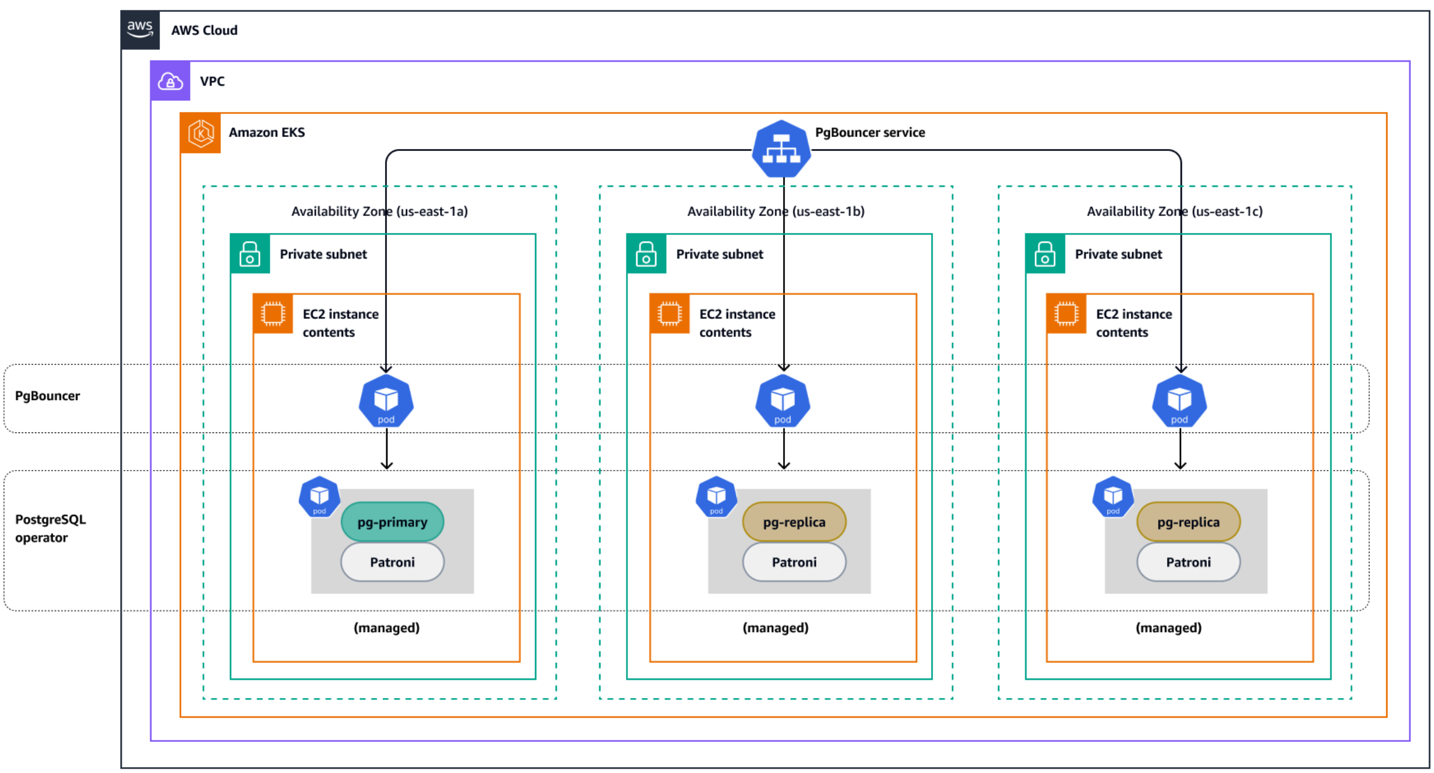
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

Target technology stack

- Amazon EKS
- Amazon Virtual Private Cloud (Amazon VPC)
- Amazon Elastic Compute Cloud (Amazon EC2)

Target architecture



This pattern builds an architecture that contains an Amazon EKS cluster with three nodes. Each node runs on a set of EC2 instances in the backend. This PostgreSQL setup follows a primary replica architecture, which is particularly effective for read-heavy use cases. The architecture includes the following components:

- **Primary database container (pg-primary)** hosts the main PostgreSQL instance where all write operations are directed.
- **Secondary replica containers (pg-replica)** host the PostgreSQL instances that replicate the data from the primary database and handle read operations.
- **PgBouncer** is a lightweight connection pooler for PostgreSQL databases that's included with PGO. It sits between the client and the PostgreSQL server, and acts as an intermediary for database connections.
- **PGO** automates the deployment and management of PostgreSQL clusters in this Kubernetes environment.
- **Patroni** is an open-source tool that manages and automates high availability configurations for PostgreSQL. It's included with PGO. When you use Patroni with PGO in Kubernetes, it plays a crucial role in ensuring the resilience and fault tolerance of a PostgreSQL cluster. For more information, see the Patroni documentation.

The workflow includes these steps:

- **Deploy the PGO operator**. You deploy the PGO operator on your Kubernetes cluster that runs on Amazon EKS. This can be done by using Kubernetes manifests or Helm charts. This pattern uses Kubernetes manifests.
- **Define PostgreSQL instances**. When the operator is running, you create custom resources (CRs) to specify the desired state of PostgreSQL instances. This includes configurations such as storage, replication, and high availability settings.
- **Operator management**. You interact with the operator through Kubernetes API objects such as CRs to create, update, or delete PostgreSQL instances.
- **Monitoring and maintenance**. You can monitor the health and performance of the PostgreSQL instances running on Amazon EKS. Operators often provide metrics and logging for monitoring purposes. You can perform routine maintenance tasks such as upgrades and patching as necessary. For more information, see Monitor your cluster performance and view logs in the Amazon EKS documentation.

- **Scaling and backup**: You can use the features provided by the operator to scale PostgreSQL instances and manage backups.

This pattern doesn't cover monitoring, maintenance, and backup operations.

Automation and scale

- You can use AWS CloudFormation to automate the infrastructure creation. For more information, see Create Amazon EKS resources with AWS CloudFormation in the Amazon EKS documentation.
- You can use GitVersion or Jenkins build numbers to automate the deployment of database instances.

Tools

AWS services

- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command line shell.

Other tools

- eksctl is a simple command line tool for creating clusters on Amazon EKS.
- kubectl is a command line utility for running commands against Kubernetes clusters.
- PGO automates and scales the management of PostgreSQL databases in Kubernetes.

Best practices

Follow these best practices to ensure a smooth and efficient deployment:

- **Secure your EKS cluster**. Implement security best practices for your EKS cluster, such as using AWS Identity and Access Management (IAM) roles for service accounts (IRSA), network policies, and VPC security groups. Limit access to the EKS cluster API server, and encrypt communications between nodes and the API server by using TLS.

- **Ensure version compatibility** between PGO and Kubernetes running on Amazon EKS. Some PGO features might require specific Kubernetes versions or introduce compatibility limitations. For more information, see Components and Compatibility in the PGO documentation.
- **Plan resource allocation** for your PGO deployment, including CPU, memory, and storage. Consider the resource requirements of both PGO and the PostgreSQL instances it manages. Monitor resource usage and scale resources as needed.
- **Design for high availability**. Design your PGO deployment for high availability to minimize downtime and ensure reliability. Deploy multiple replicas of PGO across multiple Availability Zones for fault tolerance.
- **Implement backup and restore procedures** for your PostgreSQL databases that PGO manages. Use features provided by PGO or third-party backup solutions that are compatible with Kubernetes and Amazon EKS.
- **Set up monitoring and logging** for your PGO deployment to track performance, health, and events. Use tools such as Prometheus for monitoring metrics and Grafana for visualization. Configure logging to capture PGO logs for troubleshooting and auditing.
- **Configure networking** properly to allow communications between PGO, PostgreSQL instances, and other services in your Kubernetes cluster. Use Amazon VPC networking features and Kubernetes networking plugins such as Calico or Amazon VPC CNI for network policy enforcement and traffic isolation.
- **Choose appropriate storage options** for your PostgreSQL databases, considering factors such as performance, durability, and scalability. Use Amazon Elastic Block Store (Amazon EBS) volumes or AWS managed storage services for persistent storage. For more information, see Store Kubernetes volumes with Amazon EBS in the Amazon EKS documentation.
- **Use infrastructure as code (IaC) tools** such as AWS CloudFormation to automate the deployment and configuration of PGO on Amazon EKS. Define infrastructure components—including the EKS cluster, networking, and PGO resources—as code for consistency, repeatability, and version control.

Epics

Create an IAM role

Task	Description	Skills required

Create an IAM role.	1. Create an IAM role by using the following command in the AWS CLI:
	``
	aws iam create-role \
	    --role-name
	 {YourRoleName} \
	    --assume-role-
	policy-document '{
	        "Version":
	 "2012-10-17",
	        "Statement":
	 [
	            {
	
	 "Effect": "Allow",
	
	 "Principal": {
	
	 "Service": "eks.amaz
	onaws.com"
	                },
	
	 "Action": "sts:Assu
	meRole"
	            }
	        ]
	    }' && \
	aws iam attach-role-
	policy \
	    --role-name
	 {YourRoleName}\
	    --policy-arn
	 arn:aws:iam::aws:p
	olicy/AmazonEKSClu
	sterPolicy && \
	``
		AWS administrator

Task	Description	Skills required

	``
	aws iam attach-role-policy \
	    --role-name {YourRoleName}\
	    --policy-arn arn:aws:iam::aws:policy/AmazonEKSServicePolicy && \
	aws iam attach-role-policy \
	    --role-name {YourRoleName}\
	     --policy-arn arn:aws:iam::aws:policy/CloudWatchFullAccess
	``
	2. Review the role in the AWS Management Console:
	a. Open the [IAM console](https://console.aws.amazon.com/iam/).
	b. Choose **Roles**, and search for the role name you created.
	c. Validate that the following policies are attached:
	`AmazonEKSClusterPolicy`
	`AmazonEKSServicePolicy`
	`CloudWatchFullAccess`	

Create an Amazon EKS cluster

Task	Description	Skills required

Create an Amazon EKS cluster.	If you've already deployed a cluster, skip this step. Otherwise, deploy an Amazon EKS cluster in your current AWS account by using `eksctl`, Terraform, or AWS CloudFormation. This pattern uses `eksctl` for cluster deployment.
	
	Note
	This pattern uses Amazon EC2 as a node group for Amazon EKS. If you want to use AWS Fargate, see the `managedNodeGroups` configuration in the [eksctl documentation](https://eksctl.io).
	
	1. Use the following `eksctl` input file to generate the cluster.
	
	`sample-cluster.yaml` :
	
	`apiVersion: eksctl.io/v1alpha5`
	`kind: ClusterConfig`
		AWS administrator, Terraform or eksctl administrator, Kubernetes administrator

Task	Description	Skills required
	(continued below)	

```
metadata:
  name: postgresql
  region: us-east-1
  version: "1.29"
accessConfig:
  authenticationMode
: API_AND_C
ONFIG_MAP
availabilityZones:
- us-east-1a
- us-east-1b
- us-east-1c
nodeGroups:
  - name: ng-1
    instanceType:
 m5.16xlarge
    desiredCapacity:
 2
  - name: ng-2
    instanceType:
 m5.16xlarge
    desiredCapacity:
 2
  - name: ng-3
    instanceType:
 m5.16xlarge
    desiredCapacity:
 2
vpc:
  cidr: 192.168.0
.0/16
  clusterEndpoints:
    publicAccess:
 true
  nat:
    gateway: HighlyAva
ilable
iamIdentity
Mappings:
  - arn: arn:aws:i
am::<account-id>:r
ole/<role-name> #
```

Task	Description	Skills required

	`update the IAM role ARN created in step 1`
	`    username: <user-name> # Enter the user name per your choice`
	`    noDuplicateARNs: false`
	
	2. Run the following command to create the cluster (provide the file path to your `sample-cluster.yaml` file):
	
	`eksctl create cluster -f sample-cluster.yaml`	

Validate the status of the cluster.	Run the following command to see the current status of nodes in the cluster: `kubectl get nodes` If you encounter errors, see the troubleshooting section of the Amazon EKS documentation.	AWS administrator, Terraform or eksctl administrator, Kubernetes administrator

Create an OIDC identity provider

Task	Description	Skills required
Enable the IAM OIDC provider.	As a prerequisite for the Amazon EBS Container	AWS administrator

Task	Description	Skills required
	Storage Interface (CSI) driver, you must have an existing IAM OpenID Connect (OIDC) provider for your cluster. Enable the IAM OIDC provider by using the following command: `eksctl utils associate -iam-oidc-provider --region={region} --cluster={YourClusterNameHere} --approve` For more information about this step, see the Amazon EKS documentation.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create an IAM role for the Amazon EBS CSI driver.</td><td>Use the following <code>eksctl</code> command to create the IAM role for the CSI driver:

<pre><code>eksctl create iamserviceaccount \
  --region {RegionName} \
  --name ebs-csi-controller-sa \
  --namespace kube-system \
  --cluster {YourClusterNameHere} \
  --attach-policy-arn arn:aws:iam::aws:policy/service-role/AmazonEBSCSIDriverPolicy \
  --approve \
  --role-only \
  --role-name AmazonEKS_EBS_CSI_DriverRole</code></pre>

If you use encrypted Amazon EBS drives, you have to configure the policy further. For instructions, see the Amazon EBS SCI driver documentation.</td><td>AWS administrator</td></tr>
</table>

Task	Description	Skills required
Add the Amazon EBS CSI driver.	Use the following `eksctl` command to add the Amazon EBS CSI driver: `eksctl create addon \ --name aws-ebs-csi-driver \ --cluster <YourClusterName> service-account-role-arn arn:aws:iam::$(aws sts get-caller-identity \ --query Account \ --output text):role/AmazonEKS_EBS_CSI_DriverRole \ --force`	AWS administrator

Install PGO

Task	Description	Skills required
Clone the PGO repository.	Clone the GitHub repository for PGO: `git clone https://github.com/CrunchyData/postgres-operator-examples.git`	AWS DevOps
Provide the role details for service account creation.	To grant the Amazon EKS cluster access to the required AWS resources, specify the Amazon Resource Name (ARN) of the OIDC role that you created earlier in the	AWS administrator, Kubernetes administrator

Task	Description	Skills required

	`service_account.yaml` file. This file is located in the [namespace folder](#) of the repository.
	`cd postgres-operator-examples`
	`---`
	`metadata:`
	`  annotations:`
	`    eks.amazonaws.com/role-arn: arn:aws:iam::<accountId>:role/<role_name> # Update the OIDC role ARN created earlier`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create the namespace and PGO prerequisites.</td><td>1. Run the following command to create the namespace:
<pre>kubectl apply -k
 kustomize/install/
namespace</pre>This establishes a dedicated namespace for PGO. If necessary, you can modify the <code>namespace.yml</code> file and assign the namespace a different name.
2. Run the following command to apply the default configuration to the cluster:
<pre>kubectl apply --
server-side -k
 kustomize/install/
default</pre><code>kustomize/install/default</code> provides the default configuration for the Kubernetes role-based access control (RBAC), custom resource definition (CRD), and Kubernetes Manager files.</td><td>Kunernetes administrator</td></tr>
</table>

Task	Description	Skills required
Verify the creation of pods.	Verify that the namespace and default configuration were created: `kubectl get pods -n postgres-operator`	AWS administrator, Kubernetes administrator
Verify PVCs.	Use the following command to verify persistent volume claims (PVCs): `kubectl describe pvc -n postgres-operator`	AWS administrator, Kubernetes administrator

Create and deploy an operator

Task	Description	Skills required

Create an operator.	Revise the contents of the file located at `/kustomize/postgres/postgres.yaml` to match the following:
	<pre>spec:
	  instances:
	    - name: pg-1
	      replicas: 3
	  patroni:
	    dynamicConfiguration:
	      postgresql:
	      pg_hba:
	        - "host all all 0.0.0.0/0 trust" # this line enabled</pre>
		AWS administrator, DBA, Kubernetes administrator

Task	Description	Skills required

	<pre>logical replication
	with programmatic
	access
	        - "host all
	postgres 127.0.0.1/32
	md5"
	      synchronous_mode:
	true
	 users:
	 - name: replicator
	   databases:
	     - testdb
	   options: "REPLICAT
	ION"</pre> These updates do the following:
	• Adjust the PostgreSQL configuration settings to facilitate access to the PostgreSQL instance.
	• Include configurations for replication user, database user, and superuser to enable streaming replication, database access, and cluster management.	

Deploy the operator.	Deploy the PGO operator to enable the streamlined management and operation of PostgreSQL databases in Kubernetes environments:
	<pre>kubectl apply -k
	 kustomize/postgres</pre>
		AWS administrator, DBA, Kubernetes administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Verify the deployment.</td><td>1. Validate that the operator has been deployed:
<pre>kubectl get pods -n postgres-operator --selector=postgres-operator.crunchydata.com/instance-set \   -L postgres-operator.crunchydata.com/role</pre>2. Verify that the service resource associated with the operator pod has been created:
<pre>kubectl get svc -n postgres-operator</pre>From the command output, note the primary replica (<code>primary_pod_name</code>) and read replica (<code>read_pod_name</code>). You will uses these in the next steps.</td><td>AWS administrator, DBA, Kubernetes administrator</td></tr>
</table>

Verify streaming replication

Task	Description	Skills required
Write data to the primary replica.	Use the following commands to connect to the PostgreSQL primary replica and write data to the database:	AWS administrator, Kubernetes administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>
<pre><code>kubectl exec -it
 <primary_pod_name>
 bash -n postgres-
operator</code></pre>
<pre><code>psql</code></pre>
<pre><code>CREATE TABLE customers
 (firstname text,
 customer_id serial,
 date_created timestamp
);
\dt</code></pre>
</td><td></td></tr>
<tr><td>Confirm that the read replica has the same data.</td><td>
Connect to the PostgreSQL read replica and check whether the streaming replication is working correctly:
<pre><code>kubectl exec -it
 {read_pod_name} bash -
n postgres-operator</code></pre>
<pre><code>psql</code></pre>
<pre><code>\dt</code></pre>
The read replica should have the table that you created in the primary replica in the previous step.
</td><td>AWS administrator, Kubernetes administrator</td></tr>
</table>

Troubleshooting

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td>The pod doesn't start.</td><td>

- Use the following command to inspect pod status:

```
kubectl get pods -n your-namespace
```

- Inspect the logs for any errors:

```
kubectl logs your-pod-name -n your-namespace
```

- Check pod events for any abnormal events related to your pods:

```
kubectl describe pod your-pod-name -n your-namespace
```

</td></tr>
<tr><td>Replicas are significantly behind the primary database.</td><td>

- Check for replication lag:

```
SELECT * FROM pg_stat_replication;
```

- Make sure that replicas have enough CPU and memory resources. Check resource limits:

```
kubectl describe pod your-replica-pod -n your-namespace
```

- Verify that the storage backend is performing optimally. Slow disk I/O can cause replication lag.

</td></tr>
<tr><td>You don't have visibility into the performance and health of the PostgreSQL cluster.</td><td>

- Enable Amazon CloudWatch Logs and make sure that logs are being sent to Amazon CloudWatch for analysis. For more information, see the Amazon EKS documentation.

</td></tr>
</table>

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td></td><td>Check <code>pg_stat_activity</code> :<pre><code>SELECT * FROM pg_stat_activity;</code></pre></td></tr>
<tr><td>Replication doesn't work.</td><td>Check the primary configuration by viewing the replication settings in <code>postgresql.conf</code> :<pre><code>wal_level = replica</code></pre><pre><code>max_wal_senders = 10</code></pre><pre><code>wal_keep_size = 64 # or wal_keep_segments in older versions</code></pre>
Verify that <code>pg_hba.conf</code> includes replication permissions:<pre><code>host replication replica_user all md5</code></pre>
Check replica configuration. Make sure that <code>recovery.conf</code> or equivalent settings (<code>standby.signal</code> and <code>primary_conninfo</code>) are correctly set up on replicas.</td></tr>
</table>

Simplify application authentication with mutual TLS in Amazon ECS by using Application Load Balancer

Olawale Olaleye and Shamanth Devagari, Amazon Web Services

Summary

This pattern helps you to simplify your application authentication and offload security burdens with mutual TLS in Amazon Elastic Container Service (Amazon ECS) by using Application Load Balancer (ALB). With ALB, you can authenticate X.509 client certificates from AWS Private Certificate Authority. This powerful combination helps to achieve secure communication between your services, reducing the need for complex authentication mechanisms within your applications. In addition, the pattern uses Amazon Elastic Container Registry (Amazon ECR) to store container images.

The example in this pattern uses Docker images from a public gallery to create the sample workloads initially. Subsequently, new Docker images are built to be stored in Amazon ECR. For the source, consider a Git-based system such as GitHub, GitLab, or Bitbucket, or use Amazon Simple Storage Service Amazon S3 (Amazon S3). For building the Docker images, consider using AWS CodeBuild for the subsequent images.

Prerequisites and limitations

Prerequisites

- An active AWS account with access to deploy AWS CloudFormation stacks. Make sure that you have AWS Identity and Access Management (IAM) user or role permissions to deploy CloudFormation.
- AWS Command Line Interface (AWS CLI) installed. Configure your AWS credentials on your local machine or in your environment by either using the AWS CLI or by setting the environment variables in the `~/.aws/credentials` file.
- OpenSSL installed.
- Docker installed.
- Familiarity with the AWS services described in Tools.
- Knowledge of Docker and NGINX.

Limitations

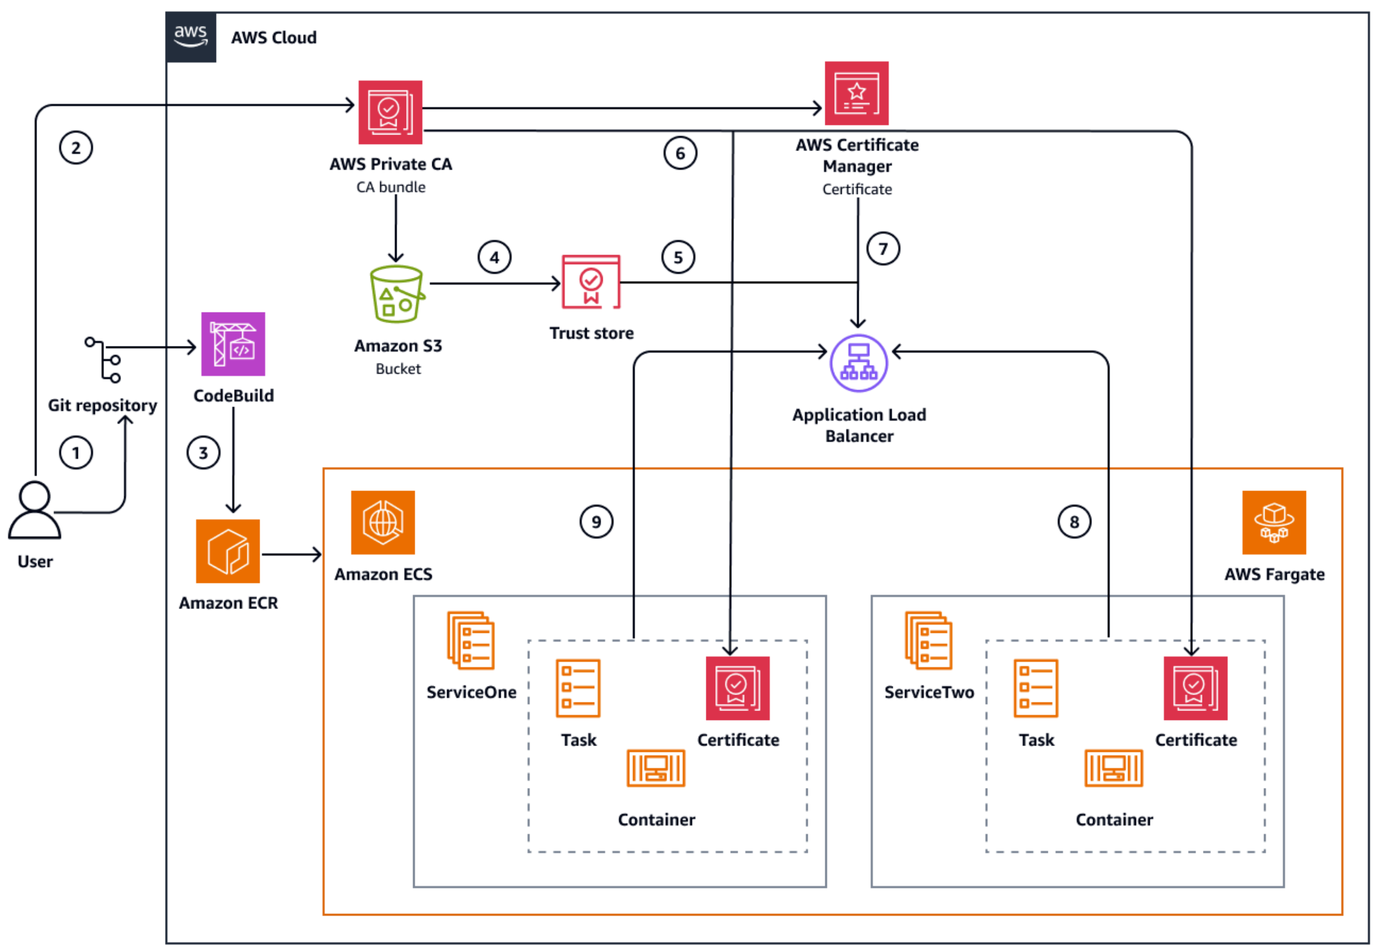
- Mutual TLS for Application Load Balancer only supports X.509v3 client certificates. X.509v1 client certificates are not supported.
- The CloudFormation template that is provided in this pattern's code repository doesn't include provisioning a CodeBuild project as part of the stack.
- Some AWS services aren't available in all AWS Regions. For Region availability, see [AWS Services by Region](). For specific endpoints, see [Service endpoints and quotas](), and choose the link for the service.

Product versions

- Docker version 27.3.1 or later
- AWS CLI version 2.14.5 or later

Architecture

The following diagram shows the architecture components for this pattern.



The diagram shows the following workflow:

1. Create a Git repository, and commit the application code to the repository.
2. Create a private certificate authority (CA) in AWS Private CA.
3. Create a CodeBuild project. The CodeBuildproject is triggered by commit changes and creates the Docker image and publishes the built image to Amazon ECR.
4. Copy the certificate chain and certificate body from the CA, and upload the certificate bundle to Amazon S3.
5. Create a trust store with the CA bundle that you uploaded to Amazon S3. Associate the trust store with the mutual TLS listeners on the Application Load Balancer (ALB).
6. Use the private CA to issue client certificates for the container workloads. Also create a private TLS certificate using AWS Private CA.
7. Import the private TLS certificate into AWS Certificate Manager (ACM), and use it with the ALB.
8. The container workload in `ServiceTwo` uses the issued client certificate to authenticate with the ALB when it communicates with the container workload in `ServiceOne`.
9. The container workload in `ServiceOne` uses the issued client certificate to authenticate with the ALB when it communicates with the container workload in `ServiceTwo`.

Automation and scale

This pattern can be fully automated by using CloudFormation, AWS Cloud Development Kit (AWS CDK) , or API operations from an SDK to provision the AWS resources.

You can use AWS CodePipeline to implement a continuous integration and continuous deployment (CI/CD) pipeline using CodeBuild to automate container image build process and deploying new releases to the Amazon ECS cluster services.

Tools

AWS services

- [AWS Certificate Manager (ACM)] helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- [AWS CloudFormation] helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.
- Amazon ECS Exec allows you to directly interact with containers without needing to first interact with the host container operating system, open inbound ports, or manage SSH keys. You can use ECS Exec to run commands in, or get a shell to, a container running on an Amazon EC2 instance or on AWS Fargate.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon EC2 instances, containers, and IP addresses, in one or more Availability Zones. ELB monitors the health of its registered targets, and routes traffic only to the healthy targets. ELB scales your load balancer as your incoming traffic changes over time. It can automatically scale to the majority of workloads.
- AWS Fargate helps you run containers without needing to manage servers or Amazon EC2 instances. Fargate is compatible with both Amazon ECS and Amazon Elastic Kubernetes Service (Amazon EKS). You can run your Amazon ECS tasks and services with the Fargate launch type or a Fargate capacity provider. To do so, package your application in containers, specify the CPU and memory requirements, define networking and IAM policies, and launch the application. Each Fargate task has its own isolation boundary and doesn't share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task.
- AWS Private Certificate Authority enables creation of private certificate authority (CA) hierarchies, including root and subordinate CAs, without the investment and maintenance costs of operating an on-premises CA.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- GitHub, GitLab, and Bitbucket are some of the commonly used Git-based source control system to keep track of source code changes.

- NGINX Open Source is an open source load balancer, content cache, and web server. This pattern uses it as a web server.
- OpenSSL is an open source library that provides services that are used by the OpenSSL implementations of TLS and CMS.

Code repository

The code for this pattern is available in the GitHub mTLS-with-Application-Load-Balancer-in-Amazon-ECS repository.

Best practices

- Use Amazon ECS Exec to run commands or get a shell to a container running on Fargate. You can also use ECS Exec to help collect diagnostic information for debugging.
- Use security groups and network access control lists (ACLs) to control inbound and outbound traffic between the services. Fargate tasks receive an IP address from the configured subnet in your virtual private cloud (VPC).

Epics

Create the repository

Task	Description	Skills required
Download the source code.	To download this pattern's source code, fork or clone the GitHub mTLS-with-Applicat ion-Load-Balancer-in-Amazon -ECS repository.	DevOps engineer
Create a Git repository.	To create a Git repository to contain the Dockerfile and the `buildspec.yaml` files, use the following steps: 1. Create a folder in your virtual environment. Name it with your project name.	DevOps engineer

Task	Description	Skills required
	2. Open a terminal on your local machine, and navigate to this folder. 3. To clone the [mTLS-with-Application-Load-Balancer-in-Amazon-ECS](https://github.com/aws-samples/mTLS-with-Application-Load-Balancer-in-Amazon-ECS) repository to your project directory, enter the following command: `git clone https://github.com/aws-samples/mTLS-with-Application-Load-Balancer-in-Amazon-ECS.git`	

Create CA and generate certificates

Task	Description	Skills required

Create a private CA in AWS Private CA.	To create a private certificate authority (CA), run the following commands in your terminal. Replace the values in the example variables with your own values.
	
	`export AWS_DEFAULT_REGION="us-west-2"`
	`export SERVICES_DOMAIN="www.example.com"`
		DevOps engineer, AWS DevOps

Task	Description	Skills required
	```export ROOT_CA_ARN=`aws acm-pca create-certificate-authority \ --certificate-authority-type ROOT \ --certificate-authority-configuration \ "KeyAlgorithm=RSA_2048, SigningAlgorithm=SHA256WITHRSA, Subject={ Country=US, State=WA, Locality=Seattle, Organization=Build on AWS, OrganizationalUnit=mTLS Amazon ECS and ALB Example, CommonName=${SERVICES_DOMAIN}}" \ --query CertificateAuthorityArn --output text` ``` For more details, see [Create a private CA in AWS Private CA](#) in the AWS documentation.	

Task	Description	Skills required

Create and install your private CA certificate.	To create and install a certificate for your private root CA, run the following commands in your terminal:
	
	1. Generate a certificate signing request (CSR).
	
	`ROOT_CA_CSR=`aws acm-pca get-certificate-authority-csr \ --certificate-authority-arn ${ROOT_CA_ARN} \ --query Csr --output text``
	
	2. Issue the root certificate.
	
	`AWS_CLI_VERSION=$( aws --version 2>&1 | cut -d/ -f2 | cut -d. -f1)`
	`[[ ${AWS_CLI_VERSION} -gt 1 ]] && ROOT_CA_CSR="$(echo ${ROOT_CA_CSR} | base64)"`
	
	`ROOT_CA_CERT_ARN=`aws acm-pca issue-certificate \ --certificate-authority-arn ${ROOT_CA_ARN} \ --template-arn arn:aws:acm-pca:::template/RootCACertificate/V1 \`
		AWS DevOps, DevOps engineer

Task	Description	Skills required
	``` --signing- algorithm SHA256WIT HRSA \ --validity Value=10,Type=YEARS \ --csr "${ROOT_C A_CSR}" \ --query Certifica teArn --output text` ``` 3. Retrieve the root certifica te. ``` ROOT_CA_CERT=`aws  acm-pca get-certi ficate \     --certificate-arn  ${ROOT_CA_CERT_ARN}  \     --certificate- authority-arn  ${ROOT_CA_ARN} \     --query Certifica te --output text` # store for later use aws acm-pca get-certi ficate \ --certificate-arn ${ROOT_CA_CERT_ARN} \ --certificate- authority-arn ${ROOT_CA_ARN} \ --query Certifica te --output text > ca-cert.pem ``` 4. Import the root CA certifica te to install it on the CA.	

Task	Description	Skills required
	```[[${AWS_CLI_VERSION} -gt 1]] && ROOT_CA_CERT="$(echo ${ROOT_CA_CERT} | base64)" aws acm-pca import-certificate-authority-certificate \ --certificate-authority-arn $ROOT_CA_ARN \ --certificate "${ROOT_CA_CERT}"``` For more details, see Installing the CA certificate in the AWS documentation.	
Request a managed certificate.	To request a private certificate in AWS Certificate Manager to use with your private ALB, use the following command: ```export TLS_CERTIFICATE_ARN=`aws acm request-certificate \ --domain-name "*.${DOMAIN_DOMAIN}" \ --certificate-authority-arn ${ROOT_CA_ARN} \ --query CertificateArn --output text` ```	DevOps engineer, AWS DevOps

Task	Description	Skills required
Use the private CA to issue a client certificate.	• To create a certificate signing request (CSR) for the two services, use the following AWS CLI command: `openssl req -out client_csr1.pem -new -newkey rsa:2048 -nodes -keyout client_private-key1.pem` `openssl req -out client_csr2.pem -new -newkey rsa:2048 -nodes -keyout client_private-key2.pem` This command returns the CSR and the private key for the two services. • To issue a certificate for the services, run the following commands to use the private CA that you created: `SERVICE_ONE_CERT_ARN=`aws acm-pca issue-certificate \` ` --certificate-authority-arn ${ROOT_CA_ARN} \`	DevOps engineer, AWS DevOps

Task	Description	Skills required
	``` --csr fileb://c lient_csr1.pem \ --signing-algorith m "SHA256WITHRSA" \ --validity Value=5,Type="YEARS" --query CertificateArn --output text`  echo "SERVICE_ONE_CERT_ ARN: ${SERVICE _ONE_CERT_ARN}"  aws acm-pca get-certi ficate \     --certificate-auth ority-arn ${ROOT_CA _ARN} \     --certificate-arn  ${SERVICE_ONE_CERT _ARN} \      | jq -r '.Certifi cate' > client_ce rt1.cert  SERVICE_TWO_CERT_ ARN=`aws acm-pca issue- certificate \ --certificate-auth ority-arn ${ROOT_CA _ARN} \ --csr fileb://c lient_csr2.pem \ --signing-algorith m "SHA256WITHRSA" \ --validity Value=5,Type="YEARS" --query CertificateArn --output text` ```	

Task	Description	Skills required

	``
	echo "SERVICE_TWO_CERT_
	ARN: ${SERVICE
	_TWO_CERT_ARN}"
	
	aws acm-pca get-certi
	ficate \
	    --certificate-auth
	ority-arn ${ROOT_CA
	_ARN} \
	    --certificate-arn
	 ${SERVICE_TWO_CERT
	_ARN} \
	     | jq -r '.Certifi
	cate' > client_ce
	rt2.cert
	``
	For more information, see [Issue private end-entity certificates]() in the AWS documentation.	

Provision AWS services

Task	Description	Skills required
Provision AWS services with the CloudFormation template.	To provision the virtual private cloud (VPC), Amazon ECS cluster, Amazon ECS services, Application Load Balancer, and Amazon Elastic Container Registry (Amazon ECR), use the CloudFormation template.	DevOps engineer
Get variables.	Verify that you have an Amazon ECS cluster with two services running. To retrieve	DevOps engineer

Task	Description	Skills required

	the resource details and store them as variables, use the following commands:
	`export LoadBalancerDNS=$(aws cloudformation describe-stacks --stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputKey==`LoadBalancerDNS`].OutputValue')`
	
	`export ECRRepositoryUri=$(aws cloudformation describe-stacks --stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputKey==`ECRRepositoryUri`].OutputValue')`
	
	`export ECRRepositoryServiceOneUri=$(aws cloudformation describe-stacks --stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputKey==`ECRRepositoryServiceOneUri`].OutputValue')`
	
	`export ECRRepositoryServiceTwoUri=$(aws cloudformation`	

Task	Description	Skills required
	``` describe-stacks -- stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputK ey==`ECRRepository ServiceTwoUri`].Ou tputValue') export ClusterName= $(aws cloudformation describe-stacks -- stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputK ey==`ClusterName`] .OutputValue') export BucketName= $(aws cloudformation describe-stacks -- stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputK ey==`BucketName`]. OutputValue') export Service1L istenerArn=$(aws cloudformation describe-stacks -- stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputK ey==`Service1Liste nerArn`].OutputVal ue') ```	

Task	Description	Skills required
	```export Service2ListenerArn=$(aws cloudformation describe-stacks --stack-name ecs-mtls \ --output text \ --query 'Stacks[0].Outputs[?OutputKey==`Service2ListenerArn`].OutputValue')```	

Task	Description	Skills required
Create a CodeBuild project.	To use a CodeBuild project to create the Docker images for your Amazon ECS services, do the following: 1. Sign in to the AWS Management Console, and open the CodeBuild console at https://console.aws.amazon.com/codesuite/codebuild/. 2. Create a new project. For **Source**, choose the Git repository that you created. For information about different kinds of Git repository integration, see [Working with connections](#) in the AWS documentation. 3. Confirm that **Privileged** mode is enabled. To build Docker images, this mode is necessary. Otherwise, the image will not build successfully. 4. Use the custom `buildspec.yaml` file shared for each service. 5. Provide values for the project name and descripti on. For more details, see [Create a build project in AWS](#)	AWS DevOps, DevOps engineer

Task	Description	Skills required
	CodeBuild in the AWS documentation.	

Task	Description	Skills required

Build the Docker images.	You can use CodeBuild to perform the image build process. CodeBuild needs permissions to interact with Amazon ECR and to work with Amazon S3.
	
	As part of the process, the Docker image is built and pushed to the Amazon ECR registry. For details about the template and the code, see [Additional information](#).
	
	(Optional) To build locally for test purposes, use the following command:
	
	`# login to ECR`
	`aws ecr get-login -password | docker login --username AWS --password-stdin $ECRRepositoryUri`
	
	`# build image for service one`
	`cd /service1`
	`aws s3 cp s3://$BucketName/serviceone/ service1/ --recursive`
	`docker build -t $ECRRepositoryServiceOneUri .`
	`docker push $ECRRepositoryServiceOneUri`
	
	`# build image for service two`
		DevOps engineer

Task	Description	Skills required
	``` cd ../service2 aws s3 cp s3://$Buc ketName/servicetwo/ service2/ --recursive docker build -t $ECRRepositoryServ iceTwoUri . docker push $ECRRepos itoryServiceTwoUri ```	

Enable mutual TLS

Task	Description	Skills required
Upload the CA certificate to Amazon S3.	To upload the CA certifica te to the Amazon S3 bucket, use the following example command: `aws s3 cp ca-cert.pem s3://$BucketName/a cm-trust-store/`	AWS DevOps, DevOps engineer

Create the trust store.	To create the trust store, use the following example command:
	``
	TrustStoreArn=`aws
	 elbv2 create-trust-
	store --name acm-pca-t
	rust-certs \
	    --ca-certificates-
	bundle-s3-bucket
	 $BucketName \
	    --ca-certificates-
	bundle-s3-key acm-
	trust-store/ca-
	cert.pem --query
	``
		AWS DevOps, DevOps engineer

Task	Description	Skills required
	``` 'TrustStores[].Tru stStoreArn' --output text` ```	
Upload client certificates.	To upload client certificates to Amazon S3 for Docker images, use the following example command: ``` # for service one aws s3 cp client_ce rt1.cert s3://$Buc ketName/serviceone/ aws s3 cp client_pr ivate-key1.pem s3:// $BucketName/serviceone / # for service two aws s3 cp client_ce rt2.cert s3://$Buc ketName/servicetwo/ aws s3 cp client_pr ivate-key2.pem s3:// $BucketName/servicetwo / ```	AWS DevOps, DevOps engineer

Task	Description	Skills required
Modify the listener.	To enable mutual TLS on the ALB, modify the HTTPS listeners by using the following commands: `aws elbv2 modify-li stener \ --listener-arn $Service1ListenerArn \ --certificates CertificateArn=$TL S_CERTIFICATE_ARN_TWO \ --ssl-policy ELBSecurityPolicy- 2016-08 \ --protocol HTTPS \ --port 8080 \ --mutual-authentic ation Mode=veri fy,TrustStoreArn=$ TrustStoreArn,Igno reClientCertificat eExpiry=false`  `aws elbv2 modify-li stener \ --listener-arn $Service2ListenerArn \ --certificates CertificateArn=$TL S_CERTIFICATE_ARN_TWO \ --ssl-policy ELBSecurityPolicy- 2016-08 \ --protocol HTTPS \ --port 8090 \`	AWS DevOps, DevOps engineer

Task	Description	Skills required
	``` --mutual-authentication Mode=verify,TrustStoreArn=$TrustStoreArn,IgnoreClientCertificateExpiry=false ``` For more information, see [Configuring mutual TLS on an Application Load Balancer](#) in the AWS documentation.	

Update the services

Task	Description	Skills required

Update the Amazon ECS task definition.	To update the Amazon ECS task definition, modify the `image` parameter in the new revision.
	
	To get the values for the respective services, update the task definitions with the new Docker images Uri that you built in the previous steps: `echo $ECRRepositoryServiceOneUri` or `echo $ECRRepositoryServiceTwoUri`
	
	``
	    "containerDefinitions": [
	        {
	``
		AWS DevOps, DevOps engineer

Task	Description	Skills required

	``
	              "name":
	 "nginx",
	              "image":
	 "public.ecr.aws/ng
	inx/nginx:latest",
	 # <----- change to new
	 Uri
	              "cpu": 0,
	``
	For more information, see [Updating an Amazon ECS task definition](#) using the console in the AWS documentation.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Update the Amazon ECS service.</td><td>Update the service with the latest task definition. This task definition is the blueprint for the newly built Docker images, and it contains the client certificate that's required for the mutual TLS authentication.

To update the service, use the following procedure:

1. Open the Amazon ECS console at https://console.aws.amazon.com/ecs/v2.
2. On the Clusters page, choose the cluster.
3. On the cluster details page, in the Services section, select the checkbox next to the service, and then choose Update.
4. To have your service start a new deployment, select Force new deployment.
5. For Task definition, choose the task definition family and the latest revision.
6. Choose Update.

Repeat the steps for the other service.</td><td>AWS administrator, AWS DevOps, DevOps engineer</td></tr>
</table>

Access the application

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Copy the application URL.</td><td>Use the Amazon ECS console to view the task. When the task status has been updated to Running, select the task. In the Task section, copy the task ID.</td><td>AWS administrator, AWS DevOps</td></tr>
<tr><td>Test your application.</td><td>To test your application, use ECS Exec to access the tasks.

1. For service one, use the following command:
<pre>container="nginx"

ECS_EXEC_TASK_ARN
="<TASK ARN>"
aws ecs execute-c
ommand --cluster
 $ClusterName \
    --task $ECS_EXEC
_TASK_ARN \
    --container
 $container \
    --interactive \
    --command "/bin/
bash"</pre>2. In the service one task’s container, use the following command to enter the internal load balancer <code>url</code> and the listener port that points to service two. Then specify the path to the client</td><td>AWS administrator, AWS DevOps</td></tr>
</table>

Task	Description	Skills required

	certificate to test the application:
	`curl -kvs https://<internal-alb-url>:8090 --key /usr/local/share/ca-certificates/client.key --cert /usr/local/share/ca-certificates/client.crt`
	3. In the service two task’s container, use the following command to enter the internal load balancer `url` and the listener port that points to service one. Then specify the path to the client certificate to test the application:
	`curl -kvs https://<internal-alb-url>:8080 --key /usr/local/share/ca-certificates/client.key --cert /usr/local/share/ca-certificates/client.crt`
	Note
	The `-k` flag in the curl commands (as part of `-kvs`) disables	

Task	Description	Skills required
	SSL certificate validation. You can remove this flag when using an SSL certificate that matches your domain name, enabling proper certificate validation.

Additional information

Editing the Dockerfile

The following code shows the commands that you edit in the Dockerfile for service 1:

```
FROM public.ecr.aws/nginx/nginx:latest
WORKDIR /usr/share/nginx/html
```

```
RUN echo "Returning response from Service 1: Ok" > /usr/share/nginx/html/index.html
ADD client_cert1.cert client_private-key1.pem /usr/local/share/ca-certificates/
RUN chmod -R 400 /usr/local/share/ca-certificates/
```

The following code shows the commands that you edit in the Dockerfile for service 2:

```
FROM public.ecr.aws/nginx/nginx:latest
WORKDIR /usr/share/nginx/html
RUN echo "Returning response from Service 2: Ok" > /usr/share/nginx/html/index.html
ADD client_cert2.cert client_private-key2.pem /usr/local/share/ca-certificates/
RUN chmod -R 400 /usr/local/share/ca-certificates/
```

If you're building the Docker images with CodeBuild, the `buildspec` file uses the CodeBuild build number to uniquely identify image versions as a tag value. You can change the `buildspec` file to fit your requirements, as shown in the following `buildspec` custom code:

```
version: 0.2

phases:
  pre_build:
    commands:
      - echo Logging in to Amazon ECR...
      - aws ecr get-login-password --region $AWS_DEFAULT_REGION | docker login --
username AWS --password-stdin $ECR_REPOSITORY_URI
      - COMMIT_HASH=$(echo $CODEBUILD_RESOLVED_SOURCE_VERSION | cut -c 1-7)
      - IMAGE_TAG=${COMMIT_HASH:=latest}
  build:
    commands:
        # change the S3 path depending on the service
      - aws s3 cp s3://$YOUR_S3_BUCKET_NAME/serviceone/ $CodeBuild_SRC_DIR/ --
recursive
      - echo Build started on `date`
      - echo Building the Docker image...
      - docker build -t $ECR_REPOSITORY_URI:latest .
      - docker tag $ECR_REPOSITORY_URI:latest $ECR_REPOSITORY_URI:$IMAGE_TAG
  post_build:
    commands:
      - echo Build completed on `date`
      - echo Pushing the Docker images...
      - docker push $ECR_REPOSITORY_URI:latest
      - docker push $ECR_REPOSITORY_URI:$IMAGE_TAG
      - echo Writing image definitions file...
```

```
      # for ECS deployment reference
      - printf '[{"name":"%s","imageUri":"%s"}]' $CONTAINER_NAME $ECR_REPOSITORY_URI:
$IMAGE_TAG > imagedefinitions.json

artifacts:
  files:
    - imagedefinitions.json
```

Build a serverless React Native mobile app by using AWS Amplify

Deekshitulu Pentakota, Amazon Web Services

Summary

This pattern shows how to create a serverless backend for a React Native mobile app by using AWS Amplify and the following AWS services:

- AWS AppSync
- Amazon Cognito
- Amazon DynamoDB

After you configure and deploy the app’s backend by using Amplify, Amazon Cognito authenticates app users and authorizes them to access the app. AWS AppSync then interacts with the frontend app and with a backend DynamoDB table to create and fetch data.

> **Note**
>
> This pattern uses a simple "ToDoList" app as an example, but you can use a similar procedure to create any React Native mobile app.

Prerequisites and limitations

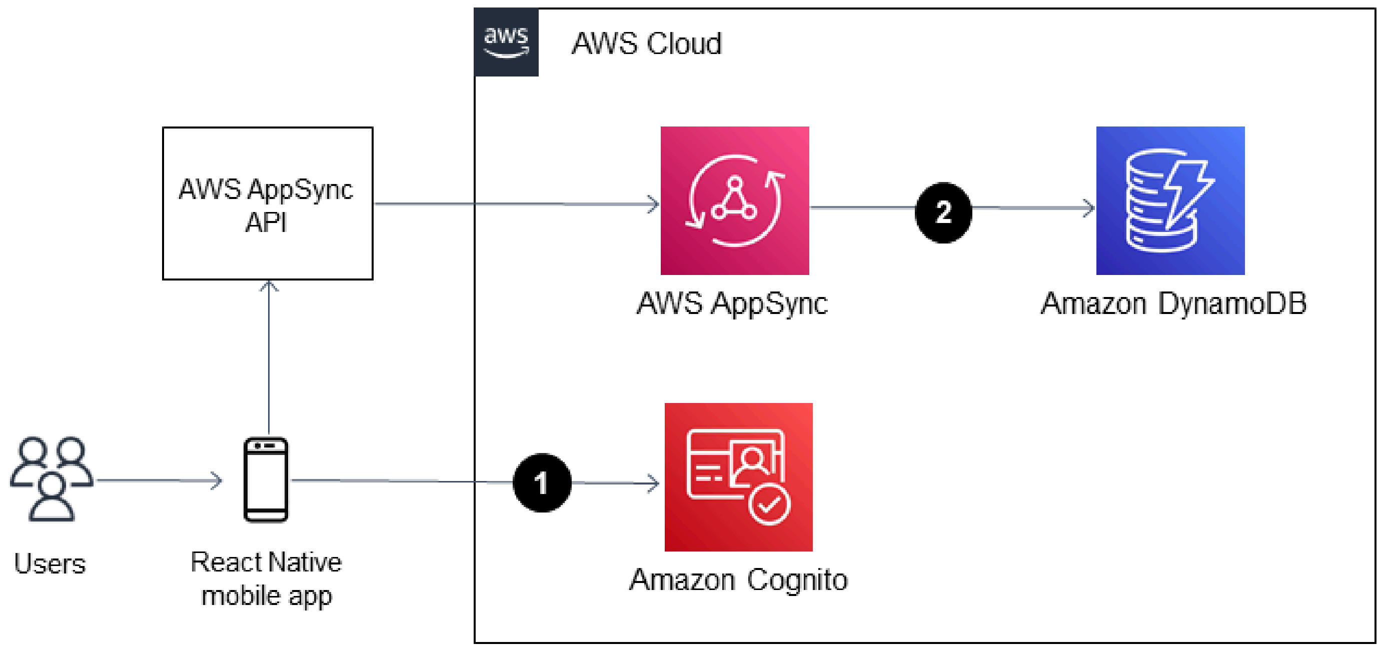
Prerequisites

- An active AWS Account
- Amplify Command Line Interface (Amplify CLI), installed and configured
- XCode (any version)
- Microsoft Visual Studio (any version, any code editor, any text editor)
- Familiarity with Amplify
- Familiarity with Amazon Cognito
- Familiarity with AWS AppSync
- Familiarity with DynamoDB
- Familiarity with Node.js

- Familiarity with npm
- Familiarity with React and React Native
- Familiarity with JavaScript and ECMAScript 6 (ES6)
- Familiarity with GraphQL

Architecture

The following diagram shows an example architecture for running a React Native mobile app's backend in the AWS Cloud:



The diagram shows the following architecture:

1. Amazon Cognito authenticates app users and authorizes them to access the app.
2. To create and fetch data, AWS AppSync uses a GraphQL API to interact with the frontend app and a backend DynamoDB table.

Tools

AWS services

- AWS Amplify is a set of purpose-built tools and features that helps frontend web and mobile developers quickly build full-stack applications on AWS.

- AWS AppSync provides a scalable GraphQL interface that helps application developers combine data from multiple sources, including Amazon DynamoDB, AWS Lambda, and HTTP APIs.
- Amazon Cognito provides authentication, authorization, and user management for web and mobile apps.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

Code

The code for the sample application that's used in this pattern is available in the GitHub aws-amplify-react-native-ios-todo-app repository. To use the sample files, follow the instructions in the **Epics** section of this pattern.

Epics

Create and run your React Native app

Task	Description	Skills required
Set up a React Native development environment.	For instructions, see Setting up the development environment in the React Native documentation.	App developer
Create and run the ToDoList React Native mobile app in iOS Simulator.	1. Create a new React Native mobile app project directory in in your local environment by running the following command in a new terminal window: `npx react-native init ToDoListAmplify` 2. Navigate to the project's root directory by running the following command:	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>cd ToDoListAmplify</code></pre>
3. Run the app by running the following command:
<pre><code>npx react-native
run-ios</code></pre></td><td></td></tr>
</table>

Initialize a new backend environment for the app

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create the backend services needed to support the app in Amplify.</td><td>1. In your local environment, run the following command from the project’s root directory (ToDoListAmplify):
<pre><code>amplify init</code></pre>
2. A prompt appears that asks you to provide information about the app. Enter the required information based on your use case. Then, press Enter.

For the ToDoList app setup used in this pattern, apply the following example configuration.

Example React Native Amplify app configuration settings</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
	``` ? Name: ToDoListAmplify ? Environment: dev ? Default editor: Visual Studio Code ? App type: javascript ? Javascript framework: react-native ? Source Directory Path: src ? Distribution Directory Path: / ? Build Command: npm run-script build ? Start Command: npm run-script start ? Select the authentication method you want to use: AWS profile ? Please choose the profile you want to use: default ``` For more information, see Create a new Amplify backend in the Amplify Dev Center documentation.	

Task	Description	Skills required
	Note The `amplify init` command provisions the following resources by using [AWS CloudFormation]():	
	• AWS Identity and Access Management (IAM) roles for authenticated and unauthenticated users (**Auth Role** and **Unauth Role**) • An Amazon Simple Storage Service (Amazon S3) bucket for deployment (for this pattern's example app, **Amplify-meta.json**) • A backend environment in [Amplify Hosting]()	

Add Amazon Cognito authentication to your Amplify React Native app

Task	Description	Skills required
Create an Amazon Cognito authentication service.	1. In your local environment, run the following command from the project's root directory (**ToDoListAmplify**): `amplify add auth`	App developer

Task	Description	Skills required

	2. A prompt appears that asks you to provide information about the authentication service's configuration settings. Enter the required information based on your use case. Then, press **Enter**.
	
	For the ToDoList app setup used in this pattern, apply the following example configuration.
	
	Example authentication service configuration settings
	
	`? Do you want to use the default authentication and security configuration? \`
	`Default configuration`
	
	`? How do you want users to be able to sign in? \`
	`Username`
	
	`? Do you want to configure advanced settings? \`
	`No, I am done`
	
	Note
	The `amplify add auth` command	

Task	Description	Skills required
	creates the necessary folders, files, and dependency files in a local folder (**amplify**) within the project's root directory. For the ToDoList app setup used in this pattern, the **aws-exports.js** is created for this purpose.	

Deploy the Amazon Cognito service to the AWS Cloud.	1. From the project's root directory, run the following Amplify CLI command:
	`amplify push`
	2. A prompt to confirm deployment appears. Enter **Yes**. Then, press **Enter**.
	
	Note
	To see the deployed services in your project, go to the Amplify console by running the following command:
	
	`amplify console`
		App developer

Task	Description	Skills required

Install the required Amplify libraries for React Native and the CocoaPods dependencies for iOS.	1. Install the required Amplify open-source client libraries by running the following command from the project's root directory:
	`npm install aws-amplify aws-amplify-react-native \ amazon-cognito-identity-js @react-native-community/netinfo \ @react-native-async-storage/async-storage`
	2. Install the required CocoaPods dependencies for iOS by running the following command:
	`npx pod-install`
		App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Import and configure the Amplify service.</td><td>In the app’s entry point file (for example, App.js), import and load the Amplify service’s configuration file by entering the following lines of code:
<pre>import Amplify from
 'aws-amplify'
import config from './
src/aws-exports'
Amplify.configur
e(config)</pre>
Note
If you receive an error after importing the Amplify service in the app’s entry point file, stop the app. Then, open XCode and select the ToDoListAmplify.xcworkspace from the project’s iOS folder and run the app.</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
Update your app's entry point file to use the withAuthe nticator Higher-order component (HOC).	**Note** The `withAuthenticator` HOC provides sign-in, sign-up, and forgot password workflows in your app by using only a few lines of code. For more information, see [Option 1: Use pre-build UI components](#) in the Amplify Dev Center. Also, [Higher-order components](#) in the React documentation. 1. In the app's entry point file (for example, **App.js**), import the `withAuthenticator` HOC by entering the following lines of code: `import { withAuthenticator } from 'aws-amplify-react-native'` 2. Export the withAuthe nticator HOC by entering the following code:	App developer

Task	Description	Skills required

	`export default withAuthenticator(App)`
	
	withAuthenticator HOC code example
	
	`import Amplify from 'aws-amplify'`
	`import config from './src/aws-exports'`
	`Amplify.configure(config)`
	`import { withAuthenticator } from 'aws-amplify-react-native';`
	
	`const App = () => {`
	`  return null;`
	`};`
	
	`export default withAuthenticator(App);`
	
	Note
	In iOS Simulator, the app shows the login screen that's provided by the Amazon Cognito service.	

Task	Description	Skills required
Test the authentication service setup.	In iOS Simulator, do the following: 1. Create a new account in the app by using a real email address. A verificat ion code is then sent to the registered email. 2. Verify the account set up by using the code that you receive in the verification email. 3. Enter the username and password that you created. Then, choose **Sign In**. A welcome screen appears. **Note** You can also open the [Amazon Cognito console] and check if a new user has been created in the **Identity Pool** or not.	App developer

Connect an AWS AppSync API and DynamoDB database to the app

Task	Description	Skills required
Create an AWS AppSync API and DynamoDB database.	1. Add an AWS AppSync API to your app and automatic ally provision a DynamoDB	App developer

Task	Description	Skills required

	database by running the following Amplify CLI command from the project's root directory:
	`amplify add api`
	2. A prompt appears that asks you to provide information about the API and database configuration settings. Enter the required information based on your use case. Then, press **Enter**. The Amplify CLI opens the GraphQL schema file in your text editor.
	
	For the ToDoList app setup used in this pattern, apply the following example configuration.
	
	Example API and database configuration settings
	`? Please select from one of the below mentioned services: \`
	`GraphQL`
	
	`? Provide API name: todolistamplify`
	
	`? Choose the default authorization type for the API \`
	`Amazon Cognito User Pool`	

Task	Description	Skills required

	<pre>Do you want to use the
	 default authentication
	 and security configura
	tion
	
	? Default configuration
	 How do you want users
	 to be able to sign in?
	 \
	Username
	
	Do you want to configure
	 advanced settings? \
	No, I am done.
	
	? Do you want to
	 configure advanced
	 settings for the
	 GraphQL API \
	No, I am done.
	
	? Do you have an
	 annotated GraphQL
	 schema? \
	No
	
	? Choose a schema
	 template: \
	Single object with
	 fields (e.g., "Todo"
	 with ID, name,
	 description)
	
	? Do you want to edit
	 the schema now? \
	Yes</pre> **Example GraphQL schema** <pre> type Todo @model {</pre>	

Task	Description	Skills required

	``
	    id: ID!
	    name: String!
	    description: String
	}
	``	

Task	Description	Skills required
Deploy the AWS AppSync API.	1. In the project's root directory, run the following Amplify CLI command: `amplify push` 2. A prompt appears that asks you to provide more information about the API and database configuration settings. Enter the required information based on your use case. Then, press **Enter**. Your app can now interact with the AWS AppSync API. For the ToDoList app setup used in this pattern, apply the following example configura tion. **Example AWS AppSync API configuration settings** **Note** The following configuration creates the GraphQL API in AWS AppSync and a **Todo** table in Dynamo DB.	App developer

Task	Description	Skills required

	<pre>? Are you sure you want to continue? Yes
	? Do you want to generate code for your newly created GraphQL API Yes
	? Choose the code generation language target javascript
	? Enter the file name pattern of graphql queries, mutations and subscriptions src/graphql/**/*.js
	? Do you want to generate/update all possible GraphQL operations - \
	queries, mutations and subscriptions Yes
	? Enter maximum statement depth \
	[increase from default if your schema is deeply nested] 2</pre>	

Task	Description	Skills required
Connect the app's frontend to the AWS AppSync API.	To use the example ToDoList app provided in this pattern, copy the code from the **App.js** file in the aws-amplify-react-native-ios-todo-app GitHub repository. Then, integrate the example code into your local environment. The example code provided in the repository’s **App.js** file does the following: • Shows the form for creating a **ToDo Item** with **Title** and **Description** fields • Displays the list of to-do items (**Title** and **Descripti on**) • Posts and fetches data by using `aws-amplify` methods	App developer

Manage tenants across multiple SaaS products on a single control plane

Ramanna Avancha, Kishan Kavala, Anusha Mandava, and Jenifer Pascal, Amazon Web Services

Summary

This pattern shows how to manage tenant lifecycles across multiple software as a service (SaaS) products on a single control plane in the AWS Cloud. The reference architecture provided can help organizations reduce the implementation of redundant, shared features across their individual SaaS products and provide governance efficiencies at scale.

Large enterprises can have multiple SaaS products across various business units. These products often need to be provisioned for use by external tenants at different subscription levels. Without a common tenant solution, IT administrators must spend time managing undifferentiated features across multiple SaaS APIs, instead of focusing on core product feature development.

The common tenant solution provided in this pattern can help centralize the management of many of an organization's shared SaaS product features, including the following:

- Security
- Tenant provisioning
- Tenant data storage
- Tenant communications
- Product management
- Metrics logging and monitoring

Prerequisites and limitations

Prerequisites

- An active AWS account
- Knowledge of Amazon Cognito or a third-party identity provider (IdP)
- Knowledge of Amazon API Gateway
- Knowledge of AWS Lambda
- Knowledge of Amazon DynamoDB

- Knowledge of AWS Identity and Access Management (IAM)
- Knowledge of AWS Step Functions
- Knowledge of AWS CloudTrail and Amazon CloudWatch
- Knowledge of Python libraries and code
- Knowledge of SaaS APIs, including the different types of users (organizations, tenants, administrators, and application users), subscription models, and tenant isolation models
- Knowledge of your organization's multi-product SaaS requirements and multi-tenant subscriptions

Limitations

- Integrations between the common tenant solution and individual SaaS products aren't covered in this pattern.
- This pattern deploys the Amazon Cognito service in a single AWS Region only.

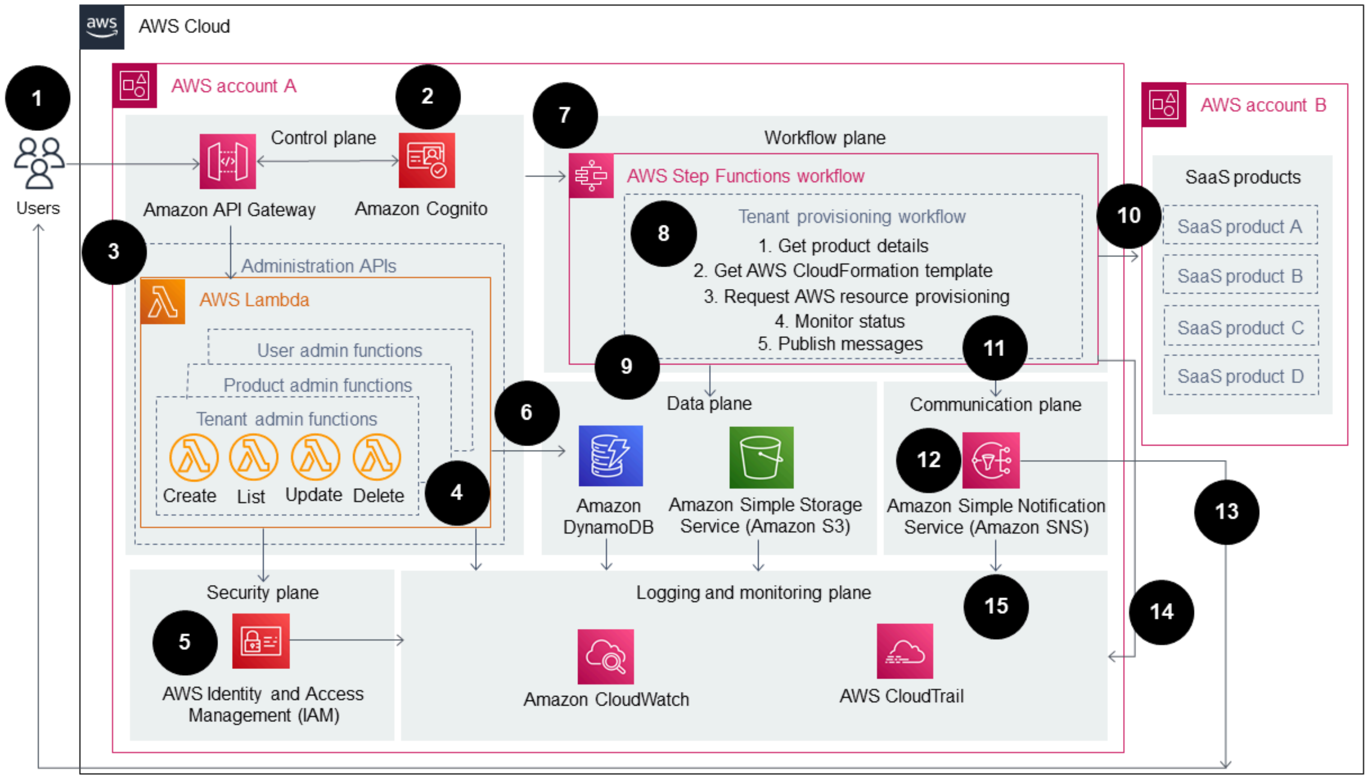
Architecture

Target technology stack

- Amazon API Gateway
- Amazon Cognito
- AWS CloudTrail
- Amazon CloudWatch
- Amazon DynamoDB
- IAM
- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)
- Amazon Simple Notification Service (Amazon SNS)
- AWS Step functions

Target architecture

The following diagram shows an example workflow for managing tenant lifecycles across multiple SaaS products on a single control plane in the AWS Cloud.



The diagram shows the following workflow:

1. An AWS user initiates tenant provisioning, product provisioning, or administration-related actions by making a call to an API Gateway endpoint.
2. The user is authenticated by an access token that's retrieved from an Amazon Cognito user pool, or another IdP.
3. Individual provisioning or administration tasks are run by Lambda functions that are integrated with API Gateway API endpoints.
4. Administration APIs for the common tenant solution (for tenants, products, and users) gather all of the required input parameters, headers, and tokens. Then, the administration APIs invoke the associated Lambda functions.
5. IAM permissions for both the administration APIs and the Lambda functions are validated by the IAM service.
6. Lambda functions store and retrieve data from the catalogs (for tenants, products, and users) in DynamoDB and Amazon S3.
7. After permissions are validated, an AWS Step Functions workflow is invoked to perform a specific task. The example in the diagram shows a tenant provisioning workflow.

8. Individual AWS Step Functions workflow tasks are run in a predetermined workflow (state machine).
9. Any essential data that's needed to run the Lambda function associated with each workflow task is retrieved from either DynamoDB or Amazon S3. Other AWS resources might need to be provisioned by using an AWS CloudFormation template.
10. If needed, the workflow sends a request to provision additional AWS resources for a specific SaaS product to that product's AWS account.
11. When the request succeeds or fails, the workflow publishes the status update as a message to an Amazon SNS topic.
12. Amazon SNS is subscribed to the Step Functions workflow's Amazon SNS topic.
13. Amazon SNS then sends the workflow status update back to the AWS user.
14. Logs of each AWS service's actions, including an audit trail of API calls, are sent to CloudWatch. Specific rules and alarms can be configured in CloudWatch for each use case.
15. Logs are archived in Amazon S3 buckets for auditing purposes.

Automation and scale

This pattern uses a CloudFormation template to help automate the deployment of the common tenant solution. The template can also help you quickly scale the associated resources up or down.

For more information, see Working with AWS CloudFormation templates in the *AWS CloudFormation User Guide*.

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- Amazon Cognito provides authentication, authorization, and user management for web and mobile apps.
- AWS CloudTrail helps you audit the governance, compliance, and operational risk of your AWS account.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

Best practices

The solution in this pattern uses a single control plane to manage the onboarding of multiple tenants and to provision access to multiple SaaS products. The control plane helps administrative users manage four other, feature-specific planes:

- Security plane
- Workflow plane
- Communication plane
- Logging and monitoring plane

Epics

Configure the security plane

Task	Description	Skills required
Establish the requirements for your multi-tenant SaaS platform.	Establish detailed requireme nts for the following:	Cloud architect, AWS systems administrator

Task	Description	Skills required
	• Tenants • Users • Roles • SaaS products • Subscriptions • Profile exchanges	
Set up the Amazon Cognito service.	Follow the instructions in Getting started with Amazon Cognito in the *Amazon Cognito Developer Guide*.	Cloud architect
Configure the required IAM policies.	Create the required IAM policies for your use case. Then, map the policies to IAM roles in Amazon Cognito. For more information, see Managing access using policies and Role-based access control in the *Amazon Cognito Developer Guide*.	Cloud administrator, Cloud architect, AWS IAM security

Task	Description	Skills required
Configure the required API permissions.	Set up API Gateway access permissions by using IAM roles and policies, and Lambda authorizers. For instructions, see the following sections of the *Amazon API Gateway Developer Guide*: • Control access to an API with IAM permissions • Use API Gateway Lambda authorizers	Cloud administrator, Cloud architect

Configure the data plane

Task	Description	Skills required
Create the required data catalogs.	1. Create DynamoDB tables to store data for the user catalogs. Make sure that you include user attribute s and roles. Also, make sure that you perform data modeling on the catalog tables to maintain the required and optional attributes for each user and role. 2. Create DynamoDB tables to store data for the product catalogs. Make sure that you model the	DBA

Task	Description	Skills required
	specific use cases for your SaaS products. 3. Create DynamoDB tables to store data for the tenant catalogs. Make sure that you set up subscript ion models for tenants, products and licensing for multi-SaaS subscriptions, and tags. For more information, see Setting up DynamoDB in the *Amazon DynamoDB Developer Guide*.	

Configure the control plane

Task	Description	Skills required
Create Lambda functions and API Gateway APIs to run required control plane tasks.	Create separate Lambda functions and API Gateway APIs to add, delete, and manage the following: • Users • Tenants • Products For more information, see Using AWS Lambda with Amazon API Gateway in the *AWS Lambda Developer Guide*.	App developer

Configure the workflow plane

Task	Description	Skills required
Identify the tasks that AWS Step Functions workflows must run.	Identify and document the detailed AWS Step Functions workflow requirements for the following: • Users • Tenants • Products **Important** Make sure that key stakeholders approve the requirements.	App owner
Create the required AWS Step Functions workflows.	1. Create the required workflows for users, tenants, and products in AWS Step Functions. For more information, see the *AWS Step Functions Developer Guide*. 2. Identify the retry and error handling mechanisms. For more information, see Handling errors, retries, and adding alerting to Step Function State Machines on the AWS Blog. 3. Implement the workflow steps by using Lambda	App developer, Build lead

Task	Description	Skills required
	functions. For instructions, see [Creating a Step Functions state machine that uses Lambda](#) in the *AWS Step Functions Developer Guide*. 4. Integrate any external services with AWS Step Functions as needed. 5. Maintain each workflow's status in a DynamoDB table and communicate each workflow's status by using Amazon SNS.	

Configure the communication plane

Task	Description	Skills required
Create Amazon SNS topics.	Create Amazon SNS topics to receive notifications about the following: • Workflow statuses • Errors • Retries For more information, see [Creating an SNS topic](#) in the *Amazon SNS Developer Guide*.	App owner, Cloud architect
Subscribe endpoints to each Amazon SNS topic.	To receive messages published to an Amazon SNS	App developer, Cloud architect

Task	Description	Skills required
	topic, you must subscribe an endpoint to each topic. For more information, see [Subscribing to an Amazon SNS topic] in the *Amazon SNS Developer Guide*.	

Configure the logging and monitoring plane

Task	Description	Skills required
Activate logging for each component of the common tenant solution.	Activate logging at the component level for each resource in the common tenant solution that you created. For instructions, see the following: • How do I turn on CloudWatch Logs for troubleshooting my API Gateway REST API or WebSocket API? (AWS Knowledge Center) • Logging using CloudWatch Logs (*AWS Step Functions Developer Guide*) • AWS Lambda function logging in Python (*AWS Lambda Developer Guide*)	App developer, AWS systems administrator, Cloud administrator

Task	Description	Skills required
	• Logging and monitoring in Amazon Cognito (*Amazon Cognito Developer Guide*) • Monitoring with Amazon CloudWatch (*Amazon DynamoDB Developer Guide*) **Note** You can consolidate logs for each resource into a centralized logging account by using IAM policies. For more information, see Centralized logging and multiple-account security guardrails.	

Provision and deploy the common tenant solution

Task	Description	Skills required
Create CloudFormation templates.	Automate the deployment and maintenance of the full common tenant solution and all its components by using CloudFormation templates. For more information, see the *AWS CloudFormation User Guide*.	App developer, DevOps engineer, CloudFormation developer

Consolidate Amazon S3 presigned URL generation and object downloads by using an endpoint associated with static IP addresses

Song Jin, Eunhye Jo, and Jun Soung Lee, Amazon Web Services

Summary

This pattern simplifies access to Amazon Simple Storage Service (Amazon S3) by creating secure, custom presigned URLs for object downloads. The solution provides a single endpoint with a unique domain and static IP addresses. It's tailored for customers who require consolidation of both API and Amazon S3 endpoints under a unified domain with static IP addresses. The use case involves users following an IP and domain allowlist firewall policy, limiting API access to specific domains and IP addresses.

The architecture employs key AWS services, including AWS Global Accelerator, Amazon API Gateway, AWS Lambda, Application Load Balancer, AWS PrivateLink, and Amazon S3. This design centralizes the API for generating presigned URLs and the Amazon S3 endpoint under a single domain, linked to an accelerator with two static IP addresses. Consequently, users can effortlessly request presigned URLs and download Amazon S3 objects through a unified domain endpoint with static IP addresses.

This architecture is especially beneficial for customers with strict policies or compliance requirements, such as those in the public, medical, and finance sectors.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A public hosted zone for your custom domain name
- A domain imported in AWS Certificate Manager (ACM) in the AWS Region of your choice

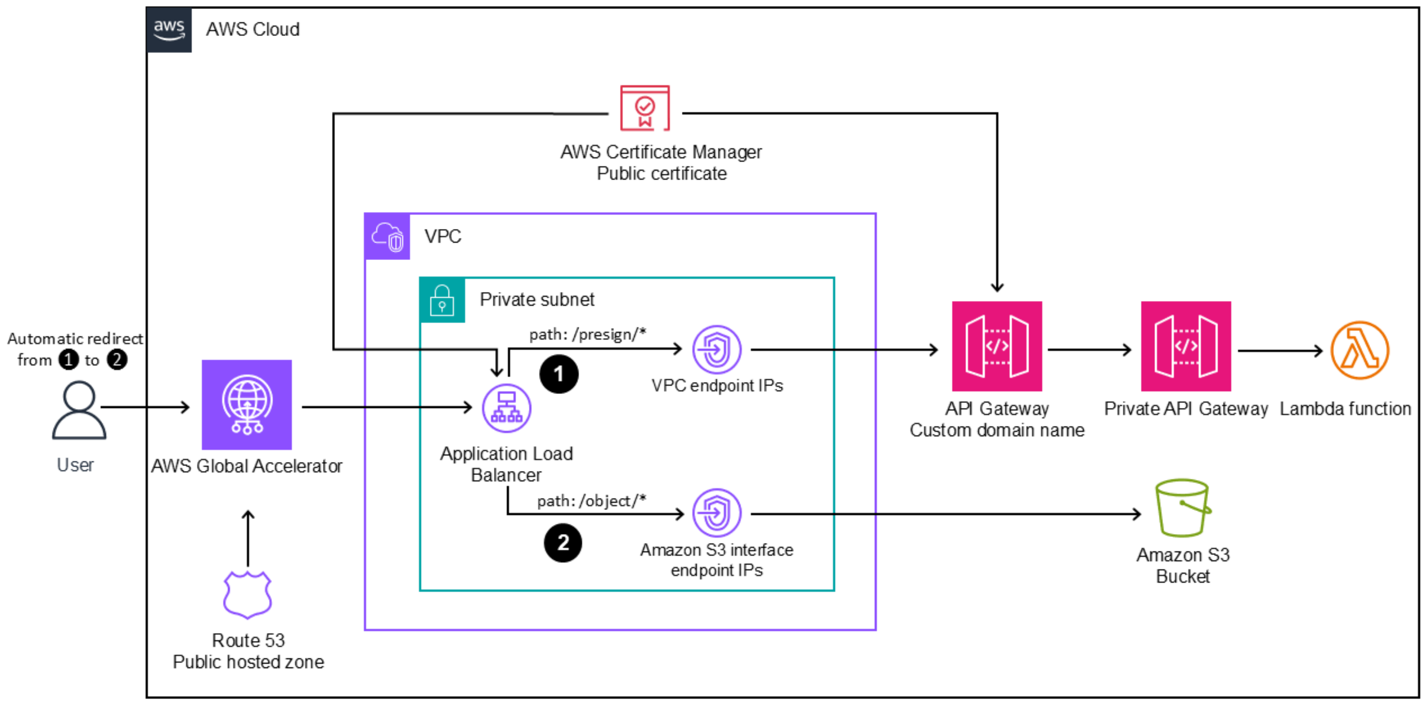
Limitations

- The Amazon S3 bucket name must match the domain name of the endpoint. This requirement is to ensure that the Amazon S3 endpoint can be served through the single API endpoint.
- The custom domain name used in API Gateway should align with the domain name of the single API endpoint.

- Some AWS services aren't available in all AWS Regions. For Region availability, see [AWS Services by Region](). For specific endpoints, see [Service endpoints and quotas](), and choose the link for the service.

Architecture

The following diagram shows the target architecture and workflow for this pattern.



The diagram illustrates the following concept and workflow:

1. A user initiates a request to generate a presigned URL by using the custom endpoint served through AWS Global Accelerator, using the custom domain name and associated IP addresses.
2. A Lambda function generates the presigned URL, pointing to the custom endpoint. It responds with a 301 redirect that contains the generated presigned URL. Through the redirected presigned URL, the user downloads the object automatically by using the custom endpoint served through Global Accelerator.

The components of the overall architecture for presigned URL generation and object download workflow are as follows:

- Provisioning of static IP addresses by Global Accelerator.
- Registration of the accelerator's alias as an A record into the Amazon Route 53 public hosted zone with the custom domain name.
- Creation of an Amazon S3 bucket with a bucket name that matches the registered custom domain name.
- Creation of VPC endpoints for API Gateway and the Amazon S3 service.
- Configuration of an internal-facing Application Load Balancer to connect to Global Accelerator.
- Assignment of a custom domain name for API Gateway with an ACM certificate attached.
- Deployment of a private API Gateway integrated with a Lambda function.
- The Lambda function is equipped with an AWS Identity and Access Management (IAM) role attached (with GetObject permissions).

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- Application Load Balancers distribute incoming application traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, in multiple Availability Zones.
- AWS Certificate Manager (ACM) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS Global Accelerator is a global service that supports endpoints in multiple AWS Regions. You can create accelerators that direct traffic to optimal endpoints over the AWS global network. This improves the availability and performance of your internet applications that are used by a global audience.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

- AWS PrivateLink helps you create unidirectional, private connections from your virtual private clouds (VPCs) to services outside of the VPC.
- Amazon Route 53 is a highly available and scalable DNS web service.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

You can deploy this pattern by using either the AWS CDK or Terraform based on your preference. The Epics section contains instructions for both deployment methods. The code for this pattern is available in the following GitHub repositories:

- **AWS CDK** – s3-presignedurl-staticips-endpoint-with-cdk
- **Terraform** – s3-presignedurl-staticips-endpoint-with-terraform

Best practices

- To enhance security in the production environment, it's crucial to implement authorization mechanisms, such as Amazon Cognito, to restrict access to the `PresignedUrl` generation API.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Prepare the environment

Task	Description	Skills required
Decide on a domain name.	Decide on a public domain name for the unified Amazon	AWS administrator, Network administrator

Task	Description	Skills required
	S3 endpoint. The domain name is also used as the Amazon S3 bucket name.	
Create a public hosted zone.	Create a public hosted zone in Amazon Route 53. Its domain name must match the domain name that's used in API Gateway.	AWS administrator, Network administrator
Prepare an SSL certificate.	Use AWS Certificate Manager (ACM) to request or import an SSL certificate for your web application domain.	AWS administrator, Network administrator

Deploy the pattern with Terraform

Task	Description	Skills required
Set up the Terraform development environment.	To set up the developme nt environment, do the following: 1. Install Terraform version 1.0 or later. 2. Clone the GitHub s3-presig nedurl-staticips-endpoint-with-terraform repository by running the following command in a terminal window: `git clone https://g ithub.com/aws-samp les/s3-presignedur`	AWS administrator, Cloud administrator

Task	Description	Skills required
	`l-staticips-endpoint-with-terraform.git`	

Task	Description	Skills required

Modify the `.tfvars` and `provider.tf` files.	1. **Create the required `.tfvars` files –** Create `apg.tfvars` files in both the `1.vpc_alb_ga` and `2.apigw_s3_lambda` directories. These files will contain your environment-specific variable values.
	• For `1.vpc_alb_ga/apg.tfvars`, create a file with the following template:
	`hcl`
	` environment_name = "test"`
	` domain = "your-domain.com"`
	` s3_bucket_prefix = "your-bucket-prefix"`
	` aws_region = "ap-northeast-2"`
	` # Change to your preferred region`
	• For `2.apigw_s3_lambda/apg.tfvars`, create a file with the following template (you'll need to update the `vpc_id` after completing step 1):
	`hcl`
	` vpc_id = "vpc-xxxxxxxxx"`
		AWS administrator, Cloud administrator

Task	Description	Skills required

	``
	# Update this with the VPC ID output from step 1
	environment_name = "test"
	domain = "your-domain.com"
	s3_bucket_prefix = "your-bucket-prefix"
	aws_region = "ap-northeast-2" # Change to your preferred region
	``
	2. **Modify the** `provider.tf` **files** – In both the `1.vpc_alb_ga` and `2.apigw_s3_lambda` folders, edit the `provider.tf` files to match your local AWS configuration:
	``
	hcl
	 provider "aws" {
	  region = "ap-northeast-2" # Change to your preferred region
	  profile = "apg" # Change to your AWS profile name
	}
	``
	Note the following:	

Task	Description	Skills required
	• Replace the placeholder values in the `.tfvars` files with your actual values. • After completing the first Terraform deployment (`1.vpc_alb_ga`), update the `vpc_id` value in `2.apigw_s3_lambda/apg.tfvars` with the VPC ID from the output. • Make sure that your AWS profile name in the `provider.tf` file matches an existing profile in your `~/.aws/credentials` file. • The domain value should match your Route 53 hosted zone domain. • The `s3_bucket_prefix` combined with domain will form your Amazon S3 bucket name (for example, `your-bucket-prefix.your-domain.com`). • If you change `aws_region`, you might also need to update the hardcoded availability zones in the `main.tf` files to match your chosen AWS Region.	

Task	Description	Skills required

Provision network resources.	To provision network resources, run the following commands:
	`cd ./2.vpc_alb_ga`
	`terraform init`
	`terraform plan --var-file=apg.tfvars`
	`terraform apply --var-file=apg.tfvars`
	During the `apply` command's execution, type **yes** when prompted.
		AWS administrator, Cloud administrator

Provision API Gateway, Amazon S3, and Lambda.	To provision network resources, use the following commands:
	`cd ./2.apigw_s3_lambda`
	`terraform init`
	`terraform plan --var-file=apg.tfvars`
	`terraform apply --var-file=apg.tfvars`
		AWS administrator, Cloud administrator

Deploy the pattern with AWS CDK

Task	Description	Skills required
Set up the AWS CDK development environment.	To set up the development environment, do the following: 1. Install the AWS CDK.	AWS administrator, Cloud administrator

Task	Description	Skills required
	2. Clone the GitHub [s3-presignedurl-staticips-endpoint-with-cdk](https://github.com/aws-samples/s3-presignedurl-staticips-endpoint-with-cdk) repository by running the following command in a terminal window: `git clone https://github.com/aws-samples/s3-presignedurl-staticips-endpoint-with-cdk.git`	

Task	Description	Skills required

Configure domain settings in the `config/index.ts` file.	To edit the options of the constant variable, use the following commands:
	
	`export const options = {`
	`    certificateArn: '{arn of the acm which created before}',`
	`    dnsAttr: {`
	`        zoneName: '{public hosted zone name}',`
	`        hostedZoneId: 'hosted zone Id',`
	`    },`
	`    domainNamePrefix: '{Prefix for the domain}',`
	`    presignPath: 'presign',`
	`    objectsPath: 'objects',`
	`};`
	
	In the commands, replace each placeholder with your own information:
	
	• Replace `'{arn of the acm which created before}'` with your ACM certificate Amazon Resource Name (ARN).
	• Replace `'{public hosted zone name}'` with your domain name.
		AWS administrator, Cloud administrator

Task	Description	Skills required
	• Replace `'hosted zone Id'` with your Route 53 hosted zone ID. • Replace `'{Prefix for the domain}'` with the domain prefix that you want to use. • Optionally, modify `'presign'` and `'objects'` paths if needed for your specific use case.	

Deploy the stacks.	To deploy two stacks, one for the virtual private cloud (VPC) and another for the application, use the following command:
	`$ npm install`
	`$ cdk synth`
	`$ cdk deploy --all`
		AWS administrator, Cloud administrator

Test the pattern

Task	Description	Skills required
Verify the IP addresses of the endpoint.	To verify that the domain for this pattern has static IP addresses, use the following command: `nslookup ${s3-bucket-prefix}.${domain}`	Network administrator

Task	Description	Skills required
Upload a test file that you can later download.	Upload the test file to the `'/objects'` folder in the Amazon S3 bucket.	AWS administrator, Cloud administrator
Invoke the API to generate a presigned URL.	To generate a presigned URL, call the URL from a browser or API client (for example, Postman) using the following format: `https://${s3-bucket-prefix}.${domain}/presign/objects/${uploaded-filename}` Replace the placeholder values in `${s3-bucket-prefix}` and `${domain}` with the values that you set in previous steps.	App owner
Check the result.	The expected result is that you should receive a 301 (Moved Permanently) redirect status code. This response will contain the presigned URL, which should automatically initiate the download of your test file.	Test engineer

Clean up with Terraform

Task	Description	Skills required
Destroy API Gateway, Amazon S3, and Lambda resources.	To delete resources, use the following commands: ```cd ./2.apigw_s3_lambda terraform init terraform plan --destroy --var-file=apg.tfvars terraform destroy --var-file=apg.tfvars```	AWS administrator, Cloud administrator
Destroy network resources.	To delete network resources, use the following commands: ```cd ./1.vpc_alb_ga terraform init terraform plan --destroy --var-file=apg.tfvars terraform destroy --var-file=apg.tfvars```	AWS administrator, Cloud administrator

Clean up with AWS CDK

Task	Description	Skills required
Destroy the stacks.	To destroy both the VPC and application stacks, use the following command: ```$ cdk destroy --all```	AWS administrator, Cloud administrator
Empty and delete the Amazon S3 buckets.	Empty and delete the object Amazon S3 bucket and the	AWS administrator, Cloud administrator

Task	Description	Skills required

	logs Amazon S3 bucket that are not deleted by default.
	
	The Amazon S3 bucket names are `${s3-bucket-prefix}.${domain}` and `${s3-bucket-prefix}.${domain}-logs` .
	
	If you prefer to use the [AWS Command Line Interface (AWS CLI)]() for deleting the buckets, use the following commands:
	
	`$ aws s3 rm s3://${s3-bucket-prefix}.${domain} --recursive`
	`$ aws s3 rb s3://${s3-bucket-prefix}.${domain} --force`
	`$ aws s3 rm s3://${s3-bucket-prefix}.${domain}-logs --recursive`
	`$ aws s3 rb s3://${s3-bucket-prefix}.${domain}-logs --force`
	
	Replace `${s3-bucket-prefix}` and `${domain}` with the values you set in previous steps.,/p>

Create a cross-account Amazon EventBridge connection in an organization

Sam Wilson and Robert Stone, Amazon Web Services

Summary

Large distributed systems use Amazon EventBridge to communicate changes in state between various Amazon Web Services (AWS) accounts in an AWS Organizations organization. However, EventBridge is generally able to target only endpoints or consumers in the same AWS account. The exception is an event bus in a different account. That event bus is a valid target. To consume events from an event bus in another account, the events must be pushed from the source account's event bus to the destination account’s event bus. To avoid challenges when managing critical events across applications within different AWS accounts, use the recommended approach presented in this pattern.

This pattern illustrates how to implement an event-driven architecture with EventBridge that involves multiple AWS accounts in an AWS Organizations organization. The pattern uses AWS Cloud Development Kit (AWS CDK) Toolkit and AWS CloudFormation.

EventBridge offers a serverless event bus that helps you receive, filter, transform, route, and deliver events. A critical component of event-driven architectures, EventBridge supports separation between producers of messages and consumers of those messages. In a single account, this is straight forward. A multi-account structure requires additional considerations for events on the event bus in one account to be consumed in other accounts within the same organization.

For information about account-specific considerations for producers and consumers, see the Additional information section.

Prerequisites and limitations

Prerequisites

- An AWS Organizations organization with at least two associated AWS accounts
- An AWS Identity and Access Management (IAM) role in both AWS accounts that allows you to provision infrastructure in both AWS accounts by using AWS CloudFormation
- Git installed locally
- AWS Command Line Interface (AWS CLI) installed locally
- AWS CDK installed locally and bootstrapped in both AWS accounts

Product versions

This pattern has been built and tested by using the following tools and versions:

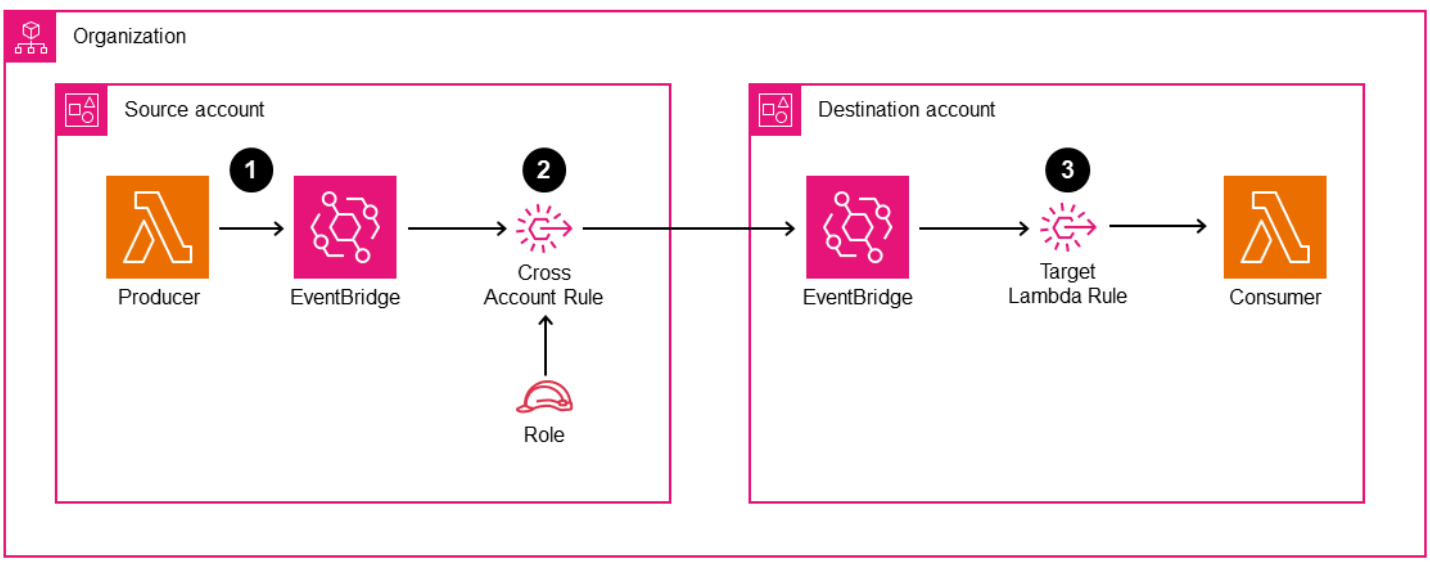
- AWS CDK Toolkit 2.126.0
- Node.js 18.19.0
- npm 10.2.3
- Python 3.12

This pattern should work with any version of AWS CDK v2 or npm. Node.js versions 13.0.0 through 13.6.0 are not compatible with AWS CDK.

Architecture

Target architecture

The following diagram shows the architecture workflow for pushing an event from one account and consuming it in another account.



The workflow contains the following steps:

1. The Producer AWS Lambda function in the Source account puts an event on the account's EventBridge event bus.
2. The cross-account EventBridge rule routes the event to an EventBridge event bus in the Destination account.

3. The EventBridge event bus in the Destination account has a target Lambda rule that invokes the Consumer Lambda function.

A best practice is to use a Dead Letter Queue (DLQ) for handling failed invocations of the Consumer Lambda function. However, the DLQ was omitted from this solution for clarity. To learn more about how to implement a DLQ in your workflows and improve your workflows' ability to recover from failures, see the Implementing AWS Lambda error handling patterns blog post.

Automation and scale

AWS CDK automatically provisions the required architecture. EventBridge can scale to thousands of records per second depending on the AWS Region. For more information, see the Amazon EventBridge quotas documentation.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code. This pattern uses the AWS CDK Toolkit, a command line cloud development kit that helps you interact with your AWS CDK app.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

Other tools

- Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub cross-account-eventbridge-in-organization repository.

Best practices

For best practices when working with EventBridge, see the following resources:

- Best practices when defining rules in Amazon EventBridge

Epics

Prepare your local AWS CDK deployment environment

Task	Description	Skills required
Configure local credentials for the Source account and Destination account.	Review Setting up new configuration and credentials, and use the authentication and credential method that makes the most sense to your environment. **Important** Be sure to configure the AWS CLI for both Source account and Destination account authentication. These instructions assume that you have configured two AWS profiles locally:	App developer

Task	Description	Skills required
	`sourceAccount` and `destinationAccount` .	

Bootstrap both AWS accounts.	To bootstrap the accounts, run the following commands:
	`cdk bootstrap --profile sourceAccount`
	`cdk bootstrap --profile destinationAccount`
		App developer

Clone the pattern code.	To clone the repository, run the following command:
	`git clone git@github.com:aws-samples/aws-cdk-examples.git`
	Then, change the directory to the newly cloned project folder:
	`cd aws-cdk-examples/python/cross-account-eventbridge-in-organization`
		App developer

Deploy ProducerStack to the Source account

Task	Description	Skills required
Modify `cdk.json` with your AWS Organizations and account details.	In the root folder of the project, make the following changes to `cdk.json`:	App developer

Task	Description	Skills required
	• `organization_id` – The Organizations ID of the accounts involved in your deployment • `event_bus_name` – `CrossAccount`, or you can rename it • `rules[].targets[].arn` – The AWS account ID of the consuming account (Destination account)	
Deploy the ProducerStack resources.	Run the following command from the project's root directory: `cdk deploy ProducerStack --profile sourceAccount` When prompted, accept the new IAM roles and other security-related permissions created through AWS CloudFormation.	App developer

Task	Description	Skills required
Verify that ProducerStack resources are deployed.	To verify the resources, do the following: 1. On the AWS Management Console for the Source account, choose **CloudFormation**. 2. From the list of stacks, choose **ProducerStack**. 3. On the **Stack Info** tab, verify that the stack status is `CREATE_COMPLETE` . Optionally, on the **Resources** tab, review the configured resources.	App developer

Deploy ConsumerStack to the Destination account

Task	Description	Skills required
Deploy the ConsumerStack resources.	Run the following command from the project's root directory: `cdk deploy ConsumerStack --profile destinationAccount` When prompted, accept the new IAM roles and other security-related permissions created through AWS CloudFormation.	App developer

Task	Description	Skills required
Verify that ConsumerStack resources are deployed	1. On the console for the Destination account, choose **CloudFormation**. 2. From the list of stacks, choose **ConsumerStack**. 3. On the **Stack Info** tab, verify that the stack status is `CREATE_COMPLETE` . Optionally, on the **Resources** tab, review the configured resources.	App developer

Produce and consume events

Task	Description	Skills required
Invoke the Producer Lambda function.	1. On the console for the Source account, choose **Lambda**. 2. From the list of functions , choose **ProducerStack-ProducerLambdaXXXX** (XXXX represents a sequence of characters automatically generated by AWS CDK). 3. Choose the **Test** tab. 4. In the **Test event** section, choose **Test**. The Event JSON text area content can be any valid JSON that is provided to	App developer

Task	Description	Skills required
	the Lambda function as the payload. In this case, the default provided JSON is sufficient. 5. Verify that the **Executing function: succeeded** message appears in a green banner above the **Test event** section.	

Task	Description	Skills required
Verify that the event was received.	1. On the console for the Destination account, choose **Lambda**. 2. From the list of functions, choose **ConsumerStack-ConsumerLambdaXXXX** (XXXX represents a sequence of characters automatically generated by AWS CDK). 3. Choose the **Monitor** tab. 4. In the **Monitor** section, choose **View CloudWatch logs**. 5. In the newly opened tab, choose the log stream name of the most recent log stream. 6. Verify that a log statement such as the following appears: `[DEBUG] 2024-04-08T19:08:10.091Z 9c16844a-f9de-444d-b621-86afe64d4cc8 Event: {'version':'0', 'id':'0b9faa96-973f-8be2-ecf8-75e4f328b980', 'detail-type':'TestType', 'source':'Producer', 'account'`	App developer

Task	Description	Skills required
	`:'XXXXXXXXXXXX', 'time':'2024-04-08T19:08:09Z', 'region':'us-east-1', 'resources': [], 'detail': {'key1':'value1', 'key2':'value2', 'key3':'value3'}}`	

Cleanup

Task	Description	Skills required
Destroy the ConsumerStack resources.	If you are using this pattern as a test, clean up the deployed resources to avoid incurring additional costs. Run the following command from the project's root directory: `cdk destroy ConsumerStack --profile destinationAccount` You will be prompted to confirm deletion of the stack.	App developer
Destroy the ProducerStack resources.	Run the following command from the project's root directory:	App developer

Task	Description	Skills required
	`cdk destroy ProducerStack --profile sourceAccount` You will be prompted to confirm deletion of the stack.	

Troubleshooting

Issue	Solution
No event was received in the Destination account.	1. Verify that the provided Organizations ID is correct. 2. Verify that the Source account is part of the provided organization. 3. Verify that the event bus rules in the Source account map to the correct information in the Destination account.
Invoking a Lambda function from the console returns the following error:: `User: arn:aws:iam::123456789012:user/XXXXX is not authorized to perform: lambda:Invoke`	Contact your AWS account administrator to receive the appropriate `lambda:Invoke` action permissions on the `ProducerStack-ProducerLambdaXXXX` Lambda function.

Additional information

Producer rule

In the Source account, an EventBridge event bus is created to accept messages from producers (as shown in the *Architecture* section). A rule with accompanying IAM permissions is created on this event bus. The rules target the EventBridge event bus in the Destination account based on the following `cdk.json` structure:

```
"rules": [
  {
    "id": "CrossAccount",
    "sources": ["Producer"],
    "detail_types": ["TestType"],
    "targets": [
      {
        "id": "ConsumerEventBus",
        "arn": "arn:aws:events:us-east-2:012345678901:event-bus/CrossAccount"
      }
    ]
  }
]
```

For each consuming event bus, the event pattern and the target event bus must be included.

Event Pattern

Event patterns filter which events this rule will apply to. For purposes of this example, the event sources and the record `detail_types` identify which events to transmit from the Source account's event bus to the Destination account's event bus.

Target event bus

This rule targets an event bus that exists in another account. The full `arn` (Amazon Resource Name) is needed to uniquely identify the target event bus, and the `id` is the logical ID used by AWS CloudFormation. The target event bus need not actually exist at the time of target rule creation.

Destination account-specific considerations

In the Destination account, an EventBridge event bus is created to receive messages from the Source account's event bus. To allow events to be published from the Source account, you must create a resource-based policy:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "AllowOrgToPutEvents",
    "Effect": "Allow",
    "Principal": "*",
    "Action": "events:PutEvents",
    "Resource": "arn:aws:events:us-east-2:012345678901:event-bus/CrossAccount",
    "Condition": {
      "StringEquals": {
        "aws:PrincipalOrgID": "o-XXXXXXXXX"
      }
    }
  }]
}
```

It's especially important to grant the `events:PutEvents` permission, which allows any other account in the same organization to publish events to this event bus. Setting `aws:PrincipalOrgId` as the organization ID grants the needed permissions.

Event pattern

You can modify the included event pattern to meet your use case:

```
rule = events.Rule(
    self,
    self.id + 'Rule' + rule_definition['id'],
    event_bus=event_bus,
    event_pattern=events.EventPattern(
        source=rule_definition['sources'],
        detail_type=rule_definition['detail_types'],
    )
)
```

To reduce unnecessary processing, the event pattern should specify that only events to be processed by the Destination account are transmitted to the Destination account's event bus.

Resource-based policy

This example uses the organization ID to control which accounts are allowed to put events on the Destination account's event bus. Consider using a more restrictive policy, such as specifying the Source account.

EventBridge quotas

Keep in mind the following quotas:

- 300 rules per event bus is the default quota. This can be expanded if necessary, but it should fit most use cases.
- Five targets per rule is the maximum allowed. We recommend that application architects should use a distinct rule for each Destination account to support fine-grained control over the event pattern.

Deliver DynamoDB records to Amazon S3 using Kinesis Data Streams and Firehose with AWS CDK

Shashank Shrivastava and Daniel Matuki da Cunha, Amazon Web Services

Summary

This pattern provides sample code and an application for delivering records from Amazon DynamoDB to Amazon Simple Storage Service (Amazon S3) by using Amazon Kinesis Data Streams and Amazon Data Firehose. The pattern's approach uses AWS Cloud Development Kit (AWS CDK) L3 constructs and includes an example of how to perform data transformation with AWS Lambda before data is delivered to the target S3 bucket on the Amazon Web Services (AWS) Cloud.

Kinesis Data Streams records item-level modifications in DynamoDB tables and replicates them to the required Kinesis data stream. Your applications can access the Kinesis data stream and view the item-level changes in near-real time. Kinesis Data Streams also provides access to other Amazon Kinesis services, such as Firehose and Amazon Managed Service for Apache Flink. This means that you can build applications that provide real-time dashboards, generate alerts, implement dynamic pricing and advertising, and perform sophisticated data analysis.

You can use this pattern for your data integration use cases. For example, transportation vehicles or industrial equipment can send high volumes of data to a DynamoDB table. This data can then be transformed and stored in a data lake hosted in Amazon S3. You can then query and process the data and predict any potential defects by using serverless services such as Amazon Athena, Amazon Redshift Spectrum, Amazon Rekognition, and AWS Glue.

Prerequisites and limitations

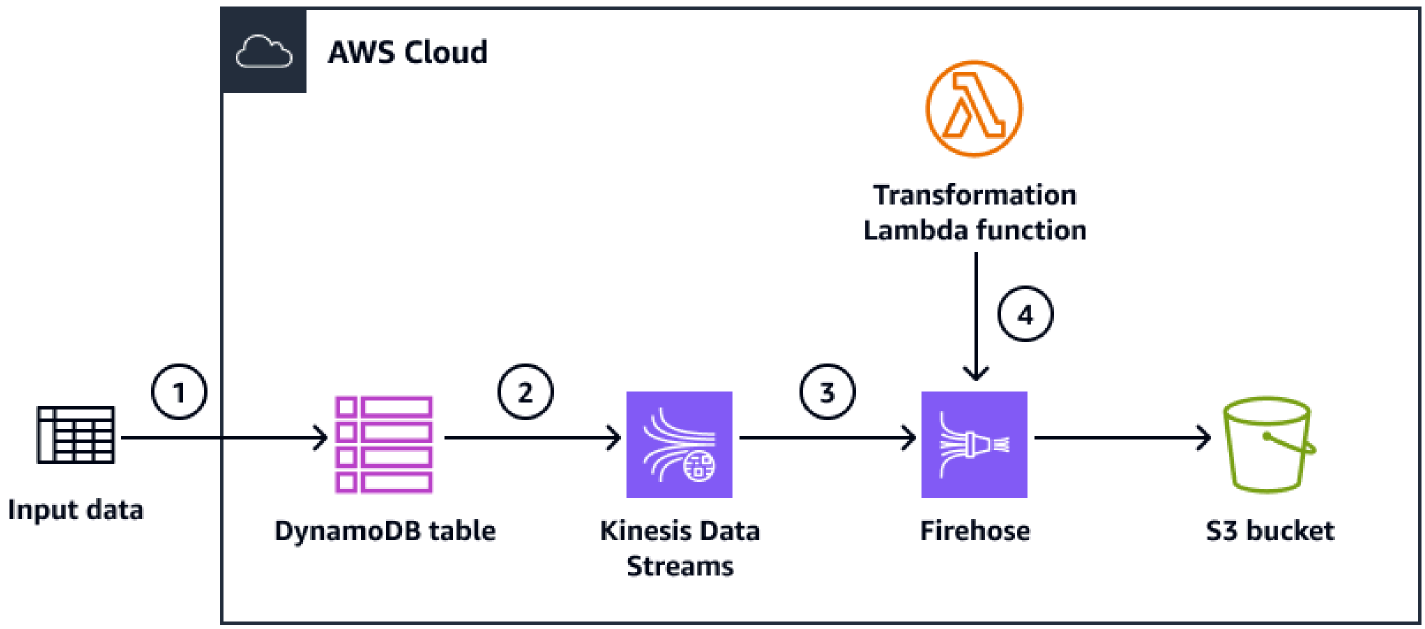
Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information, see Getting started with the AWS CLI in the AWS CLI documentation.
- Node.js (18.x+) and npm, installed and configured. For more information, see Downloading and installing Node.js and npm in the npm documentation.
- aws-cdk (2.x+), installed and configured. For more information, see Getting started with the AWS CDK in the AWS CDK documentation.

- The GitHub aws-dynamodb-kinesisfirehose-s3-ingestion repository, cloned and configured on your local machine.
- Existing sample data for the DynamoDB table. The data must use the following format: `{"SourceDataId": {"S": "123"},"MessageData":{"S": "Hello World"}}`

Architecture

The following diagram shows an example workflow for delivering records from DynamoDB to Amazon S3 by using Kinesis Data Streams and Firehose.



The diagram shows the following workflow:

1. Data is ingested using Amazon API Gateway as a proxy for DynamoDB. You can also use any other source to ingest data into DynamoDB.
2. Item-level changes are generated in near-real time in Kinesis Data Streams for delivery to Amazon S3.
3. Kinesis Data Streams sends the records to Firehose for transformation and delivery.
4. A Lambda function converts the records from a DynamoDB record format to JSON format, which contains only the record item attribute names and values.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CDK Toolkit is a command line cloud development kit that helps you interact with your AWS CDK app.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.

Code repository

The code for this pattern is available in the GitHub aws-dynamodb-kinesisfirehose-s3-ingestion repository.

Epics

Set up and configure the sample code

Task	Description	Skills required
Install the dependencies.	On your local machine, install the dependencies from the `package.json` files in the `pattern/aws-dynamodb-kinesisstreams-s3` and `sample-application` directories by running the following commands: `cd <project_root>/pattern/aws-dynamodb-kinesisstreams-s3`	App developer, General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

```
npm install && npm run
 build
```

```
cd <project_root>/sam
ple-application/
```

```
npm install && npm run
 build
```

</td><td></td></tr>
<tr><td>Generate the CloudFormation template.</td><td>1. Run the <code>cd <project_root>/sample-application/</code> command.
2. Run the <code>cdk synth</code> command to generate the CloudFormation template.
3. The <code>AwsDynamodbKinesisfirehoseS3IngestionStack.template.json</code> output is stored in the <code>cdk.out</code> directory.
4. Use AWS CDK or the AWS Management Console to process the template in CloudFormation.</td><td>App developer, General AWS, AWS DevOps</td></tr>
</table>

Deploy the resources

Task	Description	Skills required
Check and deploy the resources.	1. Run the `cdk diff` command to identify the resource types that are created by the AWS CDK construct. 2. Run the `cdk deploy` command to deploy the resources.	App developer, General AWS, AWS DevOps

Ingest data into the DynamoDB table to test the solution

Task	Description	Skills required

Ingest your sample data into the DynamoDB table.	Send a request to your DynamoDB table by running the following command in AWS CLI:
	`aws dynamodb put-item --table-name <your_table_name> --item '{"<table_partition_key>":{"S": "<partition_key_ID>"},"MessageData":{"S": "<data>"}}'`
	example:
	`aws dynamodb put-item --table-name SourceData_table`
		App developer

Task	Description	Skills required
	`--item '{"SourceDataId": {"S": "123"},"MessageData":{"S": "Hello World"}}'` By default, the `put-item` doesn't return any value as output if the operation succeeds. If the operation fails, it returns an error. The data is stored in DynamoDB and then sent to Kinesis Data Streams and Firehose. **Note** You use different approaches to add data into a DynamoDB table. For more information, see Load data into tables in the DynamoDB documentation.	

Task	Description	Skills required
Verify that a new object is created in the S3 bucket.	Sign in to the AWS Management Console and monitor the S3 bucket to verify that a new object was created with the data that you sent. For more information, see GetObject in the Amazon S3 documentation.	App developer, General AWS

Clean up resources

Task	Description	Skills required
Clean up resources.	Run the `cdk destroy` command to delete all the resources used by this pattern.	App developer, General AWS

Implement path-based API versioning by using custom domains in Amazon API Gateway

Corey Schnedl, Marcelo Barbosa, Mario Lopez Martinez, Anbazhagan Ponnuswamy, Gaurav Samudra, and Abhilash Vinod, Amazon Web Services

Summary

This pattern demonstrates how you can use the API mappings feature of custom domains to implement a path-based API versioning solution for Amazon API Gateway.

Amazon API Gateway is a fully managed service that you can use to create, publish, maintain, monitor, and secure APIs at any scale. By using the service's custom domain feature, you can create custom domain names that are simpler with more intuitive URLs that you can provide to your API users. You can use API mappings to connect API stages to a custom domain name. After you create a domain name and configure DNS records, you use API mappings to send traffic to your APIs through your custom domain name.

After an API becomes publicly available, consumers use it. As a public API evolves, its service contract also evolves to reflect new features and capabilities. However, it's unwise to change or remove existing features. Any breaking changes might impact the consumer's applications and break them at runtime. API versioning is important to avoid breaking backward compatibility and breaking a contract.

You need a clear strategy for API versioning to help consumers adopt them. Versioning APIs by using path-based URLs is the most straightforward and commonly used approach. In this type of versioning, versions are explicitly defined as part of API URIs. The following example URLs show how a consumer can use the URI to specify an API version for their request:

`https://api.example.com/api/v1/orders`

`https://api.example.com/api/v2/orders`

`https://api.example.com/api/vX/orders`

This pattern uses the AWS Cloud Development Kit (AWS CDK) to build, deploy, and test a sample implementation of a scalable path-based versioning solution for your API. AWS CDK is an open source software development framework to model and provision your cloud application resources using familiar programming languages.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Ownership of a domain is required to use this pattern's sample repository and to use Amazon API Gateway custom domain functionality. You can use Amazon Route 53 to create and manage your domains for your organization. For information about how to register or transfer a domain with Route 53, see Registering new domains in the Route 53 documentation.
- Before setting up a custom domain name for an API, you must have an SSL/TLS certificate ready in AWS Certificate Manager.
- You must create or update your DNS provider's resource record to map to your API endpoint. Without such a mapping, API requests bound for the custom domain name can't reach API Gateway.

Limitations

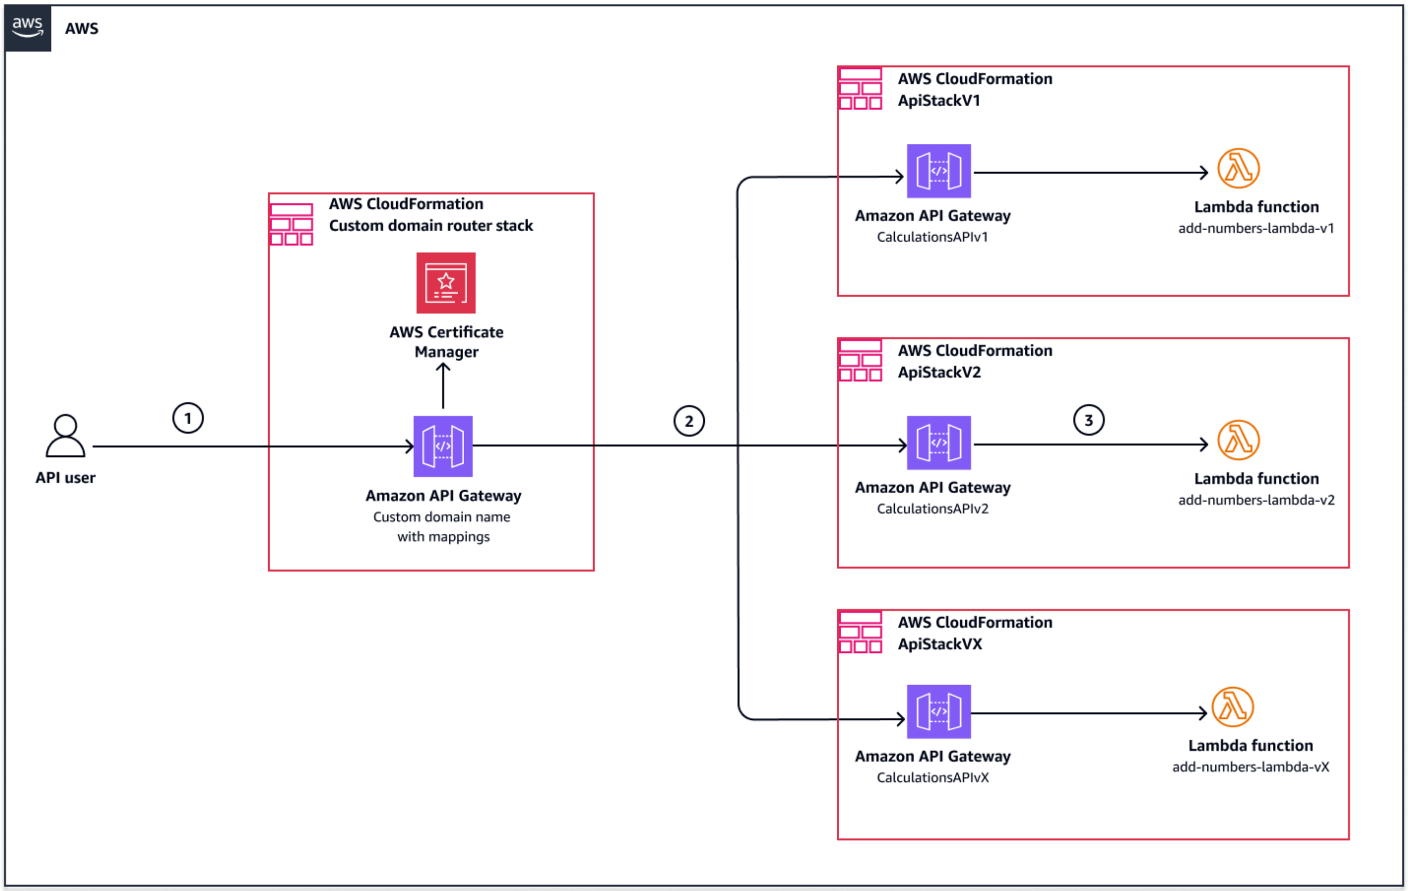
- Custom domain names are not supported for private APIs.
- A custom domain name must be unique within an AWS Region across all AWS accounts.
- To configure API mappings with multiple levels, you must use a Regional custom domain name and use the TLS 1.2 security policy.
- In an API mapping, the custom domain name and mapped APIs must be in the same AWS account.
- API mappings must contain only letters, numbers, and the following characters: `$-_.+!*'()/`
- The maximum length for the path in an API mapping is 300 characters.
- You can have 200 API mappings with multiple levels for each domain name.
- You can only map HTTP APIs to a Regional custom domain name with the TLS 1.2 security policy.
- You can't map WebSocket APIs to the same custom domain name as an HTTP API or REST API.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- This sample implementation uses AWS CDK in TypeScript version 2.149.0.

Architecture

The following diagram shows the architecture workflow.



The diagram illustrates the following:

1. The API user sends a request to Amazon API Gateway with a custom domain name.
2. API Gateway dynamically routes the user's request to an appropriate instance and stage of API Gateway, based on the path indicated in the URL of the request. The following table shows an example of how the different URL-based paths can be routed to specific stages for different instances of API Gateway.

API	Stage	Path	Default endpoint
CalculationAPIv1	api	apiv1	Enabled
CalculationAPIv2	api	apiv2	Enabled

CalculationAPIvX	api	apivX	Enabled

3. The destination API Gateway instance processes the request and returns the result to the user.

Automation and scale

We recommend that you use separate AWS CloudFormation stacks for each version of your API. With this approach, you can have complete isolation between the backend APIs that can be routed to by the custom domain API mapping feature. An advantage of this approach is that different versions of your API can be deployed or removed independently without introducing the risk of modifying another API. This approach increases resilience through isolation of CloudFormation stacks. Also, it provides you with different back-end options for your API such as AWS Lambda, AWS Fargate, HTTP endpoints, and actions of AWS services.

You can use Git branching strategies, such as Gitflow, in combination with isolated CloudFormation stacks to manage the source code that's deployed to different versions of the API. By using this option, you can maintain different versions of your API without the need to duplicate the source code for new versions. With Gitflow, you can add tags to commits within your git repository as releases are performed. As a result, you have a complete snapshot of the source code related to a specific release. As updates need to be performed, you can check out the code from a specific release, make updates, and then deploy the updated source code to the CloudFormation stack that aligns with the corresponding major version. This approach reduces the risk of breaking another API version because each version of the API has isolated source code and is deployed to separate CloudFormation stacks.

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- AWS Certificate Manager (ACM) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- AWS Cloud Development Kit (AWS CDK) is an open-source software development framework for defining your cloud infrastructure in code and provisioning it through AWS CloudFormation. This pattern's sample implementation uses the AWS CDK in TypeScript. Working with the AWS CDK in TypeScript uses familiar tools, including the Microsoft TypeScript compiler (`tsc`), Node.js, and the node package manager (`npm`). If you prefer, you can use Yarn although the examples in this

pattern use `npm`. The modules that comprise the AWS Construct Library are distributed through the `npm` repository, npmjs.org.

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Route 53 is a highly available and scalable DNS web service.
- AWS WAF is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources.

Other tools

- Bruno is an open source, git-friendly API testing client.
- cdk-nag is an open source utility that checks AWS CDK applications for best practices by using rule packs.

Code repository

The code for this pattern is available in the GitHub path-based-versioning-with-api-gateway repository.

Best practices

- Use a robust continuous integration and continuous delivery (CI/CD) pipeline to automate the testing and deployment of your CloudFormation stacks that are built with the AWS CDK. For more information related to this recommendation, see the AWS Well-Architected DevOps Guidance.
- AWS WAF is a managed firewall that easily integrates with services like Amazon API Gateway. Although AWS WAF isn't a necessary component for this versioning pattern to work, we recommend as a security best practice to include AWS WAF with API Gateway.
- Encourage API consumers to upgrade regularly to the latest version of your API so that older versions of your API can be deprecated and removed efficiently.
- Before using this approach in a production setting, implement a firewall and authorization strategy for your API.

- Implement access to the management of AWS resources of your AWS account by using the [least-privilege access model].
- To enforce best practices and security recommendations for applications built with the AWS CDK, we recommend that you use the [cdk-nag utility].

Epics

Prepare your local environment

Task	Description	Skills required
Clone the repository.	To clone the sample applicati on repository, run the following command: `git clone https://github.com/aws-samples/path-based-versioning-with-api-gateway`	App developer
Navigate to the cloned repository.	To navigate to the cloned repository folder location, run the following command: `cd api-gateway-custom-domain-versioning`	App developer
Install the required dependencies.	To install the required dependencies, run the following command: `npm install`	App developer

Deploy the CloudFormation routing stack

Task	Description	Skills required
Initiate deployment of the routing stack.	To initiate the deployment of the CloudFormation routing stack `CustomDomainRouterStack`, run the following command, replacing `example.com` with the name of the domain that you own: `npx cdk deploy CustomDomainRouterStack --parameters PrerequisiteDomainName=example.com` **Note** The stack deployment will not succeed until the following domain DNS validation task is performed successfully.	App developer

Verify domain ownership

Task	Description	Skills required
Verify ownership of your domain.	The certificate will remain in a **Pending validation** status until you prove ownership of the associated domain.	App developer, AWS systems administrator, Network administrator

Task	Description	Skills required
	To prove ownership, add CNAME records to the hosted zone that is associated with the domain. For more information, see [DNS validation](#) in the AWS Certificate Manager documentation. Adding the appropriate records enables the `CustomDomainRouterStack` deployment to succeed.	

Task	Description	Skills required
Create an alias record to point to your API Gateway custom domain.	After the certificate is issued and validated successfully, [create a DNS record](#) that points to your Amazon API Gateway custom domain URL. The custom domain URL is uniquely generated by the provisioning of the custom domain and is specified as a CloudFormation output parameter. Following is an [example of the record](#): **Routing policy**: Simple routing **Record name**: `demo.api-gateway-custom-domain-versioning.example.com` **Alias**: Yes **Record type**: A DNS record of type "A" that points to an AWS resource **Value**: `d-xxxxxxxxxx.execute-api.xx-xxxx-x.amazonaws.com` **TTL (seconds)**: 300	App developer, AWS systems administrator, Network administrator

Deploy CloudFormation stacks and invoke the API

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Deploy the <code>ApiStackV1</code> stack.</td><td>To deploy the <code>ApiStackV1</code> stack, use the following command:
<pre><code>npm run deploy-v1</code></pre>
The following CDK code adds API mapping:
<pre><code>var apiMapping = new
 CfnApiMapping(this,
 "ApiMapping", {
      apiId: this.lamb
daRestApi.restApiId,
      domainName:
 props.customDomain
Name.domainName,
      stage: "api",
      apiMappingKey:
 "api/v1",
    });</code></pre></td><td>App developer</td></tr>
<tr><td>Deploy the <code>ApiStackV2</code> stack.</td><td>To deploy the <code>ApiStackV2</code> stack, use the following command:
<pre><code>npm run deploy-v2</code></pre></td><td>App developer</td></tr>
<tr><td>Invoke the API.</td><td>To invoke the API and test the API endpoints by using Bruno, see the instructions in Additional information.</td><td>App developer</td></tr>
</table>

Clean up resources

Task	Description	Skills required
Clean up resources.	To destroy the resources associated with this sample application, use the following command: `npx cdk destroy --all` **Note** Make sure that you clean up any Route 53 DNS records that were added manually for the domain ownership verification process.	App developer

Troubleshooting

Issue	Solution
The deployment of `CustomDomainRouterStack` times out because the certificate can't be validated.	Make sure that you added the proper DNS validation CNAME records as described in the earlier task. Your new certificate might continue to display a status of **Pending validation** for up to 30 minutes after adding the DNS validation records. For more information, see DNS validation in the AWS Certificate Manager documentation.

- Implementing header-based API Gateway versioning with Amazon CloudFront – This AWS Compute Blog post offers a header-based versioning strategy as an alternative to the path-based versioning strategy outlined in this pattern.
- AWS CDK Workshop – This introductory workshop focuses on building and deploying applications on AWS by using the AWS Cloud Development Kit (AWS CDK). This workshop supports Go, Python, and TypeScript.

Additional information

Testing your API with Bruno

We recommend that you use Bruno, an open source API testing tool, to verify that the path-based routing is working properly for the sample application. This pattern provides a sample collection to facilitate testing your sample API.

To invoke and test your API, use the following steps:

1. Install Bruno.
2. Open Bruno.
3. In this pattern's code repository, select **Bruno/Sample-API-Gateway-Custom-Domain-Versioning** and open the collection.
4. To see the **Environments** dropdown in the top right of the user interface (UI), select any request in the collection.
5. In the **Environments** dropdown, select **Configure**.
6. Replace the `REPLACE_ME_WITH_YOUR_DOMAIN` value with your custom domain.
7. Choose **Save**, and then close the **Configuration** section.
8. For **Sandbox Environment**, verify that the **Active** option is selected.
9. Invoke your API by using the **->** button for the selected request.
10. Take note on how validation (passing in non-number values) is handled in V1 compared to V2.

To see screenshots of example API invocation and comparison of V1 and V2 validation, see **Testing your sample API** in the `README.md` file in this pattern's code repository.

Import the psycopg2 library to AWS Lambda to interact with your PostgreSQL database

Louis Hourcade, Amazon Web Services

Summary

[Psycopg](https://) is a PostgresSQL database adapter for Python. Developers use the `psycopg2` library to write Python applications that interact with PostgreSQL databases.

On Amazon Web Services (AWS), developers also use AWS Lambda to run code for applications or backend services. Lambda is a serverless, event-driven compute service runs code without the need to provision or manage servers.

By default, when you create a new function that uses a Python runtime (version 3.9, 3.8, or 3.7), the Lambda runtime environment is created from a base image for Lambda provided by AWS. Libraries, such as `pandas` or `psycopg2`, aren't included in the base image. To use a library, you need to bundle it in a custom package and attach it to Lambda.

There are multiple ways to bundle and attach a library, including the following:

- Deploy your Lambda function from a .zip file archive.
- Deploy your Lambda function from a custom container image.
- Create a Lambda layer, and attach it to your Lambda function.

This pattern demonstrates the first two options.

With a .zip deployment package, adding the `pandas` library to your Lambda function is relatively straightforward. Create a folder on your Linux machine, add the Lambda script together with the `pandas` library and the library's dependencies to the folder, zip the folder, and provide it as a source for your Lambda function.

Although using a .zip deployment package is a common practice, that approach doesn't work for the `psycopg2` library. This pattern first shows the error that you get if you use a .zip deployment package to add the `psycopg2` library to your Lambda function. The pattern then shows how to deploy Lambda from a Dockerfile and edit the Lambda image to make the `psycopg2` library work.

For information about the three resources that the pattern deploys, see the Additional information section.

Prerequisites and limitations

Prerequisites

- An active AWS account with sufficient permissions to deploy the AWS resources used by this pattern
- AWS Cloud Development Kit (AWS CDK) installed globally by running `npm install -g aws-cdk`
- A Git client
- Python
- Docker

Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Product versions

- AWS Lambda runtime version: Python 3.8 (The pattern can be adapted for other Python versions.)
- Psycopg2 version 2.9.3
- Pandas version 1.5.2

Architecture

Solution overview

To illustrate the challenges that you might face when using the `psycopg2` library in Lambda, the pattern deploys two Lambda functions:

- One Lambda function with the Python 3.8 runtime created from a .zip file. The `psycopg2` and `pandas` libraries are installed in this .zip deployment package by using pip.
- One Lambda function with the Python 3.8 runtime created from a Dockerfile. The Dockerfile installs the `psycopg2` and `pandas` libraries into the Lambda container image.

The first Lambda function installs the `pandas` library and its dependencies in a .zip file, and Lambda can use that library.

The second Lambda function demonstrates that by building a container image for your Lambda function, you can run the `pandas` and `psycopg2` libraries in Lambda.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- pandas is a Python-based open source tool for data analysis and manipulation.
- Psycopg is a PostgreSQL database adapter for the Python language that is designed for multithreaded applications. This pattern uses Psycopg 2.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the import-psycopg2-in-lambda-to-interact-with-postgres-database repository on GitHub.

Best practices

This pattern provides you with a working example of using AWS CDK to create a Lambda function from a Dockerfile. If you reuse this code in your application, make sure that the deployed resources meet all security requirements. Use tools such as Checkov, which scans cloud infrastructure configurations to find misconfiguration before the infrastructure is deployed.

Epics

Clone the repository and configure the deployment

Task	Description	Skills required

Clone the repository.	To clone the GitHub repository on your local machine, run the following commands:
	```git clone https://github.com/aws-samples/import-psycopg2-in-lambda-to-interact-with-postgres-database.git```
	```cd AWS-lambda-psycopg2```
		General AWS

Configure your deployment.	Edit the `app.py` file with information about your AWS account:
	```aws_acccount = "AWS_ACCOUNT_ID"```
	```region = "AWS_REGION"```
	```# Select the CPU architecture you are using to build the image (ARM or X86)```
	```architecture = "ARM"```
		General AWS

Bootstrap your AWS account and deploy the application

Task	Description	Skills required
Bootstrap your AWS account.	If you haven't already [bootstrapped your AWS environment](), run the	General AWS

Task	Description	Skills required
	following commands with the AWS credentials of your AWS account: `cdk bootstrap aws://<tooling-account-id>/<aws-region>`	
Deploy the code.	To deploy the AWS CDK application, run the following command: `cdk deploy AWSLambdaPyscopg2`	General AWS

Test the Lambda functions from the AWS Management Console

Task	Description	Skills required
Test the Lambda function created from the .zip file.	To test the Lambda function that was created from the .zip file, do the following: 1. Sign in to the console, and open the Lambda console at https://console.aws.amazon.com/lambda/. 2. Select the `lambda-from-zip` Lambda function. 3. Create a test event to invoke the function. 4. When invoked, the function should raise an	General AWS

Task	Description	Skills required
	error that includes the following message: ```"errorMessage": Unable to import module 'lambda_code': libpq.so.5: cannot open shared object, "stackTrace": [] "errorType": Runtime.ImportModuleError",``` 5. Open the Amazon CloudWatch console at https://console.aws.amazon.com/cloudwatch/. The CloudWatch logs show that the `pandas` library has been imported successfully but that the `psycopg2` library import has failed. Because Lambda doesn't find the required PostgreSQL libraries in the default image, it can't use the `psycopg2` library.	

Task	Description	Skills required

Test the Lambda function created from the Dockerfile.	To use the `psycopg2` library within your Lambda function, you must edit the Lambda Amazon Machine Image (AMI).
	
	To test the Lambda function that was created from the Dockerfile, do the following:
	
	1. Sign in to the console, and open the Lambda console.
	2. Select the `lambda-from-docker` Lambda function.
	3. Create a test event to invoke the function.
	4. When invoked, the function should run successfully.
	
	The following code shows the Dockerfile that the AWS CDK template creates:
	
	`# Start from lambda Python3.8 image`
	`FROM public.ecr.aws/lambda/python:3.8`
	
	`# Copy the lambda code, together with its requirements`
	`COPY lambda/requirements.txt ${LAMBDA_TASK_ROOT}`
		General AWS

Task	Description	Skills required

	``
	COPY lambda/lambda_code
	.py ${LAMBDA_TASK_ROOT
	}
	
	# Install postgresql-
	devel in your image
	RUN yum install -y gcc
	 postgresql-devel
	
	# install the requireme
	nts for the Lambda code
	RUN pip3 install -r
	 requirements.txt
	 --target "${LAMBDA
	_TASK_ROOT}"
	
	# Command can be
	 overwritten by
	 providing a different
	 command in the template
	 directly.
	CMD ["lambda_code.hand
	ler"]
	``
	
	The Dockerfile takes the AWS provided Lambda image for the Python 3.8 runtime and installs postgresql-devel, which contains the libraries needed to compile applicati ons that directly interact with the PostgreSQL managemen t server. The Dockerfile also installs the `pandas` and `psycopg2` libraries, which are indicated in the `requireme nts.txt` file.	

Related resources

- [AWS CDK documentation]
- [AWS Lambda documentation]

Additional information

In this pattern, the AWS CDK template provides an AWS stack with three resources:

- An [AWS Identity and Access Management (IAM) role] for the Lambda functions.
- A Lambda function with a Python 3.8 runtime. The function is deployed from the `Constructs/lambda/lambda_deploy.zip` deployment package.
- A Lambda function with a Python 3.8 runtime. The function is deployed from the Dockerfile under the `Constructs` folder

The script for both Lambda functions checks whether the `pandas` and `psycopg2` libraries are successfully imported:

```
import pandas
print("pandas successfully imported")

import psycopg2
print("psycopg2 successfully imported")

def handler(event, context):
    """Function that checks whether psycopg2  and pandas are successfully imported or
 not"""
    return {"Status": "psycopg2 and pandas successfully imported"}
```

The `lambda_deploy.zip` deployment package is built with the `Constructs/lambda/build.sh` bash script. This script creates a folder, copies the Lambda script, installs the `pandas` and `psycopg2` libraries, and generates the .zip file. To generate the .zip file yourself, run this bash script and redeploy the AWS CDK stack.

The Dockerfile starts with the AWS provided base image for Lambda with a Python 3.8 runtime. The Dockerfile installs the `pandas` and `psycopg2` libraries on top of the default image.

Integrate Amazon API Gateway with Amazon SQS to handle asynchronous REST APIs

Natalia Colantonio Favero and Gustavo Martim, Amazon Web Services

Summary

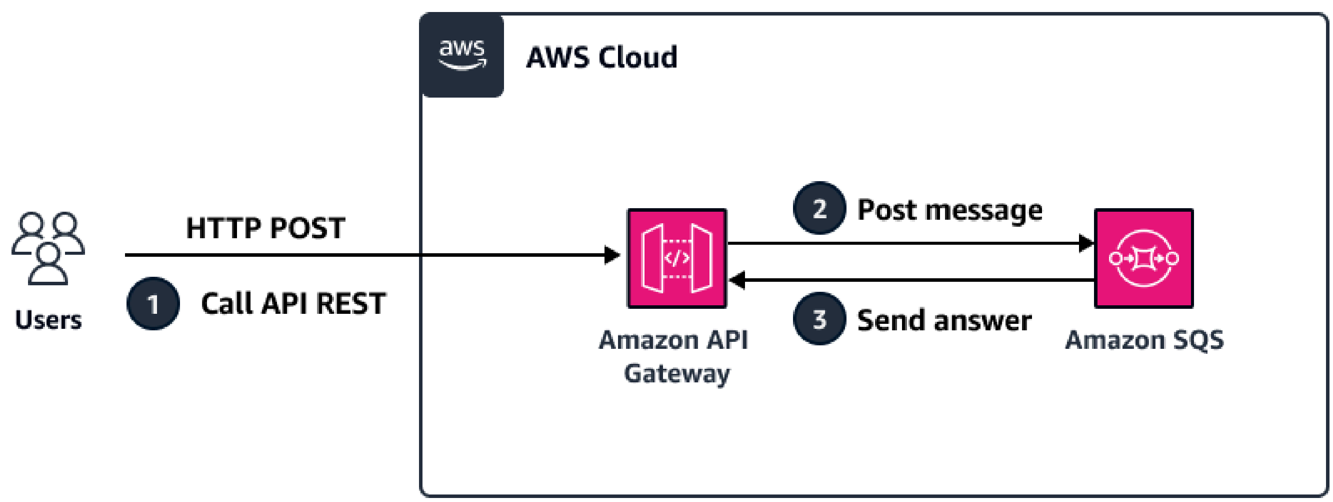
When you deploy REST APIs, sometimes you need to expose a message queue that client applications can publish. For example, you might have problems with the latency of third-party APIs and delays in responses, or you might want to avoid the response time of database queries or avoid scaling the server when there are a large number of concurrent APIs. In these scenarios, the client applications that publish to the queue only need to know that the API received the data—not what happens after the data was received.

This pattern creates a REST API endpoint by using [Amazon API Gateway](https://docs.aws.amazon.com/apigateway/latest/developerguide/welcome.html) to send a message to [Amazon Simple Queue Service (Amazon SQS)](https://docs.aws.amazon.com/AWSSimpleQueueService/latest/SQSDeveloperGuide/welcome.html). It creates an easy-to-implement integration between the two services that avoids direct access to the SQS queue.

Prerequisites and limitations

- An active AWS account

Architecture



The diagram illustrates these steps:

1. Request a POST REST API endpoint by using a tool such as Postman, another API, or other technologies.
2. API Gateway posts a message, which is received on the request's body, on the queue.
3. Amazon SQS receives the message and sends an answer to API Gateway with a success or failure code.

Tools

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

Epics

Create an SQS queue

Task	Description	Skills required
Create a queue.	To create an SQS queue that receives the messages from the REST API: 1. Sign in to your AWS account. 2. Open the Amazon SQS console at https://console.aws.amazon.com/sqs/. 3. Choose **Create queue**. 4. On the **Create queue** page, choose the correct AWS	App developer

Task	Description	Skills required
	Region from the **Region** dropdown list. 5. For **Type**, keep the default setting (**Standard**). 6. Enter a **Name** for your queue. 7. Keep the default values for all other settings. 8. Choose **Create queue**.	

Provide access to Amazon SQS

Task	Description	Skills required
Create an IAM role.	This IAM role gives API Gateway resources full access to Amazon SQS. 1. Open the IAM console at https://console.aws.amazon.com/iam/. 2. In the navigation pane, choose **Roles**, **Create role**. 3. For **Trusted entity type**, choose **AWS service**. 4. For **Use case**, choose **API Gateway** from the dropdown list, and then choose **Next**, **Next**. 5. For **Role name**, enter **AWSGatewayRoleForSQS** and an optional descripti	App developer, AWS administrator

Task	Description	Skills required
	on, and then choose **Create role**. 6. In the **Roles** pane, search for **AWSGatewayRoleForSQS**, and select its checkbox. 7. In the **Permissions policies** section, choose **Add permissions**, **Attach policies**. 8. Search for **AmazonSQSFullAccess** and select it. 9. Choose **Add permissions**. 10. In the **Summary** section of **AWSGatewayRoleForSQS**, copy the Amazon Resource Number (ARN). You will use this ID in a later step.	

Create a REST API

Task	Description	Skills required
Create a REST API.	This is the REST API that HTTP requests are sent to. 1. Open the API Gateway console at https://console.aws.amazon.com/apigateway/. 2. In the **REST API** section, choose **Build.**	App developer

Task	Description	Skills required
	3. For **API name**, enter a name and an optional description for your API, keep all other default settings, and then choose **Create API**.	

Task	Description	Skills required
Connect API Gateway to Amazon SQS.	This step enables the message to flow from inside the HTTP request’s body to Amazon SQS. 1. On the [API Gateway console](), choose the API that you created. 2. On the **Resources** page, in the **Methods** section, choose **Create method**. 3. For **Method type**, choose **POST**. 4. For **Integration type**, choose **AWS service**. 5. For **AWS Region**, choose the Region where you created your SQS queue. 6. For **AWS service**, choose **Simple Queue Service (SQS)**. 7. For HTTP method, choose **POST**. 8. For **Action type**, choose **Use path override**. 9. For **Path override**, enter **<AWS account ID>/<name of SQS queue>**. 10. For **Execution role**, paste the ARN of the role that you created earlier. 11. Choose **Create method**.	App developer

Test the REST API

Task	Description	Skills required

Test the REST API.	Run a test to check for missing configuration:
	
	1. On the [API Gateway console](https://console.aws.amazon.com/apigateway/), choose the REST API that you created.
	2. In the **Resources** pane, choose the **POST** method.
	3. Choose the **Test** tab. (Use the right arrow if the tab isn't displayed.)
	4. For **Request body**, paste the following JSON code:
	`{ "message": "lorem ipsum" }`
	5. Choose **Test**.
	
	You will receive an error that's similar to the following:
	`<UnknownOperationException/>`
		App developer

Change the API integration to forward the request properly to Amazon SQS.	Complete the configuration to fix the integration error: 1. On the [API Gateway console](https://console.aws.amazon.com/apigateway/), choose the API	App developer

Task	Description	Skills required
	you created, and then choose **POST**. 2. The **Method Execution** section shows the visual mapping between API Gateway and Amazon SQS. From this section, choose **Integration request**, and then choose **Edit**. 3. Expand the **HTTP headers** section, and then choose the **Add request header** parameter. • For **Name**, specify **Content-Type**. • For **Mapped from**, enter **'application/x-www-form-urlencoded'**. Make sure to include the single quotation marks. • Select the **Caching** checkbox. 4. Expand the **Mapping templates** section. • Choose **Add mapping template**. • For **Content type**, enter **application/json**. • For **Template body**, paste this code:	

Task	Description	Skills required
	`Action=SendMessage&MessageBody=$input.body` • Choose **Save**.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Test and validate the message in Amazon SQS.</td><td>Run a test to confirm that the test completed successfully:

1. On the API Gateway console, choose the REST API you created.
2. In the Resources pane, choose the POST method.
3. Choose the Test tab. (Use the right arrow if the tab isn't displayed.)
4. For Request body, paste the following JSON code:
<pre>{
     "message":
 "lorem ipsum"
}</pre>5. Choose Test.
6. Open the Amazon SQS console.
7. In the navigation pane, choose Queues, and then choose your queue.
8. Choose Send and receive messages.
9. Choose Poll for messages.
10. Choose Message. It should display the following:
<pre>Body { "message":
 "lorem ipsum" }</pre></td><td>App developer</td></tr>
</table>

Task	Description	Skills required

Test API Gateway with a special character.	Run a test that includes special characters (such as &) that aren't acceptable in a message:
	
	1. On the [API Gateway console](#), choose your API.
	2. Repeat the test from the earlier step by using the following JSON code:
	`{ "message": "lorem ipsum &" }`
	3. Choose **Test**.
	
	You will receive an error such as the following:
	`{ "Error": { "Code": "AccessDenied", "Message": "Access to the resource https://sqs.us-east-2.amazonaws.com/976166761794/Apg2 is denied.", "Type": "Sender" }, "RequestId": "e83c9c67-bcf6-5e9a-91e9-c737094b17ab"`
		App developer

Task	Description	Skills required
	```}``` This is because special characters aren't supported by default in the message body. In the next step, you'll configure API Gateway to support special characters. For more information about content type conversions, see the [API Gateway documentation]().	

Task	Description	Skills required

Change the API configuration to support special characters.	Adjust the configuration to accept special characters in the message:
	
	1. On the [API Gateway console](https://console.aws.amazon.com/apigateway/), choose the API you created, and then choose **POST**.
	2. Choose **Integration request**, and then choose **Edit**.
	3. Change **Content Handling** to **Convert to text.**
	4. In the **Mapping templates** section:
	• For **Content type**, enter **application/json**.
	• For **Template body**, specify:
	`Action=SendMessage&MessageBody=$util.urlEncode($input.body)`
	• Choose **Save**.
	5. Choose the **Test** tab.
	6. For **Request body**, enter the JSON code from earlier:
	`{ " message": "lorem ipsum &" }`
		App developer

Task	Description	Skills required
	7. Choose **Test**. 8. Open the [Amazon SQS console](https://console.aws.amazon.com/sqs/). 9. Select your queue, and then choose **Send and receive messages**, **Poll for messages**, **Message** as earlier. The new message should include the special character.	

Deploy the REST API

Task	Description	Skills required
Deploy the API.	To deploy the REST API: 1. Open the [API Gateway console](https://console.aws.amazon.com/apigateway/). 2. Choose your API. 3. Choose **Deploy API**. For more information about this step, see the [API Gateway documentation](https://docs.aws.amazon.com/apigateway/).	App developer
Test with an external tool.	Run a test with an external tool to confirm that the message is received successfu lly:	App developer

Task	Description	Skills required
	1. Open a tool such as Postman, Insomnia, or cURL. 2. Run your API. 3. Open the Amazon SQS console. 4. Select your queue. 5. Load messages to see the new message.	

Clean Up

Task	Description	Skills required
Delete the API.	On the API Gateway console, choose the API you created, and then choose **Delete**.	App developer
Delete the IAM role.	On the IAM console, in the **Roles** pane, select **AWSGatewayRoleForSQS**, and then choose **Delete**.	App developer
Delete the SQS queue.	On the Amazon SQS console, in the **Queues** pane, choose the SQS queue you created, and then choose **Delete**.	App developer

Process events asynchronously with Amazon API Gateway and AWS Lambda

Andrea Meroni, Mariem Kthiri, Nadim Majed, and Michael Wallner, Amazon Web Services

Summary

Amazon API Gateway is a fully managed service that developers can use to create, publish, maintain, monitor, and secure APIs at any scale. It handles the tasks involved in accepting and processing up to hundreds of thousands of concurrent API calls.

An important service quota of API Gateway is the integration timeout. The timeout is the maximum time in which a backend service must return a response before the REST API returns an error. The hard limit of 29 seconds is generally acceptable for synchronous workloads. However, that limit represents a challenge for those developers who want to use API Gateway with asynchronous workloads.

This pattern shows an example architecture to process events asynchronously using API Gateway and AWS Lambda. The architecture supports running processing jobs of duration up to 15 minutes, and it uses a basic REST API as the interface.

Projen is used to set up the local development environment and to deploy the example architecture to a target AWS account, in combination with the AWS Cloud Development Kit (AWS CDK) Toolkit, Docker, and Node.js. Projen automatically sets up a Python virtual environment with pre-commit and the tools that are used for code quality assurance, security scanning, and unit testing. For more information, see the Tools section.

Prerequisites and limitations

Prerequisites

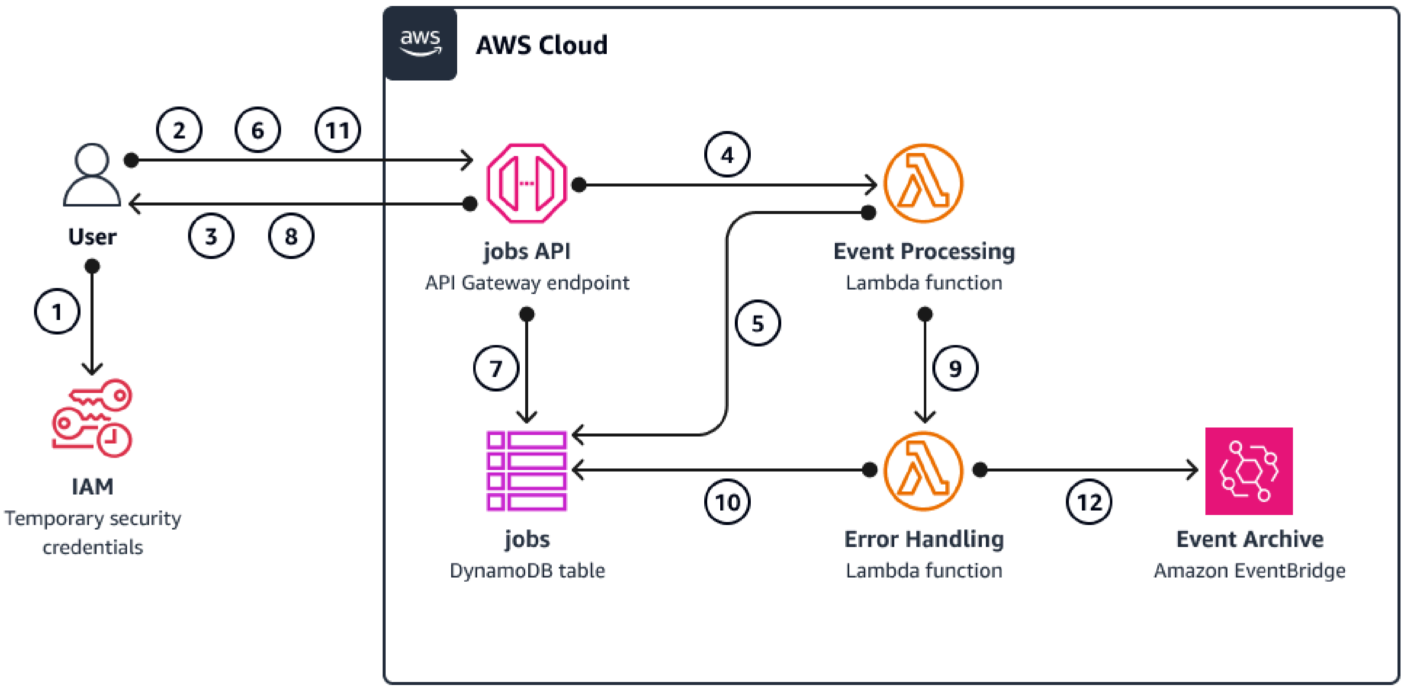
- An active AWS account
- The following tools installed on your workstation:
  - AWS Cloud Development Kit (AWS CDK) Toolkit version 2.85.0
  - Docker version 20.10.21
  - Node.js version 18.13.0
  - Projen version 0.71.111
  - Python version 3.9.16

Limitations

- The maximum runtime of a job is limited by the maximum runtime for Lambda functions (15 minutes).
- The maximum number of concurrent job requests is limited by the reserved concurrency of the Lambda function.

Architecture

The following diagram shows the interaction of the jobs API with the event-processing and error-handling Lambda functions, with events stored in an Amazon EventBridge event archive.



A typical workflow includes the following steps:

1. You authenticate against AWS Identity and Access Management (IAM) and obtain security credentials.
2. You send an HTTP `POST` request to the `/jobs` jobs API endpoint, specifying the job parameters in the request body.
3. The jobs API, which is an API Gateway REST API, returns to you an HTTP response that contains the job identifier.
4. The jobs API invokes asynchronously the event-processing Lambda function.

5. The event-processing function processes the event, and then it puts the job results in the jobs Amazon DynamoDB table
6. You send an HTTP GET request to the `/jobs/{jobId}` jobs API endpoint, with the job identifier from step 3 as `{jobId}`.
7. The jobs API queries the `jobs` DynamoDB table to retrieve the job results.
8. The jobs API returns an HTTP response that contains the job results.
9. If the event processing fails, the event-processing function sends the event to the error-handling function.
10. The error-handling function puts the job parameters in the `jobs` DynamoDB table.
11. You can retrieve the job parameters by sending an HTTP GET request to the `/jobs/{jobId}` jobs API endpoint.
12. If the error handling fails, the error-handling function sends the event to an EventBridge event archive.

    You can replay the archived events by using EventBridge.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Other tools

- autopep8 automatically formats Python code based on the Python Enhancement Proposal (PEP) 8 style guide.
- Bandit scans Python code to find common security issues.
- Commitizen is a Git commit checker and `CHANGELOG` generator.
- cfn-lint is an AWS CloudFormation linter
- Checkov is a static code-analysis tool that checks infrastructure as code (IaC) for security and compliance misconfigurations.
- jq is a command-line tool for parsing JSON.
- Postman is an API platform.
- pre-commit is a Git hooks manager.
- Projen is a project generator.
- pytest is a Python framework for writing small, readable tests.

Code repository

This example architecture code can be found in the GitHub Asynchronous Event Processing with API Gateway and Lambda repository.

Best practices

- This example architecture doesn't include monitoring of the deployed infrastructure. If your use case requires monitoring, evaluate adding CDK Monitoring Constructs or another monitoring solution.
- This example architecture uses IAM permissions to control the access to the jobs API. Anyone authorized to assume the `JobsAPIInvokeRole` will be able to invoke the jobs API. As such, the access control mechanism is binary. If your use case requires a more complex authorization model, evaluate using a different access control mechanism.
- When a user sends an HTTP `POST` request to the `/jobs` jobs API endpoint, the input data is validated at two different levels:
  - Amazon API Gateway is in charge of the first request validation.
  - The event processing function performs the second request.

  No validation is performed when the user does an HTTP `GET` request to the `/jobs/{jobId}` jobs API endpoint. If your use case requires additional input validation and an increased level of security, evaluate using AWS WAF to protect your API.

Epics

Set up the environment

Task	Description	Skills required
Clone the repository.	To clone the repository locally, run the following command: `git clone https://github.com/aws-samples/asynchronous-event-processing-api-gateway-lambda-cdk.git`	DevOps engineer

Set up the project.	Change the directory to the repository root and set up the Python virtual environment and all the tools by using [Projen](https://github.com/projen/projen):
	`cd asynchronous-event-processing-api-gateway-api-gateway-lambda-cdk`
	`npx projen`
		DevOps engineer

Install pre-commit hooks.	To install pre-commit hooks, do the following: 1. Activate the [Python virtual environment](https://docs.python.org/3/library/venv.html): `source .env/bin/activate` 2. Install the [pre-commit](https://pre-commit.com/) hooks:	DevOps engineer

Task	Description	Skills required
	`pre-commit install` `pre-commit install --hook-type commit-msg`	

Deploy the example architecture

Task	Description	Skills required
Bootstrap AWS CDK.	To bootstrap AWS CDK in your AWS account, run the following command: `AWS_PROFILE=$YOUR_AWS_PROFILE npx projen bootstrap`	AWS DevOps
Deploy the example architecture.	To deploy the example architecture in your AWS account, run the following command: `AWS_PROFILE=$YOUR_AWS_PROFILE npx projen deploy`	AWS DevOps

Test the architecture

Task	Description	Skills required
Install test prerequisites.	Install on your workstation the [AWS Command Line Interface (AWS CLI)](), [Postman](), and [jq]().	DevOps engineer

Task	Description	Skills required
	Using Postman to test this example architecture is suggested but not mandatory . If you choose an alternati ve API testing tool, make sure that it supports AWS Signature Version 4 authentic ation, and refer to the exposed API endpoints that can be inspected by exporting the REST API.	

Task	Description	Skills required

Assume the `JobsAPIInvokeRole` .	[Assume](https://docs.aws.amazon.com/cli/latest/reference/sts/assume-role.html) the `JobsAPIInvokeRole` that was printed as output from the deploy command:
	`CREDENTIALS=$(AWS_PROFILE=$<YOUR_AWS_PROFILE> aws sts assume-role \`
	`--no-cli-pager \`
	`--role-arn $<JOBS_API_INVOKE_ROLE_ARN> \`
	`--role-session-name JobsAPIInvoke)`
	`export AWS_ACCESS_KEY_ID=$(cat $CREDENTIALS | jq '.Credentials''.AccessKeyId')`
	`export AWS_SECRET_ACCESS_KEY=$(cat $CREDENTIALS | jq '.Credentials''.SecretAccessKey')`
	`export AWS_SESSION_TOKEN==$(cat $CREDENTIALS | jq '.Credentials''.SessionToken')`
		AWS DevOps

Task	Description	Skills required
Configure Postman.	1. To import the Postman collection that's included in the repository, follow the instructions in the Postman documentation. 2. Set the `JobsAPI` variables with the following values: • `accessKey` – The value of the `Credentials.AccessKeyId` attribute from the `assume-role` command • `baseUrl` – The value of the `JobsApiJobsAPIEndpoint` output from the deploy command, without the trailing slash • `region` – The value of the AWS Region where you deployed the example architecture • `seconds` – The value of the input parameter for the example job. It must be a positive integer • `secretKey` – The value of the `Credentials.SecretAccessKey` attribute from the `assume-role` command	AWS DevOps

Task	Description	Skills required
	• `sessionToken` – The value of the `Credentials.SessionToken` attribute from the `assume-role` command	
Test the example architecture.	To test the example architecture, send requests to the jobs API. For more information, see the Postman documentation.	DevOps engineer

Troubleshooting

Issue	Solution
Destruction and subsequent redeployment of the example architecture fails because the Amazon CloudWatch Logs log group `/aws/apigateway/JobsAPIAccessLogs` already exists.	1. If necessary, export your log data to Amazon S3. 2. Delete the CloudWatch Logs log group `/aws/apigateway/JobsAPIAccessLogs` . 3. Redeploy the example architecture.

Process events asynchronously with Amazon API Gateway and Amazon DynamoDB Streams

Andrea Meroni, Mariem Kthiri, Nadim Majed, Alessandro Trisolini, and Michael Wallner, Amazon Web Services

Summary

Amazon API Gateway is a fully managed service that developers can use to create, publish, maintain, monitor, and secure APIs at any scale. It handles the tasks involved in accepting and processing up to hundreds of thousands of concurrent API calls.

An important service quota of API Gateway is the integration timeout. The timeout is the maximum time in which a backend service must return a response before the REST API returns an error. The hard limit of 29 seconds is generally acceptable for synchronous workloads. However, that limit represents a challenge for those developers who want to use API Gateway with asynchronous workloads.

This pattern shows an example architecture for processing events asynchronously using API Gateway, Amazon DynamoDB Streams, and AWS Lambda. The architecture supports running parallel processing jobs with the same input parameters, and it uses a basic REST API as the interface. In this example, using Lambda as the backend limits the duration of jobs to 15 minutes. You can avoid this limit by using an alternative service to process incoming events (for example, AWS Fargate).

Projen is used to set up the local development environment and to deploy the example architecture to a target AWS account, in combination with the AWS Cloud Development Kit (AWS CDK) Toolkit, Docker and Node.js. Projen automatically sets up a Python virtual environment with pre-commit and the tools that are used for code quality assurance, security scanning, and unit testing. For more information, see the Tools section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The following tools installed on your workstation:
  - AWS Cloud Development Kit (AWS CDK) Toolkit version 2.85.0 or later

- [Docker](https://www.docker.com/) version 20.10.21 or later
- [Node.js](https://nodejs.org/en/download) version 18 or later
- [Projen](https://github.com/projen/projen) version 0.71.111 or later
- [Python](https://www.python.org/downloads/) version 3.9.16 or later

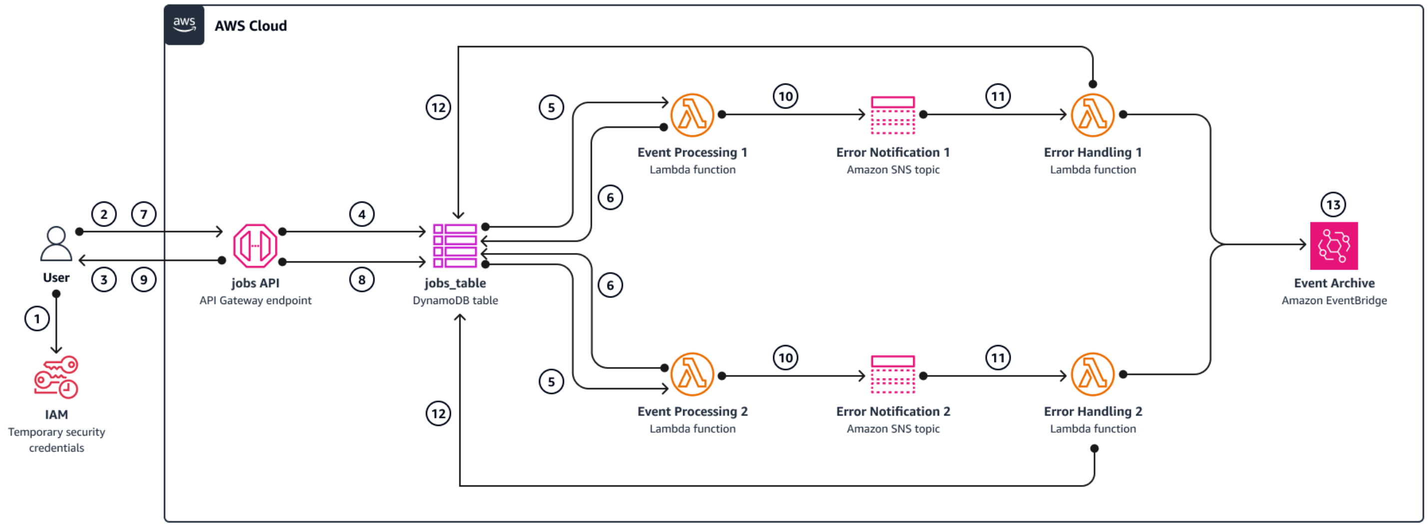
Limitations

- The advised maximum number of readers for DynamoDB Streams is two to avoid throttling.
- The maximum runtime of a job is limited by the maximum runtime for Lambda functions (15 minutes).
- The maximum number of concurrent job requests is limited by the reserved concurrency of the Lambda functions.

Architecture

Architecture

The following diagram shows the interaction of the jobs API with DynamoDB Streams and the event-processing and error-handling Lambda functions, with events stored in an Amazon EventBridge event archive.



A typical workflow includes the following steps:

1. You authenticate against AWS Identity and Access Management (IAM) and obtain security credentials.

2. You send an HTTP POST request to the /jobs jobs API endpoint, specifying the job parameters in the request body.
3. The jobs API returns to you an HTTP response that contains the job identifier.
4. The jobs API puts the job parameters in the jobs_table Amazon DynamoDB table.
5. The jobs_table DynamoDB table DynamoDB stream invokes the event-processing Lambda functions.
6. The event-processing Lambda functions process the event and then put the job results in the jobs_table DynamoDB table. To help ensure consistent results, the event-processing functions implement an optimistic locking mechanism.
7. You send an HTTP GET request to the /jobs/{jobId} jobs API endpoint, with the job identifier from step 3 as {jobId}.
8. The jobs API queries the jobs_table DynamoDB table to retrieve the job results.
9. The jobs API returns an HTTP response that contains the job results.
10. If the event processing fails, the event-processing function's source mapping sends the event to the error-handling Amazon Simple Notification Service (Amazon SNS) topic.
11. The error-handling SNS topic asynchronously pushes the event to the error-handling function.
12. The error-handling function puts the job parameters in the jobs_table DynamoDB table.

    You can retrieve the job parameters by sending an HTTP GET request to the /jobs/{jobId} jobs API endpoint.
13. If the error handling fails, the error-handling function sends the event to an Amazon EventBridge archive.

    You can replay the archived events by using EventBridge.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

Other tools

- autopep8 automatically formats Python code based on the Python Enhancement Proposal (PEP) 8 style guide.
- Bandit scans Python code to find common security issues.
- Commitizen is a Git commit checker and `CHANGELOG` generator.
- cfn-lint is an AWS CloudFormation linter
- Checkov is a static code-analysis tool that checks infrastructure as code (IaC) for security and compliance misconfigurations.
- jq is a command-line tool for parsing JSON.
- Postman is an API platform.
- pre-commit is a Git hooks manager.
- Projen is a project generator.
- pytest is a Python framework for writing small, readable tests.

Code repository

This example architecture code can be found in the GitHub Asynchronous Processing with API Gateway and DynamoDB Streams repository.

Best practices

- This example architecture doesn't include monitoring of the deployed infrastructure. If your use case requires monitoring, evaluate adding CDK Monitoring Constructs or another monitoring solution.

- This example architecture uses IAM permissions to control the access to the jobs API. Anyone authorized to assume the `JobsAPIInvokeRole` will be able to invoke the jobs API. As such, the access control mechanism is binary. If your use case requires a more complex authorization model, evaluate using a different access control mechanism.
- When a user sends an HTTP `POST` request to the `/jobs` jobs API endpoint, the input data is validated at two different levels:
  - API Gateway is in charge of the first request validation.
  - The event processing function performs the second request.

  No validation is performed when the user does an HTTP `GET` request to the `/jobs/{jobId}` jobs API endpoint. If your use case requires additional input validation and an increased level of security, evaluate using AWS WAF to protect your API.
- To avoid throttling, the DynamoDB Streams documentation discourages users from reading with more than two consumers from the same stream's shard. To scale out the number of consumers, we recommend using Amazon Kinesis Data Streams.
- Optimistic locking has been used in this example to ensure consistent updates of items in the `jobs_table` DynamoDB table. Depending on the use-case requirement, you might need to implement more reliable locking mechanisms, such as pessimistic locking.

Epics

Set up the environment

Task	Description	Skills required
Clone the repository.	To clone the repository locally, run the following command: `git clone https://github.com/aws-samples/asynchronous-event-processing-api-gateway-dynamodb-streams-cdk.git`	DevOps engineer

Task	Description	Skills required

Set up the project.	Change the directory to the repository root, and set up the Python virtual environment and all the tools by using [Projen]():
	`cd asynchronous-event-processing-api-gateway-api-gateway-dynamodb-streams-cdk`
	`npx projen`
		DevOps engineer

Install pre-commit hooks.	To install pre-commit hooks, do the following:
	1. Activate the [Python virtual environment]():
	`source .env/bin/activate`
	2. Install the [pre-commit]() hooks:
	`pre-commit install`
	`pre-commit install --hook-type commit-msg`
		DevOps engineer

Deploy the example architecture

Task	Description	Skills required
Bootstrap AWS CDK.	To bootstrap [AWS CDK]() in your AWS account, run the following command:	AWS DevOps

Task	Description	Skills required
	```AWS_PROFILE=$YOUR_AWS_PROFILE npx projen bootstrap```	
Deploy the example architecture.	To deploy the example architecture in your AWS account, run the following command: ```AWS_PROFILE=$YOUR_AWS_PROFILE npx projen deploy```	AWS DevOps

Test the architecture

Task	Description	Skills required
Install test prerequisites.	Install on your workstation the AWS Command Line Interface (AWS CLI), Postman, and jq. Using Postman to test this example architecture is suggested but not mandatory. If you choose an alternative API testing tool, make sure that it supports AWS Signature Version 4 authentication, and refer to the exposed API endpoints that can be inspected by exporting the REST API.	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Assume the `JobsAPIInvokeRole` .</td><td>

Assume the `JobsAPIInvokeRole` that was printed as output from the `deploy` command:

```
CREDENTIALS=$(AWS_PROFILE=$<YOUR_AWS_PROFILE> aws sts assume-role \
--no-cli-pager \
--role-arn $<JOBS_API_INVOKE_ROLE_ARN> \
--role-session-name JobsAPIInvoke)
export AWS_ACCESS_KEY_ID=$(cat $CREDENTIALS | jq ‘.Credentials’’.AccessKeyId’)
export AWS_SECRET_ACCESS_KEY=$(cat $CREDENTIALS | jq ‘.Credentials’’.SecretAccessKey’)
export AWS_SESSION_TOKEN==$(cat $CREDENTIALS | jq ‘.Credentials’’.SessionToken’)
```

</td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required

Configure Postman.	• To import the Postman collection that's included in the repository, follow the instructions in the [Postman documentation]().
	• Set the `JobsAPI` [variables]() with the following values:
	  • `accessKey` – The value of the `Credentials.AccessKeyId` attribute from the `assume-role` command.
	  • `baseUrl` – The value of the `JobsApiJobsAPIEndpoint` output from the `deploy` command, without the trailing slash.
	  • `region` – The value of the AWS Region where you deployed the example architecture.
	  • `seconds` – The value of the input parameter for the example job. It must be a positive integer.
	  • `secretKey` – The value of the `Credentials.SecretAccessKey` attribute from the `assume-role` command.
		AWS DevOps

Task	Description	Skills required
	• `sessionToken` – The value of the `Credentials.SessionToken` attribute from the `assume-role` command.	
Test the example architecture.	To test the example architecture, send requests to the jobs API. For more information, see the Postman documentation.	DevOps engineer

Troubleshooting

Issue	Solution
Destruction and subsequent redeployment of the example architecture fails because the Amazon CloudWatch Logs log group `/aws/apigateway/JobsAPIAccessLogs` already exists.	1. If necessary, export your log data to Amazon Simple Storage Service (Amazon S3). 2. Delete the CloudWatch Logs log group `/aws/apigateway/JobsAPIAccessLogs` . 3. Redeploy the example architecture.

Process events asynchronously with Amazon API Gateway, Amazon SQS, and AWS Fargate

Andrea Meroni, Mariem Kthiri, Nadim Majed, Alessandro Trisolini, and Michael Wallner, Amazon Web Services

Summary

Amazon API Gateway is a fully managed service that developers can use to create, publish, maintain, monitor, and secure APIs at any scale. It handles the tasks involved in accepting and processing up to hundreds of thousands of concurrent API calls.

An important service quota of API Gateway is the integration timeout. The timeout is the maximum time in which a backend service must return a response before the REST API returns an error. The hard limit of 29 seconds is generally acceptable for synchronous workloads. However, that limit represents a challenge for those developers who want to use API Gateway with asynchronous workloads.

This pattern shows an example architecture to process events asynchronously using API Gateway, Amazon Simple Queue Service (Amazon SQS) and AWS Fargate. The architecture supports running processing jobs without duration restrictions, and it uses a basic REST API as the interface.

Projen is used to set up the local development environment and to deploy the example architecture to a target AWS account, in combination with the AWS Cloud Development Kit (AWS CDK), Docker, and Node.js. Projen automatically sets up a Python virtual environment with pre-commit and the tools that are used for code quality assurance, security scanning, and unit testing. For more information, see the Tools section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The following tools installed on your workstation:
  - AWS Cloud Development Kit (AWS CDK) Toolkit version 2.85.0 or later
  - Docker version 20.10.21 or later
  - Node.js version 18 or later

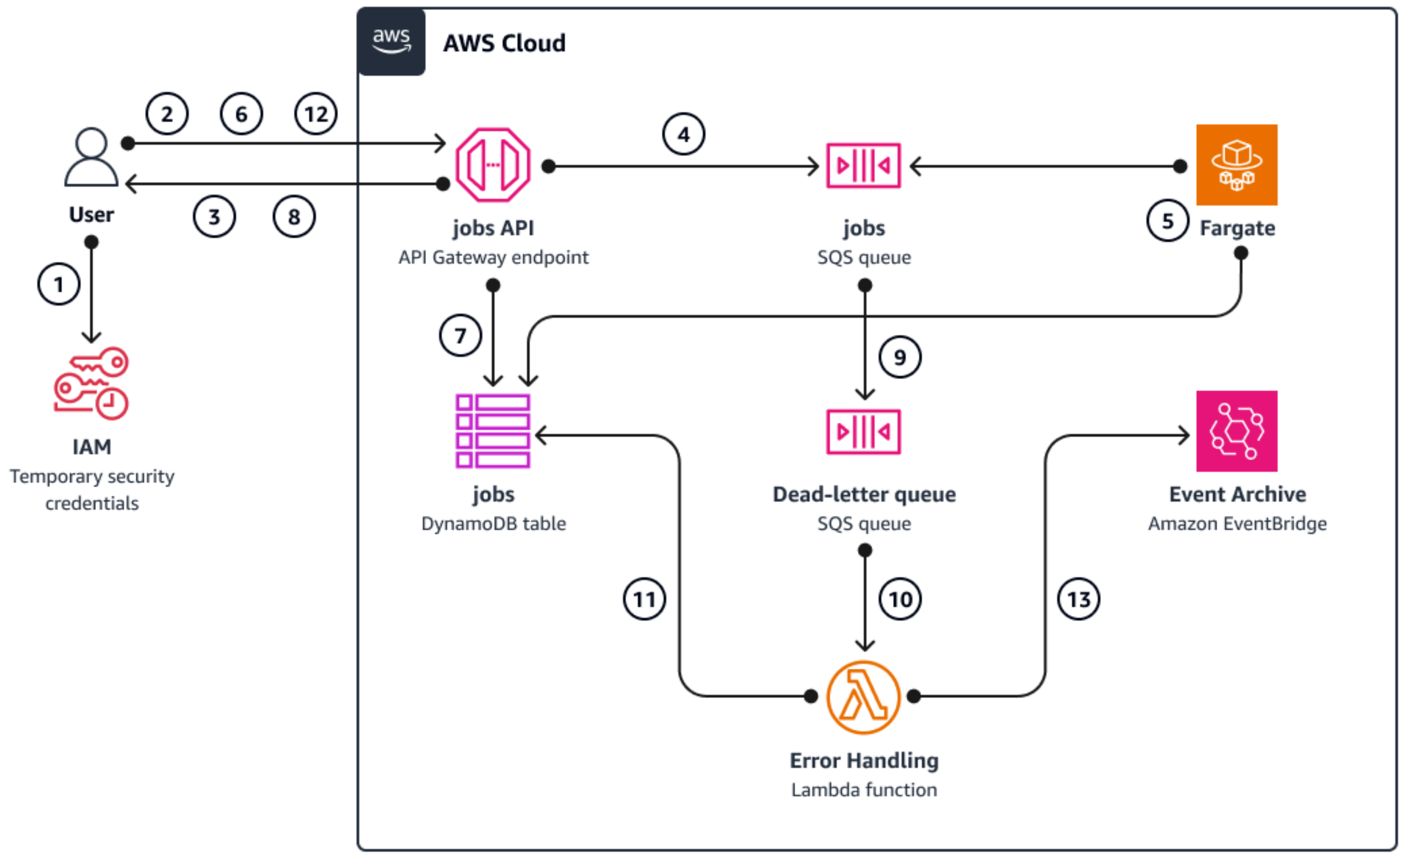
- [Projen](#) version 0.71.111 or later
- [Python](#) version 3.9.16 or later

Limitations

- Concurrent jobs are limited to 500 tasks per minute, which is the maximum number of tasks that Fargate can provision.

Architecture

The following diagram shows the interaction of the jobs API with the `jobs` Amazon DynamoDB table, the event-processing Fargate service, and the error-handling AWS Lambda function. Events are stored in an Amazon EventBridge event archive.



A typical workflow includes the following steps:

1. You authenticate against AWS Identity and Access Management (IAM) and obtain security credentials.

2. You send an HTTP `POST` request to the `/jobs` jobs API endpoint, specifying the job parameters in the request body.
3. The jobs API, which is an API Gateway REST API, returns to you an HTTP response that contains the job identifier.
4. The jobs API sends a message to the SQS queue.
5. Fargate pulls the message from the SQS queue, processes the event, and then puts the job results in the `jobs` DynamoDB table.
6. You send an HTTP `GET` request to the `/jobs/{jobId}` jobs API endpoint, with the job identifier from step 3 as `{jobId}`.
7. The jobs API queries the `jobs` DynamoDB table to retrieve the job results.
8. The jobs API returns an HTTP response that contains the job results.
9. If the event processing fails, the SQS queue sends the event to the dead-letter queue (DLQ).
10. An EventBridge event initiates the error-handling function.
11. The error-handling function puts the job parameters in the `jobs` DynamoDB table.
12. You can retrieve the job parameters by sending an HTTP `GET` request to the `/jobs/{jobId}` jobs API endpoint.
13. If the error handling fails, the error-handling function sends the event to an EventBridge archive.

    You can replay the archived events by using EventBridge.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Fargate helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It's used in conjunction with Amazon Elastic Container Service (Amazon ECS).
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.

- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

Other tools

- autopep8 automatically formats Python code based on the Python Enhancement Proposal (PEP) 8 style guide.
- Bandit scans Python code to find common security issues.
- Commitizen is a Git commit checker and `CHANGELOG` generator.
- cfn-lint is an AWS CloudFormation linter
- Checkov is a static code-analysis tool that checks infrastructure as code (IaC) for security and compliance misconfigurations.
- jq is a command-line tool for parsing JSON.
- Postman is an API platform.
- pre-commit is a Git hooks manager.
- Projen is a project generator.
- pytest is a Python framework for writing small, readable tests.

Code repository

This example architecture code can be found in the GitHub Asynchronous Processing with API Gateway and SQS repository.

Best practices

- This example architecture doesn't include monitoring of the deployed infrastructure. If your use case requires monitoring, evaluate adding CDK Monitoring Constructs or another monitoring solution.
- This example architecture uses IAM permissions to control the access to the jobs API. Anyone authorized to assume the `JobsAPIInvokeRole` will be able to invoke the jobs API. As such, the access control mechanism is binary. If your use case requires a more complex authorization model, evaluate using a different access control mechanism.

- When a user sends an HTTP POST request to the /jobs jobs API endpoint, the input data is validated at two different levels:
  - API Gateway is in charge of the first request validation.
  - The event processing function performs the second request.

  No validation is performed when the user does an HTTP GET request to the /jobs/{jobId} jobs API endpoint. If your use case requires additional input validation and an increased level of security, evaluate using AWS WAF to protect your API.

Run AWS Systems Manager Automation tasks synchronously from AWS Step Functions

Elie El khoury, Amazon Web Services

Summary

This pattern explains how to integrate AWS Step Functions with AWS Systems Manager. It uses AWS SDK service integrations to call the Systems Manager **startAutomationExecution** API with a task token from a state machine workflow, and pauses until the token returns with a success or failure call. To demonstrate the integration, this pattern implements an Automation document (runbook) wrapper around the `AWS-RunShellScript` or `AWS-RunPowerShellScript` document, and uses `.waitForTaskToken` to synchronously call `AWS-RunShellScript` or `AWS-RunPowerShellScript`. For more information about AWS SDK service integrations in Step Functions, see the AWS Step Functions Developer Guide.

Step Functions is a low-code, visual workflow service that you can use to build distributed applications, automate IT and business processes, and build data and machine learning pipelines by using AWS services. Workflows manage failures, retries, parallelization, service integrations, and observability so you can focus on higher-value business logic.

Automation, a capability of AWS Systems Manager, simplifies common maintenance, deployment, and remediation tasks for AWS services such as Amazon Elastic Compute Cloud (Amazon EC2), Amazon Relational Database Service (Amazon RDS), Amazon Redshift, and Amazon Simple Storage Service (Amazon S3). Automation gives you granular control over the concurrency of your automations. For example, you can specify how many resources to target concurrently, and how many errors can occur before an automation is stopped.

For implementation details, including runbook steps, parameters, and examples, see the Additional information section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) permissions to access Step Functions and Systems Manager

- An EC2 instance with Systems Manager Agent (SSM Agent) installed on the instance
- An IAM instance profile for Systems Manager attached to the instance where you plan to run the runbook
- A Step Functions role that has the following IAM permissions (which follow the principle of least privilege):

```
{
             "Effect": "Allow",
             "Action": "ssm:StartAutomationExecution",
             "Resource": "*"
 }
```

Product versions

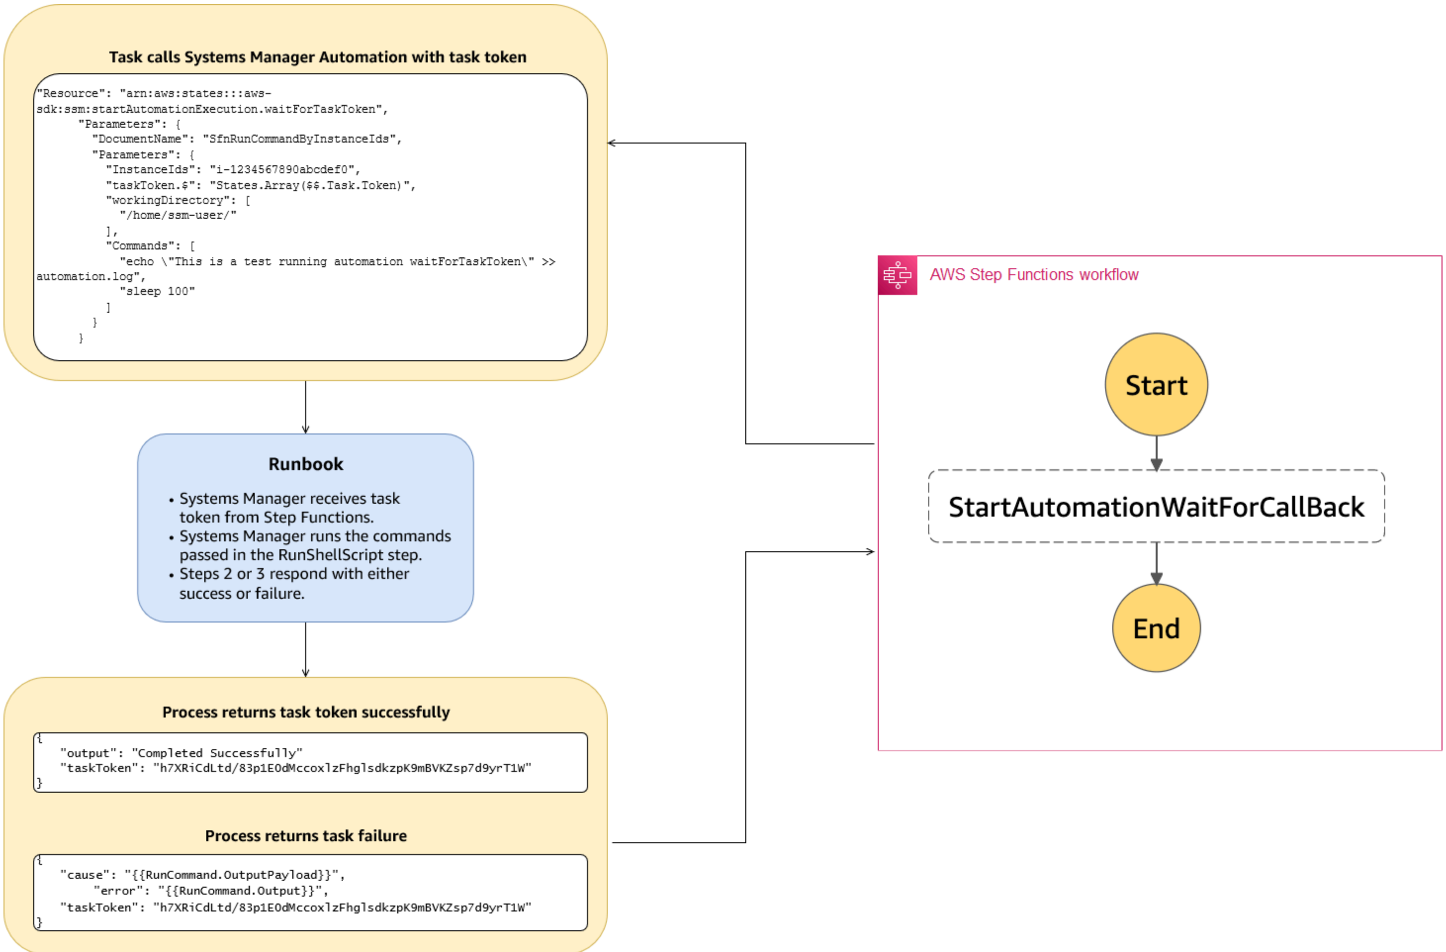
- SSM document schema version 0.3 or later
- SSM Agent version 2.3.672.0 or later

Architecture

Target technology stack

- AWS Step Functions
- AWS Systems Manager Automation

Target architecture



Automation and scale

- This pattern provides an AWS CloudFormation template that you can use to deploy the runbooks on multiple instances. (See the GitHub Step Functions and Systems Manager implementation repository.)

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

Code

The code for this pattern is available in the GitHub Step Functions and Systems Manager implementation repository.

Epics

Create runbooks

Task	Description	Skills required
Download the CloudFormation template.	Download the `ssm-automation-documents.cfn.json` template from the `cloudformation` folder of the GitHub repository.	AWS DevOps
Create runbooks.	Sign in to the AWS Management Console, open the AWS CloudFormation console, and deploy the template. For more information about deploying CloudFormation templates, see Creating a stack on the AWS CloudFormation console in the CloudFormation documentation. The CloudFormation template deploys three resources: • `SfnRunCommandByInstanceIds` – Runbook that	AWS DevOps

Task	Description	Skills required
	lets you run `AWS-RunShellScript` or `AWS-RunPowerShellScript` by using instance IDs. • `SfnRunCommandByTargets` – Runbook that lets you run `AWS-RunShellScript` or `AWS-RunPowerShellScript` by using targets. • `SSMSyncRole` – The IAM role assumed by the runbooks.	

Create a sample state machine

Task	Description	Skills required

Create a test state machine.	Follow the instructions in the [AWS Step Functions Developer Guide](https://docs.aws.amazon.com/step-functions/latest/dg/) to create and run a state machine. For the definition, use the following code. Make sure to update the `InstanceIds` value with the ID of a valid Systems Manager-enabled instance in your account.
	`{`
	`  "Comment": "A description of my state machine",`
		AWS DevOps

Task	Description	Skills required

	`"StartAt": "StartAut omationWaitForCall Back",`
	`"States": {`
	`"StartAutomationWa itForCallBack": {`
	`"Type": "Task",`
	`"Resource": "arn:aws:states::: aws-sdk:ssm:startA utomationExecution .waitForTaskToken",`
	`"Parameters": {`
	`"DocumentName": "SfnRunCommandByIn stanceIds",`
	`"Parameters": {`
	`"Instance Ids": [`
	`"i-123456 7890abcdef0"`
	`],`
	`"taskToken. $": "States.Array($$.T ask.Token)",`
	`"workingD irectory": [`
	`"/home/ssm- user/"`
	`],`
	`"Commands": [`
	`"echo \"This is a test running automation waitForTa skToken\" >> automatio n.log",`
	`"sleep 100"`
	`],`
	`"executio nTimeout": [`
	`"10800"`
	`],`	

Task	Description	Skills required

	``
	           "delivery
	Timeout": [
	               "30"
	           ],
	           "shell": [
	               "Shell"
	           ]
	             }
	       },
	       "End": true
	     }
	   }
	}
	``
	
	This code calls the runbook to run two commands that demonstrate the `waitForTaskToken` call to Systems Manager Automation.
	
	The `shell` parameter value (`Shell` or `PowerShell`) determines whether the Automation document runs `AWS-RunShellScript` or `AWS-RunPowerShellScript`.
	
	The task writes "This is a test running automation waitForTaskToken" into the `/home/ssm-user/automation.log` file, and then sleeps for 100 seconds before it responds with the task token and releases the next task in the workflow.	

Task	Description	Skills required

	If you want to call the `SfnRunCommandByTargets` runbook instead, replace the `Parameters` section of the previous code with the following:
	``
	"Parameters": {
	          "Targets": [
	            {
	              "Key": "InstanceIds",
	              "Values": [
	                "i-02573cafcfEXAMPLE",
	                "i-0471e04240EXAMPLE"
	              ]
	            }
	          ],
	``	

Task	Description	Skills required
Update the IAM role for the state machine.	The previous step automatically creates a dedicated IAM role for the state machine. However, it doesn't grant permissions to call the runbook. Update the role by adding the following permissions: `{ "Effect": "Allow", "Action": "ssm:StartAutomationExecution", "Resource": "*" }`	AWS DevOps
Validate the synchronous calls.	Run the state machine to validate the synchronous call between Step Functions and Systems Manager Automation. For sample output, see the Additional information section.	AWS DevOps

Related resources

- Getting started with AWS Step Functions (*AWS Step Functions Developer Guide*)

- send_task_success and send_task_failure API calls (Boto3 documentation)
- AWS Systems Manager Automation (*AWS Systems Manager User Guide*)

Additional information

Implementation details

This pattern provides a CloudFormation template that deploys two Systems Manager runbooks:

- `SfnRunCommandByInstanceIds` runs the `AWS-RunShellScript` or `AWS-RunPowerShellScript` command by using instance IDs.
- `SfnRunCommandByTargets` runs the `AWS-RunShellScript` or `AWS-RunPowerShellScript` command by using targets.

Each runbook implements four steps to achieve a synchronous call when using the `.waitForTaskToken` option in Step Functions.

Step	Action	Description
1	`Branch`	Checks the `shell` parameter value (`Shell` or `PowerShell`) to decide whether to run `AWS-RunShellScript` for Linux or `AWS-RunPowerShellScript` for Windows.
2	`RunCommand_Shell` or `RunCommand_PowerShell`	Takes several inputs and runs the `RunShellScript` or `RunPowerShellScript` command. For more information, check the **Details** tab for the `RunCommand_Shell` or `RunCommand_PowerShell` Automation document on the Systems Manager console.
3	`SendTaskFailure`	Runs when step 2 is aborted or canceled. It calls the Step Functions [send_task_failure](#)

		API, which accepts three parameters as input: the token passed by the state machine, the failure error, and a description of the cause of the failure.
4	`SendTaskSuccess`	Runs when step 2 is successful. It calls the Step Functions [send_task_success](#) API, which accepts the token passed by the state machine as input.

Runbook parameters

`SfnRunCommandByInstanceIds` runbook:

Parameter name	Type	Optional or required	Description
`shell`	String	Required	The instances shell to decide whether to run `AWS-RunShellScript` for Linux or `AWS-RunPowerShellScript` for Windows.
`deliveryTimeout`	Integer	Optional	The time, in seconds, to wait for a command to deliver to the SSM Agent on an instance. This parameter has a minimum value of 30 (0.5 minute) and a maximum value of 2592000 (720 hours).

`executionTimeout`	String	Optional	The time, in seconds, for a command to complete before it is considered to have failed. The default value is 3600 (1 hour). The maximum value is 172800 (48 hours).
`workingDirectory`	String	Optional	The path to the working directory on your instance.
`Commands`	StringList	Required	The shell script or command to run.
`InstanceIds`	StringList	Required	The IDs of the instances where you want to run the command.
`taskToken`	String	Required	The task token to use for callback responses.

`SfnRunCommandByTargets` runbook:

Name	Type	Optional or required	Description
`shell`	String	Required	The instances shell to decide whether to run `AWS-RunShellScript` for Linux or `AWS-RunPowerShellScript` for Windows.

`deliveryTimeout`	Integer	Optional	The time, in seconds, to wait for a command to deliver to the SSM Agent on an instance. This parameter has a minimum value of 30 (0.5 minute) and a maximum value of 2592000 (720 hours).
`executionTimeout`	Integer	Optional	The time, in seconds, for a command to complete before it is considered to have failed. The default value is 3600 (1 hour). The maximum value is 172800 (48 hours).
`workingDirectory`	String	Optional	The path to the working directory on your instance.
`Commands`	StringList	Required	The shell script or command to run.

`Targets`	MapList	Required	An array of search criteria that identifies instances by using key-value pairs that you specify. For example: `[{"Key":"InstanceIds","Values":["i-02573cafcfEXAMPLE", "i-0471e04240EXAMPLE"]}]`
`taskToken`	String	Required	The task token to use for callback responses.

Sample output

The following table provides sample output from the step function. It shows that the total run time is over 100 seconds between step 5 (`TaskSubmitted`) and step 6 (`TaskSucceeded`). This demonstrates that the step function waited for the `sleep 100` command to finish before moving to the next task in the workflow.

ID	Type	Step	Resource	Elapsed Time (ms)	Timestamp
1	`ExecutionStarted`		-	0	Mar 11, 2022 02:50:34.303 PM
2	`TaskStateEntered`	`StartAutomationWaitForCallBack`	-	40	Mar 11, 2022 02:50:34.343 PM

3	TaskScheduled	StartAutomationWaitForCallBack	-	40	Mar 11, 2022 02:50:34.343 PM
4	TaskStarted	StartAutomationWaitForCallBack	-	154	Mar 11, 2022 02:50:34.457 PM
5	TaskSubmitted	StartAutomationWaitForCallBack	-	657	Mar 11, 2022 02:50:34.960 PM
6	TaskSucceeded	StartAutomationWaitForCallBack	-	103835	Mar 11, 2022 02:52:18.138 PM
7	TaskStateExited	StartAutomationWaitForCallBack	-	103860	Mar 11, 2022 02:52:18.163 PM
8	ExecutionSucceeded		-	103897	Mar 11, 2022 02:52:18.200 PM

Run parallel reads of S3 objects by using Python in an AWS Lambda function

Eduardo Bortoluzzi, Amazon Web Services

Summary

You can use this pattern to retrieve and summarize a list of documents from Amazon Simple Storage Service (Amazon S3) buckets in real time. The pattern provides example code to parallel read objects from S3 buckets on Amazon Web Services (AWS). The pattern showcases how to efficiently run I/O bound tasks with AWS Lambda functions using Python.

A financial company used this pattern in an interactive solution to manually approve or reject correlated financial transactions in real time. The financial transaction documents were stored in an S3 bucket related to the market. An operator selected a list of documents from the S3 bucket, analyzed the total value of the transactions that the solution calculated, and decided to approve or reject the selected batch.

I/O bound tasks support multiple threads. In this example code, the concurrent.futures.ThreadPoolExecutor is used with a maximum of 30 simultaneous threads, even though Lambda functions support up to 1,024 threads (with one of those threads being your main process). This limit is because too many threads create latency issues due to context switching and utilization of computing resources. You also need to increase the maximum pool connections in `botocore` so that all threads can perform the S3 object download simultaneously.

The example code uses one 8.3 KB object, with JSON data, in an S3 bucket. The object is read multiple times. After the Lambda function reads the object, the JSON data is decoded to a Python object. In December 2024, the result after running this example was 1,000 reads processed in 2.3 seconds and 10,000 reads processed in 27 seconds using a Lambda function configured with 2,304 MB of memory. AWS Lambda supports memory configurations from 128 MB to 10,240 MB (10 GB), though increasing the Lambdamemory beyond 2,304 MB didn't help to decrease the time to run this particular I/O-bound task.

The AWS Lambda Power Tuning tool was used to test different Lambda memory configurations and verify the best performance-to-cost ratio for the task. For test results, see the Additional information section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Proficiency with Python development

Limitations

- A Lambda function can have at most 1,024 execution processes or threads.
- New AWS accounts have a Lambda memory limit of 3,008 MB. Adjust the AWS Lambda Power Tuning tool accordingly. For more information, see the Troubleshooting section.
- Amazon S3 has a limit of 5,500 GET/HEAD requests per second per partitioned prefix.

Product versions

- Python 3.9 or later
- AWS Cloud Development Kit (AWS CDK) v2
- AWS Command Line Interface (AWS CLI) version 2
- AWS Lambda Power Tuning 4.3.6 (optional)

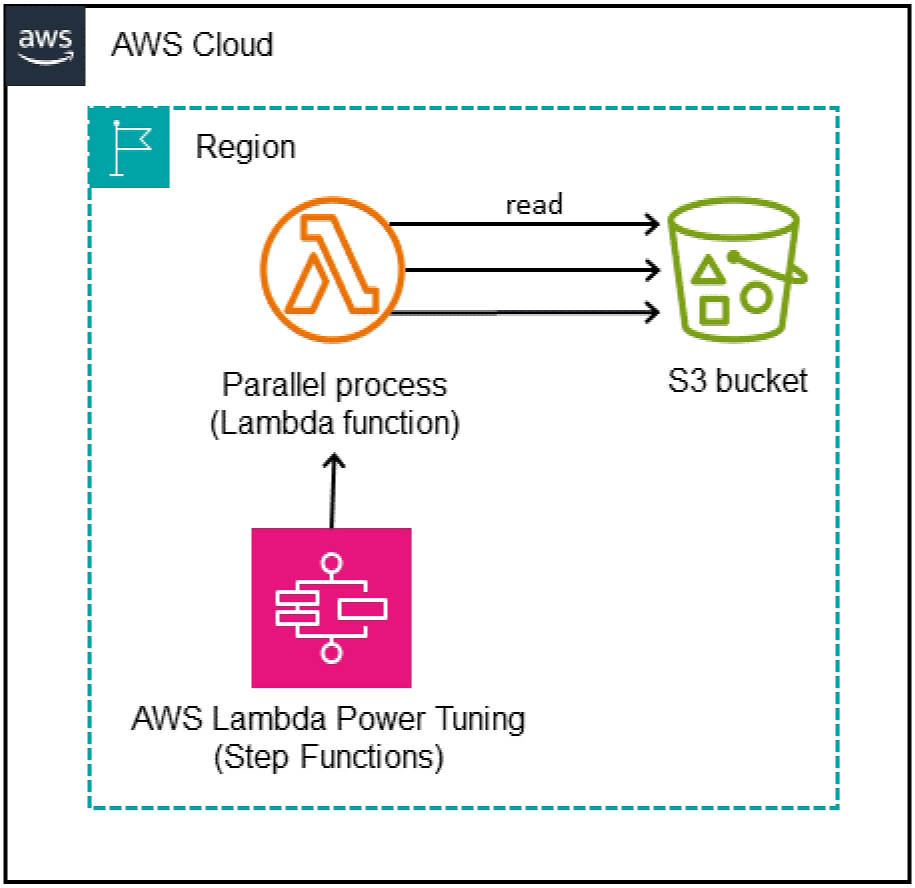
Architecture

Target technology stack

- AWS Lambda
- Amazon S3
- AWS Step Functions (if AWS Lambda Power Tuning is deployed)

Target architecture

The following diagram shows a Lambda function that reads objects from an S3 bucket in parallel. The diagram also has a Step Functions workflow for the AWS Lambda Power Tuning tool to fine-tune the Lambda function memory. This fine-tuning helps to achieve a good balance between cost and performance.



Automation and scale

The Lambda functions scale fast when required. To avoid 503 Slow Down errors from Amazon S3 during high demand, we recommend putting some limits on the scaling.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) v2 is a software development framework that helps you define and provision AWS Cloud infrastructure in code. The example infrastructure was created to be deployed with AWS CDK.
- AWS Command Line InterfaceAWS CLI is an open source tool that helps you interact with AWS services through commands in your command-line shell. In this pattern, AWS CLI version 2 is used to upload an example JSON file.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

- Amazon Simple Storage Service Amazon S3 is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

Other tools

- Python is a general-purpose computer programming language. The reuse of idle worker threads was introduced in Python version 3.8, and the Lambda function code in this pattern was created for Python version 3.9 and later.

Code repository

The code for this pattern is available in the aws-lambda-parallel-download GitHub repository.

Best practices

- This AWS CDK construct relies on your AWS account's user permissions to deploy the infrastructure. If you plan to use AWS CDK Pipelines or cross-account deployments, see Stack synthesizers.
- This example application doesn't have the access logs enabled at the S3 bucket. It's a best practice to enable access logs in production code.

Epics

Prepare the development environment

Task	Description	Skills required
Check the Python installed version.	This code has been tested specifically on Python 3.9 and Python 3.13, and it should work on all versions between these releases. To check your Python version, run `python3 -V` in your terminal, and	Cloud architect

Task	Description	Skills required
	install a newer version if needed. To verify that the required modules are installed, run `python3 -c "import pip, venv"`. No error message means the modules are properly installed and you're ready to run this example.	
Install AWS CDK.	To install the AWS CDK if it isn't already installed, follow the instructions at [Getting started with the AWS CDK](). To confirm that the installed AWS CDK version is 2.0 or later, run `cdk –version`.	Cloud architect
Bootstrap your environment.	To bootstrap your environme nt, if it hasn’t already been done, follow the instructions at [Bootstrap your environme nt for use with the AWS CDK]().	Cloud architect

Clone the example repository

Task	Description	Skills required
Clone the repository.	To clone the latest version of the repository, run the following command:	Cloud architect

Task	Description	Skills required
	`git clone --depth 1 --branch v1.2.0 \ git@github.com:aws-samples/aws-lambda-parallel-download.git`	
Change the working directory to the cloned repository.	Run the following command: `cd aws-lambda-parallel-download`	Cloud architect
Create the Python virtual environment.	To create a Python virtual environment, run the following command: `python3 -m venv .venv`	Cloud architect
Activate the virtual environment.	To activate the virtual environment, run the following command: `source .venv/bin/activate`	Cloud architect
Install the dependencies.	To install the Python dependencies, run the `pip` command: `pip install -r requirements.txt`	Cloud architect

Task	Description	Skills required
Browse the code.	(Optional) The example code that downloads an object from the S3 bucket is at `resources/parallel.py` . The infrastructure code is in the `parallel_download` folder.	Cloud architect

Deploy and test the app

Task	Description	Skills required
Deploy the app.	Run `cdk deploy`. Write down the AWS CDK outputs: • `ParallelDownloadStack.LambdaFunctionARN` • `ParallelDownloadStack.SampleS3BucketName` • `ParallelDownloadStack.StateMachineARN`	Cloud architect
Upload an example JSON file.	The repository contains an example JSON file of about 9 KB. To upload the file to the S3 bucket of the created stack, run the following command:	Cloud architect

Task	Description	Skills required
	`aws s3 cp sample.json s3://<ParallelDownloadStack.SampleS3BucketName>` Replace `<ParallelDownloadStack.SampleS3BucketName>` with the corresponding value from the AWS CDK output.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Run the app.</td><td>To run the app, do the following:
Sign in to the AWS Management Console, navigate to the Lambda console, and locate the Lambda function that has the ARN from the AWS CDK output <code>ParallelDownloadStack.LambdaFunctionARN</code> .
On the Test tab, change the Event JSON to the following:<pre>{"objectKey":
 "sample.json"}</pre>
Choose Test.
To see the result, choose details. The details will show the statistics of the parallel download, the information of the run, and the logs.</td><td>Cloud architect</td></tr>
<tr><td>Add the number of downloads.</td><td>(Optional) To run 1,500 get object calls, use the following JSON in Event JSON of the <code>Test</code> parameter:<pre>{"repeat": 1500,
 "objectKey": "sample.json"}</pre></td><td>Cloud architect</td></tr>
</table>

Optional: Run AWS Lambda Power Tuning

Task	Description	Skills required
Run the AWS Lambda Power Tuning tool.	1. Sign in to the console, and navigate to [Step Functions](https://console.aws.amazon.com/states/home). 2. Locate the state machine with the ARN from the AWS CDK output `ParallelDownloadStack.StateMachineARN`. 3. Choose **Start execution**, and paste the following JSON: `{ "lambdaARN": "<ParallelDownloadStack.LambdaFunctionARN>", "num": 10, "strategy": "balanced", "payload": {"repeat": 2000, "objectKey": "sample.json"} }` Remember to replace `<ParallelDownloadStack.LambdaFunctionARN>` with the value from the AWS CDK output. At the end of the run, the result will be on the	Cloud architect

Task	Description	Skills required
	Execution input and output tab.	
View the AWS Lambda Power Tuning results in a graph.	On the **Execution input and output** tab, copy the `visualization` property link, and paste it in a new browser tab.	Cloud architect

Clean up

Task	Description	Skills required
Remove the objects from the S3 bucket.	Before you destroy the deployed resources, you remove all the objects from the S3 bucket: `aws s3 rm s3://<ParallelDownloadStack.SampleS3BucketName> \ --recursive` Remember to replace `<ParallelDownloadStack.SampleS3BucketName>` with the value from the AWS CDK outputs.	Cloud architect
Destroy the resources.	To destroy all the resources that were created for this pilot, run the following command:	Cloud architect

Task	Description	Skills required
	`cdk destroy`	

Troubleshooting

Issue	Solution
`'MemorySize' value failed to satisfy constraint: Member must have value less than or equal to 3008`	For new accounts, you might not be able to configure more than 3,008 MB in your Lambda functions. To test using AWS Lambda Power Tuning, add the following property at the input JSON when you are starting the Step Functions execution: `"powerValues": [ 512, 1024, 1536, 2048, 2560, 3008 ]`

Related resources

- Python – concurrent.futures.ThreadPoolExecutor

- Profiling functions with AWS Lambda Power Tuning

Additional information

Code

The following code snippet performs the parallel I/O processing:

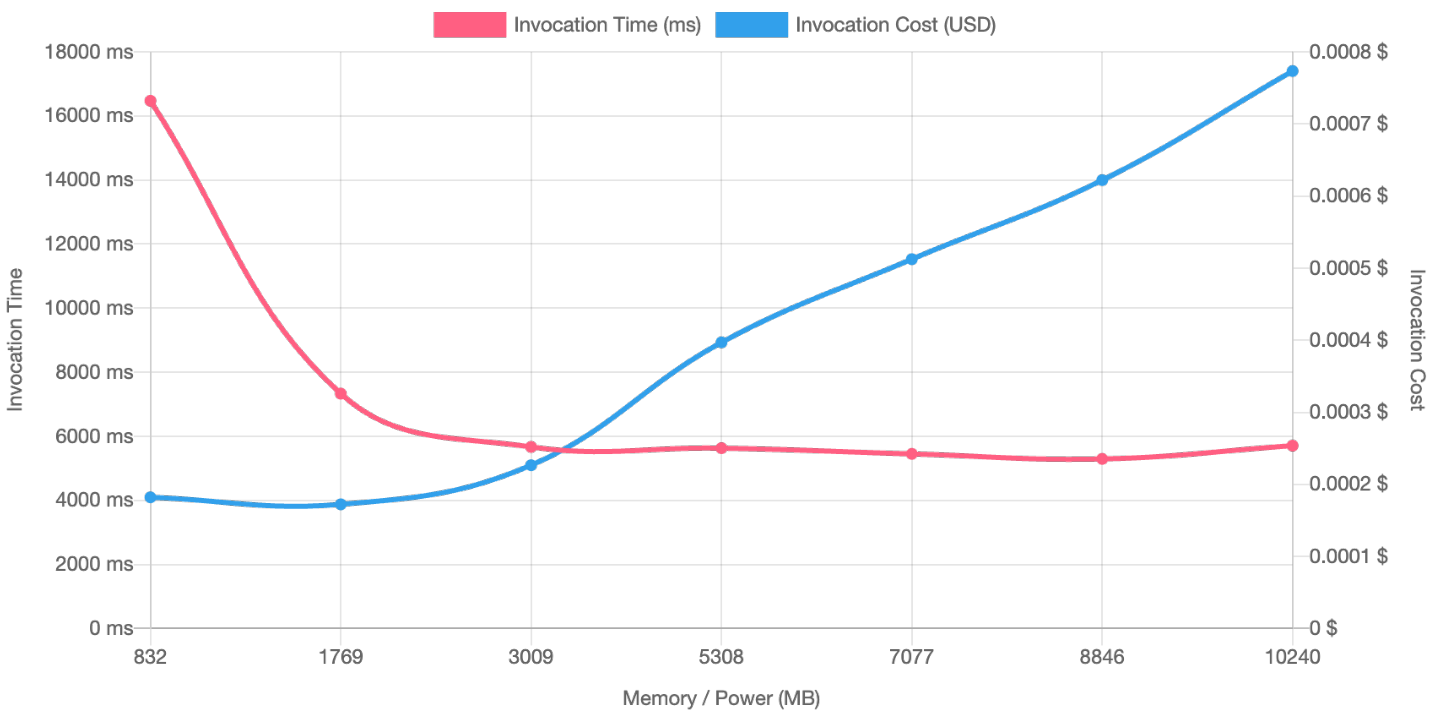
```
with ThreadPoolExecutor(max_workers=MAX_WORKERS) as executor:
  for result in executor.map(a_function, (the_arguments)):
    ...
```

The `ThreadPoolExecutor` reuses the threads when they become available.

Testing and results

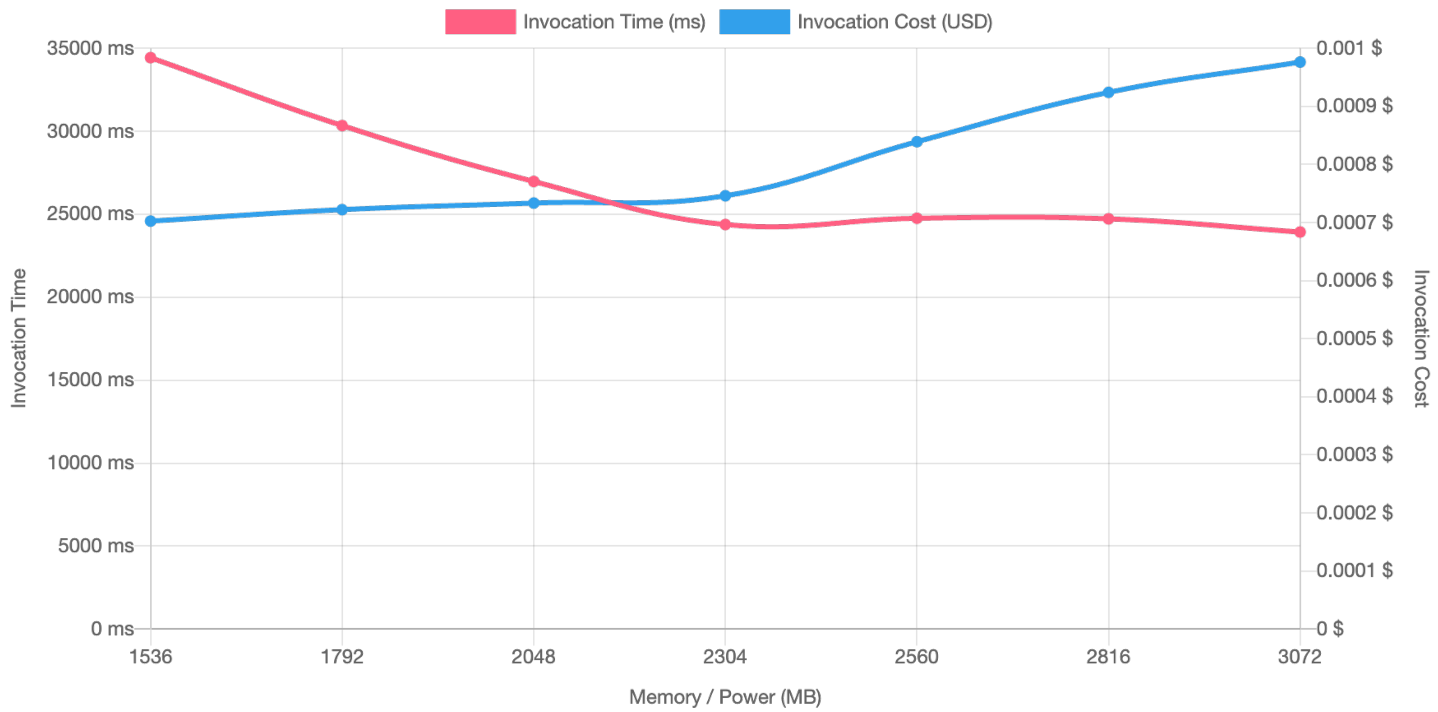
These tests were conducted in December 2024.

The first test processed 2,500 object reads, with the following result.



Starting at 3,009 MB, the processing-time level stayed almost the same for any memory increase, but the cost increased as the memory size increased.

Another test investigated the range between 1,536 MB and 3,072 MB of memory, using values that were multiples of 256 MB and processing 10,000 object reads, with the following results.



The best performance-to-cost ratio was with the 2,304 MB memory Lambda configuration.

For comparison, a sequential process of 2,500 object reads took 47 seconds. The parallel process using the 2,304 MB Lambda configuration took 7 seconds, which is 85 percent less.

Send telemetry data from AWS Lambda to OpenSearch for real-time analytics and visualization

Tabby Ward, Guy Bachar, and David Kilzer, Amazon Web Services

Summary

Modern applications are becoming increasingly distributed and event-driven, which reinforces the need for real-time monitoring and observability. AWS Lambda is a serverless computing service that plays a crucial role in building scalable and event-driven architectures. However, monitoring and troubleshooting Lambda functions can be challenging if you rely solely on Amazon CloudWatch Logs, which can introduce latency and limited retention periods.

To address this challenge, AWS introduced the Lambda Telemetry API, which enables Lambda functions to send telemetry data directly to third-party monitoring and observability tools. This API supports real-time streaming of logs, metrics, and traces, and provides a comprehensive and timely view of the performance and health of your Lambda functions.

This pattern explains how to integrate the Lambda Telemetry API with [OpenSearch](), which is an open-source, distributed search and analytics engine. OpenSearch offers a powerful and scalable platform for ingesting, storing, and analyzing large volumes of data, which makes it an ideal choice for Lambda telemetry data. Specifically, this pattern demonstrates how to send logs from a Lambda function that's written in Python directly to an OpenSearch cluster by using a Lambda extension that's provided by AWS. This solution is flexible and customizable, so you can create your own Lambda extension or alter the sample source code to change the output format as desired.

The pattern explains how to set up and configure the Lambda Telemetry API integration with OpenSearch, and includes best practices for security, cost optimization, and scalability. The objective is to help you gain deeper insights into your Lambda functions and enhance the overall observability of your serverless applications.

> Note: This pattern focuses on integrating the Lambda Telemetry API with managed OpenSearc h. However, the principles and techniques discussed are also applicable to self-managed OpenSearch and Elasticsearch.

Prerequisites and limitations

Before you begin the integration process, make sure that you have the following prerequisites in place:

AWS account: An active AWS account with appropriate permissions to create and manage the following AWS resources:

- AWS Lambda
- AWS Identity and Access Management (IAM)
- Amazon OpenSearch Service (if you're using a managed OpenSearch cluster)

OpenSearch cluster:

- You can use an existing self-managed OpenSearch cluster or a managed service such as OpenSearch Service.
- If you're using OpenSearch Service, set up your OpenSearch cluster by following the instructions in Getting started with Amazon OpenSearch Service in the OpenSearch Service documentation.
- Make sure that the OpenSearch cluster is accessible from your Lambda function and is configured with the necessary security settings, such as access policies, encryption, and authentication.
- Configure the OpenSearch cluster with the necessary index mappings and settings to ingest the Lambda telemetry data. For more information, see Loading streaming data into Amazon OpenSearch Service in the OpenSearch Service documentation.

Network connectivity:

- Ensure that your Lambda function has the necessary network connectivity to access the OpenSearch cluster. For guidance on how to configure virtual private cloud (VPC) settings, see Launching your Amazon OpenSearch Service domains within a VPC in the OpenSearch Service documentation.

IAM roles and policies:

- Create an IAM role with the necessary permissions for your Lambda function to access the OpenSearch cluster and access your credentials stored in AWS Secrets Manager.

- Attach the appropriate IAM policies to the role, such as the `AWSLambdaBasicExecutionRole` policy and any additional permissions required to interact with OpenSearch.
- Verify that the IAM permissions granted to your Lambda function allow it to write data to the OpenSearch cluster. For information about managing IAM permissions, see Defining Lambda function permissions with an execution role in the Lambda documentation.

Programming language knowledge:

- You will need basic knowledge of Python (or the programming language of your choice) to understand and modify the sample code for the Lambda function and the Lambda extension.

Development environment:

- Set up a local development environment with the necessary tools and dependencies for building and deploying Lambda functions and extensions.

AWS CLI or AWS Management Console:

- Install and configure the AWS Command Line Interface (AWS CLI) or use the AWS Management Console with appropriate credentials to interact with the required AWS services.

Monitoring and logging:

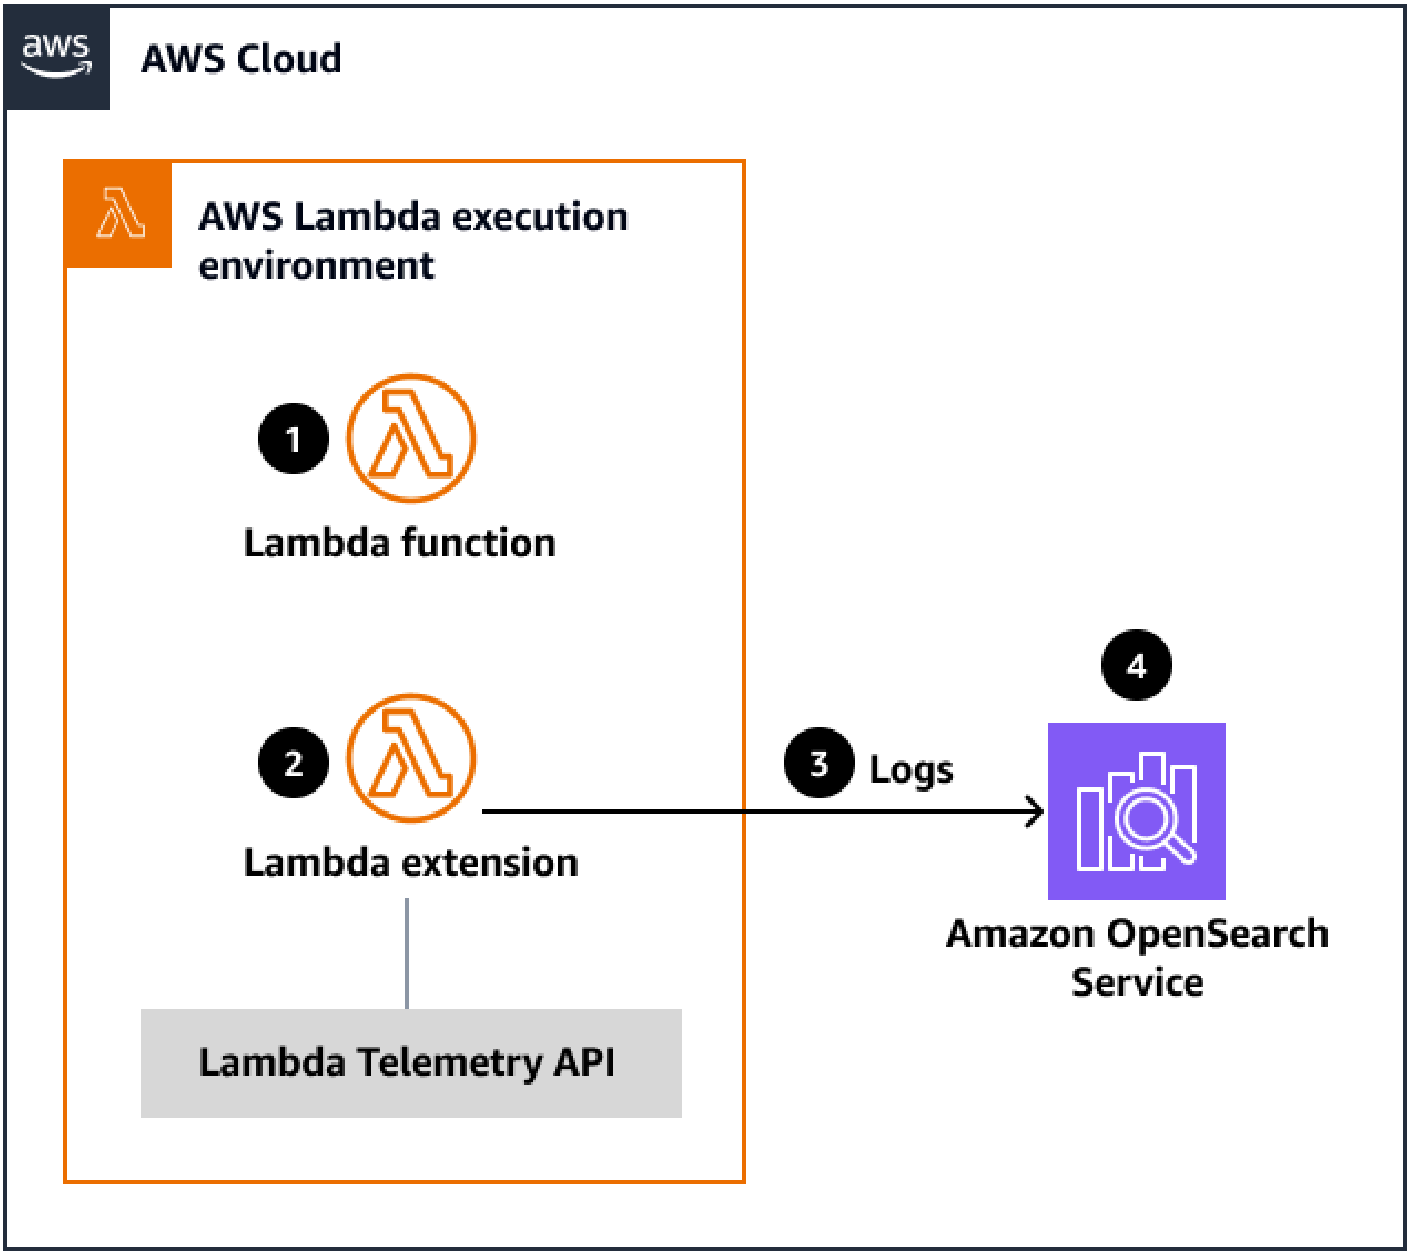
- Become familiar with monitoring and logging best practices on AWS, including services such as Amazon CloudWatch and AWS CloudTrail for monitoring and auditing purposes.
- Check CloudWatch Logs for your Lambda function to identify any errors or exceptions related to the Lambda Telemetry API integration. For troubleshooting guidance, see the Lambda Telemetry API documentation.

Architecture

This pattern uses OpenSearch Service to store logs and telemetry data that are generated by Lambda functions. This approach enables you to quickly stream logs directly to your OpenSearch cluster, which reduces the latency and costs associated with using CloudWatch Logs as an intermediary.

> **Note**
>
> Your Lambda extension code can push telemetry to OpenSearch Service, either by directly using the OpenSearch API or by using an OpenSearch client library. The Lambda extension can use the bulk operations supported by the OpenSearch API to batch telemetry events together and send them to OpenSearch Service in a single request.

The following workflow diagram illustrates the log workflow for Lambda functions when you use an OpenSearch cluster as the endpoint.



The architecture includes these components:

- Lambda function: The serverless function that generates logs and telemetry data during execution.
- Lambda extension: A Python-based extension that uses the Lambda Telemetry API to integrate directly with the OpenSearch cluster. This extension runs alongside the Lambda function in the same execution environment.
- Lambda Telemetry API: The API that enables Lambda extensions to send telemetry data, including logs, metrics, and traces, directly to third-party monitoring and observability tools.

- Amazon OpenSearch Service cluster: A managed OpenSearch cluster that's hosted on AWS. This cluster is responsible for ingesting, storing, and indexing the log data streamed from the Lambda function through the Lambda extension.

The workflow consists of these steps:

1. The Lambda function is called, and generates logs and telemetry data during its execution.
2. The Lambda extension runs alongside the function to capture the logs and telemetry data by using the Lambda Telemetry API.
3. The Lambda extension establishes a secure connection with the OpenSearch Service cluster and streams the log data in real time.
4. The OpenSearch Service cluster ingests, indexes, and stores the log data to make it available for search, analysis, and visualization through the use of tools such as Kibana or other compatible applications.

By circumventing CloudWatch Logs and sending log data directly to the OpenSearch cluster, this solution provides several benefits:

- Real-time log streaming and analysis, enabling faster troubleshooting and improved observability.
- Reduced latency and potential retention limitations associated with CloudWatch Logs.
- Flexibility to customize the Lambda extension or create your own extension for specific output formats or additional processing.
- Integration with the search, analytics, and visualization capabilities of OpenSearch Service for log analysis and monitoring.

The Epics section provides step-by-step instructions for setting up the Lambda extension, configuring the Lambda function, and integrating with the OpenSearch Service cluster. For security considerations, cost optimization strategies, and tips for monitoring and troubleshooting the solution, see the Best practices section.

Tools

AWS services

- AWS Lambda is a compute service that lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon OpenSearch Service is a fully managed service provided by AWS that makes it easy to deploy, operate, and scale OpenSearch clusters in the cloud.
- Lambda extensions extends the functionality of your Lambda functions by running custom code alongside them. You can use Lambda extensions to integrate Lambda with various monitoring, observability, security, and governance tools.
- AWS Lambda Telemetry API enables you to use extensions to capture enhanced monitoring and observability data directly from Lambda and send it to a destination of your choice.
- AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications.

Code repositories

- AWS Lambda Extensions includes demos and sample projects from AWS and AWS Partners to help you get started with building your own extensions.
- Example Lambda Telemetry Integrations for OpenSearch provides a sample Lambda extension that demonstrates how to send logs from a Lambda function to an OpenSearch cluster.

Other tools

- OpenSearch is an open-source distributed search and analytics engine that provides a powerful platform for ingesting, storing, and analyzing large volumes of data.
- Kibana is an open-source data visualization and exploration tool that you can use with OpenSearch. Note that the implementation of visualization and analytics is beyond the scope of this pattern. For more information, see the Kibana documentation and other resources.

Best practices

When you integrate the Lambda Telemetry API with OpenSearch, consider the following best practices.

Security and access control

- **Secure communication**: Encrypt all communications between your Lambda functions and the OpenSearch cluster by using HTTPS. Configure the necessary SSL/TLS settings in your Lambda extension and OpenSearch configuration.
- **IAM permissions**:
  - Extensions run in the same execution environment as the Lambda function, so they inherit the same level of access to resources such as the file system, networking, and environment variables.
  - Grant the minimum necessary IAM permissions to your Lambda functions to access the Lambda Telemetry API and write data to the OpenSearch cluster. Use the [principle of least privilege] to limit the scope of permissions.
- **OpenSearch access control**: Implement fine-grained access control in your OpenSearch cluster to restrict access to sensitive data. Use the built-in security features, such as user authentication, role-based access control, and index-level permissions, in OpenSearch.
- **Trusted extensions**: Always install extensions from a trusted source only. Use infrastructure as code (IaC) tools such as AWS CloudFormation to simplify the process of attaching the same extension configuration, including IAM permissions, to multiple Lambda functions. IaC tools also provide an audit record of the extensions and versions used previously.
- **Sensitive data handling**: When building extensions, avoid logging sensitive data. Sanitize payloads and metadata before logging or persisting them for audit purposes.

Cost optimization

- **Monitoring and alerting**: Set up monitoring and alerting mechanisms to track the volume of data being sent to OpenSearch from your Lambda functions. This will help you identify and address any potential cost overruns.
- **Data retention**: Carefully consider the appropriate data retention period for your Lambda telemetry data in OpenSearch. Longer retention periods can increase storage costs, so balance your observability needs with cost optimization.
- **Compression and indexing**: Enable data compression and optimize your OpenSearch indexing strategy to reduce the storage footprint of your Lambda telemetry data.
- **Reduced reliance on CloudWatch**: By integrating the Lambda Telemetry API directly with OpenSearch, you can potentially reduce your reliance on CloudWatch Logs, which can result in cost savings. This is because the Lambda Telemetry API enables you to send logs directly to OpenSearch, which bypasses the need to store and process the data in CloudWatch.

Scalability and reliability

- **Asynchronous processing**: Use asynchronous processing patterns, such as Amazon Simple Queue Service (Amazon SQS) or Amazon Kinesis, to decouple the Lambda function execution from the OpenSearch data ingestion. This helps maintain the responsiveness of your Lambda functions and improves the overall reliability of the system.
- **OpenSearch cluster scaling**: Monitor the performance and resource utilization of your OpenSearch cluster, and scale it up or down as needed to handle the increasing volume of Lambda telemetry data.
- **Failover and disaster recovery**: Implement a robust disaster recovery strategy for your OpenSearch cluster, including regular backups and the ability to quickly restore data in the event of a failure.

Observability and monitoring

- **Dashboards and visualizations**: Use Kibana or other dashboard tools to create custom dashboards and visualizations that provide insights into the performance and health of your Lambda functions based on the telemetry data in OpenSearch.
- **Alerting and notifications**: Set up alerts and notifications to proactively monitor for anomalies, errors, or performance issues in your Lambda functions. Integrate these alerts and notifications with your existing incident management processes.
- **Tracing and correlation**: Ensure that your Lambda telemetry data includes relevant tracing information, such as request IDs or correlation IDs, to enable end-to-end observability and troubleshooting across your distributed serverless applications.

By following these best practices, you can ensure that your integration of the Lambda Telemetry API with OpenSearch is secure, cost-effective, and scalable, and provides comprehensive observability for your serverless applications.

Epics

Build and deploy the Lambda extension layer

Task	Description	Skills required
Download the source code.	Download the sample extensions from the AWS	App developer, Cloud architect

Task	Description	Skills required
	Lambda Extensions repository.	
Navigate to the `python-example-telemetry-opensearch-extension` folder.	The AWS Lambda Extensions repository that you downloaded contains numerous examples for several use cases and language runtimes. Navigate to the python-example-telemetry-opensearch-extension folder to use the Python OpenSearch extension, which sends logs to OpenSearch.	App developer, Cloud architect
Add permissions to execute the extension endpoint.	Run the following command to make the extension endpoint executable: `chmod +x python-example-telemetry-opensearch-extension/extension.py`	App developer, Cloud architect

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install the extension dependencies locally.</td><td>Run the following command to install local dependencies for the Python code:
<pre>pip3 install -r python-example-telemetry-opensearch-extension/requirements.txt -t ./python-example-telemetry-opensearch-extension/</pre>
These dependencies will be mounted along with the extension code.</td><td>App developer, Cloud architect</td></tr>
</table>

Task	Description	Skills required

Create a .zip package for the extension to deploy it as a layer.	The extension .zip file should contain a root directory called `extensions/` , where the extension executable is located, and another root directory called `python-example-telemetry-opensearch-extension/` , where the core logic of the extension and its dependencies are located.
	
	Create the .zip package for the extension:
	
	`chmod +x extensions/python-example-telemetry-opensearch-extension`
	`zip -r extension.zip extensions python-example-telemetry-opensearch-extension`
		App developer, Cloud architect

Deploy the extension as a Lambda layer.	Publish the layer by using your extension .zip file and the following command:
	
	`aws lambda publish-layer-version \`
	`--layer-name "python-example-telemetry-opensearch-extension" \`
	`--zip-file "fileb://extension.zip"`
		App developer, Cloud architect

Integrate the extension into your function

Task	Description	Skills required
Add the layer to your function.	1. Sign in to the AWS Management Console and open the [Functions page](#) of the AWS Lambda console. 2. Select your function. 3. Under **Layers,** choose **Add a layer**. 4. Under **Choose a layer**, choose **Custom layers** as a layer source and add your layer. For more information about adding a layer to your Lambda function, see the [Lambda documentation](#).	App developer, Cloud architect
Set the environment variables for the function.	On the function page, choose the **Configuration** tab and add the following environme nt variables to your function: • URL – The URI of your OpenSearch endpoint where your logs will be sent. • `AUTH_SECRET` – The ARN of your OpenSearc h credentials stored in AWS Secrets Manager. This should be stored as a key-value pair and have	App developer, Cloud architect

Task	Description	Skills required
	two keys: `username` and `password`. • `PLATFORM_INDEX` , `FUNCTION_INDEX` , and `EXTENSION_INDEX` – The names of indexes that will store your telemetry data, function logs, and extension logs. Make sure that they adhere to the proper naming criteria. Otherwise, your indexes won't be created. • `DISPATCH_MIN_BATCH_SIZE` – The number of log events that you want to batch. However, when the function shuts down, your logs will be dispatched regardless of this setting.	

Add logging statements and test your function

Task	Description	Skills required
Add logging statements to your function.	Add logging statements to your function by using one of the built-in logging mechanisms or your logging module of choice. Here are examples of logging messages in Python:	App developer, Cloud architect

Task	Description	Skills required
	``` print("Your Log Message Here") logger = logging.getLogger(__name__) logger.info("Test Info Log.") logger.error("Test Error Log.") ```	
Test your function.	1. On the function page, choose the **Test** tab. 2. Create a test event for your function and run the test. For more information, see [Testing Lambda functions in the console](#) in the Lambda documentation. You should see **Executing function: succeeded** if everything works properly.	App developer, Cloud architect

View your logs in OpenSearch

Task	Description	Skills required
Query your indexes.	In OpenSearch, run the following command to query your indexes: ``` SELECT * FROM index-name ```	Cloud architect

Task	Description	Skills required
	Your logs should be displayed in the query results.	

Troubleshooting

Issue	Solution
Connectivity issues	• Confirm that your Lambda function has the necessary network connectivity to access the OpenSearch cluster. See the OpenSearch Service documentation for guidance on configuring VPC settings. • Verify that the IAM permissions granted to your Lambda function allow it to write data to the OpenSearch cluster. Review the Lambda documentation for information about managing IAM permissions.
Data ingestion errors	• Check CloudWatch Logs for your Lambda function to identify any errors or exceptions related to the Lambda Telemetry API integration. See the Lambda Telemetry API documentation for troubleshooting guidance. • Verify that the OpenSearch cluster is configured correctly and has the necessary index mappings and settings to ingest the Lambda telemetry data. Consult the OpenSearch documentation for more information.

Related resources

- Example Lambda Telemetry Integrations for OpenSearch (GitHub repository)

- Lambda Telemetry API (Lambda documentation)
- Introducing the AWS Lambda Telemetry API (AWS blog post)
- Integrating the AWS Lambda Telemetry API with Prometheus and OpenSearch (AWS blog post)

Additional information

Altering the log structure

The extension sends logs as a nested document to OpenSearch by default. This allows you to perform nested queries to retrieve individual column values.

If the default log output doesn't meet your specific needs, you can customize it by modifying the source code of the Lambda extension that's provided by AWS. AWS encourages customers to adapt the output to suit their business requirements. To change the log output, locate the `dispatch_to_opensearch` function in the `telemetry_dispatcher.py` file within the extension's source code and make the necessary alterations.

Set up a serverless cell router for a cell-based architecture

Mian Tariq and Ioannis Lioupras, Amazon Web Services

Summary

As the entry point to a global cell-based application's system, the cell router is responsible for efficiently assigning users to the appropriate cells and providing the endpoints to the users. The cell router handles functions such as storing user-to-cell mappings, monitoring cell capacity, and requesting new cells when needed. It's important to maintain cell-router functionality during potential disruptions.

The cell-router design framework in this pattern focuses on resilience, scalability, and overall performance optimization. The pattern uses static routing, where clients cache endpoints upon initial login and communicate directly with cells. This decoupling enhances system resilience by helping to ensure uninterrupted functionality of the cell-based application during a cell-router impairment.

This pattern uses an AWS CloudFormation template to deploy the architecture. For details about what the template deploys, or to deploy the same configuration by using the AWS Management Console, see the [Additional information](#) section.

> **Important**
>
> The demonstration, the code, and the AWS CloudFormation template presented in this pattern are intended for explanatory purposes only. The material provided is solely for the purpose of illustrating the design pattern and aiding in comprehension. The demo and code are not production-ready and should not be used for any live production activities. Any attempt to use the code or demo in a production environment is strongly discouraged and is at your own risk. We recommend consulting with appropriate professionals and performing thorough testing before implementing this pattern or any of its components in a production setting.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account

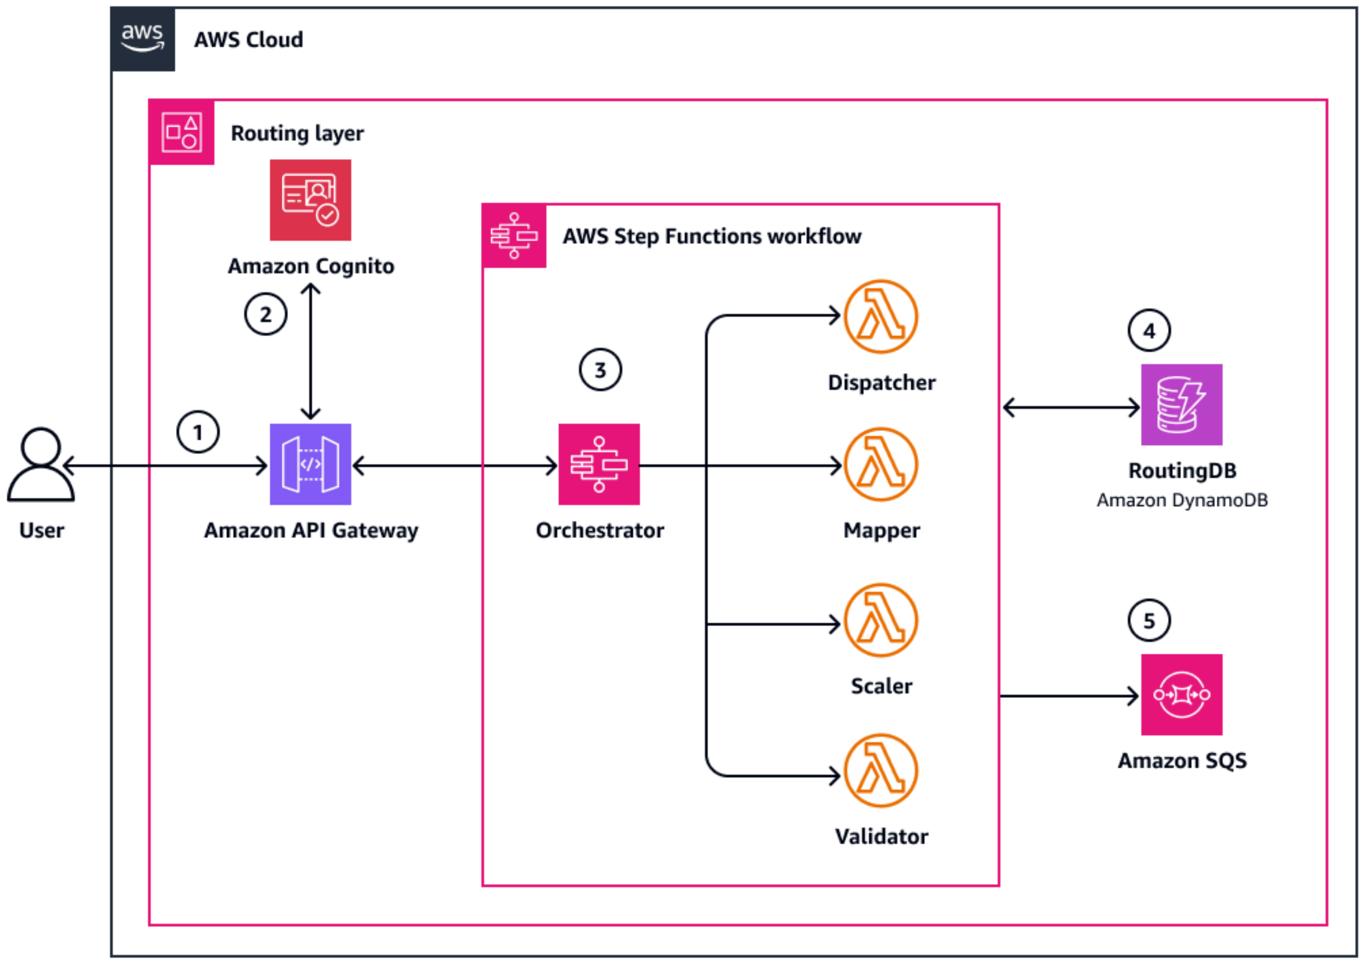
- The latest version of [AWS Command Line Interface (AWS CLI)]()
- [AWS credentials]() with the necessary permissions to create the AWS CloudFormation stack, AWS Lambda functions, and related resources

Product versions

- Python 3.12

Architecture

The following diagram shows a high-level design of the cell router.



The diagram steps through the following workflow:

1. The user contacts Amazon API Gateway, which serves as the front for the cell-router API endpoints.

2. Amazon Cognito handles the authentication and authorization.
3. The AWS Step Functions workflow consists of the following components:
   - **Orchestrator** – The `Orchestrator` uses AWS Step Functions to create a workflow, or state machine. The workflow is triggered by the cell router API. The `Orchestrator` executes Lambda functions based on the resource path.
   - **Dispatcher** – The `Dispatcher` Lambda function identifies and assigns one static cell per registered new user. The function searches for the cell with the least number of users, assigns it to the user, and returns the endpoints.
   - **Mapper** – The `Mapper` operation handles the user-to-cell mappings within the `RoutingDB` Amazon DynamoDB database that was created by the AWS CloudFormation template. When triggered, the `Mapper` function provides the already assigned users with their endpoints.
   - **Scaler** – The `Scaler` function keeps track of the cell occupancy and available capacity. When needed, the `Scaler` function can send a request through Amazon Simple Queue Service (Amazon SQS) to the Provision and Deploy layer to request new cells.
   - **Validator** – The `Validator` function validates the cell endpoints and detects any potential issues.
4. The `RoutingDB` stores cell information and attributes (API endpoints, AWS Region, state, metrics).
5. When the available capacity of cells exceeds a threshold, the cell router requests provisioning and deployment services through Amazon SQS to create new cells.

When new cells are created, `RoutingDB` gets updated from the Provision and Deploy layer. However, that process is beyond the scope of this pattern. For an overview of cell-based architecture design premises and details about the cell-router design used in this pattern, see the Additional information section.

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.

- Amazon Cognito provides authentication, authorization, and user management for web and mobile apps.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- AWS Step Functions is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications.

Other tools

- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub Serverless-Cell-Router repository.

Best practices

For best practices when building cell-based architectures, see the following AWS Well-Architected guidance:

- Reducing the Scope of Impact with Cell-Based Architecture
- AWS Well-Architected Framework Reliability Pillar: REL10-BP04 Use bulkhead architectures to limit scope of impact

Epics

Prepare source files

Task	Description	Skills required
Clone the example code repository.	To clone the Serverless-Cell-Router GitHub repository to your computer, use the following command: `git clone https://github.com/aws-samples/Serverless-Cell-Router/`	Developer
Set up AWS CLI temporary credentials.	Configure the AWS CLI with credentials for your AWS account. This walkthrough uses temporary credentials provided by the AWS IAM Identity Center **Command line or programmatic access** option. This sets the `AWS_ACCESS_KEY_ID` , `AWS_SECRET_ACCESS_KEY` , and `AWS_SESSION_TOKEN` AWS environment variables with the appropriate credentials for use with the AWS CLI.	Developer
Create an S3 bucket.	Create an S3 bucket that will be used to store and access the Serverless-Cell-Router Lambda functions for deployment by the AWS CloudFormation template.	Developer

Task	Description	Skills required
	To create the S3 bucket, use following command: `aws s3api create-bucket --bucket <bucket name> --region eu-central-1 --create-bucket-configuration LocationConstraint=eu-central-1`	

Create .zip files.	Create one .zip file for each Lambda function located in the [Functions](#) directory. These .zip files will be used to deploy the Lambda functions . On a Mac, use the following `zip` commands:
	`zip -j mapper-scr.zip Functions/Mapper.py`
	`zip -j dispatcher-scr.zip Functions/Dispatcher.py`
	`zip -j scaler-scr.zip Functions/Scaler.py`
	`zip -j cp validator-scr.zip Functions/Validator.py`
	`zip -j dynamodbDummyData-scr.zip Functions/DynamodbDummyData.py`
		Developer

Task	Description	Skills required

Copy the .zip files to the S3 bucket.	To copy all the Lambda function .zip files to the S3 bucket, use the following commands:
	
	`aws s3 cp mapper-scr.zip s3://<bucket name>`
	`aws s3 cp dispatcher-scr.zip s3://<bucket name>`
	`aws s3 cp scaler-scr.zip s3://<bucket name>`
	`aws s3 cp validator-scr.zip s3://<bucket name>`
	`aws s3 cp dynamodbDummyData-scr.zip s3://<bucket name>`
		Developer

Create the AWS CloudFormation stack

Task	Description	Skills required

Deploy the AWS CloudFormation template.	To deploy the AWS CloudFormation template, run the following AWS CLI command:
	
	`aws cloudformation create-stack --stack-name serverless.cell-router \`
	`--template-body file://Serverless-Cell-Router-Stack-v10.yaml \`

Task	Description	Skills required
Check progress.	Sign in to the AWS Management Console, open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation/, and check the progress of stack development. When the status is `CREATE_COMPLETE`, the stack has been deployed successfully.	Developer

Assess and verify

Task	Description	Skills required

Assign cells to the user.	To initiate the `Orchestrator`, run the following curl command:
	`curl -X POST \`
	`-H "Authorization: Bearer {User id_token}" \`
	`https://xxxxxx.execute-api.eu-central-1.amazonaws.com/Cell_Router_Development/cells`
	
	The `Orchestrator` triggers the execution of the `Dispatcher` function. The `Dispatcher`, in turn, verifies the existence of the
		Developer

Task	Description	Skills required
	user. If the user is found, the `Dispatcher` returns the associated cell ID and endpoint URLs. If the user isn't found, the `Dispatcher` allocates a cell to the user and sends the cell ID to the `Scaler` function for assessment of the assigned cell's residual capacity. The `Scaler` function's response is the following: `"cellID : cell-0002 , endPoint_1 : https://xxxxx.execute-api.eu-north-1.amazonaws.com/ , endPoint_2 : https://xxxxxxx.execute-api.eu-central-1.amazonaws.com/"`	

Task	Description	Skills required

Retrieve user cells.	To use the `Orchestrator` to execute the `Mapper` function, run the following command:
	`curl -X POST \ -H "Authorization: Bearer {User id_token}" \ https://xxxxxxxxx.execute-api.eu-central-1.amazonaws.com/Cell_Router_Development/mapper`
	The `Orchestrator` searches for the cell assigned to the user and returns the cell ID and URLs in the following response:
	`"cellID : cell-0002 , endPoint_1 : https://xxxxx.execute-api.eu-north-1.amazonaws.com/ , endPoint_2 : https://xxxxxxx.execute-api.eu-central-1.amazonaws.com/"`
		Developer

Clean up

Task	Description	Skills required
Clean up the resources.	To avoid incurring additiona l charges in your account, do the following: 1. Empty the S3 bucket that you created for the Lambda functions. 2. Delete the bucket. 3. Delete the AWS CloudForm ation stack.	App developer

Additional information

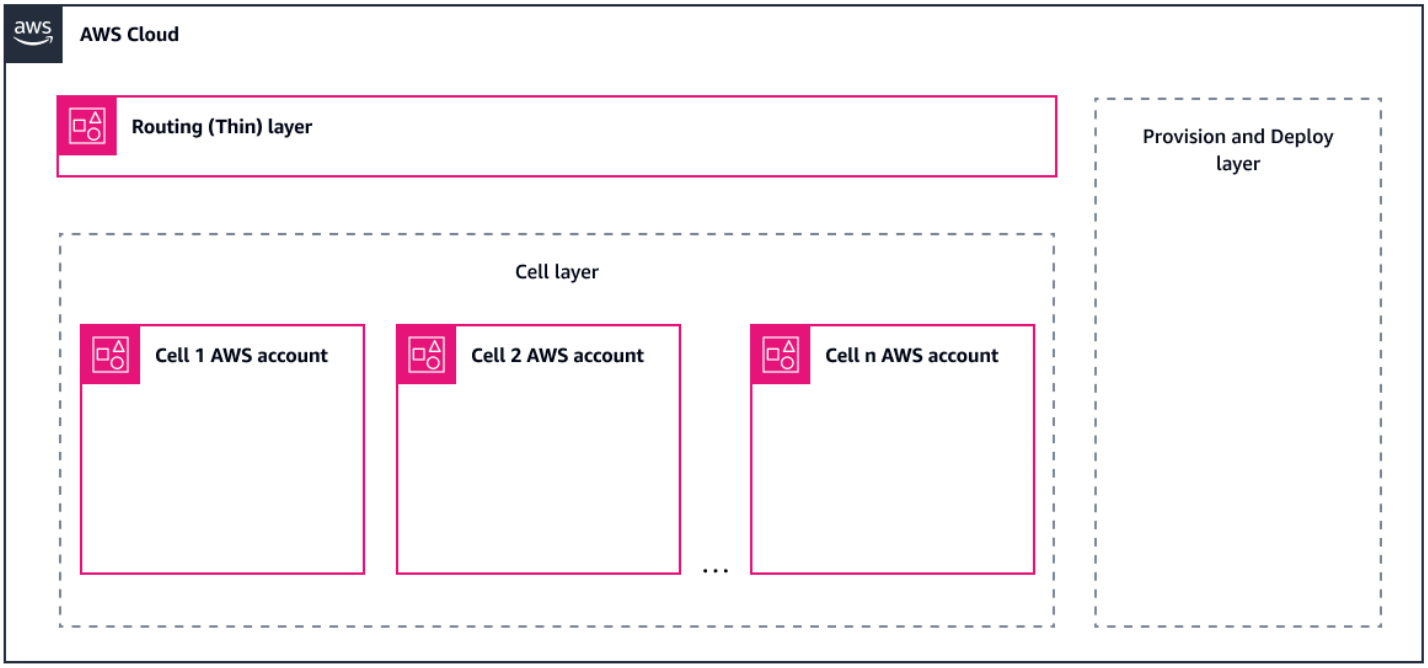
Cell-based architecture design premises

Although this pattern focuses on the cell router, it's important to understand the whole environment. The environment is structured into three discrete layers:

- The Routing layer, or Thin layer, which contains the cell router
- The Cell layer, comprising various cells
- The Provision and Deploy Layer, which provisions cells and deploys the application

Each layer sustains functionality even in the event of impairments affecting other layers. AWS accounts serve as a fault isolation boundary.

The following diagram shows the layers at a high level. The Cell layer and the Provision and Deploy layer are outside the scope of this pattern.



For more information about cell-based architecture, see [Reducing the Scope of Impact with Cell-Based Architecture: Cell routing](#).

Cell-router design pattern

The cell router is a shared component across cells. To mitigate potential impacts, it's important for the Routing layer to use a simplistic and horizontally scalable design that's as thin as possible. Serving as the system's entry point, the Routing layer consists of only the components that are required to efficiently assign users to the appropriate cells. Components within this layer don't engage in the management or creation of cells.

This pattern uses static routing, which means that the client caches the endpoints at the initial login and subsequently establishes direct communication with the cell. Periodic interactions between the client and the cell router are initiated to confirm the current status or retrieve any updates. This intentional decoupling enables uninterrupted operations for existing users in the event of cell-router downtime, and it provides continued functionality and resilience within the system.

In this pattern, the cell router supports the following functionalities:

- Retrieving cell data from the cell database in the Provision and Deploy layer and storing or updating the local database.
- Assigning a cell to each new registered user of the application by using the cell assignment algorithm.
- Storing the user-to-cells mapping in the local database.
- Checking the capacity of the cells during user assignment and raising an event for the vending machine to the Provision and Deploy layer to create cells.
- Using the cell creation criteria algorithm to provide this functionality.
- Responding to the newly registered user requests by providing the URLs of the static cells. These URLs will be cached on the client with a time to live (TTL).
- Responding to the existing user requests of an invalid URL by providing a new or updated URL.

To further understand the demonstration cell router that is set up by the AWS CloudFormation template, review the following components and steps:

1. Set up and configure the Amazon Cognito user pool.
2. Set up and configure the API Gateway API for the cell router.
3. Create a DynamoDB table.
4. Create and configure an SQS queue.
5. Implement the `Orchestrator`.
6. Implement the Lambda functions: `Dispatcher`, `Scaler`, `Mapper`, `Validator`.
7. Asses and verify.

The presupposition is that the Provision and Deploy layer is already established. Its implementation details fall beyond the scope of this artifact.

Because these components are set up and configured by an AWS CloudFormation template, the following steps are presented at a descriptive and high level. The assumption is that you have the required AWS skills to complete the setup and configuration.

1. Setup and configure the Amazon Cognito user pool

Sign in to the AWS Management Console, and open the Amazon Cognito console at https://console.aws.amazon.com/cognito/. Set up and configure an Amazon Cognito user pool named `CellRouterPool`, with app integration, hosted UI, and the necessary permissions.

2. Set up and configure the API Gateway API for the cell router

Open the API Gateway console at https://console.aws.amazon.com/apigateway/. Set up and configure an API named `CellRouter`, using an Amazon Cognito authorizer integrated with the Amazon Cognito user pool `CellRouterPool`. Implement the following elements:

- `CellRouter` API resources, including `POST` methods
- Integration with the Step Functions workflow implemented in step 5
- Authorization through the Amazon Cognito authorizer
- Integration request and response mappings
- Allocation of necessary permissions

3. Create a DynamoDB table

Open the DynamoDB console at https://console.aws.amazon.com/dynamodb/, and create a standard DynamoDB table called `tbl_router` with the following configuration:

- **Partition key** – `marketId`
- **Sort key** – `cellId`
- **Capacity mode** – Provisioned
- **Point-in-time recovery (PITR)** – Off

On the **Indexes** tab, create a global secondary index called `marketId-currentCapacity-index`. The `Scaler` Lambda function will use the index to conduct efficient searches for the cell with the lowest number of assigned users.

Create the table structure with the following attributes:

- `marketId` – Europe
- `cellId` – cell-0002
- `currentCapacity` – 2
- `endPoint_1` – <your endpoint for the first Region>
- `endPoint_2` – <your endpoint for the second Region>
- `IsHealthy` – True

- `maxCapacity` – 10
- `regionCode_1` – `eu-north-1`
- `regionCode_2` – `eu-central-1`
- `userIds` – <your email address>

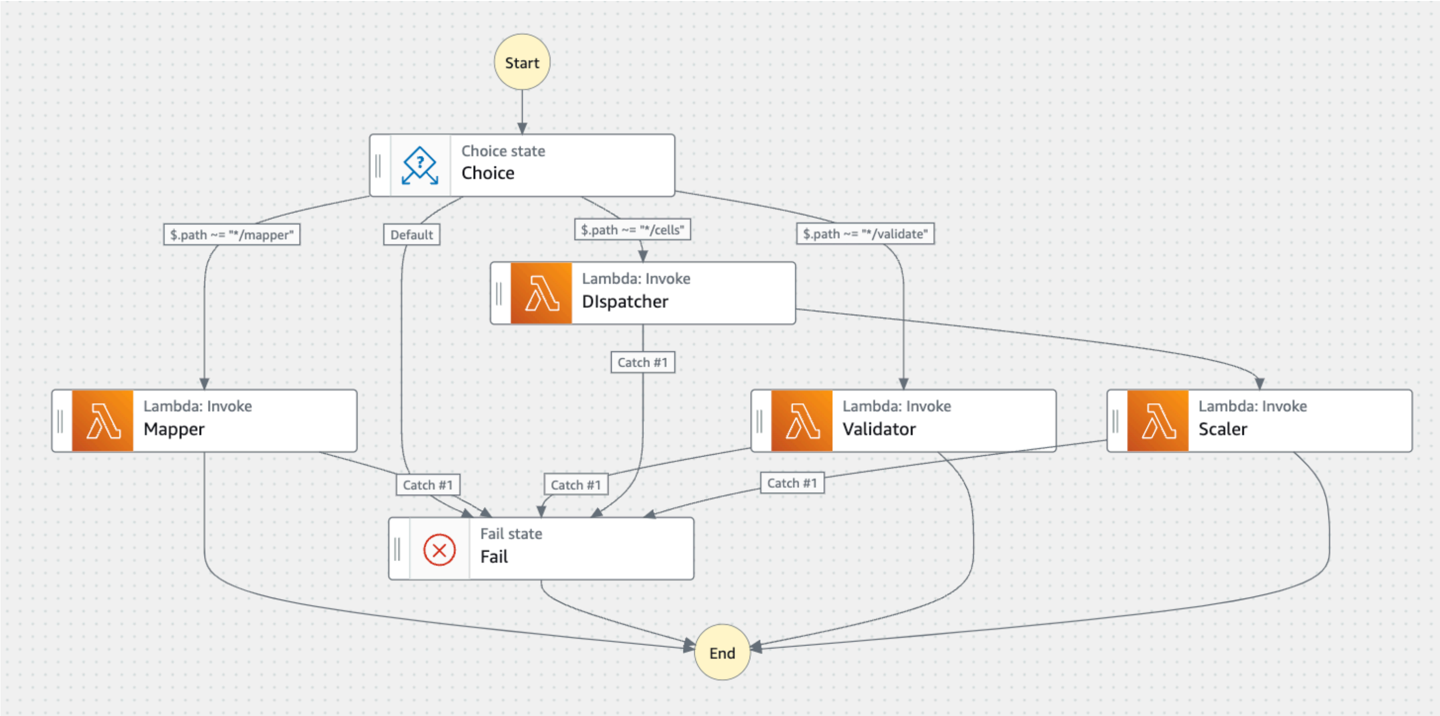
4. Create and configure an SQS queue

Open the Amazon SQS console at https://console.aws.amazon.com/sqs/, and create a standard SQS queue called `CellProvisioning` configured with **Amazon SQS key** encryption.

5. Implement the Orchestrator

Develop a Step Functions workflow to serve as the `Orchestrator` for the router. The workflow is callable through the cell router API. The workflow executes the designated Lambda functions based on the resource path. Integrate the step function with the API Gateway API for the cell router `CellRouter`, and configure the necessary permissions to invoke the Lambda functions.

The following diagram shows the workflow. The choice state invokes one of the Lambda functions. If the Lambda function is successful, the workflow ends. If the Lambda function fails, fail state is called.



6. Implement the Lambda functions

Implement the `Dispatcher`, `Mapper`, `Scaler`, and `Validator` functions. When you set up and configure each function in the demonstration, define a role for the function and assign the necessary permissions for performing required operations on the DynamoDB table `tbl_router`. Additionally, integrate each function into the workflow `Orchestrator`.

Dispatcher function

The `Dispatcher` function is responsible for identifying and assigning a single static cell for each new registered user. When a new user registers with the global application, the request goes to the `Dispatcher` function. The function processes the request by using predefined evaluation criteria such as the following:

1. **Region** – Select the cell in the market where the user is located. For example, if the user is accessing the global application from Europe, select a cell that uses AWS Regions in Europe.
2. **Proximity or latency** – Select the cell closest to the user For example, if the user is accessing the application from Holland, the function considers a cell that uses Frankfurt and Ireland. The decision regarding which cell is closest is based on metrics such as latency between the user's location and the cell Regions. For this example pattern, the information is statically fed from the Provision and Deploy layer.
3. **Health** – The `Dispatcher` function checks whether the selected cell is healthy based on the provided cell state (Healthy = true or false).
4. **Capacity** – The user distribution is based on *least number of users in a cell* logic, so the user is assigned to the cell that has least number of users.

Note

These criteria are presented to explain this example pattern only. For a real-life cell-router implementation, you can define more refined and use case–based criteria.

The `Orchestrator` invokes the Dispatcher function to assign users to cells. In this demo function, the market value is a static parameter defined as `europe`.

The `Dispatcher` function assesses whether a cell is already assigned to the user. If the cell is already assigned, the `Dispatcher` function returns the cell's endpoints. If no cell is assigned to the user, the function searches for the cell with the least number of users, assigns it to the user, and returns the endpoints. The efficiency of the cell search query is optimized by using the global secondary index.

Mapper function

The `Mapper` function oversees the storage and maintenance of user-to-cell mappings in the database. A singular cell is allocated to each registered user. Each cell has two distinct URLs—one for each AWS Region. Serving as API endpoints hosted on API Gateway, these URLs function as inbound points to the global application.

When the `Mapper` function receives a request from the client application, it runs a query on the DynamoDB table `tbl_router` to retrieve the user-to-cell mapping that is associated with the provided email ID. If it finds an assigned cell, the `Mapper` function promptly provides the cell's two URLs. The `Mapper` function also actively monitors alterations to the cell URLs, and it initiates notifications or updates to user settings.

Scaler function

The `Scaler` function manages the residual capacity of the cell. For each new user-registration request, the `Scaler` function assesses the available capacity of the cell that the `Dispatcher` function assigned to the user. If the cell has reached its predetermined limit according to the specified evaluation criteria, the function initiates a request through an Amazon SQS queue to the Provision and Deploy layer, soliciting the provisioning and deployment of new cells. The scaling of cells can be executed based on a set of evaluation criteria such as the following:

1. **Maximum users** – Each cell can have 500 maximum number of users.
2. **Buffer capacity** – The buffer capacity of each cell is 20 percent, which means that each cell can be assigned to 400 users at any time. The remaining 20 percent buffer capacity is reserved for future use cases and handling of unexpected scenarios (for example, when cell creation and provisioning services are unavailable).
3. **Cell creation** – As soon as an existing cell reaches 70 percent of capacity, a request is triggered to create an additional cell.

> **Note**
>
> These criteria are presented to explain this example pattern only. For a real-life cell-router implementation, you can define more refined and use case–based criteria.

The demonstration `Scaler` code is executed by the `Orchestrator` after the `Dispatcher` successfully assigns a cell to the newly registered user. The `Scaler`, upon receipt of the cell ID from the `Dispatcher`, evaluates whether the designated cell has adequate capacity to accommodate additional users, based on predefined evaluation criteria. If the cell's capacity is insufficient, the `Scaler` function dispatches a message to the Amazon SQS service. This message is retrieved by the service within the Provision and Deploy layer, initiating the provisioning of a new cell.

Validator function

The `Validator` function identifies and resolves issues pertaining to cell access. When a user signs in to the global application, the application retrieves the cell's URLs from the user profile settings and routes user requests to one of the two assigned Regions within the cell. If the URLs are inaccessible, the application can dispatch a validate URL request to the cell router. The cell-router `Orchestrator` invokes the `Validator`. The `Validator` initiates the validation process. Validation might include, among other checks, the following:

- Cross-referencing cell URLs in the request with URLs stored in database to identify and process potential updates
- Running a deep health check (for example, an `HTTP GET` request to the cell's endpoint)

In conclusion, the `Validator` function delivers responses to client application requests, furnishing validation status along with any required remediation steps.

The `Validator` is designed to enhance user experience. Consider a scenario where certain users encounter difficulty accessing the global application because an incident causes cells to be temporarily unavailable. Instead of presenting generic errors, the `Validator` function can provide instructive remediation steps. These steps might include the following actions:

- Inform users about the incident.
- Provide an approximate wait time before service availability.
- Provide a support contact number for obtaining additional information.

The demo code for the `Validator` function verifies that the user-supplied cell URLs in the request match the records stored in the `tbl_router` table. The `Validator` function also checks whether the cells are healthy.

Set up private access to an Amazon S3 bucket through a VPC endpoint

Martin Maritsch, Nicolas Jacob Baer, Gabriel Rodriguez Garcia, Shukhrat Khodjaev, Mohan Gowda Purushothama, and Joaquin Rinaudo, Amazon Web Services

Summary

In Amazon Simple Storage Service (Amazon S3), presigned URLs enable you to share files of arbitrary size with target users. By default, Amazon S3 presigned URLs are accessible from the internet within an expiration time window, which makes them convenient to use. However, corporate environments often require access to Amazon S3 presigned URLs to be limited to a private network only.

This pattern presents a serverless solution for securely interacting with S3 objects by using presigned URLs from a private network without internet traversal. In the architecture, users access an Application Load Balancer through an internal domain name. Traffic is routed internally through Amazon API Gateway and a virtual private cloud (VPC) endpoint for the S3 bucket. The AWS Lambda function generates presigned URLs for file downloads through the private VPC endpoint, which helps enhance security and privacy for sensitive data.

Prerequisites and limitations

Prerequisites

- A VPC that includes a subnet deployed in an AWS account that is connected to the corporate network (for example, through AWS Direct Connect).

Limitations

- The S3 bucket must have the same name as the domain, so we recommend that you check Amazon S3 bucket naming rules.
- This sample architecture doesn't include monitoring features for the deployed infrastructure. If your use case requires monitoring, consider adding AWS monitoring services.
- This sample architecture doesn't include input validation. If your use case requires input validation and an increased level of security, consider using AWS WAF to protect your API.
- This sample architecture doesn't include access logging with the Application Load Balancer. If your use case requires access logging, consider enabling load balancer access logs.

Versions

- Python version 3.11 or later
- Terraform version 1.6 or later

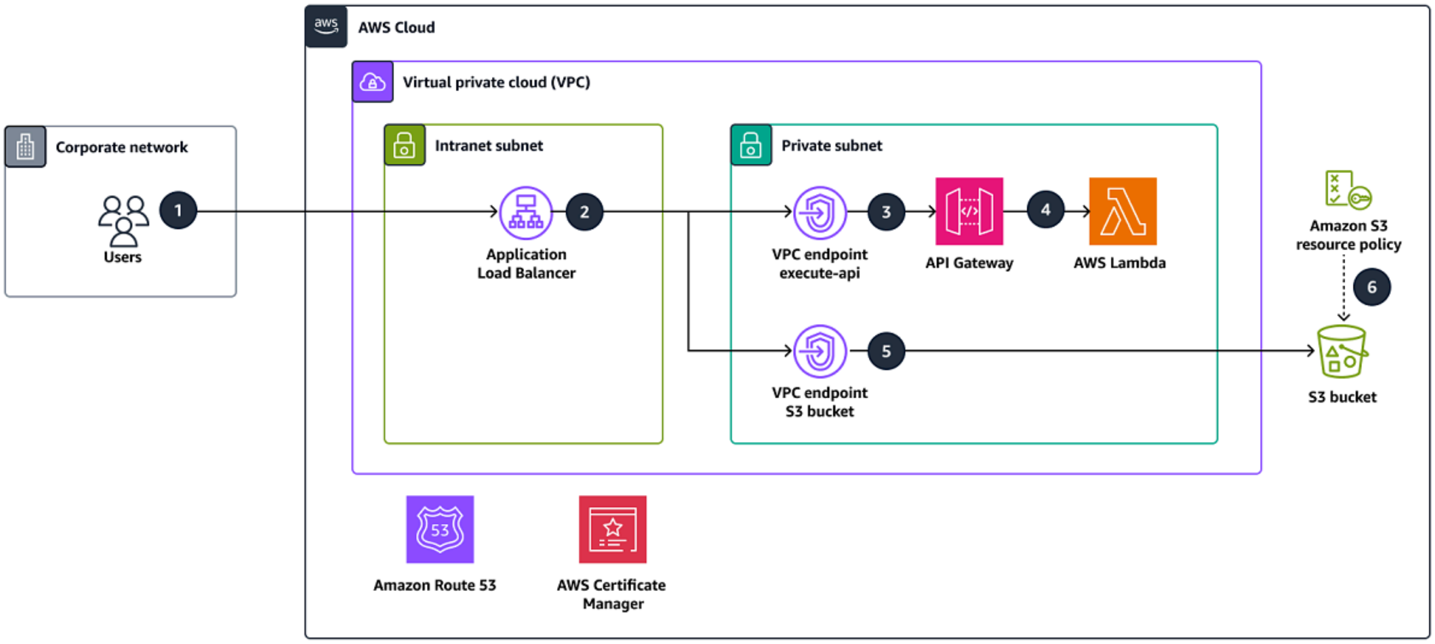
Architecture

Target technology stack

The following AWS services are used in the target technology stack:

- **Amazon S3** is the core storage service used for uploading, downloading, and storing files securely.
- **Amazon API Gateway** exposes resources and endpoints for interacting with the S3 bucket. This service plays a role in generating presigned URLs for downloading or uploading data.
- **AWS Lambda** generates presigned URLs for downloading files from Amazon S3. The Lambda function is called by API Gateway.
- **Amazon VPC** deploys resources within a VPC to provide network isolation. The VPC includes subnets and routing tables to control traffic flow.
- **Application Load Balancer** routes incoming traffic either to API Gateway or to the VPC endpoint of the S3 bucket. It allows users from the corporate network to access resources internally.
- **VPC endpoint for Amazon S3** enables direct, private communication between resources in the VPC and Amazon S3 without traversing the public internet.
- **AWS Identity and Access Management (IAM)** controls access to AWS resources. Permissions are set up to ensure secure interactions with the API and other services.

Target architecture



The diagram illustrates the following:

1. Users from the corporate network can access the Application Load Balancer through an internal domain name. We assume that a connection exists between the corporate network and the intranet subnet in the AWS account (for example, through a AWS Direct Connect connection).
2. The Application Load Balancer routes incoming traffic either to API Gateway to generate presigned URLs to download or upload data to Amazon S3, or to the VPC endpoint of the S3 bucket. In both scenarios, requests are routed internally and do not need to traverse the internet.
3. API Gateway exposes resources and endpoints to interact with the S3 bucket. In this example, we provide an endpoint to download files from the S3 bucket, but this could be extended to provide upload functionality as well.
4. The Lambda function generates the presigned URL to download a file from Amazon S3 by using the domain name of the Application Load Balancer instead of the public Amazon S3 domain.
5. The user receives the presigned URL and uses it to download the file from Amazon S3 by using the Application Load Balancer. The load balancer includes a default route to send traffic that's not intended for the API toward the VPC endpoint of the S3 bucket.
6. The VPC endpoint routes the presigned URL with the custom domain name to the S3 bucket. The S3 bucket must have the same name as the domain.

Automation and scale

This pattern uses Terraform to deploy the infrastructure from the code repository into an AWS account.

Tools

Tools

- Python is a general-purpose computer programming language.
- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.

Code repository

The code for this pattern is available in a GitHub repository at https://github.com/aws-samples/private-s3-vpce.

Best practices

The sample architecture for this pattern uses IAM permissions to control access to the API. Anyone who has valid IAM credentials can call the API. If your use case requires a more complex authorization model, you might want to use a different access control mechanism.

Epics

Deploy the solution in an AWS account

Task	Description	Skills required
Obtain AWS credentials.	Review your AWS credentials and your access to your account. For instructions, see Configuration and credential file settings in the AWS CLI documentation.	AWS DevOps, General AWS
Clone the repository.	Clone the GitHub repository provided with this pattern:	AWS DevOps, General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre>git clone https://g
ithub.com/aws-samp
les/private-s3-vpce</pre></td><td></td></tr>
<tr><td>Configure variables.</td><td>1. On your computer, in the GitHub repository, open the <code>terraform</code> folder:<pre>cd terraform</pre>2. Open the <code>example.tfvars</code> file and customize the parameters according to your needs.</td><td>AWS DevOps, General AWS</td></tr>
<tr><td>Deploy solution.</td><td>1. In the <code>terraform</code> folder, run Terraform and pass in the variables that you customized:<pre>terraform apply -
var-file="example
.tfvars"</pre>2. Confirm that the resources shown in the architecture diagram were deployed successfully.</td><td>AWS DevOps, General AWS</td></tr>
</table>

Test the solution

Task	Description	Skills required
Create a test file.	Upload a file to Amazon S3 to create a test scenario for the file download. You can use	AWS DevOps, General AWS

Task	Description	Skills required
	the [Amazon S3 console](https://console.aws.amazon.com/s3/) or the following AWS CLI command: `aws s3 cp /path/to/testfile s3://your-bucket-name/testfile`	
Test presigned URL functionality.	1. Send a request to the Application Load Balancer to create a presigned URL for the test file by using awscurl: `awscurl https://your-domain-name/api/get_url?key=testfile` This step creates a valid signature from your credentials, which will be validated by API Gateway. 2. Parse the link from the response you receive from the previous step, and open the presigned URL to download the file.	AWS DevOps, General AWS
Clean up.	Make sure to remove the resources when they are no longer required: `terraform destroy`	AWS DevOps, General AWS

Troubleshooting

Issue	Solution
S3 object key names with special characters such as number signs (#) break URL parameter s and lead to errors.	Encode URL parameters properly, and make sure that the S3 object key name follows Amazon S3 guidelines.

Troubleshoot states in AWS Step Functions by using Amazon Bedrock

Aniket Kurzadkar and Sangam Kushwaha, Amazon Web Services

Summary

AWS Step Functions error handling capabilities can help you see an error that occurs during a state in a workflow, but it can still be a challenge to find the root cause of an error and debug it. This pattern addresses that challenge and shows how Amazon Bedrock can help you resolve errors that occur during states in Step Functions.

Step Functions provides workflow orchestration, making it easier for developers to automate processes. Step Functions also provides error handling functionality that provides the following benefits:

- Developers can create more resilient applications that don't fail completely when something goes wrong.
- Workflows can include conditional logic to handle different types of errors differently.
- The system can automatically retry failed operations, perhaps with exponential backoff.
- Alternative execution paths can be defined for error scenarios, allowing the workflow to adapt and continue processing.

When an error occurs in a Step Functions workflow, this pattern shows how the error message and context can be sent to a foundation model (FM) like Claude 3 that's supported by Step Functions. The FM can analyze the error, categorize it, and suggest potential remediation steps.

Prerequisites and limitations

Prerequisites

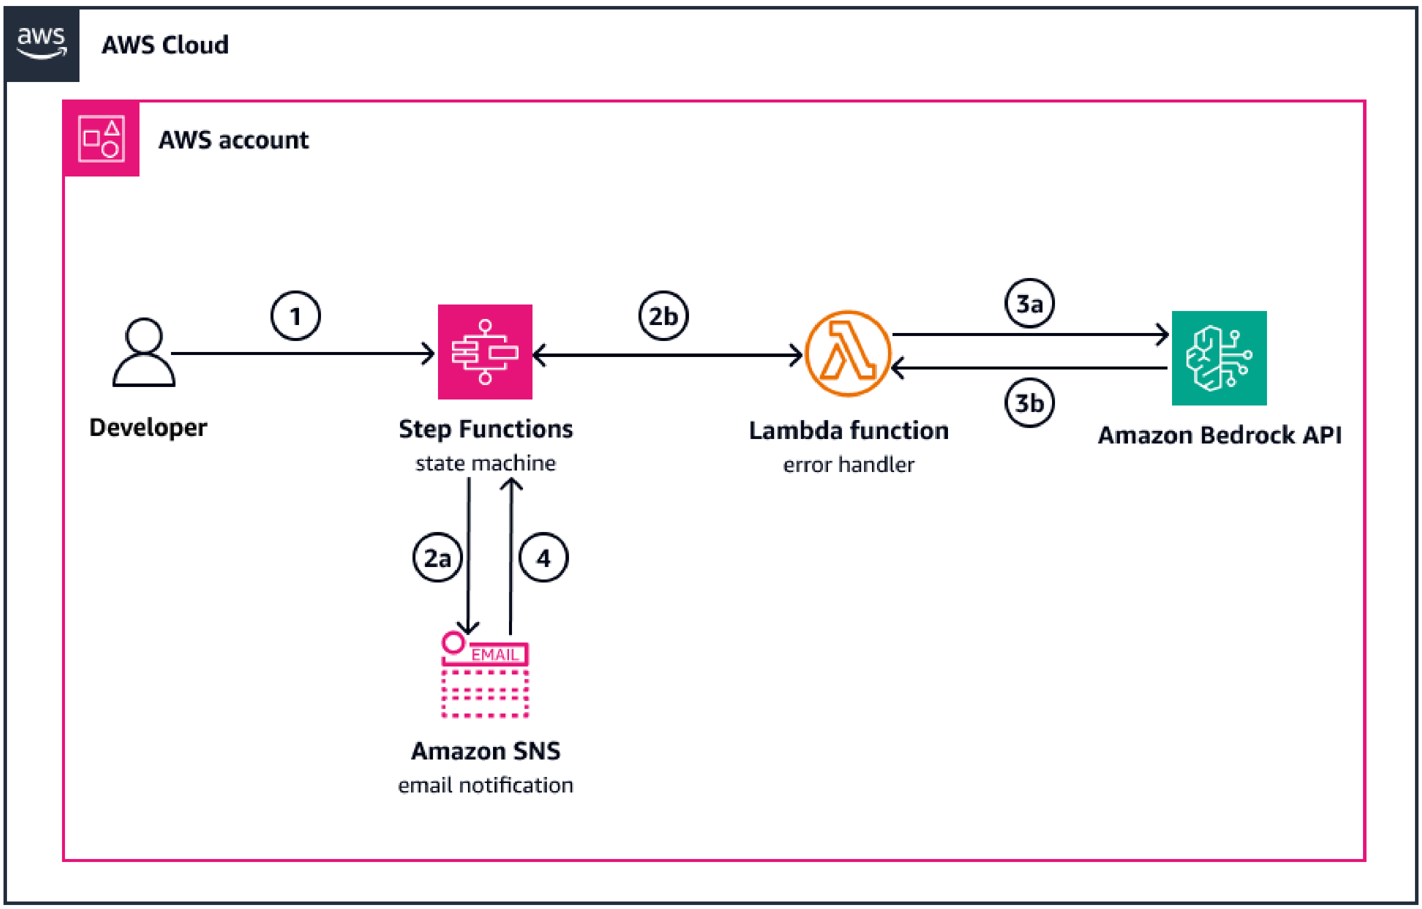
- An active AWS account
- Basic understanding of AWS Step Functions and workflows
- Amazon Bedrock API connectivity

Limitations

- You can use this pattern's approach for various AWS services. However, the results might vary according to the prompt created by AWS Lambda that's subsequently evaluated by Amazon Bedrock.
- Some AWS services aren't available in all AWS Regions. For Region availability, see [AWS services by Region](). For specific endpoints, see [Service endpoints and quotas](), and choose the link for the service.

Architecture

The following diagram shows the workflow and architecture components for this pattern.



The diagram shows the automated workflow for error handling and notification in a Step Functions state machine:

1. The developer starts a state machine's execution.
2. The Step Functions state machine begins processing its states. There are two possible outcomes:

  - (a) If all states execute successfully, the workflow proceeds directly to Amazon SNS for an email success notification.
  - (b) If any state fails, the workflow moves to the error handling Lambda function.

3. In case of an error, the following occurs:
  - (a) The Lambda function (error handler) is triggered. The Lambda function extracts the error message from the event data that the Step Functions state machine passed to it. Then the Lambda function prepares a prompt based on this error message and sends the prompt to Amazon Bedrock. The prompt requests solutions and suggestions related to the specific error encountered.
  - (b) Amazon Bedrock, which hosts the generative AI model, processes the input prompt. (This pattern uses the Anthropic Claude 3 foundation model (FM), which is one of many FMs that Amazon Bedrock supports.) The AI model analyses the error context. Then the model generates a response that can include explanations of why the error occurred, potential solutions to resolve the error, and suggestions to avoid making the same mistakes in the future.

    Amazon Bedrock returns its AI-generated response to the Lambda function. The Lambda function processes the response, potentially formatting it or extracting key information. Then the Lambda function sends the response to the state machine output.
4. After error handling or successful execution, the workflow concludes by triggering Amazon SNS to send an email notification.

Tools

AWS services

- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

Best practices

- Given that Amazon Bedrock is a generative AI model that learns from trained data, it also uses that data to train and generate context. As a best practice, conceal any private information that might lead to data leak problems.
- Although generative AI can provide valuable insights, critical error-handling decisions should still involve human oversight, especially in production environments.

Epics

Create a state machine for your workflow

Task	Description	Skills required
Create a state machine.	To create a state machine that's appropriate for your workflow, do the following: 1. Sign in to the AWS Management Console, and open the AWS Step Functions [console](#). 2. From the left navigatio n pane, choose **State machines**. 3. Choose **Create state machine**. 4. Choose a template according to your use case, or choose **Blank** to create a template according to your requirements.	AWS DevOps

Create a Lambda function

Task	Description	Skills required
Create a Lambda function.	To create a Lambda function, do the following: 1. In the AWS Management Console, navigate to the AWS Lambda console. 2. In the left navigation pane, choose **Functions** and then choose **Create function**. 3. On the **Create function** page, choose from the options to create a function. Then, enter a name in **Function name** and choose the appropria te language from the dropdown list in **Runtime**. 4. Choose **Create function**.	AWS DevOps
Set up the required logic in the Lambda code.	• To connect to the Amazon Bedrock API by using the [AWS SDK for Python (Boto3)](), use the following code. This code sets up a client for Amazon Bedrock, prepares the necessary parameters, and then sends a request to the Claude 3 model with a specified prompt.	AWS DevOps

Task	Description	Skills required

	This pattern invokes the Claude 3 model. For more information about all the supported foundation models including related model IDs, see [Supported foundation models in Amazon Bedrock](#) in the Amazon Bedrock documentation.
	
	``
	client = boto3.client(
	        service_name="bedrock-runtime", region_name="selected-region"
	    )
	
	    # Invoke Claude 3 with the text prompt
	    model_id = "your-model-id" # Select your Model ID, Based on the Model Id, Change the body format
	
	    try:
	        response = client.invoke_model(
	            modelId=model_id,
	            body=json.dumps(
	                {
	                    "anthropic_version": "bedrock-2023-05-31",

Chain AWS services together using a serverless approach

Aniket Braganza, Amazon Web Services

Summary

This pattern demonstrates a scalable, serverless approach for processing an uploaded file by chaining together Amazon Simple Storage Service (Amazon S3), Amazon Simple Notification Service (Amazon SNS), Amazon Simple Queue Service (Amazon SQS), and AWS Lambda. The uploaded file example is for demonstration purposes. You can use a serverless approach to complete other tasks by chaining together the combination of AWS services that are necessary to meet your business goals. The serverless approach employs an asynchronous workflow that relies on event-driven notifications, resilient storage, and function as a service (FaaS) computing to process requests. You can use the serverless approach to scale to meet demand while minimizing costs.

Note

There are several options for chaining AWS services together through a serverless approach. For example, you can use an approach that combines Lambda with Amazon S3 instead of Amazon SNS and Amazon SQS. However, this pattern uses Amazon SNS and Amazon SQS because this approach makes it possible to add multiple integration points into the Lambda invocation process during an event notification and to extend the implementation to include multiple listeners in a serverless orchestration while minimizing the amount of processing overhead.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Programmatic access to the AWS account. For more information, see:
  - Prerequisites in the AWS Cloud Development Kit (AWS CDK) documentation
  - Prerequisites in the AWS Command Line Interface (AWS CLI) documentation
- AWS CDK, installed
- AWS CLI, installed and configured

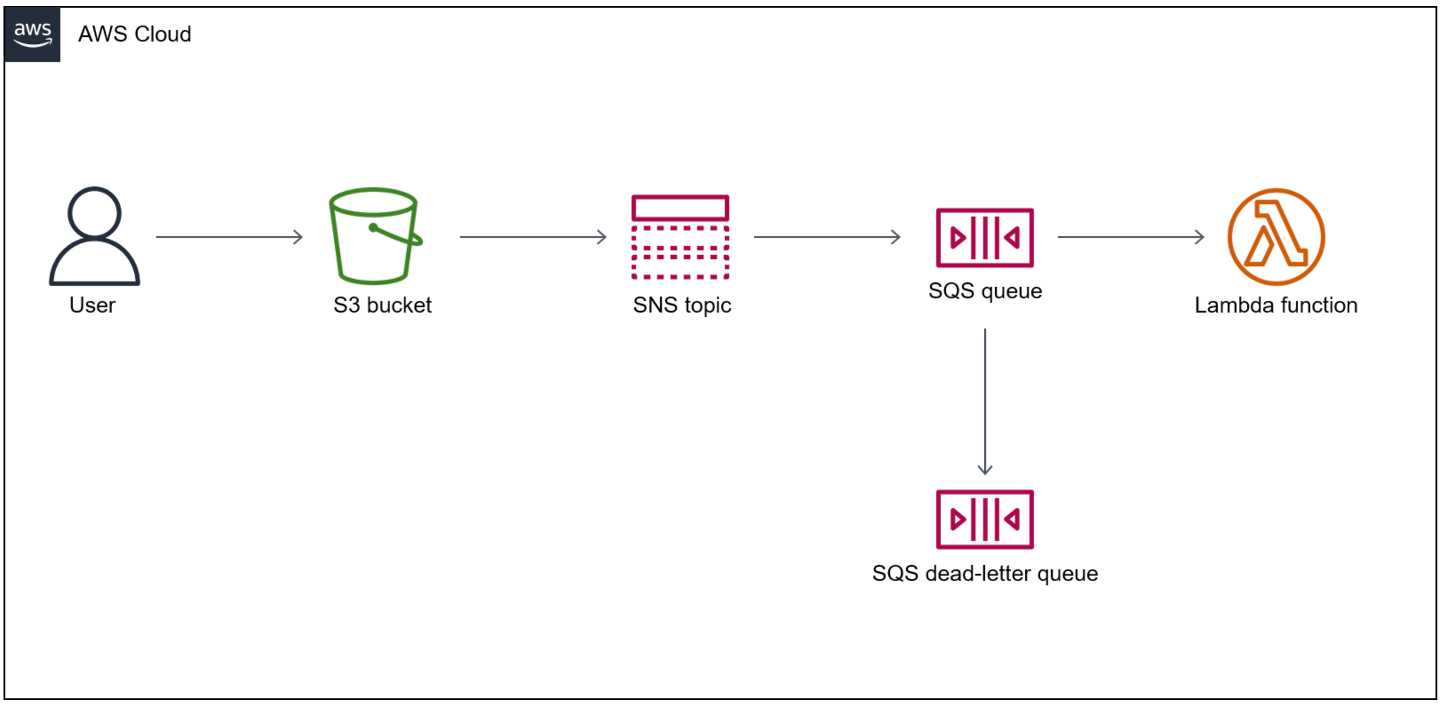
- [Python 3.9]

Product versions

- AWS CDK 2.x
- Python 3.9

Architecture

The following diagram illustrates how chained AWS services can enable a user to upload a file to an S3 bucket for processing.



The diagram shows the following workflow:

1. A user uploads a file to the S3 bucket.
2. The upload initiates an S3 event that publishes a message to an SNS topic. The message contains the details of the S3 event.
3. The message published to the SNS topic is inserted into an SQS queue, which is subscribed to and receives notifications for that topic.
4. A Lambda function polls the SQS queue (as its event source) and waits for messages to process.

5. When the Lambda function receives messages from the SQS queue, it processes them and acknowledges receipt of those messages.
6. If a message isn't processed by Lambda, then that message is returned to the SQS queue and is eventually transferred to an SQS dead-letter queue.

Technology stack

- Amazon S3
- Amazon SNS
- Amazon SQS
- AWS Lambda

Tools

AWS services

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Other tools

- AWS Cloud Development Kit (AWS CDK) is the primary tool for interacting with your AWS CDK app. It executes your app, interrogates the application model you defined, and produces and deploys the AWS CloudFormation templates generated by the AWS CDK.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Python is a high-level, interpreted general purpose programming language.

Code

The code for this pattern is available in the GitHub [Chaining S3 to SNS to SQS to Lambda]() repository.

Epics

Develop your serverless environment

Task	Description	Skills required
Clone the repository.	Clone the [repository]() and navigate to the `python/s3-sns-sqs-lambda-chain` folder.	App developer
Set up a virtual environment.	1. In the AWS CDK, run the `python3 -m venv .venv` command. 2. Run the `source .venv/bin/activate` command on MacOS/Linux or `.venv\Scripts\activate.bat` on Windows.	App developer
Install dependencies.	Run the `pip install -r requirements.txt` command.	App developer

Test the CloudFormation stack

Task	Description	Skills required
Run unit tests.	1. Run the `pip install -r requirements-dev.txt` command.	App developer, Test engineer

Task	Description	Skills required
	2. **Important** (Optional) Run the `cdk synth --no-staging > template.yml` command to generate the CloudFormation stack. You can inspect the stack, but avoid generating the staged resources and artifacts. 3. Run the `pytest` command to run all unit tests. 4. (Optional) Run the `pytest tests/unit/<test_filename>` command to run tests for a specific file.	

Deploy the CloudFormation stack

Task	Description	Skills required
Set up the bootstrap environment.	Follow the instructions in [Bootstrapping](#) in the AWS documentation to bootstrap the environment for AWS CDK deployment in each AWS Region where the CloudFormation stack will be deployed.	App developer, DevOps engineer, Data engineer

Task	Description	Skills required
	Note This step requires that you have credentials with programmatic access.	
Deploy the CloudFormation stack.	Run the `cdk deploy` command to build and deploy the stack to the AWS account.	App developer, DevOps engineer, AWS DevOps

Clean up your environment's resources

Task	Description	Skills required
Delete the CloudFormation stack and remove associated resources.	To delete the CloudForm ation stack that was created and remove all associated resources, run the `run cdk` destroy command.	App developer

Automate the setup of inter-Region peering with AWS Transit Gateway

Ram Kandaswamy, Amazon Web Services

Summary

AWS Transit Gateway connects virtual private clouds (VPCs) and on-premises networks through a central hub. Transit Gateway traffic always stays on the global Amazon Web Services (AWS) backbone and doesn't traverse the public internet, which reduces threat vectors, such as common exploits and distributed denial of service (DDoS) attacks.

If you need to communicate between two or more AWS Regions, you can use inter-Region Transit Gateway peering to establish peering connections between transit gateways in different Regions. However, manually configuring inter-Region peering with Transit Gateway can be a time-consuming process that has multiple steps. This pattern provides an automated process to remove these manual steps by using code to perform the peering. You can use this approach if you have to repeatedly configure several Regions and AWS accounts during a multi-Region organization setup.

This pattern uses an AWS CloudFormation stack that includes the AWS Step Functions workflow, AWS Lambda functions, AWS Identity and Access Management (IAM) roles, and log groups in Amazon CloudWatch Logs. You can then start a Step Functions execution and create the inter-Region peering connection for your transit gateways. To manually set up inter-Region peering, see [Peer VPCs in different AWS Regions by using AWS Transit Gateway](#).

Prerequisites and limitations

Prerequisites

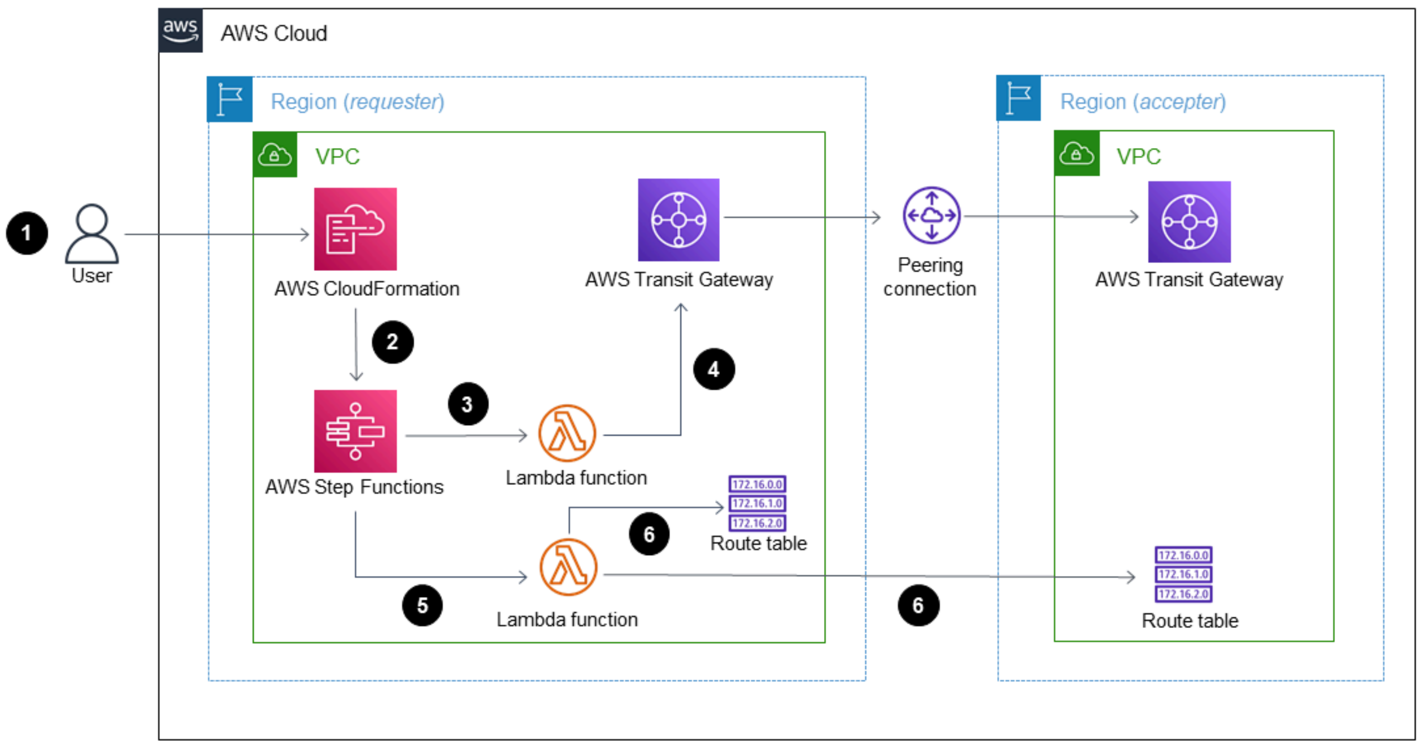
- An active AWS account.
- An existing Amazon Simple Storage Service (Amazon S3) bucket.
- Transit gateways, created and configured in the requestor Region and the acceptor Regions. The *requester* Region is where a peering request is originated and the *acceptor* Regions accept the peering request. For more information about this, see [Creating and accepting a VPC peering connection](#) in the Amazon VPC documentation.
- VPCs, installed and configured in the acceptor and requester Regions. For steps to create a VPC, see [Create the VPC](#) from [Get Started with Amazon VPC](#) in the Amazon VPC documentation.
- The VPCs must use the `addToTransitGateway` tag and `true` value.

- Security groups and network access control lists (ACLs) for your VPCs, configured according to your requirements. For more information about this, see Security groups for your VPC and Network ACLs in the Amazon VPC documentation.

AWS Regions and limitations

- Only certain AWS Regions support inter-Region peering. For a full list of Regions that support inter-Region peering, see the AWS Transit Gateway FAQs.
- In the attached sample code, the requestor Region is assumed to be `us-east-2`, and the acceptor Region is assumed to be `us-west-2`. If you want to configure different Regions, you must edit these values in all Python files. To implement a more complex setup that involves more than two Regions, you can change the Step Function to pass the Regions as a parameter to the Lambda function and run the function for each combination.

Architecture

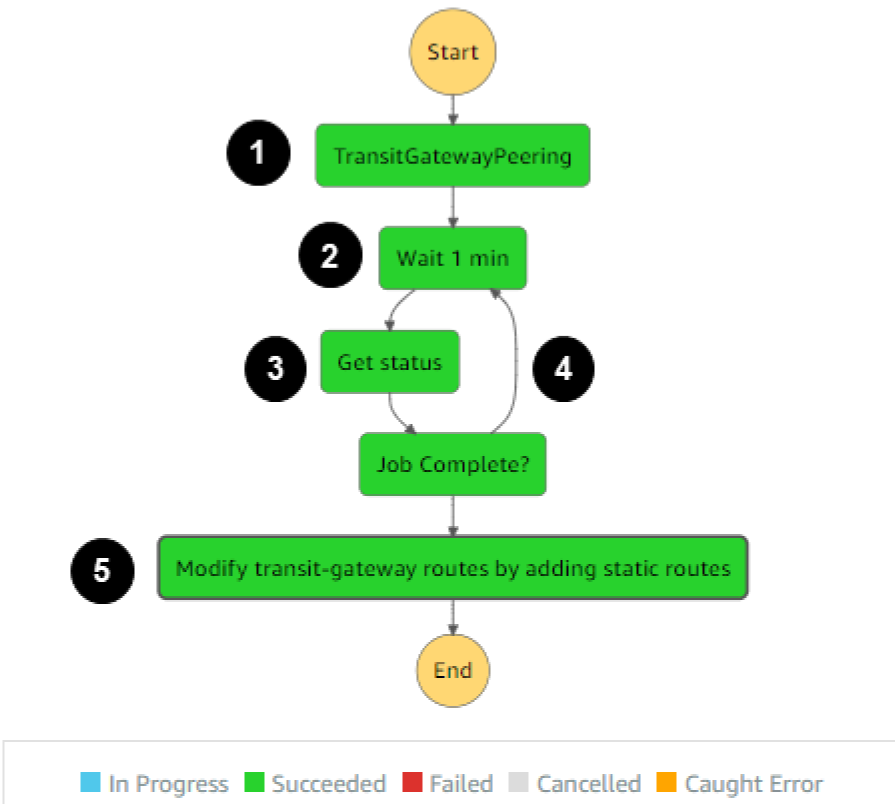


The diagram shows a workflow with the following steps:

1. The user creates an AWS CloudFormation stack.

2. AWS CloudFormation creates a Step Functions state machine that uses a Lambda function. For more information about this, see [Creating a Step Functions state machine that uses Lambda](#) in the AWS Step Functions documentation.
3. Step Functions calls a Lambda function for peering.
4. The Lambda function creates a peering connection between transit gateways.
5. Step Functions calls a Lambda function for route table modifications.
6. The Lambda function modifies the route tables by adding the Classless Inter-Domain Routing (CIDR) block of the VPCs.

Step Functions workflow



The diagram shows the following Step Functions workflow:

1. The Step Functions workflow calls the Lambda function for the transit gateway peering.
2. There is a timer call to wait for one minute.
3. The peering status is retrieved and sent to the condition block. The block is responsible for the looping.

4. If the success condition is not met, the workflow is coded to enter the timer stage.
5. If the success condition is met, a Lambda function is called to modify the route tables. After this call, the Step Functions workflow ends.

Tools

- AWS CloudFormation – AWS CloudFormation is a service that helps you model and set up your AWS resources.
- Amazon CloudWatch Logs – CloudWatch Logs helps you centralize the logs from all of your systems, applications, and AWS services that you use.
- AWS Identity and Access Management (IAM) – IAM is a web service for securely controlling access to AWS services.
- AWS Lambda – Lambda runs your code on a high-availability compute infrastructure and performs all of the administration of the compute resources.
- AWS Step Functions – Step Functions makes it easy to coordinate the components of distributed applications as a series of steps in a visual workflow.

Epics

Automate peering

Task	Description	Skills required
Upload the attached files to your S3 bucket.	Sign in to the AWS Management Console, open the Amazon S3 console, and then upload the `modify-transit-gateway-routes.zip` , `peer-transit-gateway.zip` , and `get-transit-gateway-peering-status.zip` files (attached) to your S3 bucket.	General AWS

Task	Description	Skills required
Create the AWS CloudFormation stack.	Run the following command to create an AWS CloudFormation stack using the `transit-gateway-peering.json` file (attached): `aws cloudformation create-stack --stack-name myteststack --template-body file://sampletemplate.json` The AWS CloudFormation stack creates the Step Functions workflow, the Lambda functions, IAM roles, and CloudWatch log groups. Make sure that the AWS CloudFormation template refers to the S3 bucket that contains the files that you uploaded earlier. **Note** You can also create a stack by using the AWS CloudFormation console. For more information about this, see [Creating a stack on the AWS CloudFormation console]() in the AWS	DevOps engineer

Task	Description	Skills required
	CloudFormation documentation.	
Start a new execution in Step Functions.	Open the Step Functions console and start a new execution. Step Functions calls the Lambda function and creates the peering connection for the transit gateways. You don't need an input JSON file. Verify that an attachment is available and that the connection type is **Peering**. For more information about this, see Start a new execution from Getting started with AWS Step Functions in the AWS Steps Functions documentation.	DevOps engineer, General AWS

Task	Description	Skills required
Verify the routes in the route tables.	Inter-Region peering is established between the transit gateways. The route tables are updated with the peer Region VPC's IPv4 CIDR block range. Open the Amazon VPC console and choose the **Associations** tab in the route table that corresponds to the transit gateway attachment. Verify the VPC CIDR block range of the peered Regions. For detailed steps and instructions, see [Associate a transit gateway route table] in the Amazon VPC documentation.	Network administrator

Centralize network connectivity using AWS Transit Gateway

Mydhili Palagummi and Nikhil Marrapu, Amazon Web Services

Summary

This pattern describes the simplest configuration in which AWS Transit Gateway can be used to connect an on-premises network to virtual private clouds (VPCs) in multiple AWS accounts within an AWS Region. Using this setup, you can establish a hybrid network that connects multiple VPC networks in a Region and an on-premises network. This is accomplished by using a transit gateway and a virtual private network (VPN) connection to the on-premises network.

Prerequisites and limitations

Prerequisites

- An account for hosting network services, managed as a member account of an organization in AWS Organizations
- VPCs in multiple AWS accounts, without overlapping Classless Inter-Domain Routing (CIDR) blocks

Limitations

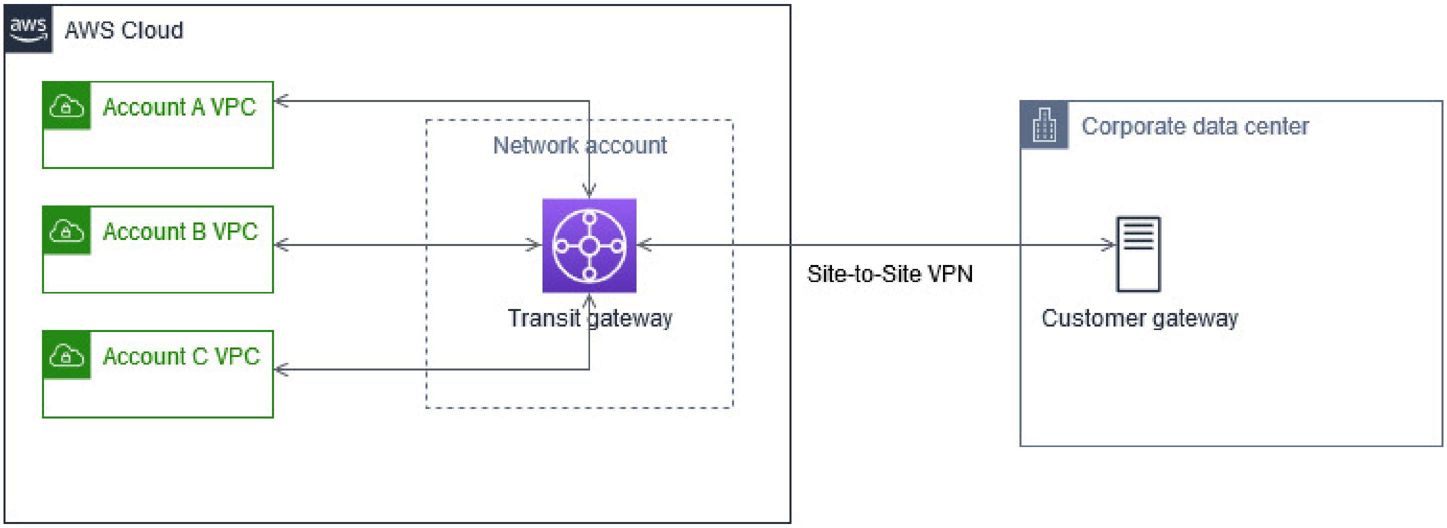
This pattern does not support the isolation of traffic between certain VPCs or the on-premises network. All the networks attached to the transit gateway will be able to reach each other. To isolate traffic, you need to use custom route tables on the transit gateway. This pattern only connects the VPCs and on-premises network by using a single default transit gateway route table, which is the simplest configuration.

Architecture

Target technology stack

- AWS Transit Gateway
- AWS Site-to-Site VPN
- VPC
- AWS Resource Access Manager (AWS RAM)

Target architecture



Tools

AWS services

- [AWS Resource Access Manager (AWS RAM)](#) helps you securely share your resources across your AWS accounts, organizational units, or your entire organization from AWS Organizations.
- [AWS Transit Gateway](#) is a central hub that connects virtual private clouds (VPCs) and on-premises networks.

Epics

Create a transit gateway in the network services account

Task	Description	Skills required
Create a transit gateway.	In the AWS account where you want to host network services, create a transit gateway in the target AWS Region. For instructions, see [Create a transit gateway](#). Note the following:	Network administrator

Task	Description	Skills required
	• Select **Default route table association**. • Select **Default route table propagation**.	

Connect the transit gateway to your on-premises network

Task	Description	Skills required
Set up a customer gateway device for the VPN connectio n.	The customer gateway device is attached on the on-premis es side of the Site-to-Site VPN connection between the transit gateway and your on-premises network. For more information, see [Your customer gateway device](#) in the AWS Site-to-Site VPN documentation. Identify or launch a supported on-premis es customer device and note its public IP address. VPN configuration is completed later in this epic.	Network administrator
In the network services account, create a VPN attachment to the transit gateway.	To set up a connection, create a VPN attachment for the transit gateway. For instructi ons, see [Transit gateway VPN attachments](#).	Network administrator
Configure the VPN on the customer gateway device in your on-premises network.	Download the configura tion file for the Site-to-Site VPN connection associated with the transit gateway and	Network administrator

Task	Description	Skills required
	configure VPN settings on the customer gateway device. For instructions, see Download the configuration file.	

Share the transit gateway in the network services account to other AWS accounts or your organization

Task	Description	Skills required
In the AWS Organizations management account, turn on sharing.	To share the transit gateway with your organization or with certain organizational units, turn on sharing in AWS Organizations. Otherwise , you would need to share the transit gateway for each account individually. For instructions, see Enable resource sharing within AWS Organizations.	AWS systems administrator
Create the transit gateway resource share in the network services account.	To allow VPCs in other AWS accounts within your organization to connect to the transit gateway, in the network services account, use the AWS RAM console to share the transit gateway resource. For instructions, see Create a resource share.	AWS systems administrator

Connect VPCs to the transit gateway

Task	Description	Skills required
Create VPC attachments in individual accounts.	In the accounts to which the transit gateway has been shared, create transit gateway VPC attachments. For instructions, see Create a transit gateway attachment to a VPC.	Network administrator
Accept the VPC attachment requests.	In the network services account, accept the transit gateway VPC attachment requests. For instructions, see Accept a shared attachment.	Network administrator

Configure routing

Task	Description	Skills required
Configure routes in individual account VPCs.	In each individual account VPC, add routes to the on-premises network and to other VPC networks, using the transit gateway as the target. For instructions, see Add and remove routes from a route table.	Network administrator
Configure routes in the transit gateway route table.	Routes from VPCs and the VPN connection should be propagated and should appear in the transit gateway default route table. If needed, create any static routes (one	Network administrator

Task	Description	Skills required
	example is static routes for the static VPN connection) in the transit gateway default route table. For instructions, see [Create a static route]().	
Add security group and network access control list (ACL) rules.	For the EC2 instances and other resources in the VPC, ensure that the security group rules and the network ACL rules allow traffic between VPCs as well as the on-premis es network. For instructi ons, see [Control traffic to resources using security groups]() and [Add and delete rules from an ACL]().	Network administrator

Test connectivity

Task	Description	Skills required
Test connectivity between VPCs.	Ensure that network ACL and security groups allow Internet Control Message Protocol (ICMP) traffic, and then ping from instances in a VPC to another VPC that is also connected to the transit gateway.	Network administrator
Test connectivity between VPCs and the on-premises network.	Ensure that network ACL rules, security group rules, and any firewalls allow ICMP traffic, and then ping	Network administrator

Task	Description	Skills required
	between the on-premises network and the EC2 instances in the VPCs. Network communication must be initiated from the on-premises network first to bring the VPN connection to UP status.

Configure HTTPS encryption for Oracle JD Edwards EnterpriseOne on Oracle WebLogic by using an Application Load Balancer

Thanigaivel Thirumalai, Amazon Web Services

Summary

This pattern explains how to configure HTTPS encryption for SSL offloading in Oracle JD Edwards EnterpriseOne on Oracle WebLogic workloads. This approach encrypts traffic between the user's browser and a load balancer to remove the encryption burden from the EnterpriseOne servers.

Many users scale the EnterpriseOne JAVA virtual machine (JVM) tier horizontally by using an AWS Application Load Balancer. The load balancer serves as the single point of contact for clients, and distributes incoming traffic across multiple JVMs. Optionally, the load balancer can distribute the traffic across multiple Availability Zones and increase the availability of EnterpriseOne.

The process described in this pattern configures encryption between the browser and the load balancer instead of encrypting the traffic between the load balancer and the EnterpriseOne JVMs. This approach is referred to as *SSL offloading*. Offloading the SSL decryption process from the EnterpriseOne web or application server to the Application Load Balancer reduces the burden on the application side. After SSL termination at the load balancer, the unencrypted traffic is routed to the application on AWS.

Oracle JD Edwards EnterpriseOne is an enterprise resource planning (ERP) solution for organizations that manufacture, construct, distribute, service, or manage products or physical assets. JD Edwards EnterpriseOne supports various hardware, operating systems, and database platforms.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Identity and Access Management (IAM) role that has permissions to make AWS service calls and manage AWS resources
- An SSL certificate

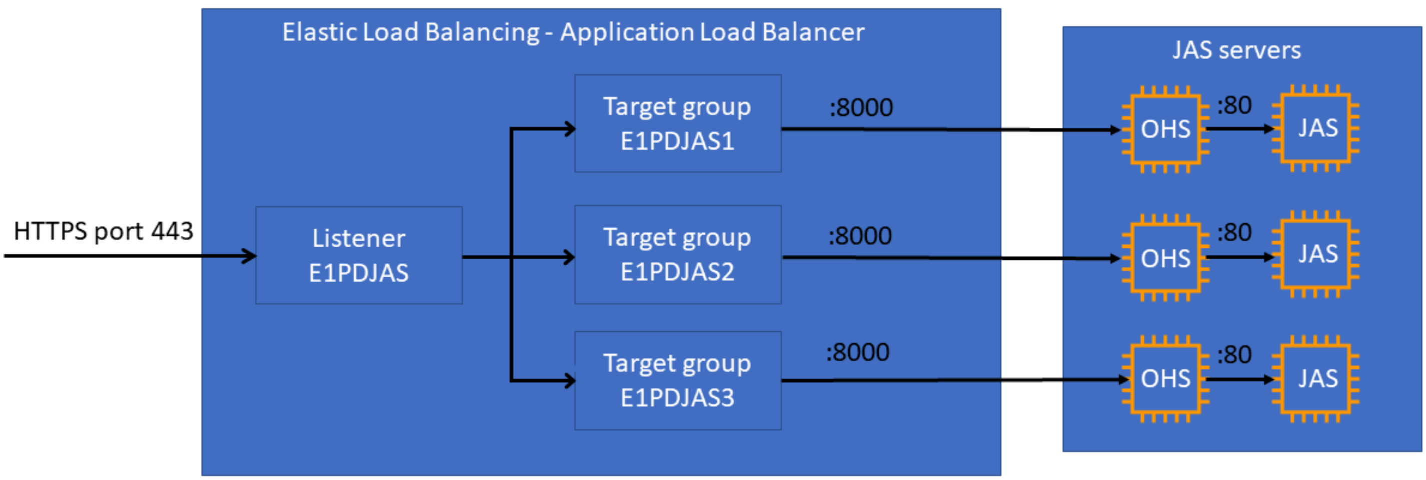
Product versions

- This pattern was tested with Oracle WebLogic 12c, but you can also use other versions.

Architecture

There are multiple approaches to perform SSL offloading. This pattern uses an Application Load Balancer and Oracle HTTP Server (OHS), as illustrated in the following diagram.

The following diagram shows the JD Edwards EnterpriseOne, Application Load Balancer, and Java Application Server (JAS) JVM layout.



Tools

AWS services

- Application Load Balancers distribute incoming application traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2 instances), in multiple Availability Zones.
- AWS Certificate Manager (ACM) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- Amazon Route 53 is a highly available and scalable DNS web service.

Best practices

- For ACM best practices, see the ACM documentation.

Epics

Set up WebLogic and OHS

Task	Description	Skills required
Install and configure Oracle components.	1. Install Fusion Middleware Infrastructure by following the standard installation process. This program helps you install and configure a WebLogic domain. For instructions, see the [Oracle documentation](). 2. Install OHS by following the standard installation process. For instructions, see the [Oracle documentation](). 3. When installation is complete, start the configuration wizard (`config.sh` file) to configure OHS. • You can update an existing domain or create a new domain. This pattern assumes that you're updating an existing domain. • For **Available Templates**, choose **Oracle Enterprise Manager-Restricted JRF** and **Oracle HTTP Server (Restricted**	JDE CNC, WebLogic administrator

Task	Description	Skills required
	JRF). Selecting these Java Required Files (JRF) options eliminates the connection to an external database. • For **Managed Servers**, **Clusters**, **Server Templates**, **Coherence Clusters**, **Machines**, **Assign Servers to Machines**, **Virtual targets**, and **Partitions**, accept the default configuration values and choose **Next** to move to the next category. • Complete the configuration details (for example, administrator host and port, listen address and port, server name) for the OHS instance (for example, `ohs1`).	

Task	Description	Skills required
Enable the WebLogic plugin at the domain level.	The WebLogic plugin is required for load balancing. To enable the plugin: 1. Log in to the WebLogic administration console by using the link: `http://<WeblogicServer>:<Adminport>/console` 2. Choose **Lock & Edit**, and then choose **Configuration**, **Web Applications**. 3. Choose the **WebLogic Plugin Enabled** (check box or dropdown option). 4. Choose **Save and Activate Changes**.	JDE CNC, WebLogic administrator

Task	Description	Skills required

Edit the configuration file.	The `mod_wl_ohs.conf` file configures proxy requests from OHS to WebLogic.
	
	1. Edit this file. It's located at:
	`$ORACLE_HOME/user_projects/domains/`
	For example:
	`/home/oracle/Oracle/Middleware/Oracle_Home/user_projects/domains/base_domain/config/fmwconfig/components/OHS/instances/ohs1`
	2. Add the WebLogic host (`WebLogicHost`) and port (`WebLogicPort`) values (This pattern assumes localhost and port 8000.)
	3. Add `WLProxySSL` and `WLProxySSLPassThrough` values as follows:
	
	`<VirtualHost *:8000>`
	`<Location /jde>`
	`WLSRequest On`
	`SetHandler weblogic-handler`
	`WebLogicHost localhost`
	`WebLogicPort 8000`
		JDE CNC, WebLogic administrator

Task	Description	Skills required
	``` WLProxySSL On WLProxySSLPassThrough On </Location> </VirtualHost> ```	

Task	Description	Skills required
Start OHS by using the Enterprise Manager.	1. Log in to Enterprise Manager Fusion Middleware by using the link: `http://<WeblogicServer>:<Adminport>/em/` 2. In **Target Navigation**, under **HTTP Server**, select the OHS instance (for example, `ohs1`). 3. Choose **Shut Down** and **Start Up** to restart the OHS instance. 4. When OHS setup is complete, you can connect to the EnterpriseOne HTML client by using your HTTP server host name with port 8000 instead of the EnterpriseOne server host name. • Old link: `http://<Webserver>:80/jde/owhtml` • New link: `http://<HTTP server or web server>:8000/jde/owhtml` If you use a port other than the default Oracle HTTP port, edit the `httpd.con`	JDE CNC, WebLogic administrator

Task	Description	Skills required

	f file to add a listener for that port in two places:
	`#[Listen] OHS_LISTEN_PORT`
	`Listen 8000`
	and:
	`#`
	`ServerName <Weblogic Server1>:8000`	

Configure the Application Load Balancer

Task	Description	Skills required
Set up a target group.	1. Create a target group for the HTTP server port 8000. 2. Register the targets under the target group with the same port. 3. Check the status of the targets to confirm that they are healthy. 4. Configure the health check settings as necessary. For detailed instructions, see the [Elastic Load Balancing documentation]().	AWS administrator
Set up the load balancer.	1. Create an Application Load Balancer with default	AWS administrator

Task	Description	Skills required
	attributes and the required virtual private cloud (VPC), security groups, and subnets. For instructi ons, see the Elastic Load Balancing documentation. 2. Add a listener entry for HTTPS 443 and forward it to the target group that you created in the previous step. (For instructions, see the Elastic Load Balancing documentation.) An HTTPS listener requires an SSL certificate. You can choose a certificate from ACM or upload one. 3. For both listeners, enable stickiness by following the instructions in the Elastic Load Balancing documenta tion.	
Add a Route 53 (DNS) record.	(Optional) You can add an Amazon Route 53 DNS record for the subdomain. This record would point to your Application Load Balancer. For instructions, see the Route 53 documentation.	AWS administrator

Troubleshooting

Issue	Solution
HTTP server doesn't appear.	If **HTTP Server** doesn't appear in the **Target Navigation** list on the Enterprise Manager console, follow these steps: 1. Under **WebLogic Domain**, **Administration**, choose **OHS Instances**. 2. Choose **Create** to create a new OHS instance. 3. Provide an instance name, and then choose **OK** to create the instance. When the instance has been created and changes have been activated, you will be able to see the HTTP server in the **Target Navigation** panel.

Connect to Application Migration Service data and control planes over a private network

Dipin Jain and Mike Kuznetsov, Amazon Web Services

Summary

This pattern explains how you can connect to an AWS Application Migration Service data plane and control plane on a private, secured network by using interface VPC endpoints.

Application Migration Service is a highly automated lift-and-shift (rehost) solution that simplifies, expedites, and reduces the cost of migrating applications to AWS. It enables companies to rehost a large number of physical, virtual, or cloud servers without compatibility issues, performance disruption, or long cutover windows. Application Migration Service is available from the AWS Management Console. This enables seamless integration with other AWS services, such as AWS CloudTrail, Amazon CloudWatch, and AWS Identity and Access Management (IAM).

You can connect from a source data center to a data plane—that is, to a subnet that serves as a staging area for data replication in the destination VPC—over a private connection by using AWS VPN services, AWS Direct Connect, or VPC peering in Application Migration Service. You can also use interface VPC endpoints powered by AWS PrivateLink to connect to an Application Migration Service control plane over a private network.

Prerequisites and limitations

Prerequisites

- **Staging area subnet** – Before you set up Application Migration Service, create a subnet to be used as a staging area for data replicated from your source servers to AWS (that is, a data plane). You must specify this subnet in the Replication Settings template when you first access the Application Migration Service console. You can override this subnet for specific source servers in the Replication Settings template. Although you can use an existing subnet in your AWS account, we recommend that you create a new, dedicated subnet for this purpose.
- **Network requirements** – The replication servers that are launched by Application Migration Service in your staging area subnet have to be able to send data to the Application Migration Service API endpoint at `https://mgn.<region>.amazonaws.com/`, where `<region>` is the code for the AWS Region you are replicating to (for example, `https://mgn.us-east-1.amazonaws.com`). Amazon Simple Storage Service (Amazon S3) service URLs are required for downloading Application Migration Service software.

- The AWS Replication Agent installer should have access to the Amazon Simple Storage Service (Amazon S3) bucket URL of the AWS Region you are using with Application Migration Service.
- The staging area subnet should have access to Amazon S3.
- The source servers on which the AWS Replication Agent is installed must be able to send data to the replication servers in the staging area subnet and to the Application Migration Service API endpoint at `https://mgn.<region>.amazonaws.com/`.

The following table lists the required ports.

Source	Destination	Port	For more informati on, see
Source data center	Amazon S3 service URLs	443 (TCP)	Communication over TCP port 443
Source data center	AWS Region-specific console address for Application Migration Service	443 (TCP)	Communication between the source servers and Applicati on Migration Service over TCP port 443
Source data center	Staging area subnet	1500 (TCP)	Communication between the source servers and the staging area subnet over TCP port 1500
Staging area subnet	AWS Region-specific console address for Application Migration Service	443 (TCP)	Communication between the staging area subnet and Application Migration Service over TCP port 443
Staging area subnet	Amazon S3 service URLs	443 (TCP)	Communication over TCP port 443

Staging area subnet	Amazon Elastic Compute Cloud (Amazon EC2) endpoint of the subnet's AWS Region	443 (TCP)	Communication over TCP port 443

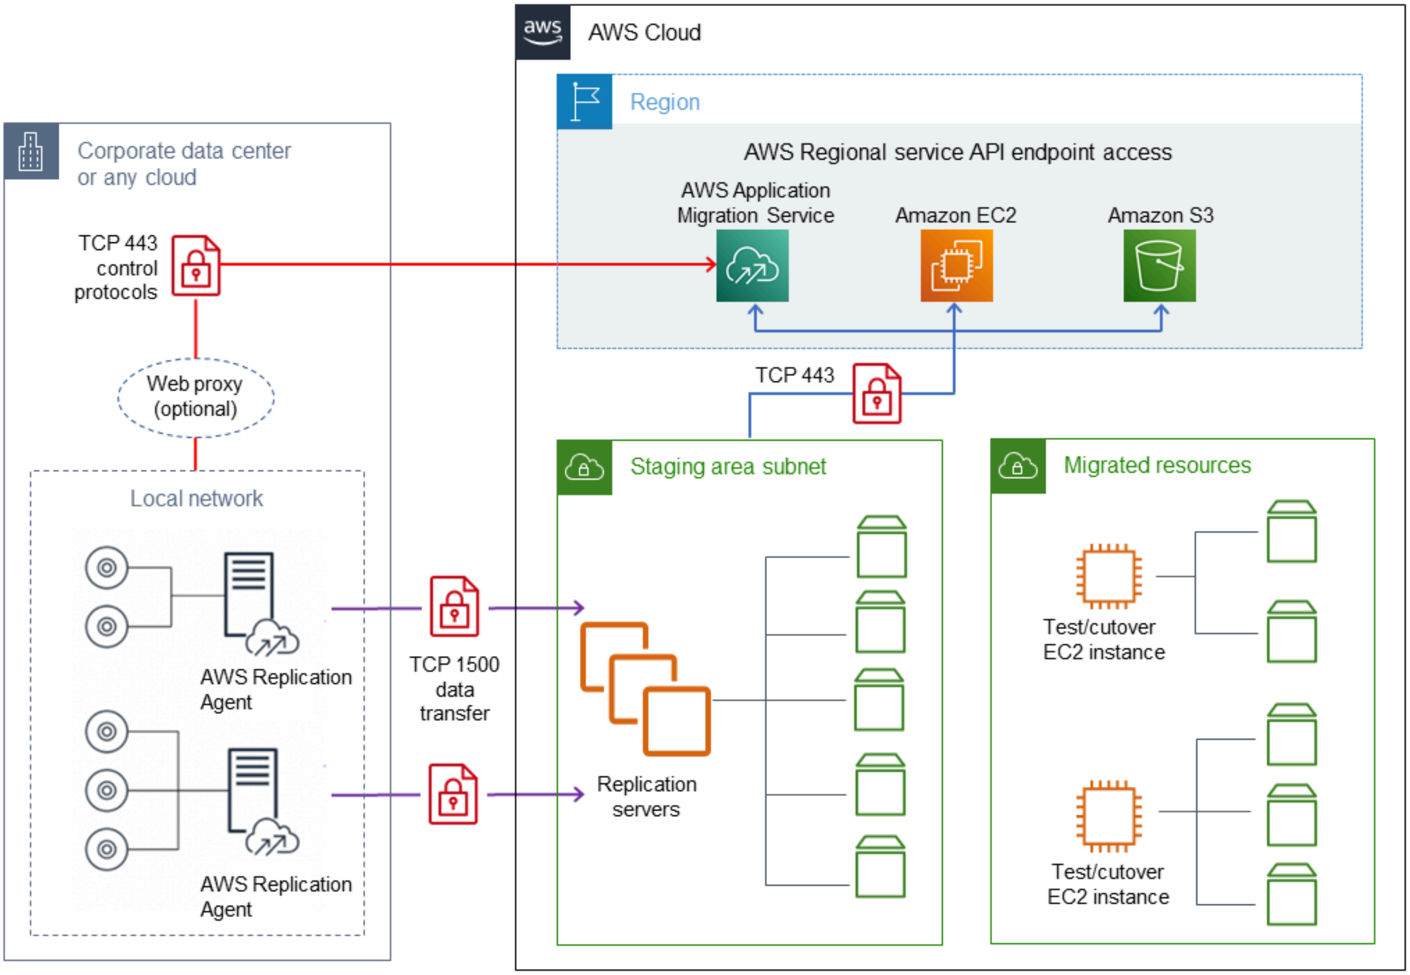
Limitations

Application Migration Service isn't currently available in all AWS Regions and operating systems.

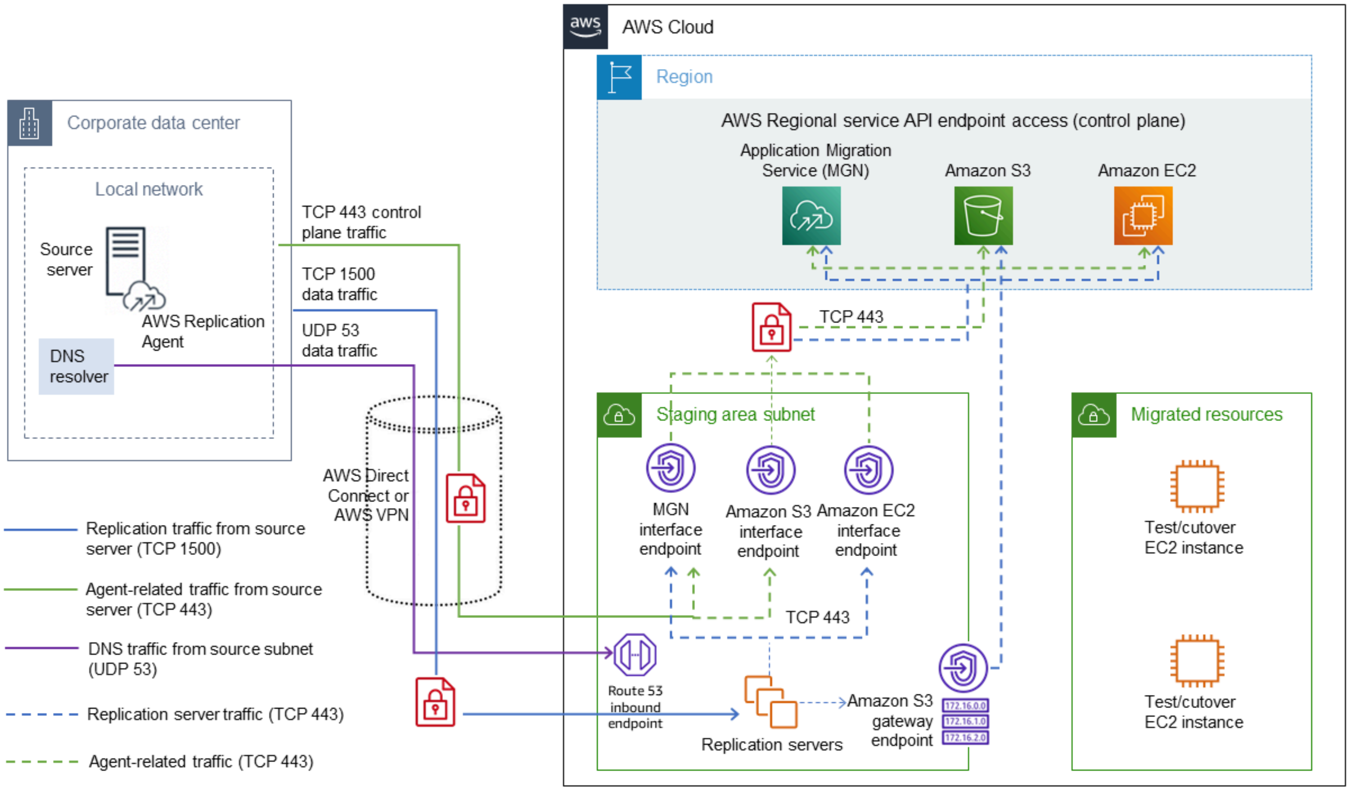
- Supported AWS Regions
- Supported operating systems

Architecture

The following diagram illustrates the network architecture for a typical migration. For more information about this architecture, see the Application Migration Service documentation and the Application Migration Service service architecture and network architecture video.



The following detailed view shows the configuration of interface VPC endpoints in the staging area VPC to connect Amazon S3 and Application Migration Service.



Tools

- [AWS Application Migration Service](#) simplifies, expedites, and reduces the cost of rehosting applications on AWS.
- [Interface VPC endpoints](#) enable you to connect to services that are powered by AWS PrivateLink without requiring an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. Instances in your VPC do not require public IP addresses to communicate with resources in the service. Traffic between your VPC and the other service does not leave the Amazon network.

Epics

Create endpoints for Application Migration Service, Amazon EC2, and Amazon S3

Task	Description	Skills required
Configure the interface endpoint for Application Migration Service.	The source data center and staging area VPC connect privately to the Application	Migration lead

Task	Description	Skills required
	Migration Service control plane through the interface endpoint that you create in the target staging area VPC. To create the endpoint: 1. Open the [Amazon Virtual Private Cloud (Amazon VPC) console](#). 2. In the navigation pane, choose **Endpoints**, **Create Endpoint**. 3. For **Service category**, choose **AWS services**. 4. For **Service Name**, enter `com.amazonaws.<region>.mgn` . For **Type**, choose **Interface**. 5. For **VPC**, select a target staging area VPC to create the endpoint. 6. For **Subnets**, select the subnets in which to create the endpoint network interfaces. 7. To turn on private DNS for the interface endpoint, in the **Additional settings** section, select **Enable DNS Name**. 8. Select a security group that allows ingress from the staging area VPC subnet over TCP 443.	

Task	Description	Skills required
	9. Choose **Create endpoint**. For more information, see [Access an AWS service using an interface VPC endpoint in the Amazon VPC](#) documenta tion.	
Configure the interface endpoint for Amazon EC2.	The staging area VPC connects privately to the Amazon EC2 API through the interface endpoint that you create in the target staging area VPC. To create the endpoint, follow the instructi ons provided in the previous story. • For service name, enter `com.amazonaws.<reg ion>.ec2` . For **Type**, choose **Interface**. • The security group must allow inbound HTTPS traffic from the staging area VPC subnet over port 443. • In the **Additional settings** section, select **Enable DNS name**.	Migration lead

Task	Description	Skills required
Configure the interface endpoint for Amazon S3.	The source data center and staging area VPC connect privately to the Amazon S3 API through the interface endpoint that you create in the target staging area VPC. To create the endpoint, follow the instructions provided in the first story. • For **Service Name**, enter `com.amazonaws.<region>.s3` . For **Type**, choose **Interface**. • The VPC security group must allow inbound HTTPS traffic from the staging area VPC subnet over port 443. • In the **Additional settings** section, clear **Enable DNS name**. Amazon S3 interface endpoints do not support private DNS names. **Note** You use an interface endpoint because gateway endpoint connections cannot be extended out of a VPC. (For details, see	Migration lead

Task	Description	Skills required
	the AWS PrivateLink documentation.)	
Configure the Amazon S3 Gateway endpoint.	During the configuration phase, the replication server has to connect to an S3 bucket to download the AWS Replication Server's software updates. However, Amazon S3 interface endpoints do not support private DNS names, and there is no way to supply an Amazon S3 endpoint DNS name to a replication server. To mitigate this issue, you create an Amazon S3 gateway endpoint in the VPC that the staging area subnet belongs to, and update the staging subnet's route tables with the relevant routes. For more information, see Create a gateway endpoint in the AWS PrivateLink documentation.	Cloud administrator

Task	Description	Skills required
Configure on-premises DNS to resolve private DNS names for endpoints.	The interface endpoints for Application Migration Service and Amazon EC2 have private DNS names that can be resolved in the VPC. However, you also need to configure on-premises servers to resolve private DNS names for these interface endpoints. There are multiple ways to configure these servers. In this pattern, we tested this functionality by forwarding on-premises DNS queries to the Amazon Route 53 Resolver inbound endpoint in the staging area VPC. For more information, see [Resolving DNS queries between VPCs and your network] in the Route 53 documentation.	Migration engineer

Connect to the Application Migration Service control plane over a private link

Task	Description	Skills required
Install AWS Replication Agent by using AWS PrivateLink.	1. Download the AWS Replication Agent to a private S3 bucket in the destination Region. 2. Log in to the source servers to be migrated.	Migration engineer

Task	Description	Skills required
	The AWS Replication Agent installer needs network access to the Application Migration Service and Amazon S3 endpoints. Because your on-premises network isn't open to Application Migration Service and Amazon S3 public endpoints, you must install the Agent with the help of the interface endpoints you created in the previous steps by using AWS PrivateLink. Here's an example for Linux: 1. Download the Agent by using the command: `wget -O ./aws-replication-installer-init.py \ https://aws-application-migration-service-<aws_region>.bucket.<s3-endpoint-DNS-name>/latest/linux/aws-replication-installer-init.py` For example, if the DNS name of the Amazon S3 interface endpoint is	

Task	Description	Skills required
	`vpce-009c8b07adb052a11-qgf8q50y.s3.us-west-1.vpce.amazonaws.com` and the AWS Region is `us-west-1`, you would use the command: `wget -O ./aws-replication-installer-init.py \ https://aws-application-migration-service-us-west-1.bucket.vpce-009c8b07adb052a11-qgf8q50y.s3.us-west-1.vpce.amazonaws.com/latest/linux/aws-replication-installer-init.py` **Note** `bucket` is a static keyword that you must add before the Amazon S3 interface endpoint DNS name. For more information, see the [Amazon S3 documentation](). 2. Install the Agent: • If you selected **Enable DNS name** when you	

Task	Description	Skills required

	created an interface endpoint for Application Migration Service, run the command:
	`sudo python3 aws-replication-installer-init.py \ --region <aws_region> \ --aws-access-key-id <access-key> \ --aws-secret-access-key <secret-key> \ --no-prompt \ --s3-endpoint <s3-endpoint-DNS-name>`
	• If you didn't select **Enable DNS name** when you created the interface endpoint for Application Migration Service, run the command:
	`sudo python3 aws-replication-installer-init.py \ --region <aws_region> \ --aws-access-key-id <access-key> \ --aws-secret-access-key <secret-key> \ --no-prompt \`	

Task	Description	Skills required

	``
	    --s3-endpoint
	 <s3-endpoint-DNS-n
	ame> \
	    --endpoint
	 <mgn-endpoint-DNS-
	name>
	``
	For more information, see [AWS Replication Agent installation instructions] in the Application Migration Service documentation.
	
	After you have establish ed your connection with Application Migration Service and installed the AWS Replication Agent, follow the instructions in the [Application Migration Service documenta tion] to migrate your source servers to your target VPC and subnet.

```

Create Infoblox objects using AWS CloudFormation custom resources and Amazon SNS

Tim Sutton, Amazon Web Services

Summary

Notice: AWS Cloud9 is no longer available to new customers. Existing customers of AWS Cloud9 can continue to use the service as normal. Learn more

Infoblox Domain Name System (DNS), Dynamic Host Configuration Protocol (DHCP), and IP address management (Infoblox DDI) enables you to centralize and efficiently control a complex hybrid environment. With Infoblox DDI, you can discover and record all network assets in one authoritative IP address management (IPAM) database, in addition to managing DNS on premises and on the Amazon Web Services (AWS) Cloud by using the same appliances.

This pattern describes how to use an AWS CloudFormation custom resource to create Infoblox objects (for example, DNS records or IPAM objects) by calling the Infoblox WAPI API. For more information about the Infoblox WAPI, see the WAPI documentation in the Infoblox documentation.

By using this pattern's approach, you can obtain a unified view of DNS records and IPAM configurations for your AWS and on-premises environments, in addition to removing manual processes that create records and provision your networks. You can use this pattern's approach for the following use cases:

- Adding an A record after creating an Amazon Elastic Compute Cloud (Amazon EC2) instance
- Adding a CNAME record after creating an Application Load Balancer
- Adding a network object after creating a virtual private cloud (VPC)
- Providing the next network range and using that range to create subnets

You can also extend this pattern and use other Infoblox device features such as adding different DNS record types or configuring Infoblox vDiscovery.

The pattern uses a hub-and-spoke design in which the hub requires connectivity to the Infoblox appliance on the AWS Cloud or on premises and uses AWS Lambda to call the Infoblox API. The spoke is in the same or a different account in the same organization in AWS Organizations, and calls the Lambda function by using an AWS CloudFormation custom resource.

Prerequisites and limitations

Prerequisites

- An existing Infoblox appliance or grid, installed on the AWS Cloud, on premises, or both, and configured with an admin user that can administer IPAM and DNS actions. For more information about this, see About admin accounts in the Infoblox documentation.
- An existing DNS authoritative zone that you want to add records on the Infoblox appliance. For more information about this, see Configuring authoritative zones in the Infoblox documentation.

- Two active AWS accounts in AWS Organizations. One account is the hub account and the other account is the spoke account.
- The hub and spoke accounts must be in the same AWS Region.
- The hub account's VPC must connect to the Infoblox appliance; for example, by using AWS Transit Gateway or VPC peering.
- AWS Serverless Application Model (AWS SAM), locally installed and configured with AWS Cloud9 or AWS CloudShell.
- The `Infoblox-Hub.zip` and `ClientTest.yaml` files (attached), downloaded to the local environment that contains AWS SAM.

Limitations

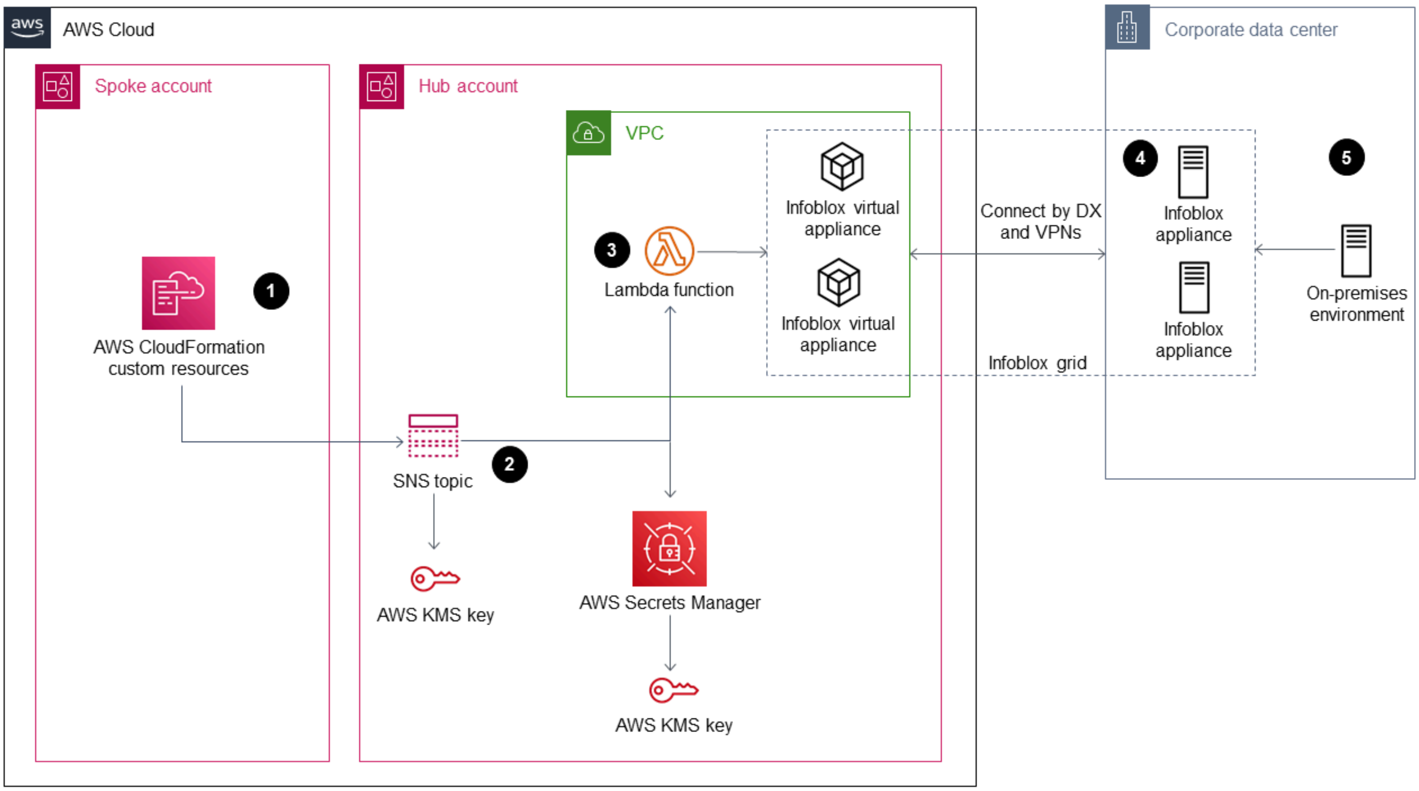
- The AWS CloudFormation custom resource's service token must be from the same Region where the stack is created. We recommend that you use a hub account in each Region, instead of creating an Amazon Simple Notification Service (Amazon SNS) topic in one Region and calling the Lambda function in another Region.

Product versions

- Infoblox WAPI version 2.7

Architecture

The following diagrams shows this pattern's workflow.



The diagram shows the following components for this pattern's solution:

1. AWS CloudFormation custom resources enable you to write custom provisioning logic in templates that AWS CloudFormation runs when you create, update, or delete stacks. When you create a stack, AWS CloudFormation sends a `create` request to an SNS topic that's monitored by an application running on an EC2 instance.
2. The Amazon SNS notification from the AWS CloudFormation custom resource is encrypted through a specific AWS Key Management Service (AWS KMS) key and access is restricted to accounts in your organization in Organizations. The SNS topic initiates the Lambda resource that calls the Infoblox WAPI API.
3. Amazon SNS invokes the following Lambda functions that take the Infoblox WAPI URL, the user name, and password AWS Secrets Manager Amazon Resource Names (ARNs) as environment variables:
   - `dnsapi.lambda_handler` – Receives the `DNSName`, `DNSType`, and `DNSValue` values from the AWS CloudFormation custom resource and uses these to create DNS A records and CNAMES.
   - `ipaddr.lambda_handler` – Receives the `VPCCIDR`, `Type`, `SubnetPrefix`, and `Network Name` values from the AWS CloudFormation custom resource and uses these to add the

network data into the Infoblox IPAM database or provide the custom resource with the next available network that can be used to create new subnets.

- `describeprefixes.lambda_handler` – Calls the `describe_managed_prefix_lists` AWS API by using the `"com.amazonaws."+Region+".s3"` filter to retrieve the required `prefix ID`.

> **Important**
>
> These Lambda functions are written in Python and are similar to each other but call different APIs.

4. You can deploy the Infoblox grid as physical, virtual, or cloud-based network appliances. It can be deployed on-premises or as a virtual appliance using a range of hypervisors, including VMware ESXi, Microsoft Hyper-V, Linux KVM, and Xen. You can also deploy the Infoblox grid on the AWS Cloud with an Amazon Machine Image (AMI).
5. The diagram shows a hybrid solution for the Infoblox grid that provides DNS and IPAM to resources on the AWS Cloud and on premises.

Technology stack

- AWS CloudFormation
- IAM
- AWS KMS
- AWS Lambda
- AWS SAM
- AWS Secrets Manager
- Amazon SNS
- Amazon VPC

Tools

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- AWS Serverless Application Model (AWS SAM) is an open-source framework that helps you build serverless applications in the AWS Cloud.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Code

You can use the `ClientTest.yaml` sample AWS CloudFormation template (attached) to test the Infoblox hub. You can customize the AWS CloudFormation template to include the custom resources from the following table.

Create an A record using the Infoblox spoke custom resource	Return values:
	
	`infobloxref` – Infoblox references
	
	Example resource:
	
	`ARECORDCustomResource:`
	
	`  Type: "Custom::InfobloxAPI"`
	
	`  Properties:`

```
    ServiceToken: !Sub  arn:aws:sns:
${AWS::Region}:${HubAccountID}:Ru
nInfobloxDNSFunction

    DNSName: 'arecordtest.compa
ny.com'

    DNSType: 'ARecord'

    DNSValue: '10.0.0.1'
```

Create a CNAME record using the Infoblox spoke custom resource

Return values:

`infobloxref` – Infoblox references

Example resource:

```
CNAMECustomResource:

  Type: "Custom::InfobloxAPI"

  Properties:

    ServiceToken: !Sub arn:aws:sns:
${AWS::Region}:${HubAccountID}:Ru
nInfoblox

    DNSFunction

    DNSName: 'cnametest.company.com'

    DNSType: 'cname'

    DNSValue: 'aws.amazon.com'
```

Create a network object using the Infoblox spoke custom resource

Return values:

`infobloxref` – Infoblox references

`network` – Network range (the same as `VPCCIDR`)

Example resource:

```
VPCCustomResource:

  Type: 'Custom::InfobloxAPI'

  Properties:

    ServiceToken: !Sub  arn:aws:sns:
${AWS::Region}:${HubAccountID}:Ru
nInfobloxNextSubnetFunction

    VPCCIDR: !Ref VpcCIDR

    Type: VPC

    NetworkName: My-VPC
```

Retrieve the next available subnet using the Infoblox spoke custom resource	**Return values:**
	`infobloxref` – Infoblox references
	`network` – The subnet's network range
	Example resource:
	`Subnet1CustomResource:`
	`  Type: 'Custom::InfobloxAPI'`
	`  DependsOn: VPCCustomResource`
	`  Properties:`
	`    ServiceToken: !Sub  arn:aws:sns:${AWS::Region}:${HubAccountID}:RunInfobloxNextSubnetFunction`
	`    VPCCIDR: !Ref VpcCIDR`
	`    Type: Subnet`
	`    SubnetPrefix: !Ref SubnetPrefix`
	`NetworkName: My-Subnet`

Epics

Create and configure the hub account's VPC

Task	Description	Skills required
Create a VPC with a connection to the Infoblox appliance.	Sign in to the AWS Management Console for your hub account and create a VPC by following the steps in the Amazon VPC on the AWS Cloud Quick Start reference	Network administrator, System administrator

Task	Description	Skills required
	deployment from AWS Quick Starts. **Important** The VPC must have HTTPS connectivity to the Infoblox appliance and we recommend that you use a private subnet for this connection.	

Task	Description	Skills required
(Optional) Create the VPC endpoints for private subnets.	VPC endpoints provide connectivity to public services for your private subnets. The following endpoints are required: • A gateway endpoint for Amazon Simple Storage Service (Amazon S3) to allow Lambda to communicate with AWS CloudFormation • An interface endpoint for Secrets Manager to enable connectivity with Secrets Manager • An interface endpoint for AWS KMS to allow the encryption of the SNS topic and Secrets Manager secret For more information about creating endpoints for private subnets, see [VPC endpoints](#) in the Amazon VPC documentation.	Network administrator, Systems administrator

Deploy the Infoblox hub

Task	Description	Skills required
Build the AWS SAM template.	1. Run the `unzip Infoblox-Hub.zip`	Developer, System administrator

Task	Description	Skills required
	command in the environment that contains AWS SAM. 2. Run the `cd Hub/` command to change your directory to the Hub directory. 3. Run the `sam build` command to process the AWS SAM template file, application code, and any language-specific files and dependencies. The `sam build` command also copies build artifacts in the format and location expected for the following story.	

Task	Description	Skills required

Deploy the AWS SAM template.	The `sam deploy` command takes the required parameters and saves them into the `samconfig.toml` file, stores the AWS CloudFormation template and Lambda functions in an S3 bucket, and then deploys the AWS CloudFormation template into your hub account.
	
	The following sample code shows how to deploy the AWS SAM template:
	
	`$ sam deploy --guided`
	
	`Configuring SAM deploy`
	`======================`
	`        Looking for config file [samconfig.toml] :  Found`
	`        Reading default arguments  :  Success`
	`        Setting default arguments for 'sam deploy'`
	`        =========================================`
	`        Stack Name [Infoblox-Hub]:`
	`        AWS Region [eu-west-1]:`
	`        Parameter InfobloxUsername:`
	`        Parameter InfobloxPassword:`
		Developer, System administrator

Task	Description	Skills required

	<pre> Parameter
	 InfobloxIPAddress
	 [xxx.xxx.xx.xxx]:
	        Parameter
	 AWSOrganisationID [o-
	xxxxxxxxx]:
	        Parameter VPCID
	 [vpc-xxxxxxxxx]:
	        Parameter
	 VPCCIDR [xxx.xxx.

Customize Amazon CloudWatch alerts for AWS Network Firewall

Jason Owens, Amazon Web Services

Summary

The pattern helps you customize the Amazon CloudWatch alerts that are generated by AWS Network Firewall. You can use predefined rules or create custom rules that determine the message, metadata, and severity of the alerts. You can then act upon these alerts or automate responses by other Amazon services, such as Amazon EventBridge.

In this pattern, you generate Suricata-compatible firewall rules. Suricata is an open-source threat detection engine. You first create simple rules and then test them to confirm that the CloudWatch alerts are generated and logged. Once you have successfully tested the rules, you modify them to define custom messages, metadata, and severities, and you then test once more to confirm the updates.

Prerequisites and limitations

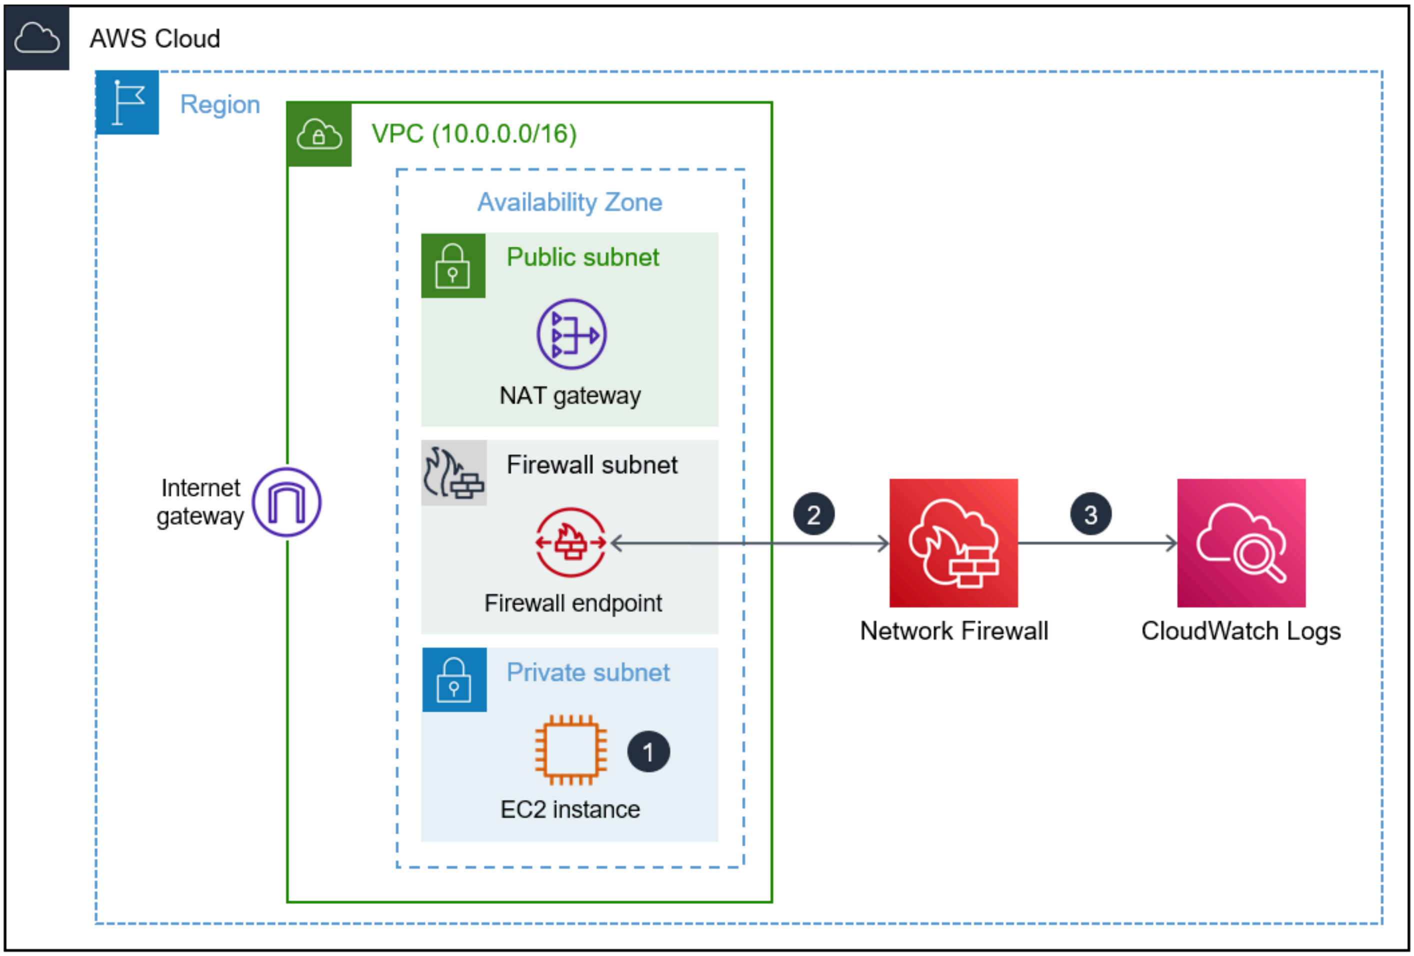
Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured on your Linux, macOS, or Windows workstation. For more information, see Installing or updating the latest version of the AWS CLI.
- AWS Network Firewall installed and configured to use CloudWatch Logs. For more information, see Logging network traffic from AWS Network Firewall.
- An Amazon Elastic Compute Cloud (Amazon EC2) instance in a private subnet of a virtual private cloud (VPC) that is protected by Network Firewall.

Product versions

- For version 1 of AWS CLI, use 1.18.180 or later. For version 2 of AWS CLI, use 2.1.2 or later.
- The classification.config file from Suricata version 5.0.2. For a copy of this configuration file, see the Additional information section.

Architecture



The architecture diagram shows the following workflow:

1. An Amazon EC2 instance in a private subnet makes a request by using either curl or Wget.
2. Network Firewall processes the traffic and generates an alert.
3. Network Firewall sends the logged alerts to CloudWatch Logs.

Tools

AWS services

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Network Firewall is a stateful, managed, network firewall and intrusion detection and prevention service for virtual private clouds (VPCs) in the AWS Cloud.

Other tools

- curl is an open-source command line tool and library.
- GNU Wget is a free command line tool.

Epics

Create the firewall rules and rule group

Task	Description	Skills required
Create rules.	1. In a text editor, create a list of rules that you want to add to the firewall. Each rule must be on a separate line. The value in the `classtype` parameter is from the default Suricata classification configuration file. For the full configura tion file contents, see the Additional information section. The following are two examples of rules. `alert http any any -> any any (content:"badstuff"; classtype:misc-activity; sid:3; rev:1;)`	AWS systems administrator, Network administrator

Task	Description	Skills required
	`alert http any any -> any any (content: "morebadstuff"; classtype:bad-unknown; sid:4; rev:1;)` 2. Save the rules in a file named `custom.rules` .	

Task	Description	Skills required

Create the rule group.	In the AWS CLI, enter the following command. This creates the rule group.
	```# aws network-firewall create-rule-group \ --rule-group-name custom --type STATEFUL \ --capacity 10 --rules file://custom.rules \ --tags Key=environment,Value=development```
	The following is an example output. Make note of the `RuleGroupArn` , which you need in a later step.
	```{ "UpdateToken": "4f998d72-973c-490a-bed2-fc3460547e23", "RuleGroupResponse": { "RuleGroupArn": "arn:aws:network-firewall:us-east-2:1234567890:stateful-rulegroup/custom", "RuleGroupName": "custom", "RuleGroupId": "238a8259-9eaf-48bb-90af-5e690cf8c48b", "Type": "STATEFUL",```
		AWS systems administrator

Task	Description	Skills required

	``"Capacity": 10,
	        "RuleGrou
	pStatus": "ACTIVE",
	        "Tags": [
	            {
	                "Key":
	 "environment",
	                "Value":
	 "development"
	            }
	        ]
	    }```	

Update the firewall policy

Task	Description	Skills required
Get the ARN of the firewall policy.	In the AWS CLI, enter the following command. This returns the Amazon Resource Name (ARN) of the firewall policy. Record the ARN for use later in this pattern. `# aws network-firewall describe-firewall \ --firewall-name aws-network-firewall-anfw \ --query 'Firewall.FirewallPolicyArn'` The following is an example ARN that is returned by this command.	AWS systems administrator

Task	Description	Skills required
	`"arn:aws:network-firewall:us-east-2:1234567890:firewall-policy/firewall-policy-anfw"`	

Task	Description	Skills required
Update the firewall policy.	In a text editor, copy the paste the following code. Replace `<RuleGroupArn>` with the value you recorded in the previous epic. Save the file as `firewall-policy-anfw.json` . ```{ "StatelessDefaultActions": ["aws:forward_to_sfe"], "StatelessFragmentDefaultActions": ["aws:forward_to_sfe"], "StatefulRuleGroupReferences": [{ "ResourceArn": "<RuleGroupArn>" }] }``` Enter the following command in the AWS CLI. This command requires an [update token](https://docs.aws.amazon.com/network-firewall/latest/developerguide/resource-managing.html#nwfw-resource-updating) to add the new rules. The token is used to confirm that the policy hasn't changed since you last retrieved it.	AWS systems administrator

Task	Description	Skills required
	<pre>UPDATETOKEN=(`aws  network-firewall  describe-firewall- policy \               -- firewall-policy-name  firewall-policy-anfw  \               --output  text --query UpdateTok en`) aws network-firewall update-firewall-po licy \ --update-token $UPDATETOKEN \ --firewall-policy- name firewall-policy- anfw \ --firewall-policy file://firewall-po licy-anfw.json</pre>	

Task	Description	Skills required

Confirm the policy updates.	(Optional) If you would like to confirm the rules were added and view the policy format, enter the following command in the AWS CLI.
	`# aws network-firewall describe-firewall-policy \ --firewall-policy-name firewall-policy-anfw \ --query FirewallPolicy`
	The following is an example output.
	`{ "StatelessDefaultActions": [ "aws:forward_to_sfe" ], "StatelessFragmentDefaultActions": [ "aws:forward_to_sfe" ], "StatefulRuleGroupReferences": [ { "ResourceArn": "arn:aws:network-firewall:us-east-2:1234567890:stateful-rulegroup/custom" }`
		AWS systems administrator

Task	Description	Skills required

	``
	    ]
	}
	``	

Test alert functionality

Task	Description	Skills required

Generate alerts for testing.	1. Log in to a test workstation within the firewall subnet.
	2. Enter commands that should generate alerts. For example, you can use `wget` or `curl`.
	`wget -U "badstuff" http://www.amazon.com -o /dev/null`
	`curl -A "morebadstuff" http://www.amazon.com -o /dev/null`
		AWS systems administrator

Validate that the alerts are logged.	1. Open the [CloudWatch console](#). 2. Navigate to the correct log group and stream. For more information, see [View log data sent to CloudWatch Logs](#) (CloudWatch Logs documentation). 3. Confirm the logged events are similar to the following examples. The examples	AWS systems administrator

Task	Description	Skills required

	show only the relevant portion of the alert.
	
	Example 1
	
	`"alert": {`
	`"action": "allowed",`
	`"signature_id": 3,`
	`"rev": 1,`
	`"signature": "",`
	`"category": "Misc activity",`
	`"severity": 3`
	`}`
	
	Example 2
	
	`"alert": {`
	`"action": "allowed",`
	`"signature_id": 4,`
	`"rev": 1,`
	`"signature": "",`
	`"category": "Potentially Bad Traffic",`
	`"severity": 2`
	`}`	

Update the firewall rules and rule group

Task	Description	Skills required
Update the firewall rules.	1. In a text editor, open the `custom.rules` file. 2. Change the first rule to be similar to the following. This rule must be entered on a single line in the file. `alert http any any -> any any (msg:"Watch out - Bad Stuff!!"; content:"badstuff"; classtype:misc-activity; priority: 2; sid:3; rev:2; metadata:custom-field-2 Danger!, custom-field More Info;)` This makes the following changes to the rule: • Adds a msg (Suricata website) string that provides text information about the signature or alert. In the generated alert, this maps to the signature. • Adjusts the default priority (Suricata website) of `misc-activity` from 3 to 2. For the default values of the various `classtype`	AWS systems administrator

Task	Description	Skills required
	s , see the Additional information section. • Adds custom metadata (Suricata website) to the alert. This is additional information that that is added to the signature. It is recommended that you use key-value pairs. • Changes the rev (Suricata website) from 1 to 2. This represents the version of the signature.	

Task	Description	Skills required

Update the rule group.	In the AWS CLI, run the following commands. Use the ARN of your firewall policy. These commands get an update token and update the rule group with the rule changes.
	`# UPDATETOKEN=(`aws network-firewall \ describe-rule-group \ --rule-group-arn arn:aws:network-firewall:us-east-2:123457890:stateful-rulegroup/custom \ --output text --query UpdateToken`)`
	`# aws network-firewall update-rule-group \ --rule-group-arn arn:aws:network-firewall:us-east-2:1234567890:stateful-rulegroup/custom \ --rules file://custom.rules \ --update-token $UPDATETOKEN`
	The following is an example output.
	`{`
		AWS systems administrator

Task	Description	Skills required
	"UpdateToken": "7536939f-6a1d-414c-96d1-bb28110996ed", "RuleGroupResponse": { "RuleGroupArn": "arn:aws:network-firewall:us-east-2:1234567890:stateful-rulegroup/custom", "RuleGroupName": "custom", "RuleGroupId": "238a8259-9eaf-48bb-90af-5e690cf8c48b", "Type": "STATEFUL", "Capacity": 10, "RuleGroupStatus": "ACTIVE", "Tags": [{ "Key": "environment", "Value": "development" }] } }	

Test the updated alert functionality

Task	Description	Skills required
Generate an alert for testing.	1. Log in to a test workstation within the firewall subnet. 2. Enter a command that should generate an alert.	AWS systems administrator

Task	Description	Skills required
	For example, you can use `curl`. `curl -A "badstuff" http://www.amazon.com -o /dev/null`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Validate the alert changed.</td><td>

1. Open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/).
2. Navigate to the correct log group and stream.
3. Confirm the logged event is similar to the following example. The example shows only the relevant portion of the alert.

```
"alert": {
    "action":
 "allowed",
    "signature_id":
 3,
    "rev": 2,
    "signature":
 "Watch out - Bad
 Stuff!!",
    "category": "Misc
 activity",
    "severity": 2,
    "metadata": {
        "custom-f
ield": [
            "More
 Info"
        ],
        "custom-f
ield-2": [
            "Danger!"
        ]
    }
}
```

</td><td>AWS systems administrator</td></tr>

Deploy resources in an AWS Wavelength Zone by using Terraform

Zahoor Chaudhrey and Luca Iannario, Amazon Web Services

Summary

AWS Wavelength helps you build infrastructure that is optimized for Multi-Access Edge Computing (MEC) applications. *Wavelength Zones* are AWS infrastructure deployments that embed AWS compute and storage services within communications service providers' (CSP) 5G networks. Application traffic from 5G devices reaches application servers running in Wavelength Zones without leaving the telecommunications network. The following facilitate network connectivity through Wavelength:

- **Virtual private clouds (VPCs) –** VPCs in an AWS account can extend to span multiple Availability Zones, including Wavelength Zones. Amazon Elastic Compute Cloud (Amazon EC2) instances and related services appear as part of your Regional VPC. VPCs are created and managed in Amazon Virtual Private Cloud (Amazon VPC).
- **Carrier gateway –** A carrier gateway enables connectivity from the subnet in the Wavelength Zone to the CSP network, the internet, or the AWS Region through the CSP's network. The carrier gateway serves two purposes. It allows inbound traffic from a CSP network in a specific location, and it allows outbound traffic to the telecommunications network and the internet.

This pattern and its associated Terraform code help you launch resources, such as Amazon EC2 instances, Amazon Elastic Block Store (Amazon EBS) volumes, VPCs, subnets, and a carrier gateway, in a Wavelength Zone.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An integrated development environment (IDE)
- Opt in to the target Wavelength Zone
- AWS Command Line Interface (AWS CLI), installed and configured
- Terraform version 1.8.4 or later, installed (Terraform documentation)
- Terraform AWS Provider version 5.32.1 or later, configured (Terraform documentation)
- Git, installed (GitHub)

- [Permissions](#) to create Amazon VPC, Wavelength, and Amazon EC2 resources

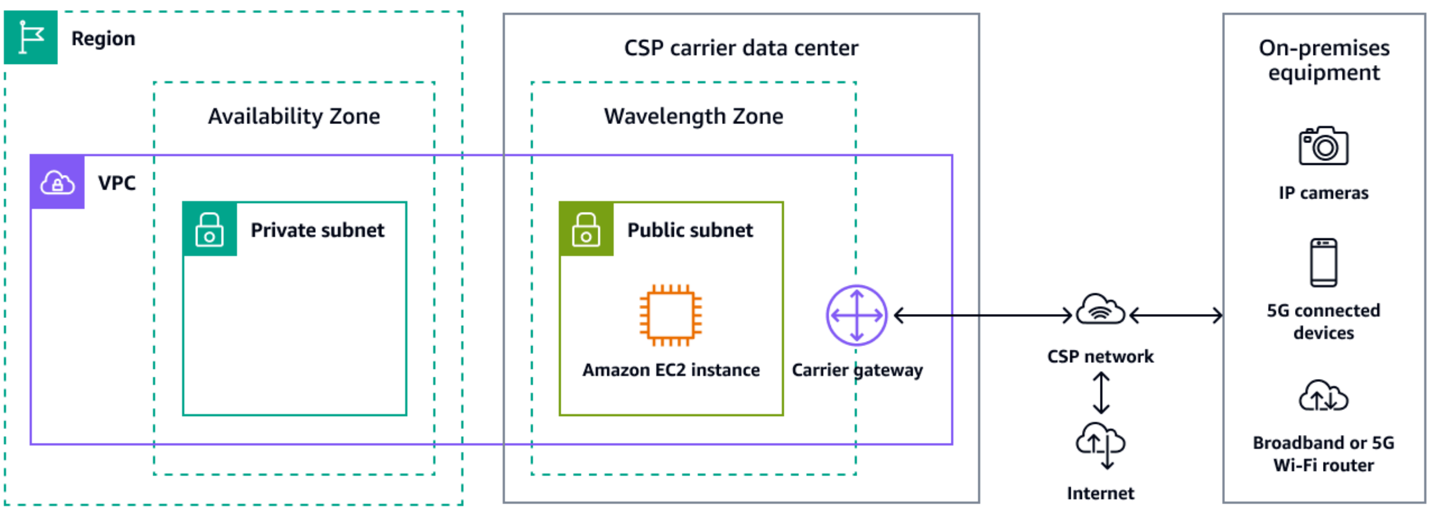
Limitations

Not all AWS Regions support Wavelength Zones. For more information, see Available Wavelength Zones in the Wavelength documentation.

Architecture

The following diagram shows how you can create a subnet and AWS resources in a Wavelength Zone. VPCs that contain a subnet in a Wavelength Zone can connect to a carrier gateway. A carrier gateway allows you to connect to the following resources:

- 4G/LTE and 5G devices on the telecommunication carrier's network.
- Fixed wireless access for select Wavelength Zone partners. For more information, see Multi-access AWS Wavelength.
- Outbound traffic to public internet resources.



Tools

AWS services

- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

- AWS Wavelength extends AWS Cloud infrastructure to telecommunication providers' 5G networks. This helps you build applications that deliver ultra-low latencies to mobile devices and end users.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub Creating AWS Wavelength Infrastructure using Terraform repository. The Terraform code deploys the following infrastructure and resources:

- A VPC
- A Wavelength Zone
- A pubic subnet in the Wavelength Zone
- A carrier gateway in the Wavelength Zone
- An Amazon EC2 instance in the Wavelength Zone

Best practices

- Before deploying, confirm that you're using the latest versions of Terraform and the AWS CLI.
- Use a continuous integration and continuous delivery (CI/CD) pipeline to deploy IaC. For more information, see Best practices for managing Terraform State files in AWS CI/CD Pipeline on AWS Blogs.

Epics

Provision the infrastructure

Task	Description	Skills required
Clone the repository.	Enter the following command to clone the Creating AWS Wavelength Infrastructure	DevOps engineer

Task	Description	Skills required
	using Terraform repository to your environment. `git clone git@github.com:aws-samples/terraform-wavelength-infrastructure.git`	

Task	Description	Skills required
Update the variables.	1. Navigate to the cloned repository. `cd terraform-wavelength-infrastructure` 2. Using any text editor, create a file called **terraform.tfvars** in the root directory. 3. Create the following variables and enter their values: • `region = <enter Region name>` • `vpc_cidr = <enter CIDR block used by VPC>` • `wavelength_subnet_cidr = <enter CIDR block for the subnet in the Wavelength Zone>` • `availabilityzone_wavelength = <enter Wavelength Zone name>` 4. Save the **terraform.tfvars** file.	DevOps engineer, Terraform

Task	Description	Skills required
Initialize the configuration.	Enter the following command to initialize the working directory. `terraform init`	DevOps engineer, Terraform
Preview the Terraform plan.	Enter the following command to compare the target state against the current state of your AWS environment. This command generates a preview of the resources that will be configured. `terraform plan`	DevOps engineer, Terraform

Task	Description	Skills required
Verify and deploy.	1. Review the configuration changes in the Terraform plan and confirm that you want to implement these changes. 2. Enter the following command to apply the plan and create the infrastructure. `terraform apply` 3. Enter `yes` to proceed. Terraform creates the architecture that is declared in the configura tion files. For more information about the architecture, see the Target architecture section of this pattern.	DevOps engineer, Terraform

Validate and clean up

Task	Description	Skills required
Verify the infrastructure deployment.	1. If you don't already have an Amazon EC2 instance in a public subnet in your AWS Region, create one. For instructions, see Launch your Linux instance or Launch your Windows instance. You will use	AWS DevOps, DevOps engineer

Task	Description	Skills required
	this instance to test the connectivity from the AWS Region to the Wavelength Zone. 2. Test the connectivity from the instance in the AWS Region to the instance in the Wavelength Zone. For instructions, see [Test the connectivity](#) in the Wavelength documentation.	
(Optional) Clean up the infrastructure.	If you need to delete all of the resources that were provisioned by Terraform, do the following: 1. Enter the following command. `terraform destroy` 2. Enter `yes` to confirm.	DevOps engineer, Terraform

Troubleshooting

Issue	Solution
Connectivity to Amazon EC2 instances in the AWS Region.	See Troubleshoot connecting to your Linux instance or Troubleshoot connecting to your Windows instance.

Issue	Solution
Connectivity to Amazon EC2 instances in the Wavelength Zone.	See Troubleshoot SSH or RDP connectivity to my EC2 instances launched in a Wavelength Zone.
Capacity in the Wavelength Zone.	See Quotas and considerations for Wavelength Zones.
Mobile or carrier connectivity from the carrier network to the AWS Region.	1. Verify that the carrier gateway is operational. Do the following: a. Open the Amazon VPC console. b. In the navigation pane, choose **Your VPCs**. c. Select the VPC that contains the Wavelength Zone. d. On the **Details** pane, for **Carrier gateway**, confirm that the value is attached. 2. Verify that any elastic IP addresses attached to instances in the Wavelength Zone are operational. Do the following: a. Open the Amazon EC2 console. b. In the navigation pane, choose **Instances**. c. Select the instance in the Wavelength Zone. d. Choose the **Network** tab. e. Confirm that the elastic network interface has an Elastic IP address attached. 3. Contact the carrier network support team.

Migrate DNS records in bulk to an Amazon Route 53 private hosted zone

Ram Kandaswamy, Amazon Web Services

Summary

Network engineers and cloud administrators need an efficient and simple way to add Domain Name System (DNS) records to private hosted zones in Amazon Route 53. Using a manual approach to copy entries from a Microsoft Excel worksheet to appropriate locations in the Route 53 console is tedious and error prone. This pattern describes an automated approach that reduces the time and effort required to add multiple records. It also provides a repeatable set of steps for multiple hosted zone creation.

This pattern uses Amazon Simple Storage Service (Amazon S3) to store records. To work with data efficiently, the pattern uses the JSON format because of its simplicity and its ability to support a Python dictionary (`dict` data type).

> **Note**
>
> If you can generate a zone file from your system, consider using the Route 53 import feature instead.

Prerequisites and limitations

Prerequisites

- An Excel worksheet that contains private hosted zone records
- Familiarity with different types of DNS records such as A record, Name Authority Pointer (NAPTR) record, and SRV record (see Supported DNS record types)
- Familiarity with the Python language and its libraries

Limitations

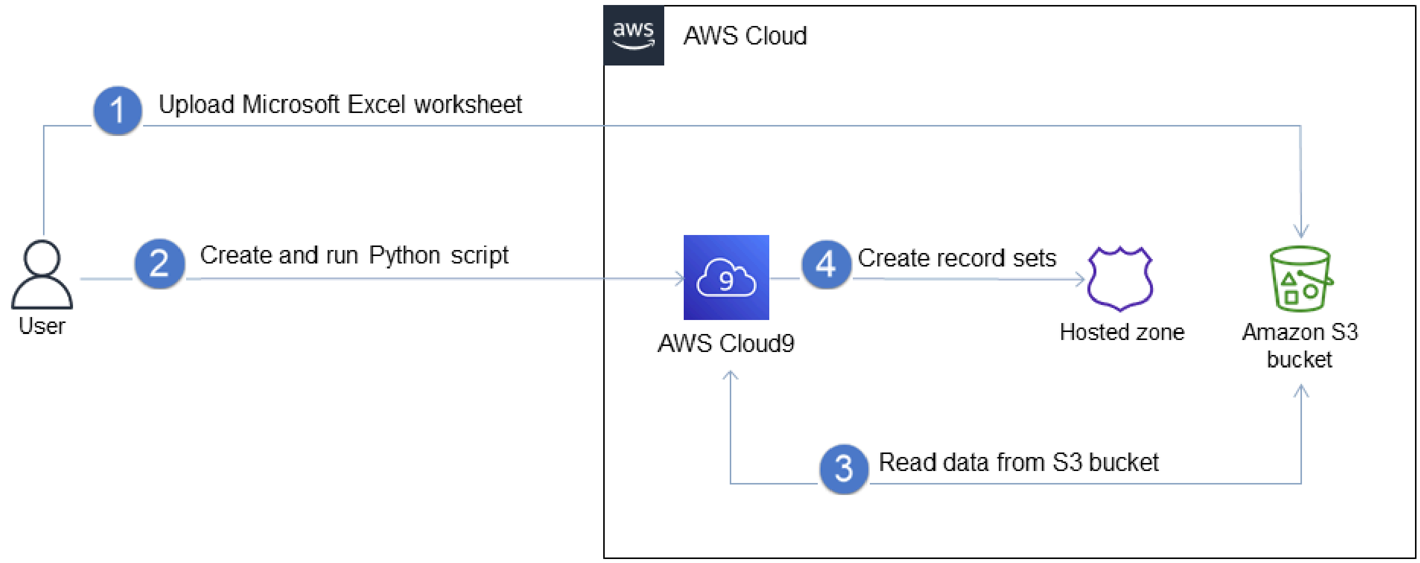
- The pattern doesn't provide extensive coverage for all use case scenarios. For example, the change_resource_record_sets call doesn't use all the available properties of the API.

- In the Excel worksheet, the value in each row is assumed to be unique. Multiple values for each fully qualified domain name (FQDN) are expected to appear in the same row. If that is not true, you should modify the code provided in this pattern to perform the necessary concatenation.
- The pattern uses the AWS SDK for Python (Boto3) to call the Route 53 service directly. You can enhance the code to use an AWS CloudFormation wrapper for the `create_stack` and `update_stack` commands, and use the JSON values to populate template resources.

Architecture

Technology stack

- Route 53 private hosted zones for routing traffic
- Amazon S3 for storing the output JSON file



The workflow consists of these steps, as illustrated in the previous diagram and discussed in the *Epics* section:

1. Upload an Excel worksheet that has the record set information to an S3 bucket.
2. Create and run a Python script that converts the Excel data to JSON format.
3. Read the records from the S3 bucket and clean the data.
4. Create record sets in your private hosted zone.

Tools

- [Route 53](#) – Amazon Route 53 is a highly available and scalable DNS web service that handles domain registration, DNS routing, and health checking.
- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

Epics

Prepare data for automation

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create an Excel file for your records.</td><td>Use the records you exported from your current system to create an Excel worksheet that has the required columns for a record, such as fully qualified domain name (FQDN), record type, Time to Live (TTL), and value. For NAPTR and SRV records, the value is a combination of multiple properties, so use Excel's <code>concat</code> method to combine these properties.
<table><tr><th>FqdnN</th><th>Recorc
e</th><th>Value</th><th>TTL</th></tr><tr><td>somet
.exam
org</td><td>A</td><td>1.1.1.</td><td>900</td></tr></table></td><td>Data engineer, Excel skills</td></tr>

</table>

Task	Description	Skills required

	input worksheet to JSON format. (Instead of an IDE, you can also use an Amazon SageMaker notebook to work with Python code.)
	
	Verify that the Python version you're using is version 3.7 or later.
	
	`python3 --version`
	
	Install the **pandas** package.
	
	`pip3 install pandas --user`	

Convert the Excel worksheet data to JSON.	Create a Python file that contains the following code to convert from Excel to JSON.
	
	`import pandas as pd`
	`data=pd.read_excel('./Book1.xls')`
	`data.to_json(path_or_buf='my.json', orient='records')`
	
	where Book1 is the name of the Excel worksheet and `my.json` is the name of the output JSON file.
		Data engineer, Python skills

Task	Description	Skills required
Upload the JSON file to an S3 bucket.	Upload the `my.json` file to an S3 bucket. For more information, see [Creating a bucket](#) in the Amazon S3 documentation.	App developer

Insert records

Task	Description	Skills required

Create a private hosted zone.	Use the [create_hosted_zone](#) API and the following Python sample code to create a private hosted zone. Replace the parameters `hostedZoneName`, `vpcRegion`, and `vpcId` with your own values.
	`import boto3`
	`import random`
	`hostedZoneName ="xxx"`
	`vpcRegion = "us-east-1"`
	`vpcId="vpc-xxxx"`
	`route53_client = boto3.client('route53')`
	`response = route53_client.create_hosted_zone(`
	`        Name= hostedZoneName,`
	`        VPC={`
	`            'VPCRegion: vpcRegion,`
	`            'VPCId': vpcId`
		Cloud architect, Network administrator, Python skills

Task	Description	Skills required

	``
	        },
	        CallerRef
	erence=str(random.
	random()*100000),
	        HostedZon
	eConfig={
	            'Comment'
	: "private hosted zone
	 created by automatio
	n",
	            'PrivateZ
	one': True
	        }
	    )
	 print(response)
	``
	You can also use an infrastructure as code (IaC) tool such as AWS CloudFormation to replace these steps with a template that creates a stack with the appropriate resources and properties.	

Task	Description	Skills required

Retrieve details as a dictionary from Amazon S3.	Use the following code to read from the S3 bucket and to get the JSON values as a Python dictionary.
	`fileobj = s3_client.get_object(`
	`        Bucket=bucket_name,`
	`        Key='my.json'`
	`        )`
	`    filedata = fileobj['Body'].read()`
	`    contents = filedata.decode('utf-8')`
	`    json_content=json.loads(contents)`
	`    print(json_content)`
	where `json_content` contains the Python dictionary.
		App developer, Python skills

Task	Description	Skills required

Clean data values for spaces and Unicode characters.	As a safety measure to ensure the correctness of data, use the following code to perform a strip operation on the values in `json_content`. This code removes the space characters at the front and end of each string. It also uses the `replace` method to remove hard (non-breaking) spaces (the `\xa0` characters).
	
	`for item in json_content:`
	`    fqn_name = unicodedata.normalize("NFKD",item["FqdnName"].replace("u'", "'").replace('\xa0', '').strip())`
	`    rec_type = item["RecordType"].replace('\xa0', '').strip()`
	`    res_rec = {`
	`      'Value': item["Value"].replace('\xa0', '').strip()`
	`                }`
		App developer, Python skills

Task	Description	Skills required
Insert records.	Use the following code as part of the previous `for` loop. `change_response = route53_client.change_resource_record_sets( HostedZoneId="xxxxxxxx", ChangeBatch={ 'Comment': 'Created by automation', 'Changes': [ { 'Action': 'UPSERT', 'ResourceRecordSet': { 'Name': fqn_name, 'Type': rec_type, 'TTL': item["TTL"], 'ResourceRecords': res_rec } } ] } )`	App developer, Python skills

Task	Description	Skills required
	Where `xxxxxxx` is the hosted zone ID from the first step of this epic.

Modify HTTP headers when you migrate from F5 to an Application Load Balancer on AWS

Sachin Trivedi, Amazon Web Services

Summary

When you migrate an application that uses an F5 Load balancer to Amazon Web Services (AWS) and want to use an Application Load Balancer on AWS, migrating F5 rules for header modifications is a common problem. An Application Load Balancer doesn't support header modifications, but you can use Amazon CloudFront as a content delivery network (CDN) and Lambda@Edge to modify headers.

This pattern describes the required integrations and provides sample code for header modification by using AWS CloudFront and Lambda@Edge.

Prerequisites and limitations

Prerequisites

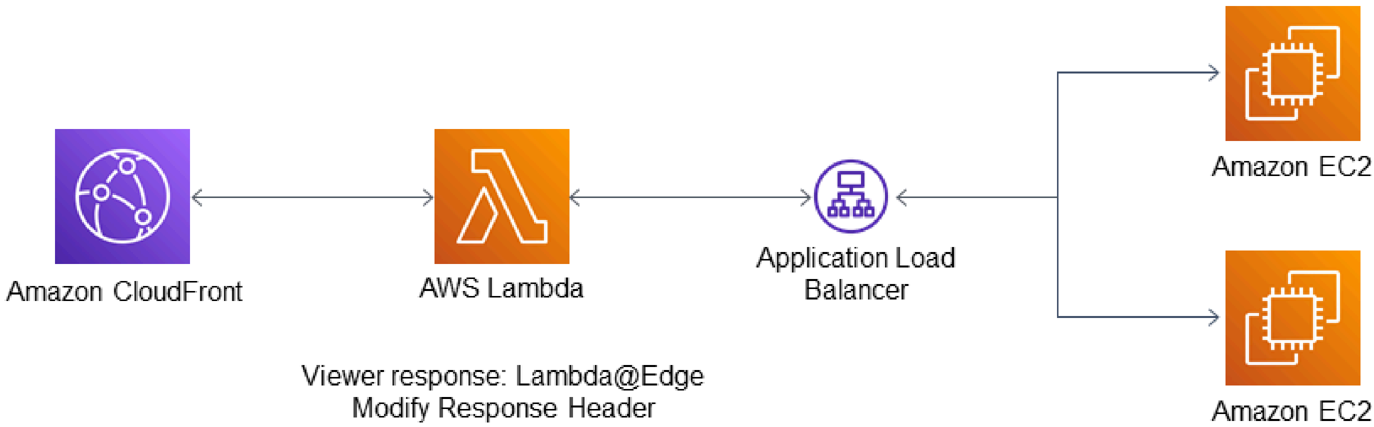
- An on-premises application that uses an F5 load balancer with a configuration that replaces the HTTP header value by using `if, else`. For more information about this configuration, see [HTTP::header](#) in the F5 product documentation.

Limitations

- This pattern applies to F5 load balancer header customization. For other third-party load balancers, please check the load balancer documentation for support information.
- The Lambda functions that you use for Lambda@Edge must be in the US East (N. Virginia) Region.

Architecture

The following diagram shows the architecture on AWS, including the integration flow between the CDN and other AWS components.



Tools

AWS services

- [Application Load Balancer](#) — An Application Load Balancer is an AWS fully managed load balancing service that functions at the seventh layer of the Open Systems Interconnection (OSI) model. It balances traffic across multiple targets and supports advanced routing requests based on HTTP headers and methods, query strings, and host-based or path-based routing.
- [Amazon CloudFront](#) – Amazon CloudFront is a web service that speeds up the distribution of your static and dynamic web content, such as .html, .css, .js, and image files, to your users. CloudFront delivers your content through a worldwide network of data centers called edge locations for lower latency and improved performance.
- [Lambda@Edge](#) — Lambda@Edge is an extension of AWS Lambda that lets you run functions to customize the content that CloudFront delivers. You can author functions in the US East (N. Virginia) Region, and then associate the function with a CloudFront distribution to automatically replicate your code around the world, without provisioning or managing servers. This reduces latency and improves the user experience.

Code

The following sample code provides a blueprint for modifying CloudFront response headers. Follow the instructions in the *Epics* section to deploy the code.

```
exports.handler = async (event, context) => {
    const response = event.Records[0].cf.response;
```

```
    const headers = response.headers;

    const headerNameSrc = 'content-security-policy';
    const headerNameValue = '*.xyz.com';

    if (headers[headerNameSrc.toLowerCase()]) {
        headers[headerNameSrc.toLowerCase()] = [{
            key: headerNameSrc,
            value: headerNameValue,
        }];
        console.log(`Response header "${headerNameSrc}" was set to ` +
                    `"${headers[headerNameSrc.toLowerCase()][0].value}"`);
    }
    else {
            headers[headerNameSrc.toLowerCase()] = [{
            key: headerNameSrc,
            value: headerNameValue,
            }];
    }
    return response;
};
```

Epics

Create a CDN distribution

Task	Description	Skills required
Create a CloudFront web distribution.	In this step, you create a CloudFront distribution to tell CloudFront where you want content to be delivered from, and the details about how to track and manage content delivery. To create a distribution by using the console, sign in to the AWS Management	Cloud administrator

Task	Description	Skills required
	Console, open the CloudFront console, and then follow the steps in the CloudFront documentation.	

Create and deploy the Lambda@Edge function

Task	Description	Skills required
Create and deploy a Lambda@Edge function.	You can create a Lambda@Edge function by using a blueprint for modifying CloudFront response headers. (Other bluePrints are available for different use cases; for more information, see Lambda@Edge example functions in the CloudFront documentation.) To create a Lambda@Edge function: 1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/. 2. Make sure that you're in the US East (N. Virginia) Region. CloudFront blueprints are available only in this Region. 3. Choose **Create function**.	AWS administrator

Task	Description	Skills required
	4. Choose **Use a blueprint**, and then enter **cloudfront** in the **Blueprints** search field. 5. Choose the **cloudfront-modify-response-header** blueprint, and then choose **Configure**. 6. On the **Basic information** page, enter the following information: a. Enter a function name. b. For **Execution role**, choose **Create a new role from AWS policy templates**. c. Associate the required AWS Identity and Access Management (IAM) role name. 7. Choose **Create function**. 8. In the **Designer** section of the page, choose your function name. 9. In the **Function code** section, replace the template code with the sample code provided previously in this pattern, in the *Code* section. 10. In the sample code, replace `xyz.com` with your domain name.	

Task	Description	Skills required
	11. Choose **Save**.	
Deploy the Lambda@Edge function.	Follow the instructions in step 4 of the *Tutorial: Creating a simple Lambda@Edge function* in the Amazon CloudFront documentation to configure the CloudFront trigger and deploy the function.	AWS administrator

Create a report of Network Access Analyzer findings for inbound internet access in multiple AWS accounts

Mike Virgilio, Amazon Web Services

Summary

Unintentional inbound internet access to AWS resources can pose risks to an organization's data perimeter. Network Access Analyzer is an Amazon Virtual Private Cloud (Amazon VPC) feature that helps you identify unintended network access to your resources on Amazon Web Services (AWS). You can use Network Access Analyzer to specify your network access requirements and to identify potential network paths that do not meet your specified requirements. You can use Network Access Analyzer to do the following:

1. Identify AWS resources that are accessible to the internet through internet gateways.
2. Validate that your virtual private clouds (VPCs) are appropriately segmented, such as isolating production and development environments and separating transactional workloads.

Network Access Analyzer analyzes end-to-end network reachability conditions and not just a single component. To determine whether a resource is internet accessible, Network Access Analyzer evaluates the internet gateway, VPC route tables, network access control lists (ACLs), public IP addresses on elastic network interfaces, and security groups. If any of these components prevent internet access, Network Access Analyzer doesn't generate a finding. For example, if an Amazon Elastic Compute Cloud (Amazon EC2) instance has an open security group that allows traffic from `0/0` but the instance is in a private subnet that isn't routable from any internet gateway, then Network Access Analyzer wouldn't generate a finding. This provides high-fidelity results so that you can identify resources that are truly accessible from the internet.

When you run Network Access Analyzer, you use Network Access Scopes to specify your network access requirements. This solution identifies network paths between an internet gateway and an elastic network interface. In this pattern, you deploy the solution in a centralized AWS account in your organization, managed by AWS Organizations, and it analyzes all of the accounts, in any AWS Region, in the organization.

This solution was designed with the following in mind:

- The AWS CloudFormation templates reduce the effort required to deploy the AWS resources in this pattern.

- You can adjust the parameters in the CloudFormation templates and **naa-script.sh** script at the time of deployment to customize them for your environment.
- Bash scripting automatically provisions and analyzes the Network Access Scopes for multiple accounts, in parallel.
- A Python script processes the findings, extracts the data, and then consolidates the results. You can choose to review the consolidated report of Network Access Analyzer findings in CSV format or in AWS Security Hub. An example of the CSV report is available in the Additional information section of this pattern.
- You can remediate findings, or you can exclude them from future analyses by adding them to the **naa-exclusions.csv** file.

Prerequisites and limitations

Prerequisites

- An AWS account for hosting security services and tools, managed as a member account of an organization in AWS Organizations. In this pattern, this account is referred to as the security account.
- In the security account, you must have a private subnet with outbound internet access. For instructions, see Create a subnet in the Amazon VPC documentation. You can establish internet access by using an NAT gateway or an interface VPC endpoint.
- Access to the AWS Organizations management account or an account that has delegated administrator permissions for CloudFormation. For instructions, see Register a delegated administrator in the CloudFormation documentation.
- Enable trusted access between AWS Organizations and CloudFormation. For instructions, see Enable trusted access with AWS Organizations in the CloudFormation documentation.
- If you're uploading the findings to Security Hub, Security Hub must be enabled in the account and AWS Region where the Amazon EC2 instance is provisioned. For more information, see Setting up AWS Security Hub.

Limitations

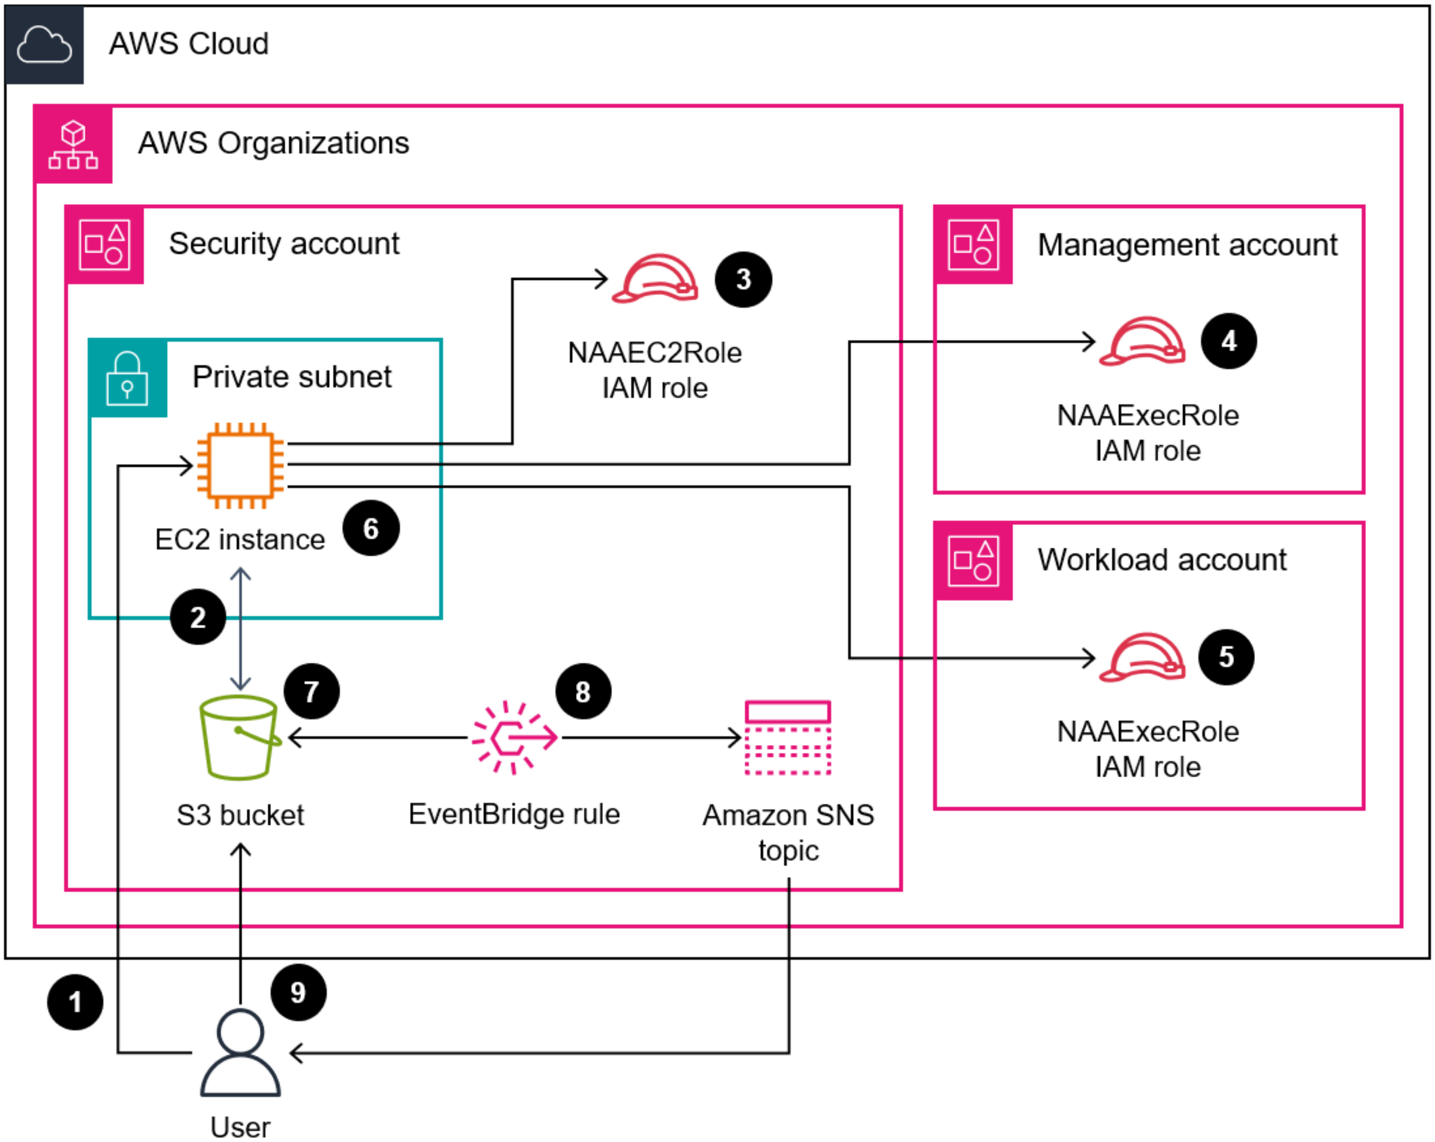
- Cross-account network paths are not currently analyzed due to limitations of the Network Access Analyzer feature.

- The target AWS accounts must be managed as an organization in AWS Organizations. If you are not using AWS Organizations, you can update the **naa-execrole.yaml** CloudFormation template and the **naa-script.sh** script for your environment. Instead, you provide a list of AWS account IDs and Regions where you want to run the script.
- The CloudFormation template is designed to deploy the Amazon EC2 instance in a private subnet that has outbound internet access. The AWS Systems Manager Agent (SSM Agent) requires outbound access to reach the Systems Manager service endpoint, and you need outbound access to clone the code repository and install dependencies. If you want to use a public subnet, you must modify the **naa-resources.yaml** template to associate an Elastic IP address with the Amazon EC2 instance.

Architecture

Target architecture

Option 1: Access findings in an Amazon S3 bucket



The diagram shows the following process:

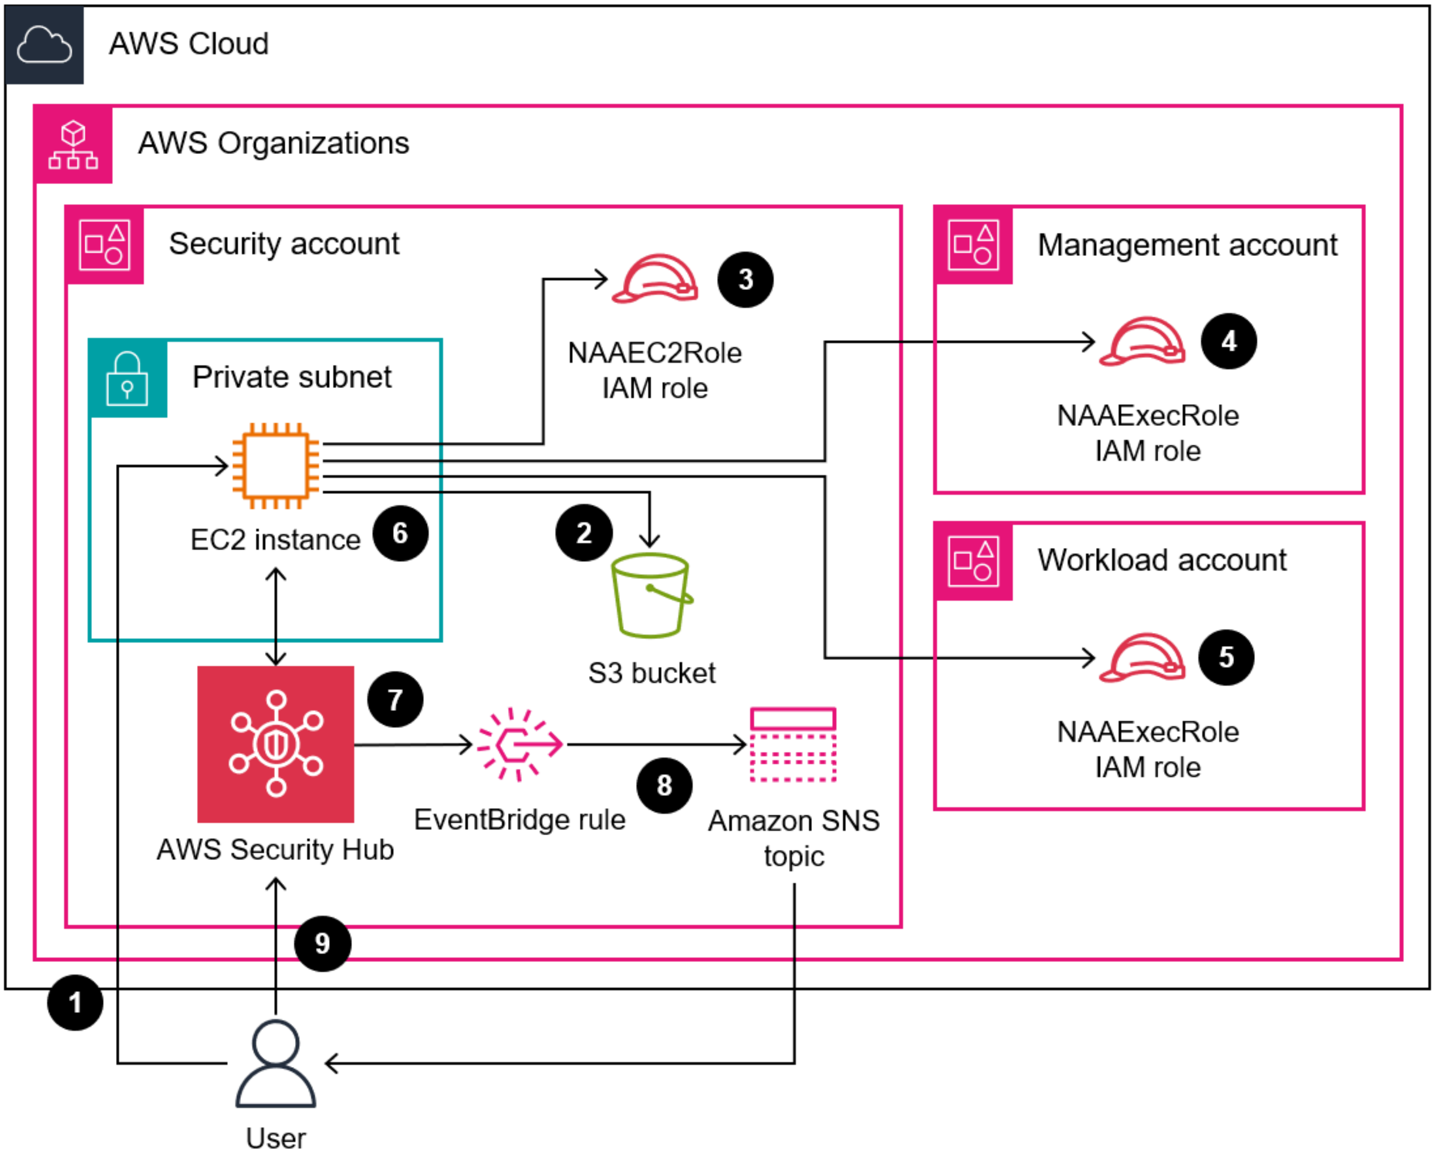
1. If you're manually running the solution, the user authenticates to the Amazon EC2 instance by using Session Manager and then runs the **naa-script.sh** script. This shell script performs steps 2–7.

   If you're automatically running the solution, the **naa-script.sh** script starts automatically on the schedule you defined in the cron expression. This shell script performs steps 2–7. For more information, see *Automation and scale* at the end of this section.

2. The Amazon EC2 instance downloads the latest **naa-exception.csv** file from the Amazon S3 bucket. This file is used later in the process when the Python script processes the exclusions.

3. The Amazon EC2 instance assumes the `NAAEC2Role` AWS Identity and Access Management (IAM) role, which grants permissions to access the Amazon S3 bucket and to assume the `NAAExecRole` IAM roles in the other accounts in the organization.
4. The Amazon EC2 instance assumes the `NAAExecRole` IAM role in the organization's management account and generates a list of the accounts in the organization.
5. The Amazon EC2 instance assumes the `NAAExecRole` IAM role in the organization's member accounts (called *workload accounts* in the architecture diagram) and performs a security assessment in each account. The findings are stored as JSON files on the Amazon EC2 instance.
6. The Amazon EC2 instance uses a Python script to process the JSON files, extract the data fields, and create a CSV report.
7. The Amazon EC2 instance uploads the CSV file to the Amazon S3 bucket.
8. An Amazon EventBridge rule detects the file upload and uses an Amazon SNS topic to send an email that notifies the user that the report is complete.
9. The user downloads the CSV file from the Amazon S3 bucket. The user imports the results into the Excel template and reviews the results.

Option 2: Access findings in AWS Security Hub



The diagram shows the following process:

1. If you're manually running the solution, the user authenticates to the Amazon EC2 instance by using Session Manager and then runs the **naa-script.sh** script. This shell script performs steps 2–7.

   If you're automatically running the solution, the **naa-script.sh** script starts automatically on the schedule you defined in the cron expression. This shell script performs steps 2–7. For more information, see *Automation and scale* at the end of this section.

2. The Amazon EC2 instance downloads the latest **naa-exception.csv** file from the Amazon S3 bucket. This file is used later in the process when the Python script processes the exclusions.

3. The Amazon EC2 instance assumes the `NAAEC2Role` IAM role, which grants permissions to access the Amazon S3 bucket and to assume the `NAAExecRole` IAM roles in the other accounts in the organization.
4. The Amazon EC2 instance assumes the `NAAExecRole` IAM role in the organization's management account and generates a list of the accounts in the organization.
5. The Amazon EC2 instance assumes the `NAAExecRole` IAM role in the organization's member accounts (called *workload accounts* in the architecture diagram) and performs a security assessment in each account. The findings are stored as JSON files on the Amazon EC2 instance.
6. The Amazon EC2 instance uses a Python script to process the JSON files and extract the data fields for import into Security Hub.
7. The Amazon EC2 instance imports the Network Access Analyzer findings to Security Hub.
8. An Amazon EventBridge rule detects the import and uses an Amazon SNS topic to send an email that notifies the user that the process is complete.
9. The user views the findings in Security Hub.

Automation and scale

You can schedule this solution to run the **naa-script.sh** script automatically on a custom schedule. To set a custom schedule, in the **naa-resources.yaml** CloudFormation template, modify the `CronScheduleExpression` parameter. For example, the default value of `0 0 * * 0` runs the solution at midnight on every Sunday. A value of `0 0 * 1-12 0` would run the solution at midnight on the first Sunday of every month. For more information about using cron expressions, see [Cron and rate expressions](#) in the Systems Manager documentation.

If you want adjust the schedule after the `NAA-Resources` stack has been deployed, you can manually edit the cron schedule in `/etc/cron.d/naa-schedule`.

Tools

AWS services

- [Amazon Elastic Compute Cloud (Amazon EC2)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.

- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Security Hub provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses Session Manager, a capability of Systems Manager.

Code repository

The code for this pattern is available in the GitHub Network Access Analyzer Multi-Account Analysis repository. The code repository contains the following files:

- **naa-script.sh** – This bash script is used to start a Network Access Analyzer analysis of multiple AWS accounts, in parallel. As defined in the **naa-resources.yaml** CloudFormation template, this script is automatically deployed to the `/usr/local/naa` folder on the Amazon EC2 instance.
- **naa-resources.yaml** – You use this CloudFormation template to create a stack in the security account in the organization. This template deploys all of the required resources for this account in order to support the solution. This stack must be deployed before the **naa-execrole.yaml** template.

  > **Note**
  >
  > If this stack is deleted and redeployed, you must rebuild the `NAAExecRole` stack set in order to rebuild the cross-account dependencies between the IAM roles.

- **naa-execrole.yaml** – You use this CloudFormation template to create a stack set that deploys the `NAAExecRole` IAM role in all accounts in the organization, including the management account.

- **naa-processfindings.py** – The **naa-script.sh** script automatically calls this Python script to process the Network Access Analyzer JSON outputs, exclude any known-good resources in the **naa-exclusions.csv** file, and then either generate a CSV file of the consolidated results or import the results into Security Hub.

Epics

Prepare for deployment

Task	Description	Skills required
Clone the code repository.	1. In a command-line interface, change your working directory to the location where you want to store the sample files. 2. Enter the following command: `git clone https://github.com/aws-samples/network-access-analyzer-multi-account-analysis.git`	AWS DevOps
Review the templates.	1. In the cloned repository, open the **naa-resources.yaml** and **naa-execrole.yaml** files. 2. Review the resources created by these templates and adjust the templates as needed for your environment. For more information, see [Working with templates](#) in	AWS DevOps

Task	Description	Skills required
	the CloudFormation documentation. 3. Save and close the **naa-resources.yaml** and **naa-execrole.yaml** files.	

Create the CloudFormation stacks

Task	Description	Skills required
Provision resources in the security account.	Using the **naa-resources.yaml** template, you create a CloudFormation stack that deploys all of the required resources in the security account. For instructions, see [Creating a stack](#) in the CloudFormation documentation. Note the following when deploying this template: 1. On the **Specify template** page, choose **Template is ready**, and then upload the **naa-resources.yaml** file. 2. On the **Specify stack details** page, in the **Stack name** box, enter `NAA-Resources`. 3. In the **Parameters** section, enter the following: • `VPCId` – Select a VPC in the account.	AWS DevOps

Task	Description	Skills required
	• `SubnetId` –– Select a private subnet that has internet access. **Note** If you select a public subnet, the Amazon EC2 instance might not be assigned a public IP address because the CloudFormation template, by default, doesn't provision and attach an Elastic IP address. • `InstanceType` – Leave the default instance type. • `InstanceImageId` – Leave the default. • `KeyPairName` – If you're using SSH for access, specify the name of an existing key pair. • `PermittedSSHInbound` – If you're using SSH for access, specify a permitted CIDR block. If you're not using SSH,	

Task	Description	Skills required
	keep the default value of `127.0.0.1` . • `BucketName` – The default value is `naa-<accountID>-<region>` . You can modify this as needed. If you specify a custom value, the account ID and Region are automatically appended to the specified value. • `EmailAddress` – Specify an email address for an Amazon SNS notification when the analysis is complete. **Note** The Amazon SNS subscription configuration must be confirmed prior to completion of the analysis, or a notification will not be sent. • `NAAEC2Role` – Keep the default unless your naming conventions require a different name for this IAM role.	

Task	Description	Skills required
	• `NAAExecRole` – Keep the default unless another name will be used when deploying the **naa-execrole.yaml** • `Parallelism` – Specify the number of parallel assessments to perform. • `Regions` – Specify the AWS Regions you want to analyze. • `ScopeNameValue` – Specify the tag that will be assigned to the scope. This tag is used to determine the Network Access Scope. • `ExclusionFile` – Specify the exclusion file name. Entries in this file will be excluded from findings. • `FindingsToCSV` – Specify whether findings should be output to CSV. Accepted values are `true` and `false`. • `FindingsToSecurityHub` – Specify whether findings should be imported into Security	

Task	Description	Skills required
	Hub. Accepted values are `true` and `false`. • `EmailNotificationsForSecurityHub` – Specify whether importing findings into Security Hub should generate email notifications. Accepted values are `true` and `false`. • `ScheduledAnalysis` – If you want the solution to run automatically on a schedule, enter `true`, and then customize the schedule in the `CronScheduleExpression` parameter. If you do not want to run the solution automatically, enter `false`. • `CronScheduleExpression` – If you're running the solution automatically, enter a cron expression to define the schedule. For more information, see *Automation and scale* in the [Architecture](#) section of this pattern.	

Task	Description	Skills required
	1. On the **Review** page, select **The following resource(s) require capabilities: [AWS::IAM::Role]**, and then choose **Create Stack**. 2. After the stack has been successfully created, in the CloudFormation console, on the **Outputs** tab, copy the `NAAEC2Role` Amazon Resource Name (ARN). You use this ARN later when deploying the **naa-execrole.yaml** file.	

Task	Description	Skills required
Provision the IAM role in the member accounts.	In the AWS Organizations management account or an account with delegated administrator permissions for CloudFormation, use the **naa-execrole.yaml** template to create a CloudFormation stack set. The stack set deploys the `NAAExecRole` IAM role in all member accounts in the organization. For instructions, see [Create a stack set with service-managed permissions](#) in the CloudFormation documentation. Note the following when deploying this template: 1. Under **Prepare template**, choose **Template is ready**, and then upload the **naa-execrole.yaml** file. 2. On the **Specify StackSet details** page, name the stack set `NAA-ExecRole` . 3. In the **Parameters** section, enter the following: • `AuthorizedARN` – Enter the `NAAEC2Role` ARN, which you copied when you created the `NAA-Resources` stack. • `NAARoleName` – Keep the default value of	AWS DevOps

Task	Description	Skills required
	`NAAExecRole` unless another name was used when deploying the **naa-resources.yaml** file. 4. Under **Permissions**, choose **Service-managed permissions**. 5. On the **Set deployment options** page, under **Deployment targets**, choose **Deploy to organization** and accept all defaults. **Note** If you want the stacks deployed to all member accounts simultaneously, set **Maximum concurrent accounts** and **Failure tolerance** to a high value, such as `100`. 6. Under **Deployment regions**, choose the Region where the Amazon EC2 instance for Network Access Analyzer is deployed. Because IAM resources are global and	

Task	Description	Skills required
	not Regional, this deploys the IAM role in all active Regions. 7. On the **Review** page, select **I acknowledge that AWS CloudFormation might create IAM resources with custom names**, and then choose **Create StackSet**. 8. Monitor the **Stack instances** tab (for individua l account status) and the **Operations** tab (for overall status) to determine when the deployment is complete.	

Task	Description	Skills required
Provision the IAM role in the management account.	Using the **naa-execrole.yaml** template, you create a CloudFormation stack that deploys the `NAAExecRole` IAM role in the managemen t account of the organizat ion. The stack set you created previously doesn't deploy the IAM role in the managemen t account. For instructions, see [Creating a stack](#) in the CloudFormation documenta tion. Note the following when deploying this template: 1. On the **Specify template** page, choose **Template is ready**, and then upload the **naa-execrole.yaml** file. 2. On the **Specify stack details** page, in the **Stack name** box, enter `NAA-ExecRole` . 3. In the **Parameters** section, enter the following: • `AuthorizedARN` – Enter the `NAAEC2Role` ARN, which you copied when you created the `NAA-Resources` stack. • `NAARoleName` – Keep the default value of `NAAExecRole` unless another name was used	AWS DevOps

Task	Description	Skills required
	when deploying the **naa-resources.yaml** file. 4. On the **Review** page, select **The following resource(s) require capabilities: [AWS::IAM::Role]**, and then choose **Create Stack**.	

Perform the analysis

Task	Description	Skills required

Customize the shell script.	1. Sign in to the security account in the organization.
	2. Using Session Manager, connect to the Amazon EC2 instance for Network Access Analyzer that you previously provisioned. For instructions, see [Connect to your Linux instance using Session Manager](). If you're unable to connect, see the [Troubleshooting]() section of this pattern.
	3. Enter the following commands to open the **naa-script.sh** file for editing:
	`sudo -i`
	`cd /usr/local/naa`
	`vi naa-script.sh`
		AWS DevOps

Task	Description	Skills required
	4. Review and modify the adjustable parameters and variables in this script as needed for your environment. For more information about customization options, see the comments at the beginning of the script. For example, instead of getting a list of all member accounts in the organization from the management account, you can modify the script to specify the AWS account IDs or AWS Regions that you want to scan, or you can reference an external file that contains these parameters. 5. Save and close the **naa-script.sh** file.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Analyze the target accounts.</td><td>
1. Enter the following commands. This runs the naa-script.sh script:
<pre><code>sudo -i
cd /usr/local/naa
screen
./naa-script.sh</code></pre>
Note the following:

The <code>screen</code> command permits the script to continue running in the event that the connectio n times out or you lose console access.
After the scan starts, you can force a screen detach by pressing Ctrl+A D. The screen detaches, and you can close the instance connectio n while the analysis proceeds.
To resume a detached session, connect to the instance, enter <code>sudo -i</code> then enter <code>screen -r</code>.

2. Monitor the output for any errors to make sure that the script is working properly. For a sample output, see the Additional
</td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	information section of this pattern. 3. Wait for the analysis to complete. If you configured email notifications, you receive an email when the results have been uploaded to the Amazon S3 bucket or imported into Security Hub.	
Option 1 – Retrieve the results from the Amazon S3 bucket.	1. Download the CSV file from the `naa-<accountID>-<region>` bucket. For instructions, see Downloading an object in the Amazon S3 documentation. 2. Delete the CSV file from the Amazon S3 bucket. This is a best practice for cost optimization. For instructions, see Deleting objects in the Amazon S3 documentation.	AWS DevOps

Task	Description	Skills required
Option 2 – Review the results in Security Hub.	1. Open the [Security Hub console](). 2. Choose **Findings** from the navigation pane. 3. Review the Network Access Analyzer findings. For instructions, see [Viewing finding lists and details]() in the Security Hub documentation. **Note** You can search findings by adding a **Title starts with** filter and entering `Network Access Analyzer`.	AWS DevOps

Remediate and exclude findings

Task	Description	Skills required
Remediate findings.	Remediate any findings that you want to address. For more information and best practices about how to create a perimeter around your AWS identities, resources, and networks, see [Building a data perimeter on AWS]() (AWS Whitepaper).	AWS DevOps

Task	Description	Skills required
Exclude resources with known-good network paths.	If Network Access Analyzer generates findings for resources that should be accessible from the internet, then you can add these resources to an exclusion list. The next time Network Access Analyzer runs, it won't generate a finding for that resource. 1. Navigate to `/usr/local/naa` , and then open the **naa-script.sh** script. Make note of the value of the `S3_EXCLUSION_FILE` variable. 2. If the value of the `S3_EXCLUSION_FILE` variable is `true`, download the **naa-exclusions.csv** file from the `naa-<accountID>-<region>` bucket. For instructions, see [Downloading an object](#) in the Amazon S3 documentation. If the value of the `S3_EXCLUSION_FILE` variable is `false`, navigate to `/usr/local/naa` and then open the **naa-exclusions.csv** file.	AWS DevOps

Task	Description	Skills required

	Note
	If the value of the `S3_EXCLUSION_FILE` variable is `false`, the script uses a local version of the exclusions file. If you later change the value to `true`, then the script overwrites the local version with the file in the Amazon S3 bucket.
	3. In the **naa-exclusions.csv** file, enter the resources that you want to exclude. Enter one resource in each line, and use the following format.
	`<resource_id>,<secgroup_id>,<sgrule_cidr>,<sgrule_portrange>,<sgrule_protocol>`
	The following is an example resource.
	`eni-1111aaaaa2222bbbb,sg-3333ccccc44`	

Task	Description	Skills required
	`44dddd,0.0.0.0/0,80 to 80,tcp` 4. Save and close the **naa-exclusions.csv** file. 5. If you downloaded the **naa-exclusions.csv** file from the Amazon S3 bucket, upload the new version. For instructions, see [Uploading objects] in the Amazon S3 documentation.	

(Optional) Update the naa-script.sh script

Task	Description	Skills required
Update the naa-script.sh script.	If you want to update the **naa-script.sh** script to the latest version in the repo, do the following: 1. Connect to the Amazon EC2 instance by using Session Manager. For instructions, see [Connect to your Linux instance using Session Manager]. 2. Enter the following command: `sudo -i`	AWS DevOps

Task	Description	Skills required

	3. Navigate to the **naa-script.sh** script directory:
	`cd /usr/local/naa`
	4. Enter the following command to stash the local script so that you can merge custom changes into the newest version:
	`git stash`
	5. Enter the following command to get the latest version of the script:
	`git pull`
	6. Enter the following command to merge the custom script with the latest version of the script:
	`git stash pop`	

(Optional) Clean up

Task	Description	Skills required
Delete all deployed resources.	You can leave the resources deployed in the accounts. If you want to deprovision all resources, do the following:	AWS DevOps

Task	Description	Skills required
	1. Delete the `NAA-ExecRole` stack provisioned in the management account. For instructions, see [Deleting a stack](#) in the CloudFormation documentation. 2. Delete the `NAA-ExecRole` stack set provisioned in the organization's management account or in the delegated administrator account. For instructions, see [Delete a stack set](#) in the CloudFormation documentation. 3. Delete all objects in the `naa-<accountID>-<region>` Amazon S3 bucket. For instructions, see [Deleting objects](#) in the Amazon S3 documentation. 4. Delete the `NAA-Resources` stack provisioned in the security account. For instructions, see [Deleting a stack](#) in the CloudFormation documentation.	

Troubleshooting

Issue	Solution
Unable to connect to the Amazon EC2 instance by using Session Manager.	The SSM Agent must be able to communicate with the Systems Manager endpoint. Do the following: 1. Validate the subnet where the Amazon EC2 instance is deployed has internet access. 2. Reboot the Amazon EC2 instance.
When deploying the stack set, the CloudFormation console prompts you to `Enable trusted access with AWS Organizations to use service-managed permissions .`	This indicates that trusted access has not been enabled between AWS Organizations and CloudFormation. Trusted access is required to deploy the service-managed stack set. Choose the button to enable trusted access. For more information, see Enable trusted access in the CloudFormation documentation.

Set up DNS resolution for hybrid networks in a multi-account AWS environment

Anvesh Koganti, Amazon Web Services

Summary

This pattern provides a comprehensive solution for setting up DNS resolution in hybrid network environments that include multiple Amazon Web Services (AWS) accounts. It enables bidirectional DNS resolution between on-premises networks and the AWS environment through Amazon Route 53 Resolver endpoints. The pattern presents two solutions to enable DNS resolution in a multi-account, centralized architecture:

- *Basic setup* doesn't use Route 53 Profiles. It helps optimize costs for small to medium deployments of lower complexity.
- *Enhanced setup* uses Route 53 Profiles to simplify operations. It is best for larger or more complex DNS deployments.

> **Note**
>
> Review the *Limitations* section for service limitations and quotas before implementation. Consider factors such as management overhead, costs, operational complexity, and team expertise when you make your decision.

Prerequisites and limitations

Prerequisites

- An AWS multi-account environment with Amazon Virtual Private Cloud (Amazon VPC) deployed across Shared Services and workload accounts (preferably set up through AWS Control Tower by following AWS best practices for account structure).
- Existing hybrid connectivity (AWS Direct Connect or AWS Site-to-Site VPN) between your on-premises network and the AWS environment.
- Amazon VPC peering, AWS Transit Gateway, or AWS Cloud WAN for Layer 3 network connectivity between VPCs. (This connectivity is required for application traffic. It is not required for DNS

resolution to work. DNS resolution operates independently of network connectivity between the VPCs.)

- DNS servers running in the on-premises environment.

Limitations

- Route 53 Resolver endpoints, rules, and Profiles are Regional constructs and might require replication in multiple AWS Regions for global organizations.
- For a comprehensive list of service quotas for Route 53 Resolver, private hosted zones, and Profiles, see Quotas in the Route 53 documentation.

Architecture

Target technology stack

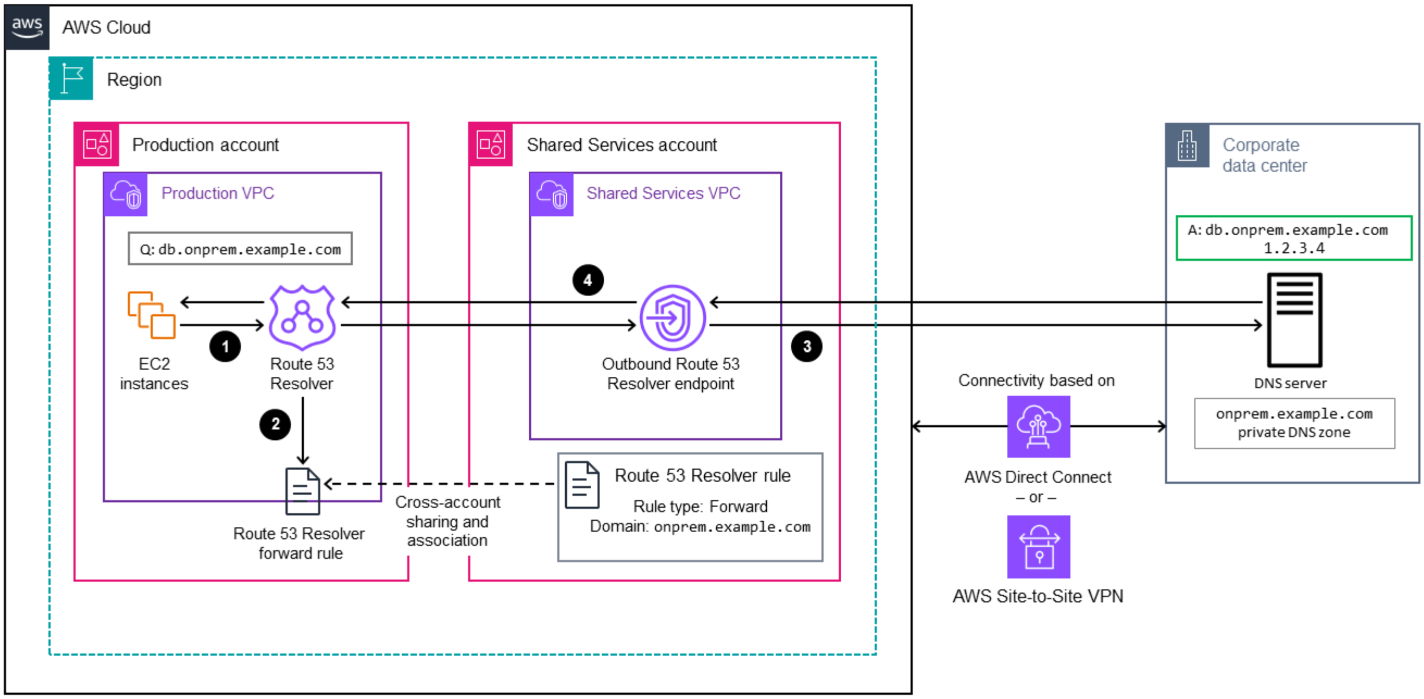
- Route 53 outbound and inbound endpoints
- Route 53 Resolver rules for conditional forwarding
- AWS Resource Access Manager (AWS RAM)
- Route 53 private hosted zone

Target architecture

Outbound and inbound endpoints

The following diagram shows the DNS resolution flow from AWS to on premises. This is the connectivity setup for outbound resolutions where the domain is hosted on premises. Here is a high-level overview of the process involved in setting this up. For details, see the Epics section.

1. Deploy outbound Route 53 Resolver endpoints in the Shared Services VPC.
2. Create Route 53 Resolver rules (forwarding rules) in the Shared Services account for domains that are hosted on premises.
3. Share and associate the rules with VPCs in other accounts that host resources that need to resolve on-premises hosted domains. This can be done in different ways depending on your use case, as described later in this section.



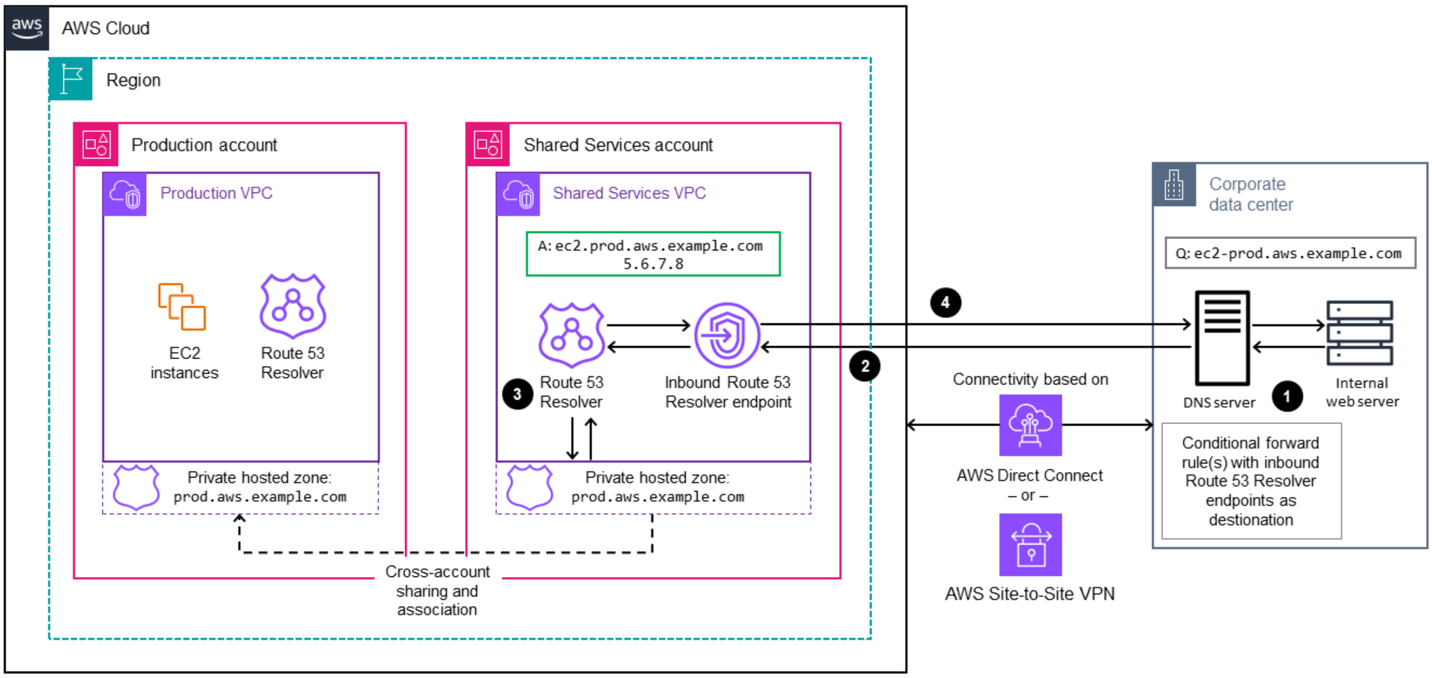
After you set up connectivity, the steps involved in the outbound resolution are as follows:

1. The Amazon Elastic Compute Cloud (Amazon EC2) instance sends a DNS resolution request for `db.onprem.example.com` to the VPC's Route 53 Resolver at the VPC+2 address.
2. Route 53 Resolver checks the Resolver rules and forwards the request to the on-premises DNS server IPs by using the outbound endpoint.
3. The outbound endpoint forwards the request to the on-premises DNS IPs. The traffic goes over the established hybrid network connectivity between the Shared Services VPC and the on-premises data center.
4. The on-premises DNS server responds back to the outbound endpoint, which then forwards the response back to the VPC's Route 53 Resolver. The Resolver returns the response to the EC2 instance.

The next diagram shows the DNS resolution flow from the on-premises environment to AWS. This is the connectivity setup for inbound resolutions where the domain is hosted on AWS. Here is a high-level overview of the process involved in setting this up. For details, see the Epics section.

1. Deploy inbound Resolver endpoints in the Shared Services VPC.
2. Create private hosted zones in the Shared Services account (centralized approach).

3. Associate the private hosted zones with the Shared Services VPC. Share and associate these zones with cross-account VPCs for VPC-to-VPC DNS resolution. This can be done in different ways depending on your use case, as described later in this section.



After you set up connectivity, the steps involved in the inbound resolution are as follows:

1. The on-premises resource sends a DNS resolution request for `ec2.prod.aws.example.com` to the on-premises DNS server.
2. The on-premises DNS server forwards the request to the inbound Resolver endpoint in the Shared Services VPC over the hybrid network connection.
3. The inbound Resolver endpoint looks up the request in the associated private hosted zone with the help of the VPC Route 53 Resolver and gets the appropriate IP address.
4. These IP addresses are sent back to the on-premises DNS server, which returns the response to the on-premises resource.

This configuration enables on-premises resources to resolve AWS private domain names by routing queries through the inbound endpoints to the appropriate private hosted zone. In this architecture, private hosted zones are centralized in a Shared Services VPC, which allows for central DNS management by a single team. These zones can be associated with many VPCs to address the VPC-to-VPC DNS resolution use case. Alternatively, you might want to delegate DNS domain ownership and management to each AWS account. In that case, each account manages its own private hosted zones and associates each zone with the central Shared Services VPC for a unified resolution with the on-premises environment. This decentralized approach is outside the scope of this pattern. For more information, see [Scaling DNS management across multiple accounts and VPCs]() in the *Hybrid Cloud DNS Options for Amazon VPC* whitepaper.

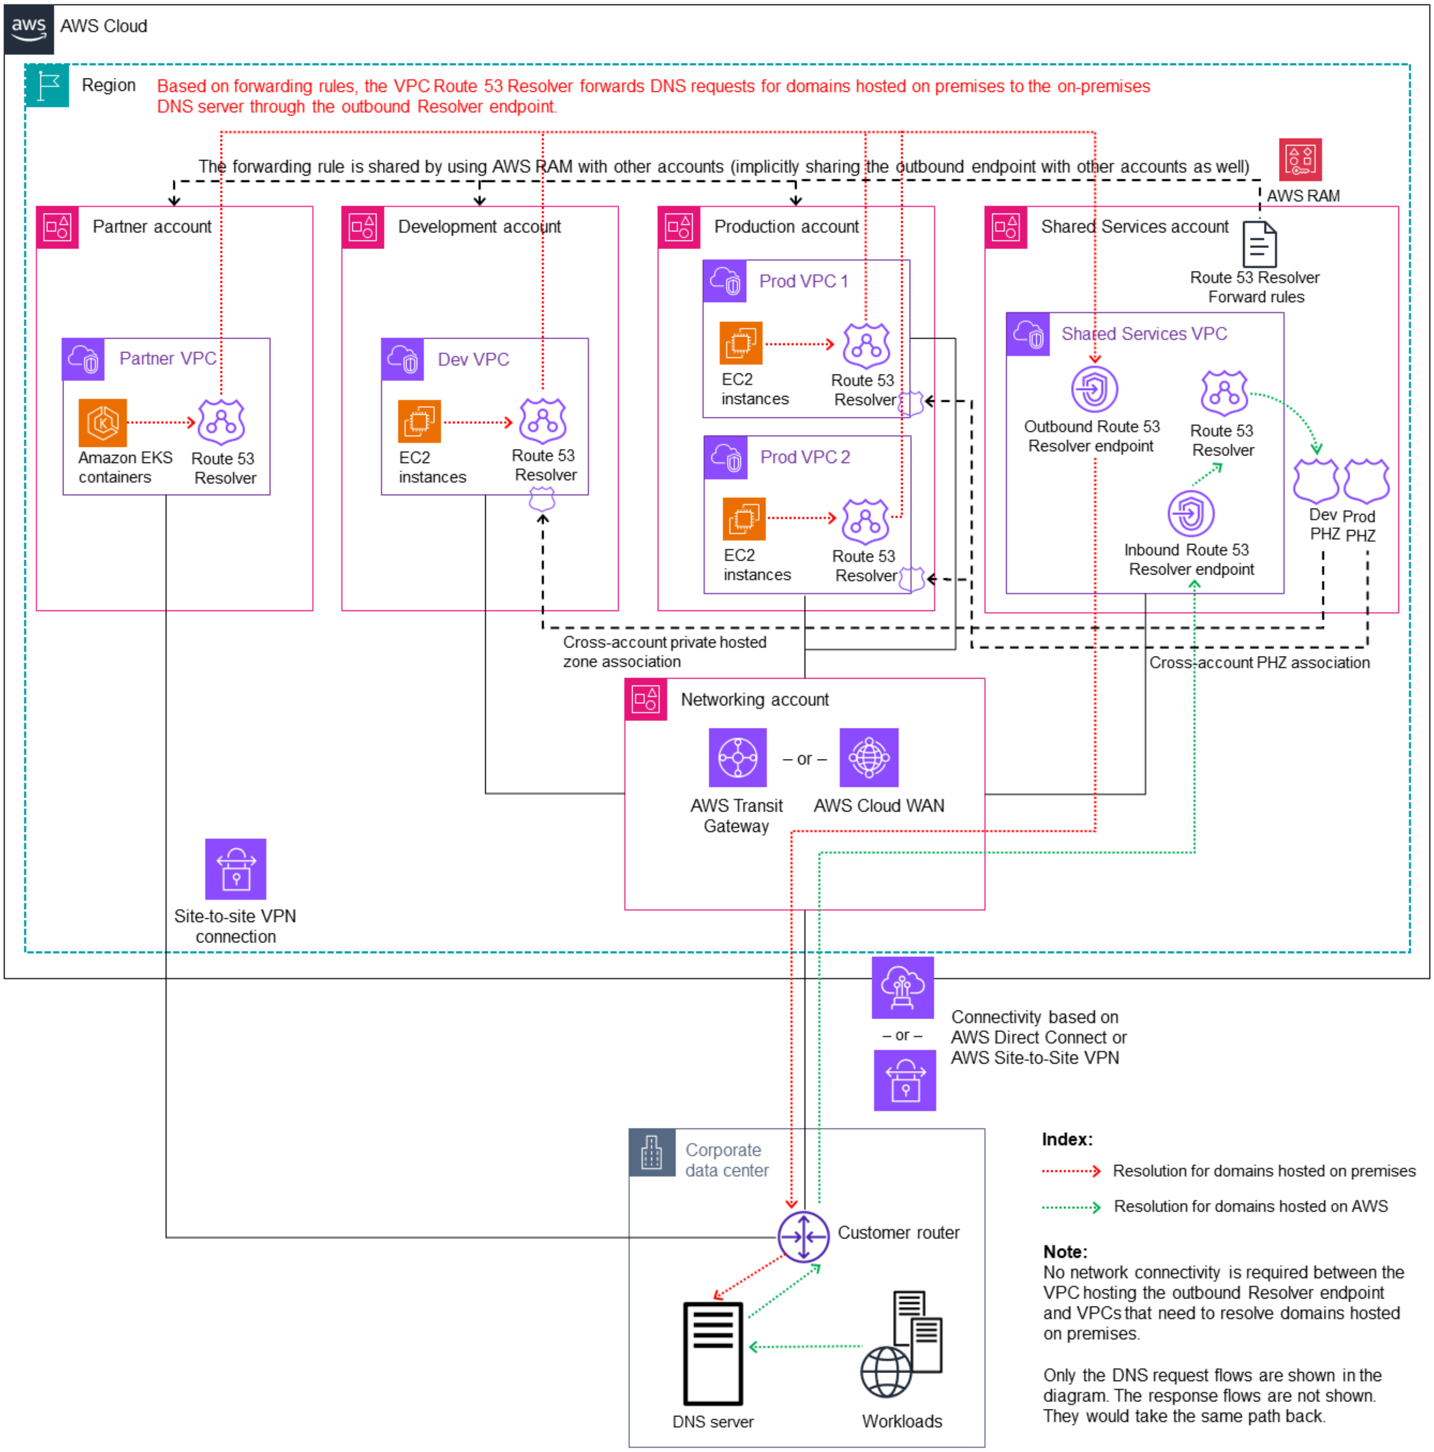
When you establish the fundamental DNS resolution flows by using Resolver endpoints, you need to determine how to manage the sharing and association of Resolver rules and private hosted zones across your AWS accounts. You can approach this in two ways: through self-managed sharing by using AWS RAM to share Resolver rules and direct private hosted zone associations, as detailed in the *Basic setup* section, or through Route 53 Profiles, as discussed in the *Enhanced setup* section. The choice depends on your organization's DNS management preferences and operational requirements. The following architecture diagrams illustrate a scaled environment that includes multiple VPCs across different accounts, which represents a typical enterprise deployment.

Basic setup

In basic setup, the implementation for hybrid DNS resolution in a multi-account AWS environment uses AWS RAM to share Resolver forwarding rules and private hosted zone associations to manage DNS queries between on-premises and AWS resources. This method uses centralized Route 53 Resolver endpoints in a Shared Services VPC that's connected to your on-premises network to handle both inbound and outbound DNS resolution efficiently.

- For outbound resolution, Resolver forwarding rules are created in the Shared Services account and then shared with other AWS accounts by using AWS RAM. This sharing is limited to accounts within the same Region. The target accounts can then associate these rules with their VPCs and enable the resources in those VPCs to resolve on-premises domain names.
- For inbound resolution, private hosted zones are created in the Shared Services account and associated with the Shared Services VPC. These zones can then be associated with VPCs in other accounts by using the Route 53 API, AWS SDKs, or the AWS Command Line Interface (AWS CLI). The resources in associated VPCs can then resolve DNS records defined in the private hosted zones, which creates a unified DNS view across your AWS environment.

The following diagram shows DNS resolution flows in this basic setup.

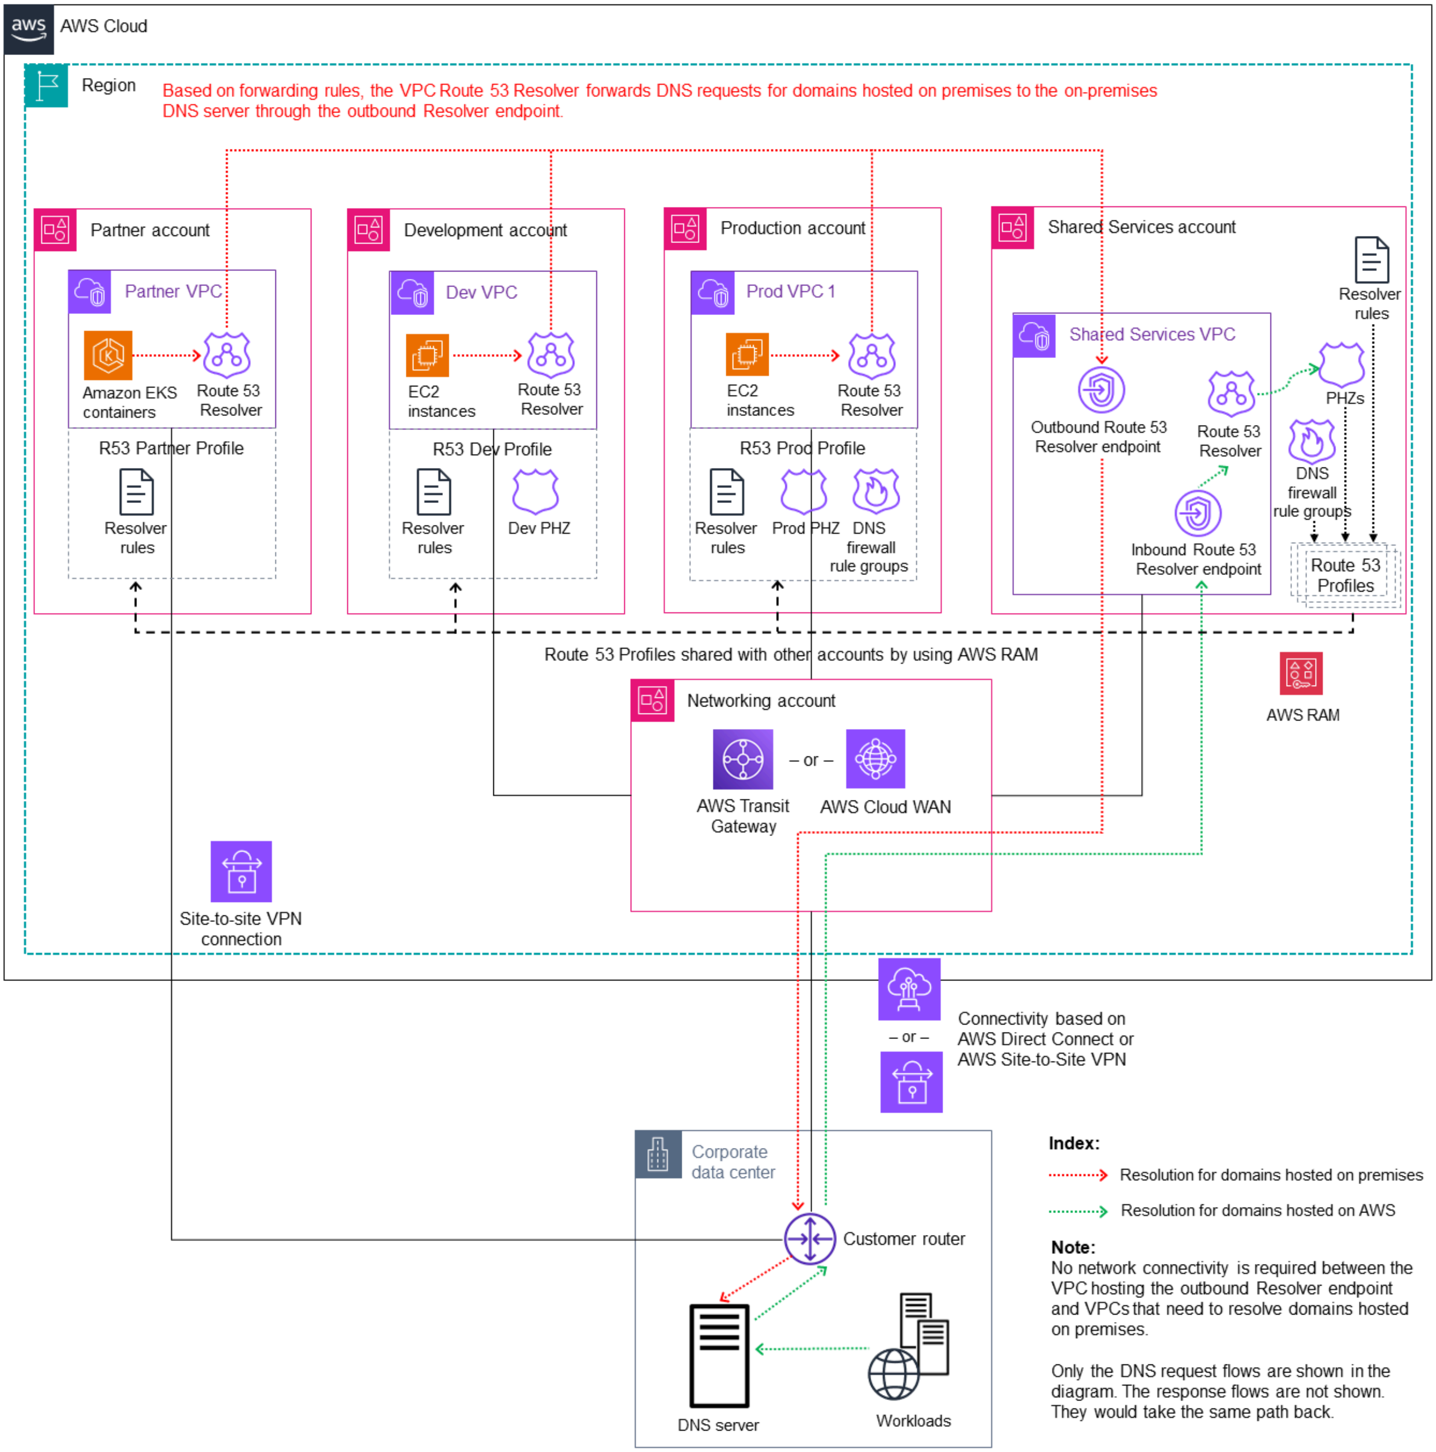


This setup works well when you work with DNS infrastructure on a limited scale. However, it can become challenging to manage as your environment grows. The operational overhead of managing how private hosted zone and Resolver rules are shared and associated with VPCs individually increases significantly with scale. Additionally, service quotas such as the 300 VPC association limit per private hosted zone can become constraining factors in large-scale deployments. Enhanced setup addresses these challenges.

Enhanced setup

Route 53 Profiles offer a streamlined solution for managing DNS resolution in hybrid networks across multiple AWS accounts. Instead of managing private hosted zones and Resolver rules individually, you can group DNS configurations into a single container that can be easily shared and applied across multiple VPCs and accounts in a Region. This setup maintains the centralized Resolver endpoint architecture in a Shared Services VPC while significantly simplifying the management of DNS configurations.

The following diagram shows DNS resolution flows in an enhanced setup.



Route 53 Profiles let you package private hosted zone associations, Resolver forwarding rules, and DNS firewall rules into a single, shareable unit. You can create Profiles in the Shared Services account and share them with member accounts by using AWS RAM. When a profile is shared and applied to target VPCs, all necessary associations and configurations are automatically handled by

the service. This significantly reduces the operational overhead of DNS management and provides excellent scalability for growing environments.

Automation and scale

Use infrastructure as code (IaC) tools such as AWS CloudFormation or Terraform to automatically provision and manage Route 53 Resolver endpoints, rules, private hosted zones, and Profiles. Integrate DNS configuration with continuous integration and continuous delivery (CI/CD) pipelines for consistency, repeatability, and rapid updates.

Tools

AWS services

- AWS Resource Access Manager (AWS RAM) helps you securely share your resources across AWS accounts to reduce operational overhead and provide visibility and auditability.
- Amazon Route 53 Resolver responds recursively to DNS queries from AWS resources and is available by default in all VPCs. You can create Resolver endpoints and conditional forwarding rules to resolve DNS namespaces between your on-premises data center and your VPCs.
- Amazon Route 53 private hosted zone is a container that holds information about how you want Route 53 to respond to DNS queries for a domain and its subdomains.
- Amazon Route 53 Profiles allow you to apply and manage DNS-related Route 53 configurations across many VPCs and in different AWS accounts in a simplified manner.

Best practices

This section provides some of the best practices for optimizing Route 53 Resolver. These represent a subset of Route 53 best practices. For a comprehensive list, see Best practices for Amazon Route 53.

Avoid loop configurations with Resolver endpoints

- Design your DNS architecture to prevent recursive routing by carefully planning VPC associations. When a VPC hosts an inbound endpoint, avoid associating it with Resolver rules that could create circular references.
- Use AWS RAM strategically when you share DNS resources across accounts to maintain clean routing paths.

For more information, see Avoid loop configurations with Resolver endpoints in the Route 53 documentation.

Scale Resolver endpoints

- For environments that require a high number of queries per second (QPS), be aware that there is a limit of 10,000 QPS per ENI in an endpoint. More ENIs can be added to an endpoint to scale DNS QPS.
- Amazon CloudWatch provides `InboundQueryVolume` and `OutboundQueryVolume` metrics (see the CloudWatch documentation). We recommend that you set up monitoring rules that alert you if the threshold exceeds a certain value (for example, 80 percent of 10,000 QPS).
- Configure stateful security group rules for Resolver endpoints to prevent connection tracking limits from causing DNS query throttling during high-volume traffic. To learn more about how connection tracking works in security groups, see Amazon EC2 security group connection tracking in the Amazon EC2 documentation.

For more information, see Resolver endpoint scaling in the Route 53 documentation.

Provide high availability for Resolver endpoints

- Create inbound endpoints with IP addresses in at least two Availability Zones for redundancy.
- Provision additional network interfaces to ensure availability during maintenance or traffic surges.

For more information, see High availability for Resolver endpoints in the Route 53 documentation.

Epics

Deploy Route 53 Resolver endpoints

Task	Description	Skills required
Deploy an inbound endpoint.	Route 53 Resolver uses the inbound endpoint to receive DNS queries from on-premises DNS resolvers. For instructions, see Forwarding inbound	AWS administrator, Cloud administrator

Task	Description	Skills required
	DNS queries to your VPCs in the Route 53 documentation. Make a note of the inbound endpoint IP address.	
Deploy an outbound endpoint.	Route 53 Resolver uses the outbound endpoint to send DNS queries to on-premises DNS resolvers. For instructions, see Forwarding outbound DNS queries to your network in the Route 53 documentation. Make a note of the output endpoint ID.	AWS administrator, Cloud administrator

Configure and share Route 53 private hosted zones

Task	Description	Skills required
Create a private hosted zone for a domain that's hosted on AWS.	This zone holds the DNS records for resources in an AWS-hosted domain (for example, `prod.aws.example.com`) that should be resolved from the on-premises environment. For instructions, see Creating a private hosted zone in the Route 53 documentation. When you create a private hosted zone, you must associate a VPC with the hosted zone owned by the same account. Select the	AWS administrator, Cloud administrator

Task	Description	Skills required
	Shared Services VPC for this purpose.	
Basic setup: Associate the private hosted zone with VPCs in other accounts.	If you're using basic setup (see the Architecture section): To enable resources in the member account VPCs to resolve DNS records in this private hosted zone, you must associate your VPCs with the hosted zone. You must authorize the association and then make the associati on programmatically. For instructions, see Associating an Amazon VPC and a private hosted zone that you created with different AWS accounts in the Route 53 documenta tion.	AWS administrator, Cloud administrator

Task	Description	Skills required
Enhanced setup: Configure and share Route 53 Profiles.	If you're using enhanced setup (see the Architecture section): 1. Create a Route 53 Profile and associate the relevant private hosted zones with it. For instructions, see Creating Route 53 Profiles in the Route 53 documentation. 2. Use AWS RAM to share the profile with member accounts and then associate the shared profile with target VPCs. For instructions, see Sharing a Route 53 Profile and Associate a Route 53 Profile to VPCs in the Route 53 documentation. **Note** Depending on your organization's structure and DNS requirements, you might need to create and manage multiple Profiles for different	AWS administrator, Cloud administrator

Task	Description	Skills required
	accounts or workloads .	

Configure and share Route 53 Resolver forwarding rules

Task	Description	Skills required
Create a forwarding rule for a domain that's hosted on premises.	This rule will instruct Route 53 Resolver to forward any DNS queries for on-premises domains (such as `onprem.example.com`) to on-premises DNS resolvers. To create this rule, you need the IP addresses of the on-premises DNS resolvers and the outbound endpoint ID. For instructions, see [Creating forwarding rules](#) in the Route 53 documentation.	AWS administrator, Cloud administrator
Basic setup: Share and associate the forwarding rule with your VPCs in other accounts.	If you're using basic setup: For the forwarding rule to take effect, you must share and associate the rule with your VPCs in other accounts. Route 53 Resolver then takes the rule into considera tion when it resolves a domain. For instructions, see [Sharing Resolver rules with other AWS accounts and using shared rules](#) and	AWS administrator, Cloud administrator

Task	Description	Skills required
	Associating forwarding rules with a VPC in the Route 53 documentation.	

Task	Description	Skills required
Enhanced setup: Configure and share Route 53 Profiles.	If you're using enhanced setup: 1. If you've already created a Route 53 Profile in the previous steps, you can use the same Profile. If not, create a Route 53 Profile and associate relevant Resolver forwarding rules with it. For instructions, see [Creating Route 53 Profiles](#) in the Route 53 documentation. 2. Use AWS RAM to share the profile with member accounts, and then associate the shared profile with target VPCs. For instructions, see [Sharing a Route 53 Profile](#) and [Associate a Route 53 Profile to VPCs](#) in the Route 53 documentation. **Note** Depending on your organization's structure and DNS requirements, you might need to create and manage multiple	AWS administrator, Cloud administrator

Task	Description	Skills required
	Profiles for different accounts or workloads .	

Configure on-premises DNS resolvers for AWS integration

Task	Description	Skills required
Configure conditional forwarding in the on-premis es DNS resolvers.	For DNS queries to be sent to AWS from the on-premises environment for resolution, you must configure condition al forwarding in the on-premises DNS resolvers to point to the inbound endpoint IP address. This instructs the DNS resolvers to forward all DNS queries for the AWS-hosted domain (for example, for `prod.aws.example.com`) to the inbound endpoint IP address for resolution by Route 53 Resolver.	Network administrator

Verify end-to-end DNS resolution in a hybrid environment

Task	Description	Skills required
Test DNS resolution from AWS to the on-premises environment.	From an instance in a VPC that has the forwarding rule associated with it, perform a DNS query for an on-premises	Network administrator

Task	Description	Skills required
	hosted domain (for example, for `db.onprem.example.com`).	
Test DNS resolution from the on-premises environment to AWS.	From an on-premises server, perform DNS resolution for an AWS-hosted domain (for example, for `ec2.prod.aws.example.com`).	Network administrator

Verify that ELB load balancers require TLS termination

Priyanka Chaudhary, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, Elastic Load Balancing (ELB) automatically distributes incoming application traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, IP addresses, and AWS Lambda functions. The load balancers use listeners to define the ports and protocols that the load balancer uses to accept traffic from users. Application Load Balancers make routing decisions at the application layer and use the HTTP/HTTPS protocols. Classic Load Balancers make routing decisions at either the transport layer, by using TCP or Secure Sockets Layer (SSL) protocols, or at the application layer, by using HTTP/HTTPS.

This pattern provides a security control that examines multiple event types for Application Load Balancers and Classic Load Balancers. When the function is invoked, AWS Lambda inspects the event and ensures that the load balancer is compliant.

The function initiates an Amazon CloudWatch Events event on the following API calls: CreateLoadBalancer, CreateLoadBalancerListeners, DeleteLoadBalancerListeners, CreateLoadBalancerPolicy, SetLoadBalancerPoliciesOfListener, CreateListener, DeleteListener, and ModifyListener. When the event detects one of these APIs, it calls AWS Lambda, which runs a Python script. The Python script evaluates to see if the listener contains an SSL certificate, and if the policy that is applied is using Transport Layer Security (TLS). If the SSL policy is determined to be anything other than TLS, the function sends an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information.

Prerequisites and limitations

Prerequisites

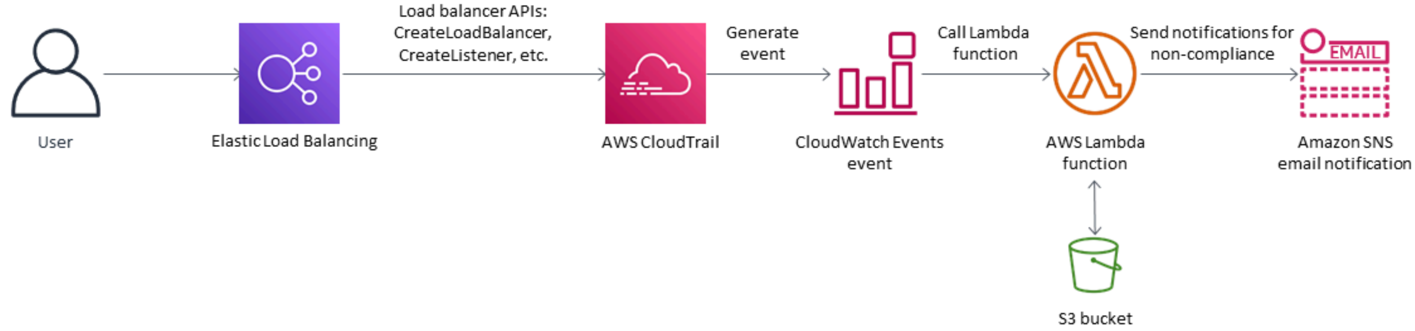
- An active AWS account

Limitations

- This security control does not check for existing load balancers, unless an update is made to the load balancer listeners.
- This security control is regional. You must deploy it in each AWS Region you want to monitor.

Architecture

Target architecture



Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

This pattern includes the following attachments:

- `ELBRequirestlstermination.zip` – The Lambda code for the security control.
- `ELBRequirestlstermination.yml` – The CloudFormation template that sets up the event and Lambda function.

Epics

Set up the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the [Amazon S3 console](https://console.aws.amazon.com/s3/), choose or create an S3 bucket to host the Lambda code .zip file. This S3 bucket must be in the same AWS Region as the load balancer that you want to evaluate. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes.	Cloud architect
Upload the Lambda code.	Upload the Lambda code (`ELBRequirestlstermination.zip` file) that's provided in the *Attachments* section to the S3 bucket.	Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Launch the AWS CloudFormation template.	Open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/) in the same AWS Region as your S3 bucket and deploy the attached template `ELBRequirestlstermination.yml` . For more information about deploying AWS CloudFormation templates, see [Creating a stack on the AWS CloudFormation console](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/cfn-console-create-stack.html) in the CloudFormation documentation.	Cloud architect
Complete the parameters in the template.	When you launch the template, you'll be prompted for the following information: • **S3 bucket:** Specify the bucket that you created or selected in the first epic. This is where you uploaded the attached Lambda code (`ELBRequirestlstermination.zip` file). • **S3 key:** Specify the location of the Lambda .zip file in your S3 bucket (for example, `ELBRequirestlstermination.zip` or `controls/ELBRequirestlsterm`	Cloud architect

Task	Description	Skills required
	`ination.zip`). Do not include leading slashes. • **Notification email:** Provide an active email address where you want to receive Amazon SNS notifications. • **Lambda logging level:** Specify the logging level and frequency for the Lambda function. Use **Info** to log detailed informational messages on progress, **Error** for error events that would still allow the deployment to continue, and **Warning** for potentially harmful situations.	

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the CloudFormation template deploys successfully, it sends a subscription email to the email address you provided. You must confirm this email subscription to start receiving violation notifications.	Cloud architect

View AWS Network Firewall logs and metrics by using Splunk

Ivo Pinto, Amazon Web Services

Summary

Many organizations use Splunk Enterprise as a centralized aggregation and visualization tool for logs and metrics from different sources. This pattern helps you configure Splunk to fetch AWS Network Firewall logs and metrics from Amazon CloudWatch Logs by using the Splunk Add-On for AWS.

To achieve this, you create a read-only AWS Identity and Access Management (IAM) role. Splunk Add-On for AWS uses this role to access CloudWatch. You configure the Splunk Add-On for AWS to fetch metrics and logs from CloudWatch. Finally, you create visualizations in Splunk from the retrieved log data and metrics.

Prerequisites and limitations

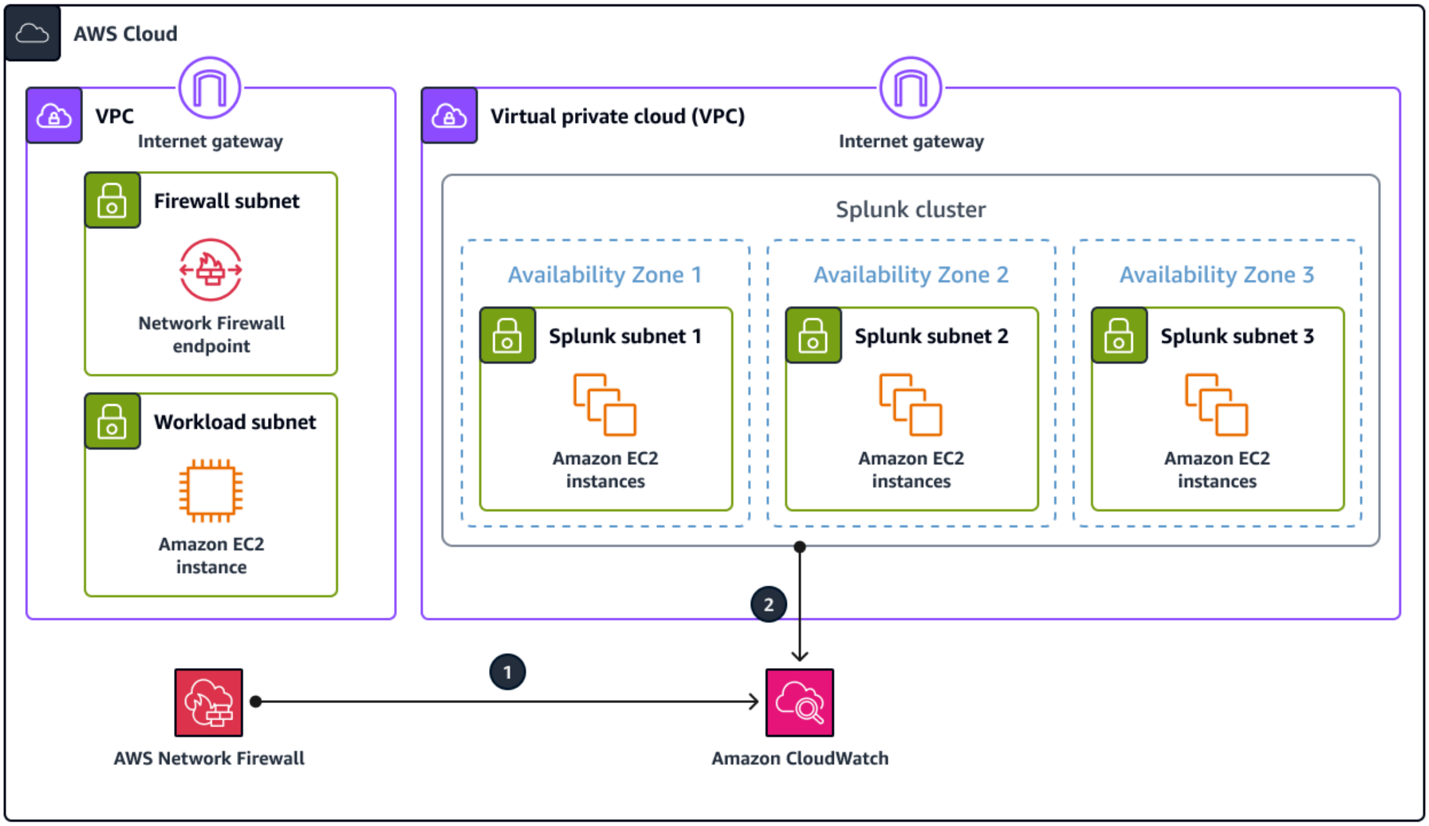
Prerequisites

- A Splunk account
- A Splunk Enterprise instance, version 8.2.2 or later
- An active AWS account
- Network Firewall, set up and configured to send logs to CloudWatch Logs

Limitations

- Splunk Enterprise must be deployed as a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances in the AWS Cloud.
- Collecting data by using an automatically discovered IAM role for Amazon EC2 is not supported in the AWS China Regions.

Architecture



The diagram illustrates the following:

1. Network Firewall publishes logs to CloudWatch Logs.
2. Splunk Enterprise retrieves metrics and logs from CloudWatch.

To populate example metrics and logs in this architecture, a workload generates traffic that passes through the Network Firewall endpoint to go to the internet. This is achieved by the use of [route tables](). Although this pattern uses a single Amazon EC2 instance as the workload, this pattern can apply to any architecture as long as Network Firewall is configured to send logs to CloudWatch Logs.

This architecture also uses a Splunk Enterprise instance in another virtual private cloud (VPC). However, the Splunk instance can be in another location, such as in the same VPC as the workload, as long as it can reach the CloudWatch APIs.

Tools

AWS services

- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Network Firewall is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud.

Other tools

- Splunk helps you monitor, visualize, and analyze log data.

Epics

Create an IAM role

Task	Description	Skills required

Create the IAM policy.	Follow the instructions in Creating policies using the JSON editor to create the IAM policy that grants read-only access to the CloudWatch Logs data and CloudWatch metrics. Paste the following policy into the JSON editor.
	`{`
	`    "Statement": [`
	`        {`
	`            "Action": [`
	` "cloudwatch:List*",`
	` "cloudwatch:Get*",`
	` "network-firewall:`
	`List*",`
		AWS administrator

Task	Description	Skills required

	` "logs:Describe*",`
	
	` "logs:Get*",`
	
	` "logs:List*",`
	
	` "logs:StartQuery",`
	
	` "logs:StopQuery",`
	
	` "logs:TestMetricFi lter",`
	
	` "logs:FilterLogEve nts",`
	
	` "network-firewall: Describe*"`
	`            ],`
	`            "Effect": "Allow",`
	`            "Resource": "*"`
	`        }`
	`    ],`
	`    "Version": "2012-10-17"`
	`}`	

Create a new IAM role.	Follow the instructions in [Creating a role to delegate permissions to an AWS service](#) to create the IAM role that the Splunk Add-On for AWS uses to access CloudWatc h. For **Permissions policies**, choose the policy that you created previously.	AWS administrator

Task	Description	Skills required
Assign the IAM role to the EC2 instances in the Splunk cluster.	1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. 2. In the navigation pane, choose **Instances**. 3. Select the EC2 instances in the Splunk cluster. 4. Choose **Actions**, **Security**, and then **Modify IAM role**. 5. Select the IAM role that you created previously, and then choose **Save**.	AWS administrator

Install the Splunk Add-On for AWS

Task	Description	Skills required
Install the add-on.	1. In the Splunk dashboard, navigate to **Splunk Apps**. 2. Search for **Splunk Add-on for Amazon Web Services**. 3. Choose **Install**. 4. Provide your Splunk credentials.	Splunk administrator
Configure the AWS credentials.	1. In the Splunk dashboard, navigate to **Splunk Add-on for AWS**. 2. Choose **Configuration**. 3. In the **Autodiscovered IAM Role** column, select the	Splunk administrator

Task	Description	Skills required
	IAM role that you created previously. For more information, see [Find an IAM role within your Splunk platform instance](#) in the Splunk documentation.	

Configure Splunk access to CloudWatch

Task	Description	Skills required
Configure the retrieval of Network Firewall logs from CloudWatch Logs.	1. In the Splunk dashboard, navigate to **Splunk Add-on for AWS**. 2. Choose **Input**. 3. Choose **Create New Input**. 4. In the list, choose **Custom Data Type**, and then choose **CloudWatch Logs**. 5. Provide the **Name**, **AWS Account**, **AWS Region**, and **Log Group** for your Network Firewall logs. 6. Choose **Save**. By default, Splunk fetches the log data every 10 minutes. This is a configurable parameter under **Advanced Settings**. For more informati on, see [Configure a CloudWatch Logs input using](#)	Splunk administrator

Task	Description	Skills required
	Splunk Web in the Splunk documentation.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Configure the retrieval of Network Firewall metrics from CloudWatch.</td><td>
1. In the Splunk dashboard, navigate to Splunk Add-on for AWS.
2. Choose Input.
3. Choose Create New Input.
4. In the list, choose CloudWatch.
5. Provide the Name, AWS Account, and AWS Region for your Network Firewall metrics.
6. Next to Metric Configura tion, choose Edit in advanced mode.
7. (Optional) Delete all preconfigured namespace s.
8. Choose Add Namespace , and then name it AWS/ NetworkFirewall.
9. In Dimension Value, add the following.
<pre><code>[{"AvailabilityZon
e":[".*"],"Engine"
:[".*"],"FirewallN
ame":[".*"]}]</code></pre>
10. For Metrics, choose All.
11. For Metric Statistics, choose Sum.
12. Choose OK.
13. Choose Save.
</td><td>Splunk administrator</td></tr>
</table>

Task	Description	Skills required
	By default, Splunk fetches the metric data every 5 minutes. This is a configurable parameter under **Advanced Settings**. For more information, see [Configure a CloudWatch input using Splunk Web](#) in the Splunk documentation.	

Create Splunk visualizations by using queries

Task	Description	Skills required
View the top source IP addresses.	1. In the Splunk dashboard, navigate to **Search & Reporting**. 2. In the **enter search here** box, enter the following. `sourcetype="aws:cloudwatchlogs" | top event.src_ip` This query displays a table of the source IP addresses with the most traffic, in descending order. 3. For a graphical representation, choose **Visualization**.	Splunk administrator
View packet statistics.	1. In the Splunk dashboard, navigate to **Search & Reporting**.	Splunk administrator

Task	Description	Skills required
	2. In the **enter search here** box, enter the following. `sourcetype="aws:cloudwatch"| timechart sum(Sum) by metric_name` This query displays a table of the metrics `DroppedPackets` , `PassedPackets` , and `ReceivedPackets` per minute. 3. For a graphical representation, choose **Visualization**.	
View the most-used source ports.	1. In the Splunk dashboard, navigate to **Search & Reporting**. 2. In the **enter search here** box, enter the following. `sourcetype="aws:cloudwatchlogs" | top event.dest_port` This query displays a table of the source ports with the most traffic, in descending order. 3. For a graphical representation, choose **Visualization**.	Splunk administrator

Send AWS WAF logs to Splunk by using AWS Firewall Manager and Amazon Data Firehose

Michael Friedenthal, Aman Kaur Gandhi, and JJ Johnson, Amazon Web Services

Summary

Historically, there were two ways to move data into Splunk: a push or a pull architecture. A *pull architecture* offers delivery data guarantees through retries, but it requires dedicated resources in Splunk that poll data. Pull architectures usually are not real time because of the polling. A *push architecture* in typically has lower latency, is more scalable, and reduces operational complexity and costs. However, it doesn't guarantee delivery and typically requires agents.

Splunk integration with Amazon Data Firehose delivers real-time streaming data to Splunk through an HTTP event collector (HEC). This integration provides the advantages of both push and pull architectures—it guarantees data delivery through retries, is near real-time, and is low latency and low complexity. The HEC quickly and efficiently sends data over HTTP or HTTPS directly to Splunk. HECs are token-based, which eliminates the need to hardcode credentials in an application or in supporting files.

In an AWS Firewall Manager policy, you can configure logging for all of the AWS WAF web ACL traffic in all of your accounts, and you can then use a Firehose delivery stream to send that log data to Splunk for monitoring, visualization, and analysis. This solution provides the following benefits:

- Central management and logging for AWS WAF web ACL traffic in all of your accounts
- Splunk integration with a single AWS account
- Scalability
- Near real-time delivery of log data
- Cost optimization through the use of a serverless solution, so you don't have to pay for unused resources.

Prerequisites and limitations

Prerequisites

- An active AWS account that is part of an organization in AWS Organizations.
- You must have the following permissions to enable logging with Firehose:

  - `iam:CreateServiceLinkedRole`
  - `firehose:ListDeliveryStreams`
  - `wafv2:PutLoggingConfiguration`
- AWS WAF and its web ACLs must be configured. For instructions, see [Getting started with AWS WAF](#).
- AWS Firewall Manager must be setup. For instructions, see [AWS Firewall Manager prerequisites](#).
- The Firewall Manager security policies for AWS WAF must be configured. For instructions, see [Getting started with AWS Firewall ManagerAWS WAF policies](#).
- Splunk must be setup with a public HTTP endpoint that can be reached by Firehose.

Limitations

- The AWS accounts must be managed in a single organization in AWS Organizations.
- The web ACL must be in the same Region as the delivery stream. If you are capturing logs for Amazon CloudFront, create the Firehose delivery stream in the US East (N. Virginia) Region, `us-east-1`.
- The Splunk add-on for Firehose is available for paid Splunk Cloud deployments, distributed Splunk Enterprise deployments, and single-instance Splunk Enterprise deployments. This add-on is not supported for free trial Splunk Cloud deployments.

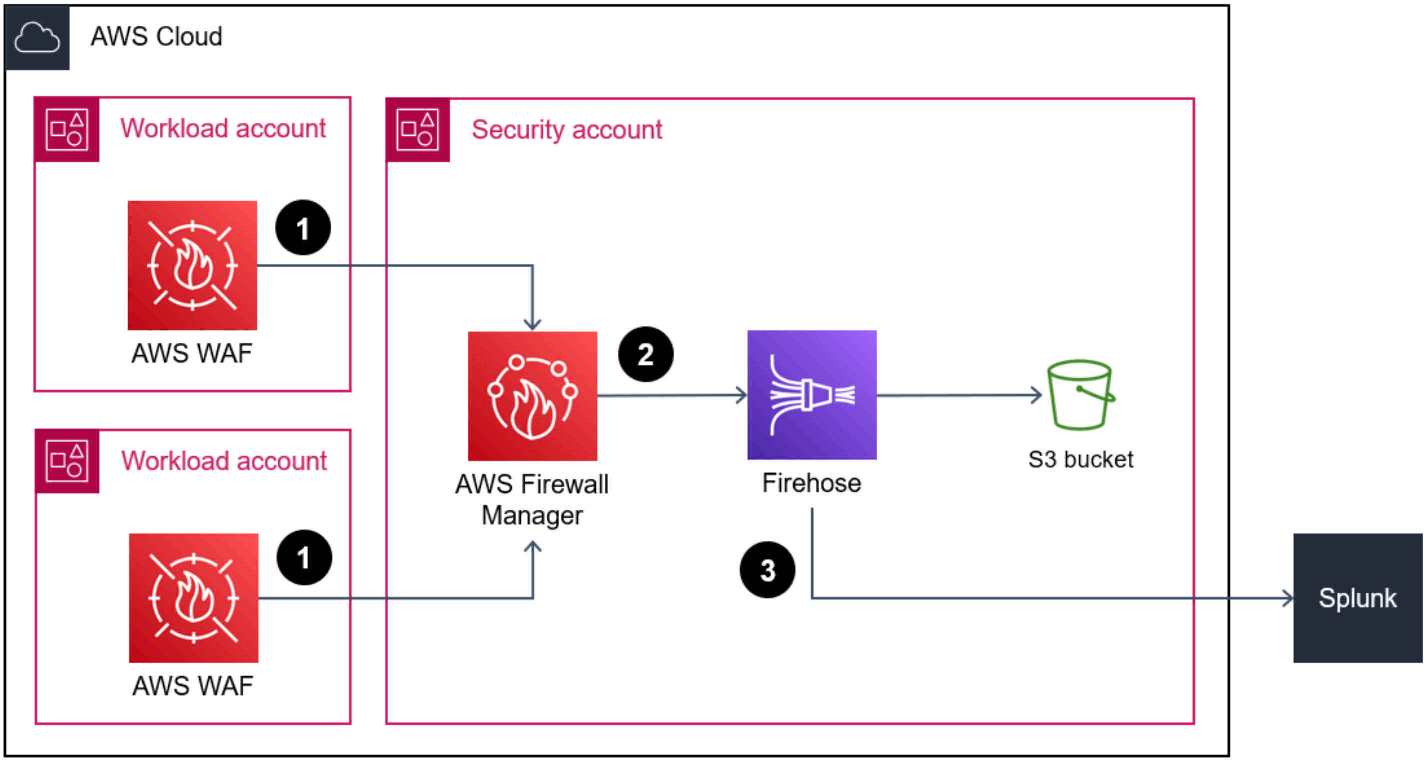
Architecture

Target technology stack

- Firewall Manager
- Firehose
- Amazon Simple Storage Service (Amazon S3)
- AWS WAF
- Splunk

Target architecture

The following image shows how you can use Firewall Manager to centrally log all AWS WAF data and send it to Splunk through Firehose.



1. The AWS WAF web ACLs send firewall log data to Firewall Manager.
2. Firewall Manager sends the log data to Firehose.
3. The Firehose delivery stream forwards the log data to Splunk and to an S3 bucket. The S3 bucket acts as a backup in the event of an error with the Firehose delivery stream.

Automation and scale

This solution is designed to scale and accommodate all AWS WAF web ALCs within the organization. You can configure all web ACLs to use the same Firehose instance. However, if you want to set up and use multiple Firehose instances, you can.

Tools

AWS services

- [AWS Firewall Manager] is a security management service that helps you to centrally configure and manage firewall rules across your accounts and applications in AWS Organizations.
- [Amazon Data Firehose] helps you deliver real-time [streaming data] to other AWS services, custom HTTP endpoints, and HTTP endpoints owned by supported third-party service providers, such as Splunk.

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS WAF is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources.

Other tools

- Splunk helps you monitor, visualize, and analyze log data.

Epics

Configure Splunk

Task	Description	Skills required
Install the Splunk App for AWS.	1. Sign in to your Splunk heavy forwarder. The default URL is `http://<IP address>:8000` . 2. In the left navigation, next to **Apps**, choose the gear button. 3. Choose **Browse more apps**. 4. Search for **AWS**. 5. For **Splunk App for AWS**, choose **Install**. 6. Enter your Splunk.com sign-in credentials, accept the terms and conditions, and then choose **Login and Install**. 7. Choose **Done**.	Security administrator, Splunk administrator
Install the add-on for AWS WAF.	Repeat the previous instructions to install the **AWS Web**	Security administrator, Splunk administrator

Task	Description	Skills required
	Application Firewall Add-on for Splunk.	

Task	Description	Skills required
Install and configure the Splunk add-on for Firehose.	1. Install and configure the Splunk add-on for Firehose. As part of the installation and configura tion, if necessary for your Splunk platform, you set up an HTTP Event Collector and prepare the infrastructure to send the log data to your indexers. See the instructions that correspond to your Splunk deployment: • Splunk Cloud deploymen t (Splunk documenta tion) • Distributed Splunk Enterprise deployment (Splunk documentation) • Single-instance Splunk Enterprise deployment (Splunk documentation) **Important** Stop this procedure after you have installed and configured the Splunk add-on. Do not proceed with the instructi ons for configuri ng Firehose to send	Security administrator, Splunk administrator

Task	Description	Skills required
	data to the Splunk platform. 2. Make note of the HTTP event collector token and the HTTP endpoint. You need this value later, when you configure the delivery stream.	

Create the Firehose delivery stream

Task	Description	Skills required
Grant Firehose access to a Splunk destination.	Configure the access policy that permits Firehose to access a Splunk destinati on and back up the log data to an S3 bucket. For more information, see [Grant Firehose access to a Splunk destination]().	Security administrator
Create a Firehose delivery stream.	In the same account where you manage the web ACLs for AWS WAF, create a delivery stream in Firehose. You are required to have an IAM role when creating a delivery stream. Firehose assumes that IAM role and gains access to the specified S3 bucket. For instructions, see [Creating a delivery stream](). Note the following:	Security administrator

Task	Description	Skills required
	• The delivery stream name must start with `aws-waf-logs-` . • For the source, choose **Direct PUT**. • For **S3 backup mode**, choose **Backup all events**, and then choose an existing bucket or create a new one. • For the destination, follow the instructions in [Choose Splunk for your destination]() in the Firehose documentation. For information about the values for Splunk endpoints and endpoint types, see [Configure Amazon Data Firehose]() in the Splunk documentation. Repeat this process for each token that you configured in the HTTP event collector.	
Test the delivery stream.	Test the delivery stream to validate that it is properly configured. For instructions, see [Test using Splunk as the destination]() in the Firehose documentation.	Security administrator

Configure Firewall Manager to log data

Task	Description	Skills required
Configure the Firewall Manager policies.	The Firewall Manager policies must be configured to enable logging and to forward logs to the correct Firehose delivery stream. For more information and instructions, see Configuring logging for an AWS WAF policy.	Security administrator

Serve static content in an Amazon S3 bucket through a VPC by using Amazon CloudFront

Angel Emmanuel Hernandez Cebrian, Amazon Web Services

Summary

When you serve static content that is hosted on Amazon Web Services (AWS), the recommended approach is to use an Amazon Simple Storage Service (S3) bucket as the origin and use Amazon CloudFront to distribute the content. This solution has two primary benefits: the convenience of caching static content at edge locations, and the ability to define web access control lists (web ACLs) for the CloudFront distribution, which helps you secure requests to the content with minimal configuration and administrative overhead.

However, there is a common architectural limitation to the standard, recommended approach. In some environments, you want virtual firewall appliances deployed in a virtual private cloud (VPC) to inspect all content, including static content. The standard approach doesn’t route traffic through the VPC for inspection. This pattern provides an alternative architectural solution. You still use a CloudFront distribution to serve static content in an S3 bucket, but the traffic is routed through the VPC by using an Application Load Balancer. An AWS Lambda function then retrieves and returns the content from the S3 bucket.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Static website content hosted in an S3 bucket.

Limitations

- The resources in this pattern must be in a single AWS Region, but they can be provisioned in different AWS accounts.
- Limits apply to the maximum request and response size that the Lambda function can receive and send, respectively. For more information, see *Limits* in Lambda functions as targets (Elastic Load Balancing documentation).
- It's important to find a good balance between performance, scalability, security, and cost-effectiveness when using this approach. Despite the high scalability of Lambda, if the number

of concurrent Lambda invocations exceeds the maximum quota, some requests are throttled. For more information, see Lambda quotas (Lambda documentation). You also need to consider pricing when using Lambda. To minimize Lambda invocations, make sure that you properly define the cache for the CloudFront distribution. For more information, see Optimizing caching and availability (CloudFront documentation).

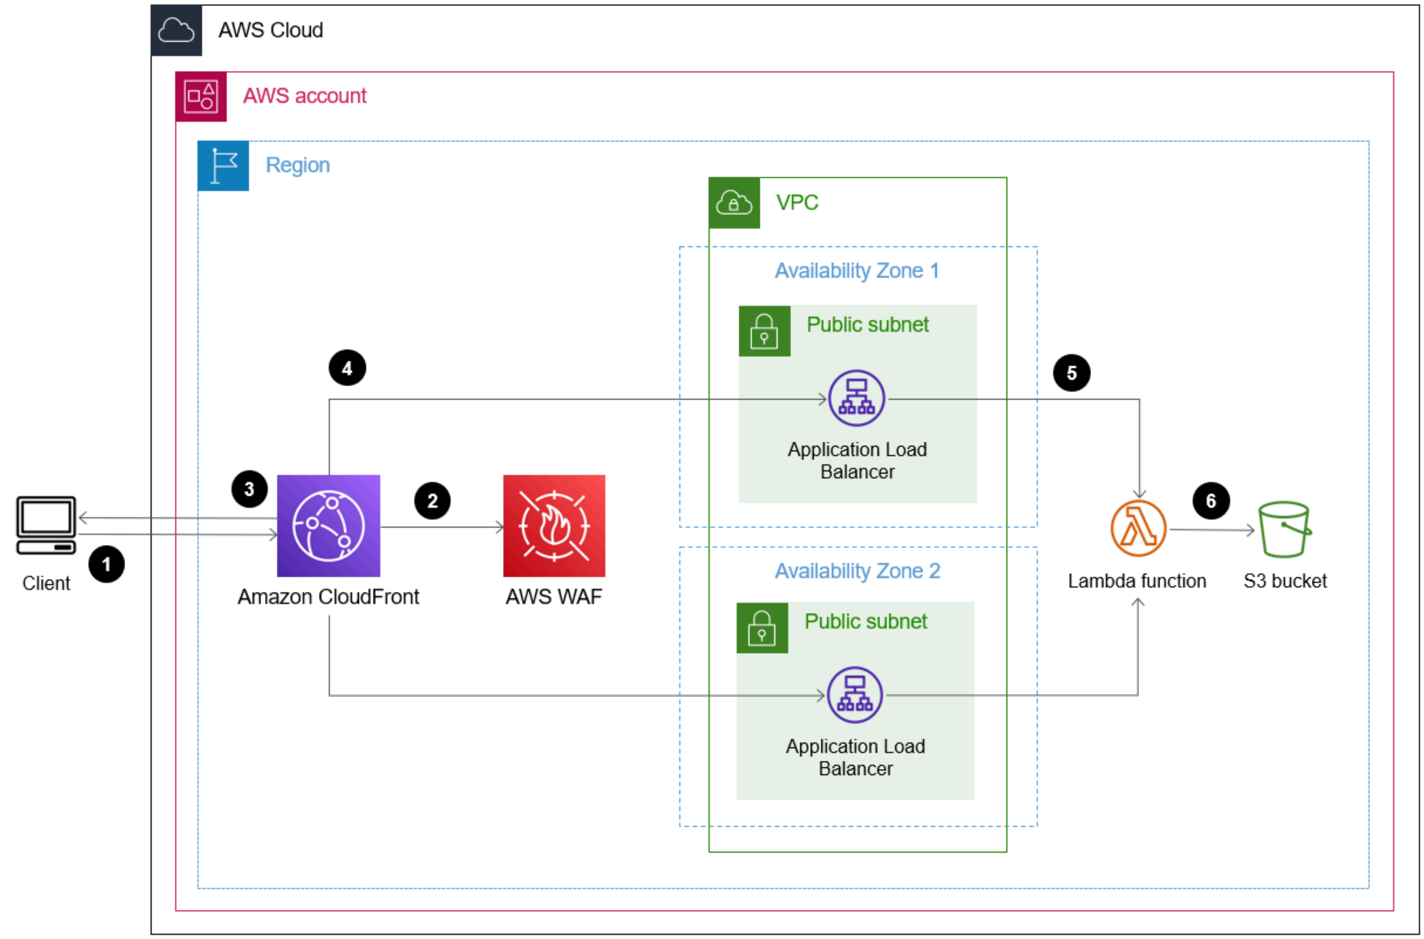
Architecture

Target technology stack

- CloudFront
- Amazon Virtual Private Cloud (Amazon VPC)
- Application Load Balancer
- Lambda
- Amazon S3

Target architecture

The following image shows the suggested architecture when you need to use CloudFront to serve static content from an S3 bucket through a VPC.



1. The client requests the URL of CloudFront distribution to get a particular website file in the S3 bucket.
2. CloudFront sends the request to AWS WAF. AWS WAF filters the request by using the web ACLs applied to the CloudFront distribution. If the request is determined to be valid, the flow continues. If the request is determined to be invalid, the client receives a 403 error.
3. CloudFront checks its internal cache. If there is a valid key matching the incoming request, the associated value is sent back to the client as a response. If not, the flow continues.
4. CloudFront forwards the request to the URL of the specified Application Load Balancer.
5. The Application Load Balancer has a listener associated with a target group based on a Lambda function. The Application Load Balancer invokes the Lambda function.
6. The Lambda function connects to the S3 bucket, perform a `GetObject` operation on it, and returns the content as a response.

Automation and scale

To automate the deployment of static content using this approach, create CI/CD pipelines to update the Amazon S3 buckets that host websites.

The Lambda function scales automatically to handle the concurrent requests, within the quotas and limitations of the service. For more information, see Lambda function scaling and Lambda quotas (Lambda documentation). For the other AWS services and features, such as CloudFront and the Application Load Balancer, AWS scales these automatically.

Tools

- Amazon CloudFront speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. In this pattern, you use an Application Load Balancer provisioned through Elastic Load Balancing to direct traffic to the Lambda function.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Use CloudFront to serve static content from Amazon S3 through a VPC

Task	Description	Skills required
Create a VPC.	Create a VPC for hosting the resources deployed in this pattern, such as the Application Load Balancer and the Lambda function. For instructions, see Create a	Cloud architect

Task	Description	Skills required
	VPC (Amazon VPC documenta tion).	
Create an AWS WAF web ACL.	Create an AWS WAF web ACL. Later in this pattern, you apply this web ACL to the CloudFront distribut ion. For instructions, see Creating a web ACL (AWS WAF documentation).	Cloud architect
Create the Lambda function.	Create the Lambda function that serves the static content hosted in the S3 bucket as a website. Use the code provided in the Additional information section of this pattern. Customize the code to identify your target S3 bucket.	General AWS

Upload the Lambda function.	Enter the following command to upload the Lambda function code to a .zip file archive in Lambda.
	`aws lambda update-function-code \`
	`--function-name  \`
	`--zip-file fileb://lambda-alb-s3-website.zip`
		General AWS

Task	Description	Skills required
Create an Application Load Balancer.	Create an internet-facing Application Load Balancer that points to the Lambda function. For instructions, see [Create a target group for the Lambda function](#) (Elastic Load Balancing documentation). For a high-availability configuration, create the Application Load Balancer and attach it to private subnets in different Availability Zones.	Cloud architect

Task	Description	Skills required

Create a CloudFront distribution.	Create a CloudFront distribution that points to the Application Load Balancer you created.
	
	1. Sign in to the AWS Management Console and open the CloudFront console at https://console.aws.amazon.com/cloudfront/v3/home.
	2. Choose **Create Distribution**.
	3. On the first page of the **Create Distribution Wizard**, in the **Web** section, choose **Get Started**.
	4. Specify settings for your distribution. For more information, see [Values that you specify when you create or update a distribution](). Note the following:
	  a. Set the Application Load Balancer as the origin.
	  b. In **Distribution settings**, choose existing web ACLs that you want to apply through AWS WAF. For more information, see [AWS WAF web ACL]().
	5. Save your changes.
		Cloud architect

Task	Description	Skills required
	6. After CloudFront creates your distribution, the value of the **Status** column for your distribution changes from **InProgress** to **Deployed**. If you chose to enable the distribution, it will be ready to process requests after the status switches to **Deployed**.

Additional information

Code

The following example Lambda function is written in Node.js. This Lambda function acts as a web server that performs a `GetObject` operation to an S3 bucket that contains the website resources.

```
/**

 * This is an AWS Lambda function created for demonstration purposes.

 * It retrieves static assets from a defined Amazon S3 bucket.

 * To make the content available through a URL, use an Application Load Balancer with a
 Lambda integration.
 *
 * Set the S3_BUCKET environment variable in the Lambda function definition.
 */

var AWS = require('aws-sdk');

exports.handler = function(event, context, callback) {

    var bucket = process.env.S3_BUCKET;
    var key = event.path.replace('/', '');

    if (key == '') {
        key = 'index.html';
    }

    // Fetch from S3
    var s3 = new AWS.S3();
    return s3.getObject({Bucket: bucket, Key: key},
       function(err, data) {

            if (err) {
                return err;
            }

            var isBase64Encoded = false;
            var encoding = 'utf8';

            if (data.ContentType.indexOf('image/') > -1) {
                isBase64Encoded = true;
                encoding = 'base64'
            }

            var resp = {
                statusCode: 200,
                headers: {
```

```
                'Content-Type': data.ContentType,
            },
            body: new Buffer(data.Body).toString(encoding),
            isBase64Encoded: isBase64Encoded
        };

        callback(null, resp);
    }
  );
};
```

Access on-premises Microsoft SQL Server tables from Microsoft SQL Server on Amazon EC2 using linked servers

Tirumala Dasari and Eduardo Valentim, Amazon Web Services

Summary

This pattern describes how to access on-premises Microsoft SQL Server database tables running on Microsoft Windows, from Microsoft SQL Server databases running or hosted on Amazon Elastic Compute Cloud (Amazon EC2) Windows or Linux instances by using linked servers.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI (Amazon Machine Image)
- AWS Direct Connect between the on-premises Microsoft SQL Server (Windows) server and the Windows or Linux EC2 instance

Product versions

- SQL Server 2016 or later

Architecture

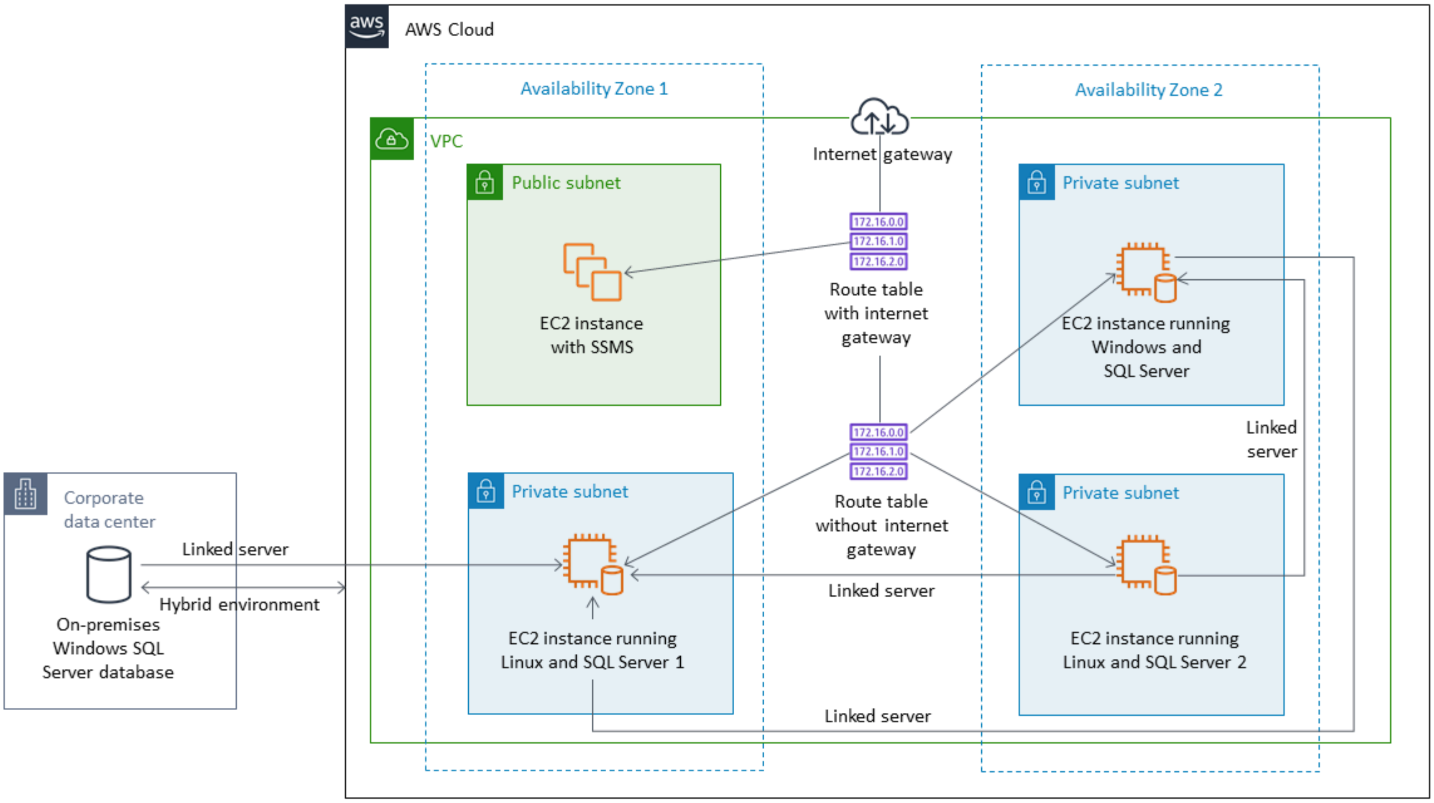
Source technology stack

- On-premises Microsoft SQL Server database running on Windows
- Amazon EC2 with Microsoft SQL Server running on Windows AMI or Linux AMI

Target technology stack

- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI
- Amazon EC2 with Microsoft SQL Server running on Windows AMI

Source and target database architecture



Tools

- [Microsoft SQL Server Management Studio (SSMS)] is an integrated environment for managing a SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

Epics

Change authentication mode to Windows for SQL Server in Windows SQL Server

Task	Description	Skills required
Connect to Windows SQL Server through SSMS.		DBA
Change the authentication mode to Windows in SQL Server from the context		DBA

Task	Description	Skills required
(right-click) menu for the Windows SQL Server instance.		

Restart the Windows MSSQL service

Task	Description	Skills required
Restart the SQL service.	1. In SSMS Object Explorer, choose the SQL Server instance. 2. Open the context (right-cl ick) menu. 3. Choose **Restart**.	DBA

Create new login and choose databases to access in Windows SQL Server

Task	Description	Skills required
In the Security tab, open the context (right-click) menu for Login and select a new login.		DBA
In the General tab, choose SQL Server authentication, enter a user name, enter the password, and then confirm the password and clear the option for changing the password at the next login.		DBA
In the Server Roles tab, choose Public.		DBA

Task	Description	Skills required
In the User Mapping tab, choose the database and schema you want to access, and then highlight the database to select database roles.	Select public and db_datareader to access data from the database tables.	DBA
Choose OK to create a user.		DBA

Add Windows SQL Server IP to Linux SQL Server host file

Task	Description	Skills required
Connect to the Linux SQL Server box through the terminal window.		DBA
Open the /etc/hosts file and add the IP address of the Windows machine with SQL Server.		DBA
Save the hosts file.		DBA

Create linked server on Linux SQL Server

Task	Description	Skills required
Create a linked server by using the stored procedures master.sys.sp_addlinkedserver and master.dbo.sp_addlinkedsrvlogin.	For more information about using these stored procedures, see the *Additional information* section.	DBA, Developer

Verify the created linked server and databases in SSMS

Task	Description	Skills required
In Linux SQL Server in SSMS, go to Linked Servers and refresh.		DBA
Expand the created linked servers and catalogs in the left pane.	You'll see the selected SQL Server databases with tables and views.	DBA

Verify that you can access Windows SQL Server database tables

Task	Description	Skills required
In the SSMS query window, run the query: "select top 3 * from [sqllin].dms_sample_win.dbo.mlb_data".	Note that the FROM clause uses a four-part syntax: computer.database.schema.table (e.g., SELECT name "SQL2 databases" FROM [sqllin].master.sys.databases). In our example, we created an alias for SQL2 in the hosts file, so you don't need to enter the actual NetBIOS name between the square brackets. If you do use the actual NetBIOS names, note that AWS defaults to NetBIOS names like Win-xxxx, and SQL Server requires square brackets for names with dashes.	DBA, Developer

Related resources

- [Release notes for SQL Server on Linux]

Additional information

Using stored procedures to create linked servers

SSMS doesn't support the creation of linked servers for Linux SQL Server, so you have to use these stored procedures to create them:

```
EXEC master.sys.sp_addlinkedserver @server= N'SQLLIN' , @srvproduct= N'SQL Server'
EXEC master.dbo.sp_addlinkedsrvlogin
 @rmtsrvname=N'SQLLIN',@useself=N'False',@locallogin=NULL,@rmtuser=N'username',@rmtpassword='Te
```

Note 1: Enter the sign-in credentials that you created earlier in Windows SQL Server in the stored procedure `master.dbo.sp_addlinkedsrvlogin`.

Note 2: `@server` name `SQLLIN` and host file entry name `172.12.12.4 SQLLIN` should be the same.

You can use this process to create linked servers for the following scenarios:

- Linux SQL Server to Windows SQL Server through a linked server (as specified in this pattern)
- Windows SQL Server to Linux SQL Server through a linked server
- Linux SQL Server to another Linux SQL Server through a linked server

Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica

sampath kathirvel, Amazon Web Services

Summary

To run the Oracle PeopleSoft enterprise resource planning (ERP) solution on Amazon Web Services (AWS), you can use Amazon Relational Database Service (Amazon RDS) or Amazon RDS Custom for Oracle, which supports legacy, custom, and packaged applications that require access to the underlying operating system and database environment. For key factors to consider when planning a migration, see Oracle database migration strategies in AWS Prescriptive Guidance.

As of this writing, RDS Custom for Oracle doesn't support the Multi-AZ option, which is available for Amazon RDS for Oracle as an HA solution using storage replication. Instead, this pattern achieves HA by using a standby database that creates and maintains a physical copy of the primary database. The pattern focuses on the steps to run a PeopleSoft application database on Amazon RDS Custom with HA by using Oracle Data Guard to set up a read replica.

This pattern also changes the read replica to read-only mode. Having your read replica in read-only mode provides additional benefits:

- Offloading read-only workloads from the primary database
- Enabling automatic repair of corrupted blocks by retrieving healthy blocks from the standby database using the Oracle Active Data Guard feature
- Using the Far Sync capability to keep the remote standby database in sync without the performance overhead associated with long-distance redo log transmission.

Using a replica in read-only mode requires the Oracle Active Data Guard option, which comes at an extra cost because it is a separately licensed feature of Oracle Database Enterprise Edition.

Prerequisites and limitations

Prerequisites

- An existing PeopleSoft application on Amazon RDS Custom. If you don't have an application, see the pattern Migrate Oracle PeopleSoft to Amazon RDS Custom.

- A single PeopleSoft application tier. However, you can adapt this pattern to work with multiple application tiers.
- Amazon RDS Custom configured with at least 8 GB of swap space.
- An Oracle Active Data Guard database license for converting the read replica into read-only mode and using it for offloading reporting tasks to the standby. For more information, see the Oracle Technology Commercial Price List.

Limitations

- General limitations and unsupported configurations for RDS Custom for Oracle
- Limitations associated with Amazon RDS Custom for Oracle read replicas

Product versions

- For Oracle Database versions supported by Amazon RDS Custom, see RDS Custom for Oracle.
- For Oracle Database instance classes supported by Amazon RDS Custom, see DB instance class support for RDS Custom for Oracle.

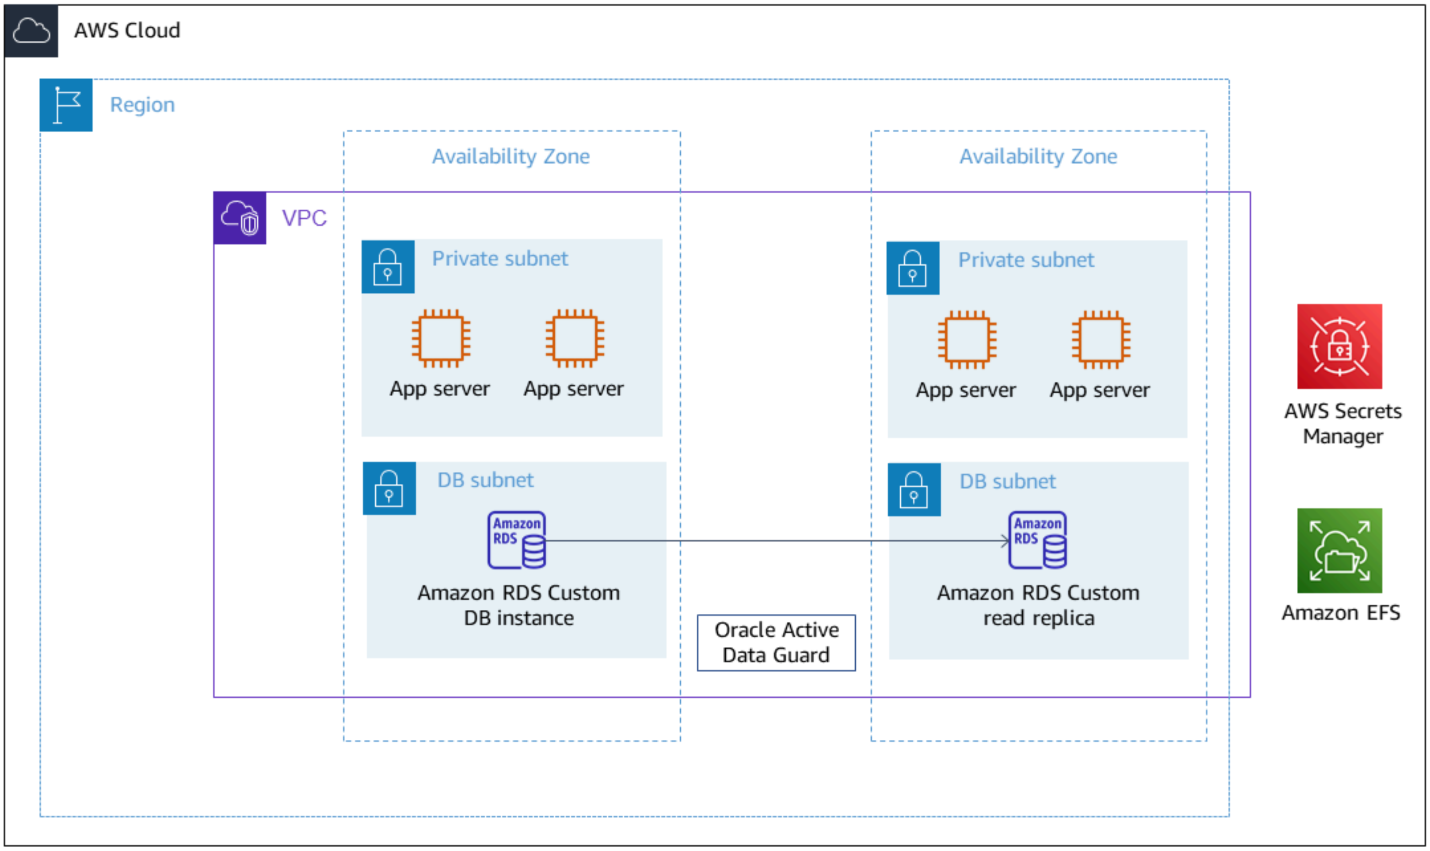
Architecture

Target technology stack

- Amazon RDS Custom for Oracle
- AWS Secrets Manager
- Oracle Active Data Guard
- Oracle PeopleSoft application

Target architecture

The following diagram shows an Amazon RDS Custom DB instance and an Amazon RDS Custom read replica. The read replica uses Oracle Active Data Guard to replicate to another Availability Zone. You can also use the read replica to offload read traffic on the primary database and for reporting purposes.



For a representative architecture using Oracle PeopleSoft on AWS, see Set up a highly available PeopleSoft architecture on AWS.

Tools

AWS services

- Amazon RDS Custom for Oracle is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager for `RDS_DATAGUARD` with the secret name `do-not-delete-rds-custom-+<<RDS Resource ID>>+-dg`.

Other Tools

- Oracle Data Guard helps you create, maintain, manage, and monitor standby databases.

Best practices

To work toward a zero data loss (RPO=0) objective, use the `MaxAvailability` Data Guard protection mode, with the redo transport `SYNC+NOAFFIRM` setting for better performance. For more information about selecting the database protection mode, see the *Additional information* section.

Epics

Create the read replica

Task	Description	Skills required
Create the read replica.	To create a read replica of the Amazon RDS Custom DB instance, follow the instructions in the [Amazon RDS documentation](#) and use the Amazon RDS Custom DB instance that you created (see the *Prerequisites* section) as the source database. By default, the Amazon RDS Custom read replica is created as a physical standby and is in the mounted state. This is intentional to ensure compliance with the Oracle Active Data Guard license. This pattern includes code for setting up a multitenant container database (CDB) or a non-CDB instance.	DBA

Change Oracle Data Guard protection mode to MaxAvailability

Task	Description	Skills required
Access the Data Guard broker configuration on the primary database.	In this example, the Amazon RDS Custom read replica is `RDS_CUSTOM_ORCL_D` for the Non-CDB instance and `RDS_CUSTOM_RDSCDB_B` for the CDB instance. The databases for Non-CDB are `orcl_a` (primary) and `orcl_d` (standby). The database names for CDB are `rdscdb_a` (primary) and `rdscdb_b` (standby). You can connect to the RDS Custom read replica directly or through the primary database. You can find the net service name for your database in the `tnsnames.ora` file located in the `$ORACLE_HOME/network/admin` directory. RDS Custom for Oracle automatically populates these entries for your primary database and your read replicas. The password for the `RDS_DATAGUARD` user is stored in AWS Secrets Manager, with secret name do-not-delete-rds-custom-+<<RDS	DBA

Task	Description	Skills required
	`Resource ID>>+-dg`. For more information on how to connect to an RDS Custom instance using the SSH (Secure Shell) key retrieved from Secrets Manager, see [Connecting to your RDS Custom DB instance using SSH](). To access the Oracle Data Guard broker configuration through the Data Guard command line (`dgmgrl`), use the following code. **Non-CDB**	

```
$ dgmgrl RDS_DATAGUARD@RDS_CUSTOM_ORCL_D
DGMGRL for Linux:

Additional information

Select your database protection mode

Oracle Data Guard provides three protection modes to configure your Data Guard environment based on your availability, protection, and performance requirements. The following table summarizes these three modes.

Protection mode	Redo transport setting	Description
MAXIMUM PERFORMANCE	`ASYNC`	For transactions happening on the primary database, redo data is asynchronously transmitted and written to the standby database redo log. Therefore, the performance impact is minimal. `MaxPerformance` can't provide RPO=0 because of asynchronous log shipping.
MAXIMUM PROTECTION	`SYNC+AFFIRM`	For transactions on the primary database, redo data is synchronously transmitted

		and written to the standby database redo log on disk before the transaction is acknowledged. If the standby database becomes unavailab le, the primary database shuts itself down to ensure transactions are protected.
MAXIMUM AVAILABILITY	`SYNC+AFFIRM`	This is similar to `MaxProtec tion` mode, except when no acknowledgement is received from the standby database. In that case, it operates as if it were in `MaxPerformance` mode to preserve the primary database availability until it's able to write its redo stream to a synchronized standby database again.

	SYNC+NOAFFIRM	For transactions on the primary database, redo is synchronously transmitted to the standby database, and the primary waits only for acknowledgement that the redo has been received on the standby, not that it has been written to the standby disk. This mode, which is also known as `FastSync`, can provide a performance benefit at the expense of potential exposure to data loss in a special case of multiple simultaneous failures.

Read replicas in RDS Custom for Oracle are created with maximum performance protection mode, which is also the default protection mode for Oracle Data Guard. The maximum performance mode provides the lowest performance impact on the primary database, which can help you meet the recovery point objective (RPO) requirement measured in seconds.

To work to achieve a zero data loss (RPO=0) objective, you can customize the Oracle Data Guard protection mode to `MaxAvailability` with the `SYNC+NOAFFIRM` setting for redo transport for better performance. Because commits on the primary database are acknowledged only after the corresponding redo vectors are successfully transmitted to the standby database, the network latency between the primary instance and replica can be crucial for commit-sensitive workloads. We recommend performing load testing for your workload to assess the performance impact when the read replica is customized to run in `MaxAvailability` mode.

Deploying the read replica in the same Availability Zone as the primary database provides lower network latency compared with deploying the read replica in a different Availability Zone. However, deploying the primary and read replicas in the same Availability Zone might not meet your HA requirements because, in the unlikely event of Availability Zone unavailability, both the primary instance and read replica instance are impacted.

Assess query performance for migrating SQL Server databases to MongoDB Atlas on AWS

Battulga Purevragchaa, Amazon Web Services

Krishnakumar Sathyanarayana, PeerIslands US Inc

Babu Srinivasan, MongoDB

Summary

This pattern provides guidance for loading MongoDB with near real-world data and assessing MongoDB query performance that is as close to the production scenario as possible. The assessment provides input to help you plan your migration to MongoDB from a relational database. The pattern uses PeerIslands Test Data Generator and Performance Analyzer to test query performance.

This pattern is particularly useful for Microsoft SQL Server migration to MongoDB, because performing schema transformations and loading data from current SQL Server instances to MongoDB can be very complex. Instead, you can load near real-world data into MongoDB, understand MongoDB performance, and fine-tune the schema design before you start the actual migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Familiarity with MongoDB Atlas
- Target MongoDB schema
- Typical query patterns

Limitations

- Data load times and performance will be limited by the MongoDB cluster instance size. We recommend that you choose instances that are recommended for production use to understand real-world performance.

- PeerIslands Test Data Generator and Performance Analyzer currently supports only online data loads and queries. Offline batch processing (for example, loading data into MongoDB by using Spark connectors) isn't yet supported.
- PeerIslands Test Data Generator and Performance Analyzer supports field relations within a collection. It doesn't support relationships across collections.

Product editions

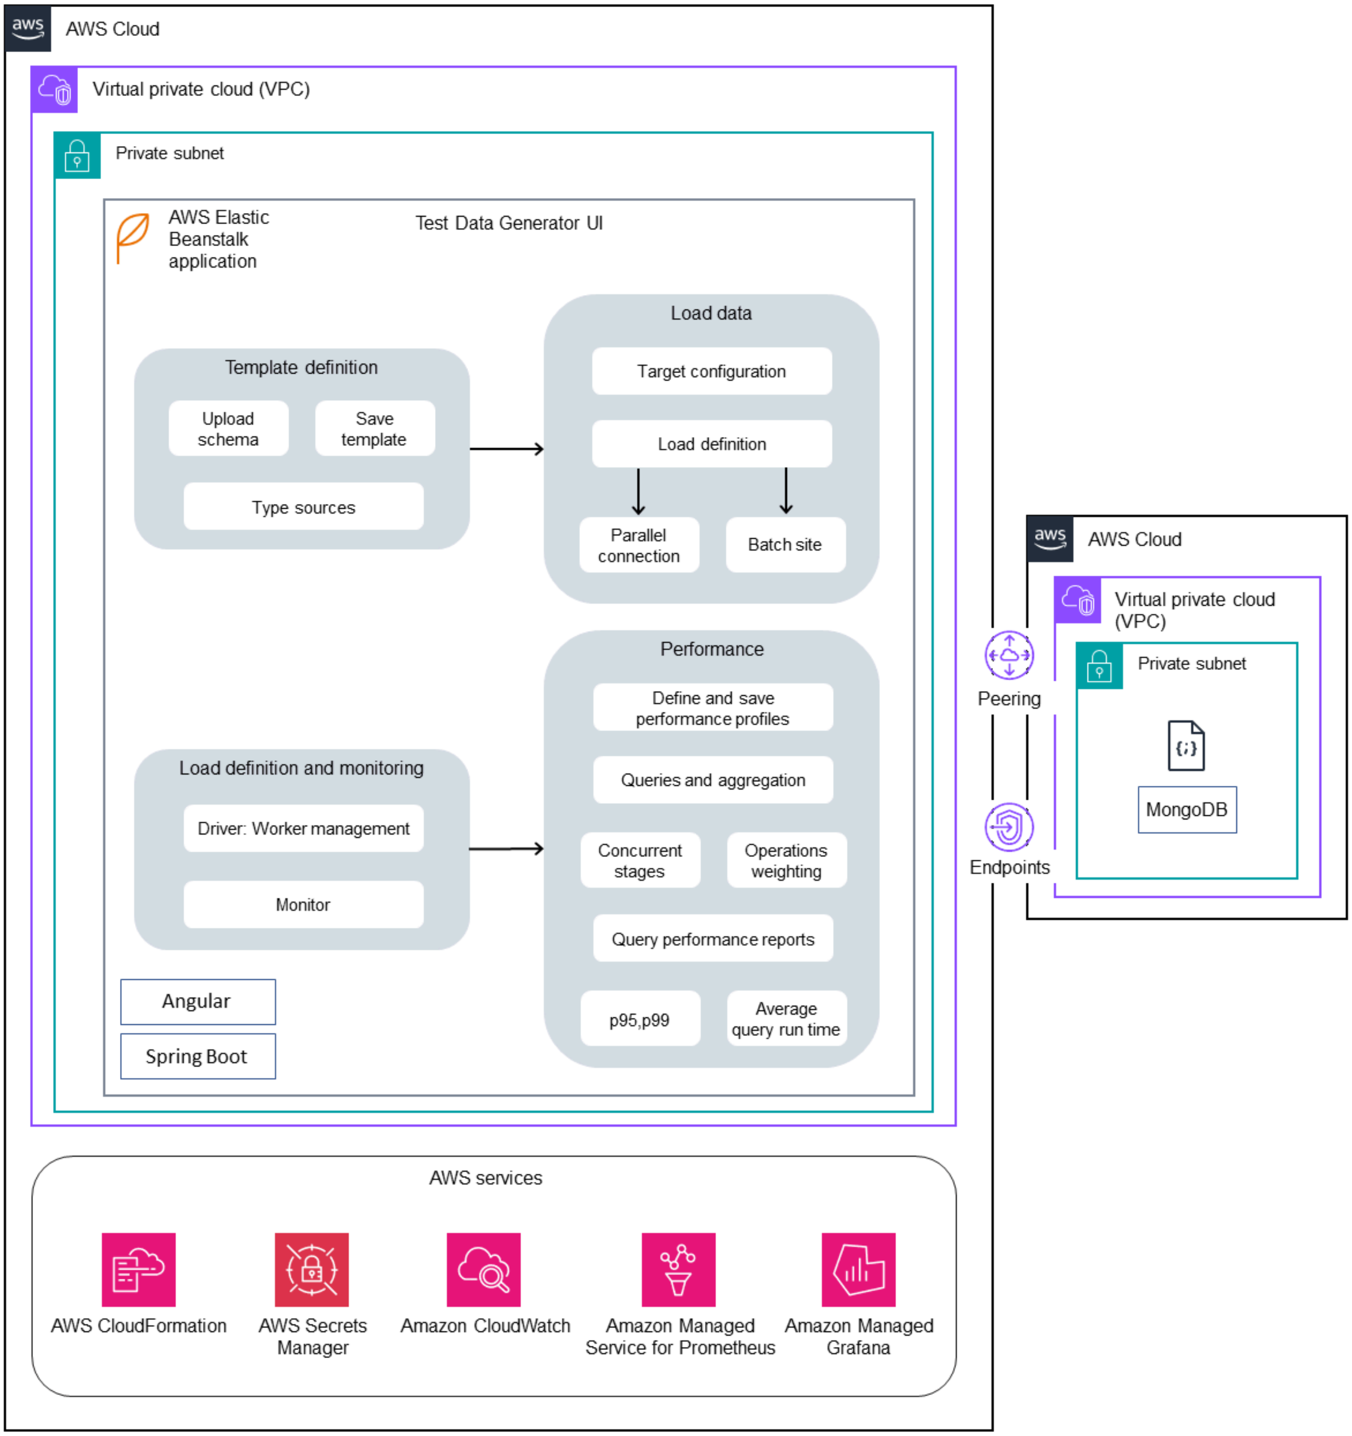
- This pattern supports both MongoDB Atlas and MongoDB Enterprise Advanced.

Architecture

Target technology stack

- MongoDB Atlas or MongoDB Enterprise Advanced

Architecture



PeerIslands Test Data Generator and Performance Analyzer is built by using Java and Angular, and stores its generated data on Amazon Elastic Block Store (Amazon EBS). The tool consists of two workflows: test data generation and performance testing.

- In test data generation, you create a template, which is the JSON representation of the data model that has to be generated. After you create the template, you can generate the data in a target collection, as defined by the load generation configuration.
- In performance testing, you create a profile. A profile is a multi-stage testing scenario where you can configure create, read, update, and delete (CRUD) operations, aggregation pipelines, the weightage for each operation, and the duration of each stage. After you create the profile, you can run performance testing on the target database based on the configuration.

PeerIslands Test Data Generator and Performance Analyzer stores its data on Amazon EBS, so you can connect Amazon EBS to MongoDB by using any MongoDB-supported connection mechanism, including peering, allow lists, and private endpoints. By default, the tool doesn't include operational components; however, it can be configured with Amazon Managed Service for Prometheus, Amazon Managed Grafana, Amazon CloudWatch, and AWS Secrets Manager if required.

Tools

- PeerIslands Test Data Generator and Performance Analyzer includes two components. The Test Data Generator component helps you generate highly customer-specific, real-world data based on your MongoDB schema. The tool is fully UI-driven with a rich data library and can be used to quickly generate billions of records on MongoDB. The tool also provides capabilities to implement relationships between fields in the MongoDB schema. The Performance Analyzer component helps you generate highly customer-specific queries and aggregations, and perform realistic performance testing on MongoDB. You can use the Performance Analyzer to test MongoDB performance with rich load profiles and parameterized queries for your specific use case.

Best practices

Epics

Understand your source data

Task	Description	Skills required
Understand the database footprint of the current SQL Server source.	Understand your current SQL Server footprint. This can be achieved by running queries against the `INFORMATION` schema of the database. Determine the number of tables and size of each table. Analyze the index associate d with each table. For more information about SQL analysis, see the blog post [SQL2Mongo: Data Migration Journey](#) on the PeerIslands website.	DBA
Understand the source schema.	Determine the table schema and the business represent ation of the data (for example, zip codes, names, and currency). Use your existing entity relationship (ER) diagram or generate the ER diagram from the existing database. For more information, see the blog post [SQL2Mongo: Data Migration Journey](#) on the PeerIslands website.	DBA
Understand query patterns.	Document the top 10 SQL queries you use. You can use the **performance_schema**	DBA

Task	Description	Skills required
	.events_statements _summary_by_digest tables that are available in the database to understand the top queries. For more information, see the blog post [SQL2Mongo: Data Migration Journey]() on the PeerIslands website.	
Understand SLA commitmen ts.	Document the target service-level agreements (SLAs) for database operations. Typical measures include query latency and queries per second. The measures and their targets are typically available in non-funct ional requirements (NFR) documents.	DBA

Define the MongoDB schema

Task	Description	Skills required
Define the target schema.	Define various options for the target MongoDB schema. For more information, see [Schemas]() in the MongoDB Atlas documentation. Consider the best practices and design patterns based on the table relations. See [Data Model Examples and Patterns]()	MongoDB engineer

Task	Description	Skills required
	in the MongoDB documentation for details.	
Define target query patterns.	Define MongoDB queries and aggregation pipelines. These queries are the equivalent of the top queries you captured for your SQL Server workload. To understand how to construct MongoDB aggregation pipelines, see the MongoDB documentation.	MongoDB engineer
Define the MongoDB instance type.	Determine the size of the instance that you plan to use for testing. For guidance, see the MongoDB documentation.	MongoDB engineer

Prepare the target database

Task	Description	Skills required
Set up the MongoDB Atlas cluster.	To set up a MongoDB cluster on AWS, follow the instructions in the MongoDB documentation.	MongoDB engineer
Create users in the target database.	Configure the MongoDB Atlas cluster for access and network security by following the instructions in the MongoDB documentation.	MongoDB engineer

Task	Description	Skills required
Create appropriate roles in AWS and configure role-based access control for Atlas.	If required, set up additiona l users by following the instructions in the MongoDB documentation. Configure authentication and authoriza tion through AWS roles.	MongoDB engineer
Set up Compass for MongoDB Atlas access.	Set up the MongoDB Compass GUI utility for ease of navigation and access.	MongoDB engineer

Set up the base load by using Test Data Generator

Task	Description	Skills required
Install Test Data Generator.	Install PeerIsland Test Data Generator in your environme nt.	MongoDB engineer
Configure Test Data Generator to generate the appropriate data.	Create a template by using the data library to generate specific data for each field in the MongoDB schema. For more information, see the MongoDB Data Generator & Perf. Analyzer video.	MongoDB engineer
Horizontally scale Test Data Generator to generate the required load.	Use the template you created to start the load generation against the target collection by configuring the required parallelism. Determine the time frames and scale to generate the necessary data.	MongoDB engineer

Task	Description	Skills required
Validate the load in MongoDB Atlas.	Check the data loaded into MongoDB Atlas.	MongoDB engineer
Generate required indexes on MongoDB.	Define indexes as required, based on query patterns. For best practices, see the [MongoDB documentation]().	MongoDB engineer

Conduct performance testing

Task	Description	Skills required
Set up load profiles in Performance Analyzer.	Create a performance testing profile in Performance Analyzer by configuring specific queries and their corresponding weightage, duration of the test run, and stages. For more informati on, see the [MongoDB Data Generator & Perf. Analyzer]() video.	MongoDB engineer
Run performance testing.	Use the performance testing profile you created to start the test against the target collection by configuri ng the required paralleli sm. Horizontally scale the performance test tool to run queries against MongoDB Atlas.	MongoDB engineer

Task	Description	Skills required
Record test results.	Record P95, P99 latency for the queries.	MongoDB engineer
Tune your schema and query patterns.	Modify indexes and query patterns to address any performance issues.	MongoDB engineer

Close the project

Task	Description	Skills required
Shut down temporary AWS resources.	Delete all temporary resources that you used for Test Data Generator and Performance Analyzer.	AWS administrator
Update performance test results.	Understand MongoDB query performance and compare it against your SLAs. If necessary, fine-tune the MongoDB schema and rerun the process.	MongoDB engineer
Conclude the project.	Close out the project and provide feedback.	MongoDB engineer

Automate blue/green deployments of Amazon Aurora global databases by using IaC principles

Ishwar Chauthaiwale, ANKIT JAIN, and Ramu Jagini, Amazon Web Services

Summary

Managing database updates, migrations, or scaling efforts can be challenging for organizations that run critical workloads on [Amazon Aurora global databases](). Ensuring that these operations are carried out seamlessly, with zero downtime, is essential to maintaining service availability and avoiding disruptions for your users.

A blue/green deployment strategy offers a solution to this challenge by allowing you to run two identical environments concurrently: blue (the current environment) and green (the new environment). A blue/green strategy enables you to implement changes, perform testing, and switch traffic between environments with minimal risk and downtime.

This pattern helps you automate the blue/green deployment process for Aurora global databases by using infrastructure as code (IaC) principles. It uses [AWS CloudFormation](), [AWS Lambda](), and [Amazon Route 53]() to simplify blue/green deployments. To improve reliability, it uses global transaction identifiers (GTIDs) for replication. GTID-based replication provides better data consistency and failover capabilities between environments compared with binary log (binlog) replication.

> **Note**
>
> This pattern assumes that you're using an Aurora MySQL-Compatible Edition global database cluster. If you're using Aurora PostgreSQL-Compatible instead, please use the PostgreSQL equivalents of the MySQL commands.

By following the steps in this pattern, you can:

- Provision a green Aurora global database: Using CloudFormation templates, you create a green environment that mirrors your existing blue environment.
- Set up GTID-based replication: You configure GTID replication to keep the blue and green environments synchronized.
- Seamlessly switch traffic: You use Route 53 and Lambda to automatically switch the traffic from the blue to the green environment after full synchronization.

- Finalize the deployment: You validate that the green environment is fully operational as the primary database, and then stop replication and clean up any temporary resources.

The approach in this pattern provides these benefits:

- Reduces downtime during critical database updates or migrations: Automation ensures a smooth transition between environments with minimal service disruption.
- Enables rapid rollbacks: If an issue arises after traffic is switched to the green environment, you can quickly revert to the blue environment and maintain service continuity.
- Enhances testing and verification: The green environment can be fully tested without affecting the live blue environment, which reduces the likelihood of errors in production.
- Ensures data consistency: GTID-based replication keeps your blue and green environments in sync, which prevents data loss or inconsistencies during migration.
- Maintains business continuity: Automating your blue/green deployments helps avoid long outages and financial losses by keeping your services available during updates or migrations.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A source Aurora MySQL-Compatible global database cluster (blue environment). Global databases provide a multi-Region configuration for high availability and disaster recovery. For instructions for setting up a global database cluster, see the Aurora documentation.
- GTID-based replication enabled on the source cluster.

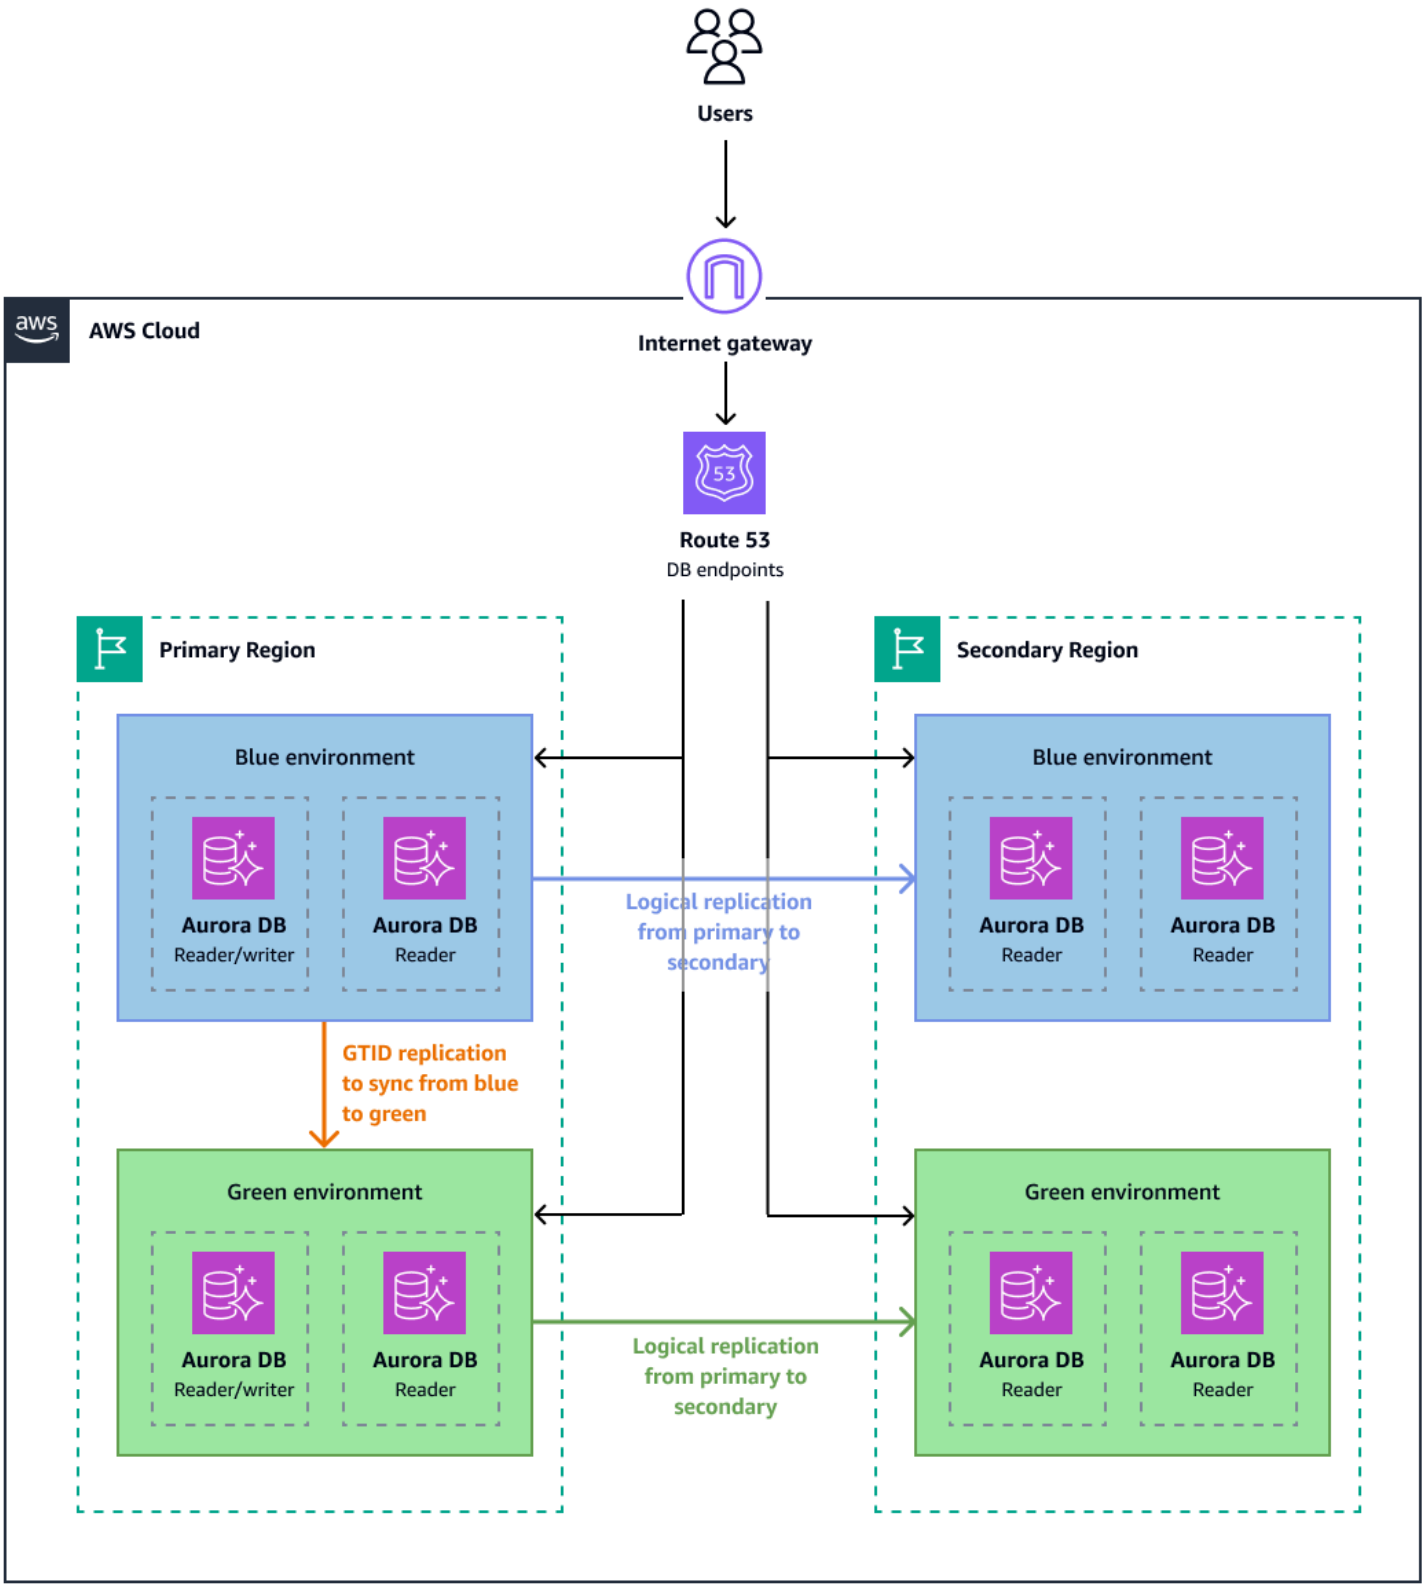
Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Product versions

- Aurora MySQL-Compatible 8.0 or later

Architecture



The diagram illustrates the following:

- Global database setup: An Aurora global database cluster is strategically deployed across two AWS Regions. This configuration enables geographic distribution and Regional redundancy for enhanced disaster recovery capabilities.
- Primary to secondary Region replication: The logical replication mechanism ensures seamless data synchronization from the primary Region to the secondary Region. This replication maintains data consistency with minimal latency across geographical distances.
- GTID-based replication between clusters: GTID-based replication maintains transactional consistency and ordered data flow between the blue primary cluster and the green primary cluster, and ensures reliable data synchronization.
- Blue primary to secondary replication: Logical replication establishes a robust data pipeline between the blue primary cluster and its secondary cluster. This replication enables continuous data synchronization and high availability.
- Route 53 DNS configuration: Route 53 hosted zone records manage the DNS resolution for all blue and green cluster database endpoints. This configuration provides seamless endpoint mapping and enables efficient traffic routing during failover scenarios.

Tools

AWS services

- Amazon Aurora is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run on AWS. You create a template that describes all the AWS resources that you want, and CloudFormation takes care of provisioning and configuring those resources for you.
- AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon Route 53 is a highly available and scalable DNS web service.

Best practices

We recommend that you thoroughly review AWS documentation to deepen your understanding of the blue/green deployment strategy, GTID-based replication, and weighted routing policies in Route 53. This knowledge is crucial for effectively implementing and managing your database migrations, ensuring data consistency, and optimizing traffic routing. By gaining a comprehensive understanding of these AWS features and best practices, you'll be better equipped to handle future updates, minimize downtime, and maintain a resilient and secure database environment.

For guidelines for using the AWS services for this pattern, see the following AWS documentation:

- Best practices with Amazon Aurora MySQL
- AWS CloudFormation best practices
- Best practices for working with AWS Lambda functions
- Best practices for Amazon Route 53

Epics

Create the green environment

Task	Description	Skills required
Create a snapshot backup from the blue cluster.	In a blue/green deploymen t, the green environment represents a new, identical version of your current (blue) database environment. You use the green environme nt to safely test updates, validate changes, and ensure stability before switching production traffic. It acts as a staging ground for implement ing database changes with minimal disruption to the live environment. To create a green environme nt, you first create a snapshot of the primary (blue) cluster in your Aurora MySQL-Com	DBA

Task	Description	Skills required
	patible global database. This snapshot serves as the foundation for creating the green environment. To create a snapshot: 1. Sign in to the AWS Management Console and open the [Amazon Relational Database Service (Amazon RDS) console](https://console.aws.amazon.com/rds/). 2. Select your primary (blue) cluster. 3. Choose **Actions**, **Take snapshot**. 4. Provide a name for the snapshot, such as `blue-green-demo` , and start the backup process. Alternatively, you can use the AWS Command Line Interface (AWS CLI) to create the snapshot: `aws rds create-db-cluster-snapshot --db-cluster-snapshot-identifier blue-green-demo --db-cluster-identifier ex-global-cluster --region eu-west-1`	

Task	Description	Skills required
	Make sure that the snapshot completes successfully before proceeding to the next step.	
Generate the CloudFormation template for your global database and its resources.	The CloudFormation IaC generator helps you generate CloudFormation templates from existing AWS resources. Use this feature to create a CloudFormation template for your existing Aurora MySQL-Compatible global database and its associated resources. This template configures subnet groups, security groups, parameter groups, and other settings. 1. Follow the [instructions in the CloudFormation documentation] to navigate to the tool and connect it to your AWS environment. 2. Select your Aurora global database and associated resources to generate the template.	DBA

Task	Description	Skills required
Modify the CloudFormation template for the green environment.	Customize the CloudFormation template to reflect the settings for the green environment. This includes updating resource names and identifiers to ensure that the green environment operates independently of the blue cluster. 1. Update the `DBClusterIdentifier` and `DBInstanceIdentifier` properties to represent the green environment. 2. Modify other resource names (for example, subnet groups and security groups) to avoid conflicts with the existing blue environment. 3. Enable GTID-based replication in the template by configuring the correct parameters, as described in the [Aurora documentation](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/). 4. Change the `SnapshotIdentifier` property to specify the AWS Region, your account ID, and the name of the snapshot from the previous step:	DBA

Task	Description	Skills required
	`SnapshotIdentifier: arn:aws:rds:<region>:<account-id>:snapshot:<snapshot-name>` **Note** If you use the `SnapshotIdentifier` property to restore a DB cluster, avoid specifying properties such as `GlobalClusterIdentifier` , `MasterUsername` , or `MasterUserPassword` .	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Deploy the CloudFormation stack to create resources for the green environment.</td><td>In this step, you deploy the customized CloudForm ation template to create the resources for the green environment.

To deploy the CloudForm ation stack:

1. Open the AWS CloudForm ation console.
2. In the upper right, choose Create stack, With new resources (standard).
3. Upload your modified CloudFormation template or specify the template URL. Choose Next.
4. Enter a stack name such as <code>GreenClusterStack</code> , and provide any necessary parameters (for example, <code>GreenClusterIdenti fier</code>). Choose Next.
5. Configure additional stack options as needed, and check the box to acknowledge that CloudFormation might create AWS Identity and Access Management (IAM) resources. Choose Next.
6. Review the stack details.
7. Choose Submit.</td><td>DBA</td></tr>
</table>

Task	Description	Skills required
	CloudFormation initiates the process of creating the green environment resources. This process might take several minutes to complete.	

Task	Description	Skills required
Validate the CloudFormation stack and resources.	When the CloudFormation stack deployment is complete, you'll need to verify that the green environment has been created successfully: 1. In the **Outputs** section of the CloudFormation stack, check the endpoints of the database cluster and database instance to verify correct setup. 2. Open the [Amazon RDS console](#) and confirm that the new Aurora database cluster (green environment) is available. 3. Make sure that all associated resources, such as subnets and security groups, have been created and linked to the green environment. After verification, your green environment is ready for further setup, including replication from the blue environment.	DBA

Configure GTID-based replication

Task	Description	Skills required
Verify GTID settings on the blue cluster.	GTIDs provide a highly reliable method for replicating data between your blue and green environments. [GTID-based replication](#) offers a resilient, simplified approach by assigning a unique identifier to every transaction in the blue environment. This method ensures that data synchronization between environments is seamless, consistent, and easier to manage than traditional binlog replication. Before you configure replication, you need to ensure that GTID-based replication is properly enabled on the blue cluster. This step guarantees that each transaction in the blue environment is uniquely tracked and can be replicated in the green environment. To confirm that GTID is enabled: 1. On the [Amazon RDS console](#), review the parameter group assigned to the blue cluster.	DBA

Task	Description	Skills required
	2. Verify that the following parameters are set: • `gtid-mode = ON` • `enforce_gtid_consistency = ON` These settings enable GTID tracking for all future transactions in the blue environment. After you confirm these settings, you can start setting up replication.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a replication user.</td><td>

To replicate data from the blue environment to the green environment, you need to create a dedicated replication user on the blue cluster. This user will be responsible for managing the replication process.

To set up the replication user:

1. Connect to the blue cluster by using a MySQL client.
2. Run the following commands to create the replication user:

```
CREATE USER 'repl_user'@'%' IDENTIFIED BY 'repl_password';
GRANT REPLICATION SLAVE ON . TO 'repl_user'@'%';
FLUSH PRIVILEGES;
```

This user now has the necessary permissions to replicate data between the two environments.

</td><td>DBA</td></tr>
</table>

Task	Description	Skills required
Configure GTID-based replication on the green cluster.	The next step is to configure the green cluster for GTID-based replication. This setup ensures that the green environment will continuously mirror all transactions that happen in the blue environment. To configure the green cluster: 1. Connect to the green cluster by using a MySQL client. 2. Run the following command to configure replication: `CHANGE MASTER TO MASTER_HOST='blue-cluster-endpoint', MASTER_USER='repl_user', MASTER_PASSWORD='repl_password', MASTER_AUTO_POSITION=1;` where: • Replace `blue-cluster-endpoint` with the endpoint of your blue cluster. • The `MASTER_AUTO_POSITION=1` setting instructs MySQL	DBA

Task	Description	Skills required
	to use GTID-based replication. It automatically positions the green cluster to replicate the blue cluster's transactions without having to track logs and positions manually.	
Start replication on the green cluster.	You can now start the replication process. On the green cluster, run the command: `START SLAVE;` This enables the green environment to start synchronizing data, and receiving and applying transactions from the blue environment.	DBA

Task	Description	Skills required
Verify the replication process.	To verify that the green environment is accurately replicating the data from the blue cluster: 1. Run the following command on the green cluster to check the replication status: `SHOW SLAVE STATUS\G;` 2. Review the output to verify the following: • `Slave_IO_Running = Yes` • `Slave_SQL_Running = Yes` • The `Retrieved_Gtid_Set` and `Executed_Gtid_Set` values are up-to-date and synchronized with the blue cluster. • There are no replication errors in the `Last_Error` field. If all indicators are correct, GTID-based replication is functioning smoothly, and the green environment is fully synchronized with the blue environment.	DBA

Switch traffic from blue to green cluster

Task	Description	Skills required
Configure Route 53 weighted routing policies.	After you verify data consistency between the blue and green environme nts, you can switch traffic from the blue cluster to the green cluster. This transitio n should be smooth and should minimize downtime and ensure the integrity of your application's database. To address these requireme nts, you can use Route 53 for DNS routing and Lambda to automate traffic switching. Additionally, a well-defined rollback plan ensures that you can revert to the blue cluster in case of any issues. The first step is to configure weighted routing in Route 53. Weighted routing allows you to control the distribut ion of traffic between the blue and green clusters, and gradually shift traffic from one environment to the other. To configure weighted routing: 1. Open the [Route 53 console](https://console.aws.amazon.com/route53/) and choose your hosted zone.	AWS DevOps

Task	Description	Skills required
	2. Create two DNS records (CNAMEs) for the database: one record for the blue cluster and one record for the green cluster. 3. Assign initial weights: • Set a low initial weight (such as 5 percent) for the green cluster to send a small portion of traffic for testing. • Set a higher weight (such as 95 percent) for the blue cluster, so it retains the majority of traffic. This configuration allows you to perform a gradual transition that reduces risk and supports real-time testing before you switch over fully. For more information about weighted routing policies, see the [Route 53 documentation]().	

Task	Description	Skills required

Deploy a Lambda function to monitor replication lag.	To ensure that the green environment is fully synchronized with the blue environment, deploy a Lambda function that monitors replication lag between the clusters. This function can check the replication status, specifically the **Seconds_Behind_Master** metric, to determine whether the green cluster is ready to handle all traffic.
	
	Here's a sample Lambda function you can use:
	
	`import boto3`
	
	`def check_replication_lag(event, context):`
	`    client = boto3.client('rds')`
	`    response = client.describe_db_instances(DBInstanceIdentifier='green-cluster-instance')`
	`    replication_status = response['DBInstances'][0]['ReadReplicaDBInstanceIdentifiers']`
	`    if replication_status:`
	`        lag = replication_status[0]['ReplicationLag']`
	`        return lag`
		AWS DevOps

Task	Description	Skills required
	```return -1``` This function checks the replication lag and returns the value. If the lag is zero, the green cluster is fully in sync with the blue cluster.	

Task	Description	Skills required

Automate DNS weight adjustment by using Lambda.	When the replication lag reaches zero, it's time to switch all traffic to the green cluster. You can automate this transition by using another Lambda function that adjusts the DNS weights in Route 53 to direct 100 percent of traffic to the green cluster.
	
	Here's an example of a Lambda function that automates the traffic switch:
	
	`import boto3`
	
	`def switch_traffic(eve nt, context):`
	`    route53 = boto3.cli ent('route53')`
	`    lag = check_rep lication_lag(event, context)`
	`    if lag == 0:`
	`        response = route53.change_res ource_record_sets(`
	`            HostedZon eId='YOUR_HOSTED_Z ONE_ID',`
	`            ChangeBat ch={`
	`                'Changes': [`
	`                    {`
	`                        'Action': 'UPSERT',`
		AWS DevOps

Task	Description	Skills required

	'ResourceRecordSet': {
	'Name': 'db.examp le.com',
	'Type': 'CNAME',
	'SetIdentifier': 'GreenCluster',
	'Weight': 100,
	'TTL': 60,
	'ResourceRecords': [{'Value': 'green-cl uster-endpoint'}]
	}
	},
	{
	'Action': 'UPSERT',
	'ResourceRecordSet': {
	'Name': 'db.examp le.com',
	'Type': 'CNAME',
	'SetIdentifier': 'BlueCluster',
	'Weight': 0,
	'TTL': 60,
	'ResourceRecords':	

Task	Description	Skills required

	``
	 [{'Value': 'blue-clu
	ster-endpoint'}]
	
	 }
	                    }
	                ]
	            }
	        )
	        return response
	``
	
	This function checks replication lag and updates the Route 53 DNS weights when the lag is zero to fully switch traffic to the green cluster.
	
	Note
	
	During the cutover process, If the blue cluster experiences heavy write traffic, consider temporarily pausing write operations during the cutover. This ensures that replication catches up, and prevents data inconsistencies between the blue and green clusters.	

Task	Description	Skills required
Verify the traffic switch.	After the Lambda function adjusts the DNS weights, you should verify that all traffic is directed to the green cluster and that the switch was successful. To verify: 1. Monitor the Route 53 DNS records to confirm that traffic is being directed to the green cluster. For more information, see the [Route 53 documentation](https://docs.aws.amazon.com/Route53/). 2. Check application performance by confirming that users are being served from the green environment. 3. Verify database connections to confirm that the green cluster is handling all database requests. 4. Monitor Amazon CloudWatch metrics for any signs of latency, replication lag, or performance degradation. For more information, see the [Aurora documentation](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/).	AWS DevOps

Task	Description	Skills required
	If everything is performing as expected, the traffic switch is complete.	

Task	Description	Skills required
If you encounter any issues, roll back changes.	Having a rollback plan is critical in case any issues arise after the traffic switch. Here's how to quickly revert to the blue cluster if necessary: 1. Revert DNS weights in Route 53: Use the same Lambda function or manually adjust the Route 53 DNS weights to direct 100 percent of traffic back to the blue cluster. 2. Monitor application performance: Immediately monitor application logs, CloudWatch metrics, and database performance to confirm that the switch back to the blue environme nt has resolved the issues. 3. Identify and resolve Issues: Investigate and address any problems with the green cluster before you attempt another traffic switch. By implementing this rollback plan, you can ensure minimal disruption to your users in the event of any unexpected issues.	AWS DevOps

Validate and stop GTID-based replication

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Stop GTID-based replication on the green cluster.</td><td>After you switch traffic from the blue environment to the green environment, you should validate the success of the transition and ensure that the green cluster is functioning as expected. Additionally, the GTID-based replication between the blue and green clusters must be stopped, because the green environment now serves as the primary database. Completing these tasks ensures that your environment is secure, streamlined, and optimized for ongoing operations.

To stop replication:

1. Use a MySQL client to connect to the green cluster.
2. Run the following SQL command to stop the replication process on the green cluster:

<code>STOP SLAVE;</code>

3. (Optional) If desired, you can reset the replication configuration to clear</td><td>DBA</td></tr>
</table>

Task	Description	Skills required
	any residual replication settings: `RESET SLAVE ALL;` When you stop the replication, the green cluster becomes fully independent and operates as the primary database environment for your workloads.	

Task	Description	Skills required
Clean up resources.	Cleaning up any temporary or unused resources that were created during the migration from the blue to the green cluster ensures that your environment remains optimized, secure, and cost-effective. The cleanup includes adjusting security settings, taking final backups, and decommiss ioning unnecessary resources. To clean up resources: 1. Update security groups: Configure the security groups that are associated with both the blue and the green clusters to reflect the new primary environme nt (green). Restrict access to the blue environment if it is no longer needed, and verify that the green cluster's security settings follow best practices. 2. Make a final backup of the green cluster: After the migration is complete, take a final snapshot of the green cluster to serve as a backup. You can use this snapshot to restore the	AWS DevOps

Task	Description	Skills required

	environment in the future if necessary.
	`aws rds create-db-snapshot --db-instance-identifier green-cluster-instance --db-snapshot-identifier green-cluster-final-snapshot`
	3. Review and remove temporary resources: Review any temporary resources that were created during the migration, such as temporary security groups, snapshots, or other configurations. Delete resources that are no longer needed to prevent unnecessary costs. For example, delete the blue cluster if it is no longer required:
	`aws rds delete-db-cluster --db-cluster-identifier blue-cluster-identifier --skip-final-snapshot`
	
	Cleaning up resources helps maintain a secure and streamlined environment, reduces costs, and ensures	

Task	Description	Skills required
	that only necessary infrastru cture remains.

Automate the replication of Amazon RDS instances across AWS accounts

Parag Nagwekar and Arun Chandapillai, Amazon Web Services

Summary

This pattern shows you how to automate the process of replicating, tracking, and rolling back your Amazon Relational Database Service (Amazon RDS) DB instances across different AWS accounts by using AWS Step Functions and AWS Lambda. You can use this automation to perform large-scale replication of RDS DB instances without any performance impact or operational overhead—regardless of the size of your organization. You can also use this pattern to help your organization comply with mandatory data governance strategies or compliance requirements that call for your data to be replicated and redundant across different AWS accounts and AWS Regions. Cross-account replication of Amazon RDS data at scale is an inefficient and error-prone manual process that can be costly and time-consuming, but the automation in this pattern can help you achieve cross-account replication safely, effectively, and efficiently.

Prerequisites and limitations

Prerequisites

- Two AWS accounts
- An RDS DB instance, up and running in the source AWS account
- A subnet group for the RDS DB instance in the destination AWS account
- An AWS Key Management Service (AWS KMS) key created in the source AWS account and shared with the destination account (For more information about policy details, see the Additional information section of this pattern.)
- An AWS KMS key in the destination AWS account to encrypt the database in the destination account

Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Product versions

- Python 3.9 (using AWS Lambda)
- PostgreSQL 11.3, 13.x, and 14.x

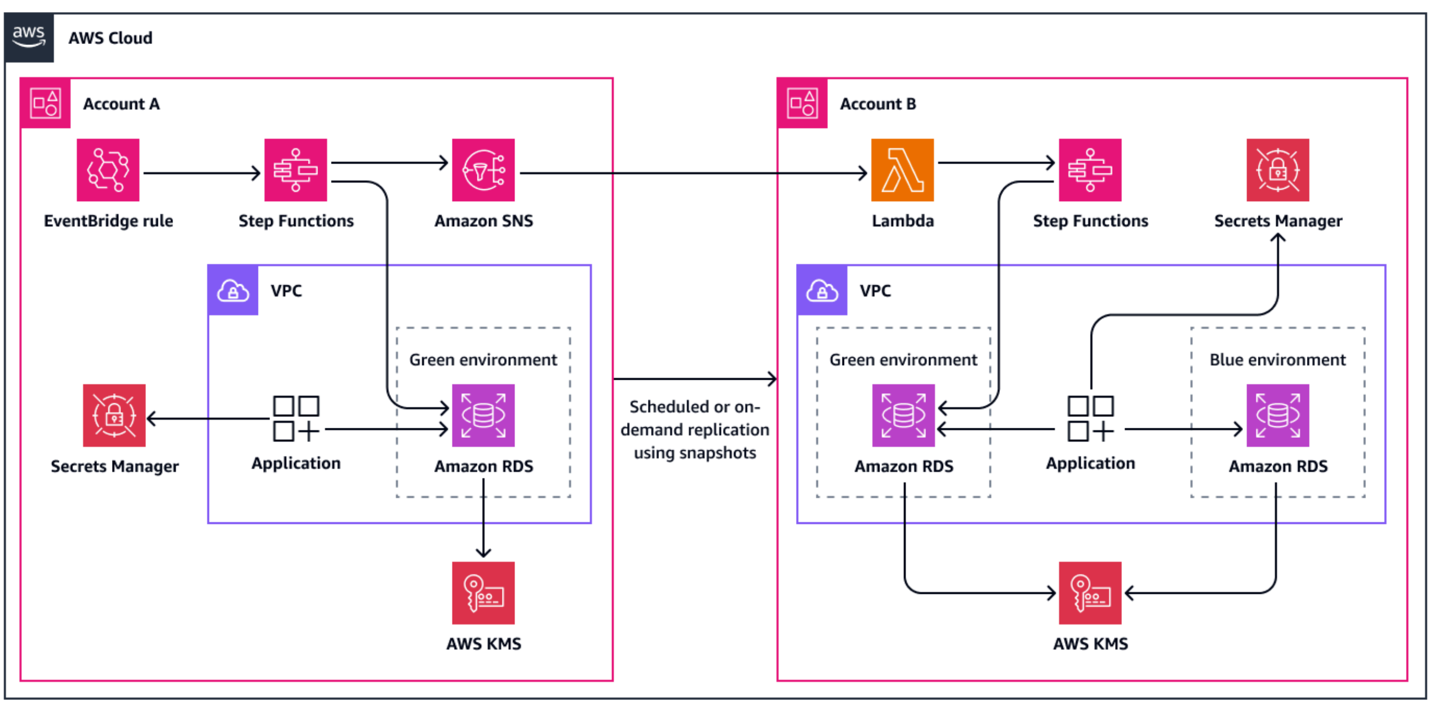
Architecture

Technology stack

- Amazon Relational Database Service (Amazon RDS)
- Amazon Simple Notification Service (Amazon SNS)
- AWS Key Management Service (AWS KMS)
- AWS Lambda
- AWS Secrets Manager
- AWS Step Functions

Target architecture

The following diagram shows an architecture for using Step Functions to orchestrate scheduled, on-demand replication of RDS DB instances from a source account (account A) to a destination account (account B).



In the source account (account A in the diagram), the Step Functions state machine performs the following:

1. Creates a snapshot from the RDS DB instance in account A.
2. Copies and encrypts the snapshot with an AWS KMS key from account A. To ensure encryption in transit, the snapshot is encrypted whether or not the DB instance is encrypted.
3. Shares the DB snapshot with account B by giving account B access to the snapshot.
4. Pushes a notification to the SNS topic, and then the SNS topic invokes the Lambda function in account B.

In the destination account (account B in the diagram), the Lambda function runs the Step Functions state machine to orchestrate the following:

1. Copies the shared snapshot from account A to account B, while using the AWS KMS key from account A to decrypt the data first and then encrypt the data by using the AWS KMS key in account B.
2. Reads the secret from Secrets Manager to capture the name of the current DB instance.
3. Restores the DB instance from the snapshot with a new name and default AWS KMS key for Amazon RDS.
4. Reads the endpoint of the new database and updates the secret in Secrets Manager with the new database endpoint, and then tags the previous DB instance so that it can be deleted later.
5. Keeps the latest N instances of the databases and deletes all the other instances.

Tools

AWS services

- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.

- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- AWS Step Functions is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications.

Code repository

The code for this pattern is available in the GitHub Crossaccount RDS Replication repository.

Epics

Automate the replication of RDS DB instances across AWS accounts with a single click

Task	Description	Skills required
Deploy the CloudFormation stack in the source account.	1. Sign in to the AWS Management Console for the source account (account A) and open the CloudFormation console. 2. In the navigation pane, choose **Stacks**. 3. Choose **Create stack**, and then choose **With existing resources (import resources)**. 4. On the **Identify resources** page, choose **Next**.	Cloud administrator, Cloud architect

Task	Description	Skills required
	5. On the **Specify template** page, select **Upload a template**. 6. Choose **Choose file**, select the `Cloudformation-SourceAccountRDS.yaml` file from the GitHub [Crossaccount RDS Replication](https://github.com) repository, and then choose **Next**. 7. For **Stack name**, enter a name for your stack. 8. In the **Parameters** section, specify the parameters that are defined in the stack template: • For **DestinationAccountNumber**, enter the account number for your destination RDS DB instance. • For **KeyName**, enter your AWS KMS key. • For **ScheduleExpression**, enter a cron expression (the default is **12:00 am daily**). • For **SourceDBIdentifier**, enter the name of the source database. • For **SourceDBSnapshotName**, enter the	

Task	Description	Skills required
	name of the snapshot or accept the default. 9. Choose **Next**. 10. On the **Configure stack options** page, leave the default values, and then choose **Next**. 11. Review your stack configuration, and then choose **Submit**. 12. Choose the **Resources** tab for your stack, and then note the Amazon Resource Name (ARN) of the SNS topic.	

Task	Description	Skills required
Deploy the CloudFormation stack in the destination account.	1. Sign in to the AWS Management Console for the destination account (account B) and open the [CloudFormation console](https://console.aws.amazon.com/cloudformation/). 2. In the navigation pane, choose **Stacks**. 3. Choose **Create stack**, and then choose **With existing resources (import resources)**. 4. On the **Identify resources** page, choose **Next**. 5. On the **Specify template** page, select **Upload a template**. 6. Choose **file**, select the `Cloudformation-DestinationAccountRDS.yaml` file from the GitHub [Crossaccount RDS Replication](https://github.com/) repository, and then choose **Next**. 7. For **Stack name**, enter a name for your stack. 8. In the **Parameters** section, specify the parameters that are defined in the stack template: • For **DatabaseName**, enter a name for your database.	Cloud architect, DevOps engineer, Cloud administrator

Task	Description	Skills required
	• For **Engine**, enter the database engine type that matches the source database. • For **DBInstanceClass**, enter the preferred database instance type or accept the default. • For **Subnetgroups**, enter the existing VPC subnet group. For instructions about creating a subnet group, see [Step 2: Create a DB subnet group] in the Amazon RDS documenta tion. • For **SecretName**, enter the path and secret name, or accept the default. • For **SGID**, enter the security group ID of your destination cluster. • For **KMSKey**, enter the ARN of the KMS key in your destination account. • For **NoOfOlderInstances** , enter the number of old copies of the RDS DB instances that you want to keep for the rollback. 9. Choose **Next**.	

Task	Description	Skills required
	10. On the **Configure stack options** page, leave the default values, and then choose **Next**. 11. Review your stack configuration, and then choose **Submit**. 12. Choose the **Resources** tab for your stack, and then note the Physical ID and ARN of `InvokeStepFunction` .	
Verify the creation of the RDS DB instance in the destination account.	1. Sign in to the AWS Management Console and open the [Amazon RDS console](https://console.aws.amazon.com/rds/). 2. In the navigation pane, choose **Databases**, and then verify that the new RDS DB instance appears under the new cluster.	Cloud administrator, Cloud architect, DevOps engineer

Task	Description	Skills required

Subscribe the Lambda function to the SNS topic.	You must run the following AWS Command Line Interface (AWS CLI) commands to subscribe the Lambda function in the destination account (account B) to the SNS topic in the source account (account A).
	
	In account A, run following command:
	
	`aws sns add-permission \ --label lambda-access --aws-account-id <DestinationAccount> \ --topic-arn <Arn of SNSTopic > \ --action-name Subscribe ListSubscriptionsByTopic`
	
	In account B, run following command:
	
	`aws lambda add-permission \ --function-name <Name of InvokeStepFunction > \ --source-arn <Arn of SNSTopic > \ --statement-id function-with-sns \ --action lambda:InvokeFunction \`
		Cloud administrator, Cloud architect, DBA

Task	Description	Skills required

	`--principal sns.amazonaws.com`
	
	In account B, run following command:
	
	`aws sns subscribe \ --protocol "lambda" \ --topic-arn <Arn of SNSTopic> \ --notification-endpoint <Arn of InvokeStepFunction>`	

Task	Description	Skills required
Sync the RDS DB instance from the source account with the destination account.	Initiate the on-demand database replication by starting the Step Functions state machine in the source account. 1. Open the [Step Functions console](https://console.aws.amazon.com/states/). 2. In the navigation pane, choose **State machines**. 3. Choose your state machine. 4. On the **Executions** tab, select your function, and then choose **Start execution** to start the workflow. **Note** A scheduler is in place to help you run the replication automatically on schedule, but the scheduler is turned off by default. You can find the name of the Amazon CloudWatch rule for the scheduler in the **Resources** tab of the CloudFormation stack in the destination account. For instructions on how to	Cloud architect, DevOps engineer, Cloud administrator

Task	Description	Skills required
	modify the CloudWatch Events rule, see Deleting or Disabling a CloudWatch Events Rule in the CloudWatch documentation.	
Roll back your database to any of the previous copies when needed.	1. Open the Secrets Manager console. 2. From the list of secrets, choose the secret that you created by using the CloudFormation template earlier. Your application uses the secret to access the database in the destination cluster. 3. To update the secret value from the details page, in the **Secret value** section, choose **Retrieve secret** value, and then choose **Edit**. 4. Enter the details of the database endpoint.	Cloud administrator, DBA, DevOps engineer

Automate database tasks in SQL Server Express edition running on Amazon EC2 by using AWS Lambda and Task Scheduler

Subhani Shaik, Amazon Web Services

Summary

This pattern demonstrates how to schedule and manage database tasks in SQL Server Express edition, which is the free version of SQL Server. However, SQL Server Express edition lacks the SQL Server Agent service that typically handles automated database operations. This pattern explains how you can use Task Scheduler and Lambda as an alternative for automating database tasks in SQL Server Express edition running on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

Task Scheduler is a built-in Windows system utility that facilitates the automatic execution of routine tasks. It provides a mechanism to schedule and manage automated operations, eliminating the need for manual intervention in recurring processes. AWS Lambda is a serverless computing service that automatically runs code in response to events, without requiring you to manage the underlying infrastructure.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) created with Amazon Virtual Private Cloud (Amazon VPC)
- An Amazon EC2 instance with Windows Server
- Amazon Elastic Block Store (Amazon EBS) volumes that are attached to an Amazon EC2 instance with Windows Server
- SQL Server Express Edition binaries

Limitations

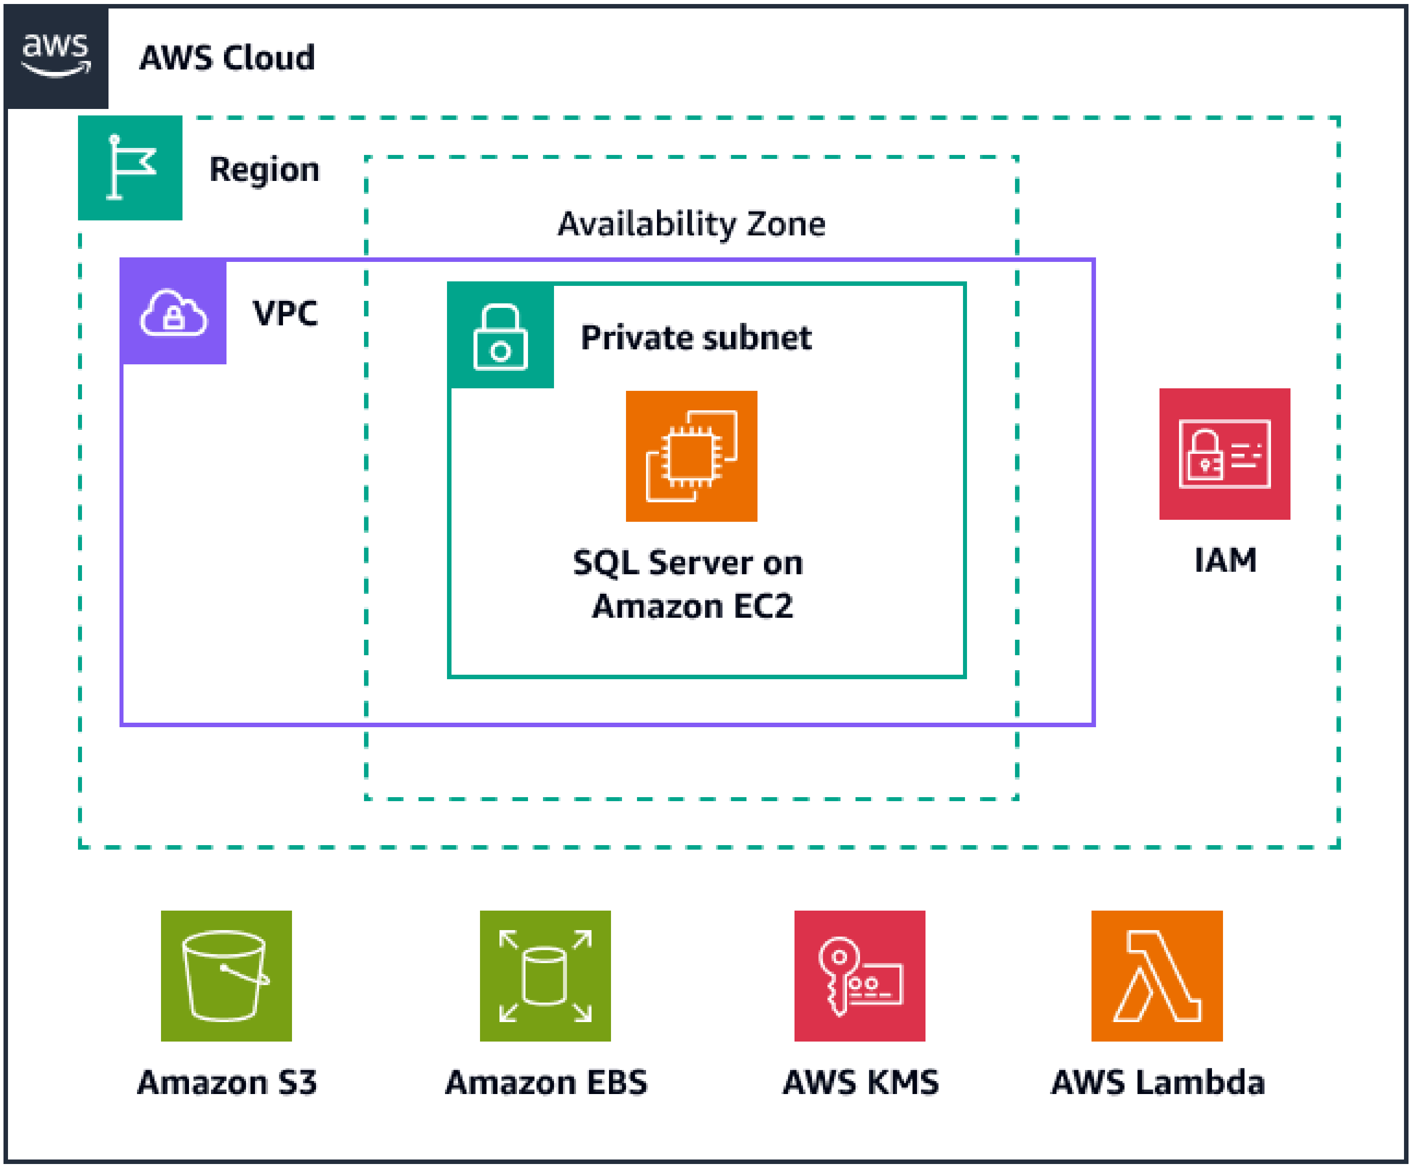
- For information about feature limitations of SQL Server Express edition, see the Microsoft website.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- SQL Server 2016 or later with SQL Server Express edition

Architecture

The following diagram shows an Amazon EC2 instance running with SQL Server Express edition installed. The instance is accessible through Remote Desktop Protocol (RDP) client or from AWS Systems Manager Session Manager. AWS Key Management Service (AWS KMS) handles the data encryption for the Amazon EBS volumes to ensure data-at-rest security. The infrastructure also includes AWS Identity and Access Management (IAM), which provides access control and manages permissions for the execution of Lambda functions. Amazon Simple Storage Service (Amazon S3) stores Lambda functions.



Tools

AWS services

- [Amazon Elastic Block Store (Amazon EBS)](#) provides block-level storage volumes for use with Amazon EC2 instances.
- [Amazon Elastic Compute Cloud (Amazon EC2)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Systems Manager Session Manager is a fully managed AWS Systems Manager tool. With Session Manager, you can manage your Amazon EC2 instances, edge devices, on-premises servers, and virtual machines (VMs).
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- Microsoft SQL Server Management Studio (SSMS) is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.
- Python is a general-purpose computer programming language. You can use it to build applications, automate tasks, and develop services on the AWS Cloud.
- Task Scheduler is a Microsoft tool that you can use to schedule routine tasks on your computer automatically.

Best practices

- Best practices for deploying Microsoft SQL Server on Amazon EC2
- Best practices for working with AWS Lambda functions
- Security best practices in IAM

Epics

Create an Amazon EC2 instance and install SQL Server Express edition

Task	Description	Skills required
Deploy an Amazon EC2 instance.	To create an Amazon EC2 instance, open the Amazon EC2 console at https://console.aws.amazon.com/ec2/ and select an [Amazon Machine Image (AMI)]() from the list of instances available for Windows Server. For more information, see [Launch an Amazon EC2 instance]() in the AWS documentation.	DBA, AWS DevOps
Install SQL Server Express edition.	To install SQL Server Express edition, complete the following steps: 1. To [connect to your Amazon EC2 instance](), choose an option: • **Option A** – Use Remote Desktop Protocol (RDP). For instructions, see [Connect to your Windows instance using an RDP client]() in the AWS documentation. • **Option B** – Use the Amazon EC2 console and AWS Systems Manager	DBA, AWS DevOps

Task	Description	Skills required
	Session Manager. For instructions, see Connect to your Amazon EC2 instance using Session Manager in the AWS documentation. 2. To download the required SQL Server Express edition, go to SQL Server Downloads on the Microsoft website. 3. To install SQL Server Express edition, follow the instructions in Plan a SQL Server installation on the Microsoft website.	

Create automated database maintenance tasks

Task	Description	Skills required
Identify routine tasks.	Identify the routine tasks that you want to automate. For example, the following tasks are eligible for automation: • Database backups (Full, differential, and transaction log) • Index maintenance and reorganization • Statistics updates • Application-specific operations	DBA

Task	Description	Skills required
	• Data cleanup or archiving	
Prepare SQL scripts.	To prepare SQL scripts, do the following: 1. Create SQL queries for each maintenance task. Following is an example [T-SQL](https://learn.microsoft.com/en-us/sql/t-sql/language-reference) query to perform a specific database backup: `Backup Database <Database_Name> To Disk='C:\Backups\Database_Name.bak'` 2. Save the script file as `<File Name>.sql` . Then, save the scripts to an accessible location on the server's local drive on the Amazon EC2 instance or a network file share.	DBA

Task	Description	Skills required
Configure access permissions.	To configure access permissio ns, do the following: 1. Set appropriate file system permissions. For instructi ons, see Configure file system permissions for Database Engine access on the Microsoft website. 2. Check that the SQL Server service account has the necessary access. For instructions, see Configure Windows service accounts and permissions on the Microsoft website. 3. Verify network connectiv ity for remote shares. For more information, see Accessing data using file shares in the AWS documentation.	DBA

Automate tasks with Task Scheduler

Task	Description	Skills required
Create batch files.	• To create a batch file, use a text editor to type the following command. Replace the parameters `username` and `password` with your own values. Then	AWS DevOps, DBA

Task	Description	Skills required

	save the file as <Name>.bat .
	`sqlcmd -S servername -U username -P password -i <T-SQL query path.sql>`
	• To create a batch file for SQL tasks, use a text editor and type the following commands. Replace the parameters ServerName , DatabaseName , username, and password with your own values. Then save the file as <Name>.bat .
	`@echo off sqlcmd -S [ServerName] -d [DatabaseName] -U username -P password -i "PathToSQLScript\Script.sql" -o "PathToOutput\Output.txt"`	

Task	Description	Skills required
Create tasks in Task Scheduler .	To create a task in Task Scheduler, use the following steps: 1. To open Task Scheduler , type **taskschd.msc** in Windows search. 2. Choose the **Action** menu, and then select **Create Basic Task**. 3. For **Name**, provide a name for the task, and then choose **Next**. 4. For **Trigger**, select the option for when you want the task to start and then choose **Next**. 5. Provide the **Start** and **Recur** information for the task, and then choose **Next**. 6. For the **Action** section, select **Start a program** and then choose **Next**. 7. For **Program/script**, specify the path for the batch file that you created in the previous task and then choose **Next**. 8. Choose **Finish**.	DBA

Task	Description	Skills required
	To run the task manually, right-click the newly created task and then select **Run**.	
View task status.	To view the status of a task in Task Scheduler, use the following steps: 1. In Task Scheduler, go to **Task Scheduler Library**, which displays all tasks. 2. To see the status of the task that you created earlier, select the task and then go to the **History** tab.	DBA, AWS DevOps

Automate tasks with AWS Lambda

Task	Description	Skills required
Implement the solution.	To implement this pattern's solution, use the following steps: 1. Create a Lambda function. For instructions, see [Create your first Lambda function] in the AWS documentation. 2. Schedule the Lambda function. For instructi ons, see [Invoke a Lambda function on a schedule] in the AWS documentation. 3. Run T-SQL queries. For more information, see	AWS DevOps, DevOps engineer

Task	Description	Skills required
	Tutorial: Using a Lambda function to access an Amazon RDS database in the AWS documentation. The tutorial explains how to connect Amazon RDS databases from Lambda functions to run SQL queries	

Troubleshooting

Issue	Solution
Lambda issues	For help with errors and issues that you might encounter when using AWS Lambda, see Troubleshooting issues in Lambda in the AWS documentation.

Automate cross-Region failover and failback by using DR Orchestrator Framework

Jitendra Kumar, Pavithra Balasubramanian, and Oliver Francis, Amazon Web Services

Summary

This pattern describes how to use DR Orchestrator Framework to orchestrate and automate the manual, error-prone steps to perform disaster recovery across Amazon Web Services (AWS) Regions. The pattern covers the following databases:

- Amazon Relational Database Service (Amazon RDS) for MySQL, Amazon RDS for PostgreSQL, or Amazon RDS for MariaDB
- Amazon Aurora MySQL-Compatible Edition or Amazon Aurora PostgreSQL-Compatible Edition (using a centralized file)
- Amazon ElastiCache (Redis OSS)

To demonstrate the functionality of DR Orchestrator Framework, you create two DB instances or clusters. The primary is in the AWS Region `us-east-1`, and the secondary is in `us-west-2`. To create these resources, you use the AWS CloudFormation templates in the `App-Stack` folder of the aws-cross-region-dr-databases GitHub repository.

Prerequisites and limitations

General prerequisites

- DR Orchestrator Framework deployed in both primary and secondary AWS Regions
- Two Amazon Simple Storage Service buckets
- A virtual private cloud (VPC) with two subnets and an AWS security group

Engine-specific prerequisites

- **Amazon Aurora** – At least one Aurora global database must be available in two AWS Regions. You can use `us-east-1` as the primary Region, and use `us-west-2` as the secondary Region.
- **Amazon ElastiCache (Redis OSS)** – An ElastiCache global datastore must be available in two AWS Regions. You can `use us-east-1` as the primary Region, and use `us-west-2` as the secondary Region.

Amazon RDS limitations

- DR Orchestrator Framework doesn't check the replication lag before doing a failover or failback. Replication lag must be checked manually.
- This solution has been tested using a primary database instance with one read replica. If you want to use more than one read replica, test the solution thoroughly before implementing it in a production environment.

Aurora limitations

- Feature availability and support vary across specific versions of each database engine and across AWS Regions. For more information on feature and Region availability for cross-Region replication, see Cross-Region read replicas.
- Aurora global databases have specific configuration requirements for supported Aurora DB instance classes and the maximum number of AWS Regions. For more information, see Configuration requirements of an Amazon Aurora global database.
- This solution has been tested using a primary database instance with one read replica. If you want to use more than one read replica, test the solution thoroughly before implementing it in a production environment.

ElastiCache limitations

- For information about Region availability for Global Datastore and ElastiCache configuration requirements, see Prerequisites and limitations in the ElastiCache documentation.

Amazon RDS product versions

Amazon RDS supports the following engine versions:

- **MySQL –** Amazon RDS supports DB instances running the following versions of MySQL: MySQL 8.0 and MySQL 5.7
- **PostgreSQL –** For information about supported versions of Amazon RDS for PostgreSQL, see Available PostgreSQL database versions.
- **MariaDB –** Amazon RDS supports DB instances running the following versions of MariaDB:
  - MariaDB 10.11
  - MariaDB 10.6

- MariaDB 10.5

Aurora product versions

- Amazon Aurora global database switchover requires Aurora MySQL-Compatible with MySQL 5.7 compatibility, version 2.09.1 and higher

  For more information, see Limitations of Amazon Aurora global databases.

ElastiCache (Redis OSS) product versions

Amazon ElastiCache (Redis OSS) supports the following Redis versions:

- Redis 7.1 (enhanced)
- Redis 7.0 (enhanced)
- Redis 6.2 (enhanced)
- Redis 6.0 (enhanced)
- Redis 5.0.6 (enhanced)

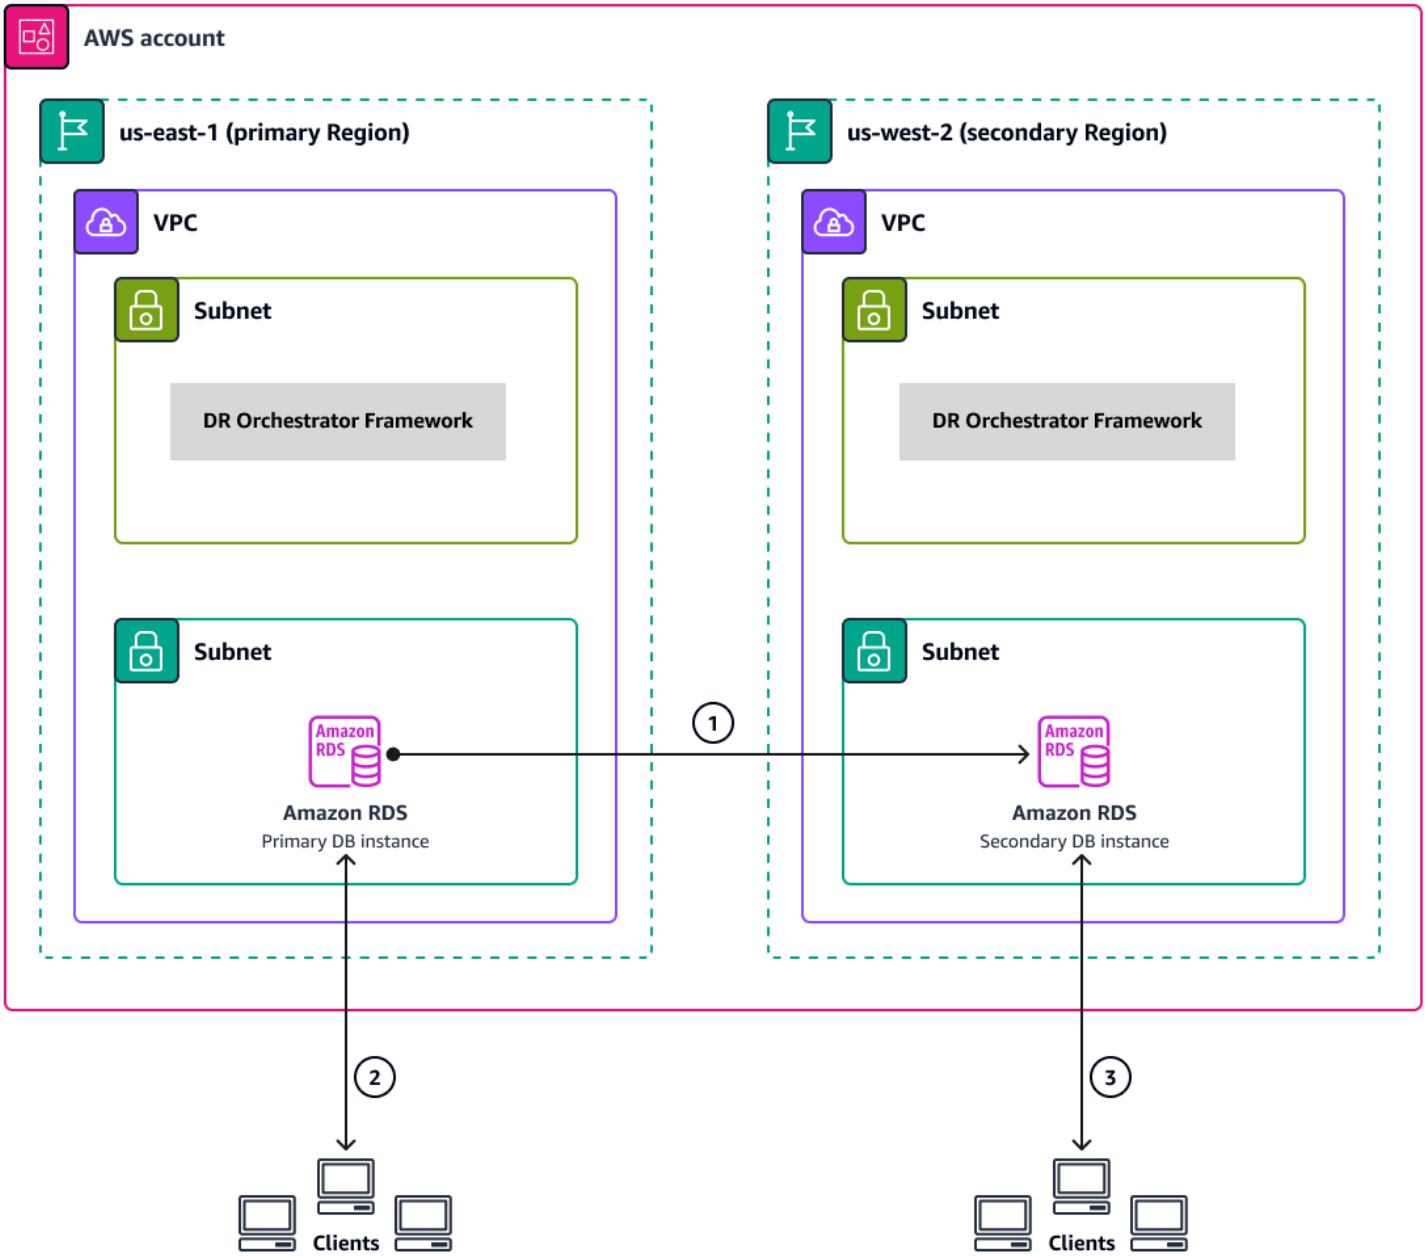
For more information, see Supported ElastiCache (Redis OSS) versions.

Architecture

Amazon RDS architecture

The Amazon RDS architecture includes the following resources:

- The primary Amazon RDS DB instance created in the primary Region (`us-east-1`) with read/write access for clients
- An Amazon RDS read replica created in the secondary Region (`us-west-2`) with read-only access for clients
- DR Orchestrator Framework deployed in both the primary and secondary Regions



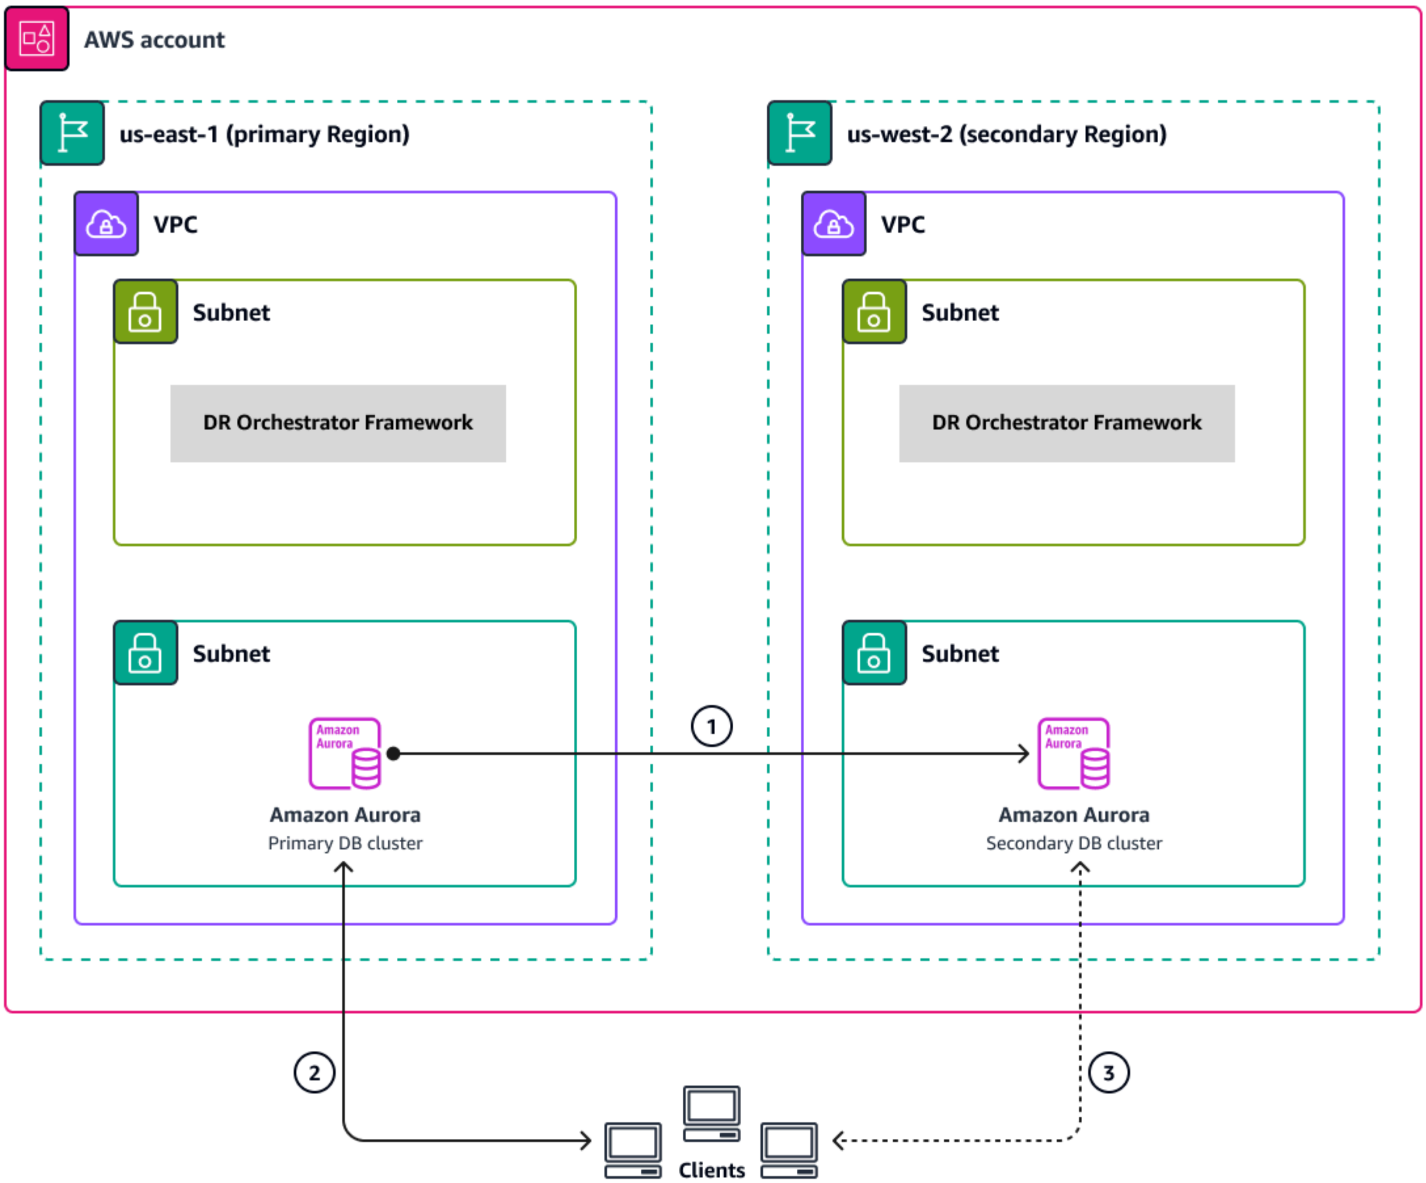
The diagram shows the following:

1. Asynchronous replication between the primary instance and the secondary instance
2. Read/write access for clients in the primary Region
3. Read-only access for clients in the secondary Region

Aurora architecture

The Amazon Aurora architecture includes the following resources:

- The primary Aurora DB cluster created in the primary Region (`us-east-1`) with an active-writer endpoint
- An Aurora DB cluster created in the secondary Region (`us-west-2`) with an inactive-writer endpoint
- DR Orchestrator Framework deployed in both the primary and secondary Regions



The diagram shows the following:

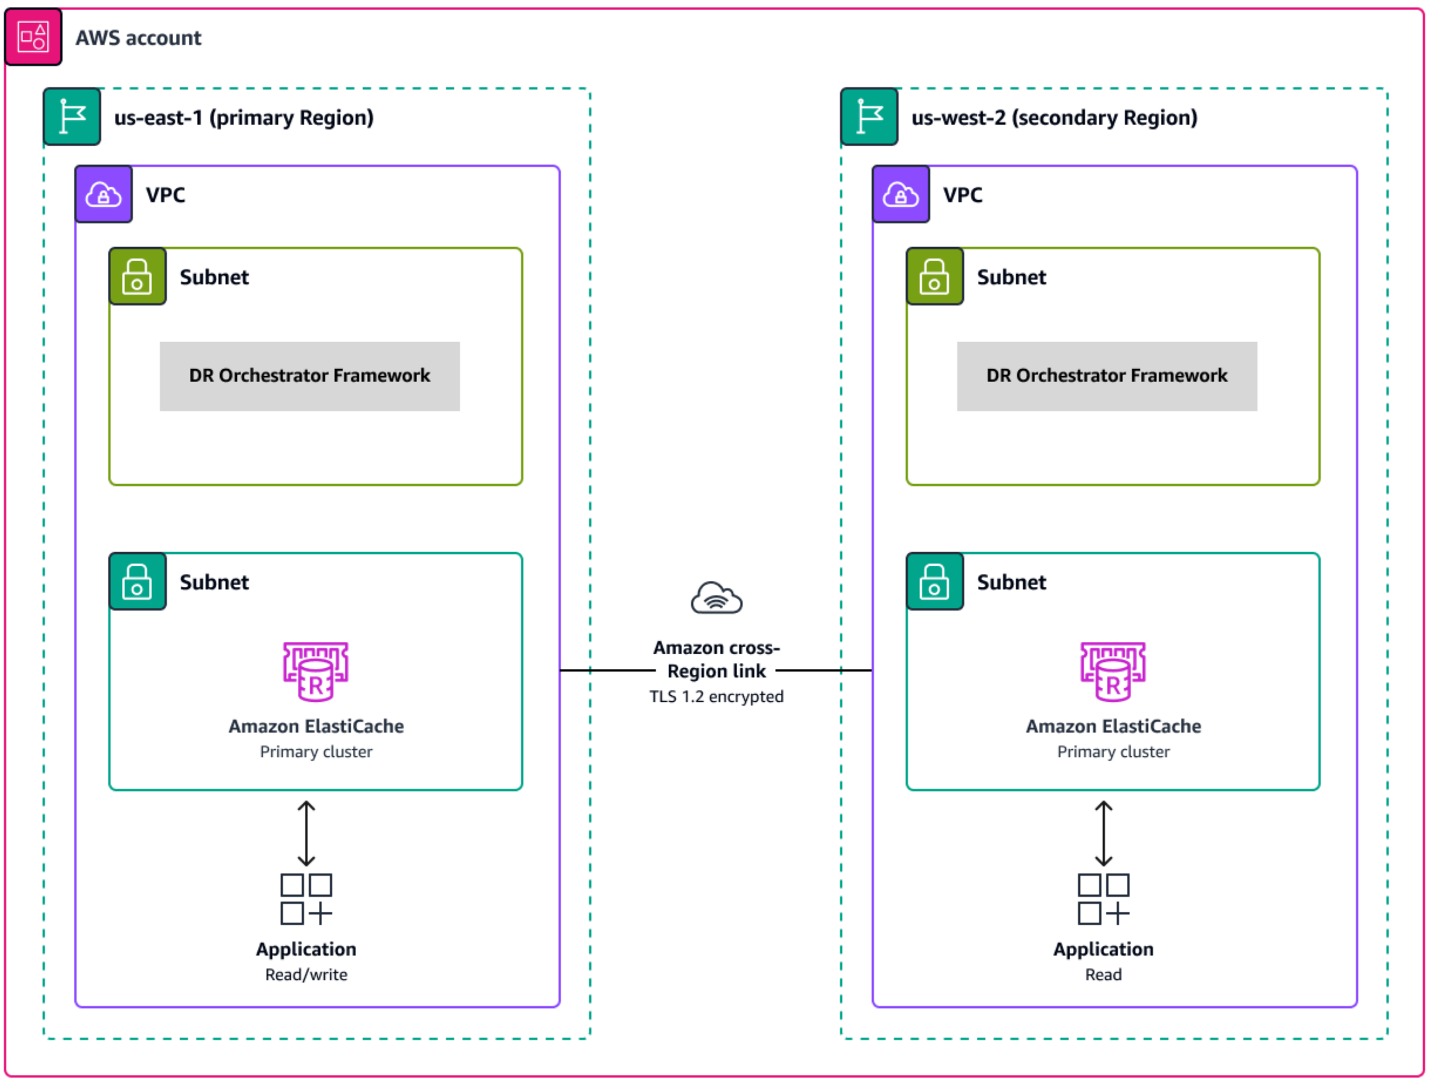
1. Asynchronous replication between the primary cluster and the secondary cluster
2. The primary DB cluster with an active-writer endpoint

3. The secondary DB cluster with an inactive-writer endpoint

ElastiCache (Redis OSS) architecture

The Amazon ElastiCache (Redis OSS) architecture includes the following resources:

- An ElastiCache (Redis OSS) global datastore created with two clusters:
  1. The primary cluster in the primary Region (`us-east-1`)
  2. The secondary cluster in the secondary Region (`us-west-2`)
- An Amazon cross-Region link with TLS 1.2 encryption between the two clusters
- DR Orchestrator Framework deployed in both primary and secondary Regions



Automation and scale

DR Orchestrator Framework is scalable and supports the failover or failback of more than one AWS database in parallel.

You can use the following payload code to fail over multiple AWS databases in your account. In this example, three AWS databases (two global databases such as Aurora MySQL-Compatible or Aurora PostgreSQL-Compatible, and one Amazon RDS for MySQL instance) fail over to the DR Region:

```
{
  "StatePayload": [
    {
      "layer": 1,
      "resources": [
        {
          "resourceType": "PlannedFailoverAurora",
          "resourceName": "Switchover (planned failover) of Amazon Aurora global
 databases (MySQL)",
          "parameters": {
            "GlobalClusterIdentifier": "!Import dr-globaldb-cluster-mysql-global-
identifier",
            "DBClusterIdentifier": "!Import dr-globaldb-cluster-mysql-cluster-
identifier"
          }
        },
        {
          "resourceType": "PlannedFailoverAurora",
          "resourceName": "Switchover (planned failover) of Amazon Aurora global
 databases (PostgreSQL)",
          "parameters": {
            "GlobalClusterIdentifier": "!Import dr-globaldb-cluster-postgres-global-
identifier",
            "DBClusterIdentifier": "!Import dr-globaldb-cluster-postgres-cluster-
identifier"
          }
        },
        {
          "resourceType": "PromoteRDSReadReplica",
          "resourceName": "Promote RDS for MySQL Read Replica",
          "parameters": {
            "RDSInstanceIdentifier": "!Import rds-mysql-instance-identifier",
            "TargetClusterIdentifier": "!Import rds-mysql-instance-global-arn"
          }
```

```
        }
      ]
    }
  ]
}
```

Tools

AWS services

- Amazon Aurora is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- Amazon ElastiCache helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud. This pattern uses Amazon ElastiCache (Redis OSS).
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, Lambda functions are used by AWS Step Functions to perform the steps.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern supports Amazon RDS for MySQL, Amazon RDS for PostgreSQL, and Amazon RDS for MariaDB.
- AWS SDK for Python (Boto3) helps you integrate your Python application, library, or script with AWS services. In this pattern, Boto3 APIs are used to communicate with the database instances or global databases.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications. In this pattern, Step Functions state machines are used to orchestrate and run the cross-Region failover and failback of the database instances or global databases.

Code repository

The code for this pattern is available in the aws-cross-region-dr-databases repository on GitHub.

Epics

Install DR Orchestrator Framework

Task	Description	Skills required
Clone the GitHub repository.	To clone the repository, run the following command: `git clone https://github.com/aws-samples/aws-cross-region-dr-databases.git`	AWS DevOps, AWS administrator

Package Lambda functions code in a .zip file archive.	Create the archive files for Lambda functions to include the DR Orchestrator Framework dependencies:
	`cd <YOUR-LOCAL-GIT-FOLDER>/DR-Orchestration-artifacts`
	
	`bash scripts/deploy-orchestrator-sh.sh`
		AWS administrator

Create S3 buckets.	S3 buckets are needed to store DR Orchestrator Framework along with your latest configuration. Create two S3 buckets, one in the primary Region (`us-east-1`), and one in the secondary Region (`us-west-2`): • `dr-orchestrator-xxxxxx-us-east-1`	AWS administrator

Task	Description	Skills required
	• `dr-orchestrator-xxxxxx-us-west-2` Replace `xxxxxx` with a random value to make the bucket names unique.	
Create subnets and security groups.	In both the primary Region (`us-east-1`) and the secondary Region (`us-west-2`), create two subnets and one security group for Lambda function deployment in your VPC: • `subnet-XXXXXXX` • `subnet-YYYYYYY` • `sg-XXXXXXXXXXXX`	AWS administrator

Task	Description	Skills required
Update the DR Orchestrator parameter files.	In the `<YOUR-LOCAL-GIT-FOLDER>/DR-Orchestration-artifacts/cloudformation` folder, update the following DR Orchestrator parameter files: • `Orchestrator-Deployer-parameters-us-east-1.json` • `Orchestrator-Deployer-parameters-us-west-2.json` Use the following parameter values, replacing x and y with the names of your resources: `[ { "ParameterKey": "TemplateStoreS3BucketName", "ParameterValue": "dr-orchestrator-xxxxxx-us-east-1" }, { "ParameterKey": "TemplateVPCId", "ParameterValue": "vpc-xxxxxx" }, {`	AWS administrator

Task	Description	Skills required

	``
	        "ParameterKey":
	 "TemplateLambdaSub
	netID1",
	        "Paramete
	rValue": "subnet-x
	xxxxx"
	    },
	    {
	        "ParameterKey":
	 "TemplateLambdaSub
	netID2",
	        "Paramete
	rValue": "subnet-y
	yyyyy"
	    },
	    {
	        "ParameterKey":
	 "TemplateLambdaSec
	urityGroupID",
	        "Paramete
	rValue": "sg-xxxxx
	xxxxx"
	    }
	]
	``	

Task	Description	Skills required
Upload the DR Orchestrator Framework code to the S3 bucket.	The code will be safer in an S3 bucket than in the local directory. Upload the `DR-Orchestration-artifacts` directory, including all files and subfolders, to the S3 buckets. To upload the code, do the following: 1. Sign in to the AWS Management Console. 2. Navigate to the Amazon S3 console. 3. Select the `dr-orchestrator-xxxxxx-us-east-1 bucket` . 4. Choose **Upload**, and then choose **Add folder**. 5. Select the `DR-Orchestration-artifacts` folder. 6. Choose **Upload**. 7. Select the `dr-orchestrator-xxxxxx-us-west-2` bucket. 8. Repeat steps 4–7.	AWS administrator

Task	Description	Skills required

Deploy DR Orchestrator Framework in the primary Region.	To deploy DR Orchestrator Framework in the primary Region (`us-east-1`), run the following commands:
	`cd <YOUR-LOCAL-GIT-FOLDER>/DR-Orchestration-artifacts/cloudformation`
	
	`aws cloudformation deploy \`
	`--region us-east-1 \`
	`--stack-name dr-orchestrator \`
	`--template-file Orchestrator-Deployer.yaml \`
	`--parameter-overrides file://Orchestrator-Deployer-parameters-us-east-1.json \`
	`--capabilities CAPABILITY_AUTO_EXPAND CAPABILITY_NAMED_IAM CAPABILITY_IAM \`
	`--disable-rollback`
		AWS administrator

Task	Description	Skills required

Deploy DR Orchestrator Framework in the secondary Region.	In the secondary Region (`us-west-2`), run the following commands:
	`cd <YOUR-LOCAL-GIT-FOLDER>/DR-Orchestration-artifacts/cloudformation`
	
	`aws cloudformation deploy \`
	`--region us-west-2 \`
	`--stack-name dr-orchestrator \`
	`--template-file Orchestrator-Deployer.yaml \`
	`--parameter-overrides file://Orchestrator-Deployer-parameters-us-west-2.json \`
	`--capabilities CAPABILITY_AUTO_EXPAND CAPABILITY_NAMED_IAM CAPABILITY_IAM \`
	`--disable-rollback`
		AWS administrator

Task	Description	Skills required
Verify the deployment.	If the AWS CloudFormation command runs successfully, it returns the following output: `Successfully created/updated stack - dr-orchestrator` Alternatively, you can navigate to the AWS CloudFormation console and verify the status of the `dr-orchestrator` stack.	AWS administrator

Create the database instances or clusters

Task	Description	Skills required
Create the database subnets and security groups.	In your VPC, create two subnets and one security group for the DB instance or global database in both the primary (`us-east-1`) and the secondary (`us-west-2`) Regions: • `subnet-XXXXXX` • `subnet-XXXXXX` • `sg-XXXXXXXXXX`	AWS administrator
Update the parameter file for the primary DB instance or cluster.	In the `<YOUR LOCAL GIT FOLDER>/App-Stack` folder, update the parameter file for the primary Region.	AWS administrator

Task	Description	Skills required
	Amazon RDS In the `RDS-MySQL-parameter-us-east-1.json` file, update `SubnetIds` and `DBSecurityGroup` with the names of resources that you created: `{ "Parameters": { "SubnetIds": "subnet-xxxxxx,subnet-xxxxxx", "DBSecurityGroup": "sg-xxxxxxxxxx", "MySqlGlobalIdentifier":"rds-mysql-instance", "InitialDatabaseName": "mysqldb", "DBPortNumber": "3789", "PrimaryRegion": "us-east-1", "SecondaryRegion": "us-west-2", "KMSKeyAliasName": "rds/rds-mysql-instance-KmsKeyId" } }`  **Amazon Aurora**  In the `Aurora-MySQL-parameter-us-east-1.json` file, update `SubnetIds` and `DBSecurit`	

Task	Description	Skills required
	`yGroup` with the names of resources that you created: `{ "Parameters": { "SubnetIds": "subnet1-xxxxxx,subnet2-xxxxxx", "DBSecurityGroup": "sg-xxxxxxxxxx", "GlobalClusterIdentifier":"dr-globaldb-cluster-mysql", "DBClusterName":"dbcluster-01", "SourceDBClusterName":"dbcluster-02", "DBPortNumber": "3787", "DBInstanceClass": "db.r5.large", "InitialDatabaseName": "sampledb", "PrimaryRegion": "us-east-1", "SecondaryRegion": "us-west-2", "KMSKeyAliasName": "rds/dr-globaldb-cluster-mysql-KmsKeyId" } }` **Amazon ElastiCache (Redis OSS)** In the `ElastiCache-parameter-us-east-1.json` file, update	

Task	Description	Skills required
	`SubnetIds` and `DBSecurityGroup` with the names of resources that you created. `{ "Parameters": { "CacheNodeType": "cache.m5.large", "DBSecurityGroup": "sg-xxxxxxxxxx", "SubnetIds": "subnet-xxxxxx,subnet-xxxxxx", "EngineVersion": "5.0.6", "GlobalReplicationGroupIdSuffix": "demo-redis-global-datastore", "NumReplicas": "1", "NumShards": "1", "ReplicationGroupId": "demo-redis-cluster", "DBPortNumber": "3788", "TransitEncryption": "true", "KMSKeyAliasName": "elasticache/demo-redis-global-datastore-KmsKeyId", "PrimaryRegion": "us-east-1", "SecondaryRegion": "us-west-2" } }`	

Task	Description	Skills required

Deploy your DB instance or cluster in the primary Region.	To deploy your instance or cluster in the primary Region (`us-east-1`), run the following commands based on your database engine.
	
	Amazon RDS
	
	`cd <YOUR-LOCAL-GIT-FOLDER>/App-Stack`
	
	`aws cloudformation deploy \`
	`--region us-east-1 \`
	`--stack-name rds-mysql-app-stack \`
	`--template-file RDS-MySQL-Primary.yaml \`
	`--parameter-overrides file://RDS-MySQL-parameter-us-east-1.json \`
	`--capabilities CAPABILITY_AUTO_EXPAND CAPABILITY_NAMED_IAM CAPABILITY_IAM \`
	`--disable-rollback`
	
	Amazon Aurora
	
	`cd <YOUR-LOCAL-GIT-FOLDER>/App-Stack`
	
	`aws cloudformation deploy \`
	`--region us-east-1 \`
	`--stack-name aurora-mysql-app-stack \`
		AWS administrator

Task	Description	Skills required
	``` --template-file Aurora- MySQL-Primary.yaml \ --parameter-overrides file://Aurora-MySQ L-parameter-us-eas t-1.json \ --capabilities CAPABILITY_AUTO_EX PAND CAPABILIT Y_NAMED_IAM CAPABILIT Y_IAM \ --disable-rollback ``` **Amazon ElastiCache (Redis OSS)** ``` cd <YOUR-LOCAL-GIT-FO LDER>/App-Stack aws cloudformation deploy \ --region us-east-1 -- stack-name elasticac he-ds-app-stack \ --template-file ElastiCache-Primar y.yaml \ --parameter-overrides file://ElastiCache -parameter-us-east -1.json \ --capabilities CAPABILITY_AUTO_EX PAND CAPABILIT Y_NAMED_IAM CAPABILIT Y_IAM \ --disable-rollback ```	

Task	Description	Skills required
	Verify that the AWS CloudFormation resources deployed successfully.	

Task	Description	Skills required

Update the parameter file for the secondary DB instance or cluster.	In the `<YOUR LOCAL GIT FOLDER>/App-Stack` folder, update the parameter file for the secondary Region.
	
	Amazon RDS
	
	In the `RDS-MySQL-parameter-us-west-2.json` file, update `SubnetIDs` and `DBSecurityGroup` with the names of resources that you created. Update the `PrimaryRegionKMSKeyArn` with the value of `MySQLKmsKeyId` taken from the **Outputs** section of the AWS CloudFormation stack for the primary DB instance:
	
	`{`
	`  "Parameters": {`
	`    "SubnetIds":`
	` "subnet-aaaaaaaaa,`
	`subnet-bbbbbbbbb",`
	`    "DBSecurityGroup":`
	` "sg-cccccccccc",`
	`    "MySqlGlobalIdenti`
	`fier":"rds-mysql-i`
	`nstance",`
	`    "InitialDatabaseNa`
	`me": "mysqldb",`
	`    "DBPortNumber":`
	` "3789",`
	`    "PrimaryRegion":`
	` "us-east-1",`
		AWS administrator

Task	Description	Skills required

	``
	    "SecondaryRegion":
	  "us-west-2",
	    "KMSKeyAliasName":
	  "rds/rds-mysql-ins
	tance-KmsKeyId",
	    "PrimaryRegionKMSK
	eyArn":"arn:aws:km
	s:us-east-1:xxxxxx
	xxx:key/mrk-xxxxxx
	xxxxxxxxxxxxxxx"
	  }
	}
	``
	
	Amazon Aurora
	
	In the `Aurora-MySQL-parameter-us-west-2.json` file, update `SubnetIDs` and `DBSecurityGroup` with the names of resources you created. Update the `PrimaryRegionKMSKeyArn` with the value of `AuroraKmsKeyId` taken from the **Outputs** section of the AWS CloudFormation stack for the primary DB instance:
	
	``
	{
	  "Parameters": {
	    "SubnetIds":
	  "subnet1-aaaaaaaaa
	,subnet2-bbbbbbbbb",
	    "DBSecurityGroup":
	  "sg-cccccccccc",
	    "GlobalClusterIden
	tifier":"dr-globaldb-
	cluster-mysql",
	``	

Task	Description	Skills required

	``
	    "DBClusterName":"dbcluster-01",
	    "SourceDBClusterName":"dbcluster-02",
	    "DBPortNumber": "3787",

Automatically back up SAP HANA databases using Systems Manager and EventBridge

Ambarish Satarkar and Gaurav Rath, Amazon Web Services

Summary

This pattern describes how to automate SAP HANA database backups using AWS Systems Manager, Amazon EventBridge, Amazon Simple Storage Service (Amazon S3), and AWS Backint Agent for SAP HANA.

This pattern provides a shell script-based approach using the `BACKUP DATA` command and removes the need to maintain scripts and job configurations for each operating system (OS) instance across numerous systems.

Note: As of April 2023, AWS Backup announced support for SAP HANA databases on Amazon Elastic Compute Cloud (Amazon EC2). For more information, see [SAP HANA databases on Amazon EC2 instances backup](#).

Based on your organization’s needs, you can use the AWS Backup service to automatically back up your SAP HANA databases or you can use this pattern.

Prerequisites and limitations

Prerequisites

- An existing SAP HANA instance with a supported release in running state on a managed Amazon Elastic Compute Cloud (Amazon EC2) instance that is configured for Systems Manager
- Systems Manager Agent (SSM Agent) 2.3.274.0 or later installed
- An S3 bucket that doesn’t have public access enabled
- An `hdbuserstore` key named `SYSTEM`
- An AWS Identity and Access Management (IAM) role for the Automation runbook to run on schedule
- `AmazonSSMManagedInstanceCore` and `ssm:StartAutomationExecution` policies are attached to Systems Manager Automation service role.

Limitations

- AWS Backint Agent for SAP HANA doesn't support deduplication.
- AWS Backint Agent for SAP HANA doesn't support data compression.

Product versions

AWS Backint Agent is supported on the following operating systems:

- SUSE Linux Enterprise Server
- SUSE Linux Enterprise Server for SAP
- Red Hat Enterprise Linux for SAP

AWS Backint Agent supports the following databases:

- SAP HANA 1.0 SP12 (single node and multiple nodes)
- SAP HANA 2.0 and later (single node and multiple nodes)

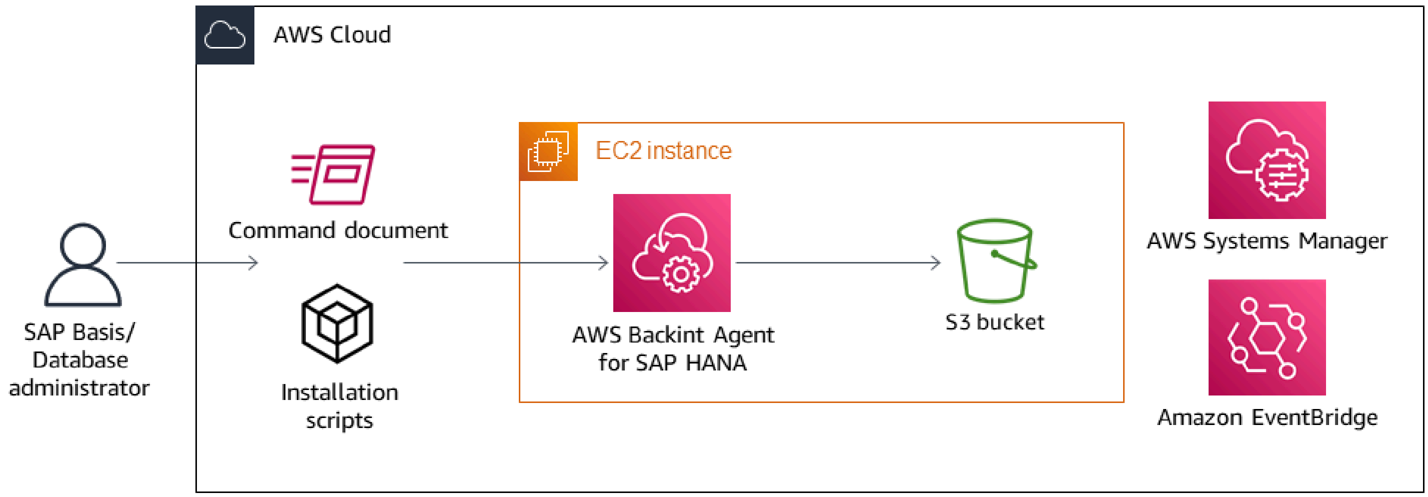
Architecture

Target technology stack

- AWS Backint Agent
- Amazon S3
- AWS Systems Manager
- Amazon EventBridge
- SAP HANA

Target architecture

The following diagram shows the installation scripts that install AWS Backint Agent, the S3 bucket, and Systems Manager and EventBridge, which use a Command document to schedule regular backups.



Automation and scale

- Multiple AWS Backint Agents can be installed by using a Systems Manager Automation runbook.
- Each run of the Systems Manager runbook can scale to *n* number of SAP HANA instances, based on target selection.
- EventBridge can automate SAP HANA backups.

Tools

- [AWS Backint Agent for SAP HANA](#) is a standalone application that integrates with your existing workflows to back up your SAP HANA database to an S3 bucket that you specify in the configuration file. AWS Backint Agent supports full, incremental, and differential backups of SAP HANA databases. It runs on an SAP HANA database server, where backups and catalogs are transferred from the SAP HANA database to the AWS Backint Agent.
- [Amazon EventBridge](#) is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.
- [Amazon Simple Storage Service (Amazon S3)](#) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- [AWS Systems Manager](#) helps you to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources.

Code

The code for this pattern is available in the aws-backint-automated-backup GitHub repository.

Epics

Create an hdbuserstore key SYSTEM

Task	Description	Skills required

Create an hdbuserstore key.	1. Navigate to `/usr/sap/<SID>/HDB<Inst No>/exe`.
	2. Run the following command, with XX as the SAP HANA database instance number.
	`hdbuserstore -i set SYSTEM <hostname>:3XX13@SYSTEMDB SYSTEM`
	For example, for an SAP HANA host `saphanadb` with instance number `00`, run the following command.
	`hdbuserstore -i set SYSTEM saphanadb:30013@SYSTEMDB SYSTEM`
		AWS administrator, SAP HANA Administrator

Install AWS Backint Agent

Task	Description	Skills required
Install AWS Backint Agent.	Follow the instructions in [Install and configure AWS Backint Agent for SAP HANA]() in the AWS Backint Agent documentation.	AWS administrator, SAP HANA administrator

Create the Systems Manager Command document

Task	Description	Skills required
Create the Systems Manager Command document.	1. Sign in to the AWS Management Console and open the AWS Systems Manager Console. 2. Choose **Documents,** and choose **Owned by me**. 3. Confirm that you are in the same AWS Region as your SAP HANA database. 4. Choose **Create document**, **Command or session** to create your document. 5. Use a unique and descripti ve name, with no spaces (for example, **SAP HANA-Backup**). 6. Make sure that **Document type** is set to **Command document**.	AWS administrator, SAP HANA administrator

Task	Description	Skills required
	7. Under the **Content** header, there is some sample code. Make sure that you choose the **JSON** code type, and replace the code with the code from the `HDB_Backup_SSM_Document.json` file from the [GitHub repository](https://github.com). 8. Choose **Create document**. 9. Check your document in the **Owned by me** section.	

Schedule backups on a regular frequency

Task	Description	Skills required
Schedule regular backups using Amazon EventBridge.	1. Open the Amazon EventBridge console, choose **Rules**, and choose **Create rule**. 2. On the **Define rule detail** screen, enter a unique name and description for your rule, and use the default event bus. 3. Under **Rule type**, choose **Schedule**, and choose **Next**. 4. On then **Define schedule** screen, choose the appropriate schedule pattern and cron or rate	AWS administrator, SAP HANA administrator

Task	Description	Skills required
	expression based on the required frequency. 5. On the **Select targets** screen, for **Target type**, choose **AWS service**. Under **Select a target**, choose **Systems Manager Run Command**. 6. Choose the document that you created earlier. 7. Under **Target key** and **Target value**, provide the instance ID. You can use tag names and tag values to add multiple instances. 8. Under **Configure automation parameter s**, choose **Constant** for incremental or different ial backups. If you want full backup, choose **No Parameters**. 9. Choose whether to create a new role or to use an existing role. If you use an existing role, make sure that it has the policies required to invoke the target. 10. Keep the default additional settings, and choose **Next**. 11. The **Configure tags** screen is optional. Choose **next**.	

Task	Description	Skills required
	12.On the **Review and create** screen, review the rule settings, and choose **Create**. The rule should be successfully created. You can verify backup success from the S3 bucket path. `s3:/<your_bucket_name>/<target folder>/<SID>/usr/sap/<SID>/SYS/global/hdb/backint/DB_<SID>/` You can also verify backups from the SAP HANA backup catalog.

Automatically generate a PynamoDB model and CRUD functions for Amazon DynamoDB by using a Python application

Vijit Vashishtha, Dheeraj Alimchandani, and Dhananjay Karanjkar, Amazon Web Services

Summary

It's common to require entities and create, read, update, and delete (CRUD) operations functions to efficiently perform Amazon DynamoDB database operations. PynamoDB is a Python-based interface that supports Python 3. It also provides features such as support for Amazon DynamoDB transactions, automatic attribute value serialization and deserialization, and compatibility with common Python frameworks, such as Flask and Django. This pattern helps developers working with Python and DynamoDB by providing a library that streamlines the automatic creation of PynamoDB models and CRUD operation functions. While it generates essential CRUD functions for database tables, it can also reverse engineer PynamoDB models and CRUD functions from Amazon DynamoDB tables. This pattern is designed to simplify database operations by using a Python-based application.

The following are the key features of this solution:

- **JSON schema to PynamoDB model** – Automatically generate PynamoDB models in Python by importing a JSON schema file.
- **CRUD function generation** – Automatically generate functions to perform CRUD operations on DynamoDB tables.
- **Reverse engineering from DynamoDB** – Use PynamoDB object-relational mapping (ORM) to reverse engineer PynamoDB models and CRUD functions for existing Amazon DynamoDB tables.

Prerequisites and limitations

Prerequisites

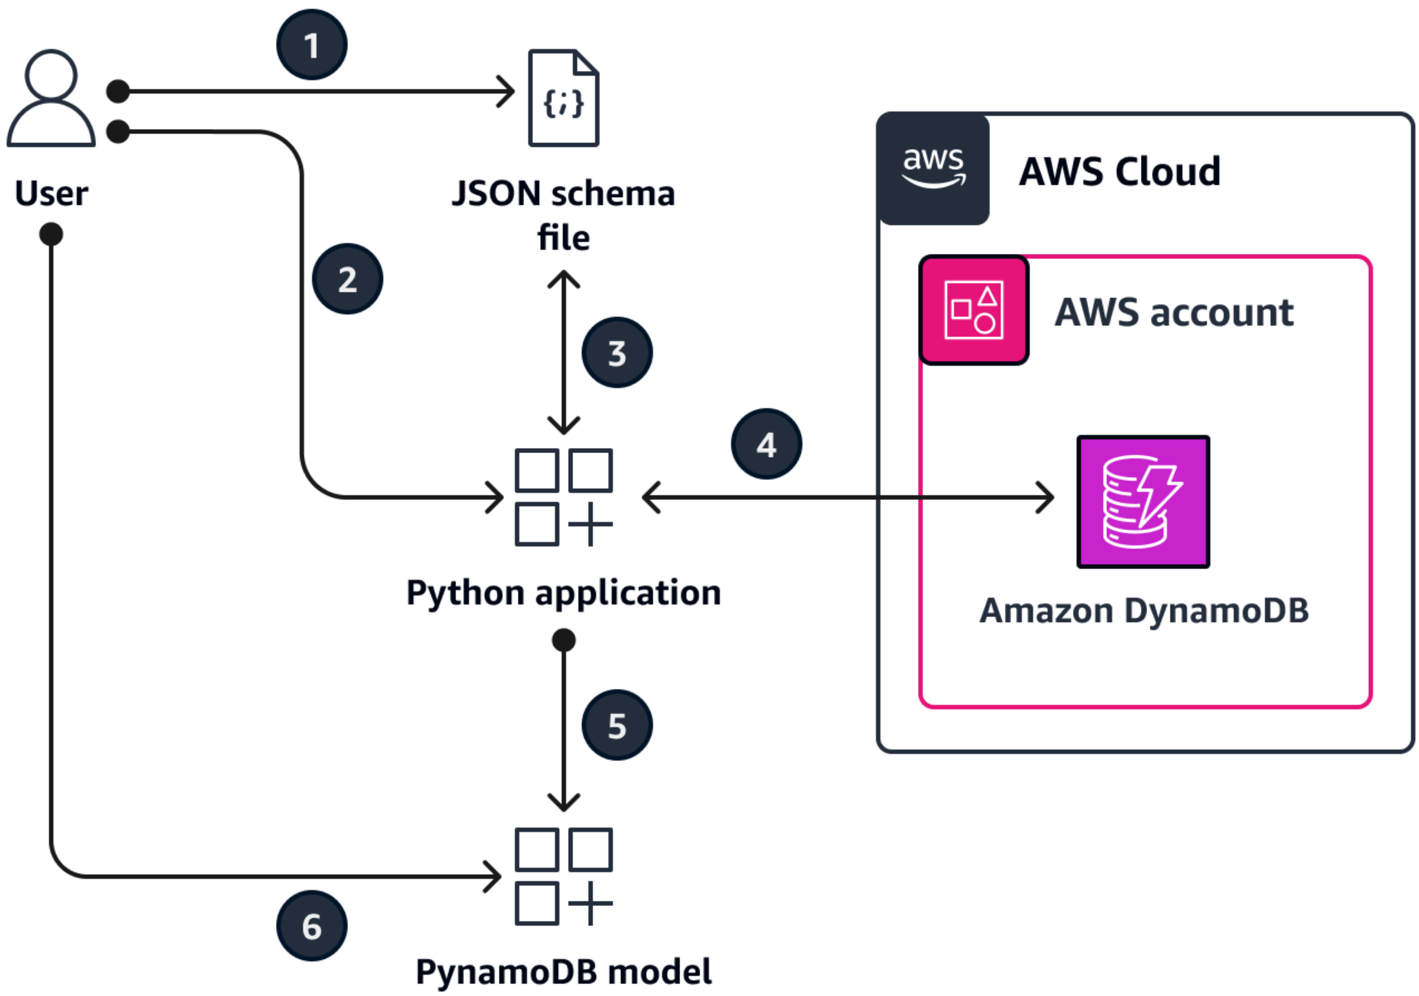
- An active AWS account
- Python version 3.8 or later, downloaded and installed
- Jinja2 version 3.1.2 or later, downloaded and installed
- Amazon DynamoDB tables for which you want to generate ORM
- AWS Command Line Interface (AWS CLI), installed and configured
- PynamoDB version 5.4.1 or later, installed

Architecture

Target technology stack

- JSON script
- Python application
- PynamoDB model
- Amazon DynamoDB database instance

Target architecture



1. You create an input JSON schema file. This JSON schema file represents the attributes of the respective DynamoDB tables that you want to create PynamoDB models from and CRUD functions for. It contains the following three important keys:
   - `name` –The name of the target DynamoDB table.

  - `region` – The AWS Region where the table is hosted
  - `attributes` – The attributes that are part of the target table, such as the partition key (also known as a *hash attribute*), sort key, local secondary indexes, global secondary indexes, and any non-key attributes. This tool expects the input schema to only provide the non-key attributes as the application fetches the key attributes directly from the target table. For an example of how to specify attributes in the JSON schema file, see the Additional information section of this pattern.

2. Run the Python application and provide the JSON schema file as an input.
3. The Python application reads the JSON schema file.
4. The Python application connects to the DynamoDB tables to derive the schema and data types. The application runs the describe_table operation and fetches the key and index attributes for the table.
5. The Python application combines the attributes from the JSON schema file and DynamoDB table. It uses the Jinja template engine to generate a PynamoDB model and corresponding CRUD functions.
6. You access the PynamoDB model to perform CRUD operations on the DynamoDB table.

Tools

AWS services

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

Other tools

- Jinja is an extensible templating engine that compiles templates into optimized Python code. This pattern uses Jinja to to generate dynamic content by embedding placeholders and logic within templates.
- PynamoDB is a Python-based interface for Amazon DynamoDB.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub [Auto-generate PynamoDB models and CRUD functions]() repository. The repository is divided into two main parts: the controller package and the templates.

Controller package

The controller Python package contains the main application logic that helps generate the PynamoDB model and the CRUD functions. It contains the following:

- `input_json_validator.py` – This Python scripts validates the input JSON schema file and creates the Python objects that contain the list of target DynamoDB tables and the required attributes for each.
- `dynamo_connection.py` – This script establishes a connection to the DynamoDB table and uses the `describe_table` operation to extract the attributes that are necessary to create the PynamoDB model.
- `generate_model.py` – This script contains a Python class `GenerateModel` that creates the PynamoDB model based on the input JSON schema file and the `describe_table` operation.
- `generate_crud.py` – For the DynamoDB tables that are defined in the JSON schema file, this script uses the `GenerateCrud` operation to create the Python classes.

Templates

This Python directory contains the following Jinja templates:

- `model.jinja` – This Jinja template contains the template expression for generating the PynamoDB model script.
- `crud.jinja` – This Jinja template contains the template expression for generating the CRUD functions script.

Epics

Set up the environment

Task	Description	Skills required
Clone the repository.	Enter the following command to clone the [Auto-generate]()	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>PynamoDB models and CRUD functions repository.
<pre><code>git clone https://github.com/aws-samples/amazon-reverse-engineer-dynamodb.git</code></pre></td><td></td></tr>
<tr><td>Set up the Python environment.</td><td>1. Navigate into the top-level directory in the cloned repository.
<pre><code>cd amazon-reverse-engineer-dynamodb</code></pre>2. Enter the following command to install the required libraries and packages.
<pre><code>pip install -r requirements.txt</code></pre></td><td>App developer</td></tr>
</table>

Generate the PynamoDB model and CRUD functions

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Modify the JSON schema file.</td><td>1. Navigate into the top-level directory in the cloned repository.
<pre><code>cd amazon-reverse-engineer-dynamodb</code></pre>2. Open the <code>test.json</code> file in your preferred editor.</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
	You can use this file as a reference to create your own JSON schema file, or you can update the values in this file to match your environment. 3. Modify the name, AWS Region, and attributes values for your target DynamoDB tables. **Note** If you define a table that does not exist in the JSON schema file, this solution does not generate models or CRUD functions for that table. 4. Save and close the `test.json` file. We recommend that you save this file with a new name.	

Task	Description	Skills required
Run the Python application.	Enter the following command to generate the PynamoDB models and CRUD functions, where `<input_schema.json>` is the name of your JSON schema file. `python main.py --file <input_schema.json>`	App developer

Verify the PynamoDB model and CRUD functions

Task	Description	Skills required
Verify the generated PynamoDB model.	1. In the top-level directory of the cloned repository, enter the following command to navigate into the `models` repository. `cd models` 2. By default, this solution names the PynamoDB model file `demo_model.py`. Validate that this file is present.	App developer
Verify the generated CRUD functions.	1. In the top-level directory of the cloned repository, enter the following command to navigate into the `crud` repository.	App developer

Task	Description	Skills required
	`cd crud` 2. By default, this solution names the script `demo_crud.py` . Validate that this file is present. 3. Use the Python classes in the `demo_crud.py` file to perform a CRUD operation on the target DynamoDB table. Confirm that the operation completed successfully.

Block public access to Amazon RDS by using Cloud Custodian

abhay kumar and Dwarika Patra, Amazon Web Services

Summary

Many organizations run their workloads and services on multiple cloud vendors. In these hybrid cloud environments, the cloud infrastructure needs strict cloud governance, in addition to the security provided by the individual cloud providers. A cloud database such as Amazon Relational Database Service (Amazon RDS) is one important service that must be monitored for any access and permission vulnerabilities. Although you can restrict access to the Amazon RDS database by configuring a security group, you can add a second layer of protection to prohibit actions such as public access. Blocking public access helps you with General Data Protection Regulation (GDPR), Health Insurance Portability and Accountability Act (HIPAA), National Institute of Standards and Technology (NIST), and Payment Card Industry Data Security Standard (PCI DSS) compliance.

Cloud Custodian is an open-source rules engine that you can use to enforce access restrictions for Amazon Web Services (AWS) resources such as Amazon RDS. With Cloud Custodian, you can set rules that validate the environment against defined security and compliance standards. You can use Cloud Custodian to manage your cloud environments by helping to ensure compliance with security policies, tag policies, and garbage collection of unused resources and cost management. With Cloud Custodian, you can use a single interface for implementing governance in a hybrid cloud environment. For example, you could use the Cloud Custodian interface to interact with AWS and Microsoft Azure, reducing the effort of working with mechanisms such as AWS Config, AWS security groups, and Azure policies.

This pattern provides instructions for using Cloud Custodian on AWS to enforce restriction of public accessibility on Amazon RDS instances.

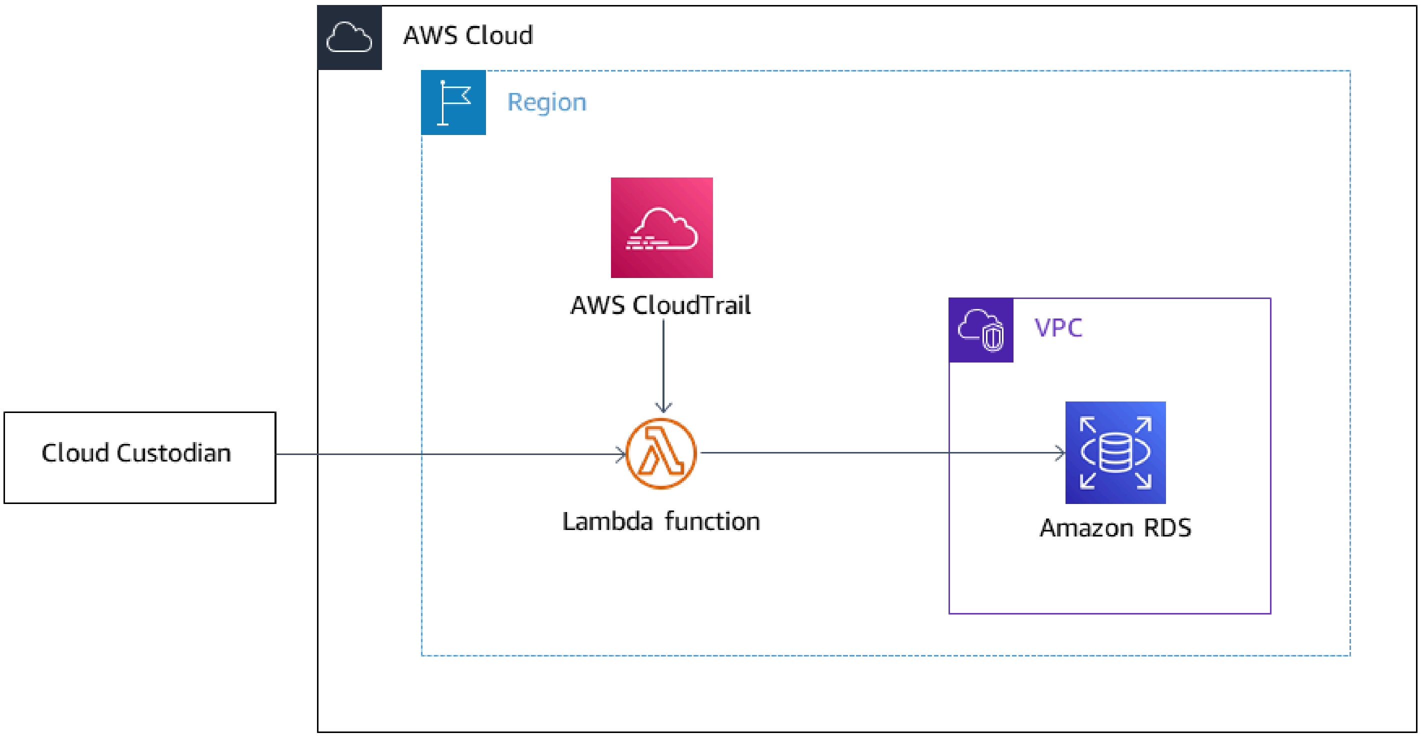
Prerequisites and limitations

Prerequisites

- An active AWS account
- [A key pair](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/ec2-key-pairs.html)
- AWS Lambda installed

Architecture

The following diagram shows Cloud Custodian deploying the policy to AWS Lambda, AWS CloudTrail initiating the `CreateDBInstance` event, and the Lambda function setting `PubliclyAccessible` to false on Amazon RDS.



Tools

AWS services

- [AWS CloudTrail](https://docs.aws.amazon.com/awscloudtrail/latest/userguide/cloudtrail-user-guide.html) helps you audit the governance, compliance, and operational risk of your AWS account.
- [AWS Command Line Interface (AWS CLI)](https://docs.aws.amazon.com/cli/latest/userguide/cli-chap-welcome.html) is an open-source tool that helps you interact with AWS services through commands in your command line shell.
- [AWS Identity and Access Management (IAM)](https://docs.aws.amazon.com/IAM/latest/UserGuide/introduction.html) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](https://docs.aws.amazon.com/lambda/latest/dg/welcome.html) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Relational Database Service (Amazon RDS)](https://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/Welcome.html) helps you set up, operate, and scale a relational database in the AWS Cloud.

Other tools

- Cloud Custodian unifies the tools and scripts that many organizations use to manage their public cloud accounts into one open source tool. It uses a stateless rules engine for policy definition and enforcement, with metrics, structured outputs, and detailed reporting for cloud infrastructure. It integrates tightly with a serverless runtime to provide real-time remediation and response with low operational overhead.

Epics

Set up the AWS CLI

Task	Description	Skills required
Install the AWS CLI.	To install the AWS CLI, follow the instructions in the AWS documentation.	AWS administrator

Set up AWS credentials.	Configure the settings that the AWS CLI uses to interact with AWS, including the AWS Region and the output format that you want to use.
	
	`$>aws configure`
	`AWS Access Key ID [None]: <your_access_key_id>`
	`AWS Secret Access Key [None]: <your_secret_access_key>`
	`Default region name [None]:`
	`Default output format [None]:`
	
	For more information, see the AWS documentation.
		AWS administrator

Task	Description	Skills required
Create an IAM role.	To create an IAM role with the Lambda execution role, run the following command. `aws iam create-role --role-name lambda-ex --assume-role-policy-document '{"Version": "2012-10-17","Statement": [{ "Effect": "Allow", "Principal": {"Service": "lambda.amazonaws.com"}, "Action": "sts:AssumeRole"}]}`	AWS DevOps

Set up Cloud Custodian

Task	Description	Skills required
Install Cloud Custodian.	To install Cloud Custodian for your operating system and environment, follow the instructions in the Cloud Custodian documentation.	DevOps engineer
Check the Cloud Custodian schema.	To see the complete list of Amazon RDS resources against which you can run policies, use the following command. `custodian schema aws.rds`	DevOps engineer
Create the Cloud Custodian policy.	Save the code that's under *Cloud Custodian policy file*	DevOps engineer

Task	Description	Skills required
	in the Additional information section using a YAML extension.	
Define Cloud Custodian actions to change the publicly accessible flag.	1. Locate the custodian code (for example, `/Users/abcd/custodian/lib/python3.9/site-packages/c7n/resources/rds.py`). 2. Locate the `RDSSetPublicAvailability` class in `rds.py`, and modify this class by using the code that's under *c7n resources rds.py file* in the Additional information section.	DevOps engineer
Perform a dry run.	(Optional) To check which resources are identified by the policy without running any actions on the resources, use the following command. `custodian run -dryrun <policy_name>.yaml -s <output_directory>`	DevOps engineer

Deploy the policy

Task	Description	Skills required
Deploy the policy by using Lambda.	To create the Lambda function that will run the	DevOps engineer

Task	Description	Skills required
	policy, use the following command. ```custodian run -s policy.yaml``` This policy will then be initiated by the AWS CloudTrail `CreateDBInstance` event. As a result, AWS Lambda will set the publicly accessible flag to `false` for instances that match the criteria.

 class RDSSetPublicAvailability(BaseAction):

     schema = type_schema(
         "set-public-access",
         state={'type': 'boolean'})
     permissions = ('rds:ModifyDBInstance',)

     def set_accessibility(self, r):
         client = local_session(self.manager.session_factory).client('rds')
         waiter = client.get_waiter('db_instance_available')
         waiter.wait(DBInstanceIdentifier=r['DBInstanceIdentifier'])
         client.modify_db_instance(
             DBInstanceIdentifier=r['DBInstanceIdentifier'],
             PubliclyAccessible=self.data.get('state', False))

     def process(self, rds):
         with self.executor_factory(max_workers=2) as w:
             futures = {w.submit(self.set_accessibility, r): r for r in rds}
             for f in as_completed(futures):
                 if f.exception():
                     self.log.error(
                         "Exception setting public access on %s  \n %s",
                         futures[f]['DBInstanceIdentifier'], f.exception())
         return rds
```

Security Hub integration

Cloud Custodian can be integrated with AWS Security Hub to send security findings and attempt remediation actions. For more information, see Announcing Cloud Custodian Integration with AWS Security Hub.

Configure cross-account access to Amazon DynamoDB

Shashi Dalmia, Imhoertha Ojior, and Esteban Serna Parra, Amazon Web Services

Summary

This pattern explains the steps for configuring cross-account access to Amazon DynamoDB by using resource-based policies. For workloads that use DynamoDB, it's becoming more common to use workload isolation strategies to minimize security threats and to meet compliance requirements. Implementing workload isolation strategies often requires cross-account and cross-Region access to DynamoDB resources by using AWS Identity and Access Management (IAM) identity-based policies. This involves setting IAM permissions and establishing a trust relationship between the AWS accounts.

Resource-based policies for DynamoDB greatly simplify the security posture for cross-account workloads. This pattern provides steps and sample code to demonstrate how you can configure AWS Lambda functions in one AWS account to write data to a DynamoDB database table in a different account.

Prerequisites and limitations

Prerequisites

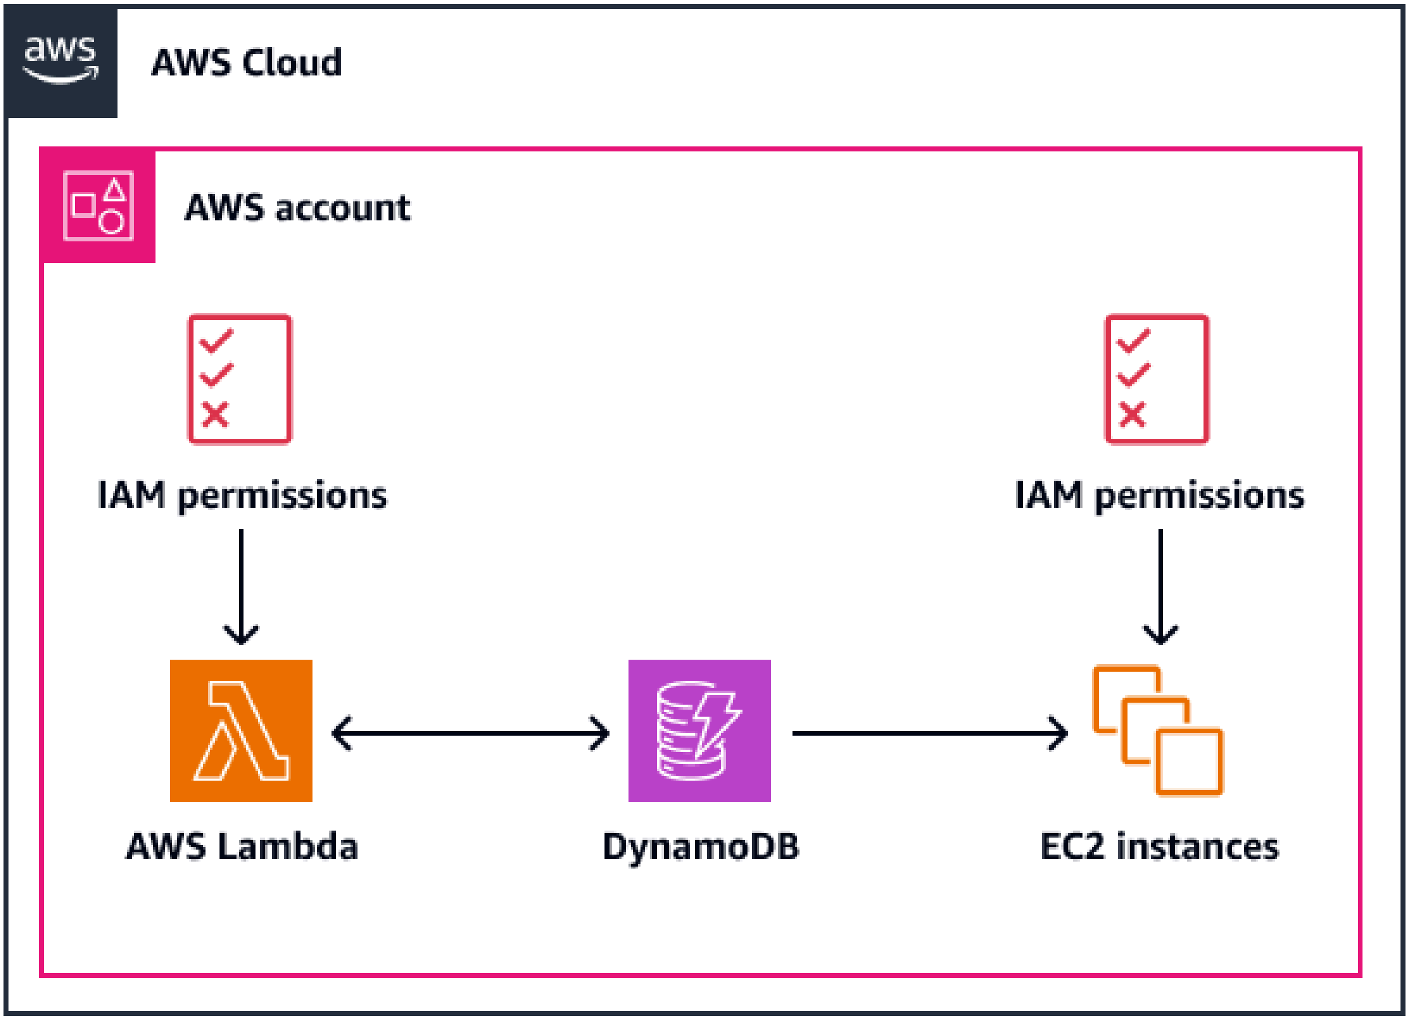
- Two active AWS accounts. This pattern refers to these accounts as *Account A* and *Account B*.
- AWS Command Line Interface (AWS CLI) installed and configured to access Account A, to create the DynamoDB table. The other steps in this pattern provide instructions for using the IAM, DynamoDB, and Lambda consoles. If you're planning to use AWS CLI instead, configure it to access both accounts.

Limitations

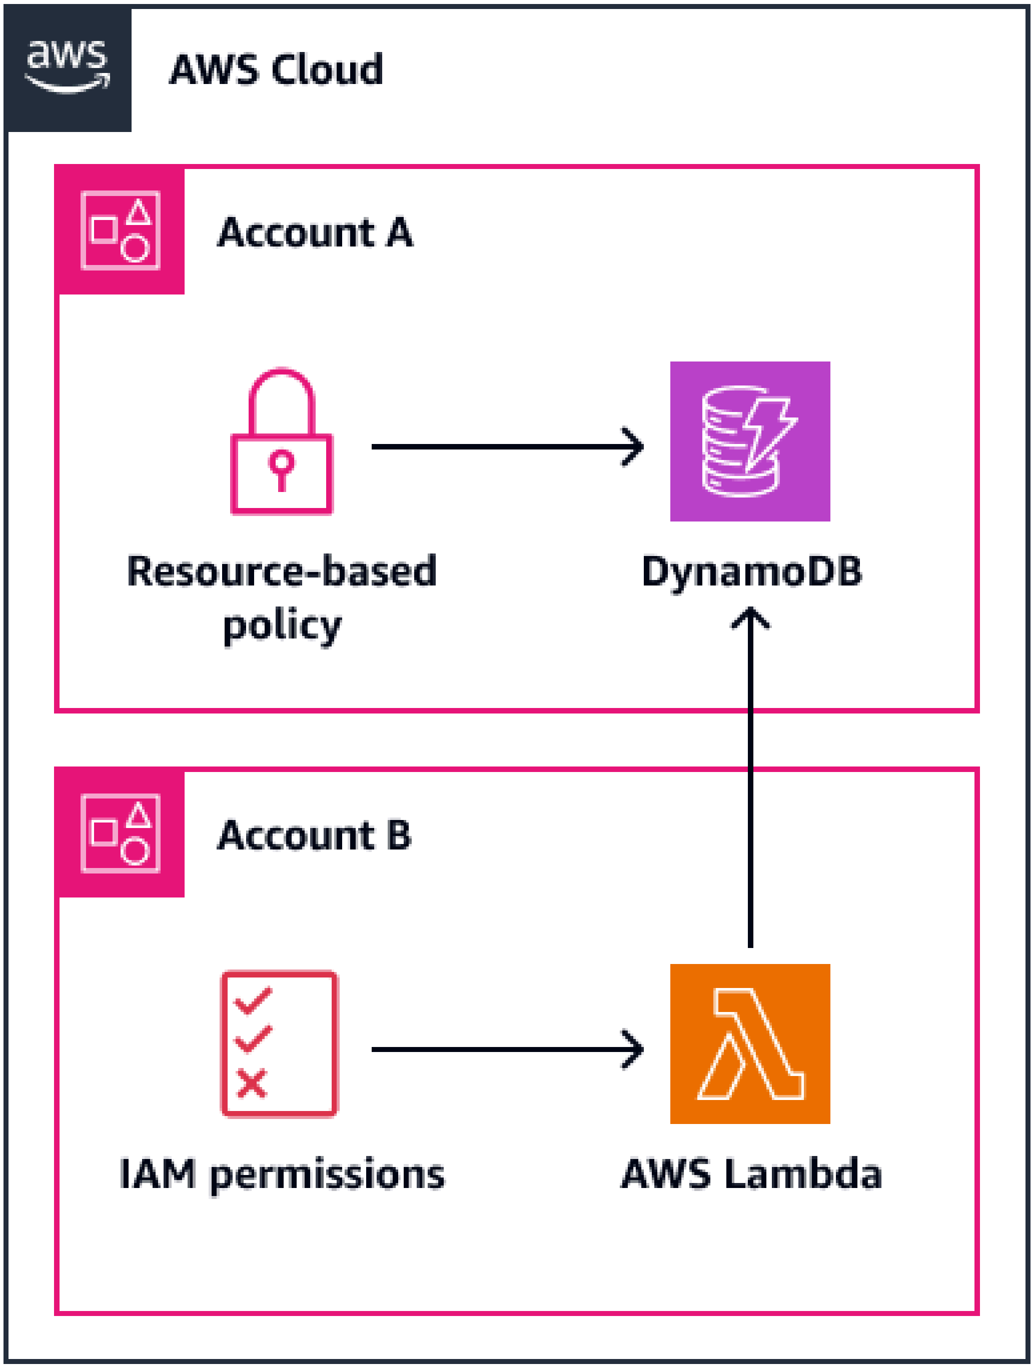
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

The following diagram shows a single-account architecture. AWS Lambda, Amazon Elastic Compute Cloud (Amazon EC2), and DynamoDB are all in the same account. In this scenario, Lambda functions and Amazon EC2 instances can access DynamoDB. To grant access to the DynamoDB table, you can create an identity-based policy in IAM, or you can create a resource-based policy in DynamoDB.



The following diagram shows a multi-account architecture. If resources in one AWS account require access to a DynamoDB table in a different account, you need to set up a resource-based policy in DynamoDB to grant the required access. For example, in the following diagram, access to the DynamoDB table in Account A is granted to a Lambda function in Account B by using a resource-based policy.



This pattern describes cross-account access between Lambda and DynamoDB. You can use similar steps for other AWS services if the appropriate permissions are configured on both accounts. For example, if you want to provide a Lambda function access to an Amazon Simple Storage Service (Amazon S3) bucket in Account A, you can create a [resource-based policy] in Amazon S3 and add the permissions to the [Lambda execution role] in Account B.

Tools

AWS services

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Code

This pattern includes sample code in the Additional information section to show how you can configure a Lambda function in Account B to write to the DynamoDB table in Account A. The code is provided only for illustration and testing purposes. If you're implementing this pattern in a production environment, use the code as a reference, and customize it for your own environment.

Best practices

- Follow the best practices for resource-based policies in the DynamoDB documentation.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Create an IAM policy and role for the Lambda function in Account B

Task	Description	Skills required
Create a policy in Account B.	This IAM policy allows the PutItem action for a DynamoDB table in Account A.	General AWS

Task	Description	Skills required

	1. Sign in to Account B in the AWS Management Console.
	2. Open the [IAM console](https://console.aws.amazon.com/iam/).
	3. In the navigation pane, choose **Policies**, and then choose **Create policy**.
	4. On the **Specify permissions** page, for the policy editor, select **JSON**.
	5. Enter the following policy.
	<pre>{
	  "Version": "2012-10-17",
	  "Statement": [
	    {
	      "Sid": "Statement1",
	      "Effect": "Allow",
	      "Action": "dynamodb:PutItem",
	      "Resource": "arn:aws:dynamodb:<Region>:<Account-A-ID>:table/Table-Account-A"
	    }
	  ]
	}</pre>6. Replace `<Region>` and `<Account-A-ID>` with your values, and then choose **Next**.
	7. For **Policy name**, enter a unique name for your	

Task	Description	Skills required
	policy, such as `DynamoDB-PutItem-Policy` . 8. (Optional) Add a policy description. 9. Choose **Create policy**.	

Task	Description	Skills required
Create a role in Account B.	The Lambda function in Account B uses this IAM role to access the DynamoDB table in Account A. 1. Open the [IAM console](https://console.aws.amazon.com/iam/). 2. In the navigation pane, choose **Roles**, and then choose **Create role**. 3. For **Select trusted entity**, choose **AWS service**. 4. In the **Use case** section, choose **Lambda**. 5. Choose **Next: Permissions**. 6. In the **Filter policies** box, enter **DynamoDB**. 7. In the list of DynamoDB policies, choose `DynamoDB-PutItem-Policy` . 8. Clear the **Filter policies** box, and then enter **Lambda**. 9. In the list of Lambda policies, choose **AWSLambdaExecute**. 10. Choose **Next: Name, review, and create**. 11. For **Role name**, enter a unique name for your role, such as `DynamoDB-PutItemAccess` .	General AWS

Task	Description	Skills required
	12.(Optional) Add a role description. 13.(Optional) Add metadata to the role by attaching tags as key-value pairs. 14.Choose **Create role**. For more information about creating roles, see the [IAM documentation]().	
Note the role ARN.	1. Open the [IAM console](). 2. In the navigation pane, choose **Roles**. 3. In the search box, enter `DynamoDB-PutItemAccess` , and then choose the role. 4. On the summary page for the role, copy the Amazon Resource Name (ARN). You use the ARN when you set up the Lambda function.	General AWS

Create a DynamoDB table in Account A

Task	Description	Skills required
Create a DynamoDB table.	Use the following AWS CLI command to create a DynamoDB table. `aws dynamodb create-table \`	General AWS

Task	Description	Skills required

	<pre> --table-name Table-
	Account-A \\
	    --attribute-defini
	tions \\
	      Attribute
	Name=category,Attr
	ibuteType=S \\
	      Attribute
	Name=item,Attribut
	eType=S \\
	    --key-schema \\
	      Attribute
	Name=category,KeyT
	ype=HASH \\
	      Attribute
	Name=item,KeyType=
	RANGE \\
	    --provisioned-thro
	ughput \\
	      ReadCapac
	ityUnits=5,WriteCa
	pacityUnits=5 \\
	    --resource-policy \\
	      '{
	          "Version":
	 "2012-10-17",
	          "Statement":
	 [
	            {
	
	               "Sid":
	 "Statement1",
	               "Effect":
	 "Allow",
	               "Principa
	l": {
	                  "AWS":
	 "arn:aws:iam::<Acc
	ount-B-ID>:role/<R
	ole-Name>"
	               },</pre>	

Task	Description	Skills required

	``
	                "Action":
	 "dynamodb:PutItem",
	                "Resource
	": "arn:aws:dynamodb:
	<Region>:<Account-
	A-ID>:table/Table-
	Account-A"
	            }
	
	         ]
	      }'
	``
	
	Replace the following in this code sample:
	
	• `<Account-B-ID>` is the ID of Account B.
	• `<Role-Name>` is the name of the IAM role that you created, such as `DynamoDB-PutItemAccess`.
	• `<Region>` is the AWS Region where you are creating the DynamoDB table.
	• `<Account-A-ID>` is the ID of Account A.
	
	Note
	
	You specify the resource-based policy configuration in the `create-table` statement by using	

Task	Description	Skills required
	the `--resource-policy` flag. This policy refers to the ARN for the DynamoDB table in Account A. For more information about creating tables, see the [DynamoDB documentation]().	

Create a Lambda function in Account B

Task	Description	Skills required
Create a Lambda function to write data to DynamoDB.	1. Sign in to Account B in the AWS Management Console. 2. Open the [Lambda console](). 3. In the navigation pane, choose **Functions**, and then choose **Create function**. 4. For **Name**, enter `lambda_write_function` . 5. For **Runtime**, choose **Python 3.8** or later. 6. Under **Change default execution role**, choose **Use an existing role**. 7. For **Existing role**, choose the IAM role that	General AWS

Task	Description	Skills required
	you created, such as `DynamoDB-PutItemAccess` . 8. Choose **Create function**. 9. In the **Code** tab, paste the sample code that is provided in the [Additional information](#) section of this pattern. Replace the following in this code sample: • `<Account-A-ID>` is the ID of Account A. • `<Region>` is the AWS Region where you created the DynamoDB table. 10. Choose **Deploy**. 11. Choose **Test**. This prompts you to configure a test event. Create a new event with your preferred name, such as `MyTestEventForWrite` , and then save the configuration. 12. Choose **Test** again. This runs the Lambda function with the event name you provided. 13. Check the output from the function. It should indicate that the function accessed the DynamoDB table in	

Task	Description	Skills required
	Account A and was able to write data to it. For more information about creating Lambda functions, see the [Lambda documenta tion]().	

Clean up

Task	Description	Skills required
Delete resources.	To avoid incurring costs associated with the resources created in this pattern, do the following to delete these resources: 1. In Account B, delete the Lambda function you created to connect to DynamoDB. For instructi ons, see the [Lambda documentation](). 2. In Account A, delete the DynamoDB table you created. For instructi ons, see the [DynamoDB documentation](). 3. For security best practices , delete the IAM policy (`DynamoDB-PutItem-Policy`) when it is no longer needed. For more	General AWS

Task	Description	Skills required
	information, see the IAM documentation. 4. For security best practices , delete the IAM role (`DynamoDB-PutItemAccess`) when it is no longer needed. For more information, see the IAM documentation.	

Troubleshooting

Issue	Solution
When creating the Lambda function, you receive a `ResourceNotFoundException` error.	Confirm that you have correctly entered the AWS Region and ID of Account A. These are part of the ARN for the DynamoDB table.

Related resources

- Getting started with DynamoDB (DynamoDB documentation)
- Getting started with Lambda (Lambda documentation)
- Using resource-based policies for DynamoDB (DynamoDB documentation)
- Creating IAM policies (IAM documentation)
- Cross-account policy evaluation logic (IAM documentation)
- IAM JSON policy elements reference (IAM documentation)

Additional information

Sample code

```
import boto3
```

```
from datetime import datetime

dynamodb_client = boto3.client('dynamodb')

def lambda_handler(event, context):
     now = datetime.now().isoformat()
     data = dynamodb_client.put_item(TableName='arn:aws:dynamodb:<Region>:<Account-
A-ID>:table/Table-Account-A', Item={"category": {"S": "Fruit"},"item": {"S":
 "Apple"},"time": {"S": now}})
     return data
```

> **Note**
>
> When the DynamoDB client is instantiated, the ARN of the DynamoDB table is provided instead of the table name. This is required so that the Lambda function connects to the correct DynamoDB table when it runs.

Configure read-only routing in an Always On availability group in SQL Server on AWS

Subhani Shaik, Amazon Web Services

Summary

This pattern covers how to use the standby secondary replica in SQL Server Always On by offloading the read-only workloads from the primary replica to the secondary replica.

Database mirroring has one-to-one mapping. You can't read the secondary database directly, so you must create snapshots. The Always On availability group feature was introduced in Microsoft SQL Server 2012. In later versions, major functionalities have been introduced, including read-only routing. In Always On availability groups, you can read the data directly from the secondary replica by changing the replica mode to read-only.

The Always On availability groups solution supports high availability (HA), disaster recovery (DR), and an alternative to database mirroring. Always On availability groups work at the database level and maximize the availability of a set of user databases.

SQL Server uses the read-only routing mechanism to redirect the incoming read-only connections to the secondary read replica. To achieve this, you should add the following parameters and values in the connection string:

- `ApplicationIntent=ReadOnly`
- `Initial Catalog=<database name>`

Prerequisites and limitations

Prerequisites

- An active AWS account with a virtual private cloud (VPC), two Availability Zones, private subnets, and a security group
- Two Amazon Elastic Compute Cloud (Amazon EC2) machines with [SQL Server 2019 Enterprise Edition Amazon Machine Image] with [Windows Server Failover Clustering (WSFC)] configured at the instance level and an Always On availability group configured at the SQL Server level between the primary node (`WSFCNODE1`) and the secondary node (`WSFCNODE2`), which are part of the AWS Directory Service for Microsoft Active Directory directory named `tagechtalk.com`

- One or more nodes configured to accept `read-only` in the secondary replica
- A listener named `SQLAG1` for the Always On availability group
- SQL Server Database Engine running with the same service account on two nodes
- SQL Server Management Studio (SSMS)
- A test database named `test`

Product Versions

- SQL Server 2014 and later

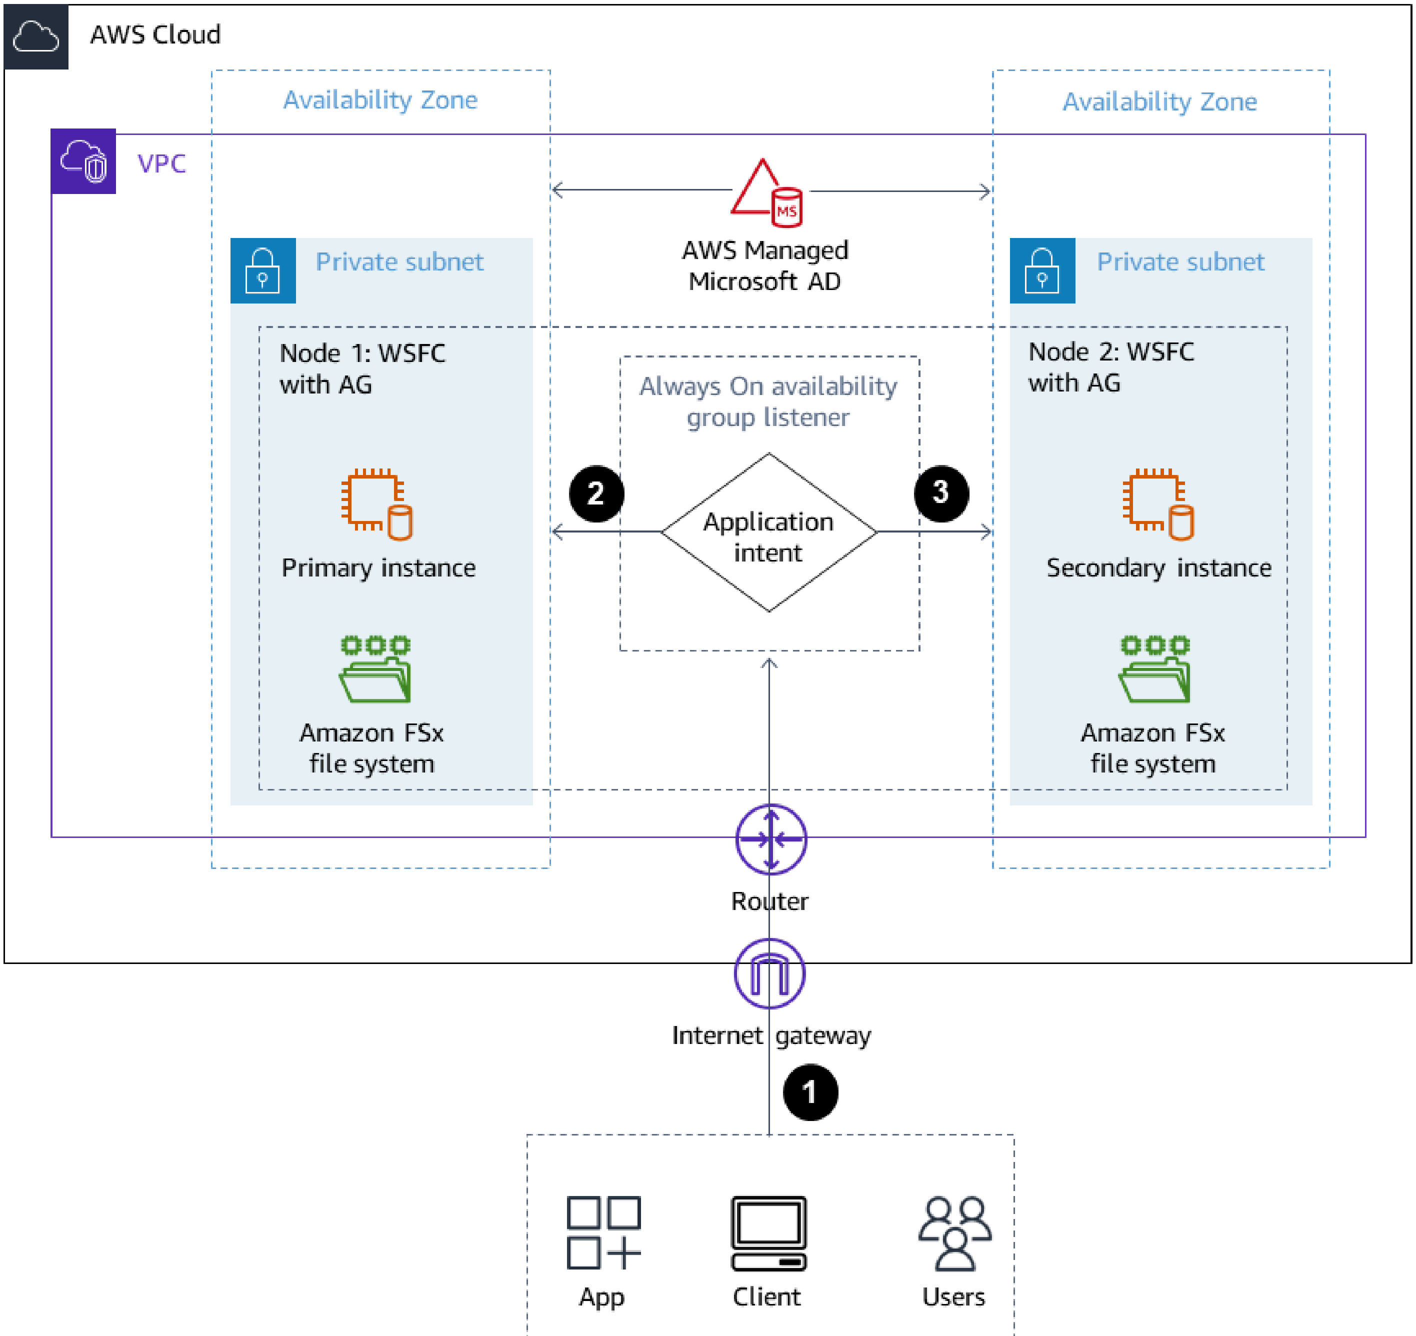
Architecture

Target technology stack

- Amazon EC2
- AWS Managed Microsoft AD
- Amazon FSx

Target architecture

The following diagram shows how the Always On availability group (AG) listener redirects queries that contain the `ApplicationIntent` parameter in the connection to the appropriate secondary node.



1. A request is sent to the Always On availability group listener.
2. If the connection string does not have the `ApplicationIntent` parameter, the request is sent to the primary instance.
3. If the connection string contains `ApplicationIntent=ReadOnly`, the request is sent to the secondary instance with read-only routing configuration , which is WSFC with an Always On availability group.

Tools

AWS services

- AWS Directory Service for Microsoft Active Directory enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon FSx provides file systems that support industry-standard connectivity protocols and offer high availability and replication across AWS Regions.

Other services

- SQL Server Management Studio (SSMS) is a tool for connecting, managing, and administering the SQL Server instances.
- sqlcmd is a command-line utility.

Best practices

For more information about Always On availability groups, see the SQL Server documentation.

Epics

Set up read-only routing

Task	Description	Skills required
Update the replicas to read-only.	To update both the primary and the secondary replica to read-only, connect to the primary replica from SSMS, and run the *Step 1* code from the *Additional information* section.	DBA
Create the routing URL.	To create routing URL for both replicas, run the *Step 2* code from the *Additional*	DBA

Task	Description	Skills required
	information section. In this code, `tagechtalk.com` is the name of the AWS Managed Microsoft AD directory.	
Create the routing list.	To create the routing list for both replicas, run the Step 3 code from the *Additional information* section.	DBA
Validate the routing list.	Connect to the primary instance from SQL Server Management Studio, and run the *Step 4* code from the *Additional information* section to validate the routing list.	DBA

Test the read-only routing

Task	Description	Skills required
Connect by using the ApplicationIntent parameter.	1. From SSMS, connect to the Always On availability group listener name with `ApplicationIntent= ReadOnly;Initial Catalog=test` . 2. The connection is establish ed with the secondary replica. To test this, run the following command to show the connected server name.	DBA

Task	Description	Skills required
	`SELECT SERVERPROPERTY('ComputernamePhysicalNetBios')` The output will show the current secondary replica name (`WSFCNODE2`).	

Task	Description	Skills required
Perform a failover.	1. From SSMS, connect to the Always On availability group listener name. 2. Verify that the primary and secondary database are in sync, with no data loss. 3. Perform a failover so that the current primary replica becomes the secondary replica, and the secondary replica becomes the primary replica. 4. From SSMS, connect to the Always On availability group listener name with `ApplicationIntent=ReadOnly;Initial Catalog=test` . 5. The connection is established with the secondary replica. To test this, show the connected server name by running the following command. `SELECT SERVERPROPERTY('ComputernamePhysicalNetBios')` It will display the current secondary replica name (`WSFCNODE1`).	DBA

Connect by using the sqlcmd command-line utility

Task	Description	Skills required
Connect by using sqlcmd.	To connect from sqlcmd, run the *Step 5* code from the *Additional information* section at the command prompt. After you are connected, run the following command to show the connected server name. `SELECT SERVERPROPERTY('ComputernamePhysicalNetBios') .` The output will display the current secondary replica name (`WSFCNODE1`).	DBA

Troubleshooting

Issue	Solution
Creating the listener fails with the message 'The WSFC cluster could not bring the Network Name resource online'.	For information, see the Microsoft blog post Create Listener Fails with Message 'The WSFC cluster could not bring the Network Name resource online'.
Potential issues, including other listener issues or network access issues.	See Troubleshoot Always On Availability Groups Configuration (SQL Server) in the Microsoft documentation.

Related resources

- Configure read-only routing for an Always On availability group
- Troubleshoot Always On Availability Groups Configuration (SQL Server)

Additional information

Step 1. Update the replicas to read-only

```
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH (SECONDARY_ROLE
 (ALLOW_CONNECTIONS = READ_ONLY))
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (SECONDARY_ROLE
 (ALLOW_CONNECTIONS = READ_ONLY))
GO
```

Step 2. Create the routing URL

```
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH (SECONDARY_ROLE
 (READ_ONLY_ROUTING_URL = N'TCP://WSFCNode1.tagechtalk.com:1433'))
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (SECONDARY_ROLE
 (READ_ONLY_ROUTING_URL = N'TCP://WSFCNode2.tagechtalk.com:1433'))
GO
```

Step 3. Create the routing list

```
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE1' WITH
 (PRIMARY_ROLE(READ_ONLY_ROUTING_LIST=('WSFCNODE2','WSFCNODE1')));
GO
ALTER AVAILABILITY GROUP [SQLAG1] MODIFY REPLICA ON N'WSFCNODE2' WITH (PRIMARY_ROLE
 (READ_ONLY_ROUTING_LIST=('WSFCNODE1','WSFCNODE2')));
GO
```

Step 4. Validate the routing list

```
SELECT AGSrc.replica_server_name AS PrimaryReplica, AGRepl.replica_server_name AS
 ReadOnlyReplica, AGRepl.read_only_routing_url AS RoutingURL , AGRL.routing_priority
 AS RoutingPriority FROM sys.availability_read_only_routing_lists AGRL INNER JOIN
 sys.availability_replicas AGSrc ON AGRL.replica_id = AGSrc.replica_id INNER JOIN
```

```
sys.availability_replicas AGRepl ON AGRL.read_only_replica_id = AGRepl.replica_id
INNER JOIN sys.availability_groups AV ON AV.group_id = AGSrc.group_id ORDER BY
PrimaryReplica
```

Step 5. SQL Command Utility

```
sqlcmd -S SQLAG1,1433 -E -d test -K ReadOnly
```

Connect by using an SSH tunnel in pgAdmin

Jeevan Shetty and Bhanu Ganesh Gudivada, Amazon Web Services

Summary

For security reasons, it's always good to place databases in a private subnet. Queries against the database can be run by connecting through an Amazon Elastic Compute Cloud (Amazon EC2) bastion host in a public subnet on the Amazon Web Services (AWS) Cloud. This requires installing software, such as pgAdmin or DBeaver, which are commonly used by developers or database administrators, on the Amazon EC2 host.

Running pgAdmin on a Linux server and accessing it through a web browser requires the installation of additional dependencies, permissions setup, and configuration.

As an alternate solution, developers or database administrators can connect to a PostgreSQL database by using pgAdmin to enable an SSH tunnel from their local system. In this approach, pgAdmin uses the Amazon EC2 host in the public subnet as an intermediary host before connecting to the database. The diagram in the *Architecture* section shows the setup.

> **Note**
>
> Ensure that the security group attached to the PostgreSQL database allows connection on port 5432 from the Amazon EC2 host.

Prerequisites and limitations

Prerequisites

- An existing AWS account
- A virtual private cloud (VPC) with a public subnet and a private subnet
- An EC2 instance with a security group attached
- An Amazon Aurora PostgreSQL-Compatible Edition database with a security group attached
- A Secure Shell (SSH) key pair for setting up the tunnel

Product versions

- pgAdmin version 6.2+

- Amazon Aurora PostgreSQL-Compatible Edition version 12.7+

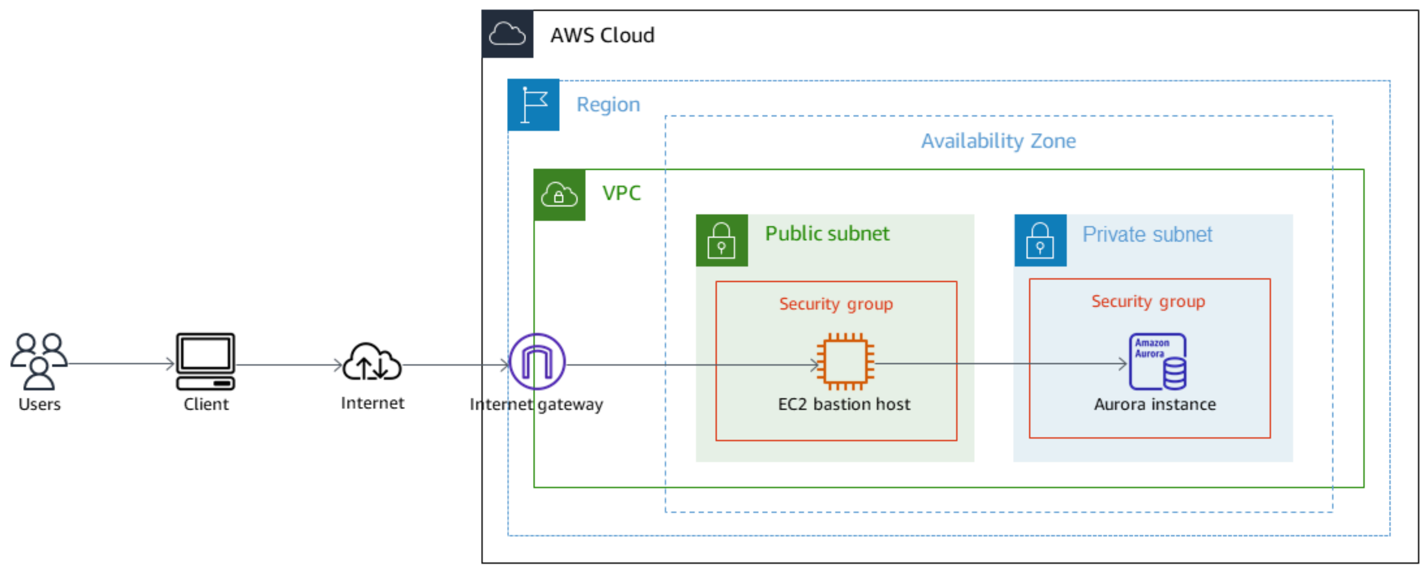
Architecture

Target technology stack

- Amazon EC2
- Amazon Aurora PostgreSQL-Compatible

Target architecture

The following diagram shows using pgAdmin with an SSH tunnel to connect through an internet gateway to the EC2 instance, which connects to the database.



Tools

AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/Aurora.AuroraPostgreSQL.html) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon Elastic Compute Cloud (Amazon EC2)](https://docs.aws.amazon.com/ec2/) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

Other services

- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Epics

Create the connection

Task	Description	Skills required
Create a server.	In pgAdmin, choose **Create**, and then choose **Server**. For additional help with setting up pgAdmin to register a server, configure a connectio n, and connect through SSH tunneling by using the Server Dialog, see the links in the *Related resources* section.	DBA
Provide a name for the server.	On the **General** tab, enter a name.	DBA
Enter the database details.	On the **Connection** tab, enter values for the following: • **Host name/address** • **Port** • **Maintenance database** • **Username** • **Password**	DBA
Enter the Amazon EC2 server details.	On the **SSH Tunnel** tab, provide the details of the Amazon EC2 instance that is in the public subnet.	DBA

Task	Description	Skills required
	• Set **Use SSH tunneling** to **Yes** to specify that pgAdmin should use an SSH tunnel when connecting to the specified server. • In the **Tunnel host** field, specify the name or IP address of the SSH host (for example, 10.x.x.x). • In the **Tunnel port** field, specify the port of the SSH host (for example, 22). • In the **Username** field, specify the name of a user with login privileges for the SSH host (for example, ec2-user). • Specify the type of authentication as **Identity file** so that pgAdmin will use a private key file when connecting. • Include the location of the Privacy Enhanced Mail (PEM) file in the **Identity file** field. The .pem file is the Amazon EC2 key pair.	
Save and connect.	Choose **Save** to complete the setup and connect to the Aurora PostgreSQL-Compatible database by using the SSH tunnel.	DBA

Convert JSON Oracle queries into PostgreSQL database SQL

Pinesh Singal and Lokesh Gurram, Amazon Web Services

Summary

This migration process for moving from on-premises to the Amazon Web Services (AWS) Cloud uses the AWS Schema Conversion Tool (AWS SCT) to convert the code from an Oracle database into a PostgreSQL database. Most of the code is automatically converted by AWS SCT. However, JSON-related Oracle queries are not automatically converted.

Starting from Oracle 12.2 version, Oracle Database supports various JSON functions that help in converting JSON-based data into ROW-based data. However, AWS SCT doesn't automatically convert JSON-based data into language that is supported by PostgreSQL.

This migration pattern primarily focuses on manually converting the JSON-related Oracle queries with functions such as `JSON_OBJECT`, `JSON_ARRAYAGG`, and `JSON_TABLE` from an Oracle database to a PostgreSQL database.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An on-premises Oracle database instance (up and running)
- An Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition database instance (up and running)

Limitations

- JSON-related queries require a fixed `KEY` and `VALUE` format. Not using that format returns the wrong result.
- If any change in JSON structure adds new `KEY` and `VALUE` pairs in the result section, the corresponding procedure or function must be changed in the SQL query.
- Some JSON-related functions are supported in earlier versions of Oracle and PostgreSQL but with fewer capabilities.

Product versions

- Oracle Database version 12.2 and later
- Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible version 9.5 and later
- AWS SCT latest version (tested using version 1.0.664)

Architecture

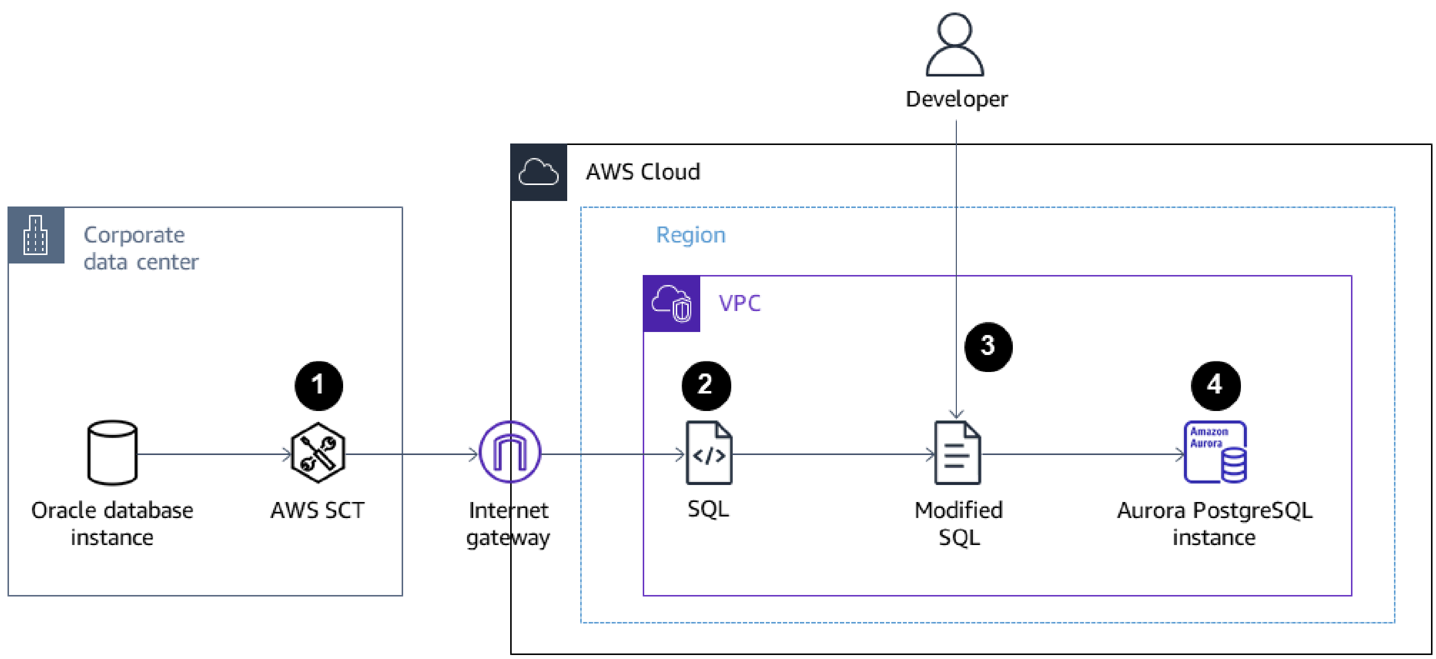
Source technology stack

- An Oracle database instance with version 19c

Target technology stack

- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database instance with version 13

Target architecture



1. Use AWS SCT with the JSON function code to convert the source code from Oracle to PostgreSQL.
2. The conversion produces PostgreSQL-supported migrated .sql files.
3. Manually convert the non-converted Oracle JSON function codes to PostgreSQL JSON function codes.

4. Run the .sql files on the target Aurora PostgreSQL-Compatible DB instance.

Tools

AWS services

- Amazon Aurora is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that’s compatible with the target database.

Other services

- Oracle SQL Developer is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.
- pgAdmin or DBeaver. pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects. DBeaver is a universal database tool.

Best practices

Oracle query has type `CAST` as the default when using the `JSON_TABLE` function. A best practice is to use `CAST` in PostgreSQL too, using double greater-than characters (>>).

For more information, see *Postgres_SQL_Read_JSON* in the *Additional information* section.

Epics

Convert the JSON into ROW format

Task	Description	Skills required
Convert the JSON data on the Oracle database.	Write an Oracle SQL query to read the JSON data into ROW format. For more details and example syntax, see *Oracle_SQL_Read_JSON* in the *Additional information* section.	Migration engineer
Convert the JSON data on the PostgreSQL database.	Write a PostgreSQL query to read the JSON data into ROW format. For more details and example syntax, see *Postgres_SQL_Read_JSON* in the *Additional information* section.	Migration engineer

Manually convert the JSON data using the SQL query and report the output in JSON format

Task	Description	Skills required
Perform aggregations and validation on the Oracle SQL query.	To manually convert the JSON data, perform a join, aggregation, and validation on the Oracle SQL query, and report the output in JSON format. Use the code under *Oracle_SQL_JSON_Aggregation_Join* in the *Additional information* section. 1. JOIN – The JSON-formatted data is passed as an input parameter to the query. An inner JOIN is made between this static data and the JSON data in the Oracle DB table `aws_test_table`. 2. Aggregation with validation – The JSON data has `KEY` and `VALUE` parameters with values such as `accountNumber`, `parentAccountNumber`, `businessUnitId` and `positionId`, which are used for `SUM` and `COUNT` aggregations. 3. JSON format – After the join and the aggregation, the data is reported	Migration engineer

Convert the Oracle procedure into a PostgreSQL function that contains JSON queries

Task	Description	Skills required
Convert the JSON queries in the Oracle procedure into rows.	For the example Oracle procedure, use the previous Oracle query and the code under *Oracle_procedure_with_JSON_Query* in the *Additional information* section.	Migration engineer
Convert the PostgreSQL functions that have JSON queries into row-based data.	For the example PostgreSQL functions, use the previous PostgreSQL query and the code that's under *Postgres_function_with_JSON_Query* in the *Additional information* section.	Migration engineer

  }
}');
```

3. Oracle_SQL_Read_JSON

The following code blocks show how to convert Oracle JSON data into row format.

Example query and syntax

```
SELECT   JSON_OBJECT(
 'accountCounts' VALUE JSON_ARRAYAGG(
            JSON_OBJECT(
                'businessUnitId' VALUE business_unit_id,
                        'parentAccountNumber' VALUE parent_account_number,
                        'accountNumber' VALUE account_number,
                        'totalOnlineContactsCount' VALUE online_contacts_count,
                        'countByPosition' VALUE
                    JSON_OBJECT(
                        'taxProfessionalCount' VALUE tax_count,
                        'attorneyCount' VALUE attorney_count,
                        'nonAttorneyCount' VALUE non_attorney_count,
                        'clerkCount' VALUE clerk_count
                               ) ) ) ) FROM
    (SELECT   tab_data.business_unit_id,
            tab_data.parent_account_number,
            tab_data.account_number,
            SUM(1) online_contacts_count,
            SUM(CASE WHEN tab_data.position_id = '0095' THEN  1 ELSE 0 END) tax_count,
            SUM(CASE    WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END)
 attorney_count,
            SUM(CASE    WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END)
 non_attorney_count,
```

```
            SUM(CASE    WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END)
clerk_count
       FROM aws_test_table scco,JSON_TABLE ( json_doc, '$' ERROR ON ERROR
 COLUMNS (
         parent_account_number NUMBER PATH
          '$.data.account.parentAccountNumber',
           account_number NUMBER PATH '$.data.account.accountNumber',
           business_unit_id NUMBER PATH '$.data.account.businessUnitId',
           position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'    )
           ) AS tab_data
           INNER JOIN JSON_TABLE ( '{
       "accounts": [{
         "accountNumber": 42000,
         "parentAccountNumber": 32000,
         "businessUnitId": 7
       }, {
         "accountNumber": 42001,
         "parentAccountNumber": 32001,
         "businessUnitId": 6
       }]
     }', '$.accounts[*]' ERROR ON ERROR
     COLUMNS (
     parent_account_number PATH '$.parentAccountNumber',
     account_number PATH '$.accountNumber',
     business_unit_id PATH '$.businessUnitId')
     ) static_data
     ON ( static_data.parent_account_number = tab_data.parent_account_number
          AND static_data.account_number = tab_data.account_number
          AND static_data.business_unit_id = tab_data.business_unit_id )
       GROUP BY
           tab_data.business_unit_id,
           tab_data.parent_account_number,
           tab_data.account_number );
```

The JSON document stores the data as collections. Each collection can have KEY and VALUE pairs. Every VALUE can have nested KEY and VALUE pairs. The following table provides information about reading the specific VALUE from the JSON document.

KEY	HIERARCHY or PATH to be used to get the VALUE	VALUE
`profileType`	`metadata` -> `profileType`	"P"

`positionId`	`data` -> `positionId`	"0100"
`accountNumber`	`data` -> `account` -> `accountNumber`	42000

In the previous table, the KEY `profileType` is a VALUE of the `metadata` KEY. The KEY `positionId` is a VALUE of the `data` KEY. The KEY `accountNumber` is a VALUE of the `account` KEY, and the `account` KEY is a VALUE of the `data` KEY.

Example JSON document

```
{
  "metadata" : {
    "upperLastNameFirstName" : "ABC XYZ",
    "upperEmailAddress" : "abc@gmail.com",
"profileType" : "P"
  },
  "data" : {
    "onlineContactId" : "032323323",
    "displayName" : "Abc, Xyz",
    "firstName" : "Xyz",
    "lastName" : "Abc",
    "emailAddress" : "abc@gmail.com",
    "productRegistrationStatus" : "Not registered",
"positionId" : "0100",
    "arrayPattern" : " -",
    "account" : {
      "companyId" : "SMGE",
      "businessUnitId" : 7,
"accountNumber" : 42000,
      "parentAccountNumber" : 32000,
      "firstName" : "john",
      "lastName" : "doe",
      "street1" : "retOdertcaShr ",
      "city" : "new york",
      "postalcode" : "XY ABC",
      "country" : "United States"
    },
    "products" : [
      {
        "appUserGuid" : "i0acc4450000001823fbad478e2eab8a0",
```

```
        "id" : "0000000046",
        "name" : "ProView",
        "domain" : "EREADER",
        "registrationStatus" : false,
        "status" : "11"
      }
    ]
  }
}
```

SQL query that is used to get the selected fields from the JSON document

```
select parent_account_number,account_number,business_unit_id,position_id from
 aws_test_table aws,JSON_TABLE ( json_doc, '$' ERROR ON ERROR
COLUMNS (
parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
account_number NUMBER PATH '$.data.account.accountNumber',
business_unit_id NUMBER PATH '$.data.account.businessUnitId',
position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'
)) as sc
```

In the previous query, `JSON_TABLE` is a built-in function in Oracle that converts the JSON data into row format. The JSON_TABLE function expects parameters in JSON format.

Every item in `COLUMNS` has a predefined `PATH`, and there an appropriate `VALUE` for a given `KEY` is returned in row format.

Result from the previous query

PARENT_ACCOUNT_NUMBER	ACCOUNT_NUMBER	BUSINESS_UNIT_ID	POSITION_ID
32000	42000	7	0100
32001	42001	6	0090

4. Postgres_SQL_Read_JSON

Example query and syntax

```
select *
```

```
from (
select (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER as
 parentAccountNumber,
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER as accountNumber,
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER as businessUnitId,
(json_doc::json->'data'->>'positionId')::VARCHAR as positionId
from aws_test_pg_table) d ;
```

In Oracle, PATH is used to identify the specific KEY and VALUE. However, PostgreSQL uses a HIERARCHY model for reading KEY and VALUE from JSON. The same JSON data mentioned under `Oracle_SQL_Read_JSON` is used in the following examples.

SQL query with type CAST not allowed

(If you force type CAST, the query fails with a syntax error.)

```
select *
from (
select (json_doc::json->'data'->'account'->'parentAccountNumber') as
 parentAccountNumber,
(json_doc::json->'data'->'account'->'accountNumber')as accountNumber,
(json_doc::json->'data'->'account'->'businessUnitId') as businessUnitId,
(json_doc::json->'data'->'positionId')as positionId
from aws_test_pg_table) d ;
```

Using a single greater-than operator (>) will return the VALUE defined for that KEY. For example, KEY: `positionId`, and VALUE: `"0100"`.

Type CAST is not allowed when you use the single greater-than operator (>).

SQL query with type CAST allowed

```
select *
from (
select (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER as
 parentAccountNumber,
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER as accountNumber,
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER as businessUnitId,
(json_doc::json->'data'->>'positionId')::varchar as positionId
from aws_test_pg_table) d ;
```

To use type CAST, you must use the double greater-than operator. If you use the single greater-than operator, the query returns the VALUE defined (for example, KEY: `positionId`, and VALUE: `"0100"`). Using the double greater-than operator (>>) will return the actual value defined for that KEY (for example, KEY: `positionId`, and VALUE: `0100`, without double quotation marks).

In the preceding case, `parentAccountNumber` is type CAST to INT, `accountNumber` is type CAST to INT, `businessUnitId` is type CAST to INT, and `positionId` is type CAST to VARCHAR.

The following tables show query results that explain role of the single greater-than operator (>) and the double greater-than operator (>>).

In the first table table, the query uses the single greater-than operator (>). Each column is in JSON type and can't be converted into another data type.

parentAccountNumber	accountNumber	businessUnitId	positionId
2003565430	2003564830	7	"0100"
2005284042	2005284042	6	"0090"
2000272719	2000272719	1	"0100"

In the second table, the query uses the double greater-than operator (>>). Each column supports type CAST based on the column value. For example, INTEGER in this context.

parentAccountNumber	accountNumber	businessUnitId	positionId
2003565430	2003564830	7	0100
2005284042	2005284042	6	0090
2000272719	2000272719	1	0100

5. Oracle_SQL_JSON_Aggregation_Join

Example query

```
SELECT
    JSON_OBJECT(
        'accountCounts' VALUE JSON_ARRAYAGG(
            JSON_OBJECT(
                'businessUnitId' VALUE business_unit_id,
                        'parentAccountNumber' VALUE parent_account_number,
                        'accountNumber' VALUE account_number,
                        'totalOnlineContactsCount' VALUE online_contacts_count,
                        'countByPosition' VALUE
                    JSON_OBJECT(
                        'taxProfessionalCount' VALUE tax_count,
                        'attorneyCount' VALUE attorney_count,
                        'nonAttorneyCount' VALUE non_attorney_count,
                        'clerkCount' VALUE clerk_count
                               ) ) ) )
FROM
    (SELECT
            tab_data.business_unit_id,
            tab_data.parent_account_number,
            tab_data.account_number,
            SUM(1) online_contacts_count,
            SUM(CASE WHEN tab_data.position_id = '0095' THEN  1 ELSE 0 END) tax_count,
            SUM(CASE    WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END)
 attorney_count,
            SUM(CASE    WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END)
 non_attorney_count,
            SUM(CASE    WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END)
 clerk_count

        }]
      }', '$.accounts[*]' ERROR ON ERROR
      COLUMNS (
      parent_account_number PATH '$.parentAccountNumber',
      account_number PATH '$.accountNumber',
      business_unit_id PATH '$.businessUnitId')
      ) static_data
      ON ( static_data.parent_account_number = tab_data.parent_account_number
           AND static_data.account_number = tab_data.account_number
           AND static_data.business_unit_id = tab_data.business_unit_id )
        GROUP BY
            tab_data.business_unit_id,
            tab_data.parent_account_number,
            tab_data.account_number
    );
```

To convert the row-level data into JSON format, Oracle has built-in functions such as `JSON_OBJECT`, `JSON_ARRAY`, `JSON_OBJECTAGG`, and `JSON_ARRAYAGG`.

- `JSON_OBJECT` accepts two parameters: `KEY` and `VALUE`. The `KEY` parameter should be hardcoded or static in nature. The `VALUE` parameter is derived from table output.
- `JSON_ARRAYAGG` accepts `JSON_OBJECT` as a parameter. This helps in grouping the set of `JSON_OBJECT` elements as a list. For example, if you have a `JSON_OBJECT` element that has multiple records (multiple `KEY` and `VALUE` pairs in the dataset), `JSON_ARRAYAGG` appends the dataset and creates a list. According to the Data Structure language, `LIST` is group of elements. In this context, `LIST` is a group of `JSON_OBJECT` elements.

The following example shows one `JSON_OBJECT` element.

```
{
   "taxProfessionalCount": 0,
   "attorneyCount": 0,
   "nonAttorneyCount": 1,
   "clerkCount": 0
}
```

This next example shows two `JSON_OBJECT` elements, with `LIST` indicated by square braces (`[ ]`).

```
[
    {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
,
    {
        "taxProfessionalCount": 2,
        "attorneyCount": 1,
        "nonAttorneyCount": 3,
        "clerkCount":4
      }
]
```

Example SQL query

```
SELECT
    JSON_OBJECT(
        'accountCounts' VALUE JSON_ARRAYAGG(
            JSON_OBJECT(
                'businessUnitId' VALUE business_unit_id,
                        'parentAccountNumber' VALUE parent_account_number,
                        'accountNumber' VALUE account_number,
                        'totalOnlineContactsCount' VALUE online_contacts_count,
                        'countByPosition' VALUE
                    JSON_OBJECT(
                        'taxProfessionalCount' VALUE tax_count,
                        'attorneyCount' VALUE attorney_count,
                        'nonAttorneyCount' VALUE non_attorney_count,
                        'clerkCount' VALUE clerk_count
                               )
                        )
                                          )
               )
FROM
    (SELECT
            tab_data.business_unit_id,
            tab_data.parent_account_number,
            tab_data.account_number,
            SUM(1) online_contacts_count,
            SUM(CASE WHEN tab_data.position_id = '0095' THEN  1 ELSE   0 END
```

```
            )      tax_count,
            SUM(CASE    WHEN tab_data.position_id = '0100' THEN        1    ELSE
  0 END
            )      attorney_count,

            SUM(CASE    WHEN tab_data.position_id = '0090' THEN        1    ELSE
  0 END
            )      non_attorney_count,

            SUM(CASE    WHEN tab_data.position_id = '0050' THEN        1    ELSE
  0 END
            )      clerk_count

        FROM
            aws_test_table scco,  JSON_TABLE ( json_doc, '$' ERROR ON ERROR
            COLUMNS (
            parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
            account_number NUMBER PATH '$.data.account.accountNumber',
            business_unit_id NUMBER PATH '$.data.account.businessUnitId',
            position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'    )
            ) AS tab_data
            INNER JOIN JSON_TABLE ( '{
        "accounts": [{
          "accountNumber": 42000,
          "parentAccountNumber": 32000,
          "businessUnitId": 7
        }, {
          "accountNumber": 42001,
          "parentAccountNumber": 32001,
          "businessUnitId": 6
        }]
      }', '$.accounts[*]' ERROR ON ERROR
      COLUMNS (
      parent_account_number PATH '$.parentAccountNumber',
      account_number PATH '$.accountNumber',
      business_unit_id PATH '$.businessUnitId')
      ) static_data ON ( static_data.parent_account_number =
 tab_data.parent_account_number
                        AND static_data.account_number = tab_data.account_number

                        AND static_data.business_unit_id =
 tab_data.business_unit_id )
        GROUP BY
            tab_data.business_unit_id,
```

```
            tab_data.parent_account_number,
            tab_data.account_number
    );
```

Example output from the previous SQL query

```
{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "accountNumber": 42000,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

6. Postgres_SQL_JSON_Aggregation_Join

The PostgreSQL built-in functions `JSON_BUILD_OBJECT` and `JSON_AGG` convert the ROW-level data into JSON format. PostgreSQL `JSON_BUILD_OBJECT` and `JSON_AGG` are equivalent to Oracle `JSON_OBJECT` and `JSON_ARRAYAGG`.

Example query

```
select
JSON_BUILD_OBJECT ('accountCounts',
    JSON_AGG(
        JSON_BUILD_OBJECT ('businessUnitId',businessUnitId
        ,'parentAccountNumber',parentAccountNumber
        ,'accountNumber',accountNumber
        ,'totalOnlineContactsCount',online_contacts_count,
        'countByPosition',
            JSON_BUILD_OBJECT (
            'taxProfessionalCount',tax_professional_count
            ,'attorneyCount',attorney_count
            ,'nonAttorneyCount',non_attorney_count
            ,'clerkCount',clerk_count
            )
        )
    )
)
from (
with tab as (select * from (
select (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER as
 parentAccountNumber,
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER as accountNumber,
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER as businessUnitId,
(json_doc::json->'data'->>'positionId')::varchar as positionId
from aws_test_pg_table) a ) ,
tab1 as ( select
(json_array_elements(b.jc -> 'accounts') ->> 'accountNumber')::integer accountNumber,
(json_array_elements(b.jc -> 'accounts') ->> 'businessUnitId')::integer
 businessUnitId,
(json_array_elements(b.jc -> 'accounts') ->> 'parentAccountNumber')::integer
 parentAccountNumber
from (
select '{
        "accounts": [{
          "accountNumber": 42001,
          "parentAccountNumber": 32001,
          "businessUnitId": 6
        }, {
          "accountNumber": 42000,
          "parentAccountNumber": 32000,
          "businessUnitId": 7
        }]
      }'::json as jc) b)
```

```
select
tab.businessUnitId::text,
tab.parentAccountNumber::text,
tab.accountNumber::text,
SUM(1) online_contacts_count,
SUM(CASE WHEN tab.positionId::text = '0095' THEN 1 ELSE 0  END)
  tax_professional_count,
SUM(CASE WHEN tab.positionId::text = '0100' THEN 1 ELSE 0  END)      attorney_count,
SUM(CASE  WHEN tab.positionId::text = '0090' THEN      1  ELSE      0 END)
  non_attorney_count,
SUM(CASE  WHEN tab.positionId::text = '0050' THEN      1  ELSE      0 END)
  clerk_count
from tab1,tab
where tab.parentAccountNumber::INTEGER=tab1.parentAccountNumber::INTEGER
and tab.accountNumber::INTEGER=tab1.accountNumber::INTEGER
and tab.businessUnitId::INTEGER=tab1.businessUnitId::INTEGER
GROUP BY      tab.businessUnitId::text,
            tab.parentAccountNumber::text,
            tab.accountNumber::text) a;
```

Example output from the preceding query

Output from Oracle and PostgreSQL is exactly the same.

```
{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "accountNumber": 42000,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
```

```
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

7.Oracle_procedure_with_JSON_Query

This code converts the Oracle procedure into a PostgreSQL function that has JSON SQL queries. It shows how the query transposes JSON into rows and the reverse.

```
CREATE OR REPLACE PROCEDURE p_json_test(p_in_accounts_json IN varchar2,
 p_out_accunts_json  OUT varchar2)
IS
BEGIN
/*
p_in_accounts_json paramter should have following format:
       {
        "accounts": [{
          "accountNumber": 42000,
          "parentAccountNumber": 32000,
          "businessUnitId": 7
        }, {
          "accountNumber": 42001,
          "parentAccountNumber": 32001,
          "businessUnitId": 6
        }]
      }
*/
SELECT
    JSON_OBJECT(
        'accountCounts' VALUE JSON_ARRAYAGG(
            JSON_OBJECT(
                'businessUnitId' VALUE business_unit_id,
                        'parentAccountNumber' VALUE parent_account_number,
                        'accountNumber' VALUE account_number,
                        'totalOnlineContactsCount' VALUE online_contacts_count,
                        'countByPosition' VALUE
                    JSON_OBJECT(
                        'taxProfessionalCount' VALUE tax_count,
```

```
                        'attorneyCount' VALUE attorney_count,
                        'nonAttorneyCount' VALUE non_attorney_count,
                        'clerkCount' VALUE clerk_count
                               ) ) ) )
into p_out_accunts_json
FROM
    (SELECT
            tab_data.business_unit_id,
            tab_data.parent_account_number,
            tab_data.account_number,
            SUM(1) online_contacts_count,
            SUM(CASE WHEN tab_data.position_id = '0095' THEN  1 ELSE 0 END) tax_count,
            SUM(CASE    WHEN tab_data.position_id = '0100' THEN 1 ELSE 0 END)
 attorney_count,
            SUM(CASE    WHEN tab_data.position_id = '0090' THEN 1 ELSE 0 END)
 non_attorney_count,
            SUM(CASE    WHEN tab_data.position_id = '0050' THEN 1 ELSE 0 END)
 clerk_count
        FROM aws_test_table scco,JSON_TABLE ( json_doc, '$' ERROR ON ERROR
            COLUMNS (
            parent_account_number NUMBER PATH '$.data.account.parentAccountNumber',
            account_number NUMBER PATH '$.data.account.accountNumber',
            business_unit_id NUMBER PATH '$.data.account.businessUnitId',
            position_id VARCHAR2 ( 4 ) PATH '$.data.positionId'    )
            ) AS tab_data
            INNER JOIN JSON_TABLE ( p_in_accounts_json, '$.accounts[*]' ERROR ON ERROR

      COLUMNS (
      parent_account_number PATH '$.parentAccountNumber',
      account_number PATH '$.accountNumber',
      business_unit_id PATH '$.businessUnitId')
      ) static_data
      ON ( static_data.parent_account_number = tab_data.parent_account_number
           AND static_data.account_number = tab_data.account_number
           AND static_data.business_unit_id = tab_data.business_unit_id )
        GROUP BY
            tab_data.business_unit_id,
            tab_data.parent_account_number,
            tab_data.account_number
    );
EXCEPTION
WHEN OTHERS THEN
   raise_application_error(-20001,'Error while running the JSON query');
END;
```

```
/
```

Running the procedure

The following code block explains how you can run the previously created Oracle procedure with example JSON input to the procedure. It also gives you the result or output from this procedure.

```
set serveroutput on;
declare
v_out varchar2(30000);
v_in varchar2(30000):= '{
        "accounts": [{
          "accountNumber": 42000,
          "parentAccountNumber": 32000,
          "businessUnitId": 7
        }, {
          "accountNumber": 42001,
          "parentAccountNumber": 32001,
          "businessUnitId": 6
        }]
      }';
begin
  p_json_test(v_in,v_out);
  dbms_output.put_line(v_out);
end;
/
```

Procedure output

```
{
  "accountCounts": [
    {
      "businessUnitId": 6,
      "parentAccountNumber": 32001,
      "accountNumber": 42001,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
```

```
    {
      "businessUnitId": 7,
      "parentAccountNumber": 32000,
      "accountNumber": 42000,
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

8.Postgres_function_with_JSON_Query

Example function

```
CREATE OR REPLACE  FUNCTION f_pg_json_test(p_in_accounts_json  text)
RETURNS text
LANGUAGE plpgsql
AS
$$
DECLARE
 v_out_accunts_json   text;
BEGIN
SELECT
JSON_BUILD_OBJECT ('accountCounts',
    JSON_AGG(
        JSON_BUILD_OBJECT ('businessUnitId',businessUnitId
        ,'parentAccountNumber',parentAccountNumber
        ,'accountNumber',accountNumber
        ,'totalOnlineContactsCount',online_contacts_count,
        'countByPosition',
            JSON_BUILD_OBJECT (
            'taxProfessionalCount',tax_professional_count
            ,'attorneyCount',attorney_count
            ,'nonAttorneyCount',non_attorney_count
            ,'clerkCount',clerk_count
            ))))
INTO v_out_accunts_json
FROM (
WITH tab AS (SELECT * FROM (
```

```
SELECT (json_doc::json->'data'->'account'->>'parentAccountNumber')::INTEGER AS
 parentAccountNumber,
(json_doc::json->'data'->'account'->>'accountNumber')::INTEGER AS accountNumber,
(json_doc::json->'data'->'account'->>'businessUnitId')::INTEGER AS businessUnitId,
(json_doc::json->'data'->>'positionId')::varchar AS positionId
FROM aws_test_pg_table) a ) ,
tab1 AS ( SELECT
(json_array_elements(b.jc -> 'accounts') ->> 'accountNumber')::integer accountNumber,
(json_array_elements(b.jc -> 'accounts') ->> 'businessUnitId')::integer businessUnitId,
(json_array_elements(b.jc -> 'accounts') ->> 'parentAccountNumber')::integer
 parentAccountNumber
FROM (
SELECT p_in_accounts_json::json AS jc) b)
SELECT
tab.businessUnitId::text,
tab.parentAccountNumber::text,
tab.accountNumber::text,
SUM(1) online_contacts_count,
SUM(CASE WHEN tab.positionId::text = '0095' THEN 1 ELSE 0  END)
  tax_professional_count,
SUM(CASE WHEN tab.positionId::text = '0100' THEN 1 ELSE 0  END)      attorney_count,
SUM(CASE  WHEN tab.positionId::text = '0090' THEN      1  ELSE      0 END)
  non_attorney_count,
SUM(CASE  WHEN tab.positionId::text = '0050' THEN      1  ELSE      0 END)
  clerk_count
FROM tab1,tab
WHERE tab.parentAccountNumber::INTEGER=tab1.parentAccountNumber::INTEGER
AND tab.accountNumber::INTEGER=tab1.accountNumber::INTEGER
AND tab.businessUnitId::INTEGER=tab1.businessUnitId::INTEGER
GROUP BY      tab.businessUnitId::text,
            tab.parentAccountNumber::text,
            tab.accountNumber::text) a;
RETURN v_out_accunts_json;
END;
$$;
```

Running the function

```
select    f_pg_json_test('{
        "accounts": [{
          "accountNumber": 42001,
          "parentAccountNumber": 32001,
          "businessUnitId": 6
```

```
        }, {
          "accountNumber": 42000,
          "parentAccountNumber": 32000,
          "businessUnitId": 7
        }]
      }')   ;
```

Function output

The following output is similar to the Oracle procedure output. The difference is that this output is in Text format.

```
{
  "accountCounts": [
    {
      "businessUnitId": "6",
      "parentAccountNumber": "32001",
      "accountNumber": "42001",
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 0,
        "nonAttorneyCount": 1,
        "clerkCount": 0
      }
    },
    {
      "businessUnitId": "7",
      "parentAccountNumber": "32000",
      "accountNumber": "42000",
      "totalOnlineContactsCount": 1,
      "countByPosition": {
        "taxProfessionalCount": 0,
        "attorneyCount": 1,
        "nonAttorneyCount": 0,
        "clerkCount": 0
      }
    }
  ]
}
```

Copy Amazon DynamoDB tables across accounts using AWS Backup

Ramkumar Ramanujam, Amazon Web Services

Summary

When working with Amazon DynamoDB on AWS, a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that is in the production environment. As a standard practice, each environment uses a different AWS account.

AWS Backup supports cross-Region and cross-account backup and restoration of data for DynamoDB, Amazon Simple Storage Service (Amazon S3), and other AWS services. This pattern provides the steps for using AWS Backup cross-account backup and restore to copy DynamoDB tables between AWS accounts.

Prerequisites and limitations

Prerequisites

- Two active AWS accounts that belong to the same organization in AWS Organizations
- Permissions to create DynamoDB tables in both accounts
- AWS Identity and Access Management (IAM) permissions to create and use AWS Backup vaults

Limitations

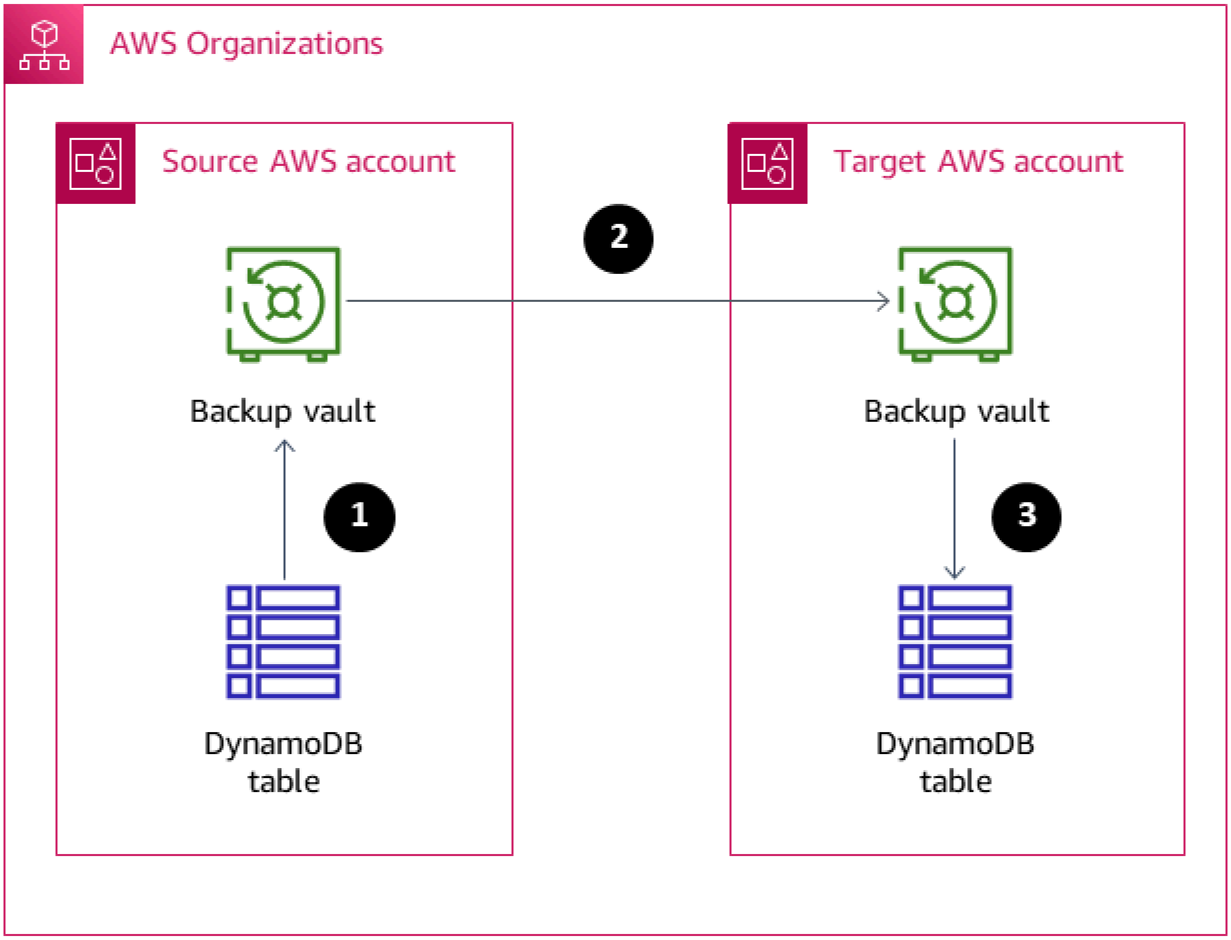
- Source and target AWS accounts should be part of the same organization in AWS Organizations.

Architecture

Target technology stack

- AWS Backup
- Amazon DynamoDB

Target architecture



1. Create the DynamoDB table backup in the AWS Backup backup vault in the source account.
2. Copy the backup to the backup vault in the target account.
3. Restore the DynamoDB table in the target account by using the backup from the backup vault in the target account.

Automation and scale

You can use AWS Backup to schedule backups to run at specific intervals.

Tools

- AWS Backup is a fully-managed service for centralizing and automating data protection across AWS services, in the cloud, and on premises. Using this service, you can configure backup policies and monitor activity for your AWS resources in one place. It allows you to automate and consolidate backup tasks that were previously performed service by service, and removes the need to create custom scripts and manual processes.

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

Epics

Turn on AWS Backup features in the source and target accounts

Task	Description	Skills required
Turn on advanced features for DynamoDB and cross-account backup.	In both the source and the target AWS accounts, do the following: 1. On the AWS Managemen t Console, open the AWS Backup console. 2. Choose **Settings**. 3. Under **Advanced features for Amazon DynamoDB backups**, confirm that **Advanced features** is enabled, or choose **Enable**. 4. Under **Cross-account management**, for **Cross-account backup**, choose **Enable**.	AWS DevOps, Migration engineer

Create backup vaults in the source and target accounts

Task	Description	Skills required
Create backup vaults.	In both the source and the target AWS accounts, do the following:	AWS DevOps, Migration engineer

Task	Description	Skills required
	1. On the [AWS Backup console](#), choose **Backup vaults**. 2. Choose **Create Backup vault**. 3. Copy the Amazon Resource Name (ARN) of the backup vault and save it. The ARNs of both the source and the target backup vaults will be required when you copy the DynamoDB table backup between the source and target accounts.	

Perform backup and restore using backup vaults

Task	Description	Skills required
In the source account, create a DynamoDB table backup.	To create a backup for the DynamoDB table in the source account, do the following: 1. On the AWS Backup **Dashboard** page, choose **Create on-demand backup**. 2. In the **Settings** section, for **Resource type**, select **DynamoDB**, and then select the table name.	AWS DevOps, DBA, Migration engineer

Task	Description	Skills required
	3. In the **Backup vault** dropdown list, select the backup vault that you created in the source account. 4. Select the **Retention period** that you want. 5. Choose **Create on-demand backup**. A new backup job is created. To monitor the status of the backup job, on the AWS Backup **Jobs** page, choose the **Backup Jobs** tab. All active, in-progress, and completed backup jobs are listed on this tab.	

Task	Description	Skills required
Copy the backup from the source account to the target account.	After the backup job is complete, copy the DynamoDB table backup from the backup vault in the source account to the backup vault in the target account. To copy the backup vault, in the source account, do the following: 1. On the [AWS Backup console](), choose **Backup vaults**. 2. Under **Backups**, choose the DynamoDB table backup. 3. Choose **Actions**, **Copy**. 4. Enter the AWS Region of the target account. 5. For **External vault ARN**, enter the ARN of the backup vault that you created in the target account. 6. To copy backups from the source account to the target account, in the target account backup vault, enable access from a different account.	AWS DevOps, Migration engineer, DBA

Task	Description	Skills required
Restore the backup in the target account.	In the target AWS account, do the following: 1. On the AWS Backup console, choose **Backup vaults**. 2. Under **Backups**, select the backup that you copied from the source account. 3. Choose **Actions**, **Restore**. 4. Enter the name of the target DynamoDB table that you want to restore.	AWS DevOps, DBA, Migration engineer

Copy Amazon DynamoDB tables across accounts using a custom implementation

Ramkumar Ramanujam, Amazon Web Services

Summary

When working with Amazon DynamoDB on Amazon Web Services (AWS), a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that are in the production environment. As a standard practice, each environment uses a different AWS account.

DynamoDB now supports cross-account backup using AWS Backup. For information about associated storage costs when using AWS Backup, see AWS Backup pricing. When you use AWS Backup to copy across accounts, the source and target accounts must be part of an AWS Organizations organization. There are other solutions for cross-account backup and restore using AWS services such as AWS Glue. Using those solutions, however, increases the application footprint, because there are more AWS services to deploy and maintain.

You can also use Amazon DynamoDB Streams to capture table changes in the source account. Then you can initiate an AWS Lambda function, and make the corresponding changes in the target table in the target account. But that solution applies to use cases in which source and target tables must always be kept in sync. It might not apply to development, testing, and staging environments where data are updated frequently.

This pattern provides steps to implement a custom solution to copy a Amazon DynamoDB table from one account to another. This pattern can be implemented using common programming languages such as C#, Java, and Python. We recommend using a language that is supported by an AWS SDK.

Prerequisites and limitations

Prerequisites

- Two active AWS accounts
- DynamoDB tables in both the accounts
- Knowledge of AWS Identity and Access Management (IAM) roles and policies
- Knowledge of how to access Amazon DynamoDB tables using any common programming language, such as C#, Java, or Python

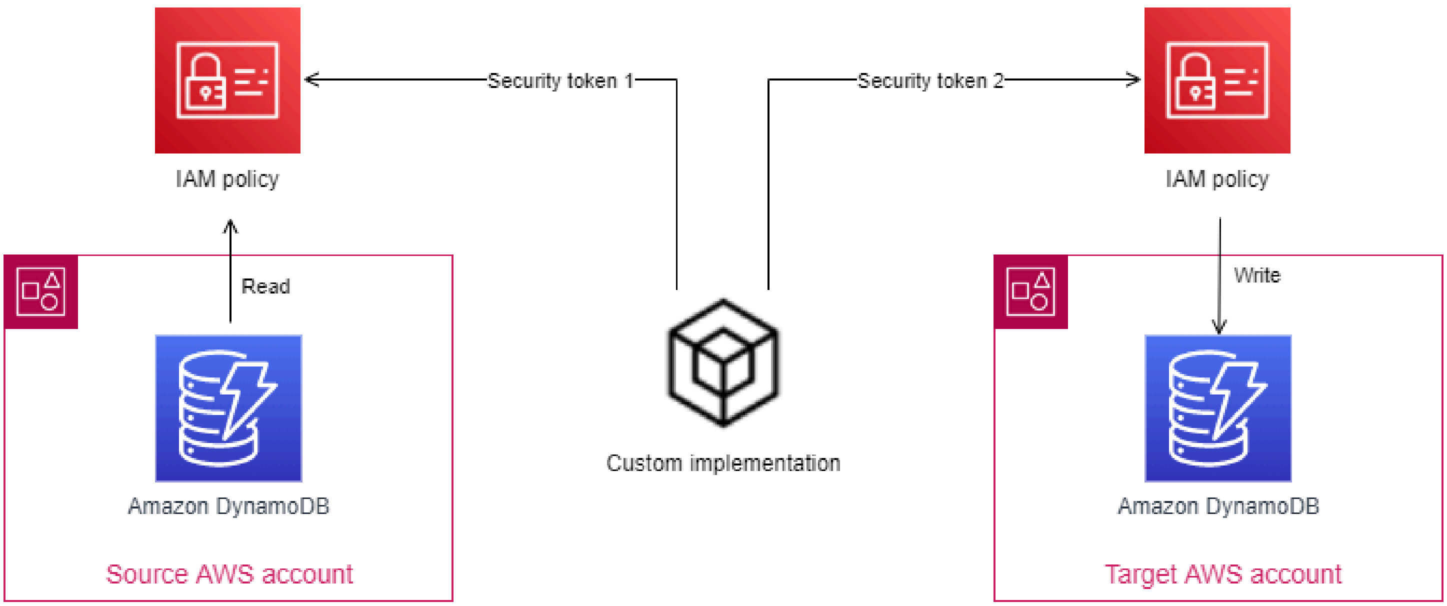
Limitations

This pattern applies to DynamoDB tables that are around 2 GB or smaller. With additional logic to handle connection or session interruptions, throttling, and failures and retries, it can be used for larger tables.

The DynamoDB scan operation, which reads items from the source table, can fetch only up to 1 MB of data in a single call. For larger tables, greater than 2 GB, this limitation can increase the total time to perform a full table copy.

Architecture

The following diagram shows the custom implementation between the source and target AWS accounts. IAM policies and security tokens are used with the custom implementation. Data is read from Amazon DynamoDB in the source account and written to DynamoDB in the target account.



Automation and scale

This pattern applies to DynamoDB tables that are smaller in size, around 2 GB.

To apply this pattern for larger tables, address the following issues:

- During the table copy operation, two active sessions are maintained, using different security tokens. If the table copy operation takes longer than the token expiration times, you must put in place logic to refresh the security tokens.

- If enough read capacity units (RCUs) and write capacity units (WCUs) are not provisioned, reads or writes on the source or target table might get throttled. Be sure to catch and handle these exceptions.
- Handle any other failures or exceptions and put a retry mechanism in place to retry or continue from where the copy operation failed.

Tools

Tools

- Amazon DynamoDB – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- The additional tools required will differ based on the programming language that you choose for the implementation. For example, if you use C#, you will need Microsoft Visual Studio and the following NuGet packages:
  - `AWSSDK`
  - `AWSSDK.DynamoDBv2`

Code

The following Python code snippet deletes and recreates a DynamoDB table using the Boto3 library.

Do not use the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` of an IAM user because these are long-term credentials, which should be avoided for programmatic access to AWS services. For more information about temporary credentials, see the *Best practices* section.

The `AWS_ACCESS_KEY_ID`, `AWS_SECRET_ACCESS_KEY`, and `TEMPORARY_SESSION_TOKEN` used in the following code snippet are temporary credentials fetched from AWS Security Token Service (AWS STS).

```
import boto3
import sys
import json

#args = input-parameters = GLOBAL_SEC_INDEXES_JSON_COLLECTION,
 ATTRIBUTES_JSON_COLLECTION, TARGET_DYNAMODB_NAME, TARGET_REGION, ...
```

```
#Input param: GLOBAL_SEC_INDEXES_JSON_COLLECTION
#[{"IndexName":"Test-index","KeySchema":[{"AttributeName":"AppId","KeyType":"HASH"},
{"AttributeName":"AppType","KeyType":"RANGE"}],"Projection":
{"ProjectionType":"INCLUDE","NonKeyAttributes":["PK","SK","OwnerName","AppVersion"]}}]

#Input param: ATTRIBUTES_JSON_COLLECTION
#[{"AttributeName":"PK","AttributeType":"S"},
{"AttributeName":"SK","AttributeType":"S"},
{"AttributeName":"AppId","AttributeType":"S"},
{"AttributeName":"AppType","AttributeType":"N"}]

region = args['TARGET_REGION']
target_ddb_name = args['TARGET_DYNAMODB_NAME']

global_secondary_indexes = json.loads(args['GLOBAL_SEC_INDEXES_JSON_COLLECTION'])
attribute_definitions = json.loads(args['ATTRIBUTES_JSON_COLLECTION'])

# Drop and create target DynamoDB table
dynamodb_client = boto3.Session(
        aws_access_key_id=args['AWS_ACCESS_KEY_ID'],
        aws_secret_access_key=args['AWS_SECRET_ACCESS_KEY'],
        aws_session_token=args['TEMPORARY_SESSION_TOKEN'],
    ).client('dynamodb')

# Delete table
print('Deleting table: ' + target_ddb_name + ' ...')

try:
    dynamodb_client.delete_table(TableName=target_ddb_name)

    #Wait for table deletion to complete
    waiter = dynamodb_client.get_waiter('table_not_exists')
    waiter.wait(TableName=target_ddb_name)
    print('Table deleted.')
except dynamodb_client.exceptions.ResourceNotFoundException:
    print('Table already deleted / does not exist.')
    pass

print('Creating table: ' + target_ddb_name + ' ...')

table = dynamodb_client.create_table(
    TableName=target_ddb_name,
    KeySchema=[
        {
```

```
            'AttributeName': 'PK',
            'KeyType': 'HASH'  # Partition key
        },
        {
            'AttributeName': 'SK',
            'KeyType': 'RANGE'  # Sort key
        }
    ],
    AttributeDefinitions=attribute_definitions,
    GlobalSecondaryIndexes=global_secondary_indexes,
    BillingMode='PAY_PER_REQUEST'
)

waiter = dynamodb_client.get_waiter('table_exists')
waiter.wait(TableName=target_ddb_name)

print('Table created.')
```

Best practices

Temporary credentials

As a security best practice, while accessing AWS services programmatically, avoid using the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` of an IAM user because these are long-term credentials. Always try to use temporary credentials to access AWS services programmatically.

As an example, a developer hardcodes the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` of an IAM user in the application during development but fails to remove the hardcoded values before pushing changes to code repository. These exposed credentials can be used by unintended or malicious users, which can have serious implications (especially if the exposed credentials have admin privileges). These exposed credentials should be deactivated or deleted immediately by using the IAM console or AWS Command Line Interface (AWS CLI).

To get temporary credentials for programmatic access to AWS services, use AWS STS. Temporary credentials are valid only for the specified time (from 15 minutes up to 36 hours). The maximum allowed duration of temporary credentials varies depending on such factors as role settings and role chaining. For more information about AWS STS, see the documentation.

Epics

Set up DynamoDB tables

Task	Description	Skills required
Create DynamoDB tables.	Create DynamoDB tables, with indexes, in both source and target AWS accounts. Set the capacity provision ing as on-demand mode, which allows DynamoDB to scale read/write capacitie s dynamically based on the workload. Alternatively, you can use provisioned capacity with 4000 RCUs and 4000 WCUs.	App developer, DBA, Migration engineer
Populate the source table.	Populate the DynamoDB table in the source account with test data. Having at least 50 MB or more of test data helps you to see the peak and average RCUs consumed during table copy. You can then change the capacity provisioning as needed.	App developer, DBA, Migration engineer

Set up credentials to access the DynamoDB tables

Task	Description	Skills required
Create IAM roles to access the source and target DynamoDB tables.	Create an IAM role in the source account with permissions to access (read) the DynamoDB table in the source account. Add the source account as a trusted entity for this role. Create an IAM role in the target account with permissions to access (create, read, update, delete) the DynamoDB table in the target account. Add the target account as a trusted entity for this role.	App developer, AWS DevOps

Copy table data from one account to another

Task	Description	Skills required
Get temporary credentials for the IAM roles.	Get temporary credentials for IAM role created in source account. Get temporary credentials for IAM role created in target account. One way to get the temporary credentials for the	App developer, Migration engineer

Task	Description	Skills required
	IAM role is to use AWS STS from the AWS CLI. `aws sts assume-role --role-arn arn:aws:iam::<account-id>:role/<role-name> --role-session-name <session-name> --profile <profile-name>` Use the appropriate AWS profile (corresponding to the source or target account). For more information about different ways to get temporary credentials, see the following: • AWS Security Token Service API Reference • Getting IAM role credentials for CLI access	

Task	Description	Skills required
Initialize the DynamoDB clients for source and target DynamoDB access.	Initialize the DynamoDB clients, which are provided by the AWS SDK, for the source and target DynamoDB tables. • For the source DynamoDB client, use the temporary credentials fetched from the source account. • For the target DynamoDB client, use the temporary credentials fetched from the target account. For more information about making requests by using IAM temporary credentials, see the AWS documentation.	App developer

Task	Description	Skills required
Drop and recreate the target table.	Delete and recreate the target DynamoDB table (along with indexes) in the target account, using the target account DynamoDB client. Deleting all records from a DynamoDB table is a costly operation because it consumes provisioned WCUs. Deleting and recreating the table avoids those extra costs. You can add indexes to a table after you create it, but this takes 2–5 minutes longer. Creating indexes during table creation, by passing the indexes collection to the `createTable` call, is more efficient.	App developer

Task	Description	Skills required
Perform the table copy.	Repeat the following steps until all data are copied: • Perform a scan on the table in the source account, using the source DynamoDB client. Each DynamoDB scan retrieves only 1 MB of data from the table, so you must repeat this operation until all items, or records, are read. • For each set of scanned items, write the items to the table in the target account, with the target DynamoDB client, using the `BatchWriteItem` call in AWS SDK for DynamoDB. This reduces the number of `PutItem` requests made to DynamoDB. • `BatchWriteItem` has a limitation of 25 writes or puts, or up to 16 MB. You must add logic to accumulate scanned items in counts of 25 before calling `BatchWriteItem` . `BatchWriteItem` returns a list of items that could not be successfully copied. Using this list, add retry logic to perform another	App developer

Task	Description	Skills required
	`BatchWriteItem` call with only those items that did not succeed. For more information, see the reference implementation in C# (for dropping, creating, and populating tables) in the *Attachments* section. An example table config JavaScript Object Notation (JSON) file is also attached.

- Using temporary credentials with AWS resources

Additional information

This pattern was implemented using C# to copy a DynamoDB table with 200,000 items (average item size of 5 KB and table size of 250 MB). The target DynamoDB table was set up with provisioned capacity of 4000 RCUs and 4000 WCUs.

The complete table copy operation (from source account to target account), including dropping and recreating the table, took 5 minutes. Total capacity units consumed: 30,000 RCUs and approximately 400,000 WCUs.

For more information on DynamoDB capacity modes, see Read/Write capacity mode in the AWS documentation.

Create detailed cost and usage reports for Amazon RDS and Amazon Aurora

Lakshmanan Lakshmanan, Amazon Web Services

Sudarshan Narasimhan, None

Summary

This pattern shows how to track usage costs for Amazon Relational Database Service (Amazon RDS) or Amazon Aurora clusters by configuring user-defined cost allocation tags. You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for clusters across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level, and then analyze the data in Amazon Athena.

Prerequisites and limitations

Prerequisites

- An active AWS account
- One or more Amazon RDS or Amazon Aurora instances

Limitations

For tagging restrictions, see the AWS Billing User Guide.

Architecture

Target technology stack

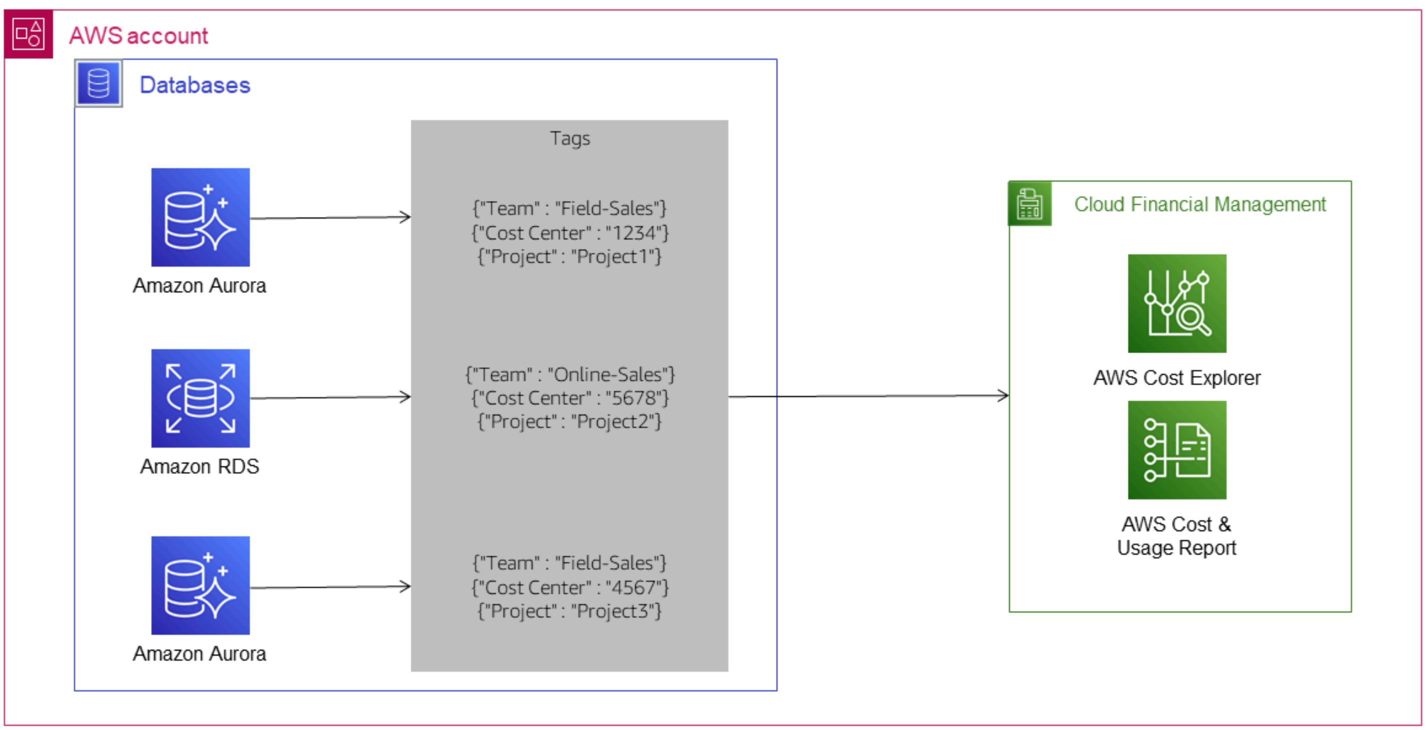
- Amazon RDS or Amazon Aurora
- AWS Cost and Usage Report
- AWS Cost Explorer
- Amazon Athena

Workflow and architecture

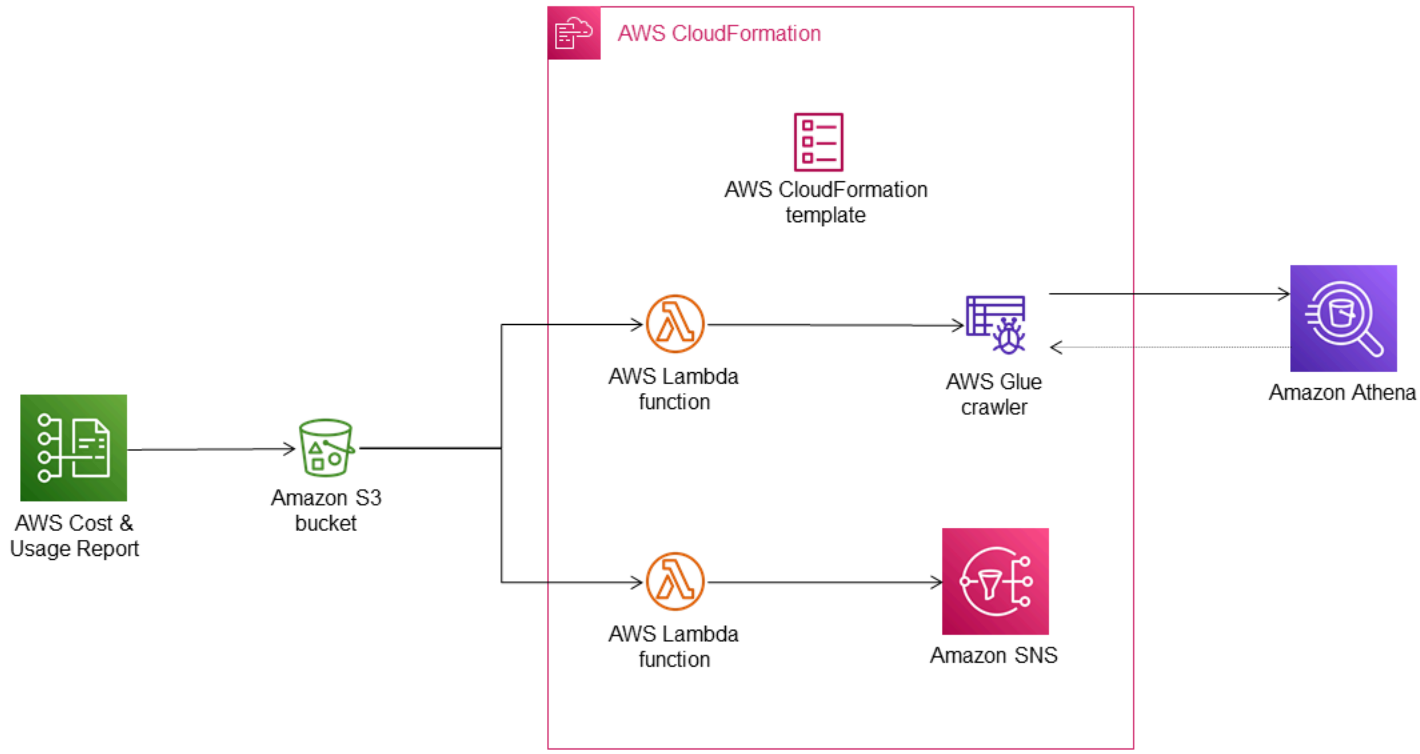
The tagging and analysis workflow consists of these steps:

1. A data engineer, database administrator, or AWS administrator creates user-defined cost allocation tags for the Amazon RDS or Aurora clusters.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.
4. A data engineer, database administrator, or AWS administrator creates a monthly cost allocation report.
5. A data engineer, database administrator, or AWS administrator analyzes the monthly cost allocation report by using Amazon Athena.

The following diagram shows how to apply tags to track usage costs for Amazon RDS or Aurora instances.



The following architecture diagram shows how the cost allocation report is integrated with Amazon Athena for analysis.



The monthly cost allocation report is stored in an Amazon S3 bucket that you specify. When you set up Athena with the AWS CloudFormation template, as described in the *Epics* section, the template provisions several additional resources, including an AWS Glue crawler, an AWS Glue database, an Amazon Simple Notification System (Amazon SNS) event, AWS Lambda functions, and AWS Identity and Access Management (IAM) roles for the Lambda functions. As new cost data files arrive in the S3 bucket, event notifications are used to forward these files to a Lambda function for processing. The Lambda function initiates an AWS Glue crawler job to create or update the table in the AWS Glue Data Catalog. This table is then used to query data in Athena.

Tools

- Amazon Athena is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- Amazon Aurora is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.

- AWS CloudFormation is an infrastructure as code (IaC) service that allows you to easily model, provision, and manage AWS and third-party resources.
- AWS Cost Explorer helps you view and analyze your AWS costs and usage.

Epics

Create and activate tags for your Amazon RDS or Aurora cluster

Task	Description	Skills required
Create user-defined cost allocation tags for your Amazon RDS or Aurora cluster.	To add tags to a new or existing Amazon RDS or Aurora cluster, follow the instructions in Adding, listing, and removing tags in the *Amazon Aurora User Guide*. **Note** For information about how to set up an Amazon Aurora cluster, see the instructions for MySQL and PostgreSQL in the *Amazon Aurora User Guide*.	AWS administrator, Data engineer, DBA
Activate the user-defined cost allocation tags.	Follow the instructions in Activating user-defined cost allocation tags in the *AWS Billing User Guide*.	AWS administrator

Create cost and usage reports

Task	Description	Skills required
Create and configure cost and usage reports for your clusters.	1. Sign in to the AWS Management Console and open the [AWS Billing console](https://console.aws.amazon.com/billing/). 2. In the left navigation pane, choose **Cost & Usage Reports**. 3. Choose **Create report**. 4. Provide a report name, keep the default settings for other options, and then choose **Next**. 5. Choose **Configure** and provide the details of an existing S3 bucket. You can also choose to create a new S3 bucket from this screen. Choose **Next**. 6. Verify the default policy that will be applied to your bucket, select the confirmation check box, and then choose **Save**. 7. For **Report path prefix**, specify the prefix you want to prepend to the report name. 8. For **Time granularity**, choose **Hourly**, **Daily** or **Monthly**, depending on how often you want data	App owner, AWS administrator, DBA, General AWS, Data engineer

Task	Description	Skills required
	to be collected for the report. 9. For **Report versioning**, choose whether you want new versions of the report to be created separately or overwrite the existing report with each version. 10. For **Enable report data integration for**, choose **Amazon Athena**. Verify that the compression type is set to Parquet. 11. Choose **Next**. 12. Review the report settings, and then choose **Review and Complete**. The data will be available in 24 hours.	

Analyze cost and usage report data

Task	Description	Skills required
Analyze the cost and usage report data.	1. Set up and use Athena to analyze the report data. For instructions, see [Querying Cost and Usage Reports using Amazon Athena](#) in the *AWS Cost and Usage Reports User Guide*. We recommend	App owner, AWS administr ator, DBA, General AWS, Data engineer

Task	Description	Skills required
	that you use the AWS CloudFormation template provided by Athena. 2. Run Athena queries. For example, you can use the following SQL query to check the status of the data refresh. `select status from cost_and_usage_data_status` For more information, see Running Amazon Athena queries in the *AWS Cost and Usage Reports User Guide*. **Note** When you run your SQL query, make sure that the correct database is selected from the dropdown list.

Deploy SQL Server failover cluster instances on Amazon EC2 and Amazon FSx by using Terraform

Mark Hudson and Matt Burgess, Amazon Web Services

Summary

This pattern uses Terraform to deploy SQL Server failover cluster instances (FCIs) across Windows Server Failover Cluster (WSFC) nodes on Amazon Elastic Compute Cloud (Amazon EC2). In addition, the pattern uses Amazon FSx shared storage for data and log files.

When SQL Server databases are migrated to AWS, the first choice is Amazon RDS for SQL Server. However, sometimes Amazon RDS for SQL Server isn't suitable and SQL Server must be deployed on Amazon EC2 in a highly available architecture. In this solution, SQL Server FCIs are installed across WSFC nodes.

The Terraform module included with this pattern provisions up to two Amazon EC2 SQL Server instances. An Amazon FSx for Windows File Server file system acts as the quorum witness and stores shared data and log files. Regardless of the number of instances configured, the SQL Server instance nodes will always create and join an FCI cluster to ensure environmental parity. (Typically, one instance is configured for development and two instances for production environments.) For configurations that use two nodes for high availability, an internal Network Load Balancer is provisioned. The Network Load Balancer uses a health probe configured on the FCI cluster to identify which node is the primary.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Amazon Virtual Private Cloud (Amazon VPC) with two subnets in separate Availability Zones.
- Amazon VPC [DHCP option set](). Configure the domain name to resolve to your Active Directory domain name and the domain and NetBIOS name servers to point to your Active Directory domain controllers. For more information, see *VPC configuration* in [Additional information]().
- AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD).
- Custom Amazon Machine Image (AMI). For more details, see *AMI configuration* in [Additional information]().

- Amazon Simple Storage Service (Amazon S3) bucket containing the SQL Server ISO image. This prerequisite is only required if using EC2 Image Builder with the provided `component.yaml` file to build the custom AMI.
- AWS Key Management Service (AWS KMS) encryption key.
- By default, SQL Server is installed using a developer edition product key. Production systems are expected to use a valid product key passed to the module by the relevant variable.

Limitations

- This solution requires AWS Managed Microsoft AD. However, if you prefer, you can use a self-managed Active Directory implementation instead. To do so, modify the included Amazon FSx Terraform module to remove the `active_directory_id` attribute. Then, add the four attributes that are required for self-managed Active Directory as shown in the Terraform documentation.
- SQL Server is set up to use mixed mode authentication. If you prefer, you can use Windows-only authentication. To do so, in the provided user data script, remove the `/SECURITYMODE` and `/SAPWD` parameters that are supplied to the `setup.exe` command. You can remove the `sql_accounts.tf` file, and you can modify the `instances.tf` file to remove the `sql_sa_password` entry.
- When deleting a deployed cluster, you must remove the corresponding virtual computer objects and individual computer objects in Active Directory. To remove the objects, use Active Directory administrative tools.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

This solution was tested with the following versions:

- Windows Server 2019
- SQL Server 2019
- Terraform v0.13.0

Architecture

Source technology stack

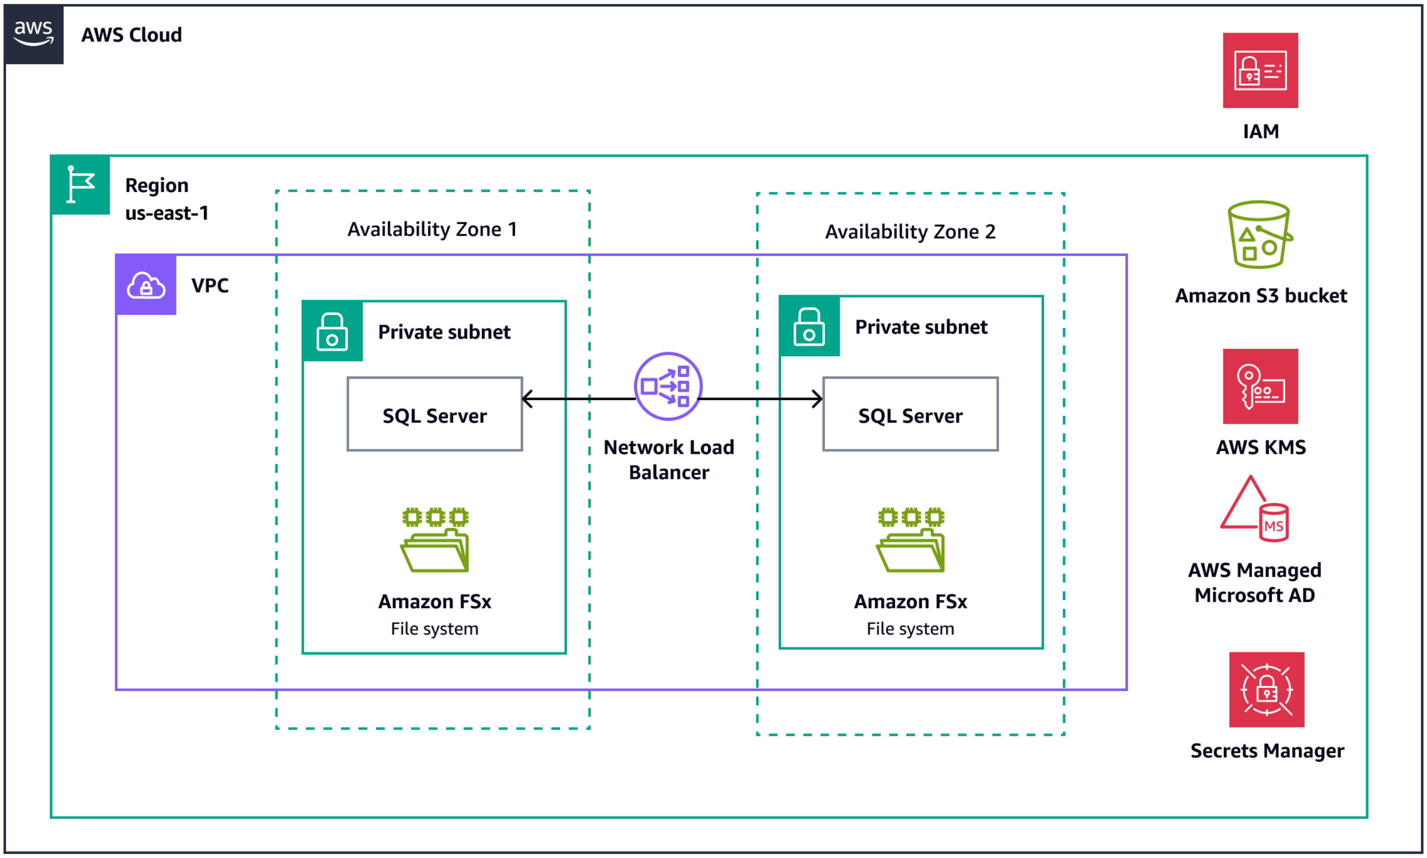
- SQL Server

Target technology stack

- SQL Server FCI on WSFC nodes using Amazon EC2
- Amazon FSx for Windows File Server
- Amazon S3 bucket
- AWS Secrets Manager
- AWS Managed Microsoft AD
- AWS KMS
- AWS Identity and Access Management (IAM)

Target architecture

The following diagram shows the architecture for this solution.



The diagram shows the following:

- An IAM role providing the EC2 instances access to AWS KMS and Secrets Manager
- Two SQL Server nodes deployed on Amazon EC2 instances in private subnets across two Availability Zones
- A Network Load Balancer for facilitating connections to the active SQL Server instance (not deployed when setting up a single node cluster)
- Amazon FSx for Windows File Server file system deployed in both private subnets for shared storage by the SQL Server nodes
- Secrets Manager for storing Active Directory and SQL Server credentials and configuration
- Amazon S3 bucket for storing the SQL Server installation image
- AWS Managed Microsoft AD for Windows authentication
- AWS KMS for creating the encryption key

Automation and scale

You can automate the deployment of the target architecture by using the Terraform modules that are in the GitHub repository. You must modify the `terraform.tfvars` file to include variable values that are specific to your environment. The Amazon S3 bucket, AWS Managed Microsoft AD components, AWS KMS encryption key, and some secrets are prerequisites for this deployment and are not included in the Terraform code.

Tools

AWS services

- AWS Directory Service for Microsoft Active Directory enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud. In this pattern, AWS Managed Microsoft AD is used for Windows Server and SQL Server authentication and for DNS.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down. In this pattern, SQL Server failover cluster instances are installed on Amazon EC2 instances.
- EC2 Image Builder helps you automate the creation, management, and deployment of customized server images.
- Amazon FSx for Windows File Server provides fully managed shared storage on Windows Server. In this pattern, FSx for Windows File Server provides shared storage for SQL Server data and log files and the quorum witness.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data. In this pattern, it's used to encrypt Secrets Manager secrets, the SQL Server storage on Amazon Elastic Block Store (Amazon EBS) volumes, and the FSx for Windows File Server file system.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, Active Directory credentials for installing and running SQL Server, the `sa` user credentials, and the database connection information are stored in Secrets Manager.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. This pattern uses an Amazon S3 bucket to store the SQL Server installation image.

- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- Microsoft SQL Server FCIs are installed across Windows Server cluster nodes. In addition, they can be installed across multiple subnets. In this pattern, SQL Server FCI instances are installed across WSFC nodes.
- Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. In this pattern, Terraform is used to create the resources and configure the SQL Server FCI instances.
- Windows Server Failover Clustering provides infrastructure features that support the high-availability of hosted server applications such as SQL Server. In this pattern, the FCI nodes make use of WSFC functionality to provide local high availability through redundancy at the instance level.

Code repository

The code for this pattern is available in the GitHub cluster-amazon-elastic-compute-cloud-amazon-fsx-microsoft-sql-server repository. The following resources are available in the repository:

- A `README.md` file that provides an overview of the solution and additional installation and usage information
- A base set of Terraform configuration files and an Amazon FSx specific module to provision the components for this pattern
- An instance setup script that is run as an Amazon EC2 user data script
- A `component.yaml` file that Image Builder can use to create a custom AMI

Best practices

Security and patching

- The AMI prerequisite installations and configurations are the minimum requirements to deploy SQL Server FCI clusters. Additional software and configurations might be required to comply with your organization's standards and security requirements.

- After deployment, patch Windows on an ongoing basis. Either directly patch the running instances, or create a new AMI with the latest Windows patches and replace the instances (one at a time) using the new AMI. AWS releases new Windows AMIs monthly that contain the latest operating system patches, drivers, and launch agents. We recommend that you check for the latest AMI when you launch new instances, or when you build your own custom images.
- The Amazon EC2 instances are configured to allow all outgoing traffic. When deployed in a production environment, outbound rules in the security group should be put in place to restrict this traffic to the required destinations.
- The FSx for Windows File Server file system can automatically record audit logs for file share and file and folder access and ship them to your desired destination if this is a requirement in your environment.
- Rotate Secrets Manager secrets automatically on a regular basis. For the Amazon EC2 instance key pair, consider an automated rotation solution as described in [How to use AWS Secrets Manager to securely store and rotate SSH key pairs](). For the Active Directory credentials and SQL Server `sa` credential secrets, set up automated rotation according to your policies for password management.

Active Directory management

- As part of the FCI cluster, Windows generates a Computer Name Object (CNO) in Active Directory. The CNO responds to DNS requests and forwards traffic to the active SQL node. We do *not* recommend using this Active Directory-provided DNS. The TTL is too high to provide a reasonable failover time and often takes upwards of 5 minutes to reflect the new primary IP address. In contrast, for highly available installations, the internal Network Load Balancer is configured to failover within 30 seconds.
- An Active Directory domain administrator is required to create the cluster. This requirement is because of the elevated permissions required to create the cluster objects and modify permissions in Active Directory. However, the SQL Server services don't need to run as a domain administrator. Therefore, we recommend that you create a second Active Directory user for this purpose. However, you can eliminate this user if the services will run as the domain administrator user. In that case, the domain administrator user must be added to the Active Directory administrators group that is created as part of this pattern.

Epics

Set up cluster credentials

Task	Description	Skills required
Create Active Directory groups.	In AWS Managed Microsoft AD, create the following groups: • **Cluster administrator group** – This group will be added to the local Administrators group on each cluster node. • **Cluster remote desktop group** – This group will be added to the local Remote Desktop Users group on each cluster node. For more details, see Creating an AWS Managed Microsoft AD group in the AWS documentation.	AD administrator
Create Active Directory users.	In AWS Managed Microsoft AD, create the following users • **Domain administrator user** – Use this account to create the cluster. • **Domain user** – The SQL Server services will use this account to run. Add this user to the cluster administrator group that	AD administrator

Task	Description	Skills required
	you created in the previous task. For more details, see [Creating an AWS Managed Microsoft AD user](#) in the AWS documentation.	
Add Active Directory credentials to secrets.	Use Secrets Manager to create four secrets to store the following information: • Domain administrator user's username • Domain administrator user's password • Domain user's username • Domain user's password For more details, see [Create an AWS Secrets Manager secret](#) in the AWS documenta tion.	AWS administrator

Prepare the environment

Install the cluster

Task	Description	Skills required
Modify the Terraform variables.	Update the supplied `terraform.tfvars` file to set all variables to values appropriate for your environment. For example, update the `domain_group_administrators` and `domain_group_rdp_users` variables to use your Active Directory domain name and the name of the previously created Active Directory groups.	AWS DevOps
Initialize Terraform.	To see the proposed deployment, navigate to the root of the repository. Use	AWS DevOps

Task	Description	Skills required
	the Terraform command line interface (CLI) to run `terraform init` and then run `terraform plan`.	
Deploy resources.	To deploy the SQL cluster and associated resources, use the Terraform CLI to run `terraform apply`.	AWS DevOps, AWS administr ator

Task	Description	Skills required
Validate the deployment.	To validate the deployment, use the following steps: 1. Connect to one of the deployed Windows Amazon EC2 instances by using Remote Desktop. 2. For more details, see Connect to your Windows instance using RDP in the AWS documentation. 3. Open the Windows Failover Cluster Manager. Validate that the cluster was created, and that the SQL Server role was created and is running. 4. To test connectivity and authentication with SQL Server, use a database tool such as SQL Server Management Studio to connect to the SQL Server endpoint. (The endpoint value is stored in Secrets Manager.) For more details, see Connect to Microsoft SQL Server on Amazon EC2 in the AWS documentation.	DBA, AWS systems administr ator

Troubleshooting

Issue	Solution
Terraform provisioning completed but Windows Failover Cluster Manager does not show a cluster has been created or the cluster is in a non-operable state.	The entire installation of the resources and configuration of the clusters can can take 45-60 minutes. After Terraform has completed , the user data script must run to completion, which requires multiple reboots. To monitor progress, you can use the `Checkpoints` directory in the `C:\` drive and the SQL Server installation logs in `C:\Program Data\Microsoft SQL Server\150\Log` . When finished, the **Installation Complete** message is available in the `C:\ProgramData\Amazon\EC2-Windows\Launch\Log\UserdataExecution.log` file.
After provisioning a functioning cluster, using Terraform to delete and re-create the cluster does not succeed. Terraform completes, but the cluster is not set up properly.	Part of the provisioning process involves registering machines and virtual objects to Active Directory and Active Directory DNS. When computer names exist for the Amazon EC2 cluster nodes and the cluster node, FCI cannot initialize correctly and will fail provisioning. To fix this issue, perform the following steps: 1. Delete the Amazon EC2 nodes, cluster virtual computer, and cluster id in Active Directory users and computers. 2. Delete the DNS entry for the cluster virtual computer in Active Directory DNS. 3. Run the following command to delete the cluster id random string Terraform resource `terragrunt destroy -target=random_string.cluster_id` . This

Issue	Solution
	action will delete the existing Amazon EC2 instances. 4. Run `terraform apply`, and expect the following three new resources: Two FCI Amazon EC2 instances and 1 random string cluster id.

Additional information

Terraform module information

This module uses a mixture of AMI configuration and user data configuration to obtain a good mix of provisioning time and stability. During provisioning, Windows requires multiple restarts and waits. A checkpoints method has been implemented to protect against infinite loops during restarts of the persistent user data. User data is configured to be persistent. Therefore, the user data configuration scripts have, and must continue, to be developed to be idempotent. Idempotency streamlines the updating process, allowing for instances to be swapped out during an update cycle without manual configuration to rejoin or re-create FCI clusters.

SQL Server connection strings and failover clustering

The module will publish a secret containing the endpoint address that should be used in connection strings for this database. The secret name follows the format `{environment_name}/sqlserver/{cluster_name}/endpoint`. For installations where only one node is used, you can expect this to be the IP address of the Amazon EC2 instance SQL Server interface. For high availability installations (two instances), you can expect this to be the DNS name of the internal Network Load Balancer.

Failover clustering virtual IPs aren't supported in this module. A virtual IP must remain in the same subnet in order to work. In AWS, a single subnet can't span multiple Availability Zones. Therefore, the use of virtual IPs would remove the ability for this module to be considered highly available.

Each Amazon EC2 instance is given three private IP addresses. Their usais as follows:

- **Primary IP for network traffic** – The source IP for egress traffic.
- **FCI communications –** Used to maintain the state and sync of the failover cluster.
- **SQL Server (TCP port 1433) –** Listener and also listens for heartbeat traffic to determine which instance is primary.

VPC configuration

The prerequisites list a DHCP options set that's configured to use Active Directory for DNS resolution. However, this prerequisite isn't a hard requirement. The hard requirement is that the EC2 instances must be able to resolve your Active Directory domain name. Meeting this requirement can be accomplished in other ways, such as by using Amazon Route 53 Resolver endpoints. For more information, see Integrating your Directory Service's DNS resolution with Amazon Route 53 Resolvers (AWS Blog post).

AMI configuration

The AMI used in this pattern must contain the following prerequisite software and configurations:

1. Download and expand the SQL Server 2019 installation files into `C:\SQL_Install_media`.
2. Install the following Windows features:
   - `Install-WindowsFeature Failover-Clustering`
   - `Install-WindowsFeature RSAT-AD-PowerShell`
   - `Install-WindowsFeature RSAT-AD-Tools`
   - `Install-WindowsFeature RSAT-Clustering-Mgmt`
   - `Install-WindowsFeature RSAT-Clustering-PowerShell`
   - `Install-WindowsFeature RSAT-Clustering-CmdInterface`
3. Disable the Windows firewall as follows:

- Get-NetFirewallProfile | Set-NetFirewallProfile -Enabled False

4. Enable CredSSP authentication method (replace <domain> with your organization's Windows domain name) as follows:
   - Enable-WSManCredSSP -Role "Server" -Force
   - Enable-WSManCredSSP -Role "Client" -DelegateComputer *.<domain>.com -Force
5. Set the following registry keys:
   - Allow NTLM authentication credentials:
     - HKLM:\Software\Policies\Microsoft\Windows\CredentialsDelegation
       - Name: AllowFreshCredentialsWhenNTLMOnly
       - Value: 1
       - Type: REG_DWORD
   - Allow local domain computers to use NTLM from PowerShell:
     - Path: HKLM:\Software\Policies\Microsoft\Windows\CredentialsDelegation\AllowFreshCredentialsWhenNTLMOnly
       - Name: 1
       - Value: wsman/*.<domain>.com
       - Type: REG_SZ
6. Set up the [PowerShell Gallery]() as follows:
   - [Net.ServicePointManager]::SecurityProtocol = [Net.SecurityProtocolType]::Tls12
   - Install-PackageProvider -Name NuGet -MinimumVersion 2.8.5.201 -Force
   - Set-PSRepository -Name PSGallery -InstallationPolicy Trusted
7. Install the following Windows PowerShell modules*:
   - Install-Module -Name ComputerManagementDsc
   - Install-Module -Name FailOverClusterDsc
   - Install-Module -Name PSDscResources
   - Install-Module -Name xSmbShare
   - Install-Module -Name xActiveDirectory
   - Install-Module -Name SqlServer

To use Image Builder to create the AMI, follow the instructions in Create an image pipeline using the EC2 Image Builderconsole wizard in the Image Builder documentation. To create the recipe's component with the previous prerequisites, use the following steps:

1. Download the component.yaml file from the `ami` folder of the GitHub repository.
2. Copy the contents into a new Image Builder component.
3. Update the following placeholders with your information:
   - `<domain>` – Your Active Directory domain name
   - `<bucket_name>` – Name of the Amazon S3 bucket that contains the SQL Server image

Emulate Oracle PL/SQL associative arrays in Amazon Aurora PostgreSQL and Amazon RDS for PostgreSQL

Rajkumar Raghuwanshi, Bhanu Ganesh Gudivada, and Sachin Khanna, Amazon Web Services

Summary

This pattern describes how to emulate Oracle PL/SQL associative arrays with empty index positions in Amazon Aurora PostgreSQL and Amazon RDS for PostgreSQL environments. It also describes some of the differences between Oracle PL/SQL associative arrays and PostgreSQL arrays with regard to how each handles empty index positions during migrations.

We provide a PostgreSQL alternative to using `aws_oracle_ext` functions for handling empty index positions when migrating an Oracle database. This pattern uses an additional column to store index positions, and it maintains Oracle's handling of sparse arrays while incorporating native PostgreSQL capabilities.

Oracle

In Oracle, collections can be initialized as empty and populated using the `EXTEND` collection method, which appends `NULL` elements to the array. When working with PL/SQL associative arrays indexed by `PLS_INTEGER`, the `EXTEND` method adds `NULL` elements sequentially, but elements can also be initialized at nonsequential index positions. Any index position that isn't explicitly initialized remains empty.

This flexibility allows for sparse array structures where elements can be populated at arbitrary positions. When iterating through collections using a `FOR LOOP` with `FIRST` and `LAST` bounds, only the initialized elements (whether `NULL` or with a defined value) are processed, while empty positions are skipped.

PostgreSQL (Amazon Aurora and Amazon RDS)

PostgreSQL handles empty values differently from `NULL` values. It stores empty values as distinct entities that use one byte of storage. When an array has empty values, PostgreSQL assigns sequential index positions just like non-empty values. But sequential indexing requires additional processing because the system must iterate through all indexed positions, including the empty ones. This makes traditional array creation inefficient for sparse datasets.

AWS Schema Conversion Tool

The AWS Schema Conversion Tool (AWS SCT) typically handles Oracle-to-PostgreSQL migrations using `aws_oracle_ext` functions. In this pattern, we propose an alternative approach that uses native PostgreSQL capabilities, which combines PostgreSQL array types with an additional column for storing index positions. The system can then iterate through arrays using just the index column.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS Identity and Access Management (IAM) user with administrator permissions.
- An instance that's compatible with Amazon RDS or Aurora PostgreSQL.
- A basic understanding of relational databases.

Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Product versions

This pattern was tested with the following versions:

- Amazon Aurora PostgreSQL 13.3
- Amazon RDS for PostgreSQL 13.3
- AWS SCT 1.0.674
- Oracle 12c EE 12.2

Architecture

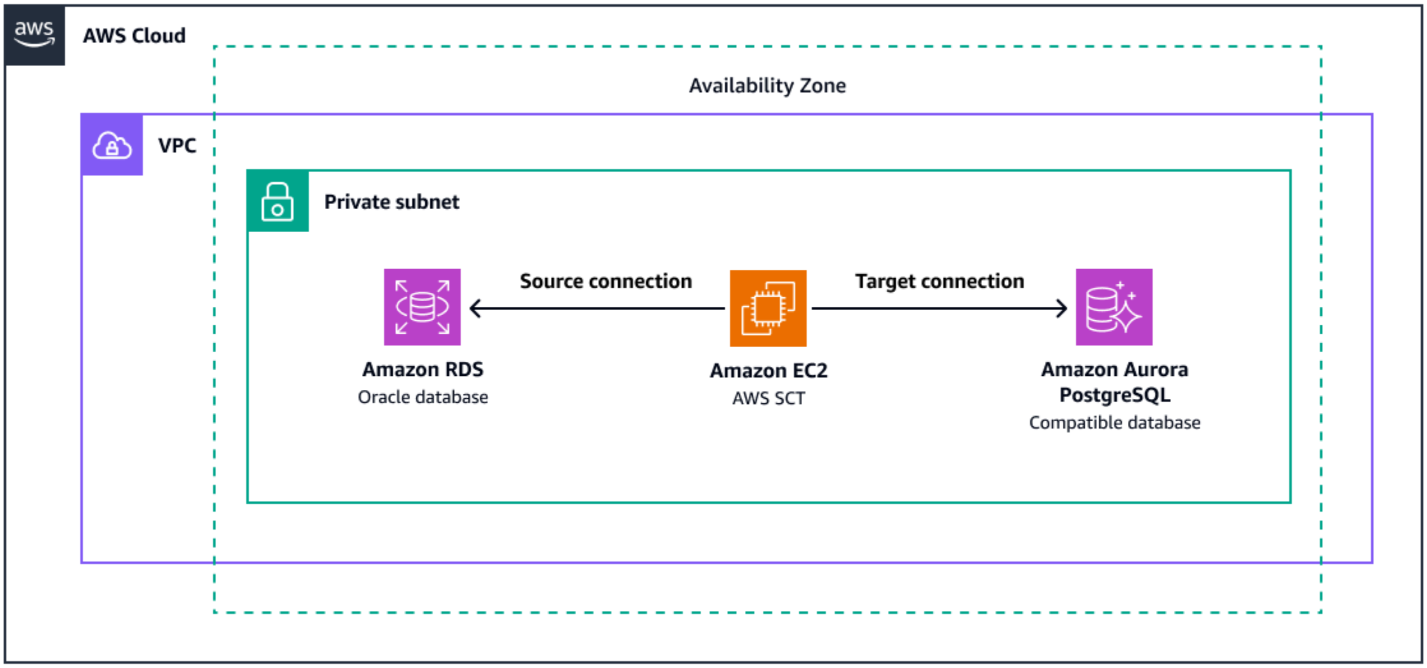
Source technology stack

- On-premises Oracle database

Target technology stack

- Amazon Aurora PostgreSQL
- Amazon RDS for PostgreSQL

Target architecture



The diagram shows the following:

- A source Amazon RDS for Oracle database instance
- An Amazon EC2 instance with AWS SCT for converting Oracle functions to the PostgreSQL equivalent
- A target database that's compatible with Amazon Aurora PostgreSQL

Tools

AWS services

- Amazon Aurora is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Relational Database Service (Amazon RDS) for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

Other tools

- Oracle SQL Developer is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.
- pgAdmin is an open source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects. In this pattern, pgAdmin connects to the RDS for PostgreSQL database instance and queries the data. Alternatively, you can use the psql command line client.

Best practices

- Test data set boundaries and edge scenarios.
- Consider implementing error handling for out-of-bounds index conditions.
- Optimize queries to avoid scanning sparse data sets.

Create a source PL/SQL block in Oracle.	Create a source PL/SQL block in Oracle that uses the following associative array:	DBA

Task	Description	Skills required

	<pre>DECLARE
	    TYPE country_codes
	 IS TABLE OF VARCHAR2(
	100) INDEX BY pls_integ
	er;
	    cc country_codes;
	    cc_idx NUMBER :=
	 NULL;
	BEGIN
	    cc(7) := 'India';
	    cc(3) := 'UK';
	    cc(5) := 'USA';
	    cc(0) := 'China';
	    cc(-2) := 'Invalid'
	;
	    dbms_output.put_li
	ne('cc_length:' ||
	 cc.COUNT);
	    IF (cc.COUNT > 0)
	 THEN
	        cc_idx :=
	 cc.FIRST;
	        FOR i IN
	 1..cc.COUNT LOOP
	            dbms_outp
	ut.put_line('cc_id
	x:' || cc_idx || '
	 country:' || cc(cc_idx
	));
	            cc_idx :=
	 cc.next(cc_idx);
	        END LOOP;
	    END IF;
	END;</pre>	

Task	Description	Skills required
Run the PL/SQL block.	Run the source PL/SQL block in Oracle. If there are gaps between the index values of an associative array, no data is stored in those gaps. This allows the Oracle loop to iterate only through the index positions.	DBA

Review the output.	Five elements were inserted into the array (`cc`) at nonconsecutive intervals. The array count is shown in the following output:
	`cc_length:5`
	`cc_idx:-2 country:I`
	`nvalid`
	`cc_idx:0 country:China`
	`cc_idx:3 country:UK`
	`cc_idx:5 country:USA`
	`cc_idx:7 country:India`
		DBA

PostgreSQL associative array behavior (target)

Task	Description	Skills required

Create a target PL/pgSQL block in PostgreSQL.	Create a target PL/pgSQL block in PostgreSQL that uses the following associative array:
	`DO $$`
	`DECLARE`
	`    cc character`
	` varying(100)[];`
		DBA

Task	Description	Skills required

	``
	    cc_idx integer :=
	 NULL;
	BEGIN
	    cc[7] := 'India';
	    cc[3] := 'UK';
	    cc[5] := 'USA';
	    cc[0] := 'China';
	    cc[-2] := 'Invalid'
	;
	    RAISE NOTICE
	 'cc_length: %',
	 ARRAY_LENGTH(cc, 1);
	    IF (ARRAY_LE
	NGTH(cc, 1) > 0) THEN
	        FOR i IN
	 ARRAY_LOWER(cc,
	 1)..ARRAY_UPPER(cc,
	 1)
	        LOOP
	            RAISE NOTICE
	 'cc_idx:% country:%',
	 i, cc[i];
	        END LOOP;
	    END IF;
	END;
	$$;
	``	

Run the PL/pgSQL block.	Run the target PL/pgSQL block in PostgreSQL. If there are gaps between the index values of an associative array, no data is stored in those gaps. This allows the Oracle loop to iterate only through the index positions.	DBA

Task	Description	Skills required
Review the output.	The array length is greater than 5 because NULL is stored in the gaps between index positions. As shown in the following output, the loop completes 10 iterations to retrieve 5 values in the array. ``` cc_length:10 cc_idx:-2 country:Invalid cc_idx:-1 country:<NULL> cc_idx:0 country:China cc_idx:1 country:<NULL> cc_idx:2 country:<NULL> cc_idx:3 country:UK cc_idx:4 country:<NULL> cc_idx:5 country:USA cc_idx:6 country:<NULL> cc_idx:7 country:India ```	DBA

Emulate Oracle associative array behavior

Task	Description	Skills required
Create a target PL/pgSQL block with an array and user-defined type.	To optimize performance and match Oracle's functionality, we can create a user-defined type that stores both index positions and their corresponding data. This	DBA

Task	Description	Skills required

	approach reduces unnecessary iterations by maintaining direct associations between indices and values.
	
	``
	DO $$
	DECLARE
	    cc country_codes[];
	    cc_append country_codes := NULL;
	    i record;
	BEGIN
	    cc_append.idx = 7;
	    cc_append.val = 'India';
	    cc := array_append(cc, cc_append);
	    cc_append.idx = 3;
	    cc_append.val = 'UK';
	    cc := array_append(cc, cc_append);
	    cc_append.idx = 5;
	    cc_append.val = 'USA';
	    cc := array_append(cc, cc_append);
	    cc_append.idx = 0;
	    cc_append.val = 'China';
	    cc := array_append(cc, cc_append);
	    cc_append.idx = -2;
	    cc_append.val = 'Invalid';
	    cc := array_append(cc, cc_append);
	    RAISE NOTICE 'cc_length: %', ARRAY_LENGTH(cc, 1);
	``	

Task	Description	Skills required

	``
	    IF (ARRAY_LE
	NGTH(cc, 1) > 0) THEN
	        FOR i IN (
	            SELECT
	                *
	            FROM
	
	 unnest(cc)
	            ORDER BY
	                idx)
	                LOOP
	
	 RAISE NOTICE 'cc_idx:
	% country:%', i.idx,
	 i.val;
	                END
	 LOOP;
	    END IF;
	END;
	$$;
	``	

Run the PL/pgSQL block.	Run the target PL/pgSQL block. If there are gaps between the index values of an associative array, no data is stored in those gaps. This allows the Oracle loop to iterate only through the index positions.	DBA

Task	Description	Skills required

Review the output.	As shown in the following output, the user-defined type stores only populated data elements, which means that the array length matches the number of values. As a result, LOOP iterations are optimized to process only existing data, eliminating the need to track empty positions.
	`cc_length:5`
	`cc_idx:-2 country:Invalid`
	`cc_idx:0 country:China`
	`cc_idx:3 country:UK`
	`cc_idx:5 country:USA`
	`cc_idx:7 country:India`
		DBA

Enable encrypted connections for PostgreSQL DB instances in Amazon RDS

Rohit Kapoor, Amazon Web Services

Summary

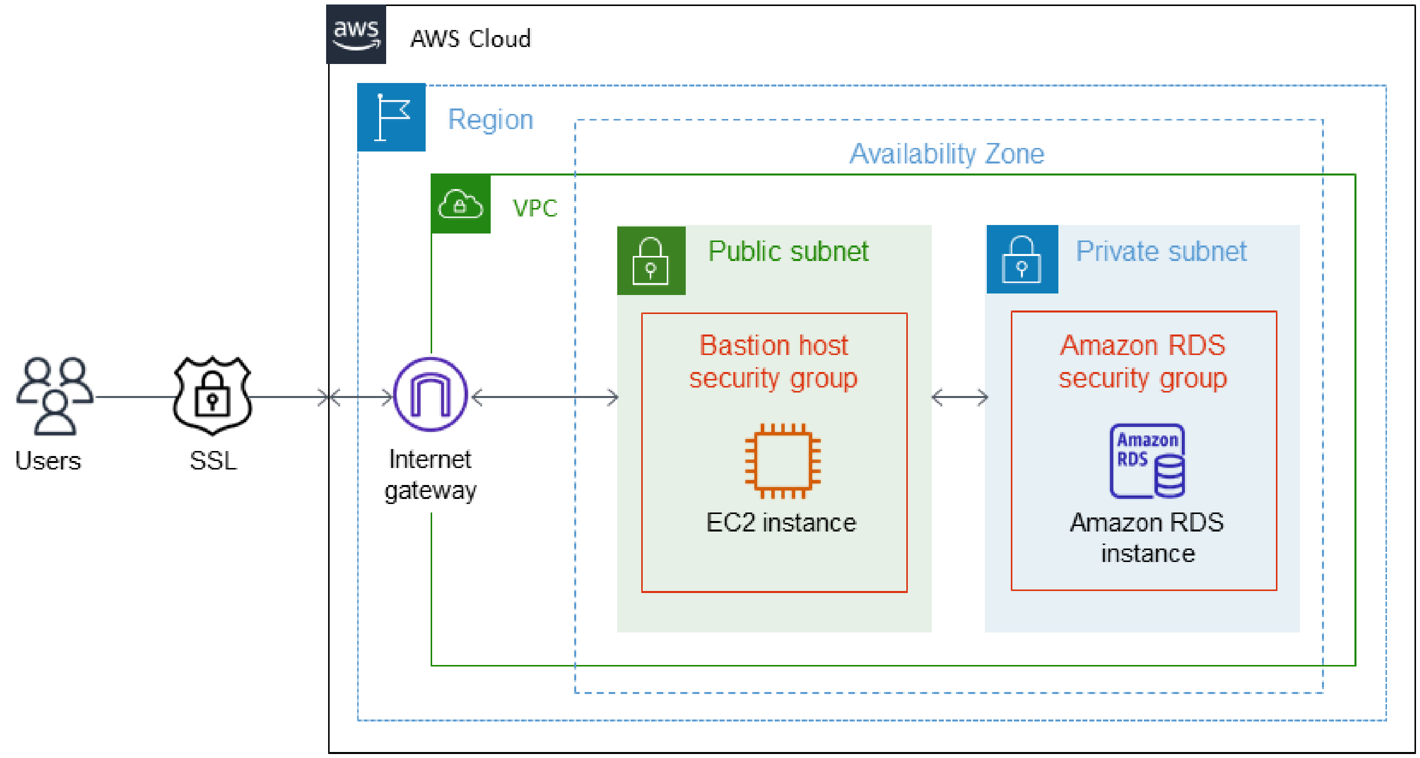
Amazon Relational Database Service (Amazon RDS) supports SSL encryption for PostgreSQL DB instances. Using SSL, you can encrypt a PostgreSQL connection between your applications and your Amazon RDS for PostgreSQL DB instances. By default, Amazon RDS for PostgreSQL uses SSL/TLS and expects all clients to connect by using SSL/TLS encryption. Amazon RDS for PostgreSQL supports TLS versions 1.1 and 1.2.

This pattern describes how you can enable encrypted connections for an Amazon RDS for PostgreSQL DB instance. You can use the same process to enable encrypted connections for Amazon Aurora PostgreSQL-Compatible Edition.

Prerequisites and limitations

- An active AWS account
- An Amazon RDS for PostgreSQL DB instance
- An SSL bundle

Architecture



Tools

- pgAdmin is an open-source administration and development platform for PostgreSQL. You can use pgAdmin on Linux, Unix, macOS, and Windows to manage your database objects in PostgreSQL 10 and later.
- PostgreSQL editors provide a more user-friendly interface to help you create, develop, and run queries, and to edit code according to your requirements.

Best practices

- Monitor unsecure database connections.
- Audit database access rights.
- Make sure that backups and snapshots are encrypted at rest.
- Monitor database access.
- Avoid unrestricted access groups.
- Enhance your notifications with Amazon GuardDuty.
- Monitor policy adherence regularly.

Epics

Download a trusted certificate and import it into your trust store

Task	Description	Skills required
Load a trusted certificate to your computer.	To add certificates to the Trusted Root Certification Authorities store for your computer, follow these steps. (These instructions use Window Server as a example.) 1. In Windows Server, choose **Start**, **Run**, and then type **mmc**. 2. In the console, choose **File**, **Add/Remove Snap-in**. 3. Under **Available snap-ins**, choose **Certificates**, and then choose **Add**. 4. Under **This snap-in will always manage certifica tes for**, choose **Computer account**, **Next**. 5. Choose **Local computer**, **Finish**. 6. If you have no more snap-ins to add to the console, choose **OK**. 7. In the console tree, double-click **Certificates**. 8. Right-click **Trusted Root Certification Authorities**.	DevOps engineer, Migration engineer, DBA

Task	Description	Skills required
	9. Choose **All Tasks**, **Import** to import the downloaded certificates. 10. Follow the steps in the Certificate Import Wizard.	

Force SSL connections

Task	Description	Skills required
Create a parameter group and set the rds.force_ssl parameter.	If the PostgreSQL DB instance has a custom parameter group, edit the parameter group and change `rds.force_ssl` to 1. If the DB instance uses the default parameter group that doesn't have `rds.force_ssl` enabled, create a new parameter group. You can modify the new parameter group by using the Amazon RDS API or manually as in the following instructions. To create a new parameter group: 1. Sign in to the AWS Management console and open [the Amazon RDS console](https://console.aws.amazon.com/rds/) for the AWS Region that hosts the DB instance.	DevOps engineer, Migration engineer, DBA

Task	Description	Skills required
	2. In the navigation pane, choose **Parameter groups**. 3. Choose **Create parameter group**, and set the following values: • For **Parameter group family**, choose **postgres14**. • For **Group name**, type **pgsql-<database_instance>-ssl**. • For **Description**, enter a free-form description for the parameter group you're adding. • Choose **Create**. 4. Choose the parameter group that you created. 5. From **Parameter group actions**, choose **Edit**. 6. Find **rds.force_ssl** and change its setting to **1**. **Note** Conduct client-side testing before changing this parameter. 7. Choose **Save changes**.	

Task	Description	Skills required
	To associate the parameter group with your PostgreSQL DB instance: 1. On the Amazon RDS console, in the navigatio n pane, choose **Databases** , and then choose the PostgreSQL DB instance. 2. Choose **Modify**. 3. Under **Additional configuration**, choose the new parameter group, and then choose **Continue**. 4. Under **Schedule modificat ions**, choose **Apply immediately**. 5. Choose **Modify DB instance**. For more information, see the Amazon RDS documentation.	
Force SSL connections.	Connect to the Amazon RDS for PostgreSQL DB instance. Connection attempts that don’t use SSL are rejected with an error message. For more information, see the Amazon RDS documentation.	DevOps engineer, Migration engineer, DBA

Install SSL extension

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install the SSL extension.</td><td>
1. Launch a psql or pgAdmin connection as a DBA.
2. Call the ssl_is_used() function to determine if SSL is being used.
<pre><code>select ssl_is_used();</code></pre>
The function returns <code>t</code> if the connection is using SSL; otherwise, it returns <code>f</code>.
3. Install the SSL extension.
<pre><code>create extension
 sslinfo;
show ssl;
select ssl_cipher();</code></pre>
For more information, see the Amazon RDS documentation.</td><td>DevOps engineer, Migration engineer, DBA</td></tr>
</table>

Configure your PostgreSQL client for SSL

Task	Description	Skills required
Configure a client for SSL.	By using SSL, you can start the PostgreSQL server with support for encrypted connections that use TLS protocols. The server listens for both standard and SSL connections on the same TCP	DevOps engineer, Migration engineer, DBA

Task	Description	Skills required

	port, and negotiates with any connecting client on whether to use SSL. By default, this is a client option.
	
	If you're using the psql client:
	
	1. Make sure that the Amazon RDS certificate has been loaded to your local computer.
	2. Launch an SSL client connection by adding the following:
	
	`psql postgres -h SOMEHOST.amazonaws.com -p 8192 -U someuser sslmode=verify-full sslrootcert=rds-ssl-ca-cert.pem`
	`select ssl_cipher();`
	
	For other PostgreSQL clients:
	
	• Modify the respective application public key parameter. This might be available as an option, as part of your connection string, or as a property on the connection page in GUI tools.	

Task	Description	Skills required
	Review the following pages for these clients: • pgAdmin documentation • JDBC documentation	

Troubleshooting

Issue	Solution
Cannot download the SSL certificate.	Check your connection to the website, and retry downloading the certificate to your local computer.

Encrypt an existing Amazon RDS for PostgreSQL DB instance

Piyush Goyal, Shobana Raghu, and Yaser Raja, Amazon Web Services

Summary

This pattern explains how to encrypt an existing Amazon Relational Database Service (Amazon RDS) for PostgreSQL DB instance in the AWS Cloud with minimal downtime. This process works for Amazon RDS for MySQL DB instances as well.

You can enable encryption for an Amazon RDS DB instance when you create it, but not after it's created. However, you can add encryption to an unencrypted DB instance by creating a snapshot of your DB instance, and then creating an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot to get an encrypted copy of your original DB instance. If your project allows for downtime (at least for write transactions) during this activity, this is all you need to do. When the new, encrypted copy of the DB instance becomes available, you can point your applications to the new database. However, if your project doesn't allow for significant downtime for this activity, you need an alternate approach that helps minimize the downtime. This pattern uses the AWS Database Migration Service (AWS DMS) to migrate and continuously replicate the data so that the cutover to the new, encrypted database can be done with minimal downtime.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently, with minimal impact on performance. You don't need to modify your database client applications to use encryption.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An unencrypted Amazon RDS for PostgreSQL DB instance
- Experience working with (creating, modifying, or stopping) AWS DMS tasks (see [Working with AWS DMS tasks](#) in the AWS DMS documentation)
- Familiarity with AWS Key Management Service (AWS KMS) for encrypting databases (see the [AWS KMS documentation](#))

Limitations

- You can enable encryption for an Amazon RDS DB instance only when you create it, not after the DB instance is created.
- Data in unlogged tables will not be restored using snapshots. For more information, review Best practices for working with PostgreSQL.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- AWS DMS does not automatically transfers the Sequences therefore additional steps are required to handle this.

For more information, see Limitations of Amazon RDS encrypted DB instances in the Amazon RDS documentation.

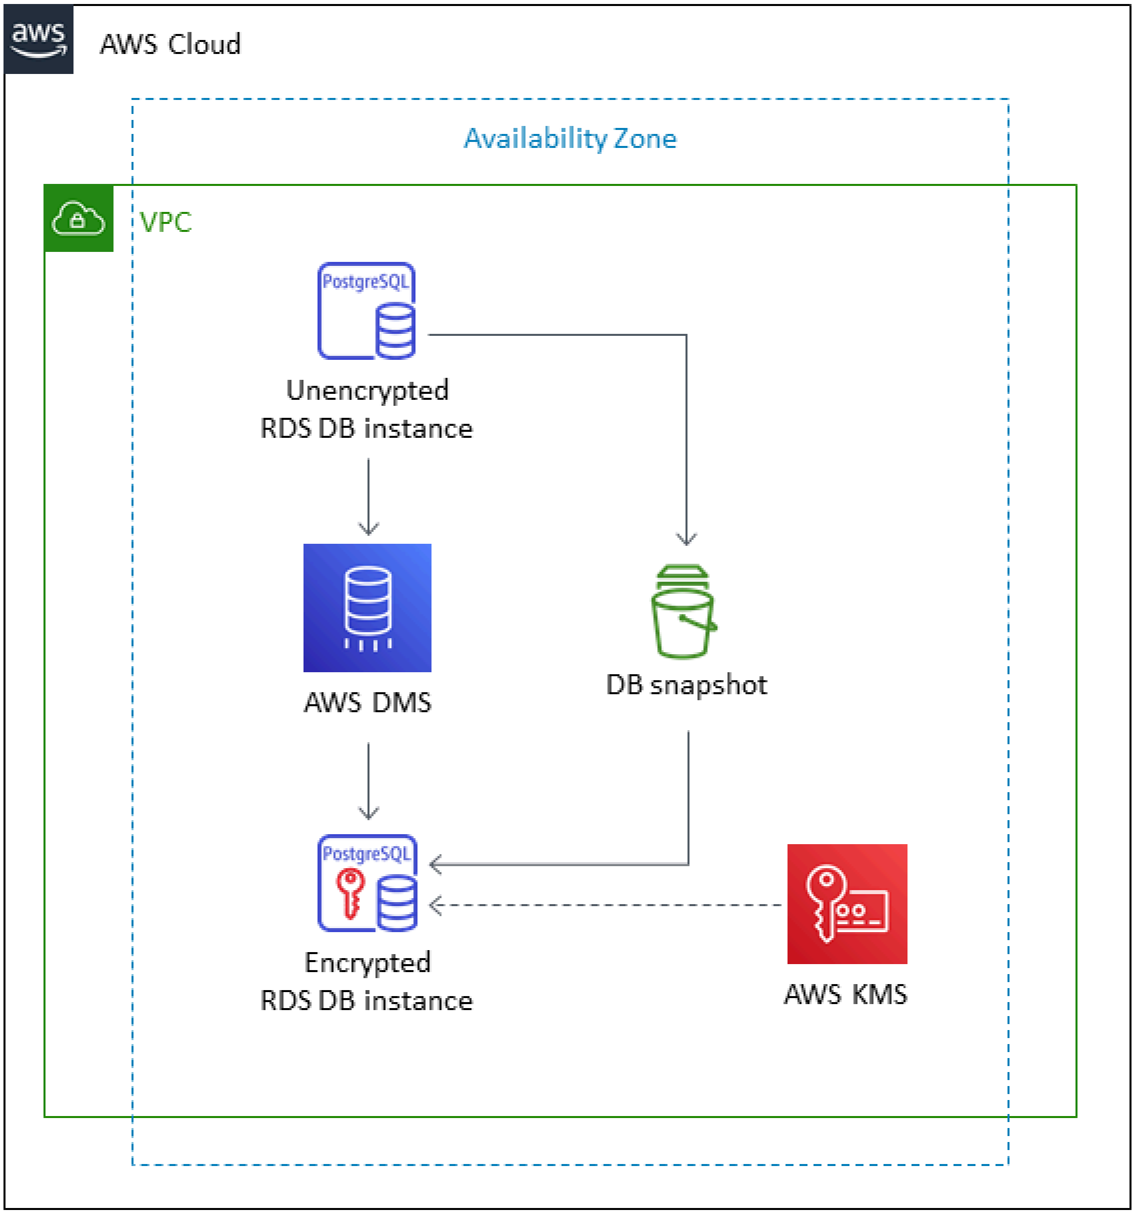
Architecture

Source architecture

- Unencrypted RDS DB instance

Target architecture

- Encrypted RDS DB instance
  - The destination RDS DB instance is created by restoring the DB snapshot copy of the source RDS DB instance.
  - An AWS KMS key is used for encryption while restoring the snapshot.
  - An AWS DMS replication task is used to migrate the data.



Tools

Tools used to enable encryption:

- AWS KMS key for encryption – When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don't specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region. For more information about using KMS keys for Amazon RDS encryption, see [Encrypting Amazon RDS Resources](#).

Tools used for ongoing replication:

- AWS DMS – You can use AWS Database Migration Service (AWS DMS) to replicate changes from the source DB to the target DB. It is important to keep the source and target DB in sync to keep downtime to a minimum. For information about setting up AWS DMS and creating tasks, see the AWS DMS documentation.

Epics

Create a snapshot of the source DB instance and encrypt it

Task	Description	Skills required
Check the details for the source PostgreSQL DB instance.	On the Amazon RDS console, choose the source PostgreSQ L DB instance. On the **Configuration** tab, make sure that encryption isn't enabled for the instance. For a screen illustration, see the Additional information section.	DBA
Create the DB snapshot.	Create a DB snapshot of the instance you want to encrypt. The amount of time it takes to create a snapshot depends on the size of your database. For instructions, see Creating a DB snapshot in the Amazon RDS documentation.	DBA
Encrypt the snapshot.	In the Amazon RDS console navigation pane, choose **Snapshots**, and select the DB snapshot you created. For **Actions**, choose **Copy Snapshot**. Provide the destination AWS Region and	DBA

Task	Description	Skills required
	the name of the DB snapshot copy in the corresponding fields. Select the **Enable Encryption** checkbox. For **Master Key**, specify the KMS key identifier to use to encrypt the DB snapshot copy. Choose **Copy Snapshot**. For more information, see [Copying a snapshot](#) in the Amazon RDS documentation.	

Prepare the target DB instance

Task	Description	Skills required
Restore the DB snapshot.	On the Amazon RDS console, choose **Snapshots**. Choose the encrypted snapshot that you created. For **Actions**, choose **Restore Snapshot**. For **DB Instance Identifier**, provide a unique name for the new DB instance. Review the instance details, and then choose **Restore DB Instance**. A new, encrypted DB Instance will be created from your snapshot. For more informati on, see [Restoring from a DB snapshot](#) in the Amazon RDS documentation.	DBA
Migrate data by using AWS DMS.	On the AWS DMS console, create an AWS DMS task.	DBA

Task	Description	Skills required
	For **Migration type**, choose **Migrate existing data and replicate ongoing changes**. In **Task Settings**, for **Target table preparation mode**, choose **Truncate**. For more information, see Creating a task in the AWS DMS documentation.	
Enable data validation.	In **Task Settings**, choose **Enable validation**. This enables you to compare the source data to the target data to verify that the data was migrated accurately.	DBA
Disable constraints on the target DB instance.	Disable any triggers and foreign key constraints on the target DB instance, and then start the AWS DMS task. For more information about disabling triggers and foreign key constraints, see the AWS DMS documentation.	DBA
Verify data.	After the full load is complete, verify the data on the target DB instance to see if it matches the source data. For more information, see AWS DMS data validation in the AWS DMS documentation.	DBA

Cut over to the target DB instance

Task	Description	Skills required
Stop write operations on the source DB instance.	Stop the write operations on the source DB instance so that application downtime can begin. Verify that AWS DMS has completed the replication for the data in the pipeline. Enable triggers and foreign keys on the target DB instance.	DBA
Update database sequences	If the source database contains any sequence numbers, verify and update the sequences in the target database.	DBA
Configure the application endpoint.	Configure your application connections to use the new Amazon RDS DB instance endpoints. The DB instance is now encrypted.	DBA, Application owner

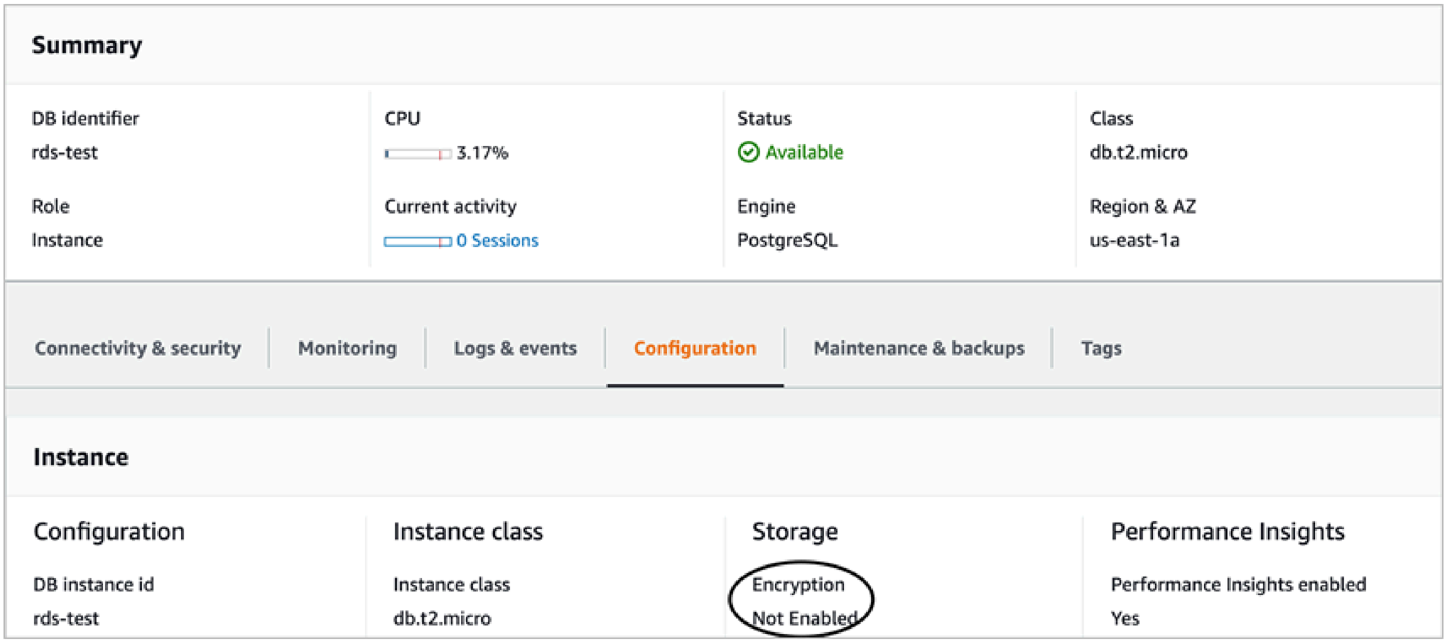
Additional information

Checking the encryption for the source PostgreSQL DB instance:



Additional notes for this pattern:

- Enable replication on PostgreSQL by setting the `rds.logical_replication` parameter to 1.

Important note: Replication slots retain the write ahead log (WAL) files until the files are externally consumed—for example, by `pg_recvlogical`; by extract, transform, and load (ETL) jobs; or by AWS DMS. When you set the `rds.logical_replication` parameter value to 1, AWS DMS sets the `wal_level`, `max_wal_senders`, `max_replication_slots`, and `max_connections` parameters. If logical replication slots are present but there is no consumer for the WAL files retained by the replication slot, you might see an increase in the transaction log disk usage and a constant decrease in free storage space. For more information and steps to resolve this issue, see the article [How can I identify what is causing the "No space left on device" or "DiskFull" error on Amazon RDS for PostgreSQL?]() in the AWS Support Knowledge Center.

- Any schema changes that you make to the source DB instance after you create the DB snapshot will not be present on the target DB instance.
- After you create an encrypted DB instance, you can't change the KMS key used by that DB instance. Be sure to determine your KMS key requirements before you create your encrypted DB instance.
- You must disable triggers and foreign keys on the target DB instance before you run the AWS DMS task. You can re-enable these when the task is complete.

Enforce automatic tagging of Amazon RDS databases at launch

Susanne Kangnoh and Archit Mathur, Amazon Web Services

Summary

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the Amazon Web Services (AWS) Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

You can use tagging to categorize your AWS resources in different ways. Relational database tagging is useful when you have many resources in your account and you want to quickly identify a specific resource based on the tags. You can use Amazon RDS tags to add custom metadata to your RDS DB instances. A tag consists of a user-defined key and value. We recommend that you create a consistent set of tags to meet your organization's requirements.

This pattern provides an AWS CloudFormation template to help you monitor and tag RDS DB instances. The template creates an Amazon CloudWatch Events event that watches for the AWS CloudTrail **CreateDBInstance** event. (CloudTrail captures API calls for Amazon RDS as events.) When it detects this event, it calls an AWS Lambda function that automatically applies tag keys and values that you define. The template also sends out a notification that the instance has been tagged, by using Amazon Simple Notification Service (Amazon SNS).

Prerequisites and limitations

Prerequisites

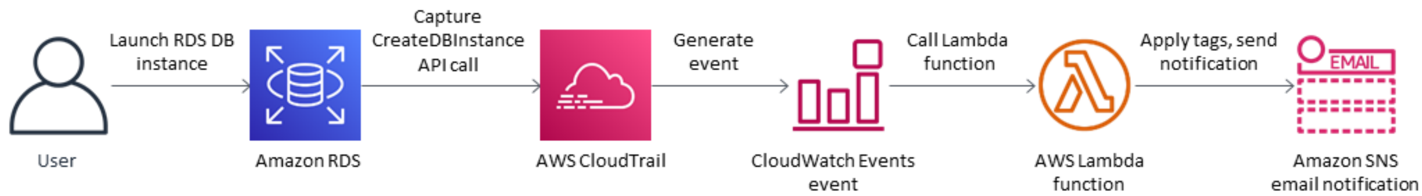
- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the Lambda code.
- An email address where you would like to receive tagging notifications.

Limitations

- The solution supports CloudTrail **CreateDBInstance** events. It does not create notifications for any other events.

Architecture

Workflow architecture



Automation and scale

- You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

Tools

AWS services

- AWS CloudTrail – AWS CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
- AWS Lambda – AWS Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

Code

This pattern includes an attachment with two files:

- `index.zip` is a compressed file that includes the Lambda code for this pattern.
- `rds.yaml` is a CloudFormation template that deploys the Lambda code.

See the *Epics* section for information about how to use these files.

Epics

Deploy the Lambda code

Task	Description	Skills required
Upload the code to an S3 bucket.	Create a new S3 bucket or use an existing S3 bucket to upload the attached `index.zip` file (Lambda code). This bucket must be in the same AWS Region as the resources (RDS DB instances) that you want to monitor.	Cloud architect
Deploy the CloudFormation template.	Open the Cloudformation console in the same AWS Region as the S3 bucket, and deploy the `rds.yaml` file that's provided in the attachment. In the next epic, provide values for the template parameters.	Cloud architect

Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or selected in the first epic. This S3 bucket contains the .zip file for the Lambda code and must be in the same AWS Region as the CloudFormation template and the RDS DB instances that you want to monitor.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, `index.zip` or `controls/index.zip`).	Cloud architect
Provide an email address.	Provide an active email address where you want to receive violation notifications.	Cloud architect
Specify a logging level.	Specify the logging level and verbosity. `Info` designates detailed informational messages on the application's progress and should be used only for debugging. `Error` designates error events that could still allow the application to continue running. `Warning` designates	Cloud architect

Task	Description	Skills required
	potentially harmful situation s.	
Enter the tag keys and values for your RDS DB instances.	Enter the required tag keys and values that you want to automatically apply to the RDS instance. For more information, see Tagging Amazon RDS resources in the AWS documentation.	Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the email subscript ion.	When the CloudFormation template deploys successfu lly, it sends a subscription email message to the email address you provided. To receive notifications when your instances are tagged, you must confirm this email subscription.	Cloud architect

Estimate the cost of a DynamoDB table for on-demand capacity

Moinul Al-Mamun, Amazon Web Services

Summary

[Amazon DynamoDB](#) is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This Amazon Web Services (AWS) serverless offering is getting popular because of its consistent performance and scalability. You do not need to provision underlying infrastructure. Your single table can grow up to petabytes.

With on-demand capacity mode, you pay per request for the data reads and writes that your application performs on the tables. AWS charges are based on the accumulated read request units (RRUs) and write request units (WRUs) in a month. DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. It supports continuous backup with point-in-time-recovery (PITR). DynamoDB monitors the size of your PITR-enabled tables continuously throughout the month to determine your backup charges.
