By migrating your on-premises [ThoughtSpot Falcon databases](#) to the Amazon Web Services (AWS) Cloud, you can access cloud-based data lakes and data warehouses that increase your business agility, security, and application reliability, in addition to reducing your overall infrastructure costs. Amazon Redshift helps to significantly lower the cost and operational overhead of a data warehouse. You can also use Amazon Redshift Spectrum to analyze large amounts of data in its native format without data loading.

This pattern describes the steps and process for migrating a ThoughtSpot Falcon database from an on-premises data center to an Amazon Redshift database on the AWS Cloud.

Prerequisites and limitations

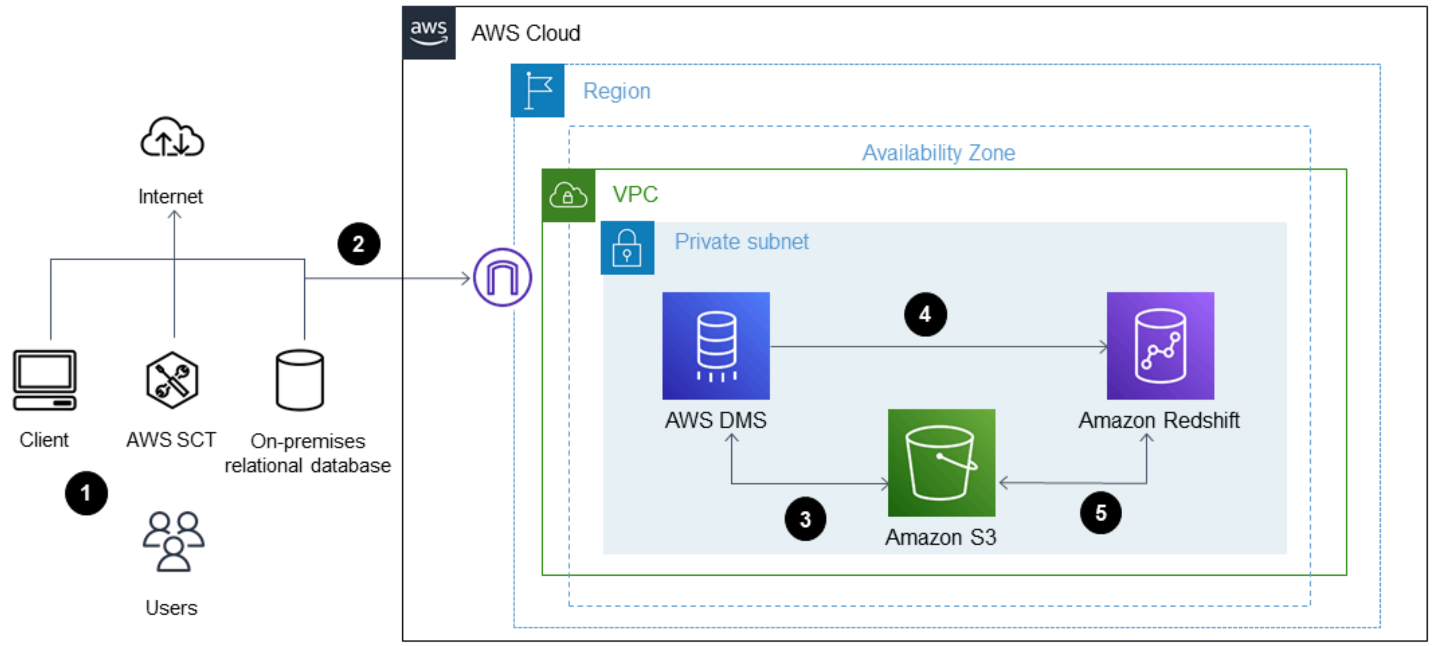
Prerequisites

- An active AWS account
- A ThoughtSpot Falcon database hosted in an on-premises data center

Product versions

- ThoughtSpot version 7.0.1

Architecture



The diagram shows the following workflow:

1. Data is hosted in an on-premises relational database.
2. AWS Schema Conversion Tool (AWS SCT) converts the data definition language (DDL) that is compatible with Amazon Redshift.
3. After the tables are created, you can migrate the data by using AWS Database Migration Service (AWS DMS).
4. The data is loaded into Amazon Redshift.
5. The data is stored in Amazon Simple Storage Service (Amazon S3) if you use Redshift Spectrum or already host the data in Amazon S3.

Tools

- AWS DMS – AWS Data Migration Service (AWS DMS) helps you quickly and securely migrate databases to AWS.
- Amazon Redshift – Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools.

- AWS SCT – AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another.

Epics

Prepare for the migration

Task	Description	Skills required
Identify the appropriate Amazon Redshift configuration.	Identify the appropriate Amazon Redshift cluster configuration based on your requirements and data volume. For more information, see Amazon Redshift clusters in the Amazon Redshift documentation.	DBA
Research Amazon Redshift to evaluate if it meets your requirements.	Use the Amazon Redshift FAQs to understand and evaluate whether Amazon Redshift meets your requirements.	DBA

Prepare the target Amazon Redshift cluster

Task	Description	Skills required
Create an Amazon Redshift cluster.	Sign in to the AWS Management Console, open the Amazon Redshift console, and then create an Amazon Redshift cluster in a virtual private cloud (VPC).	DBA

Task	Description	Skills required
	For more information, see Creating a cluster in a VPC in the Amazon Redshift documentation.	
Conduct a PoC for your Amazon Redshift database design.	Follow Amazon Redshift best practices by conducting a proof of concept (PoC) for your database design. For more information, see Conducting a proof of concept for Amazon Redshift in the Amazon Redshift documentation.	DBA
Create database users.	Create the users in your Amazon Redshift database and grant the appropriate roles for access to the schema and tables. For more information, see Grant access privileges for a user or user group in the Amazon Redshift documentation.	DBA

Task	Description	Skills required
Apply configuration settings to the target database.	Apply configuration settings to the Amazon Redshift database according to your requirements. For more information about enabling database, session, and server-level parameter s, see the Configuration reference in the Amazon Redshift documentation.	DBA

Create objects in the Amazon Redshift cluster

Task	Description	Skills required
Manually create tables with DDL in Amazon Redshift.	(Optional) If you use AWS SCT, the tables are automatic ally created. However, if there are failures when replicating DDLs, you have to manually create the tables	DBA
Create external tables for Redshift Spectrum.	Create an external table with an external schema for Amazon Redshift Spectrum. To create external tables, you must be the owner of the external schema or a database superuser. For more information, see Creating external tables for Amazon Redshift Spectrum	DBA

Task	Description	Skills required
	in the Amazon Redshift documentation.	

Migrate data using AWS DMS

Task	Description	Skills required
Use AWS DMS to migrate the data.	After you create the DDL of the tables in the Amazon Redshift database, migrate your data to Amazon Redshift by using AWS DMS. For detailed steps and instructions, see [Using an Amazon Redshift database as a target for AWS DMS] in the AWS DMS documentation.	DBA
Use the COPY command to load the data.	Use the Amazon Redshift COPY command to load the data from Amazon S3 to Amazon Redshift. For more information, see [Using the COPY command to load from Amazon S3] in the Amazon Redshift documenta tion.	DBA

Validate the Amazon Redshift cluster

Task	Description	Skills required
Validate the source and target records.	Validate the table count for the source and target records that were loaded from your source system.	DBA
Implement Amazon Redshift best practices for performance tuning.	Implement Amazon Redshift best practices for table and database design. For more information, see the blog post [Top 10 performance tuning techniques for Amazon Redshift]().	DBA
Optimize query performance.	Amazon Redshift uses SQL-based queries to interact with data and objects in the system. Data manipulation language (DML) is the subset of SQL that you can use to view, add, change, and delete data. DDL is the subset of SQL that you use to add, change, and delete database objects such as tables and views. For more information, see [Tuning query performance]() in the Amazon Redshift documentation.	DBA
Implement WLM.	You can use workload management (WLM) to define multiple query queues and	DBA

Task	Description	Skills required
	route queries to appropriate queues at runtime. For more information, see Implementing workload management in the Amazon Redshift documentation.	
Work with concurrency scaling.	By using the Concurrency Scaling feature, you can support virtually unlimited concurrent users and concurrent queries, with consistently fast query performance. For more information, see Working with concurrency scaling in the Amazon Redshift documentation.	DBA
Use Amazon Redshift best practices for table design.	When you plan your database, certain important table design decisions can strongly influence overall query performance. For more information about choosing the most appropriate table design option, see Amazon Redshift best practices for designing tables in the Amazon Redshift documentation.	DBA

Task	Description	Skills required
Create materialized views in Amazon Redshift.	A materialized view contains a precomputed results set based on an SQL query over one or more base tables. You can issue `SELECT` statement s to query a materialized view in the same way that you query other tables or views in the database. For more information, see [Creating materialized views in Amazon Redshift]() in the Amazon Redshift documenta tion.	DBA
Define joins between the tables.	To search more than one table at the same time in ThoughtSpot, you must define joins between the tables by specifying columns that contain matching data across two tables. These columns represent the `primary key` and `foreign key` of the join. You can define them by using the `ALTER TABLE` command in Amazon Redshift or ThoughtSpot. For more information, see [ALTER TABLE]() in the Amazon Redshift documentation.	DBA

Set up ThoughtSpot connection to Amazon Redshift

Task	Description	Skills required
Add an Amazon Redshift connection.	Add an Amazon Redshift connection to your on-premises ThoughtSpot Falcon database. For more information, see [Add an Amazon Redshift connection] in the ThoughtSpot documentation.	DBA
Edit the Amazon Redshift connection.	You can edit the Amazon Redshift connection to add tables and columns. For more information, see [Edit an Amazon Redshift connection] in the ThoughtSpot documentation.	DBA
Remap the Amazon Redshift connection.	Modify the connection parameters by editing the source mapping .yaml file that was created when you added the Amazon Redshift connection. For example, you can remap the existing table or column to a different table or column in an existing database connection. ThoughtSpot recommends that you check the dependencies before and after you remap a table or	DBA

Task	Description	Skills required
	column in a connection to ensure that they display as required. For more information, see [Remap an Amazon Redshift connection] in the ThoughtSpot documentation.	
Delete a table from the Amazon Redshift connection.	(Optional) If you attempt to remove a table in an Amazon Redshift connection, ThoughtSpot checks for dependencies and shows a list of dependent objects. You can choose the listed objects to delete them or remove the dependency. You can then remove the table. For more information, see [Delete a table from an Amazon Redshift connection] in the ThoughtSpot documentation.	DBA

Task	Description	Skills required
Delete a table with dependent objects from an Amazon Redshift connection.	(Optional) If you try to delete a table with dependent objects, the operation is blocked. A `Cannot delete` window appears, with a list of links to dependent objects. When all the dependencies are removed, you can then delete the table For more information, see [Delete a table with dependent objects from an Amazon Redshift connection](#) in the ThoughtSpot documentation.	DBA
Delete an Amazon Redshift connection.	(Optional) Because a connection can be used in multiple data sources or visualizations, you must delete all of the sources and tasks that use that connection before you can delete the Amazon Redshift connection. For more information, see [Delete an Amazon Redshift connection](#) in the ThoughtSpot documentation.	DBA

Task	Description	Skills required
Check connection reference for Amazon Redshift.	Make sure that you provide the required information for your Amazon Redshift connection by using the Connection reference in the ThoughtSpot documentation.	DBA

Migrate an Oracle database to Amazon DynamoDB using AWS DMS

Rambabu Karnena, Amazon Web Services

Summary

This pattern walks you through the steps for migrating an Oracle database to Amazon DynamoDB using AWS Database Migration Service (AWS DMS). It covers three types of source databases:

- On-premises Oracle databases
- Oracle databases on Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Relational Database Service (Amazon RDS) for Oracle DB instances

In this proof of concept, this pattern focuses on migrating from an Amazon RDS for Oracle DB instance.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An application connecting to an Amazon RDS for Oracle database
- A table created in the source Amazon RDS for Oracle database with a primary key and sample data

Limitations

- Oracle database objects, such as procedures, functions, packages, and triggers, are not considered for migration because Amazon DynamoDB does not support these database objects.

Product versions

- This pattern applies to all editions and versions of Oracle databases that are supported by AWS DMS. For more information, see using an Oracle database as a source for AWS DMS and using an Amazon DynamoDB database as a target for AWS DMS. We recommend that you use the latest versions of AWS DMS for the most comprehensive version and feature support.

Architecture

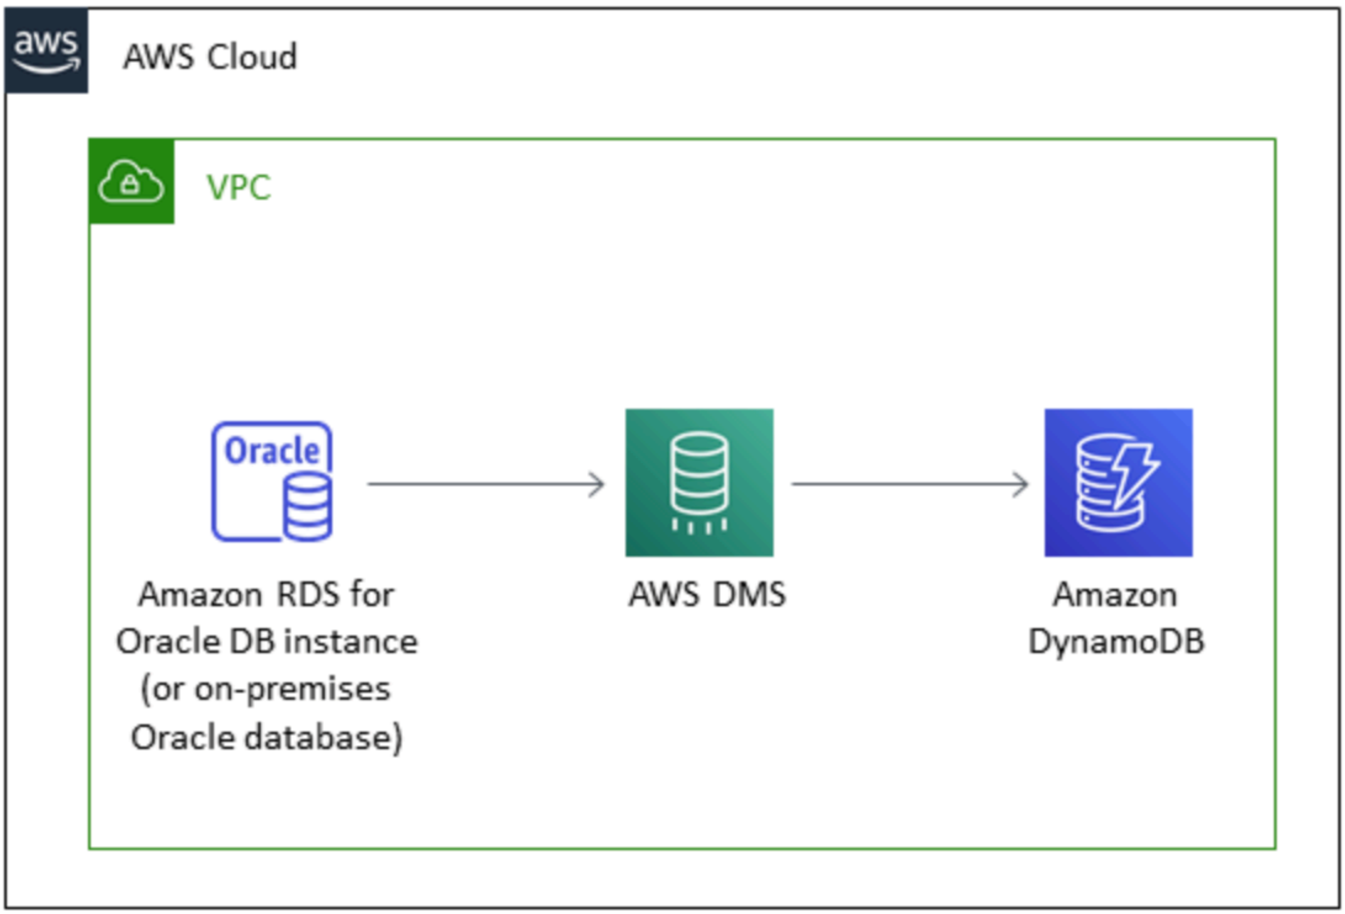
Source technology stack

- Amazon RDS for Oracle DB instances, Oracle on Amazon EC2, or on-premises Oracle databases

Target technology stack

- Amazon DynamoDB

AWS data migration architecture



Tools

- [AWS Database Migration Service (AWS DMS)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [Amazon Relational Database Service (Amazon RDS)](#) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle.

Epics

Plan the migration

Task	Description	Skills required
Create a VPC.	In your AWS account, create a virtual private cloud (VPC) and a private subnet.	Systems administrator
Create security groups and network access control lists.	For more information, see the AWS documentation.	Systems administrator
Configure and start the Amazon RDS for Oracle DB instance.	For more information, see the AWS documentation.	DBA, Systems administrator

Migrate data

Task	Description	Skills required
Create an IAM role to access DynamoDB.	In the AWS Identity and Access Management (IAM) console, create the role, attach the policy `AmazonDynamoDBFullAccess to it`, and select AWS DMS as the service.	Systems administrator
Create an AWS DMS replication instance for migration.	The replication instance should be in the same	Systems administrator

Task	Description	Skills required
	Availability Zone and VPC as the source database.	
Create source and target endpoints in AWS DMS.	To create the source database endpoint, you have two options: • On the Amazon RDS console, choose **Databases**, **DB identifier**, **Connectivity & Security**, and choose the endpoint. • On the AWS DMS console, choose **Select RDS DB instance**. To create the target database endpoint, choose the role Amazon Resource Name (ARN) from the previous task to access DynamoDB.	Systems administrator
Create an AWS DMS task to load the source Oracle database tables to DynamoDB.	Choose the source and destination endpoint names and the replication instance from the previous steps. The type can be full load. Choose the Oracle schema and specify **%** to select all tables.	Systems administrator
Validate the tables in DynamoDB.	To view the migration results, choose **Tables** from the left navigation pane in the DynamoDB console.	DBA

Migrate the application

Task	Description	Skills required
Modify the application code.	To connect to and retrieve data from DynamoDB, update the application code.	App owner, DBA, Systems administrator

Cut over

Task	Description	Skills required
Switch the application clients to use DynamoDB.		DBA, App owner, Systems administrator

Close the project

Task	Description	Skills required
Shut down AWS resources.	For example, the shut down the Amazon RDS for Oracle instance, DynamoDB, and the AWS DMS replication instance.	DBA, Systems administrator
Gather metrics.	Metrics include the time to migrate, the percentages of manual work and work performed by the tool, and cost savings.	DBA, App owner, Systems administrator

Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS

Saurav Mishra and Eduardo Valentim, Amazon Web Services

Summary

This pattern describes how to speed up loading a partitioned table from Oracle to PostgreSQL by using AWS Database Migration Service (AWS DMS), which doesn't support native partitioning. The target PostgreSQL database can be installed on Amazon Elastic Compute Cloud (Amazon EC2), or it can be an Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition DB instance.

Uploading a partitioned table includes the following steps:

1. Create a parent table similar to the Oracle partition table, but don't include any partition.
2. Create child tables that will inherit from the parent table that you created in step 1.
3. Create a procedure function and trigger to handle the inserts in the parent table.

However, because the trigger is fired for every insert, the initial load using AWS DMS can be very slow.

To speed up initial loads from Oracle to PostgreSQL 9.0, this pattern creates a separate AWS DMS task for each partition and loads the corresponding child tables. You then create a trigger during cutover.

PostgreSQL version 10 supports native partitioning. However, you might decide to use inherited partitioning in some cases. For more information, see the [Additional information](#) section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle database with a partitioned table
- A PostgreSQL database on AWS

Product versions

- PostgreSQL 9.0

Architecture

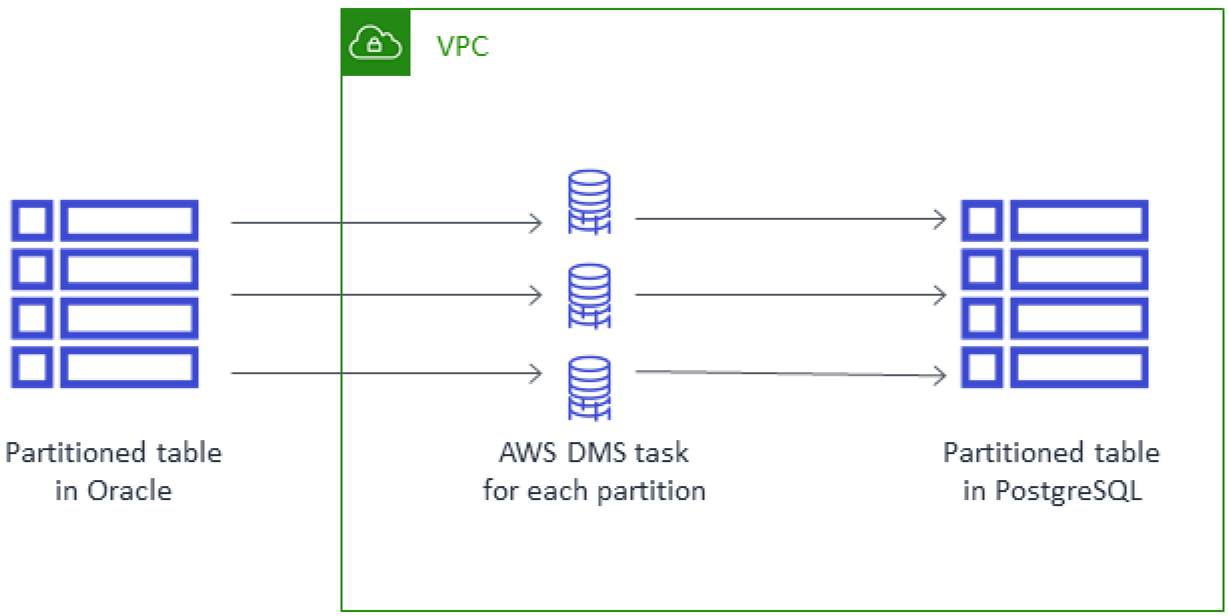
Source technology stack

- A partitioned table in Oracle

Target technology stack

- A partitioned table in PostgreSQL (on Amazon EC2, Amazon RDS for PostgreSQL, or Aurora PostgreSQL)

Target architecture



Tools

- [AWS Database Migration Service (AWS DMS)] helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

Epics

Set up AWS DMS

Task	Description	Skills required
Create the tables in PostgreSQL.	Create the parent and corresponding child tables in PostgreSQL with the required check conditions for partition s.	DBA
Create the AWS DMS task for each partition.	Include the filter condition of the partition in the AWS DMS task. Map the partitions to the corresponding PostgreSQ L child tables.	DBA
Run the AWS DMS tasks using full load and change data capture (CDC).	Make sure that the `StopTaskCachedChan gesApplied` parameter is set to `true` and the `StopTaskCachedChan gesNotApplied` parameter is set to `false`.	DBA

Cut over

Task	Description	Skills required
Stop the replication tasks.	Before you stop the tasks, confirm that the source and destination are in sync.	DBA
Create a trigger on the parent table.	Because the parent table will receive all insert and update commands, create a	DBA

Task	Description	Skills required
	trigger that will route these commands to the respectiv e child tables based on the partitioning condition.	

Related resources

- AWS DMS
- Table Partitioning (PostgreSQL documentation)

Additional information

Although PostgreSQL version 10 supports native partitioning, you might decide to use inherited partitioning for the following use cases:

- Partitioning enforces a rule that all partitions must have the same set of columns as the parent, but table inheritance supports children having extra columns.
- Table inheritance supports multiple inheritances.
- Declarative partitioning supports only list and range partitioning. With table inheritance, you can divide the data as you want. However, if the constraint exclusion can't prune partitions effectively, query performance will suffer.
- Some operations need a stronger lock when using declarative partitioning than when using table inheritance. For example, adding or removing a partition to or from a partitioned table requires an `ACCESS EXCLUSIVE` lock on the parent table, whereas a `SHARE UPDATE EXCLUSIVE` lock is enough for regular inheritance.

When you use separate job partitions, you can also reload partitions if there are any AWS DMS validation issues. For better performance and replication control, run tasks on separate replication instances.

Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL

Jitender Kumar, Srini Ramaswamy, and Neha Sharma, Amazon Web Services

Summary

This pattern provides guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for MySQL DB instance on Amazon Web Services (AWS). The pattern uses AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT).

The pattern provides best practices for handling the migration of stored procedures. It also covers and code changes to support the application layer.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Amazon RDS for Oracle source database.
- An Amazon RDS for MySQL target database. Source and target databases should be in the same virtual private cloud (VPC). If you're using multiple VPCs, or you must have the required access permissions.
- Security groups that allow connectivity between the source and target databases, AWS SCT, the application server, and AWS DMS.
- A user account with the required privilege to run AWS SCT on the source database.
- Supplemental logging enabled for running AWS DMS on the source database.

Limitations

- The source and target Amazon RDS database size limit is 64 TB. For Amazon RDS size information, see the AWS documentation.
- Oracle is case-insensitive for database objects, but MySQL is not. AWS SCT can handle this issue while creating an object. However, some manual work is required to support full case insensitivity.
- This migration doesn't use MySQL extensions to enable Oracle-native functions. AWS SCT handles most of the conversion, but some work is required to change code manually.

- Java Database Connectivity (JDBC) driver changes are required in the application.

Product versions

- Amazon RDS for Oracle 12.2.0.1 and later. For currently supported RDS for Oracle versions, see the AWS documentation.
- Amazon RDS for MySQL 8.0.15 and later. For currently supported RDS for MySQL versions, see the AWS documentation.
- AWS DMS version 3.3.0 and later. See the AWS documentation for more information about AWS DMS supported source endpoints and target endpoints.
- AWS SCT version 1.0.628 and later. See the AWS SCT source and target endpoint support matrix in the AWS documentation.

Architecture

Source technology stack

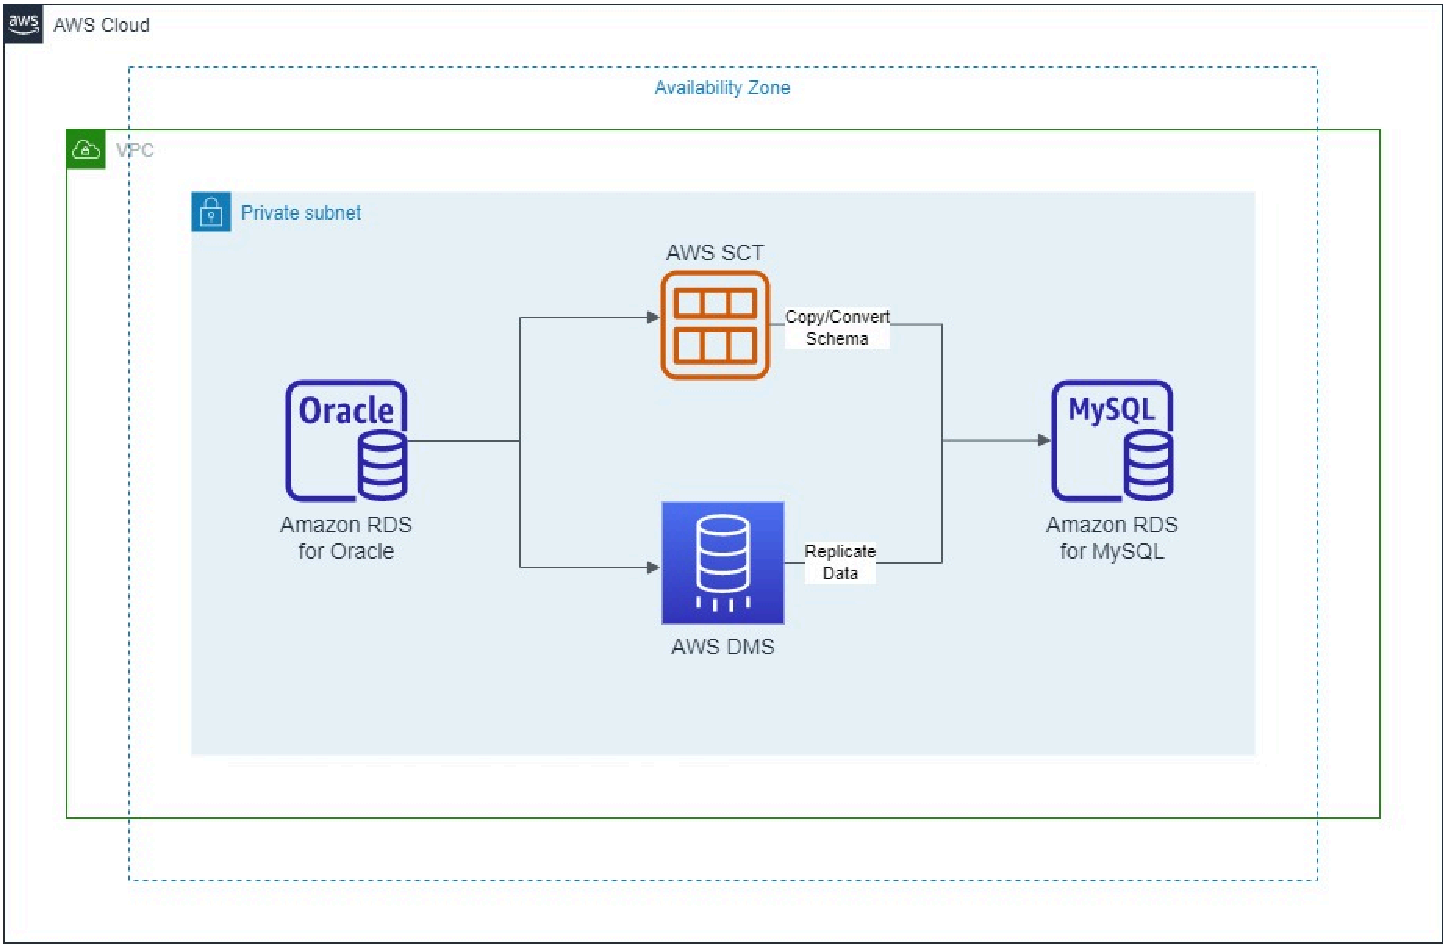
- Amazon RDS for Oracle. For more information, see Using an Oracle database as a source for AWS DMS.

Target technology stack

- Amazon RDS for MySQL. For more information, see Using a MySQL-Compatible database as a target for AWS DMS.

Migration architecture

In the following diagram, AWS SCT copies and converts schema objects from the Amazon RDS for Oracle source database and sends the objects to the Amazon RDS for MySQL target database. AWS DMS replicates data from the source database and sends it to the Amazon RDS for MySQL instance.



Tools

- AWS Data Migration Service helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle and Amazon RDS for MySQL.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

Epics

Prepare for migration

Task	Description	Skills required
Validate the source and target database versions and engines.		DBA
Identify hardware requirements for the target server instance.		DBA, SysAdmin
Identify storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type (capacity, storage features, network features).		DBA, SysAdmin
Identify network-access security requirements for the source and target databases.		DBA, SysAdmin
Choose an application migration strategy.	Consider whether you want full downtime or partial downtime for cutover activities.	DBA, SysAdmin, App owner

Configure infrastructure

Task	Description	Skills required
Create a VPC and subnets.		SysAdmin

Task	Description	Skills required
Create security groups and network access control lists (ACLs).		SysAdmin
Configure and start the Amazon RDS for Oracle instance.		DBA, SysAdmin
Configure and start the Amazon RDS for MySQL instance.		DBA, SysAdmin
Prepare a test case for validation of code conversion.	This will help in unit-testing for the converted code.	DBA, Developer
Configure the AWS DMS instance.		
Configure source and target endpoints in AWS DMS.		

Migrate data

Task	Description	Skills required
Generate the target database script using AWS SCT.	Check the accuracy of the code that was converted by AWS SCT. Some manual work will be required.	DBA, Developer
In AWS SCT, choose the "Case Insensitive" setting.	In AWS SCT, choose Project Settings, Target Case Sensitivi ty, Case Insensitive.	DBA, Developer

Task	Description	Skills required
In AWS SCT, choose not to use the Oracle native function.	In Project Settings, check the functions TO_CHAR/TO_NUMBER/TO_DATE.	DBA, Developer
Make changes for "sql%notfound" code.	You might have to convert the code manually.	
Query on tables and objects in stored procedures (use lowercase queries).		DBA, Developer
Create the primary script after all changes are made, and then deploy the primary script on the target database.		DBA, Developer
Unit-test stored procedures and application calls using sample data.		
Clean up data that was created during unit testing.		DBA, Developer
Drop foreign key constraints on the target database.	This step is required to load initial data. If you don't want to drop the foreign key constraints, you must create a migration task for data specific to the primary and secondary tables.	DBA, Developer
Drop primary keys and unique keys on the target database.	This step results in better performance for the initial load.	DBA, Developer
Enable supplemental logging on the source database.		DBA

Task	Description	Skills required
Create a migration task for the initial load in AWS DMS, and then run it.	Choose the option to migrate existing data.	DBA
Add the primary keys and foreign keys to the target database.	Constraints need to be added after the initial load.	DBA, Developer
Create a migration task for ongoing replication.	Ongoing replication keeps the target database synchronized with the source database.	DBA

Migrate applications

Task	Description	Skills required
Replace Oracle native functions with MySQL native functions.		App owner
Make sure that only lowercase names are used for database objects in SQL queries.		DBA, SysAdmin, App owner

Cut over to the target database

Task	Description	Skills required
Shut down the application server.		App owner
Validate that the source and target databases are in sync.		DBA, App owner

Task	Description	Skills required
Stop the Amazon RDS for Oracle DB instance.		DBA
Stop the migration task.	This will stop automatic ally after you complete the previous step.	DBA
Change the JDBC connection from Oracle to MySQL.		App owner, DBA
Start the application.		DBA, SysAdmin, App owner

Close the project

Task	Description	Skills required
Review and validate the project documents.		DBA, SysAdmin
Gather metrics about time to migrate, percentage of manual versus tool tasks, cost savings, etc.		DBA, SysAdmin
Stop and delete AWS DMS instances.		DBA
Remove the source and target endpoints.		DBA
Remove migration tasks.		DBA
Take a snapshot of the Amazon RDS for Oracle DB instance.		DBA

Task	Description	Skills required
Delete the Amazon RDS for Oracle DB instance.		DBA
Shut down and delete any other temporary AWS resources you used.		DBA, SysAdmin
Close the project and provide any feedback.		DBA

Migrate from IBM Db2 on Amazon EC2 to Aurora PostgreSQL-Compatible using AWS DMS and AWS SCT

Sirsendu Halder and Abhimanyu Chhabra, Amazon Web Services

Summary

This pattern provides guidance for migrating an IBM Db2 database on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon Aurora PostgreSQL-Compatible Edition DB instance. This pattern uses AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT) for data migration and schema conversion.

The pattern targets an online migration strategy with little or no downtime for a multi-terabyte IBM Db2 database that has a high number of transactions. We recommend that you convert the columns in primary keys (PKs) and foreign keys (FKs) with the data type `NUMERIC` to `INT` or `BIGINT` in PostgreSQL for better performance.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source IBM Db2 database on an EC2 instance

Product versions

- DB2/LINUXX8664 version 11.1.4.4 and later

Architecture

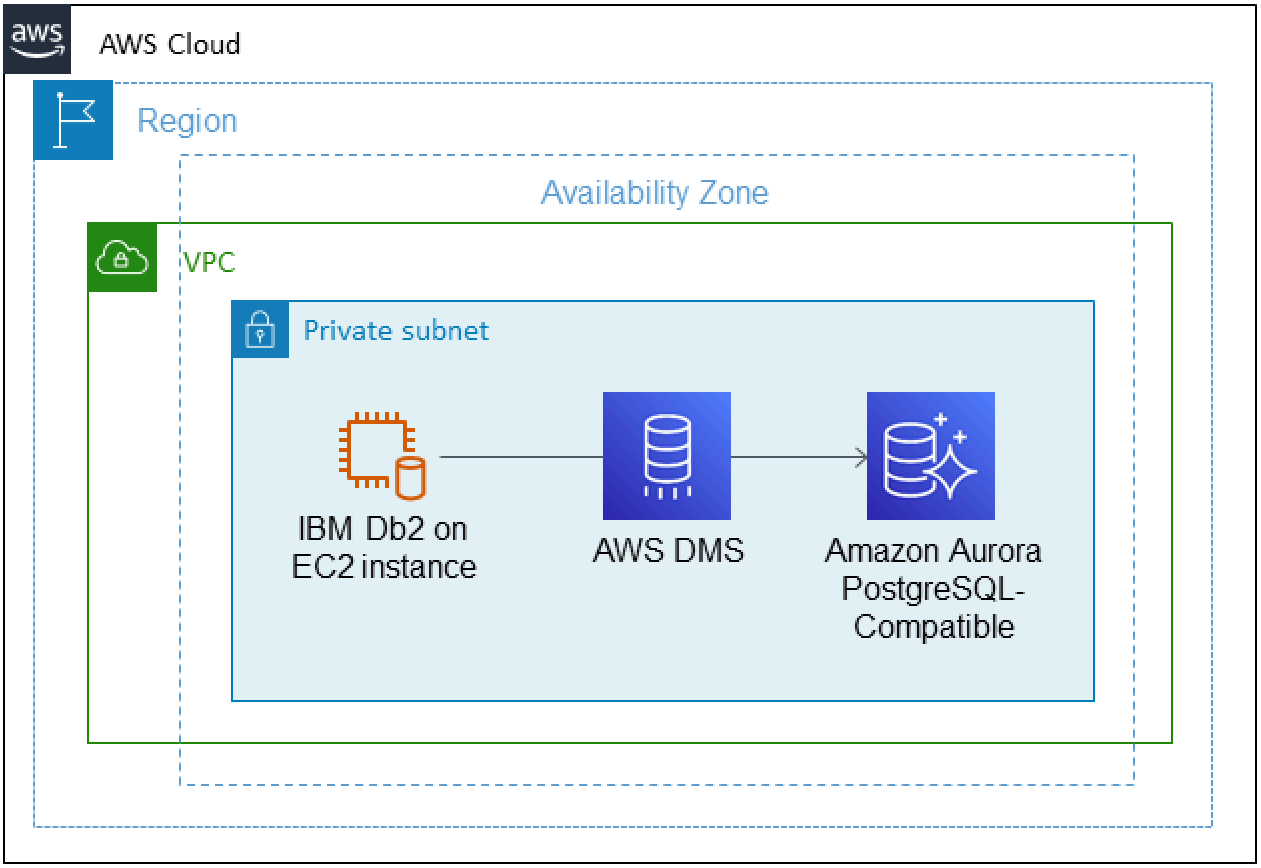
Source technology stack

- A Db2 database on an EC2 instance

Target technology stack

- An Aurora PostgreSQL-Compatible version 10.18 or later DB instance

Database migration architecture



Tools

- [AWS Database Migration Service (AWS DMS)](https://docs.aws.amazon.com/dms/latest/userguide/Welcome.html) helps you migrate databases into the AWS Cloud or between combinations of cloud and on-premises setups. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. You can use AWS DMS to migrate your data to and from the most widely used commercial and open-source databases. AWS DMS supports heterogeneous migrations between different database platforms, such as IBM Db2 to Aurora PostgreSQL-Compatible version 10.18 or higher. For details, see Sources for Data Migration and Targets for Data Migration in the AWS DMS documentation.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format that's compatible with the target database. Any objects that are not automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan the application source code for embedded SQL statements and convert them.

Epics

Set up the environment

Task	Description	Skills required
Create an Aurora PostgreSQL-Compatible DB instance.	To create the DB instance, follow the instructions in the [AWS documentation](). For engine type, choose **Amazon Aurora**. For edition, choose **Amazon Aurora PostgreSQL-Compatible Edition**. The Aurora PostgreSQL-Compatible version 10.18 or later DB instance should be in the same virtual private cloud (VPC) as the source IBM Db2 database.	Amazon RDS

Convert your database schema

Task	Description	Skills required
Install and verify AWS SCT.	1. Install AWS SCT by following the steps in the [AWS SCT documentation](). 2. Verify the installation by following the procedures in the [AWS SCT documentation]().	AWS administrator, DBA, Migration engineer
Start AWS SCT and create a project.	To start the AWS SCT tool and create a new project to run a database migration assessment report, follow the	Migration engineer

Task	Description	Skills required
	instructions in the [AWS SCT documentation].	
Add database servers and create a mapping rule.	1. Add source and target database servers by following the instructions in the [AWS SCT documenta tion]. 2. Create a mapping rule to define the target database platform for your source database. For instructi ons, see the [AWS SCT documentation].	Migration engineer
Create a database migration assessment report.	Create the database migration assessment report by following the steps in the [AWS SCT documentation].	Migration engineer
View the assessment report.	Use the **Summary** tab of the database migration assessment report to view the report and analyze the data. This analysis will help you determine the complexit y of the migration. For more information, see the [AWS SCT documentation].	Migration engineer

Task	Description	Skills required
Convert the schema.	To convert your source database schemas: 1. On the AWS SCT console, choose **View**, and then **Main view**. 2. Select the object or parent node from your source schema, open the context (right-click) menu, and then choose **Convert schema**. For more information, see the [AWS SCT documentation]().	Migration engineer
Apply the converted database schema to the target DB instance.	1. Choose the schema element in the right panel of your project that displays the planned schema for your target DB instance. 2. Open the context (right-cl ick) menu for the schema element, and then choose **Apply to database**. For more information, see the [AWS SCT documentation]().	Migration engineer

Migrate your data

Task	Description	Skills required
Set up a VPC and DB parameter groups.	Set up a VPC and DB parameter groups, and configure the inbound rules and parameters required for migration. For instructions, see the [AWS DMS documentation](). For the VPC security group, select both the EC2 instance for Db2 and the Aurora PostgreSQL-Compatible DB instance. This replication instance must be in the same VPC as the source and target DB instances.	Migration engineer
Prepare source and target DB instances.	Prepare the source and target DB instances for migration . In a production environme nt, the source database will already exist. For the source database, the server name must be the public Domain Name System (DNS) of the EC2 instance where Db2 is running. For user name, you can use `db2inst1` followed by the port, which will be 5000 for IBM Db2.	Migration engineer

Task	Description	Skills required
Create an Amazon EC2 client and endpoints.	1. Create an Amazon EC2 client. You use this client to populate your source database with data to replicate. You also use this client to verify replication by running queries on the target database. 2. Create endpoints for the source database and target DB instance to use for the next steps. For instructi ons, see the [AWS DMS documentation](). You must create separate endpoints for the source and target databases. For Aurora PostgreSQL-Compatible version 10.18 or later, the port will be 5432, and you can get the server name from the DB instance's endpoint.	Migration engineer
Create a replication instance.	Create a replication instance by using the AWS DMS console and specify the source and target endpoints . The replication instance performs the data migration between the endpoints. For more information, see the [AWS DMS documentation]().	Migration engineer

Task	Description	Skills required
Create an AWS DMS task to migrate the data.	Create a task to load the source IBM Db2 tables to the target PostgreSQL DB instance by following the steps in the [AWS DMS documentation](). • For source and target, use the source and destination endpoint names. • The migration type can be full load. • For the schema rule, you can use the `inst1` schema from the Db2 database. • For the table name, specify `%` to migrate all tables. When the load is complete, you'll see the Db2 tables of the `inst1` schema appearing in the Aurora PostgreSQL-Compatible database.	Migration engineer

Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS

Kumar Babu P G, Amazon Web Services

Summary

This pattern describes how to migrate an on-premises Oracle 8i or 9i database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL. AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source, so Quest SharePlex replicates data from an on-premises 8i or 9i database to an intermediate Oracle database (Oracle 10g or 11g), which is compatible with AWS DMS.

From the intermediate Oracle instance, the schema and data are migrated to the PostgreSQL database on AWS by using AWS Schema Conversion Tool (AWS SCT) and AWS DMS. This method helps achieve continuous streaming of data from the source Oracle database to the target PostgreSQL DB instance with minimum replication lag. In this implementation, the downtime is limited to the length of time it takes to create or validate all the foreign keys, triggers, and sequences on the target PostgreSQL database.

The migration uses an Amazon Elastic Compute Cloud (Amazon EC2) instance with Oracle 10g or 11g installed to host the changes from the source Oracle database. AWS DMS uses this intermediate Oracle instance as the source to stream the data to Amazon RDS for PostgreSQL or Aurora PostgreSQL. Data replication can be paused and resumed from the on-premises Oracle database to the intermediate Oracle instance. It can also be paused and resumed from the intermediate Oracle instance to the target PostgreSQL database so you can validate the data by using either AWS DMS data validation or a custom data validation tool.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises data center
- AWS Direct Connect configured between the on-premises data center and AWS
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors installed either on a local machine or on the EC2 instance where AWS SCT is installed
- Familiarity with using an Oracle database as an AWS DMS source

- Familiarity with using a PostgreSQL database as an AWS DMS target
- Familiarity with Quest SharePlex data replication

Limitations

- The database size limit is 64 TB
- The on-premises Oracle database must be Enterprise Edition

Product versions

- Oracle 8i or 9i for the source database
- Oracle 10g or 11g for the intermediate database
- PostgreSQL 9.6 or later

Architecture

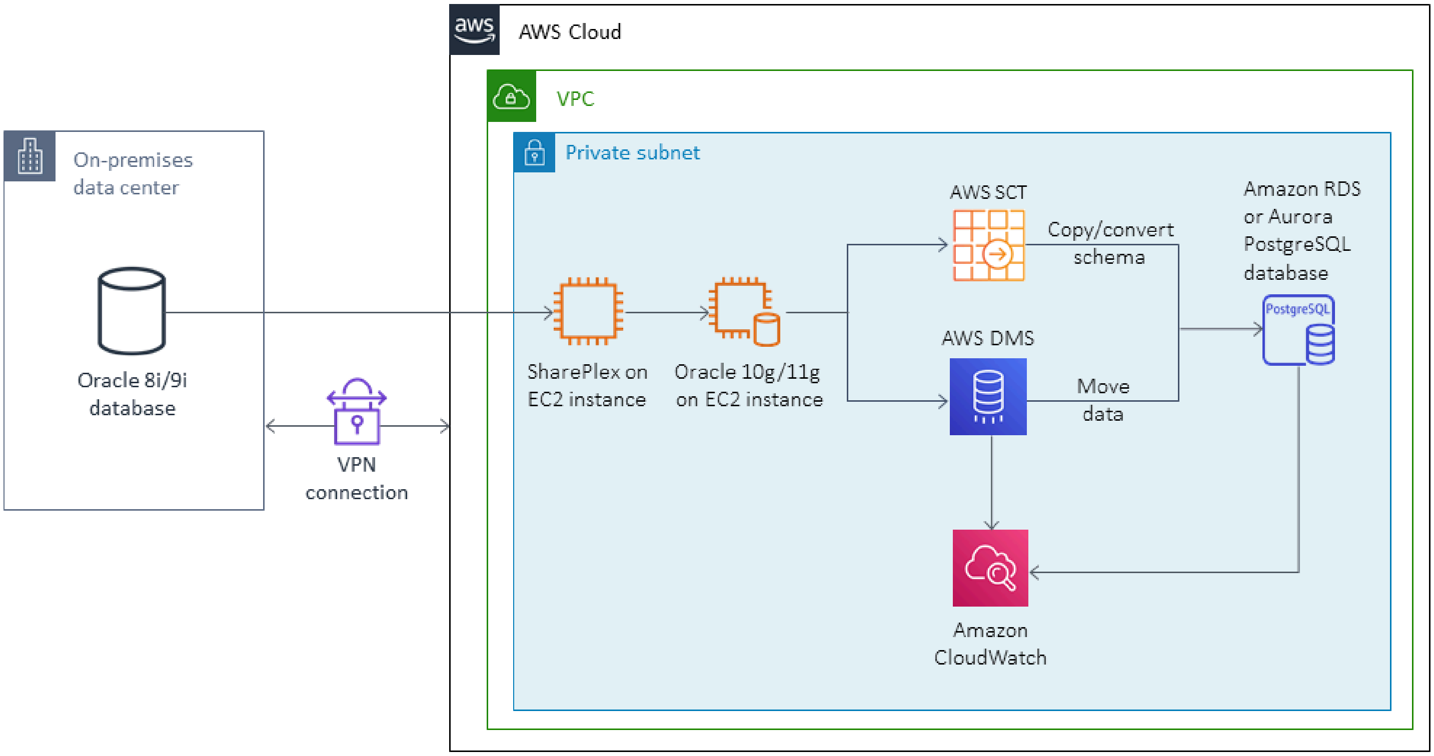
Source technology stack

- Oracle 8i or 9i database
- Quest SharePlex

Target technology stack

- Amazon RDS for PostgreSQL or Aurora PostgreSQL

Source and target architecture



Tools

- **AWS DMS** – AWS Database Migration Service (AWS DMS) helps you migrate databases quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.
- **AWS SCT** – AWS Schema Conversion Tool (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database. Objects that cannot be automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan your application source code for embedded SQL statements and convert them as part of a database schema conversion project. During this process, AWS SCT performs cloud-native code optimization by converting legacy Oracle and SQL Server functions to their AWS equivalents, to help you modernize your applications while migrating your databases. When schema conversion is complete, AWS SCT can help migrate data from a range of data warehouses to Amazon Redshift by using built-in data migration agents.
- **Quest SharePlex** – Quest SharePlex is an Oracle-to-Oracle data replication tool for moving data with minimal downtime and no data loss.

Epics

Create the EC2 instance and install Oracle

Task	Description	Skills required
Set up the network for Amazon EC2.	Create the virtual private cloud (VPC), subnets, internet gateway, route tables, and security groups.	AWS SysAdmin
Create the new EC2 instance.	Select the Amazon Machine Image (AMI) for the EC2 instance. Choose the instance size and configure instance details: the number of instances (1), the VPC and subnet from the previous step, auto-assign public IP, and other options. Add storage, configure security groups, and launch the instance. When prompted, create and save a key pair for the next step.	AWS SysAdmin
Install Oracle on the EC2 instance.	Acquire the licenses and the required Oracle binaries, and install Oracle 10g or 11g on the EC2 instance.	DBA

Set up SharePlex on an EC2 instance and configure data replication

Task	Description	Skills required
Set up SharePlex.	Create an Amazon EC2 instance and install the	AWS SysAdmin, DBA

Task	Description	Skills required
	SharePlex binaries that are compatible with Oracle 8i or 9i.	
Configure data replication.	Follow SharePlex best practices to configure data replication from an on-premises Oracle 8i/9i database to an Oracle 10g/11g instance.	DBA

Convert the Oracle database schema to PostgreSQL

Task	Description	Skills required
Set up AWS SCT.	Create a new report, and then connect to Oracle as the source and PostgreSQL as the target. In project settings, open the SQL Scripting tab and change the target SQL script to Multiple Files.	DBA
Convert the Oracle database schema.	In the Action tab, choose Generate Report, Convert Schema, and then Save as SQL.	DBA
Modify the SQL scripts generated by AWS SCT.		DBA

Create and configure the Amazon RDS DB instance

Task	Description	Skills required
Create the Amazon RDS DB instance.	In the Amazon RDS console, create a new PostgreSQL DB instance.	AWS SysAdmin, DBA
Configure the DB instance.	Specify the DB engine version, DB instance class, Multi-AZ deployment, storage type, and allocated storage. Enter the DB instance identifier, a master user name, and a master password.	AWS SysAdmin, DBA
Configure network and security.	Specify the VPC, subnet group, public accessibility, Availability Zone preference, and security groups.	AWS SysAdmin, DBA
Configure database options.	Specify the database name, port, parameter group, encryption, and master key.	AWS SysAdmin, DBA
Configure backups.	Specify the backup retention period, backup window, start time, duration, and whether to copy tags to snapshots.	AWS SysAdmin, DBA
Configure monitoring options.	Enable or disable enhanced monitoring and performance insights.	AWS SysAdmin, DBA
Configure maintenance options.	Specify auto minor version upgrade, maintenance	AWS SysAdmin, DBA

Task	Description	Skills required
	window, and the start day, time, and duration.	
Run the pre-migration scripts from AWS SCT.	On the Amazon RDS instance, run these scripts: create_da tabase.sql, create_se quence.sql, create_table.sql, create_view.sql, and create_fu nction.sql.	AWS SysAdmin, DBA

Migrate data by using AWS DMS

Task	Description	Skills required
Create a replication instance in AWS DMS.	Complete the fields for the name, instance class, VPC (same as for the EC2 instance) , Multi-AZ, and public accessibility. In the advanced configuration section, specify allocated storage, subnet group, Availability Zone, VPC security groups, and AWS Key Management Service (AWS KMS) root key.	AWS SysAdmin, DBA
Create the source database endpoint.	Specify the endpoint name, type, source engine (Oracle), server name (Amazon EC2 private DNS name), port, SSL mode, user name, password, SID, VPC (specify the VPC that has the replication instance) , and replication instance. To test the connection, choose	AWS SysAdmin, DBA

Task	Description	Skills required
	Run Test, and then create the endpoint. You can also configure the following advanced settings: maxFileSize and numberDataTypeScale.	
Create the AWS DMS replication task.	Specify the task name, replication instance, source and target endpoints, and replication instance. For migration type, choose "Migrate existing data and replicate ongoing changes." Clear the "Start task on create" check box.	AWS SysAdmin, DBA
Configure the AWS DMS replication task settings.	For target table preparation mode, choose "Do nothing." Stop the task after the full load completes to create primary keys. Specify limited or full LOB mode, and enable control tables. Optionally, you can configure the CommitRate advanced setting.	DBA

Task	Description	Skills required
Configure the table mappings.	In the table mappings section, create an Include rule for all tables in all schemas included in the migration, and then create an Exclude rule. Add three transformation rules to convert the schema, table, and column names to lowercase, and add any other rules needed for this specific migration.	DBA
Start the task.	Start the replication task. Make sure that the full load is running. Run ALTER SYSTEM SWITCH LOGFILE on the primary Oracle database to kick-start the task.	DBA
Run the mid-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run these scripts: create_index.sql and create_constraint.sql.	DBA
Restart the task to continue change data capture (CDC).	In the Amazon RDS for PostgreSQL DB instance, run VACUUM, and restart the AWS DMS task to apply the cached CDC changes.	DBA

Cut over to the PostgreSQL database

Task	Description	Skills required
Check the AWS DMS logs and metadata tables.	Validate any errors and fix if required.	DBA
Stop all Oracle dependencies.	Shut down listeners on the Oracle database and run ALTER SYSTEM SWITCH LOGFILE. Stop the AWS DMS task when it shows no activity.	DBA
Run the post-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run these scripts: create_foreign_key_constraint.sql and create_triggers.sql.	DBA
Complete any additional Amazon RDS for PostgreSQL steps.	Increment sequences to match Oracle if needed, run VACUUM and ANALYZE, and take a snapshot for compliance.	DBA
Open the connections to Amazon RDS for PostgreSQL.	Remove the AWS DMS security groups from Amazon RDS for PostgreSQL, add production security groups, and point your applications to the new database.	DBA
Clean up AWS DMS resources.	Remove the endpoints, replication tasks, replication instances, and the EC2 instance.	SysAdmin, DBA

Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS

Kumar Babu P G and Pragnesh Patel, Amazon Web Services

Summary

This pattern describes how to migrate an on-premises legacy Oracle 8i or 9i database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition.

AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source, so this pattern uses an intermediate Oracle database instance that's compatible with AWS DMS, such as Oracle 10g or 11g. It also uses the materialized views feature to migrate data from the source Oracle 8i/9i instance to the intermediate Oracle 10g/11g instance.

AWS Schema Conversion Tool (AWS SCT) converts the database schema, and AWS DMS migrates the data to the target PostgreSQL database.

This pattern helps users who want to migrate from legacy Oracle databases with minimum database downtime. In this implementation, the downtime would be limited to the length of time it takes to create or validate all the foreign keys, triggers, and sequences on the target database.

The pattern uses Amazon Elastic Compute Cloud (Amazon EC2) instances with an Oracle 10g/11g database installed to help AWS DMS stream the data. You can temporarily pause streaming replication from the on-premises Oracle database to the intermediate Oracle instance to enable AWS DMS to catch up on data validation or to use another data validation tool. The PostgreSQL DB instance and intermediate Oracle database will have the same data when AWS DMS has finished migrating current changes.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises data center
- AWS Direct Connect configured between the on-premises data center and AWS
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors installed either on a local machine or on the EC2 instance where AWS SCT is installed

- Familiarity with [using an Oracle database as an AWS DMS source]
- Familiarity with [using a PostgreSQL database as an AWS DMS target]

Limitations

- The database size limit is 64 TB

Product versions

- Oracle 8i or 9i for the source database
- Oracle 10g or 11g for the intermediate database
- PostgreSQL 10.17 or later

Architecture

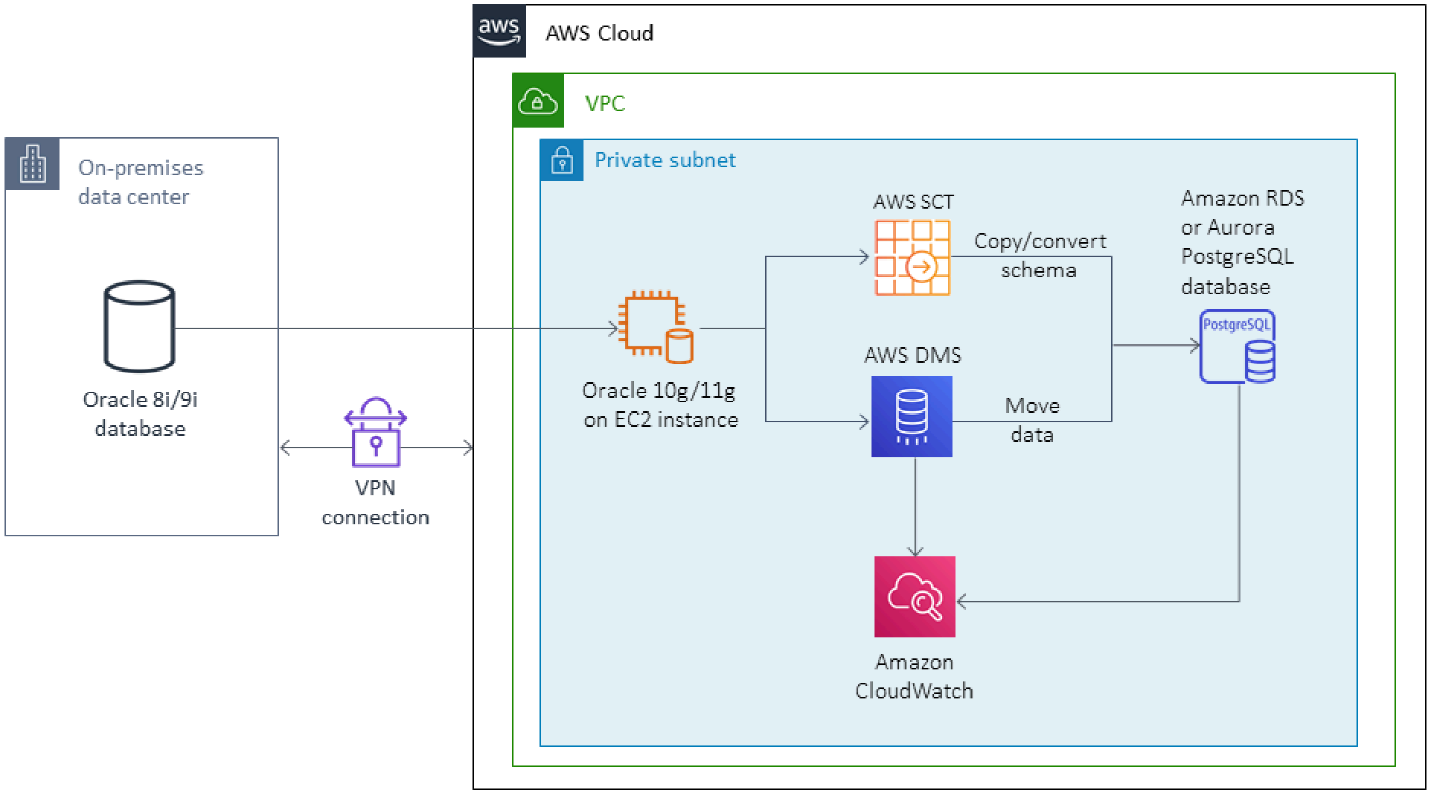
Source technology stack

- Oracle 8i or 9i database

Target technology stack

- Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible

Target architecture



Tools

- AWS DMS helps migrate databases quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.
- AWS SCT automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database. Objects that cannot be automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan your application source code for embedded SQL statements and convert them as part of a database schema conversion project. During this process, AWS SCT performs cloud-native code optimization by converting legacy Oracle and SQL Server functions to their AWS equivalents, to help you modernize your applications while migrating your databases. When schema conversion is complete, AWS SCT can help migrate data from a range of data warehouses to Amazon Redshift by using built-in data migration agents.

Best practices

For best practices for refreshing materialized views, see the following Oracle documentation:

- Refreshing materialized views
- Fast refresh for materialized views

Epics

Install Oracle on an EC2 instance and create materialized views

Task	Description	Skills required
Set up the network for the EC2 instance.	Create the virtual private cloud (VPC), subnets, internet gateway, route tables, and security groups.	AWS SysAdmin
Create the EC2 instance.	Select the Amazon Machine Image (AMI) for the EC2 instance. Choose the instance size and configure instance details: the number of instances (1), the VPC and subnet from the previous step, auto-assign public IP, and other options. Add storage, configure security groups, and launch the instance. When prompted, create and save a key pair for the next step.	AWS SysAdmin
Install Oracle on the EC2 instance.	Acquire the licenses and the required Oracle binaries, and install Oracle 10g or 11g on the EC2 instance.	DBA

Task	Description	Skills required
Configure Oracle networking.	Modify or add entries in `listener.ora` to connect to the on-premises source Oracle 8i/9i database, and then create the database links.	DBA
Create materialized views.	Identify the database objects to replicate in the source Oracle 8i/9i database, and then create materialized views for all the objects by using the database link.	DBA
Deploy scripts to refresh materialized views at required intervals.	Develop and deploy scripts to refresh materialized views at required intervals on the Amazon EC2 Oracle 10g/11g instance. Use the increment al refresh option to refresh materialized views.	DBA

Convert the Oracle database schema to PostgreSQL

Task	Description	Skills required
Set up AWS SCT.	Create a new report, and then connect to Oracle as the source and PostgreSQL as the target. In project settings, open the **SQL Scripting** tab. Change the target SQL script to **Multiple Files**. (AWS SCT doesn't support Oracle 8i/9i databases, so you have to	DBA

Task	Description	Skills required
	restore the schema-only dump on the intermediate Oracle 10g/11g instance and use it as a source for AWS SCT.)	
Convert the Oracle database schema.	On the **Action** tab, choose **Generate Report**, **Convert Schema**, and then **Save as SQL**.	DBA
Modify the SQL scripts.	Make modifications based on best practices. For example, switch to suitable data types and develop PostgreSQL equivalents for Oracle-sp ecific functions.	DBA, DevDBA

Create and configure the Amazon RDS DB instance to host the converted database

Task	Description	Skills required
Create the Amazon RDS DB instance.	In the Amazon RDS console, create a new PostgreSQL DB instance.	AWS SysAdmin, DBA
Configure the DB instance.	Specify the DB engine version, DB instance class, Multi-AZ deployment, storage type, and allocated storage. Enter the DB instance identifier, a master user name, and a master password.	AWS SysAdmin, DBA

Task	Description	Skills required
Configure network and security.	Specify the VPC, subnet group, public accessibility, Availability Zone preference, and security groups.	DBA, SysAdmin
Configure database options.	Specify the database name, port, parameter group, encryption, and master key.	DBA, AWS SysAdmin
Configure backups.	Specify the backup retention period, backup window, start time, duration, and whether to copy tags to snapshots.	AWS SysAdmin, DBA
Configure monitoring options.	Enable or disable enhanced monitoring and performance insights.	AWS SysAdmin, DBA
Configure maintenance options.	Specify auto minor version upgrade, maintenance window, and the start day, time, and duration.	AWS SysAdmin, DBA
Run the pre-migration scripts from AWS SCT.	On the target Amazon RDS for PostgreSQL instance, create the database schema by using the SQL scripts from AWS SCT with other modifications. These might include running multiple scripts and including user creation, database creation, schema creation, tables, views, functions, and other code objects.	AWS SysAdmin, DBA

Migrate data by using AWS DMS

Task	Description	Skills required
Create a replication instance in AWS DMS.	Complete the fields for the name, instance class, VPC (same as for the EC2 instance) , Multi-AZ, and public accessibility. In the advanced configuration section, specify allocated storage, subnet group, Availability Zone, VPC security groups, and AWS Key Management Service (AWS KMS) key.	AWS SysAdmin, DBA
Create the source database endpoint.	Specify the endpoint name, type, source engine (Oracle), server name (the EC2 instance's private DNS name), port, SSL mode, user name, password, SID, VPC (specify the VPC that has the replicati on instance), and replicati on instance. To test the connection, choose **Run Test**, and then create the endpoint. You can also configure the following advanced settings: **maxFileSize** and **numberDat aTypeScale**.	AWS SysAdmin, DBA
Connect AWS DMS to Amazon RDS for PostgreSQL.	Create a migration security group for connections across VPCs, if your PostgreSQL database is in another VPC.	AWS SysAdmin, DBA

Task	Description	Skills required
Create the target database endpoint.	Specify the endpoint name, type, source engine (PostgreSQL), server name (Amazon RDS endpoint), port, SSL mode, user name, password, database name, VPC (specify the VPC that has the replication instance), and replication instance. To test the connection, choose **Run Test**, and then create the endpoint. You can also configure the following advanced settings: **maxFileSize** and **numberDataTypeScale**.	AWS SysAdmin, DBA
Create the AWS DMS replication task.	Specify the task name, replication instance, source and target endpoints, and replication instance. For migration type, choose **Migrate existing data and replicate ongoing changes**. Clear the **Start task on create** check box.	AWS SysAdmin, DBA
Configure the AWS DMS replication task settings.	For target table preparation mode, choose **Do nothing**. Stop the task after full load completes (to create primary keys). Specify limited or full LOB mode, and enable control tables. Optionally, you can configure the **CommitRate** advanced setting.	DBA

Task	Description	Skills required
Configure the table mappings.	In the **Table mappings** section, create an Include rule for all tables in all schemas included in the migration, and then create an Exclude rule. Add three transformation rules to convert the schema, table, and column names to lowercase, and add any other rules you need for this specific migration.	DBA
Start the task.	Start the replication task. Make sure that the full load is running. Run `ALTER SYSTEM SWITCH LOGFILE` on the primary Oracle database to start the task.	DBA
Run the mid-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run the following scripts: `create_index.sql` and `create_constraint.sql` (if the complete schema wasn't initially created).	DBA
Resume the task to continue change data capture (CDC).	Run `VACUUM` on the Amazon RDS for PostgreSQL DB instance, and restart the AWS DMS task to apply cached CDC changes.	DBA

Cut over to the PostgreSQL database

Task	Description	Skills required
Check the AWS DMS logs and validation tables.	Check and fix any replication or validation errors.	DBA
Stop using the on-premises Oracle database and its dependencies.	Stop all Oracle dependencies, shut down listeners on the Oracle database, and run `ALTER SYSTEM SWITCH LOGFILE`. Stop the AWS DMS task when it shows no activity.	DBA
Run the post-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run these scripts: `create_foreign_key_constraint.sql` and `create_triggers.sql` . Make sure that the sequences are up to date.	DBA
Complete additional Amazon RDS for PostgreSQL steps.	Increment sequences to match Oracle if needed, run `VACUUM` and `ANALYZE`, and take a snapshot for compliance.	DBA
Open the connections to Amazon RDS for PostgreSQL.	Remove the AWS DMS security groups from Amazon RDS for PostgreSQL, add production security groups, and point your applications to the new database.	DBA
Clean up the AWS DMS objects.	Remove the endpoints, replication tasks, replicati	SysAdmin, DBA

Task	Description	Skills required
	on instances, and the EC2 instance.

Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT

Anil Kunapareddy, Amazon Web Services

Harshad Gohil, None

Summary

Managing Oracle databases on Amazon Elastic Compute Cloud (Amazon EC2) instances requires resources and can be costly. Moving these databases to an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance will ease your job by optimizing the overall IT budget. Amazon RDS for MySQL also provides features like Multi-AZ, scalability, and automatic backups.

This pattern walks you through the migration of a source Oracle database on Amazon EC2 to a target Amazon RDS for MySQL DB instance. It uses AWS Database Migration Service (AWS DMS) to migrate the data, and AWS Schema Conversion Tool (AWS SCT) to convert the source database schema and objects to a format that's compatible with Amazon RDS for MySQL.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source database with instance and listener services running, in ARCHIVELOG mode
- A target Amazon RDS for MySQL database, with sufficient storage for data migration

Limitations

- AWS DMS does not create a schema on the target database; you have to do that. The schema name must already exist for the target. Tables from the source schema are imported to user/schema, which AWS DMS uses to connect to the target instance. You must create multiple replication tasks if you have to migrate multiple schemas.

Product versions

- All Oracle database editions for versions 10.2 and later, 11g and up to 12.2, and 18c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS and

Using a MySQL-Compatible Database as a Target for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.

- AWS DMS supports versions 5.5, 5.6, and 5.7 of MySQL.

Architecture

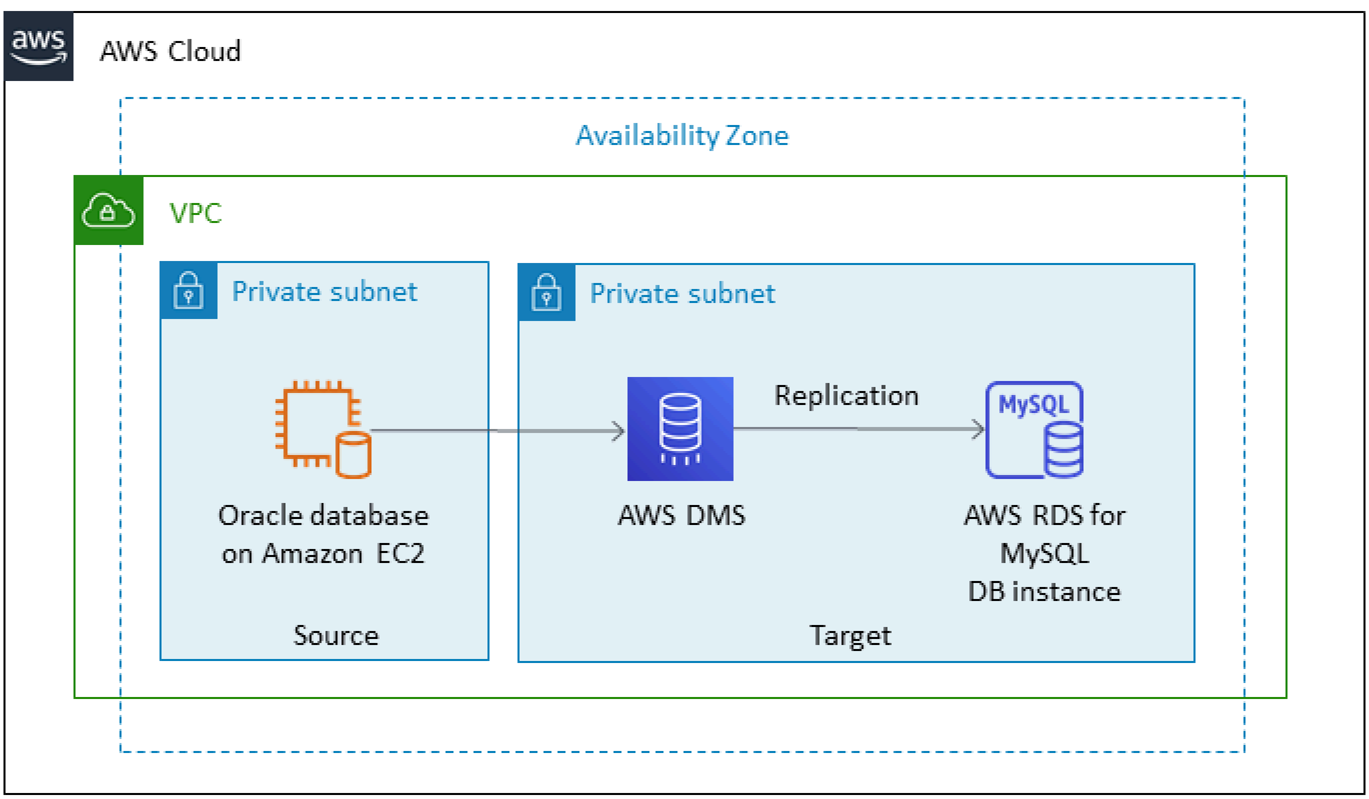
Source technology stack

- An Oracle database on an EC2 instance

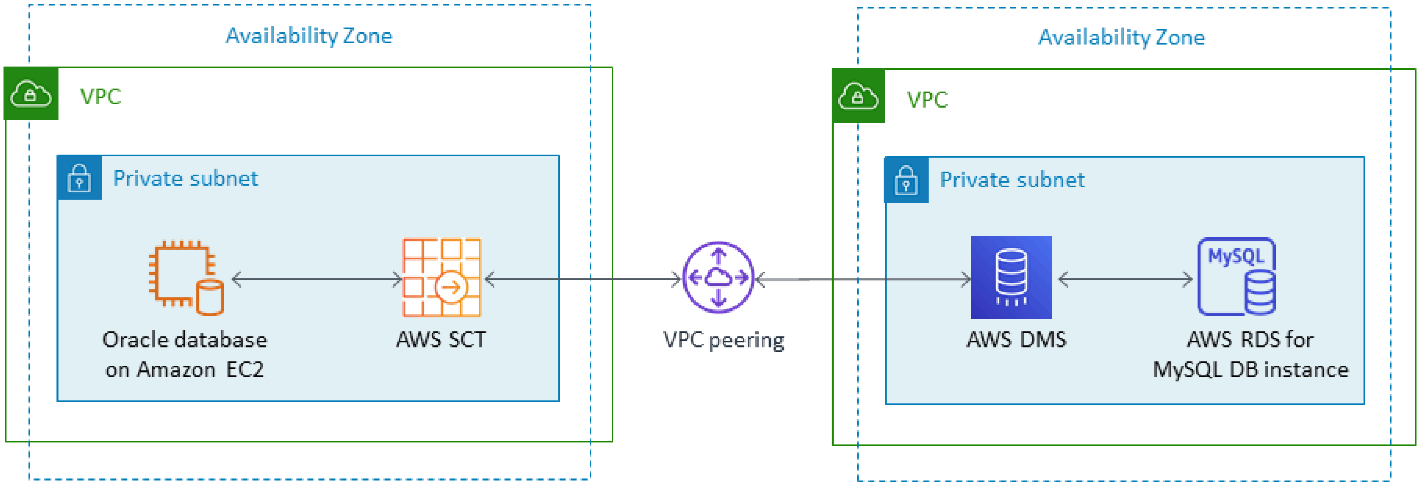
Target technology stack

- Amazon RDS for MySQL DB instance

Data migration architecture



Source and target architecture



Tools

- **AWS DMS** - [AWS Database Migration Service](#) (AWS DMS) is a web service you can use to migrate data from your database that is on-premises, on an Amazon RDS DB instance, or in a database on an EC2 instance, to a database on an AWS service such as Amazon RDS for MySQL or an EC2 instance. You can also migrate a database from an AWS service to an on-premises database. You can migrate data between heterogeneous or homogeneous database engines.
- **AWS SCT** - [AWS Schema Conversion Tool](#) (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format that's compatible with the target database. After converting your database schema and code objects using AWS SCT, you can use AWS DMS to migrate data from the source database to the target database to complete your migration projects.

Epics

Plan the migration

Task	Description	Skills required
Identify the source and target database versions and engines.		DBA/Developer

Task	Description	Skills required
Identify the DMS replication instance.		DBA/Developer
Identify storage requireme nts such as storage type and capacity.		DBA/Developer
Identify network requireme nts such as latency and bandwidth.		DBA/Developer
Identify hardware requireme nts for the source and target server instances (based on Oracle compatibility list and capacity requirements).		DBA/Developer
Identify network access security requirements for source and target databases.		DBA/Developer
Install AWS SCT and Oracle drivers.		DBA/Developer
Determine a backup strategy.		DBA/Developer
Determine availability requirements.		DBA/Developer
Identify application migration and switch-over strategy.		DBA/Developer
Select the proper DB instance type based on capacity, storage, and network features.		DBA/Developer

Configure the environment

Task	Description	Skills required
Create a virtual private cloud (VPC). The source, target, and replication instance should be in the same VPC. It is also good to have these in the same Availability Zone.		Developer
Create the necessary security groups for database access.		Developer
Generate and configure a key pair.		Developer
Configure subnets, Availability Zones, and CIDR blocks.		Developer

Configure the source: Oracle database on EC2 instance

Task	Description	Skills required
Install Oracle Database on Amazon EC2 with required users and roles.		DBA
Perform the three steps in the next column to access Oracle from outside the EC2 instance.	1. Change the local host in `tnsnames` to the Amazon EC2 public DNS. 2. Change the local host in `listener` to the Amazon EC2 public DNS. 3. Stop and restart the listener.	DBA

Task	Description	Skills required
When Amazon EC2 is restarted, the public DNS changes. Make sure to update Amazon EC2 public DNS in 'tnsnames' and 'listener' or use an Elastic IP address.		DBA/Developer
Configure the EC2 instance security group so that the replication instance and required clients can access the source database.		DBA/Developer

Configure the target: Amazon RDS for MySQL

Task	Description	Skills required
Configure and start the Amazon RDS for MySQL DB instance.		Developer
Create the necessary tablespace in the Amazon RDS for MySQL DB instance.		DBA
Configure the security group so that the replicati on instance and required clients can access the target database.		Developer

Configure AWS SCT and create a schema in the target database

Task	Description	Skills required
Install AWS SCT and Oracle drivers.		Developer
Enter the appropriate parameters and connect to the source and target.		Developer
Generate a schema conversio n report.		Developer
Correct the code and schema as necessary, especially tablespaces and quotes, and run on the target database.		Developer
Validate the schema on source vs. target before migrating data.		Developer

Migrate data using AWS DMS

Task	Description	Skills required
For full-load and change data capture (CDC) or just CDC, you must set an extra connection attribute.		Developer
The user specified in the AWS DMS source Oracle database definitions must be granted all the required privilege s. For a complete list, see https://docs.aws.amazon.com		DBA/Developer

Task	Description	Skills required
/dms/latest/userguide/CHAP_Source.Oracle.html#CHAP_Source.Oracle.Self-Managed.		
Enable supplemental logging in the source database.		DBA/Developer
For full-load and change data capture (CDC) or just CDC, enable ARCHIVELOG mode in the source database.		DBA
Create source and target endpoints, and test the connections.		Developer
When the endpoints are connected successfully, create a replication task.		Developer
Select CDC only (or) full load plus CDC in the task to capture changes for continuous replication only (or) full load plus ongoing changes, respectively.		Developer
Run the replication task and monitor Amazon CloudWatch logs.		Developer
Validate the data in the source and target databases.		Developer

Migrate your application and cut over

Task	Description	Skills required
Follow the steps for your application migration strategy.		DBA, Developer, App owner
Follow the steps for your application cutover/switch-over strategy.		DBA, Developer, App owner

Close the project

Task	Description	Skills required
Validate the schema and data in source vs. target databases.		DBA/Developer
Gather metrics around time to migrate, percent of manual vs. tool, cost savings, etc.		DBA/Developer/AppOwner
Review the project documents and artifacts.		DBA/Developer/AppOwner
Shut down temporary AWS resources.		DBA/Developer
Close out the project and provide feedback.		DBA/Developer/AppOwner

Migrate from Oracle to Amazon DocumentDB using AWS DMS

Sashikanta Pattanayak and Munesh Siddappa, Amazon Web Services

Summary

This pattern provides guidance for migrating an Oracle database to an Amazon DocumentDB (with MongoDB compatibility) database by using AWS Database Migration Service (AWS DMS). This approach can be applied to an on-premises Oracle source database as well as an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance. This pattern uses an Amazon RDS Oracle DB source instance as an example.

Amazon DocumentDB (with MongoDB compatibility) is a fully managed, MongoDB-compatible document database service that makes it easy to store, query, and index JSON data.

The use case for this pattern is one-to-one replication of an Oracle database table to an Amazon DocumentDB collection. The pattern uses AWS DMS replication tasks to read the table structure of the Oracle database, create the corresponding collection in Amazon DocumentDB, and perform a full load migration. You can view and query your data in Amazon DocumentDB, the same as you would in MongoDB.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Familiarity with using Oracle databases
- Familiarity with using Amazon DocumentDB
- For the Oracle user, `SELECT ANY TABLE` privilege
- For the Amazon DocumentDB use, the privilege required to dump data

Limitations

The following limitations apply when using Amazon DocumentDB as a target for AWS DMS:

- In Amazon DocumentDB, collection names can't contain the dollar symbol ($). In addition, database names can't contain any Unicode characters.

- AWS DMS doesn't support merging of multiple source tables into a single Amazon DocumentDB collection.
- When AWS DMS processes changes from a source table that doesn't have a primary key, any large binary object (LOB) columns in that table are ignored.
- If the **Change table** option is enabled and AWS DMS encounters a source column named "_id", that column appears as "__id" (two underscores) in the change table.
- If you choose Oracle as a source endpoint, the Oracle source must have full supplemental logging enabled. Otherwise, if there are columns at the source that weren't changed, the data is loaded into Amazon DocumentDB as null values.

Product versions

- Amazon RDS for Oracle version 11.2.0.3 or later
- AWS DMS version 3.1.3 or later (for the latest version information, see Using Amazon DocumentDB as a Target for AWS DMS in the AWS DMS documentation)

Architecture

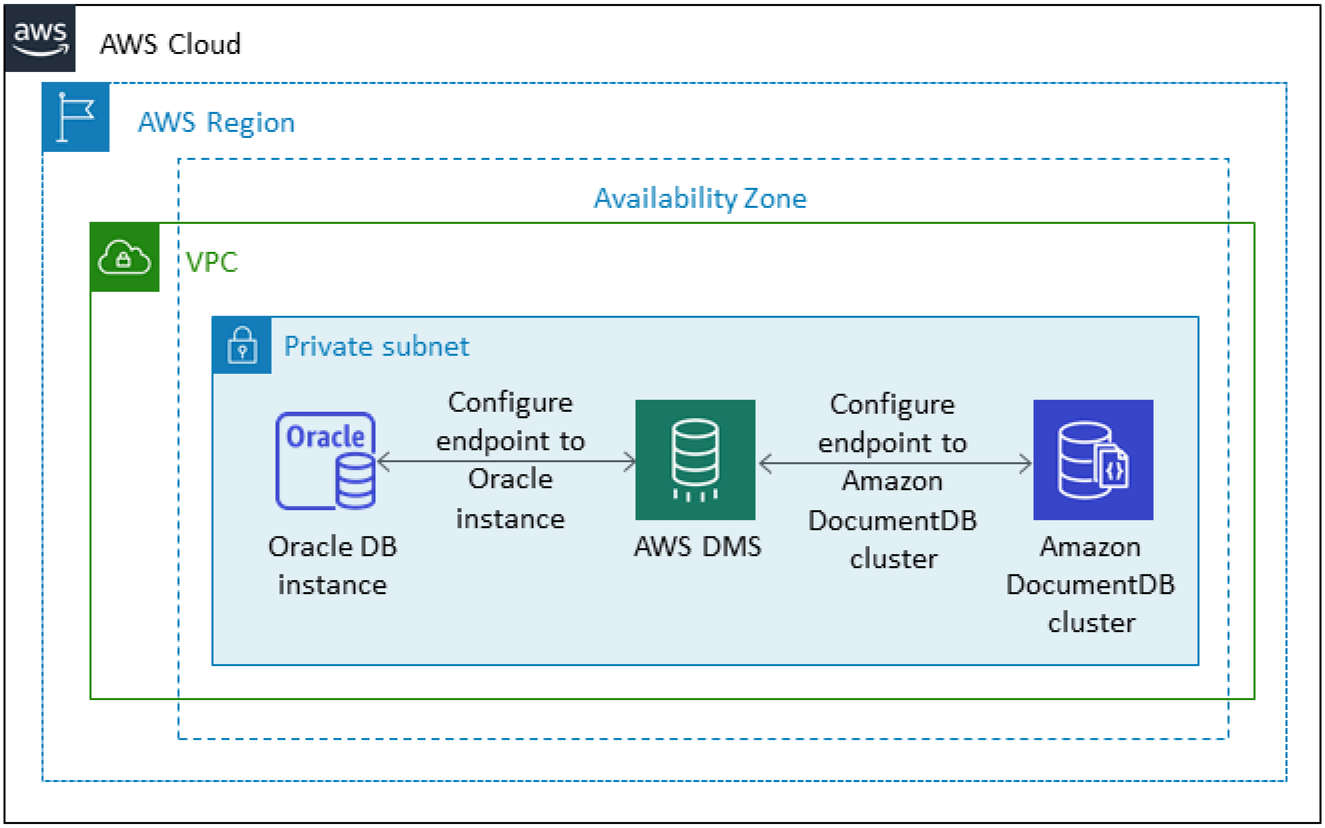
Source technology stack

- Amazon RDS for Oracle DB instance

Target technology stack

- Amazon DocumentDB

Source and target architecture



Tools

- **AWS DMS** – AWS Database Migration Service (AWS DMS) is a web service that you can use to migrate data from a source data store to a target data store. The AWS DMS User Guide specifies the Oracle source database versions and editions that are supported for use with AWS DMS. For additional information relevant to this pattern, see Using Amazon DocumentDB as a Target for AWS DMS.
- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS cloud. Your Amazon DocumentDB cluster should be running in your default virtual private cloud (VPC). To interact with your Amazon DocumentDB cluster, you must launch an EC2 instance into your default VPC, in the same AWS Region where you created your Amazon DocumentDB cluster. For details, refer to Launch an Amazon EC2 instance in the Amazon DocumentDB documentation.

Epics

Plan the migration

Task	Description	Skills required
Validate the source and target database versions and engines.		AWS Admin
Choose the proper instance type (capacity, storage features, network features).		AWS Admin
Identify network/host access security requirements for the source and target databases.		AWS Admin
Create an outbound security group to the source and target databases.		AWS Admin
Create and configure an EC2 instance for Amazon DocumentDB.		AWS Admin

Configure infrastructure

Task	Description	Skills required
Create a VPC and subnets.		AWS Admin
Create security groups and network access control lists (ACLs).		AWS Admin

Task	Description	Skills required
Configure and start the source Amazon RDS for Oracle instance.		AWS Admin
Configure and start the Amazon DocumentDB instance.		AWS Admin

Prepare the source database

Task	Description	Skills required
Verify that the Oracle database can be connected using the connection details.		AWS Admin
Verify that the Oracle user has the SELECT ANY TABLE privilege.		AWS Admin

Prepare the target database

Task	Description	Skills required
Create the Amazon DocumentDB cluster by choosing the proper instance class and number of instances .		AWS Admin

Configure Amazon EC2

Task	Description	Skills required
Configure the EC2 instance.	To interact with your Amazon DocumentDB cluster, you must launch an EC2 instance into your default VPC, in the same AWS Region where you created your Amazon DocumentDB cluster. Configure the AWS Region, VPCs, Availability Zones, and subnets for the EC2 instance.	AWS Admin
Configure the key pair.	A public/private key pair allows you to connect securely to the EC2 instance after it launches.	AWS Admin
Set the bastion host CIDR ranges (optional).	Set the CIDR IP range that is allowed for external Secure Shell (SSH) access to the bastion host instances.	AWS Admin

Migrate data – full load

Task	Description	Skills required
Create an AWS DMS replicati on instance.		AWS Admin
Create source and target endpoints.		AWS Admin
Create AWS DMS replication tasks for a full load.		AWS Admin

Test the migration

Task	Description	Skills required
Connect to the Amazon DocumentDB cluster through the EC2 instance.		AWS Admin
Connect to the cluster using the mongo shell.	For instructions, see the Amazon DocumentDB links in the References and Help section.	AWS Admin
Verify the results of the migration.		AWS Admin

Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT

Veeranjaneyulu Grandhi and vinod kumar, Amazon Web Services

Summary

This pattern walks you through the steps for migrating an Oracle database on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon Relational Database Service (Amazon RDS) for MariaDB DB instance. The pattern uses AWS Data Migration Service (AWS DMS) for data migration and AWS Schema Conversion Tool (AWS SCT) for schema conversion.

Managing Oracle databases on EC2 instances requires more resources and is more costly than using a database on Amazon RDS. Amazon RDS makes it easy to set up, operate, and scale a relational database in the cloud. Amazon RDS provides cost-efficient and resizable capacity while automating time-consuming administration tasks such as hardware provisioning, database setup, patching, and backups.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A source Oracle database with instance and listener services up and running. This database should be in ARCHIVELOG mode.
- Familiarity with Using an Oracle Database as a Source for AWS DMS.
- Familiarity with Using Oracle as a Source for AWS SCT.

Limitations

- Database size limit: 64 TB

Product versions

- All Oracle database editions for versions 10.2 and later, 11g and up to 12.2, and 18c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS and the AWS SCT version table in the AWS documentation.

- Amazon RDS supports MariaDB Server Community Server versions 10.3, 10.4, 10.5, and 10.6. For the latest list of supported versions, see the Amazon RDS documentation.

Architecture

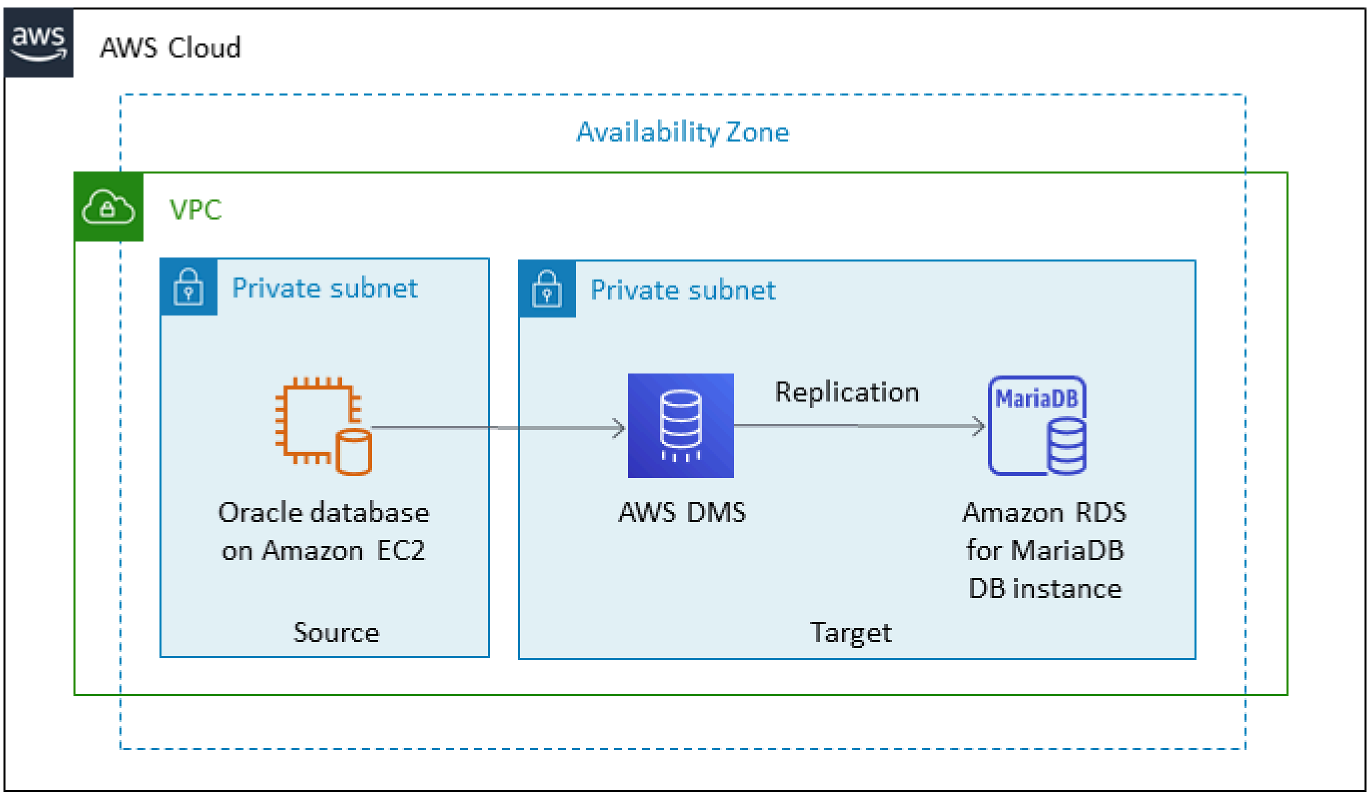
Source technology stack

- An Oracle database on an EC2 instance

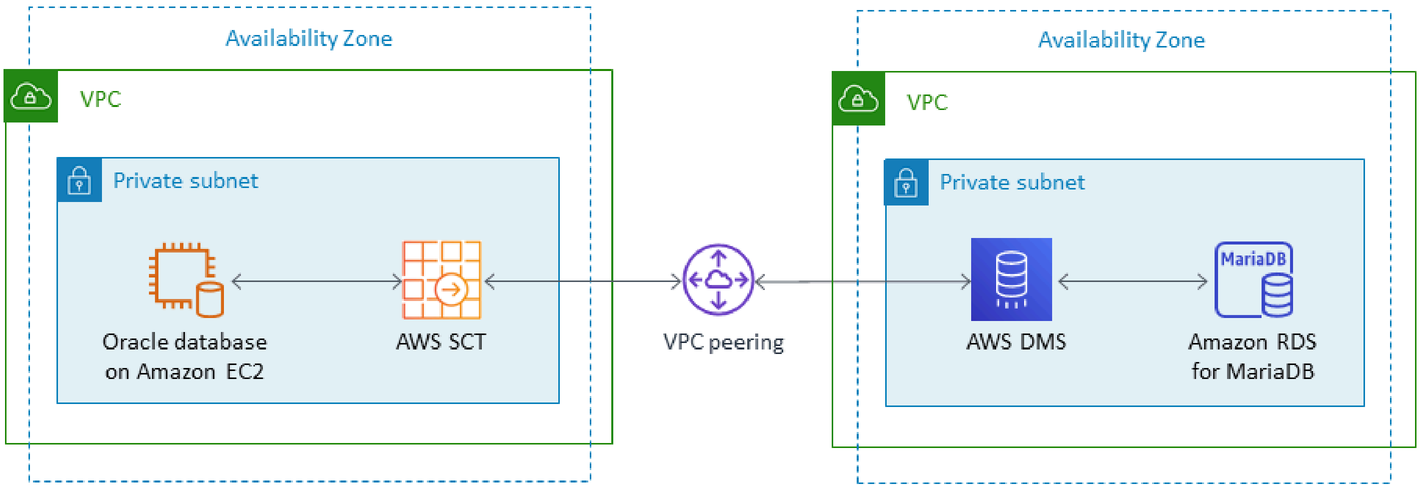
Target technology stack

- Amazon RDS for MariaDB

Data migration architecture



Target architecture



Tools

- AWS Schema Conversion Tool (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects—including views, stored procedures, and functions—to a format compatible with the target database. After converting your database schema and code objects using AWS SCT, you can use AWS DMS to migrate data from the source database to the target database to complete your migration projects. For more information, see Using Oracle as a Source for AWS SCT in the AWS SCT documentation.
- AWS Database Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases. AWS DMS supports homogeneous migrations such as Oracle to Oracle, as well as heterogeneous migrations between different database platforms, such as Oracle or Microsoft SQL Server to Amazon Aurora. To learn more about migrating Oracle databases, see Using an Oracle Database as a Source for AWS DMS in the AWS DMS documentation.

Epics

Plan for the migration

Task	Description	Skills required
Identify versions and database engines.	Identify the source and target database versions and engines.	DBA, Developer
Identify the replication instance.	Identify the AWS DMS replication instance.	DBA, Developer
Identify storage requireme nts.	Identify storage type and capacity.	DBA, Developer
Identify network requireme nts.	Identify network latency and bandwidth.	DBA, Developer
Identify hardware requireme nts.	Identify hardware requireme nts for the source and target server instances (based on the Oracle compatibility list and capacity requirements).	DBA, Developer
Identify security requireme nts.	Identify network-access security requirements for the source and target databases.	DBA, Developer
Install drivers.	Install the latest AWS SCT and Oracle drivers.	DBA, Developer
Determine a backup strategy.		DBA, Developer
Determine availability requirements.		DBA, Developer

Task	Description	Skills required
Choose an application migration/switchover strategy.		DBA, Developer
Select the instance type.	Select the proper instance type based on capacity, storage, and network features.	DBA, Developer

Configure the environment

Task	Description	Skills required
Create a virtual private cloud (VPC).	The source, target, and replication instances should be in the same VPC and in the same Availability Zone (recommended).	Developer
Create security groups.	Create the necessary security groups for database access.	Developer
Generate a key pair.	Generate and configure a key pair.	Developer
Configure other resources.	Configure subnets, Availabil ity Zones, and CIDR blocks.	Developer

Configure the source

Task	Description	Skills required
Launch the EC2 instance.	For instructions, see the [Amazon EC2 documentation]().	Developer

Task	Description	Skills required
Install the Oracle database.	Install the Oracle database on the EC2 instance, with required users and roles.	DBA
Follow the steps in the task description to access Oracle from outside of the EC2 instance.	1. Change the local host in `tnsnames` to the Amazon EC2 public DNS. 2. Change the local host in `listener` to the Amazon EC2 public DNS. 3. Stop and restart the listener.	DBA
Update the Amazon EC2 public DNS.	After the EC2 instance restarts, the public DNS changes. Make sure to update the Amazon EC2 public DNS in `tnsnames` and `listener`, or use an Elastic IP address.	DBA, Developer
Configure the EC2 instance security group.	Configure the EC2 instance security group so the replicati on instance and required clients can access the source database.	DBA, Developer

Configure the target Amazon RDS for MariaDB environment

Task	Description	Skills required
Start the RDS DB instance.	Configure and start the Amazon RDS for MariaDB DB instance.	Developer

Task	Description	Skills required
Create tablespaces.	Create any necessary tablespaces in the Amazon RDS MariaDB database.	DBA
Configure a security group.	Configure a security group so the replication instance and required clients can access the target database.	Developer

Configure AWS SCT

Task	Description	Skills required
Install drivers.	Install the latest AWS SCT and Oracle drivers.	Developer
Connect.	Enter appropriate parameter s and then connect to the source and target.	Developer
Generate a schema conversio n report.	Generate an AWS SCT schema conversion report.	Developer
Correct the code and schema as necessary.	Make any necessary correctio ns to the code and schema (especially tablespaces and quotation marks).	DBA, Developer
Validate the schema.	Validate the schema on the source versus the target before loading data.	Developer

Migrate data using AWS DMS

Task	Description	Skills required
Set a connection attribute.	For full-load and change data capture (CDC) or just for CDC, set an extra connection attribute. For more informati on, see the [Amazon RDS documentation]().	Developer
Enable supplemental logging.	Enable supplemental logging on the source database.	DBA, Developer
Enable archive log mode.	For full-load and CDC (or just for CDC), enable archive log mode on the source database.	DBA
Create and test endpoints.	Create source and target endpoints and test the connections. For more information, see the [Amazon DMS documentation]().	Developer
Create a replication task.	When the endpoints are connected successfully, create a replication task. For more information, see the [Amazon DMS documentation]().	Developer
Choose replication type.	Choose **CDC only** or **Full load plus CDC** in the task to capture changes for continuous replication only, or for full load and ongoing changes, respectively.	Developer

Task	Description	Skills required
Start and monitor the task.	Start the replication task and monitor Amazon CloudWatch logs. For more information, see the [Amazon DMS documentation]().	Developer
Validate the data.	Validate the data in the source and target databases.	Developer

Migrate applications and cut over to the target database

Task	Description	Skills required
Follow the chosen application migration strategy.		DBA, App owner, Developer
Follow the chosen application cutover/switchover strategy.		DBA, App owner, Developer

Close the project

Task	Description	Skills required
Validate the schema and data.	Ensure that the schema and data are validated successfully in the source versus the target before project closure.	DBA, Developer
Gather metrics.	Gather metrics for time to migrate, percentage of manual versus tool tasks, cost savings, and similar criteria.	DBA, App owner, Developer

Task	Description	Skills required
Review documentation.	Review the project documents and artifacts.	DBA, App owner, Developer
Shut down resources.	Shut down temporary AWS resources.	DBA, Developer
Close the project.	Close the migration project and provide any feedback.	DBA, App owner, Developer

Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT

Sergey Dmitriev and Naresh Damera, Amazon Web Services

Summary

This pattern walks you through the migration of an on-premises Oracle database to an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance. It uses AWS Database Migration Service (AWS DMS) to migrate the data, and AWS Schema Conversion Tool (AWS SCT) to convert the source database schema and objects to a format that's compatible with Amazon RDS for MySQL.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle database in an on-premises data center

Limitations

- Database size limit: 64 TB

Product versions

- All Oracle database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.
- AWS DMS currently supports MySQL versions 5.5, 5.6, and 5.7. For the latest list of supported versions, see Using a MySQL-Compatible Database as a Target for AWS DMS in the AWS documentation.

Architecture

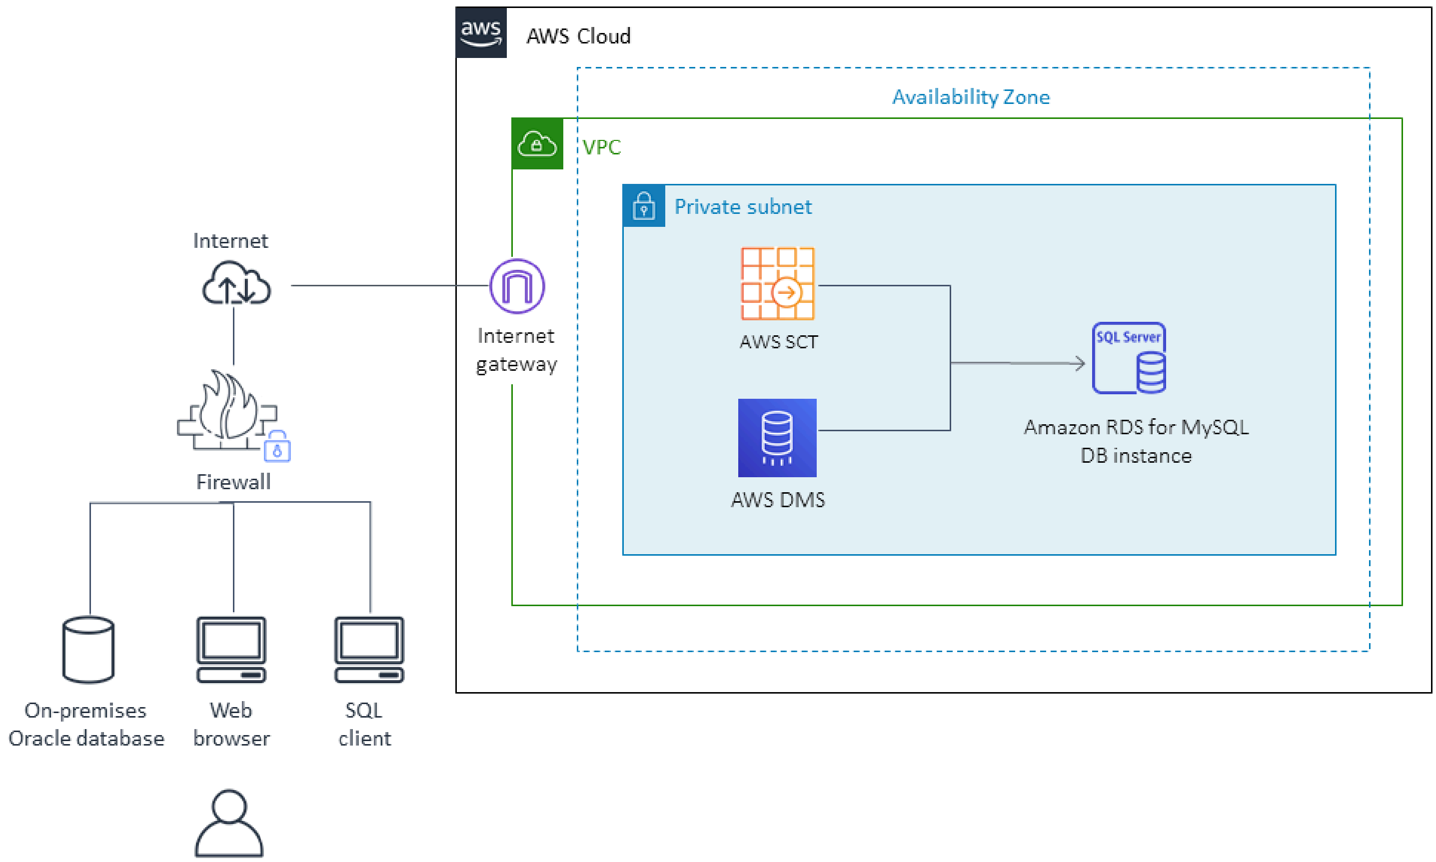
Source technology stack

- On-premises Oracle database

Target technology stack

- Amazon RDS for MySQL DB instance

Data migration architecture



Tools

- **AWS DMS** - [AWS Database Migration Services](https://docs.aws.amazon.com/dms/) (AWS DMS) helps you migrate relational databases, data warehouses, NoSQL databases, and other types of data stores. You can use AWS DMS to migrate your data into the AWS Cloud, between on-premises instances (through an AWS Cloud setup), or between combinations of cloud and on-premises setups.
- **AWS SCT** - [AWS Schema Conversion Tool](https://docs.aws.amazon.com/SchemaConversionTool/) (AWS SCT) is used to convert your database schema from one database engine to another. The custom code that the tool converts includes views, stored procedures, and functions. Any code that the tool cannot convert automatically is clearly marked so that you can convert it yourself.

Epics

Plan the migration

Task	Description	Skills required
Validate the source and target database version and engine.		DBA
Identify the hardware requirements for the target server instance.		DBA, SysAdmin
Identify the storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type based on capacity, storage features, and network features.		DBA, SysAdmin
Identify the network access security requirements for the source and target databases.		DBA, SysAdmin
Identify the application migration strategy.		DBA, SysAdmin, App owner

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.		SysAdmin

Task	Description	Skills required
Create the security groups and network access control lists (ACLs).		SysAdmin
Configure and start an Amazon RDS DB instance.		DBA, SysAdmin

Migrate data

Task	Description	Skills required
Migrate the database schema by using AWS SCT.		DBA
Migrate data by using AWS DMS.		DBA

Migrate the application

Task	Description	Skills required
Use AWS SCT to analyze and convert the SQL code inside the application code.	For more information, see https://docs.aws.amazon.com/SchemaConversionTool/latest/userguide/CHAP_Converting.App.html.	App owner
Follow the application migration strategy.		DBA, SysAdmin, App owner

Cut over

Task	Description	Skills required
Switch the application clients over to the new infrastru cture.		DBA, SysAdmin, App owner

Close the project

Task	Description	Skills required
Shut down the temporary AWS resources.		DBA, SysAdmin
Review and validate the project documents.		DBA, SysAdmin
Gather metrics around time to migrate, % of manual vs. tool, cost savings, etc.		DBA, SysAdmin
Close out the project and provide feedback.

Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL by using an Oracle bystander and AWS DMS

Cady Motyka, Amazon Web Services

Summary

This pattern describes how you can migrate an on-premises Oracle database to either of the following PostgreSQL-compatible AWS database services with minimal downtime:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

The solution uses AWS Database Migration Service (AWS DMS) to migrate the data, AWS Schema Conversion Tool (AWS SCT) to convert the database schema, and an Oracle bystander database to help manage the migration. In this implementation, the downtime is restricted to however long it takes to create or validate all of the foreign keys on the database.

The solution also uses Amazon Elastic Compute Cloud (Amazon EC2) instances with an Oracle bystander database to help control the stream of data through AWS DMS. You can temporarily pause streaming replication from the on-premises Oracle database to the Oracle bystander to activate AWS DMS to catch up on data validation, or to use another data validation tool. The Amazon RDS for PostgreSQL DB instance or Aurora PostgreSQL-Compatible DB instance and the bystander database will have the same data when AWS DMS finishes migrating current changes.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle database in an on-premises data center with an Active Data Guard standby database configured
- AWS Direct Connect configured between the on-premises data center and AWS Secrets Manager for storing the database secrets
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed either on a local machine or on the EC2 instance where AWS SCT is installed
- Familiarity with using an Oracle database as a source for AWS DMS

- Familiarity with using a PostgreSQL database as a target for AWS DMS

Limitations

- Database size limit: 64 TB

Product versions

- AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g and up to 12.2, 18c, and 19c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.
- AWS DMS supports PostgreSQL versions 9.4 and later (for versions 9.x), 10.x, 11.x, 12.x, and 13.x. For the latest information, see Using a PostgreSQL Database as a Target for AWS DMS in the AWS documentation.

Architecture

Source technology stack

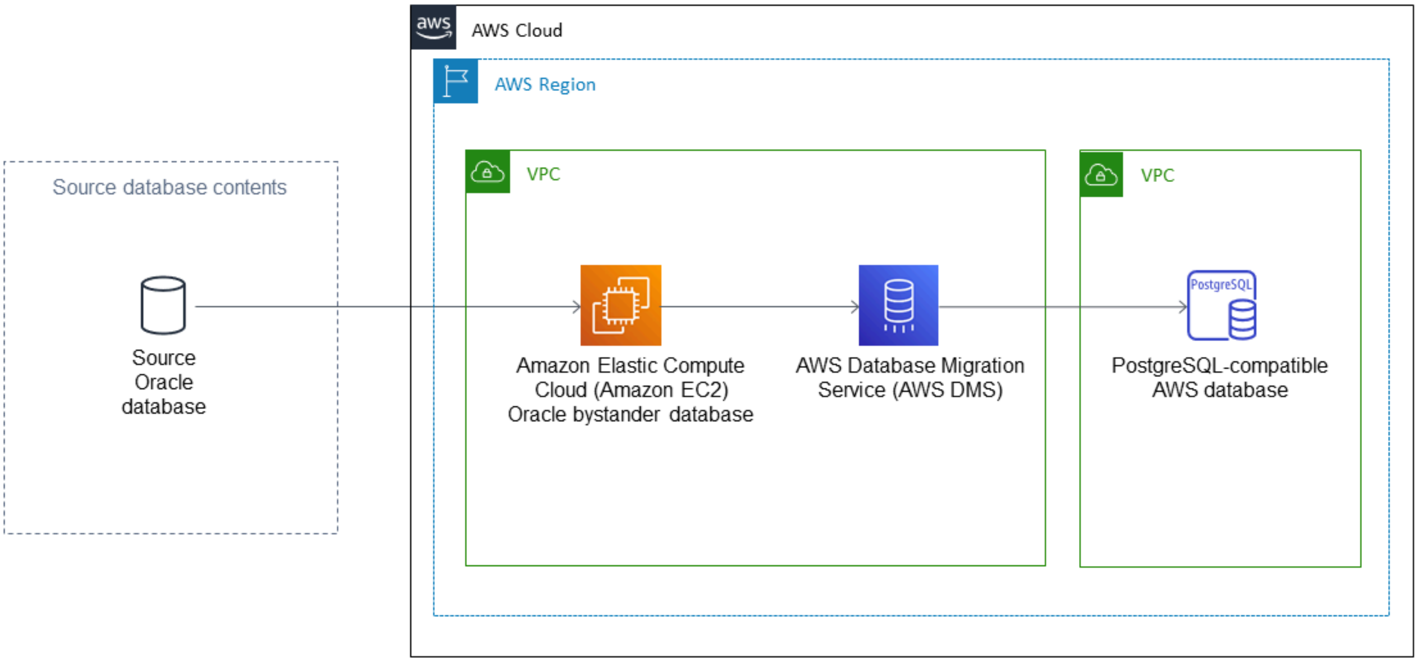
- An on-premises Oracle database
- An EC2 instance that holds a bystander for the Oracle database

Target technology stack

- Amazon RDS for PostgreSQL or Aurora PostgreSQL instance, PostgreSQL 9.3 and later

Target architecture

The following diagram shows an example workflow for migrating an Oracle database to a PostgreSQL-compatible AWS database by using AWS DMS and an Oracle bystander:



Tools

- [AWS Database Migration Service (AWS DMS)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [AWS Schema Conversion Tool (AWS SCT)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.
- [Amazon Relational Database Service (Amazon RDS)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.

Epics

Convert the Oracle database schema to PostgreSQL

Task	Description	Skills required
Set up AWS SCT.	Create a new report, and connect to Oracle as the source and PostgreSQL as the target. In **Project Settings**, go to the **SQL Scripting** tab.	DBA

Task	Description	Skills required
	Change the **Target SQL Script** to **Multiple Files**. These files will be used later and named the following: • create_database.sql • create_sequence.sql • create_table.sql • create_view.sql • create_function.sql	
Convert the Oracle database schema.	In the **Action** tab, choose **Generate Report**. Then, choose **Convert Schema** and choose **Save as SQL**.	DBA
Modify the scripts.	For example, you might want to modify the script if a number in the source schema has been converted to numeric format in PostgreSQ L, but you want to use **BIGINT** instead for better performan ce.	DBA

Create and configure the Amazon RDS DB instance

Task	Description	Skills required
Create the Amazon RDS DB instance.	In the correct AWS Region, create a new PostgreSQL DB instance. For more informati on, see [Creating a PostgreSQ L DB instance and connecting](#)	AWS SysAdmin, DBA

Task	Description	Skills required
	to a database on a PostgreSQL DB instance in the Amazon RDS documentation.	
Configure DB instance specifications.	Specify the DB engine version, DB instance class, Multi-AZ deployment, storage type, and allocated storage. Enter the DB instance identifier, a primary user name, and a primary password.	AWS SysAdmin, DBA
Configure network and security.	Specify the virtual private cloud (VPC), subnet group, public accessibility, Availability Zone preference, and security groups.	DBA, SysAdmin
Configure database options.	Specify the database name, port, parameter group, encryption, and KMS key.	AWS SysAdmin, DBA
Configure backups.	Specify the backup retention period, backup window, start time, duration, and whether to copy tags to snapshots.	AWS SysAdmin, DBA
Configure monitoring options.	Activate or deactivate enhanced monitoring and performance insights.	AWS SysAdmin, DBA
Configure maintenance options.	Specify auto minor version upgrade, maintenance window, and start day, time, and duration.	AWS SysAdmin, DBA

Task	Description	Skills required
Run the pre-migration scripts from AWS SCT.	On the Amazon RDS instance, run the following scripts generated by AWS SCT: • create_database.sql • create_sequence.sql • create_table.sql • create_view.sql • create_function.sql	AWS SysAdmin, DBA

Configure the Oracle bystander in Amazon EC2

Task	Description	Skills required
Set up the network for Amazon EC2.	Create the new VPC, subnets, internet gateway, route tables, and security groups.	AWS SysAdmin
Create the EC2 instance.	In the appropriate AWS Region, create a new EC2 instance. Select the Amazon Machine Image (AMI), choose the instance size, and configure instance details: number of instances (1), the VPC and subnet you created in the previous task, auto-assign public IP, and other options. Add storage, configure security groups, and launch. When prompted, create and save a key pair for the next step.	AWS SysAdmin

Task	Description	Skills required
Connect the Oracle source database to the EC2 instance.	Copy the IPv4 public IP address and DNS to a text file and connect by using SSH as follows: **ssh -i "your_file.pem" ec2-user@<your-IP-address-or-public-DNS>**.	AWS SysAdmin
Set up the initial host for a bystander in Amazon EC2.	Set up SSH keys, bash profile, ORATAB, and symbolic links. Create Oracle directories.	AWS SysAdmin, Linux Admin
Set up the database copy for a bystander in Amazon EC2	Use RMAN to create a database copy, enable supplemental logging, and create the standby control file. After copying is complete, place the database in recovery mode.	AWS SysAdmin, DBA
Set up Oracle Data Guard.	Modify your **listener.ora** file and start the listener. Set up a new archive destination. Place the bystander in recovery mode, replace temporary files to avoid future corruption, install a crontab if necessary to prevent the archive directory from running out of space, and edit the **manage-trclog-files-oracle.cfg** file for the source and standby.	AWS SysAdmin, DBA

Task	Description	Skills required
Prep the Oracle database to sync shipping.	Add the standby log files and change the recovery mode. Change the log shipping to **SYNC AFFIRM** on both the source primary and the source standby. Switch logs on primary, confirm via the Amazon EC2 bystander alert log that you are using the standby log files, and confirm that the redo stream is flowing in SYNC.	AWS SysAdmin, DBA

Migrate data with AWS DMS

Task	Description	Skills required
Create a replication instance in AWS DMS.	Complete the fields for the name, instance class, VPC (same as the Amazon EC2 instance), Multi-AZ, and public accessibility. Under **Advance**, specify allocated storage, subnet group, Availability Zone, VPC security groups, and AWS Key Management Service (AWS KMS) key.	AWS SysAdmin, DBA
Create the source database endpoint.	Specify the endpoint name, type, source engine (Oracle), server name (Amazon EC2 private DNS name), port, SSL mode, user name, password,	AWS SysAdmin, DBA

Task	Description	Skills required
	SID, VPC (specify the VPC that has the replication instance) , and replication instance. To test the connection, choose **Run Test**, and then create the endpoint. You can also configure the following advanced settings: **maxFileSi ze** and **numberDataTypeScal e**.	
Connect AWS DMS to Amazon RDS for PostgreSQL.	Create a migration security group for connections across VPCs.	AWS SysAdmin, DBA
Create the target database endpoint.	Specify the endpoint name, type, source engine (PostgreS QL), server name (Amazon RDS endpoint), port, SSL mode, user name, password, database name, VPC (specify the VPC that has the replicati on instance), and replicati on instance. To test the connection, choose **Run Test**, and then create the endpoint. You can also configure the following advanced settings: **maxFileSize** and **numberDat aTypeScale**.	AWS SysAdmin, DBA

Task	Description	Skills required
Create the AWS DMS replicati on task.	Specify the task name, replication instance, source and target endpoints, and replication instance. For migration type, choose **Migrate existing data and replicate ongoing changes**. Clear the **Start task on create** checkbox.	AWS SysAdmin, DBA
Configure the AWS DMS replication task settings.	For target table preparation mode, choose **Do nothing**. Stop task after full load completes (to create primary keys). Specify limited or full LOB mode, and activate control tables. Optionally, you can configure the **CommitRat e** advance setting.	DBA
Configure table mappings.	In the **Table mappings** section, create an **Include** rule for all tables in all schemas included in the migration, and then create an **Exclude** rule. Add three transformation rules to convert the schema, table, and column names to lowercase, and add any other rules needed for this specific migration.	DBA

Task	Description	Skills required
Start the task.	Start the replication task. Make sure that the full load is running. Run **ALTER SYSTEM SWITCH LOGFILE** on the primary Oracle database to kick-start the task.	DBA
Run the mid-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run the following scripts generated by AWS SCT: • create_index.sql • create_constraint.sql	DBA
Restart the task to continue change data capture (CDC).	Run **VACUUM** on the Amazon RDS for PostgreSQL DB instance, and restart the AWS DMS task to apply cached CDC changes.	DBA

Cut over to the PostgreSQL database

Task	Description	Skills required
Review the AWS DMS logs and validation tables for any errors.	Check and fix any replication or validation errors.	DBA
Stop all Oracle dependencies.	Stop all Oracle dependencies, shut down listeners on the Oracle database, and run **ALTER SYSTEM SWITCH LOGFILE**. Stop the AWS DMS task when it shows no activity.	DBA

Task	Description	Skills required
Run the post-migration scripts from AWS SCT.	In Amazon RDS for PostgreSQL, run the following scripts generated by AWS SCT: • create_foreign_key_constraint.sql • create_triggers.sql	DBA
Complete additional Amazon RDS for PostgreSQL steps.	Increment sequences to match Oracle if needed, run **VACUUM** and **ANALYZE**, and take a snapshot for compliance.	DBA
Open the connections to Amazon RDS for PostgreSQL.	Remove the AWS DMS security groups from Amazon RDS for PostgreSQL, add production security groups, and point your applications to the new database.	DBA
Clean up AWS DMS objects.	Remove the endpoints, replication tasks, replication instances, and the EC2 instance.	SysAdmin, DBA

Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate

Dhairya Jindani, Sindhusha Paturu, and Rajeshkumar Sabankar, Amazon Web Services

Summary

This pattern shows how to migrate an Oracle database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL by using Oracle Cloud Infrastructure (OCI) GoldenGate.

By using Oracle GoldenGate, you can replicate data between your source database and one or more destination databases with minimal downtime.

> **Note**
>
> The source Oracle database can be either on-premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. You can use a similar procedure when using on-premises replication tools.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Oracle GoldenGate license
- Java Database Connectivity (JDBC) driver to connect to the PostgreSQL database
- Schema and tables created with the AWS Schema Conversion Tool (AWS SCT) on the target Amazon RDS for PostgreSQL database

Limitations

- Oracle GoldenGate can replicate existing table data (initial load) and ongoing changes (change data capture) only

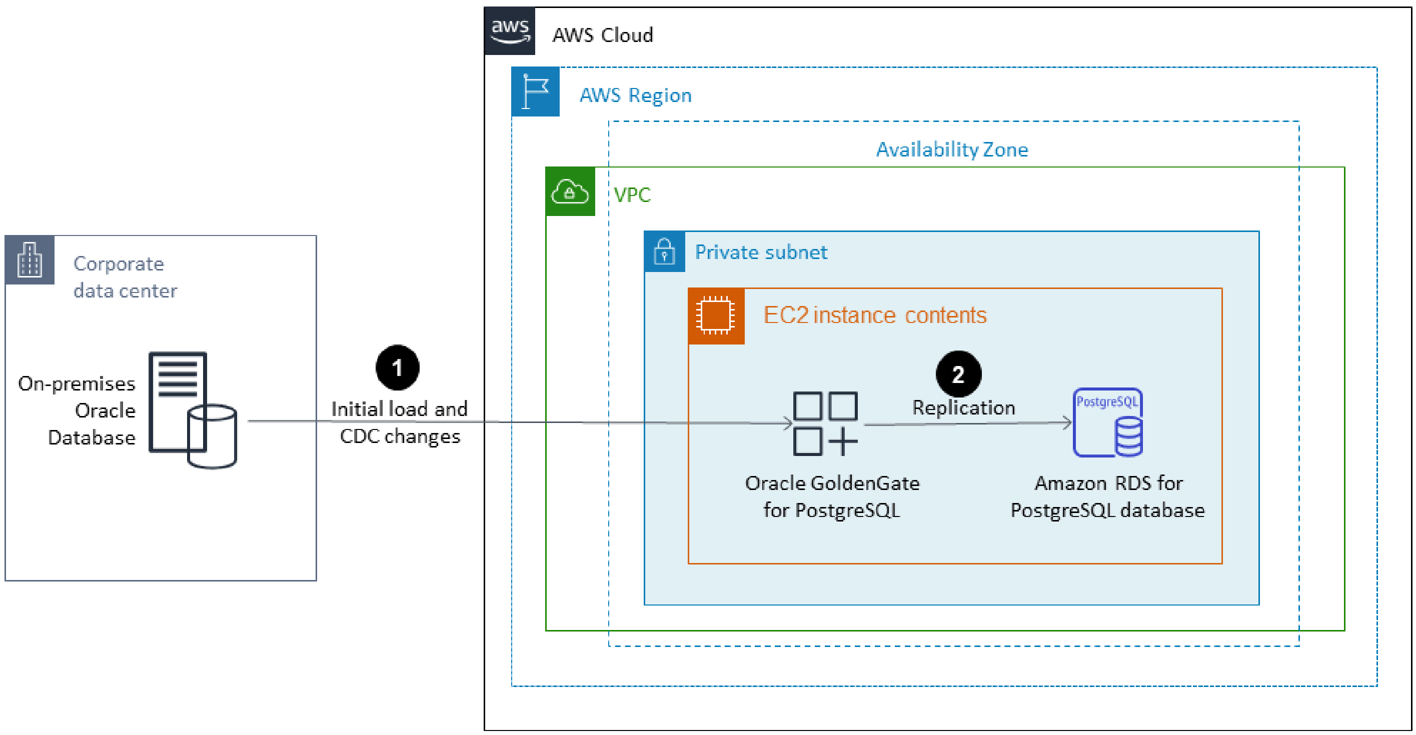
Product versions

- Oracle Database Enterprise Edition 10g or newer versions

- Oracle GoldenGate 12.2.0.1.1 for Oracle or newer versions
- Oracle GoldenGate 12.2.0.1.1 for PostgreSQL or newer versions

Architecture

The following diagram shows an example workflow for migrating an Oracle database to Amazon RDS for PostgreSQL by using Oracle GoldenGate:



The diagram shows the following workflow:

1. The Oracle GoldenGate [Extract process](#) runs against the source database to extract data.
2. The Oracle GoldenGate [Replicat process](#) delivers the extracted data to the target Amazon RDS for PostgreSQL database.

Tools

- Oracle GoldenGate helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.

Epics

Download and install Oracle GoldenGate

Task	Description	Skills required
Download Oracle GoldenGat e.	Download the following versions of Oracle GoldenGat e: • Oracle GoldenGat e 12.2.0.1.1 for Oracle or a newer version • Oracle GoldenGat e 12.2.0.1.1 for PostgreSQ L or a newer version To download the software, see Oracle GoldenGate Downloads on the Oracle website.	DBA
Install Oracle GoldenGate for Oracle on the source Oracle Database server.	For instructions, see the Oracle GoldenGate documentation.	DBA
Install Oracle GoldenGate for PostgreSQL database on the Amazon EC2 instance.	For instructions, see the Oracle GoldenGate documentation.	DBA

Configure Oracle GoldenGate on the source and target databases

Task	Description	Skills required
Set up Oracle GoldenGate for Oracle Database on the source database.	For instructions, see the Oracle GoldenGate documentation.	DBA

Task	Description	Skills required
	Make sure that you configure the following: • Supplemental logging • Oracle GoldenGate users • Any required grants and permissions • Parameter files • Manager process • Directory • **GLOBALS** files • Oracle Wallet	
Set up Oracle GoldenGate for PostgreSQL on the target database.	For instructions, see [Part VI Using Oracle GoldenGate for PostgreSQL] on the Oracle website. Make sure that you configure the following: • Manager process • **GLOBALS** files • Oracle Wallet	DBA

Configure the data capture

Task	Description	Skills required
Set up the Extract process in the source database.	In the source Oracle Database, create an extract file to extract data.	DBA

Task	Description	Skills required
	For instructions, see ADD EXTRACT in the Oracle documentation. **Note** The extract file includes the creation of the extract parameter file and trail file directory.	
Set up a data pump to transfer the trail file from the source to the target database.	Create an EXTRACT parameter file and trail file directory by following the instructions in PARFILE in *Database Utilities* on the Oracle website. For more information, see What is a Trail? in *Fusion Middleware Understanding Oracle GoldenGate* on the Oracle website.	DBA

Task	Description	Skills required
Set up replication on the Amazon EC2 instance.	Create a replication parameter file and trail file directory. For more information about creating replication parameter files, see section [3.5 Validating a parameter file]() in the Oracle Database documentation. For more information about creating a trail file directory , see [Creating a trail]() in the Oracle Cloud documentation. **Important** Make sure that you add a checkpoint table entry in the GLOBALS file at the target. For more information, see [What is a Replicat?]() in *Fusion Middleware Understanding Oracle GoldenGate* on the Oracle website.	DBA

Configure the data replication

Task	Description	Skills required
In the source database, create a parameter file to extract data for the initial load.	Follow the instructions in [Creating a parameter file in GGSCI](#) in the Oracle Cloud documentation. **Important** Make sure that the Manager is running on the target.	DBA
In the target database, create a parameter file to replicate data for the initial load.	Follow the instructions in [Creating a parameter file in GGSCI](#) in the Oracle Cloud documentation. **Important** Make sure that you add and start the Replicat process.	DBA

Cut over to the Amazon RDS for PostgreSQL database

Task	Description	Skills required
Stop the Replicat process and make sure that the source and target databases are in sync.	Compare row counts between the source and target databases to make sure that the data replication was successful.	DBA

Task	Description	Skills required
Configure data definition language (DDL) support.	Run the DDL script for creating triggers, sequence, synonyms, and referential keys on PostgreSQL. **Note** You can use any standard SQL client application to connect to a database in your DB cluster. For example, you can use pgAdmin to connect to your DB instance.	DBA

Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT

Piyush Goyal and Brian motzer, Amazon Web Services

Summary

This pattern provides guidance for migrating Oracle databases to an Amazon Redshift cloud data warehouse in the Amazon Web Services (AWS) Cloud by using AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT). The pattern covers source Oracle databases that are on premises or installed on an Amazon Elastic Compute Cloud (Amazon EC2) instance. It also covers Amazon Relational Database Service (Amazon RDS) for Oracle databases.

Prerequisites and limitations

Prerequisites

- An Oracle database that is running in an on-premises data center or in the AWS Cloud
- An active AWS account
- Familiarity with using an Oracle database as a source for AWS DMS
- Familiarity with using an Amazon Redshift database as a target for AWS DMS
- Knowledge of Amazon RDS, Amazon Redshift, the applicable database technologies, and SQL
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, where AWS SCT is installed

Product versions

- For self-managed Oracle databases, AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.*x*), 11g and up to 12.2, 18c, and 19c. For Amazon RDS for Oracle databases that AWS manages, AWS DMS supports all Oracle database editions for versions 11g (versions 11.2.0.4 and later) and up to 12.2, 18c, and 19c. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

Architecture

Source technology stack

One of the following:

- An on-premises Oracle database

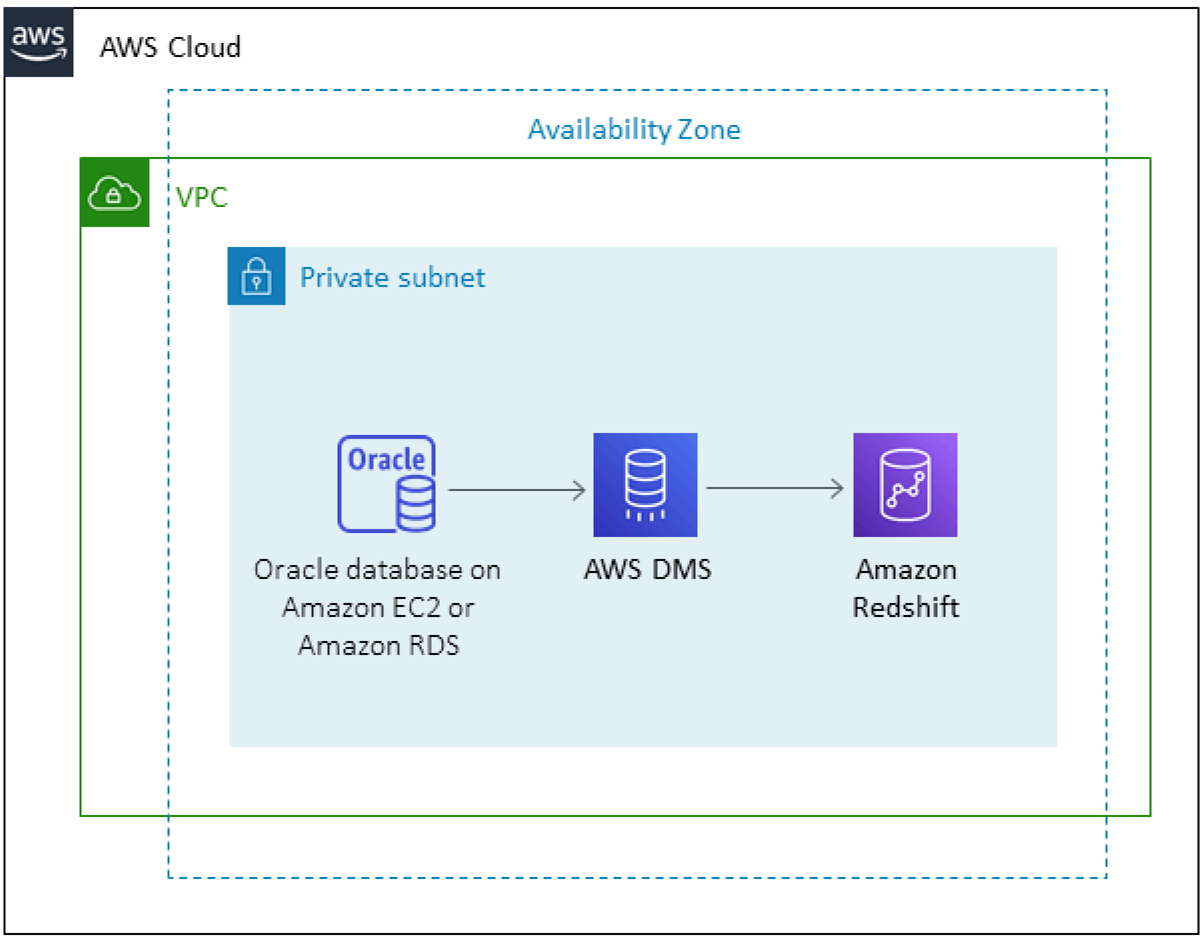
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

Target technology stack

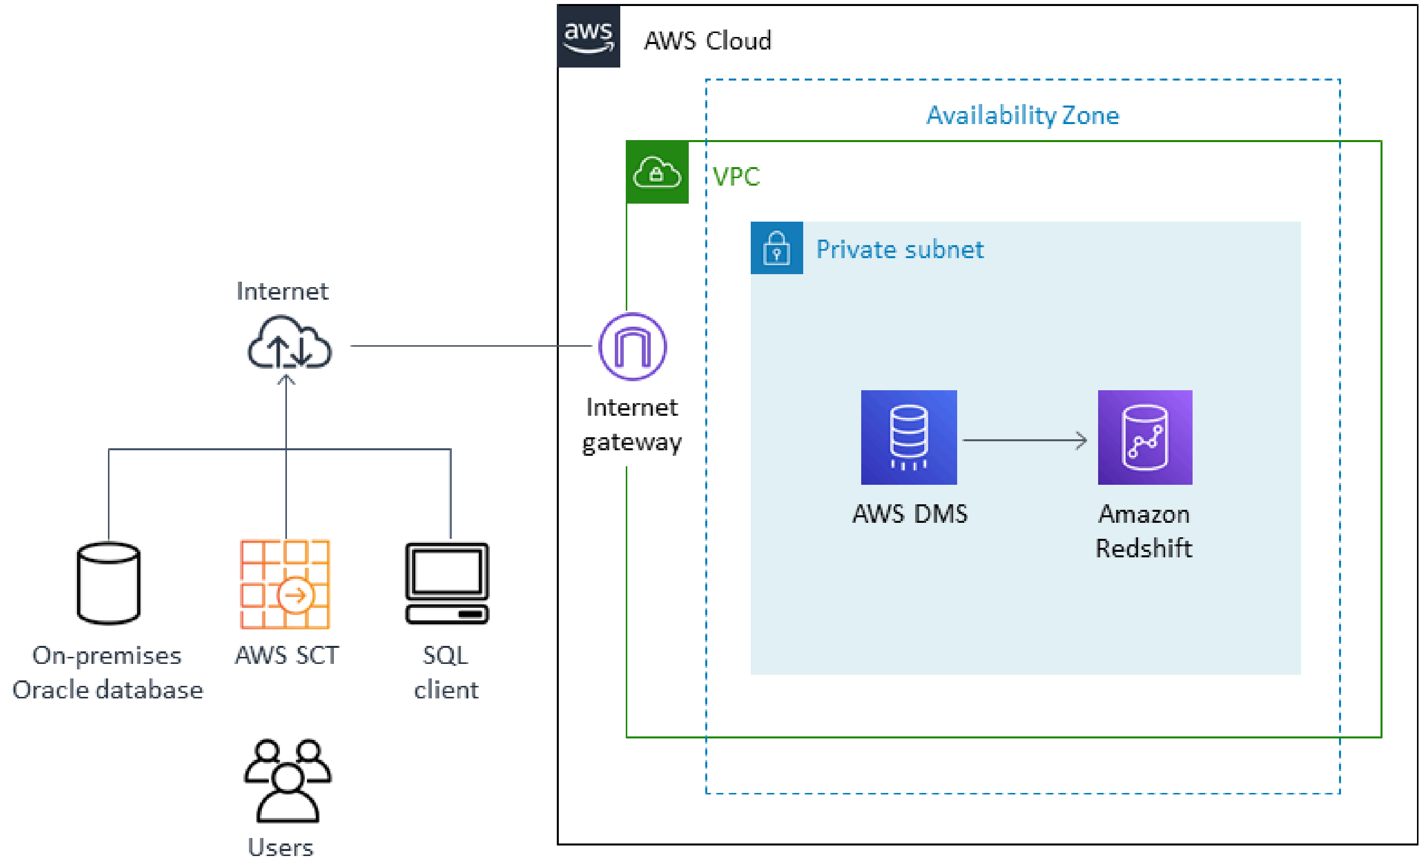
- Amazon Redshift

Target architecture

From an Oracle database running in the AWS Cloud to Amazon Redshift:



From an Oracle database running in an on-premises data center to Amazon Redshift:



Tools

- AWS DMS - AWS Data Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from most widely used commercial and open-source databases.
- AWS SCT - AWS Schema Conversion Tool (AWS SCT) can be used to convert your existing database schema from one database engine to another. It supports various database engines, including Oracle, SQL Server, and PostgresSQL, as sources.

Epics

Prepare for the migration

Task	Description	Skills required
Validate the database versions.	Validate the source and target database versions and make	DBA

Task	Description	Skills required
	sure they are supported by AWS DMS. For informati on about supported Oracle Database versions, see Using an Oracle database as a source for AWS DMS. For information about using Amazon Redshift as a target, see Using an Amazon Redshift database as a target for AWS DMS.	
Create a VPC and security group.	In your AWS account, create a virtual private cloud (VPC), if it doesn't exist. Create a security group for outbound traffic to source and target databases. For more informati on, see the Amazon Virtual Private Cloud (Amazon VPC) documentation.	Systems administrator
Install AWS SCT.	Download and install the latest version of AWS SCT and its corresponding drivers. For more information, see Installing, verifying, and updating the AWS SCT.	DBA
Create a user for the AWS DMS task.	Create an AWS DMS user in the source database and grant it READ privileges. This user will be used by both AWS SCT and AWS DMS.	DBA

Task	Description	Skills required
Test the DB connectivity.	Test the connectivity to the Oracle DB instance.	DBA
Create a new project in AWS SCT.	Open the AWS SCT tool and create a new project.	DBA
Analyze the Oracle schema to be migrated.	Use AWS SCT to analyze the schema to be migrated, and generate a database migration assessment report. For more information, see [Creating a database migration assessment report] in the AWS SCT documentation.	DBA
Review the assessment report.	Review the report for migration feasibility. Some DB objects might require manual conversion. For more information about the report, see [Viewing the assessment report] in the AWS SCT documentation.	DBA

Prepare the target database

Task	Description	Skills required
Create an Amazon Redshift cluster.	Create an Amazon Redshift cluster within the VPC that you created previously. For more information, see [Amazon Redshift clusters]	DBA

Task	Description	Skills required
	in the Amazon Redshift documentation.	
Create database users.	Extract the list of users, roles, and grants from the Oracle source database. Create users in the target Amazon Redshift database and apply the roles from the previous step.	DBA
Evaluate database parameters.	Review the database options, parameters, network files, and database links from the Oracle source database, and evaluate their applicability to the target.	DBA
Apply any relevant settings to the target.	For more information about this step, see [Configuration reference] in the Amazon Redshift documentation.	DBA

Create objects in the target database

Task	Description	Skills required
Create an AWS DMS user in the target database.	Create an AWS DMS user in the target database and grant it read and write privileges. Validate the connectivity from AWS SCT.	DBA
Convert the schema, review the SQL report, and save any errors or warnings.	For more information, see [Converting database schemas]	DBA

Task	Description	Skills required
	using the AWS SCT in the AWS SCT documentation.	
Apply the schema changes to the target database or save them as a .sql file.	For instructions, see Saving and applying your converted schema in the AWS SCT in the AWS SCT documentation.	DBA
Validate the objects in the target database.	Validate the objects that were created in the previous step in the target database. Rewrite or redesign any objects that weren't successfully converted.	DBA
Disable foreign keys and triggers.	Disable any foreign key and triggers. These can cause data loading issues during the full load process when running AWS DMS.	DBA

Migrate data using AWS DMS

Task	Description	Skills required
Create an AWS DMS replication instance.	Sign in to the AWS Management Console, and open the AWS DMS console. In the navigation pane, choose **Replication instances**, **Create replication instance**. For detailed instructions, see step 1 in *Getting started with AWS DMS* in the AWS DMS documentation.	DBA

Task	Description	Skills required
Create source and target endpoints.	Create source and target endpoints, Test the connectio n from the replication instance to both source and target endpoints. For detailed instructions, see step 2 in *Getting started with AWS DMS* in the AWS DMS documenta tion.	DBA
Create a replication task.	Create a replication task and select the appropria te migration method. For detailed instructions, see step 3 in *Getting started with AWS DMS* in the AWS DMS documentation.	DBA
Start the data replication.	Start the replication task and monitor the logs for any errors.	DBA

Migrate your application

Task	Description	Skills required
Create application servers.	Create the new application servers on AWS.	Application owner
Migrate the application code.	Migrate the application code to the new servers.	Application owner
Configure the application server.	Configure the application server for the target database and drivers.	Application owner

Task	Description	Skills required
Optimize the application code.	Optimize the application code for the target engine.	Application owner

Cut over to the target database

Task	Description	Skills required
Validate users.	In the target Amazon Redshift database, validate users and grant them roles and privileges.	DBA
Validate that the application is locked.	Make sure that the application is locked, to prevent further changes.	Application owner
Validate the data.	Validate the data in the target Amazon Redshift database.	DBA
Enable foreign keys and triggers.	Enable foreign keys and triggers in the target Amazon Redshift database.	DBA
Connect to the new database.	Configure the application to connect to the new Amazon Redshift database.	Application owner
Perform final checks.	Perform a final, comprehensive system check before going live.	DBA, Application owner
Go live.	Go live with the target Amazon Redshift database.	DBA

Close the migration project

Task	Description	Skills required
Shut down temporary AWS resources.	Shut down temporary AWS resources such as the AWS DMS replication instance and the EC2 instance used for AWS SCT.	DBA, Systems administrator
Review documents.	Review and validate the migration project documents .	DBA, Systems administrator
Gather metrics.	Collect information about the migration project, such as the time to migrate, the percentage of manual versus tool tasks, and total cost savings.	DBA, Systems administrator
Close out the project.	Close out the project and provide feedback.	DBA, Systems administrator

Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT

Senthil Ramasamy, Amazon Web Services

Summary

This pattern describes how to migrate an Oracle database to Amazon Aurora PostgreSQL-Compatible Edition by using AWS Data Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT).

The pattern covers source Oracle databases that are on premises, Oracle databases that are installed on Amazon Elastic Compute Cloud (Amazon EC2) instances, and Amazon Relational Database Service (Amazon RDS) for Oracle databases. The pattern converts these databases to Aurora PostgreSQL-Compatible.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Oracle database in an on-premises data center or in the AWS Cloud.
- SQL clients installed either on a local machine or on an EC2 instance.
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed on either a local machine or an EC2 instance where AWS SCT is installed.

Limitations

- Database size limit: 128 TB
- If the source database supports a commercial off-the-shelf (COTS) application or is vendor-specific, you might not be able to convert it to another database engine. Before using this pattern, confirm that the application supports Aurora PostgreSQL-Compatible.

Product versions

- For self-managed Oracle databases, AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g, and up to 12.2, 18c, and 19c. For the latest list of supported Oracle database versions (both self-managed and Amazon RDS for Oracle), see Using an Oracle database as a source for AWS DMS and Using a PostgreSQL database as a target for AWS DMS.

- We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.
- Aurora supports the PostgreSQL versions listed in Amazon Aurora PostgreSQL releases and engine versions.

Architecture

Source technology stack

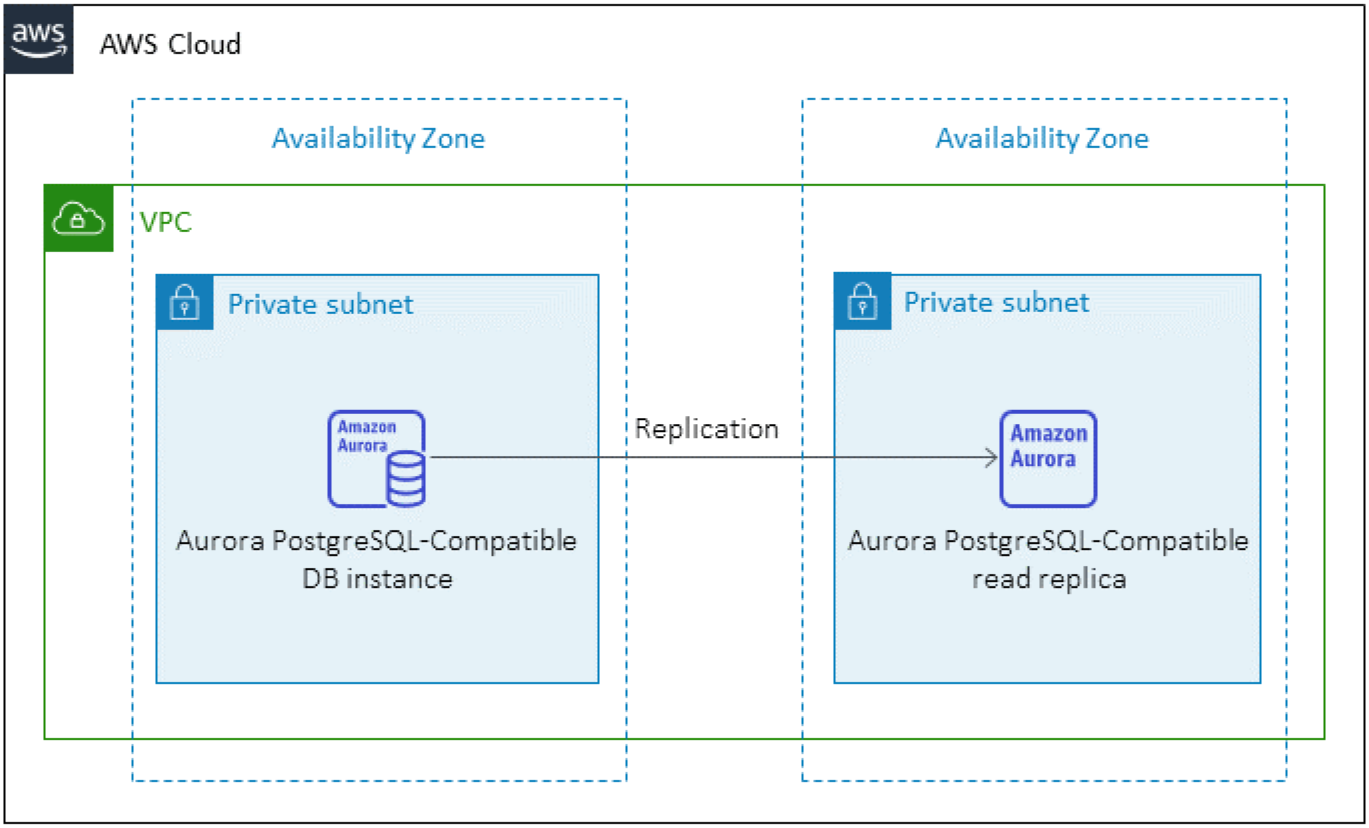
One of the following:

- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

Target technology stack

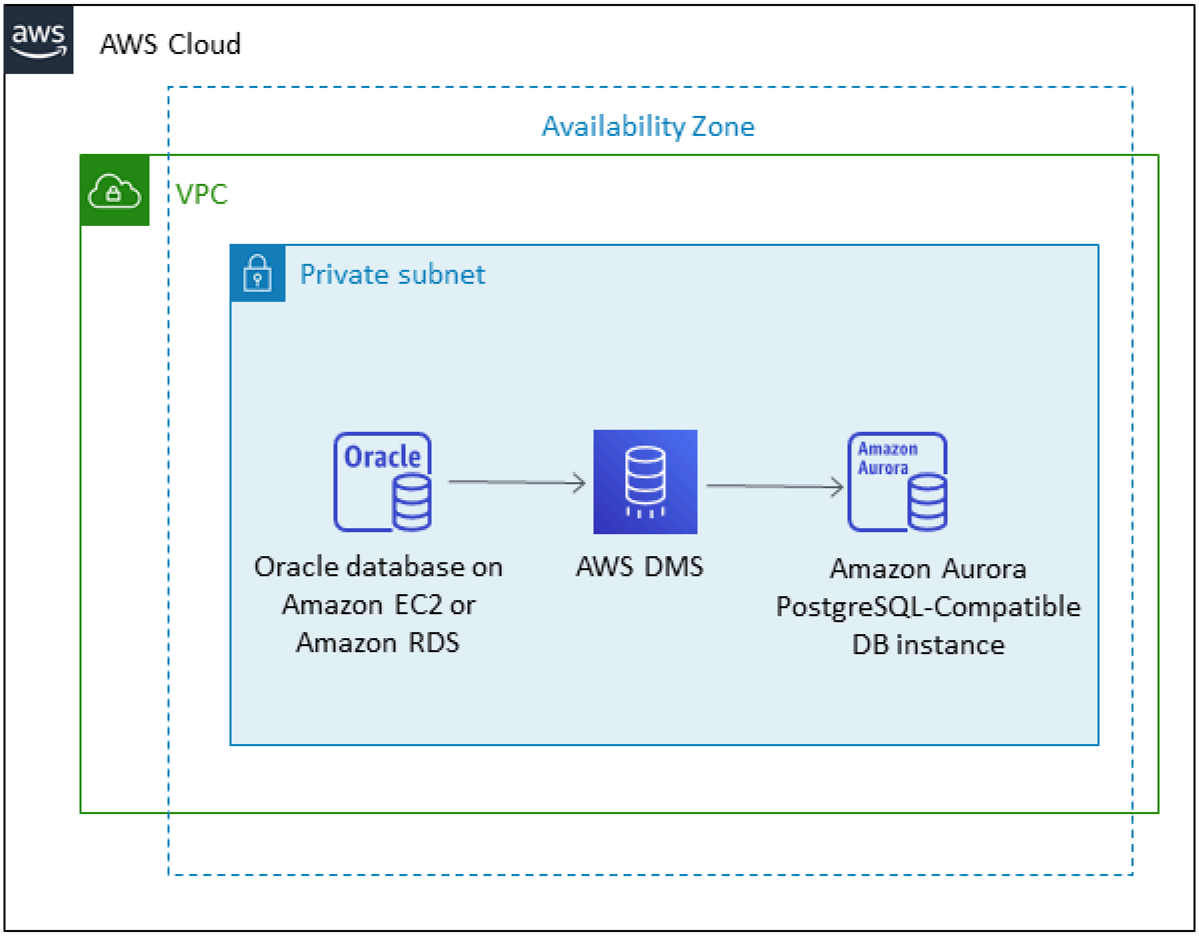
- Aurora PostgreSQL-Compatible

Target architecture

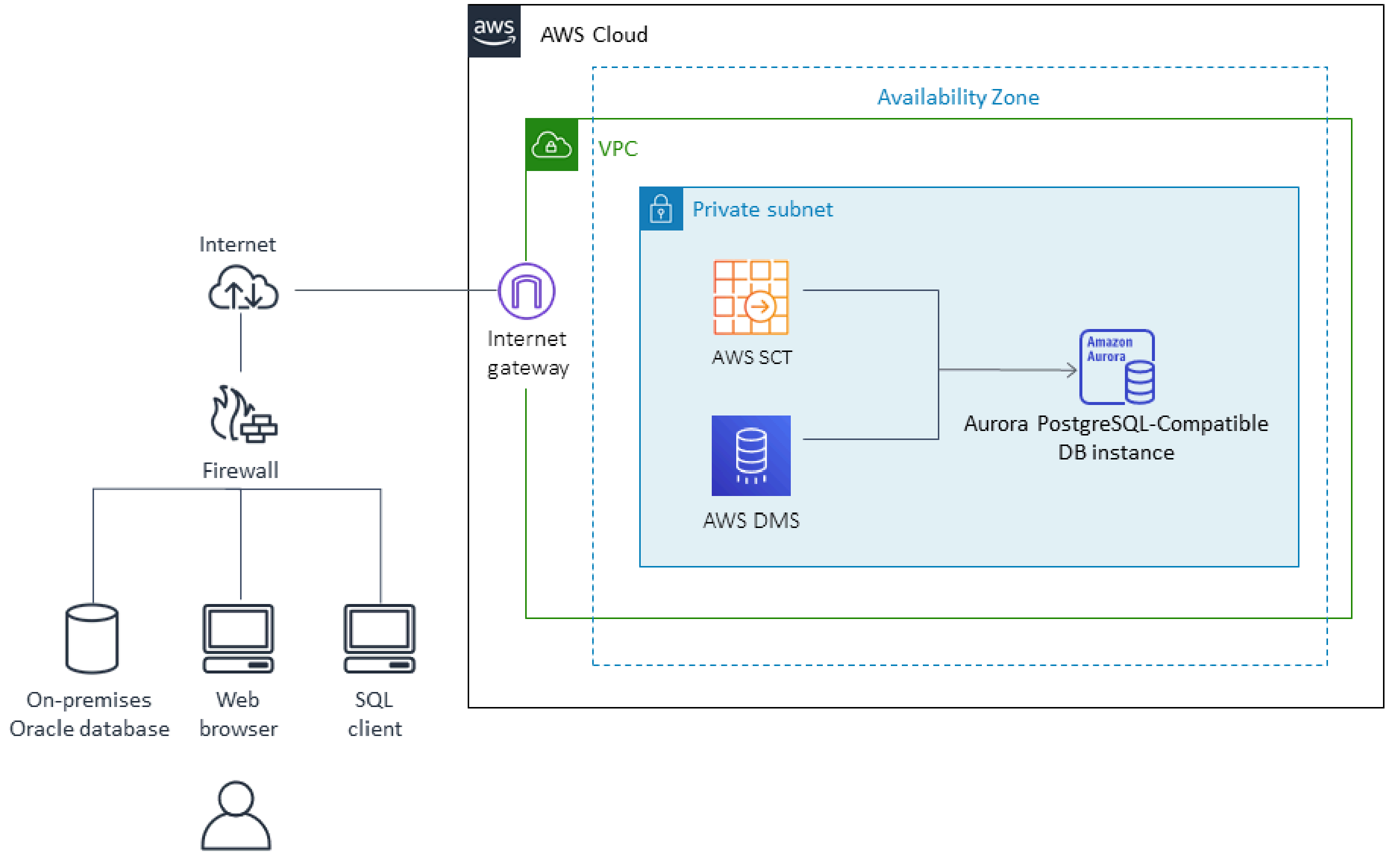


Data migration architecture

- From an Oracle database running in the AWS Cloud



- From an Oracle database running in an on-premises data center



Tools

- [AWS Database Migration Service (AWS DMS)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [AWS Schema Conversion Tool (AWS SCT)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

Epics

Prepare for the migration

Task	Description	Skills required
Prepare the source database.	To prepare the source database, see [Using Oracle Database as a source for](#)	DBA

Task	Description	Skills required
	AWS SCT in the AWS SCT documentation.	
Create an EC2 instance for AWS SCT.	Create and configure an EC2 instance for AWS SCT, if required.	DBA
Download AWS SCT.	Download the latest version of AWS SCT and associated drivers. For more information, see Installing, verifying, and updating AWS SCT in the AWS SCT documentation.	DBA
Add users and permissions.	Add and validate the prerequisite users and permissions in the source database.	DBA
Create an AWS SCT project.	Create an AWS SCT project for the workload, and connect to the source database. For instructions, see Creating an AWS SCT project and Adding database servers in the AWS SCT documentation.	DBA

Task	Description	Skills required
Evaluate feasibility.	Generate an assessment report, which summarizes action items for schemas that can't be converted automatically and provides estimates for manual conversion efforts. For more information, see [Creating and reviewing the database migration assessment report]() in the AWS SCT documentation.	DBA

Prepare the target database

Task	Description	Skills required
Create a target Amazon RDS DB instance.	Create a target Amazon RDS DB instance, using Amazon Aurora as the database engine. For instructions, see [Creating an Amazon RDS DB instance]() in the Amazon RDS documentation.	DBA
Extract users, roles, and permissions.	Extract the list of users, roles, and permissions from the source database.	DBA
Map users.	Map the existing database users to the new database users.	App owner
Create users.	Create users in the target database.	DBA, App owner

Task	Description	Skills required
Apply roles.	Apply roles from the previous step to the target database.	DBA
Check options, parameters, network files, and database links.	Review the source database for options, parameters, network files, and database links, and then evaluate their applicability to the target database.	DBA
Apply settings.	Apply any relevant settings to the target database.	DBA

Transfer objects

Task	Description	Skills required
Configure AWS SCT connectiv ity.	Configure AWS SCT connectiv ity to the target database.	DBA
Convert the schema using AWS SCT.	AWS SCT automatically converts the source database schema and most of the custom code to a format that is compatible with the target database. Any code that the tool cannot convert automatically is clearly marked so that you can convert it manually.	DBA
Review the report.	Review the generated SQL report and save any errors and warnings.	DBA

Task	Description	Skills required
Apply automated schema changes.	Apply automated schema changes to the target database or save them as a .sql file.	DBA
Validate objects.	Validate that AWS SCT created the objects on the target.	DBA
Handle items that weren't converted.	Manually rewrite, reject, or redesign any items that failed to convert automatically.	DBA, App owner
Apply role and user permissio ns.	Apply the generated role and user permissions and review any exceptions.	DBA

Migrate the data

Task	Description	Skills required
Determine the method.	Determine the method for migrating data.	DBA
Create a replication instance.	Create a replication instance from the AWS DMS console. For more information, see [Working with an AWS DMS replication instance](#) in the AWS DMS documentation.	DBA
Create the source and target endpoints.	To create endpoints, follow the instructions in [Creating source and target endpoints](#)	DBA

Task	Description	Skills required
	in the AWS DMS documentation.	
Create a replication task.	To create a task, see Working with AWS DMS tasks in the AWS DMS documentation.	DBA
Start the replication task and monitor the logs.	For more information about this step, see Monitoring AWS DMS tasks in the AWS DMS documentation.	DBA

Migrate the application

Task	Description	Skills required
Analyze and convert SQL items in the application code.	Use AWS SCT to analyze and convert the SQL items in the application code. When you convert your database schema from one engine to another, you also need to update the SQL code in your applications to interact with the new database engine instead of the old one. You can view, analyze, edit, and save the converted SQL code.	App owner
Create application servers.	Create the new application servers on AWS.	App owner
Migrate the application code.	Migrate the application code to the new servers.	App owner

Task	Description	Skills required
Configure the application servers.	Configure the applicati on servers for the target database and drivers.	App owner
Fix code.	Fix any code that's specific to the source database engine in your application.	App owner
Optimize code.	Optimize your application code for the target database engine.	App owner

Cut over

Task	Description	Skills required
Cut over to the target database.	Perform the cutover to the new database.	DBA
Lock the application.	Lock the application from any further changes.	App owner
Validate changes.	Validate that all changes were propagated to the target database.	DBA
Redirect to the target database.	Point the new applicati on servers to the target database.	App owner
Check everything.	Perform a final, comprehen sive system check.	App owner
Go live.	Complete final cutover tasks.	App owner

Close the project

Task	Description	Skills required
Shut down temporary resources.	Shut down the temporary AWS resources such as the AWS DMS replication instance and the EC2 instance used for AWS SCT.	DBA, App owner
Update feedback.	Update feedback on the AWS DMS process for internal teams.	DBA, App owner
Revise process and templates.	Revise the AWS DMS process and improve the template if necessary.	DBA, App owner
Validate documents.	Review and validate the project documents.	DBA, App owner
Gather metrics.	Gather metrics to evaluate the time to migrate, percent of manual versus tool cost savings, and so on.	DBA, App owner
Close the project.	Close the migration project and provide feedback to stakeholders.	DBA, App owner

Migrate data from an on-premises Oracle database to Aurora PostgreSQL

Michelle Deng and Shunan Xiang, Amazon Web Services

Summary

This pattern provides guidance for data migration from an on-premises Oracle database to Amazon Aurora PostgreSQL-Compatible Edition. It targets an online data migration strategy with a minimal amount of downtime for multi-terabyte Oracle databases that contain large tables with high data manipulation language (DML) activities. An Oracle Active Data Guard standby database is used as the source to offload data migration from the primary database. The replication from the Oracle primary database to standby can be suspended during the full load to avoid ORA-01555 errors.

Table columns in primary keys (PKs) or foreign keys (FKs), with data type NUMBER, are commonly used to store integers in Oracle. We recommend that you convert these to INT or BIGINT in PostgreSQL for better performance. You can use the AWS Schema Conversion Tool (AWS SCT) to change the default data type mapping for PK and FK columns. (For more information, see the AWS blog post [Convert the NUMBER data type from Oracle to PostgreSQL](#).) The data migration in this pattern uses AWS Database Migration Service (AWS DMS) for both full load and change data capture (CDC).

You can also use this pattern to migrate an on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL, or an Oracle database that's hosted on Amazon Elastic Compute Cloud (Amazon EC2) to either Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Oracle source database in an on-premises data center with Active Data Guard standby configured
- AWS Direct Connect configured between the on-premises data center and the AWS Cloud
- Familiarity with using an Oracle database as a source for AWS DMS
- Familiarity with using a PostgreSQL database as a target for AWS DMS

Limitations

- Amazon Aurora database clusters can be created with up to 128 TiB of storage. Amazon RDS for PostgreSQL database instances can be created with up to 64 TiB of storage. For the latest storage information, see Amazon Aurora storage and reliability and Amazon RDS DB instance storage in the AWS documentation.

Product versions

- AWS DMS supports all Oracle database editions for versions 10.2 and later (for versions 10.x), 11g and up to 12.2, 18c, and 19c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS in the AWS documentation.

Architecture

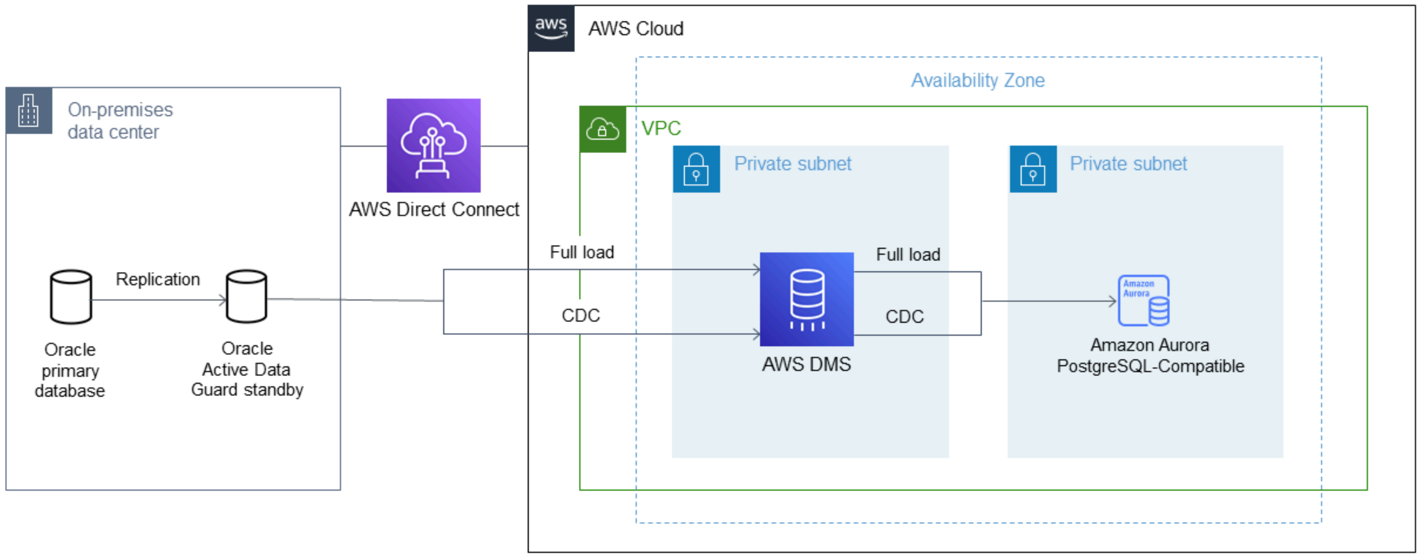
Source technology stack

- On-premises Oracle databases with Oracle Active Data Guard standby configured

Target technology stack

- Aurora PostgreSQL-Compatible

Data migration architecture



Tools

- **AWS DMS** - AWS Database Migration Service (AWS DMS) supports several source and target databases. See Using an Oracle Database as a Source for AWS DMS in the AWS DMS documentation for a list of supported Oracle source and target database versions and editions. If the source database is not supported by AWS DMS, you must select another method for migrating the data in Phase 6 (in the *Epics* section). **Important note:** Because this is a heterogeneous migration, you must first check to see whether the database supports a commercial off-the-shelf (COTS) application. If the application is COTS, consult the vendor to confirm that Aurora PostgreSQL-Compatible is supported before proceeding. For more information, see AWS DMS Step-by-Step Migration Walkthroughs in the AWS documentation.
- **AWS SCT** - The AWS Schema Conversion Tool (AWS SCT) facilitates heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. The custom code that the tool converts includes views, stored procedures, and functions. Any code that the tool cannot convert automatically is clearly marked so that you can convert it yourself.

Epics

Plan the migration

Task	Description	Skills required
Validate the source and target database versions.		DBA
Install AWS SCT and drivers.		DBA
Add and validate the AWS SCT prerequisite users and grants-source database.		DBA
Create an AWS SCT project for the workload, and connect to the source database.		DBA

Task	Description	Skills required
Generate an assessment report and evaluate feasibili ty.		DBA, App owner

Prepare the target database

Task	Description	Skills required
Create an Aurora PostgreSQL-Compatible target database.		DBA
Extract users, roles, and grants list from the source database.		DBA
Map the existing database users to the new database users.		App owner
Create users in the target database.		DBA
Apply roles from the previous step to the target Aurora PostgreSQL-Compatible database.		DBA
Review database options, parameters, network files, and database links from the source database, and evaluate their applicability to the target database.		DBA, App owner

Task	Description	Skills required
Apply any relevant settings to the target database.		DBA

Prepare for database object code conversion

Task	Description	Skills required
Configure AWS SCT connectiv ity to the target database.		DBA
Convert the schema in AWS SCT, and save the converted code as a .sql file.		DBA, App owner
Manually convert any database objects that failed to convert automatically.		DBA, App owner
Optimize the database code conversion.		DBA, App owner
Separate the .sql file into multiple .sql files based on the object type.		DBA, App owner
Validate the SQL scripts in the target database.		DBA, App owner

Prepare for data migration

Task	Description	Skills required
Create an AWS DMS replicati on instance.		DBA

Task	Description	Skills required
Create the source and target endpoints.	If the data type of the PKs and FKs is converted from NUMBER in Oracle to BIGINT in PostgreSQL, consider specifying the connection attribute `numberDataTypeScale=-2` when you create the source endpoint.	DBA

Migrate data – full load

Task	Description	Skills required
Create the schema and tables in the target database.		DBA
Create AWS DMS full-load tasks by either grouping tables or splitting a big table based on the table size.		DBA
Stop the applications on the source Oracle databases for a short period.		App owner
Verify that the Oracle standby database is synchronous with the primary database, and stop the replication from the primary database to the standby database.		DBA, App owner
Start applications on the source Oracle database.		App owner

Task	Description	Skills required
Start the AWS DMS full-load tasks in parallel from the Oracle standby database to the Aurora PostgreSQL-Compatible database.		DBA
Create PKs and secondary indexes after the full load is complete.		DBA
Validate the data.		DBA

Migrate data – CDC

Task	Description	Skills required
Create AWS DMS ongoing replication tasks by specifying a custom CDC start time or system change number (SCN) when the Oracle standby was synchronized with the primary database, and before the applications were restarted in the previous task.		DBA
Start AWS DMS tasks in parallel to replicate ongoing changes from the Oracle standby database to the Aurora PostgreSQL-Compatible database.		DBA

Task	Description	Skills required
Re-establish the replicati on from the Oracle primary database to the standby database.		DBA
Monitor the logs and stop the applications on the Oracle database when the target Aurora PostgreSQ L-Compatible database is almost synchronous with the source Oracle database.		DBA, App owner
Stop the AWS DMS tasks when the target is fully synchronized with the source Oracle database.		DBA
Create FKs and validate the data in the target database.		DBA
Create functions, views, triggers, sequences, and other object types in the target database.		DBA
Apply role grants in the target database.		DBA

Migrate the application

Task	Description	Skills required
Use AWS SCT to analyze and convert the SQL statements inside the application code.		App owner
Create new application servers on AWS.		App owner
Migrate the application code to the new servers.		App owner
Configure the application server for the target database and drivers.		App owner
Fix any code that's specific to the source database engine in the application.		App owner
Optimize the application code for the target database.		App owner

Cut over

Task	Description	Skills required
Point the new application server to the target database.		DBA, App owner
Perform sanity checks.		DBA, App owner
Go live.		DBA, App owner

Close the project

Task	Description	Skills required
Shut down temporary AWS resources.		DBA, Systems administrator
Review and validate the project documents.		DBA, App owner
Gather metrics for time to migrate, percentage of manual versus tool use, cost savings, and similar data.		DBA, App owner
Close out the project and provide feedback.		DBA, App owner

Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS

Amit Kumar, Amazon Web Services

Summary

This pattern provides guidance for migrating an SAP Adaptive Server Enterprise (ASE) database to an Amazon Relational Database Service (Amazon RDS) DB instance that's running Microsoft SQL Server. The source database can be located in an on-premises data center or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. The pattern uses AWS Database Migration Service (AWS DMS) to migrate data and (optionally) computer-aided software engineering (CASE) tools to convert the database schema.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An SAP ASE database in an on-premises data center or on an EC2 instance
- A target Amazon RDS for SQL Server database that's up and running

Limitations

- Database size limit: 64 TB

Product versions

- SAP ASE version 15.7 or 16.x only. For the latest information, see Using an SAP Database as a Source for AWS DMS.
- For Amazon RDS target databases, AWS DMS supports Microsoft SQL Server versions on Amazon RDS for the Enterprise, Standard, Web, and Express editions. For the latest information about supported versions, see the AWS DMS documentation. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.

Architecture

Source technology stack

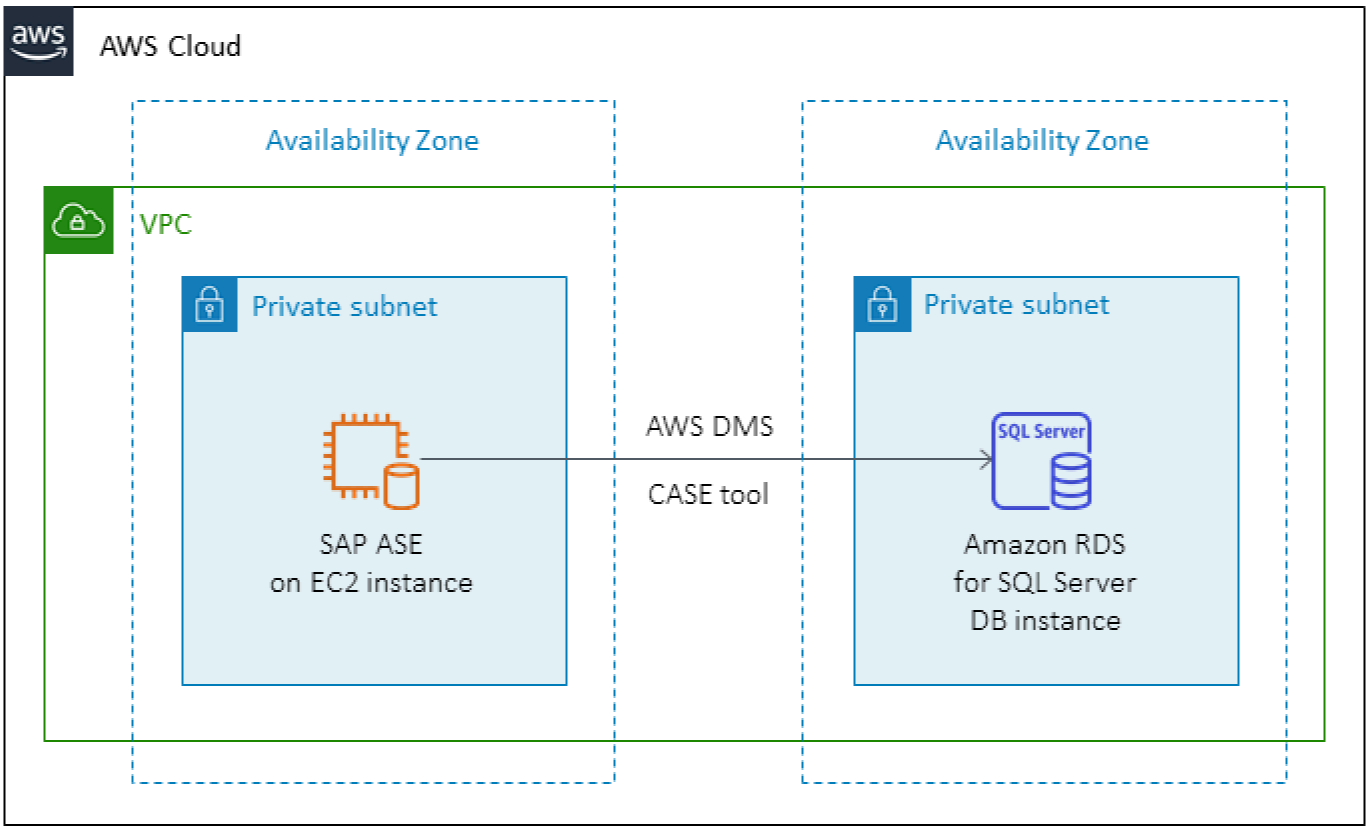
- An SAP ASE database that's on premises or on an Amazon EC2 instance

Target technology stack

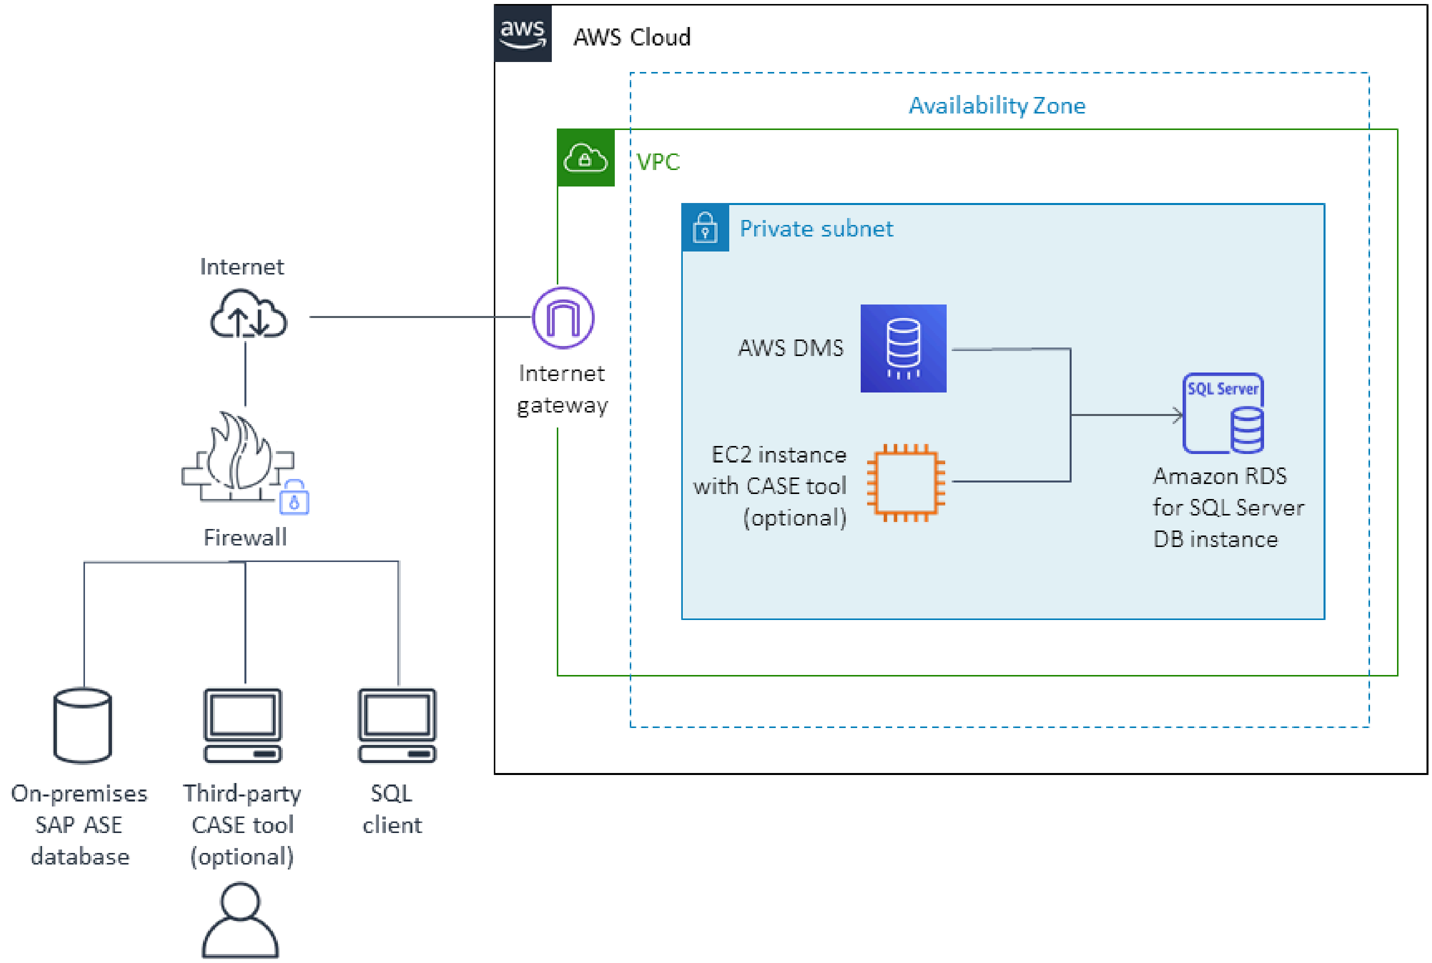
- An Amazon RDS for SQL Server DB instance

Source and target architecture

From an SAP ASE database on Amazon EC2 to an Amazon RDS for SQL Server DB instance:



From an on-premises SAP ASE database to an Amazon RDS for SQL Server DB instance:



Tools

- [AWS Database Migration Service](#) (AWS DMS) is a web service you can use to migrate data from your database that is on-premises, on an Amazon RDS DB instance, or in a database on an EC2 instance, to a database on an AWS service such as Amazon RDS for SQL Server or an EC2 instance. You can also migrate a database from an AWS service to an on-premises database. You can migrate data between heterogeneous or homogeneous database engines.
- For schema conversions, you can optionally use [erwin Data Modeler](#) or [SAP PowerDesigner](#).

Epics

Plan the migration

Task	Description	Skills required
Validate the source and target database versions.		DBA
Identify the storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type based on capacity, storage features, and network features.		DBA, SysAdmin
Identify the network access security requirements for the source and target databases.		DBA, SysAdmin
Identify the application migration strategy.		DBA, SysAdmin, App owner

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.		SysAdmin
Create security groups and network access control lists (ACLs).		SysAdmin
Configure and start an Amazon RDS DB instance.		SysAdmin

Migrate data - option 1

Task	Description	Skills required
Migrate the database schema manually or use a CASE tool such as erwin Data Modeler or SAP PowerDesigner.		DBA

Migrate data - option 2

Task	Description	Skills required
Migrate data using AWS DMS.		DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, SysAdmin, App owner

Cut over

Task	Description	Skills required
Switch the application clients over to the new infrastru cture.		DBA, SysAdmin, App owner

Close the project

Task	Description	Skills required
Shut down the temporary AWS resources.		DBA, SysAdmin
Review and validate the project documents.		DBA, SysAdmin, App owner
Gather metrics such as time to migrate, percentage of manual versus automated tasks, and cost savings.		DBA, SysAdmin, App owner
Close out the project and provide feedback.		DBA, SysAdmin, App owner

Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS

Marcelo Fernandes, Amazon Web Services

Summary

This pattern provides guidance for migrating an on-premises Microsoft SQL Server database to Amazon Redshift by using AWS Data Migration Service (AWS DMS).

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Microsoft SQL Server database in an on-premises data center
- Completed prerequisites for using an Amazon Redshift database as a target for AWS DMS, as discussed in the AWS DMS documentation

Product versions

- SQL Server 2005-2019, Enterprise, Standard, Workgroup, Developer, and Web editions. For the latest list of supported versions, see Using a Microsoft SQL Server Database as a Source for AWS DMS in the AWS documentation.

Architecture

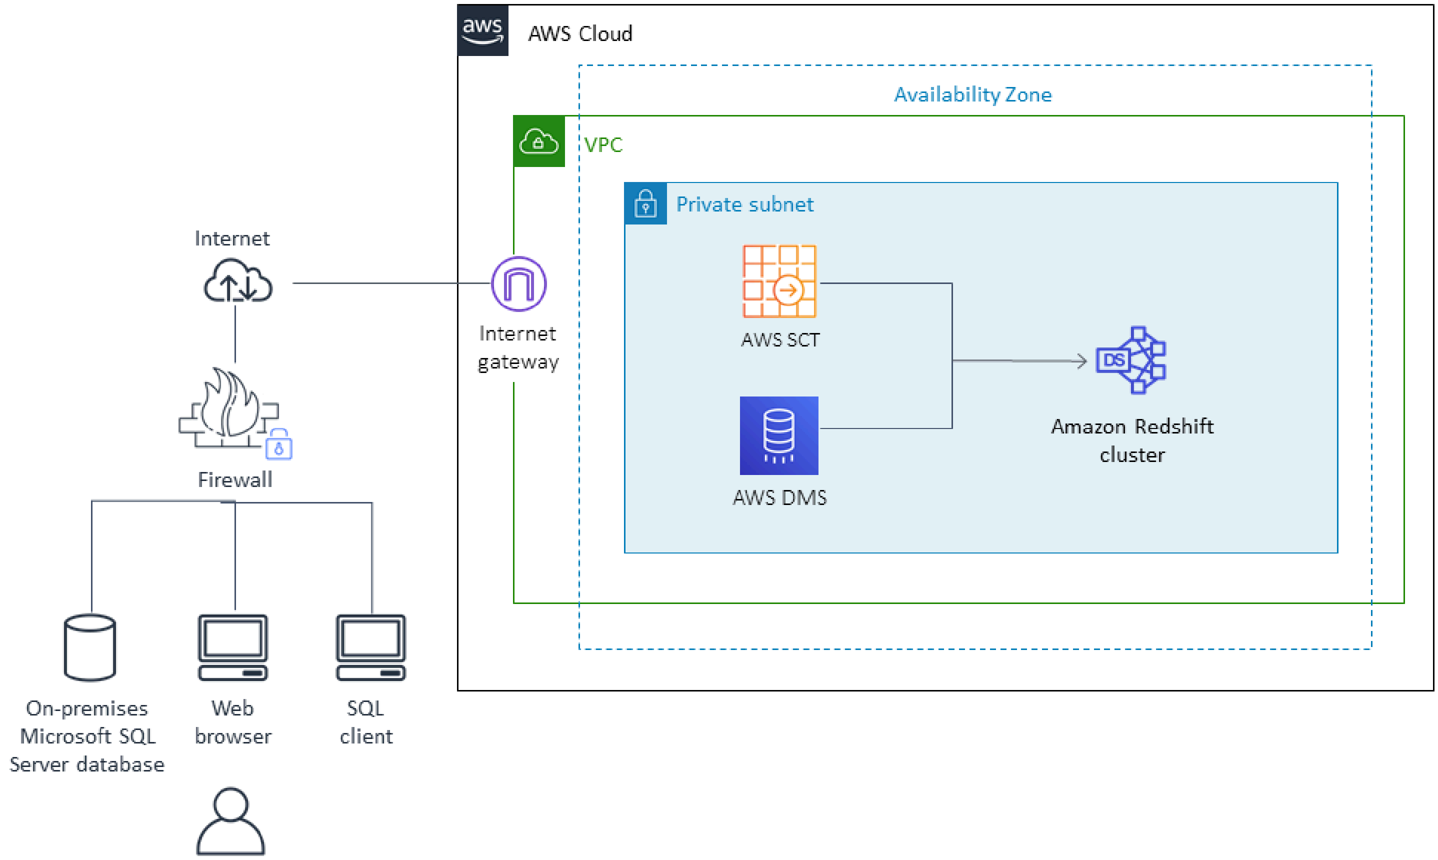
Source technology stack

- An on-premises Microsoft SQL Server database

Target technology stack

- Amazon Redshift

Data migration architecture



Tools

- [AWS DMS](#) is a data migration service that supports several types of source and target databases. For information about the Microsoft SQL Server database versions and editions that are supported for use with AWS DMS, see [Using a Microsoft SQL Server Database as a Source for AWS DMS](#) in the AWS DMS documentation. If AWS DMS doesn't support your source database, you must select an alternative method for data migration.

Epics

Plan the migration

Task	Description	Skills required
Validate the source and target database version and engine.		DBA

Task	Description	Skills required
Identify the hardware requirements for the target server instance.		DBA, Systems administrator
Identify the storage requirements (storage type and capacity).		DBA, Systems administrator
Choose the proper instance type based on capacity, storage features, and network features.		DBA, Systems administrator
Identify the network access security requirements for the source and target databases.		DBA, Systems administrator
Identify the application migration strategy.		DBA, App owner, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).	For more information, see [Working with a DB instance in a VPC](#) in the AWS documenta tion.	Systems administrator
Create security groups.		Systems administrator
Configure and start an Amazon Redshift cluster.	For more information, see [Create a sample Amazon Redshift cluster](#) in the	DBA, Systems administrator

Task	Description	Skills required
	Amazon Redshift documenta tion.	

Migrate data

Task	Description	Skills required
Migrate the data from the Microsoft SQL Server database by using AWS DMS.		DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, App owner, Systems administrator

Cut over

Task	Description	Skills required
Switch the application clients over to the new infrastru cture.		DBA, App owner, Systems administrator

Close the project

Task	Description	Skills required
Shut down the temporary resources.		DBA, Systems administrator

Task	Description	Skills required
Review and validate the project documents.		DBA, App owner, Systems administrator
Gather metrics such as time to migrate, percentage of manual versus automated tasks, and cost savings.		DBA, App owner, Systems administrator
Close out the project and provide feedback.		DBA, App owner, Systems administrator

Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents

Neha Thakur, Amazon Web Services

Summary

This pattern outlines steps for migrating an on-premises Microsoft SQL Server source database to an Amazon Redshift target database by using AWS Schema Conversion Tool (AWS SCT) data extraction agents. An agent is an external program that is integrated with AWS SCT but performs data transformation elsewhere and interacts with other AWS services on your behalf.

Prerequisites and limitations

Prerequisites

- A Microsoft SQL Server source database used for the data warehouse workload in an on-premises data center
- An active AWS account

Product versions

- Microsoft SQL Server version 2008 or later. For the latest list of supported versions, see [AWS SCT documentation](https://docs.aws.amazon.com/SchemaConversionTool/latest/userguide/CHAP_Welcome.html).

Architecture

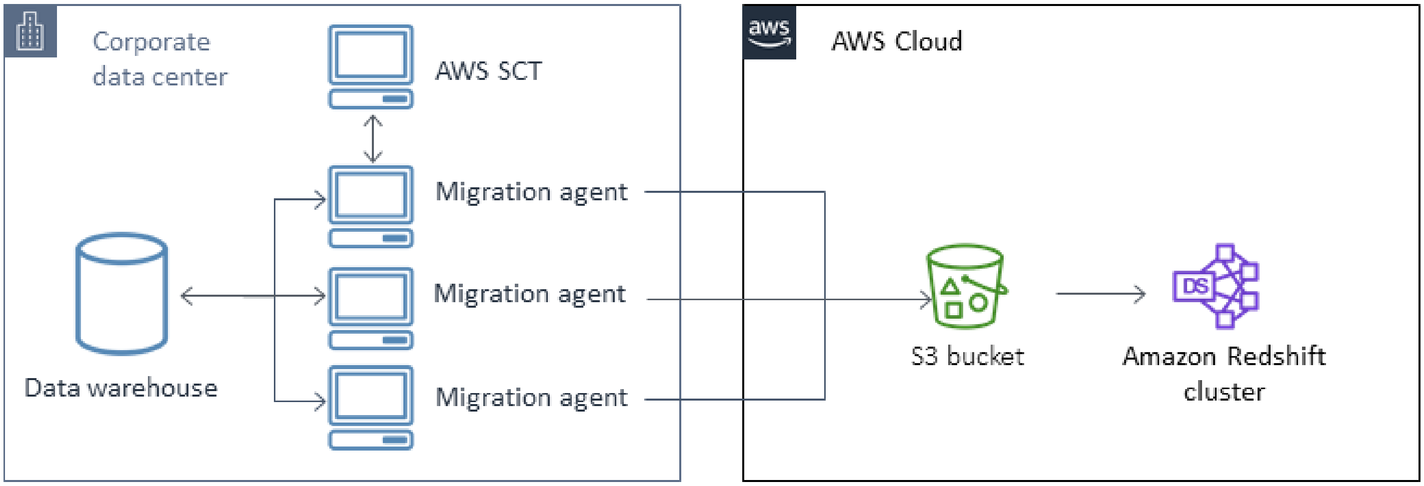
technology stackSource

- An on-premises Microsoft SQL Server database

technology stackTarget

- Amazon Redshift

Data migration architecture



Tools

- AWS Schema Conversion Tool (AWS SCT) handles heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. When the source and target databases are very different, you can use an AWS SCT agent to perform additional data transformation. For more information, see Migrating Data from an On-Premises Data Warehouse to Amazon Redshift in the AWS documentation.

Best practices

- Best practices for AWS SCT
- Best practices for Amazon Redshift

Epics

Prepare for migration

Task	Description	Skills required
Validate the source and target database versions and engines.		DBA

Task	Description	Skills required
Identify hardware requireme nts for the target server instance.		DBA, SysAdmin
Identify storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper instance type (capacity, storage features, network features).		DBA, SysAdmin
Identify network access security requirements for the source and target databases.		DBA, SysAdmin
Choose an application migration strategy.		DBA, SysAdmin, App owner

Configure infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.		SysAdmin
Create security groups.		SysAdmin
Configure and start the Amazon Redshift cluster.		SysAdmin

Migrate data

Task	Description	Skills required
Migrate the data using the AWS SCT data extraction agents.		DBA

Migrate applications

Task	Description	Skills required
Follow the chosen application migration strategy.		DBA, SysAdmin, App owner

Cut over to the target database

Migrate legacy applications from Oracle Pro*C to ECPG

Sai Parthasaradhi and Mahesh Balumuri, Amazon Web Services

Summary

Most legacy applications that have embedded SQL code use the Oracle Pro*C precompiler to access the database. When you migrate these Oracle databases to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition, you have to convert your application code to a format that's compatible with the precompiler in PostgreSQL, which is called ECPG. This pattern describes how to convert Oracle Pro*C code to its equivalent in PostgreSQL ECPG.

For more information about Pro*C, see the Oracle documentation. For a brief introduction to ECPG, see the Additional information section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database
- An Oracle database running on premises

Tools

- The PostgreSQL packages listed in the next section.
- AWS CLI – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

Epics

Set the build environment on CentOS or RHEL

Task	Description	Skills required

Install PostgreSQL packages.	Install the required PostgreSQL packages by using the following commands.
	`yum update -y`
	`yum install -y yum-utils`
	`rpm -ivh https://download.postgresql.org/pub/repos/yum/reporpms/EL-8-x86_64/pgdg-redhat-repo-latest.noarch.rpm`
	`dnf -qy module disable postgresql`
		App developer, DevOps engineer

Install the header files and libraries.	Install the `postgresql12-devel` package, which contains header files and libraries, by using the following commands. Install the package in both the development and the runtime environments to avoid errors in the runtime environment.
	`dnf -y install postgresql12-devel`
	`yum install ncompress zip ghostscript jq unzip wget git -y`
		App developer, DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>For the development environment only, also run the following commands.<pre><code>yum install zlib-devel
 make -y
ln -s /usr/pgsql-12/
bin/ecpg /usr/bin/</code></pre></td><td></td></tr>
<tr><td>Configure the environment path variable.</td><td>Set the environment path for PostgreSQL client libraries.<pre><code>export PATH=$PATH:/usr/
pgsql-12/bin</code></pre></td><td>App developer, DevOps engineer</td></tr>
</table>

Task	Description	Skills required

Install additional software as necessary.	If required, install **pgLoader** as a replacement for **SQL*Loader** in Oracle.
	`wget -O /etc/yum.repos.d/pgloader-ccl.repo https://dl.packager.io/srv/opf/pgloader-ccl/master/installer/el/7.repo`
	`yum install pgloader-ccl -y`
	`ln -s /opt/pgloader-ccl/bin/pgloader /usr/bin/`
	If you're calling any Java applications from Pro*C modules, install Java.
	`yum install java -y`
	Install **ant** to compile the Java code.
	`yum install ant -y`
		App developer, DevOps engineer

Task	Description	Skills required

Install the AWS CLI.	Install the AWS CLI to run commands to interact with AWS services such as AWS Secrets Manager and Amazon Simple Storage Service (Amazon S3) from your applications.
	`cd /tmp/`
	`curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"`
	`unzip awscliv2.zip`
	`./aws/install -i /usr/local/aws-cli -b /usr/local/bin --update`
		App developer, DevOps engineer

Identify the programs to be converted.	Identify the applications that you want to convert from Pro*C to ECPG.	App developer, App owner

Convert Pro*C code to ECPG

Task	Description	Skills required
Remove unwanted headers.	Remove the `include` headers that are not required in PostgreSQL, such as `oci.h`, `oratypes`, and `sqlda`.	App owner, App developer
Update variable declarations.	Add `EXEC SQL` statements for all variable declarations	App developer, App owner

Task	Description	Skills required
	that are used as host variables. Remove the `EXEC SQL VAR` declarations such as the following from your application. `EXEC SQL VAR query IS STRING(2048);`	

Task	Description	Skills required

Update ROWNUM functionality.	The ROWNUM function isn't available in PostgreSQL. Replace this with the ROW_NUMBER window function in SQL queries.
	
	Pro*C code:
	
	`SELECT SUBSTR(RTRIM(FILE_NAME,'.txt'),12) INTO :gcpclFileseq FROM (SELECT FILE_NAME FROM DEMO_FILES_TABLE WHERE FILE_NAME LIKE '%POC%' ORDER BY FILE_NAME DESC) FL2 WHERE ROWNUM <=1 ORDER BY ROWNUM;`
	
	ECPG code:
	
	`SELECT SUBSTR(RTRIM(FILE_NAME,'.txt'),12) INTO :gcpclFileseq FROM (SELECT FILE_NAME , ROW_NUMBER() OVER (ORDER BY FILE_NAME DESC) AS ROWNUM FROM demo_schema.DEMO_FILES_TABLE WHERE FILE_NAME LIKE '%POC%' ORDER BY FILE_NAME DESC) FL2`
		App developer, App owner

Task	Description	Skills required
	``` WHERE ROWNUM <=1 ORDER BY ROWNUM; ```	

Update function parameters to use alias variables.	In PostgreSQL, function parameters can't be used as host variables. Overwrite them by using an alias variable.
	
	Pro*C code:
	
	``
	int processData(int
	 referenceId){
	  EXEC SQL char
	 col_val[100];
	  EXEC SQL select
	 column_name
	 INTO :col_val from
	 table_name where
	 col=:referenceId;
	}
	``
	
	ECPG code:
	
	``
	int processData(int
	 referenceIdParam){
	  EXEC SQL int reference
	Id = referenceIdParam;
	  EXEC SQL char
	 col_val[100];
	  EXEC SQL select
	 column_name
	 INTO :col_val from
	 table_name where
	 col=:referenceId;
	}
	``
		App developer, App owner

Task	Description	Skills required
Update struct types.	Define `struct` types in `EXEC SQL BEGIN` and `END` blocks with `typedef` if the `struct` type variables are used as host variables. If the `struct` types are defined in header (`.h`) files, include the files with `EXEC SQL` include statements. Pro*C code: Header file (`demo.h`) `struct s_partiti on_ranges { char sc_table_ group[31]; char sc_table_ name[31]; char sc_range_ value[10]; }; struct s_partiti on_ranges_ind { short ss_table_ group; short ss_table_ name; short ss_range_ value; };` ECPG code: Header file (`demo.h`)	App developer, App owner

Task	Description	Skills required

	``
	EXEC SQL BEGIN DECLARE
	 SECTION;
	typedef struct
	{
	  char sc_table_
	group[31];
	  char sc_table_
	name[31];
	  char sc_range_
	value[10];
	} s_partition_ranges;
	typedef struct
	{
	  short ss_table_
	group;
	  short ss_table_
	name;
	  short ss_range_
	value;
	} s_partition_ranges
	_ind;
	EXEC SQL END DECLARE
	 SECTION;
	``
	Pro*C file (demo.pc)
	``
	#include "demo.h"
	struct s_partiti
	on_ranges gc_partit
	ion_data[MAX_PART_
	TABLE] ;
	struct s_partiti
	on_ranges_ind
	 gc_partition_data_
	ind[MAX_PART_TABLE] ;
	``
	ECPG file (demo.pc)
	``
	exec sql include
	 "demo.h"
	``	

Task	Description	Skills required
	``` EXEC SQL BEGIN DECLARE SECTION; s_partition_ranges gc_partition_data[MAX_PART_TABLE] ; s_partition_ranges_ind gc_partition_data_ ind[MAX_PART_TABLE] ; EXEC SQL END DECLARE SECTION; ```	
Modify logic to fetch from cursors.	To fetch multiple rows from cursors by using array variables, change the code to use `FETCH FORWARD`. Pro*C code: ``` EXEC SQL char aPoeFiles [MAX_FILES][FILENA ME_LENGTH]; EXEC SQL FETCH filename_ cursor into :aPoeFile s; ``` ECPG code: ``` EXEC SQL char aPoeFiles [MAX_FILES][FILENA ME_LENGTH]; EXEC SQL int fetchSize = MAX_FILES; EXEC SQL FETCH FORWARD :fetchSiz e filename_cursor into :aPoeFiles; ```	App developer, App owner

Task	Description	Skills required

Modify package calls that don't have return values.	Oracle package functions that don’t have return values should be called with an indicator variable. If your application includes multiple functions that have the same name or if the unknown type functions generate runtime errors, typecast the values to the data types.
	
	Pro*C code:
	
	`void ProcessData (char *data , int id)`
	`{`
	`EXEC SQL EXECUTE BEGIN`
	`pkg_demo.process_data (:data, :id);`
	`END;`
	`END-EXEC;`
	`}`
	
	ECPG code:
	
	`void ProcessData (char *dataParam, int idParam )`
	`{`
	`EXEC SQL char *data = dataParam;`
	`EXEC SQL int id = idParam;`
		App developer, App owner

Task	Description	Skills required

	``
	        EXEC SQL short
	 rowInd;
	        EXEC SQL short
	 rowInd = 0;
	        EXEC SQL SELECT
	 pkg_demo.process_data
	 (
	
	 inp_data => :data::te
	xt,
	
	 inp_id => :id
	              )
	 INTO :rowInd;
	}
	``	

Task	Description	Skills required

Rewrite SQL_CURSOR variables.	Rewrite the SQL_CURSOR variable and its implement ation.
	
	Pro*C code:
	
	`/* SQL Cursor */`
	`SQL_CU`
	`RSOR      demo_cursor;`
	`EXEC SQL`
	` ALLOCATE :demo_cursor;`
	`EXEC SQL EXECUTE`
	`  BEGIN`
	`      pkg_demo.`
	`get_cursor(`
	`        demo_cur=`
	`>:demo_cursor`
	`      );`
	`  END;`
	`END-EXEC;`
	
	ECPG code:
	
	`EXEC SQL DECLARE`
	` demo_cursor CURSOR FOR`
	` SELECT`
	`         * from`
	`    pkg_demo.open_file`
	`name_rc(`
	`            demo_cur=`
	`>refcursor`
	`          ) ;`
	`EXEC SQL char open_file`
	`name_rcInd[100];`
	`# As the below function`
	` returns cursor_name`
	` as`
	`# return we need to`
	` use char[] type as`
	` indicator.`
		App developer, App owner

Task	Description	Skills required
	`EXEC SQL SELECT pkg_demo.get_cursor ( demo_cur=>'demo_cursor' ) INTO :open_filename_rcInd;`	
Apply common migration patterns.	• Change SQL queries so they're compatible with PostgreSQL. • Move anonymous blocks, when they aren't supported in ECPG, to the database. • Remove `dbms_application_info` logic, which isn't supported by PostgreSQL. • Move `EXEC SQL COMMIT` statements after the cursor close. If you commit queries while in the loop to fetch the records from the cursor, the cursor is closed and a cursor doesn't exist error is displayed. • For information about handling exceptions in ECPG and error codes, see [Error Handling](#) in the PostgreSQL documentation.	App developer, App owner

Task	Description	Skills required
Enable debugging, if required.	To run the ECPG program in debug mode, add the following command inside the main function block. `ECPGdebug(1, stderr);`	App developer, App owner

Compile ECPG programs

Task	Description	Skills required

Create an executable file for ECPG.	If you have an embedded SQL C source file named `prog1.pgc` , you can create an executable program by using the following sequence of commands.
	`ecpg prog1.pgc`
	`cc -I/usr/local/pgsql/include -c prog1.c`
	`cc -o prog1 prog1.o -L/usr/local/pgsql/lib -lecpg`
		App developer, App owner

Create a make file for compilation.	Create a make file to compile the ECPG program, as shown in the following sample file.
	`CFLAGS ::= $(CFLAGS) -I/usr/pgsql-12/include -g -Wall`
	`LDFLAGS ::= $(LDFLAGS) -L/usr/pgsql-12/lib -Wl,-rpath,/usr/pgsql-12/lib`
		App developer, App owner

Task	Description	Skills required

```
LDLIBS ::= $(LDLIBS) -
lecpg
PROGRAMS = test
.PHONY: all clean
%.c: %.pgc
      ecpg $<
all: $(PROGRAMS)
clean:
    rm -f $(PROGRAM
S) $(PROGRAMS:%=%.c)
 $(PROGRAMS:%=%.o)
```

Test the application

Task	Description	Skills required
Test the code.	Test the converted application code to make sure that it functions correctly.	App developer, App owner, Test engineer

Related resources

- ECPG - Embedded SQL in C (PostgreSQL documentation)
- Error Handling (PostgreSQL documentation)
- Why Use the Oracle Pro*C/C++ Precompiler (Oracle documentation)

Additional information

PostgreSQL has an embedded SQL precompiler, ECPG, which is equivalent to the Oracle Pro*C precompiler. ECPG converts C programs that have embedded SQL statements to standard C code by replacing the SQL calls with special function calls. The output files can then be processed with any C compiler tool chain.

Input and output files

ECPG converts each input file you specify on the command line to the corresponding C output file. If an input file name doesn’t have a file extension, .pgc is assumed. The file's extension is replaced by `.c` to construct the output file name. However, you can override the default output file name by using the `-o` option.

If you use a dash (`-`) as the input file name, ECPG reads the program from standard input and writes to standard output, unless you override that by using the `-o` option.

Header files

When the PostgreSQL compiler compiles the pre-processed C code files, it looks for the ECPG header files in the PostgreSQL `include` directory. Therefore, you might have to use the `-I` option to point the compiler to the correct directory (for example, `-I/usr/local/pgsql/include`).

Libraries

Programs that use C code with embedded SQL have to be linked against the `libecpg` library. For example, you can use the linker options `-L/usr/local/pgsql/lib -lecpg`.

Converted ECPG applications call functions in the `libpq` library through the embedded SQL library (`ecpglib`), and communicate with the PostgreSQL server by using the standard frontend/backend protocol.

Migrate virtual generated columns from Oracle to PostgreSQL

Veeranjaneyulu Grandhi, Rajesh Madiwale, and Ramesh Pathuri, Amazon Web Services

Summary

In version 11 and earlier, PostgreSQL doesn't provide a feature that is directly equivalent to an Oracle virtual column. Handling virtual generated columns while migrating from Oracle Database to PostgreSQL version 11 or earlier is difficult for two reasons:

- Virtual columns aren't visible during migration.
- PostgreSQL doesn't support the `generate` expression before version 12.

However, there are workarounds to emulate similar functionality. When you use AWS Database Migration Service (AWS DMS) to migrate data from Oracle Database to PostgreSQL version 11 and earlier, you can use trigger functions to populate the values in virtual generated columns. This pattern provides examples of Oracle Database and PostgreSQL code that you can use for this purpose. On AWS, you can use Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition for your PostgreSQL database.

Starting with PostgreSQL version 12, generated columns are supported. Generated columns can either be calculated from other column values on the fly, or calculated and stored. PostgreSQL generated columns are similar to Oracle virtual columns.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle database
- Target PostgreSQL databases (on Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible)
- PL/pgSQL coding expertise

Limitations

- Applies only to PostgreSQL versions before version 12.
- Applies to Oracle Database version 11g or later.

- Virtual columns are not supported in data migration tools.
- Applies only to columns defined in the same table.
- If a virtual generated column refers to a deterministic user-defined function, it cannot be used as a partitioning key column.
- The output of the expression must be a scalar value. It cannot return an Oracle supplied datatype, a user-defined type, `LOB`, or `LONG RAW`.
- Indexes that are defined against virtual columns are equivalent to function-based indexes in PostgreSQL.
- Table statistics must be gathered.

Tools

- [pgAdmin 4](#) is an open source management tool for PostgreSQL. This tool provides a graphical interface that simplifies the creation, maintenance, and use of database objects.
- [Oracle SQL Developer](#) is a free, integrated development environment for working with SQL in Oracle databases in both traditional and cloud deployments.

Epics

Create source and target database tables

Task	Description	Skills required
Create a source Oracle Database table.	In Oracle Database, create a table with virtual generated columns by using the following statement. `CREATE TABLE test.gene rated_column ( CODE NUMBER, STATUS VARCHAR2(12) DEFAULT 'PreOpen', FLAG CHAR(1) GENERATED ALWAYS AS (CASE UPPER(STATUS) WHEN 'OPEN' THEN 'N' ELSE`	DBA, App developer

Task	Description	Skills required
	``` 'Y' END) VIRTUAL VISIBLE); ``` In this source table, the data in the `STATUS` column is migrated through AWS DMS to the target database. The `FLAG` column, however, is populated by using `generate by` functionality, so this column isn't visible to AWS DMS during migration. To implement the functionality of `generated by`, you must use triggers and functions in the target database to populate the values in the `FLAG` column, as shown in the next epic.	

Task	Description	Skills required
Create a target PostgreSQL table on AWS.	Create a PostgreSQL table on AWS by using the following statement. `CREATE TABLE test.generated_column ( code integer not null, status character varying(12) not null , flag character(1) );` In this table, the `status` column is a standard column. The `flag` column will be a generated column based on the data in the `status` column.	DBA, App developer

Create a trigger function to handle the virtual column in PostgreSQL

Task	Description	Skills required
Create a PostgreSQL trigger.	In PostgreSQL, create a trigger. `CREATE TRIGGER tgr_gen_column AFTER INSERT OR UPDATE OF status ON test.generated_column FOR EACH ROW`	DBA, App developer

Task	Description	Skills required
	```EXECUTE FUNCTION test.tgf_gen_column();```	

Task	Description	Skills required
Create a PostgreSQL trigger function.	In PostgreSQL, create a function for the trigger. This function populates a virtual column that is inserted or updated by the application or AWS DMS, and validates the data. ```CREATE OR REPLACE FUNCTION test.tgf_gen_column() RETURNS trigger AS $VIRTUAL_COL$ BEGIN IF (TG_OP = 'INSERT') THEN IF (NEW.flag IS NOT NULL) THEN RAISE EXCEPTION 'ERROR: cannot insert into column "flag"' USING DETAIL = 'Column "flag" is a generated column.'; END IF; END IF; IF (TG_OP = 'UPDATE') THEN IF (NEW.flag::VARCHAR != OLD.flag::varchar) THEN RAISE EXCEPTION 'ERROR: cannot update column "flag"' USING DETAIL = 'Column "flag" is a generated column.'; END IF; END IF; IF TG_OP IN ('INSERT','UPDATE') THEN```	DBA, App developer

Task	Description	Skills required

	``
	IF (old.flag is NULL)
	 OR (coalesce(old.stat
	us,'') != coalesce(
	new.status,'')) THEN
	UPDATE test.gene
	rated_column
	SET flag = (CASE
	 UPPER(status) WHEN
	 'OPEN' THEN 'N' ELSE
	 'Y' END)
	WHERE code = new.code;
	END IF;
	END IF;
	RETURN NEW;
	END
	$VIRTUAL_COL$ LANGUAGE
	 plpgsql;
	``	

Test data migration by using AWS DMS

Task	Description	Skills required
Create a replication instance.	To create a replication instance, follow the [instructions](#) in the AWS DMS documentation. The replication instance should be in the same virtual private cloud (VPC) as your source and target databases.	DBA, App developer
Create source and target endpoints.	To create the endpoints, follow the [instructions](#) in the AWS DMS documentation.	DBA, App developer
Test the endpoint connections.	You can test the endpoint connections by specifying the	DBA, App developer

Task	Description	Skills required
	VPC and replication instance and choosing **Run test**.	
Create and start a full load task.	For instructions, see Creating a Task and Full-load task settings in the AWS DMS documentation.	DBA, App developer
Validate the data for the virtual column.	Compare the data in the virtual column in the source and target databases. You can validate the data manually or write a script for this step.	DBA, App developer

Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible

Rakesh Raghav and anuradha chintha, Amazon Web Services

Summary

As part of your migration journey from Oracle to Amazon Aurora PostgreSQL-Compatible Edition on the Amazon Web Services (AWS) Cloud, you might encounter multiple challenges. For example, migrating code that relies on the Oracle `UTL_FILE` utility is always a challenge. In Oracle PL/SQL, the `UTL_FILE` package is used for file operations, such as read and write, in conjunction with the underlying operating system. The `UTL_FILE` utility works for both server and client machine systems.

Amazon Aurora PostgreSQL-Compatible is a managed database offering. Because of this, it isn't possible to access files on the database server. This pattern walks you through the integration of Amazon Simple Storage Service (Amazon S3) and Amazon Aurora PostgreSQL-Compatible to achieve a subset of `UTL_FILE` functionality. Using this integration, we can create and consume files without using third-party extract, transform, and load (ETL) tools or services.

Optionally, you can set up Amazon CloudWatch monitoring and Amazon SNS notifications.

We recommend thoroughly testing this solution before implementing it in a production environment.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Database Migration Service (AWS DMS) expertise
- Expertise in PL/pgSQL coding
- An Amazon Aurora PostgreSQL-Compatible cluster
- An S3 bucket

Limitations

This pattern doesn't provide the functionality to act as a replacement for the Oracle `UTL_FILE` utility. However, the steps and sample code can be enhanced further to achieve your database modernization goals.

Product versions

- Amazon Aurora PostgreSQL-Compatible Edition 11.9

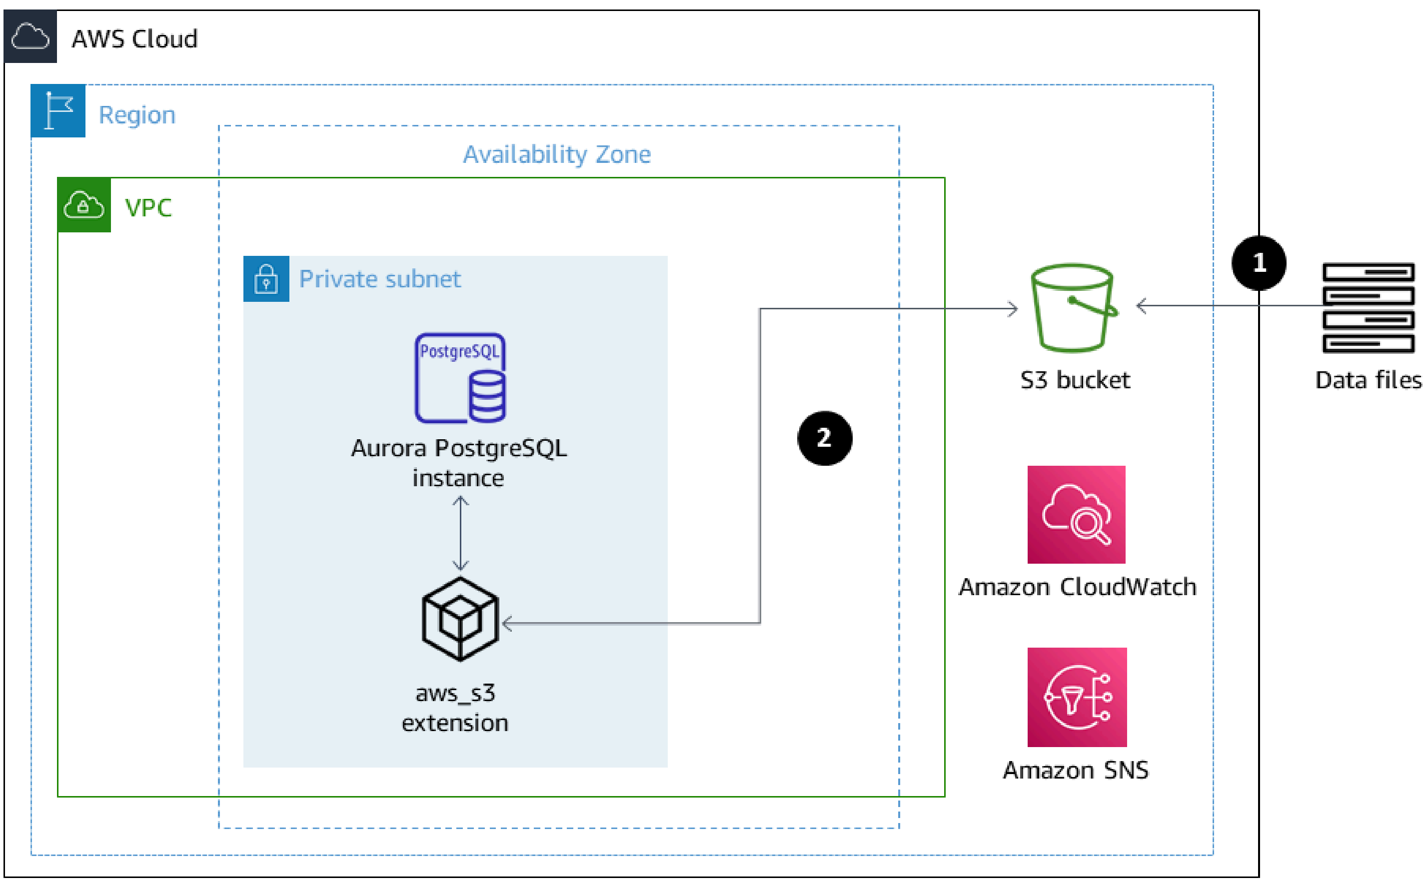
Architecture

Target technology stack

- Amazon Aurora PostgreSQL-Compatible
- Amazon CloudWatch
- Amazon Simple Notification Service (Amazon SNS)
- Amazon S3

Target architecture

The following diagram shows a high-level representation of the solution.



1. Files are uploaded from the application into the S3 bucket.

2. The `aws_s3` extension accesses the data, using PL/pgSQL, and uploads the data to Aurora PostgreSQL-Compatible.

Tools

- Amazon Aurora PostgreSQL-Compatible – Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine. It combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases.
- AWS CLI – The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. With only one tool to download and configure, you can control multiple AWS services from the command line and automate them through scripts.
- Amazon CloudWatch – Amazon CloudWatch monitors Amazon S3 resources and use.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. In this pattern, Amazon S3 provides a storage layer to receive and store files for consumption and transmission to and from the Aurora PostgreSQL-Compatible cluster.
- aws_s3 – The `aws_s3` extension integrates Amazon S3 and Aurora PostgreSQL-Compatible.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients. In this pattern, Amazon SNS is used to send notifications.
- pgAdmin – pgAdmin is an open-source management tool for Postgres. pgAdmin 4 provides a graphical interface for creating, maintaining, and using database objects.

Code

To achieve the required functionality, the pattern creates multiple functions with naming similar to `UTL_FILE`. The *Additional information* section contains the code base for these functions.

In the code, replace `testaurorabucket` with the name of your test S3 bucket. Replace `us-east-1` with the AWS Region where your test S3 bucket is located.

Epics

Integrate Amazon S3 and Aurora PostgreSQL-Compatible

Task	Description	Skills required
Set up IAM policies.	Create AWS Identity and Access Management (IAM) policies that grant access to the S3 bucket and objects in it. For the code, see the *Additional information* section.	AWS administrator, DBA
Add Amazon S3 access roles to Aurora PostgreSQL.	Create two IAM roles: one role for read and one role for write access to Amazon S3. Attach the two roles to the Aurora PostgreSQL-Compatible cluster: • One role for the S3Export feature • One role for the S3Import feature For more information, see the Aurora PostgreSQL-Compatible documentation on importing and exporting data to Amazon S3.	AWS administrator, DBA

Set up the extensions in Aurora PostgreSQL-Compatible

Task	Description	Skills required
Create the aws_commons extension.	The `aws_commons` extension is a dependency of the `aws_s3` extension.	DBA, Developer
Create the aws_s3 extension.	The `aws_s3` extension interacts with Amazon S3.	DBA, Developer

Validate Amazon S3 and Aurora PostgreSQL-Compatible integration

Task	Description	Skills required
Test importing files from Amazon S3 into Aurora PostgreSQL.	To test importing files into Aurora PostgreSQL-Compatible, create a sample CSV file and upload it into the S3 bucket. Create a table definition based on the CSV file, and load the file into the table by using the `aws_s3.table_import_from_s3` function.	DBA, Developer
Test exporting files from Aurora PostgreSQL to Amazon S3.	To test exporting files from Aurora PostgreSQL-Compatible, create a test table, populate it with data, and then export the data by using the `aws_s3.query_export_to_s3` function.	DBA, Developer

To mimic the UTL_FILE utility, create wrapper functions

Task	Description	Skills required
Create the utl_file_utility schema.	The schema keeps the wrapper functions together. To create the schema, run the following command. `CREATE SCHEMA utl_file_utility;`	DBA, Developer
Create the file_type type.	To create the `file_type` type, use the following code. `CREATE TYPE utl_file_utility.file_type AS ( p_path character varying(30), p_file_name character varying );`	DBA/Developer
Create the init function.	The `init` function initializes common variable such as `bucket` or `region`. For the code, see the *Additional information* section.	DBA/Developer
Create the wrapper functions.	Create the wrapper functions `fopen`, `put_line`, and `fclose`. For code, see the *Additional information* section.	DBA, Developer

Test the wrapper functions

Task	Description	Skills required
Test the wrapper functions in write mode.	To test the wrapper functions in write mode, use the code provided in the *Additional information* section.	DBA, Developer
Test the wrapper functions in append mode.	To test the wrapper functions in append mode, use the code provide in the *Additional information* section.	DBA, Developer

            "Resource": [
    "arn:aws:s3:::testaurorabucket/
*",                "arn:aws:s3:::test
aurorabucket"
            ]
        }
    ]
}
```

Create the init function

To initialize common variables, such as `bucket` or `region`, create the `init` function by using the following code.

```
CREATE OR REPLACE FUNCTION utl_file_utility.init(
```

```
    )
    RETURNS void
    LANGUAGE 'plpgsql'

    COST 100
    VOLATILE
AS $BODY$
BEGIN
      perform set_config
      ( format( '%s.%s','UTL_FILE_UTILITY', 'region' )
      , 'us-east-1'::text
      , false );

      perform set_config
      ( format( '%s.%s','UTL_FILE_UTILITY', 's3bucket' )
      , 'testaurorabucket'::text
      , false );
END;
$BODY$;
```

Create the wrapper functions

Create the `fopen`, `put_line`, and `fclose` wrapper functions.

fopen

```
CREATE OR REPLACE FUNCTION utl_file_utility.fopen(
    p_file_name character varying,
    p_path character varying,
    p_mode character DEFAULT 'W'::bpchar,
    OUT p_file_type utl_file_utility.file_type)
    RETURNS utl_file_utility.file_type
    LANGUAGE 'plpgsql'

    COST 100
    VOLATILE
AS $BODY$
declare
    v_sql character varying;
    v_cnt_stat integer;
    v_cnt integer;
    v_tabname character varying;
    v_filewithpath character varying;
    v_region character varying;
```

```
    v_bucket character varying;

BEGIN
    /*initialize common variable */
    PERFORM utl_file_utility.init();
    v_region := current_setting( format( '%s.%s', 'UTL_FILE_UTILITY', 'region' ) );
    v_bucket :=  current_setting( format( '%s.%s', 'UTL_FILE_UTILITY', 's3bucket' ) );

    /* set tabname*/
    v_tabname := substring(p_file_name,1,case when strpos(p_file_name,'.') = 0 then
 length(p_file_name) else strpos(p_file_name,'.') - 1 end );
    v_filewithpath := case when NULLif(p_path,'') is null then p_file_name else
 concat_ws('/',p_path,p_file_name) end ;
    raise notice 'v_bucket %, v_filewithpath % , v_region %', v_bucket,v_filewithpath,
 v_region;

    /* APPEND MODE HANDLING; RETURN EXISTING FILE DETAILS IF PRESENT ELSE CREATE AN
 EMPTY FILE */
    IF p_mode = 'A' THEN
        v_sql := concat_ws('','create temp table if not exists ', v_tabname,' (col1
 text)');
        execute v_sql;

        begin
        PERFORM aws_s3.table_import_from_s3
            ( v_tabname,
            '',
            'DELIMITER AS ''#''',
            aws_commons.create_s3_uri
            (     v_bucket,
                v_filewithpath ,
                v_region)
            );
        exception
            when others then
             raise notice 'File load issue ,%',sqlerrm;
             raise;
        end;
        execute concat_ws('','select count(*) from ',v_tabname) into v_cnt;

        IF v_cnt > 0
        then
            p_file_type.p_path := p_path;
            p_file_type.p_file_name := p_file_name;
```

```

```

Test your setup and wrapper functions

Use the following anonymous code blocks to test your setup.

Test the write mode

The following code writes a file named `s3inttest` in the S3 bucket.

```
do $$
declare
l_file_name varchar := 's3inttest' ;
l_path varchar := 'integration_test' ;
```

```
l_mode char(1) := 'W';
l_fs utl_file_utility.file_type ;
l_status boolean;

begin
select * from
utl_file_utility.fopen( l_file_name, l_path , l_mode ) into l_fs ;
raise notice 'fopen : l_fs : %', l_fs;

select * from
utl_file_utility.put_line( l_file_name, l_path ,'this is test file:in s3bucket: for
 test purpose', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;

select * from utl_file_utility.fclose( l_file_name , l_path ) into l_status ;
raise notice 'fclose : l_status %', l_status;

end;
$$
```

Test the append mode

The following code appends lines onto the `s3inttest` file that was created in the previous test.

```
do $$
declare
l_file_name varchar := 's3inttest' ;
l_path varchar := 'integration_test' ;
l_mode char(1) := 'A';
l_fs utl_file_utility.file_type ;
l_status boolean;

begin
select * from
utl_file_utility.fopen( l_file_name, l_path , l_mode ) into l_fs ;
raise notice 'fopen : l_fs : %', l_fs;

select * from
utl_file_utility.put_line( l_file_name, l_path ,'this is test file:in s3bucket: for
 test purpose : append 1', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;

select * from
```

```
utl_file_utility.put_line( l_file_name, l_path ,'this is test file:in s3bucket : for
 test purpose : append 2', l_mode ) into l_status ;
raise notice 'put_line : l_status %', l_status;

select * from utl_file_utility.fclose( l_file_name , l_path ) into l_status ;
raise notice 'fclose : l_status %', l_status;

end;
$$
```

Amazon SNS notifications

Optionally, you can set up Amazon CloudWatch monitoring and Amazon SNS notifications on the S3 bucket. For more information, see Monitoring Amazon S3 and Setting up Amazon SNS Notifications.

Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL

Venkatramana Chintha and Eduardo Valentim, Amazon Web Services

Summary

This pattern describes a step-by-step approach to validate objects after migrating an Oracle database to Amazon Aurora PostgreSQL-Compatible Edition.

This pattern outlines usage scenarios and steps for database object validation; for more detailed information, see Validating database objects after migration using AWS SCT and AWS DMS on the AWS Database blog.

Prerequisites and limitations

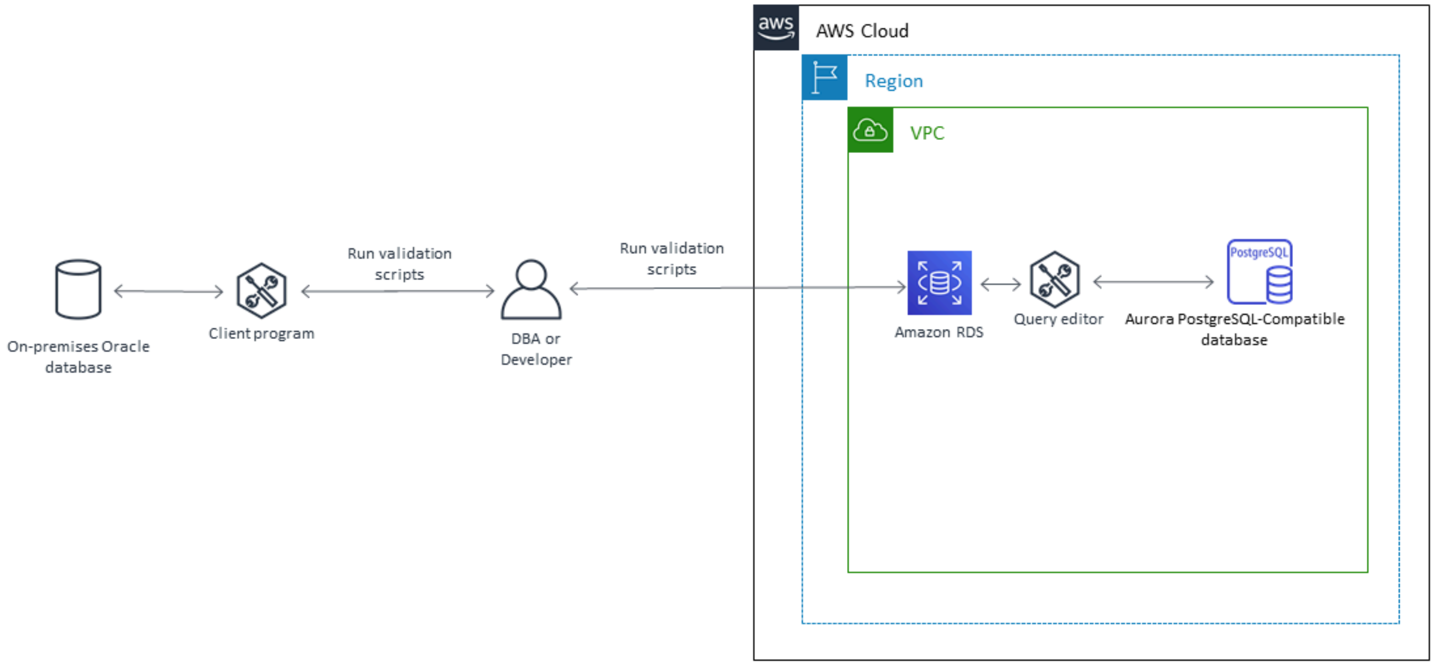
Prerequisites

- An active AWS account.
- An on-premises Oracle database that was migrated to an Aurora PostgreSQL-Compatible database.
- Sign-in credentials that have the AmazonRDSDataFullAccess policy applied, for the Aurora PostgreSQL-Compatible database.
- This pattern uses the query editor for Aurora Serverless DB clusters, which is available in the Amazon Relational Database Service (Amazon RDS) console. However, you can use this pattern with any other query editor.

Limitations

- Oracle SYNONYM objects are not available in PostgreSQL but can be partially validated through **views** or SET search_path queries.
- The Amazon RDS query editor is available only in certain AWS Regions and for certain MySQL and PostgreSQL versions.

Architecture



Tools

Tools

- Amazon Aurora PostgreSQL-Compatible Edition – Aurora PostgreSQL-Compatible is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases.
- Amazon RDS – Amazon Relational Database Service (Amazon RDS) makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.
- Query Editor for Aurora Severless – Query editor helps you run SQL queries in the Amazon RDS console. You can run any valid SQL statement on the Aurora Serverless DB cluster, including data manipulation and data definition statements.

To validate the objects, use the full scripts in the "Object validation scripts" file in the "Attachments" section. Use the following table for reference.

Oracle object	Script to use

Packages	Query 1
Tables	Query 3
Views	Query 5
Sequences	Query 7
Triggers	Query 9
Primary keys	Query 11
Indexes	Query 13
Check constraints	Query 15
Foreign keys	Query 17

PostgreSQL object	Script to use
Packages	Query 2
Tables	Query 4
Views	Query 6
Sequences	Query 8
Triggers	Query 10
Primary keys	Query 12
Indexes	Query 14
Check constraints	Query 16
Foreign keys	Query 18

Epics

Validate objects in the source Oracle database

Task	Description	Skills required
Run the "packages" validation query in the source Oracle database.	Download and open the "Object validation scripts" file from the "Attachments" section. Connect to the source Oracle database through your client program. Run the "Query 1" validations script from the "Object validation scripts" file. Important: Enter your Oracle user name instead of "your_schema" in the queries. Make sure you record your query results.	Developer, DBA
Run the "tables" validation query.	Run the "Query 3" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "views" validation query.	Run the "Query 5" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "sequences" count validation.	Run the "Query 7" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "triggers" validation query.	Run the "Query 9" script from the "Object validation scripts"	Developer, DBA

Task	Description	Skills required
	file. Make sure you record your query results.	
Run the "primary keys" validation query.	Run the "Query 11" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "indexes" validation query.	Run the "Query 13" validation script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "check constraints" validation query.	Run the "Query 15" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "foreign keys" validation query.	Run the "Query 17" validation script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA

Validate objects in the target Aurora PostgreSQL-Compatible database

Task	Description	Skills required
Connect to the target Aurora PostgreSQL-Compatible database by using the query editor.	Sign in to the AWS Management Console and open the Amazon RDS console. In the upper-right corner, choose the AWS Region in which you created	Developer, DBA

Task	Description	Skills required
	the Aurora PostgreSQL-Compatible database. In the navigation pane, choose "Databases," and choose the target Aurora PostgreSQL-Compatible database. In "Actions," choose "Query." Important: If you haven't connected to the database before, the "Connect to database" page opens. You then need to enter your database information, such as user name and password.	
Run the "packages" validation query.	Run the "Query 2" script from the "Object validation scripts" file in the "Attachments" section. Make sure you record your query results.	Developer, DBA
Run the "tables" validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the "Query 4" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA

Task	Description	Skills required
Run the "views" validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the "Query 6" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "sequences" count validation.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the "Query 8" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "triggers" validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the "Query 10" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "primary keys" validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the "Query 12" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA

Task	Description	Skills required
Run the "indexes" validation query.	Return to the query editor for the Aurora PostgreSQL-Compatible database, and run the "Query 14" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "check constraints" validation query.	Run the "Query 16" script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA
Run the "foreign keys" validation query.	Run the "Query 18" validatio n script from the "Object validation scripts" file. Make sure you record your query results.	Developer, DBA

Compare source and target database validation records

Task	Description	Skills required
Compare and validate both query results.	Compare the query results of the Oracle and Aurora PostgreSQL-Compatible databases to validate all objects. If they all match, then all objects have been successfully validated.	Developer, DBA

Accelerate the discovery and migration of Microsoft workloads to AWS

Ali Alzand, Amazon Web Services

Summary

This pattern shows you how to use the Migration Validator Toolkit PowerShell module to discover and migrate your Microsoft workloads to AWS. The module works by performing multiple checks and validations for common tasks associated with any Microsoft workload. For example, the module checks for instances that might have multiple disks attached to it or instances that use many IP addresses. For a full list of checks that the module can perform, see the Checks section on the module's GitHub page.

The Migration Validator Toolkit PowerShell module can help your organization reduce the time and effort involved in discovering what applications and services are running on your Microsoft workloads. The module can also help you identify the configurations of your workloads so that you can find out if your configurations are supported on AWS. The module also provides recommendations for next steps and mitigation actions, so that you can avoid any misconfigurations before, during, or after your migration.

Prerequisites and limitations

Prerequisites

- Local administrator account
- PowerShell 4.0

Limitations

- Works only on Microsoft Windows Server 2012 R2 or later

Tools

Tools

- PowerShell 4.0

Code repository

The Migration Validator Toolkit PowerShell module for this pattern is available in the GitHub migration-validator-toolkit-for-microsoft-workloads repository.

Epics

Run the Migration Validator Toolkit PowerShell module on a single target

Task	Description	Skills required
Download, extract, import, and invoke the module.	Choose one of the following methods to download and deploy the module: • Run the PowerShell script • Download and extract the .zip file • Clone the GitHub repository **Run the PowerShell script** In PowerShell, run the following example code: `#MigrationValidatorToolkit $uri = 'https://github.com/aws-samples/migration-validator-toolkit-for-microsoft-workloads/archive/refs/heads/main.zip' $destination = (Get-Location).Path if ((Test-Path -Path "$destination\MigrationValidatorToolkit.zip" -PathType Leaf) -or (Test-Path -Path "$destination\Migr`	System Administrator

Task	Description	Skills required

	``
	ationValidatorTool
	kit")) {
	    write-host "File
	 $destination\Migra
	tionValidatorToolk
	it.zip or folder
	 $destination\Migra
	tionValidatorToolkit
	 found, exiting"
	}else {
	    Write-host "Enable
	 TLS 1.2 for this
	 PowerShell session
	 only."
	    [Net.ServicePointM
	anager]::SecurityP
	rotocol = [Net.Secu
	rityProtocolType]:
	:Tls12
	    $webClient =
	 New-Object System.Ne
	t.WebClient
	    Write-host
	 "Downloading Migration
	ValidatorToolkit.zip"
	    $webClient.Downloa
	dFile($uri, "$destina
	tion\MigrationVali
	datorToolkit.zip")
	    Write-host
	 "MigrationValidato
	rToolkit.zip download
	 successfully"
	    Add-Type -Assembly
	 "system.io.compres
	sion.filesystem"
	    [System.IO.Compres
	sion.ZipFile]::Ext
	ractToDirectory("$
	destination\Migrat
	ionValidatorToolki
	t.zip","$destinati
	``	

Task	Description	Skills required

	`on\MigrationValidatorToolkit")`
	`    Write-host "Extracting MigrationValidatorToolkit.zip complete successfully"`
	`    Import-Module "$destination\MigrationValidatorToolkit\migration-validator-toolkit-for-microsoft-workloads-main\MigrationValidatorToolkit.psm1"; Invoke-MigrationValidatorToolkit`
	`}`
	
	The code downloads the module from a .zip file. Then, the code extracts, imports, and invokes the module.
	
	Download and extract the .zip file
	
	1. Download the [.zip file](#) (download).
	2. Extract the .zip file.
	3. Follow the steps in the *Invoke the module manually* story of this guide.
	
	Clone the GitHub repository
	
	1. To clone the GitHub [migration-validato](#)	

Task	Description	Skills required
	[r-toolkit-for-microsoft-wor kloads](#) repository, run the following Git command in a terminal window: `git clone https://github.com/aws-samples/migration-validator-toolkit-for-microsoft-workloads.git` 2. Follow the steps in the *Invoke the module manually* story of this guide.	

Task	Description	Skills required

Invoke the module manually.	1. Go to the directory where the downloaded module is stored.
	2. To generate the output of your choice, run one of the following commands as an administrator in PowerShell:
	
	Format-Table format:
	`Import-Module .\MigrationValidatorToolkit.psm1;Invoke-MigrationValidatorToolkit`
	
	Format-List format:
	`Import-Module .\MigrationValidatorToolkit.psm1;Invoke-MigrationValidatorToolkit -List`
	
	Out-GridView format:
	`Import-Module .\MigrationValidatorToolkit.psm1;Invoke-MigrationValidatorToolkit -GridView`
	
	ConvertTo-Csv format:
	`Import-Module .\MigrationValidatorToolkit`
		System Administrator

Task	Description	Skills required
	`.psm1;Invoke-MigrationValidatorToolkit -csv`	

Run the Migration Validator Toolkit PowerShell module on multiple targets

Task	Description	Skills required
Download the .zip file or clone the GitHub repository.	Choose one of the following options: • Download the zip file. (download). • To clone the GitHub migration-validator-toolkit-for-microsoft-workloads repository, run the following Git command in a terminal window: `git clone https://github.com/aws-samples/migration-validator-toolkit-for-microsoft-workloads.git`	System Administrator
Update the server.csv list.	If you downloaded the .zip file, follow these steps: 1. Extract the .zip file. 2. Go to the `MigrationValidatorToolkit\Inputs\` directory.	System Administrator

Task	Description	Skills required
	3. Update `serverlist.csv` with the host name of your target computers.	
Invoke the module.	You can use any computer within the domain that uses a domain user that has administrator access to target computers. 1. Download the source code as a .zip file and extract the file. 2. As an administrator in PowerShell, run the following command: `Import-Module .\MigrationValidatorToolkit.psm1;Invoke-DomainComputers` The output .csv file is saved in `MigrationValidatorToolkit\Outputs\folder` with the prefix name `DomainComputers_MigrationAutomations_YYYY-MM-DDTHH-MM-SS`.	System Administrator

Troubleshooting

Issue	Solution
`MigrationValidatorToolkit` writes information about executions, commands, and errors to log files on the running host.	You can view log files manually in the following location: 1. Go to the `MigrationValidatorToolkit\logs\` directory. 2. Locate the log file. The format of the log file name is: `ComputerName_MigrationValidatorToolkit_YYYY-MM-SSTHH-MM-SS.log`

Additional information

Frequently asked questions

Where can I run the Migration Validator Toolkit PowerShell module?

You can run the module on Microsoft Windows Server 2012 R2 or later.

When do I run this module?

We recommend that you run the module during the assess phase of the migration journey.

Does the module modify my existing servers?

No. All actions in this module are read-only.

How long does it take to run the module?

It typically takes 1–5 minutes to run the module, but it depends on the resource allocation of your server.

What permissions does the module need to run?

You must run the module from a local administrator account.

Can I run the module on physical servers?

Yes, as long as the operating system is Microsoft Windows Server 2012 R2 or later.

How do I run the module at scale for multiple servers?

To run the module on multiple domain-joined computers at scale, follow the steps in the *Run the Migration Validator Toolkit PowerShell module on multiple targets* epic of this guide. For non domain-joined computers, use a remote invocation or run the module locally by following the steps in the *Run the Migration Validator Toolkit PowerShell module on a single target* epic of this guide.

Create an approval process for firewall requests during a rehost migration to AWS

Srikanth Rangavajhala, Amazon Web Services

Summary

If you want to use AWS Application Migration Service or Cloud Migration Factory on AWS for a rehost migration to the AWS Cloud, one of the prerequisites is that you must keep TCP ports 443 and 1500 open. Typically, opening these firewall ports requires approval from your information security (InfoSec) team.

This pattern outlines the process to obtain a firewall request approval from an InfoSec team during a rehost migration to the AWS Cloud. You can use this process to avoid rejections of your firewall request by the InfoSec team, which can become expensive and time consuming. The firewall request process has two review and approval steps between AWS migration consultants and leads who work with your InfoSec and application teams to open the firewall ports.

This pattern assumes that you are planning a rehost migration with AWS consultants or migration specialists from your organization. You can use this pattern if your organization doesn't have a firewall approval process or firewall request blanket approval form. For more information about this, see the *Limitations* section of this pattern. For more information on network requirements for Application Migration Service, see Network requirements in the Application Migration Service documentation.

Prerequisites and limitations

Prerequisites

- A planned rehost migration with AWS consultants or migration specialists from your organization
- The required port and IP information to migrate the stack
- Existing and future state architecture diagrams
- Firewall information about the on-premises and destination infrastructure, ports, and zone-to-zone traffic flow
- A firewall request review checklist (attached)
- A firewall request document, configured according to your organization's requirements
- A contact list for the firewall reviewers and approvers, including the following roles:
  - **Firewall request submitter** – AWS migration specialist or consultant. The firewall request submitter can also be a migration specialist from your organization.

- **Firewall request reviewer –** Typically, this is the single point of contact (SPOC) from AWS.
- **Firewall request approver** – An InfoSec team member.

Limitations

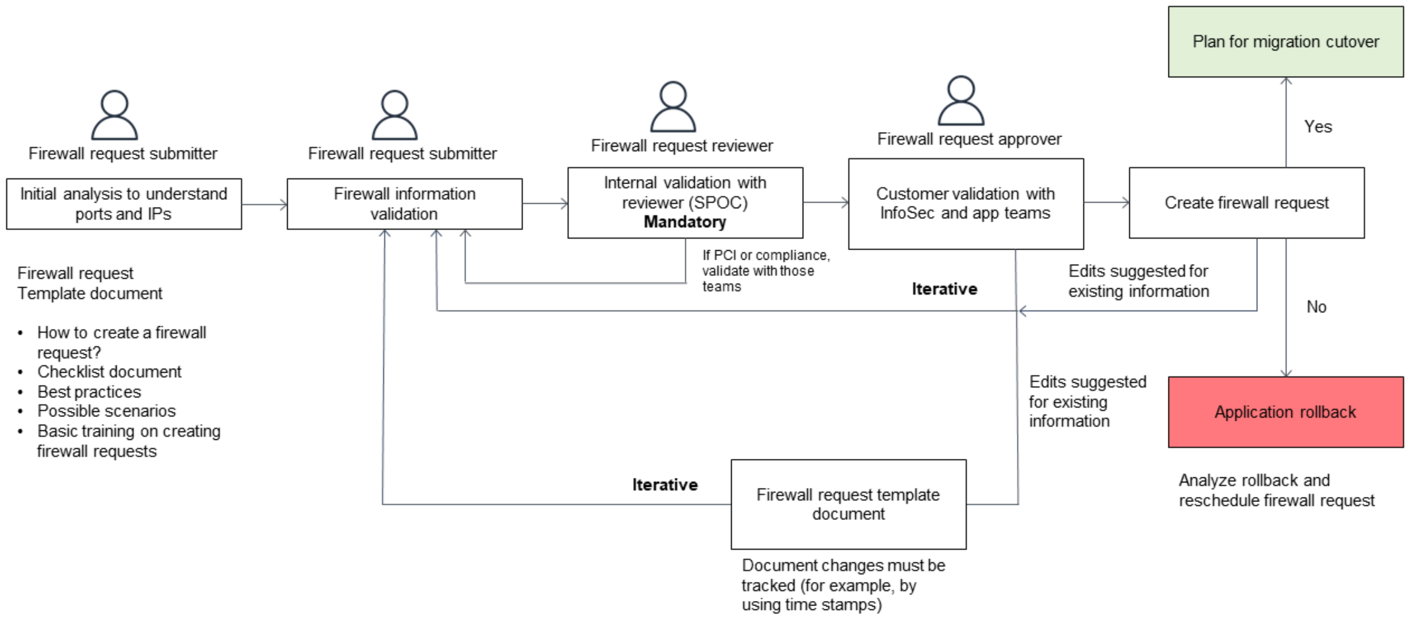
- This pattern describes a generic firewall request approval process. Requirements can vary for individual organizations.
- Make sure that you track changes to your firewall request document.

The following table shows the use cases for this pattern.

Does your organization have an existing firewall approval process?	Does your organization have an existing firewall request form?	Suggested action
Yes	Yes	Collaborate with AWS consultants or your migration specialists to implement your organization's process.
No	Yes	Use this pattern's firewall approval process. Use either an AWS consultant or a migration specialist from your organization to submit the firewall request blanket approval form.
No	No	Use this pattern's firewall approval process. Use either an AWS consultant or a migration specialist from your organization to submit the firewall request blanket approval form.

Architecture

The following diagram shows the steps for the firewall request approval process.



Tools

You can use scanner tools such as Palo Alto Networks or SolarWinds to analyze and validate firewalls and IP addresses.

Epics

Analyze the firewall request

Task	Description	Skills required
Analyze the ports and IP addresses.	The firewall request submitter completes an initial analysis to understand the required firewall ports and IP addresses. After this is complete, they request that your InfoSec team open the required ports and map the IP addresses.	AWS Cloud engineer, migration specialist

Validate the firewall request

Task	Description	Skills required
Validate the firewall informati on.	The AWS Cloud engineer schedules a meeting with your InfoSec team. During this meeting, the engineer examines and validates the firewall request information. Typically, the firewall request submitter is the same person as the firewall requester. This validation phase can become iterative based on the feedback given by the approver if anything is observed or recommended.	AWS Cloud engineer, migration specialist
Update the firewall request document.	After the InfoSec team shares their feedback, the firewall request document is edited, saved, and re-uploaded. This document is updated after each iteration. We recommend that you store this document in a version-controlled storage folder. This means that all changes are tracked and correctly applied.	AWS Cloud engineer, migration specialist

Submit the firewall request

Task	Description	Skills required
Submit the firewall request.	After the firewall request approver has approved the firewall blanket approval request, the AWS Cloud engineer submits the firewall request. The request specifies the ports that must be open and IP addresses that are required to map and update the AWS account. You can make suggestions or provide feedback after the firewall request is submitted . We recommend that you automate this feedback process and send any edits through a defined workflow mechanism.	AWS Cloud engineer, migration specialist

Ingest and migrate EC2 Windows instances into an AWS Managed Services account

Anil Kunapareddy and Venkatramana Chintha, Amazon Web Services

Summary

This pattern explains the step-by-step process of migrating and ingesting Amazon Elastic Compute Cloud (Amazon EC2) Windows instances into an Amazon Web Services (AWS) Managed Services (AMS) account. AMS can help you manage the instance more efficiently and securely. AMS provides operational flexibility, enhances security and compliance, and helps you optimize capacity and reduce costs.

This pattern starts with an EC2 Windows instance that you have migrated to a staging subnet in your AMS account. A variety of migration services and tools are available to perform this task, such as AWS Application Migration Service.

To make a change to your AMS-managed environment, you create and submit a request for change (RFC) for a particular operation or action. Using an AMS workload ingest (WIGS) RFC, you ingest the instance into the AMS account and create a custom Amazon Machine Image (AMI). You then create the AMS-managed EC2 instance by submitting another RFC to create an EC2 stack. For more information, see AMS Workload Ingest in the AMS documentation.

Prerequisites and limitations

Prerequisites

- An active, AMS-managed AWS account
- An existing landing zone
- Permissions to make changes in the AMS-managed VPC
- An Amazon EC2 Windows instance in a staging subnet in your AMS account
- Completion of the general prerequisites for migrating workloads using AMS WIGS
- Completion of the Windows prerequisites for migrating workloads using AMS WIGS

Limitations

- This pattern is for EC2 instances operating Windows Server. This pattern doesn't apply to instances running other operating systems, such as Linux.

Architecture

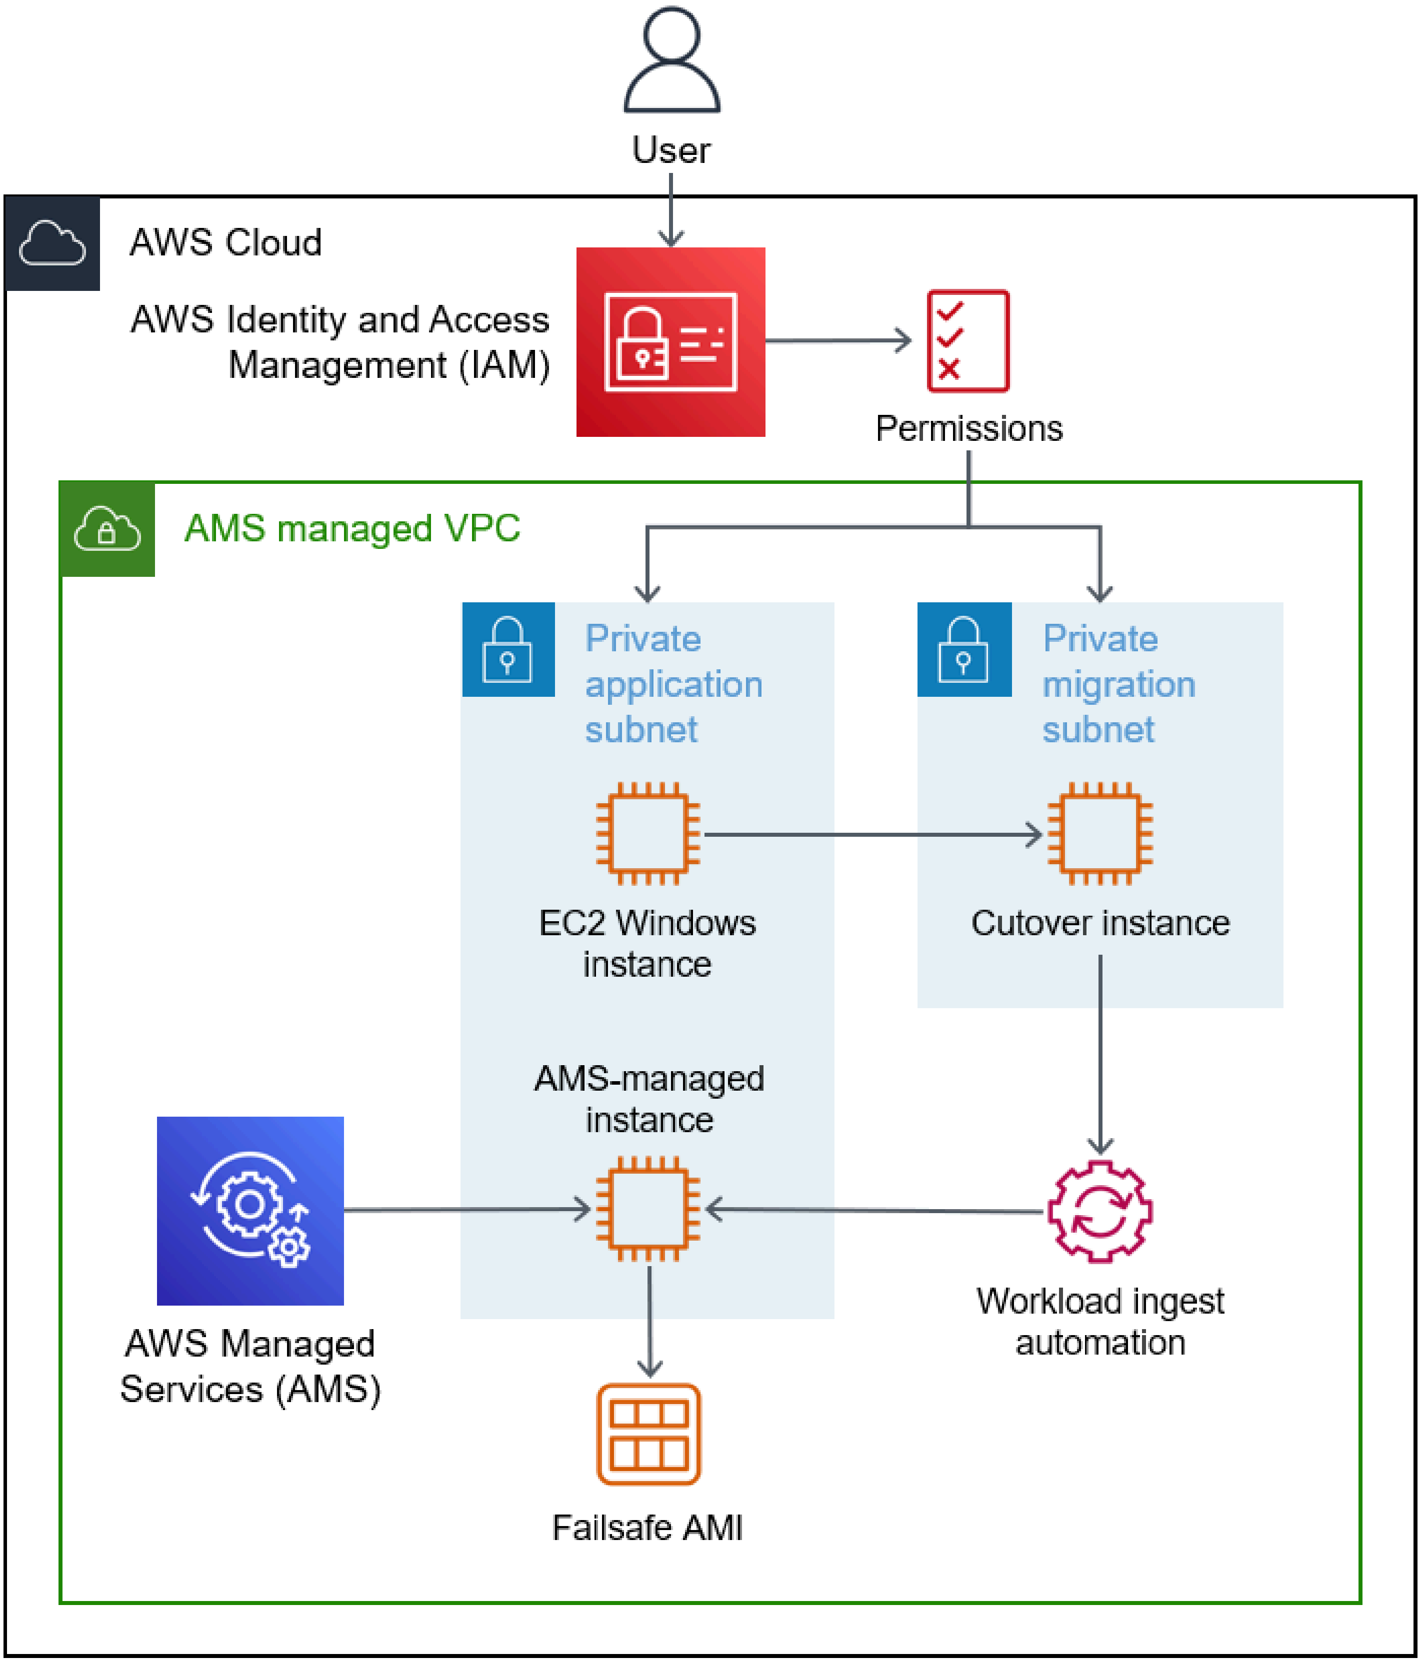
Source technology stack

Amazon EC2 Windows instance in a staging subnet in your AMS account

Target technology stack

Amazon EC2 Windows instance managed by AWS Managed Services (AMS)

Target architecture



User
AWS Cloud
AWS Identity and Access Management (IAM)
Permissions
AMS managed VPC
Private application subnet
Private migration subnet
EC2 Windows instance
Cutover instance
AMS-managed instance
AWS Managed Services (AMS)
Workload ingest automation
Failsafe AMI

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Managed Services (AMS) helps you operate more efficiently and securely by providing ongoing management of your AWS infrastructure, including monitoring, incident management, security guidance, patch support, and backup for AWS workloads.

Other services

- PowerShell is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.

Epics

Configure settings on the instance

Task	Description	Skills required
Change the DNS Client settings.	1. On the source EC2 instance, open Command Prompt as an administr ator, type `gpedit.msc` , and then press **Enter**. 2. In the Local Group Policy Editor, navigate to **Computer Configuration**, **Administrative Templates** ,**Network**, **DNS Client**. 3. For **Primary DNS suffix**, choose **Not configured**.	Migration engineer

Task	Description	Skills required
	4. For **Primary DNS suffix devolution**, choose **Not configured**.	
Change the Windows Update settings.	1. In the Local Group Policy Editor, navigate to **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Windows Update**. 2. For **Specify intranet Microsoft update service location**, choose **Not configured**. 3. For **Configure Automatic Updates**, choose **Not configured**. 4. For **Automatic Updates detection frequency**, choose **Not configured**. 5. Close the Local Group Policy Editor.	Migration engineer
Enable the firewall.	1. On the source EC2 instance, open Command Prompt as an administrator, type `services.msc` , and then press **Enter**. 2. In Windows Services, enable **Firewall**. 3. Close Windows Services.	Migration engineer

Prepare the instance for AMS WIGS

Task	Description	Skills required
Clean up and prepare the instance.	1. Using a bastion host and local credentials, create a Remote Desktop Protocol (RDP) connection to the EC2 instance in the staging subnet. 2. Remove all legacy software, antivirus software, and backup solutions that aren't required in AMS.	Migration engineer

Repair the sppnp.dll file.	1. Go to `C:\Windows\System32\sppnp.dll` .
	2. Rename `sppnp.dll` to `sppnp_old.dll` .
	3. Using PowerShell and administrator credentials, enter the following commands:
	`dism /online /cleanup-image /restorehealth`
	`sfc /scannow`
	4. Restart the EC2 Windows instance.
		Migration engineer

Run the pre-WIG validation script.	1. Download the Windows WIGS Pre-ingestion Validation zip file (`windows-prewings-`	Migration engineer

Task	Description	Skills required
	`valication.zip`) from [Migrating workloads : Windows pre-ingestion validation]() in the AMS documentation. 2. Run the Windows pre-WIG validation script and verify the results. 3. If the validation fails, fix the issue, and rerun the validation script until the validation succeeds.	
Create the failsafe AMI.	After the pre-WIG validation passes, create a pre-ingestion AMI as follows: 1. Choose **Deployment**, **Advanced stack components**, **AMI**, **Create**. 2. During creation, add a tag `Key=Name, Value=APPLICATION-ID_IngestReady` . 3. Wait until AMI is created before proceeding. For more information, see [AMI | Create]() in the AMS documentation.	Migration engineer

Ingest and validate the instance

Task	Description	Skills required
Submit the RFC to create the workload ingest stack.	Submit a request for change (RFC) to start the AMS WIGS. For instructions, see [Workload Ingest Stack: Creating](#) in the AMS documentation. This starts the workload ingestion and installs all the software required by AMS, including backup tools, Amazon EC2 management software, and antivirus software.	Migration engineer

Validate successful migration.	After the workload ingestion is complete, you can see the AMS-managed instance and AMS-ingested AMI.
	
	1. Log in to the AMS-manag ed instance with domain credentials.
	2. Validate the domain joining as follows:
	  a. In Windows Explorer, right-click **This PC**, and then choose **Properties**.
	  b. In the Device Specifica tion section, confirm that the domain appears in the **Full device name**.
	3. Validate the source and target disk drives.
		Migration engineer

Launch the instance in the target AMS account

Task	Description	Skills required
Submit the RFC to create an EC2 stack.	1. Using the AMS-ingested AMI of the Windows instance, prepare an RFC for an EC2 stack according to the instructions in [Create EC2 stack instance](#) in AMS documentation. In the EC2 stack RFC, provide all the parameters, including the server name, tags, target VPC, target subnet, instance type, target security groups, ingestion AMI, and role. 2. Submit the RFC for the EC2 stack, and then wait for the instance to be successfully created.	Migration engineer

Migrate a Couchbase Server database to Amazon EC2

Subhani Shaik, Amazon Web Services

Summary

This pattern describes how you can migrate Couchbase Server from an on-premises environment to Amazon Elastic Compute Cloud (Amazon EC2) on AWS.

Couchbase Server is a distributed NoSQL (JSON document) database that provides relational database capabilities. Migrating a Couchbase Server database to AWS can provide increased scalability, improved performance, cost efficiency, enhanced security, simplified management, and global reach, which can benefit applications that require high availability and low latency data access. You also gain access to advanced features through AWS managed services.

Couchbase Server on AWS provides the following key features:

- Memory-first architecture
- High availability, disaster recovery, and load balancing
- Multi-master, multi-Region deployment for optimal performance

For more information about key benefits, see the Additional information section and the Couchbase website.

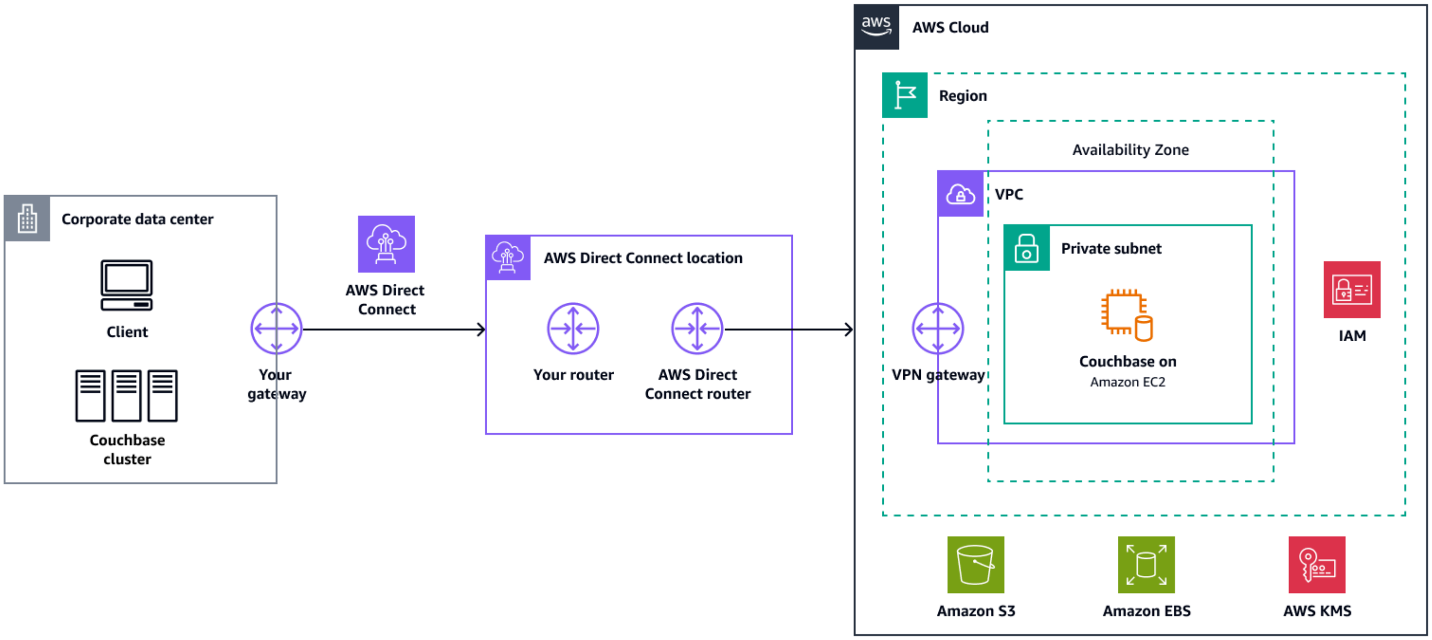
Prerequisites and limitations

Prerequisites

- An active AWS account with a virtual private cloud (VPC), two Availability Zones, private subnets, and a security group. For instructions, see Create a VPC in the Amazon Virtual Private Cloud (Amazon VPC) documentation.
- Connectivity enabled between source and target environments. For information about the TCX ports used by Couchbase Server, see the Couchbase documentation.

Architecture

The following diagram shows the high-level architecture for migrating Couchbase Server to AWS.



From the on-premises Couchbase cluster, data moves through a customer gateway by using [AWS Direct Connect](). The data passes through a router and an AWS Direct Connect route and reaches the VPC through an [AWS Virtual Private Network (AWS VPN)]() gateway. The VPC contains an EC2 instance that is running Couchbase Server. The AWS infrastructure also includes [AWS Identity and Access Management (IAM)]() for access control, [AWS Key Management Service (AWS KMS)]() for data encryption, [Amazon Elastic Block Store (Amazon EBS)]() for block storage, and [Amazon Simple Storage Service (Amazon S3)]() for data storage.

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Direct Connect links your internal network to a AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.

Best practices

- Installing and configuring Couchbase on different operating platforms
- Best practices for deploying Couchbase Server on AWS
- Creating a Couchbase cluster

- Performance best practices for Couchbase applications
- Security best practices for Couchbase Server
- Storage best practices for Couchbase Server databases

Epics

Deploy an Amazon EC2 instance for Couchbase Server

Task	Description	Skills required
Open the Amazon EC2 console.	Sign in to the AWS Management Console and open the Amazon EC2 console.	DevOps engineer, Couchbase administrator
Deploy an Amazon EC2 instance.	Launch an EC2 instance that matches the on-premises Couchbase Server configura tions. For more informati on about how to deploy an EC2 instance, see Launch an Amazon EC2 instance in the Amazon EC2 documentation.	DevOps engineer, Couchbase administrator

Install and configure Couchbase Server on Amazon EC2

Task	Description	Skills required
Install a Couchbase cluster.	Review Couchbase Server deployment guidelines before you install Couchbase Server on Amazon EC2. To install Couchbase Server, see the Couchbase Server documentation	Couchbase administrator

Task	Description	Skills required
Configure the cluster.	To configure the cluster, see Cluster Configuration Options in the Couchbase documentation.	Couchbase administrator

Add a new node and rebalance the Couchbase cluster

Task	Description	Skills required
Add a node for the EC2 instance.	Add the newly deployed EC2 instance that has Couchbase installed to the existing on-premises cluster. For instructions, see Add a Node and Rebalance in the Couchbase Server documentation.	Couchbase administrator
Rebalance the cluster.	The rebalancing process makes the newly added node with the EC2 instance an active member of the Couchbase cluster. For instructions, see Add a Node and Rebalance in the Couchbase Server documentation	Couchbase administrator

Reconfigure connections

Task	Description	Skills required
Remove the on-premises nodes and rebalance.	You can now remove the on-premises nodes from the cluster. After removing the	Couchbase administrator

Task	Description	Skills required
	nodes, follow the rebalance process to redistribute data, indexes, event processing, and query processing among available nodes in the cluster. For instructions, see Remove a Node and Rebalance in the Couchbase Server documenta tion.	
Update connection parameter s.	Update your application's connection parameters to use the new Amazon EC2 IP address, so your application can connect to the new node.	Couchbase application developer

Additional information

Key benefits

Migrating your Couchbase database to AWS provides the following advantages:

Scalability. You can scale your Couchbase cluster up or down based on demand without having to manage physical hardware, so you can easily accommodate fluctuating data volumes and application usage. AWS provides:

- Vertical and horizontal scaling options
- Global deployment capabilities
- Load balancing across AWS Regions
- Database scaling solutions
- Content delivery optimization

Performance optimization. AWS provides a high-performance network infrastructure and optimized instance types to ensure fast data access and low latency for your Couchbase database.

- High performance computing (HPC) options
- Global content delivery through Amazon CloudFront
- Multiple storage options
- Advanced database services, including Amazon Relational Database Service (Amazon RDS) and Amazon DynamoDB
- Low-latency connections with AWS Direct Connect

Cost optimization. Select the appropriate instance type and configuration to balance performance and cost based on your workload. Pay only for the resources you use. This can potentially reduce your operational costs by eliminating the need to manage on-premises hardware and taking advantage of AWS Cloud economies of scale.

- Reserved instances can help you plan ahead and reduce your costs substantially when you use Couchbase on AWS.
- Automatic scaling prevents over-provisioning and helps you optimize your utilization and cost efficiencies.

Enhanced security. Benefit from the robust security features on AWS, such as data encryption, access controls, and security groups to help protect the sensitive data you store in Couchbase. Additional benefits:

- The AWS Shared Responsibility Model clearly differentiates between the security *of* the cloud (AWS responsibility) and security *in* the cloud (customer responsibility).
- AWS compliance supports major security standards.
- AWS provides advanced encryption options.

- AWS Identity and Access Management (IAM) helps you manage secure access to your resources.

Simplified management. AWS provides managed services for Couchbase, so you can focus on application development instead of managing the underlying infrastructure.

Global reach. You can deploy your Couchbase cluster across multiple AWS Regions to achieve low latency for users around the world. You can deploy your databases entirely in the cloud or in a hybrid environment. You can safeguard your data with built-in enterprise-grade security and fast, efficient bidirectional synchronization of data from the edge to the cloud. At the same time, you can simplify development with a consistent programming model for building web and mobile apps.

Business continuity:

- **Data backup and recovery**. In case of an issue, you can use AWS Backup to ensure data resiliency and easy recovery. For disaster recovery options, see the AWS Well-Architected Framework documentation.
- **Couchbase multi-Region deployment**: To deploy a Couchbase database in a multi-Region AWS environment, you can subscribe to Couchbase Server in AWS Marketplace, use AWS CloudFormationtemplates to create separate Couchbase clusters in each Region, and then configure cross-Region replication to synchronize data across Regions. This configuration ensures high availability and geographic redundancy across multiple Regions. For more information, see Deploy Couchbase Server Using AWS Marketplace in the Couchbase documentation.

Infrastructure agility:

- Rapid resource provisioning and deprovisioning
- Global infrastructure reach
- Automatic scaling based on demand
- Infrastructure as Code (IaC) for consistent deployments
- Multiple instance types that are optimized for different workloads

Innovation enablement:

- Access to the latest technologies, including AI/ML, IoT, and analytics
- Managed services, which reduce operational overhead
- Modern application development practices

- Serverless computing options

Operational excellence:

- Centralized monitoring and logging
- Automated resource management
- Predictive maintenance capabilities
- Enhanced visibility into resource usage
- Streamlined deployment processes

Modernization opportunities:

- Microservices architecture
- DevOps practices implementation
- Cloud-native application development
- Legacy application modernization

Competitive advantages:

- Faster time to market
- Improved customer experience
- Data-driven decision-making
- Enhanced business intelligence

Migrate Db2 for LUW to Amazon EC2 by using log shipping to reduce outage time

Feng Cai, Ambarish Satarkar, and Saurabh Sharma, Amazon Web Services

Summary

When customers migrate their IBM Db2 for LUW (Linux, UNIX, and Windows) workloads to Amazon Web Services (AWS), using Amazon Elastic Compute Cloud (Amazon EC2) with the Bring Your Own License (BYOL) model is the fastest way. However, migrating large amounts of data from on-premises Db2 into AWS can be a challenge, especially when the outage window is short. Many customers try to set the outage window to less than 30 minutes, which leaves little time for the database itself.

This pattern covers how to accomplish a Db2 migration with a short outage window by using transaction log shipping. This approach applies to Db2 on a little-endian Linux platform.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Db2 instance running on EC2 instance that matches the on-premises file system layouts
- An Amazon Simple Storage Service (Amazon S3) bucket accessible to the EC2 instance
- An AWS Identity and Access Management (IAM) policy and role to make programmatic calls to Amazon S3
- Synchronized time zone and system clocks on Amazon EC2 and the on-premises server
- The on-premises network connected to AWS through AWS Site-to-Site VPN or AWS Direct Connect

Limitations

- The Db2 on-premises instance and Amazon EC2 must be on the same platform family.
- The Db2 on-premises workload must be logged. To block any unlogged transaction, set `blocknonlogged=yes` in the database configuration.

Product versions

- Db2 for LUW version 11.5.9 and later

Architecture

Source technology stack

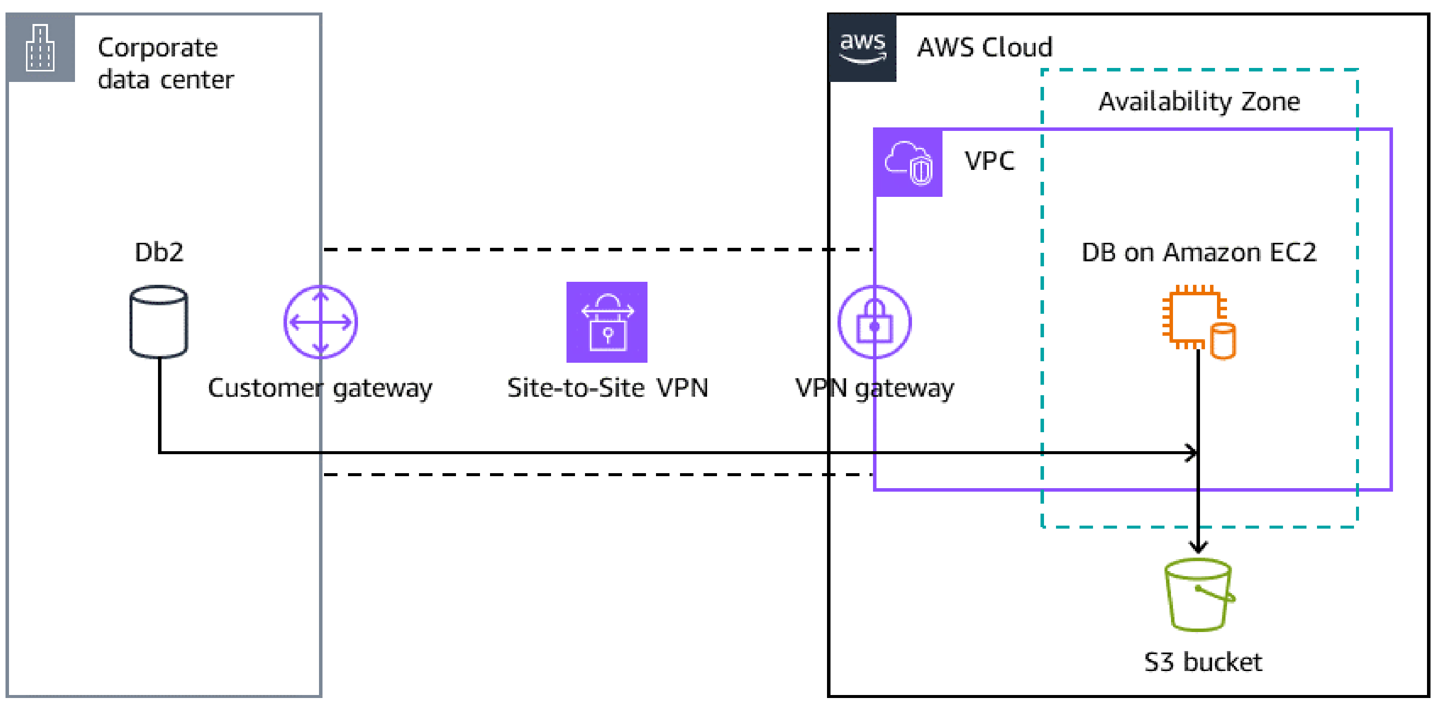
- Db2 on Linux x86_64

Target technology stack

- Amazon EBS
- Amazon EC2
- AWS Identity and Access Management (IAM)
- Amazon S3
- AWS Site-to-Site VPN or Direct Connect

Target architecture

The following diagram shows one Db2 instance running on-premises with a virtual private network (VPN) connection to Db2 on Amazon EC2. The dotted lines represent the VPN tunnel between your data center and the AWS Cloud.



Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Direct Connect links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Site-to-Site VPN helps you pass traffic between instances that you launch on AWS and your own remote network.

Other tools

- db2cli is the Db2 interactive CLI command.

Best practices

- On the target database, use gateway endpoints for Amazon S3 to access the database backup image and log files in Amazon S3.
- On the source database, use AWS PrivateLink for Amazon S3 to send the database backup image and log files to Amazon S3.

Epics

Set environment variables

Task	Description	Skills required
Set environment variables.	This pattern uses the following names: • Instance name: `db2inst1` • Database name: `SAMPLE` You can change them to fit your environment.	DBA

Configure the on-premises Db2 server

Task	Description	Skills required

Set up the AWS CLI.	To download and install the latest version of the AWS CLI, run the following commands:
	`$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"`
	`unzip awscliv2.zip`
	`sudo ./aws/install`
		Linux administrator

Set up a local destination for Db2 archive logs.	To keep the target database on Amazon EC2 in sync with the on-premises source database, the latest transacti on logs need be retrieved from the source.	DBA

Task	Description	Skills required

	In this setup, `/db2logs` is set by `LOGARCHMETH2` on the source as a staging area. The archived logs in this directory will be synced into Amazon S3 and accessed by Db2 on Amazon EC2. The pattern uses `LOGARCHMETH2` because `LOGARCHMETH1` might have been configured to use a third-party vendor tool that AWS CLI command cannot access. To retrieve the logs, run the following command:
	`db2 connect to sample`
	`db2 update db cfg for SAMPLE using LOGARCHMETH2 disk:/db2logs`	

Run an online database backup.	Run an online database backup, and save it to the local backup file system: `db2 backup db sample online to /backup`	DBA

Set up the S3 bucket and IAM policy

Task	Description	Skills required
Create an S3 bucket.	Create an S3 bucket for the on-premises server to send the backup Db2 images and	AWS systems administrator

Task	Description	Skills required
	log files to on AWS. The bucket will also be accessed by Amazon EC2: `aws s3api create-bucket --bucket logshipmig-db2 --region us-east-1`	

Task	Description	Skills required

Create an IAM policy.	The `db2bucket.json` file contains the IAM policy to access the Amazon S3 bucket:
	``{
	    "Version":
	 "2012-10-17",
	    "Statement": [
	        {
	            "Effect":
	 "Allow",
	            "Action": [
	
	 "kms:GenerateDataK
	ey",
	
	 "kms:Decrypt",
	
	 "s3:PutObject",
	
	 "s3:GetObject",
	
	 "s3:AbortMultipart
	Upload",
	
	 "s3:ListBucket",
	
	 "s3:DeleteObject",
	
	 "s3:GetObjectVersi
	on",
	
	 "s3:ListMultipartU
	ploadParts"
	            ],
	            "Resource":
	 [
	
	 "arn:aws:s3:::logs
	hipmig-db2/*",```
		AWS administrator, AWS systems administrator

Task	Description	Skills required

	<pre>"arn:aws:s3:::logs
	hipmig-db2"
	            ]
	        }
	    ]
	}</pre> To create the policy, use the following AWS CLI command: <pre>aws iam create-policy \\
	      --policy-name
	 db2s3policy \\
	      --policy-document
	 file://db2bucket.j
	son</pre> The JSON output shows the Amazon Resource Name (ARN) for the policy, where `aws_account_id` represents your account ID: <pre>"Arn": "arn:aws:
	iam::aws_account_i
	d:policy/db2s3policy"</pre>	

Task	Description	Skills required
Attach the IAM policy to the IAM role used by the EC2 instance.	In most AWS environments, a running EC2 instance has an IAM Role set by your systems administrator. If the IAM role is not set, create the role and choose **Modify IAM role** on the EC2 console to associate the role with the EC2 instance that hosts the Db2 database. Attach the IAM policy to the IAM role with the policy ARN: `aws iam attach-role-policy \ --policy-arn "arn:aws:iam::aws_account_id:policy/db2s3policy" \ --role-name db2s3role` After the policy is attached, any EC2 instance associated with the IAM role can access the S3 bucket.	AWS administrator, AWS systems administrator

Send the source database backup image and log files to Amazon S3

Task	Description	Skills required
Configure the AWS CLI on the on-premises Db2 server.	Configure the AWS CLI with the `Access Key ID` and `Secret Access Key` generated in the earlier step:	AWS administrator, AWS systems administrator

Task	Description	Skills required

	<pre>$ aws configure
	AWS Access Key ID
	 [None]: *************
	AWS Secret Access Key
	 [None]: *********
	******************
	Default region name
	 [None]: us-east-1
	Default output format
	 [None]: json</pre>	

Send the backup image to Amazon S3.	Earlier, an online database backup was saved to the `/backup` local directory. To send that backup image to the S3 bucket, run the following command:
	<pre>aws s3 sync /backup
	 s3://logshipmig-db2/
	SAMPLE_backup</pre>
		AWS administrator, Migration engineer

Task	Description	Skills required
Send the Db2 archive logs to Amazon S3.	Sync the on-premises Db2 archive logs with the S3 bucket that can be accessed by the target Db2 instance on Amazon EC2: `aws s3 sync /db2logs s3://logshipmig-db2/SAMPLE_LOG` Run this command periodically by using cron or other scheduling tools. The frequency depends on how often the source database archives transaction log files.	AWS administrator, Migration engineer

Connect Db2 on Amazon EC2 to Amazon S3 and start the database sync

Task	Description	Skills required
Create a PKCS12 keystore.	Db2 uses a Public-Key Cryptography Standards (PKCS) encryption keystore to keep the AWS access key secure. Create a keystore and configure the source Db2 instance to use it: `gsk8capicmd_64 -keydb -create -db "/home/db2inst1/.keystore/db2s3.p12" -pw "<password>" -type pkcs12 -stash`	DBA

Task	Description	Skills required
	`db2 "update dbm cfg using keystore_location /home/db2inst1/.keystore/db2s3.p12 keystore_type pkcs12"`	

Create the Db2 storage access alias.	To create the [storage access alias](https://www.ibm.com/docs/en/db2/11.5?topic=commands-catalog-storage-access), use the following script syntax:
	
	`db2 "catalog storage access alias <alias_name> vendor S3 server <S3 endpoint> container '<bucket_name>'"`
	
	For example, your script might look like the following:
	
	`db2 "catalog storage access alias DB2AWSS3 vendor S3 server s3.us-east-1.amazonaws.com container 'logshipmig-db2'"`
		DBA

Task	Description	Skills required

Set the staging area.	By default, Db2 uses `DB2_OBJECT_STORAGE_LOCAL_STAGING_PATH` as the staging area to upload and download files to and from Amazon S3. The default path is `sqllib/tmp/RemoteStorage.xxxx` under the instance home directory, with `xxxx` referring to the Db2 partition number. Note that the staging area must have enough capacity to hold the backup images and log files. You can use the registry to point the staging area into a different directory.
	
	We also recommend using `DB2_ENABLE_COS_SDK=ON`, `DB2_OBJECT_STORAGE_SETTINGS=EnableStreamingRestore`, and the link to the `awssdk` library to bypass the Amazon S3 staging area for database backup and restore:
	
	`#By root:`
	`cp -rp /home/db2inst1/sqllib/lib64/awssdk/RHEL/7.6/* /home/db2inst1/sqllib/lib64/`
	
	`#By db2 instance owner:`
		DBA

Task	Description	Skills required
	``` db2set DB2_OBJEC T_STORAGE_LOCAL_ST AGING_PATH=/db2stage db2set DB2_ENABL E_COS_SDK=ON Db2set DB2_OBJEC T_STORAGE_SETTINGS =EnableStreamingRe store db2stop db2start ```	
Restore the database from the backup image.	Restore the target database on Amazon EC2 from the backup image in the S3 bucket: ``` db2 restore db sample from DB2REMOTE:// DB2AWSS3/logshipmig- db2/SAMPLE_backup replace existing ```	DBA

Task	Description	Skills required

Roll forward the database.	After the restore is complete, the target database will be put into rollforward pending state. Configure `LOGARCHMETH1` and `LOGARCHMETH2` so that Db2 knows where to get the transaction log files:
	`db2 update db cfg for SAMPLE using LOGARCHMETH1 'DB2REMOTE://DB2AWSS3//SAMPLE_LOGS/'`
	`db2 update db cfg for SAMPLE using LOGARCHMETH2 OFF`
	Start database rollforward:
	`db2 ROLLFORWARD DATABASE sample to END OF LOGS`
	This command processes all log files that have been transferred to the S3 bucket. Run it periodically based on the frequency of the `s3 sync` command on the on-premises Db2 servers. For example, if `s3 sync` runs at each hour, and it takes 10 minutes to sync all the log files, set the command to run at 10 minutes after each hour.
		DBA

Bring Db2 on Amazon EC2 online during the cutover window

Task	Description	Skills required

Bring the target database online.	During the cutover window, do one of the following:
	
	• Put the on-premises database in `ADMIN MODE`, and run the `s3 sync` command to force the last transaction log to be archived.
	• Shut down the database.
	
	After the last transaction log is synced into Amazon S3, run the `ROLLFORWARD` command for the final time:
	
	`db2 rollforward DB sample to END OF LOGS`
	`db2 rollforward DB sample complete`
	
	`Rollforward Status`
	`....`
	`Rollforward status = not pending`
	`....`
	`DB20000I The ROLLFORWARD command completed successfully.`
	
	`db2 activate db sample`
	`DB20000I The ACTIVATE DATABASE command`
		DBA

Task	Description	Skills required
	`completed successfully.` Bring the target database online, and point the application connections to Db2 on Amazon EC2.	

Troubleshooting

Issue	Solution
If multiple databases have the same instance name and database name on different hosts (DEV, QA, PROD), backups and logs might go to the same subdirectory.	Use different S3 buckets for DEV, QA, and PROD, and add the hostname as subdirectory prefix to avoid confusion.
If there are multiple backup images in the same location, you will get the following error when you restore: `SQL2522N More than one backup file matches the time stamp value provided for the backed up database image.`	In the `restore` command, add the timestamp of the backup: `db2 restore db sample from DB2REMOTE://DB2AWSS3/logshipmig-db2/SAMPLE_backup taken at 20230628164042 replace existing`

Migrate Db2 for LUW to Amazon EC2 with high availability disaster recovery

Feng Cai, Aruna Gangireddy, and Venkatesan Govindan, Amazon Web Services

Summary

When customers migrate their IBM Db2 LUW (Linux, UNIX, and Windows) workload to Amazon Web Services (AWS), using Amazon Elastic Compute Cloud (Amazon EC2) with the Bring Your Own License (BYOL) model is the fastest way. However, migrating large amounts of data from on-premises Db2 into AWS can be a challenge, especially when the outage window is short. Many customers try to set the outage window to less than 30 minutes, which leaves little time for the database itself.

This pattern covers how to accomplish a Db2 migration with a short outage window by using Db2 high availability disaster recovery (HADR). This approach applies to Db2 databases that are on the little-endian Linux platform and are not using Data Partitioning Feature (DPF).

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Db2 instance running on an Amazon EC2 instance that matches the on-premises file system layouts
- An Amazon Simple Storage Service (Amazon S3) bucket accessible to the EC2 instance
- An AWS Identity and Access Management (IAM) policy and role to make programmatic calls to Amazon S3
- Synchronized time zone and system clocks on Amazon EC2 and the on-premises server
- The on-premises network connected to AWS through AWS Site-to-Site VPN or AWS Direct Connect
- Communication between the on-premises server and Amazon EC2 on HADR ports

Limitations

- The Db2 on-premises instance and Amazon EC2 must be on the same platform family.
- HADR is not supported in a partitioned database environment.

- HADR doesn’t support the use of raw I/O (direct disk access) for database log files.
- HADR doesn’t support infinite logging.
- `LOGINDEXBUILD` must be set to `YES`, which will increase the log usage for rebuilding the index.
- The Db2 on-premises workload must be logged. Set `blocknonlogged=yes` in the database configuration to block any unlogged transactions.

Product versions

- Db2 for LUW version 11.5.9 and later

Architecture

Source technology stack

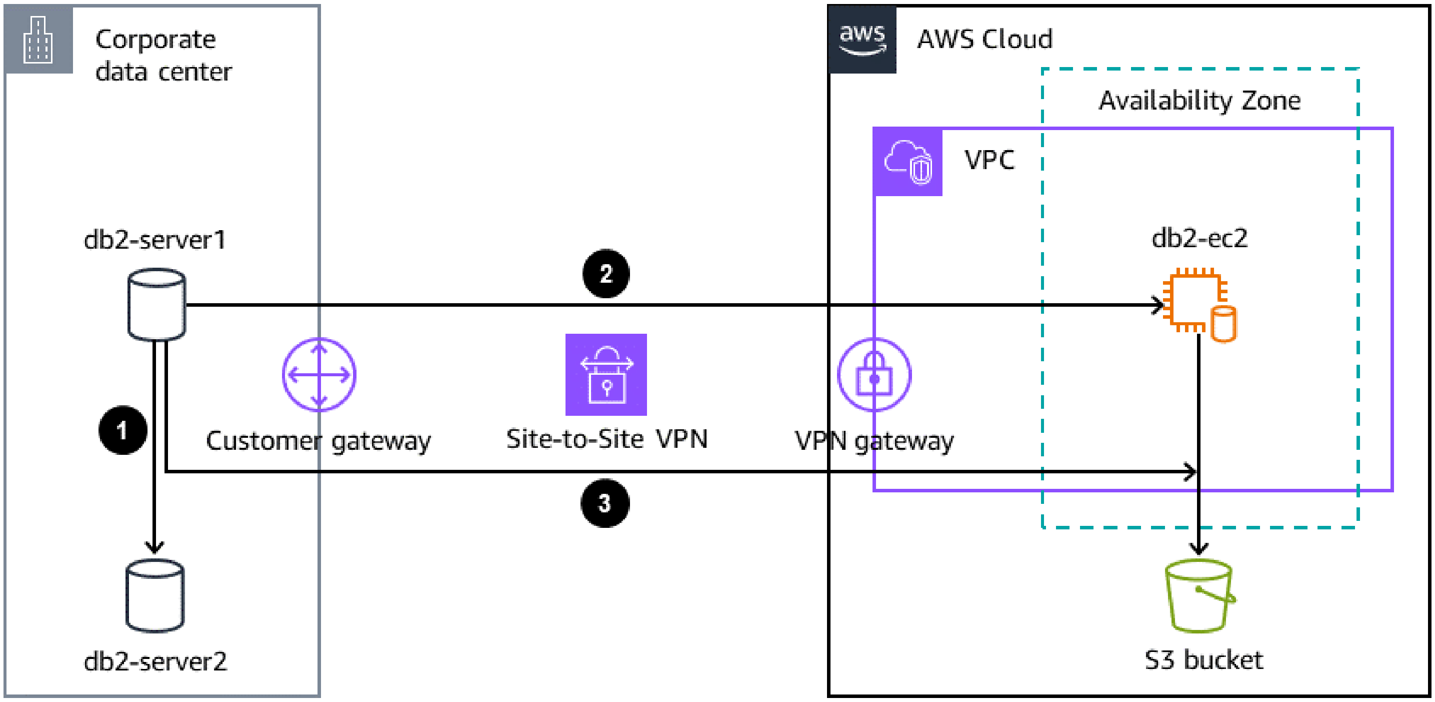
- Db2 on Linux x86_64

Target technology stack

- Amazon EC2
- AWS Identity and Access Management (IAM)
- Amazon S3
- AWS Site-to-Site VPN

Target architecture

In the following diagram, Db2 on premises is running on `db2-server1` as the primary. It has two HADR standby targets. One standby target is on premises and is optional. The other standby target, `db2-ec2`, is on Amazon EC2. After the database is cut over to AWS, `db2-ec2` becomes the primary.



1. Logs are streamed from the primary on-premises database to the standby on-premises database.
2. Using Db2 HADR, logs are streamed from the primary on-premises database through Site-to-Site VPN to Db2 on Amazon EC2.
3. Db2 backup and archive logs are sent from the primary on-premises database to the S3 bucket on AWS.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Direct Connect links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Site-to-Site VPN helps you pass traffic between instances that you launch on AWS and your own remote network.

Other tools

- db2cli is the Db2 interactive CLI command.

Best practices

- On the target database, use gateway endpoints for Amazon S3 to access the database backup image and log files in Amazon S3.
- On the source database, use AWS PrivateLink for Amazon S3 to send the database backup image and log files to Amazon S3.

Epics

Set environment variables

Task	Description	Skills required
Set environment variables.	This pattern uses the following names and ports: 1. Db2 on-premises hostname: `db2-server1` 2. HADR standby hostname: `db2-server2` (if HADR is currently running on premises) 3. Amazon EC2 hostname: `db2-ec2` 4. Instance name: `db2inst1` 5. Database name: `SAMPLE` 6. HADR ports:	DBA

Task	Description	Skills required
	• `db2-server1: 50010` • `db2-server2: 50011` • `db2-ec2: 50012` You can change them to fit your environment.	

Configure the on-premises Db2 server

Task	Description	Skills required

Set up AWS CLI.	To download and install the latest version of AWS CLI, run the following commands:
	`$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"`
	`unzip awscliv2.zip`
	`sudo ./aws/install`
		Linux administrator

Set up a local destination for Db2 archive logs.	Conditions such as heavy update batch jobs and network slowdowns can cause the HADR standby server to have a lag. To catch up, the standby server needs the transaction logs from the primary server. The sequence of places to request logs is the following:	DBA

Task	Description	Skills required

	• The active log directory on the primary server
	• The `LOGARCHMETH1` or `LOGARCHMETH2` location on the standby server
	• The `LOGARCHMETH1` or `LOGARCHMETH2` location on the primary server
	
	In this setup, `/db2logs` is set by `LOGARCHMETH2` on the source as a staging area. The archived logs in this directory will be synced into Amazon S3 and accessed by Db2 on Amazon EC2. The pattern uses `LOGARCHMETH2` because `LOGARCHMETH1` might have been configured to use a third-party vendor tool that the AWS CLI command cannot access:
	
	`db2 connect to sample`
	`db2 update db cfg for SAMPLE using LOGARCHMETH2 disk:/db2logs`	

Run an online database backup.	Run an online database backup, and save it to the local backup file system: `db2 backup db sample online to /backup`	DBA

Set up the S3 bucket and IAM policy

Task	Description	Skills required
Create an S3 bucket.	Create an S3 bucket for the on-premises server to send the backup Db2 images and log files to on AWS. The bucket will be accessed by Amazon EC2: ```aws s3api create-bucket --bucket hadrmig-db2 --region us-east-1```	AWS administrator
Create an IAM policy.	The `db2bucket.json` file contains the IAM policy for accessing the S3 bucket: ```{ "Version": "2012-10-17", "Statement": [{ "Effect": "Allow", "Action": ["kms:GenerateDataKey", "kms:Decrypt", "s3:PutObject", "s3:GetObject", "s3:AbortMultipartUpload", "s3:ListBucket",```	AWS administrator, AWS systems administrator

Task	Description	Skills required

	``
	 "s3:DeleteObject",
	
	 "s3:GetObjectVersi
	on",
	
	 "s3:ListMultipartU
	ploadParts"
	            ],
	            "Resource":
	 [
	
	 "arn:aws:s3:::hadr
	mig-db2/*",
	
	 "arn:aws:s3:::hadr
	mig-db2"
	            ]
	        }
	    ]
	}
	``
	To create the policy, use the following AWS CLI command:
	``
	aws iam create-policy \
	      --policy-name
	 db2s3hapolicy \
	      --policy-document
	 file://db2bucket.j
	son
	``
	The JSON output shows the Amazon Resource Name (ARN) for the policy, where `aws_account_id` represents your account ID:	

Task	Description	Skills required
	```"Arn": "arn:aws:iam::aws_account_id:policy/db2s3hapolicy"```	
Attach the IAM policy to the IAM role.	Usually, the EC2 instance with Db2 running would have an IAM role assigned by the systems administrator. If no IAM role is assigned, you can choose **Modify IAM role** on the Amazon EC2 console. Attach the IAM policy to the IAM role associated with the EC2 instance. After the policy is attached, the EC2 instance can access the S3 bucket: ```aws iam attach-role-policy --policy-arn "arn:aws:iam::aws_account_id:policy/db2s3hapolicy" --role-name db2s3harole```	

Send the source database backup image and log files to Amazon S3

Task	Description	Skills required
Configure AWS CLI on the on-premises Db2 server.	Configure AWS CLI with the `Access Key ID` and `Secret Access Key` that you generated earlier:	AWS administrator, AWS systems administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>$ aws configure
AWS Access Key ID
 [None]: *************
AWS Secret Access Key
 [None]: *********
****
Default region name
 [None]: us-east-1
Default output format
 [None]: json</code></pre></td><td></td></tr>
<tr><td>Send the backup image to Amazon S3.</td><td>Earlier, an online database backup was saved to the <code>/backup</code> local directory. To send that backup image to the S3 bucket, run the following command:<pre><code>aws s3 sync /backup
 s3://hadrmig-db2/S
AMPLE_backup</code></pre></td><td>AWS administrator, AWS systems administrator</td></tr>
</table>

Task	Description	Skills required
Send the Db2 archive logs to Amazon S3.	Sync the on-premises Db2 archive logs with the Amazon S3 bucket that can be accessed by the target Db2 instance on Amazon EC2: `aws s3 sync /db2logs s3://hadrmig-db2/SAMPLE_LOGS` Run this command periodically by using cron or other scheduling tools. The frequency depends on how often the source database archives transaction log files.	

Connect Db2 on Amazon EC2 to Amazon S3 and start the initial database sync

Task	Description	Skills required
Create a PKCS12 keystore.	Db2 uses a Public-Key Cryptography Standards (PKCS) encryption keystore to keep the AWS access key secure. Create a keystore, and configure the source Db2 to use it: `gsk8capicmd_64 -keydb -create -db "/home/db2inst1/.keystore/db2s3.p12" -pw "<password>" -type pkcs12 -stash`	DBA

Task	Description	Skills required
	```db2 "update dbm cfg using keystore_location /home/db2inst1/.keystore/db2s3.p12 keystore_type pkcs12"```	

Create the Db2 storage access alias.	Db2 uses a storage access alias to access Amazon S3 directly with the `INGEST`, `LOAD`, `BACKUP DATABASE`, or `RESTORE DATABASE` commands.
	
	Because you assigned an IAM role to the EC2 instance, `USER` and `PASSWORD` are not required:
	
	`db2 "catalog storage access alias <alias_name> vendor S3 server <S3 endpoint> container '<bucket_name>'"`
	
	For example, your script might look like the following:
	
	`db2 "catalog storage access alias DB2AWSS3 vendor S3 server s3.us-east-1.amazonaws.com container 'hadrmig-db2'"`
		DBA

Task	Description	Skills required

Set the staging area.	We recommend using `DB2_ENABLE_COS_SDK =ON` , `DB2_OBJECT_STORAGE_SETTINGS =EnableStreamingRestore` , and the link to the `awssdk` library to bypass the Amazon S3 staging area for database backup and restore:
	
	`#By root:`
	`cp -rp /home/db2inst1/sqllib/lib64/awssdk/RHEL/7.6/* /home/db2inst1/sqllib/lib64/`
	
	`#By db2 instance owner:`
	`db2set DB2_OBJECT_STORAGE_LOCAL_STAGING_PATH=/db2stage`
	`db2set DB2_ENABLE_COS_SDK=ON`
	`db2set DB2_OBJECT_STORAGE_LOCAL_STAGING_PATH=/db2stage`
	`db2stop`
	`db2start`
		DBA

Task	Description	Skills required

Restore the database from the backup image.	Restore the target database on Amazon EC2 from the backup image in the S3 bucket:
	`db2 create db sample on /data1`
	`db2 restore db sample from DB2REMOTE:// DB2AWSS3/hadrmig-db2/ SAMPLE_backup replace existing`
		DBA

Set up HADR with no HADR on premises

Task	Description	Skills required
Configure the on-premises Db2 server as the primary.	Update the database configuration settings for HADR on `db2-server1` (the on-premises source) as the primary. Set `HADR_SYNCMODE` to `SUPERASYNC` mode, which has the shortest transaction response time: `db2 update db cfg for sample using HADR_LOCAL_HOST db2-server1 HADR_LOCAL_SVC 50010 HADR_REMOTE_HOST db2-ec2 HADR_REMOTE_SVC 50012 HADR_REMOTE_INST db2inst1 HADR_SYNCMODE`	DBA

Task	Description	Skills required
	SUPERASYNC DB20000 I The UPDATE DATABASE CONFIGURATION command completed successfu lly Some network delays between the on-premises data center and AWS are expected. (You can set a different HADR_SYNCMODE value based on network reliability. For more informati on, see the Related resources section).	
Change the target database log archive destination.	Change the target database log archive destination to match the Amazon EC2 environment: `db2 update db cfg for SAMPLE using LOGARCHMETH1 'DB2REMOTE://DB2AWSS3//SAMPLE_LOGS/' LOGARCHMETH2 OFF DB20000I The UPDATE DATABASE CONFIGURATION command completed successfully`	DBA

Task	Description	Skills required
Configure HADR for Db2 on the Amazon EC2 server.	Update database configura tion for HADR on `db2-ec2` as standby: `db2 update db cfg for sample using HADR_LOCAL_HOST db2-ec2 HADR_LOCA L_SVC 50012 HADR_REMO TE_HOST db2-server1 HADR_REMOTE_SVC 50010 HADR_REMOTE_INST db2inst1 HADR_SYNC MODE SUPERASYN C DB20000I The UPDATE DATABASE CONFIGURATION command completed successfu lly`	DBA

Task	Description	Skills required
Verify HADR setup.	Verify the HADR parameters on the source and target Db2 servers. To verify the setup on `db2-server1` , run the following command: `db2 get db cfg for sample|grep HADR HADR database role = PRIMARY HADR local host name (HADR_LOCAL_HOST) = db2-server1 HADR local service name (HADR_LOCAL_SVC) = 50010 HADR remote host name (HADR_REMOTE_HOST) = db2-ec2 HADR remote service name (HADR_REMOTE_SVC) = 50012 HADR instance name of remote server (HADR_REMOTE_INST) = db2inst1 HADR timeout value (HADR_TIMEOUT) = 120 HADR target list (HADR_TARGET_LIST) = HADR log write synchronization mode`	DBA

Task	Description	Skills required

	``
	    (HADR_SYNCMODE) =
	 NEARSYNC
	 HADR spool log data
	 limit (4KB)
	 (HADR_SPOOL_LIMIT) =

	 HADR SSL certifica
	te label
	 (HADR_SSL_LABEL) =
	 HADR SSL Hostname
	 Validation
	 (HADR_SSL_HOST_VAL) =
	 OFF
	``
	
	The `HADR_LOCAL_HOST` , `HADR_LOCAL_SVC` , `HADR_REMOTE_HOST` , and `HADR_REMOTE_SVC`	

Task	Description	Skills required
	parameters indicate the one primary and one standby HADR setup.	

Start up the Db2 HADR instance.	Start the Db2 HADR instance on the standby server `db2-ec2` first:
	`db2 start hadr on db sample as standby`
	`DB20000I  The START HADR ON DATABASE command completed successfully.`
	Start Db2 HADR on the primary (source) server `db2-server1` :
	`db2 start hadr on db sample as primary`
	`DB20000I  The START HADR ON DATABASE command completed successfully.`
	The HADR connection between Db2 on premises and on Amazon EC2 has now been successfully established. The Db2 primary server `db2-server1` starts streaming transaction log records to `db2-ec2` in real time.
		DBA

Set up HADR when HADR exists on premises

Task	Description	Skills required
Add Db2 on Amazon EC2 as an auxiliary standby.	If HADR is running on the on-premises Db2 instance, you can add Db2 on Amazon EC2 as an auxiliary standby using `HADR_TARGET_LIST` by running the following commands on `db2-ec2`: `db2 update db cfg for sample using HADR_LOCAL_HOST db2-ec2 HADR_LOCAL_SVC 50012 HADR_REMOTE_HOST db2-server1 HADR_REMOTE_SVC 50010 HADR_REMOTE_INST db2inst1 HADR_SYNCMODE SUPERASYNC DB20000I The UPDATE DATABASE CONFIGURATION command completed successfully. db2 update db cfg for sample using HADR_TARGET_LIST "db2-server1:50010 |db2-server2:50011 " DB20000I The UPDATE DATABASE CONFIGURATION command completed successfully.`	DBA

Task	Description	Skills required
Add the auxiliary standby information to the on-premises servers.	Update `HADR_TARGET_LIST` on the two on-premises servers (primary and standby). On `db2-server1`, run the following code: `db2 update db cfg for sample using HADR_TARGET_LIST "db2-server2:50011|db2-ec2:50012" DB20000I The UPDATE DATABASE CONFIGURATION command completed successfully. SQL1363W One or more of the parameters submitted for immediate modification were not changed dynamically. For these configuration parameters, the database must be shutdown and reactivated before the configuration parameter changes become effective.`  On `db2-server2`, run the following code:	DBA

Task	Description	Skills required
	`db2 update db cfg for sample using HADR_TARGET_LIST "db2-server1:50010|db2-ec2:50012" DB20000I The UPDATE DATABASE CONFIGURATION command completed successfully. SQL1363W One or more of the parameters submitted for immediate modification were not changed dynamically. For these configuration parameters, the database must be shutdown and reactivated before the configuration parameter changes become effective.`	

Task	Description	Skills required
Verify HADR setup.	Verify the HADR parameters on the source and target Db2 servers. On `db2-server1` , run the following code: `db2 get db cfg for sample|grep HADR HADR database role = PRIMARY HADR local host name (HADR_LOCAL_HOST) = db2-server1 HADR local service name (HADR_LOCAL_SVC) = 50010 HADR remote host name (HADR_REMOTE_HOST) = db2-server2 HADR remote service name (HADR_REMOTE_SVC) = 50011 HADR instance name of remote server (HADR_REMOTE_INST) = db2inst1 HADR timeout value (HADR_TIMEOUT) = 120 HADR target list (HADR_TARGET_LIST) = db2-server2:50011|db2-ec2:50012`	

Task	Description	Skills required

	``
	 HADR log write
	 synchronization mode
	     (HADR_SYNCMODE) =
	 NEARSYNC
	 HADR spool log data
	 limit (4KB)
	 (HADR_SPOOL_LIMIT) =
	 AUTOMATIC(52000)
	 HADR log replay delay
	 (seconds) (HADR_REP
	LAY_DELAY) = 0
	 HADR peer window
	 duration (seconds)
	 (HADR_PEER_WINDOW) = 0
	 HADR SSL certifica
	te label
	 (HADR_SSL_LABEL) =
	 HADR SSL Hostname
	 Validation
	 (HADR_SSL_HOST_VAL) =

	 limit (4KB)
	 (HADR_SPOOL_LIMIT) =
	 AUTOMATIC(52000)
	 HADR log replay delay
	 (seconds) (HADR_REP
	LAY_DELAY) = 0
	 HADR peer window
	 duration (seconds)
	 (HADR_PEER_WINDOW) = 0
	 HADR SSL certifica
	te label
	 (HADR_SSL_LABEL) =
	 HADR SSL Hostname
	 Validation
	 (HADR_SSL_HOST_VAL) =
	 OFF
	``
	
	On db2-ec2, run the following code:	

Task	Description	Skills required

	``
	db2 get db cfg for
	 sample|grep HADR
	 HADR database role
	
	         = STANDBY
	 HADR local host name
	               (HADR_LOC
	AL_HOST) = db2-ec2
	 HADR local service
	 name
	 (HADR_LOCAL_SVC) =
	 50012
	 HADR remote host name
	              (HADR_REM
	OTE_HOST) = db2-serve
	r1
	 HADR remote service
	 name
	 (HADR_REMOTE_SVC) =
	 50010
	 HADR instance name
	 of remote server
	 (HADR_REMOTE_INST) =
	 db2inst1
	 HADR timeout value
	
	 (HADR_TIMEOUT) = 120
	 HADR target list
	              (HADR_TAR
	GET_LIST) = db2-serve
	r1:50010|db2-serve
	r2:50011
	 HADR log write
	 synchronization mode
	     (HADR_SYNCMODE) =
	 SUPERASYNC
	 HADR spool log data
	 limit (4KB)
	 (HADR_SPOOL_LIMIT) =
	 AUTOMATIC(52000)
	``	

Task	Description	Skills required

	<pre>HADR log replay delay (seconds) (HADR_REPLAY_DELAY) = 0
	HADR peer window duration (seconds) (HADR_PEER_WINDOW) = 0
	HADR SSL certificate label (HADR_SSL_LABEL) =
	HADR SSL Hostname Validation (HADR_SSL_HOST_VAL) = OFF</pre> The `HADR_LOCAL_HOST` , `HADR_LOCAL_SVC` , `HADR_REMOTE_HOST` , `HADR_REMOTE_SVC` , and `HADR_TARGET_LIST` parameters indicate the one primary and two standby HADR setup.	

Task	Description	Skills required

Stop and start Db2 HADR.	`HADR_TARGET_LIST` is now set up on all three servers. Each Db2 server is aware of the other two. Stop and restart HADR (brief outage) to take advantage of the new configuration.
	
	On `db2-server1`, run the following commands:
	
	`db2 stop hadr on db sample`
	`db2 deactivate db sample`
	`db2 activate db sample`
	
	On `db2-server2`, run the following commands:
	
	`db2 deactivate db sample`
	`db2 start hadr on db sample as standby`
	`SQL1766W  The command completed successfully`
	
	On `db2-ec2`, run the following commands:
	
	`db2 start hadr on db sample as standby`
	`SQL1766W  The command completed successfully`
	
	On `db2-server1`, run the following commands:
		DBA

Task	Description	Skills required

	<pre>db2 start hadr on db
	 sample as primary
	SQL1766W The command
	 completed successfully</pre> The HADR connection between Db2 on premises and on Amazon EC2 is now successfully established. The Db2 primary server `db2-server1` starts streaming transaction log records to both `db2-server2` and `db2-ec2` in real time.	

Make Db2 on Amazon EC2 as primary during the cutover window

Task	Description	Skills required

Make sure that there is no HADR lag on the standby server.	Check HADR status from the primary server `db2-server1`. Don't be alarmed when `HADR_STATE` is in `REMOTE_CATCHUP` status, which is normal when `HADR_SYNCMODE` is set to `SUPERASYNC`. The `PRIMARY_LOG_TIME` and `STANDBY_REPLAY_LOG_TIME` show that they are in sync: <pre>db2pd -hadr -db sample
	
	    HADR_ROLE = PRIMARY</pre>
		DBA

Task	Description	Skills required

	``
	     REPLAY_TYPE =
	 PHYSICAL
	
	   HADR_SYNCMODE =
	 SUPERASYNC
	
	  STANDBY_ID = 2
	
	 LOG_STREAM_ID = 0
	
	      HADR_STATE =
	 REMOTE_CATCHUP
	.....
	
	 PRIMARY_LOG_TIME =
	 10/26/2022 02:11:32.
	000000 (1666750292)
	
	 STANDBY_LOG_TIME =
	 10/26/2022 02:11:32.
	000000 (1666750292)
	              STANDBY_R
	EPLAY_LOG_TIME =
	 10/26/2022 02:11:32.
	000000 (1666750292)
	``	

Task	Description	Skills required

Run HADR takeover.	To complete the migration, make `db2-ec2` the primary database by running the HADR takeover command. Use the command `db2pd` to verify the `HADR_ROLE` value:
	
	`db2 TAKEOVER HADR ON DATABASE sample`
	`DB20000I  The TAKEOVER HADR ON DATABASE command completed successfully.`
	
	`db2pd -hadr -db sample`
	`Database Member 0 -- Database SAMPLE -- Active -- Up 0 days 00:03:25 -- Date 2022-10-26-02.46.45.048988`
	
	`HADR_ROLE = PRIMARY`
	`REPLAY_TYPE = PHYSICAL`
	
	To complete the migration to AWS, point the application connections to Db2 on Amazon EC2.	

Troubleshooting

Issue	Solution
If you use NAT for firewall and security reasons, the host can have two IP addresses (one internal and one external), which can cause an HADR IP address check failure. The `START HADR ON DATABASE` command will return the following message: `HADR_LOCAL_HOST:HADR_LOCAL_SVC (-xx-xx-xx-xx.:50011 (xx.xx.xx .xx:50011)) on remote database is different from HADR_REMOTE_HOST:H ADR_REMOTE_SVC (xx-xx-xx- xx.:50011 (x.x.x.x:50011)) on local database.`	To support HADR in a NAT environment, you can configure the `HADR_LOCAL_HOST` with both the internal and external address. For example, if the Db2 server has the internal name `host1` and the external name `host1E`, `HADR_LOCAL_HOST` can be `HADR_LOCA L_HOST: "host1 | host1E"` .

Migrate an on-premises Microsoft SQL Server database to Amazon EC2 using Application Migration Service

Senthil Ramasamy, Amazon Web Services

Summary

This pattern describes the steps for migrating a Microsoft SQL Server database from an on-premises data center to an Amazon Elastic Compute Cloud (Amazon EC2) instance. It uses the AWS Application Migration Service (AWS MGN) to rehost your database using an automated lift-and-shift migration. AWS MGN performs block-level replication of your source database server.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Microsoft SQL Server database in an on-premises data center

Limitations

- Your network bandwidth may be limited between the on-premises data center and AWS.
- AWS MGN is limited to databases that are hosted on standalone servers with dedicated storage. It doesn't support migrating clustered database systems and database systems where the rate of change exceeds a network's throughput.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Product versions

- All versions of Microsoft SQL Server database
- Windows and Linux operating systems that support AWS MGN

Architecture

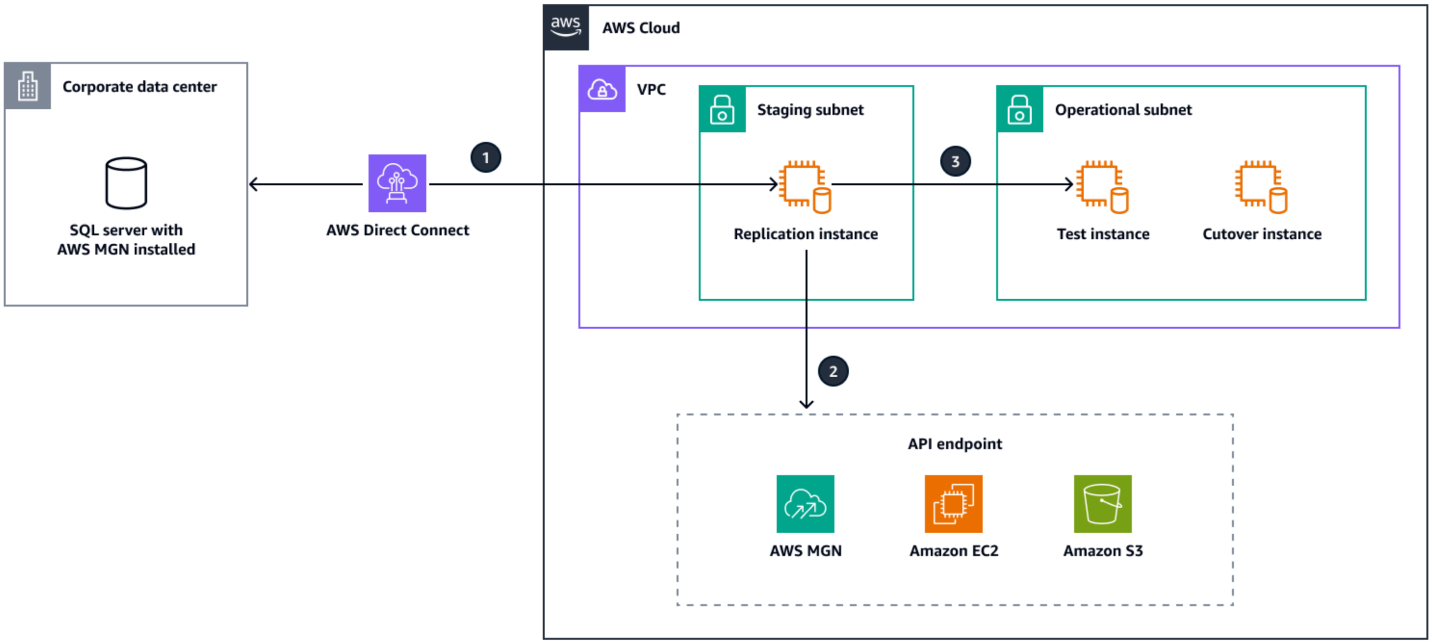
Source technology stack

An on-premises Microsoft SQL Server database

Target technology stack

A Microsoft SQL Server database on an Amazon EC2 instance

Target architecture



This architecture uses AWS MGN to replicate data from an on-premises corporate data center to AWS. The diagram shows the data replication process, API communications, and the test and cutover phases.

1. Data replication:
   - AWS MGN replicates data from the on-premises corporate data center to AWS and initiates ongoing replication of changes.
   - Replication servers in the staging subnet receive and process the data.
2. API communication:
   - Replication servers connect to AWS MGN, Amazon EC2, and Amazon Simple Storage Service (Amazon S3) API endpoints through TCP port 443.
   - AWS MGN manages the migration.
   - Amazon EC2 manages instance operations.
3. Test and cutover:
   - Test instances launch in the operational subnet using replicated data.
   - After successful testing, AWS MGN creates cutover instances for the final migration.

Tools

- AWS Application Migration Service (AWS MGN) helps you rehost (*lift and shift*) applications to the AWS Cloud without change and with minimal downtime.
- AWS Direct Connect links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Best practices

- Set up API regional endpoints for AWS MGN, Amazon EC2, and Amazon S3 in the virtual private cloud (VPC) to prohibit public access from the internet.
- Set up AWS MGN launch settings to launch target database servers in a private subnet.
- Allow only required ports in database security groups.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Set up AWS MGN

Task	Description	Skills required
Configure AWS MGN.	Search for the AWS Applicati on Migration Service in the AWS Management Console, and initiate the setup process. This will create a replicati on template and redirect you to the MGN console	DBA, Migration engineer

Task	Description	Skills required
	Source servers page. As you configure the MGN service, choose a service role from the generated list.	
Add source server.	Add details of your on-premises source database server, and then add the server.	DBA, Migration engineer
Install the AWS MGN agent on the source server.	Download the AWS MGN agent installer to your local system, and transfer the installer to your source database server. To validate the installer hash, see Validating the downloaded AWS Replication Agent installer for Windows 2012.	DBA, Migration engineer

Install AWS MGN agent on source machines

Task	Description	Skills required
Generate client IAM credentials.	Before you install the AWS MGN agent, generate AWS credentials by creating a new IAM user with the appropriate permissions. For more information, see AWS managed policies for AWS Application Migration Service and Generating the required AWS credentials.	DBA, Migration engineer

Task	Description	Skills required
Install the agent on the source server.	Install the agent on the source machine that hosts the Microsoft SQL Server database. For more informati on, see Installing the AWS Replication Agent on Windows servers. Provide the following AWS credentials: • AWS Region • AWS access key ID • AWS secret access key Your unique AWS credentials enable the AWS MGN agent to authenticate and perform migration tasks.	App owner, DBA, Migration engineer

Task	Description	Skills required
Choose disks to replicate.	After entering your AWS credentials, the installer verifies that your server meets the minimum requirements for agent installation (for example, whether the server has enough disk space to install the AWS MGN agent). The installer displays the volume labels and storage details. To replicate your database using AWS MGN service, select the applicable disks on your source server. Enter the path of each disk, separated by commas. If you want to replicate all of the disks, leave the path blank. After you confirm the selected disks, the installation proceeds.	DBA, Migration engineer

Task	Description	Skills required
Monitor synchronization progress.	AWS Replication Agent initiates the synchronization process by first taking a snapshot of the selected disks and then replicating the data. You can monitor the synchronization progress from the **Source server** page in the AWS MGN console. For more information, see [Monitor the server in the migration lifecycle]().	DBA, Migration engineer

Replication using AWS MGN

Task	Description	Skills required
Manage replication progress.	After you start the initial synchronization, your source server appears in the AWS MGN console, where you can manage and monitor the migration. The console displays an estimated time for complete replication, which is based on the total size of selected disks and available network bandwidth.	DBA, Migration engineer
Verify the synchronization.	After the disks on the source server are fully synchronized, verify that all selected disks are listed as fully synced and	App owner, DBA, Migration engineer

Task	Description	Skills required
	no errors are reported in the console. The AWS MGN console will then automatically transitio n the migration lifecycle status to **Ready for testing**, indicating that the replicate d environment in AWS is prepared for performance and functionality testing.	

Test and cut over

Task	Description	Skills required
Configure launch settings.	Choose the source server in the AWS MGN console, and update the launch settings for the target test instance. From the source **Server details** page, navigate to the **Launch settings** tab to configure the test instance. Choose a cost-effective instance type and Amazon Elastic Block Store (Amazon EBS) volume type, and then configure the security groups and network requirements. For more information, see [Launch settings]().	DBA, Migration engineer

Task	Description	Skills required
Launch the target test instance.	Navigate to the AWS MGN console of your synchroni zed source machine, and launch a target test instance by choosing **Test and cut over** and then **Launch test instances**. This creates a launch job that deploys the test instance using your configured settings. The instance launches in the AWS Cloud and replicates your source database server's environme nt. Monitor the launch progress from the **Launch history** page, where you can track the instance creation and address any issues.	DBA, Migration engineer

Task	Description	Skills required
Validate the target test instance.	Validate the Amazon EC2 database server: 1. Ensure the AWS MGN console shows that the test instance is running successfully. 2. Use an RDP client to log in. 3. From the **Start** menu, open **SQL Server Configuration Manager**. 4. Verify the status of SQL Server services, including SQL Server (`MSSQLSERVER`) and SQL Server Agent, ensuring they are intact and set to the correct startup type. 5. Compare disk settings and configurations between the test instance and the source database server, confirming that drive letters, volumes, disk allocations, and necessary directories are mapped correctly. 6. Connect to the SQL Server on the test Amazon EC2 instance and verify that all source databases have migrated and appear in the database list.	DBA, Migration engineer

Task	Description	Skills required
	Conduct validation tests to ensure the database functions as expected.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Rename the server.</td><td>AWS MGN migration involves a storage-level copy of your on-premises source server. Your SQL Server EC2 instance contains only the original source server's details in its binaries, so update the binary information to reflect the new server's name.

Use SQL Server Management Studio (SSMS) to connect to your SQL Server EC2 instance.
Check the server’s name:
<pre><code>SELECT @@SERVERNAME
 AS 'Current Server
 Name';</code></pre>
Rename the SQL Server instance by replacing <code>NEW_SERVER_NAME</code> with the name of your server:
<pre><code>EXEC sp_dropserver
 'OLD_SERVER_NAME'
EXEC sp_addserver
 'NEW_SERVER_NAME',
 'local';</code></pre>
Verify that the server name is correct:
<pre><code>SELECT @@SERVERNAME
 AS 'Updated Server
 Name';</code></pre>
</td><td>DBA, Migration engineer</td></tr>
</table>

Task	Description	Skills required
	5. Restart the SQL Server instance.	

Task	Description	Skills required
Launch the cutover instance.	In the AWS MGN console, on the **Source servers** page, confirm that the migration lifecycle status of the server is **Ready for cutover**. Configure the launch settings for the cutover instance, ensuring that the settings mirror your on-premises environment. Before initiating the cutover, shut down your on-premises database, which ensures the following: • All ongoing transactions are complete. • No new transactions will occur during the cutover process. • Data synchronization between the source and target disks is complete. Initiate the cutover instance in the AWS MGN console. When the cutover instance is operational, log in to the instance and perform the following tests: 1. Ensure that SQL Server starts correctly and that the databases are accessibl e.	App owner, DBA, Migration engineer, Migration lead

Task	Description	Skills required
	2. Validate that your data is intact and consistent with the source server. 3. Run any application tests to confirm that they perform as expected. 4. In the AWS MGN console, set the migration state to **Cutover complete**. 5. Begin routing traffic to the EC2 instance.	

Troubleshooting

Issue	Solution
The initial synchronization fails at the authentication step.	This is a network connectivity issue. The replication server can't connect to AWS MGN.

Migrate VMware VMs with HCX Automation by using PowerCLI

Giri Nadiminty and Hassan Adekoya, Amazon Web Services

Naveen Deshwal, None

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to migrate VMware on-premises virtual machines (VMs) to VMware Cloud on AWS by using VMware Hybrid Cloud Extension (HCX) Automation powered by VMware PowerCLI scripts. PowerCLI is a command-line tool that's built on Windows PowerShell. It helps you manage VMware software, and automates infrastructure and migration tasks.

You can adapt this pattern for migration between any combination of vCenters, software-defined data centers (SDDCs), and cloud environments. The PowerCLI scripts included with this pattern use automation instead of mouse clicks for all VM configuration and scheduling tasks, so they provide time savings in migration activities and help reduce the risk of human error.

Prerequisites and limitations

Prerequisites

- A VMware Cloud on AWS account with SDDC
- An existing on-premises or cloud-based vCenter or SDDC
- A user account with the necessary permissions for source and destination vCenters or SDDCs
- HCX Site Pairing with HCX Network Extension (HCX-NE) configured between source and destination vCenters or SDDCs
- VMware PowerCLI installed on your server of choice

Limitations

- If the source vCenter uses cross-vCenter NSX, the PowerCLI module will not work. Use a scripting method (such as Python) with the HCX API instead of PowerCLI.

- If the migrated VMs need new names or IP addresses, use a scripting method (such as Python) with the HCX API.
- This pattern doesn't populate the .csv file, which is required. You can populate the file by using VMware vRealize Network Insight (vRNI) or some other method.

Product versions

- VMware vSphere version 5 or later
- VMware HCX version 4.4 or later
- VMware PowerCLI version 12.7 or later

Architecture

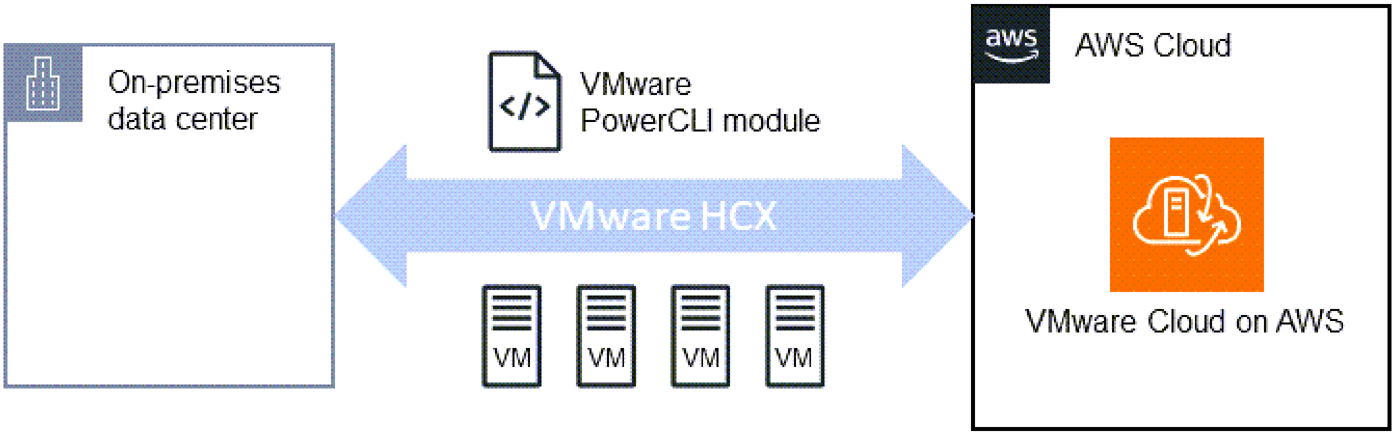
Source technology stack

- On-premises or cloud-based VMware

Target technology stack

- VMware Cloud on AWS

Target architecture



Tools

AWS services

- VMware Cloud on AWS is a service jointly designed by AWS and VMware to help you migrate and extend your on-premises VMware vSphere-based environments to the AWS Cloud.

Other tools

- VMware Hybrid Cloud Extension (HCX) is a utility for migrating workloads from your on-premises VMware environment to VMware Cloud on AWS without changing the underlying platform. Note: This product was formerly known as Hybrid Cloud Extension and NSX Hybrid Connect. This pattern uses HCX for VM migration.
- VMware PowerCLI is a command-line tool for automating VMware vSphere and vCloud management. You run PowerCLI commands in Windows PowerShell by using PowerShell cmdlets. This pattern uses PowerCLI to run migration commands.

Code

Simple, self-contained script

We recommend that you use this single-machine script for initial testing, to verify that configuration options are accepted and behave as expected. For instructions, see the Epics section.

```
<# Manual Variables #>
$HcxServer = "[enterValue]"
$SrcNetworkName = "[enterValue]"
$DstNetworkName = "[enterValue]"
$DstComputeName = "[enterValue]"
$DstDSName = "[enterValue]"
$DstFolderName = "[enterValue]"
$vmName = "[enterValue]"

<# Environment Setup #>
Connect-HCXServer -Server $HcxServer
$HcxDstSite = Get-HCXSite -Destination
$HcxSrcSite = Get-HCXSite -Source
$SrcNetwork = Get-HCXNetwork -Name $SrcNetworkName -Type VirtualWire -Site $HcxSrcSite
$DstNetwork = Get-HCXNetwork -Name $DstNetworkName -Type NsxtSegment -Site $HcxDstSite
$DstCompute = Get-HCXContainer -Name $DstComputeName -Site $HcxDstSite
$DstDS = Get-HCXDatastore -Name $DstDSName -Site $HcxDstSite
$DstFolder = Get-HCXContainer -name $DstFolderName -Site $HcxDstSite
$vm = Get-HCXVM -Name $vmName
```

```
<# Migration #>
$NetworkMapping = New-HCXNetworkMapping -SourceNetwork $SrcNetwork -DestinationNetwork
 $DstNetwork
$NewMigration = New-HCXMigration -VM $vm -MigrationType vMotion -SourceSite $HcxSrcSite
 -DestinationSite $HcxDstSite -Folder $DstFolder -TargetComputeContainer $DstCompute
 -TargetDatastore $DstDS -NetworkMapping $NetworkMapping -DiskProvisionType Thin
 -UpgradeVMTools $True -RemoveISOs $True -ForcePowerOffVm $True -RetainMac $True -
UpgradeHardware $True -RemoveSnapshots $True
```

Full-featured, .csv-based script

After testing is complete, you can use the following script in your production environments. For instructions, see the Epics section.

```
<# Schedule #>
write-host("Getting Time for Scheduling")
$startTime = [DateTime]::Now.AddDays(12)
$endTime = [DateTime]::Now.AddDays(15)

<# Migration #>
Connect-HCXServer -Server [enterValue]
write-host("Getting Source Site")
$HcxSrcSite = Get-HCXSite
write-host("Getting Target Site")
$HcxDstSite = Get-HCXSite -Destination
$HCXVMS = Import-CSV .\Import_VM_list.csv
ForEach ($HCXVM in $HCXVMS) {
    $DstFolder = Get-HCXContainer $HCXVM.DESTINATION_VM_FOLDER -Site $HcxDstSite
    $DstCompute = Get-HCXContainer $HCXVM.DESTINATION_COMPUTE  -Site $HcxDstSite
    $DstDatastore = Get-HCXDatastore $HCXVM.DESTINATION_DATASTORE -Site $HcxDstSite
    $SrcNetwork = Get-HCXNetwork $HCXVM.SOURCE_NETWORK -Type VirtualWire -Site
 $HcxSrcSite
    $DstNetwork = Get-HCXNetwork $HCXVM.DESTINATION_NETWORK -Type NsxtSegment -Site
 $HcxDstSite
    $NetworkMapping = New-HCXNetworkMapping -SourceNetwork $SrcNetwork -
DestinationNetwork $DstNetwork
    $NewMigration = New-HCXMigration -VM (Get-HCXVM $HCXVM.VM_NAME) -MigrationType
 Bulk -SourceSite $HcxSrcSite -DestinationSite $HcxDstSite -Folder $DstFolder -
TargetComputeContainer $DstCompute -TargetDatastore $DstDatastore -NetworkMapping
 $NetworkMapping -DiskProvisionType Thin -UpgradeVMTools $True -RemoveISOs $True -
ForcePowerOffVm $True -RetainMac $True -UpgradeHardware $True -RemoveSnapshots $True -
ScheduleStartTime $startTime -ScheduleEndTime $endTime
    Start-HCXMigration -Migration $NewMigration -Confirm:$false
```

```
}
```

Epics

Collect information for manual variables

Task	Description	Skills required
Find the source and destinati on vCenter and SDDC server names.	PowerCLI scripts require the variables described in this epic. You can gather this information in advance for ease of script use. In the HCX section of the vSphere console, choose **Infrastructure**, **Site Pairing**. Make a note of the source and destination server names that are displayed.	Cloud architect
Find the source and destinati on HCX names.	In the HCX section of the vSphere console, choose **System**, **Administration**. Make a note of the source and destination HCX names that are displayed.	Cloud architect
Find the source and destinati on network names.	In the HCX section of the vSphere console, choose **System**, **Network Extension**. Make a note of the source and destination network names. **Note** As an alternative, you can get the source and destination	Cloud architect

Task	Description	Skills required
	network names by using the PowerCLI **Get-HCXNetwork** and **Get-HCXNetwork-Destination** commands after you connect to the HCX server.	
Gather additional information from the vSphere console.	On the vSphere console, collect the following information: • Names of VMs that you want to migrate • Destination compute environment (cluster/host) • Destination datastore • Destination VM folder name	Cloud architect

Make migration decisions

Task	Description	Skills required
Determine migration options.	Determine the following: • `MigrationType` – The HCX-assisted migration types are vMotion, bulk, cold, and RAV. Your choice depends on your downtime requirements, network bandwidth, migration time frame, and workload	Cloud architect

Task	Description	Skills required
	type. For more information, see the AWS blog post [Migrating Workloads to VMware Cloud on AWS with Hybrid Cloud Extension (HCX)](). • `DiskProvisionType (Thin, Thick)` • `UpgradeVMTools ($True, $False)` • `RemoveISOs ($True, $False)` • `ForcePowerOffVm ($True, $False)` • `RetainMac ($True, $False)` • `UpgradeHardware ($True, $False)` • `RemoveSnapshots ($True, $False)` For more Information about each option, see the [VMware developer documentation]().	

Run the simple script for initial testing

Task	Description	Skills required
Copy the script.	The simple version of the script is self-contained in a single file. You can use it to	Cloud architect

Task	Description	Skills required
	test the migration of a single machine. Copy the first script from the *Code* section of this pattern and store it on the computer that has the VMware PowerCLI module installed. (To install PowerCLI, follow the instructions in the VMware documentation.)	
Set script variables.	Set all the variables in the `Manual Variables` section of the script.	Cloud architect
Set migration variables.	Set all the `New-HCXMigration` settings in the `Migration` section of the script.	Cloud architect
Specify sites.	(Optional) If the source or destination has multiple sites, specify the sites manually in the `Environment Setup` section of the script. If the source and destination have single sites, the script will automatically look the information up.	Cloud architect

Task	Description	Skills required
Run the script.	On the server where PowerCLI is installed, from an elevated PowerShell window, run the script, and enter your credentials when prompted.	Cloud architect
Validate the script.	Confirm that VM migration has been initiated.	Cloud architect

Run the full-featured script to migrate multiple VMs

Task	Description	Skills required
Create and populate the .csv file.	Create a .csv file called `Import_VM_list.csv` on your computer and populate it with the following sample content: `VM_NAME,DESTINATION_VM_FOLDER,DESTINATION_COMPUTE,DESTINATION_DATASTORE,SOURCE_NETWORK,DESTINATION_NETWORK [enterValue],[enterValue],[enterValue],[enterValue],[enterValue],[enterValue]` Replace each `[enterValue]` in the .csv file with the information you collected earlier.	Cloud architect

Task	Description	Skills required
	Note You can populate the .csv file by using VMware vRealize Network Insight (vRNI) or some other method.	
Copy the script.	The full-featured version of the script uses informati on from an external .csv file to automatically migrate multiple VMs. Copy the second script from the *Code* section of this pattern and store it on the computer that has the VMware PowerCLI module installed, in the same folder as the .csv file.	Cloud architect

Task	Description	Skills required
Modify the script.	Edit the script to make the following changes: • Line 7: Set the HCX server variable (`Connect-HCXServer`). • Line 12: (Optional) If you set the .csv filename differently, update it. • Lines 3-4: (Optional) Set the schedule. • Line 20: (Optional) Specify the `New-HCXMigration` settings in the `Migration` section. • Lines 9 and 11: (Optional) If the source or destination includes multiple sites, specify the desired sites manually.	Cloud architect
Run the script.	On the server where PowerCLI is installed, from an elevated PowerShell window, run the script, and enter your credentials when prompted.	Cloud architect
Validate the script.	Confirm that VM migration has been initiated.	Cloud architect

Troubleshooting

Issue	Solution
The script fails with the error message: "All source networks are not mapped to target!"	If the source vCenter uses cross-vCenter NSX, the PowerCLI module will not work. Use a scripting method (such as Python) with the HCX API instead of PowerCLI. This is a known limitation of the PowerCLI script.
The script fails with the error message: "Connect-HCXServer Error: Unauthorized"	The credentials you entered don't provide the necessary permissions.

Migrate an F5 BIG-IP workload to F5 BIG-IP VE on the AWS Cloud

Suresh Veeragoni and Deepak Kumar, Amazon Web Services

Summary

Organizations are looking to migrate to the AWS Cloud to increase their agility and resilience. After you migrate your F5 BIG-IP security and traffic management solutions to the AWS Cloud, you can focus on agility and adoption of high-value operational models across your enterprise architecture.

This pattern describes how to migrate an F5 BIG-IP workload to an F5 BIG-IP Virtual Edition (VE) workload on the AWS Cloud. The workload will be migrated by rehosting the existing environment and deploying aspects of replatforming, such as service discovery and API integrations. AWS CloudFormation templates accelerate your workload's migration to the AWS Cloud.

This pattern is intended for technical engineering and architectural teams that are migrating F5 security and traffic management solutions, and accompanies the guide Migrating from F5 BIG-IP to F5 BIG-IP VE on the AWS Cloud on the AWS Prescriptive Guidance website.

Prerequisites and limitations

Prerequisites

- An existing on-premises F5 BIG-IP workload.
- Existing F5 licenses for BIG-IP VE versions.
- An active AWS account.
- An existing virtual private cloud (VPC) configured with an egress through a NAT gateway or Elastic IP address, and configured with access to the following endpoints: Amazon Simple Storage Service (Amazon S3), Amazon Elastic Compute Cloud (Amazon EC2), AWS Security Token Service (AWS STS), and Amazon CloudWatch. You can also modify the Modular and scalable VPC architecture Quick Start as a building block for your deployments.
- One or two existing Availability Zones, depending on your requirements.
- Three existing private subnets in each Availability Zone.
- AWS CloudFormation templates, available in the F5 GitHub repository.

During the migration, you might also use the following, depending on your requirements:

- An F5 Cloud Failover Extension to manage Elastic IP address mapping, secondary IP mapping, and route table changes.

- If you use multiple Availability Zones, you will need to use the F5 Cloud Failover Extensions to handle the Elastic IP mapping to virtual servers.
- You should consider using F5 Application Services 3 (AS3), F5 Application Services Templates (FAST), or another infrastructure as code (IaC) model to manage the configurations. Preparing the configurations in an IaC model and using code repositories will help with the migration and your ongoing management efforts.

Expertise

- This pattern requires familiarity with how one or more VPCs can be connected to existing data centers. For more information about this, see Network-to-Amazon VPC connectivity options in the Amazon VPC documentation.
- Familiarity is also required with F5 products and modules, including Traffic Management Operating System (TMOS), Local Traffic Manager (LTM), Global Traffic Manager (GTM), Access Policy Manager (APM), Application Security Manager (ASM), Advanced Firewall Manager (AFM), and BIG-IQ.

Product versions

- We recommend that you use F5 BIG-IP version 13.1 or later, although the pattern supports F5 BIG-IP version 12.1 or later.

Architecture

Source technology stack

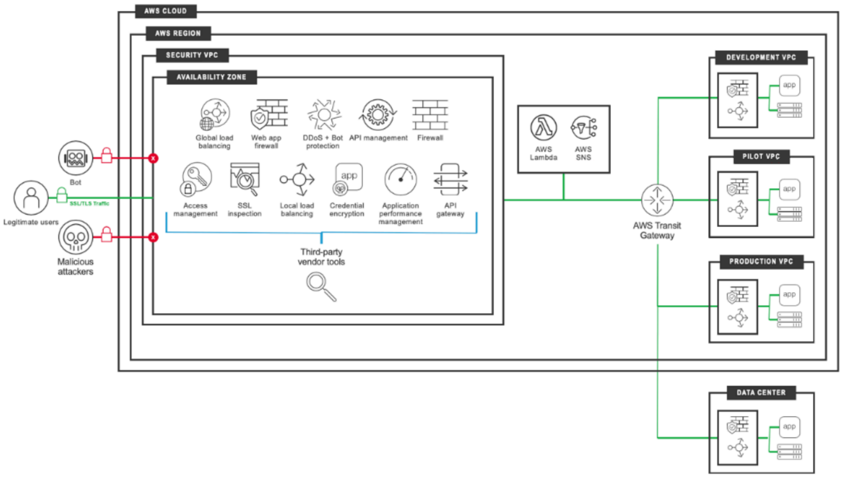
- F5 BIG-IP workload

Target technology stack

- Amazon CloudFront
- CloudWatch
- Amazon EC2
- Amazon S3
- Amazon VPC
- AWS Global Accelerator

- AWS STS
- AWS Transit Gateway
- F5 BIG-IP VE

Target architecture



Tools

- [AWS CloudFormation](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/Welcome.html) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- [Amazon CloudFront](https://docs.aws.amazon.com/AmazonCloudFront/latest/DeveloperGuide/Introduction.html) speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- [Amazon CloudWatch](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/WhatIsCloudWatch.html) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [Amazon Elastic Compute Cloud (Amazon EC2)](https://docs.aws.amazon.com/ec2/) provides scalable computing capacity in the AWS Cloud You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Identity and Access Management (IAM)](https://docs.aws.amazon.com/IAM/latest/UserGuide/introduction.html) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Amazon Simple Storage Service (Amazon S3)](https://docs.aws.amazon.com/AmazonS3/latest/userguide/Welcome.html) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Security Token Service (AWS STS)](https://docs.aws.amazon.com/STS/latest/APIReference/welcome.html) helps you request temporary, limited-privilege credentials for users.
- [AWS Transit Gateway](https://docs.aws.amazon.com/vpc/latest/tgw/what-is-transit-gateway.html) is a central hub that connects virtual private clouds (VPCs) and on-premises networks.

- [Amazon Virtual Private Cloud (Amazon VPC)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Discovery and assessment

Task	Description	Skills required
Assess the performance of F5 BIG-IP.	Collect and record the performance metrics of the applications on the virtual server, and metrics of systems that will be migrated. This will help to correctly size the target AWS infrastructure for better cost optimization.	F5 Architect, Engineer and Network Architect, Engineer
Evaluate the F5 BIG-IP operating system and configuration.	Evaluate which objects will be migrated and if a network structure needs to be maintained, such as VLANs.	F5 Architect, Engineer
Evaluate F5 license options.	Evaluate which license and consumption model you will require. This assessmen t should be based on your evaluation of the F5 BIG-IP operating system and configuration.	F5 Architect, Engineer
Evaluate the public applicati ons.	Determine which applicati ons will require public IP addresses. Align those applications to the required instances and clusters to meet performance and service-level	F5 Architect, Cloud Architect , Network Architect, Engineer, App Teams

Task	Description	Skills required
	agreement (SLA) requireme nts.	
Evaluate internal applications.	Evaluate which applications will be used by internal users. Make sure you know where those internal users sit in the organization and how those environments connect to the AWS Cloud. You should also make sure those applications can use domain name system (DNS) as part of the default domain.	F5 Architect, Cloud Architect , Network Architect, Engineer, App Teams
Finalize the AMI.	Not all F5 BIG-IP versions are created as Amazon Machine Images (AMIs). You can use the F5 BIG-IP Image Generator Tool if you have specific required quick-fix engineering (QFE) versions. For more information about this tool, see the "Related resources" section.	F5 Architect, Cloud Architect, Engineer
Finalize the instance types and architecture.	Decide on the instance types, VPC architecture, and interconnected architecture.	F5 Architect, Cloud Architect, Network Architect, Engineer

Complete security and compliance-related activities

Task	Description	Skills required
Document the existing F5 security policies.	Collect and document existing F5 security policies. Make sure you create a copy of them in a secure code repository.	F5 Architect, Engineer
Encrypt the AMI.	(Optional) Your organizat ion might require encryptio n of data at rest. For more information about creating a custom Bring Your Own License (BYOL) image, see the "Related resources" section.	F5 Architect, Engineer Cloud Architect, Engineer
Harden the devices.	This will help protect against potential vulnerabilities.	F5 Architect, Engineer

Configure your new AWS environment

Task	Description	Skills required
Create edge and security accounts.	Sign in to the AWS Management Console and create the AWS accounts that will provide and operate the edge and security services. These accounts might be different from the accounts that operate VPCs for shared services and applications. This step can be completed as part of a landing zone.	Cloud Architect, Engineer

Task	Description	Skills required
Deploy edge and security VPCs.	Set up and configure the VPCs required to deliver edge and security services.	Cloud Architect, Engineer
Connect to the source data center.	Connect to the source data center that hosts your F5 BIG-IP workload.	Cloud Architect, Network Architect, Engineer
Deploy the VPC connections.	Connect the edge and security service VPCs to the application VPCs.	Network Architect, Engineer
Deploy the instances.	Deploy the instances by using the CloudFormation templates from the "Related resources" section.	F5 Architect, Engineer
Test and configure instance failover.	Make sure that the AWS Advanced HA iAPP template or F5 Cloud Failover Extension is configured and operating correctly.	F5 Architect, Engineer

Configure networking

Task	Description	Skills required
Prepare the VPC topology.	Open the Amazon VPC console and make sure that your VPC has all the required subnets and protections for the F5 BIG-IP VE deployment.	Network Architect, F5 Architect, Cloud Architect, Engineer
Prepare your VPC endpoints.	Prepare the VPC endpoints for Amazon EC2, Amazon S3,	Cloud Architect, Engineer

Task	Description	Skills required
	and AWS STS if an F5 BIG-IP workload does not have access to a NAT Gateway or Elastic IP address on a TMM interface.	

Migrate data

Task	Description	Skills required
Migrate the configuration.	Migrate the F5 BIG-IP configuration to F5 BIG-IP VE on the AWS Cloud.	F5 Architect, Engineer
Associate the secondary IPs.	Virtual server IP addresses have a relationship with the secondary IP addresses assigned to the instances. Assign secondary IP addresses and make sure "Allow remap/reassignment" is selected.	F5 Architect, Engineer

Test configurations

Task	Description	Skills required
Validate the virtual server configurations.	Test the virtual servers.	F5 Architect, App Teams

Finalize operations

Task	Description	Skills required
Create the backup strategy.	Systems must be shut down to create a full snapshot. For more information, see "Updating an F5 BIG-IP virtual machine" in the "Related resources" section.	F5 Architect, Cloud Architect, Engineer
Create the cluster failover runbook.	Make sure that the failover runbook process is complete.	F5 Architect, Engineer
Set up and validate logging.	Configure F5 Telemetry Streaming to send logs to the required destinations.	F5 Architect, Engineer

Complete the cutover

Task	Description	Skills required
Cut over to the new deployment.		F5 Architect, Cloud Architect , Network Architect, Engineer, AppTeams

Migrate an on-premises Go web application to AWS Elastic Beanstalk by using the binary method

Suhas Basavaraj and Shumaz Mukhtar Kazi, Amazon Web Services

Summary

This pattern describes how to migrate an on-premises Go web application to AWS Elastic Beanstalk. After the application is migrated, Elastic Beanstalk builds the binary for the source bundle and deploys it to an Amazon Elastic Compute Cloud (Amazon EC2) instance.

As a rehost migration strategy, this pattern's approach is fast and requires no code changes, which means less testing and migration time.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An on-premises Go web application.
- A GitHub repository that contains your Go application's source code. If you do not use GitHub, there are other ways to [create an application source bundle for Elastic Beanstalk](#).

Product versions

- The most recent Go version supported by Elastic Beanstalk. For more information, see the [Elastic Beanstalk documentation](#).

Architecture

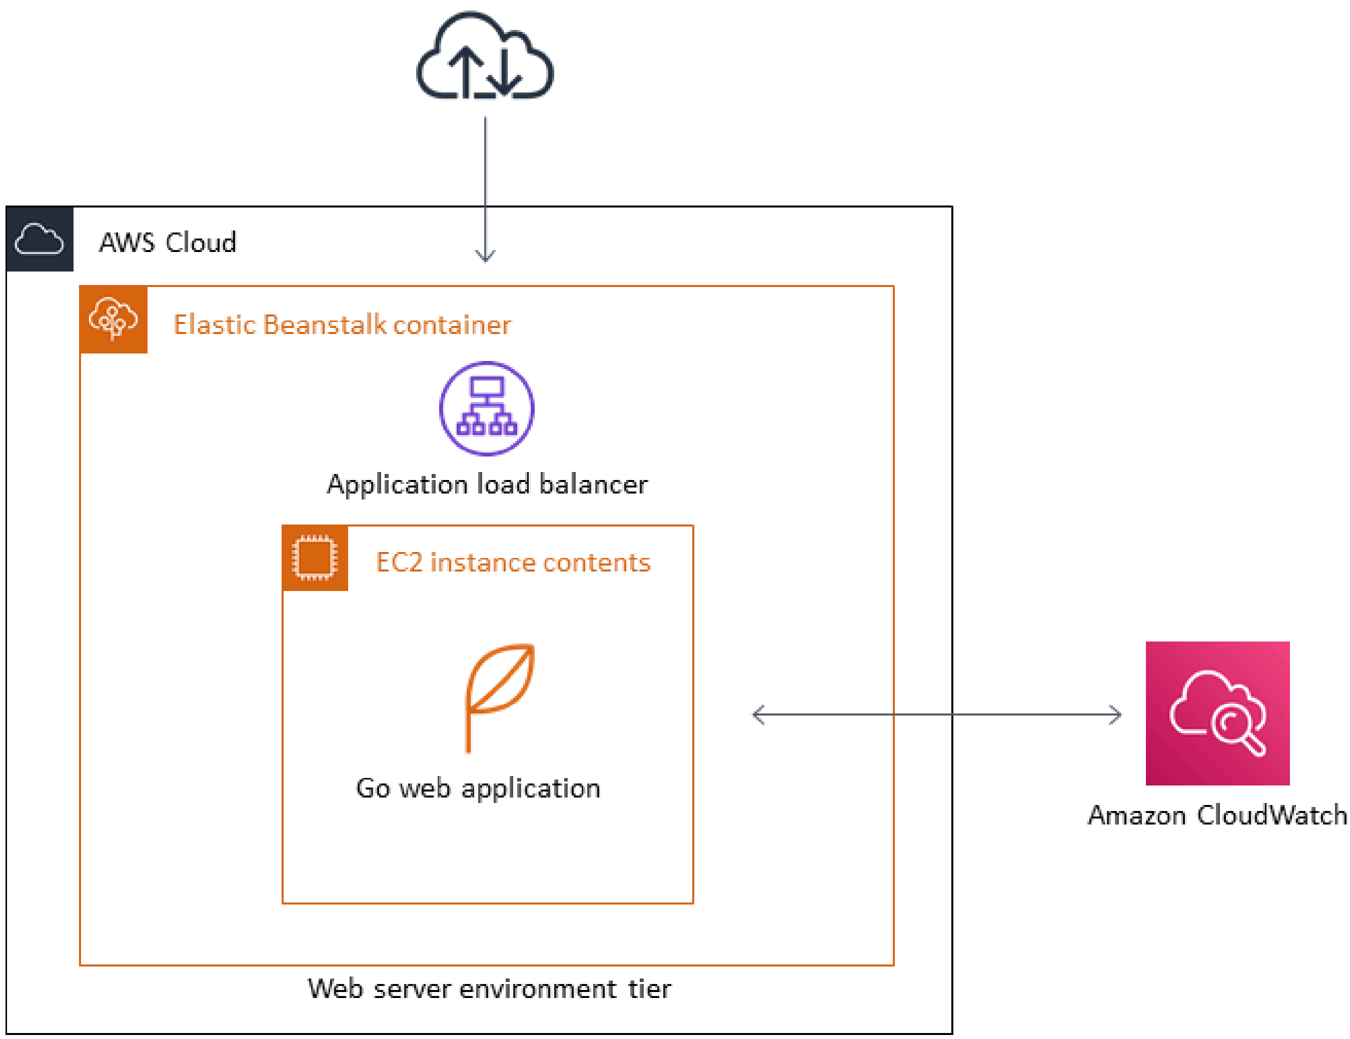
Source technology stack

- An on-premises Go web application

Target technology stack

- AWS Elastic Beanstalk
- Amazon CloudWatch

Target architecture



Tools

- AWS Elastic Beanstalk quickly deploys and manages applications in the AWS Cloud without users having to learn about the infrastructure that runs those applications. Elastic Beanstalk reduces management complexity without restricting choice or control.
- GitHub is an open-source distributed version control system.

Epics

Create the Go web application source bundle .zip file

Task	Description	Skills required
Create the source bundle for the Go application.	Open the GitHub repository that contains your Go application's source code and prepare the source bundle. The source bundle contains an `application.go` source file in the root directory, which hosts the main package for your Go application. If you do not use GitHub, see the *Prerequisites* section earlier in this pattern for other ways to create your application source bundle.	System Admin, Application Developer
Create a configuration file.	Create an `.ebextensions` folder in your source bundle, and then create an `options.config` file inside this folder. For more information, see the [Elastic Beanstalk documentation]().	System Admin, Application Developer
Create the source bundle .zip file.	Run the following command. `git archive -o ../godemoapp.zip HEAD` This creates the source bundle .zip file. Download and save the .zip file as a local file.	System Admin, Application Developer

Task	Description	Skills required
	Important The .zip file cannot exceed 512 MB and cannot include a parent folder or top-level directory.	

Migrate the Go web application to Elastic Beanstalk

Task	Description	Skills required
Choose the Elastic Beanstalk application.	1. Sign in to the AWS Management Console and open the [Elastic Beanstalk console](). 2. From the **Regions** list, choose your AWS Region. 3. In the navigation pane, choose **Applications**, and then choose an existing Elastic Beanstalk applicati on or create one. For instructions on how to create an Elastic Beanstalk application, see the [Elastic Beanstalk documentation]().	System Admin, Application Developer
Initiate the Elastic Beanstalk web server environment.	1. On the application overview page, choose **Create a new environme**	System Admin, Application Developer

Task	Description	Skills required
	nt, and then choose **Web server environment**. 2. Complete the **Environment name** and **Domain name** fields. 3. Choose **Platform version**, and select **Go** as your platform.	
Upload the source bundle .zip file to Elastic Beanstalk.	1. In **Application code**, choose **Upload your code**, and then choose **Local file**. 2. Choose the .zip file that contains your source bundle. 3. In **Version label**, give the file a unique name, and then choose **Create environment**.	System Admin, Application Developer
Test the deployed Go web application.	You will be redirected to the Elastic Beanstalk application's overview page. At the top of the overview, next to **Environment ID**, choose the URL that ends in `elasticbeanstalk.com` to navigate to your application. Your application must use this name in its configuration file as an environment variable and display it on the web page.	System Admin, Application Developer

Troubleshooting

Issue	Solution
Unable to access the application through an Application Load Balancer.	Check the target group that contains your Elastic Beanstalk application. If it's unhealthy , log in to your Elastic Beanstalk instance and check the `nginx.conf` file configuration to verify that it routes to the correct health status URL. You might need to change the target group health check URL.

Migrate an on-premises SFTP server to AWS using AWS Transfer for SFTP

Akash Kumar, Amazon Web Services

Summary

This pattern describes how to migrate an on-premises file transfer solution that uses the Secure Shell (SSH) File Transfer Protocol (SFTP) to the AWS Cloud by using the AWS Transfer for SFTP service. Users generally connect to an SFTP server either through its domain name or by fixed IP. This pattern covers both cases.

AWS Transfer for SFTP is a member of the AWS Transfer Family. It is a secure transfer service that you can use to transfer files into and out of AWS storage services over SFTP. You can use AWS Transfer for SFTP with Amazon Simple Storage Service (Amazon S3) or Amazon Elastic File System (Amazon EFS). This pattern uses Amazon S3 for storage.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing SFTP domain name or fixed SFTP IP.

Limitations

- The largest object that you can transfer in one request is currently 5 GiB. For files that are larger than 100 MiB, consider using Amazon S3 multipart upload.

Architecture

Source technology stack

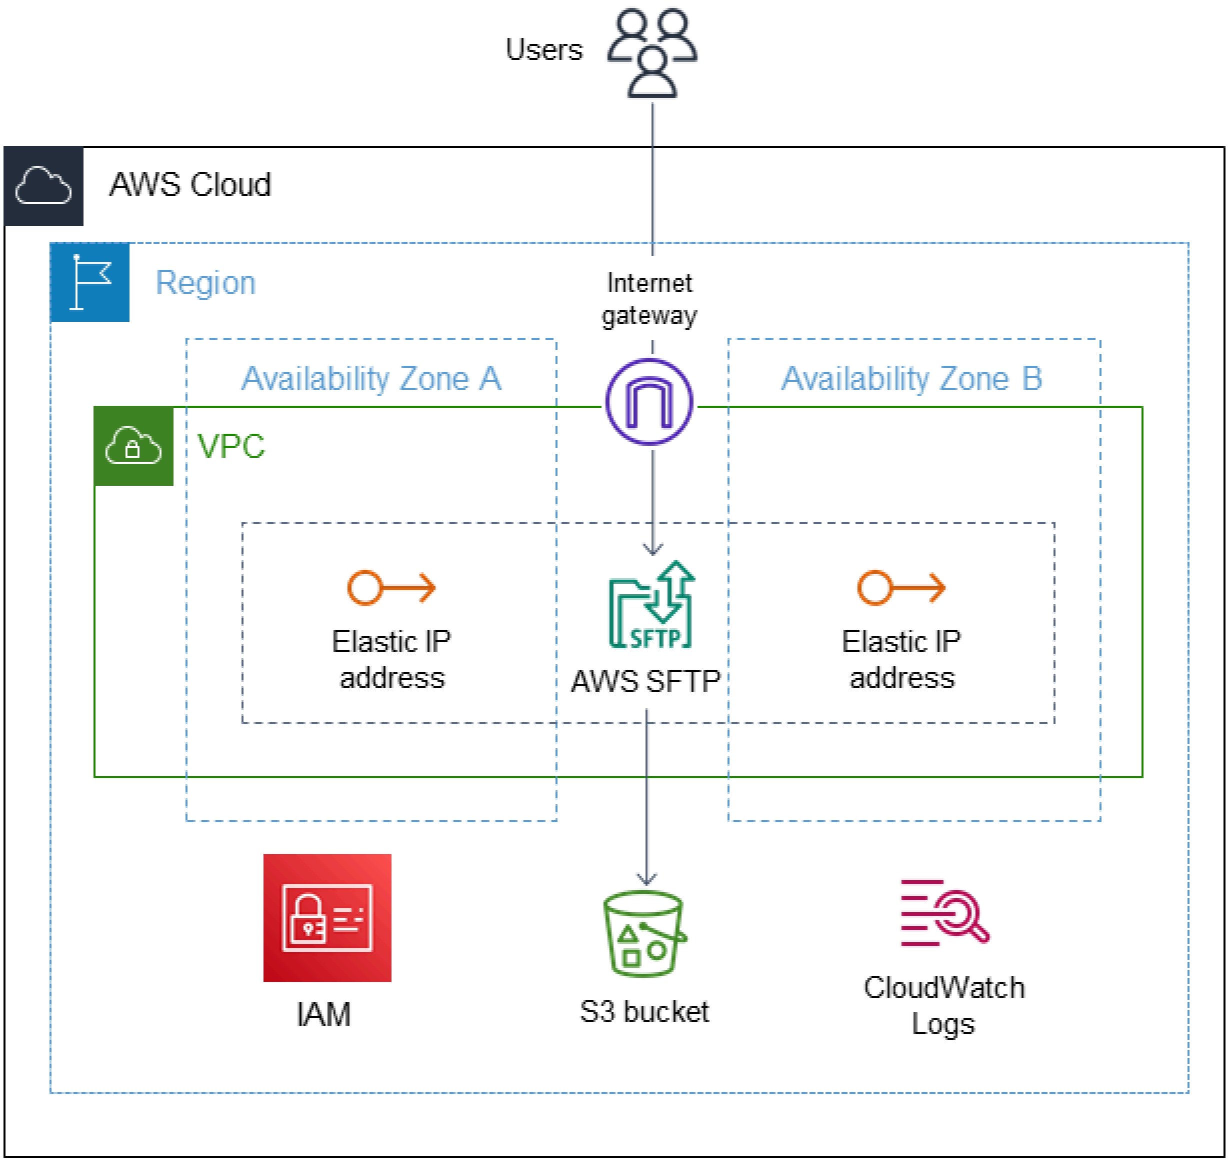
- On-premises flat files or database dump files.

Target technology stack

- AWS Transfer for SFTP
- Amazon S3
- Amazon Virtual Private Cloud (Amazon VPC)

- AWS Identity and Access Management (IAM) roles and policies
- Elastic IP addresses
- Security groups
- Amazon CloudWatch Logs (optional)

Target architecture



Automation and scale

To automate the target architecture for this pattern, use the attached AWS CloudFormation templates:

- `amazon-vpc-subnets.yml` provisions a virtual private cloud (VPC) with two public and two private subnets.
- `amazon-sftp-server.yml` provisions the SFTP server.
- `amazon-sftp-customer.yml` adds users.

Tools

AWS services

- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. This pattern uses Amazon S3 as the storage system for file transfers.
- AWS Transfer for SFTP helps you transfer files into and out of AWS storage services over the SFTP protocol.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Create a VPC

Task	Description	Skills required
Create a VPC with subnets.	Open the Amazon VPC console. Create a virtual private cloud (VPC) with two public subnets. (The second subnet provides high availabil ity.) —or—	Developer, Systems administr ator

Task	Description	Skills required
	You can deploy the attached CloudFormation template, `amazon-vpc-subnets .yml` , in the [CloudFormation console](#) to automate the tasks in this epic.	
Add an internet gateway.	Provision an internet gateway and attach it to the VPC.	Developer, Systems administr ator
Migrate an existing IP.	Attach an existing IP to the Elastic IP address. You can create an Elastic IP address from your address pool and use it.	Developer, Systems administr ator

Provision an SFTP server

Task	Description	Skills required
Create an SFTP server.	Open the [AWS Transfer Family console](#). Follow the instructions in [Create an internet-facing endpoint for your server](#) in the AWS Transfer Family documenta tion to create an SFTP server with an internet-facing endpoint. For **Endpoint type**, choose **VPC hosted**. For **Access**, choose **Internet Facing**. For **VPC**, choose the VPC you created in the previous epic.	Developer, Systems administr ator

Task	Description	Skills required
	—or— You can deploy the attached CloudFormation template, `amazon-sftp-server .yml` , in the [CloudFormation console](#) to automate the tasks in this epic.	
Migrate the domain name.	Attach the existing domain name to the custom hostname. If you're using a new domain name, use the **Amazon Route 53 DNS** alias. For an existing domain name, choose **Other DNS**. For more information, see [Working with custom hostnames](#) in the AWS Transfer Family documentation.	Developer, Systems administr ator
Add a CloudWatch logging role.	(Optional) if you want to enable CloudWatch logging, create a `Transfer` role with the CloudWatch Logs API operations `logs:CreateLogGrou p` , `logs:CreateLogStre am` , `logs:Desc ribeLogStreams` , and `logs:PutLogEvents` . For more information, see [Log activity with CloudWatch](#) in the AWS Transfer Family documentation.	Developer, system administr ator

Task	Description	Skills required
Save and submit.	Choose **Save**. For **Actions**, choose **Start** and wait for the SFTP server to be created with the status **Online**.	Developer, Systems administr ator

Map Elastic IP addresses to the SFTP server

Task	Description	Skills required
Stop the server so you can modify settings.	On the [AWS Transfer Family console](https://console.aws.amazon.com/transfer/), choose **Servers**, and then select the SFTP server you created. For **Actions**, choose **Stop**. When the server is offline, choose **Edit** to modify its settings.	Developer, system administr ator
Choose Availability Zones and subnets.	In the **Availability Zones** section, choose the Availabil ity Zones and subnets for your VPC.	Developer, Systems administr ator
Add Elastic IP addresses.	For **IPv4 Addresses**, choose an Elastic IP address for each subnet, and then choose **Save**.	Developer, Systems administr ator

Add users

Task	Description	Skills required
Create an IAM role for users to access the S3 bucket.	Create a IAM role for `Transfer` and add `s3:ListBu`	Developer, Systems administr ator

Task	Description	Skills required
	`cket` , `s3:GetBucketLocation` , and `s3:PutObject` with the S3 bucket name as a resource. For more information, see [Create an IAM role and policy](#) in the AWS Transfer Family documentation. —or— You can deploy the attached CloudFormation template, `amazon-sftp-customer.yml` , in the [CloudFormation console](#) to automate the tasks in this epic.	
Create an S3 bucket.	Create a S3 bucket for the application.	Developer, Systems administrator
Create optional folders.	(Optional) If you want to store files for users separately, in specific Amazon S3 folders, add folders as appropriate.	Developer, Systems administrator
Create an SSH public key.	To create an SSH key pair, see [Generate SSH keys](#) in the AWS Transfer Family documentation.	Developer, Systems administrator

Task	Description	Skills required
Add users.	On the [AWS Transfer Family console](), choose **Servers**, select the SFTP server you created, and then choose **Add user**. For **Home directory**, choose the S3 bucket you created. For **SSH public key**, specify the public key portion of the SSH key pair. Add users for the SFTP server, and then choose **Add**.	Developer, Systems administrator

Test the SFTP server

Task	Description	Skills required
Update the security group.	In the **Security Groups** section of your SFTP server, add your test machine's IP to gain SFTP access.	Developer
Use an SFTP client utility to test the server.	Test file transfers by using any SFTP client utility. For a list of clients and instructions, see [Transferring files using a client]() in the AWS Transfer Family documentation.	Developer

Migrate an on-premises VM to Amazon EC2 by using AWS Application Migration Service

Thanh Nguyen, Amazon Web Services

Summary

When it comes to application migration, organizations can take different approaches to rehost (lift and shift) the application's servers from the on-premises environment to the Amazon Web Services (AWS) Cloud. One way is to provision new Amazon Elastic Compute Cloud (Amazon EC2) instances and then install and configure the application from scratch. Another approach is to use third-party or AWS native migration services to migrate multiple servers at the same time.

This pattern outlines the steps for migrating a supported virtual machine (VM) to an Amazon EC2 instance on the AWS Cloud by using AWS Application Migration Service. You can use the approach in this pattern to migrate one or multiple virtual machines manually, one by one, or automatically by creating appropriate automation scripts based on the outlined steps.

Prerequisites and limitations

Prerequisites

- An active AWS account in one of the AWS Regions that support Application Migration Service
- Network connectivity between the source server and target EC2 server through a private network by using AWS Direct Connect or a virtual private network (VPN), or through the internet

Limitations

- For the latest list of supported Regions, see the [Supported AWS Regions].
- For a list of supported operating systems, see the [Supported operating systems] and the *General* section of [Amazon EC2 FAQs].

Architecture

Source technology stack

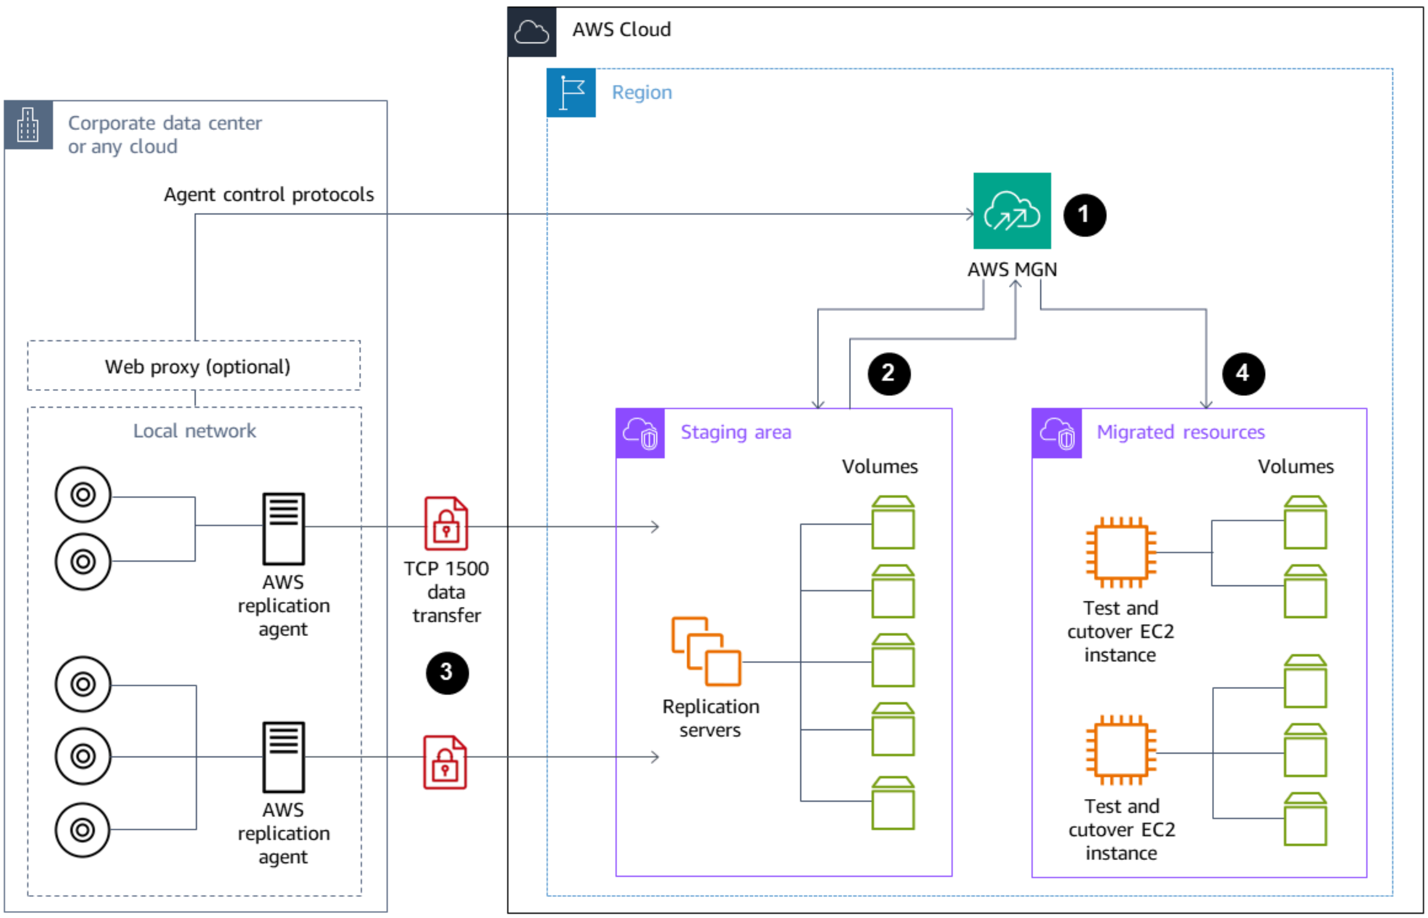
- A physical, virtual, or cloud-hosted server running an operating system supported by Amazon EC2

Target technology stack

- An Amazon EC2 instance running the same operating system as the source VM
- Amazon Elastic Block Store (Amazon EBS)

Source and target architecture

The following diagram shows the high-level architecture and main components of the solution. In the on-premises data center, there are virtual machines with local disks. On AWS, there is a staging area with replication servers and a migrated resources area with EC2 instances for test and cutover. Both subnets contain EBS volumes.

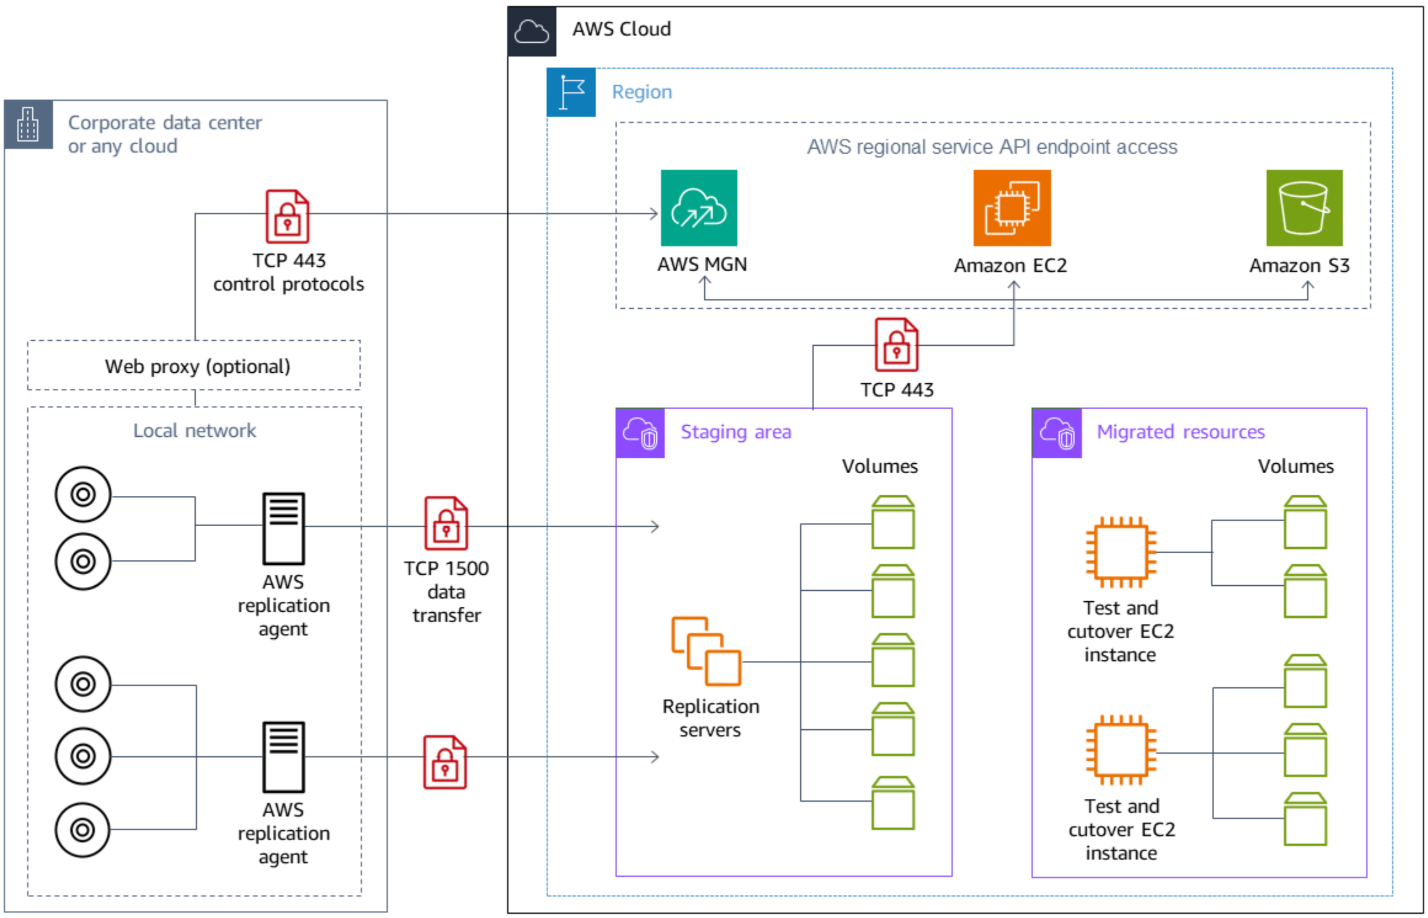


1. Initialize AWS Application Migration Service.
2. Set up the staging area server configuration and reporting, including staging area resources.
3. Install agents on source servers, and use continuous block-level data replication (compressed and encrypted).

4. Automate orchestration and system conversion to shorten the cutover window.

Network architecture

The following diagram shows the high-level architecture and main components of the solution from the networking perspective, including required protocols and ports for communication between primary components in the on-premises data center and on AWS.



Tools

- [AWS Application Migration Service](https://docs.aws.amazon.com/mgn/latest/ug/what-is-application-migration-service.html) helps you rehost (*lift and shift*) applications to the AWS Cloud without change and with minimal downtime.

Best practices

- Do not take the source server offline or perform a reboot until the cutover to the target EC2 instance is complete.

- Provide ample opportunity for the users to perform user acceptance testing (UAT) on the target server to identify and resolve any issues. Ideally, this testing should start at least two weeks before cutover.
- Frequently monitor the server replication status on the Application Migration Service console to identify issues early on.
- Use temporary AWS Identity and Access Management (IAM) credentials for agent installation instead of permanent IAM user credentials.

Epics

Generate AWS credentials

Task	Description	Skills required
Create the AWS Replication Agent IAM role.	Sign in with administrative permissions to the AWS account. On the AWS Identity and Access Management (IAM) [console](https://console.aws.amazon.com/iam/), create an IAM role: 1. On the IAM console, choose **Roles**. 2. Choose **Create role**. 3. On the **Select trusted entity** page, in **Trusted entity type** section, select **AWS Account**. 4. In the **An AWS account** section, select **This account (<*account-id*>)**. 5. Choose **Next**. 6. On the **Add permissions** page, search for the `AWSApplicationMigr`	AWS administrator, Migration engineer

Task	Description	Skills required
	`ationAgentInstallationPolicy` policy, select the check box next to the policy name. 7. Choose **Next**. 8. On the **Role details** page, enter **MGN_Agent_Installation_Role** as the role name. 9. Verify that the fields are correct, and then choose **Create role**.	

Task	Description	Skills required
Generate temporary security credentials.	On a machine with AWS Command Line Interface (AWS CLI) installed, sign in with administrative permissions. Or alternatively (within a supported AWS Region), on the AWS Management Console, sign in with administrative permissions to the AWS account, and open AWS CloudShell. Generate temporary credentials with the following command, replacing `<account-id>` with the AWS account ID. `aws sts assume-role --role-arn arn:aws:iam::<account-id>:role/MGN_Agent_Installation_Role --role-session-name mgn_installation_session_role` From the output of the command, copy the values for `AccessKeyId` , `SecretAccessKey` , and `SessionToken` . Store them in a safe location for later use.	AWS administrator, Migration engineer

Task	Description	Skills required
	Important These temporary credentials will expire after one hour. If you need credentials after one hour, repeat the previous steps.	

Initialize Application Migration Service and create the Replication Settings template

Task	Description	Skills required
Initialize the service.	On the console, sign in with administrative permissions to the AWS account. Choose **Application Migration Service**, and then choose **Get started**.	AWS administrator, Migration engineer
Create and configure the Replication Settings template.	1. Provide the following configuration details: a. Select the staging area subnet. b. Select the replication server instance type (`t3.small` by default). c. Select the EBS volume type (gp3 by default). d. Select the EBS encryptio n option.	AWS administrator, Migration engineer

Task	Description	Skills required
	e. Ensure that the **Always use Application Migration Service security group** check box is selected. f. Select the **Use private IP for data replication (VPN, DirectConnect, VPC peering)** check box if you are using private network connectivity between the on-premises environment and AWS. g. Select the **Throttle network bandwidth (per server - in Mbps)** check box if you want to limit the network bandwidth for Application Migration Service. 2. Choose **Create template**. Application Migration Service will automatically create all the IAM roles required to facilitate data replication and the launching of migrated servers.	

Install AWS Replication Agents on source machines

Task	Description	Skills required
Have the required AWS credentials ready.	When you run the installer file on a source server, you will need to enter the temporary credentials that you generated earlier, including `AccessKeyId` , `SecretAccessKey` , and `SessionToken` .	Migration engineer, AWS administrator
For Linux servers, install the agent.	Copy the installer command, log in to your source servers, and run the installer. For detailed instructions, see the [AWS documentation]().	AWS administrator, Migration engineer
For Windows servers, install the agent.	Download the installer file to each server, and then run the installer command. For detailed instructions, see the [AWS documentation]().	AWS administrator, Migration engineer
Wait for initial data replicati on to be completed.	When the agent has been installed, the source server will appear on the Applicati on Migration Service console, in the **Source servers** section. Wait while the server undergoes initial data replication.	AWS administrator, Migration engineer

Configure launch settings

Task	Description	Skills required
Specify the server details.	On the Application Migration Service console, choose the **Source servers** section, and then choose a server name from the list to access the server details.	AWS administrator, Migration engineer
Configure the launch settings.	Choose the **Launch settings** tab. You can configure a variety of settings, including general launch settings and EC2 launch template settings. For detailed instructions, see the [AWS documentation]().	AWS administrator, Migration engineer

Perform a test

Task	Description	Skills required
Test the source servers.	1. On the Application Migration Service console, in the **Source servers** section, ensure that the source servers' **Migration lifecycle** is **Ready for testing** and that **Data replication status** is **Healthy**. 2. Select the check box to the left of each source server.	AWS administrator, Migration engineer

Task	Description	Skills required
	3. Choose **Test and Cutover**, and then choose **Launch Test Instance**. 4. When prompted, choose **Launch**. The servers will be launched.	
Verify that the test completed successfully.	After the test server is completely launched, the **Alerts** status on the page will show **Launched** for each server.	AWS administrator, Migration engineer
Test the server.	Perform testing against the test server to ensure that it functions as expected.	AWS administrator, Migration engineer

Schedule and perform a cutover

Task	Description	Skills required
Schedule a cutover window.	Schedule an appropriate cutover timeframe with relevant teams.	AWS administrator, Migration engineer
Perform the cutover.	1. On the Application Migration console, on the **Source Servers** page, select the check box to the left of each source server. 2. Choose **Test and Cutover**, and select **Mark as 'Ready for cutover'**.	AWS administrator, Migration engineer

Task	Description	Skills required
	3. Verify that each source server's **Migration lifecycle** is **Ready for cutover**. 4. Choose **Test and Cutover**, and then select **Launch cutover instances**. 5. When prompted, choose **Launch**. The servers will be launched. The source server's **Migration lifecycle** will change to **Cutover in progress**.	
Verify that the cutover completed successfully.	After the cutover servers are completely launched, the **Alerts** status on the **Source Servers** page will show **Launched** for each server.	AWS administrator, Migration engineer
Test the server.	Perform testing against the cutover server to ensure that it functions as expected.	AWS administrator, Migration engineer
Finalize the cutover.	Choose **Test and Cutover**, and then select **Finalize cutover** to finalize the migration process.	AWS administrator, Migration engineer

Migrate small sets of data from on premises to Amazon S3 using AWS SFTP

Charles Gibson and Sergiy Shevchenko, Amazon Web Services

Summary

This pattern describes how to migrate small sets of data (5 TB or less) from on-premises data centers to Amazon Simple Storage Service (Amazon S3) by using AWS Transfer for SFTP (AWS SFTP). The data can be either database dumps or flat files.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Direct Connect link established between your data center and AWS

Limitations

- The data files must be less than 5 TB. For files over 5 TB, you can perform a multipart upload to Amazon S3 or choose another data transfer method.

Architecture

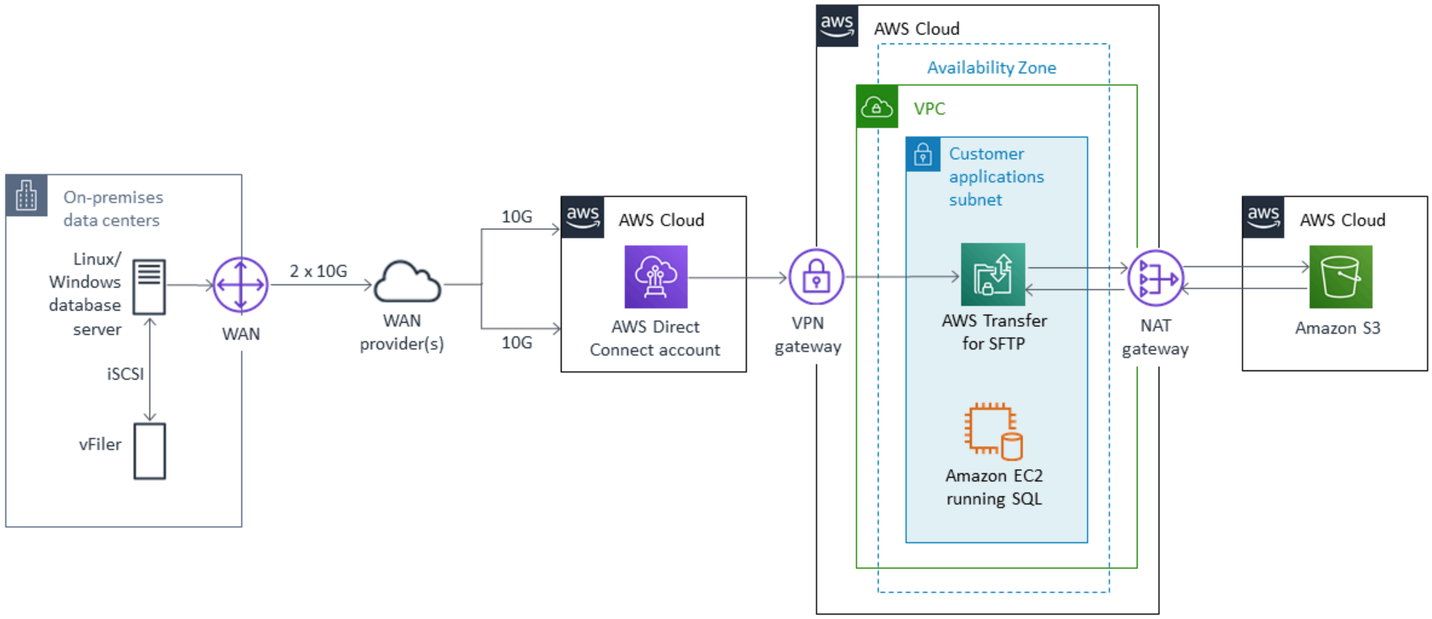
Source technology stack

- On-premises flat files or database dumps

Target technology stack

- Amazon S3

Source and target architecture



Tools

- [AWS SFTP](#) – Enables the transfer of files directly into and out of Amazon S3 using Secure File Transfer Protocol (SFTP).
- [AWS Direct Connect](#) – Establishes a dedicated network connection from your on-premises data centers to AWS.
- [VPC endpoints](#) – Enable you to privately connect a VPC to supported AWS services and VPC endpoint services powered by AWS PrivateLink without an internet gateway, network address translation (NAT) device, VPN connection, or AWS Direct Connect connection. Instances in a VPC don't require public IP addresses to communicate with resources in the service.

Epics

Prepare for the migration

Task	Description	Skills required
Document the current SFTP requirements.		Application owner, SA
Identify the authentication requirements.	Requirements may include key-based authentication,	Application owner, SA

Task	Description	Skills required
	user name or password, or identity provider (IdP).	
Identify the application integration requirements.		Application owner
Identify the users who require the service.		Application owner
Determine the DNS name for the SFTP server endpoint.		Networking
Determine the backup strategy.		SA, DBA (if data is transferr ed)
Identify the application migration or cutover strategy.		Application owner, SA, DBA

Configure the infrastructure

Task	Description	Skills required
Create one or more virtual private clouds (VPCs) and subnets in your AWS account.		Application owner, AMS
Create the security groups and network access control list (ACL).		Security, Networking, AMS
Create the S3 bucket.		Application owner, AMS
Create the identity and access management (IAM) role.	Create an IAM policy that includes the permissions to enable AWS SFTP to access your S3 bucket. This IAM policy determines what level	Security, AMS

Task	Description	Skills required
	of access you provide SFTP users. Create another IAM policy to establish a trust relationship with AWS SFTP.	
Associate a registered domain (optional).	If you have your own registere d domain, you can associate it with the SFTP server. You can route SFTP traffic to your SFTP server endpoint from a domain or from a subdomain.	Networking, AMS
Create an SFTP server.	Specify the identity provider type used by the service to authenticate your users.	Application owner, AMS
Open an SFTP client.	Open an SFTP client and configure the connection to use the SFTP endpoint host. AWS SFTP supports any standard SFTP client. Commonly used SFTP clients include OpenSSH, WinSCP, Cyberduck, and FileZilla. You can get the SFTP server host name from the AWS SFTP console.	Application owner, AMS

Plan and test

Task	Description	Skills required
Plan the application migration.	Plan for any application configuration changes required, set the migration	Application owner, AMS

Task	Description	Skills required
	date, and determine the test schedule.	
Test the infrastructure.	Test in a non-production environment.	Application owner, AMS

Migrate from Oracle GlassFish to AWS Elastic Beanstalk

Sandeep Bondugula, Amazon Web Services

Summary

This pattern describes how to migrate a Java application running on an on-premises Oracle GlassFish server to AWS Elastic Beanstalk in the AWS Cloud.

On AWS, the Java application is deployed on a Docker GlassFish server with AWS Elastic Beanstalk, which runs in an Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group.

Additional features:

- Amazon Elastic Beanstalk acts as a wrapper for several underlying resources. It sets up Elastic Load Balancing (which handles incoming traffic from Amazon Route 53), disperses the traffic to one or more EC2 instances, and also serves as a deployment tool.
- To migrate an on-premises database to Amazon Relational Database Service (Amazon RDS), update the database connection details. In the backend database, you can configure Amazon RDS Multi-AZ deployments and choose the database engine type.
- You can use Multi-AZ deployment for high availability along with the Auto Scaling group and scaling policy to improve resiliency.
- You can set up a scaling policy based on Amazon CloudWatch metrics.
- In AWS Elastic Beanstalk, you can configure the underlying Elastic Load Balancing settings and Amazon EC2 Auto Scaling.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An on-premises Java application running on GlassFish
- A Java Web Application Resource (WAR) file

Product versions

- Oracle Glassfish 4.1.2 and 5.0

- Java 7 GlassFish 4.0
- Java 8 GlassFish 4.1 or later

Architecture

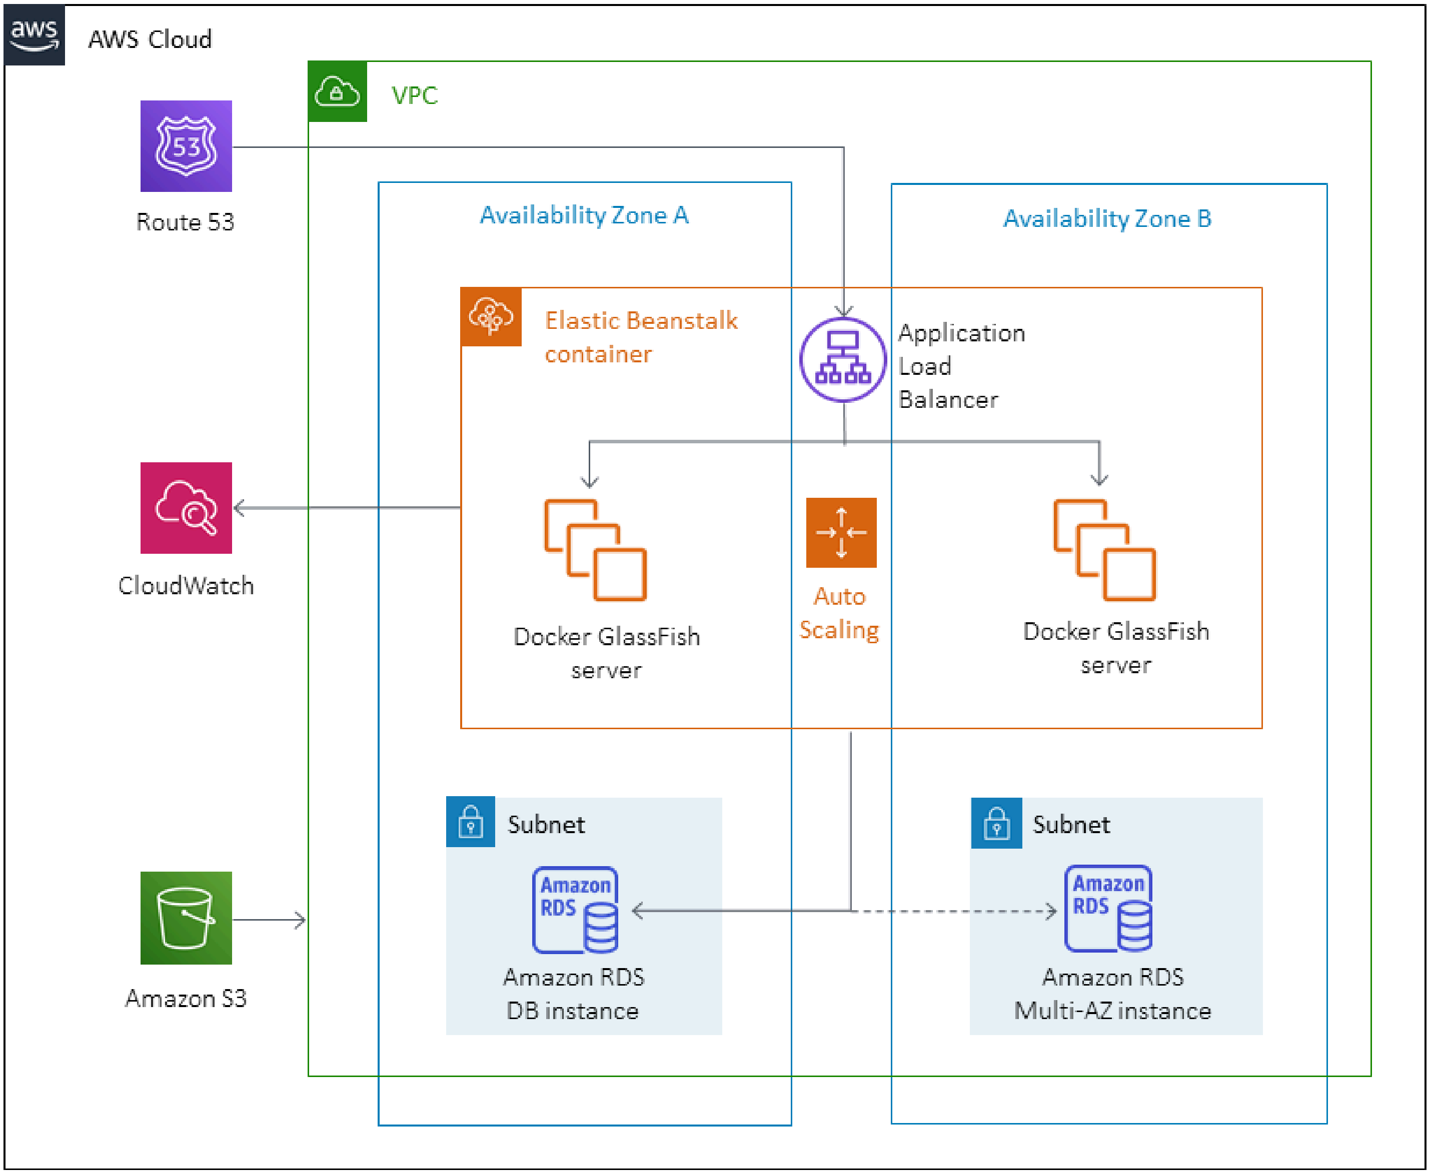
Source technology stack

- Applications developed in GlassFish

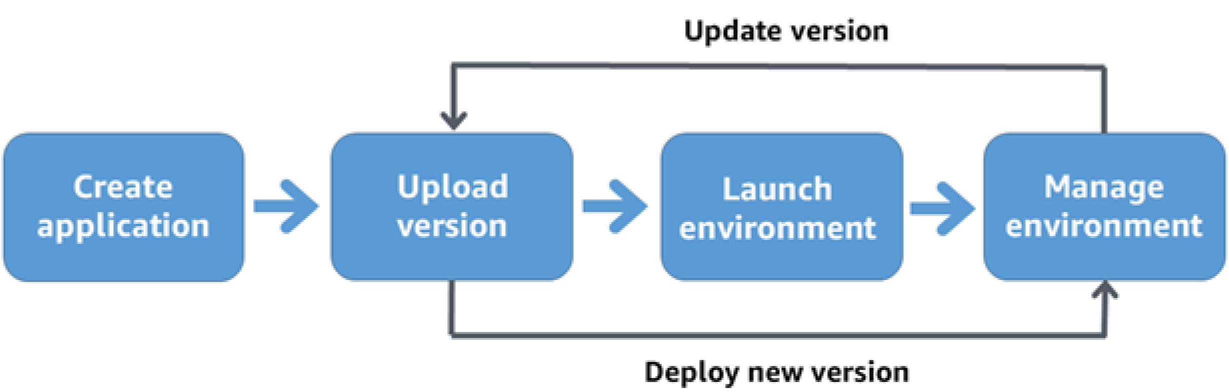
Target technology stack

- Elastic Beanstalk

Target architecture



Deployment workflow



Tools

- Amazon Elastic Beanstalk – A service for deploying and scaling web applications and services developed with Java, .NET, PHP, Node.js, Python, Ruby, Go, and Docker on servers including Apache, NGINX, Passenger, and IIS.
- Amazon CloudWatch – Provides data and actionable insights to monitor applications, responds to systemwide performance changes, optimizes resource utilization, and provides a unified view of operational health.
- Docker – A platform that packages software into standardized units to build, test, and deploy applications quickly.
- Java – A general-purpose programming language. Java is class-based, object-oriented, and designed to have fewer implementation dependencies.

Epics

Set up a VPC

Task	Description	Skills required
Create a virtual private cloud (VPC) instance with the required information.		SysAdmin
Create at least two subnets within the VPC.		SysAdmin
Create a route table per requirements.		SysAdmin

Set up Amazon S3

Task	Description	Skills required
Create an Amazon Simple Storage Service (Amazon S3) bucket.		SysAdmin

Task	Description	Skills required
Copy the WAR file to the S3 bucket and upload the application code.		SysAdmin

Create an IAM role

Task	Description	Skills required
Create an AWS Identity and Access Management (IAM) role.	You can use the default "aws-elasticbeanstalk-ec2-role" profile, or let Elastic Beanstalk create it automatic ally.	SysAdmin

Set up Elastic Beanstalk

Task	Description	Skills required
Open the Elastic Beanstalk dashboard.		SysAdmin
Create a new application and choose the web server environment.		SysAdmin
Choose GlassFish Docker as the preconfigured platform.		SysAdmin
Upload the code.	Provide the S3 bucket file URL or ZIP file from local system files.	SysAdmin

Task	Description	Skills required
Choose the environment type.	In Configuration Capacity settings, choose either Single Instance or Load Balancer.	SysAdmin
Configure Load Balancer.	If you chose Load Balancer in the previous step, configure the Multi-AZ deployment.	SysAdmin
In Configuration Security settings, choose the previousl y created IAM role.		SysAdmin
In Configuration Security settings, if you have an existing key pair, use it or create a new Amazon EC2 key pair.		SysAdmin
In Configuration Monitoring settings, configure Amazon CloudWatch.		SysAdmin
In Configuration Security settings, choose the previousl y created VPC.		SysAdmin
Choose Create Environment.		SysAdmin

Test the application

Task	Description	Skills required
Test the application by using the URL provided in the created environment.		

Task	Description	Skills required
Apply the Domain Name Service (DNS) changes in Amazon Route 53.

Migrate an on-premises Oracle database to Oracle on Amazon EC2

Baji Shaik and Pankaj Choudhary, Amazon Web Services

Summary

This pattern walks you through the steps for migrating an on-premises Oracle database to Oracle on an Amazon Elastic Compute Cloud (Amazon EC2) instance. It describes two options for migration: using AWS Data Migration Service (AWS DMS) or using native Oracle tools such as RMAN, Data Pump import/export, transportable tablespaces, and Oracle GoldenGate.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle database in an on-premises data center

Limitations

- The target operating system (OS) must be supported by Amazon EC2. For a complete list of supported systems, see Amazon EC2 FAQs.

Product versions

- Oracle versions 10.2 and later (for versions 10.x), 11g and up to 12.2, and 18c for the Enterprise, Standard, Standard One, and Standard Two editions. For the latest list of versions supported by AWS DMS, see "On-premises and Amazon EC2 instance databases" in Sources for Data Migration in the AWS DMS documentation.

Architecture

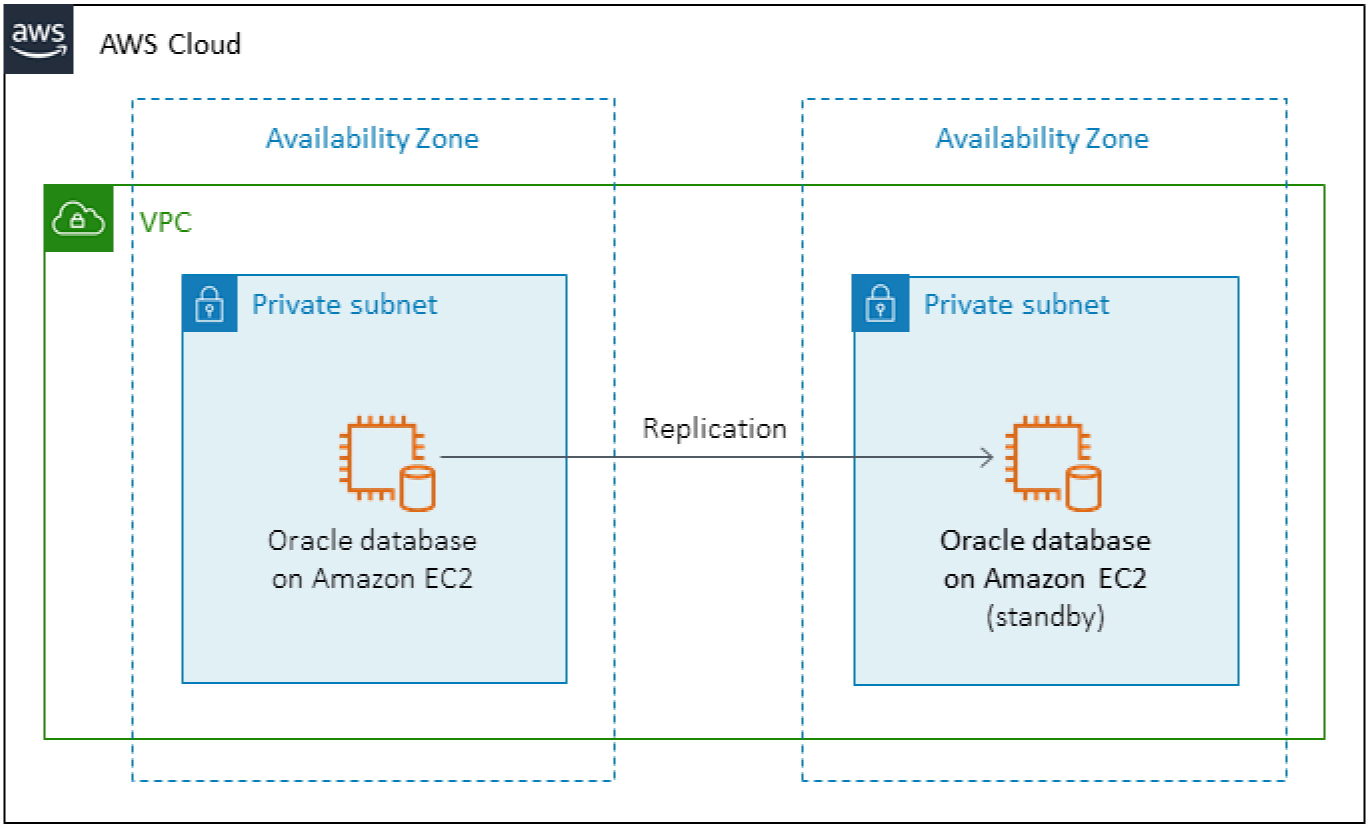
Source technology stack

- An on-premises Oracle database

Target technology stack

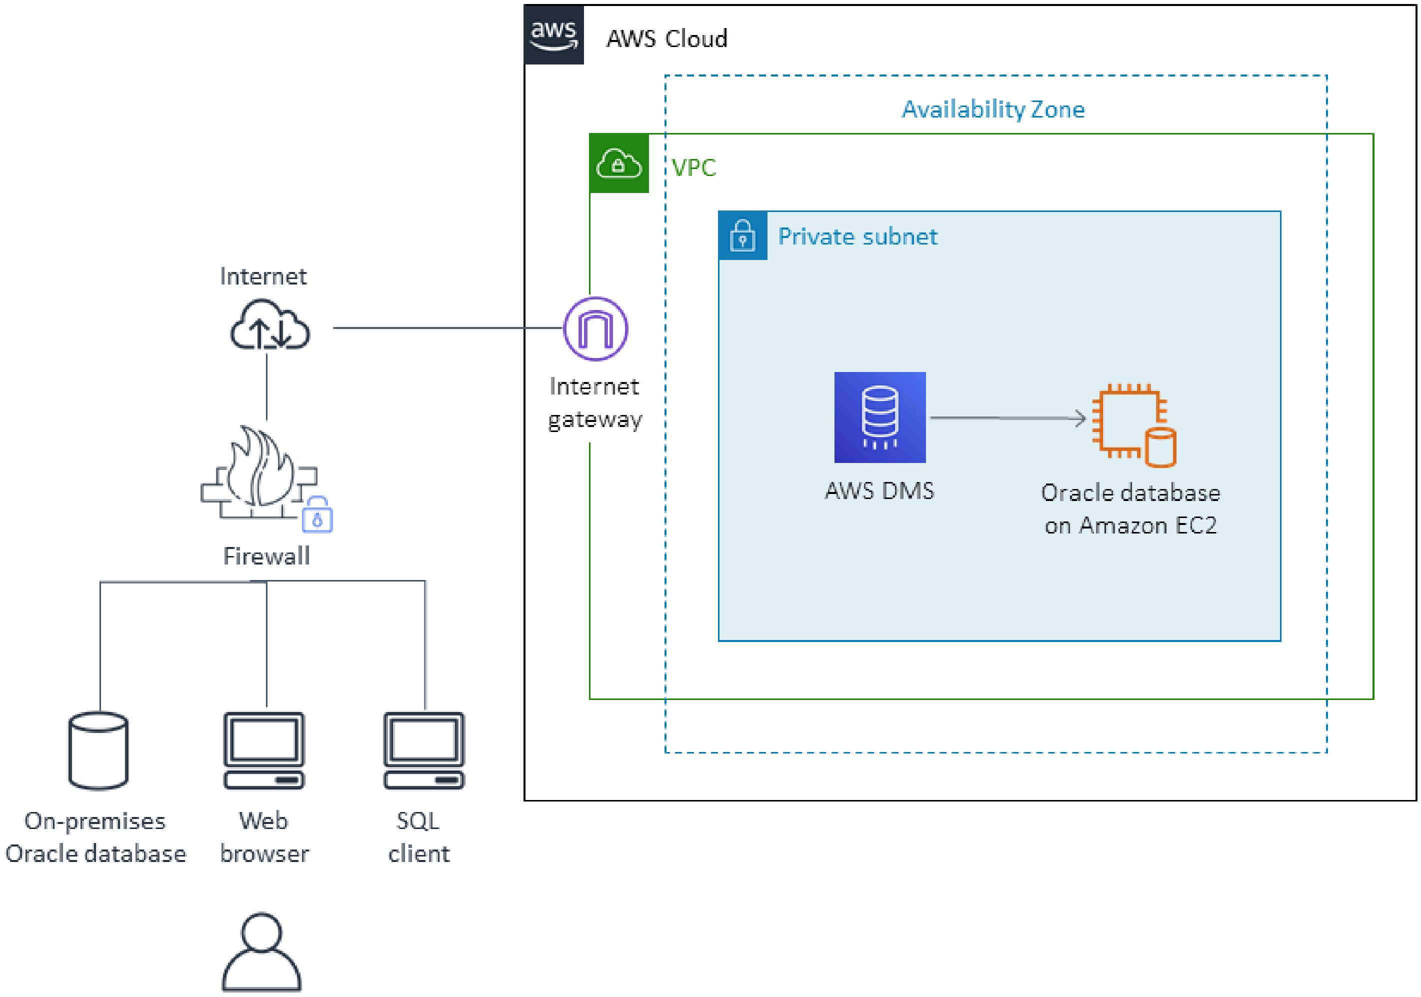
- An Oracle database instance on Amazon EC2

Target architecture

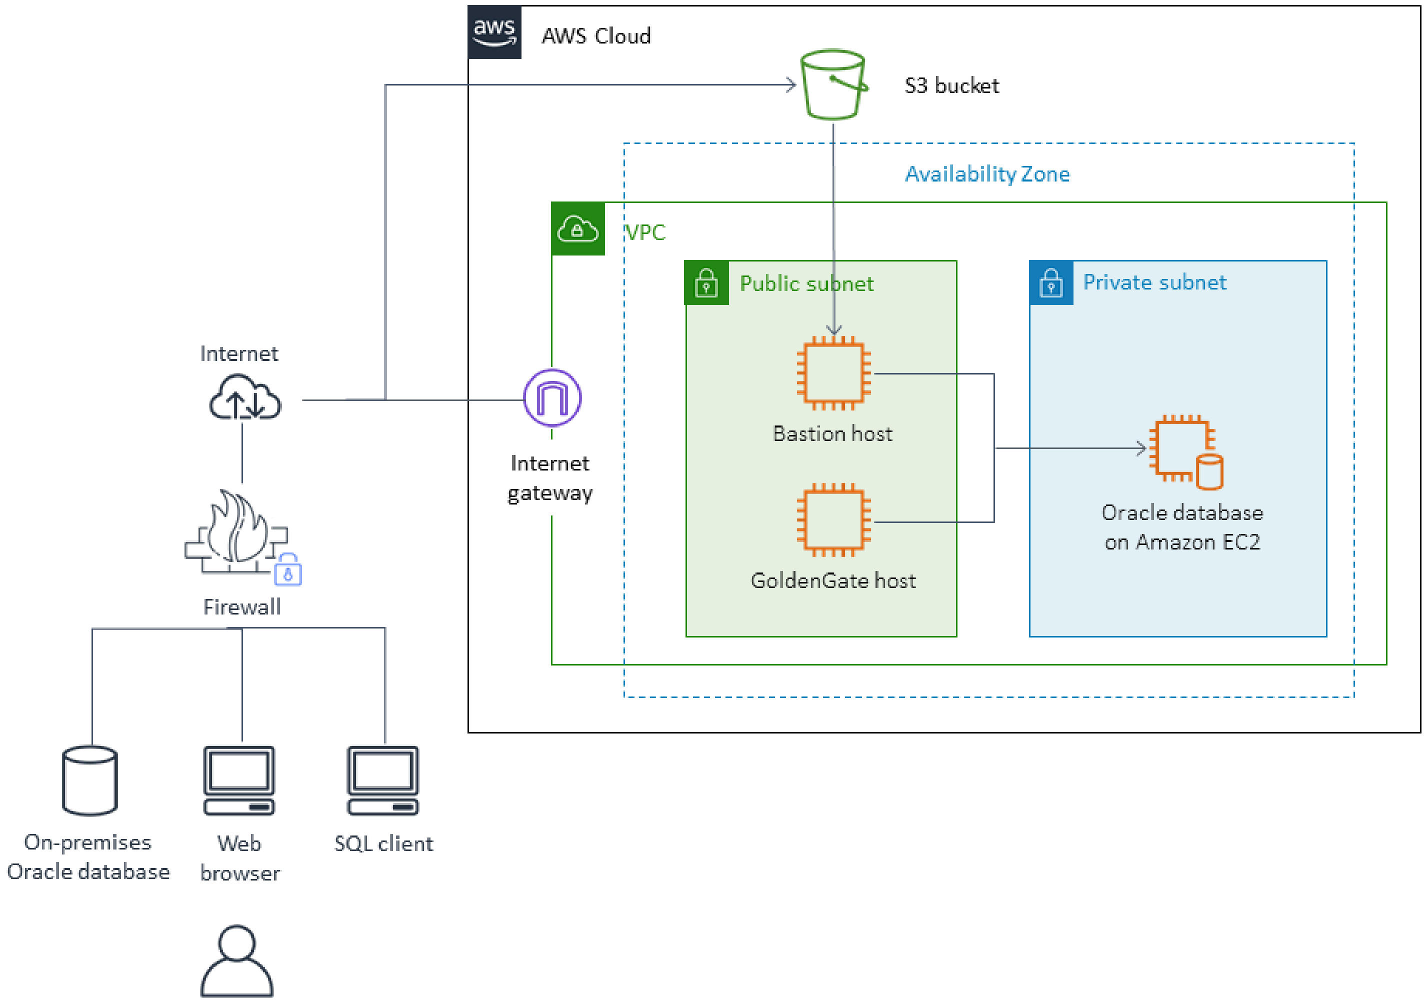


Data migration architecture

Using AWS DMS:



Using native Oracle tools:



Tools

- **AWS DMS -** [AWS Database Migration Services](https://aws.amazon.com/dms/) (AWS DMS) supports several types of source and target databases. For information about the database versions and editions that are supported, see [Using an Oracle Database as a Source for AWS DMS](https://docs.aws.amazon.com/dms/latest/userguide/CHAP_Source.Oracle.html). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- **Native Oracle tools -** RMAN, Data Pump import/export, transportable tablespaces, Oracle GoldenGate

Epics

Plan the migration

Task	Description	Skills required
Validate the versions of the source and target databases.		DBA
Identify the version of the target OS.		DBA, SysAdmin
Identify hardware requireme nts for the target server instance based on the Oracle compatibility list and capacity requirements.		DBA, SysAdmin
Identify storage requirements (storage type and capacity).		DBA, SysAdmin
Identify network requireme nts (latency and bandwidth).		DBA, SysAdmin
Choose the proper instance type based on capacity, storage features, and network features.		DBA, SysAdmin
Identify network/host access security requirements for source and target databases.		DBA, SysAdmin
Identify a list of OS users required for Oracle software installation.		DBA, SysAdmin

Task	Description	Skills required
Download AWS Schema Conversion Tool (AWS SCT) and drivers.		DBA
Create an AWS SCT project for the workload, and connect to the source database.		DBA
Generate SQL files for the creation of objects (tables, indexes, sequences, etc.).		DBA
Determine a backup strategy.		DBA, SysAdmin
Determine availability requirements.		DBA
Identify the application migration/switch-over strategy.		DBA, SysAdmin, App owner

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets in your AWS account.		SysAdmin
Create security groups and network access control lists (ACLs).		SysAdmin
Configure and start the EC2 instance.		SysAdmin

Install the Oracle software

Task	Description	Skills required
Create the OS users and groups required for the Oracle software.		DBA, SysAdmin
Download the required version of Oracle software.		
Install the Oracle software on the EC2 instance.		DBA, SysAdmin
Create objects like tables, primary keys, views, and sequences by using the scripts generated by AWS SCT.		DBA

Migrate data - option 1

Task	Description	Skills required
Use native Oracle tools or third-party tools to migrate database objects and data.	Oracle tools include Data Pump import/export, RMAN, transportable tablespaces, and GoldenGate.	DBA

Migrate data - option 2

Task	Description	Skills required
Determine the migration method.		DBA

Task	Description	Skills required
Create a replication instance in the AWS DMS console.		DBA
Create source and target endpoints.		DBA
Create a replication task.		DBA
Enable change data capture (CDC) to capture changes for a continuous replication.		DBA
Run the replication task and monitor logs.		DBA
Create secondary objects like indexes and foreign keys when the full load is done.		DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, SysAdmin, App owner

Cut over

Task	Description	Skills required
Follow the application cutover/switch-over strategy.		DBA, SysAdmin, App owner

Close the project

Task	Description	Skills required
Shut down temporary AWS Secrets Manager resources.		DBA, SysAdmin
Review and validate the project documents.		DBA, SysAdmin, App owner
Gather metrics around time to migrate, % of manual vs. tool, cost savings, etc.		DBA, SysAdmin, App owner
Close out the project and provide feedback.

Migrate an on-premises Oracle database to Amazon EC2 by using Oracle Data Pump

Navakanth Talluri, Amazon Web Services

Summary

When migrating databases, you must consider factors such as the source and target database engines and versions, migration tools and services, and acceptable downtime periods. If you're migrating an on-premises Oracle database to Amazon Elastic Compute Cloud (Amazon EC2), you can use Oracle tools, such as Oracle Data Pump and Oracle Recovery Manager (RMAN). For more information about strategies, see Migrating Oracle databases to the AWS Cloud.

Oracle Data Pump helps you extract the logical, consistent backup of the database and restore it to the target EC2 instance. This pattern describes how to migrate an on-premises Oracle database to an EC2 instance by using Oracle Data Pump and the `NETWORK_LINK` parameter, with minimal downtime. The `NETWORK_LINK` parameter starts an import through a database link. The Oracle Data Pump Import (impdp) client on the target EC2 instance connects to the source database, retrieves data from it, and writes the data directly to the database on the target instance. There are no backup, or *dump*, files used in this solution.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An on-premises Oracle database that:
  - Isn't an Oracle Real Application Clusters (RAC) database
  - Isn't an Oracle Automatic Storage Management (Oracle ASM) database
  - Is in read-write mode.
- You have created an AWS Direct Connect link between your on-premises data center and AWS. For more information, see Create a connection (Direct Connect documentation).

Product versions

- Oracle Database 10g release 1 (10.1) and later

Architecture

Source technology stack

- A standalone (non-RAC and non-ASM) Oracle database server in an on-premises data center

Target technology stack

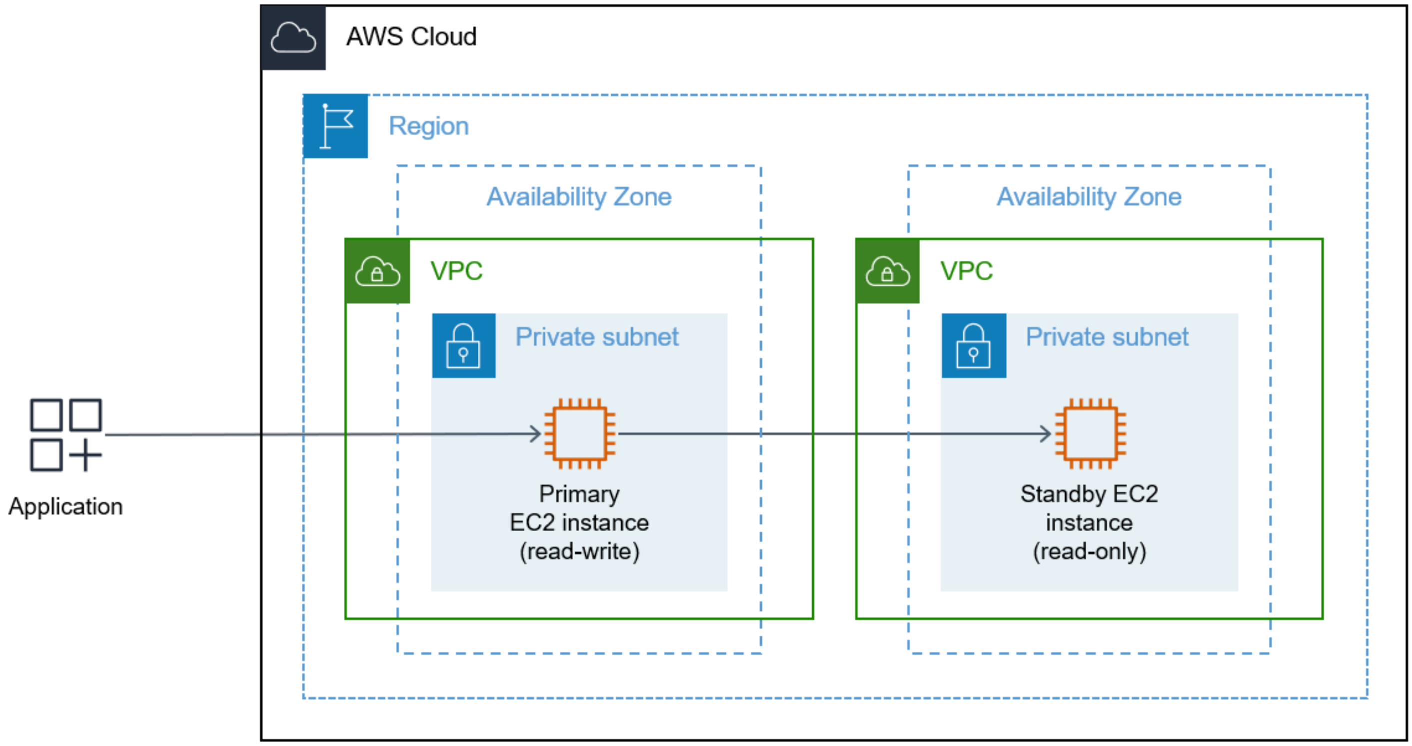
- An Oracle database running on Amazon EC2

Target architecture

The reliability pillar of the AWS Well-Architected Framework recommends creating data backups to help provide high availability and resiliency. For more information, see Architecting for high availability in *Best Practices for Running Oracle Database on AWS*. This pattern sets up primary and standby databases on EC2 instances by using Oracle Active Data Guard. For high availability, the EC2 instances should be in different Availability Zones. However, the Availability Zones can be in the same AWS Region or in different AWS Regions.

Active Data Guard provides read-only access to a physical standby database and applies redo changes continuously from the primary database. Based on your recovery point objective (RPO) and recovery time objective (RTO), you can choose between synchronous and asynchronous redo transport options.

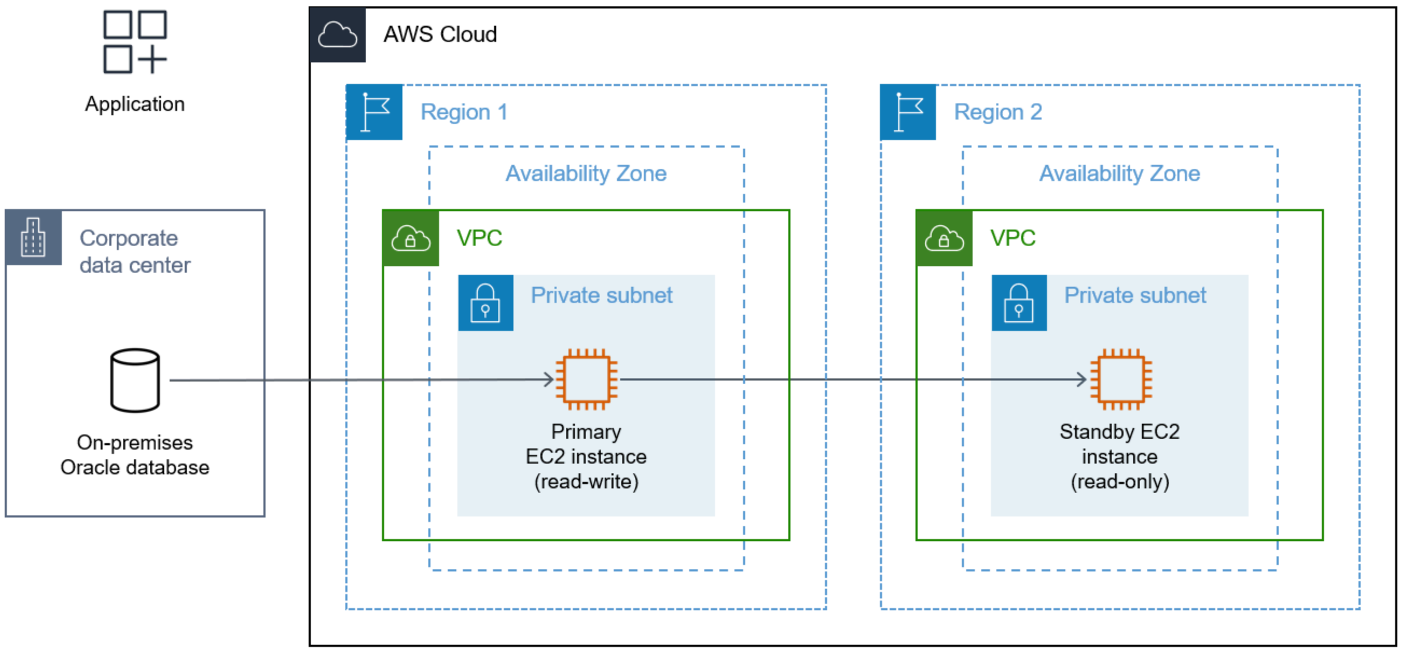
The following image shows the target architecture if the primary and standby EC2 instances are in different AWS Regions.



Data migration architecture

After you have finished setting up the target architecture, you use Oracle Data Pump to migrate the on-premises data and schemas to the primary EC2 instance. During cutover, applications can't access the on-premises database or the target database. You shut down these applications until they can be connected to the new target database on the primary EC2 instance.

The following image shows the architecture during the data migration. In this sample architecture, the primary and standby EC2 instances are in different AWS Regions.



Tools

AWS services

- AWS Direct Connect links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

Other tools and services

- Oracle Active Data Guard helps you create, maintain, manage, and monitor standby databases.
- Oracle Data Pump helps you move data and metadata from one database to another at high speeds.

Best practices

- Best Practices for Running Oracle Database on AWS
- Importing data using NETWORK_LINK

Epics

Set up the EC2 instances on AWS

Task	Description	Skills required
Identify the source hardware configuration for the on-premises host and the kernel parameters.	Validate the on-premises configuration, including storage size, input/output operations per second (IOPS), and CPU. This is important for Oracle licensing, which is based on CPU cores.	DBA, SysAdmin
Create the infrastructure on AWS.	Create the virtual private clouds (VPCs), private subnets, security groups, network access control lists (ACLs), route tables, and internet gateway. For more information, see the following : • VPCs and subnets • Tutorial: Create a VPC for use with a database instance	DBA, AWS systems administr ator
Set up the EC2 instances by using Active Data Guard.	Configure AWS EC2 instances by using an Active Data Guard configuration, as described in the AWS Well-Architected Framework. The version of Oracle Database on the EC2 instance can be different from the on-premises version because this pattern uses	DBA, AWS systems administr ator

Task	Description	Skills required
	logical backups. Note the following: • Put the target database in read-write mode. • On the target database, provide the Transpare nt Network Substrate (TNS) detail for the source database. For more information, see: • Starting Up a Database (Oracle documentation) • Creating and Configuring an Oracle Database (Oracle documentation)	

Migrate the database to Amazon EC2

Task	Description	Skills required
Create a dblink to the on-premises database from the EC2 instance.	Create a database link (dblink) between the Oracle database on the EC2 instance and the on-premises Oracle database. For more informati on, see Using Network Link Import to Move Data (Oracle documentation).	DBA

Task	Description	Skills required
Verify the connection between the EC2 instance and the on-premises host.	Use the dblink to confirm that the connection between the EC2 instance and the on-premises database is functioning. For instructions, see CREATE DATABASE LINK (Oracle documentation).	DBA
Stop all applications connected to the on-premises database.	After the database downtime is approved, shut down any applications and dependent jobs that connent to your on-premises database. You can do this either from the application directly or from the database by using cron. For more information, see Use the Crontab Utility to Schedule Tasks on Oracle Linux.	DBA, App developer
Schedule the data migration job.	On the target host, use the command `impdb` to schedule the Data Pump import. This connects the target database to the on-premises host and starts the data migration . For more information, see Data Pump Import and NETWORK_LINK (Oracle documentation).	DBA

Task	Description	Skills required
Validate the data migration.	Data validation is a crucial step. For data validation, you can use custom tools or Oracle tools, such as a combination of dblink and SQL queries.	DBA

Cut over

Task	Description	Skills required
Put the source database in read-only mode.	Confirm that the application is shut down and no changes are being made to the source database. Open the source database in read-only mode. This helps you avoid any open transactions. For more information, see `ALTER DATABASE` in [SQL Statements](#) (Oracle documentation).	DBA, DevOps engineer, App developer
Validate the object count and data.	To validate the data and object, use custom tools or Oracle tools, such as a combination of dblink and SQL queries.	DBA, App developer
Connect the applications to the database on the primary EC2 instance.	Change the application's connection attribute to point to the new database you created on the primary EC2 instance.	DBA, App developer

Task	Description	Skills required
Validate the application performance.	Start the application. Validate the functionality and performance of the applicati on by using Automated Workload Repository (Oracle documentation).	App developer, DevOps engineer, DBA

Migrate RHEL BYOL systems to AWS License-Included instances by using AWS MGN

Mike Kuznetsov, Amazon Web Services

Summary

When you migrate your workloads to AWS by using AWS Application Migration Service (AWS MGN), you might have to lift and shift (rehost) your Red Hat Enterprise Linux (RHEL) instances and change the license from the default Bring Your Own License (BYOL) model to an AWS License Included (LI) model during migration. AWS MGN supports a scalable approach that uses Amazon Machine Image (AMI) IDs. This pattern describes how to accomplish the license change on RHEL servers during the rehost migration at scale. It also explains how to change the license for a RHEL system that's already running on Amazon Elastic Compute Cloud (Amazon EC2).

Prerequisites and limitations

Prerequisites

- Access to the target AWS account
- AWS MGN initialized in the target AWS account and Region for the migration (not required if you have already migrated from your on-premises system to AWS)
- A source RHEL server with a valid RHEL license

Architecture

This pattern covers two scenarios:

- Migrating a system from on premises directly into an AWS LI instance by using AWS MGN. For this scenario, follow the instructions in the first epic (*Migrate to LI instance - option 1*) and third epic.
- Changing the licensing model from BYOL to LI for a previously migrated RHEL system that's already running on Amazon EC2. For this scenario, follow the instructions in the second epic (*Migrate to LI instance - option 2*) and third epic.

> **Note**
>
> The third epic involves reconfiguring the new RHEL instance to use the Red Hat Update Infrastructure (RHUI) servers provided by AWS. This process is the same for both scenarios.

Tools

AWS services

- AWS Application Migration Service (AWS MGN) helps you rehost (lift and shift) applications to the AWS Cloud without change and with minimal downtime.

Epics

Migrate to LI instance - option 1 (for an on-premises RHEL system)

Task	Description	Skills required
Find the AMI ID of the RHEL AWS LI instance in the target Region.	Visit AWS Marketplace or use the Amazon EC2 console to find the RHEL AMI ID that matches the version of the RHEL source system (for example, RHEL-7.7), and write down the AMI ID. On the Amazon EC2 console, you can filter the AMIs by using one of the following search terms: • Description = Provided by Red Hat, Inc. • AMI name = RHEL-7.7	Cloud administrator
Configure AWS MGN launch settings.	1. On the AWS MGN console, add the source RHEL system: Install the AWS Replication Agent and	Cloud administrator

Task	Description	Skills required
	add the source server by following the instructi ons in the [AWS MGN documentation](). 2. On the **Source servers** page, choose the source RHEL system, and then choose the **Launch settings** tab. 3. In the **General launch settings** section, choose **Edit**. To disable automatic selection and manually specify the target instance type, change **Instance type right sizing** to **None**, and then choose **Save settings**. This lets you use the instance type that you configure in your Amazon EC2 launch template. For more information, see the [AWS MGN documentation](). 4. In the **EC2 Launch Template** section, choose **Modify**. In the **About modifying EC2 launch templates** dialog box, choose **Modify** again. This opens the Amazon EC2 console so you can change the template for this instance.	

Task	Description	Skills required
	5. Review the key considerations in the [AWS MGN documentation](). **Note** You can disregard the warning against choosing your own AMI. 6. On the [Amazon EC2 console](), in the new launch template, modify the following: • For **AMI**, specify the AMI ID you identified previously, or search for RHEL-*x* and specify the version you require (for example, RHEL-7.7). • For **Instance type**, set the desired target instance type. • Leave the following sections unchanged: **Key pair (login)**, **Network settings** (unless you want to specify a target subnet and security groups), **Storage**, **Resource tags** (unless you want to add or modify any tags).	

Task	Description	Skills required
	• (Optional) In the **Advanced details** section, specify the IAM instance profile role, if needed for future management by AWS Systems Manager. 7. Choose **Create template version**, and then choose the link in the success message to view the launch template. 8. Choose **Actions**, **Set default version**. For **Template version**, select the latest version (version 2 for a new system), and then choose **Set as default version**. AWS MGN will now use this version of the launch template to launch test or cutover instances. For more information, see the [AWS MGN documentation]().	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Validate settings.</td><td>

On the AWS MGN console, on the Source servers page, choose your source server, and then choose the Launch settings tab.
In the EC2 Launch Template section, verify that the Instance type, Subnet, and Security groups parameters are set correctly.

Note
This section doesn't display the AMI ID you selected. To see the ID, you can open the Amazon EC2 console, Launch Templates view, and search for the template ID that's shown in this section.
</td><td>Cloud administrator</td></tr>
</table>

Task	Description	Skills required
Launch the new LI instance.	1. When the initial sync is complete, the **Migration lifecycle** column for the server on the AWS MGN console **Source servers** page changes to **Ready for testing**. To launch the new test instance, choose your source server, open the **Test and cutover** menu, and then choose **Launch test instances**. Choose **View job details** to monitor the status of the launch job. For more information, see the [AWS MGN documentation](). 2. Wait for the launch job to complete, and then open the launched EC2 instance details page. Choose the **Details** tab and verify that the **Instance details** section contains the following: • Platform details: "Red Hat Enterprise Linux" • AMI name: The name of AMI you specified in the EC2 launch template 3. Cut over to the new LI instance by following the instructions in the [AWS MGN documentation]().	Cloud administrator

Task	Description	Skills required
	4. Reconfigure the new instance to use the AWS-provided RHUI servers by following the steps in the last epic.	

Migrate to LI instance - option 2 (for a RHEL BYOL EC2 instance)

Task	Description	Skills required
Migrate your RHEL BYOL EC2 instance to an AWS LI instance.	You can switch RHEL systems that you previously migrated to AWS as BYOL to AWS LI instances by moving their disks (Amazon Elastic Block Store volumes) and attaching them to a new LI instance. To make this switch, follow these steps: 1. Launch a new target RHEL instance from a RHEL LI AMI. Make sure that the AMI you selected: • Uses the same RHEL version as your current RHEL instance. • Has the same boot-up process (BIOS or UEFI) as your current RHEL instance. For example, if the source server is BIOS-based, use the AWS Marketplace RHEL AMI	Cloud administrator

Task	Description	Skills required
	that is also BIOS-based; for UEFI-based systems, choose the UEFI-based AMI. 2. Stop both instances: the new LI instance and the original source instance. 3. Detach all EBS volumes (including the root disk) from the new LI instance and delete them. 4. Detach all EBS volumes (including the root disk) from the old source instance and attach them to the new LI instance. Keep the same mapping of volumes to devices. (For example, the EBS volume that was previousl y attached to the `/dev/sda` drive must be attached as `/dev/sda` to the new instance.) 5. Delete the source (now diskless) instance. 6. Start the new LI instance. Log in to the instance and reconfigure it to use the AWS-provided RHUI servers by following the steps in the next epic.	

Reconfigure RHEL OS to use AWS-provided RHUI – both options

Task	Description	Skills required
Deregister the OS from the Red Hat subscription and license.	After migration and successful cutover, the RHEL system has to be removed from the Red Hat subscription to stop consuming the Red Hat license and avoid double billing. To remove RHEL OS from the Red Hat subscription, follow the process described in the [Red Hat Subscription Management (RHSM) documentation](). Use the CLI command: `subscription-manager unregister` You can also disable the subscription manager plugin to stop checking the status of the subscription on every **yum** call. To do this, edit the configuration file `/etc/yum/pluginconf.d/subscription-manager.conf` and change the parameter `enabled=1` to `enabled=0` .	Linux or system administrator
Replace the old update configuration (RHUI, Red	You must reconfigure the migrated RHEL system	Linux or system administrator

Task	Description	Skills required
Hat Satellite network, yum repositories) with the AWS-provided RHUI.	to use the AWS-provided RHUI servers. This gives you access to the RHUI servers within AWS Regions without requiring the external update infrastructure. The change involves the following process: 1. Back up the existing **yum** configuration. 2. Remove the old RHUI (**yum** repositories) configuration and packages. 3. Add the new AWS-provided RHUI configuration and certificate packages. You have to retrieve these from another RHEL instance on AWS because these configuration packages are available only on AWS-provided RHUI servers. Here are the detailed steps and commands: 1. Back up the existing **yum** configuration and certificates by copying all `/etc/yum*` and `/etc/pki/*` folders to a backup location. For example: `mkdir yum-backup`	

Task	Description	Skills required

	`cp -ra /etc/yum* /etc/pki ./yum-backup`
	`tar czf yum-backup.tgz ./yum-backup`
	2. Remove the old RHUI configuration and packages:
	a. Find all installed RHUI packages:
	`sudo rpm -qa | grep rhui`
	b. Delete these packages:
	`sudo yum remove $(rpm -qa | grep rhui)`
	c. Remove the `/etc/yum/vars/releasever` file, if it exists.
	3. Add the new AWS-provided RHUI and certificate packages. You must retrieve these from another RHEL instance on AWS. There are several ways to do this. For example, you can follow the instructions provided in the [Red Hat Knowledgebase article](#):
	a. Launch another RHEL (RHEL-EC2) instance from [AWS Marketplace](#).	

Task	Description	Skills required

	b. Download two packages from this instance: the latest RHUI client configuration package and the certificate authority (CA) certificates. For example, run this command from your desktop:
	`ssh RHEL-EC2 "sudo yumdownloader ca-certificates rh-amazon-rhui-client"`
	c. Copy the packages from the RHEL-EC2 instance to the new migrated system. For example:
	`scp RHEL-EC2:rh-amazon-rhui-client\* RHEL-EC2:ca-certificates\* .`
	`ssh <migrated-instance> "mkdir /tmp/amazon"`
	`scp rh-amazon-rhui-client* ca-certificates* <migrated-instance>:/tmp/amazon`
	d. Install the new RHUI and CA configuration packages on the migrated instance:	

Task	Description	Skills required
	`ssh <migrated-instance> "sudo rpm -Uhv /tmp/amazon/*"`	

Validate the configuration.	On the target migrated instance, verify that the new configuration is correct:
	`sudo yum clean all`
	`sudo yum repolist`
		Linux or system administrator

Migrate an on-premises SAP ASE database to Amazon EC2

Sergey Dmitriev and Gergely Cserdi, Amazon Web Services

Summary

This pattern describes how to migrate an SAP Adaptive Server Enterprise (ASE) database from an on-premises host to an Amazon Elastic Compute Cloud (Amazon EC2) instance. The pattern covers the use of AWS Database Migration Service (AWS DMS) or SAP ASE native tools such as ASE Cockpit, Sybase Central for ASE, and DBA Cockpit for migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An SAP ASE source database in an on-premises data center

Limitations

- The source database must be less than 64 TB

Product versions

- SAP ASE version 15.x and 16.x or later

Architecture

Source technology stack

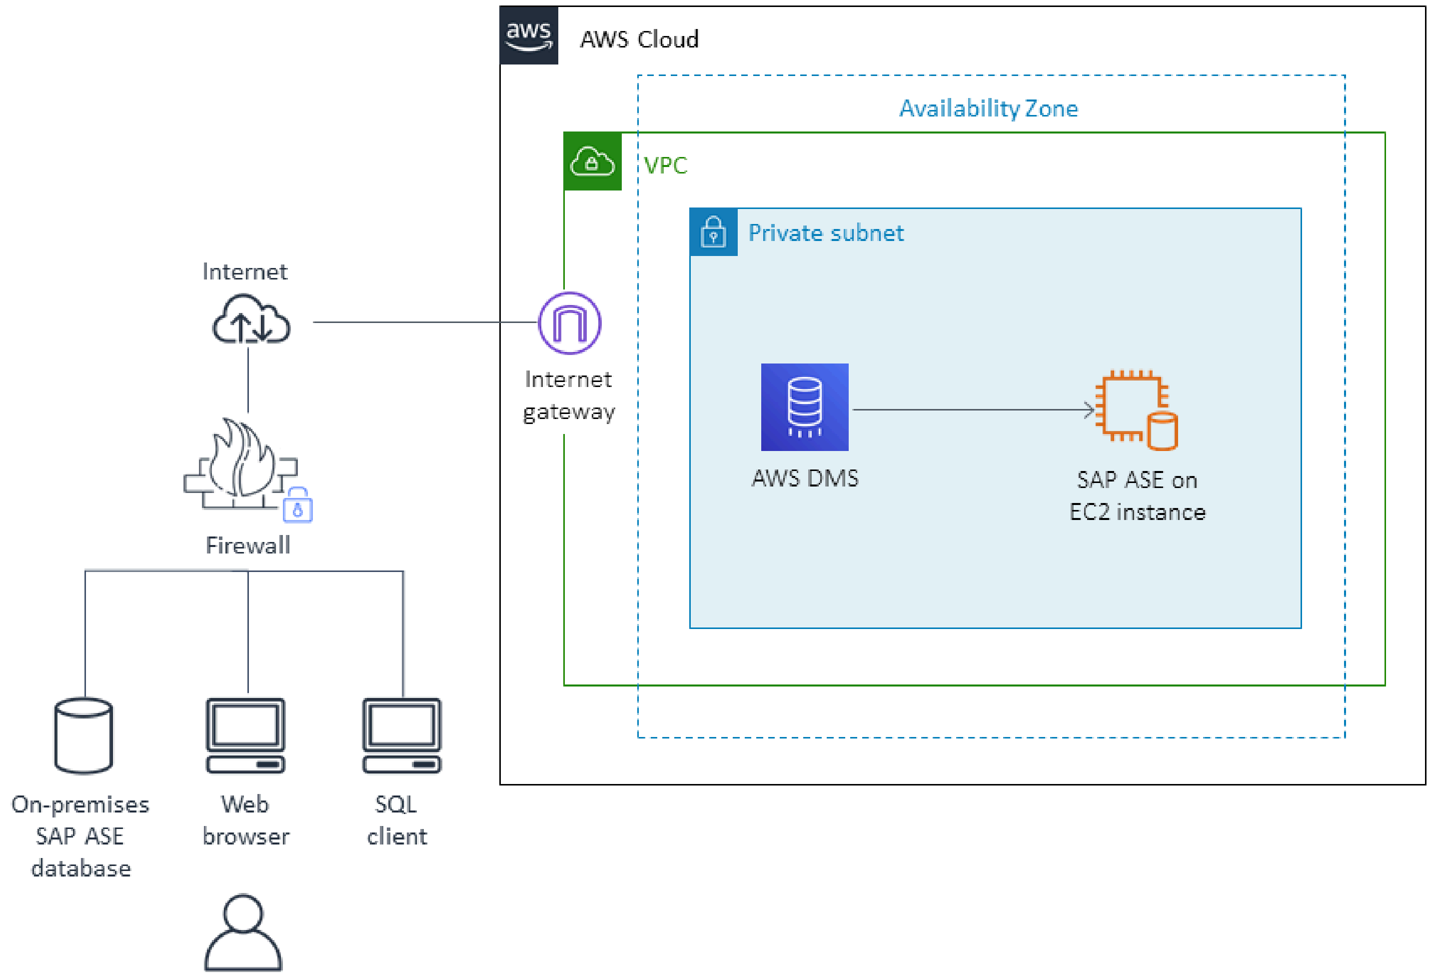
- On-premises SAP ASE database

Target technology stack

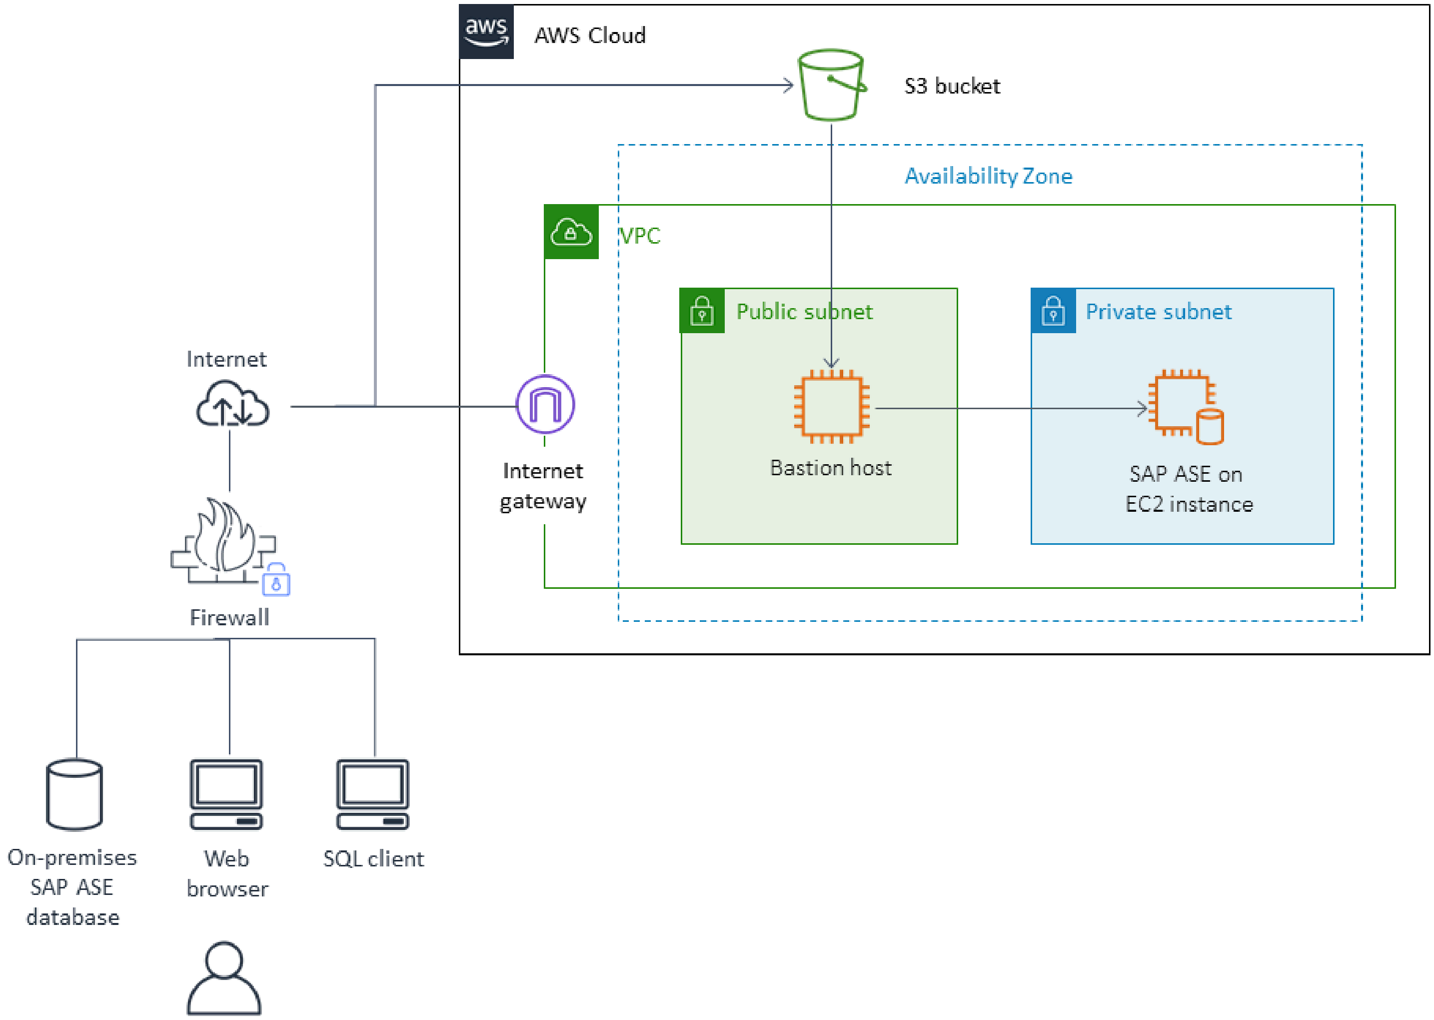
- SAP ASE database on an EC2 instance

Database migration architecture

Using AWS DMS:



Using native SAP ASE tools:



Tools

- **AWS DMS** - AWS Data Migration Service (AWS DMS) supports several different source and target databases. For more information, see Sources for Data Migration and Targets for Data Migration. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- **SAP ASE** - Native tools include ASE Cockpit, Sybase Central for ASE, and DBA Cockpit.

Epics

Analyze the migration

Task	Description	Skills required
Validate the source and target database versions.		DBA
Identify the target OS version.		DBA, SysAdmin
Identify the hardware requirements for the target server instance based on the SAP ASE compatibility list and capacity requirements.		DBA, SysAdmin
Identify the requirements for the storage type and capacity.		DBA, SysAdmin
Identify the network requirements including latency and bandwidth.		DBA, SysAdmin
Choose the proper instance type, capacity, storage features, and network features.		DBA, SysAdmin
Identify the network and host access security requireme nts for the source and target databases.		DBA, SysAdmin
Identify a list of operating system users required for the SAP ASE software installation.		DBA, SysAdmin

Task	Description	Skills required
Determine the backup strategy.		DBA
Determine the availability requirements.		DBA
Identify the application migration and switchover strategy.		DBA, SysAdmin, App owner

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.		SysAdmin
Create security groups and the network access control list (ACL).		SysAdmin
Configure and start the EC2 instance.		SysAdmin

Install the software

Task	Description	Skills required
Create the OS users and groups required for SAP ASE software to work.		DBA, SysAdmin
Download the required version of SAP ASE software.		DBA, SysAdmin

Task	Description	Skills required
Install the SAP ASE database, backup server software, and replication server software on the EC2 instance and then configure the server.		DBA, SysAdmin

Migrate the data - option 1

Task	Description	Skills required
Migrate the database objects and data by using native SAP ASE tools or third-party tools.	See the documentation for the SAP ASE or third-par ty tools. These include ASE Cockpit, Sybase Central for ASE, and DBA Cockpit.	DBA

Migrate the data - option 2

Task	Description	Skills required
Migrate the data by using AWS DMS.		DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, SysAdmin, App owner

Cut over

Task	Description	Skills required
Follow the application cutover or switchover strategy.		DBA, SysAdmin, App owner

Close the project

Task	Description	Skills required
Shut down the temporary AWS resources.		DBA, SysAdmin
Validate and review the project documents.		DBA, SysAdmin, App owner
Gather metrics around time to migrate, percent of manual versus tool cost savings, and so on.		DBA, SysAdmin, App owner
Close the project and provide any feedback.		DBA, SysAdmin, App owner

Migrate an on-premises Microsoft SQL Server database to Amazon EC2

Senthil Ramasamy, Amazon Web Services

Summary

This pattern describes how to migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on an Amazon Elastic Compute Cloud (Amazon EC2) instance. It covers two options for migration: using AWS Database Migration Service (AWS DMS) or using native Microsoft SQL Server tools such as backup and restore, Copy Database Wizard, or copy and attach database.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An operating system supported by Amazon EC2 (for a complete list of supported operating system versions, see [Amazon EC2 FAQs])
- A Microsoft SQL Server source database in an on-premises data center

Product versions

- For on-premises and Amazon EC2 instance databases, AWS DMS supports:
  - SQL Server versions 2005, 2008, 2008R2, 2012, 2014, 2016, 2017, and 2019
  - Enterprise, Standard, Workgroup, Developer, and Web editions
- For the latest list of supported versions, see [Using a Microsoft SQL Server Database as a Target for AWS DMS].

Architecture

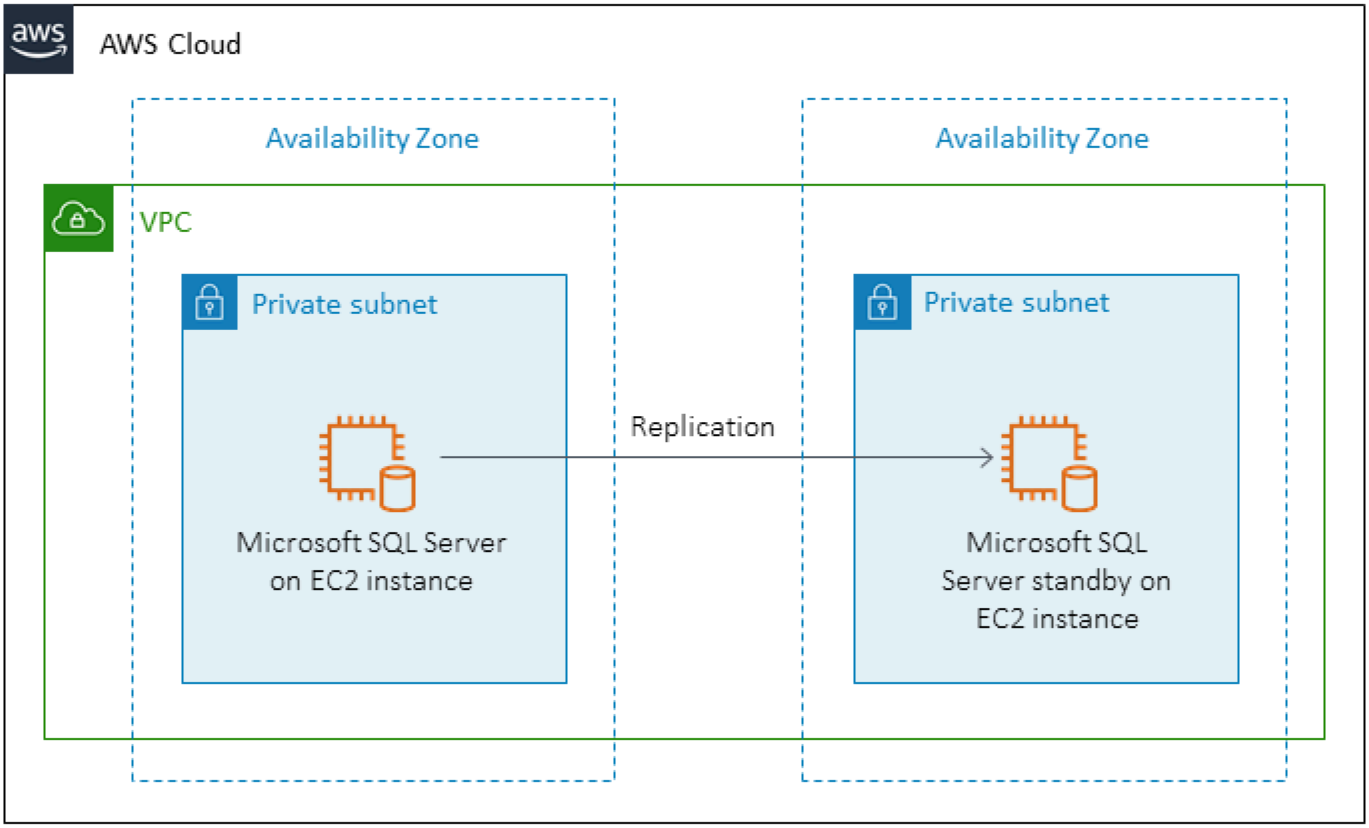
Source technology stack

- On-premises Microsoft SQL Server database

Target technology stack

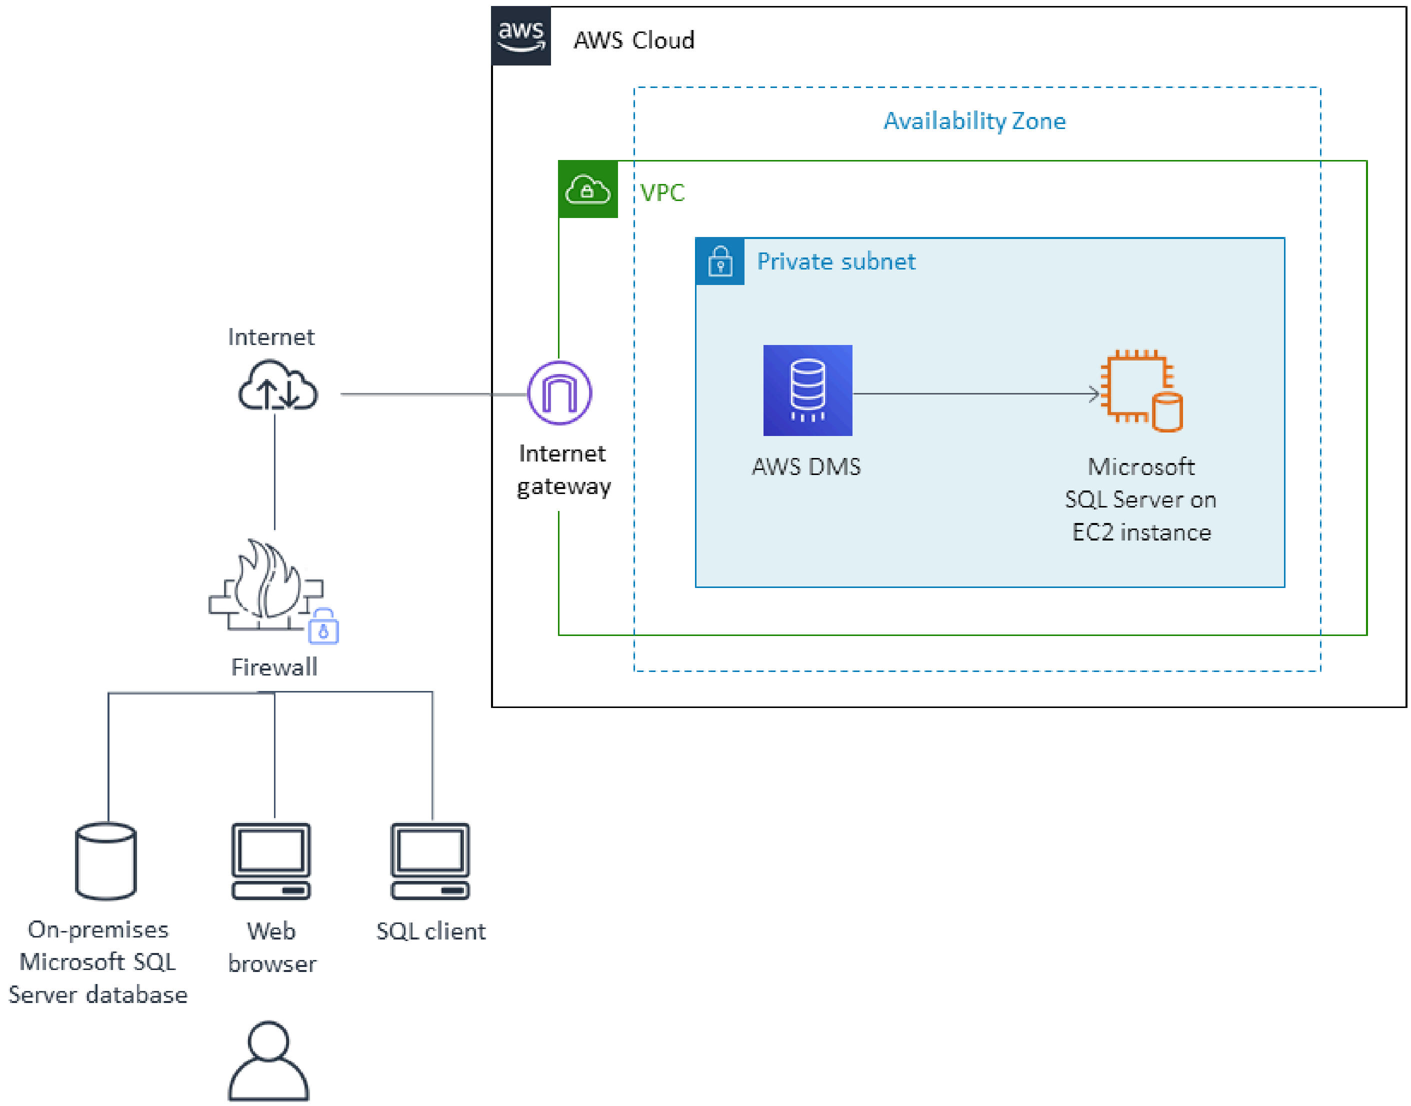
- Microsoft SQL Server database on an EC2 instance

Target architecture

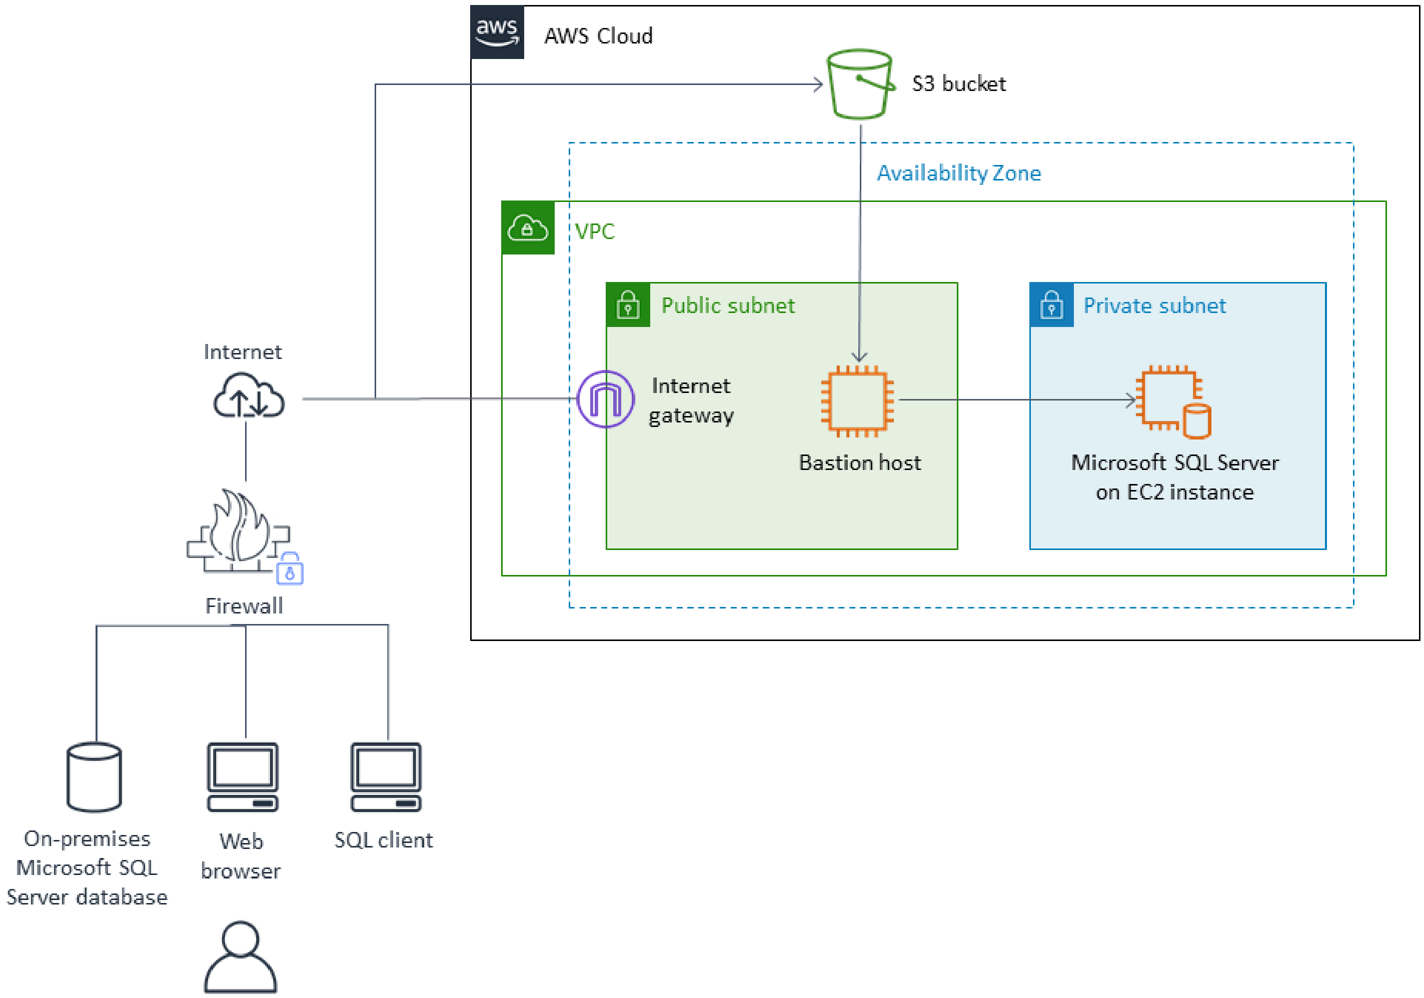


Data migration architecture

- Using AWS DMS



- Using native SQL Server tools



Tools

- [AWS Database Migration Service (AWS DMS)] helps you migrate your data to and from widely used commercial and open-source databases, including Oracle, SQL Server, MySQL, and PostgreSQL. You can use AWS DMS to migrate your data into the AWS Cloud, between on-premises instances (through an AWS Cloud setup), or between combinations of cloud and on-premises setups.
- [AWS Schema Conversion Tool (AWS SCT)] supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.
- Native Microsoft SQL Server tools include backup and restore, Copy Database Wizard, and copy and attach database.

Epics

Plan the migration

Task	Description	Skills required
Validate the source and target database versions.		DBA
Identify the target operating system version.		DBA, Systems administrator
Identify the hardware requirements for the target server instance based on the Microsoft SQL Server compatibility list and capacity requirements.		DBA, Systems administrator
Identify the storage requirements for type and capacity.		DBA, Systems administrator
Identify the network requirements, including latency and bandwidth.		DBA, Systems administrator
Choose the EC2 instance type based on capacity, storage features, and network features.		DBA, Systems administrator
Identify the network and host access security requireme nts for the source and target databases.		DBA, Systems administrator
Identify a list of users required for the Microsoft		DBA, Systems administrator

Task	Description	Skills required
SQL Server software installat ion.		
Determine the backup strategy.		DBA
Determine the availability requirements.		DBA
Identify the application migration and cutover strategy.		DBA, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.		Systems administrator
Create security groups and network access control list (ACL).		Systems administrator
Configure and start an EC2 instance.		Systems administrator

Install the software

Task	Description	Skills required
Create the users and groups required for Microsoft SQL Server software.		DBA, Systems administrator

Task	Description	Skills required
Download the Microsoft SQL Server software.		DBA, Systems administrator
Install Microsoft SQL Server software on the EC2 instance and configure the server.		DBA, Systems administrator

Migrate the data - option 1

Task	Description	Skills required
Use native Microsoft SQL Server tools or third-party tools to migrate the database objects and data.	Tools include backup and restore, Copy Database Wizard, and copy and attach database. For more information, see the guide [Migrating Microsoft SQL Server databases to the AWS Cloud]().	DBA

Migrate the data - option 2

Task	Description	Skills required
Migrate the data by using AWS DMS.	For more information about using AWS DMS, see the links in the [Related resources]() section.	DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.	Use AWS Schema Conversion Tool (AWS SCT) to analyze and modify SQL code that’s embedded in application source code.	DBA, App owner

Cut over

Task	Description	Skills required
Follow the application switch-over strategy.		DBA, App owner, Systems administrator

Close the project

Task	Description	Skills required
Shut down all temporary AWS resources.	Temporary resources include the AWS DMS replication instance and the EC2 instance for AWS SCT.	DBA, Systems administrator
Review and validate the project documents.		DBA, App owner, Systems administrator
Gather metrics around time to migrate, percent of manual versus tool cost savings, and so on.		DBA, App owner, Systems administrator
Close the project and provide feedback.		DBA, App owner, Systems administrator

Migrate an on-premises MySQL database to Amazon EC2

Lorenzo Mota, Amazon Web Services

Summary

This pattern provides guidance for migrating an on-premises MySQL database to a MySQL database on an Amazon Elastic Compute Cloud (Amazon EC2) instance. The pattern discusses the use of AWS Database Migration Service (AWS DMS) or native MySQL tools such as **mysqldump** for the migration. It focuses on full database migration to a MySQL DB instance.

The pattern is primarily for DBAs and solutions architects. It can be used in small or large projects, in a testing or final migration phase. We recommend that you run at least one testing cycle before you use this pattern in a production environment.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A MySQL source database in an on-premises data center

Product versions

- MySQL version 5.5 and later
- A target operating system supported by Amazon EC2; see [Amazon EC2 FAQs]

Architecture

Source technology stack

- An on-premises MySQL database

Target technology stack

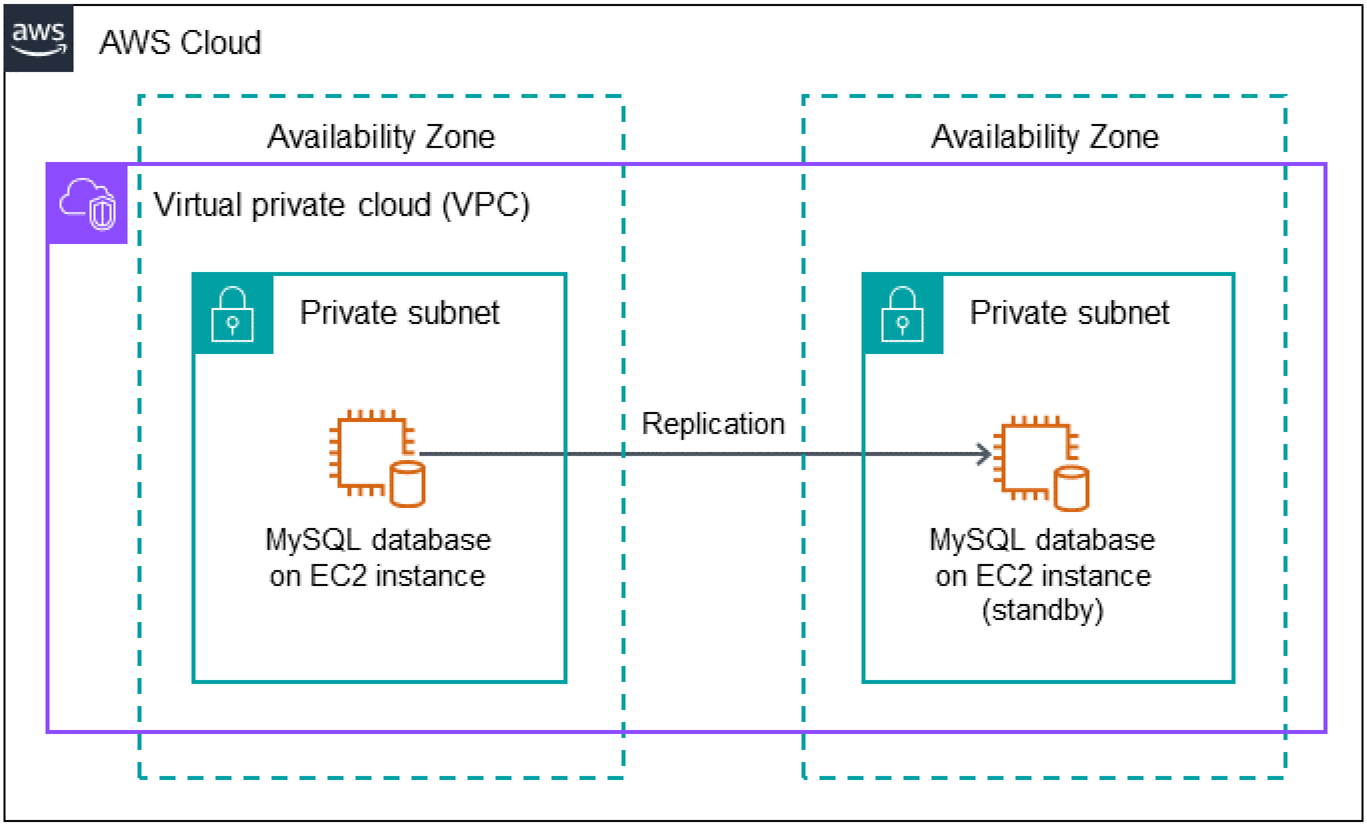
- A MySQL database instance on Amazon EC2

AWS data migration methods

- AWS DMS
- Native MySQL tools such as mysqldump, or third-party tools such as Percona XtraBackup

Target architecture

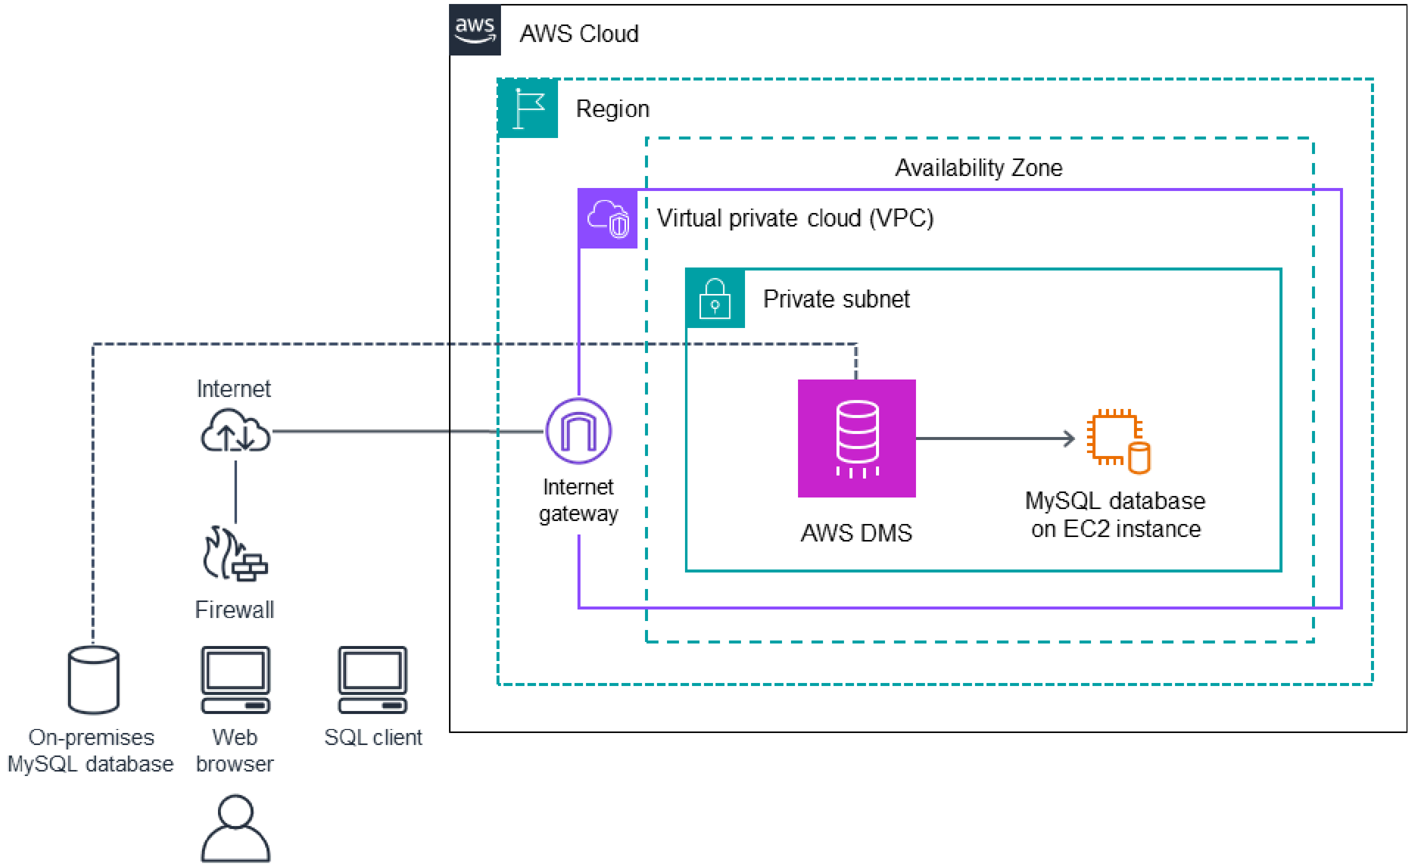
The following diagram illustrates the target Amazon EC2 implementation after cutover.



AWS data migration architecture

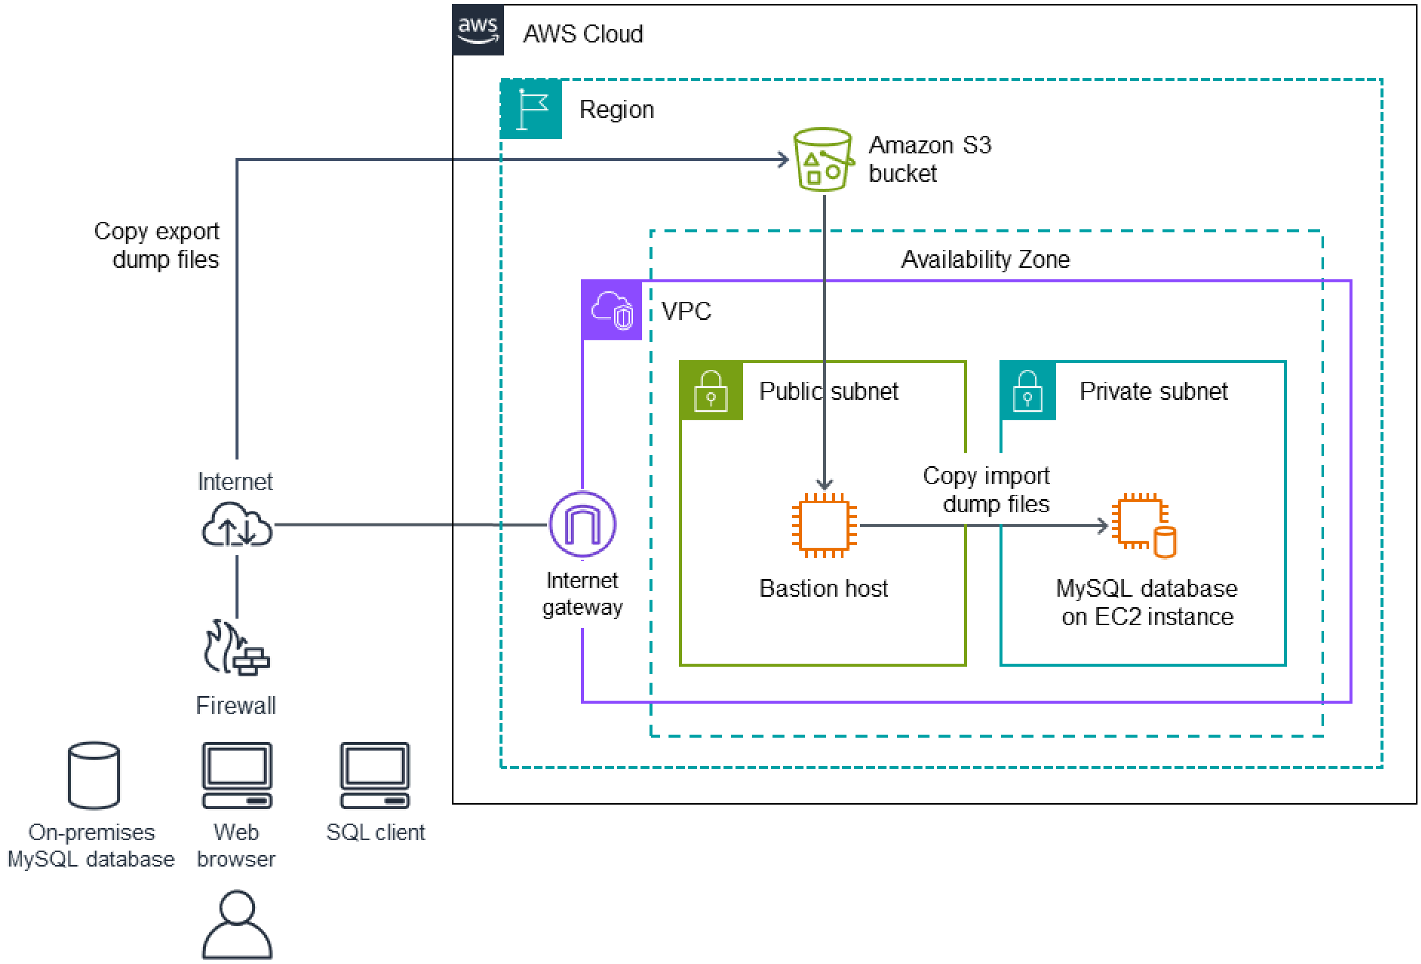
Using AWS DMS:

The following diagram illustrates the data migration workflow based on AWS DMS for sending full and incremental changes to the target MySQL database until cutover. The network connection from on premises to AWS depends on the requirements of the SQL client and is outside the scope of this pattern.



Using other MySQL tools:

The following diagram illustrates the data migration workflow based on using MySQL tools to generate export dump files from the on-premises database. These files are moved to Amazon Simple Storage Service (Amazon S3) and imported into the target MySQL database before cutover. The network connection from on premises to AWS depends on the requirements of the SQL client and is outside the scope of this pattern.



Notes:

- Depending on down time considerations and the size of the database for the final cutover, you can use AWS DMS or another change data capture (CDC) tool to minimize the cutover time. When you use a CDC tool such as AWS DMS, you can migrate to the target database in minutes.
- An offline strategy with **mysqldump** can suffice if the size of the database and network latency allow for a short cutover migration window. (We recommend that you perform testing to get an approximate time.)
- Usually a CDC strategy through AWS DMS requires more monitoring and complexity than an offline option.

Tools

AWS services

- AWS Database Migration Service (AWS DMS) supports several source and target databases. For information about MySQL source and target databases supported by AWS DMS, see Using a MySQL-compatible database as a source for AWS DMS and Using a MySQL-compatible database as a target for AWS DMS. If your source database isn't supported by AWS DMS, you must choose another method to migrate your data.

Other tools

- mysqldump is a MySQL utility that creates a dump file from a MySQL database for backup or migration purposes.
- Percona XtraBackup is an open source utility for performing non-blocking backups on MySQL databases.

Epics

Plan the migration

Task	Description	Skills required
Validate the database versions.	Validate the versions of the source and target databases . For information about MySQL versions supported by AWS DMS, see Sources for AWS DMS and Targets for AWS DMS in the AWS DMS documentation.	DBA
Identify the target operating system.	Determine the version of the target operating system. For a list of target operating systems supported by Amazon EC2, see Amazon EC2 FAQs.	DBA, Systems administrator
Identify hardware requireme nts.	Determine the hardware requirements for the target	DBA, Systems administrator

Task	Description	Skills required
	server instance based on the MySQL compatibility list and capacity requirements.	
Identify storage requireme nts.	Determine the storage type and capacity for the target database.	DBA, Systems administrator
Identify network requireme nts.	Determine networking requirements such as latency and bandwidth.	DBA, Systems administrator
Choose the target instance type.	Choose the target instance type based on capacity, storage features, and network features.	DBA, Systems administrator
Identify security requireme nts.	Determine the network or host access security requirements for the source and target databases.	DBA, Systems administrator
Identify users.	Determine the list of operating system users for the MySQL software installat ion. For more information, see the MySQL documentation.	DBA, Systems administrator
Determine a backup strategy.		DBA
Determine availability requirements.		DBA
Identify the application migration or switchover strategy.		DBA, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC) and subnets.	Configure route tables, internet gateway, NAT gateways, and subnets. For more information, see [VPC configuration options] in the Amazon VPC documentation.	Systems administrator
Create security groups and network access control lists (ACLs).	Configure ports (default for MySQL is 3306) and CIDR ranges or specific IPs depending on your requireme nts.	Systems administrator
Configure and start an EC2 instance.	For instructions, see [Launch an EC2 instance] in the Amazon EC2 documentation.	Systems administrator

Install MySQL software

Task	Description	Skills required
Create users and groups.	Create the operating system users and groups who need access to the server and database. For more informati on, see [Access Control and Account Management] in the MySQL documentation.	DBA, Systems administrator
Download MySQL.	Download the MySQL software. For instructions and binaries, see [Installing MySQL] in the MySQL documentation.	DBA, Systems administrator

Task	Description	Skills required
Install MySQL on the EC2 instance and configure the server.	Connect to your EC2 instance and install the MySQL software. For more informati on, see Connect to your EC2 instance in the Amazon EC2 documentation.	DBA, Systems administrator

Migrate data – option 1

Task	Description	Skills required
Migrate data with native MySQL or third-party tools.	This option uses native MySQL tools or third-party tools to migrate database objects and data. For instructi ons, see the documenta tion for mysqldump or Percona XtraBackup (for physical migration). For more information about using these tools, see the AWS blog post Migration options for MySQL to Amazon RDS for MySQL or Amazon Aurora MySQL.	DBA

Migrate data – option 2

Task	Description	Skills required
Migrate data with AWS DMS.	For more information, see High-level view of	DBA

Task	Description	Skills required
	[AWS DMS](#) in the AWS DMS documentation.	

Prepare for cutover

Task	Description	Skills required
Gather object counts.	Gather object counts from source database and new target databases. Fix any discrepancies in the target database.	DBA
Check dependencies.	Confirm that dependencies (links) to and from other databases are still valid and work correctly.	DBA
Test.	If this is a testing cycle, perform query testing, gather metrics, and fix any issues.	DBA

Cut over

Task	Description	Skills required
Move clients.	Switch the application clients over to the new infrastru cture.	DBA, App owner, Systems administrator
Provide support.	Provide support during functional application testing.	DBA

Close the project

Task	Description	Skills required
Shut down resources.	Shut down the AWS DMS replication instance and other temporary AWS resources.	DBA, Systems administrator
Review and project documents.	Review and validate the project documents.	DBA, App owner, Systems administrator
Collect metrics.	Collect metrics such as time to migrate, percentage of manual changes compared with tool-aided changes, and cost savings.	DBA, App owner, Systems administrator
Close out project.	Close out the migration project and provide feedback.	DBA, App owner, Systems administrator
Decommission source database.	Decommission the on-premis es MySQL database.	DBA, Systems administrator

Reduce homogeneous SAP migration cutover time by using Application Migration Service

Pavel Rubin, Diego Valverde, and Sunil Yadav, Amazon Web Services

Summary

This pattern outlines the steps for migrating SAP workloads by using AWS Application Migration Service. Application Migration Service facilitates cutovers by using block-level replication to maintain replication volumes that continually sync from their sources.

SAP workloads include the applications SAP Customer Relationship Management (SAP CRM), SAP Enterprise Resource Planning (ERP), and SAP Business Warehouse (SAP BW).

Prerequisites and limitations

Prerequisites

- An active AWS account with stable network connectivity between source SAP servers and the destination virtual private cloud (VPC) on AWS
- An SAP Adaptive Server Enterprise (ASE) source database for Linux or Windows in an on-premises data center

Limitations

- The target operating system must be supported by Amazon Elastic Compute Cloud (Amazon EC2). For more information, see Amazon EC2 FAQs.

Architecture

Source technology stack

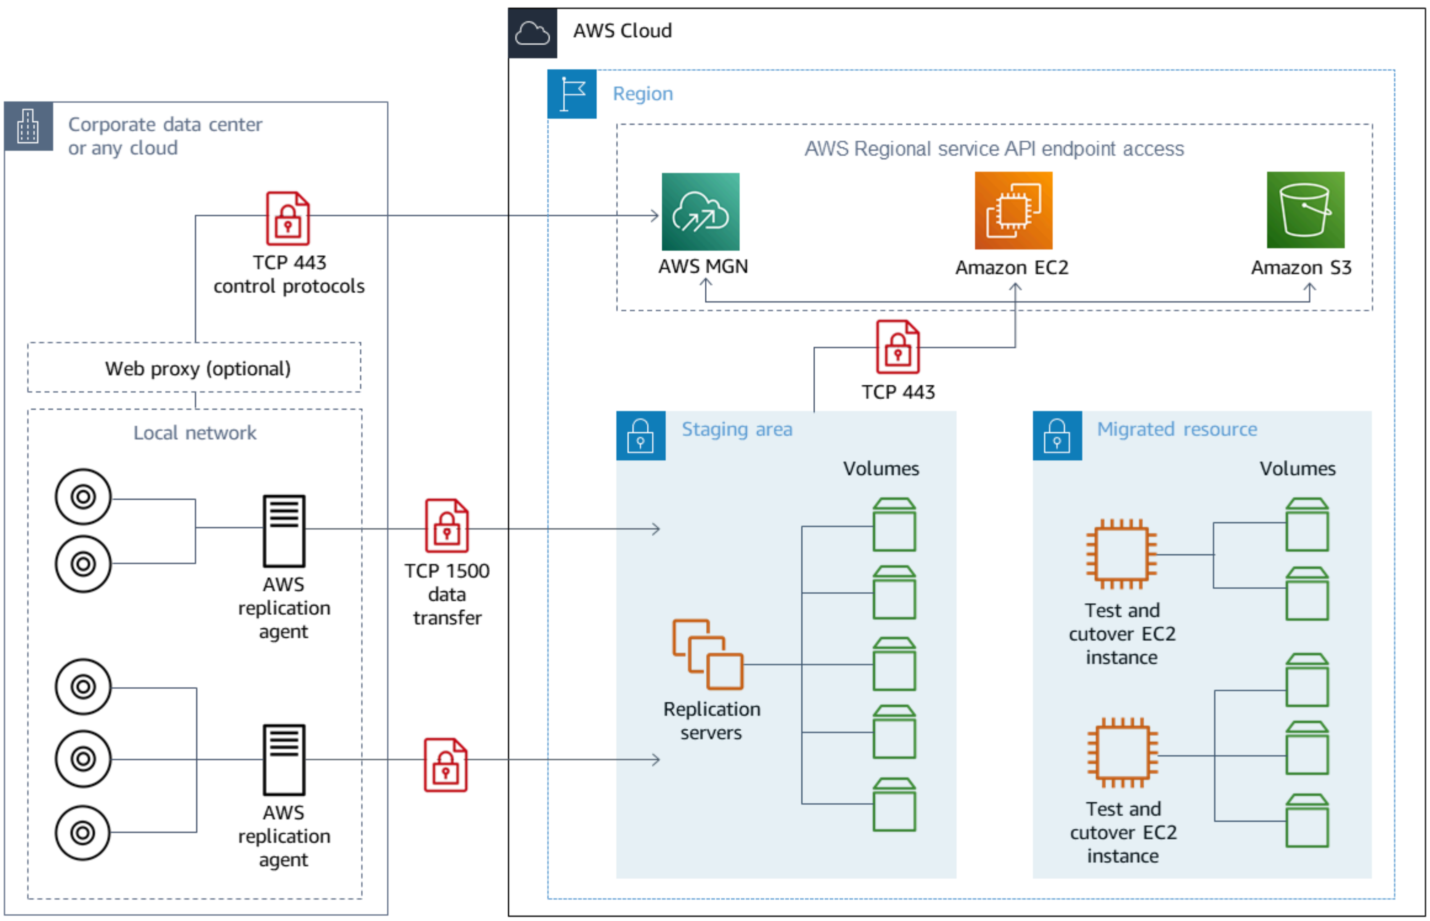
- An SAP ASE database

Target technology stack

- Amazon EC2
- Amazon Elastic Block Store (Amazon EBS)

Source and target architecture

The following diagram shows migration from the on-premises servers through the Replication Agent to the Application Migration Service endpoint. An Amazon Simple Storage Service (Amazon S3) endpoint is used to access installation and configuration files. The subnets for the staging area and the migrated resources contain EC2 instances, with data storage on EBS volumes. Port TCP 443 is used to connect the source machine network to Application Migration Service, and to connect the staging area subnets to the Application Migration Service, Amazon EC2, and Amazon S3 Regional endpoints. Port TCP 1500 is used for data replication between the local network and the staging area.



Tools

- AWS Application Migration Service helps you rehost (*lift-and-shift*) applications to the AWS Cloud without change and with minimal downtime.
- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Security Token Service (AWS STS) helps you request temporary, limited-privilege credentials for users.

Epics

Initialize Application Migration Service

Task	Description	Skills required
Initialize Application Migration Service.	Initialize Application Migration Service in the AWS Region where you want to deploy the SAP ASE database. AWS provides an automated setup the first time that you navigate to the Application Migration Service page in each Region.	AWS administrator
Manually create service roles.	(Optional) If you want to use automation (for example, AWS Control Tower) to set up the account, you can manually create the six AWS Identity and Access Management (IAM) roles that are required for installation, replication, and launches. For instructions, see the AWS documentation.	AWS administrator
Create a Replication Settings template.	The Replication Settings template defines the subnet,	General AWS

Task	Description	Skills required
	instance type, Amazon EBS encryption, and how data is routed. For detailed settings information, see the [AWS documentation]().	

Generate credentials for Agent installation

Task	Description	Skills required
Create a new IAM Role.	On the IAM console, navigate to **Roles**, and choose **Create role**. For the **Trusted entity type**, choose **AWS account**, and then choose **Next**.	AWS systems administrator
Attach AWSApplicationMigr ationAgentPolicy to the IAM Role.	The AWS managed `AWSApplicationMigr ationAgentPolicy` policy contains the necessary permissions to perform Application Migration Service Agent installation. After you attach the policy, choose **Next**.	AWS systems administrator
Complete the role creation.	Assign a friendly name, and choose **Create role**.	AWS systems administrator
Generate temporary credentia ls.	To generate the access key ID, secret access key, and session token, follow the instructions in the [AWS STS documenta]()	AWS systems administrator

Task	Description	Skills required
	tion. These credentials are used during Agent installat ion.	

Install the Application Migration Service Agent on the SAP source machine

Task	Description	Skills required
Download the Agent installer on the SAP source machine.	Download the Agent installer appropriate for your source operating system: Windows or Linux.	App owner
Install the AWS Replication Agent.	When you run the Agent installer file on a source machine, you are first asked to enter your access key, secret access key, session token, and the Region to replicate to. Use the temporary credentials from the IAM role that you previously created, and the same Region that you configured during initializ ation.	App owner
Wait for initial data replicati on.	After the Agent is installed, the source machine appears on the **Machines** tab on the Application Migration Service console.	App owner

Configure the target machine's Launch template

Task	Description	Skills required
Update the Launch template for the source server.	Each source server uses a unique EC2 Launch template that informs the configura tion of the target EC2 server. You can edit this template if you want to customize the Amazon EC2 configuration of your migrated server.	General AWS
Set the default Launch template version.	After you make the required changes to the Launch template, specify to use this updated version as the default Launch template. For more information, see the AWS documentation.	General AWS
Turn off Instance type right sizing.	(Optional) Instance type right sizing provides automatic instance type recommend ations based on the configura tion of the source SAP server. We recommend turning off this setting so that you can specify customized instance types in the Launch template.	General AWS

Perform a test

Task	Description	Skills required
Initiate a test launch.	On the Application Migration Service console, select one or	General AWS, Migration engineer, Migration lead

Task	Description	Skills required
	more servers, and then select **Launch test instances** under **Test and Cutover**.	
Wait for the conversion and launch process to be completed.	You can review the launch process on the **Launch history** tab. After the machine has successfully launched as an EC2 instance, the **Alerts** tab will be updated to **Launched**.	
Verify that the test completed successfully.	Connect to the launched instance through Remote Desktop Protocol (RDP) or SSH (Secure Shell), and perform the appropriate application checks. For example, log in to the SAP interface and validate functionality.	Migration engineer, App owner
Update the source lifecycle.	If testing was successful, update the source machine lifecycle to **Mark as "Ready for cutover"** on the **Test and Cutover** tab.	Migration engineer, Migration lead

Schedule and perform a cutover to the Amazon EC2 target

Task	Description	Skills required
Schedule a cutover window.		Cutover lead, Migration lead, App owner

Task	Description	Skills required
Initiate a cutover launch.	Select one or more servers. On the **Test and Cutover** tab, select **Launch cutover instances** under **Test and Cutover** on the Application Migration Service console.	Migration engineer
Wait for the conversion and launch processes to be completed.	You can review the launch process on the **Launch history** tab. After the machine has successfully launched as an EC2 instance, the **Alerts** tab will be updated to **Launched**.	
Verify that the cutover completed successfully.	Connect to the launched instance through RDP or SSH, and perform the appropriate application checks.	App owner, Migration engineer
Update the source lifecycle.	If cutover was successful, update the source machine lifecycle by selecting **Finalize cutover** on the **Test and Cutover** tab.	Migration engineer

Rehost on-premises workloads in the AWS Cloud: migration checklist

Srikanth Rangavajhala, Amazon Web Services

Summary

Rehosting on-premises workloads in the Amazon Web Services (AWS) Cloud involves the following migration phases: planning, pre-discovery, discovery, build, test, and cutover. This pattern outlines the phases and their related tasks. The tasks are described at a high level and support about 75% of all application workloads. You can implement these tasks over two to three weeks in an agile sprint cycle.

You should review and vet these tasks with your migration team and consultants. After the review, you can gather the input, eliminate or re-evaluate tasks as necessary to meet your requirements, and modify other tasks to support at least 75% of the application workloads in your portfolio. You can then use an agile project management tool such as Atlassian Jira or Rally Software to import the tasks, assign them to resources, and track your migration activities.

The pattern assumes that you're using AWS Cloud Migration Factory to rehost your workloads, but you can use your migration tool of choice.

Amazon Macie can help identify sensitive data in your knowledge bases, stored as data sources, model invocation logs, and prompt stores in Amazon Simple Storage Service (Amazon S3) buckets. For more information, see the Macie documentation.

Prerequisites and limitations

Prerequisites

- Project management tool for tracking migration tasks (for example, Atlassian Jira or Rally Software)
- Migration tool for rehosting your workloads on AWS (for example, Cloud Migration Factory)

Architecture

Source platform

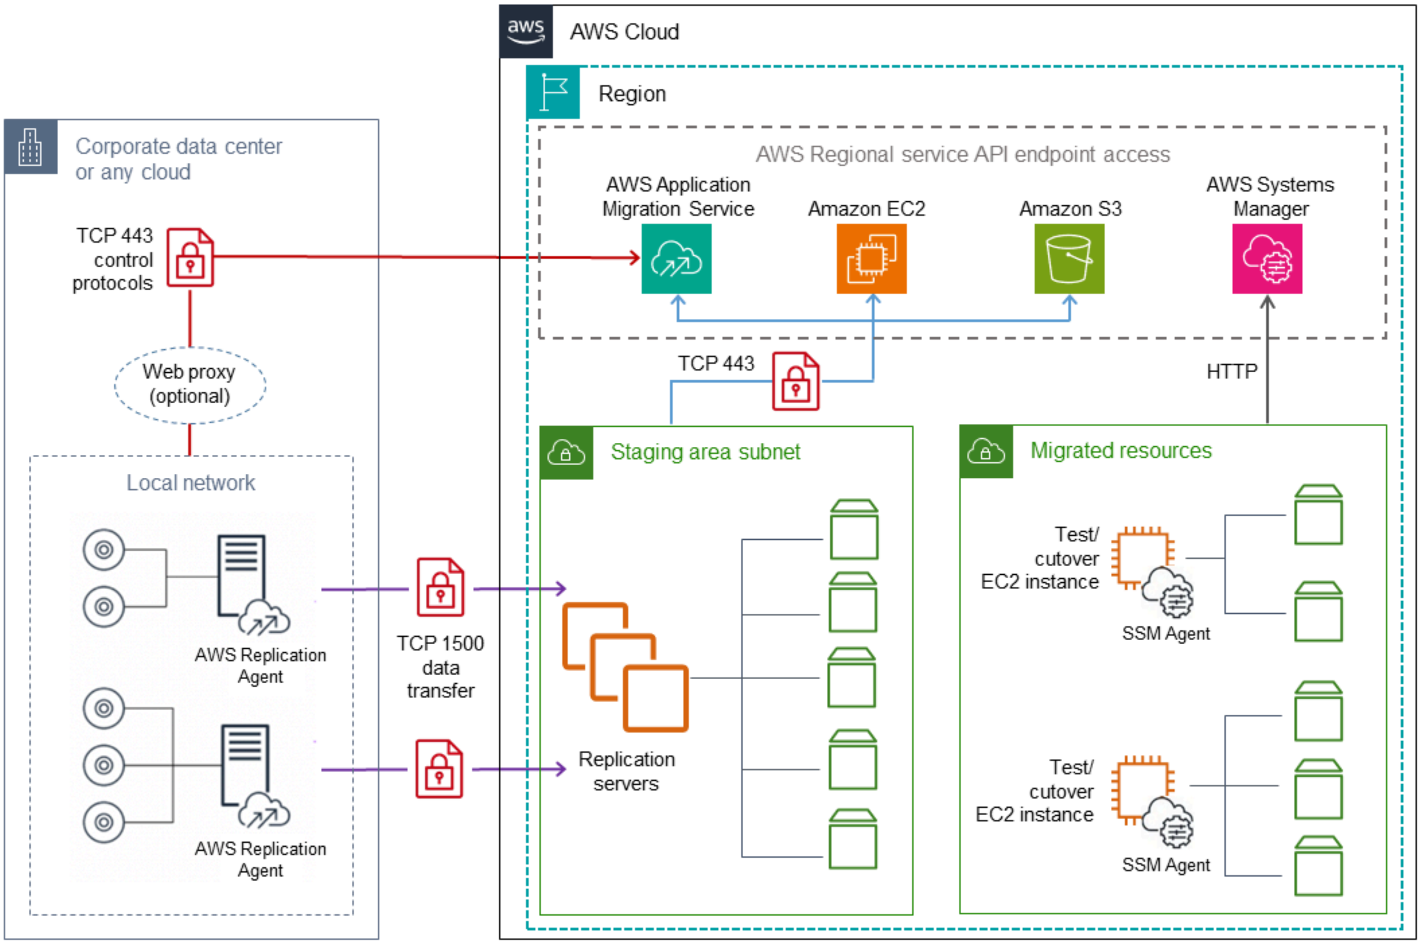
- On-premises source stack (including technologies, applications, databases, and infrastructure)

Target platform

- AWS Cloud target stack (including technologies, applications, databases, and infrastructure)

Architecture

The following diagram illustrates rehosting (discovering and migrating servers from an on-premises source environment to AWS) by using Cloud Migration Factory and AWS Application Migration Service.



Tools

- You can use a migration and project management tool of your choice.

Epics

Planning phase

Task	Description	Skills required
Groom the pre-discovery backlog.	Conduct the pre-discovery backlog grooming working session with department leads and application owners.	Project manager, Agile scrum leader
Conduct the sprint planning working session.	As a scoping exercise, distribute the applications that you want to migrate across sprints and waves.	Project manager, Agile scrum leader

Pre-discovery phase

Task	Description	Skills required
Confirm application knowledge.	Confirm and document the application owner and their knowledge of the application. Determine whether there's another point person for technical questions.	Migration specialist (intervie wer)
Determine application compliance requirements.	Confirm with the application owner that the application doesn't have to comply with requirements for Payment Card Industry Data Security Standard (PCI DSS), Sarbanes-Oxley Act (SOX), personall y identifiable information (PII), or other standards. If compliance requirements	Migration specialist (intervie wer)

Task	Description	Skills required
	exist, teams must finish their compliance checks on the servers that will be migrated.	
Confirm production release requirements.	Confirm the requirements for releasing the migrated application to production (such as release date and downtime duration) with the application owner or technical contact.	Migration specialist (intervie wer)
Get server list.	Get the list of servers that are associated with the targeted application.	Migration specialist (intervie wer)
Get the logical diagram that shows the current state.	Obtain the current state diagram for the application from the enterprise architect or the application owner.	Migration specialist (intervie wer)
Create a logical diagram that shows the target state.	Create a logical diagram of the application that shows the target architecture on AWS. This diagram should illustrate servers, connectiv ity, and mapping factors.	Enterprise architect, Business owner
Get server information.	Collect information about the servers that are associate d with the application, including their configuration details.	Migration specialist (intervie wer)

Task	Description	Skills required
Add server information to the discovery template.	Add detailed server informati on to the application discovery template (see `mobilize-applicati on-questionnaire.x lsx` in the attachment for this pattern). This template includes all the application-related security, infrastru cture, operating system, and networking details.	Migration specialist (intervie wer)
Publish the application discovery template.	Share the application discovery template with the application owner and migration team for common access and use.	Migration specialist (intervie wer)

Discovery phase

Task	Description	Skills required
Confirm server list.	Confirm the list of servers and the purpose of each server with the application owner or technical lead.	Migration specialist
Identify and add server groups.	Identify server groups such as web servers or applicati on servers, and add this information to the application discovery template. Select the tier of the application (web,	Migration specialist

Task	Description	Skills required
	application, database) that each server should belong to.	
Fill in the application discovery template.	Complete the details of the application discovery template with the help of the migration team, application team, and AWS.	Migration specialist
Add missing server details (middleware and OS teams).	Ask middleware and operating system (OS) teams to review the application discovery template and add any missing server details, including database informati on.	Migration specialist
Get inbound/outbound traffic rules (network team).	Ask the network team to get the inbound/outbound traffic rules for the source and destination servers. The network team should also add existing firewall rules, export these to a security group format, and add existing load balancers to the application discovery template.	Migration specialist
Identify required tagging.	Determine the tagging requirements for the applicati on.	Migration specialist

Task	Description	Skills required
Create firewall request details.	Capture and filter the firewall rules that are required to communicate with the application.	Migration specialist, Solutions architect, Network lead
Update the EC2 instance type.	Update the Amazon Elastic Compute Cloud (Amazon EC2) instance type to be used in the target environment, based on infrastructure and server requirements.	Migration specialist, Solutions architect, Network lead
Identify the current state diagram.	Identify or create the diagram that shows the current state of the application. This diagram will be used in the information security (InfoSec) request.	Migration specialist, Solutions architect
Finalize the future state diagram.	Finalize the diagram that shows the future (target) state for the application. This diagram will also be used in the InfoSec request.	Migration specialist, Solutions architect
Create firewall or security group service requests.	Create firewall or security group service requests (for development/QA, pre-produ ction, and production). If you're using Cloud Migration Factory, include replication-specific ports if they're not already open.	Migration specialist, Solutions architect, Network lead

Task	Description	Skills required
Review firewall or security group requests (InfoSec team).	In this step, the InfoSec team reviews and approves the firewall or security group requests that were created in the previous step.	InfoSec engineer, Migration specialist
Implement firewall security group requests (network team).	After the InfoSec team approves the firewall requests, the network team implements the required inbound/outbound firewall rules.	Migration specialist, Solutions architect, Network lead

Build phase (repeat for development/QA, pre-production, and production environments)

Task	Description	Skills required
Import the application and server data.	1. Verify that you are logged in to your migration execution server as a domain user with local administrator permissio ns on the in-scope source servers. 2. Use the migration intake form to import the attributes for the in-scope source servers. For additional information, see the [Cloud Migration Factory Implementation Guide]().	Migration specialist, Cloud administrator

Task	Description	Skills required
	If you aren't using Cloud Migration Factory, follow the instructions for setting up your migration tool.	
Check prerequisites for source servers.	Connect with the in-scope source servers to verify prerequisites such as TCP port 1500, TCP port 443, root volume free space, .NET Framework version, and other parameters. These are required for replication. For additional information, see the [Cloud Migration Factory Implementation Guide]().	Migration specialist, Cloud administrator
Create a service request to install replication agents.	Create a service request to install replication agents on the in-scope servers for development/QA, pre-produ ction, or production.	Migration specialist, Cloud administrator
Install the replication agents.	Install the replication agents on the in-scope source servers on the development/QA, pre-production, or productio n machines. For additional information, see the [Cloud Migration Factory Implement ation Guide]().	Migration specialist, Cloud administrator

Task	Description	Skills required
Push the post-launch scripts.	Application Migration Service supports post-launch scripts to help you automate OS-level activities such as installing or uninstalling software after you launch target instances. This step pushes the post-launch scripts to Windows or Linux machines, depending on the servers identified for migration. For instructions, see the [Cloud Migration Factory Implementation Guide].	Migration specialist, Cloud administrator
Verify the replication status.	Confirm the replication status for the in-scope source servers automatically by using the provided script. The script repeats every five minutes until the status of all source servers in the given wave changes to **Healthy**. For instructions, see the [Cloud Migration Factory Implementation Guide].	Migration specialist, Cloud administrator

Task	Description	Skills required
Create the admin user.	A local admin or sudo user on source machines might be needed to troubleshoot any issues after migration cutover from the in-scope source servers to AWS. The migration team uses this user to log in to the target server when the authentication server (for example, the DC or LDAP server) is not reachable. For instructions for this step, see the Cloud Migration Factory Implementation Guide.	Migration specialist, Cloud administrator
Validate the launch template.	Validate the server metadata to make sure it works successfully and has no invalid data. This step validates both test and cutover metadata. For instructions, see the Cloud Migration Factory Implementation Guide.	Migration specialist, Cloud administrator

Test phase (repeat for development/QA, pre-production, and production environments)

Task	Description	Skills required
Create a service request.	Create a service request for the infrastructure team and other teams to perform application cutover to development/QA, pre-produ	Migration specialist, Cloud administrator

Task	Description	Skills required
	ction, or production instances .	
Configure a load balancer (optional).	Configure required load balancers, such as an Application Load Balancer or an F5 load balancer with iRules.	Migration specialist, Cloud administrator
Launch instances for testing.	Launch all target machines for a given wave in Application Migration Service in test mode. For additional information, see the Cloud Migration Factory Implementation Guide.	Migration specialist, Cloud administrator
Verify the target instance status.	Verify the status of the target instance by checking the bootup process for all in-scope source servers in the same wave. It may take up to 30 minutes for the target instances to boot up. You can check the status manually by logging in to the Amazon EC2 console, searching for the source server name, and reviewing the **Status check** column. The status **2/2 checks passed** indicates that the instance is healthy from an infrastructure perspective.	Migration specialist, Cloud administrator

Task	Description	Skills required
Modify DNS entries.	Modify Domain Name System (DNS) entries. (Use `resolv.conf` or `host.conf` for a Microsoft Windows environment.) Configure each EC2 instance to point to the new IP address of this host. **Note** Make sure that there are no DNS conflicts between on-premises and AWS Cloud servers. This step and the following steps are optional, depending on the environment where the server is hosted.	Migration specialist, Cloud administrator
Test connectivity to backend hosts from EC2 instances.	Check the logins by using the domain credentials for the migrated servers.	Migration specialist, Cloud administrator
Update the DNS A record.	Update the DNS A record for each host to point to the new Amazon EC2 private IP address.	Migration specialist, Cloud administrator

Task	Description	Skills required
Update the DNS CNAME record.	Update the DNS CNAME record for virtual IPs (load balancer names) to point to the cluster for web and application servers.	Migration specialist, Cloud administrator
Test the application in applicable environments.	Log in to the new EC2 instance and test the applicati on in the development/ QA, pre-production, and production environments.	Migration specialist, Cloud administrator
Mark as ready for cutover.	When testing is complete, change the status of the source server to indicate that it's ready for cutover, so users can launch a cutover instance. For instructions, see the Cloud Migration Factory Implement ation Guide.	Migration specialist, Cloud administrator

Cutover phase

Task	Description	Skills required
Create production deploymen t plan.	Create a production deployment plan (including a backout plan).	Migration specialist, Cloud administrator
Notify operations team of downtime.	Notify the operations team of the downtime schedule for the servers. Some teams might require a change request or service request	Migration specialist, Cloud administrator

Task	Description	Skills required
	(CR/SR) ticket for this notification.	
Replicate production machines.	Replicate production machines by using Application Migration Service or another migration tool.	Migration specialist, Cloud administrator
Shut down in-scope source servers.	After you verify the source servers' replication status, you can shut down the source servers to stop transactions from client applications to the servers. You can shut down the source servers in the cutover window. For more information, see the [Cloud Migration Factory Implementation Guide]().	Cloud administrator
Launch instances for cutover.	Launch all target machines for a given wave in Application Migration Service in cutover mode. For more information, see the [Cloud Migration Factory Implementation Guide]().	Migration specialist, Cloud administrator

Task	Description	Skills required
Retrieve target instance IPs.	Retrieve the IPs for target instances. If the DNS update is a manual process in your environment, you would need to get the new IP addresses for all target instances. For more information, see the Cloud Migration Factory Implementation Guide.	Migration specialist, Cloud administrator
Verify target server connections.	After you update the DNS records, connect to the target instances with the host name to verify the connections. For more information, see the Cloud Migration Factory Implementation Guide.	Migration specialist, Cloud administrator

Set up Multi-AZ infrastructure for a SQL Server Always On FCI by using Amazon FSx

Manish Garg, T.V.R.L.Phani Kumar Dadi, Nishad Mankar, and RAJNEESH TYAGI, Amazon Web Services

Summary

If you need to migrate a large number of Microsoft SQL Server Always On Failover Cluster Instances (FCIs) quickly, this pattern can help you minimize provisioning time. By using automation and Amazon FSx for Windows File Server, it reduces manual efforts, human-made errors, and the time required to deploy a large number of clusters.

This pattern sets up the infrastructure for SQL Server FCIs in a Multi-Availability Zone (Multi-AZ) deployment on Amazon Web Services (AWS). The provisioning of the AWS services required for this infrastructure is automated by using [AWS CloudFormation](https://aws.amazon.com/cloudformation/) templates. SQL Server installation and cluster node creation on an [Amazon Elastic Compute Cloud (Amazon EC2)](https://aws.amazon.com/ec2/) instance is performed by using PowerShell commands.

This solution uses a highly available Multi-AZ [Amazon FSx for Windows](https://aws.amazon.com/fsx/windows/) file system as the shared witness for storing the SQL Server database files. The Amazon FSx file system and EC2 Windows instances that host SQL Server are joined to the same AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) domain.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS user with sufficient permissions to provision resources using AWS CloudFormation templates
- AWS Directory Service for Microsoft Active Directory
- Credentials in AWS Secrets Manager to authenticate to AWS Managed Microsoft AD in a key-value pair:
  - `ADDomainName`: <Domain Name>
  - `ADDomainJoinUserName`: <Domain Username>
  - `ADDomainJoinPassword`:<Domain User Password>
  - `TargetOU`: <Target OU Value>

> **Note**
>
> You will use the same key name in AWS Systems Manager automation for the AWS Managed Microsoft AD join activity.

- SQL Server media files for SQL Server installation and Windows service or domain accounts created, which will be used during cluster creation
- A virtual private cloud (VPC), with two public subnets in separate Availability Zones, two private subnets in the Availability Zones, an internet gateway, NAT gateways, route table associations, and a jump server

Product versions

- Windows Server 2012 R2 and Microsoft SQL Server 2016

Architecture

Source technology stack

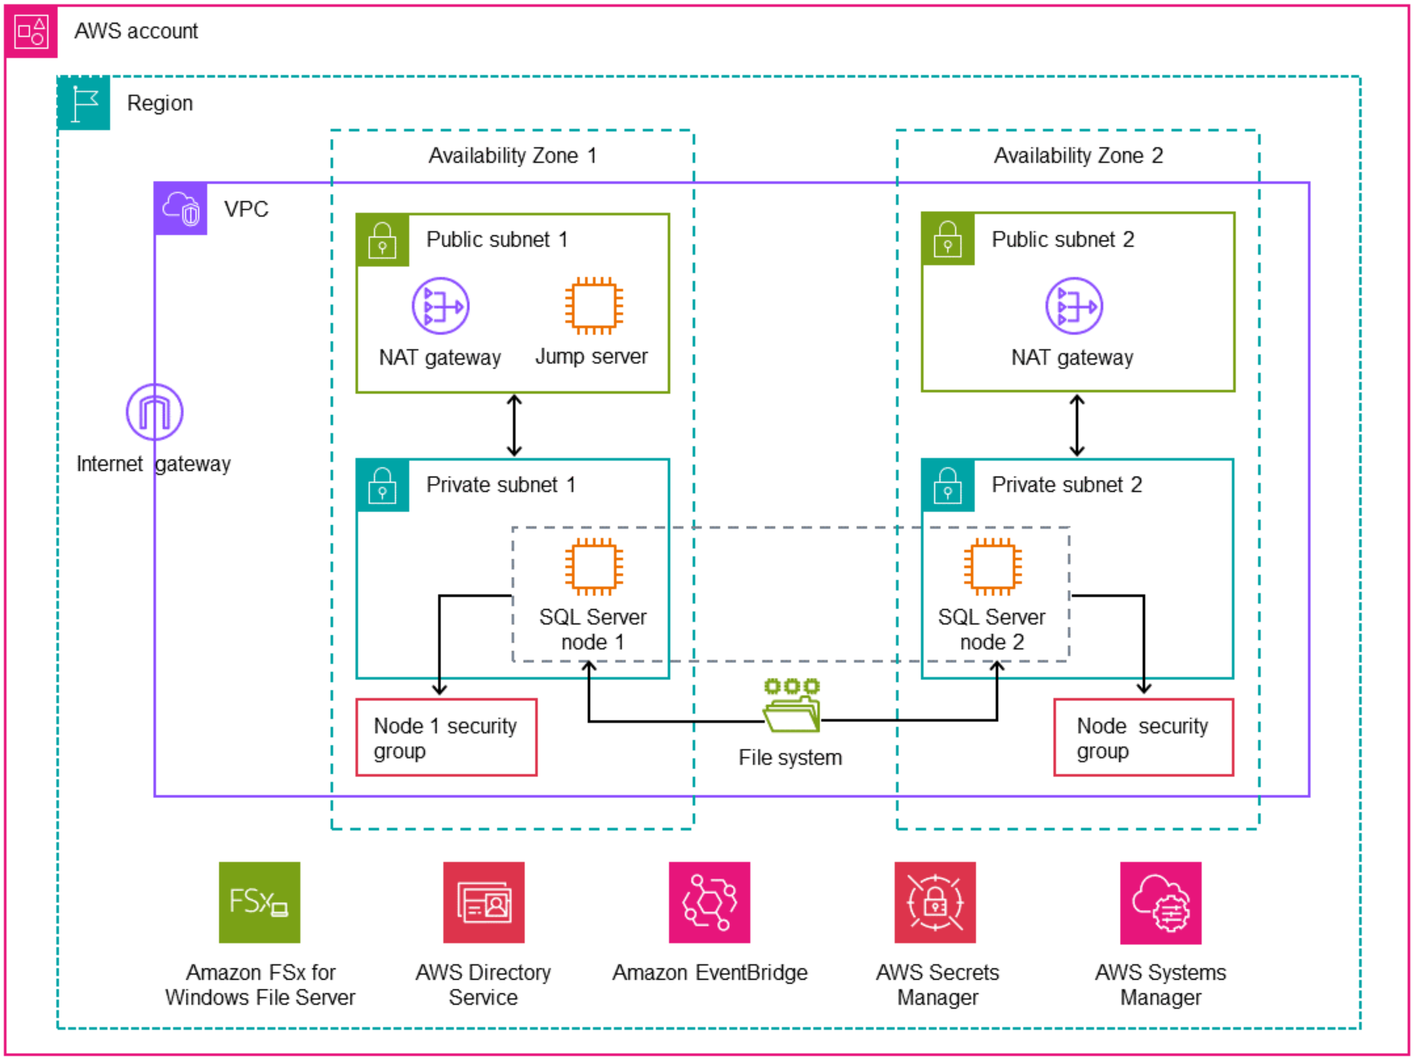
- On-premises SQL Server with FCIs using a shared drive

Target technology stack

- AWS EC2 instances
- Amazon FSx for Windows File Server
- AWS Systems Manager Automation runbook
- Network configurations (VPC, subnets, internet gateway, NAT gateways, jump server, security groups)
- AWS Secrets Manager
- AWS Managed Microsoft AD
- Amazon EventBridge
- AWS Identity and Access Management (IAM)

Target architecture

The following diagram shows an AWS account in a single AWS Region, with a VPC that includes two Availability Zones, two public subnets with NAT gateways, a jump server in the first public subnet, two private subnets, each with an EC2 instance for a SQL Server node in a node security group, and an Amazon FSx file system connecting to each of the SQL Server nodes. AWS Directory Service, Amazon EventBridge, AWS Secrets Manager, and AWS Systems Manager are also included.



Automation and scale

- You can use AWS Systems Manager to join AWS Managed Microsoft AD and perform the SQL Server installation.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Directory Service provides multiple ways to use Microsoft Active Directory (AD) with other AWS services such as Amazon Elastic Compute Cloud (Amazon EC2), Amazon Relational Database Service (Amazon RDS) for SQL Server, and Amazon FSx for Windows File Server.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

Other tools

- PowerShell is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS. This pattern uses PowerShell scripts.

Code repository

The code for this pattern is available in the GitHub aws-windows-failover-cluster-automation repository.

Best practices

- The IAM roles that are used to deploy this solution should adhere to the principle of least privilege. For more information, see the IAM documentation.
- Follow the AWS CloudFormation best practices.

Epics

Deploy the infrastructure

Task	Description	Skills required
Deploy the Systems Manager CloudFormation stack.	1. Sign in to your AWS account, and open the AWS Management Console. 2. Navigate to the CloudFormation console, and create the Systems Manager CloudFormation stack by uploading the `ssm.yaml` template. Provide values for the following parameters: • **StateUnJoinAssociationLoggingBucketName** – Provide a name for the S3 bucket that the template will create for logging purposes. • **SSMAssociationADUnjoinName** – Provide a name for the `AWS::SSM::Association` resource. • **SSMAutomationDocumentName** – Provide a name for the Systems Manager Automation runbook. • **EventBridgeName** – Provide a name for the EventBridge event bus.	AWS DevOps, DevOps engineer

Task	Description	Skills required
	3. Deploy the Systems Manager CloudFormation stack by launching the `ssm.yaml` CloudFormation template. The template will create the Systems Manager Atomation runboook that is initiated when a new EC2 instance with the tag `ADJoined: FSXADD` launches. The Automation runbook will add the instance to AWS Managed Microsoft AD directory.	

Task	Description	Skills required
Deploy the infrastructure stack.	After successful deploymen t of the Systems Manager stack, create the `infra` stack, which includes EC2 instance nodes, security groups, the Amazon FSx for Windows File Server file system, and the IAM role. 1. Navigate to the CloudForm ation console and launch the `infra-cf.yaml` template. To deploy this stack, the following parameters are required: • `ActiveDirectoryId` – ID for AWS Managed Microsoft AD • `ADDnsIpAddresses1` – Primary DNS IP address of AWS Managed Microsoft AD • `ADDnsIpAddresses2` – Secondary DNS IP address of AWS Managed Microsoft AD • `FSxSecurityGroupName` – Name of the Amazon FSx security group • `FSxWindowsFileSystemName` – Name of the Amazon FSx drive	AWS DevOps, DevOps engineer

Task	Description	Skills required
	• `ImageID` – ID of the base Windows 2012 R2 image or Amazon Machine Image (AMI) used to create the SQL Server instance node • `KeyPairName` – Key-value pair to attach to the EC2 instance nodes for access • `Node1SecurityGroupName` – Name of the first node security group • `Node2SecurityGroupName` – Name of the second node security group • `OUSecretName` – Name of the secret that contains the AWS Managed Microsoft AD information • `PrivateSubnet1` – ID of the first private subnet • `PrivateSubnet2` – ID of the second private subnet • `SqlFSxFCIName` – Name of the tag applied to the primary and secondary nodes and to Amazon FSx.	

Task	Description	Skills required
	• `SqlFSxServerNetBIOSName1` – Name of the primary EC2 instance node (maximum of 15 characters) • `SqlFSxServerNetBIOSName2` – Name of the secondary EC2 instance node (maximum of 15 characters) • `VPC` – VPC ID • `WorkloadInstanceType` – Type of EC2 instance Deploy the `infra` stack. The stack will create all the infrastructure components that are required to set up Windows SQL Server FCI. 2. After the EC2 instance nodes are launched, the Systems Manager Automation document will be invoked to join these instances to AWS Managed Microsoft AD. You can track the progress on the Systems Manager console **Automation** page.	

Set up the Windows SQL Server Always On FCI

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install Windows tools.</td><td>1. Log in to the primary EC2 instance, which is node 1. To install the Windows features (Active Directory and FCI Tools), run the following PowerShell script.
<pre>Install-WindowsFeature -Name RSAT-AD-Powershell,Failover-Clustering -IncludeManagementTools
Install-WindowsFeature -Name RSAT-Clustering,RSAT-ADDS-Tools,RSAT-AD-Powershell,RSAT-DHCP,RSAT-DNS-Server</pre>2. Log in to the secondary EC2 instance, which is node 2, and run same script to enable features on node 2.</td><td>AWS DevOps, DevOps engineer, DBA</td></tr>
<tr><td>Prestage the cluster computer objects in Active Directory Domain Services.</td><td>To prestage the cluster name object (CNO) in Active Directory Domain Services (AD DS) and prestage a virtual computer object (VCO) for a clustered role, follow the instructions in the Windows Server documentation.</td><td>AWS DevOps, DBA, DevOps engineer</td></tr>
</table>

Task	Description	Skills required
Create the WSFC.	To create the Windows Server Failover Clustering (WSFC) cluster, do the following: 1. Log in to the primary EC2 instance, which is node 1. To create the Amazon FSx file share and grant full access to the listed AD service account, run the following code. `Invoke-Command -ComputerName "<FSx Windows Remote PowerShell Endpoint>" -ConfigurationName FSxRemoteAdmin -scriptblock { New-FSxSmbShare -Name "SQLDB" -Path "D:\share" -Description "SQL Databases Share" -ContinuouslyAvailable $true -FolderEnumerationMode AccessBased -EncryptData $true grant-fsxsmbshareaccess -name SQLDB -AccountName "<domain\user>" -accessRight Full }` This command will also create the continuously available (CA) file share,	AWS DevOps, DBA, DevOps engineer

Task	Description	Skills required
	which is optimized for use by Microsoft SQL Server. 2. To create the failover cluster on the primary instance (node 1), run the following command. `New-Cluster -Name <CNO Name> -Node <Node1 Name>, <Node2 Name> -StaticAddress <Node1 Secondary Private IP>, <Node2 Secondary Private IP>` The command requires the following parameters: • `Name` – The name of the cluster (CNO) • `Node` – The names of the primary and secondary nodes, respectively • `StaticAddress` – The secondary IP addresses of the primary and secondary nodes, respectively **Important** A domain administrator or regular user must have administrator permission on	

Task	Description	Skills required
	both the nodes to create the Windows Server Failover Clustering (WSFC) cluster. Otherwise , the previous command will fail and return the message, You `do not have administrator privilege on servers.` 3. After the cluster is created, run the following command to attach the file share witness. `Set-ClusterQuorum -FileShareWitness \\<FSx Windows Remote PowerShell Endpoint>\share\witness`	

Task	Description	Skills required
Install the SQL Server failover cluster.	After the WSFC cluster is set up, install the SQL Server cluster on the primary instance (node1). 1. In the T drive on both nodes, create `tempdb` and `log` folders. The folders are used in the PowerShell commands. 2. After you copy the SQL Server media files for SQL Server installation on both nodes, run the following PowerShell command on node 1 to install SQL Server on node 1. `D:\setup.exe /Q `` ` `/ACTION=InstallFailoverCluster `` ` `/IACCEPTSQLSERVERLICENSETERMS `` ` `/FEATURES="SQL,IS,BC,Conn" `` ` `/INSTALLSHAREDDIR="C:\Program Files\Microsoft SQL Server" `` ` `/INSTALLSHAREDWOWDIR="C:\Program Files (x86)\Microsoft SQL Server" `` ` `/RSINSTALLMODE="FilesOnlyMode" `` ` `/INSTANCEID="MSSQLSERVER" `` `	AWS DevOps, DBA, DevOps engineer

Task	Description	Skills required
	`/INSTANCENAME="MSSQLSERVER" `` `/FAILOVERCLUSTERGROUP="SQL Server (MSSQLSERVER)" `` `/FAILOVERCLUSTERIPADDRESSES="IPv4;<2nd Sec Private Ip node1>;Cluster Network 1;<subnet mask>" `` `/FAILOVERCLUSTERNETWORKNAME="<Fail over cluster Network Name>" `` `/INSTANCEDIR="C:\Program Files\Microsoft SQL Server" `` `/ENU="True" `` `/ERRORREPORTING=0 `` `/SQMREPORTING=0 `` `/SAPWD="<Domain User password>" `` `/SQLCOLLATION="SQL_Latin1_General_CP1_CI_AS" `` `/SQLSYSADMINACCOUNTS="<domain\username>" `` `/SQLSVCACCOUNT="<domain\username>" /SQLSVCPASSWORD="<Domain User password>" `` `/AGTSVCACCOUNT="<domain\username>" /AGTSVCPASSWORD="<Domain User password>" `` `/ISSVCACCOUNT="<domain\username>" /ISSVCPASSWORD="<Domain User password>" ``	

Task	Description	Skills required

	`/FTSVCACCOUNT="NT Service\MSSQLFDLauncher"` `` ` ``
	`/INSTALLSQLDATADIR="\\<FSX DNS name>\share\Program Files\Microsoft SQL Server"` `` ` ``
	`/SQLUSERDBDIR="\\<FSX DNS name>\share\data"` `` ` ``
	`/SQLUSERDBLOGDIR="\\<FSX DNS name>\share\log"` `` ` ``
	`/SQLTEMPDBDIR="T:\tempdb"` `` ` ``
	`/SQLTEMPDBLOGDIR="T:\log"` `` ` ``
	`/SQLBACKUPDIR="\\<FSX DNS name>\share\SQLBackup"` `` ` ``
	`/SkipRules=Cluster_VerifyForErrors` `` ` ``
	`/INDICATEPROGRESS`	

Task	Description	Skills required
Add a secondary node to the cluster.	To add SQL Server to the secondary node (node 2), run the following PowerShell command. `D:\setup.exe /Q ` /ACTION=AddNode ` /IACCEPTSQLSERVERLICENSETERMS ` /INSTANCENAME="MSSQLSERVER" ` /FAILOVERCLUSTERGROUP="SQL Server (MSSQLSERVER)" ` /FAILOVERCLUSTERIPADDRESSES="IPv4;<2nd Sec Private Ip node2>;Cluster Network 2;<subnet mask>" ` /FAILOVERCLUSTERNETWORKNAME="<Fail over cluster Network Name>" ` /CONFIRMIPDEPENDENCYCHANGE=1 ` /SQLSVCACCOUNT="<domain\username>" /SQLSVCPASSWORD="<Domain User password>" ` /AGTSVCACCOUNT="domain\username>" /AGTSVCPASSWORD="<Domain User password>" ` /FTSVCACCOUNT="NT Service\MSSQLFDLauncher" ` /SkipRules=Cluster_VerifyForErrors ``	AWS DevOps, DBA, DevOps engineer

Task	Description	Skills required
	`/INDICATEPROGRESS`	
Test the SQL Server FCI.	1. On the Windows instance for one of the nodes, in **Administrative Tools**, launch the **Failover Cluster Manager**. 2. Navigate to **Nodes**, and confirm that the node status is **Status Running**. 3. Select **Roles**, open the context (right-click) menu for SQL Server (MSSQLSER VER), and select **Move and Select Node**. 4. After the node selection , SQL Server should be running on the other node.	DBA, DevOps engineer

Clean up resources

Task	Description	Skills required
Clean up resources.	To clean up the resources, use the AWS CloudFormation stack deletion process: 1. Open the [AWS CloudForm ation console](https://console.aws.amazon.com/cloudformation/). 2. On the **Stacks** page, select the `infra` stack. The stack must be currently running. 3. In the stack details pane, choose **Delete**.	AWS DevOps, DBA, DevOps engineer

Task	Description	Skills required
	4. Select **Delete stack** when prompted. 5. Repeat steps 2-4 for the `ssm` stack. After the stack deletion is complete, the stacks will be in the `DELETE_COMPLETE` state. Stacks in the `DELETE_COMPLETE` state aren't displayed in the CloudFormation console by default. To display deleted stacks, you must change the stack view filter as described in [Viewing deleted stacks on the AWS CloudFormation console](#). If the deletion failed, a stack will be in the `DELETE_FAILED` state. For solutions, see [Delete stack fails](#) in the CloudFormation documentation.	

Troubleshooting

Issue	Solution
AWS CloudFormation template failure	If the CloudFormation template fails during deployment, do the following: 1. Open the [AWS CloudFormation console](#).

Issue	Solution
	2. On the **Stacks** page in the CloudFormation console, select the stack. 3. Choose **Events**, and check the stack status.
AWS Managed Microsoft AD join failure	To troubleshoot the join issues, follow these steps: 1. Open the Systems Manager console. 2. Select the deployment Region. 3. In the left pane, choose **Automation**, and locate the failed Automation runbook. 4. Open the Automation runbook, and check for the **Execution status and Execution steps**. 5. Investigate the details of the failed step to see the exact error or failure.

Use BMC Discovery queries to extract migration data for migration planning

Ben Tailor-Hamblin, Emma Baldry, Simon Cunningham, and Shabnam Khan, Amazon Web Services

Summary

This guide provides query examples and steps to help you extract data from your on-premises infrastructure and applications by using BMC Discovery. The pattern shows you how to use BMC Discovery queries to scan your infrastructure and extract software, service, and dependency information. The extracted data is required for the assess and mobilize phases of a large-scale migration to the Amazon Web Services (AWS) Cloud. You can use this data to make critical decisions about which applications to migrate together as part of your migration plan.

Prerequisites and limitations

Prerequisites

- A license for BMC Discovery (formerly BMC ADDM) or the software as a service (SaaS) version of BMC Helix Discovery
- On-premises or SaaS version of BMC Discovery, installed

> **Note**
>
> For on-premises versions of BMC Discovery, you must install the application on a client network with access to all networking and server devices that are in scope for a migration across multiple data centers. Access to the client network must be provided according to application installation instructions. If the scanning of Windows Server information is required, then you must set up a Windows proxy manager device in the network.

- Networking access to allow the application to scan devices across data centers, if you're using BMC Helix Discovery

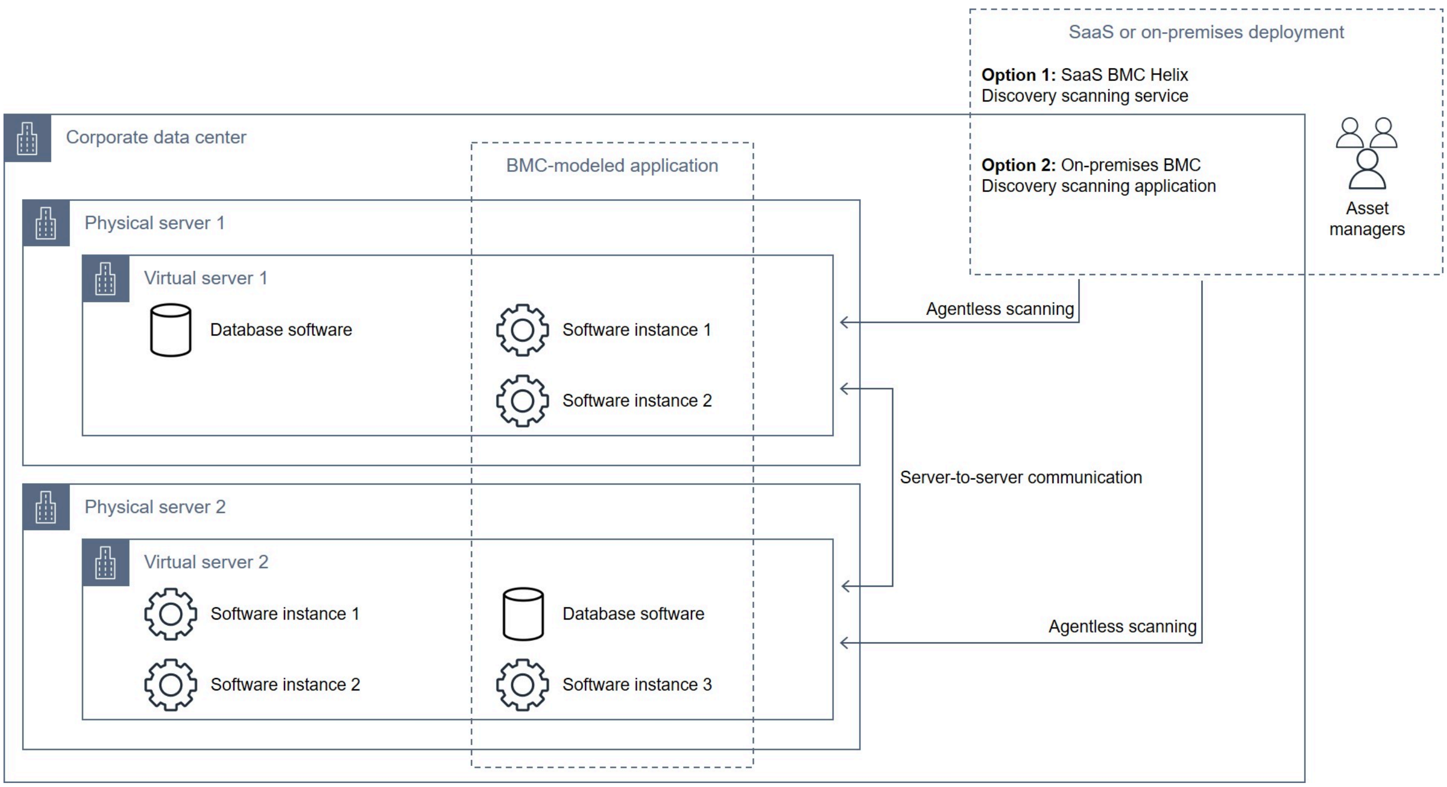
Product versions

- BMC Discovery 22.2 (12.5)
- BMC Discovery 22.1 (12.4)
- BMC Discovery 21.3 (12.3)
- BMC Discovery 21.05 (12.2)

- BMC Discovery 20.08 (12.1)
- BMC Discovery 20.02 (12.0)
- BMC Discovery 11.3
- BMC Discovery 11.2
- BMC Discovery 11.1
- BMC Discovery 11.0
- BMC Atrium Discovery 10.2
- BMC Atrium Discovery 10.1
- BMC Atrium Discovery 10.0

Architecture

The following diagram shows how asset managers can use BMC Discovery queries to scan BMC-modeled applications in both SaaS and on-premises environments.



The diagram shows the following workflow: An asset manager uses BMC Discovery or BMC Helix Discovery to scan database and software instances running on virtual servers hosted on multiple physical servers. The tool can model applications with components spanning multiple virtual and physical servers.

Technology stack

- BMC Discovery
- BMC Helix Discovery

Tools

- BMC Discovery is a data center discovery tool that helps you automatically discover your data center.
- BMC Helix Discovery is a SaaS-based discovery and dependency modeling system that helps you dynamically model your data assets and their dependencies.

Best practices

It's a best practice to map application, dependency, and infrastructure data when you migrate to the cloud. Mapping helps you understand the complexity of your current environment and the dependencies among various components.

The asset information these queries provide is important for several reasons:

1. **Planning –** Understanding the dependencies between components helps you plan the migration process more effectively. For example, you might need to migrate certain components first in order to ensure that others can be migrated successfully.
2. **Risk assessment –** Mapping the dependencies between components can help you identify any potential risks or issues that can arise during the migration process. For example, you might discover that certain components rely on outdated or unsupported technologies that could cause issues in the cloud.
3. **Cloud architecture –** Mapping your application and infrastructure data can also help you to design a suitable cloud architecture that meets your organizational needs. For example, you might need to design a multi-tier architecture to support high availability or scalability requirements.

Overall, mapping application, dependency, and infrastructure data is a crucial step in the cloud migration process. The mapping exercise can help you better understand your current environment, identify any potential issues or risks, and design a suitable cloud architecture.

Epics

Identify and evaluate discovery tooling

Task	Description	Skills required
Identify ITSM owners.	Identify the IT Service Management (ITSM) owners (usually by reaching out to the operational support teams).	Migration lead
Check CMDB.	Identify the number of configuration managemen t databases (CMDBs) that contain asset information, and then identify the sources of that information.	Migration lead
Identify discovery tools and check for use of BMC Discovery.	If your organization is using BMC Discovery to send data about your environment to the CMDB tool, check the scope and coverage of its scans. For example, check if BMC Discovery is scanning all data centers and if the access servers are located in perimeter zones.	Migration lead
Check the level of application modelling.	Check if applications are modelled in BMC Discovery . If not, recommend the use of the BMC Discovery tool to model which running software instances provide an application and business service.	Migration engineer, Migration lead

Extract infrastructure data

Task	Description	Skills required
Extract data on physical and virtual servers.	To extract data on the physical and virtual servers scanned by BMC Discovery, use [Query Builder](#) to run the following query: `search Host show key as 'Serverid', virtual, name as 'HOSTNAME', os_type as 'osName', os_version as 'OS Version', num_logical_processors as 'Logical Processor Counts', cores_per_processor as 'Cores per Processor', logical_ram as 'Logical RAM', #Consumer:StorageUse:Provider:DiskDrive.size as 'Size'` **Note** You can use extracted data to determine the appropriate instance sizes for migration.	Migration engineer, Migration lead
Extract data on modeled applications.	If your applications are modeled in BMC Discovery , you can extract data about the servers that run the application software. To get	BMC Discovery application owner

Task	Description	Skills required
	the server names, use Query Builder to run the following query: `search SoftwareInstance show key as 'ApplicationID', #RunningSoftware:HostedSoftware:Host:Host.key as 'ReferenceID', type, name` **Note** Applications are modeled in BMC Discovery by a collection of running software instances. The application is dependent on all the servers that run the application software.	

Task	Description	Skills required
Extract data on databases.	To get a list of all scanned databases and the servers these databases are running on, use [Query Builder](#) to run the following query: `search Database show key as 'Key', name, type as 'Source Engine Type', #Detail:Detail:ElementWithDetail:SoftwareInstance.name as 'Software Instance', #Detail:Detail:ElementWithDetail:SoftwareInstance.product_version as 'Product Version', #Detail:Detail:ElementWithDetail:SoftwareInstance.edition as 'Edition', #Detail:Detail:ElementWithDetail:SoftwareInstance.#RunningSoftware:HostedSoftware:Host:Host.key as 'ServerID'`	App owner

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Extract data on server communication.</td><td>To get information on all the network communications between servers that's collected by BMC Discovery from historic network communications logs, use Query Builder to run the following query:<pre><code>search Host
 TRAVERSE InferredElement:Inference:Associate:DiscoveryAccess
 TRAVERSE DiscoveryAccess:DiscoveryAccessResult:DiscoveryResult:NetworkConnectionList
 TRAVERSE List:List:Member:DiscoveredNetworkConnection
 PROCESS WITH networkConnectionInfo</code></pre></td><td>BMC Discovery application owner</td></tr>
<tr><td>Extract data on application discovery.</td><td>To get information on application dependencies, use Query Builder to run the following query:<pre><code>search SoftwareInstance
 show key as 'SRC App ID', #Dependant:Dependency:DependedUpon:SoftwareInstance.key as 'DEST App ID'</code></pre></td><td>BMC Discovery application owner</td></tr>
</table>

Task	Description	Skills required
Extract data on business services.	To extract data on business services provided by hosts, use [Query Builder](#) to run the following query: `search Host show name, #Host:HostedSoftware:AggregateSoftware:BusinessService.name as 'Name'`	BMC Discovery application owner

Troubleshooting

Issue	Solution
A query fails to run or contains unpopulated columns.	Review the asset records in BMC Discovery and determine which fields you require. Then, replace these fields in the query by using the [Query Builder](#).
The details of a dependent asset aren't populated.	This is likely due to access permissions or network connectivity. The discovery tool might not have the necessary permissions to access certain assets, particularly if they are on different networks or in different environments. We recommend that you work closely with discovery subject matter experts to ensure that all relevant assets are identified.

Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication

Durga Prasad Cheepuri and Eduardo Valentim, Amazon Web Services

Summary

Warning: IAM users have long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

This pattern walks you through the steps for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle source database to a different AWS account and AWS Region. The pattern uses a DB snapshot for a one-time full data load, and enables AWS Database Migration Service (AWS DMS) for ongoing replication.

Prerequisites and limitations

Prerequisites

- An active AWS account that contains the source Amazon RDS for Oracle database, which has been encrypted using a non-default AWS Key Management Service (AWS KMS) key
- An active AWS account in a different AWS Region from the source database, to use for the target Amazon RDS for Oracle database
- Virtual private cloud (VPC) peering between the source and target VPCs
- Familiarity with using an Oracle database as a source for AWS DMS
- Familiarity with using an Oracle database as a target for AWS DMS

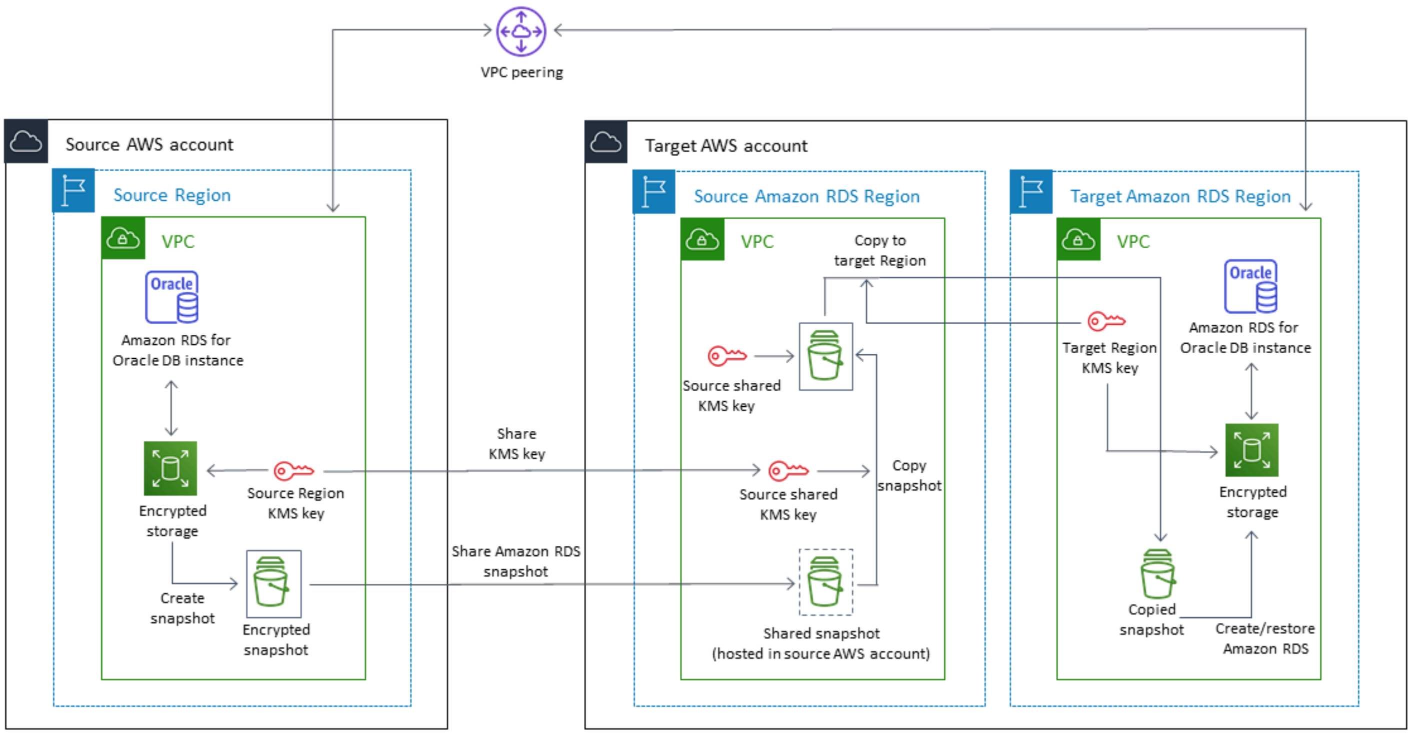
Product versions

- Oracle versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c. For the latest list of supported versions and editions, see Using an Oracle Database as a Source for AWS DMS and with Using an Oracle database as a target for AWS DMS in the AWS documentation. For Oracle versions supported by Amazon RDS, see Oracle on Amazon RDS.

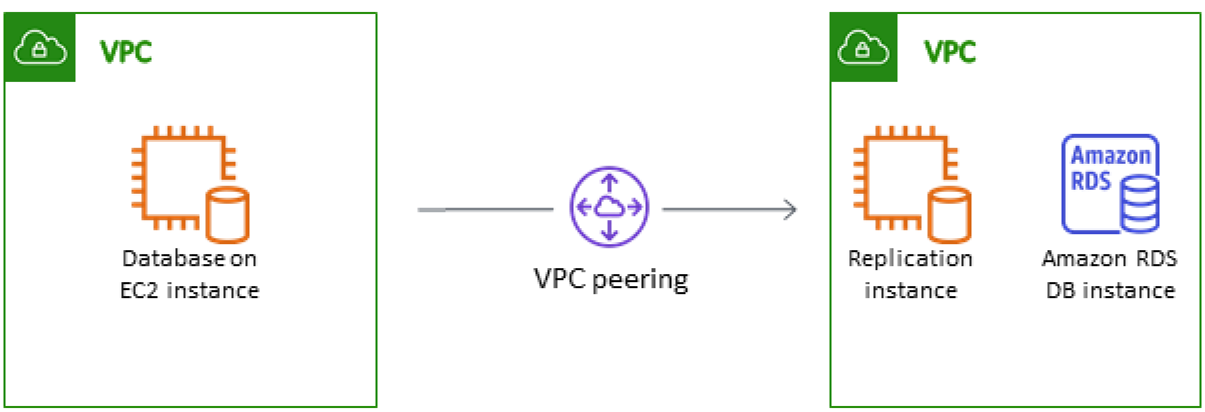
Architecture

Source and target technology stacks

- Amazon RDS for Oracle DB instance



Ongoing replication architecture



Tools

Tools used for one-time full data load

- Amazon Relational Database Service (Amazon RDS) creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. The amount of time it takes to create a snapshot varies with the size of your databases. Because the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot. For more information about using DB snapshots, see Creating a DB Snapshot in the Amazon RDS documentation.
- AWS Key Management Service (AWS KMS) creates a key for Amazon RDS encryption. When you create an encrypted DB instance, you can also supply the AWS KMS key identifier for your encryption key. If you don't specify an AWS KMS key identifier, Amazon RDS uses your default encryption key for your new DB instance. AWS KMS creates your default encryption key for your AWS account. Your AWS account has a different default encryption key for each AWS Region. For this pattern, the Amazon RDS DB instance should be encrypted using the non-default AWS KMS key. For more information about using AWS KMS keys for Amazon RDS encryption, see Encrypting Amazon RDS resources in the Amazon RDS documentation.

Tools used for ongoing replication

- AWS Database Migration Service (AWS DMS) is used to replicate ongoing changes and to keep the source and target databases in sync. For more information about using AWS DMS for ongoing replication, see Working with an AWS DMS replication instance in the AWS DMS documentation.

Epics

Configure your source AWS account

Task	Description	Skills required
Prepare the source Oracle DB instance.	Let the Amazon RDS for Oracle DB instance run in ARCHIVELOG mode, and set the retention period. For details, see Working with an AWS managed Oracle	DBA

Task	Description	Skills required
	database as a source for AWS DMS.	
Set supplemental logging for the source Oracle DB instance.	Set database-level and table-level supplemental logging for the Amazon RDS for Oracle DB instance. For details, see Working with an AWS managed Oracle database as a source for AWS DMS.	DBA
Update the AWS KMS key policy in the source account.	Update the AWS KMS key policy in the source AWS account to allow the target AWS account to use the encrypted Amazon RDS AWS KMS key. For details, see the AWS KMS documentation.	SysAdmin
Create a manual Amazon RDS DB snapshot of the source DB instance.		AWS IAM user
Share the manual, encrypted Amazon RDS snapshot with the target AWS account.	For details, see Sharing a DB snapshot.	AWS IAM user

Configure your target AWS account

Task	Description	Skills required
Attach a policy.	In the target AWS account, attach an AWS Identity and Access Management (IAM)	SysAdmin

Task	Description	Skills required
	policy to the root IAM user, to allow the IAM user to copy an encrypted DB snapshot using the shared AWS KMS key.	
Switch to the source AWS Region.		AWS IAM user
Copy the shared snapshot.	In the Amazon RDS console, in the **Snapshots** pane, choose **Shared with Me**, and select the shared snapshot. Copy the snapshot to the same AWS Region as the source database by using the Amazon Resource Name (ARN) for the AWS KMS key used by the source database. For details, see [Copying a DB snapshot]().	AWS IAM user
Switch to the target AWS Region, and create a new AWS KMS key.		AWS IAM user
Copy the snapshot.	Switch to the source AWS Region. On the Amazon RDS console, in the **Snapshots** pane, choose **Owned by Me**, and select the copied snapshot. Copy the snapshot to the target AWS Region by using the AWS KMS key for the new target AWS Region.	AWS IAM user

Task	Description	Skills required
Restore the snapshot.	Switch to the target AWS Region. On the Amazon RDS console, in the **Snapshots** pane, choose **Owned by Me**. Select the copied snapshot and restore it to an Amazon RDS for Oracle DB instance. For details, see [Restoring from a DB snapshot]().	AWS IAM user

Prepare your source database for ongoing replication

Task	Description	Skills required
Create an Oracle user with the appropriate permissions.	Create an Oracle user with the required privileges for Oracle as a source for AWS DMS. For details, see the [AWS DMS documentation]().	DBA
Configure the source database for Oracle LogMiner or Oracle Binary Reader.		DBA

Prepare your target database for ongoing replication

Task	Description	Skills required
Create an Oracle user with the appropriate permissions.	Create an Oracle user with the required privileges for Oracle as a target for AWS DMS. For details, see the [AWS DMS documentation]().	DBA

Create AWS DMS components

Task	Description	Skills required
Create a replication instance in the target AWS Region.	Create a replication instance in the VPC of the target AWS Region. For details, see the AWS DMS documentation.	AWS IAM user
Create source and target endpoints with required encryption, and test connections.	For details, see the AWS DMS documentation.	DBA
Create replication tasks.	1. For the migration type, choose ongoing replication. 2. For the change data capture (CDC) start point, use the Oracle system change number (SCN) when the Amazon RDS snapshot was taken for full load, or the timestamp when the full load was taken. 3. For `TargetTablePrepMode` , choose **DO_NOTHING**. If the task has large binary object (LOB) data tables, choose **Limited LOB mode**, and set the **max LOB size** to the maximum size of the LOB data in the table. 4. Enable logging.	IAM user

Task	Description	Skills required
	5. Group tables that are related through keys into a single task. If there are tables with a large amount of LOB data and the table has no relationship with other tables, create a separate task for it with the LOB settings described previously. For details, see the [AWS DMS documentation]().	
Start the tasks and monitor them.	For details, see the [AWS DMS documentation]().	AWS IAM user
Enable validation on the task if needed.	Note that enabling validatio n does have a performance impact on the replication. For details, see the [AWS DMS documentation]().	AWS IAM user

Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX

Deepak Kumar, Amazon Web Services

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes the use of VMware Hybrid Cloud Extension (HCX) to migrate your on-premises virtual machines (VMs) and applications to VMware Cloud on Amazon Web Services (AWS). The migration uses VMware enterprise-class software-defined data center (SDDC) software on the AWS Cloud to provide optimized access to AWS services.

VMware Cloud on AWS integrates compute, storage, and network virtualization products (vSphere, vSAN, and VMware NSX) with VMware vCenter server management, which is optimized to run on dedicated, elastic, bare-metal AWS infrastructure. The resulting infrastructure is low-maintenance, simplified, and hyper-converged.

With this service, IT teams can manage their cloud-based resources with familiar VMware tools. For more information, see VMware Cloud on AWS on the VMware website.

VMware HCX supports three types of cloud migrations:

- **Hybridity (data center extension):** Extending an existing, on-premises VMware SDDC to AWS to provide footprint expansion, on-demand capacity, a testing/development environment, and virtual desktops.
- **Cloud evacuation (data center-wide infrastructure refresh):** Consolidating data centers and moving completely to the AWS Cloud (including handling data center co-location or end of lease).
- **Application-specific migration:** Moving individual applications to the AWS Cloud to meet specific business needs.

Prerequisites and limitations

Prerequisites

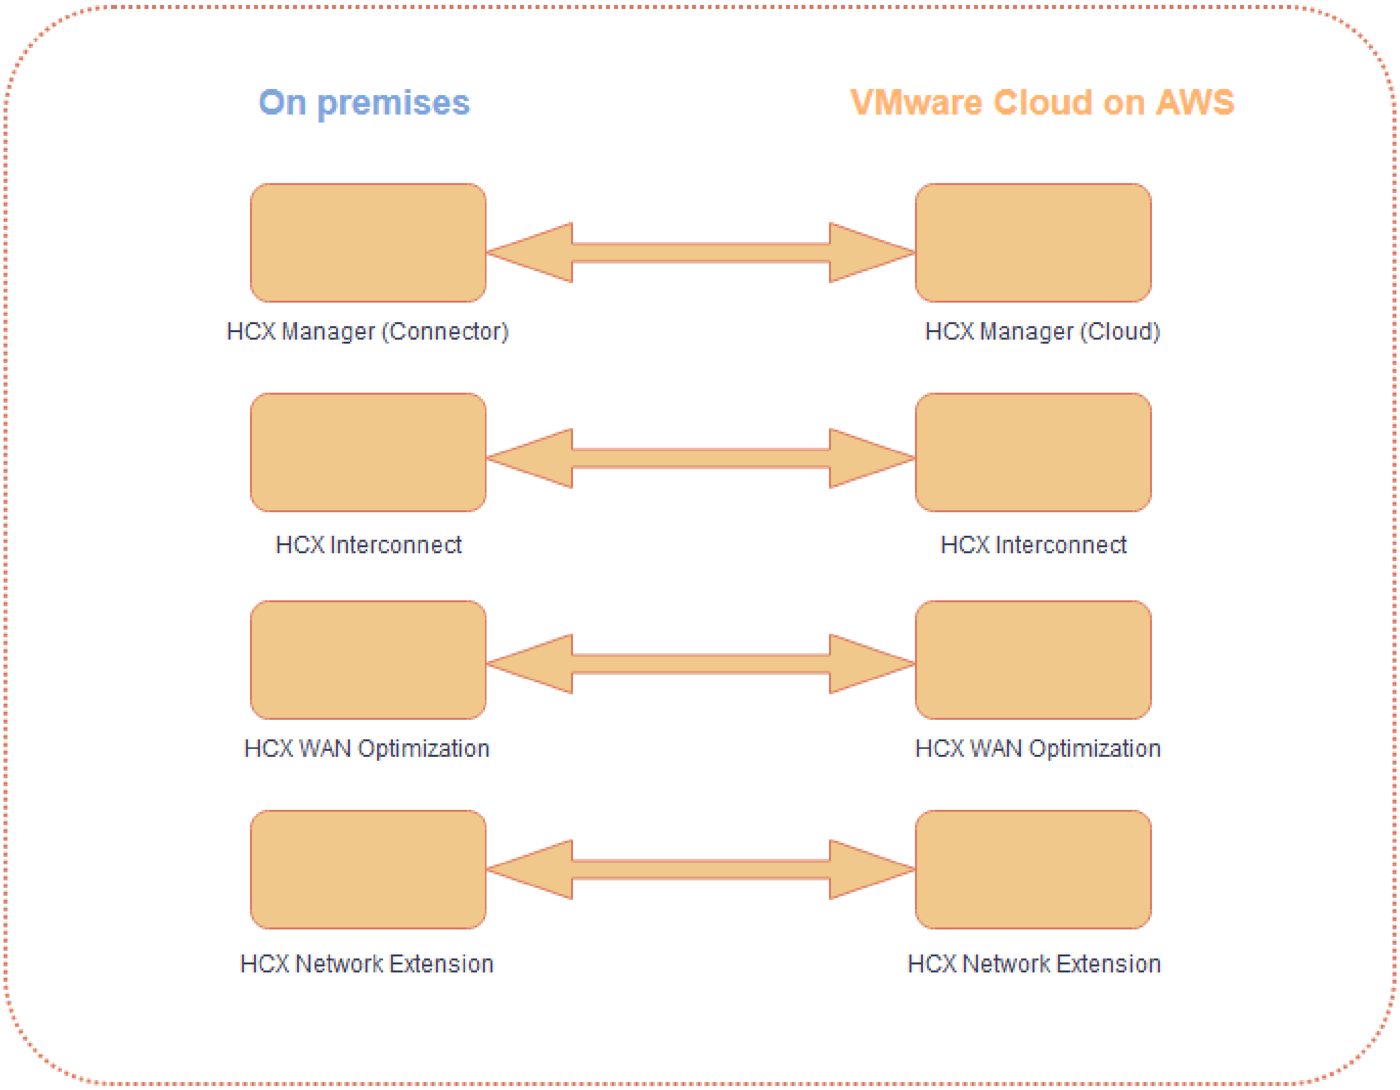
- Sign up for an AWS account (required for VMware Cloud SDDC creation).
- Sign up for a My VMware account. Register at https://my.vmware.com/web/vmware/ and fill out all fields.
- Check the version of vCenter and hosts, and collect the number of VMs. If possible, ask for an RVTools export to display information about your virtual environments. We recommend vCenter version 6.0 or later.
- You must deploy distributed virtual switches if you want to extend data center networks (L2), test vMotion by using HCX, or analyze application dependency by using vRealize Network Insight.
- Pick a non-conflicting on-premises current management subnet network to create the SDDC on VMware Cloud on AWS.
- Validate HCX requirements by reviewing the prerequisites provided in the VMware HCX User Guide.
- Identify and group VMs for waves of migration. Check for VMs that you can use for testing.
- Collect any data about relative bandwidth consumption, WAN compression, and data transfer speed.

Notes

- No need for VMware NSX-V or NSX-T on premises.
- No additional costs for HCX (it's included in VMware Cloud on AWS).

Architecture

The following diagram shows the HCX solution built on multiple component services. Each component supports a specific function in the HCX solution. For more information about each HCX component, see the blog post Migrating Workloads to VMware Cloud on AWS with Hybrid Cloud Extension (HCX).



Source technology stack

- On-premises VMs and applications managed by VMware vSphere

Target technology stack

- VMware Cloud on AWS

Tools

- VMware HCX – VMware HCX is a tool that you can use to migrate your applications and workloads across data centers and cloud environments. It is included with VMware Cloud on AWS.

Epics

Plan the migration

Task	Description	Skills required
Choose a migration strategy.	Decide whether you want to extend your data center (hybridity), move all your data centers (cloud evacuation), or move specific applications to AWS.	SysAdmin, App owner
Validate HCX requirements.	For migration information, review the VMware HCX User Guide.	SysAdmin, App owner

Migrate to VMware Cloud on AWS

Task	Description	Skills required
Migrate your VMs or applicati ons.	For more information, see Hybrid Migration with VMware HCX in the VMware documentation.	SysAdmin, App owner

Migrate an Amazon RDS DB instance to another VPC or account

Dhrubajyoti Mukherjee, Amazon Web Services

Summary

This pattern provides guidance for migrating an Amazon Relational Database Service (Amazon RDS) DB instance from one virtual private cloud (VPC) to another in the same AWS account, or from one AWS account to another AWS account.

This pattern is useful if you want to migrate your Amazon RDS DB instances to another VPC or account for separation or security reasons (for example, when you want to place your application stack and database in different VPCs).

Migrating a DB instance to another AWS account involves steps such as taking a manual snapshot, sharing it, and restoring the snapshot in the target account. This process can be time-consuming, depending on database changes and transaction rates. It also causes database downtime, so plan ahead for the migration. Consider a blue/green deployment strategy to minimize downtime. Alternatively, you can evaluate AWS Data Migration Service (AWS DMS) to minimize downtime for the change. However, this pattern doesn't cover this option. To learn more, see the AWS DMS documentation.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) permissions required for the VPC, subnets, and Amazon RDS console

Limitations

- Changes to a VPC cause a database reboot, resulting in application outages. We recommend that you migrate during low peak times.
- Limitations when migrating Amazon RDS to another VPC:
  - The DB instance you're migrating must be a single instance with no standby. It must not be a member of a cluster.
  - Amazon RDS must not be in multiple Availability Zones.

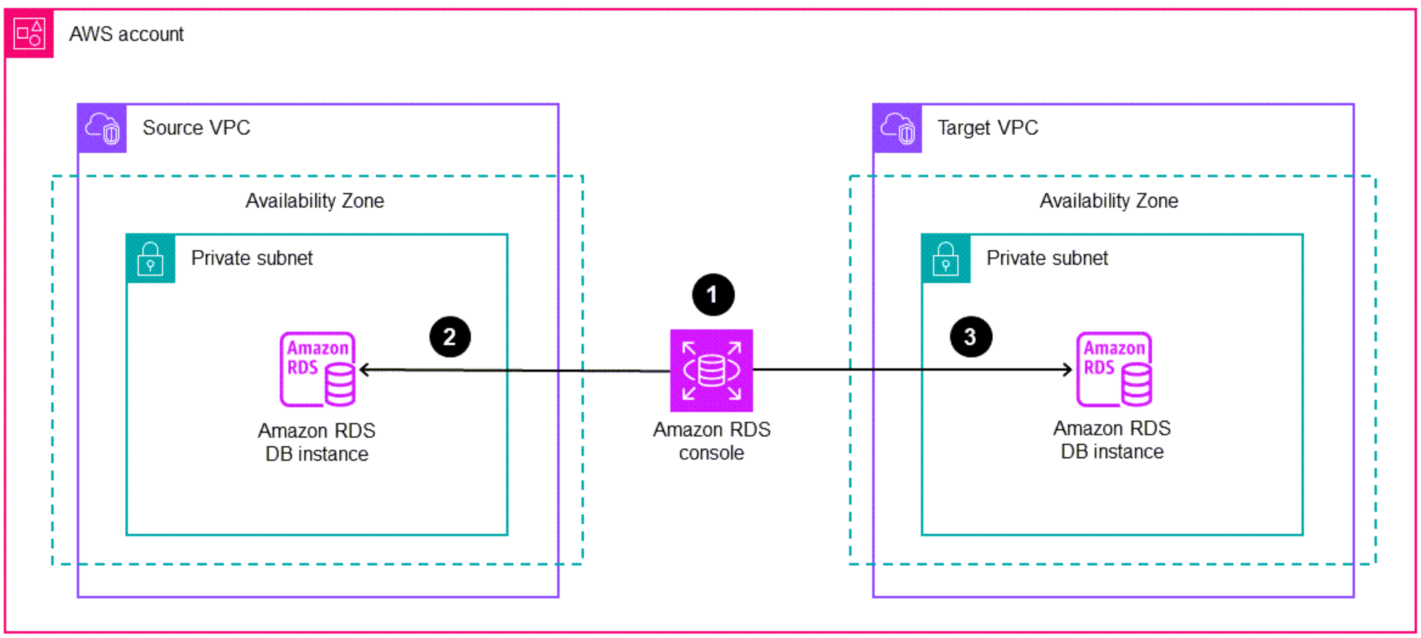
- Amazon RDS must not have any read replicas.
- The subnet group created in the target VPC must have subnets from the Availability Zone where the source database is running.

- Limitations when migrating Amazon RDS to another AWS account:
  - Sharing snapshots encrypted with the default service key for Amazon RDS isn't currently supported.

Architecture

Migrating to a VPC in the same AWS account

The following diagram shows the workflow for migrating an Amazon RDS DB instance to a different VPC in the same AWS account.

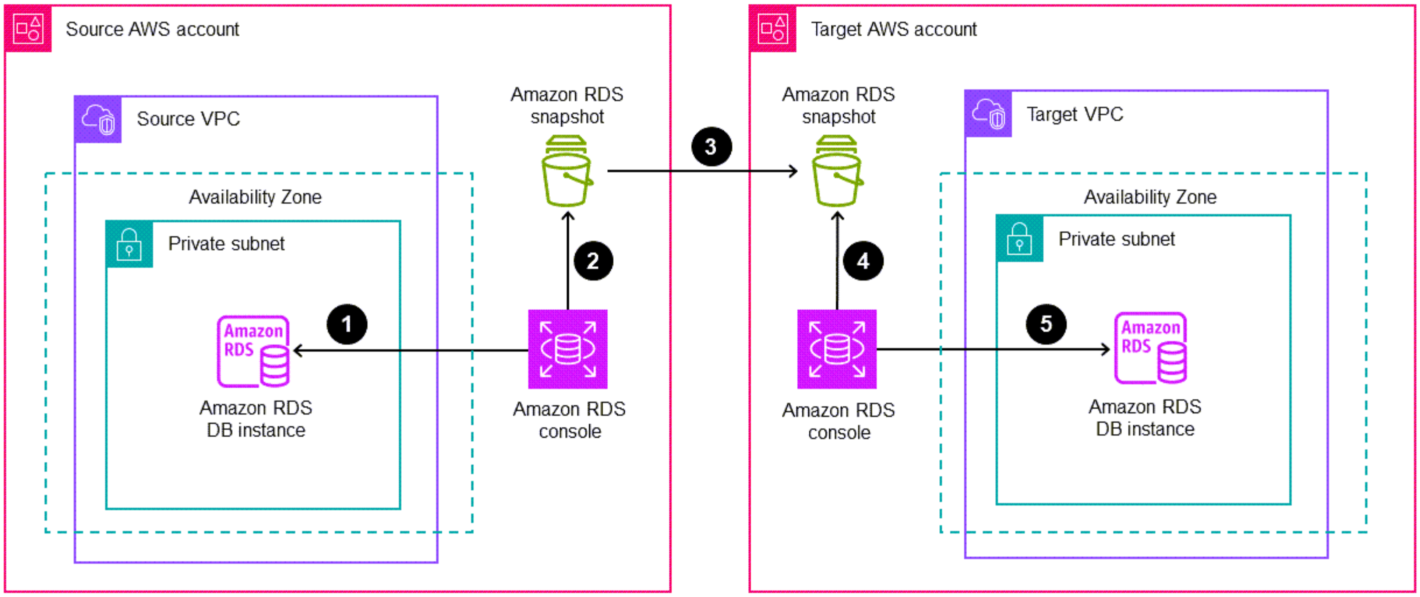


The steps consist of the following. See the Epics section for detailed instructions.

1. Create a DB subnet group in the target VPC. A DB subnet group is a collection of subnets that you can use to specify a specific VPC when you create DB instances.
2. Configure the Amazon RDS DB instance in the source VPC to use the new DB subnet group.
3. Apply the changes to migrate the Amazon RDS DB to the target VPC.

Migrating to a different AWS account

The following diagram shows the workflow for migrating an Amazon RDS DB instance to a different AWS account.



The steps consist of the following. See the Epics section for detailed instructions.

1. Access the Amazon RDS DB instance in the source AWS account.
2. Create an Amazon RDS snapshot in the source AWS account.
3. Share the Amazon RDS snapshot with the target AWS account.
4. Access the Amazon RDS snapshot in the target AWS account.
5. Create an Amazon RDS DB instance in the target AWS account.

Tools

AWS services

- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Best practices

- If database downtime is a concern when migrating an Amazon RDS DB instance to another account, we recommend that you use AWS DMS. This service provides data replication, which causes less than five minutes of outage time.

Epics

Migrate to a different VPC in the same AWS account

Task	Description	Skills required
Create a new VPC.	On the Amazon VPC console, create a new VPC and subnets with the desired propertie s and IP address ranges. For detailed instructions, see the Amazon VPC documentation.	Administrator
Create a DB subnet group.	On the Amazon RDS console: 1. Choose **Subnet groups**, **Create DB subnet group.** 2. Enter the subnet group name, description, and VPC ID. 3. Add the subnets that belong to the subnet group. Add subnets to cover at least two Availabil ity Zones. 4. Choose **Create**. For additional informati on, see the Amazon RDS documentation.	Administrator

Task	Description	Skills required
Modify the Amazon RDS DB instance to use the new subnet group.	On the Amazon RDS console: 1. In the navigation pane, choose **Databases**, and then choose the Amazon RDS DB instance to be migrated. 2. In the **Connectivity** section, choose the subnet group that's associated with the target VPC. 3. In the **Schedule modificat ions** section, choose **Apply immediately**. When the migration to the target VPC is complete, the target VPC's default security group is assigned to the Amazon RDS DB instance. You can configure a new security group for that VPC with the required inbound and outbound rules to your DB instance. Alternatively, use the AWS Command Line Interface (AWS CLI) to perform the migration to the target VPC by explicitly providing the new VPC security group ID. For example:	Administrator

Task	Description	Skills required
	`aws rds modify-db-instance \ --db-instance-identifier testrds \ --db-subnet-group-name new-vpc-subnet-group \ --vpc-security-group-ids sg-idxxxx \ --apply-immediately`	

Migrate to a different AWS account

Task	Description	Skills required
Create a new VPC and subnet group in the target AWS account.	1. On the Amazon VPC console, create a new VPC with the desired properties and IP address ranges. For detailed instructions, see the Amazon VPC documentation. 2. Create subnets for the new VPC by following the instructions in the Amazon VPC documentation. 3. On the Amazon RDS console, create DB subnet groups. For instructions, see the Amazon RDS documentation.	Administrator

Task	Description	Skills required
Share a manual snapshot of the database and share it with the target account.	1. Take a manual snapshot of the source database by following the instructi ons in the Amazon RDS documentation. 2. Share the snapshot with the target AWS account by providing the target account ID. For instructi ons, see the re:Post article about sharing DB snapshots with other accounts.	Administrator
Launch a new Amazon RDS DB instance.	Launch a new Amazon RDS DB instance from the shared snapshot in the target AWS account. For instructions, see the Amazon RDS documenta tion.	Administrator

Related resources

Migrate an Amazon RDS for Oracle DB instance to another VPC

Pinesh Singal, Amazon Web Services

Summary

This migration pattern provides step-by-step guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle database (DB) instance from one virtual private cloud (VPC) to another VPC in same Amazon Web Services (AWS) account. For example, you can use this pattern if your business requires that the database and the Amazon Elastic Compute Cloud (Amazon EC2) application server are in the same VPC.

The pattern describes an online migration strategy with almost no downtime for a multi-terabyte Oracle source database with a high number of transactions.

To move an Amazon RDS for Oracle DB instance to another VPC, you must change the Amazon RDS subnet group. This subnet group needs to be preconfigured with the new VPC and required subnets. During the VPC change from one network to another, the Amazon RDS instance reboots, so the database won't be accessible while the movement is in progress.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Two VPCs with private subnets
- An Amazon RDS for Oracle database instance (up and running), configured with inbound and outbound security groups

Limitations

- A DB instance that spans multiple Availability Zones (Multi-AZ) is not supported. This pattern, however, provides a way to work around this limitation.
- The DB instance can’t be migrated while a read replica is turned on.
- The subnet group in the new VPC should be in the same Availability Zone as the database.
- Migration should occur during scheduled maintenance period or low-traffic times, because moving the DB to another VPC causes a database reboot, resulting in application outages for few minutes.

Product versions

- Amazon RDS for Oracle DB instance, 12.1.0.2 and later

Architecture

Source technology stack

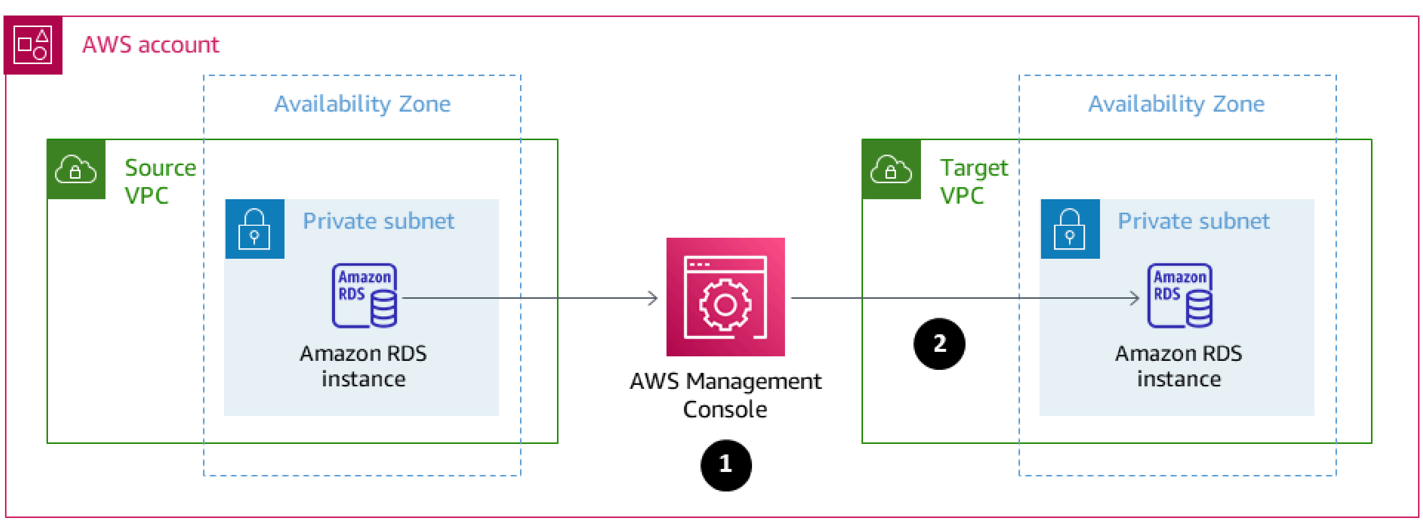
- An Amazon RDS for Oracle 12.1.0.2.v22 DB instance in a VPC
- A VPC configured in a separate route table
- Amazon RDS subnet groups configured in a VPC
- Amazon RDS option groups (if needed)

Target technology stack

- Amazon RDS for Oracle database instance with version 12.1.0.2.v22 in another VPC
- Amazon VPC configured in separate route
- Amazon RDS Subnet Groups configured in new VPC
- Amazon RDS Option Groups (if needed)

Source and target architecture

The following diagram shows using the console to move the Amazon RDS for Oracle DB from a private subnet in one VPC to a private subnet in a different VPC.



1. Use the console to modify the source Amazon RDS for Oracle DB instance.
2. In the target VPC, modify the subnet group, and modify the option group if used.

Tools

- Amazon RDS – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks. This pattern uses Amazon RDS for Oracle.

Epics

Change the configuration of the Amazon RDS for Oracle database in the existing VPC

Task	Description	Skills required
Create a subnet group.	Configure a subnet group in Amazon RDS.	General AWS
Create an option group.	(Optional) Configure an option group in Amazon RDS.	General AWS
Modify the Amazon RDS for Oracle DB instance.	Modify the database with the subnet group and option group.	General AWS, DBA
Update the Oracle database, if necessary.	To migrate the source Amazon RDS for Oracle database, make the following changes: • Remove read replicas, if they exist. • Turn off the Multi-AZ feature, if it's turned on.	General AWS

Configure the Amazon RDS for Oracle database in the target VPC

Task	Description	Skills required
Create a subnet group.	In Amazon RDS, configure a subnet group using the subnet of the new VPC and the Availability Zone of the database.	General AWS
Create an option group.	(Optional) Configure an option group in Amazon RDS.	General AWS
Modify the Amazon RDS for Oracle database.	Modify the database with new subnet group and option group of the new VPC. You can apply these changes immediately or in a maintenance window. The modification can take several minutes to complete. During the modification, you will see the following status changes: • moving-to-vpc • Configuring-enhanced-monitoring • Modifying • Available The modification will attach the default security group of the new VPC. Attach a new security group as needed by Amazon RDS for Oracle.	General AWS, DBA

Task	Description	Skills required
Update the Amazon RDS for Oracle database, if necessary.	After migrating to the target Amazon RDS for Oracle database in the new VPC, make the following modifications, if needed: • Turn on read replicas, if they existed in the source database. • Turn on the Multi-AZ feature, if it was turned on in the source database.	General AWS
Test application connectivity.	Perform a database connectivity test from any application. Confirm that the modified Amazon RDS for Oracle DB in the new VPC is connected and is accessible from the application.	App owner

Migrate an Amazon Redshift cluster to an AWS Region in China

Jing Yan, Amazon Web Services

Summary

This pattern provides a step-by-step approach to migrate an Amazon Redshift cluster to an AWS Region in China from another AWS Region.

This pattern uses SQL commands to recreate all the database objects, and uses the UNLOAD command to move this data from Amazon Redshift to an Amazon Simple Storage Service (Amazon S3) bucket in the source Region. The data is then migrated to an S3 bucket in the AWS Region in China. The COPY command is used to load data from the S3 bucket and transfer it to the target Amazon Redshift cluster.

Amazon Redshift doesn't currently support cross-Region features such as snapshot copying to AWS Regions in China. This pattern provides a way to work around that limitation. You can also reverse the steps in this pattern to migrate data from an AWS Region in China to another AWS Region.

Prerequisites and limitations

Prerequisites

- Active AWS accounts in both a China Region and an AWS Region outside China
- Existing Amazon Redshift clusters in both a China Region and an AWS Region outside China

Limitations

- This is an offline migration, which means the source Amazon Redshift cluster cannot perform write operations during the migration.

Architecture

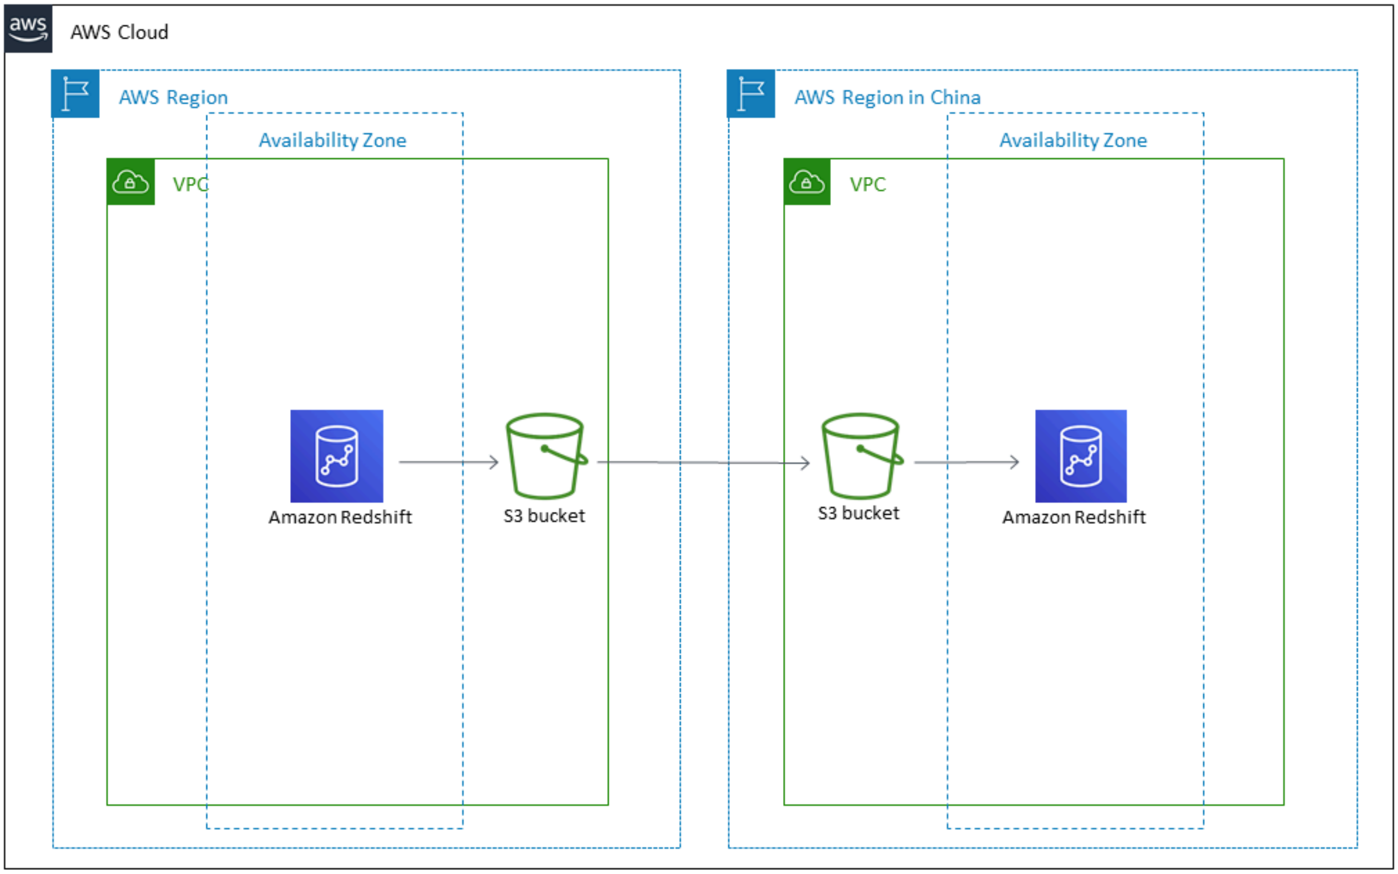
Source technology stack

- Amazon Redshift cluster in an AWS Region outside China

Target technology stack

- Amazon Redshift cluster in an AWS Region in China

Target architecture



Tools

Tools

- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers scalability, data availability, security, and performance. You can use Amazon S3 to store data from Amazon Redshift, and you can copy data from an S3 bucket to Amazon Redshift.
- Amazon Redshift – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud.
- psql – psql is a terminal-based front-end to PostgreSQL.

Epics

Prepare for migration in the source Region

Task	Description	Skills required
Launch and configure an EC2 instance in the source Region.	Sign in to the AWS Management Console and open the Amazon Elastic Compute Cloud (Amazon EC2) console. Your current Region is displayed in the navigation bar at the top of the screen. This Region cannot be an AWS Region in China. From the Amazon EC2 console dashboard, choose "Launch instance," and create and configure an EC2 instance. Important: Ensure your EC2 security groups for inbound rules allow unrestricted access to TCP port 22 from your source machine. For instructi ons on how to launch and configure an EC2 instance, see the "Related resources" section.	DBA, Developer
Install the psql tool.	Download and install PostgreSQL. Amazon Redshift does not provide the psql tool, it is installed with PostgreSQL. For more information about using psql and installing PostgreSQ	DBA

Task	Description	Skills required
	L tools, see the "Related resources" section.	
Record the Amazon Redshift cluster details.	Open the Amazon Redshift console, and choose "Clusters " in the navigation pane. Then choose the Amazon Redshift cluster name from the list. On the "Properties" tab, in the "Database configurations" section, record the "Database name" and "Port." Open the "Connection details" section and record the "Endpoint ," which is in the "endpoint :<port>/<databasename>" format. Important: Ensure your Amazon Redshift security groups for inbound rules allow unrestricted access to TCP port 5439 from your EC2 instance.	DBA

Task	Description	Skills required
Connect psql to the Amazon Redshift cluster.	At a command prompt, specify the connection information by running the "psql -h <endpoint> -U <userid> -d <databasename> -p <port>" command. At the psql password prompt, enter the password for the "<userid>" user. You are then connected to the Amazon Redshift cluster and can interactively enter commands.	DBA
Create an S3 bucket.	Open the Amazon S3 console, and create an S3 bucket to hold the files exported from Amazon Redshift. For instructi ons on how to create an S3 bucket, see the "Related resources" section.	DBA, AWS General

Task	Description	Skills required
Create an IAM policy that supports unloading data.	Open the AWS Identity and Access Management (IAM) console and choose "Policies ." Choose "Create policy," and choose the "JSON" tab. Copy and paste the IAM policy for unloading data from the "Additional information" section. Important: Replace "s3_bucket_name" with your S3 bucket's name. Choose "Review policy," and enter a name and description for the policy. Choose "Create policy."	DBA
Create an IAM role to allow UNLOAD operation for Amazon Redshift.	Open the IAM console and choose "Roles." Choose "Create role," and choose "AWS service" in "Select type of trusted entity." Choose "Redshift" for the service, choose "Redshift – Customiza ble," and then choose "Next." Choose the "Unload" policy you created earlier, and choose "Next." Enter a "Role name," and choose "Create role."	DBA

Task	Description	Skills required
Associate IAM role with the Amazon Redshift cluster.	Open the Amazon Redshift console, and choose "Manage IAM roles." Choose "Availabl e roles" from the dropdown menu and choose the role you created earlier. Choose "Apply changes." When the "Status" for the IAM role on the "Manage IAM roles" shows as "In-sync", you can run the UNLOAD command.	DBA
Stop write operations to the Amazon Redshift cluster.	You must remember to stop all write operations to the source Amazon Redshift cluster until the migration is complete.	DBA

Prepare for migration in the target Region

Task	Description	Skills required
Launch and configure an EC2 instance in the target Region.	Sign in to the AWS Management Console for a Region in China, either Beijing or Ningxia. From the Amazon EC2 console, choose "Launch instance," and create and configure an EC2 instance. Important: Make sure your Amazon EC2 security groups for inbound rules allow unrestricted access to TCP port 22 from your source	DBA

Task	Description	Skills required
	machine. For further instructions on how to launch and configure an EC2 instance, see the "Related resources" section.	
Record the Amazon Redshift cluster details.	Open the Amazon Redshift console, and choose "Clusters " in the navigation pane. Then choose the Amazon Redshift cluster name from the list. On the "Properties" tab, in the "Database configurations" section, record the "Database name" and "Port." Open the "Connection details" section and record the "Endpoint ," which is in the "endpoint :<port>/<databasename>" format. Important: Make sure your Amazon Redshift security groups for inbound rules allow unrestricted access to TCP port 5439 from your EC2 instance.	DBA

Task	Description	Skills required
Connect psql to the Amazon Redshift cluster.	At a command prompt, specify the connection information by running the "psql -h <endpoint> -U <userid> -d <databasename> -p <port>" command. At the psql password prompt, enter the password for the "<userid>" user. You are then connected to the Amazon Redshift cluster and can interactively enter commands.	DBA
Create an S3 bucket.	Open the Amazon S3 console, and create an S3 bucket to hold the exported files from Amazon Redshift. For help with this and other stories, see the "Related resources" section.	DBA
Create an IAM policy that supports copying data.	Open the IAM console and choose "Policies." Choose "Create policy," and choose the "JSON" tab. Copy and paste the IAM policy for copying data from the "Additional information" section. Important: Replace "s3_bucket_name" with your S3 bucket's name. Choose "Review policy," enter a name and description for the policy. Choose "Create policy."	DBA

Task	Description	Skills required
Create an IAM role to allow COPY operation for Amazon Redshift.	Open the IAM console and choose "Roles." Choose "Create role," and choose "AWS service" in "Select type of trusted entity." Choose "Redshift" for the service, choose "Redshift – Customiza ble," and then choose "Next." Choose the "Copy" policy you created earlier, and choose "Next." Enter a "Role name," and choose "Create role."	DBA
Associate IAM role with the Amazon Redshift cluster.	Open the Amazon Redshift console, and choose "Manage IAM roles." Choose "Availabl e roles" from the dropdown menu and choose the role you created earlier. Choose "Apply changes." When the "Status" for the IAM role on the "Manage IAM roles" shows as "In-sync", you can run the "COPY" command.	DBA

Verify source data and object information before beginning the migration

Task	Description	Skills required
Verify the rows in the source Amazon Redshift tables.	Use the scripts in the "Additional information" section to verify and record the number of rows in the source Amazon Redshift	DBA

Task	Description	Skills required
	tables. Remember to split the data evenly for the UNLOAD and COPY scripts. This will improve the data unloading and loading efficiency, because the data quantity covered by each script will be balanced.	
Verify the number of database objects in the source Amazon Redshift cluster.	Use the scripts in the "Additional information" section to verify and record the number of databases, users, schemas, tables, views, and user-defined functions (UDFs) in your source Amazon Redshift cluster.	DBA
Verify SQL statement results before migration.	Some SQL statements for data validation should be sorted according to actual business and data situations. This is to verify the imported data to ensure it is consistent and displayed correctly.	DBA

Migrate data and objects to the target Region

Task	Description	Skills required
Generate Amazon Redshift DDL scripts.	Generate Data Definition Language (DDL) scripts by using the links from the "SQL statements to query Amazon Redshift" section	DBA

Task	Description	Skills required
	in the "Additional informati on" section. These DDL scripts should include the "create user," "create schema," "privileges on schema to user," "create table/view," "privileges on objects to user," and "create function" queries.	
Create objects in the Amazon Redshift cluster for the target Region.	Run the DDL scripts by using the AWS Command Line Interface (AWS CLI) in the AWS Region in China. These scripts will create objects in the Amazon Redshift cluster for the target Region.	DBA
Unload source Amazon Redshift cluster data to the S3 bucket.	Run the UNLOAD command to unload data from the Amazon Redshift cluster in the source Region to the S3 bucket.	DBA, Developer
Transfer source Region S3 bucket data to target Region S3 bucket.	Transfer the data from your source Region S3 bucket to the target S3 bucket. Because the "$ aws s3 sync" command cannot be used, make sure you use the process outlined in the "Transferring Amazon S3 data from AWS Regions to AWS Regions in China" article in the "Related resources" section.	Developer

Task	Description	Skills required
Load data into the target Amazon Redshift cluster.	In the psql tool for your target Region, run the COPY command to load data from the S3 bucket to the target Amazon Redshift cluster.	DBA

Verify the data in the source and target Regions after the migration

Task	Description	Skills required
Verify and compare the number of rows in the source and target tables.	Verify and compare the number of table rows in the source and target Regions to ensure all are migrated.	DBA
Verify and compare the number of source and target database objects.	Verify and compare all database objects in the source and target Regions to ensure all are migrated.	DBA
Verify and compare SQL script results in the source and target Regions.	Run the SQL scripts prepared before the migration. Verify and compare the data to ensure that the SQL results are correct.	DBA
Reset the passwords of all users in the target Amazon Redshift cluster.	After the migration is complete and all data is verified, you should reset all user passwords for the Amazon Redshift cluster in the AWS Region in China.	DBA

Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport

Raunak Rishabh and Jitender Kumar, Amazon Web Services

Summary

This pattern describes the steps for migrating extremely large databases between two Amazon Relational Database Service (Amazon RDS) for PostgreSQL DB instances by using the **pg_transport** extension. This extension provides a physical transport mechanism to move each database. By streaming the database files with minimal processing, it provides an extremely fast method for migrating large databases between DB instances with minimal downtime. This extension uses a pull model where the target DB instance imports the database from the source DB instance.

Prerequisites and limitations

Prerequisites

- Both DB instances must run the same major version of PostgreSQL.
- The database must not exist on the target. Otherwise, the transport fails.
- No extension other than **pg_transport** must be enabled in the source database.
- All source database objects must be in the default **pg_default** tablespace.
- The security group of the source DB instance should allow traffic from the target DB instance.
- Install a PostgreSQL client like [psql] or [PgAdmin] to work with the Amazon RDS PostgreSQL DB instance. You can install the client either in your local system or use an Amazon Elastic Compute Cloud (Amazon EC2) instance. In this pattern, we use psql on an EC2 instance.

Limitations

- You can't transport databases between different major versions of Amazon RDS for PostgreSQL.
- The access privileges and ownership from the source database are not transferred to the target database.
- You can't transport databases on read replicas or on parent instances of read replicas.
- You can't use **reg** data types in any database tables that you plan to transport with this method.
- You can run up to 32 total transports (including both imports and exports) at the same time on a DB instance.

- You cannot rename or include/exclude tables. Everything is migrated as is.

Caution

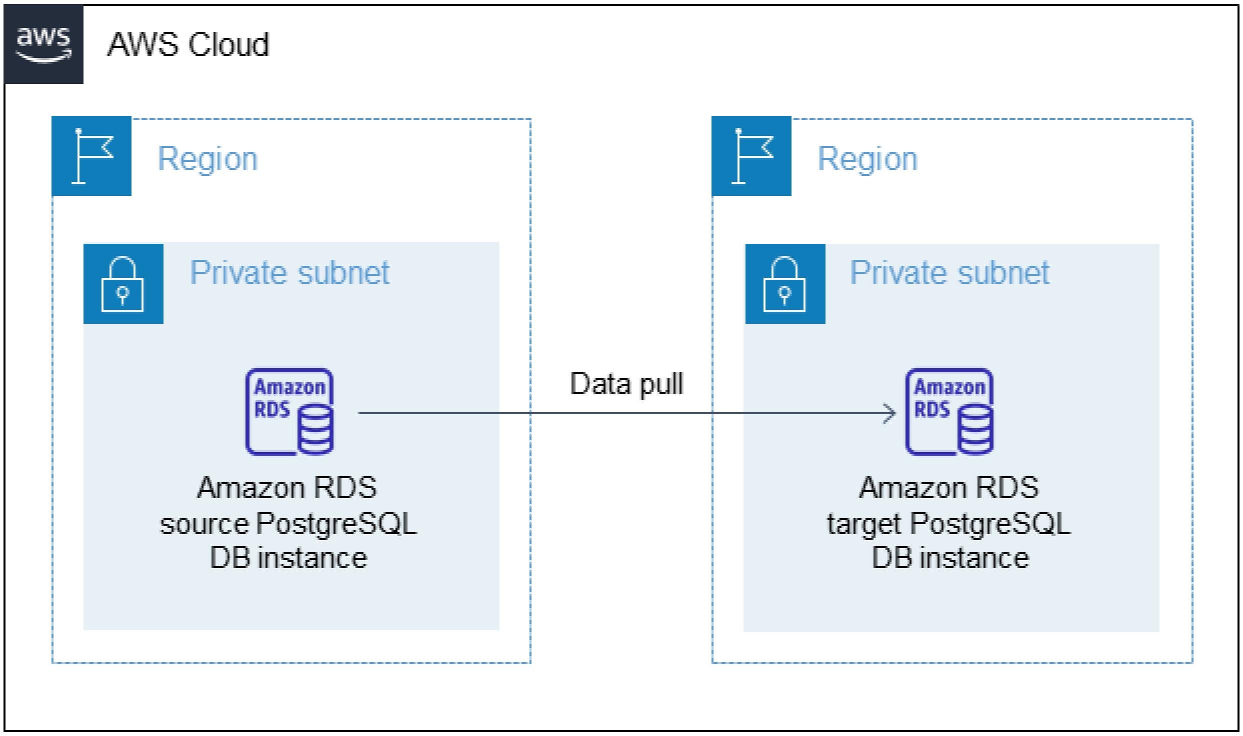
- Make backups before removing the extension, because removing the extension also removes dependent objects and some data that's critical to the operation of the database.
- Consider the instance class and processes running on other databases on the source instance when you determine the number of workers and `work_mem` values for **pg_transport**.
- When the transport starts, all connections on the source database are ended and the database is put into read-only mode.

> **Note**
>
> When the transport is running on one database, it doesn't affect other databases on the same server.

Product versions

- Amazon RDS for PostgreSQL 10.10 and later, and Amazon RDS for PostgreSQL 11.5 and later. For the latest version information, see Transporting PostgreSQL Databases Between DB Instances in the Amazon RDS documentation.

Architecture



Tools

- **pg_transport** provides a physical transport mechanism to move each database. By streaming the database files with minimal processing, physical transport moves data much faster than traditional dump and load processes and requires minimal downtime. PostgreSQL transportable databases use a pull model where the destination DB instance imports the database from the source DB instance. You install this extension on your DB instances when you prepare the source and target environments, as explained in this pattern.
- psql enables you to connect to, and work with, your PostgreSQL DB instances. To install **psql** on your system, see the PostgreSQL Downloads page.

Epics

Create the target parameter group

Task	Description	Skills required
Create a parameter group for the target system.	Specify a group name that identifies it as a target	DBA

Task	Description	Skills required
	parameter group; for example, `pgtarget-param-group` . For instructions, see the [Amazon RDS documentation]().	

Task	Description	Skills required
Modify the parameters for the parameter group.	Set the following parameters: 1. Add `pg_transport` to the `shared_preload_libraries` parameter. `shared_preload_libraries = pg_stat_statements, pg_transport` 2. Set the `pg_transport.num_workers` parameter. Choose the number of workers you want to run the transport with. The value you set determines the number of `transport.send_file` workers that will be created in the source. 3. Increase the the value of `max_worker_processes` to more than three times the value of `pg_transport.num_workers`. For example, if you set the value of `pg_transport.num_workers` to 4, the `max_worker_processes` value should be at least 13. If this fails,	DBA

Task	Description	Skills required
	pg_transport recommends a minimum value. 4. Set `pg_transport.timing` to 1. This setting enables the reporting of timing information during the transport. 5. Set the `pg_transport.work_mem` parameter. This parameter specifies the maximum memory to allocate to each worker. The default value is 128 MB. For more information about these parameters, see the [Amazon RDS documentation]().	

Create the source parameter group

Task	Description	Skills required
Create a parameter group for the source system.	Specify a group name that identifies it as a source parameter group; for example, `pgsource-param-group` . For instructions, see the [Amazon RDS documentation]().	DBA
Modify the parameters for the parameter group.	Set the following parameters:	DBA

Task	Description	Skills required
	1. Add `pg_transport` to the `shared_preload_libraries` parameter. `shared_preload_libraries = pg_stat_statements, pg_transport` 2. Set the `pg_transport.num_workers` parameter. The value of this parameter defined in the target determines the number of `transport.send_file` workers to be used. If you have an import running on this instance, increase this value, but consider the number of workers that are already running. 3. Increase the the value of `max_worker_processes` to more than three times the value of `pg_transport.num_workers` on the target. For example, if you set the value of `pg_transport.num_workers` to 4 on the target, the `max_worker_processes` value on the source	

Task	Description	Skills required
	should be at least 13. If this fails, **pg_transport** recommends a minimum value. 4. Set the `pg_transport.work_mem` parameter. This parameter specifies the maximum memory to allocate to each worker. The default value is 128 MB. For more information about these parameters, see the [Amazon RDS documentation]().	

Prepare the target environment

Task	Description	Skills required
Create a new Amazon RDS for PostgreSQL DB instance to transport your source database to.	Determine the instance class and PostgreSQL version based on your business requirements.	DBA, Systems administrator, Database architect
Modify the security group of the target to allow connections on the DB instance port from the EC2 instance.	By default, the port for the PostgreSQL instance is 5432. If you're using another port, connections to that port must be open for the EC2 instance.	DBA, Systems administrator
Modify the instance, and assign the new target parameter group.	For example, `pgtarget-param-group` .	DBA

Task	Description	Skills required
Restart the target Amazon RDS DB instance.	The parameters `shared_preload_libraries` and `max_worker_processes` are static parameters and require a reboot of the instance.	DBA, Systems administrator
Connect to the database from the EC2 instance using psql.	Use the command: `psql -h <rds_end_point> -p PORT -U username -d database -W`	DBA
Create the pg_transport extension.	Run the following query as a user with the `rds_superuser` role: `create extension pg_transport;`	DBA

Prepare the source environment

Task	Description	Skills required
Modify the security group of the source to allow connections on the DB instance port from the Amazon EC2 instance and target DB instance	By default, the port for PostgreSQL instance is 5432. If you're using another port, connections to that port must be open for the EC2 instance.	DBA, Systems administrator
Modify the instance and assign the new source parameter group.	For example, `pgsource-param-group` .	DBA

Task	Description	Skills required
Restart the source Amazon RDS DB instance.	The parameters `shared_preload_libraries` and `max_worker_processes` are static parameters and require a reboot of the instance.	DBA
Connect to the database from the EC2 instance using psql.	Use the command: `psql -h <rds_end_point> -p PORT -U username -d database -W`	DBA
Create the pg_transport extension and remove all other extensions from the databases to be transported.	The transport will fail if there are any extensions other than **pg_transport** installed on the source database. This command must by run by a user with the `rds_superuser` role.	DBA

Perform the transport

Task	Description	Skills required
Perform a dry run.	Use the `transport.import_from_server` function to perform a dry run first: `SELECT transport.import_from_server( 'source-db-instance-endpoint', source-db-instance-port,`	DBA

Task	Description	Skills required
	``` 'source-db-instance-user', 'source-user-password', 'source-database-name', 'destination-user-password', 'true'); ``` The last parameter of this function (set to `true`) defines the dry run. This function displays any errors that you would see when you run the main transport. Resolve the errors before you run the main transport.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>If the dry run is successful, initiate the database transport.</td><td>Run the <code>transport.import_from_server</code> function to perform the transport. It connects to the source and imports the data.<pre><code>SELECT transport.import_from_server('source-db-instance-endpoint', source-db-instance-port,
 'source-db-instance-user', 'source-user-password', 'source-database-name',
 'destination-user-password', false);</code></pre>The last parameter of this function (set to <code>false</code>) indicates that this isn't a dry run.</td><td>DBA</td></tr>
<tr><td>Perform post-transport steps.</td><td>After the database transport is complete:
Validate the data in the target environment.
Add all the roles and permissions to the target.
Enable all required extensions in the target and source, if required.
Revert the value of the <code>max_worker_processes</code> parameter.</td><td>DBA</td></tr>
</table>

Export a Microsoft SQL Server database to Amazon S3 by using AWS DMS

Sweta Krishna, Amazon Web Services

Summary

Organizations often need to copy databases to Amazon Simple Storage Service (Amazon S3) for database migration, backup and restore, data archiving, and data analytics. This pattern describes how you can export a Microsoft SQL Server database to Amazon S3. The source database can be hosted on premises or on Amazon Elastic Compute Cloud (Amazon EC2) or Amazon Relational Database Service (Amazon RDS) for Microsoft SQL Server on the Amazon Web Services (AWS) Cloud.

The data is exported by using AWS Database Migration Service (AWS DMS). By default, AWS DMS writes full load and change data capture (CDC) data in comma-separated value (.csv) format. For more compact storage and faster query options, this pattern uses the Apache Parquet (.parquet) format option.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Identity and Access Management (IAM) role for the account with write, delete, and tag access to the target S3 bucket, and AWS DMS (`dms.amazonaws.com`) added as a trusted entity to this IAM role
- An on-premises Microsoft SQL Server database (or Microsoft SQL Server on an EC2 instance or an Amazon RDS for SQL Server database)
- Network connectivity between the virtual private cloud (VPC) on AWS and the on-premises network provided by AWS Direct Connect or a virtual private network (VPN)

Limitations

- A VPC-enabled (gateway VPC) S3 bucket isn't currently supported in AWS DMS versions earlier than 3.4.7.
- Changes to the source table structure during full load are not supported.
- AWS DMS full large binary object (LOB) mode is not supported.

Product versions

- Microsoft SQL Server versions 2005 or later for the Enterprise, Standard, Workgroup, and Developer editions.
- Support for Microsoft SQL Server version 2019 as a source is available in AWS DMS versions 3.3.2 and later.

Architecture

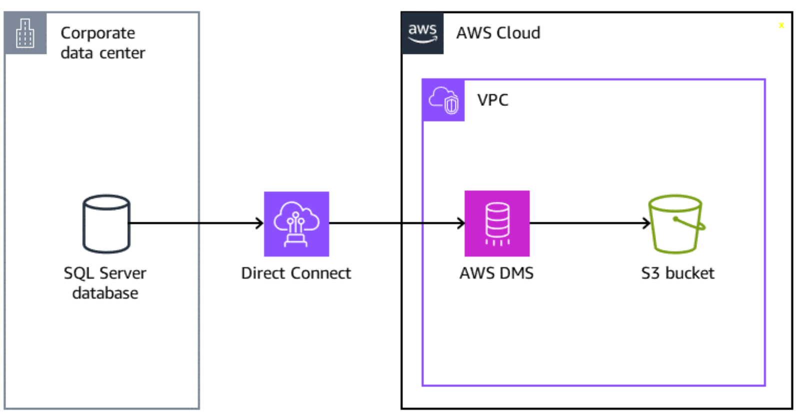
Source technology stack

- An on-premises Microsoft SQL Server database (or Microsoft SQL Server on an EC2 instance or an Amazon RDS for SQL Server database)

Target technology stack

- AWS Direct Connect
- AWS DMS
- Amazon S3

Target architecture



Tools

- [AWS Database Migration Service (AWS DMS)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

- AWS Direct Connect links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Epics

Prepare for the migration

Task	Description	Skills required
Validate the database version.	Validate the source database version and make sure that it’s supported by AWS DMS. For information about supported SQL Server database versions, see Using a Microsoft SQL Server database as a source for AWS DMS.	DBA
Create a VPC and security group.	In your AWS account, create a VPC and security group. For more information, see the Amazon VPC documentation.	System Administrator
Create a user for the AWS DMS task.	Create an AWS DMS user in the source database and grant it READ permissions. This user will be used by AWS DMS.	DBA
Test the DB connectivity.	Test the connectivity to the SQL Server DB instance from the AWS DMS user.	DBA

Task	Description	Skills required
Create an S3 bucket.	Create the target S3 bucket. This bucket will hold the migrated table data.	Systems administrator
Create an IAM policy and role.	1. To create an IAM policy with bucket permissio ns, use the code in the *Additional information* section. 2. Create the role for AWS DMS, and attach the policy to the role.	Systems administrator

Migrate data by using AWS DMS

Task	Description	Skills required
Create an AWS DMS replicati on instance.	Sign in to the AWS Management Console, and open the AWS DMS console. In the navigation pane, choose **Replication instances** , **Create replication instance**. For instructions, see step 1 in the AWS DMS documentation.	DBA
Create source and target endpoints.	Create source and target endpoints. Test the connectio n from the replication instance to both source and target endpoints. For instructi ons, see step 2 in the AWS DMS documentation.	DBA

Task	Description	Skills required
Create a replication task.	Create a replication task, and select full load or full load with change data capture (CDC) to migrate data from SQL Server to the S3 bucket. For instructions, see step 3 in the AWS DMS documentation.	DBA
Start the data replication.	Start the replication task, and monitor the logs for any errors.	DBA

Validate the data

Task	Description	Skills required
Validate the migrated data.	On the console, navigate to your target S3 bucket. Open the subfolder that has the same name as the source database. Confirm that the folder contains all the tables that were migrated from the source database.	DBA

Clean up resources

Task	Description	Skills required
Shut down and delete temporary AWS resources.	Shut down temporary AWS resources that you created for the data migration, such as the AWS DMS replication	DBA

Task	Description	Skills required
	instance, and delete them after you validate the export.

- Using Amazon S3 as a target for AWS Database Migration Service
- Using an S3 bucket as an AWS DMS target (AWS re:Post)

Additional information

Use the following code to add an IAM policy with S3 bucket permissions for the AWS DMS role. Replace `bucketname` with the name of your bucket.

```
{
     "Version": "2012-10-17",
     "Statement": [
         {
             "Effect": "Allow",
             "Action": [
                 "s3:PutObject",
                 "s3:DeleteObject"
             ],
             "Resource": [
                 "arn:aws:s3:::bucketname*"
             ]
         },
         {
             "Effect": "Allow",
             "Action": [
                 "s3:ListBucket"
             ],
             "Resource": [
                 "arn:aws:s3:::bucketname*"
             ]
         }
     ]
```

```
}
```

Migrate OpenText TeamSite workloads to the AWS Cloud

Battulga Purevragchaa, Amazon Web Services

Michael Stewart and Carlos Marruenda Molina, None

Summary

> Warning: This scenario requires IAM users with programmatic access and long-term credentia ls, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed. Access keys can be updated if necessary. For more information, see Updating access keys in the *IAM user guide*.

Many OpenText Experience Platform instances are hosted on premises or on traditional hosting solutions with fixed capacity and legacy cost models. Migrating your OpenText Experience Platform workloads to the Amazon Web Services (AWS) Cloud provides additional capabilities and value by increasing your business agility and integration opportunities, in addition to reducing your overall ownership cost.

This pattern provides steps and a template to migrate OpenText TeamSite workloads to the AWS Cloud. The pattern helps you understand how to scope and budget your migration projects by providing a detailed *Epics* section that guides you through an OpenText TeamSite migration process.

This pattern was developed by AWS and TBSCG, an AWS Partner, and accompanies the guide Migrating OpenText TeamSite and Media Management workloads to the AWS Cloud on the AWS Prescriptive Guidance website.

Prerequisites and limitations

Prerequisites

- At least one active AWS account
- An OpenText workload hosted in an on-premises data center or on another cloud provider
- Active OpenText licenses

The migration process also requires the roles and responsibilities that are described in the following table.

Role	Responsibilities
Sponsor	Internal sponsorship
Delivery manager	Migration delivery
Solutions architect	Define the current and new architecture
DevOps engineer	DevOps activities
QA tester	System-level testing
Product owner	Task prioritization based on business requirements
TeamSite authors	Migration user acceptance testing (UAT)
TeamSite administrator	Migration UAT
OpenText lead	OpenText product specialist
OpenText developer	OpenText product specialist
Pricing specialist	AWS and OpenText licensing
IT security	IT security baseline
Third-party integration developer	Rework existing integrations
Front-end developer	Make changes to migrated front-end code
Database administrator	Database configuration

Limitations

- Ensure compatibility with your target operating systems (OSs). You can use the compatibility matrix from the product release notes of the OpenText product version that you are migrating.

Architecture

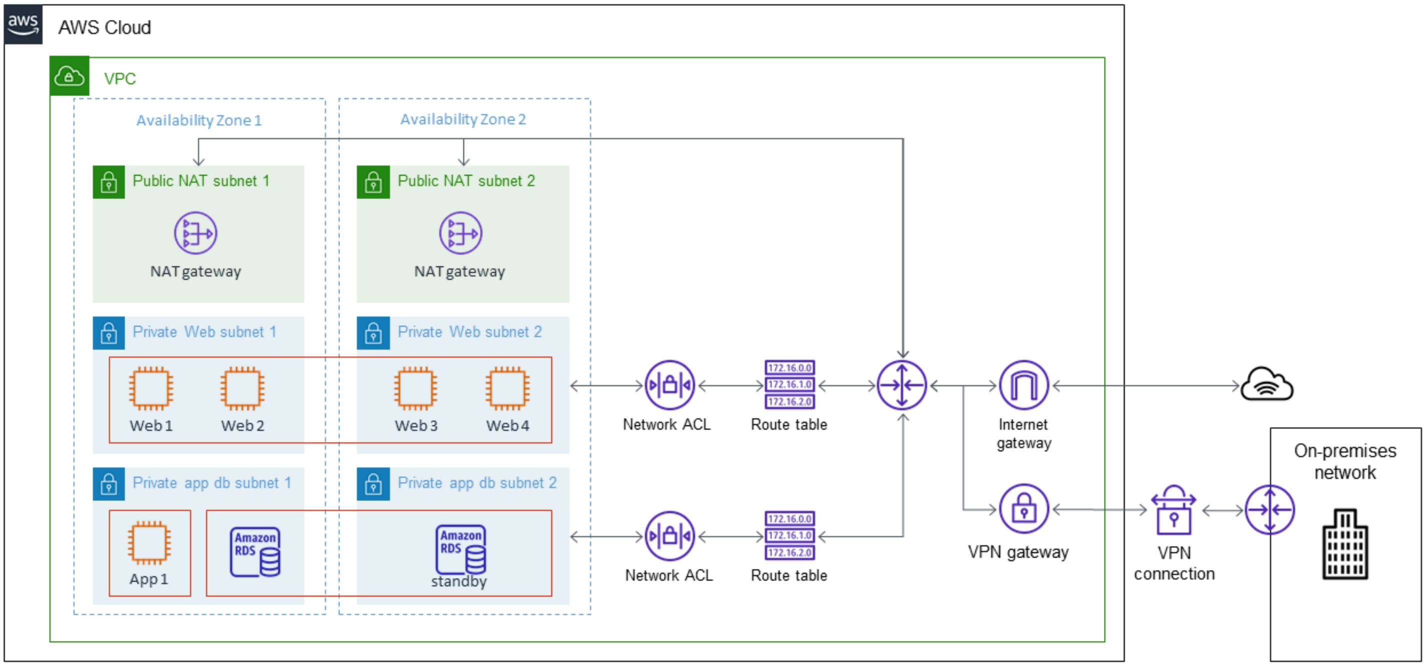
Source technology stack

- OpenText customer experience solutions hosted on premises or on another cloud provider:
  - OpenText TeamSite
  - OpenText LiveSite
  - OpenText Media Management
  - OpenText MediaBin

Target technology stack

- An OpenText Customer Experience platform hosted on the AWS Cloud and that uses the following AWS services:
  - Amazon Elastic Compute Cloud (Amazon EC2)
  - Amazon Elastic Container Service (Amazon ECS)
  - Amazon OpenSearch Service
  - Elastic Load Balancing
  - AWS Lambda
  - Amazon API Gateway
  - Amazon Relational Database Service (Amazon RDS)
  - Amazon Elastic Block Store (Amazon EBS)
  - Amazon Simple Storage Service (Amazon S3)

Target architecture



Tools

- [AWS Database Migration Service (AWS DMS)](https://docs.aws.amazon.com/dms/) is a cloud service that makes it easy to migrate relational databases, data warehouses, NoSQL databases, and other types of data stores.
- [AWS Application Migration Service](https://docs.aws.amazon.com/mgn/) automates the conversion of your source servers to run natively on AWS. It also simplifies application modernization with built-in and custom optimization options.

Epics

Discovery and assessment

Task	Description	Skills required
Hold workshops on discovery requirements.	Hold workshops with business and technical teams to discover the current landscape, gather requirements, and validate the migration strategy.	Sponsor (optional), Delivery manager, Solutions architect , OpenText lead, Product owner

Task	Description	Skills required
	Depending on your migration's complexity and scope, your organization might require several workshops. **Duration**: Two weeks	
Analyze solution and migration requirements.	Analyze and document the business, functional, and technical requirements that influence the design of the planned solution and migration process. **Duration**: One week	Solutions architect, OpenText lead, Product owner
Document your existing OpenText architecture.	Document your existing OpenText architecture, including core components and all related applications and services. **Duration**: One week	Solutions architect, OpenText lead, Product owner
Define the planned AWS architecture.	Define your planned AWS architecture based on the identified components, requirements, and using the OpenText compatibility matrix. You can find the OpenText compatibility matrix in the release notes of your OpenText TeamSite version. **Duration**: One week	Solutions architect, OpenText lead, Product owner, IT security

Task	Description	Skills required
Assess the size of your planned AWS architecture.	Size requirements vary for different architectural components depending on the workload and other non-functional requirements. **Duration**: Two days	Solutions architect, OpenText lead
Calculate the TCO.	Calculate the total cost of ownership (TCO) for your proposed solution. **Duration**: Two days	Solutions architect, Pricing specialist
Define the migration strategy for each component.	Define and document which of the seven common migration strategies (7 Rs) to use for each core or additiona l component that must be migrated to the AWS Cloud. **Duration**: One week	Solutions architect, OpenText lead, Product owner
Define the migration process for the components.	Define the detailed migration process for each of your workload's components. **Duration**: One week	Solutions architect, OpenText lead, Product owner, IT security
Define the global migration process and dependencies.	Create a global migration process and calendar that includes the migration details for components, dependenc ies, and business continuity. **Duration**: Three days	Solutions architect, OpenText lead, Product owner, IT security

Security and compliance activities

Task	Description	Skills required
Create security policies.	Configure the customer managed security policies in your AWS accounts. These should include password complexity and rotation, in addition to automatically turning off unused accounts. For more information about customer managed policies, see Customer managed policies in the AWS Identity and Access Management (IAM) documentation.	Solutions architect
Create IAM users.	Create the IAM users that require access to the AWS Management Console, AWS Command Line Interface (AWS CLI), and AWS SDK. For more information about creating IAM users, see Creating an IAM user in your AWS account in the IAM documentation.	Solutions architect
Create IAM groups.	Create the required IAM user groups (for example, administrator or developer groups) and add IAM users to those groups.	Solutions architect

Task	Description	Skills required
	For more information about IAM user groups, see IAM user groups in the IAM documenta tion.	
Attach security policies.	Attach security policies to the IAM groups or roles. For more information about this, see Attaching a policy to an IAM user group in the IAM documentation.	Solutions architect
Turn on detailed billing.	For more information about billing, see Monitoring your usage and costs in the AWS Billing and Cost Management documentation.	Solutions architect
Check the contact details for your accounts.	Make sure that the contact details for your accounts are up to date and map to more than one individual in your organization. For more information, see Managing an AWS account in the AWS Billing and Cost Management documentation.	Solutions architect, Product owner

Task	Description	Skills required
Add security contact information.	Configure your contact information with your security contact information. For more information about this, see Managing an AWS account in the AWS Billing and Cost Management documentation.	Solutions architect, IT security
Set up IAM roles for EC2 instances.	Configure the IAM roles for the EC2 instances. For more information about this, see IAM roles for Amazon EC2 in the Amazon EC2 documentation.	Solutions architect
Configure access to AWS Support.	Attach an IAM policy to IAM users that require access to AWS Support for Support Center and to create support cases. For more information about this, see Access permissions for AWS Support in the AWS Support documentation.	Solutions architect

Task	Description	Skills required
Enable CloudTrail.	Automatically enable AWS CloudTrail in all your AWS Regions. For more information about this, see Using `create-trail` in the AWS CloudTrail documentation.	Solutions architect
Enable CloudTrail log file validation.	Enable the validation of CloudTrail log files. For more information about this, see Enabling log file integrity validation for CloudTrail in the AWS CloudTrail documentation.	Solutions architect
Restrict access to any S3 buckets that contain CloudTrail logs.	Apply a bucket policy restricting access to S3 buckets that contain CloudTrail log files. For more information about this, see Amazon S3 bucket policy for CloudTrail in the AWS CloudTrail documentation.	Solutions architect
Integrate CloudTrail with CloudWatch Logs	Integrate trails generated by CloudTrail with Amazon CloudWatch Logs. For more information about this, see Sending events to CloudWatch Logs in the AWS CloudTrail documentation	Solutions architect

Task	Description	Skills required
Enable AWS Config in all required Regions.	Automatically enable AWS Config in all required Regions. You can set up AWS Config by using AWS CLI. For more information, see Setting Up AWS Config with the AWS CLI in the AWS Config documenta tion.	Solutions architect
Enable logging of S3 bucket access.	Automate S3 bucket access logging with CloudTrail. For more information about this, see Enabling CloudTrail event logging for S3 buckets and objects in the Amazon S3 documentation.	Solutions architect
Configure AWS KMS key policies for CloudTrail.	Automate the configuration of AWS Key Managemen t Service (AWS KMS) key policies for CloudTrail. For more information about this, see Configure AWS KMS key policies for CloudTrai l in the AWS CloudTrail documentation.	Solutions architect

Task	Description	Skills required
Encrypt CloudTrail logs at rest.	Configure server-side encryption of CloudTrail logs using customer managed keys held in AWS KMS. For more information about this, see Encrypting CloudTrail log files with AWS KMS managed keys (SSE-KMS) in the AWS CloudTrail documentation.	Solutions architect
Automatically rotate KMS keys.	Configure the rotation of AWS KMS keys. For more information about this, see How to enable and disable automatic key rotation in the AWS KMS documentation.	Solutions architect
Configure CloudWatch alarms.	Configure the Amazon CloudWatch alarms that are initiated by specific events. For example, unauthorized requests to APIs or use of the root account. For more information about this, see How to receive notifications when your AWS account’s root access keys are used from the AWS Security Blog.	Solutions architect

Task	Description	Skills required
Configure security groups.	Configure security groups to ensure that unrestricted inbound traffic is not allowed on ports 22 and 3389.	Solutions architect
Turn on VPC flow logging.	Capture rejected IP traffic to and from network interface s in your virtual private cloud (VPC) and configure CloudWatch to capture it. For more information about this, see Creating a flow log in the Amazon VPC documenta tion.	Solutions architect
Modify the default security group to restrict all traffic.	Modify each VPC's default security group so that traffic is denied by default and access is explicitly granted through your security groups. For more information about this, see Security groups for your VPC in the Amazon VPC documentation.	Solutions architect
Configure routing tables between the VPCs.	Configure the routing tables for VPC peering with the least access necessary. For more information about this, see Updating your route tables for a VPC peering connection in the Amazon VPC documentation.	Solutions architect

Setup activities for the new AWS infrastructure

Task	Description	Skills required
Provision the AWS infrastru cture.	Create the AWS accounts and resources. **Duration**: Two weeks	DevOps engineer, Solutions architect
Set up DevOps tools and processes.	Set up DevOps tools and procedures, such as continuou s integration and continuous delivery (CI/CD) pipelines and automated testing framework s.	DevOps engineer, Solutions architect
Automate the migration of core components.	Use existing templates or scripts to automate the installation and configura tion of OpenText products including TeamSite, LiveSite, OpenDeploy and MediaBin. **Duration**: One week	DevOps engineer, Solutions architect, OpenText lead
Automate the migration of additional components.	Analyze and automate the migration of additiona l applications that are integrated with OpenText core components (for example, additional databases, communica tion, monitoring, or cache components). **Duration**: Two weeks	DevOps engineer, Solutions architect, OpenText lead
Adapt core components.	Make any required changes to customizations of OpenText	Solutions architect, OpenText lead, OpenText developer

Task	Description	Skills required
	core components (for example, integrations).	, Third-party integration developer, Front-end developer
Implement and configure additional services.	Provision, configure, and implement any new AWS services, such as AWS Lambda functions or Amazon API Gateway.	DevOps engineer, Solutions architect, Third-party integration developer, Front-end developer
Migrate or refactor other components.	Migrate additional components, including any required refactoring. This includes external applications such as custom-made reporting portals or existing API integration layers.	DevOps engineer, Solutions architect, Third-party integration developer, Front-end developer
Carry out migration in development environment.	Automated migration activities for the development environment, including system provisioning, data migration, application migration, installation, and configuration.	DevOps engineer
Carry out migration in production environment.	Automated migration activities for the production environment, including system provisioning, data migration, application migration, installation, and configuration.	DevOps engineer

Networking activities

Task	Description	Skills required
Define CIDR blocks for each VPC.	Define the Classless Inter-Domain Routing (CIDR) block (the IP range and mask) for each non-default VPC. **Duration**: Less than one week	DevOps engineer, Solutions architect
Define subnets and Availability Zones.	Define the subnets and Availability Zones that are used in each non-default VPC. **Duration**: Less than one week	DevOps engineer, Solutions architect
Define security groups.	Define security groups and security group rules for controlling security on AWS resources. **Duration**: Less than one week	DevOps engineer, Solutions architect
Define network ACLs.	Define the network access control lists (ACLs) to control security at subnet boundaries. **Duration**: Less than one week	DevOps engineer, Solutions architect

Migrate databases

Task	Description	Skills required
Prepare the source databases.	Use AWS DMS to prepare each source database for ongoing replication to the AWS Cloud.	DevOps engineer, Solutions architect

Task	Description	Skills required
Create the databases for the OpenText core components.	Create the databases required by the Opentext TeamSite, LiveSite, and MediaBin components. Make sure that users and access rights are correctly configured according to the OpenText installation documentation.	Solutions architect, OpenText lead, OpenText developer
Copy data from source database servers.	Automate the process of copying data for OpenText core components from the source database server to the target database server.	Solutions architect, OpenText lead, OpenText developer
Synchronize data from the database servers.	Automate the process of performing regular data synchronization from the source databases to the target databases.	OpenText developer

Content migration activities

Task	Description	Skills required
Copy the OpenText TeamSite content stores.	Automate the process of copying the content stores from the source OpenText TeamSite server to the target OpenText TeamSite server.	Solutions architect, OpenText lead, OpenText developer
Map users and groups.	Internal mapping of internal OpenText TeamSite user IDs to target system IDs.	OpenText lead

Task	Description	Skills required
Synchronize the OpenText TeamSite content stores.	Automate the process of performing regular synchroni zing of source and target content stores. This is implemented as part of the migration and QA process.	OpenText developer
Copy data from web servers.	Automate the process of copying data from the source web servers to the target web servers.	Solutions architect, OpenText lead, OpenText developer
Synchronize the web server data.	Automate the process of performing regular synchroni zing of source and target web server data.	OpenText developer
Copy data from web server file system.	Automate the process of copying content and other web assets from the source web server file system to the target web servers.	Solutions architect, OpenText lead, OpenText developer
Synchronize the web server file systems.	Automate the process of performing regular synchroni zing of content and other web assets from the source web server file system to the target web servers.	OpenText developer

Task	Description	Skills required
Generate feeds and indexes.	Automate the process of running any processes that generate feeds or other indexes (for example, web search) that uses OpenText TeamSite or web server content as a data source.	Solutions architect, OpenText lead, OpenText developer
Synchronize the generation of feeds and indexes.	Automate the process of performing regular regenerat ion of feeds and indexes after data synchronizations.	OpenText developer

Testing and QA activities

Task	Description	Skills required
Perform migration QA.	Test the target AWS environment, applicati ons, and services to ensure the automated migration processes are correctly built and configured.	DevOps engineer, OpenText lead, QA tester
Carry out performance testing.	Test the performance in terms of responsiveness and stability under a particula r workload. Investigate, measure, validate, or verify other quality attributes of the destination system, such as scalability and reliability. For this test to be useful, you must have a testing	DevOps engineer, OpenText lead

Task	Description	Skills required
	environment that is the same size as your production environment. **Duration**: Between one and two weeks	
Security testing.	Vulnerability scanning and penetration testing to reveal potential flaws in the security mechanisms of an applicati on that protect data and maintain functionality as required. For this test to be useful, you must have a testing environment that is equivalen t to your production environment in terms of networking and security. **Duration**: Between one and two weeks	DevOps engineer, OpenText lead

Operational integration activities

Task	Description	Skills required
Check operational readiness.	Understand how you currently perform IT operations and how you will operate in the AWS Cloud. You can achieve this business outcome by defining a cloud operating model.	DevOps engineer, OpenText lead, Service delivery manager

Task	Description	Skills required
	Duration: One week	
Invest in operations automation.	Invest in automation to deliver an AWS operating model.	DevOps engineer, OpenText lead, Service delivery manager
Integrate operations.	Continue using current IT tools and extend them through integration to the AWS Cloud.	DevOps engineer, OpenText lead, Service delivery manager

Cutover activities

Task	Description	Skills required
Switch DNS.	Manually switch the domain name system (DNS) from existing hosts to hosts based in the AWS Cloud. **Duration**: One hour	DevOps engineer, OpenText lead
Test disaster recovery.	Test disaster recovery, backup restore, and run your automated tests. **Duration**: One day	DevOps engineer, OpenText lead, QA tester
Validate monitoring and analytics.	Validate that the monitoring and analytics are working. **Duration**: Two hours	DevOps engineer, OpenText lead
Turn off old environment and request the server’s shutdown.	**Duration**: Three days	DevOps engineer, OpenText lead

Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS

Sai Krishna Namburu and Sindhusha Paturu, Amazon Web Services

Summary

This pattern describes how to split Oracle character large object (CLOB) values into individual rows in Amazon Aurora PostgreSQL-Compatible Edition and Amazon Relational Database Service (Amazon RDS) for PostgreSQL. PostgreSQL doesn't support the CLOB data type.

Tables with interval partitions are identified in the source Oracle database, and the table name, the type of partition, the interval of the partition, and other metadata are captured and loaded into the target database. You can load CLOB data that is less than 1 GB in size into target tables as text by using AWS Database Migration Service (AWS DMS), or you can export the data in CSV format, load it into an Amazon Simple Storage Service (Amazon S3) bucket, and migrate it to your target PostgreSQL database.

After migration, you can use the custom PostgreSQL code that is provided with this pattern to split the CLOB data into individual rows based on the new line character identifier (`CHR(10)`) and populate the target table.

Prerequisites and limitations

Prerequisites

- An Oracle database table that has interval partitions and records with a CLOB data type.
- An Aurora PostgreSQL-Compatible or Amazon RDS for PostgreSQL database that has a table structure that's similar to the source table (same columns and data types).

Limitations

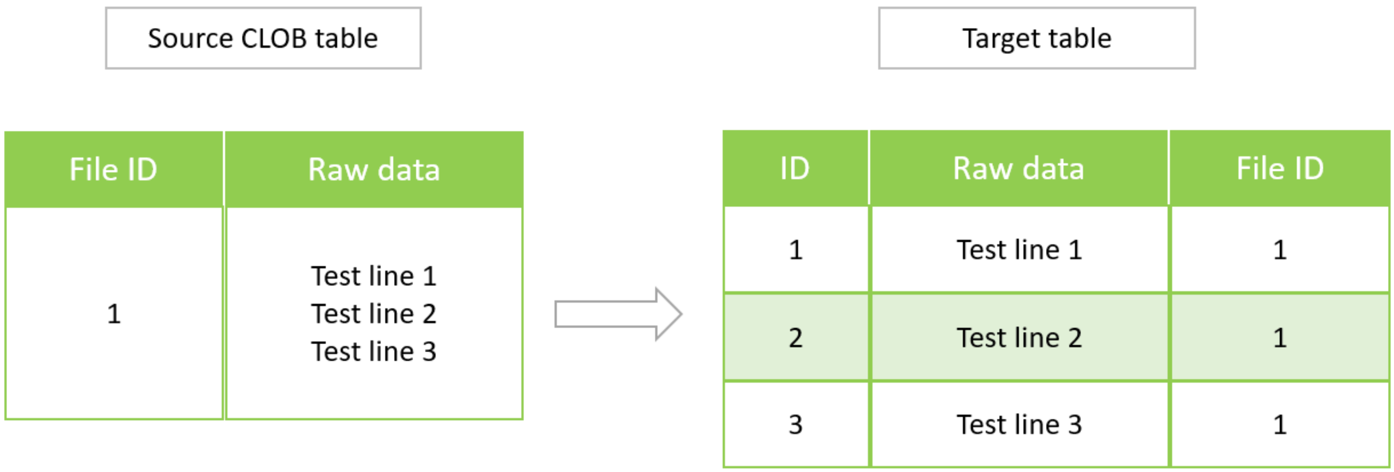
- The CLOB value cannot exceed 1 GB.
- Each row in the target table must have a new line character identifier.

Product versions

- Oracle 12c
- Aurora Postgres 11.6

Architecture

The following diagram shows a source Oracle table with CLOB data, and the equivalent PostgreSQL table in Aurora PostgreSQL-Compatible version 11.6.



Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

You can use the following client tools to connect to, access, and manage your Aurora PostgreSQL-Compatible and Amazon RDS for PostgreSQL databases. (These tools aren't used within this pattern.)

- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

- DBeaver is an open-source database tool for developers and database administrators. You can use the tool to manipulate, monitor, analyze, administer, and migrate your data.

Best practices

For best practices for migrating your database from Oracle to PostgreSQL, see the AWS blog post Best practices for migrating an Oracle database to Amazon RDS PostgreSQL or Amazon Aurora PostgreSQL: Migration process and infrastructure considerations.

For best practices for configuring the AWS DMS task for migrating large binary objects, see Migrating large binary objects (LOBs) in the AWS DMS documentation.

Epics

Identify the CLOB data

Task	Description	Skills required
Analyze the CLOB data.	In the source Oracle database, analyze the CLOB data to see whether it contains column headers, so you can determine the method for loading the data into the target table. To analyze the input data, use the following query. `SELECT * FROM clobdata_or;`	Developer
Load the CLOB data to the target database.	Migrate the table that has CLOB data to an interim (staging) table in the Aurora or Amazon RDS target database. You can use AWS DMS or upload the data as	Migration engineer, DBA

Task	Description	Skills required
	a CSV file to an Amazon S3 bucket. For information about using AWS DMS for this task, see [Using an Oracle database as a source]() and [Using a PostgreSQL database as a target]() in the AWS DMS documentation. For information about using Amazon S3 for this task, see [Using Amazon S3 as a target]() in the AWS DMS documentation.	

Validate the target PostgreSQL table.	Validate the target data, including headers, against the source data by using the following queries in the target database.
	
	`SELECT * FROM clobdata_pg;`
	`SELECT * FROM clobdatatarget;`
	
	Compare the results against the query results from the source database (from the first step).
		Developer

Task	Description	Skills required
Split the CLOB data into separate rows.	Run the custom PostgreSQL code provided in the Additional information section to split the CLOB data and insert it into separate rows in the target PostgreSQL table.	Developer

Validate the data.

Task	Description	Skills required

Validate the data in the target table.	Validate the data inserted into the target table by using the following queries.
	`SELECT * FROM clobdata_pg;`
	`SELECT * FROM clobdatatarget;`
		Developer

- CLOB data type (Oracle documentation)
- Data types (PostgreSQL documentation)

Additional information

PostgreSQL function for splitting CLOB data

```
do
$$
declare
totalstr varchar;
```

```
str1 varchar;
str2 varchar;
pos1 integer := 1;
pos2 integer ;
len integer;

begin
        select rawdata||chr(10) into totalstr from clobdata_pg;
        len :=  length(totalstr) ;
        raise notice 'Total length : %',len;
        raise notice 'totalstr : %',totalstr;
        raise notice 'Before while loop';

        while pos1 < len  loop

                  select position (chr(10) in totalstr) into pos2;
                 raise notice '1st position of new line : %',pos2;

                str1 := substring (totalstr,pos1,pos2-1);
                raise notice 'str1 : %',str1;

                   insert into clobdatatarget(data) values (str1);
                   totalstr := substring(totalstr,pos2+1,len);
                   raise notice 'new totalstr :%',totalstr;
                len :=  length(totalstr) ;

        end loop;
end
$$
LANGUAGE 'plpgsql' ;
```

Input and output examples

You can use the following examples to try out the PostgreSQL code before you migrate your data.

Create an Oracle database with three input lines.

```
CREATE TABLE clobdata_or (
```

```
id INTEGER GENERATED ALWAYS AS IDENTITY,
rawdata clob  );

insert into clobdata_or(rawdata) values (to_clob('test line 1') || chr(10) ||
 to_clob('test line 2') || chr(10) || to_clob('test line 3') || chr(10));
COMMIT;

SELECT * FROM clobdata_or;
```

This displays the following output.

id	rawdata
1	test line 1 test line 2 test line 3

Load the source data into a PostgreSQL staging table (`clobdata_pg`) for processing.

```
SELECT * FROM clobdata_pg;

CREATE TEMP TABLE clobdatatarget (id1 SERIAL,data VARCHAR );

<Run the code in the additional information section.>

SELECT * FROM clobdatatarget;
```

This displays the following output.

id1	data
1	test line 1
2	test line 2
3	test line 3

Migrate an on-premises Oracle database to Amazon RDS for Oracle by using direct Oracle Data Pump Import over a database link

Rizwan Wangde, Amazon Web Services

Summary

Numerous patterns cover migrating on-premises Oracle databases to Amazon Relational Database Service (Amazon RDS) for Oracle by using Oracle Data Pump, a native Oracle utility that is the preferred way to migrate large Oracle workloads. These patterns typically involve exporting application schemas or tables into dump files, transferring the dump files to a database directory on Amazon RDS for Oracle, and then importing the application schemas and data from the dump files.

Using that approach, a migration can take longer depending on the size of the data and the time that it takes to transfer the dump files to the Amazon RDS instance. In addition, the dump files reside on the Amazon RDS instance's Amazon Elastic Block Store (Amazon EBS) volume, which must be large enough for the database and the dump files. When the dump files are deleted after import, the empty space cannot be retrieved, so you continue to pay for unused space.

This pattern mitigates those issues by performing a direct import on the Amazon RDS instance by using the Oracle Data Pump API (`DBMS_DATAPUMP`) over a database link. The pattern initiates a simultaneous export and import pipeline between the source and target databases. This pattern doesn't require sizing an EBS volume for the dump files because no dump files are created or stored on the volume. This approach saves the monthly cost of unused disk space.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
- A virtual private cloud (VPC) configured with private subnets across at least two Availability Zones, to provide the network infrastructure for the Amazon RDS instance.
- An Oracle database in an on-premises data center, or self-managed on Amazon Elastic Compute Cloud (Amazon EC2).
- An existing Amazon RDS for Oracle instance in a single Availability Zone. Using a single Availability Zone improves write performance during migration. A Multi-AZ deployment can be enabled 24–48 hours before cutover.

This solution can also use Amazon RDS Custom for Oracle as a target.

- AWS Direct Connect (recommended for large sized databases).
- Network connectivity and firewall rules on premises configured to allow an inbound connection from the Amazon RDS instance to the on-premises Oracle database.

Limitations

- The database size limit on Amazon RDS for Oracle is 64 tebibytes (TiB) as of December 2022.
- The maximum size of a single file on an Amazon RDS for Oracle DB instances is 16 TiB. This is important to know because you might need to spread tables across multiple tablespaces.

Product versions

- Source database: Oracle Database version 10g Release 1 and later.
- Target database: For the latest list of supported versions and editions on Amazon RDS, see Amazon RDS for Oracle in the AWS documentation.

Architecture

Source technology stack

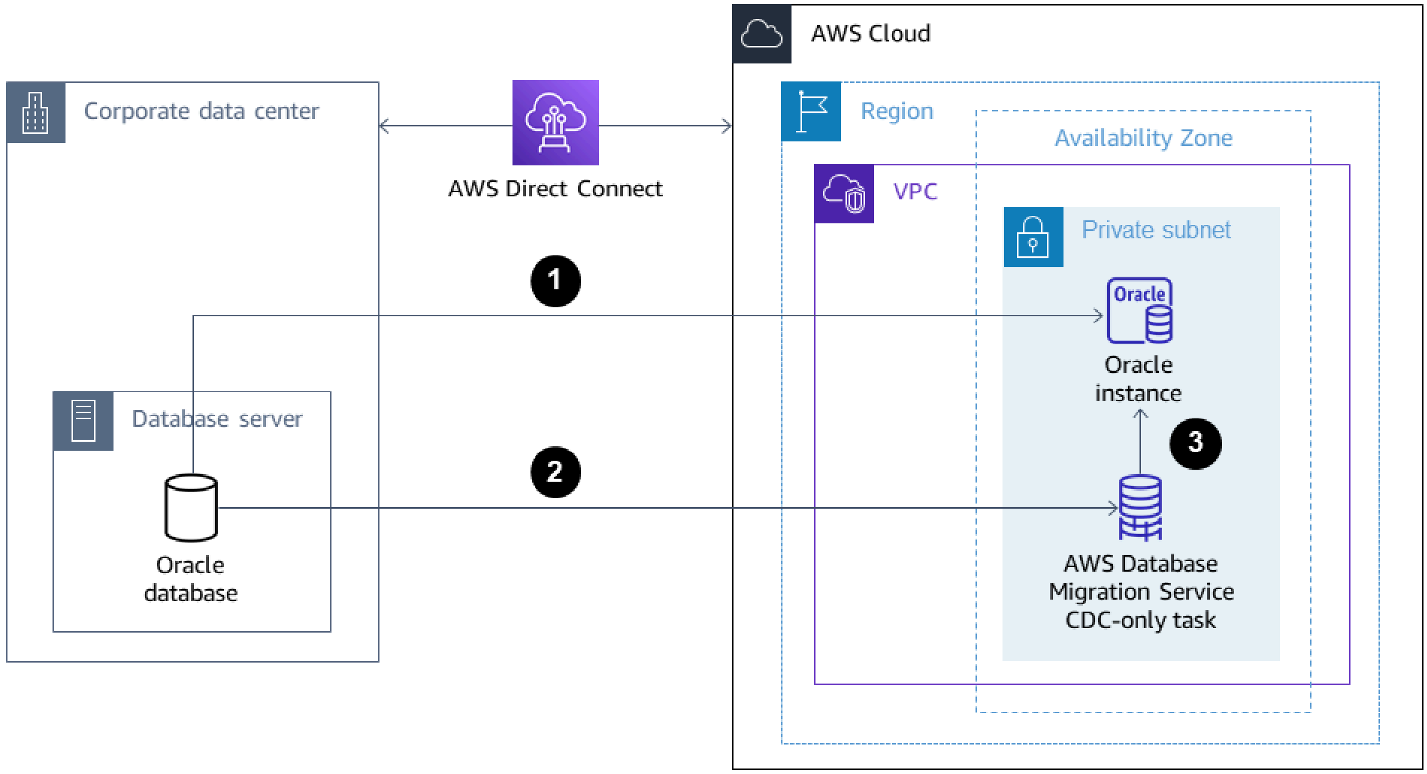
- Self-managed Oracle database on premises or in the cloud

Target technology stack

- Amazon RDS for Oracle or Amazon RDS Custom for Oracle

Target architecture

The following diagram shows the architecture for migrating from an on-premises Oracle database to Amazon RDS for Oracle in a Single-AZ environment. The arrow directions depict the data flow in the architecture. The diagram doesn't show what component is initiating the connection.



1. The Amazon RDS for Oracle instance connects to the on-premises source Oracle database to perform a full-load migration over the database link.
2. AWS Database Migration Service (AWS DMS) connects to the on-premises source Oracle database to perform ongoing replication by using change data capture (CDC).
3. CDC changes are applied to the Amazon RDS for Oracle database.

Tools

AWS services

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups. This pattern uses CDC and the **Replicate data changes only** setting.
- AWS Direct Connect links your internal network to a AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- Amazon Relational Database Service helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.

Other tools

- Oracle Data Pump helps you move data and metadata from one database to another at high speeds.
- Client tools such as Oracle Instant Client or SQL Developer are used to connect and run SQL queries on the database.

Best practices

Although AWS Direct Connect uses dedicated, private network connections between the on-premises network and AWS, consider the following options for additional security and data encryption for data in transit:

- A virtual private network (VPN) using AWS Site-to-Site VPN or an IPsec VPN connection from the on-premises network to the AWS network
- Oracle Database Native Network Encryption configured on the on-premises Oracle database
- Encryption using TLS

Epics

Prepare the on-premises source Oracle database

Task	Description	Skills required
Set up network connectivity from the target database to the source database.	Configure the on-premises network and firewall to allow incoming connection from the target Amazon RDS instance to the on-premises source Oracle database.	Network administrator, Security engineer
Create a database user with the appropriate privileges.	Create a database user in the on-premises source Oracle database with privileges to migrate data between the source and target using Oracle Data Pump:	DBA

Task	Description	Skills required
	```GRANT CONNECT to <migration_user>; GRANT DATAPUMP_EXP_FULL_DATABASE to <migration_user>; GRANT SELECT ANY TABLE to <migration_user>;```	

Task	Description	Skills required

Prepare the on-premises source database for AWS DMS CDC migration.	(Optional) Prepare the on-premises source Oracle database for AWS DMS CDC migration after completion of Oracle Data Pump Full Load:
	
	1. Configure the additional privileges required to manage FLASHBACK during Oracle Data Pump migration:
	`GRANT FLASHBACK ANY TABLE to <migration_user>;`
	`GRANT FLASHBACK ARCHIVE ADMINISTER to <migration_user>;`
	2. To configure user account privileges required on a self-managed Oracle source for AWS DMS, see the [AWS DMS documentation](#).
	3. To prepare an Oracle self-managed source database for CDC using AWS DMS, see the [AWS DMS documentation](#).
		DBA

Install and configure SQL Developer.	Install and configure [SQL Developer](#) to connect and run SQL queries on the source and target databases.	DBA, Migration engineer

Task	Description	Skills required
Generate a script to create the tablespaces.	Use the following example SQL query to generate the script on the source database: `SELECT 'CREATE TABLESPACE ' tablespace_name ' DATAFILE SIZE 1G AUTOEXTEND ON MAXSIZE UNLIMITED;' from dba_tablespaces where tablespace_name not in ('SYSTEM', 'SYSAUX','TEMP','UNDOTBS1') order by 1;` The script will be applied on the target database.	DBA
Generate a script to create users, profiles, roles, and privileges.	To generate a script to create the database users, profiles, roles, and privileges, use the scripts from the Oracle Support document [How to Extract DDL for User including Privileges and Roles Using dbms_metadata.get_ddl (Doc ID 2739952.1)]() (Oracle account required). The script will be applied on the target database.	DBA

Prepare the target Amazon RDS for Oracle instance

Task	Description	Skills required

Create a database link to the source database and verify connectivity.	To create a database link to the on-premises source database, you can use the following example command:
	`CREATE DATABASE LINK link2src CONNECT TO <migration_user_account> IDENTIFIED BY <password> USING '(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=<dns or ip address of remote db>) (PORT=<listener port>))(CONNECT_DATA=(SID=<remote SID>)))';`
	To verify connectivity, run the following SQL command:
	`select * from dual@link2src;`
	Connectivity is successful if the response is X.
		DBA

Run the scripts to prepare the target instance.	Run the previously generated scripts to prepare the target Amazon RDS for Oracle instance: 1. Tablespaces	DBA, Migration engineer

Task	Description	Skills required
	2. Profiles 3. Roles This helps ensure that the Oracle Data Pump migration can create the schemas and their objects.	

Perform a full-load migration by using Oracle Data Pump Import over a database link

Task	Description	Skills required
Migrate the required schemas.	To migrate the required schemas from the source on-premises database to the target Amazon RDS instance, use the code in the Additional information section: • To migrate a single schema, run *Code 1* from the Additional information section. • To migrate multiple schemas, run *Code 2* from the Additional information section. To tune the performance of the migration, you can adjust the number of parallel processes by running the following command:	DBA

Task	Description	Skills required
	`DBMS_DATAPUMP.SET_ PARALLEL (handle => v_hdnl, degree => 4);`	
Gather schema statistics to improve performance.	The Gather Schema Statistics command returns the Oracle query optimizer statistic s gathered for database objects. By using this information, the optimizer can select the best execution plan for any query against these objects: `EXECUTE DBMS_STAT S.GATHER_SCHEMA_ST ATS(ownname => '<schema_name>');`	DBA

Perform a full-load migration and CDC replication by using Oracle Data Pump and AWS DMS

Task	Description	Skills required
Capture the SCN on the source on-premises Oracle database.	Capture the system change number (SCN) on the source on-premises Oracle database. You will use the SCN for full-load import and as the starting point for CDC replication. To generate the current SCN on the source database, run the following SQL statement:	DBA

Task	Description	Skills required
	`SELECT current_scn FROM V$DATABASE;`	

Task	Description	Skills required
Perform the full-load migration of the schemas.	To migrate the required schemas (`FULL LOAD`) from the source on-premises database to the target Amazon RDS instance, do the following: • To migrate a single schema, run *Code 3* from the [Additional information](#) section. • To migrate multiple schemas, run *Code 4* from the [Additional information](#) section. In the code, replace `<CURRENT_SCN_VALUE_IN_SOURCE_DATABASE>` with the SCN that you captured from the source database: `DBMS_DATAPUMP.SET_PARAMETER (handle => v_hdnl, name => 'FLASHBACK_SCN', value => <CURRENT_SCN_VALUE_IN_SOURCE_DATABASE>);` To tune the performance of the migration, you can adjust the number of parallel processes:	DBA

Task	Description	Skills required
	`DBMS_DATAPUMP.SET_ PARALLEL (handle => v_hdnl, degree => 4);`	
Disable the triggers under the migrated schemas.	Before you begin the AWS DMS CDC-only task, disable the `TRIGGERS` under the migrated schemas.	DBA
Gather schema statistics to improve performance.	The Gather Schema Statistics command returns the Oracle query optimizer statistic s gathered for database objects: `EXECUTE DBMS_STAT S.GATHER_SCHEMA_ST ATS(ownname => '<schema_name>');` By using this information, the optimizer can select the best execution plan for any query against these objects.	DBA

Task	Description	Skills required
Use AWS DMS to perform an ongoing replication from the source to target.	Use AWS DMS to perform an ongoing replication from the source Oracle database to the target Amazon RDS for Oracle instance. For more information, see Creating tasks for ongoing replication using AWS DMS and the blog post How to work with native CDC support in AWS DMS.	DBA, Migration engineer

Cut over to Amazon RDS for Oracle

Task	Description	Skills required
Enable Multi-AZ on the instance 48 hours before cutover.	If this is a production instance, we recommend enabling Multi-AZ deploymen t on the Amazon RDS instance to provide the benefits of high availability (HA) and disaster recovery (DR).	DBA, Migration engineer
Stop the AWS DMS CDC-only task (if CDC was turned on).	1. Ensure the source latency and target latency on the AWS DMS task's Amazon CloudWatch metrics show 0 seconds. 2. Stop the AWS DMS CDC-only task.	DBA

Task	Description	Skills required
Enable the triggers.	Enable the TRIGGERS that you disabled before the CDC task was created.	DBA

    DBMS_DATAPUMP.SET_PARAMETER (handle => v_hdnl, name => 'FLASHBACK_SCN', value =>
 <CURRENT_SCN_VALUE_IN_SOURCE_DATABASE>); -- SCN required for AWS DMS CDC only task.
    DBMS_DATAPUMP.SET_PARALLEL (handle => v_hdnl, degree => 4);  -- Number of parallel
 processes performing export and import
    DBMS_DATAPUMP.START_JOB(v_hdnl);
END;
/
```

Scenario where a mixed migration approach can work better

In rare scenarios where the source database contains tables with millions of rows and very large-sized LOBSEGMENT columns, this pattern will slow down the migration. Oracle migrates LOBSEGMENTs over the network link one at a time. It extracts a single row (along with the LOB column data) from the source table, and inserts the row into the target table, repeating the process until all rows are migrated. Oracle Data Pump over the database link doesn't support bulk load or direct path load mechanisms for LOBSEGMENTs.

In this situation, we recommend the following:

- Skip the identified tables during the Oracle Data Pump migration by adding the following metadata filter:

```
dbms_datapump.metadata_filter(handle =>h1, name=>'NAME_EXPR', value => 'NOT IN
 (''TABLE_1'',''TABLE_2'')');
```

- Use an AWS DMS task (full-load migration, with CDC replication if required) to migrate the identified tables. AWS DMS will extract multiple rows from the source Oracle database, and insert them in a batch to the target Amazon RDS instance, which improves performance.

Migrate Oracle PeopleSoft to Amazon RDS Custom

Gaurav Gupta, Amazon Web Services

Summary

Oracle PeopleSoft is an enterprise resource planning (ERP) solution for enterprise-wide processes. PeopleSoft has a three-tier architecture: client, application, and database. PeopleSoft can be run on Amazon Relational Database Service (Amazon RDS). Now, you can also run PeopleSoft on Amazon RDS Custom, which provides access to the underlying operating system.

Amazon RDS Custom for Oracle is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. When you migrate your Oracle database to Amazon RDS Custom, Amazon Web Services (AWS) can manage backup tasks and high availability, while you can focus on maintaining your PeopleSoft application and functionality. For key factors to consider for a migration, see Oracle database migration strategies in AWS Prescriptive Guidance.

This pattern focuses on the steps to migrate a PeopleSoft database on Amazon Elastic Compute Cloud (Amazon EC2) to Amazon RDS Custom by using an Oracle Recovery Manager (RMAN) backup. It uses an Amazon Elastic File System (Amazon EFS) shared file system between the EC2 instance and Amazon RDS Custom, although you can also use Amazon FSx or any shared drive. The pattern uses an RMAN full backup (sometimes referred to as a level 0 backup).

Prerequisites and limitations

Prerequisites

- An Oracle version 19C source database that is running on Amazon EC2 with Oracle Linux 7, Oracle Linux 8, Red Hat Enterprise Linux (RHEL) 7, or RHEL 8. In the examples for this pattern, the source database name is `FSDM092`, but this isn't a requirement.

> **Note**
>
> You can also use this pattern with on-premises Oracle source databases. You must have the appropriate network connectivity between the on-premises network and a virtual private cloud (VPC).

- A PeopleSoft 9.2 demo instance.

- A single PeopleSoft application tier. However, you can adapt this pattern to work with multiple application tiers.
- Amazon RDS Custom configured with at least 8 GB of swap space.

Limitations

This pattern doesn't support the following configurations:

- Setting the database `ARCHIVE_LAG_TARGET` parameter to a value outside the 60–7200 range
- Disabling the DB instance log mode (`NOARCHIVELOG`)
- Turning off the Amazon Elastic Block Store (Amazon EBS) optimized attribute of the EC2 instance
- Modifying the original EBS volumes attached to the EC2 instance
- Adding new EBS volumes or changing the volume type from gp2 to gp3
- Changing the extension format for the `LOG_ARCHIVE_FORMAT` parameter (requires `*.arc`)
- Multiplexing or changing the control file location and name (it has to be `/rdsdbdata/db/*DBNAME*/controlfile/control-01.ctl`)

For additional information about these and other unsupported configurations, see the Amazon RDS documentation.

Product versions

For Oracle Database versions and instance classes supported by Amazon RDS Custom, see Requirements and limitations for Amazon RDS Custom for Oracle.

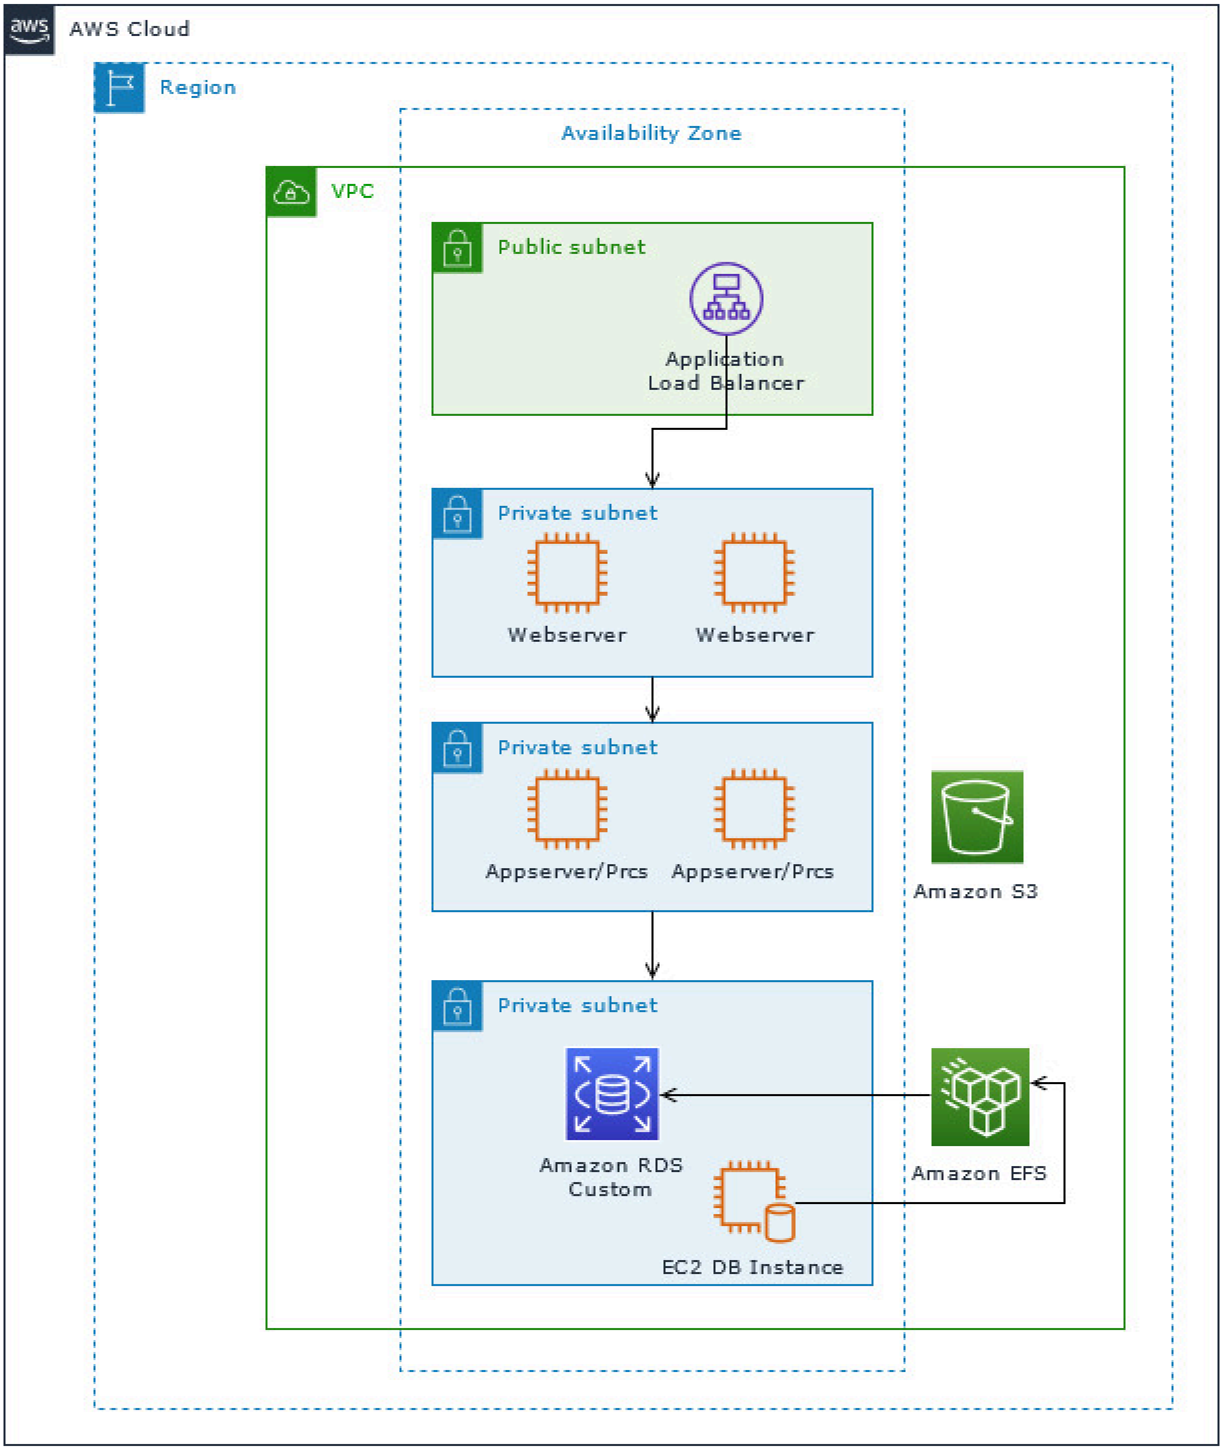
Architecture

Target technology stack

- Application Load Balancer
- Amazon EFS
- Amazon RDS Custom for Oracle
- AWS Secrets Manager
- Amazon Simple Storage Service (Amazon S3)

Target architecture

The following architecture diagram represents a PeopleSoft system running in a single Availability Zone on AWS. The application tier is accessed through an Application Load Balancer. Both the application and the databases are in private subnets, and the Amazon RDS Custom and Amazon EC2 database instance use an Amazon EFS shared file system to store and access the RMAN backup files. Amazon S3 is used for creating the custom RDS Oracle engine and for storing the redo logs metadata.



Tools

Tools

AWS services

- Amazon RDS Custom for Oracle is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks, such as backups and high availability.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud. This pattern uses an Amazon EFS shared file system to store and access the RMAN backup files.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager to create the `RDSADMIN` and `ADMIN` users and to change the `sys` and `system` passwords.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones. This pattern uses an Application Load Balancer.

Other tools

- Oracle Recovery Manager (RMAN) provides backup and recovery support for Oracle databases. This pattern uses RMAN to perform a hot backup of the source Oracle database on Amazon EC2 that is restored on Amazon RDS Custom.

Best practices

- For database initialization parameters, customize the standard pfile that's provided by the Amazon RDS Custom DB instance for PeopleSoft instead of using the spfile from the Oracle source database. This is because white spaces and comments cause issues when creating read replicas in Amazon RDS Custom. For more information about database initialization parameters, see Oracle Support Note 1100831.1 (requires an Oracle Support account).

- Amazon RDS Custom uses Oracle automatic memory management by default. If you want to use the Hugemem kernel, you can configure Amazon RDS Custom to use automatic shared memory management instead.
- Leave the `memory_max_target` parameter enabled by default. The framework uses this in the background to create read replicas.
- Enable Oracle Flashback Database. This feature is useful when reinstating the standby in failover (not switchover) testing scenarios.

Epics

Set up the DB instance and file system

Task	Description	Skills required
Create the DB instance.	In the Amazon RDS console, create an Amazon RDS Custom for Oracle DB instance with a DB name called FSDMO92 (or your source database name). For instructions, see [Working with Amazon RDS Custom](#) in the AWS documentation and the [Amazon RDS Custom for Oracle – New Control Capabilities in Database Environment](#) blog post. This ensures that the database name is set to the same name as the source database. (If kept blank, the EC2 instance and database name will be set to `ORCL`.)	DBA

Perform an RMAN full backup of the source Amazon EC2 database

Task	Description	Skills required
Create a backup script.	Create an RMAN backup script to back up the database to the Amazon EFS file system that you mounted (`/efs` in the following example). You can use the example code or run one of your existing RMAN scripts. ```#!/bin/bash Dt=`date +'%Y%m%d-%H%M'` BACKUP_LOG="rman-${ORACLE_SID}-$Dt" export TAGDATE=`date +%Y%m%d%H%M`; LOGPATH=/u01/scripts/logs rman target / >> $LOGPATH/rman-${ORACLE_SID}-$Dt << EOF SQL "ALTER SYSTEM SWITCH LOGFILE"; SQL "ALTER SESSION SET NLS_DATE_FORMAT="DD.MM.YYYY HH24:MI:SS""; RUN { ALLOCATE CHANNEL ch11 TYPE DISK MAXPIECESIZE 5G; ALLOCATE CHANNEL ch12 TYPE DISK MAXPIECESIZE 5G; BACKUP AS COMPRESSED BACKUPSET FULL DATABASE```	DBA

Task	Description	Skills required

	``
	 FORMAT '/efs/rma
	n_backup/FSCM/%d_%T_
	%s_%p_FULL' ;
	  SQL "ALTER SYSTEM
	 ARCHIVE LOG CURRENT";
	  BACKUP FORMAT '/efs/
	rman_backup/FSCM/%d_
	%T_%s_%p_ARCHIVE'
	 ARCHIVELOG ALL DELETE
	 ALL INPUT ;
	  BACKUP CURRENT
	 CONTROLFILE FORMAT '/
	efs/rman_backup/FSCM/
	%d_%T_%s_%p_CONTROL';
	}
	EXIT;
	EOF
	``	

Run the backup script.	To run the RMAN backup script, log in as the Oracle Home User, and run the script. ``` $ chmod a+x rman_back up.sh $ ./rman_backup.sh & ```	DBA

Task	Description	Skills required

Check for errors and note the name of the backup file.	Check the RMAN log file for errors. If everything looks fine, list the backup of the control file by running the following command.
	``RMAN> list backup of controlfile;
	
	using target database control file instead of recovery catalog```
	Note the name of the output file.
	``List of Backup Sets
	===================
	
	BS Key Type LV Size Device Type Elapsed Time Completion Time
	------- ---- -- ---------- ----------- ------------ ---------------
	12 Full 21.58M DISK 00:00:01 13-JUL-22
	        BP Key: 12 Status: AVAILABLE Compressed: NO Tag: TAG20220713T150155
	        Piece Name: /efs/rman_backup/FSCM/FSDMO92_20220713_12_1_CONTROL
	  Control File Included: Ckp SCN: 165591599```
		DBA

Task	Description	Skills required
	`85898 Ckp time: 13-JUL-22` You will use the backup control file `/efs/rman_backup/FSCM/FSDMO92_20220713_12_1_CONTROL` when you restore the database on Amazon RDS Custom.	

Shut down the source application tier

Task	Description	Skills required

Shut down the application.	To shut down the source application tier, use the `psadmin` utility or the `psadmin` command line utility.
	
	1. To shut down the webserver, run the following command.
	`psadmin -w shutdown -d "webserver domain name"`
	2. To shut down the application server, run the following command.
	`psadmin -c shutdown -d "application server domain name"`
		DBA, PeopleSoft Administrator

Task	Description	Skills required
	3. To shut down the process scheduler, run the following command. `psadmin -p stop -d "process scheduler domain name"`	

Configure the target Amazon RDS Custom database

Task	Description	Skills required
Install the nfs-utils rpm package.	To install the `nfs-utils rpm` package, run the following command. `$ yum install -y nfs-utils`	DBA
Mount the EFS storage.	Get the Amazon EFS mount command from the Amazon EFS console page. Mount the EFS file system on the Amazon RDS instance by using a Network File System (NFS) client. `sudo mount -t nfs4 -o nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport fs-xxxxxxxxxx.efs.eu-west-1.amazonaws.com:/ /efs`	DBA

Task	Description	Skills required
	```sudo mount -t nfs4 -o nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport fs-xxxxxxxxxx.efs.eu-west-1.amazonaws.com:/ /efs```	

Drop the starter database and create the directories to store the database files

Task	Description	Skills required
Pause automation mode.	You have to pause automation mode on your Amazon RDS Custom DB instance before you proceed with the next steps, to make sure that automation doesn't interfere with the RMAN restore activity. You can pause the automation by using the AWS console or the AWS Command Line Interface (AWS CLI) command (make sure that you have configured the AWS CLI first). ```aws rds modify-db-instance \ --db-instance-identifier peoplesoft-fscm-92 \ --automation-mode all-paused \```	DBA

Task	Description	Skills required
	``` --resume-full-au tomation-mode-minute 360 \ --region eu-west-1 ``` When you specify the duration of the pause, make sure that you leave enough time for the RMAN restore. This depends on the size of the source database, so modify the 360 value accordingly. Also, make sure that the total time of the paused automation does not overlap with the backup or maintenance window of the database.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create and modify the parameter file for PeopleSoft</td><td>To create and modify the pfile for PeopleSoft, use the standard pfile created with the Amazon RDS Custom DB instance. Add the parameters you need for PeopleSoft.

1. Switch to <code>rds user rdsdb</code> by running the following command.<pre><code>$ sudo su - rdsdb</code></pre>2. Log in to SQL*Plus on the starter database, and create the pfile by running the following command.<pre><code>SQL> create pfile
 from spfile;</code></pre>This creates the pfile in <code>$ORACLE_HOME/dbs</code> .
3. Make a backup of this pfile.
4. Edit the pfile to add or update PeopleSof t parameters.<pre><code>*._gby_hash_aggreg
ation_enabled=false

*._unnest_subqu
ery=false

*.nls_language='
AMERICAN'</code></pre></td><td>DBA</td></tr>
</table>

Task	Description	Skills required
	``` *.nls_length_sem antics='CHAR' *.nls_territ ory='AMERICA' *.open_cursors=1000 *.db_files=1200 *.undo_tablespace=' UNDOTBS1' ``` PeopleSoft related parameters can be found in Oracle Support Note 1100831.1. 5. Remove the spfile reference from the pfile. ``` *.spfile='/rdsdbbi n/oracle/dbs/spfil eFSDM092.ora' ```	

Drop the starter database.	To drop the existing Amazon RDS Custom database, use the following code.
	``
	$ sqlplus / as sysdba
	SQL> shutdown immediate
	;
	SQL> startup mount
	 exclusive restrict;
	SQL> drop database;
	SQL> exit
	``	

Task	Description	Skills required
Restore the Amazon RDS Custom database from the backup.	Restore the database by using the following script. The script will first restore the control file and then restore the entire database from the backup pieces stored on the EFS mount. ```#!/bin/bash Dt=`date +'%Y%m%d-%H%M'` BACKUP_LOG="rman-${ORACLE_SID}-$Dt" export TAGDATE=`date +%Y%m%d%H%M`; LOGPATH=/rdsdbdata/scripts/logs rman target / >> $LOGPATH/rman-${ORACLE_SID}-$Dt << EOF restore controlfile from "/efs/rman_backup/FSCM/FSDM092_20220713_12_1_CONTROL"; alter database mount; run { set newname for database to '/rdsdbdata/db/FSDM092_A/datafile/%f_%b'; SET NEWNAME FOR TEMPFILE 1 TO '/rdsdbdata/db/FSDM092_A/datafile/%f_%b'; RESTORE DATABASE; SWITCH DATAFILE ALL; SWITCH TEMPFILE ALL; RECOVER DATABASE;```	DBA

Task	Description	Skills required

	``
	}

	 group 3;
	alter database open
	 resetlogs;
	EXIT
	EOF
	``	

Retrieve passwords from Secrets Manager, create users, and change passwords

Task	Description	Skills required
Retrieve the password from Secrets Manager.	You can perform this step by using the AWS console or the AWS CLI. The following steps show instructions for the console. 1. Sign in to the AWS Management Console and open the Amazon RDS console. 2. In the navigation pane, choose **Databases**, and then select the Amazon RDS database. 3. Choose the **Configuration** tab, and note the resource ID for the instance. It will be in the format `db-<ID>` (for example, `db-73GJNHLGDNZNDOXNWXSECUW6LE`). 4. Open the Secrets Manager console. 5. Choose the secret that has the same name as `do-not-delete-custom-<resource_id>` , where `resource-id` refers to the resource ID that you noted in step 3. 6. Choose **Retrieve secret value**.	DBA

Task	Description	Skills required
	This password will be same for the `sys`, `system`, `rdsadmin`, and `admin` users.	

Task	Description	Skills required

Create the RDSADMIN user.	`RDSADMIN` is the database user for monitoring and orchestrating the Amazon RDS Custom DB instance. Because the starter database was dropped and the target database was restored from the source using RMAN, you must recreate this user after the restore operation to make sure that Amazon RDS Custom monitoring works as expected. You also must create a separate profile and tablespace for the `RDSADMIN` user.
	
	1. Enter the following commands at a SQL prompt.
	
	`SQL> set echo on feedback on serverout on`
	`SQL> @?/rdbms/admin/utlpwdmg.sql`
	`SQL> ALTER PROFILE DEFAULT`
	`LIMIT`
	`FAILED_LOGIN_ATTEMPTS UNLIMITED`
	`PASSWORD_LIFE_TIME UNLIMITED`
	`PASSWORD_VERIFY_FUNCTION NULL;`
		DBA

Task	Description	Skills required
	2. Create the profile `RDSADMIN`. ```SQL> set echo on feedback on serverout on SQL> alter session set "_oracle_script"=true; SQL> CREATE PROFILE RDSADMIN LIMIT COMPOSITE_LIMIT UNLIMITED SESSIONS_PER_USER UNLIMITED CPU_PER_SESSION UNLIMITED CPU_PER_CALL UNLIMITED LOGICAL_READS_PER_SESSION UNLIMITED LOGICAL_READS_PER_CALL UNLIMITED IDLE_TIME UNLIMITED CONNECT_TIME UNLIMITED PRIVATE_SGA UNLIMITED FAILED_LOGIN_ATTEMPTS 10 PASSWORD_LIFE_TIME UNLIMITED PASSWORD_REUSE_TIME UNLIMITED PASSWORD_REUSE_MAX UNLIMITED PASSWORD_VERIFY_FUNCTION NULL PASSWORD_LOCK_TIME 86400/86400```	

Task	Description	Skills required

	`PASSWORD_GRACE_TIME 604800/86400;`
	3. Create the `RDSADMIN` tablespace.
	`SQL> CREATE BIGFILE TABLESPACE rdsadmin '/rdsdbdata/db/FSDMO92_A/datafile/rdsadmin.dbf' DATAFILE SIZE 7M AUTOEXTEND ON NEXT 1m LOGGING ONLINE PERMANENT BLOCKSIZE 8192 EXTENT MANAGEMENT LOCAL AUTOALLOCATE DEFAULT NOCOMPRESS SEGMENT SPACE MANAGEMENT AUTO;`
	4. Create the `RDSADMIN` user. Replace the `RDSADMIN` password with the password you obtained earlier from Secrets Manager.
	`SQL> CREATE USER rdsadmin IDENTIFIED BY xxxxxxxxxx DEFAULT TABLESPACE rdsadmin TEMPORARY TABLESPACE TEMP profile rdsadmin ;`
	5. Grant privileges to RDSADMIN.	

Task	Description	Skills required

	<pre>SQL> GRANT "CONNECT"
	 TO RDSADMIN WITH
	 ADMIN OPTION;
	SQL> GRANT "RESOURCE
	" TO RDSADMIN WITH
	 ADMIN OPTION;
	SQL> GRANT "DBA" TO
	 RDSADMIN;
	SQL> GRANT "SELECT_C
	ATALOG_ROLE" TO
	 RDSADMIN WITH ADMIN
	 OPTION;
	SQL> GRANT ALTER
	 SYSTEM TO RDSADMIN;
	SQL> GRANT UNLIMITED
	 TABLESPACE TO
	 RDSADMIN;
	SQL> GRANT SELECT ANY
	 TABLE TO RDSADMIN;
	SQL> GRANT ALTER
	 DATABASE TO
	 RDSADMIN;
	SQL> GRANT ADMINISTER
	 DATABASE TRIGGER TO
	 RDSADMIN;
	SQL> GRANT ANY OBJECT
	 PRIVILEGE TO RDSADMIN
	 WITH ADMIN OPTION;
	SQL> GRANT INHERIT
	 ANY PRIVILEGES TO
	 RDSADMIN;
	SQL> ALTER USER
	 RDSADMIN DEFAULT ROLE
	 ALL;</pre>6. Set the SYS, SYSTEM, and DBSNMP user profiles to RDSADMIN.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>SQL> set echo on
 feedback on serverout
 on
SQL> alter user SYS
 profile RDSADMIN;
SQL> alter user SYSTEM
 profile RDSADMIN;
SQL> alter user DBSNMP
 profile RDSADMIN;</code></pre></td><td></td></tr>
<tr><td>Create the master user.</td><td>Because the starter database was dropped and the target database was restored from the source by using RMAN, you must recreate the master user. In this example, the master user name is <code>admin</code>.<pre><code>SQL> create user
 admin identified by
 <password>;
SQL> grant dba to admin</code></pre></td><td>DBA</td></tr>
</table>

Task	Description	Skills required

Change the system passwords .	Change the system passwords by using the password you retrieved from Secrets Manager.
	`SQL> alter user sys identified by xxxxxxxxxxx;`
	`SQL> alter user system identified by xxxxxxxxxx;`
	If you don't change these passwords, Amazon RDS Custom displays the error message, "The database monitoring user or user credentials have changed."
		DBA

Configure the TNS entries for Amazon RDS Custom and PeopleSoft

Task	Description	Skills required
Configure the tnsnames file.	To connect to the database from the application tier, configure the `tnsnames.ora` file so you can connect to the database from the application tier. In the following example, you can see that there is a soft link to the `tnsnames.ora` file, but the file is empty by default.	DBA

Task	Description	Skills required

	<pre>$ cd /rdsdbbin/oracle/n
	etwork/admin
	$ ls -ltr
	-rw-r--r-- 1 rdsdb
	 database 1536 Feb 14
	 2018 shrept.lst
	lrwxrwxrwx 1 rdsdb
	 database 30 Apr 5
	 13:19 listener.ora -
	> /rdsdbdata/config/
	listener.ora
	lrwxrwxrwx 1 rdsdb
	 database 28 Apr 5
	 13:19 sqlnet.ora -
	> /rdsdbdata/config/
	sqlnet.ora
	lrwxrwxrwx 1 rdsdb
	 database 30 Apr 5
	 13:19 tnsnames.ora -
	> /rdsdbdata/config/
	tnsnames.ora</pre>
	1. Create the `tsnames.ora` entry. Because of the way Amazon RDS automation parses the files, you have to make sure that the entry doesn't contain any white spaces, comments, or extra lines. Otherwise, you might run into issues when using some of the APIs, such [as create-db-instance-read-replica](#).
	2. Replace the port, host, and SID in accordance with your PeopleSoft	

Task	Description	Skills required

	database requirements. Use the following code as an example.
	
	`$ vi tnsnames.ora`
	
	`FSDMO92=(DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP)(HOST = x.x.x.x)(PORT = 1521))) (CONNECT_DATA = (SERVER = DEDICATED) (SID = FSDMO92)))`
	
	3. To confirm that the PeopleSoft database can be reached, run the following command.
	
	`$ tnsping FSDMO92`
	
	`TNS Ping Utility for Linux: Version 19.0.0.0.0 - Production on 14-JUL-2022 10:16:45`
	
	`Copyright (c) 1997, 2021, Oracle.  All rights reserved.`
	
	`Used parameter files: /rdsdbbin/oracle/network/admin/sqlnet.ora`
	
	`Used TNSNAMES adapter to resolve the alias`	

Task	Description	Skills required
	```Attempting to contact (DESCRIPTION = (ADDRESS_LIST = (ADDRESS = (PROTOCOL = TCP)(HOST = x.x.x.x)(PORT = 1521))) (CONNECT_DATA = (SERVER = DEDICATED) (SID = FSDM092))) OK (0 msec)```	

Create the spfile softlink

Task	Description	Skills required
Create the spfile softlink.	1. To create spfile in the location `/rdsdbdata/admin/FSDM092/pfile` , run the following command. ```SQL> create spfile='/rdsdbdata/admin/FSDM092/pfile/spfileFSDM092.ora' from pfile;``` 2. Navigate to `$ORACLE_HOME/dbs` , and create a soft link for the spfile. ```ln -s '/rdsdbdata/admin/FSDM092/pfile/spfileFSDM092.ora' spfileFSDM092.ora```	DBA

Task	Description	Skills required
	3. After this file is created, you can shut down and start the database by using the spfile.	

Perform post-migration steps

Task	Description	Skills required
Validate the schema, connections, and maintenan ce tasks.	To finalize the migration, perform the following tasks. • Gather schema statistics. • Ensure that the PeopleSoft application tier can connect to the new Amazon RDS Custom database. • Set up your backup and maintenance schedules.	DBA

Migrate Oracle ROWID functionality to PostgreSQL on AWS

Rakesh Raghav and Ramesh Pathuri, Amazon Web Services

Summary

This pattern describes options for migrating the `ROWID` pseudocolumn functionality in Oracle Database to a PostgreSQL database in Amazon Relational Database Service (Amazon RDS) for PostgreSQL, Amazon Aurora PostgreSQL-Compatible Edition, or Amazon Elastic Compute Cloud (Amazon EC2).

In an Oracle database, the `ROWID` pseudocolumn is a physical address of a row in a table. This pseudocolumn is used to uniquely identify a row even if the primary key isn't present on a table. PostgreSQL has a similar pseudocolumn called `ctid`, but it cannot be used as a `ROWID`. As explained in the PostgreSQL documentation, `ctid` might change if it's updated or after every `VACUUM` process.

There are three ways you can create the `ROWID` pseudocolumn functionality in PostgreSQL:

- Use a primary key column instead of `ROWID` to identify a row in a table.
- Use a logical primary/unique key (which might be a composite key) in the table.
- Add a column with auto-generated values and make it a primary/unique key to mimic `ROWID`.

This pattern walks you through all three implementations and describes the advantages and disadvantages of each option.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Procedural Language/PostgreSQL (PL/pgSQL) coding expertise
- Source Oracle Database
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible cluster, or an EC2 instance to host the PostgreSQL database

Limitations

- This pattern provides workarounds for the `ROWID` functionality. PostgreSQL doesn't provide an equivalent to `ROWID` in Oracle Database.

Product versions

- PostgreSQL 11.9 or later

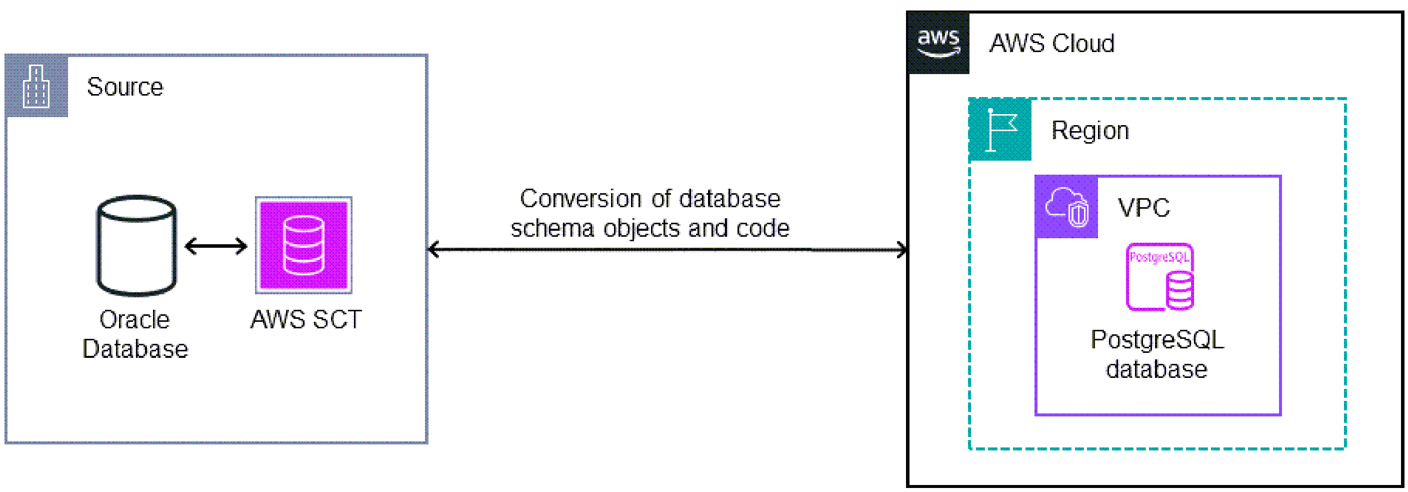
Architecture

Source technology stack

- Oracle Database

Target technology stack

- Aurora PostgreSQL-Compatible, Amazon RDS for PostgreSQL, or an EC2 instance with a PostgreSQL database



Implementation options

There are three options to work around the lack of `ROWID` support in PostgreSQL, depending on whether your table has a primary key or unique index, a logical primary key, or an identity attribute. Your choice depends on your project timelines, your current migration phase, and dependencies on application and database code.

Option	Description	Advantages	Disadvantages
Primary key or unique index	If your Oracle table has a primary key, you can use the attributes of this key to uniquely identify a row.	• No dependenc y on proprietary database features. • Minimal impact on performance, because primary key fields are indexed.	• Requires changes to application and database code that relies on `ROWID` to switch to primary key fields.
Logical primary/u nique key	If your Oracle table has a logical primary key, you can use the attributes of this key to uniquely identify a row. A logical primary key consists of an attribute or a set of attributes that can uniquely identify a row, but it isn't enforced on the database through a constraint.	• No dependenc y on proprietary database features.	• Requires changes to application and database code that relies on `ROWID` to switch to primary key fields. • Significant impact on performance if the attribute s of the logical primary key aren't indexed. However, you can add a unique index to prevent performan ce issues.
Identity attribute	if your Oracle table doesn't have a primary key, you can create an additional field as `GENERATED ALWAYS AS IDENTITY`. This attribute generates	• No dependenc y on proprietary database features. • PostgreSQL database populates the attribute and maintains its uniqueness.	• Requires changes to application and database code that relies on `ROWID` to switch to identity attribute. • Significant impact on performance

	a unique value whenever data is inserted into the table, so it can be used to uniquely identify a row for Data Manipulation Language (DML) operations.		if the additional field isn't indexed. However, you can add an index to prevent performan ce issues.

Tools

- [Amazon Relational Database Service (Amazon RDS) for PostgreSQL] helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- [Amazon Aurora PostgreSQL-Compatible Edition] is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [AWS Command Line Interface (AWS CLI)] is an open-source tool that helps you interact with AWS services through commands in your command-line shell. In this pattern, you can use the AWS CLI to run SQL commands through **pgAdmin**.
- [pgAdmin] is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
- [AWS Schema Conversion Tool (AWS SCT)] supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

Epics

Identify the source tables

Task	Description	Skills required
Identify Oracle tables that use the `ROWID` attribute.	Use the AWS Schema Conversion Tool (AWS SCT) to identify Oracle tables that have `ROWID` functionality. For	DBA or developer

Task	Description	Skills required
	more information, see the AWS SCT documentation. —or— In Oracle, use the DBA_TAB_COLUMNS view to identify tables that have a ROWID attribute. These fields might be used to store alphanumeric 10-byte characters. Determine the usage and convert these to a VARCHAR field if appropriate.	
Identify code that references these tables.	Use AWS SCT to generate a migration assessment report to identify procedures affected by ROWID. For more information, see the AWS SCT documentation. —or— In the source Oracle database, use the text field of the dba_source table to identify objects that use ROWID functionality.	DBA or developer

Determine primary key usage

Task	Description	Skills required
Identify tables that don't have primary keys.	In the source Oracle database, use DBA_CONSTRAINTS to	DBA or developer

Task	Description	Skills required

	identify tables that don't have primary keys. This informati on will help you determine the strategy for each table. For example:
	`select dt.*`
	`from dba_tables dt`
	`where not exists (select 1`
	`from all_constraints ct`
	`where ct.owner = Dt.owner`
	`and ct.table_name = Dt.table_name`
	`and ct.constraint_type = 'P'`
	`)`
	`and dt.owner = '{schema}'`	

Identify and apply the solution

Task	Description	Skills required
Apply changes for tables that have a defined or logical primary key.	Make the application and database code changes shown in the [Additional informati on](#) section to use a unique primary key or a logical primary key to identify a row in your table.	DBA or developer

Task	Description	Skills required
Add an additional field to tables that don't have a defined or logical primary key.	Add an attribute of type `GENERATED ALWAYS AS IDENTITY`. Make the application and database code changes shown in the Additional information section.	DBA or developer
Add an index if necessary.	Add an index to the additiona l field or logical primary key to improve SQL performance.	DBA or developer

- ROWID Pseudocolumn (Oracle documentation)

Additional information

The following sections provide Oracle and PostgreSQL code examples to illustrate the three approaches.

Scenario 1: Using a primary unique key

In the following examples, you create the table `testrowid_s1` with `emp_id` as the primary key.

Oracle code:

```
create table testrowid_s1 (emp_id integer, name varchar2(10), CONSTRAINT testrowid_pk
 PRIMARY KEY (emp_id));
INSERT INTO testrowid_s1(emp_id,name) values (1,'empname1');
INSERT INTO testrowid_s1(emp_id,name) values (2,'empname2');
INSERT INTO testrowid_s1(emp_id,name) values (3,'empname3');
INSERT INTO testrowid_s1(emp_id,name) values (4,'empname4');
commit;
```

```
SELECT rowid,emp_id,name FROM testrowid_s1;
ROWID                  EMP_ID NAME
------------------ ---------- ----------
AAAF3pAAAAAAAMOAAA          1 empname1
AAAF3pAAAAAAAMOAAB          2 empname2
AAAF3pAAAAAAAMOAAC          3 empname3
AAAF3pAAAAAAAMOAAD          4 empname4

UPDATE testrowid_s1 SET name = 'Ramesh' WHERE rowid = 'AAAF3pAAAAAAAMOAAB' ;
commit;

SELECT rowid,emp_id,name FROM testrowid_s1;
ROWID                  EMP_ID NAME
------------------ ---------- ----------
AAAF3pAAAAAAAMOAAA          1 empname1
AAAF3pAAAAAAAMOAAB          2 Ramesh
AAAF3pAAAAAAAMOAAC          3 empname3
AAAF3pAAAAAAAMOAAD          4 empname4
```

PostgreSQL code:

```
CREATE TABLE public.testrowid_s1
(
    emp_id integer,
    name character varying,
    primary key (emp_id)
);

insert into public.testrowid_s1 (emp_id,name) values
(1,'empname1'),(2,'empname2'),(3,'empname3'),(4,'empname4');

select emp_id,name from testrowid_s1;
 emp_id |   name
--------+----------
      1 | empname1
      2 | empname2
      3 | empname3
      4 | empname4

update testrowid_s1 set name = 'Ramesh' where emp_id = 2 ;

select emp_id,name from testrowid_s1;
 emp_id |   name
```

```
--------+----------
       1 | empname1
       3 | empname3
       4 | empname4
       2 | Ramesh
```

Scenario 2: Using a logical primary key

In the following examples, you create the table `testrowid_s2` with `emp_id` as the logical primary key.

Oracle code:

```
create table testrowid_s2 (emp_id integer, name varchar2(10) );
INSERT INTO testrowid_s2(emp_id,name) values (1,'empname1');
INSERT INTO testrowid_s2(emp_id,name) values (2,'empname2');
INSERT INTO testrowid_s2(emp_id,name) values (3,'empname3');
INSERT INTO testrowid_s2(emp_id,name) values (4,'empname4');
commit;

SELECT rowid,emp_id,name FROM testrowid_s2;
ROWID                  EMP_ID NAME
------------------ ---------- ----------
AAAF3rAAAAAAAMeAAA          1 empname1
AAAF3rAAAAAAAMeAAB          2 empname2
AAAF3rAAAAAAAMeAAC          3 empname3
AAAF3rAAAAAAAMeAAD          4 empname4

UPDATE testrowid_s2 SET name = 'Ramesh' WHERE rowid = 'AAAF3rAAAAAAAMeAAB' ;
commit;

SELECT rowid,emp_id,name FROM testrowid_s2;
ROWID                  EMP_ID NAME
------------------ ---------- ----------
AAAF3rAAAAAAAMeAAA          1 empname1
AAAF3rAAAAAAAMeAAB          2 Ramesh
AAAF3rAAAAAAAMeAAC          3 empname3
AAAF3rAAAAAAAMeAAD          4 empname4
```

PostgreSQL code:

```
CREATE TABLE public.testrowid_s2
(
```

```
    emp_id integer,
    name character varying
);

insert into public.testrowid_s2 (emp_id,name) values
(1,'empname1'),(2,'empname2'),(3,'empname3'),(4,'empname4');

select emp_id,name from testrowid_s2;
 emp_id |   name
--------+----------
      1 | empname1
      2 | empname2
      3 | empname3
      4 | empname4

update testrowid_s2 set name = 'Ramesh' where emp_id = 2 ;

select emp_id,name from testrowid_s2;
 emp_id |   name
--------+----------
      1 | empname1
      3 | empname3
      4 | empname4
      2 | Ramesh
```

Scenario 3: Using an identity attribute

In the following examples, you create the table `testrowid_s3` with no primary key and by using an identity attribute.

Oracle code:

```
create table testrowid_s3 (name varchar2(10));
INSERT INTO testrowid_s3(name) values ('empname1');
INSERT INTO testrowid_s3(name) values ('empname2');
INSERT INTO testrowid_s3(name) values ('empname3');
INSERT INTO testrowid_s3(name) values ('empname4');
commit;

SELECT rowid,name FROM testrowid_s3;
ROWID              NAME
------------------ ----------
AAAF3sAAAAAAAMmAAA empname1
```

```
AAAF3sAAAAAAAMmAAB empname2
AAAF3sAAAAAAAMmAAC empname3
AAAF3sAAAAAAAMmAAD empname4

UPDATE testrowid_s3 SET name = 'Ramesh' WHERE rowid = 'AAAF3sAAAAAAAMmAAB' ;
commit;

SELECT rowid,name FROM testrowid_s3;
ROWID              NAME
------------------ ----------
AAAF3sAAAAAAAMmAAA empname1
AAAF3sAAAAAAAMmAAB Ramesh
AAAF3sAAAAAAAMmAAC empname3
AAAF3sAAAAAAAMmAAD empname4
```

PostgreSQL code:

```
CREATE TABLE public.testrowid_s3
(
    rowid_seq bigint generated always as identity,
    name character varying
);

insert into public.testrowid_s3 (name) values
('empname1'),('empname2'),('empname3'),('empname4');

select rowid_seq,name from testrowid_s3;
 rowid_seq |   name
-----------+----------
         1 | empname1
         2 | empname2
         3 | empname3
         4 | empname4

update testrowid_s3 set name = 'Ramesh' where rowid_seq = 2 ;

select rowid_seq,name from testrowid_s3;
 rowid_seq |   name
-----------+----------
         1 | empname1
         3 | empname3
         4 | empname4
         2 | Ramesh
```

Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database

Sai Parthasaradhi and Veeranjaneyulu Grandhi, Amazon Web Services

Summary

This pattern shows how to migrate Oracle Database error codes to an [Amazon Aurora PostgreSQL-Compatible Edition](https://aws.amazon.com/rds/aurora/postgresql-features/) database by using a predefined metadata table.

Oracle Database error codes don't always have a corresponding PostgreSQL error code. This difference in error codes can make it difficult to configure the processing logic of the procedures or functions in the target PostgreSQL architecture.

You can simplify the process by storing the source and target database error codes that are meaningful to your PL/pgSQL program in a metadata table. Then, configure the table to flag valid Oracle Database error codes and map them to their PostgreSQL equivalents before continuing with the remaining process logic. If the Oracle Database error code isn't in the metadata table, the process exits with the exception. Then, you can manually review the error details and add the new error code to the table if your program requires it.

By using this configuration, your Amazon Aurora PostgreSQL-Compatible database can handle errors in the same way that your source Oracle database does.

> **Note**
>
> Configuring a PostgreSQL database to handle Oracle Database error codes correctly usually requires changes to the database and application code.

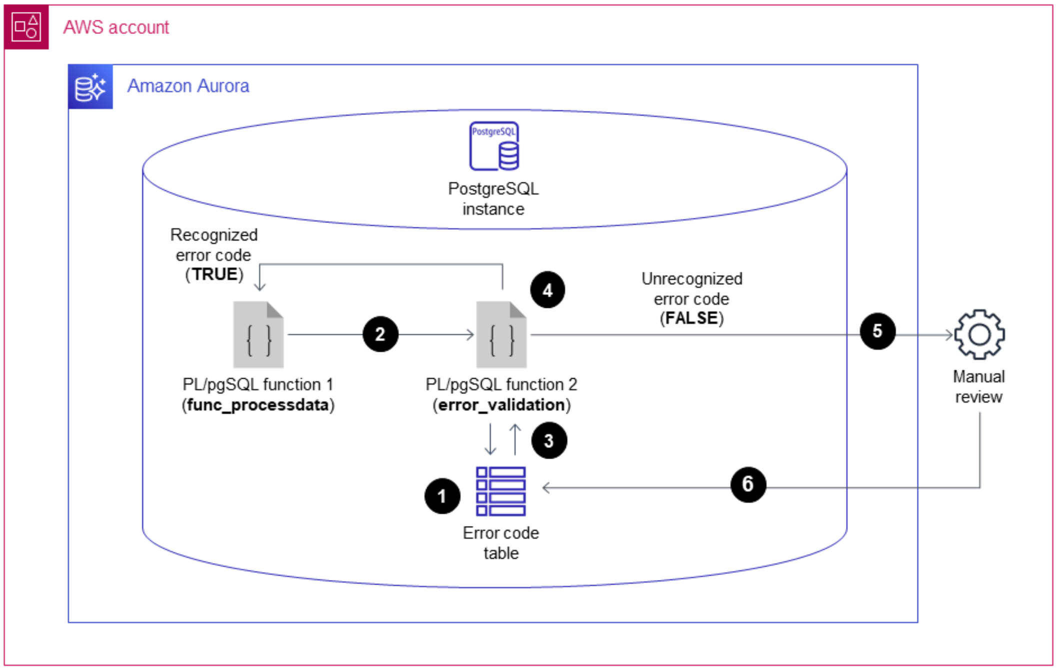
Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle Database with instance and listener services up and running
- An Amazon Aurora PostgreSQL-Compatible cluster that's up and running
- Familiarity with Oracle Database
- Familiarity with PostgreSQL databases

Architecture

The following diagram shows an example Amazon Aurora PostgreSQL-Compatible database workflow for data error code validation and handling:



The diagram shows the following workflow:

1. A table holds Oracle Database error codes and classifications and their equivalent PostgreSQL error codes and classifications. The table includes a **valid_error** column that classifies if specific, predefined error codes are valid or not.
2. When a PL/pgSQL function (**func_processdata**) throws an exception, it invokes a second PL/pgSQL function (**error_validation**).
3. The **error_validation** function accepts the Oracle Database error code as an input argument. Then, the function checks the incoming error code against the table to see if the error is included in the table.
4. If the Oracle Database error code is included in the table, then the **error_validation** function returns a **TRUE** value and the process logic continues. If the error code isn't included in the table, then the function returns a **FALSE** value, and the process logic exits with an exception.
5. When the function returns a **FALSE** value, then the error details are manually reviewed by the application's functional lead to determine its validity.

6. The new error code is then either manually added to the table or not. If the error code is valid and added to the table, then the **error_validation** function returns a **TRUE** value the next time the exception occurs. If the error code isn't valid, and the process must fail when the exception occurs, then the error code isn't added to the table.

Technology stack

- Amazon Aurora PostgreSQL
- pgAdmin
- Oracle SQL Developer

Tools

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- pgAdmin is an open-source administration and development tool for PostgreSQL. It provides a graphical interface that simplifies the creation, maintenance, and use of database objects.
- Oracle SQL Developer is a free, integrated development environment that simplifies the development and management of Oracle Database in both traditional and cloud deployments.

Epics

Migrate Oracle Database error codes to your Amazon Aurora PostgreSQL-Compatible database

Task	Description	Skills required

Create a table in the Amazon Aurora PostgreSQL-Compatible database.	Run the following PostgreSQL CREATE TABLE command:
	`(`
	`source_error_code numeric NOT NULL,`
	`target_error_code character varying NOT NULL,`
		PostgreSQL Developer, Oracle, RDS/Aurora for PostgreSQL

Task	Description	Skills required
	``` valid_error character varying(1) NOT NULL); ```	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add PostgreSQL error codes and their corresponding Oracle Database error codes to the table.</td><td>Run the PostgreSQL INSERT command to add the required error code values to the error_codes table.

The PostgreSQL error codes must use the character varying data type (SQLSTATE value). The Oracle error codes must use the numeric data type (SQLCODE value).

Example Insert statements:

<pre>insert into error_codes values (-1817,'22007','Y');
insert into error_codes values (-1816,'22007','Y');
insert into error_codes values (-3114,'08006','N');</pre>
Note

If you’re catching Oracle-specific Java database connectivity (JDBC) exceptions, you must replace those exceptions with either generic cross-database exceptions or switch</td><td>PostgreSQL Developer, Oracle, RDS/Aurora for PostgreSQL</td></tr>
</table>

Task	Description	Skills required
	to PostgreSQL-specific exceptions.	
Create a PL/pgSQL function to validate error codes.	Create a PL/pgSQL function by running the PostgreSQL CREATE FUNCTION command. Make sure that the function does the following: • Accepts the Oracle error codes thrown by a program. • Checks if error codes are present in the **error_codes** table. • Returns **TRUE** or **FALSE** value, based on if the error code is present in the metadata table or not.	PostgreSQL Developer, Oracle, RDS/Aurora for PostgreSQL

Task	Description	Skills required
Manually review new error codes as they're recorded by the PL/pgSQL function.	Manually review the new error codes. If a new error code is valid for your use case, add it to the **error_codes** table by running the PostgreSQL **INSERT** command. -or- If a new error code isn't valid for your use case, don't add it to the table. The process logic will continue to fail and exit with exception when the error occurs.	PostgreSQL Developer , Oracle, RDS/Aurora for PostgreSQL

Migrate Redis workloads to Redis Enterprise Cloud on AWS

Antony Prasad Thevaraj, Amazon Web Services

Srinivas Pendyala, Redis

Summary

This pattern discusses the high-level process for migrating Redis workloads to Redis Enterprise Cloud on Amazon Web Services (AWS). It describes the migration steps, provides information about the selection of tools available, and discusses the advantages, disadvantages, and steps for using each tool. Optionally, if you require additional help in migrating workloads from Redis, you can engage Redis Professional Services.

If you run Redis OSS or Redis Enterprise Software on premises, you're familiar with the significant administrative overhead and operational complexity of maintaining your Redis databases in your data center. By migrating your workloads to the cloud, you can significantly reduce this operational burden and take advantage of Redis Enterprise Cloud, which is a fully hosted database as a service (DBaaS) offering from Redis. This migration helps increase your business agility, improves application reliability, and reduces overall costs while you gain access to the newest Redis Enterprise Cloud on AWS features such as 99.999% availability, architectural simplicity, and scale.

There are potential applications for Redis Enterprise Cloud in the financial services, retail, healthcare, and gaming sectors, as well as in use cases that require solutions for fraud detection, real-time inventory, claims processing, and session management. You can use Redis Enterprise Cloud to connect to your AWS resources—for example, to an application server that is running on Amazon Elastic Compute Cloud (Amazon EC2) instances, or to a microservice that is deployed as an AWS Lambda service.

Prerequisites and limitations

Assumptions

- You are currently operating an on-premises database system that you want to migrate to the cloud.
- You have identified the migration requirements for your workloads, including:
  - Data consistency requirements
  - Infrastructure and system environment requirements

  - Data mapping and transformation requirements
  - Functional testing requirements
  - Performance testing requirements
  - Validation requirements
  - Defined cutover strategy
- You have assessed timelines and cost estimates required for the migration.
- Your requirements take into consideration the scope of the work and the systems and databases you have identified to be part of the migration.
- You have identified the stakeholders along with their roles and responsibilities in a responsible, accountable, consulted, informed (RACI) matrix.
- You have received the necessary agreement and approvals from all stakeholders.

Cost

Depending on the technical specifications of your existing source database (for example, memory sizing, throughput, and total data size), a Redis solutions architect can size the target system on Redis Enterprise Cloud. For general pricing information, see Redis Pricing on the Redis website.

People and skills

The migration process involves the following roles and responsibilities.

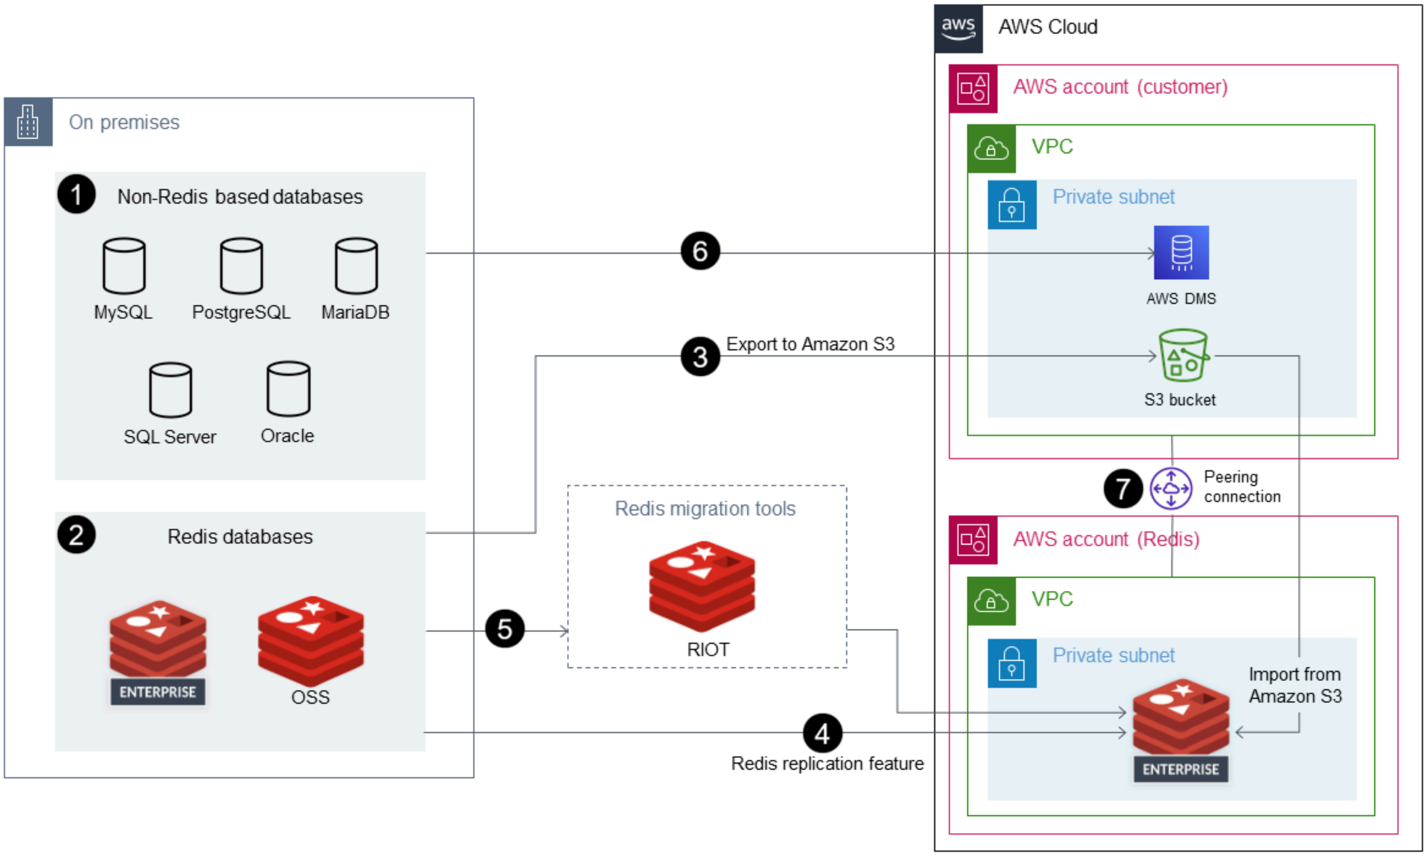
Role	Description	Skills required
Migration solutions architect	A technical architect who has expertise in defining, planning, and implementing migration strategies	Technical and application-level understanding of source and target systems; experienc e with migrating workloads to the cloud
Data architect	A technical architect who has broad experience in defining, implementing, and deliverin g data solutions for a wide variety of databases	Data modeling for structured and unstructured data, deep understanding and experienc e in implementing databases for an enterprise

Redis solutions architect	A technical architect who can help architect an optimally sized Redis cluster for the appropriate use case	Expertise in architecting and deploying Redis solutions for a wide variety of use cases
Cloud solutions architect	A technical architect who has a deeper understanding of cloud solutions, especially on AWS	Expertise in architecting solutions for the cloud; workload migration and application modernization experience
Enterprise architect	A technical architect who has a complete understanding of the technical landscape at your organization, who has a shared vision for the future roadmap, and who practices and establishes standardized architectural best practices across all teams in your organization	Software architecture certifications such as TOGAF, foundational software engineering skills, and solutions architecture and enterprise architecture expertise
IT or DevOps engineer	An engineer who is responsib le for creating and maintaini ng the infrastructure, including monitoring the infrastructure for issues, performing maintenance tasks, and making updates as needed.	Strong understanding of various technologies, including operating systems, networking, and cloud computing; familiarity with programming languages such as Python, Bash, and Ruby, as well as tools such as Docker, Kubernetes, and Ansible

Architecture

Migration options

The following diagram shows options for migrating your on-premises (Redis-based or other) data sources to AWS. It shows several migration tools that you can choose from, such as exporting Redis Database (RDB) files to Amazon Simple Storage Service (Amazon S3), using the Redis replication feature, or using AWS DMS.

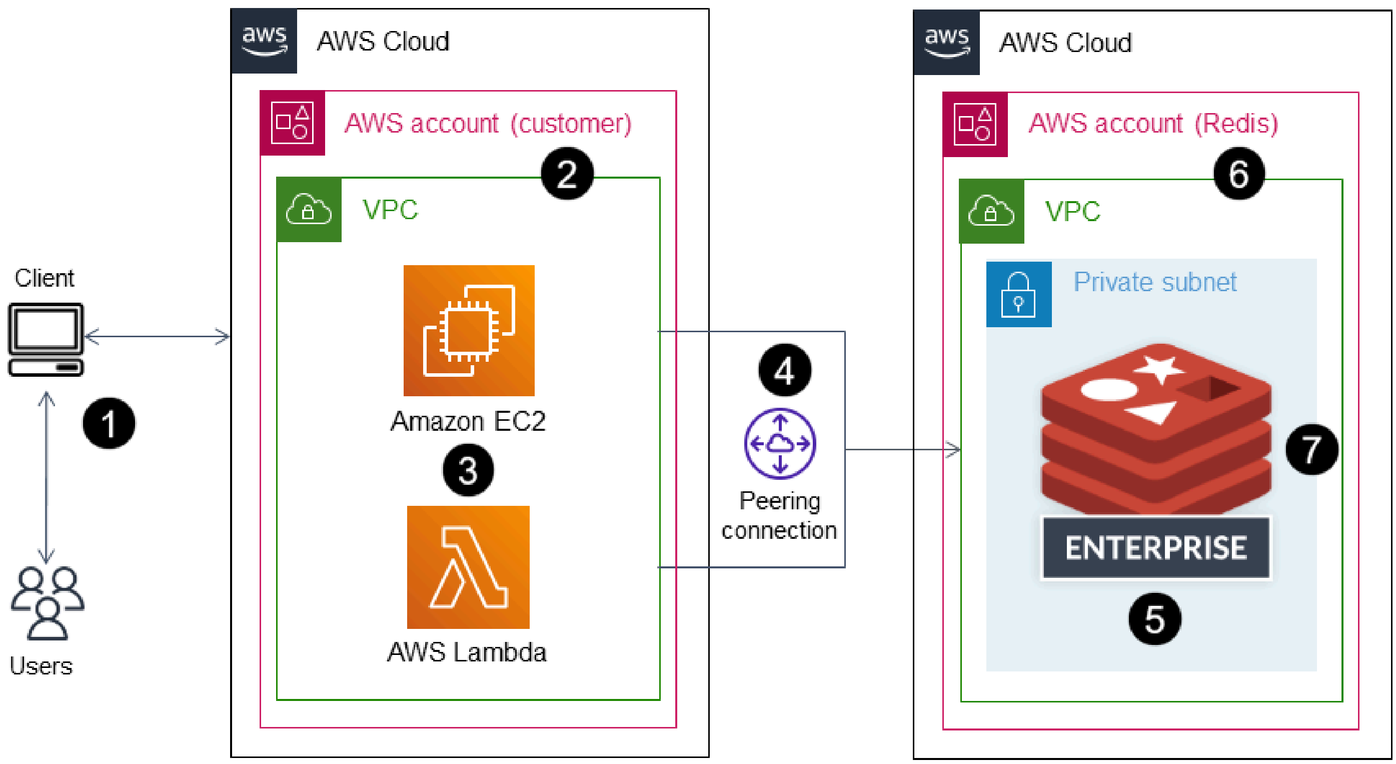


1. On-premises data sources: Databases that aren't based on Redis, such as MySQL, PostgreSQL, Oracle, SQL Server, or MariaDB.
2. On-premises data sources: Redis protocol-based databases such as Redis OSS and Redis Enterprise Software.
3. The simplest way to migrate data from Redis-based databases is to export RDB files and import them into the target Redis Enterprise Cloud on AWS.
4. Alternatively, you can migrate the data from source to target by using the replication feature (`ReplicaOf`) in Redis.
5. If your data migration requirements include transformation of data, you can employ Redis Input/Output Tools (RIOT) to migrate the data.
6. Alternatively, you can use AWS Data Migration Service (AWS DMS) to migrate the data from SQL-based databases.

7. You must use virtual private cloud (VPC) peering for AWS DMS to migrate the data successfully into the target Redis Enterprise Cloud on AWS.

Target architecture

The following diagram shows a typical deployment architecture for Redis Enterprise Cloud on AWS and illustrates how it can be used with key AWS services.



1. You can connect to the business applications that are backed by Redis Enterprise Cloud on AWS.
2. You can run business applications in your own AWS account, in a VPC within that account.
3. You can use Redis Enterprise Cloud database endpoints to connect to your applications. Examples include an application server running on EC2 instances, a microservice deployed as an AWS Lambda service, an Amazon Elastic Container Service (Amazon ECS) application, or an Amazon Elastic Kubernetes Service (Amazon EKS) application.
4. Business applications running in your VPC require a VPC peer connection to the Redis Enterprise Cloud VPC. This enables the business applications to connect securely over private endpoints.
5. Redis Enterprise Cloud on AWS is an in-memory NoSQL database platform deployed as a DBaaS on AWS and is fully managed by Redis.

6. Redis Enterprise Cloud is deployed within a VPC in a standard AWS account that is created by Redis.
7. For security reasons, Redis Enterprise Cloud is deployed in a private subnet that can be accessed at both private and public endpoints. We recommend that you connect your client applications to Redis on private endpoints. If you plan to use a public endpoint, we strongly recommend that you enable TLS to encrypt the data between your client applications and Redis Enterprise Cloud.

The Redis migration methodology aligns with the AWS migration methodology, which is illustrated in Mobilize your organization to accelerate large-scale migrations on the AWS Prescriptive Guidance website.

Automation and scale

The environment setup tasks for the migration can be automated through AWS Landing Zone and infrastructure as code (IaC) templates for automation and scale. These are discussed in the Epics section of this pattern.

Tools

Based on your data migration requirements, you can choose from a selection of technological options to migrate your data to Redis Enterprise Cloud on AWS. The following table describes and compares these tools.

Tool	Description	Advantages	Disadvantages
RDB export and import	You export the data from the source (for example, Redis OSS or Redis Enterprise Software) database in the form of RDB files. If your database is provided through a Redis OSS Cluster, you export each master shard to an RDB.	• Simple. • Works with any Redis-based solution that can export data in RDB format as a source (includin g Redis OSS and Redis Enterprise Software). • Achieves data consistency with a simple process.	• Doesn't address data transform ation requirements or support logical database merges. • Time-consuming for larger datasets. • No delta migration support can lead to longer downtime.

You then import all the RDB files in one step. If your source database is based on an OSS Cluster but your target database isn't using the OSS Cluster API, you have to change your application source code to use a standard Redis client library.

Data transformation requirements or logical database merges require a more complex process, which is explained under *Logical database merge* later in this table.

[Redis replication feature](#) (active-passive)	You can continuously replicate data from a Redis OSS, Enterprise Software, or Enterprise Cloud database to a Redis Enterprise Cloud database. After the initial synchronization, the Redis replication feature (`ReplicaOf`) performs a delta migration, which means that there's nearly no observed application downtime. The Redis replication feature is intended to be used in an active-passive way. The target is assumed to be passive and gets fully resynchronized (flushed and synchronized from the source database). Therefore, switching between the source and the target is somewhat more complicated. It's possible to replicate from a Redis OSS Cluster to a	• Supports continuous replication (initial data load followed by deltas). • Nearly no downtime (depends on replication lag). • Achieves data consistency.	• Only one site is intended to be active, so switching between sites is more complicated. • Supports a maximum of 32 master shards when you migrate from an OSS Cluster.

	standard clustered Redis Enterprise Cloud database by specifying all the master shards of the OSS Cluster as sources. However, the Redis replicati on feature allows a maximum of 32 source databases.		
AWS DMS	You can use AWS DMS to migrate data from any supported source database to a target Redis data store with minimal downtime. For more information, see Using Redis as a target for AWS DMS in the AWS DMS documentation.	• Supports the migration of both NoSQL and SQL data sources. • Works well with other AWS services. • Supports live migration and change data capture (CDC) use cases.	• Redis key-value s cannot contain special characters such as %. • Doesn't support the migration of data that has special characters in rows or in field names. • Doesn't support full large binary object (LOB) mode.

Logical database merge	Special database merge requirements might require a custom data migration solution. For example, you might have four logical databases (`SELECT 0..3`) in Redis OSS, but you might want to use a single database endpoint instead of moving the data to multiple Redis Enterprise Cloud databases. Redis Enterprise doesn’t support selectable logical databases, so you would have to transform the source database’s physical data model. For example, you could map each database index to a prefix (`0` to `usr`, `1` to `cmp`, and so on), and then use a migration script or an extract, transform, and load (ETL) tool to output an RDB file, which you can then import into the target database.	• Granular control on shaping the data during migration to the target system by using custom scripts.	• If you decide not to complete the migration, rollback can be very challenging, especially if newer data has to be rolled back to source systems. • Cost to build can be high if the goal is to build a one-off solution for a one-time migration. • Maintenance costs for code, infrastructure, development time, and other areas can be high if migration requirements change frequently.

In addition, you can use the following tools and services from AWS.

Assessment and discovery tools:

- AWS Application Discovery Service
- Migration Evaluator

Application and server migration tools:

- AWS Application Migration Service

Database migration tools:

- AWS Schema Conversion Tool (AWS SCT)
- AWS Database Migration Service (AWS DMS)

Data migration tools:

- AWS Storage Gateway
- AWS DataSync
- AWS Direct Connect
- AWS Snowball
- Amazon Data Firehose

Migration management:

- AWS Migration Hub

AWS Partner solutions:

- AWS Migration Competency Partners

Epics

Complete discovery and assessment tasks

Task	Description	Skills required
Identify workloads.	Identify the suitable candidate workloads that you want to migrate. Consider the following before you choose a workload for migration: • What is the business value in migrating or not migrating this workload? • Is there a contingency plan if this workload doesn't successfully migrate to the target system? Ideally, choose a workload that has maximum business impact with minimum risks involved. Keep the overall process iterative and migrate in small increments.	Data architect, Business champions, Migration project sponsors
Identify data sources and requirements; design data model.	Redis runs a workshop to accelerate discovery and to define migration planning for the project. As a part of this workshop, Redis teams identify the data sources and source data model requireme nts, and analyze how these can be remodeled in Redis Enterprise Cloud.	Redis solutions architect

Task	Description	Skills required
	The Redis migration team (Professional Services) performs a detailed data model design exercise with your organization. As a part of this exercise, the Redis team: • Identifies target Redis data structures. • Defines the data mapping strategy. • Documents the migration approach and recommend ations. • Reviews and finalizes the data model with the stakeholders.	

Task	Description	Skills required
Identify the characteristics of the source database.	Identify the Redis product that is used in the source and target environments. For example: • Is the source database an OSS Cluster database, a standalone Redis database, or a Redis Enterprise database? • Will the target database be a Redis Enterprise standard database or an OSS Cluster-compatible database? • What are the implications concerning the application source code?	Data architect
Gather current system SLA and other sizing metrics.	Determine the current service-level agreements (SLAs) expressed in terms of throughput (operations per second), latency, overall memory size per database, and high availability (HA) requirements.	Data architect

Task	Description	Skills required
Identify the characteristics of the target system.	Determine the answers to these questions: • How much data has to be migrated? • How long does it take to migrate the given amount of data? • What are the downtime requirements for the migration? Is it acceptable for your service or applicati on to be unavailable for a specific period? If so, for how long? • How consistent should the migrated data be? Can the target database be in a slightly inconsistent (outdated) state? • Does data have to be transformed before it is loaded to the target database? (For example, you might want to convert selectable DB indexes to prefixes before migration.) • Is the source database reachable from the target database's host (for example, from a peer VPC or from a public endpoint using encryption)?	Data architect, Redis solutions architect (optional)

Task	Description	Skills required
	• Complete a data sizing and Redis Cluster sizing exercise with a Redis technical architect. • Identify networking requirements, infrastru cture requirements, software versions, and software licensing, and procure any components before the migration. • Are there any security concerns associated with the transfer of this data?	
Identify dependencies.	Identify the upstream and downstream dependenc ies of the current system to be migrated. Make sure that the migration work is in alignment with other dependent system migration s. For example, if you're planning to migrate other business applications from on premises to the AWS Cloud, identify these applications and align them based on project goals, timelines, and stakeholders.	Data architect, enterprise architect

Task	Description	Skills required
Identify migration tools.	Depending on your data migration requirements (such as source data or downtime requirements), you can use any of the tools described previously in the Tools section. In addition, you can use: • Bidirectional (active-active) replication by using CRDB deployment. • Custom export/import scripts (for example, by using `DUMP/RESTORE` commands). • Additional export/import tools and helper tools such as RIOT, ECstats2, or ETL tools. • IaC tools such as Terraform or AWS CloudFormation templates.	Migration solutions architect, Redis solutions architect
Create a contingency plan.	Establish a contingency plan to roll back, in case you encounter problems during migration.	Project management, Technical teams, including architect

Complete security and compliance tasks

Task	Description	Skills required
Secure the Redis administration console.	To secure the administration console, follow the instructions in the Redis documentation.	IT infrastructure administrator
Secure the Redis database.	See the following pages in the Redis documentation to: • Define role-based access control. • Define network security. • Enable TLS.	
Secure Redis Cloud APIs.	When you enable the API, you can manage the API keys for all owners of your Redis Cloud account. For an overview of the security features of the API, see the API authentication documentation on the Redis website.	IT infrastructure administrator

Set up the new environment

Task	Description	Skills required
Set up a new environment on AWS.	This task includes: • AWS Landing Zone setup activities. The landing zone supports: • Multi-account deployments	IT or DevOps engineer

Task	Description	Skills required
	- Minimum security baseline - Automated way to provision new accounts with a security baseline and ISV prerequisites (networking, security configuration, and so on) - Notifications, centralized logging, and monitoring - ISV software configuration activities. This includes configurations that need to be included in the migration, such as product and workload settings and changes. - IaC activities such as configuring or customizi ng AWS CloudFormation or Terraform templates.	

Task	Description	Skills required
Deploy the migration architecture.	1. Set up Redis Enterprise Cloud on AWS. 2. Install migration tools such as RIOT or AWS DMS. See the Tools section for a list of available tools. 3. Establish connectivity between the application, migration, and database layers. 4. Create a sample workload that can flow through each layer and migrate a small set of sample data. You are now ready to run the actual data migration pipelines and test them.	IT or DevOps engineer

Set up networking

Task	Description	Skills required
Establish connectivity.	Establish connectivity between the on-premises infrastructure and AWS Cloud resources. Use security groups, AWS Direct Connect, and other resources to achieve this functionality. For more information, see Connect Your Data Center to AWS on the AWS website.	IT or DevOps engineer

Task	Description	Skills required
Set up VPC peering.	Establish VPC peering between the VPCs that run business applications (or the EC2 instances that run migration tools or the AWS DMS replication server) and the VPC that runs Redis Enterprise Cloud. For instructions, see Get started with Amazon VPC in the Amazon VPC documentation, and Enable VPC peering in the Redis documentation.	IT or DevOps engineer

Migrate data

Task	Description	Skills required
Choose a data migration tool.	Review the table in the Tools section to see descriptions, advantages, and disadvantages of these tools: • RDS export and import • Redis replication feature (`ReplicaOf`) • AWS DMS • Logical database merge The following rows describe the data migration tasks associated with each tool.	Migration solutions architect

Task	Description	Skills required
Option 1: Use RDB export and import.	1. Disconnect the source: Stop the traffic on the source database (for example, by disconnecting business applications). 2. Export: Export the source database's data as an RDB file. 3. Stage: Upload the data to a location that is accessibl e to the Redis Enterprise Cloud instances on AWS (for example, you can upload them to an S3 bucket or FTP server). 4. Import: Import the RDB files (by listing them all in one import step) to your Redis Enterprise Cloud target database. 5. Cut over: Move to the target database (for example, by connecting your application connect to it). For more information, see the [Redis documentation].	Migration solutions architect, Redis solutions architect

Task	Description	Skills required
Option 2: Use the Redis replication feature (active-p assive).	1. Connect database: Establish a `ReplicaOf` link between the source and target databases. 2. Run an initial sync: Wait until the initial synchroni zation between the source and target databases is complete. 3. Disconnect the source: Stop the traffic on the source database (for example, by disconnecting the application). 4. Run delta replication: Wait until the delta is replicated on the target database. 5. Cut over: Move to the target database (for example, by connecting your application to it). 6. Delete: Remove the `ReplicaOf` link between the source and target databases. For more information, see the Redis documentation.	Migration solutions architect, Redis solutions architect

Task	Description	Skills required
Option 3: Use AWS DMS.	1. Set up an AWS DMS replication instance: This instance performs all migration processes. For instructions: Working with an AWS DMS replication instance in the AWS DMS documentation. 2. Define the source database: Define the source endpoint. Test the connectivity between the source endpoint and the AWS DMS replication server. For instructions: Creating source and target endpoints in the AWS DMS documentation. 3. Set up the target database: Set up Redis Enterprise Cloud on AWS and set up the database to migrate to. 4. Define the target database: Define the target endpoint. Make sure that VPC peering is established between the VPC where AWS DMS is running and the VPC that hosts Redis Enterprise Cloud on AWS. Test the connectivity between the AWS DMS replication server and the target database.	Migration solutions architect, Redis solutions architect

Task	Description	Skills required
	5. Create an AWS DMS task: Create a task or a set of tasks to define the tables and replication processes you want to use to migrate the data. For instructions: [Working with AWS DMS tasks](#) in the AWS DMS documentation. 6. Migrate: Migrate the data by running the AWS DMS task. 7. Cut over: Move to the target database (for example, by connecting your application to it).	
Option 4: Use logical database merge.	This option involves using a migration script or ETL tool that can transform the source database's physical data model and generating an RDB file. Redis Professional Services can help with this step, if needed.	Migration solutions architect, Redis solutions architect

Migrate your application

Task	Description	Skills required
Align project management timelines and goals.	Align the migration project goals, milestones, and timelines of the application	Project management

Task	Description	Skills required
	layer with that of the Redis data migration project.	
Align testing activities.	After the application layer is migrated and modernized in the AWS Cloud, point the application layer to the newly migrated Redis Enterprise Cloud on AWS for testing.	Testing

Test

Task	Description	Skills required
Implement test plans.	Run the data migration routines and the scripts that were developed during the implementation phase in a testing environment, per test requirements, at your site.	Testing
Test data quality.	Test data quality after you migrate the data.	Testing
Test functionality.	Test data queries and the application layer to ensure that the application is performing at the same level as in the source system.	Testing

Cut over

Task	Description	Skills required
Make the cutover decision.	After all application-level and database-level testing is complete, the executive leadership team and stakeholders make the final decision regarding whether to cut over to the new environment on AWS based on the final results confirmed by the testing teams.	Project management, Business champions
Cut over to the AWS Cloud.	When you have confirmed that everything is in place, point the application layer to the newly migrated data and point clients to the new application layer that is running based on the new Redis Enterprise Cloud system on AWS.	IT or DevOps engineer, Data architect, Migration solutions architect, Redis solutions architect

Additional information

For standard security requirements for migrating Redis workloads to the AWS Cloud, see the Best Practices for Security, Identity, and Compliance on the AWS website, and the Redis Trust Center on the Redis website.

Migrate SAP ASE on Amazon EC2 to Amazon Aurora PostgreSQL-Compatible using AWS SCT and AWS DMS

Amit Kumar and Ankit Gupta, Amazon Web Services

Summary

This pattern describes how to migrate an SAP Adaptive Server Enterprise (SAP ASE) database that is hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance to Amazon Aurora PostgreSQL-Compatible Edition by using AWS Schema Conversion Tool (AWS SCT) and AWS Database Migration Service (AWS DMS). The pattern focuses on both data definition language (DDL) conversions for stored objects and data migration.

Aurora PostgreSQL-Compatible supports online transaction processing (OLTP) workloads. This managed service provides configurations that automatically scale on demand. It can automatically start up, shut down, scale up, or scale down your database based on your application's needs. You can run your database in the cloud without managing any database instances. Aurora PostgreSQL-Compatible provides a cost-effective option for infrequent, intermittent, or unpredictable workloads.

The migration process consists of two main phases:

- Converting the database schema by using AWS SCT
- Migrating the data by using AWS DMS

Detailed instructions for both phases are provided in the *Epics* section. For information about troubleshooting issues that are specific to using AWS DMS with SAP ASE databases, see Troubleshooting issues with SAP ASE in the AWS DMS documentation.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source SAP ASE database on an EC2 instance with server, database, and listener services up and running
- A target Aurora PostgreSQL-Compatible database

Limitations

- The port number for connections must be 5432.
- The huge_pages feature is on by default but can be modified.
- Point-in-time recovery (PITR) granularity is 5 minutes.
- Cross-Region replication is currently not available.
- The maximum storage size for an Aurora database is 128 TiB.
- You can create up to 15 read replicas.
- The table size limit is constrained only by the size of the Aurora cluster volume, so the maximum table size for an Aurora PostgreSQL-Compatible DB cluster is 32 TiB. We recommend that you follow best practices for table design, such as partitioning large tables.

Product versions

- Source database: AWS DMS currently supports SAP ASE 15, 15.5, 15.7, and 16.x. See the AWS DMS User Guide for the latest information about SAP ASE version support.
- Target database: PostgreSQL 9.4 and later (for version 9.x), 10.x, 11.x, 12.x, 13.x, and 14.x. See the AWS DMS User Guide for the latest supported PostgreSQL versions.
- Amazon Aurora 1.x or later. For the latest information, see Aurora PostgreSQL-Compatible releases and engine versions in the Aurora documentation.

Architecture

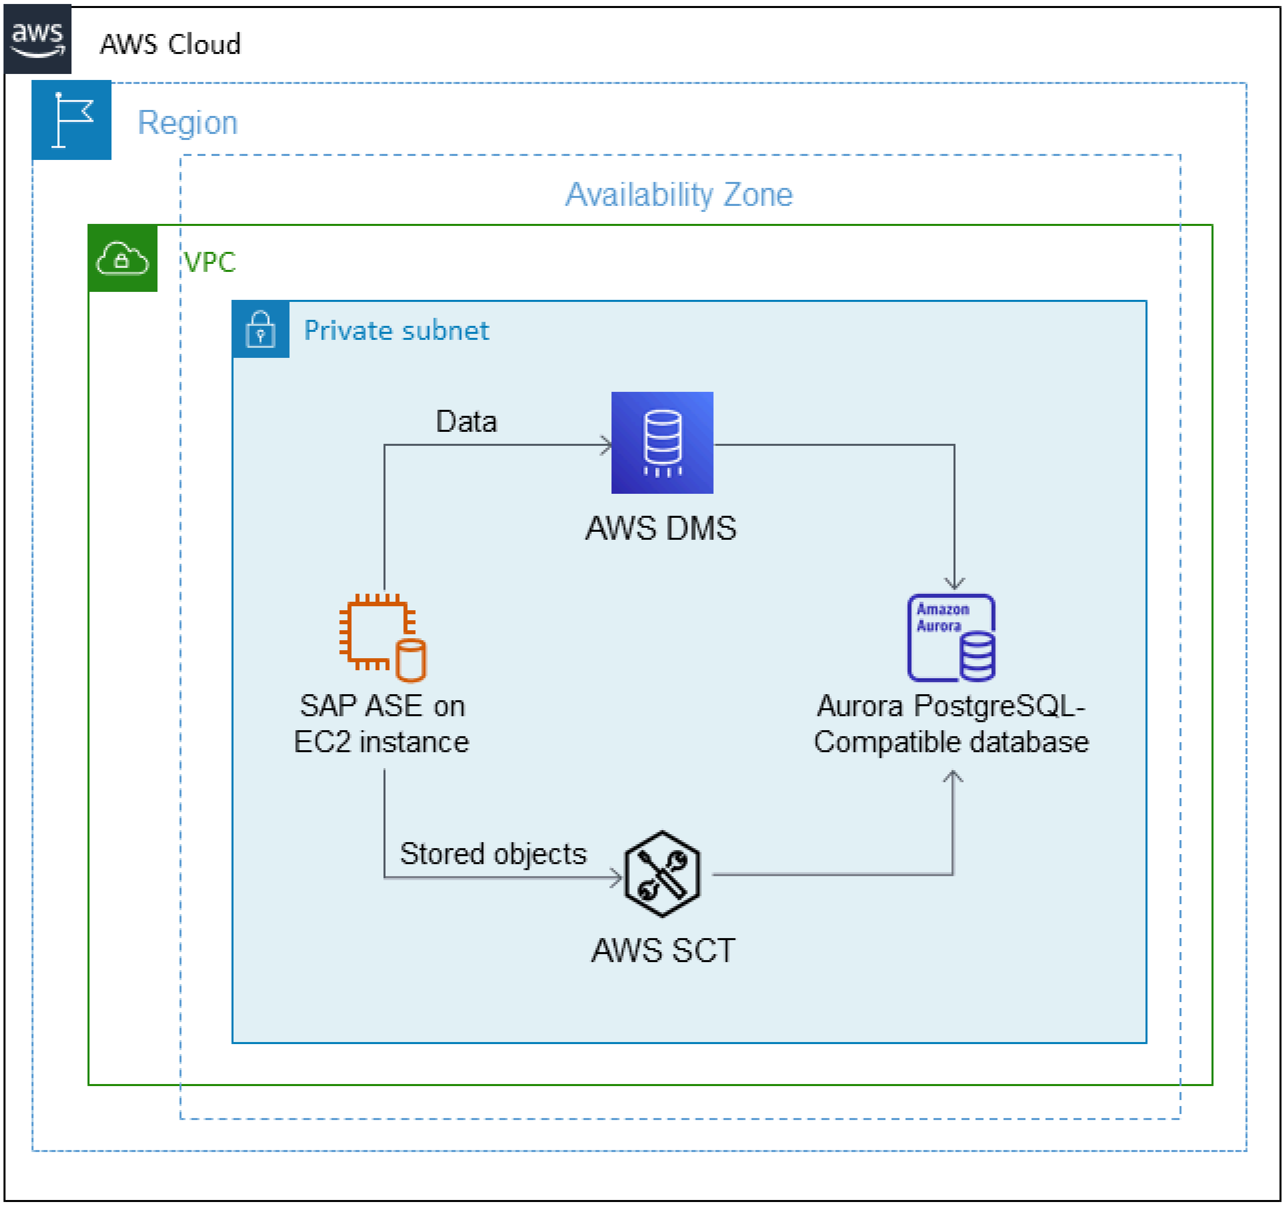
Source technology stack

- SAP ASE database running on Amazon EC2

Target technology stack

- Aurora PostgreSQL-Compatible database

Migration architecture



Tools

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and most of the custom code to a format that's compatible with the target database.
- AWS DMS supports several different source and target databases. For more information, see Sources for Data Migration and Targets for Data Migration in the AWS DMS documentation. For

the most comprehensive version and feature support, we recommend that you use the latest version of AWS DMS.

Epics

Set up the environment

Task	Description	Skills required
Configure network access in the source EC2 instance.	Set up security groups in the EC2 instance that hosts your source SAP ASE database. For instructions, see Amazon EC2 security groups for Linux instances in the Amazon EC2 documentation.	Systems administrator
Create your target Aurora PostgreSQL-Compatible DB cluster.	Install, configure, and launch an Aurora PostgreSQL-Compatible cluster for your target database. For more information, see Creating an Amazon Aurora DB cluster in the Aurora documentation.	DBA
Set up authorization for the target DB cluster.	Set up security groups and firewalls for the target database. For instructions, see Creating an Amazon Aurora DB cluster in the Aurora documentation.	DBA, Systems administrator

Convert your database schema with AWS SCT

Task	Description	Skills required
Launch AWS SCT.	Launch AWS SCT by following the instructions in the [AWS SCT documentation](). AWS SCT provides a project-based user interface to automatically convert the database schema of your SAP ASE source database into a format that's compatible with your target Aurora PostgreSQL-Compatible DB instance.	DBA
Create AWS SCT endpoints.	Create endpoints for the source SAP ASE and target PostgreSQL databases. For instructions, see the [AWS SCT documentation]().	DBA
Create an assessment report.	Create a database migration assessment report to evaluate the migration and detect any incompatible objects and functions. For instructions, see the [AWS SCT documentation]().	DBA
Convert the schema.	Convert the database schema by following the instructions in the [AWS SCT documentation]().	DBA

Task	Description	Skills required
Validate database objects.	If AWS SCT cannot convert a database object, it will identify its name and other details. You must convert these objects manually. To identify these mismatches, follow the instructions in the AWS blog post [Validate database objects after migrating from SAP ASE to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL]().	DBA

Analyze the AWS DMS migration

Task	Description	Skills required
Validate the source and target database versions.	Check the SAP ASE database versions for compatibility with AWS DMS. For more information, see Sources for AWS DMS and Targets for AWS DMS in the AWS DMS documentation.	DBA
Identify the requirements for the storage type and capacity.	Choose the appropriate storage capacity for the target database based on the size of your source database.	DBA, Systems administrator

Task	Description	Skills required
Choose the instance type, capacity, and other features of the replication instance.	Choose the instance type, capacity, storage features, and network features that meet your requirements. For guidance, see [Choosing the right AWS DMS replication instance for your migration] in the AWS DMS documentation.	DBA, Systems administrator
Identify network access security requirements.	Identify the network access security requirements for the source and target databases. Follow the guidance in [Setting up a network for a replication instance] in the AWS DMS documentation.	DBA, Systems administrator

Migrate the data

Task	Description	Skills required
Migrate the data by creating a migration task in AWS DMS.	To migrate data, create a task and follow the instructions in the [AWS DMS documentation.] We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.	DBA
Validate the data.	To validate that your data was migrated accurately from the	DBA

Task	Description	Skills required
	source database to the target database, follow the data validation guidelines provided in the AWS DMS documenta tion.	

Migrate the application

Task	Description	Skills required
Identify the application migration strategy.	Choose one of the seven strategies (7Rs) for migrating applications to the cloud.	DBA, App owner, Systems administrator
Follow the application migration strategy.	Complete the database tasks identified by the application team, including updating DNS connection details for the target database and updating dynamic queries.	DBA, App owner, Systems administrator

Cut over to the target database

Task	Description	Skills required
Switch the application clients over to the new infrastru cture.	Switch the connection from the source database to the target database. For more information, see the Cut over section of the *Migration strategy for relational databases*.	DBA, App owner, Systems administrator

Close the project

Task	Description	Skills required
Shut down the temporary AWS resources.	Terminate all migration tasks, replication instances , endpoints, and other AWS SCT and AWS DMS resources. For more information, see the [AWS DMS documentation]().	DBA, Systems administrator
Review and validate the project documents.	Validate all the steps in the project documentation to ensure that all tasks have been completed successfully.	DBA, App owner, Systems administrator
Close the project.	Close the migration project and provide any feedback.	DBA, App owner, Systems administrator

Migrate Windows SSL certificates to an Application Load Balancer using ACM

Chandra Sekhar Yaratha and Igor Kovalchuk, Amazon Web Services

Summary

The pattern provides guidance for using AWS Certificate Manager (ACM) to migrate existing Secure Sockets Layer (SSL) certificates from websites that are hosted on on-premises servers or Amazon Elastic Compute Cloud (Amazon EC2) instances on Microsoft Internet Information Services (IIS). The SSL certificates can then be used with Elastic Load Balancing on AWS.

SSL protects your data, affirms your identity, provides better search engine rankings, helps meet Payment Card Industry Data Security Standard (PCI DSS) requirements, and improves customer trust. Developers and IT teams that manage these workloads want their web applications and infrastructure, including the IIS server and Windows Server, to remain compliant with their baseline policies.

This pattern covers manually exporting existing SSL certificates from Microsoft IIS, converting them from Personal Information Exchange (PFX) format to the Private Enhanced Mail (PEM) format that ACM supports, and then importing them into ACM in your AWS account. It also describes how to create an Application Load Balancer for your application and configure the Application Load Balancer to use your imported certificates. HTTPS connections are then terminated on the Application Load Balancer, and you don't need further configuration overhead on the web server. For more information, see [Create an HTTPS listener for your Application Load Balancer](#).

Windows servers use .pfx or .p12 files to contain the public key file (SSL certificate) and its unique private key file. The Certificate Authority (CA) provides you with your public key file. You use your server to generate the associated private key file where the certificate signing request (CSR) was created.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) on AWS with at least one private and one public subnet in each Availability Zone used by your targets
- IIS version 8.0 or later running on Windows Server 2012 or later
- A web application running on IIS

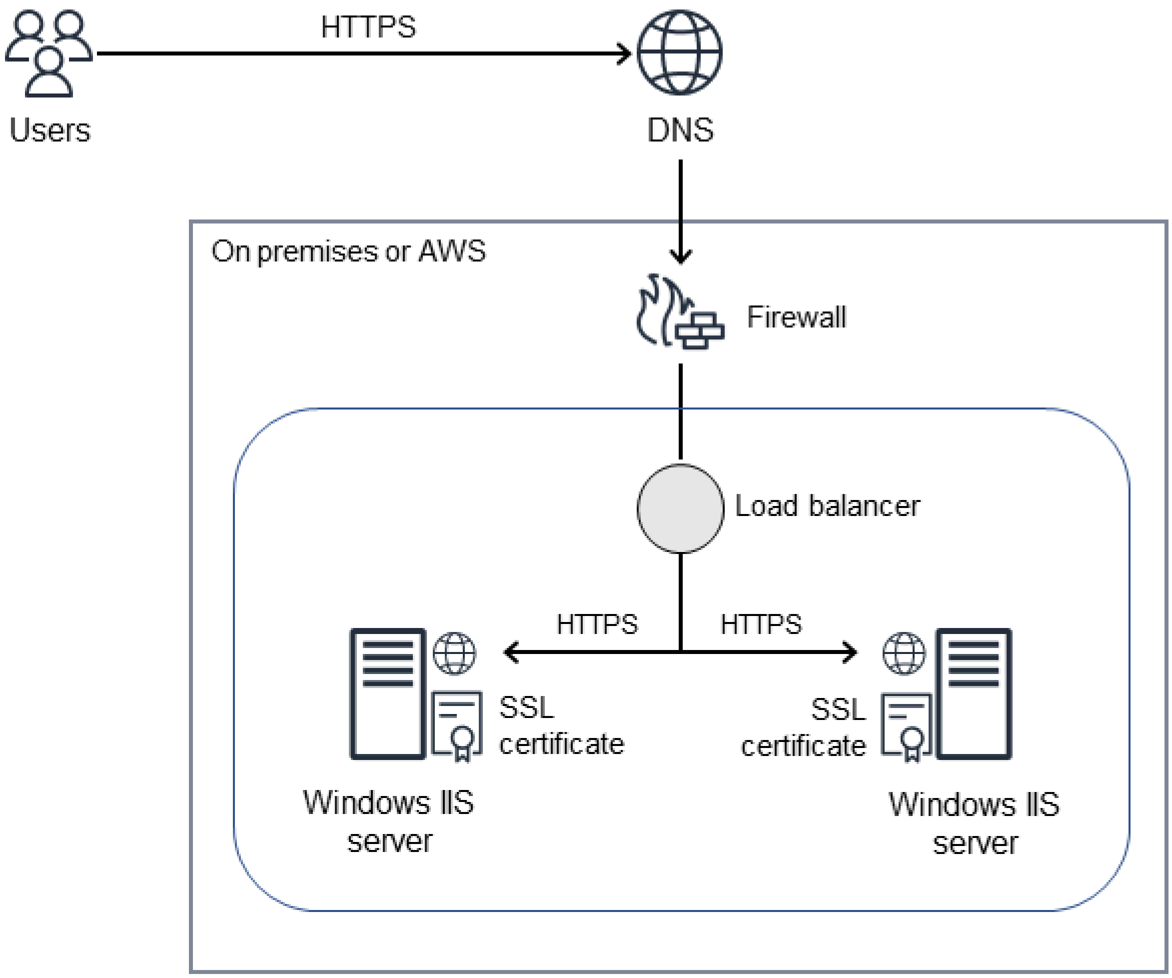
- Administrator access to the IIS server

Architecture

Source technology stack

- IIS web server implementation with SSL to ensure that data is transmitted securely in an encrypted connection (HTTPS)

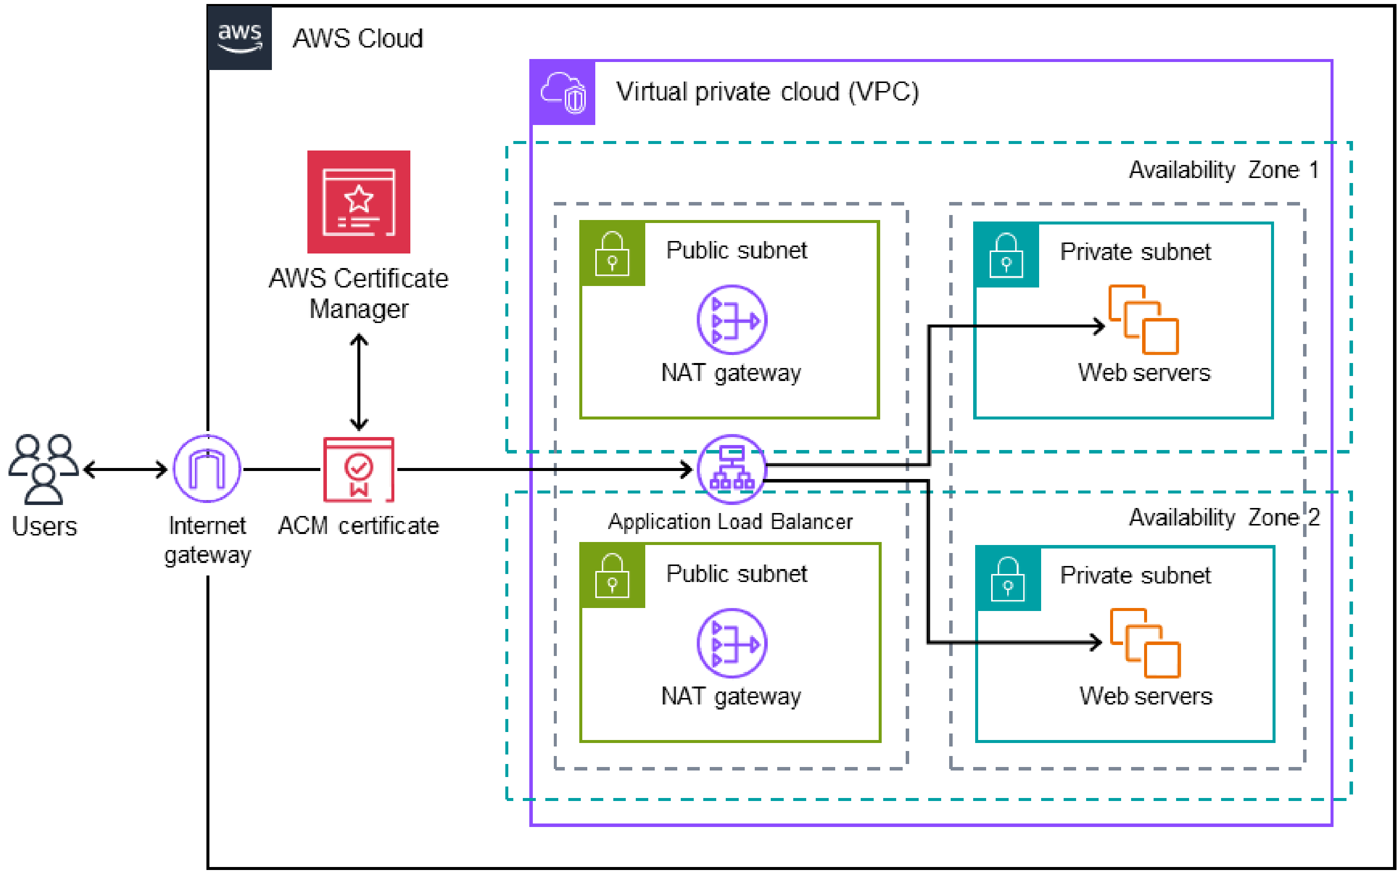
Source architecture



Target technology stack

- ACM certificates in your AWS account
- An Application Load Balancer configured to use imported certificates
- Windows Server instances in the private subnets

Target architecture



Tools

- AWS Certificate Manager (ACM) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across EC2 instances, containers, and IP addresses in one or more Availability Zones.

Best practices

- Enforce traffic redirects from HTTP to HTTPS.
- Configure security groups for your Application Load Balancer properly to allow inbound traffic only to specific ports.
- Launch your EC2 instances in different Availability Zones to ensure high availability.

- Configure your application's domain to point to the Application Load Balancer's DNS name instead of its IP address.
- Make sure that the Application Load Balancer has application-layer health checks configured.
- Configure the threshold for health checks.
- Use Amazon CloudWatch to monitor the Application Load Balancer.

Epics

Export a .pfx file

Task	Description	Skills required
Export the .pfx file from Windows Server.	To export the SSL certificate as a .pfx file from the on-premises IIS manager in Windows Server: 1. Choose **Start**, **Administrative**, **Internet Information Services (IIS) Manager**. 2. Select the server name, and under **Security**, double-click **Server Certificates**. 3. Choose the certificate that you want to export, and then choose **Export**. 4. In the **Export Certificate** box, choose a location, path, and name for your .pfx file. 5. Specify and confirm a password for your .pfx file.	Systems administrator

Task	Description	Skills required
	Note You need this password when you install the .pfx file. 6. Choose OK. Your .pfx file should now be saved to the location and path you specified.	

Convert the PFX-encoded certificate to PEM format

Task	Description	Skills required
Download and install the OpenSSL toolkit.	1. Download and install [Win32/Win64 OpenSSL](https://slproweb.com/products/Win32OpenSSL.html) from the Shining Light Productions website. 2. Add the location of the OpenSSL binaries to your system PATH variable, so the binaries can be available for command-line use.	Systems administrator
Convert the PFX-encoded certificate to PEM format.	The following steps convert the PFX-encoded, signed certificate file into three files in PEM format:	Systems administrator

Task	Description	Skills required
	• `cert-file.pem` contains the SSL/TLS certificate for the resource. • `privatekey.pem` contains the private key of the certificate with no password protection. • `ca-chain.pem` contains the root certificate of the CA. To convert the PFX encoded certificate: 1. Run Windows PowerShell. 2. Use the following command to extract the private key of the certificate from the PFX file. Enter the certificate password when prompted. `openssl pkcs12 -in <filename>.pfx -nocerts -out withpw-privatekey.pem` The command generates a PEM-encoded private key file named `privatekey.pem` . Enter a passphrase to protect the private key file when prompted.	

Task	Description	Skills required

	3. Run the following command to remove the passphrase. When prompted, provide the passphrase that you created in step 2.
	`openssl rsa -in withpw-privatekey.pem -out privatekey.pem`
	If the command is successful, it displays the message "writing RSA key."
	4. Use the following command to transfer the certificate from the PFX file to a PEM file.
	`openssl pkcs12 -in <file_name>.pfx -clcerts -nokeys -out cert-file.pem`
	This creates a PEM-encoded certificate file named `cert-file.pem` . If the command is successful, it displays the message "MAC verified OK."
	5. Create a CA chain file from the PFX file. The following command creates a CA	

Task	Description	Skills required
	chain file named `ca-chain.pem` . ```openssl pkcs12 -in <file_name>.pfx -cacerts -nokeys -chain -out ca-chain.pem``` If the command is successful, it displays the message "MAC verified OK."	

Import a certificate into ACM

Task	Description	Skills required
Prepare to import the certificate.	On the ACM console, choose **Import a certificate**.	Cloud administrator
Provide the certificate body.	For **Certificate body**, paste the PEM-encoded certificate that you want to import. For more information about the commands and steps described in this and other tasks in this epic, see Importing a certificate in the ACM documentation.	Cloud administrator
Provide the certificate private key.	For **Certificate private key**, paste the PEM-encoded, unencrypted private key	Cloud administrator

Task	Description	Skills required
	that matches the certificate's public key.	
Provide the certificate chain.	For **Certificate chain**, paste the PEM-encoded certificate chain, which is stored in the `CertificateChain.pem` file.	Cloud administrator
Import the certificate.	Choose **Review and import**. Confirm that the informati on about your certificate is correct, and then choose **Import**.	Cloud administrator

Create an Application Load Balancer

Task	Description	Skills required
Create and configure the load balancer and listeners.	Follow the instructions in the Elastic Load Balancing documentation to configure a target group, register targets, and create an Application Load Balancer and listener. Add a second listener (HTTPS) for port 443.	Cloud administrator

Troubleshooting

Issue	Solution
Windows PowerShell doesn't recognize the OpenSSL command even after you add it to the system path.	Check `$env:path` to make sure that it includes the location of the OpenSSL binaries. If it doesn’t, run the following command in PowerShell: `$env:path = $env:path + ";C:\OpenSSL-Win64\bin"`

Migrate a messaging queue from Microsoft Azure Service Bus to Amazon SQS

Nisha Gambhir, Amazon Web Services

Summary

This pattern describes how to migrate a .NET Framework or .NET Core web or console application from using the Microsoft Azure Service Bus queue messaging platform to Amazon Simple Queue Service (Amazon SQS).

Applications use messaging services to send data to, and receive data from, other applications. These services help build decoupled, highly scalable microservices, distributed systems, and serverless applications in the cloud.

Azure Service Bus queues are part of a broader Azure messaging infrastructure that supports queuing and publish/subscribe messaging.

Amazon SQS is a fully managed message queuing service that enables you to decouple and scale microservices, distributed systems, and serverless applications. Amazon SQS eliminates the complexity and overhead associated with managing and operating message-oriented middleware, and enables developers to focus on differentiating work. Using Amazon SQS, you can send, store, and receive messages between software components at any volume, without losing messages or requiring other services to be available.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A .NET Framework or .NET Core web or console application that uses Azure Service Bus queues (sample code attached)

Product versions

- .NET Framework 3.5 or later, or .NET Core 1.0.1, 2.0.0, or later

Architecture

Source technology stack

- A .NET (Core or Framework) web or console application that uses an Azure Service Bus queue to send messages

Target technology stack

- Amazon SQS

Tools

Tools

- Microsoft Visual Studio

Code

To create an AWS Identity and Access management (IAM) policy for Amazon SQS:

1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/.

2. In the navigation pane on the left, choose **Policies**, and then choose **Create policy**.

3. Choose the **JSON** tab, and paste the following code:

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Sid": "VisualEditor0",
         "Effect": "Allow",
         "Action": [
            "sqs:DeleteMessage",
            "sqs:GetQueueUrl",
            "sqs:ChangeMessageVisibility",
            "sqs:SendMessageBatch",
            "sqs:ReceiveMessage",
            "sqs:SendMessage",
            "sqs:GetQueueAttributes",
            "sqs:ListQueueTags",
            "sqs:ListDeadLetterSourceQueues",
            "sqs:DeleteMessageBatch",
```

```
                "sqs:PurgeQueue",
                "sqs:DeleteQueue",
                "sqs:CreateQueue",
                "sqs:ChangeMessageVisibilityBatch",
                "sqs:SetQueueAttributes"
            ],
            "Resource": "arn:aws:sqs:*:<AccountId>:*"
        },
        {
            "Sid": "VisualEditor1",
            "Effect": "Allow",
            "Action": "sqs:ListQueues",
            "Resource": "*"
        }
    ]
}
```

4. Choose **Review policy**, type a name, and then choose **Create policy**.

5. Attach the newly created policy to your existing IAM role or create a new role.

Epics

Set up Amazon SQS in AWS

Task	Description	Skills required
Create an IAM policy for Amazon SQS.	Create the IAM policy that will provide access to Amazon SQS. See the Code section for a sample policy.	System engineer
Create an AWS profile.	Create a new profile by running the AWS Tools for PowerShell command Set-AWSCredential. This command stores your access key and secret key in your default credentials file under the profile name you specify. Link the Amazon SQS policy	System engineer

Task	Description	Skills required
	you created earlier with this account. Keep the AWS access key ID and secret access key. These will be required in the next steps.	
Create an SQS queue.	You can create a standard queue or a first in, first out (FIFO) queue. For instructions, see the link in the References section.	System engineer

Revise your .NET application code

Task	Description	Skills required
Install AWS Toolkit for Visual Studio.	This toolkit is an extension for Microsoft Visual Studio and makes it easier for you to build and deploy .NET applications in AWS. For installation and usage instructions, see the link in the References section.	Application developer
Install the AWSSDK.SQS NuGet package.	You can install AWSSDK.SQS by choosing "Manage NuGet Package" in Visual Studio or by running the command "Install-Package AWSSDK.SQ S".	Application developer
Create an AWSCredentials object in your .NET applicati on.	The sample application in the attachment shows how to create a BasicAWSCredential	Application developer

Task	Description	Skills required
	s object, which inherits from AWSCredentials. You can use the access key ID and secret access key from earlier, or let the object pick these from the .aws folder as part of the user profile at run time.	
Create an SQS client object.	Create an SQS client object (AmazonSQSClient) for .NET Framework. This is part of the Amazon.SQS namespace. This object is required instead of IQueueClient, which is part of the Microsoft.Azure.Se rviceBus namespace.	Application developer
Call the SendMessageAsync method to send messages to the SQS queue.	Change the code that sends the message to the queue to use the amazonSqsClient.Se ndMessageAsync method. For details, see the attached code sample.	Application developer
Call the ReceiveMessageAsyn c method to receive messages from the SQS queue.	Change the code that receives the message to use the amazonSqsClient.ReceiveMess ageAsync method. For details, see the attached code sample.	Application developer

Task	Description	Skills required
Call the DeleteMessageAsync method to delete messages from the SQS queue.	To delete messages, change the code from the queueClie nt.CompleteAsync method to the amazonSqsClient.De leteMessageAsync method. For details, see the attached code sample.	Application developer

Related resources

- AWS SDK for .NET Developer Guide
- Messaging Using Amazon SQS
- Creating and Using an Amazon SQS Queue with the AWS SDK for .NET
- Send an Amazon SQS Message
- Receive a Message from an Amazon SQS Queue
- Delete a Message from an Amazon SQS Queue
- AWS Toolkit for Visual Studio

Additional information

This pattern includes two sample applications (see the attachments section):

- **AzureSbTestApp** includes code that uses the Azure Service Bus queue.
- **AmazonSqsTestApp** uses Amazon SQS. This is a console application that uses .NET Core 2.2 and includes examples for sending and receiving messages.

Notes:

- queueClient is an object of IQueueClient, which is part of the Microsoft.Azure.ServiceBus namespace (included in the Microsoft.Azure.ServiceBus NuGet package).
- amazonSqsClient is an object of AmazonSQSClient, which is part of the Amazon.SQS namespace (included in the AWSSDK.SQS NuGet package).

- Depending upon where the code is running, say if its running on EC2, the role needs to have permission to write into the SQS Queue.

Migrate a relational database to MongoDB Atlas on AWS

Battulga Purevragchaa and Igor Alekseev, Amazon Web Services

Babu Srinivasan, MongoDB

Summary

This pattern describes the steps for migrating from a relational database such as SQL Server, MySQL, or PostgreSQL to MongoDB Atlas in the AWS Cloud. It uses MongoDB Relational Migrator to help accelerate the data migration from relational databases to MongoDB Atlas.

The pattern accompanies the guide Migrating to MongoDB Atlas on AWS on the AWS Prescriptive Guidance website. It provides the implementation steps for one of the migration scenarios that are discussed in that guide. For additional migration scenarios, see the following patterns on the AWS Prescriptive Guidance website:

- Migrate a self-hosted MongoDB environment to MongoDB Atlas on AWS
- Stream data from IBM Db2, SAP, Sybase, and other databases to MongoDB Atlas on AWS

The pattern is intended for AWS System Integrator (SI) Partners and AWS users.

Prerequisites and limitations

Prerequisites

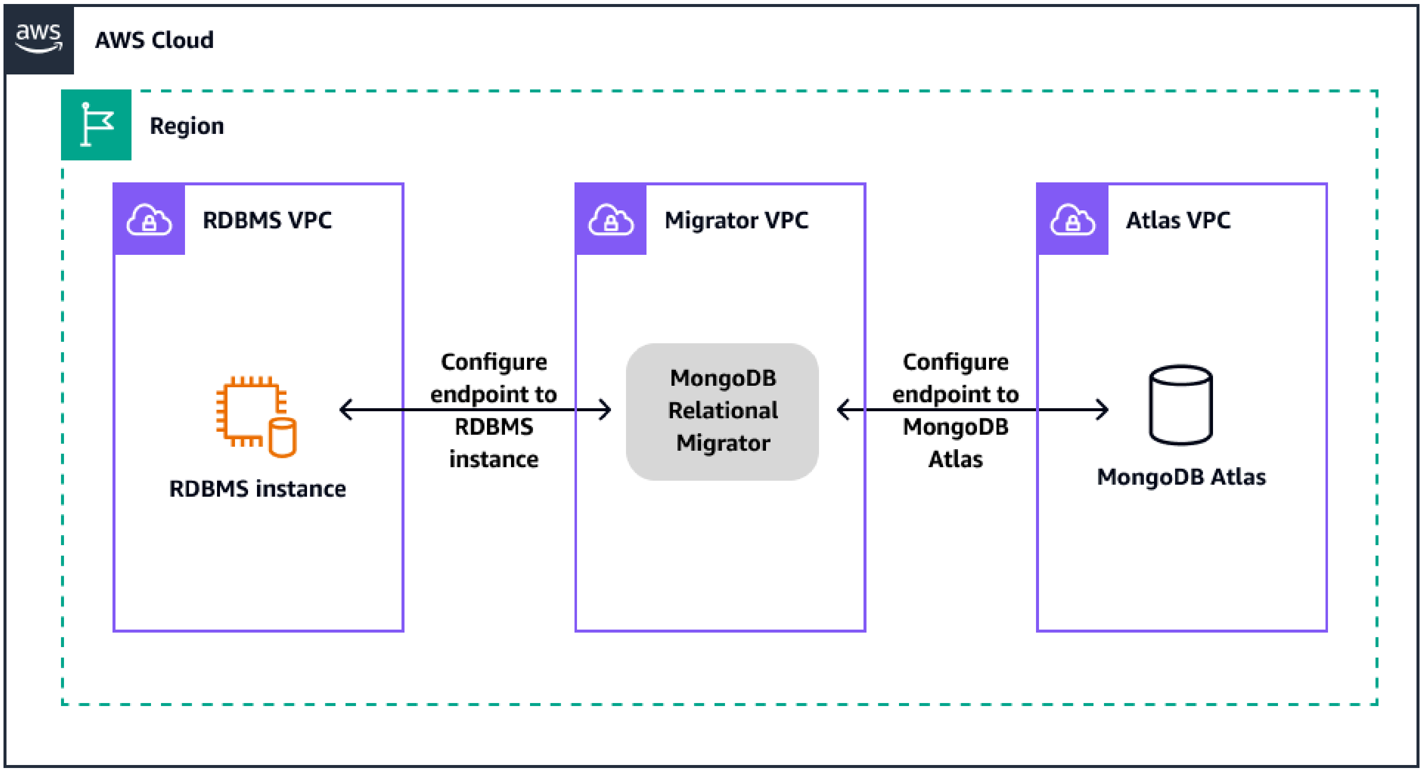
- A source relational database (Oracle Database, SQL Server, PostgreSQL, MySQL, SAP/Sybase ASE, and others) to migrate to MongoDB Atlas.
- Familiarity with relational databases, MongoDB Atlas, and AWS services. This pattern explains some of the migration steps at a high level. Additional details will be added in future versions.

Product versions

- MongoDB version 5.0 or later

Architecture

The following diagram shows the migration from a relational database management system (RDBMS) database to MongoDB Atlas on AWS.



For MongoDB Atlas reference architectures that support different usage scenarios, see [Migrating to MongoDB Atlas on AWS] on the AWS Prescriptive Guidance website.

Tools

- MongoDB Atlas is a fully managed database as a service (DBaaS) for deploying and managing MongoDB databases in the cloud.
- MongoDB Relational Migrator provides a smooth transition of data from traditional relational databases to MongoDB. It helps automate the conversion process and transforms the structured data model of relational databases into the flexible document format provided by MongoDB. The Relational Migrator preserves data integrity and relationships to simplify the migration. Organizations can take advantage of the scalability, performance, and versatility benefits that MongoDB provides while retaining the familiarity of their existing data.

Best practices

For best practices for using MongoDB on AWS, see the posts on the AWS Partner Network Blog.

Epics

Discovery and assessment

Task	Description	Skills required
Determine the parameters and size of the relational database.	Estimate the working set size by using the Relational Migrator recommendations and information from `db.stats()` for the total index space. Assume that a percentage of your data space will be accessed frequently. This task should take approximately one week. For more information and examples for this and the other stories in this epic, see the Related resources section.	App owner, DBA
Estimate network bandwidth requirements.	To estimate your network bandwidth requirements, multiply the average document size by the number of documents served per second. Consider the maximum traffic that any node on your cluster will bear as the basis. To calculate downstream data transfer rates from your cluster to client applications, use the sum of the total documents returned over a period of time. If your applications read from secondary nodes,	DBA

Task	Description	Skills required
	divide this number of total documents by the number of nodes that can serve read operations. To find the average document size for a database, use the `db.stats().avgObjSize` command. This task will typically take one day.	
Select the Atlas tier.	Follow the instructions in the [MongoDB documentation](#) to select the correct Atlas cluster tier.	DBA

Migrate a self-hosted MongoDB environment to MongoDB Atlas on AWS

Battulga Purevragchaa and Igor Alekseev, Amazon Web Services

Babu Srinivasan, MongoDB

Summary

This pattern describes the steps for migrating from a self-managed MongoDB environment (including MongoDB Community Server, Enterprise Server, Enterprise Advanced, mLab, or any managed MongoDB cluster) to MongoDB Atlas in the AWS Cloud. It uses the Atlas Live Migration Service to help accelerate the data migration from MongoDB to MongoDB Atlas.

The pattern accompanies the guide Migrating to MongoDB Atlas on AWS on the AWS Prescriptive Guidance website. It provides the implementation steps for one of the migration scenarios that are discussed in that guide. For additional migration scenarios, see the following patterns on the AWS Prescriptive Guidance website:

- Migrate a relational database to MongoDB Atlas on AWS
- Stream data from IBM Db2, SAP, Sybase, and other databases to MongoDB Atlas on AWS

The pattern is intended for AWS Systems Integrator (SI) Partners and AWS users.

Prerequisites and limitations

Prerequisites

- A source MongoDB Enterprise Advanced, Community Server, or other self-managed MongoDB environment to migrate to MongoDB Atlas.
- Familiarity with MongoDB, MongoDB Atlas, and AWS services. This pattern explains some of the migration steps at a high level. Additional details will be added in future versions.

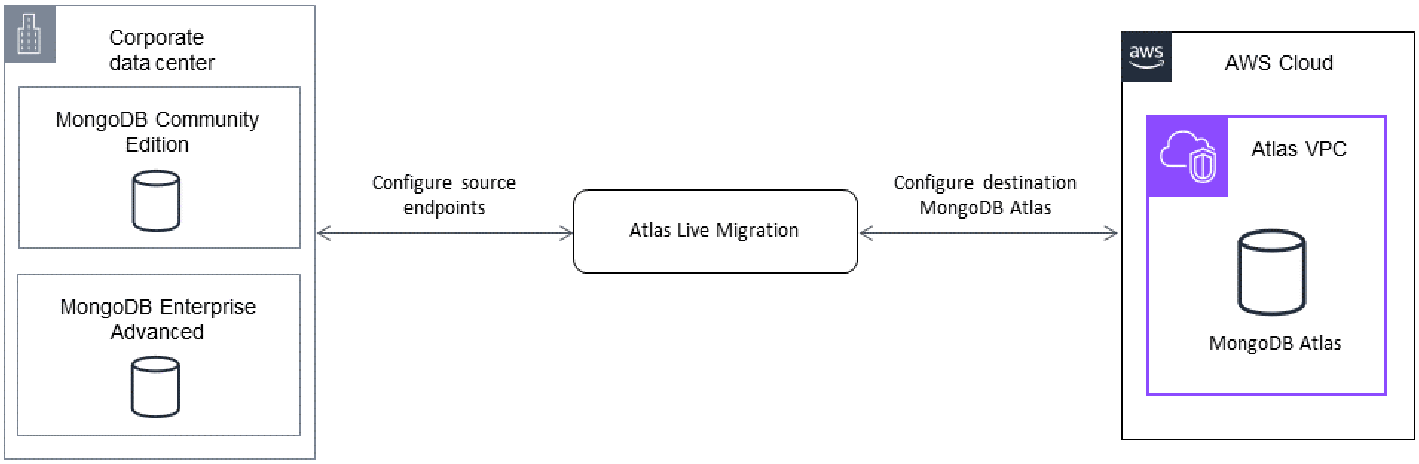
Product versions

- MongoDB version 6.0.13 or later

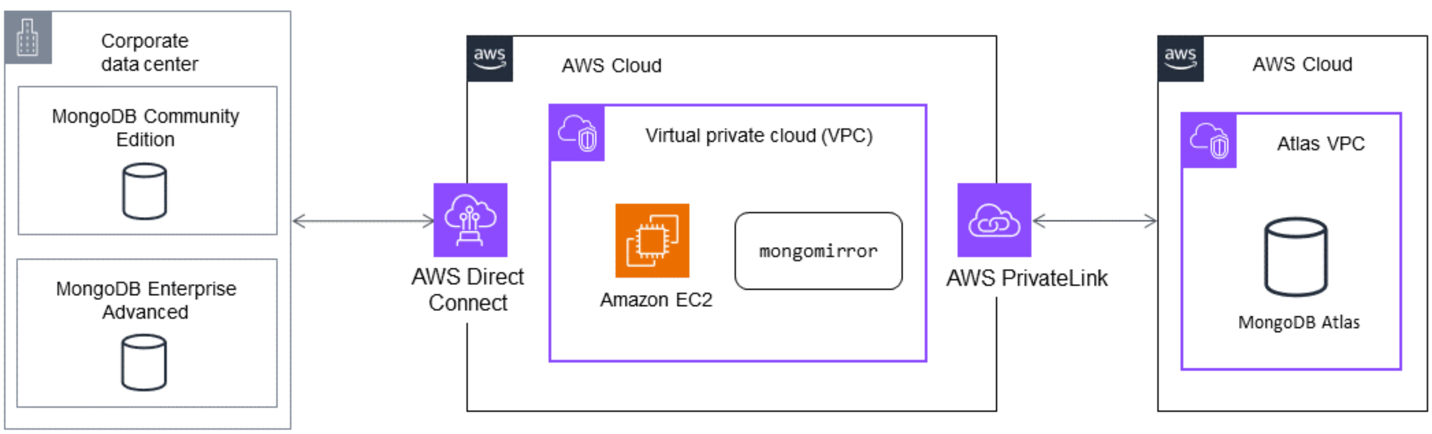
Architecture

The following diagram shows the Atlas Live Migration Service that is used to migrate data from a MongoDB Enterprise Advanced database and a MongoDB Community database to MongoDB

Atlas on AWS. Use this service when you need to migrate large, complex databases to MongoDB Atlas with minimal downtime and continuous data synchronization. This pattern uses Atlas Live Migration Service.



The following diagram shows the MongoDB mirror service (`mongomirror`) that you can also use to migrate data from a MongoDB Enterprise Advanced database and a MongoDB Community database to MongoDB Atlas on AWS over a secured [AWS PrivateLink](https://aws.amazon.com/privatelink/) connection. Use `mongomirror` for ongoing data replication between on-premises MongoDB and MongoDB Atlas. This tool is ideal for disaster recovery or phased migrations but is outside the scope of this pattern.



For more MongoDB Atlas reference architectures that support different usage scenarios, see Migrating to MongoDB Atlas on AWS on the AWS Prescriptive Guidance website.

Tools

- MongoDB Atlas is a fully managed database as a service (DbaaS) for deploying and managing MongoDB databases in the cloud.

- Atlas Live Migration Service is a free MongoDB utility that helps migrate databases to Atlas. This service keeps the source database in sync with the destination database until cutover. When you're ready to cut over, you stop your application instances, point them to the destination Atlas cluster, and restart them. To access this service, choose **Database options** from your MongoDB Atlas cluster.
- mongomirror is a tool for manually migrating data from an existing MongoDB replica set to a MongoDB Atlas replica set. `mongomirror` doesn't require you to shut down your existing replica set or applications, doesn't import user or role data, or copy the configuration database. You can download `mongomirror` from the MongoDB documentation.

Best practices

For best practices for using MongoDB on AWS, see the posts on the AWS Partner Network Blog.

Epics

Discovery and assessment

Task	Description	Skills required
Determine the cluster size.	Estimate the working set size by using the information from `db.stats()` for the total index space. Assume that a percentage of your data space will be accessed frequentl y. Or, you can estimate your memory requirements based on your own assumptio ns. This task should take approximately one week. For more information and examples for this and the other stories in this epic, see the Related resources section.	DBA, App owner
Estimate network bandwidth requirements.	To estimate your network bandwidth requireme	DBA

Task	Description	Skills required
	nts, multiply the average document size by the number of documents served per second. Consider the maximum traffic that any node on your cluster will bear as the basis. To calculate downstream data transfer rates from your cluster to client applications, use the sum of the total documents returned over a period of time. If your applications read from secondary nodes, divide this number of total documents by the number of nodes that can serve read operations. To find the average document size for a database, use the `db.stats().avgObjSize` command. This task will typically take one day.	
Select the Atlas tier.	Follow the instructions in the MongoDB documentation to select the correct Atlas cluster tier.	DBA

Set up a new MongoDB Atlas environment on AWS

Task	Description	Skills required
Create a new MongoDB Atlas cluster on AWS.	Log in to Atlas and open the **Overview** page for your project. Choose the **Create** button to create a cluster. For more information, see the MongoDB documentation.	DBA
Select AWS Regions and global cluster configuration.	Select from the list of available AWS Regions for your Atlas cluster. Configure global clusters if required. For more information, see the MongoDB documentation.	DBA
Select the cluster tier.	Select your preferred cluster tier. Your tier selection determines factors such as memory, storage, and IOPS specification.	DBA
Configure additional cluster settings.	Configure additional cluster settings such as MongoDB version, backup, and encryption options. For more information about these options, see the Related resources section.	DBA

Configure security and compliance

Task	Description	Skills required
Authenticate and authorize users.	You must create and authenticate the database users who will access the MongoDB Atlas clusters. To access clusters in a project, users must belong to that project, and they can belong to multiple projects. Atlas also supports authentication based on AWS Identity and Access Management (IAM). For more information, see the MongoDB documentation.	DBA
Create custom roles.	(Optional) Atlas supports creating custom roles in cases where the built-in Atlas database user permissio ns don't cover the set of permissions you want.	DBA
Set up VPC peering.	(Optional) Atlas supports virtual private cloud (VPC) peering with other VPCs on AWS.	AWS administrator
Set up an AWS PrivateLink endpoint.	(Optional) You can set up private endpoints on AWS by using AWS PrivateLink. For more information, see the Amazon VPC documentation.	AWS administrator
Enable two-factor authentic ation.	(Optional) Atlas supports two-factor authentication	AWS administrator

Task	Description	Skills required
	(2FA) to help users control access to their Atlas accounts.	
Set up user authentication and authorization with LDAP.	(Optional) Atlas supports performing user authentic ation and authorization with Lightweight Directory Access Protocol (LDAP).	AWS administrator
Set up unified AWS access.	(Optional) Some Atlas features, including Atlas Data Lake and encryption at rest using customer key management, use IAM roles for authentication.	AWS administrator
Set up encryption at rest using AWS KMS.	(Optional) Atlas supports using AWS Key Management Service (AWS KMS) to encrypt storage engines and cloud provider backups.	AWS administrator
Set up client-side field-level encryption.	(Optional) Atlas supports client-side field level encryption, including automatic encryption of fields.	AWS administrator

Migrate data

Task	Description	Skills required
Select your target replica set in MongoDB Atlas.	Navigate to the destinati on Atlas cluster and choose the ellipsis (...) button. On	DBA

Task	Description	Skills required
	the cluster list, this button appears below the cluster name. In cluster details, the button appears on the right, next to the **Connect** and **Configuration** buttons. For more information, see the [MongoDB documentation]().	
Add the Atlas Live Migration Service to the access list.	Add the Atlas Live Migration Service to the access list in your AWS source cluster. This helps prepare the source environment to connect to the target Atlas cluster.	DBA
Perform migration with Atlas Live Migration Service.	Choose **Start migration**. When the **Prepare to Cutover** button turns green, perform the cutover. Review Atlas cluster performance metrics. Consider updating the database connection in all application layers to point to the new database.	DBA

Configure operational integration

Task	Description	Skills required
Connect to the MongoDB Atlas cluster.	Make sure that MongoDB Atlas cluster connectivity works as expected.	App owner
Interact with cluster data.	Test the cluster data.	DBA

Task	Description	Skills required
Monitor your clusters.	Verify that your clusters are set up correctly.	DBA
Back up and restore cluster data.	Schedule backups with a regular cadence for cluster data.	DBA

Troubleshooting

Issue	Solution

Error: Could not reach specified source	• Make sure that you added the correct subnet ranges to the IP access list on the source cluster. You can find the four required subnet ranges in the Live Migration modal window.
	• Confirm that the hostname that you specified resolves to a public IP address. At a command prompt, use one of the following commands:
	`nslookup <hostname>`
	`ping <hostname>`
	• Make sure that you are not using a [VPC peering connection](), which isn't compatible with pull live migration. If a VPC peering connection is your only option, use `mongomirror` instead.

Error: Could not resolve hostname	No IP address was found for the given hostname. Confirm that the given hostname is correct and publicly accessible.

Issue	Solution
Any other error	If you encounter any other errors, see Troubleshoot Live Migration (Pull) in the MongoDB documentation.

Additional information

For additional information, see the following topics in the MongoDB documentation:

- To move data to a serverless instance, use Compass to export and import data, or migrate data with self-managed tools. To learn more, see Serverless Instance Limitations.
- To load data into a new cluster in Atlas, see Load Data into Atlas.
- To make a copy of your cluster for testing purposes, see Backup Methods for a Self-Managed Deployment.
- If the application that you want to migrate requires a near-continuous uptime, contact MongoDB Support and share your uptime requirements and cluster configuration.
- For additional information, see Migrate or Import Data.

Migrate an Oracle JD Edwards EnterpriseOne database to AWS by using Oracle Data Pump and AWS DMS

Thanigaivel Thirumalai, Amazon Web Services

Summary

You can migrate and run your JD Edwards EnterpriseOne database on Amazon Relational Database Service (Amazon RDS). When you migrate your database to Amazon RDS, AWS can take care of backup tasks and high availability setup, so you can concentrate on maintaining your EnterpriseOne application and its functionality. For a comprehensive list of key factors to consider during the migration process, see Oracle database migration strategies in AWS Prescriptive Guidance.

There are multiple ways to migrate an EnterpriseOne database, including:

- Using Oracle Universal Batch Engine (UBE) R98403 for schema and table creation, and using AWS Database Migration Service (AWS DMS) for migration
- Using DB native tools for schema and table creation and using AWS DMS for migration
- Using DB native tools for the migration of existing data (full load) and using AWS DMS for change data capture (CDC) tasks

This pattern covers the third option. It explains how to migrate your on-premises EnterpriseOne databases to Amazon RDS for Oracle by using Oracle Data Pump with AWS DMS and its CDC feature.

Oracle JD Edwards EnterpriseOne is an enterprise resource planning (ERP) solution for organizations that manufacture, construct, distribute, service, or manage products or physical assets. JD Edwards EnterpriseOne supports various hardware, operating systems, and database platforms.

When you migrate critical ERP applications such as JD Edwards EnterpriseOne, minimizing downtime is key. AWS DMS minimizes downtime by supporting both full load and continuous replication from the source database to the target database. AWS DMS also provides real-time monitoring and logging for the migration, which can help you identify and resolve any issues that could cause downtime.

When you replicate changes with AWS DMS, you must specify a time or system change number (SCN) as the starting point for reading changes from the database logs. It's crucial to keep these

logs accessible on the server for a designated amount of time (we recommend 15 days) to ensure that AWS DMS has access to these changes.

Prerequisites and limitations

Prerequisites

- An Amazon RDS for Oracle database provisioned in your AWS Cloud environment as the target database. For instructions, see the Amazon RDS documentation.
- An EnterpriseOne database that's running on premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance on AWS.

> **Note**
>
> This pattern is designed for migrating from on premises to AWS, but it was tested by using an EnterpriseOne database on an EC2 instance. If you plan to migrate from your on-premises environment, you must configure the appropriate network connectivity.

- Schema details. Identify which Oracle database schema (for example, DV920) you plan to migrate for EnterpriseOne. Before you start the migration process, gather the following details about the schema:
  - Schema size
  - The number of objects per object type
  - The number of invalid objects

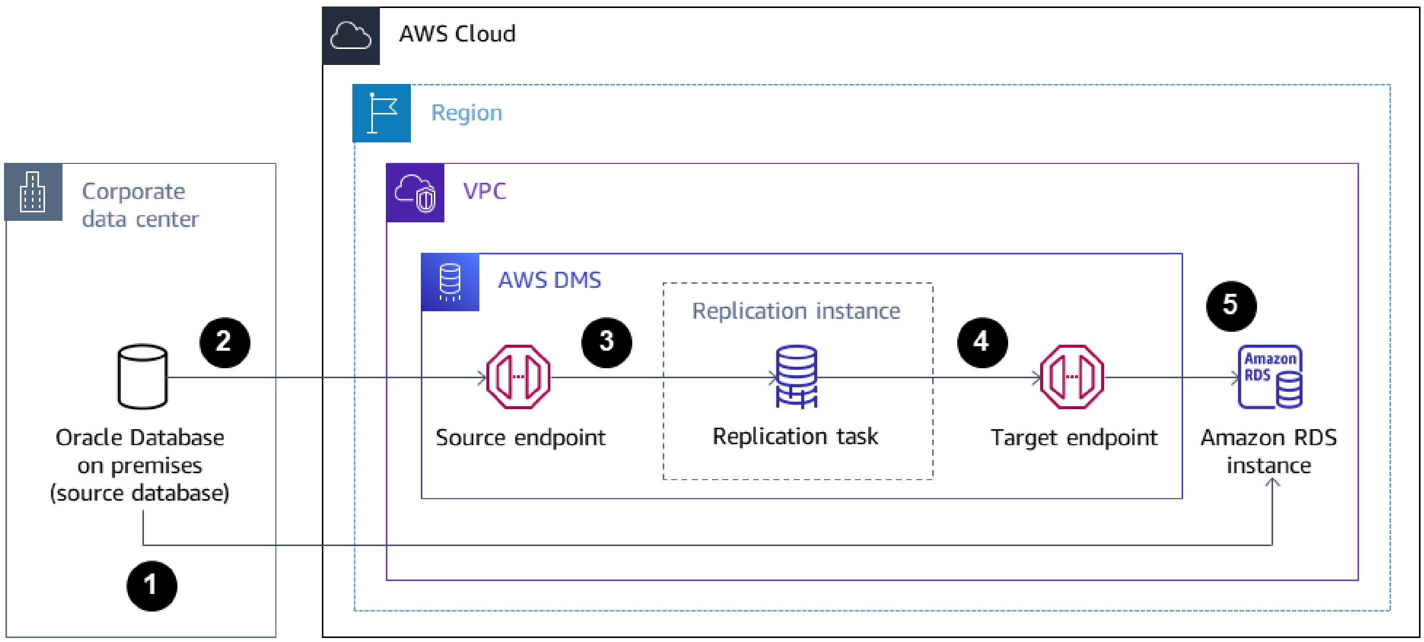
Limitations

- You have to create any schemas you want on the target Amazon RDS for Oracle database—AWS DMS doesn't create these for you. (The Epics section describes how to use Data Pump to export and import schemas.) The schema name must already exist for the target Oracle database. Tables from the source schema are imported to the user or the schema, and AWS DMS uses the administrator or system account to connect to the target instance. To migrate multiple schemas, you can create multiple replication tasks. You can also migrate data to different schemas on a target instance. To do this, use schema transformation rules on the AWS DMS table mappings.
- This pattern has been tested with a demo dataset. We recommend that you validate compatibility for your dataset and customization.

- This pattern uses an EnterpriseOne database that's running on Microsoft Windows. However, you can use the same process with other operating systems that are supported by AWS DMS.

Architecture

The following diagram shows a system that's running EnterpriseOne on an Oracle database as the source database, and an Amazon RDS for Oracle database as the target database. The data is exported from the source Oracle database and imported into the target Amazon RDS for Oracle database by using Oracle Data Pump, and replicated for CDC updates by using AWS DMS.



1. Oracle Data Pump extracts data from the source database, and the data is sent to the Amazon RDS for Oracle database target.
2. CDC data is sent from the source database to a source endpoint in AWS DMS.
3. From the source endpoint, the data is sent to the AWS DMS replication instance, where the replication task is performed.
4. After the replication task is complete, the data is sent to the target endpoint in AWS DMS.
5. From the target endpoint, the data is sent to the Amazon RDS for Oracle database instance.

Tools

AWS services

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Relational Database Service (Amazon RDS) for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.

Other services

- Oracle Data Pump helps you move data and metadata from one database to another at high speed.

Best practices

Migrating LOBs

If your source database contains large binary objects (LOBs) that need to be migrated to the target database, AWS DMS provides the following options:

- **Full LOB mode** – AWS DMS migrates all the LOBs from the source to the target database regardless of their size. Although the migration is slower than the other modes, the advantage is that data isn't truncated. For better performance, you can create a separate task on the new replication instance to migrate the tables that have LOBs that are larger than a few megabytes.
- **Limited LOB mode** – You specify the maximum size of LOB column data, which allows AWS DMS to pre-allocate resources and apply the LOBs in bulk. If the size of the LOB columns exceeds the size that is specified in the task, AWS DMS truncates the data and sends warnings to the AWS DMS log file. You can improve performance by using limited LOB mode if your LOB data size is within the limited LOB size.
- **Inline LOB mode** – You can migrate LOBs without truncating the data or slowing the performance of your task by replicating both small and large LOBs. First, specify a value for the `InlineLobMaxSize` parameter, which is available only when full LOB mode is set to `true`. The AWS DMS task transfers the small LOBs inline, which is more efficient. Then, AWS DMS migrates the large LOBs by performing a lookup from the source table. However, inline LOB mode works only during the full load phase.

Generating sequence values

During the AWS DMS CDC process, incremental sequence numbers aren't replicated from the source database. To avoid discrepancies in sequence values, you must generate the most recent sequence value from the source for all sequences, and apply it to the target Amazon RDS for Oracle database.

AWS Secrets Manager

To help manage your credentials, we recommend that you follow the instructions in the blog post Manage your AWS DMS endpoint credentials with AWS Secrets Manager.

Performance

- **Replication instances** – For guidance on choosing the best instance size, see Selecting the best size for a replication instance in the AWS DMS documentation.
- **Connectivity options** – To avoid latency issues, we recommend that you choose the right connectivity option. AWS Direct Connect provides the shortest path to AWS resources, because it is a dedicated connection between your corporate data centers and AWS. While in transit, your network traffic remains on the AWS global network and never goes over the internet. This reduces the chance of hitting bottlenecks or unexpected increases in latency when compared with using VPN or the public internet.
- **Network bandwidth** – To optimize performance, verify that your network throughput is fast. If you are using a VPN tunnel between your on-premises source database and AWS DMS, ensure that the bandwidth is sufficient for your workload.
- **Task parallelism** – You can speed up data replication by loading multiple tables in parallel during full load. This pattern uses of RDBMS endpoints, so this option applies only to the full load process. Task parallelism is controlled by the `MaxFullLoadSubTasks` parameter, which determines how many full load sub-tasks are run in parallel. By default, this parameter is set to 8, which means that eight tables (if selected in table mapping) are loaded together during full mode. You can adjust this parameter in the full-load task settings section of the JSON script for the task.
- **Table parallelism** – AWS DMS also enables you to load a single large table by using multiple parallel threads. This is particularly useful for Oracle source tables that have billions of records as well as multiple partitions and subpartitions. If the source table isn't partitioned, you can use column boundaries for parallel loads.
- **Split loads** – When you split loads across multiple tasks or AWS DMS instances, remember transaction boundaries when you capture changes.

Epics

Use Oracle Data Pump to export the EnterpriseOne schema

Task	Description	Skills required

Generate the SCN.	When the source database is active and in use by the EnterpriseOne application, initiate the data export with Oracle Data Pump. You must first generate a system change number (SCN) from the source database for both data consistency during the export with Oracle Data Pump and as a starting point for CDC in AWS DMS.
	
	To generate the current SCN from your source database, use the following SQL statement:
	
	`SQL> select current_scn from v$database;`
	
	`CURRENT_SCN`
	`-----------`
	`   30009727`
	
	Save the generated SCN. You will use the SCN when you export the data and to create the AWS DMS replication task.
		DBA

Create the parameter file.	To create a parameter file for exporting the schema, you can use the following code.	DBA

Task	Description	Skills required
	``` directory=DMS_DATA _PUMP_DIR logfile=export_dms.log dumpfile=export_dms_d ata.dmp schemas=<schema name> flashback_scn=<SCN from previous command> ``` **Note** You can also define your own `DATA_PUMP_DIR` by using the following commands, based on your requirements. ``` SQL> CREATE OR REPLACE DIRECTORY DMS_DATA_ PUMP_DIR AS '<Directo ry for dump>'; Directory created. SQL> GRANT READ, WRITE ON DIRECTORY DMS_DATA_ PUMP_DIR TO SYSTEM; Grant succeeded. ```	

Task	Description	Skills required
Export the schema.	To perform the export, use the `expdp` utility as follows: ``` C:\Users\Administr ator>expdp system/ ********@<DB Name> PARFILE='<Path to PAR file create above>' Export: Release 19.0.0.0.0 - Productio n on *** *** ** **:**:** **** Version 19.3.0.0.0 Copyright (c) 1982, 2019, Oracle and/or its affiliates. All rights reserved. Connected to: Oracle Database 19c Standard Edition 2 Release 19.0.0.0.0 - Productio n Starting "SYSTEM". Use Oracle Data Pump to import the EnterpriseOne schema

Task	Description	Skills required
Transfer the dump file to the target instance.	To transfer your files by using the `DBMS_FILE_TRANSFER` utility, you need to create a database link from the source database to the Amazon RDS for Oracle instance. After the link is established, you can use the utility to transfer the Data Pump files directly to the Amazon RDS instance. Alternatively, you can transfer the Data Pump files to [Amazon Simple Storage Service (Amazon S3)](#) and then import them into the Amazon RDS for Oracle instance. For	DBA

Task	Description	Skills required

	more information about this option, see the [Additional information](#) section.
	
	To create a database link ORARDSDB that connects to the Amazon RDS master user at the target DB instance, run the following commands on the source database:
	
	`sqlplus / as sysdba`
	
	`SQL*Plus: Release 19.0.0.0.0 on *** *** ** **:**:** ****`
	`Version 19.3.0.0.0`
	
	`Copyright (c) 1982, 2019, Oracle.  All rights reserved.`
	
	`Connected to:`
	`Oracle Database 19c Standard Edition 2 Release 19.0.0.0.0`
	`Version 19.3.0.0.0`
	
	`SQL> create database link orardsdb connect to admin identified by "******" using '(DESCRIPTION = (ADDRESS = (PROTOCOL = TCP)(HOST = orcl.******.us-east-1.rds.amazonaws.com)(PORT = 1521))(CONNECT_DATA = (SERVER = DEDICATED`	

Task	Description	Skills required
	```) (SERVICE_NAME = orcl)))'; Database link created. SQL> ```	
Test the database link.	Test the database link to make sure that you can connect to the Amazon RDS for Oracle target database by using `sqlplus`. ``` SQL> select name from v $database@orardsdb; NAME --------- ORCL ```	DBA

Task	Description	Skills required

Transfer the dump file to the target database.	To copy the dump file over to the Amazon RDS for Oracle database, you can either use the default `DATA_PUMP_DIR` directory or you can create your own directory by using the following code, which has to run on the target Amazon RDS instance:
	
	```exec rdsadmin.rdsadmin_util.create_directory(p_directory_name => 'DMS_TARGET_PUMP_DIR');```
	
	```PL/SQL procedure successfully completed.```
	
	The following script copies a dump file named `EXPORT_DMS_DATA.DMP` from the source instance to a target Amazon RDS for Oracle database by using the database link named `orardsdb`. You must run the script on the source database instance.
	
	```BEGIN DBMS_FILE_TRANSFER.PUT_FILE(source_directory_object => 'DMS_DATA_PUMP_DIR',```
		DBA

Task	Description	Skills required
	```source_file_name => 'EXPORT_DMS_DATA.DMP', destination_directory_object => 'DMS_TARGET_PUMP_DIR', destination_file_name => 'EXPORT_DMS_DATA.DMP', destination_database => 'orardsdb'); END; PL/SQL procedure successfully completed.```	
List the dump file in the target database.	After the PL/SQL procedure is complete, you can list the data dump file in the Amazon RDS for Oracle database by using the following code: ```select * from table (rdsadmin.rds_file_util.listdir(p_directory => 'DMS_TARGET_PUMP_DIR'));```	DBA

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create JDE-specific users in the target Instance.</td><td>Create a JD Edwards profile and role by using these commands in the target instance:

 Indexes>;
Tablespace created.
</pre></td><td>DBA, JDE CNC</td></tr>
</table>

Task	Description	Skills required
Initiate the import on the target database.	Before you start the import process, set up the roles, schemas, and tablespaces on the target Amazon RDS for Oracle database by using the data dump file. To perform the import, access the target database with the Amazon RDS primary user account, and use the connection string name in the `tnsnames.ora` file, which includes the Amazon RDS for Oracle Database `tns-entry`. If necessary, you can include a remap option to import the data dump file into a different tablespace or under a different schema name. To start the import, use the following code: `impdp admin@orardsdb directory=DMS_TARGET_PUMP_DIR logfile=import.log dumpfile=EXPORT_DMS_DATA.DMP` To ensure a successful import, check the import log file for any errors, and review details such as object count, row count, and invalid objects. If	DBA

Task	Description	Skills required
	there are any invalid objects, recompile them. Additionally, compare the source and target database objects to confirm that they match.	

Provision an AWS DMS replication instance with the source and target endpoints

Task	Description	Skills required
Download the template.	Download the AWS CloudFormation [DMS_instance.yaml](#) template to provision the AWS DMS replication instance and its source and target endpoints.	Cloud administrator, DBA
Start the stack creation.	1. Sign in to the AWS Management Console, and open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation. 2. Choose **Create stack**. 3. For **Specify template**, choose **Upload a template file**. 4. Choose **Choose file**. 5. Choose the `DMS_instance.yaml` file. 6. Choose **Next**.	Cloud administrator, DBA
Specify the parameters.	1. For **Stack name**, enter your stack name.	Cloud administrator, DBA

Task	Description	Skills required
	2. For **AWS DMS Instance Parameters**, enter the following parameters: • **DMSInstanceType** – Choose the required instance for the AWS DMS replication instance, based on your business needs. • **DMSStorageSize** – Enter the storage size for the AWS DMS instance, based on the size of your migration. 3. For **Source Oracle Database Configura tion**, enter the following parameters: • **SourceOracleEndpoi ntID** – The source Oracle database server name • **SourceOracleDataba seName** – The source database service name or session ID (SID) as applicable • **SourceOracleUserName** – The source database username (the default is `system`) • **SourceOracleDBPass word** – The source	

Task	Description	Skills required
	database username's password • **SourceOracleDBPort** – The source database port 4. For **Target RDS for Oracle Database Configura tion**, enter the following parameters: • **TargetRDSOracleEnd pointID** – The target RDS database endpoint • **TargetRDSOracleDat abaseName** – The target RDS database name • **TargetRSOracleUser Name** – The target RDS username • **TargetRDSOracleDBP assword** – The target RDS password • **TargetOracleDBPort** – The target RDS database port 5. For **VPC, Subnet and Security Group Configura tion**, enter the following parameters: • **VPCID** – The VPC for the replication instance • **VPCSecurityGroupId** – The VPC security group for the replication instance	

Task	Description	Skills required
	• **DMSSubnet1** – The subnet for Availability Zone 1 • **DMSSubnet2** – The subnet for Availability Zone 2 6. Choose **Next**.	
Create the stack.	1. On the **Configure stack options** page, for **Tags**, enter any optional values. 2. Choose **Next**. 3. On the **Review** page, verify the details, and then choose **Submit**. The provisioning should complete in approximately 5–10 minutes. It is complete when the AWS CloudForm ation Stacks page shows **CREATE_COMPLETE**.	Cloud administrator, DBA

Task	Description	Skills required
Set up the endpoints.	1. Open the AWS DMS console at https://console.aws.amazon.com/dms/v2/. 2. For **Resource managemen t**, choose **Replication instances**, and then review the replication instances. 3. For **Resource managemen t**, choose **Endpoints**, and then review the endpoints.	Cloud administrator, DBA
Test connectivity.	After the source and target endpoints shows the status as **Active**, test the connectiv ity. Choose **Run test** for each endpoint (source and target) to make sure that the status shows as successful.	Cloud administrator, DBA

Create an AWS DMS replication task for live replication

Task	Description	Skills required
Create the replication task.	Create the AWS DMS replicati on task by using the following steps: 1. Open the AWS DMS console at https://console.aws.amazon.com/dms/v2/. 2. In the navigation pane, under **Migrate Data**,	Cloud administrator, DBA

Task	Description	Skills required
	choose **Database migration task**. 3. In the **Task configuration** box, for **Task identifier**, enter your task identifier. 4. For **Replication instance**, choose the DMS replication instance that you created. 5. For **Source database endpoint**, choose your source endpoint. 6. For **Target database endpoint**, choose your target Amazon RDS for Oracle database. 7. For **Migration type**, choose **Replicate data changes only**. If you receive a message that supplemen tal logging needs to be turned on, follow the instructions in the Troubleshooting section. 8. In the **Task settings** box, choose **Specify log sequence number**. 9. For **System change number**, enter the Oracle database SCN that you generated from the source Oracle database. 10. Choose **Enable validation**.	

Task	Description	Skills required
	11. Choose **Enable CloudWatch Logs**. By activating this feature, you can validate the data and [Amazon CloudWatch](https://aws.amazon.com/cloudwatch/) logs to review the AWS DMS replication instance logs. 12. Under **Selection rules**, complete the following: • For **Schema**, choose **Enter a schema**. • For **Schema name**, enter the JDE Schema name (for example: **DV920**). • For **Table name**, enter **%**. • For **Action**, choose **Include**. 13. Choose **Create task**. After you create the task, AWS DMS migrates ongoing changes to the Amazon RDS for Oracle database instance from the SCN that you provided under CDC start mode. You can also verify the migration by reviewing the CloudWatch logs.	

Task	Description	Skills required
Repeat the replication task.	Repeat the previous steps to create replication tasks for other JD Edwards schemas that are part of the migration.	Cloud administrator, DBA, JDE CNC administrator

Validate the database schema on the target Amazon RDS for Oracle database

Task	Description	Skills required
Validate the data transfer.	After the AWS DMS task starts, you can check the **Table statistics** tab on the **Tasks** page to see the changes made to the data. You can monitor the status of ongoing replication in the console on the **Database migration tasks** page. For more information, see AWS DMS data validation.	Cloud administrator, DBA

Cut over

Task	Description	Skills required
Stop replication.	Discontinue the replicati on procedure and stop the source application services.	Cloud administrator, DBA
Launch the JD Edwards application.	Launch the target JD Edwards presentation and logic tier application on AWS, and	DBA, JDE CNC administrator

Task	Description	Skills required
	direct it to the Amazon RDS for Oracle database. When you access the applicati on, you should notice that all connections are now establish ed with the Amazon RDS for Oracle database.	
Turn off the source database.	After you confirm that there are no more connections, you can turn the source database off.	DBA

Troubleshooting

Issue	Solution

You receive a warning message to enable [supplemental logging](https://docs.aws.amazon.com/dms/latest/userguide/CHAP_Source.Oracle.html#CHAP_Source.Oracle.Self-Managed.Configuration.SupplementalLogging) in the source database for on-going replication	Enter these commands to enable supplemen tal logging:
	
	`SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (ALL) COLUMNS;`
	`SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (PRIMARY KEY) COLUMNS;`
	`SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (UNIQUE) COLUMNS;`
	`SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (FOREIGN KEY) COLUMNS;`
	`SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (PRIMARY KEY) COLUMNS;`
	`SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (UNIQUE) COLUMNS;`

AWS DMS has supplemental logging turned off.	Supplemental logging is turned off by default in AWS DMS. To turn it on for a source Oracle endpoint:

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td></td><td>

Sign in to the AWS Management Console and open the AWS DMS console at https://console.aws.amazon.com/dms/v2/.
Choose Endpoints.
Choose the Oracle source endpoint that you want to add supplemental logging to.
Choose Modify.
Choose Advanced, and then add the following code to the Extra connection attributes text box:
<pre><code>addSupplementalLogging=Y</code></pre>
Choose Modify.

</td></tr>
<tr><td>Supplemental logging isn’t enabled at the CDB level.</td><td>

Enter this command:
<pre><code>SQL> alter session set container =
 CDB$ROOT;

Session altered.</code></pre>
Repeat the steps to enable supplemental logging.

</td></tr>
<tr><td>You receive the error message: "Test Endpoint failed: Application-Status: 1020912, Applicati on-Message: LogMiner is not supported in Oracle PDB environment Endpoint initializ ation failed."</td><td>
If you encounter this error message, you can use Binary Reader instead of LogMiner.
Under Endpoint settings, add this line to the extra connection attributes for your source database:
<pre><code>useLogMinerReader=N;useBfile=Y;</code></pre>
</td></tr>
</table>

Additional information

Transfer files using Amazon S3

To transfer the files to Amazon S3, you can use the AWS CLI or the Amazon S3 console. After you transfer the files to Amazon S3, you can use the Amazon RDS for Oracle instance to import the Data Pump files from Amazon S3.

If you choose to transfer the dump file using Amazon S3 integration as an alternate method, perform the follow steps:

1. Create an S3 bucket.
2. Export the data from the source database using Oracle Data Pump.
3. Upload the Data Pump files to the S3 bucket.
4. Download the Data Pump files from the S3 bucket to the target Amazon RDS for Oracle database.
5. Perform the import using the Data Pump files.

> **Note**
>
> To transfer large data files between S3 and RDS instances, we recommend that you use the Amazon S3 Transfer Acceleration feature.

Migrate an Oracle PeopleSoft database to AWS by using AWS DMS

sampath kathirvel, Amazon Web Services

Summary

Oracle PeopleSoft is an enterprise resource planning (ERP) solution for enterprise-wide processes. PeopleSoft has a three-tier architecture: client, application, and database. PeopleSoft can be run on Amazon Relational Database Service (Amazon RDS).

If you migrate your Oracle database to Amazon RDS, Amazon Web Services (AWS) can take care of backup tasks and high availability, leaving you free to concentrate on maintaining your PeopleSoft application and its functionality. For a comprehensive list of key factors to consider during the migration process, see Oracle database migration strategies in AWS Prescriptive Guidance.

This pattern provides a solution for migrating your on-premises Oracle databases to Amazon RDS for Oracle using Oracle Data Pump with AWS Database Migration Service (AWS DMS) and its change data capture (CDC) feature.

When migrating critical ERP applications such as Oracle PeopleSoft, minimizing the downtime is key. AWS DMS minimizes downtime by supporting both full load and continuous replication. from the source database to the target database. AWS DMS also provides real-time monitoring and logging of the migration, which can help you to identify and resolve any issues that could cause downtime.

When replicating changes with AWS DMS, you must specify a time or system change number (SCN) as the starting point for AWS DMS to read changes from the database logs. It's crucial to keep these logs accessible on the server for a designated amount of time to ensure that AWS DMS has access to these changes.

Prerequisites and limitations

Prerequisites

- Provisioned Amazon RDS for Oracle database in your AWS Cloud environment as the target database.
- An Oracle PeopleSoft database running on premises or on Amazon Elastic Compute Cloud (Amazon EC2) in the AWS Cloud.

> **Note**
>
> This pattern is designed for migrating from on premises to AWS, but it was tested by using Oracle Database on an Amazon EC2 instance. For migrating from on premises, you will need to configure the appropriate network connectivity.

- Schema details. When migrating an Oracle PeopleSoft application to Amazon RDS for Oracle, it is necessary to identify which Oracle database schema (for example, `SYSADM`) to migrate. Before starting the migration process, gather the following details about the schema:
  - Size
  - The number of objects per object type
  - The number of invalid objects.

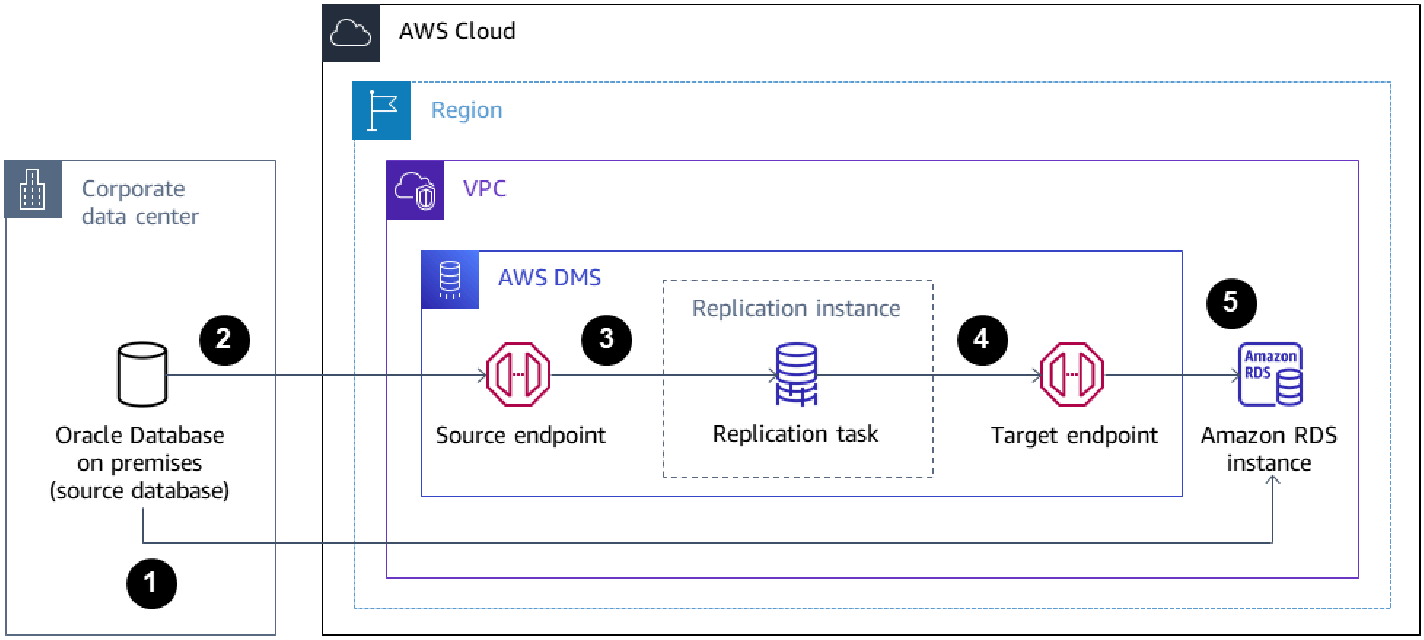
  This information will aid in the migration process.

Limitations

- This scenario has been tested only with the PeopleSoft DEMO database. It hasn't been tested with a large dataset.

Architecture

The following diagram shows an instance running an Oracle database as the source database and an Amazon RDS for Oracle database as the target database. The data is exported and imported from the source Oracle database to the target Amazon RDS for Oracle database using Oracle Data Pump and replicated for CDC changes using AWS DMS.



1. The initial step involves extracting data from the source database by using Oracle Data Pump, followed by sending it to the Amazon RDS for Oracle database target.
2. Data is sent from the source database to a source endpoint in AWS DMS.
3. From the source endpoint, the data is sent to the AWS DMS replication instance, where the replication task is performed.
4. After the replication task is completed, the data is sent to the target endpoint in AWS DMS.
5. From the target endpoint, the data is sent to the Amazon RDS for Oracle database instance.

Tools

AWS services

- [AWS Database Migration Service (AWS DMS)] helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Relational Database Service (Amazon RDS) for Oracle] helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.

Other services

- [Oracle Data Pump] helps you move data and metadata from one database to another at high speeds.

Best practices

Migrating LOBs

If your source database contains large binary objects (LOBs) that need to be migrated to the target database, AWS DMS provides the following options:

- **Full LOB mode –** AWS DMS migrates all the LOBs from the source to the target database regardless of their size. Although the migration is slower, the advantage is that data isn't truncated. For better performance, you can create a separate task on the new replication instance to migrate the tables that have LOBs larger than a few megabytes.
- **Limited LOB mode –** You specify the maximum size of LOB column data, which allows AWS DMS to pre-allocate resources and apply the LOBs in bulk. If the size of the LOB columns exceeds the size that is specified in the task, AWS DMS truncates the data and sends warnings to the AWS DMS log file. You can improve performance by using Limited LOB mode if your LOB data size is within the Limited LOB size.
- **Inline LOB mode –** You can migrate LOBs without truncating the data or slowing the performance of your task by replicating both small and large LOBs. First, specify a value for the InlineLobMaxSize parameter, which is available only when Full LOB mode is set to true. The AWS DMS task transfers the small LOBs inline, which is more efficient. Then, AWS DMS migrates the large LOBs by performing a lookup from the source table. However, Inline LOB mode works only during the full load phase.

Generating sequence values

Keep in mind that during the change data capture process with AWS DMS, incremental sequence numbers are not replicated from the source database. To avoid discrepancies in sequence values, you must generate the most recent sequence value from the source for all sequences, and apply it to the target Amazon RDS for Oracle database.

Credential management

To help secure your AWS resources, we recommend following the best practices for AWS Identity and Access Management (IAM).

Epics

Provision an AWS DMS replication instance with the source and target endpoints

Task	Description	Skills required
Download the template.	Download the DMS_instance.yaml AWS CloudFormation template to provision the AWS DMS replication instance and its source and target endpoints.	Cloud administrator, DBA
Start the stack creation.	1. On the AWS Management Console, choose **CloudFormation**. 2. Choose **Create stack**. 3. For **Specify template**, choose **Upload a template file**. 4. Choose **Choose file**. 5. Choose the `DMS_instance.yaml` file. 6. Choose **Next**.	Cloud administrator, DBA
Specify the parameters.	1. For **Stack name**, enter your stack name. 2. Under **AWS DMS Instance Parameters**, enter the following parameters: • **DMSInstanceType** – Choose the required instance for the AWS DMS replication instance, based on your business needs.	Cloud administrator, DBA

Task	Description	Skills required
	• **DMSStorageSize –** Enter the storage size for the AWS DMS instance, based on the size of your migration. 3. Under **Source Oracle Database Configura tion**, enter the following parameters: • **SourceOracleEndpoi ntID –** The source Oracle database server name • **SourceOracleDataba seName –** The source database service name or session ID (SID) as applicable • **SourceOracleUserName –** The source database username (the default is system) • **SourceOracleDBPass word –** The source database username's password • **SourceOracleDBPort –** The source database port 4. Under **Target RDS for Oracle Database Configuration**, enter the following parameters:	

Task	Description	Skills required
	• **TargetRDSOracleEndpointID** – The target RDS database endpoint • **TargetRDSOracleDatabaseName** – The target RDS database name • **TargetRSOracleUserName** – The target RDS username • **TargetRDSOracleDBPassword** – The target RDS password • **TargetOracleDBPort** – The target RDS database port 5. Under **VPC, Subnet and Security Group Configuration**, enter the following parameters: • **VPCID** – The VPC for the replication instance • **VPCSecurityGroupId** – The VPC security group for the replication instance • **DMSSubnet1** – The subnet for Availability Zone 1 • **DMSSubnet2** – The subnet for Availability Zone 2 6. Choose **Next**.	

Task	Description	Skills required
Create the stack.	1. On the **Configure stack options** page, for **Tags**, enter any optional values. 2. Choose **Next**. 3. On the **Review** page, verify the details, and then choose **Submit**. The provisioning should complete in approximately 5–10 minutes. It is complete when the AWS CloudForm ation Stacks page shows **CREATE_COMPLETE**.	Cloud administrator, DBA
Set up the endpoints.	1. From the AWS Managemen t Console, choose **Database Migration Services**. 2. Under Resource management, choose **Replication instances**. 3. Under Resource management, choose **Endpoints**.	Cloud administrator, DBA
Test connectivity.	After the source and target endpoints shows status as Active, test the connectivity. Choose **Run test** for each endpoint (source and target) to make sure that the status shows as successful.	Cloud administrator, DBA

Export the PeopleSoft schema from the on-premises Oracle database by using Oracle Data Pump

Task	Description	Skills required

Generate the SCN.	When the source database is active and in use by the application, initiate the data export with Oracle Data Pump. You must first generate a system change number (SCN) from the source database for both data consistency during the export with Oracle Data Pump and as a starting point for change data capture in AWS DMS.
	
	To generate the current SCN from your source database, enter the following SQL statement.
	
	`SQL> select name from v$database;`
	`SQL> select name from v$database;`
	`NAME`
	`---------`
	`PSFTDMO`
	`SQL> SELECT current_scn FROM v$database;`
	`CURRENT_SCN`
	`-----------`
	`23792008`
	
	Save the generated SCN to use when you export the data
		DBA

Task	Description	Skills required
	and for creating the AWS DMS replication task.	

Task	Description	Skills required

Create the parameter file.	To create a parameter file for exporting the schema, you can use the following code.
	`$ cat exp_datapmp.par`
	`userid=system/*******`
	`directory=DATA_PUMP_DIR`
	`logfile=export_dms_sample_user.log`
	`dumpfile=export_dms_sample_data_%U.dmp`
	`schemas=SYSADM`
	`flashback_scn=23792008`
	Note
	You can also define your own `DATA_PUMP_DIR` by using the following commands, based on your requirements.
	`SQL> CREATE OR REPLACE DIRECTORY DATA_PUMP_DIR AS '/opt/oracle/product/19c/dbhome_1/dmsdump/';`
	`Directory created.`
	`SQL> GRANT READ, WRITE ON DIRECTORY DATA_PUMP_DIR TO system;`
	`Grant succeeded.`
	`SQL>`
		DBA

Task	Description	Skills required
	``` SQL> SELECT owner, directory_name, directory_path FROM dba_directories WHERE directory_name='DA TA_PUMP_DIR'; OWNER DIRECTORY_NAME DIRECTORY_PATH --------------------- ------------------ ------------------ ------------------ ------------------ --------------------- SYS DATA_PUMP_DIR /opt/ oracle/product/19c/dbh ome_1/dmsdump/ ```	

Task	Description	Skills required
Export the schema.	To perform the export, use the `expdp` utility. `$ expdp parfile=e xp_datapmp.par .... Transferring the dump file with DBMS_FILE _TRANSFER to Target: . . exported "SYSADM". "PS_XML_TEMPLT_LNG" 6.320 KB 0 rows . . exported "SYSADM". "PS_XML_TEMPLT_LNK" 6.328 KB 0 rows . . exported "SYSADM". "PS_XML_XLATDEF_LNG" 6.320 KB 0 rows . . exported "SYSADM". "PS_XML_XLATITM_LNG" 7.171 KB 0 rows . . exported "SYSADM". "PS_XPQRYRUNCNTL" 7.601 KB 0 rows . . exported "SYSADM". "PS_XPQRYRUNPARM" 7.210 KB 0 rows . . exported "SYSADM". "PS_YE_AMOUNTS" 9.351 KB 0 rows . . exported "SYSADM". "PS_YE_DATA" 16.58 KB 0 rows . . exported "SYSADM". "PS_YE_EE" 6.75 KB 0 rows . . exported "SYSADM". "PS_YE_W2CP_AMOUNTS" 9.414 KB 0 rows`	DBA

Task	Description	Skills required
	``` . . exported "SYSADM". "PS_YE_W2CP_DATA" 20.94 KB 0 rows . . exported "SYSADM". "PS_YE_W2C_AMOUNTS" 10.27 KB 0 rows . . exported "SYSADM". "PS_YE_W2C_DATA" 20.95 KB 0 rows . . exported "SYSADM". "PS_ZBD_JOBCODE_TBL" 14.60 KB 0 rows . . exported "SYSADM". "PTGRANTTBL" 5.468 KB 0 rows Master table "SYSTEM". "SYS_EXPORT_SCHEMA _01" successfully loaded/unloaded ** Dump file set for SYSTEM.SYS_EXPORT_ SCHEMA_01 is: /opt/oracle/pr oduct/19c/dbhome_1 /dmsdump/export_dm s_sample_data_01.dmp Job "SYSTEM"."SYS_EXPO RT_SCHEMA_01" successfully completed at Mon Dec 19 20:13:57 2022 elapsed 0 00:38:22 ```	

Import the PeopleSoft schema into the Amazon RDS for Oracle database by using Oracle Data Pump

Task	Description	Skills required

Transfer the dump file to the target instance.	To transfer your files using `DBMS_FILE_TRANSFER` , you need to create a database link from the source database to the Amazon RDS for Oracle instance. After the link is established, you can use the utility to transfer the Data Pump files directly to the RDS instance.
	
	Alternatively, you can transfer the Data Pump files to [Amazon Simple Storage Service (Amazon S3)](#) and then import them into the Amazon RDS for Oracle instance. For more information about this option, see the Additional information section.
	
	To create a database link `ORARDSDB` that connects to the Amazon RDS master user at the target DB instance, run the following commands on the source database.
	
	`$sqlplus / as sysdba`
	`$ SQL> create database link orardsdb connect to admin identified by "*****" using '(DESCRIP`
		DBA

Task	Description	Skills required
	``` TION = (ADDRESS = (PROTOCOL = TCP)(HOST = testpsft.*******.u s-west-2.rds.amazo naws.com)(PORT = 1521))(CONNECT_DATA = (SERVER = DEDICATED) (SERVICE_NAME = orcl)))'; Database link created. ```	
Test the database link.	Test the database link to make sure that you can connect using sqlplus to the Amazon RDS for Oracle target database. ``` SQL> SQL> select name from v $database@orardsdb; NAME --------- ORCL SQL> ```	DBA

Task	Description	Skills required

Transfer the dump file to the target database.	To copy the dump file over to Amazon RDS for Oracle database, you can either use the default `DATA_PUMP_DIR` directory or you can create your own directory using the following code.
	`exec rdsadmin.rdsadmin_util.create_directory(p_directory_name => ‘TARGET_PUMP_DIR’);`
	The following script copies a dump file named `export_dms_sample_data_01.dmp` from the source instance to a target Amazon RDS for Oracle database using the database link named `orardsdb`.
	`$ sqlplus / as sysdba`
	`SQL>`
	`BEGIN`
	`DBMS_FILE_TRANSFER.PUT_FILE(`
	`source_directory_object => 'DATA_PUMP_DIR',`
	`source_file_name => 'export_dms_sample_data_01.dmp',`
	`destination_directory_object => 'TARGET_PUMP_DIR’',`
		DBA

Task	Description	Skills required
	```destination_file_name => 'export_dms_sample_data_01.dmp', destination_database => 'orardsdb'); END; / PL/SQL procedure successfully completed .```	
List the dump file in the target database.	After the PL/SQL procedure is completed, you can list the data dump file in the Amazon RDS for Oracle database by using the following code. ```SQL> select * from table (rdsadmin.rds_file_util.listdir(p_directory => ‘TARGET_PUMP_DIR’));```	DBA

Task	Description	Skills required
Initiate the import on the target database.	Before you start the import process, set up the roles, schemas, and tablespaces on the target Amazon RDS for Oracle database by using the data dump file. To perform the import, access the target database with the Amazon RDS master user account, and use the connection string name in the `tnsnames.ora` file, which includes the Amazon RDS for Oracle Database `tns-entry`. If necessary, you can include a remap option to import the data dump file into a different tablespace or under a different schema name. To start the import, use the following code. `impdp admin@orardsdb directory=TARGET_PUMP_DIR logfile=import.log dumpfile=export_dms_sample_data_01.dmp` To ensure a successful import, check the import log file for any errors, and review details such as object count, row	DBA

Task	Description	Skills required
	count, and invalid objects. If there are any invalid objects, recompile them. Additionally, compare the source and target database objects to confirm that they match.	

Create an AWS DMS replication task using CDC to perform live replication

Task	Description	Skills required
Create the replication task.	Create the AWS DMS replication task by using the following steps: 1. On the AWS DMS console, under **Conversion & migration**, choose **Database migration task**. 2. Under **Task configuration**, for **Task identifier**, enter your task identifier. 3. For **Replication instance**, choose the DMS replication instance that you created. 4. For **Source database endpoint**, choose your source endpoint. 5. For **Target database endpoint**, choose your target Amazon RDS for Oracle database. 6. For **Migration type**, choose **Replicate data**	Cloud administrator, DBA

Task	Description	Skills required
	changes only. If you receive a message that supplemental logging needs to be turned on, follow the instructions in the *Additional information* section. 7. Under **Task settings**, select **Specify log sequence number**. 8. For **System change number**, enter the Oracle database SCN that you generated from the source Oracle database. 9. Choose **Enable validation**. 10. Choose **Enable CloudWatch Logs**. By activating this feature, you can validate the data and [Amazon CloudWatch](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/WhatIsCloudWatchLogs.html) logs to review the AWS DMS replication instance logs. 11. Under **Selection rules**, complete the following: • For **Schema**, choose **Enter a schema**. • For **Schema name**, enter **SYSADM**. • For **Table name**, enter **%**.	

Task	Description	Skills required
	• For **Action**, choose **Include**. 12. Under **Transformation rules**, complete the following: • For **Target**, choose **Table**. • For **Scheme name**, choose **Enter a schema**. • For **Schema name**, enter SYSADM. • For **Action**, choose **Rename to**. 13. Choose **Create task**. After you create the task, it migrates the CDC to the Amazon RDS for Oracle database instance from the SCN that you provided under CDC start mode. You can also verify by reviewing the CloudWatch logs.	

Validate the database schema on the target Amazon RDS for Oracle database

Task	Description	Skills required
Validate the data transfer.	After the AWS DMS task starts, you can check the **Table statistics** tab on the **Tasks** page to see the changes made to the data.	Cloud administrator, DBA

Task	Description	Skills required
	You can monitor the status of ongoing replication in the console on the **Database migration tasks** page. For more information, see AWS DMS data validation.	

Cut over

Task	Description	Skills required
Stop replication.	Discontinue the replication procedure and halt the source application services.	Cloud administrator, DBA
Launch the PeopleSoft middle tier.	Launch the target PeopleSof t middle tier application in AWS, and direct it to the recently migrated Amazon RDS for Oracle database. When you access the applicati on, you should notice that all app connections are now established with the Amazon RDS for Oracle database.	DBA, PeopleSoft administr ator
Turn off the source database.	After you confirm that there are no more connections to the source database, it can be turned off.	DBA

- [Best Practices for AWS Database Migration Service]
- [Migrating Oracle Databases to the AWS Cloud]

Additional information

Transfer files using Amazon S3

To transfer the files to Amazon S3, you can use the AWS CLI or the Amazon S3 console. After you transfer the files to Amazon S3, you can use the Amazon RDS for Oracle instance to import the Data Pump files from Amazon S3.

If you choose to transfer the dump file using Amazon S3 integration as an alternate method, perform the follow steps:

1. Create an S3 bucket.
2. Export the data from the source database using Oracle Data Pump.
3. Upload the Data Pump files to the S3 bucket.
4. Download the Data Pump files from the S3 bucket to the target Amazon RDS for Oracle database.
5. Perform the import using the Data Pump files.

> **Note**
>
> To transfer large data files between S3 and RDS instances, it is recommended to use the Amazon S3 Transfer Acceleration feature.

Activate supplemental logging

If you receive a warning message to enable supplemental logging in the source database for on-going replication, use the following steps.

```
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (ALL) COLUMNS;
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (PRIMARY KEY) COLUMNS;
```

```
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (UNIQUE) COLUMNS;
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (FOREIGN KEY) COLUMNS;
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (PRIMARY KEY) COLUMNS
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (UNIQUE) COLUMNS;
```

Migrate an on-premises MySQL database to Amazon RDS for MySQL

Lorenzo Mota, Amazon Web Services

Summary

This pattern provides guidance for migrating an on-premises MySQL database to Amazon Relational Database Service (Amazon RDS) for MySQL. The pattern discusses the use of AWS Database Migration Service (AWS DMS) or native MySQL tools such as **mysqldump** for a full database migration. This pattern is primarily for DBAs and solution architects. It can be used in small or large projects as a testing procedure (we recommend at least one testing cycle) or as a final migration procedure.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A MySQL source database in an on-premises data center

Limitations

- Database size limit: 64 TB

Product versions

- MySQL versions 5.5, 5.6, 5.7, 8.0. For the latest list of supported versions, see MySQL on Amazon RDS in the AWS documentation. If you're using AWS DMS, see also Using a MySQL-Compatible Database as a Target for AWS DMS for MySQL versions currently supported by AWS DMS.

Architecture

Source technology stack

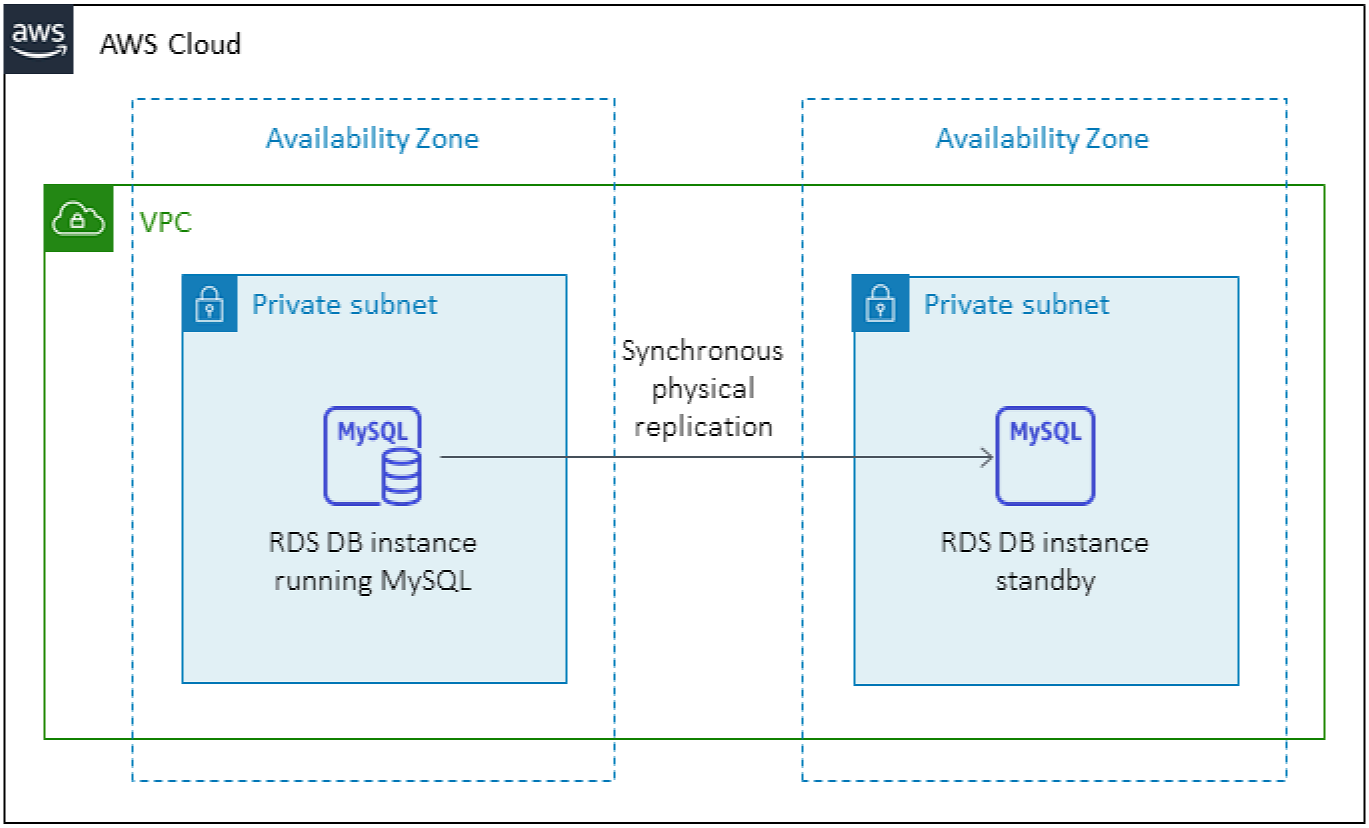
- An on-premises MySQL database

Target technology stack

- An Amazon RDS DB instance running MySQL

Target architecture

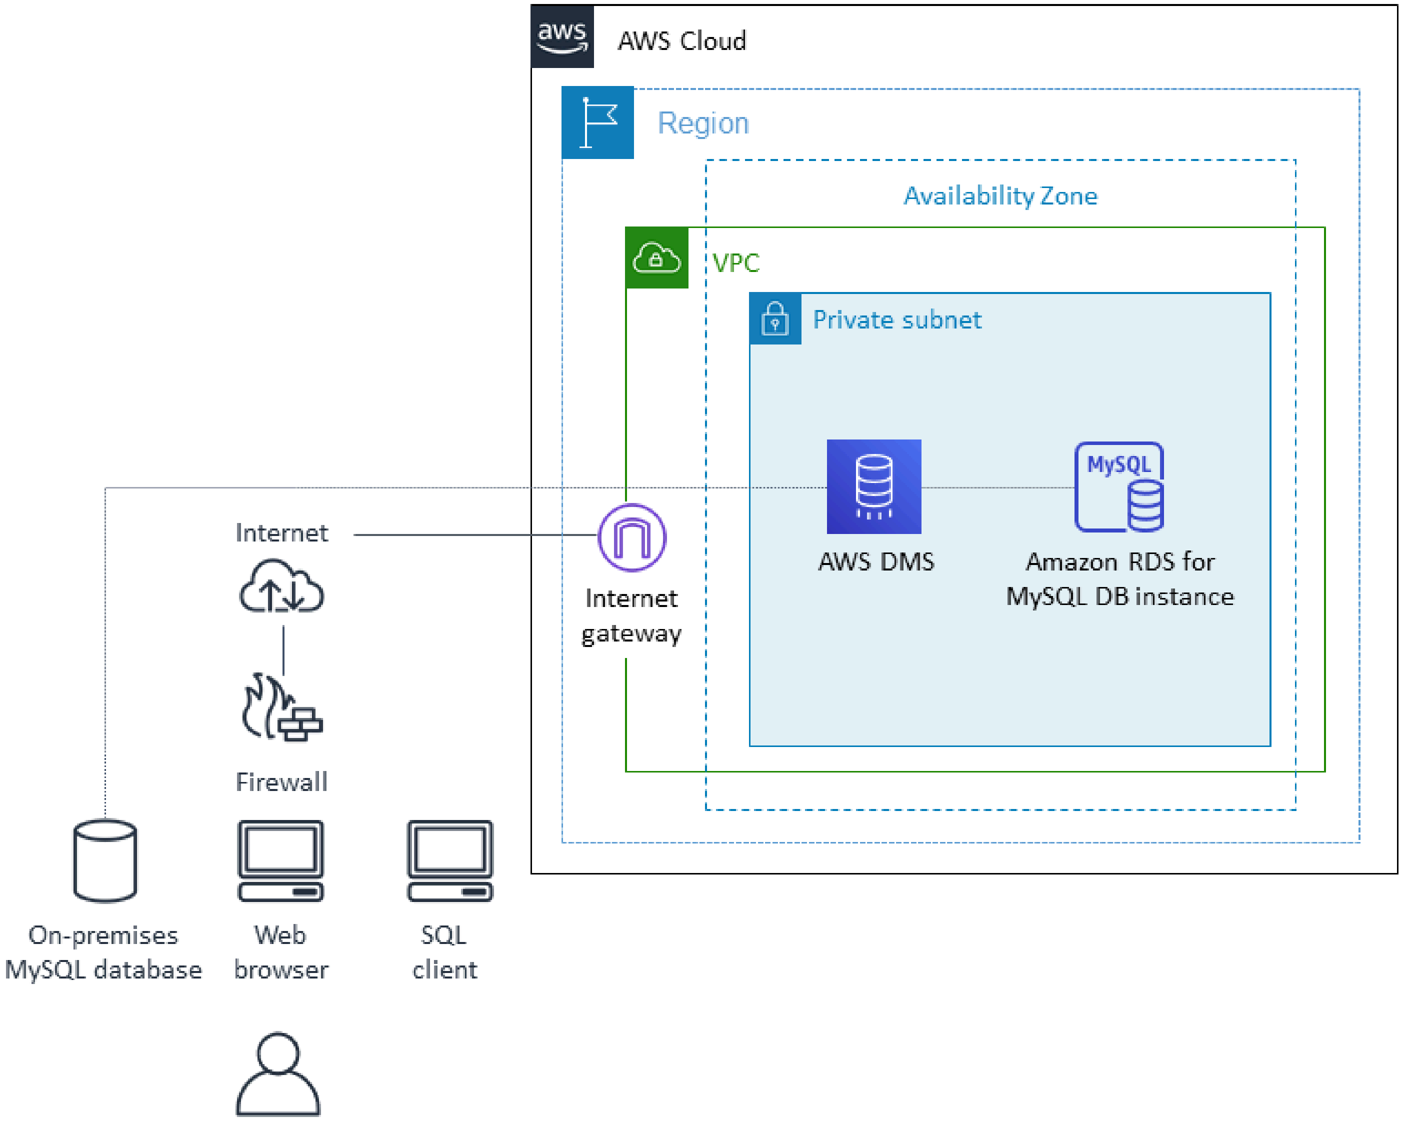
The following diagram shows the target Amazon RDS for MySQL implementation after migration.



AWS data migration architecture

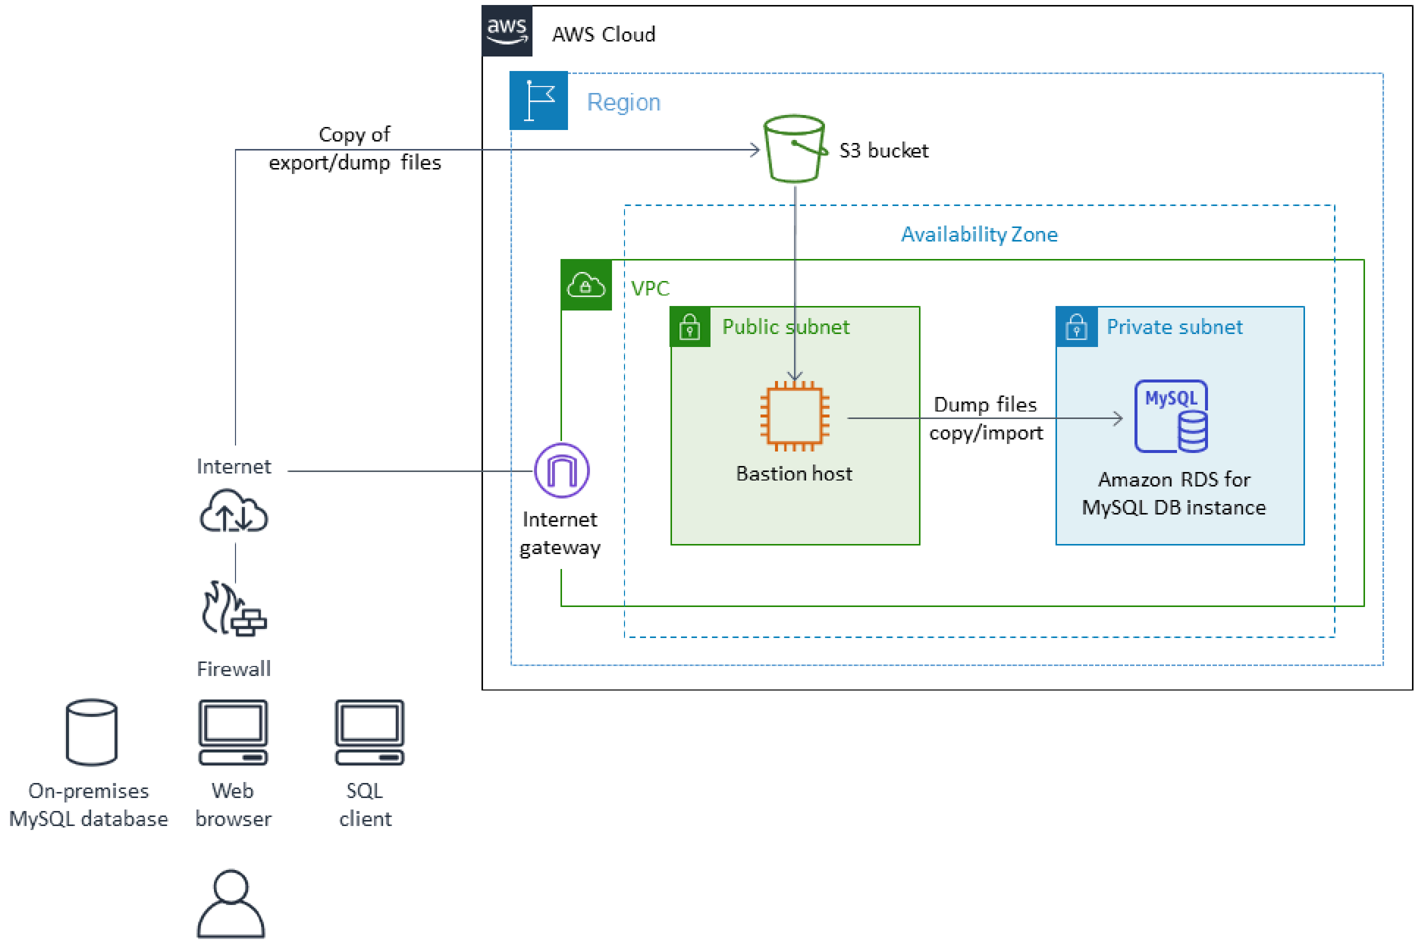
Using AWS DMS:

The following diagram shows the data migration architecture when you use AWS DMS to send full and incremental changes until cutover. The network connection from on premises to AWS depends on your requirements and is out of scope for this pattern.



Using native MySQL tools:

The following diagram shows the data migration architecture when you use native MySQL tools. The export dump files are copied to Amazon Simple Storage Service (Amazon S3) and imported into the Amazon RDS for MySQL database in AWS before the cutover. The network connection from on premises to AWS depends on your requirements and is out of scope for this pattern.



Notes:

- Depending on downtime requirements and the size of the database, using AWS DMS or a change data capture (CDC) tool minimizes cutover time. AWS DMS can help reduce cutover time to the new target to a minimum (typically minutes). An offline strategy with **mysqldump** can suffice if the size of the database and network latency allow for a short window. (We recommend testing to get an approximate time.)
- Usually a CDC strategy such as AWS DMS requires more monitoring and complexity than offline options.

Tools

- **AWS services**: AWS Database Migration Service (AWS DMS) helps you migrate data stores to the AWS Cloud or between combinations of cloud and on-premises setups. For information about MySQL source and target databases supported by AWS DMS, see Migrating MySQL-Compatible

Databases to AWS. If your source database isn't supported by AWS DMS, you must choose another method to migrate your data.

- **Native MySQL tools**: mysqldump
- **Third-party tools**: Percona XtraBackup

Epics

Plan the migration

Task	Description	Skills required
Validate database versions.	Validate the source and target database versions.	DBA
Identify hardware requireme nts.	Identify the hardware requirements for the target server.	DBA, Systems administrator
Identify storage requireme nts.	Identify storage requireme nts (such as storage type and capacity) for the target database.	DBA, Systems administrator
Choose the instance type.	Choose the target instance type based on capacity, storage features, and networking features.	DBA, Systems administrator
Identify network access requirements.	Identify the security requirements for network access for the source and target databases.	DBA, Systems administrator
Identify unsupported objects.	Identify unsupported objects (if any) and determine the migration effort.	DBA

Task	Description	Skills required
Identify dependencies.	Identify any dependencies on remote databases.	DBA
Determine the application migration strategy.	Determine the strategy for migrating client applications.	DBA, App owner, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).	Configure route tables, internet gateway, NAT gateways, and subnets. For more information, see VPCs and Amazon RDS in the Amazon RDS documentation.	Systems administrator
Create security groups.	Configure ports and CIDR ranges or specific IPs depending on your requireme nts. The default port for MySQL is 3306. For more information, see Controlling access with security groups in the Amazon RDS documenta tion.	Systems administrator
Configure and start an Amazon RDS for MySQL DB instance.	For instructions, see Creating an Amazon RDS DB instance in the Amazon RDS documentation. Check for supported versions.	Systems administrator

Migrate data – option 1 (using native tools)

Task	Description	Skills required
Use native MySQL tools or third-party tools to migrate database objects and data.	For instructions, see the documentation for MySQL tools such as mysqldump and Percona XtraBackup (for physical migration). For more information about options, see the blog post Migration options for MySQL to Amazon RDS for MySQL or Amazon Aurora MySQL.	DBA

Migrate data – option 2 (using AWS DMS)

Task	Description	Skills required
Migrate data with AWS DMS.	For instructions, see the AWS DMS documentation.	DBA

Perform preliminary tasks before cutover

Task	Description	Skills required
Fix object count discrepancies.	Collect object counts from the source database and new target database. Fix discrepan cies in the target database.	DBA
Check dependencies.	Check whether dependenc ies (links) to and from other databases are valid and work as expected.	DBA

Task	Description	Skills required
Perform tests.	If this is a testing cycle, perform query testing, gather metrics, and fix issues.	DBA

Cut over

Task	Description	Skills required
Switch to the target database.	Switch client applications to the new infrastructure.	DBA, App owner, Systems administrator
Provide testing support.	Provide support for functiona l application testing.	DBA

Close the project

Task	Description	Skills required
Shut down resources.	Shut down the temporary AWS resources you created for the migration.	DBA, Systems administrator
Validate project documents.	Review and validate the project documents.	DBA, App owner, Systems administrator
Gather metrics.	Gather metrics such as time to migrate, percentage of manual versus automated effort, cost savings, and so on.	DBA, App owner, Systems administrator
Close out the project.	Close out the project and provide feedback.	DBA, App owner, Systems administrator
Decommission the source database.	When all migration and cutover tasks are complete,	DBA, Systems administrator

Task	Description	Skills required
	decommission the on-premises database.

Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server

Henrique Lobao, Jonathan Pereira Cruz, and Vishal Singh, Amazon Web Services

Summary

This pattern provides guidance for migrating from an on-premises Microsoft SQL Server database to Amazon Relational Database Service (Amazon RDS) for SQL Server. It describes two options for migration: using AWS Data Migration Service (AWS DMS) or using native Microsoft SQL Server tools such as Copy Database Wizard.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Microsoft SQL Server database in an on-premises data center

Limitations

- Database size limit: 16 TB

Product versions

- SQL Server 2014-2019, Enterprise, Standard, Workgroup, and Developer editions. For the latest list of supported versions and features, see Microsoft SQL Server on Amazon RDS in the AWS documentation. If you're using AWS DMS, see also Using a Microsoft SQL Server Database as a Target for AWS DMS for SQL Server versions supported by AWS DMS.

Architecture

Source technology stack

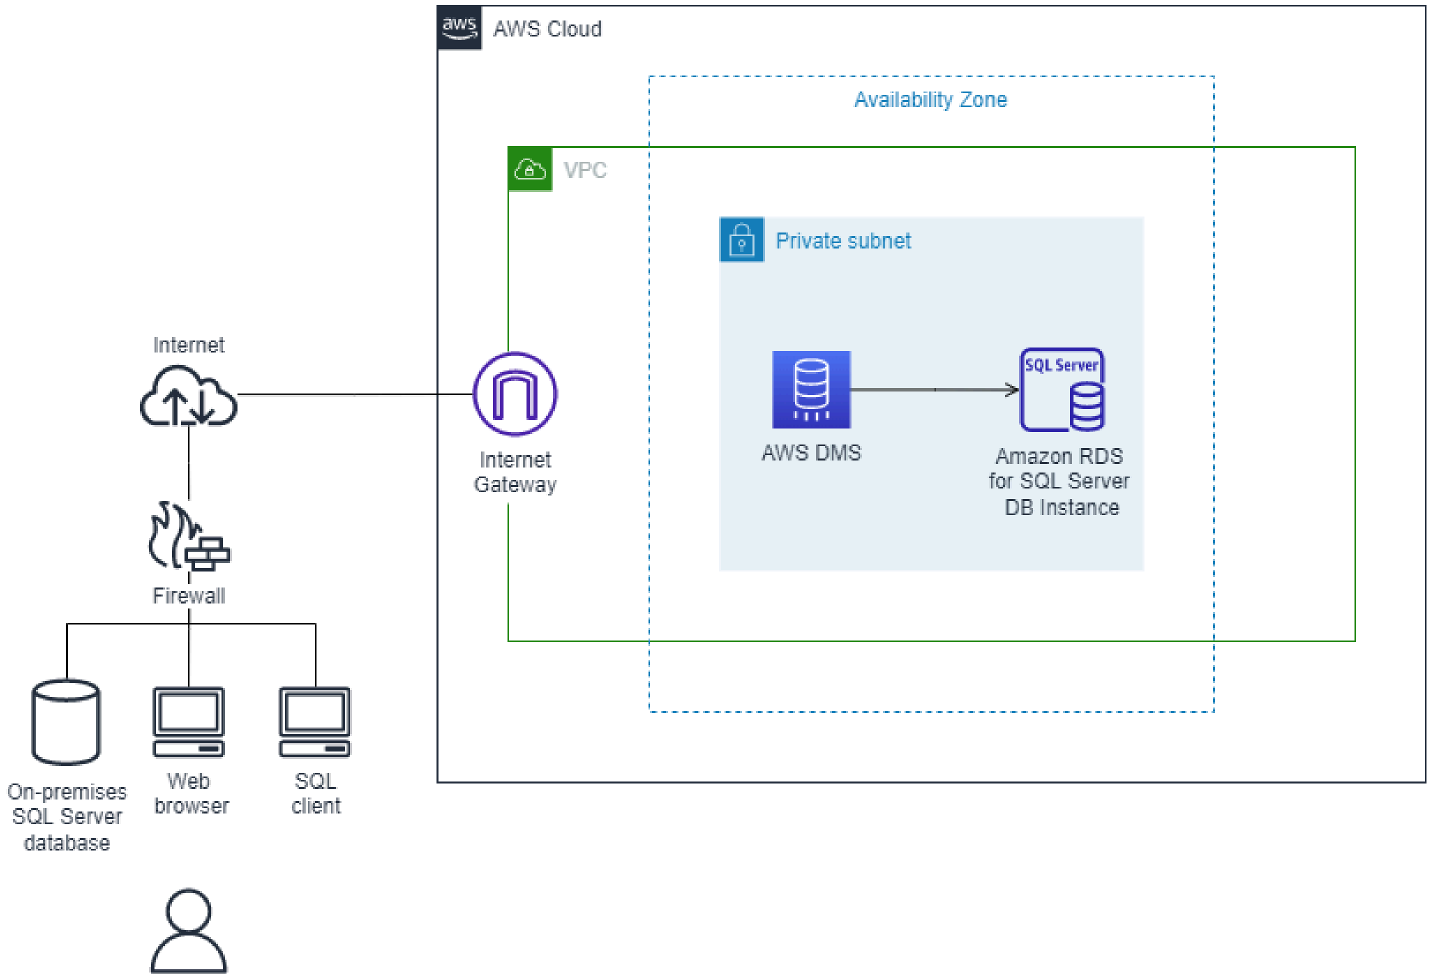
- An on-premises Microsoft SQL Server database

Target technology stack

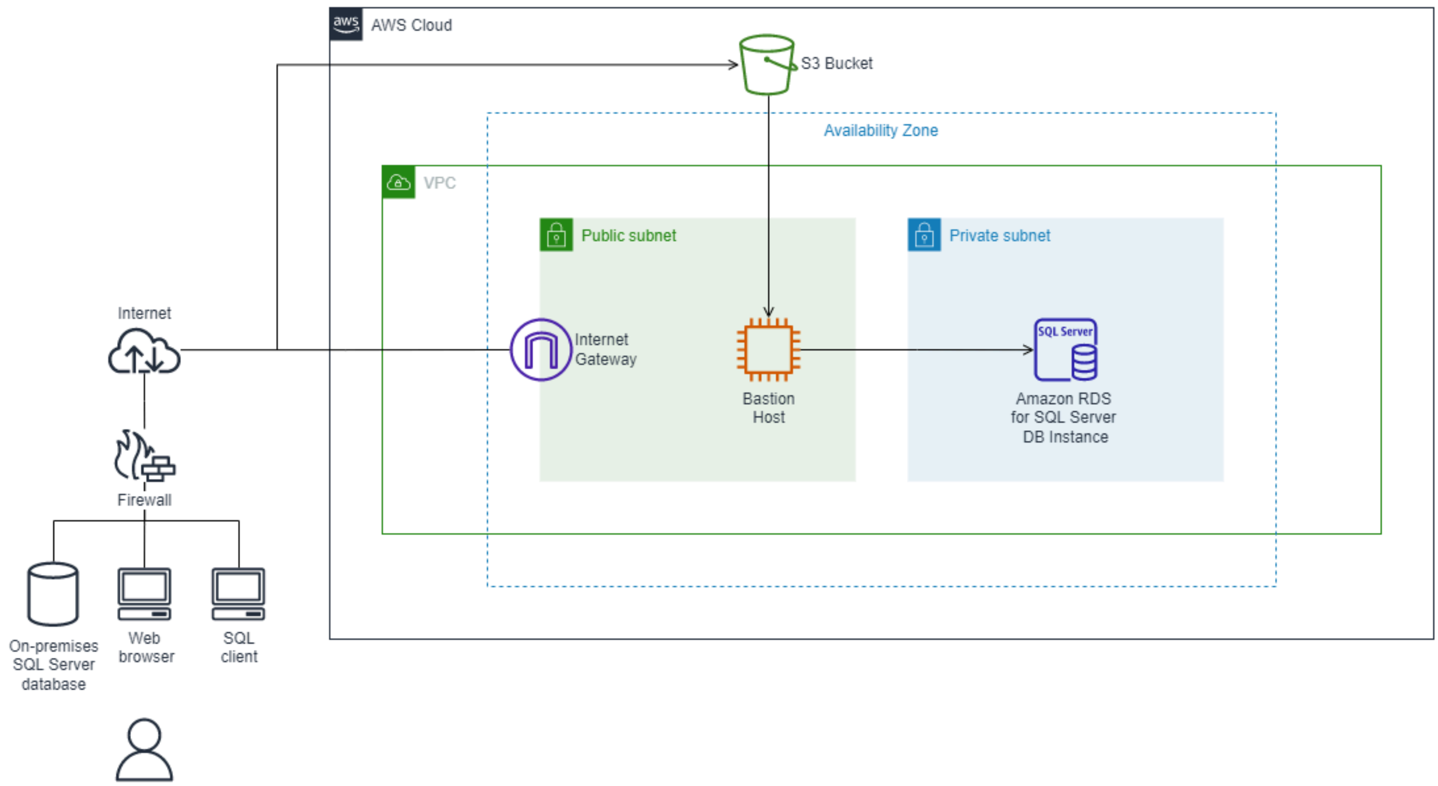
- An Amazon RDS for SQL Server DB instance

Source and target architecture

Using AWS DMS:



Using native SQL Server tools:



Tools

- AWS DMS supports several types of source and target databases. For details, see AWS DMS Step-by-Step Walkthroughs. If AWS DMS doesn't support the source database, select another method for migrating the data.
- Native Microsoft SQL Server tools include backup and restore, Copy Database Wizard, copy and attach database.

Epics

Plan the migration

Task	Description	Skills required
Validate the source and target database version and engine.		DBA

Task	Description	Skills required
Identify the hardware requirements for the target server instance.		DBA, Systems administrator
Identify the storage requirements (storage type and capacity).		DBA, Systems administrator
Choose the proper instance type based on capacity, storage features, and network features.		DBA, Systems administrator
Identify the network access security requirements for source and target databases.		DBA, Systems administrator
Identify the application migration strategy.		DBA, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).		Systems administrator
Create security groups.		Systems administrator
Configure and start an Amazon RDS DB instance.		DBA, Systems administrator

Migrate data - option 1

Task	Description	Skills required
Use native SQL Server tools or third-party tools to migrate database objects and data.		DBA

Migrate data - option 2

Task	Description	Skills required
Migrate data with AWS DMS.		DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, App owner, Systems administrator

Cut over

Task	Description	Skills required
Switch the application clients over to the new infrastru cture.		DBA, App owner, Systems administrator

Close the project

Task	Description	Skills required
Shut down the temporary AWS resources.		DBA, Systems administrator
Review and validate the project documents.		DBA, App owner, Systems administrator
Gather metrics such as time to migrate, percentage of manual versus automated tasks, and cost savings.		DBA, App owner, Systems administrator
Close out the project and provide feedback.		DBA, App owner, Systems administrator

Migrate data from Microsoft Azure Blob to Amazon S3 by using Rclone

Suhas Basavaraj, Aidan Keane, and Corey Lane, Amazon Web Services

Summary

This pattern describes how to use Rclone to migrate data from Microsoft Azure Blob object storage to an Amazon Simple Storage Service (Amazon S3) bucket. You can use this pattern to perform a one-time migration or an ongoing synchronization of the data. Rclone is a command-line program written in Go and is used to move data across various storage technologies from cloud providers.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Data stored in Azure Blob container service

Architecture

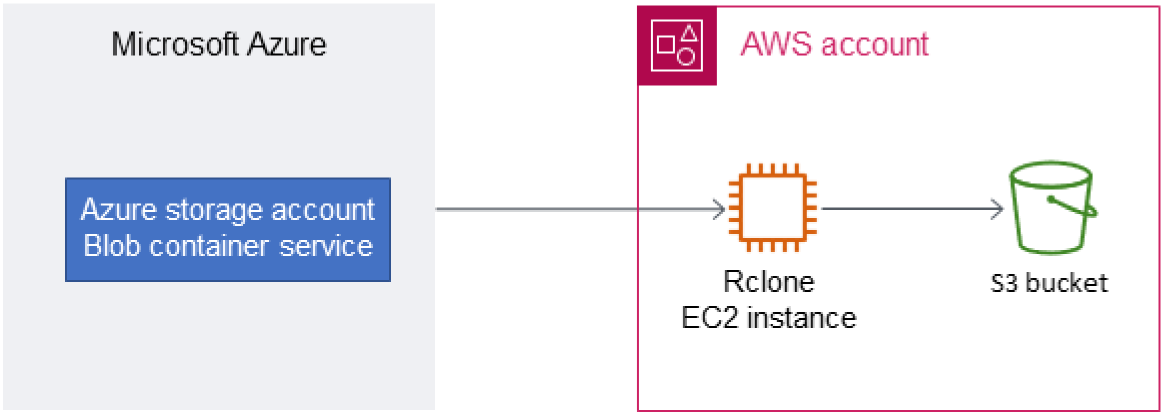
Source technology stack

- Azure Blob storage container

Target technology stack

- Amazon S3 bucket
- Amazon Elastic Compute Cloud (Amazon EC2) Linux instance

Architecture



Tools

- [Amazon Simple Storage Service (Amazon S3)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Rclone](#) is an open-source command-line program inspired by **rsync**. It is used to manage files across many cloud storage platforms.

Best practices

When you migrate data from Azure to Amazon S3, be mindful of these considerations to avoid unnecessary costs or slow transfer speeds:

- Create your AWS infrastructure in the same geographical Region as the Azure storage account and Blob container—for example, AWS Region `us-east-1` (N. Virginia) and Azure region `East US`.
- Avoid using NAT Gateway if possible, because it accrues data transfer fees for both ingress and egress bandwidth.
- Use a [VPC gateway endpoint for Amazon S3](#) to increase performance.
- Consider using an AWS Graviton2 (ARM) processor-based EC2 instance for lower cost and higher performance over Intel x86 instances. Rclone is heavily cross-compiled and provides a precompiled ARM binary.

Epics

Prepare AWS and Azure cloud resources

Task	Description	Skills required
Prepare a destination S3 bucket.	Create a new S3 bucket in the appropriate AWS Region or choose an existing bucket as the destination for the data you want to migrate.	AWS administrator
Create an IAM instance role for Amazon EC2.	Create a new AWS Identity and Access Management (IAM) role for Amazon EC2. This role gives your EC2 instance write access to the destination S3 bucket.	AWS administrator
Attach a policy to the IAM instance role.	Use the IAM console or AWS Command Line Interface (AWS CLI) to create an inline policy for the EC2 instance role that allows write access permissions to the destinati on S3 bucket. For an example policy, see the Additional information section.	AWS administrator
Launch an EC2 instance.	Launch an Amazon Linux EC2 instance that is configured to use the newly created IAM service role. This instance will also need access to Azure public API endpoints through the internet.	AWS administrator

Task	Description	Skills required
	Note Consider using [AWS Graviton-based EC2 instances](#) to lower costs. Rclone provides ARM-compiled binaries.	
Create an Azure AD service principal.	Use the Azure CLI to create an Azure Active Directory (Azure AD) service principal that has read-only access to the source Azure Blob storage container. For instructions, see the [Additional information](#) section. Store these credentials on your EC2 instance to the location `~/azure-principal.json` .	Cloud administrator, Azure

Install and configure Rclone

Task	Description	Skills required
Download and install Rclone.	Download and install the Rclone command-line program. For installation instructions, see the [Rclone installation documentation](#).	General AWS, Cloud administrator
Configure Rclone.	Copy the following `rclone.conf` sample file. Replace `AZStorage`	General AWS, Cloud administrator

Task	Description	Skills required

	`Account` with your Azure Storage account name and `us-east-1` with the AWS Region where your S3 bucket is located. Save this file to the location `~/.config/rclone/rclone.conf` on your EC2 instance.
	
	`[AZStorageAccount]`
	`type = azureblob`
	`account = AZStorage Account`
	`service_principal_file = azure-principal.json`
	
	`[s3]`
	`type = s3`
	`provider = AWS`
	`env_auth = true`
	`region = us-east-1`	

Task	Description	Skills required

Verify Rclone configuration.	To confirm that Rclone is configured and permissions are working properly, verify that Rclone can parse your configuration file and that objects inside your Azure Blob container and S3 bucket are accessible. See the following for example validation commands.
	
	• List the configured remotes in the configuration file. This will ensure that your configuration file is being parsed correctly. Review the output to make sure that it matches your `rclone.conf` file.
	
	`rclone listremotes`
	`AZStorageAccount:`
	`s3:`
	
	• List the Azure Blob containers in the configured account. Replace `AZStorageAccount` with the storage account name that you used in the `rclone.conf` file.
	
	`rclone lsd AZStorageAccount:`
	`2020-04-29 08:29:26 docs`
		General AWS, Cloud administrator

Task	Description	Skills required

	• List the files in the Azure Blob container. Replace docs in this command with an actual Blob container name in your Azure storage account.
	`rclone ls AZStorageAccount:docs`
	`824884 administrator-en.a4.pdf`
	• List the buckets in your AWS account.
	`[root@ip-10-0-20-157 ~]# rclone lsd s3:`
	`2022-03-07 01:44:40 amzn-s3-demo-bucket1`
	`2022-03-07 01:45:16 amzn-s3-demo-bucket2`
	`2022-03-07 02:12:07 amzn-s3-demo-bucket3`
	• List the files in the S3 bucket.
	`[root@ip-10-0-20-157 ~]# rclone ls s3:amzn-s3-demo-bucket1`
	`template0.yaml`
	`template1.yaml`	

Migrate data using Rclone

Task	Description	Skills required

Migrate data from your containers.	Run the Rclone copy or sync command.
	
	Example: copy
	
	This command copies data from the source Azure Blob container to the destination S3 bucket.
	
	`rclone copy AZStorageAccount:blob-container s3:amzn-s3-demo-bucket1`
	
	Example: sync
	
	This command synchronizes data between the source Azure Blob container and the destination S3 bucket.
	
	`rclone sync AZStorageAccount:blob-container s3:amzn-s3-demo-bucket1`
	
	Important
	When you use the **sync** command, data that isn't present in the source container will be deleted from
		General AWS, Cloud administrator

Task	Description	Skills required
	the destination S3 bucket.	
Synchronize your containers.	After the initial copy is complete, run the Rclone **sync** command for ongoing migration so that only new files that are missing from the destination S3 bucket will be copied.	General AWS, Cloud administr ator
Verify that data has been migrated successfully.	To check that data was successfully copied to the destination S3 bucket, run the Rclone lsd and ls commands.	General AWS, Cloud administr ator

- Rclone commands (Rclone documentation)

Additional information

Example role policy for EC2 instances

This policy gives your EC2 instance read and write access to a specific bucket in your account. If your bucket uses a customer managed key for server-side encryption, the policy might need additional access to AWS Key Management Service (AWS KMS) .

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
```

```
            "Effect": "Allow",
            "Action": [
                "s3:ListBucket",
                "s3:DeleteObject",
                "s3:GetObject",
                "s3:PutObject",
                "s3:PutObjectAcl"
            ],
            "Resource": [
              "arn:aws:s3:::amzn-s3-demo-bucket/*",
              "arn:aws:s3:::amzn-s3-demo-bucket"
            ]
        },
        {
            "Effect": "Allow",
            "Action": "s3:ListAllMyBuckets",
            "Resource": "arn:aws:s3:::*"
        }
    ]
}
```

Creating a read-only Azure AD service principal

An Azure service principal is a security identity that is used by customer applications, services, and automation tools to access specific Azure resources. Think of it as a user identity (login and password or certificate) with a specific role and tightly controlled permissions to access your resources. To create a read-only service principal to follow least privilege permissions and protect data in Azure from accidental deletions, follow these steps:

1. Log in to your Microsoft Azure cloud account portal and launch Cloud Shell in PowerShell or use the Azure Command-Line Interface (CLI) on your workstation.
2. Create a service principal and configure it with [read-only](#) access to your Azure Blob storage account. Save the JSON output of this command to a local file called `azure-principal.json`. The file will be uploaded to your EC2 instance. Replace the placeholder variables that are shown in braces ({ and }) with your Azure subscription ID, resource group name, and storage account name.

   ```
   az ad sp create-for-rbac `
   --name AWS-Rclone-Reader `
   --role "Storage Blob Data Reader" `
   ```

```
--scopes /subscriptions/{Subscription ID}/resourceGroups/{Resource Group Name}/
providers/Microsoft.Storage/storageAccounts/{Storage Account Name}
```

Migrate from Couchbase Server to Couchbase Capella on AWS

Battulga Purevragchaa and Saurabh Shanbhag, Amazon Web Services

Mark Gamble, None

Summary

Couchbase Capella is a fully managed, NoSQL database as a service (DBaaS) for mission-critical applications (for example, user profiles or online catalogs and inventory management). Couchbase Capella manages your DBaaS workload in a Couchbase-managed Amazon Web Services (AWS) account. Capella makes it easy to run and manage multiple-cluster, multiple–AWS Region, multicloud, and hybrid-cloud replication within a single interface.

Couchbase Capella helps you instantly scale your Couchbase Server applications, helping you create multi-node clusters in minutes. Couchbase Capella supports all Couchbase Server features, including SQL++, Full Text Search, Eventing Service, and Analytics Service. It also removes the need to manage installations, upgrades, backups, and general database maintenance.

This pattern describes the steps and best practices for migrating a self-managed Couchbase Server environment to the AWS Cloud. The pattern provides a repeatable process for migrating data and indexes from Couchbase Server clusters, running either on premises or in the cloud, to Couchbase Capella. Using these steps helps you avoid issues during your migration and speeds up your overall migration process.

This pattern provides the following two migration options:

- **Option 1** is appropriate if you have fewer than 50 indexes to migrate.

- **Option 2** is appropriate if you have more than 50 indexes to migrate.

You can also set up sample data on your self-managed Couchbase Server to follow along with the migration guide.

If you choose migration **option 2**, or if you are using scopes or collections other than the default value, you must use the example configuration file, which is in the *Additional information* section.

Prerequisites and limitations

Prerequisites

- An existing Couchbase Capella paid account. You can also create a Couchbase Capella account on AWS and use the Couchbase Capella free trial, and then upgrade to a paid account to configure your cluster for the migration.. To start with the trial version, follow the instructions in Getting Started with Couchbase Capella.
- An existing self-managed Couchbase Server environment either on premises or deployed on a cloud service provider.
- For migration option 2, Couchbase Shell and a configuration file. To create the configuration file, you can use the example file that's in the *Additional information* section.
- Familiarity with administering Couchbase Server and Couchbase Capella.
- Familiarity with opening TCP ports and running commands in a command line interface (CLI).

The migration process also requires the roles and expertise described in the following table.

Role	Expertise	Responsibilities
Couchbase administrator	• Familiarity with Couchbase Server and Couchbase Capella • Basic command line knowledge is helpful but not required	• Couchbase Server and Capella–specific tasks
Systems administrator, IT administrator	• Familiarity with the self-managed Couchbase Server system environment and administration	• Opening ports and determining IP addresses on self-managed Couchbase Server cluster nodes

Limitations

- This pattern is used to migrate data, indexes, and Couchbase Full Text Search indexes from Couchbase Server to Couchbase Capella on AWS. The pattern doesn't apply to migrating Couchbase Eventing Service, or to Couchbase Analytics.
- Couchbase Capella is available in multiple AWS Regions. For up-to-date information on the Regions that Capella supports, see Amazon Web Services in the Couchbase documentation.

Product versions

- [Couchbase Server (Community or Enterprise) Edition version 5.x or later]

Architecture

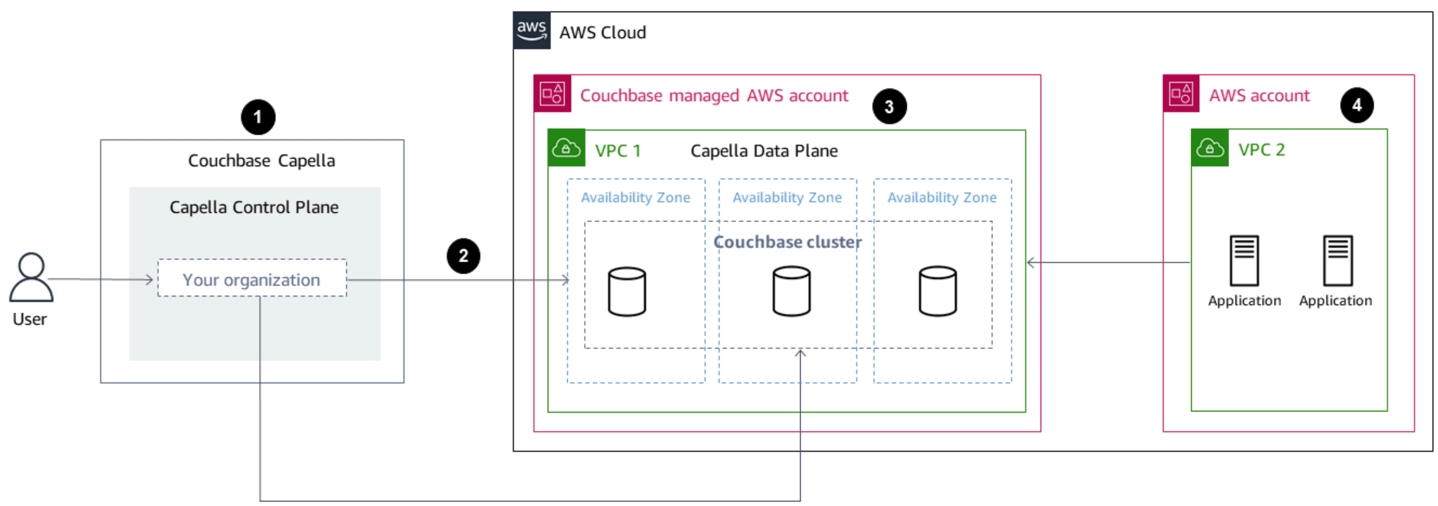
Source technology stack

- Couchbase Server

Target technology stack

- Couchbase Capella

Target architecture



1. You access Couchbase Capella by using the **Capella Control Plane**. You can use the Capella Control Plane to do the following:
   - Control and monitor your account.
   - Manage clusters and data, indexes, users and groups, access permissions, monitoring, and events.
2. Clusters are created.
3. The **Capella Data Plane** is in the Couchbase-managed AWS account. After you create a new cluster, Couchbase Capella deploys it across multiple Availability Zones in the selected AWS Region.

4. You can develop and deploy Couchbase applications in a VPC in your AWS account. Typically, this VPC accesses the Capella Data Plane through VPC peering.

Tools

- Couchbase Cross Data Center Replication (XDCR) helps replicate data across clusters that are located in different cloud providers and different data centers. It is used to migrate data into Couchbase Capella from self-managed Couchbase Server clusters.

> **Note**
>
> XDCR cannot be used with Couchbase Server Community Edition to migrate to Couchbase Capella. Instead, you can use cbexport. For more information, see the *Migrate data from Community Edition* epic.

- Couchbase Shell is a command line shell for Couchbase Server and Couchbase Capella to access local and remote Couchbase clusters. In this pattern, Couchbase Shell is used to migrate indexes.
- cbexport is a Couchbase utility for exporting data from Couchbase cluster. Included in Couchbase Server CLI tools.

Epics

Prepare the migration

Task	Description	Skills required
Evaluate the size of the self-managed Couchbase Server cluster.	Log in to the Couchbase Web Console for Couchbase Server, and assess your self-managed cluster's nodes and buckets. 1. To show a list of cluster nodes, choose the **Servers** tab in the navigation bar. 2. Record the number of nodes, and then choose	Couchbase administrator

Task	Description	Skills required
	each node on the list to display its properties. 3. Record the memory and storage for each individual node. 4. Choose the **Buckets** tab in the navigation bar, and then choose each bucket in the list to display its properties. Record the RAM quota and conflict resolutio n setting for each bucket. You will use your self-mana ged Couchbase Server cluster configurations as a general guide for sizing and configuri ng the target cluster on Couchbase Capella. For help with a more detailed Couchbase Capella sizing exercise, [contact Couchbase]().	

Task	Description	Skills required
Record Couchbase Service distribution on the self-managed Couchbase Server cluster.	1. On the Couchbase Web Console, choose the **Servers** tab to display the list of cluster nodes. 2. Choose each node to display its properties and then record the Couchbase Service distribution for each node (Data Service, Query Service, Index Service, Search Service, Analytics Service, and Eventing Service).	Couchbase administrator
Record the IP addresses of the self-managed Couchbase Server cluster nodes.	(Ignore this step if you are using Community Edition.) Record the IP address for each node in your cluster. They will be added to the allow list on your Couchbase Capella cluster later.	Couchbase administrator, Systems administrator

Deploy and configure resources on Couchbase Capella

Task	Description	Skills required
Choose a template.	1. Log in to your Couchbase Capella Control Plane, choose the **Dashboard** tab or the **Clusters** tab in the main navigation, and then choose **Create Cluster**. 2. Using the information that you recorded from	Couchbase administrator

Task	Description	Skills required
	the evaluation of your self-managed Couchbase Server cluster, choose the cluster template that meets the configura tion's requirements. If you don't find an appropriate template, choose **Custom Template** in the **Cluster Sizing** editor.	
Choose and configure the nodes.	Choose and configure the nodes to match your self-managed Couchbase Server cluster environme nt, including the number of nodes, services distribut ion, compute or RAM, and storage. Couchbase Capella uses multidimensional scaling best practices. Services and nodes can be chosen only according to deployment best practices. This might mean that you can't exactly match your self-managed Couchbase Server cluster's configura tions.	Couchbase administrator

Task	Description	Skills required
Deploy the cluster.	Choose a support zone and support package, and then deploy the cluster. For detailed steps and instructions, see [Create a cluster](#) in the Couchbase documentation. **Important** If you are using the Couchbase Capella free trial, you must convert it to a paid account before beginning your migration. To convert your account, open the **Billing** section of the Couchbase Capella Control Plane, and then choose **Add Activation ID**. The Activation ID is sent to your billing contact email address after you complete a purchase agreement with Couchbase Sales, or after you make a purchase through [AWS Marketplace](#).	Couchbase administrator

Task	Description	Skills required
Create a database credential user.	A database credential user is specific to a cluster and consists of a user name, password, and a set of bucket privileges. This user is required for creating buckets and accessing bucket data. In the Couchbase Capella Control Plane, create a database credential for the new cluster by following the instructions in [Configure database credentials](#) in the Couchbase Capella documentation. **Note** An organization user needs organizat ional role credentia ls assigned to them if they want to access bucket data on a particular cluster, either remotely or through the Couchbase Capella UI. This is separate from database credentia ls, which are typically used by apps and integrations. Creating the organizational	Couchbase administrator

Task	Description	Skills required
	user allows you to create and manage the target buckets on your Couchbase Capella cluster.	
If using migration option 2, install Couchbase Shell.	You can install Couchbase Shell on any system that has network access to both your self-managed Couchbase Server and the Couchbase Capella clusters. For more information, see [Install Couchbase Shell version 1.0.0-beta.5]() in the Couchbase Shell documentation. Confirm that Couchbase Shell is installed by [testing a connection to your self-managed cluster]() in a command line terminal.	Couchbase administrator, Systems administrator

Task	Description	Skills required
Allow IP addresses.	1. In the Couchbase Capella Control Plane, choose **Clusters**, and then choose your target cluster. 2. Choose the **Connect** tab for the cluster, and record the connection endpoint for your cluster that is listed under **Manage Allowed IP**. 3. To add the IP address for the system where you installed Couchbase Shell and the IP address of your self-managed Couchbase Server cluster instances as allowed IP addresses, do the following: a. Under **Wide Area Network**, choose **Manage Allowed IP**. b. Choose **Add Allowed IP**, enter the IP address for the system where you installed Couchbase Shell, and then choose **Add IP**. c. Repeat the previous step to add the IP address of your self-managed Couchbase Server cluster instance.	Couchbase administrator, Systems administrator

Task	Description	Skills required
	For more information about allowed IP addresses, see Configure allowed IP addresses in the Couchbase documentation.	

Task	Description	Skills required
Configure certificates.	1. To download the root certificate for your cluster, under **Root Certificate**, choose **Download**. 2. Save the root certifica te using the .pem file extension in a folder on the system that will run Couchbase Shell. 3. Next, log in to your self-managed Couchbase Server Web Console, choose **Security** in the left navigation bar, and then choose the **Certificates** tab. 4. Copy the root certifica te for your self-managed Couchbase Server cluster and save it as a .pem file to the same folder where you saved the root certificate file for your Couchbase Capella cluster. For more information about the root certifica te, see [Root certificate in the Couchbase Server documentation]().	Couchbase administrator, Systems administrator

Task	Description	Skills required
Create the configuration file for Couchbase Shell.	Create a configuration dotfile in the Couchbase Shell installation's home directory (for example, `/<HOME_DIRECTORY>/.cbsh/config`). For more information, see Config dotfiles in the Couchbase documentation. Add connection properties for the source and target clusters to the configuration file. You can use the example configuration file that's in the *Additional information* section and edit the settings for your clusters. Save the configuration file with the updated settings to the `.cbsh` folder (for example, `/<HOME_DIRECTORY>/.cbsh/config`).	Couchbase administrator, Systems administrator

Task	Description	Skills required
Create target buckets.	For each source bucket, create one target bucket in your Couchbase Capella cluster by following the instructions in [Create a bucket](#) in the Couchbase documentation. Your target bucket configurations must match the bucket names, memory settings, and conflict resolution settings of the buckets in your self-managed Couchbase Server cluster.	Couchbase administrator

Task	Description	Skills required

Create scopes and collections.	Every bucket contains a default scope and collection with the keyspace `_default._default` . If you are using any other keyspaces for your scope and collection, you must create identical keyspaces in the target Capella cluster.
	
	1. Open the command line terminal on the system where you installed Couchbase Shell.
	2. To start Couchbase Shell, run the following command.
	`./cbsh`
	3. For each bucket that you want to migrate, create scopes and collections in the Capella cluster by running the following commands. Make sure that you replace <BUCKET_NAME> with the name of the bucket that you want to migrate.
	
	`scopes --clusters "On-Prem-Cluster" --bucket <BUCKET_NAME> | select scope | where scope !`
		Couchbase administrator

Task	Description	Skills required
	(continued)	

```
= "_default" | each
 { |it| scopes create
 $it.scope --clusters
 "Capella-Cluster" }
collections --cluster
s "On-Prem-Cluster"
 --bucket <BUCKET_N
AME> | select scope
 collection | where
 $it.scope != "_default
" | where $it.colle
ction != "_default" |
 each { |it| collectio
ns create $it.colle
ction --clusters
 "Capella-Cluster" --
bucket <BUCKET_NAME> --
scope $it.scope }
```

Migrate the data from Enterprise Edition

Task	Description	Skills required
Open TCP ports on the self-managed Couchbase Server cluster nodes.	Make sure that the appropriate ports are open for XDCR communication on the self-managed Couchbase Server cluster's nodes. For more information, see the [Couchbase Server ports documentation]().	Couchbase administrator, Systems administrator
If you are using Couchbase Server Enterprise Edition, set up Couchbase XDCR.	1. In the Couchbase Capella Control Plane main navigation, choose **Clusters**, and then choose	Couchbase administrator

Task	Description	Skills required
	the target cluster for migration. 2. Under **Root Certificate**, choose **Copy**. 3. Log in to your self-managed Couchbase Server Web Console, and in the main navigation, choose **XDCR**. Then choose **Add Remote**. 4. Enter the following settings: • **Cluster Name** – A name for the Capella cluster connection • **IP/Hostname** – The connection endpoint for your Couchbase Capella cluster • **Username for Remote Cluster** – The database user for your Couchbase Capella cluster • **Password** – The database user password for your Couchbase Capella cluster • **Enable Secure Connection** – Selected • **Full (TLS encrypt password and data)** – Selected 5. Paste the Capella cluster root certificate you copied	

Task	Description	Skills required
	earlier, and then choose **Save**.	
Start Couchbase XDCR.	1. In your self-managed Couchbase Server Web Console, choose **XDCR** in the main navigation, and then choose **Add Replicati on**. 2. Enter the following settings: • **Replicate From Bucket** – Select the source bucket for migration. • **Remote Bucket** – Enter the target bucket name. • **Remote Cluster** – Select the target cluster you created earlier. 3. Choose **Save Replication**. The replication process should begin within a few seconds.	Couchbase administrator

Migrate the indexes by using option 1

Task	Description	Skills required
Migrate self-managed cluster indexes to Couchbase Capella.	**Important** We recommend this process if you have fewer than 50 indexes to migrate. If you	Couchbase administrator, Systems administrator

Task	Description	Skills required
	have more than 50 indexes to migrate, we recommend that you use migration option 2. 1. On the Couchbase Web Console, choose **Indexes**. 2. In the list of indexes, choose the first index that you want to migrate. The index definition is then displayed. 3. Copy the index definition by using the `CREATE` statement, but don't copy `WITH { "defer_build":true }`. For example, from the following example index definition, you would copy only ``CREATE INDEX `cityindex` ON `travel-sample`(`city`)``. ``CREATE INDEX `cityindex` ON `travel-sample`(`city`) WITH { "defer_build":true }`` 4. In the Couchbase Capella Control Plane, choose	

Task	Description	Skills required
	Clusters, and then choose the target cluster. 5. On the Tools dropdown list, choose **Query Workbench**. Paste the `CREATE` statement that you copied earlier into the **Query Editor**, and then choose **Execute**. This creates and builds the index. 6. To confirm that the index is created, choose **Indexes** from the **Tools** dropdown list. The list shows that the index was created and built. 7. Repeat this process for each index that must be migrated.	

Migrate the indexes by using option 2

Task	Description	Skills required
Migrate the index definitions.	**Important** We recommend this process if you have more than 50 indexes to migrate. If you have fewer than 50 indexes to migrate, we recommend that	Couchbase administrator, Systems administrator

Task	Description	Skills required

	you use migration option 1.
	
	1. Open the command line terminal on the system where you installed Couchbase Shell.
	2. To start Couchbase Shell, run the following command.
	`./cbsh`
	3. To connect to the self-managed Couchbase Server cluster, run the following command.
	`cb-env cluster On-Prem-Cluster`
	4. To migrate index definitions from the self-managed Couchbase Server cluster to the Couchbase Capella cluster, run the following command for each bucket that you want to migrate. Make sure that you replace `<BUCKET_NAME>` with the bucket name that corresponds to the indexes that you want to migrate. This migration option requires that your	

Task	Description	Skills required
	target bucket names are identical to the source bucket names. `query indexes --definitions | where bucket =~ <BUCKET_NAME>| get definition | each { |it| query $it --clusters Capella-Cluster }`	

Task	Description	Skills required

Build the index definitions.	1. To switch context to the Couchbase Capella cluster, run the following command:
	`cb-env cluster Capella-Cluster`
	2. To build the index definitions that were migrated to the Couchbase Capella cluster, run the following command, replacing `<BUCKET_NAME>` with the bucket name that corresponds to the indexes that you want to build.
	`query 'SELECT RAW CONCAT("BUILD INDEX ON ", k , "(['", CONCAT2 ("','", inames), "']);") FROM system:indexes AS s LET bid = CONCAT("` ",s.bucket_id, "`"), sid = CONCAT("`", s.scope_id, "`"), kid = CONCAT("` ", s.keyspace_id, "`"), k = NVL2(bid, CONCAT2(".", bid, sid, kid), kid) WHERE s.namespace_id = "default" AND s.bucket_id = "" GROUP BY k LETTING`
		Couchbase administrator, Systems administrator

Task	Description	Skills required
	` inames = ARRAY_AGG (s.name) FILTER (WHERE s.state = 'deferred') HAVING ARRAY_LENGTH(inames) > 0;' | each { | it| query $it }` 3. Repeat for each bucket.	

Migrate full-text search indexes

Task	Description	Skills required
Migrate self-managed cluster full-text search indexes to Couchbase Capella.	1. In the Couchbase Web Console, choose **Search**. 2. In the list of full-text search (FTS) indexes, choose the first FTS index that you want to migrate, choose **Show index definition JSON,** and choose **Copy to Clipboard**. Make a note of the **index name** and the **bucket** it belongs to. 3. In the Couchbase Capella Control Plane, choose **Clusters** and then choose the target cluster. 4. On the Tools dropdown list, choose **Full Text Search**.	Couchbase administrator

Task	Description	Skills required
	5. Choose **Import Index**, and paste the FTS index definition. 6. Enter the **Index Name**, select the correct **Bucket**, as noted on the self-managed cluster, and then choose **Create**. 7. Repeat this process for each FTS index that must be migrated.	

Migrate data from Couchbase Community Edition

Task	Description	Skills required

Export data from self-managed Couchbase Server Community Edition.	Encrypted XDCR is not available in Couchbase Community Edition. You can export data from Couchbase Community Edition and then manually import the data into Couchbase Capella.
	
	To export data from the source bucket, use `cbexport` at the command line.
	
	The following command is provided as an example.
	
	`cbexport json \`
	`--cluster localhost \`
	`--bucket <SOURCE BUCKET NAME> \`
		Couchbase administrator

Task	Description	Skills required

	<pre>--format lines \
	--username <USERNAME>
	 \
	--password <PASSWORD>
	 \
	--include-key cbkey \
	--scope-field cbscope \
	--collection-field
	 cbcoll \
	--output cbexporte
	d_data.json</pre> Note that `cbkey`, `cbscope`, `cbcoll`, and `cbexported_data.json` are arbitrary labels. They will be referenced later in the process, so if you choose to name them differently, make note of it.	

Task	Description	Skills required
Import data into Couchbase Capella.	1. In the Couchbase Capella Control Plane, choose **Clusters**, and then choose the target cluster. 2. In the **Tools** dropdown list, choose **Import**. This will open a wizard with the following six steps: a. **Bucket** – Choose the target bucket. b. **File** – Choose **JSON**, choose **Lines**, and then choose **Using your web browser**. If you have a large amount of data, you can explore the **Manually** option. Select the file created by `cbexport`. c. **Collections** – Choose **Custom Collection Mapping**. If your Community Edition database does not use scopes or collections, or it uses only **_default**, you can choose the **Select Single Collection** option instead. For **Collection Mapping Expression**, enter	Couchbase administrator

Task	Description	Skills required
	`%cbscope%.%cbcoll%` . To verify that this expression works correctly, you can paste example data, such as the following. `{ "cbscope" :"inventory", "cbcoll":"landmark ", "cbkey":" landmark_3991" }` d. **Key** – Choose **Customer Generation**. (If you don't care about preserving the keys of the data you're importing, you can select **Automatically Generated UUID** instead and proceed to step 5.) For **Key Name Generator Expression**, enter **%cbkey%**. To verify that this expression works correctly, paste some example data. e. **Configurations** – Choose **Ignore fields**, and enter **cbscope,cbcoll,cbkey**. These fields contain transitory information that does not need to be in the target bucket after an import. Leave	

Task	Description	Skills required
	the other settings at their defaults. f. **Import** – Review, and choose **Import** when you're ready. Wait for the upload and data import. For large files, Couchbase Capella supports command line import using cURL. You can explore Import options in more detail at [Import data](#) in the Couchbase Capella documentation.	

Test and verify the migration

Task	Description	Skills required
Verify data migration.	1. In the Couchbase Capella Control Plane, choose **Clusters**, and then choose the target cluster in your cluster list. 2. Choose the **Buckets** tab for your target cluster. Verify that the number of **Items** (documents) in the target bucket matches the number of items in the source bucket.	Couchbase administrator

Task	Description	Skills required
	3. In the target cluster, in the **Tools** dropdown list, choose **Documents**. Verify that all documents were migrated. 4. (Optional) After all data is migrated, you can shut down the replicati on by deleting it. For more information, see [Delete a replication](#) in the Couchbase documentation.	
Verify index migration.	In the Couchbase Capella Control Plane, in the **Tools** dropdown list for your target cluster, choose **Indexes**. Verify that the indexes are migrated and built.	Couchbase administrator
Verify query results.	1. In the Couchbase Capella Control Plane, in the **Tools** dropdown list for your target cluster, choose **Query Workbench**. 2. Run a sample N1QL query or a query used in your application. Make sure that you receive the same results as when you run the query in your self-managed Couchbase Server cluster.	Couchbase administrator

Task	Description	Skills required
Verify full-text search results (applicable if you migrated FTS indexes).	1. In the Couchbase Capella Control Plane, in the **Tools** dropdown list for your target cluster, choose **Full Text Search**. 2. Select an FTS index by choosing its name. 3. Choose **Search**. 4. Enter a sample search query, and choose **Search**. 5. Verify that the results are the same as when you run the search on your self-managed cluster.	Couchbase administrator

Additional information

The following code is an example configuration file for Couchbase Shell.

```
Version = 1

[[clusters]]
identifier = "On-Prem-Cluster"
hostnames = ["<SELF_MANAGED_COUCHBASE_CLUSTER>"]
default-bucket = "travel-sample"
username = "<SELF_MANAGED_ADMIN>"
password = "<SELF_MANAGED_ADMIN_PWD>"
tls-cert-path = "/<ABSOLUTE_PATH_TO_SELF_MANAGED_ROOT_CERT>"
data-timeout = "2500ms"
connect-timeout = "7500ms"
query-timeout = "75s"

[[clusters]]
identifier = "Capella-Cluster"
hostnames = ["<COUCHBASE_CAPELLA_ENDPOINT>"]
default-bucket = "travel-sample"
username = "<CAPELLA_DATABASE_USER>"
password = "<CAPELLA_DATABASE_USER_PWD>"
tls-cert-path = "/<ABSOLUTE_PATH_TO_COUCHBASE_CAPELLA_ROOT_CERT>"
data-timeout = "2500ms"
connect-timeout = "7500ms"
query-timeout = "75s"
```

Before you save the configuration file, use the following table to make sure that you added your own source and target cluster information.

<SELF_MANAGED_COUCHBASE_CLUSTER>	Use the IP address for your self-managed Couchbase Server cluster.
<SELF_MANAGED_ADMIN>	Use the administrator user for your self-managed Couchbase Server cluster.
<ABSOLUTE_PATH_TO_SELF_MANAGED_ROOT_CERT>	Use the absolute path to the saved root certificate file for your self-managed Couchbase Server cluster.

<COUCHBASE_CAPELLA_ENDPOINT>	Use the connection endpoint for your Couchbase Capella cluster.
<CAPELLA_DATABASE_USER>	Use the database user for your Couchbase Capella cluster.
<CAPELLA_DATABASE_USER_PWD>	Use the database user password for your Couchbase Capella cluster.
<ABSOLUTE_PATH_TO_COUCHBASE_CAPELLA_ROOT_CERT>	Use the absolute path to the saved root certificate file for your Couchbase Capella cluster.

Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2

Neal Ardeljan and Afroz Khan, Amazon Web Services

Summary

This pattern walks you through the steps for migrating from an on-premises Red Hat Enterprise Linux (RHEL) 6.9 or later system that's running IBM WebSphere Application Server (WAS) to RHEL 8 running Apache Tomcat on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

The pattern can be applied to the following source and target versions:

- WebSphere Application Server 7.x to Apache Tomcat 8 (with Java 7 or later)
- WebSphere Application Server 8.x to Apache Tomcat 8 (with Java 7 or later)
- WebSphere Application Server 8.5.5.x to Apache Tomcat 9 (with Java 8 or later)
- WebSphere Application Server 8.5.5.x to Apache Tomcat 10 (with Java 8 or later)

Prerequisites and limitations

Prerequisites

- An active AWS account
- Source Java code, with the following assumptions:
  - Uses the Java Development Kit (JDK) version of Java 7 or later
  - Uses the Spring or Apache Struts framework
  - Doesn't use the Enterprise Java Beans (EJB) framework or any other WebSphere server functionality that's not readily available for Tomcat
  - Primarily uses servlets or Java Server Pages (JSPs)
  - Uses Java Database Connectivity (JDBC) connectors to connect to databases
- Source IBM WebSphere Application Server version 7.x or higher
- Target Apache Tomcat version 8.5 or higher

Architecture

Source technology stack

- A web application built using the Apache Struts Model-View-Controller (MVC) framework
- A web application running on IBM WebSphere Application Server version 7.x or 8.x
- A web application that uses a Lightweight Directory Access Protocol (LDAP) connector to connect to an LDAP directory (iPlanet/eTrust)
- An application that uses IBM Tivoli Access Manager (TAM) connectivity to update the TAM user password (in the present implementation, applications use PD.jar)

On-premises databases

- Oracle Database 21c (21.0.0.0)
- Oracle Database 19c (19.0.0.0)
- Oracle Database 12c Release 2 (12.2.0.1)
- Oracle Database 12c Release 1 (12.1.0.2)

Target technology stack

- Apache Tomcat version 8 (or later) running on RHEL on an EC2 instance
- Amazon Relational Database Service (Amazon RDS) for Oracle

For more information about the Oracle versions supported by Amazon RDS, see the [Amazon RDS for Oracle](#) website.

Target architecture

Tools

- Application tier: Rebuilding Java application into a WAR file.
- Database tier: Oracle native backup and restore.
- Apache Tomcat migration tool for Jakarta EE. This tool takes a web application written for Java EE 8 that runs on Apache Tomcat 9 and converts it automatically to run on Apache Tomcat 10, which implements Jakarta EE 9.

Epics

Plan the migration

Task	Description	Skills required
Complete the application discovery, current state footprint, and performance baseline.		BA, Migration Lead
Validate the source and target database versions.		DBA
Identify the hardware requirements for the target server EC2 instance.		DBA, SysAdmin
Identify storage requirements (storage type and capacity).		DBA, SysAdmin
Choose the proper EC2 instance type based on capacity, storage features, and network features.		DBA, SysAdmin
Identify the network access security requirements for the source and target databases.		DBA, SysAdmin

Task	Description	Skills required
Identify the application migration strategy and tooling.		DBA, Migration Lead
Complete the migration design and migration guide for the application.		Build Lead, Migration Lead
Complete the application migration runbook.		Build Lead, Cutover Lead, Testing Lead, Migration Lead

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).		SysAdmin
Create the security groups.		SysAdmin
Configure and start Amazon RDS for Oracle.		DBA, SysAdmin

Migrate data

Task	Description	Skills required
Create or obtain access to the endpoints to fetch the database backup files.		DBA
Use the native database engine or a third-party tool to migrate database objects and data.	For details, see "Migrating database objects and data" in the *Additional information* section.	DBA

Migrate the application

Task	Description	Skills required
Lodge the change request (CR) for migration.		Cutover Lead
Obtain the CR approval for migration.		Cutover Lead
Follow the application migration strategy per the application migration runbook.	For details, see "Setting up the application tier" in the *Additional information* section.	DBA, Migration Engineer, App owner
Upgrade the application (if necessary).		DBA, Migration Engineer, App owner
Complete the functional, non-functional, data validation, SLA, and performance tests.		Testing Lead, App Owner, App Users

Cut over

Task	Description	Skills required
Obtain signoff from the application owner or business owner.		Cutover Lead
Switch the application clients to the new infrastructure.		DBA, Migration Engineer, App owner

Close the project

Task	Description	Skills required
Shut down temporary AWS resources.		DBA, Migration Engineer, SysAdmin
Review and validate the project documents.		Migration Lead
Gather metrics such as time to migrate, percentage of manual versus automated tasks, and cost savings.		Migration Lead
Close out the project and provide feedback.		Migration Lead, App Owner

Additional information

Migrating database objects and data

For example, if you're using native Oracle backup/restore utilities:

1. Create the Amazon Simple Storage Service (Amazon S3) backup for database backup files (optional).
2. Back up the Oracle DB data to the network shared folder.
3. Log in to the migration staging server to map the network share folder.
4. Copy data from the network share folder to the S3 bucket.
5. Request an Amazon RDS Multi-AZ deployment for Oracle.
6. Restore the on-premises database backup to Amazon RDS for Oracle.

Setting up the application tier

1. Install Tomcat 8 (or 9/10) from the Apache Tomcat website.
2. Package the application and shared libraries into a WAR file.
3. Deploy the WAR file in Tomcat.
4. Monitor the start log to `Linux cat` any missing shared libraries from WebSphere.
5. Watch the start record to `Linux cat` any WebSphere-specific deployment descriptor extensions.
6. Collect any missing dependent Java libraries from the WebSphere server.
7. Amend WebSphere-specific deployment descriptor elements with Tomcat-compatible equivalents.
8. Rebuild the WAR file with the dependent Java libraries and updated deployment descriptors.
9. Update the LDAP configuration, database configuration, and test connections (see Realm Configuration HOW-TO and JNDI Datasource HOW-TO in the Apache Tomcat documentation).
10. Test the installed application against the restored Amazon RDS for Oracle database.
11. Create an Amazon Machine Image (AMI) for Linux from the EC2 instance.
12. Launch the completed architecture with the Application Load Balancer and Auto Scaling group.
13. Update the URLs (by using the WebSEAL junction) to point to the Application Load Balancer.
14. Update the configuration management database (CMDB).

Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2 with Auto Scaling

Kevin Yung and Afroz Khan, Amazon Web Services

Summary

This pattern provides guidance for migrating a Java application from IBM WebSphere Application Server to Apache Tomcat on an Amazon Elastic Compute Cloud (Amazon EC2) instance with Amazon EC2 Auto Scaling enabled.

By using this pattern, you can achieve:

- A reduction in IBM licensing costs
- High availability using Multi-AZ deployment
- Improved application resiliency with Amazon EC2 Auto Scaling

Prerequisites and limitations

Prerequisites

- Java applications (version 7.*x* or 8.*x*) should be developed in LAMP stacks.
- The target state is to host Java applications on Linux hosts. This pattern has been successfully implemented in a Red Hat Enterprise Linux (RHEL) 7 environment. Other Linux distributions can follow this pattern, but the configuration of the Apache Tomcat distribution should be referenced.
- You should understand the Java application's dependencies.
- You must have access to the Java application source code to make changes.

Limitations and replatforming changes

- You should understand the enterprise archive (EAR) components and verify that all libraries are packaged in the web component WAR files. You need to configure the [Apache Maven WAR Plugin] and produce WAR file artifacts.
- When using Apache Tomcat 8, there is a known conflict between servlet-api.jar and the application package built-in jar files. To resolve this issue, delete servlet-api.jar from the application package.

- You must configure WEB-INF/resources located in the *classpath* of the Apache Tomcat configuration. By default, the JAR libraries are not loaded in the directory. Alternatively, you can deploy all the resources under src/main/resources.
- Check for any hard-coded context roots within the Java application, and update the new context root of Apache Tomcat.
- To set JVM runtime options, you can create the configuration file setenv.sh in the Apache Tomcat bin folder; for example, JAVA_OPTS, JAVA_HOME**,** etc.
- Authentication is configured at the container level and is set up as a realm in Apache Tomcat configurations. Authentication is established for any of the following three realms:
  - JDBC Database Realm looks up users in a relational database accessed by the JDBC driver.
  - DataSource Database Realm looks up users in a database that is accessed by JNDI.
  - JNDI Directory Realm looks up users in the Lightweight Directory Access Protocol (LDAP) directory that is accessed by the JNDI provider. The look-ups require:
    - LDAP connection details: user search base, search filter, role base, role filter
    - The key JNDI Directory Realm: Connects to LDAP, authenticates users, and retrieves all groups in which a user is a member
- Authorization: In the case of a container with a role-based authorization that checks the authorization constraints in web.xml, web resources must be defined and compared to the roles defined in the constraints. If LDAP doesn't have group-role mapping, you must set the attribute <security-role-ref> in web.xml to achieve group-role mapping. To see an example of a configuration document, see the Oracle documentation.
- Database connection: Create a resource definition in Apache Tomcat with an Amazon Relational Database Service (Amazon RDS) endpoint URL and connection details. Update the application code to reference a DataSource by using JNDI lookup. An existing DB connection defined in WebSphere would not work, as it uses WebSphere's JNDI names. You can add a <resource-ref> entry in web.xml with the JNDI name and DataSource type definition. To see a sample configuration document, see the Apache Tomcat documentation.
- Logging: By default, Apache Tomcat logs to the console or to a log file. You can enable realm-level tracing by updating *logging.properties* (see Logging in Tomcat). If you are using Apache Log4j to append logs to a file, you must download tomcat-juli and add it to the *classpath*.
- Session management: If you are retaining IBM WebSEAL for application load balancing and session management, no change is required. If you are using an Application Load Balancer or Network Load Balancer on AWS to replace the IBM WebSEAL component, you must set up

session management by using an Amazon ElastiCache instance with a Memcached cluster and set up Apache Tomcat to use open-source session management.

- If you are using the IBM WebSEAL forward proxy, you must set up a new Network Load Balancer on AWS. Use the IPs provided by the Network Load Balancer for WebSEAL junction configurations.
- SSL configuration: We recommend that you use Secure Sockets Layer (SSL) for end-to-end communications. To set up an SSL server configuration in Apache Tomcat, follow the instructions in the Apache Tomcat documentation.

Architecture

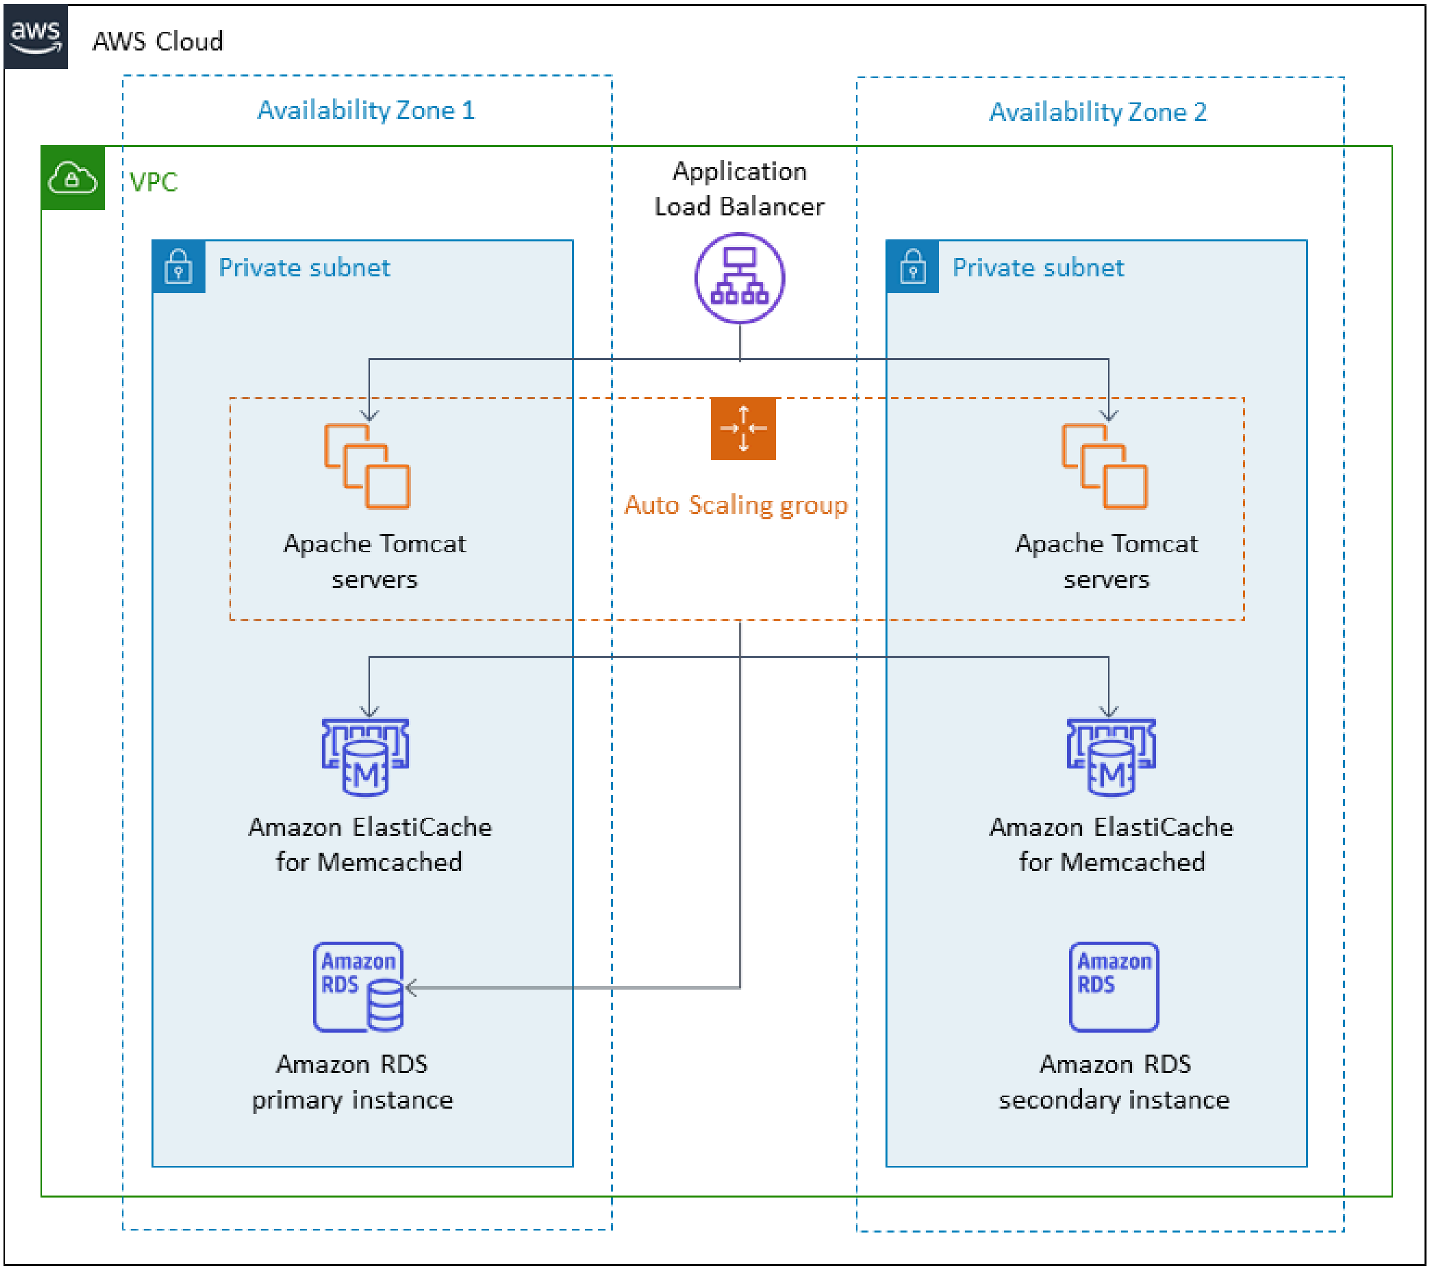
Source technology stack

- IBM WebSphere Application Server

Target technology stack

- The architecture uses Elastic Load Balancing (version 2). If you are using IBM WebSEAL for Identify management and load balancing, you can select a Network Load Balancer on AWS to integrate with the IBM WebSEAL reverse proxy.
- Java applications are deployed to an Apache Tomcat application server, which runs on an EC2 instance in an Amazon EC2 Auto Scaling group. You can set up a scaling policy based on Amazon CloudWatch metrics such as CPU utilization.
- If you're retiring the use of IBM WebSEAL for load balancing, you can use Amazon ElastiCache for Memcached for session management.
- For the back-end database, you can deploy High Availability (Multi-AZ) for Amazon RDS and select a database engine type.

Target architecture



Tools

- [AWS CloudFormation]
- [AWS Command Line Interface (AWS CLI)]
- Apache Tomcat (version 7.*x* or 8.*x*)
- RHEL 7 or Centos 7
- [Amazon RDS Multi-AZ deployment]
- [Amazon ElastiCache for Memcached] (optional)

Epics

Set up the VPC

Task	Description	Skills required
Create a virtual private cloud (VPC).		
Create subnets.		
Create routing tables if necessary.		
Create network access control lists (ACLs).		
Set up AWS Direct Connect or a corporate VPN connection.		

Replatform the application

Task	Description	Skills required
Refactor the application build Maven configuration to generate the WAR artifacts.		
Refactor the application dependency data sources in Apache Tomcat.		
Refactor the application source codes to use JNDI names in Apache Tomcat.		
Deploy the WAR artifacts into Apache Tomcat.		

Task	Description	Skills required
Complete application validations and tests.		

Configure the network

Task	Description	Skills required
Configure the corporate firewall to allow the connection to dependency services.		
Configure the corporate firewall to allow end-user access to Elastic Load Balancing on AWS.		

Create the application infrastructure

Task	Description	Skills required
Create and deploy the application on an EC2 instance.		
Create an Amazon ElastiCac he for Memcached cluster for session management.		
Create an Amazon RDS Multi-AZ instance for the backend database.		

Task	Description	Skills required
Create SSL certificates and import them into AWS Certificate Manager (ACM).		
Install SSL certificates on load balancers.		
Install SSL certificates for Apache Tomcat servers.		
Complete application validations and tests.		

Cut over

Task	Description	Skills required
Shut down the existing infrastructure.		
Restore the database from production to Amazon RDS.		
Cut over the application by making DNS changes.

Migrate a .NET application from Microsoft Azure App Service to AWS Elastic Beanstalk

Raghavender Madamshitti, Amazon Web Services

Summary

This pattern describes how to migrate a .NET web application hosted on Microsoft Azure App Service to AWS Elastic Beanstalk. There are two ways to migrate applications to Elastic Beanstalk:

- Use AWS Toolkit for Visual Studio - This plugin for the Microsoft Visual Studio IDE provides the easiest and most straightforward way to deploy custom .NET applications to AWS. You can use this approach to deploy .NET code directly to AWS and to create supporting resources, such as Amazon Relational Database Service (Amazon RDS) for SQL Server databases, directly from Visual Studio.
- Upload and deploy to Elastic Beanstalk - Each Azure App Service includes a background service called Kudu, which is useful for capturing memory dumps and deployment logs, viewing configuration parameters, and accessing deployment packages. You can use the Kudu console to access Azure App Service content, extract the deployment package, and then upload the package to Elastic Beanstalk by using the upload and deploy option in the Elastic Beanstalk console.

This pattern describes the second approach (uploading your application to Elastic Beanstalk through Kudu). The pattern also uses the following AWS services: AWS Elastic Beanstalk, Amazon Virtual Private Cloud (Amazon VPC), Amazon CloudWatch, Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling, Amazon Simple Storage Service (Amazon S3), and Amazon Route 53.

The .NET web application is deployed to AWS Elastic Beanstalk, which runs in an Amazon EC2 Auto Scaling Group. You can set up a scaling policy based on Amazon CloudWatch metrics such as CPU utilization. For a database, you can use Amazon RDS in a Multi-AZ environment, or Amazon DynamoDB, depending on your application and business requirements.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A .NET web application running in Azure App Service
- Permission to use the Azure App Service Kudu console

Product versions

- .NET Core (x64) 1.0.1, 2.0.0, or later, or .NET Framework 4.x, 3.5 (see .NET on Windows Server platform history)
- Internet Information Services (IIS) version 8.0 or later, running on Windows Server 2012 or later
- .NET 2.0 or 4.0 Runtime.

Architecture

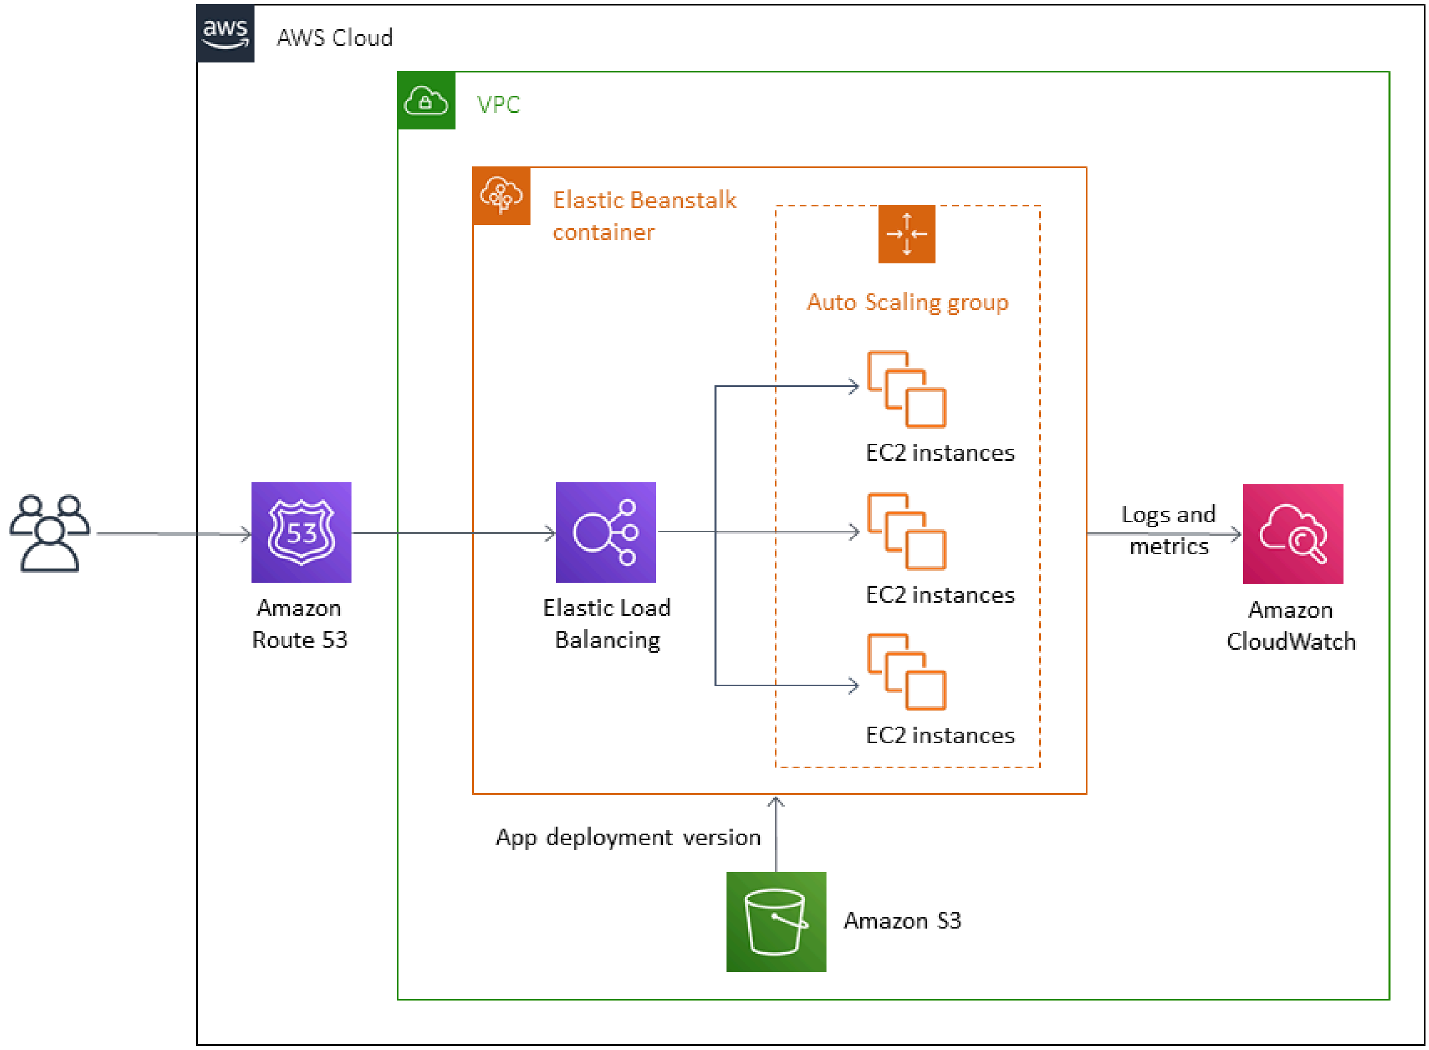
Source technology stack

- Application developed using .NET Framework 3.5 or later, or .NET Core 1.0.1, 2.0.0, or later, and hosted on Azure App Service (web app or API app)

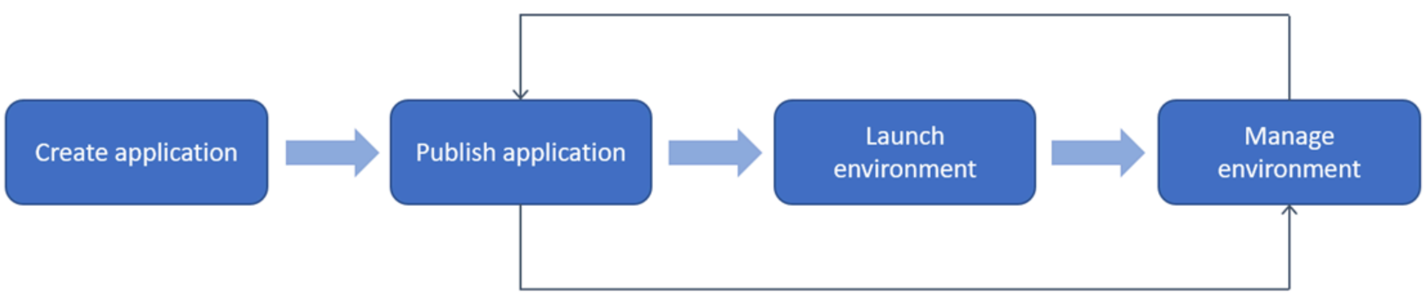
Target technology stack

- AWS Elastic Beanstalk running in an Amazon EC2 Auto Scaling group

Migration architecture



Deployment workflow



Tools

Tools

- .NET Core or .NET Framework

- C#
- IIS
- Kudu console

AWS services and features

- AWS Elastic Beanstalk – Elastic Beanstalk is an easy-to-use service for deploying and scaling .NET web applications. Elastic Beanstalk automatically manages capacity provisioning, load balancing, and auto scaling.
- Amazon EC2 Auto Scaling group – Elastic Beanstalk includes an Auto Scaling group that manages the Amazon EC2 instances in the environment. In a single-instance environment, the Auto Scaling group ensures that there is always one instance running. In a load-balanced environment, you can configure the group with a range of instances to run, and Amazon EC2 Auto Scaling adds or removes instances as needed, based on load.
- Elastic Load Balancing – When you enable load balancing in AWS Elastic Beanstalk, it creates a load balancer that distributes traffic among the EC2 instances in the environment.
- Amazon CloudWatch – Elastic Beanstalk automatically uses Amazon CloudWatch to provide information about your application and environment resources. Amazon CloudWatch supports standard metrics, custom metrics, and alarms.
- Amazon Route 53 – Amazon Route 53 is a highly available and scalable cloud Domain Name System (DNS) web service. You can use Route 53 alias records to map custom domain names to AWS Elastic Beanstalk environments.

Epics

Set up a VPC

Task	Description	Skills required
Set up a virtual private cloud (VPC).	In your AWS account, create a VPC with the required information.	System administrator
Create subnets.	Create two or more subnets in your VPC.	System administrator

Task	Description	Skills required
Create a route table.	Create a route table, based on your requirements.	System administrator

Set up Elastic Beanstalk

Task	Description	Skills required
Access the Azure App Service Kudu console.	Access Kudu through the Azure portal by navigating to the App Service dashboard, and then choosing **Advanced Tools**, **Go**. Or, you can modify the Azure App Service URL as follows: `https://<appservicename>.scm.azurewebsites.net` .	App developer, System administrator
Download the deployment package from Kudu.	Navigate to Windows PowerShell by choosing the **DebugConsole** option. This will open the Kudo console. Go to the `wwwroot` folder and download it. This will download the Azure App Service deployment package as a zip file. For an example, see the attachment.	App developer, System administrator
Create a package for Elastic Beanstalk.	Unzip the deployment package that you downloaded from Azure App Service. Create a JSON file called `aws-windows-deployment-manifest.json`	App developer, System administrator

Task	Description	Skills required
	(this file is required only for .NET Core applications). Create a zip file that includes `aws-windows-deployment-manifest.json` and the Azure App Service deployment package file. For an example, see the attachment.	
Create a new Elastic Beanstalk application.	Open the Elastic Beanstalk console. Choose an existing application or create a new application.	App developer, System administrator
Create the environment.	In the Elastic Beanstalk console **Actions** menu, choose **Create environment**. Select the web server environment and .NET/IIS platform. For application code, choose **Upload**. Upload the zip file that you prepared for Elastic Beanstalk, and then choose **Create Environment**.	App developer, System administrator
Configure Amazon CloudWatch.	By default, basic CloudWatch monitoring is enabled. If you want to change the configuration, in the Elastic Beanstalk wizard, choose the published application, and then choose **Monitoring**.	System administrator

Task	Description	Skills required
Verify that the deployment package is in Amazon S3.	When the application environment has been created, you can find the deployment package in the S3 bucket.	App developer, System administrator
Test the application.	When the environment has been created, use the URL provided in the Elastic Beanstalk console to test the application.	System administrator

Migrate from Oracle WebLogic to Apache Tomcat (TomEE) on Amazon ECS

Anya Epishcheva and Harshad Gohil, Amazon Web Services

Summary

This pattern discusses the steps for migrating an on-premises Oracle Solaris SPARC system running Oracle WebLogic to a Docker container-based installation running [Apache TomEE](https://tomee.apache.org/) (Apache Tomcat with added container support) with Amazon Elastic Container Service (Amazon ECS).

For information about migrating databases that are associated with the applications you are migrating from Oracle WebLogic to Tomcat, see the database migration patterns in this catalog.

Best practices

Steps for migrating Java and Java Enterprise Edition (Java EE) web applications vary, depending on the number of container-specific resources used by the application. Spring-based applications are typically easier to migrate, because they have a small number of dependencies on the deployment container. In contrast, Java EE applications that use Enterprise JavaBeans (EJBs) and managed container resources such as thread pools, Java Authentication and Authorization Service (JAAS), and Container-Managed Persistence (CMP) require more effort.

Applications developed for Oracle Application Server frequently use the Oracle Identity Management suite. Customers migrating to open-source application servers frequently choose to re-implement identity and access management using SAML-based federation. Others use Oracle HTTP Server Webgate for cases when migrating from the Oracle Identity Management suite isn't an option.

Java and Java EE web applications are great candidates for deployment on AWS services that are Docker-based, such as AWS Fargate and Amazon ECS. Customers frequently choose a Docker image with the latest version of the target application server (such as TomEE) and the Java Development Kit (JDK) pre-installed. They install their applications on top of the base Docker image, publish it in their Amazon Elastic Container Registry (Amazon ECR) registry, and use it for scalable deployment of their applications on AWS Fargate or Amazon ECS.

Ideally, application deployment is elastic; that is, the number of application instances scales in or out, depending on traffic or workload. This means that application instances need to come online or be terminated to adjust capacity for demand.

When moving a Java application to AWS, consider making it stateless. This is a key architectural principle of the AWS Well-Architected Framework that will enable horizontal scaling using containerization. For example, most Java-based web applications store user-session information locally. To survive application instance termination due to automatic scaling in Amazon Elastic Compute Cloud (Amazon EC2) or for other reasons, user-session information should be stored globally so that web application users can continue to work seamlessly and transparently without reconnecting or relogging into a web application. There are several architectural options for this approach, including Amazon ElastiCache for Redis, or storing session state in a global database. Application servers such as TomEE have plugins, which enable session storage and management via Redis, databases, and other global data stores.

Use a common, centralized logging and debugging tool that is easily integrated with Amazon CloudWatch and AWS X-Ray. Migration provides an opportunity to improve application lifecycle capabilities. For example, you might want to automate the build process so that changes are easily made using a continuous integration and continuous delivery (CI/CD) pipeline. This may require changes to the application so that it can be deployed without any downtime.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Source Java code and JDK
- Source application built with Oracle WebLogic
- Defined solution for identity and access management (SAML or Oracle Webgate)
- Defined solution for application session management (moving like-for-like or with Amazon ElastiCache, or making the application stateless if needed)
- Understanding if the team needs to refactor J2EE-specific libraries for portability to Apache TomEE (see Java EE 7 Implementation Status on the Apache website)
- Hardened TomEE image based on your security requirements
- Container image with pre-installed target TomEE
- Application remediation agreed and implemented if needed (for example, logging debug build, authentication)

Product versions

- Oracle WebLogic OC4J, 9i, 10g
- Tomcat 7 (with Java 1.6 or later)

Architecture

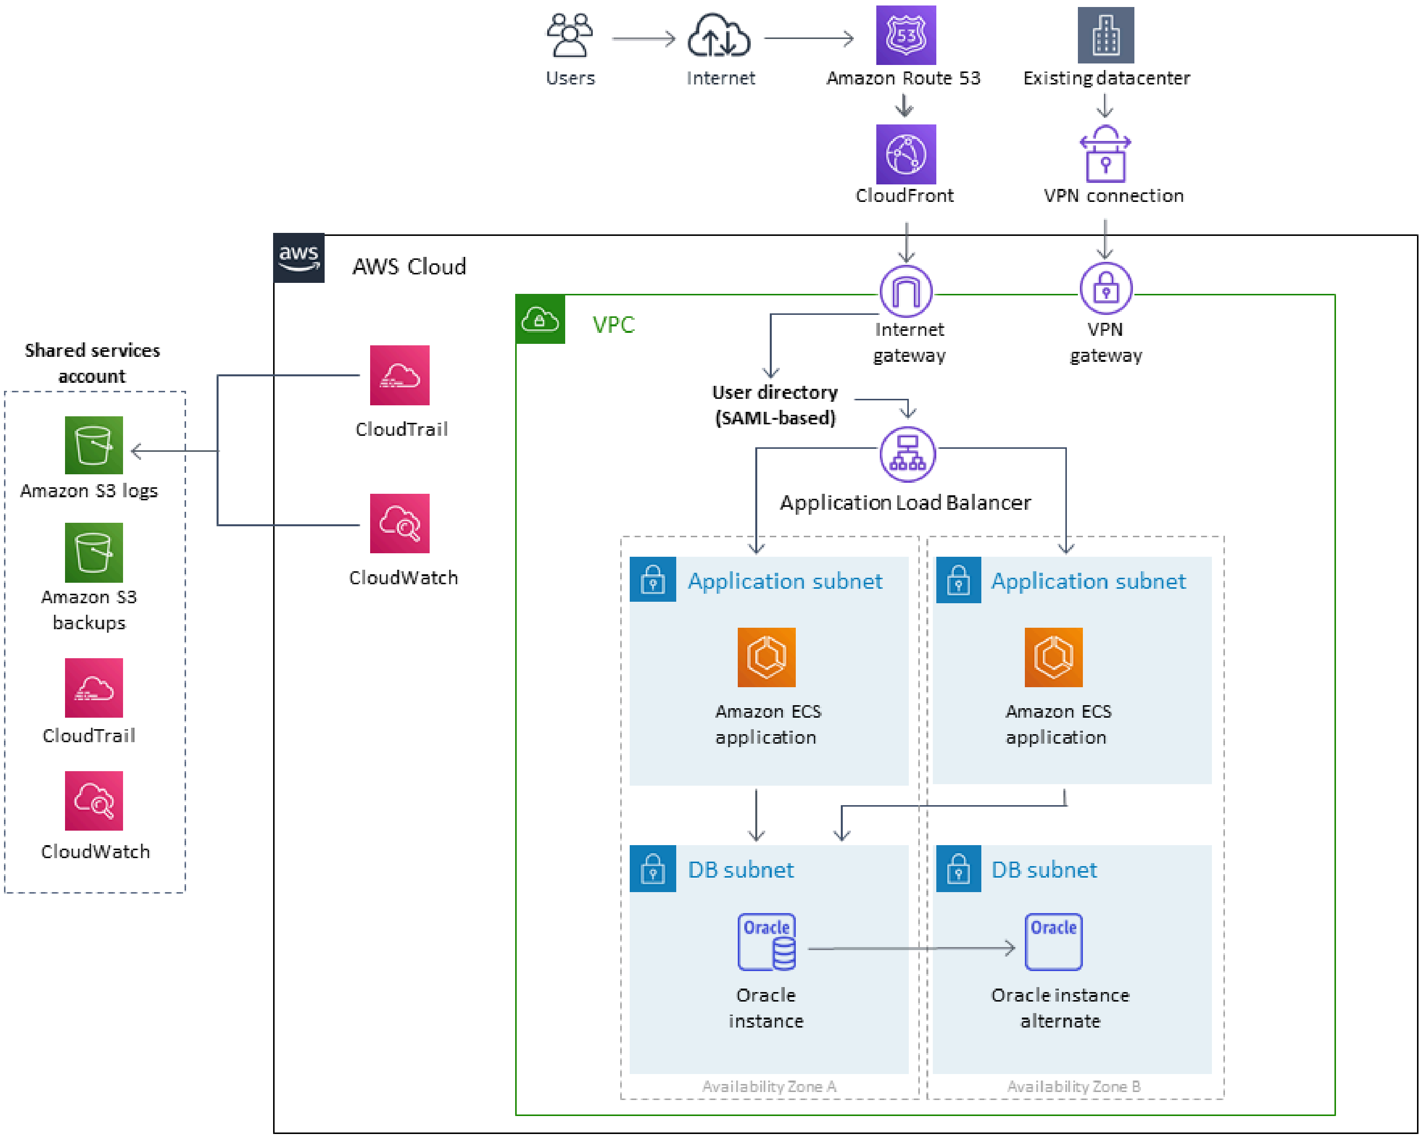
Source technology stack

- Web application built using Oracle WebLogic
- Web application using Oracle Webgate or SAML authentication
- Web applications connected to Oracle Database version 10g and later

Target technology stack

- TomEE (Apache Tomcat with added container support) running on Amazon ECS (see also Deploying Java Web Applications and Java Microservices on Amazon ECS)
- Amazon Relational Database Service (Amazon RDS) for Oracle; for Oracle versions supported by Amazon RDS, see Amazon RDS for Oracle

Target architecture



Tools

To operate on TomEE, a Java application must be rebuilt into a .war file. In some cases, application changes may be required to operate the application on TomEE; you should check to make sure that the necessary configuration options and environment properties are defined correctly.

Also, Java Naming and Directory Interface (JNDI) lookups and JavaServer Pages (JSP) namespaces should be defined correctly. Consider checking file names used by the application to avoid naming collisions with built-in T libraries. For example, persistence.xml is a file name used by the Apache OpenJPA framework (which is bundled with OpenEJB in TomEE) for configuration purposes. The persistence.xml file in PUI contains Spring framework bean declarations.

TomEE version 7.0.3 and later (Tomcat 8.5.7 and later) returns an HTTP 400 response (bad request) for raw (unencoded) URLs with special characters. The server response appears as a blank page to the end-user. Earlier versions of TomEE and Tomcat allowed the use of certain unencoded special characters in URLs; however, it's considered unsafe, as stated on the CVE-2016-6816 website. To resolve the URL encoding issue, the URLs passed to the browser directly via JavaScript must be encoded with the **encodeURI()** method instead of being used as raw strings.

After you deploy the .war file in TomEE, monitor *start log* to *Linux cat* for any missing shared libraries and Oracle-specific extensions to add missing components from Tomcat libraries.

General procedure

- Configure the application on TomEE.
- Identify and reconfigure application server-specific configuration files and resources from source to target format.
- Identify and reconfigure JNDI resources.
- Adjust EJB namespace and lookups to the format required by the target application server (if applicable).
- Reconfigure JAAS application container-specific security roles and principle mappings (if applicable).
- Package the application and shared libraries into a .war file.
- Deploy the .war file in TomEE by using the Docker container provided.
- Monitor *start log* to identify any missing shared library and deployment descriptor extensions. If any are found, go back to the first task.
- Test the installed application against the restored Amazon RDS database.
- Launch the complete architecture with a load balancer and Amazon ECS cluster by following the instructions in Deploy Docker Containers.
- Update the URLs to point to the load balancer.
- Update the configuration management database (CMDB).

Epics

Plan the migration

Task	Description	Skills required
Perform application discovery (current state footprint and performance baseline).		BA, Migration Lead
Validate source and target database versions and engines.		DBA
Validate the source and target application design (identity and session management).		DBA, Migration Engineer, App owner
Identify hardware and storage requirements for the target server instance.		DBA, SysAdmin
Choose the proper instance type based on capacity, storage features, and network features.		DBA, SysAdmin
Identify network access security requirements for the source and target databases.		DBA, SysAdmin
Identify application migration strategy and tooling.		DBA, Migration Lead
Complete the migration design and migration guide for the application.		Build Lead, Migration Lead

Task	Description	Skills required
Complete the application migration runbook.		Build Lead, Cutover Lead, Testing Lead, Migration Lead

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).		SysAdmin
Create security groups.		SysAdmin
Configure and start the Amazon RDS DB instance.		DBA, SysAdmin
Configure Amazon ECS deployment.		SysAdmin
Package your application as a Docker image.		SysAdmin
Push the image to the Amazon ECR registry (or skip this step and push it to the Amazon ECS cluster).		SysAdmin
Configure the task definitio n for the application and Amazon ECS service options.		SysAdmin
Configure your cluster, review security settings, and set AWS Identity and Access Management (IAM) roles.		SysAdmin

Task	Description	Skills required
Launch your setup and run tests according to your application migration runbook.		SysAdmin

Migrate data

Task	Description	Skills required
Get your security assurance team's permission to move production data to AWS.		DBA, Migration Engineer, App owner
Create and obtain access to endpoints to fetch database backup files.		DBA
Use the native database engine or third-party tools to migrate database objects and data.		DBA
Run necessary tests from the application migration runbook to confirm successful data migration.		DBA, Migration Engineer, App owner

Migrate the application

Task	Description	Skills required
Create a change request (CR) for migration.		Cutover Lead

Task	Description	Skills required
Obtain CR approval for migration.		Cutover Lead
Follow the application migration strategy from the application migration runbook.		DBA, Migration Engineer, App owner
Upgrade the application (if required).		DBA, Migration Engineer, App owner
Complete functional, non-functional, data validation, SLA, and performance tests.		Testing Lead, App Owner, App Users

Cut over

Task	Description	Skills required
Obtain signoff from the application or business owner.		Cutover Lead
Run a table topic exercise to walk through all the steps of the cutover runbook.		DBA, Migration Engineer, App owner
Switch application clients to the new infrastructure.		DBA, Migration Engineer, App owner

Close the project

Task	Description	Skills required
Shut down temporary AWS resources.		DBA, Migration Engineer, SysAdmin

Task	Description	Skills required
Review and validate the project documents.		Migration Lead
Gather metrics around time to migrate, % of manual vs. tool, cost savings, etc.		Migration Lead
Close out the project and provide feedback.		Migration Lead, App Owner

Migrate an Oracle database from Amazon EC2 to Amazon RDS for Oracle using AWS DMS

Chethan Gangadharaiah and Brian motzer, Amazon Web Services

Summary

This pattern describes the steps for migrating an Oracle database on Amazon Elastic Compute Cloud (Amazon EC2) to Amazon Relational Database Service (Amazon RDS) for Oracle by using AWS Database Migration Service (AWS DMS). The pattern also uses Oracle SQL Developer or SQL *Plus to connect to your Oracle DB instance, and includes an AWS CloudFormation template that automates some of the tasks.

Migrating to Amazon RDS for Oracle enables you to focus on your business and applications while Amazon RDS takes care of database administration tasks such as provisioning databases, backup and recovery, security patches, version upgrades, and storage management.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Machine Image (AMI) for Oracle Database on Amazon EC2

Product versions

- AWS DMS supports Oracle versions 11g (version 11.2.0.3.v1 and later), 12c, and 18c for Amazon RDS instance databases for the Enterprise, Standard, Standard One, and Standard Two editions. For the latest information about supported versions, see [Using an Oracle Database as a Target for AWS DMS] in the AWS documentation. (The attached AWS CloudFormation templates use Oracle version 12c as the source database.)
- Oracle SQL Developer 4.0.3

Architecture

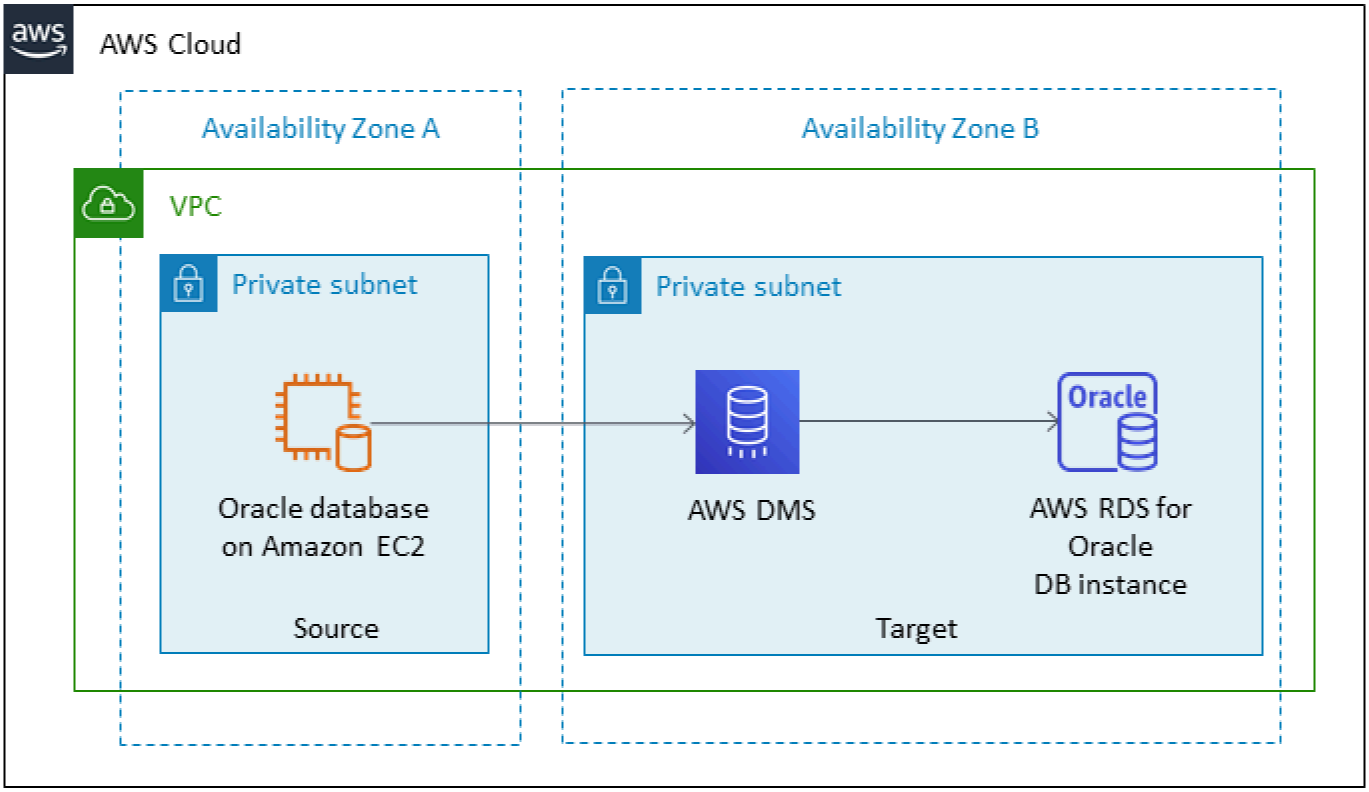
Source architecture

- Oracle Database on Amazon EC2

Target architecture

- Amazon RDS for Oracle

Migration architecture



Tools

- [AWS DMS](#) – AWS Database Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. It supports both homogeneous and heterogeneous migrations. For information about the Oracle database versions and editions that are supported, see [Using an Oracle Database as a Source for AWS DMS](#) and [Using an Oracle Database as a Target for AWS DMS](#) in the AWS documentation.
- **Oracle SQL Developer or SQL *Plus** – These tools enable you to connect to the Amazon RDS for Oracle DB instance.

Epics

Set up your target database

Task	Description	Skills required
Create an Amazon RDS for Oracle DB instance.	Sign in to the AWS Management Console and open the Amazon RDS console at https://console.aws.amazon.com/rds/. Create an Oracle DB instance by selecting the appropriate engine, template, database credentials setting, instance type, storage, Multi-AZ settings, virtual private cloud (VPC) and configuration, login credentials, and additional settings for the Oracle database. For instructions, view the links in the "Related resources" section. Or use the AWS CloudFormation template (Create_RDS.yaml) in the attachment to create the Amazon RDS for Oracle DB instance.	Developer
Connect to Amazon RDS and grant privileges to the Oracle user.	Modify the security group to open the appropriate ports to connect from the local machine and the AWS DMS replication instance. When you configure connectivity, make sure that the "Publicly accessible" option is selected	Developer

Task	Description	Skills required
	so you can connect to the database from outside the VPC. Connect to Amazon RDS with Oracle SQL Developer or SQL *Plus by using the login credentials, create an AWS DMS user, and provide the required privileges to the AWS DMS user to modify the database.	

Configure the security group of the source EC2 instance

Task	Description	Skills required
Check if the Oracle database is up and running.	Use Secure Shell (SSH) to connect to the EC2 instance, and try connecting to the Oracle database by using SQL *Plus.	Developer
Modify the security group.	Modify the security group of the EC2 instance to open appropriate ports, so you can connect from your local machine and the AWS DMS replication instance.	Developer

Set up AWS DMS

Task	Description	Skills required
Create an AWS DMS replicati on instance.	In AWS DMS, create a replicati on instance in the same VPC	DBA

Task	Description	Skills required
	as your Amazon RDS for Oracle DB instance. Specify the name and description for the replication instance, choose the instance class and replication engine version (use the default), choose the VPC in which you created the Amazon RDS DB instance, set Multi-AZ settings if required, allocate storage, specify the Availability Zone, and configure additional settings. Alternatively, you can use the AWS CloudFormation template (DMS.yaml) in the attachment to implement this step.	

Task	Description	Skills required
Connect to the source and target database endpoints.	Create the source and target database endpoints by specifying the endpoint identifier, engine, server, port, login credentials, and extra connection attributes. For the source server, use the public DNS of the EC2 instance that's hosting the Oracle database. For the target server, use the endpoint of Amazon RDS for Oracle. Run a test to verify that the source and target connections are working. Alternatively, you can use the AWS CloudFormation template (DMS.yaml) in the attachment to implement this step.	DBA

Task	Description	Skills required
Create an AWS DMS task.	Create an AWS DMS task to migrate data from the source endpoint to the target endpoint, to set up replicati on between the source and destination endpoint, or both. When creating the AWS DMS task, specify the replication instance, source endpoint, target endpoint, migration type (data only, replication only, or both), table mapping, and filter. Run the AWS DMS task, monitor the task, check the table statistics, and check logs in Amazon CloudWatc h. Alternatively, you can use the AWS CloudFormation template (DMS.yaml) in the attachment to implement this step.	DBA

Migrate an on-premises Oracle database to Amazon OpenSearch Service using Logstash

Aditya Goteti, Amazon Web Services

Summary

This pattern describes how to move data from an on-premises Oracle database to Amazon OpenSearch Service using Logstash. It includes architectural considerations and some required skill sets and recommendations. The data can be from a single table or from multiple tables in which a full-text search will need to be performed.

OpenSearch Service can be configured within a virtual private cloud (VPC), or it can be placed publicly with IP-based restrictions. This pattern describes a scenario where OpenSearch Service is configured within a VPC. Logstash is used to collect the data from the Oracle database, parse it to JSON format, and then feed the data into OpenSearch Service.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Java 8 (required by Logstash 6.4.3)
- Connectivity between the on-premises database servers and Amazon Elastic Compute Cloud (Amazon EC2) instances in a VPC, established using AWS Virtual Private Network (AWS VPN)
- A query to retrieve the required data to be pushed to OpenSearch Service from the database
- Oracle Java Database Connectivity (JDBC) drivers

Limitations

- Logstash cannot identify records that are hard-deleted from the database

Product versions

- Oracle Database 12c
- OpenSearch Service 6.3
- Logstash 6.4.3

Architecture

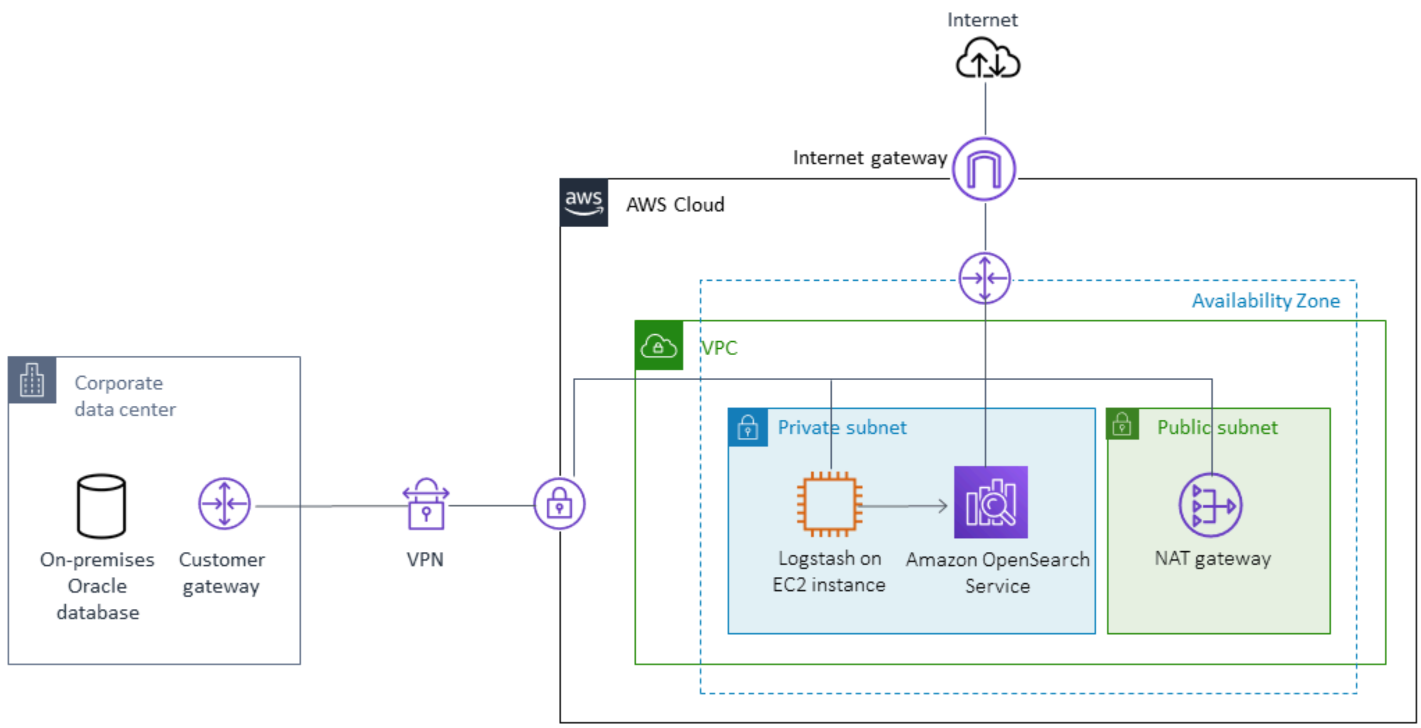
Source technology stack

- On-premises Oracle database
- On-premises AWS VPN

Target technology stack

- VPC
- EC2 instance
- OpenSearch Service
- Logstash
- NAT Gateway (for operating system updates on EC2 instances and to install Java 8, Logstash, and plugins)

Data migration architecture



Tools

- Logstash 6.4.3

- JDBC input plugin (download and more information)
- Logstash output plugin (logstash-output-amazon_es)
- Oracle JDBC drivers

Epics

Plan the migration

Task	Description	Skills required
Identify the size of the source data.	The size of the source data is one of the parameters that you use to determine the number of shards to be configured in an index.	DBA, Database developer
Analyze the data types of each column and correspon ding data.	OpenSearch Service dynamically maps the data type when a previously unseen field is found in the document. If there are any specific data types or formats (for example, date fields) that need to be explicitly declared, identify the fields and define the mapping for those fields during index creation.	App owner, Developer, Database developer
Determine if there are any columns with primary or unique keys.	To avoid duplication of records in Amazon OpenSearc h Service during updates or inserts, you need to configure the `document_id` setting in the output section of the `amazon_es` plugin (for example, `document_id => "%{customer_id}"` where	App owner, Developer

Task	Description	Skills required
	`customer_id` is a primary key).	
Analyze the number and frequency of new records added; check how frequently the records are deleted.	This task is required to understand the growth rate of source data. If data is intensively read and insertion s are rare, you can have a single index. If new records are inserted frequently and there are no deletions, the shard size can easily exceed the recommended maximum size of 50 GB. In this case, you can dynamically create an index by configuring index patterns in Logstash and in the code where you can access it by using an alias.	App owner, Developer
Determine how many replicas are required.		App owner, Developer
Determine the number of shards to be configured on the index.		App owner, Developer
Identify the instance types for dedicated master nodes, data nodes, and the EC2 instance.	For more information, see the Related resources section.	App owner, Developer
Determine the number of dedicated master nodes and data nodes required.	For more information, see the Related resources section.	

Migrate data

Task	Description	Skills required
Launch an EC2 instance.	Launch an EC2 instance within the VPC to which AWS VPN is connected.	Amazon VPC constructs, AWS VPN
Install Logstash on the EC2 instance.		Developer
Install the Logstash plugins.	Install the required Logstash plugins `jdbc-input` and `logstash-output-amazon_es` .	Developer
Configure Logstash.	Create the Logstash keystore to store sensitive information such as AWS Secrets Manager keys and database credentials, and then place the references in a Logstash configuration file.	Developer
Configure the dead letter queue and persistent queue.	By default, when Logstash encounters an event that it cannot process because the data contains a mapping error or some other issue, the Logstash pipeline either hangs or drops the unsuccessful event. To protect against data loss in this situation, you can configure Logstash to write unsuccessful events to a dead letter queue instead of dropping them. To protect against data loss	Developer

Task	Description	Skills required
	during abnormal terminati on, Logstash has a persistent queue feature that will store the message queue on disk. Persistent queues provide the data durability in Logstash.	
Create the Amazon OpenSearch Service domain.	Create the Amazon OpenSearch Service domain with an access policy that doesn't require signing requests with AWS Identity and Access Managemen t (IAM) credentials. The Amazon OpenSearch Service domain must be created within the same VPC. You should also select the instance types and set the number of dedicated and master nodes based on your analysis.	Developer
Configure the required Amazon OpenSearch Service logs.	For more information, see the [OpenSearch Service documentation]().	
Create the index.		Developer

Task	Description	Skills required
Start Logstash.	Run Logstash as a backgroun d service. Logstash runs the configured SQL query, pulls the data, converts it to JSON format, and feeds it to OpenSearch Service. For the initial load, do not configure the scheduler in the Logstash configuration file.	Developer

Task	Description	Skills required
Check documents.	Check the number of documents on the index and whether all documents are present in the source database. During initial load, they are added to the index and used to stop Logstash. Change the Logstash configuration to add a scheduler that runs at a fixed interval depending on client requirements, and restart Logstash. Logstash will pick only the records that were updated or added after the last run, and the last run timestamp is stored in the file that is configured with the property `last_run_metadata_path => "/usr/share/logstash/.logstash_jdbc_last_run"` in the Logstash configuration file.	Developer

Migrate an on-premises Oracle database to Amazon RDS for Oracle

Baji Shaik and Pavan Pusuluri, Amazon Web Services

Summary

This pattern describes the steps for migrating on-premises Oracle databases to Amazon Relational Database Service (Amazon RDS) for Oracle. As part of the migration process, you create a migration plan and consider important factors about your target database infrastructure based on your source database. You can choose one of two migration options based on your business requirements and use case:

- AWS Database Migration Service (AWS DMS) – You can use AWS DMS to migrate databases to the AWS Cloud quickly and securely. Your source database remains fully operational during the migration, which minimizes downtime to applications that rely on the database. You can reduce migration time by using AWS DMS to create a task that captures ongoing changes after you complete an initial full-load migration through a process called change data capture (CDC).
- Native Oracle tools – You can migrate databases by using native Oracle tools, such as Oracle and Data Pump Export and Data Pump Import with Oracle GoldenGate for CDC. You can also use native Oracle tools such as the original Export utility and original Import utility to reduce the full-load time.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An on-premises Oracle database
- An Amazon RDS Oracle database (DB) instance

Limitations

- Database size limit: 64 TB

Product versions

- Oracle versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2 and 18c. For the latest list of supported versions and editions, see Amazon RDS for Oracle in the AWS documentation.

For Oracle versions supported by AWS DMS, see [Using an Oracle database as a source for AWS DMS] in the AWS DMS documentation.

Architecture

Source technology stack

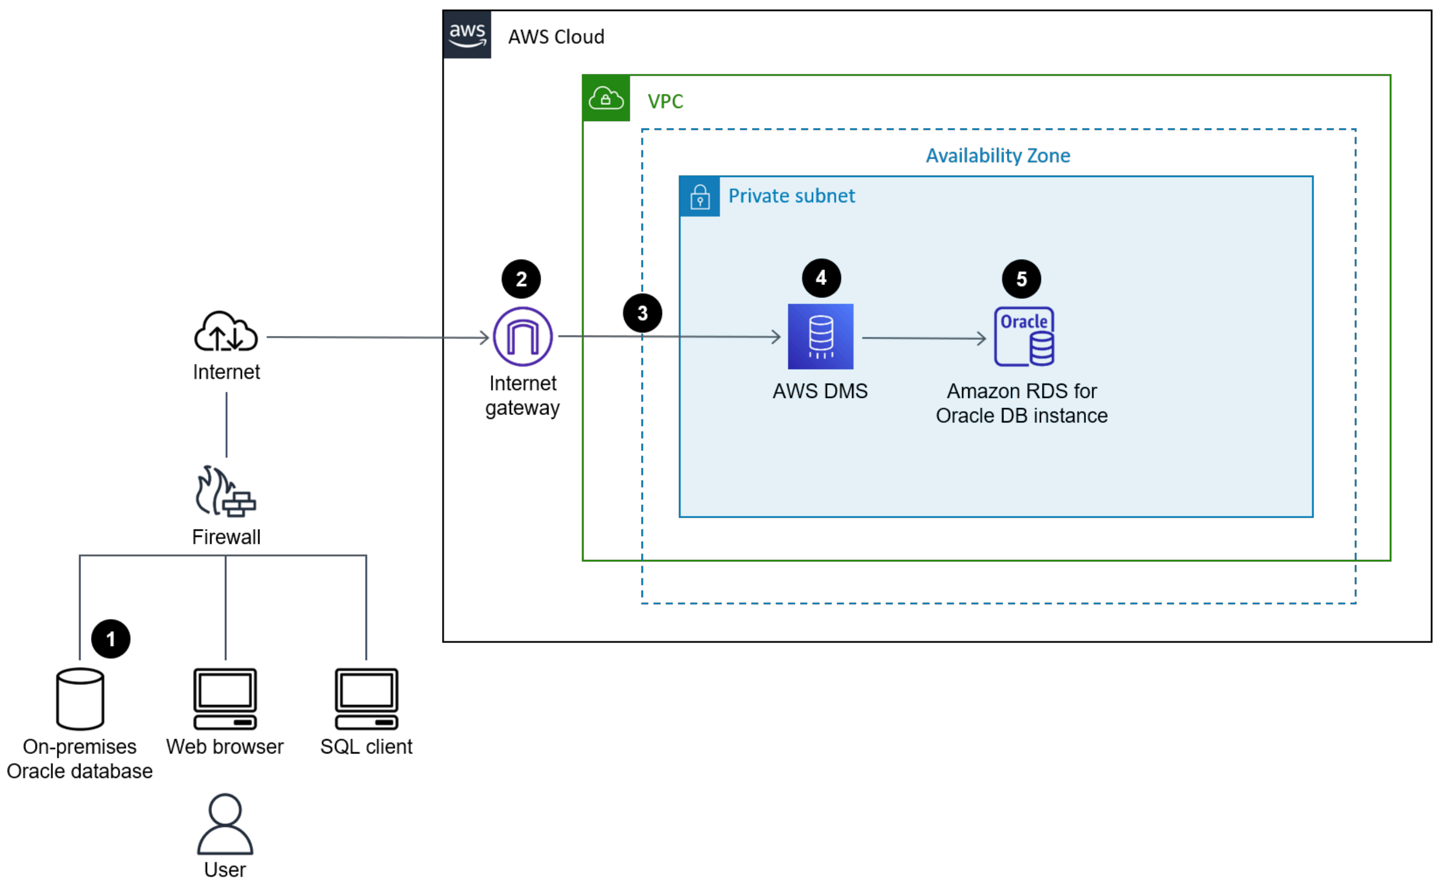
- On-premises Oracle databases

Target technology stack

- Amazon RDS for Oracle

Source and target architecture

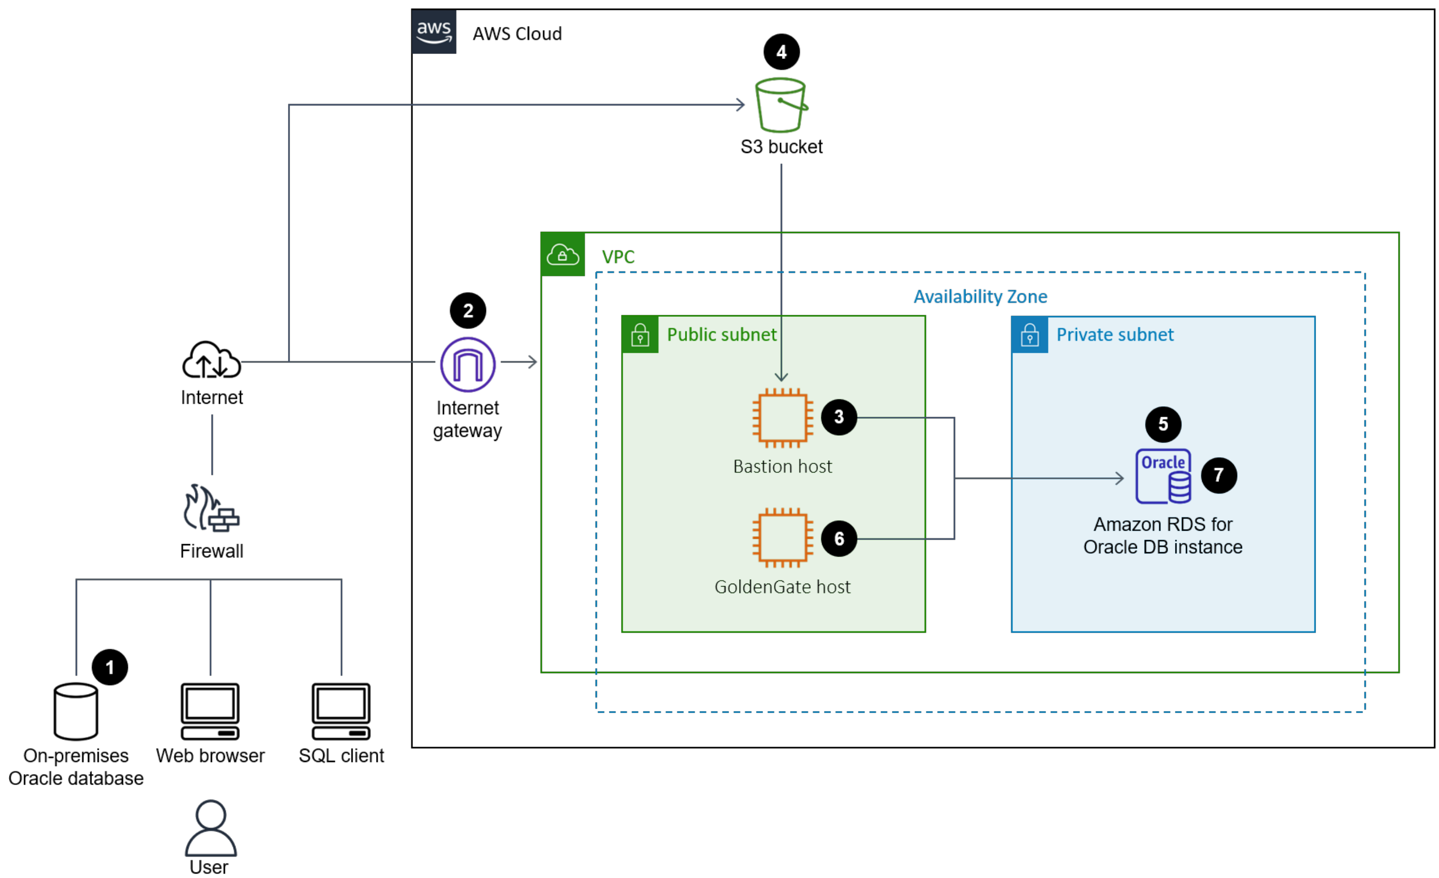
The following diagram shows how to migrate an on-premises Oracle database to Amazon RDS for Oracle by using AWS DMS.



The diagram shows the following workflow:

1. Create or use an existing database user, grant the required AWS DMS permissions to that user, turn on ARCHIVELOG mode, and then set up supplemental logging.
2. Configure the internet gateway between the on-premises and AWS network.
3. Configure source and target endpoints for AWS DMS.
4. Configure AWS DMS replication tasks to migrate the data from the source database to the target database.
5. Complete the post-migration activities on the target database.

The following diagram shows how to migrate an on-premises Oracle database to Amazon RDS for Oracle by using native Oracle tools.



The diagram shows the following workflow:

1. Create or use an existing database user and grant the required permissions to back up the Oracle database by using Oracle Export (`exp`) and Import (`imp`) utilities.
2. Configure the internet gateway between the on-premises and AWS network.
3. Configure the Oracle client on the Bastion host to take the backup database.

4. Upload the backup database to an Amazon Simple Storage Service (Amazon S3) bucket.
5. Restore the database backup from Amazon S3 to an Amazon RDS for Oracle database.
6. Configure Oracle GoldenGate for CDC.
7. Complete the post-migration activities on the target database.

Tools

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Native Oracle tools help you perform a homogeneous migration. You can use Oracle Data Pump to migrate data between your source and target databases. This pattern uses Oracle Data Pump to perform the full load from the source database to the target database.
- Oracle GoldenGate helps you perform logical replication between two or more databases. This pattern uses GoldenGate to replicate the delta changes after the initial load by using Oracle Data Pump.

Epics

Plan the migration

Task	Description	Skills required
Create project documents and record database details.	1. Document your migration goals, migration requireme nts, key project stakehold ers, project milestones, project deadlines, key metrics, migration risks, and risk mitigation plans. 2. Document critical informati on about your source database, including RAM, IOPS, and CPUs. You will later use this information to determine the appropria te target DB instance.	DBA

Task	Description	Skills required
	3. Validate the versions of your source and target databases.	
Identify storage requireme nts.	Identify and document your storage requirements, including the following: 1. Calculate the storage allocated for the source DB instance. 2. Gather the historical growth metrics from the source DB instance. 3. Forecast future growth for the target DB instance. **Note** For [General Purpose (gp2) SSD volumes](), you get three IOPS per 1 GB of storage. Allocate storage by calculati ng the total number of read and write IOPS on the source database.	DBA, SysAdmin

Task	Description	Skills required
Choose the proper instance type based on compute requirements.	1. Determine the compute requirements of the target DB instance. 2. Identify performance issues. 3. Consider the factors for determining the appropria te instance type: • CPU utilization of the source DB instance • IOPS (read and write) for the source DB instance • Memory footprint on the source DB instance	SysAdmin
Identify network access security requirements.	1. Identify and document the network access security requirements for your source and target databases. 2. Configure the appropria te security groups for enabling the application to communicate with the database.	DBA, SysAdmin

Task	Description	Skills required
Identify the application migration strategy.	1. Determine and document the migration cutover strategy. 2. Determine and document your application’s recovery time objective (RTO) and recovery point objective (RPO), and then plan for the cutover accordingly.	DBA, SysAdmin, App owner
Identify migration risks.	Assess the database and document migration specific risks and mitigations. For example: • Identify no-logging tables and highlight the risk of data loss in the event of recovery. • Extract the source database users and privileges, and highlight the conflicts with Amazon RDS privileges. • Review the alert log for any Oracle-specific errors and warnings. • Identify the supported and unsupported features of the target DB instance. • Review the deprecated features of the target DB version engine.	DBA

Configure the infrastructure

Task	Description	Skills required
Create a VPC.	Create a new Amazon Virtual Private Cloud (Amazon VPC) for the target DB instance.	SysAdmin
Create security groups.	Create a security group in your new VPC to allow inbound connections to the DB instance.	SysAdmin
Create an Amazon RDS for Oracle DB instance.	Create the target DB instance with the new VPC and security group, and then start the instance.	SysAdmin

Option 1 - Use native Oracle or third-party tools to migrate data

Task	Description	Skills required
Prepare the source database.	1. Create a Data Pump directory or use an existing one. 2. Create a migration user and grant permissions to perform the Data Pump extract. 3. Extract roles, users, and tablespaces from the source database as a SQL script. 4. Transfer the extracted Data Pump dump to the target	DBA, SysAdmin

Task	Description	Skills required
	DB instance `data pump` directory.	

Task	Description	Skills required
Prepare the target database.	1. Confirm that all the database options (for example, text and Java) are installed or enabled on the target Amazon RDS for Oracle DB instance. 2. Create a Data Pump directory or use an existing one. 3. Create a migration user and grant permissions to perform the Data Pump import. 4. Create the required tablespaces, users, and roles on the target DB instance. 5. Import the transferred Data Pump export dump to the target database. 6. Create any indexes excluded during import or object creation. 7. Create any constraints excluded during import. 8. Validate or recompile invalid objects. 9. Rebuild the invalid indexes. 10. Validate the database object counts between the source and the target databases.	DBA, SysAdmin

Task	Description	Skills required
	11. Resolve any discrepancies found between object counts.	

Option 2 - Use AWS DMS to migrate data

Task	Description	Skills required
Prepare the data.	1. Clean the data in the source database. 2. Create a replication instance. 3. Create a source endpoint and target endpoint. 4. Identify the number of tables and objects to be migrated.	DBA
Migrate the data.	1. Drop foreign key constraints and triggers on the target database. 2. Drop secondary indexes on the target database. 3. Configure AWS DMS full-load task settings from the source database to the target database. 4. Enable foreign keys. 5. Enable AWS DMS CDC to replicate ongoing changes. 6. Enable triggers. 7. Update the sequences.	DBA

Task	Description	Skills required
	8. Validate the source and target data.	

Cut over to the target database

Task	Description	Skills required
Switch the application clients to the new infrastructure.	1. Stop all application services and client connections pointing to Oracle. 2. Run the AWS DMS tasks. 3. Set up a rollback task (for example, reverse CDC from the Amazon RDS database to the on-premises Oracle database). 4. Validate the data. 5. Start the application services on the new target database by configuri ng Amazon Route 53 to the new Amazon RDS for Oracle DB instance. 6. Add Amazon CloudWatc h monitoring to your new Amazon RDS for Oracle DB instance.	DBA, SysAdmin, App owner
Implement your rollback plan.	1. Stop all application services pointing to the Amazon RDS for Oracle DB instance.	DBA, App owner

Task	Description	Skills required
	2. Roll back the changes to the source on-premises Oracle database by using an AWS DMS task. 3. Stop the AWS DMS tasks running from the on-premises Oracle database to the Amazon RDS for Oracle database. 4. Configure the applications back on the source Oracle database. 5. Confirm the rollback deployment is complete.	

Close out the migration project

Task	Description	Skills required
Clean up resources.	Shut down or remove the temporary AWS resources, such as the AWS DMS replicati on instance and S3 bucket.	DBA, SysAdmin
Review project documents.	Review your migration planning documents and goals, and then confirm that you completed all required migration steps.	DBA, SysAdmin, App owner
Gather metrics.	Record key migration metrics, including how long it took to complete the migration, the percentage of manual vs.	DBA, SysAdmin, App owner

Task	Description	Skills required
	tool-based tasks, cost savings, and other relevant metrics.	
Close out the project.	Close out the migration project and capture feedback about the effort.	DBA, SysAdmin, App owner

Migrate an on-premises Oracle database to Amazon RDS for Oracle using Oracle Data Pump

Mohan Annam and Brian motzer, Amazon Web Services

Summary

This pattern describes how to migrate an Oracle database from an on-premises data center to an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance by using Oracle Data Pump.

The pattern involves creating a data dump file from the source database, storing the file in an Amazon Simple Storage Service (Amazon S3) bucket, and then restoring the data to an Amazon RDS for Oracle DB instance. This pattern is useful when you encounter limitations using AWS Database Migration Service (AWS DMS) for the migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The required permissions to create roles in AWS Identity and Access Management (IAM) and for an Amazon S3 multipart upload
- The required permissions to export data from the source database
- AWS Command Line Interface (AWS CLI) installed and configured

Product versions

- Oracle Data Pump is available only for Oracle Database 10g Release 1 (10.1) and later versions.

Architecture

Source technology stack

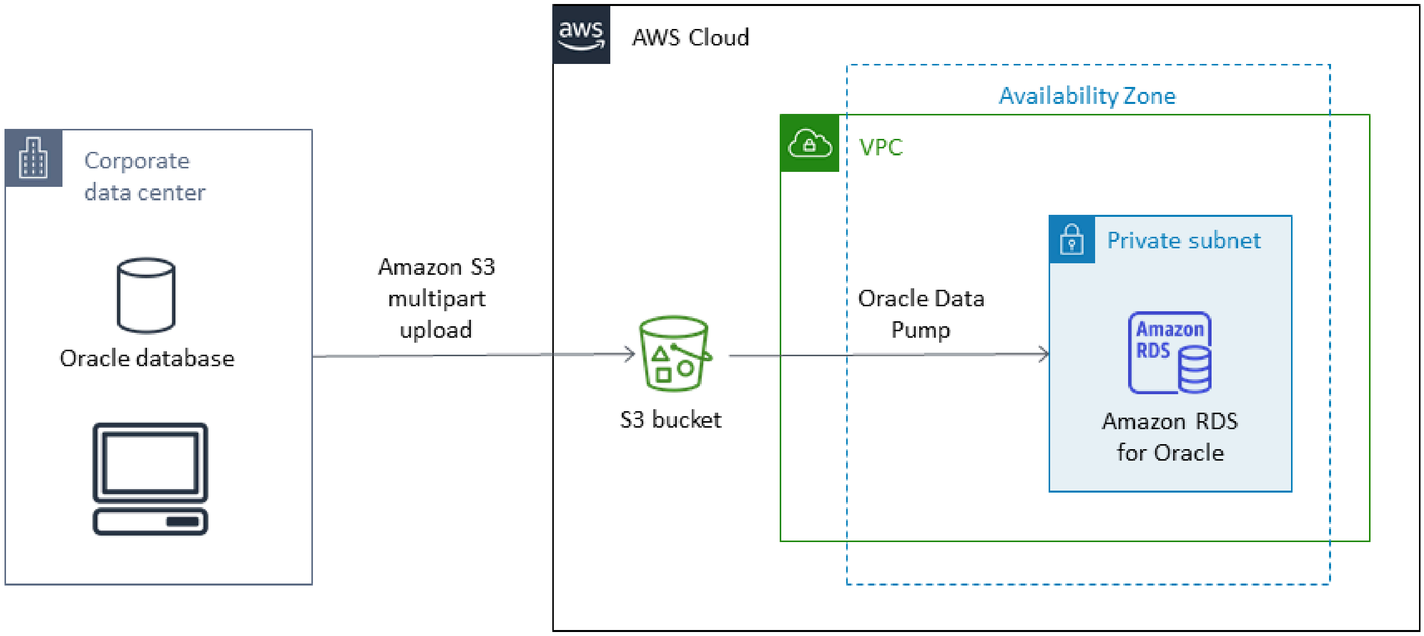
- On-premises Oracle databases

Target technology stack

- Amazon RDS for Oracle

- SQL client (Oracle SQL Developer)
- An S3 bucket

Source and target architecture



Tools

AWS services

- [AWS Identity and Access Management (IAM)](https://docs.aws.amazon.com/IAM/latest/UserGuide/introduction.html) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them. In this pattern, IAM is used to create the roles and policies necessary for migrating data from Amazon S3 to Amazon RDS for Oracle.
- Amazon Relational Database Service (Amazon RDS) for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Oracle Data Pump helps you move data and metadata from one database to another at high speeds. In this pattern, Oracle Data Pump is used to export the data dump (.dmp) file to the

Oracle server, and to import it into Amazon RDS for Oracle. For more information, see Importing data into Oracle on Amazon RDS in the Amazon RDS documentation.

- Oracle SQL Developer is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments. It interacts with both the on-premises Oracle database and Amazon RDS for Oracle to run the SQL commands required for exporting and importing data.

Epics

Create an S3 bucket

Task	Description	Skills required
Create the bucket.	To create the S3 bucket, follow the instructions in the AWS documentation.	AWS systems administrator

Create the IAM role and assign policies

Task	Description	Skills required
Configure IAM permissions.	To configure permissions, follow the instructions in the AWS documentation.	AWS systems administrator

Create the target Amazon RDS for Oracle DB instance and associate the Amazon S3 integration role

Task	Description	Skills required
Create the target Amazon RDS for Oracle DB instance.	To create the Amazon RDS for Oracle instance, follow the instructions in the AWS documentation.	AWS systems administrator

Task	Description	Skills required
Associate the role with the DB instance.	To associate the role with the instance, follow the instructions in the [AWS documentation]().	DBA

Create the database user on the target database

Task	Description	Skills required

Create the user.	Connect to the target Amazon RDS for Oracle database from Oracle SQL Developer or SQL*Plus, and run the following SQL command to create the user to import the schema into.
	`create user SAMPLE_SCHEMA identified by <PASSWORD>;`
	`grant create session, resource to <USER NAME>;`
	`alter user <USER NAME> quota 100M on users;`
		DBA

Create the export file from the source Oracle database

Task	Description	Skills required
Create a data dump file.	To create a dump file named `sample.dmp` in the `DATA_PUMP_DIR` directory for exporting the SAMPLE_SC	DBA

Task	Description	Skills required

	HEMA user, use the following script.
	
	``
	DECLARE
	    hdnl NUMBER;
	BEGIN
	    hdnl := dbms_data
	pump.open(operation
	 => 'EXPORT',
	
	           job_mode =>
	 'SCHEMA',
	
	           job_name =>
	 NULL);
	
	    dbms_datapump.add_
	file(handle => hdnl,
	
	         filename =>
	 'sample.dmp',
	
	        directory =>
	 'DATA_PUMP_DIR',
	
	         filetype =>
	 dbms_datapump.ku$_
	file_type_dump_file);
	
	    dbms_datapump.add_
	file(handle => hdnl,
	
	         filename =>
	 'export.log',
	
	        directory =>
	 'DATA_PUMP_DIR',
	
	         filetype =>
	 dbms_datapump.ku$_
	file_type_log_file);
	``	

Task	Description	Skills required

	``
	    dbms_datapump.meta
	data_filter(hdnl,
	 'SCHEMA_EXPR', 'IN
	 (''SAMPLE_SCHEMA''
	)');
	
	    dbms_datapump.star
	t_job(hdnl);
	END;
	/
	``
	Review the export details by reviewing the `export.log` file in your local `DATA_PUMP_DIR` directory.	

Upload the dump file to the S3 bucket

Task	Description	Skills required
Upload the data dump file from the source to the S3 bucket.	Using AWS CLI, run the following command. `aws s3 cp sample.dmp s3://<bucket_created_epic_1>/`	DBA

Download the export file from the S3 bucket to the RDS instance

Task	Description	Skills required
Download the data dump file to Amazon RDS	To copy the dump file `sample.dmp` from the S3 bucket to the Amazon RDS	AWS systems administrator

Task	Description	Skills required
	for Oracle database, run the following SQL command. In this example, the `sample.dmp` file is downloaded from the S3 bucket `my-s3-integration1` to the Oracle directory `DATA_PUMP_DIR`. Make sure that you have sufficient disk space allocated to your RDS instance to accommodate both the database and the export file. ```-- If you want to download all the files in the S3 bucket remove the p_s3_prefix line. SELECT rdsadmin.rdsadmin_s3_tasks.download_from_s3(p_bucket_name => 'my-s3-integration', p_s3_prefix => 'sample.dmp', p_directory_name => 'DATA_PUMP_DIR') AS TASK_ID FROM DUAL;``` The previous command outputs a task ID. To review the status of the download by reviewing the data in the task ID, run the following command.	

Task	Description	Skills required

	`SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('BDUMP','dbtask-<task_id>.log'));`
	
	To see the files in the `DATA_PUMP_DIR` directory, run the following command.
	
	`SELECT filename, type,filesize/1024/1024 size_megs,to_char(mtime,'DD-MON-YY HH24:MI:SS') timestamp FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => upper('DATA_PUMP_DIR'))) order by 4;`	

Import the dump file into the target database

Task	Description	Skills required

Restore the schema and data to Amazon RDS.	To import the dump file into the `sample_schema` database schema, run the following SQL command from SQL Developer or SQL*Plus.
	
	`DECLARE`
	`hdnl NUMBER;`
	`BEGIN`
		DBA

Task	Description	Skills required

	``
	hdnl := DBMS_DATA
	PUMP.OPEN(operation
	 => 'IMPORT', job_mode
	 => 'SCHEMA', job_name=
	>null);
	
	DBMS_DATAPUMP.ADD_
	FILE(handle => hdnl,
	 filename => 'sample.d
	mp', directory =>
	 'DATA_PUMP_DIR',
	 filetype => dbms_data
	pump.ku$_file_type
	_dump_file);
	
	DBMS_DATAPUMP.ADD_FILE
	(handle => hdnl,
	 filename => 'import.l
	og', directory =>
	 'DATA_PUMP_DIR',
	 filetype => dbms_data
	pump.ku$_file_type
	_log_file);
	
	DBMS_DATAPUMP.
	METADATA_FILTER(hd
	nl,'SCHEMA_EXPR','
	IN (''SAMPLE_SCHEMA''
	)');
	
	DBMS_DATAPUMP.START_J
	OB(hdnl);
	
	END;
	/
	``
	To see the log file from the import, run the following command.	

Task	Description	Skills required
	```SELECT text FROM table(rdsadmin.rds_file_util.read_text_file('DATA_PUMP_DIR','import.log'));```	

Remove the dump file from the DATA_PUMP_DIR directory

Task	Description	Skills required

List and clean up the export files.	List and remove the export files in the `DATA_PUMP_DIR` directory, run the following commands.
	```-- List the files SELECT filename, type,filesize/1024/1024 size_megs,to_char(mtime,'DD-MON-YY HH24:MI:SS') timestamp FROM TABLE(rdsadmin.rds_file_util.listdir(p_directory => upper('DATA_PUMP_DIR'))) order by 4;```
	```-- Remove the files EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','sample.dmp'); EXEC UTL_FILE.FREMOVE('DATA_PUMP_DIR','import.log');```
		AWS systems administrator

Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical

Rajesh Madiwale, Amazon Web Services

Summary

This pattern outlines steps for migrating a PostgreSQL database (version 9.5 and later) from Amazon Elastic Compute Cloud (Amazon EC2) to Amazon Relational Database Service (Amazon RDS) for PostgreSQL by using the PostgreSQL **pglogical** extension. Amazon RDS now supports the pglogical extension for PostgreSQL version 10.

Prerequisites and limitations

Prerequisites

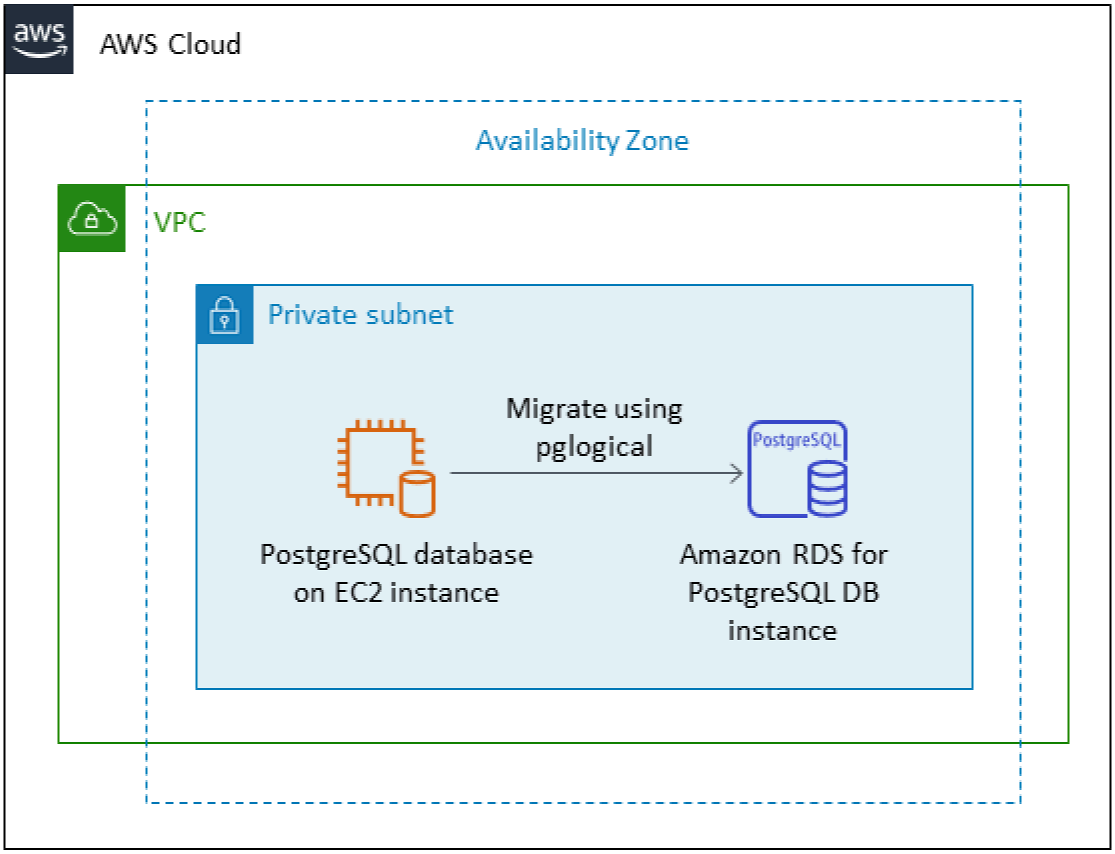
- Choose the right type of Amazon RDS instance. For more information, see Amazon RDS Instance Types.
- Make sure that the source and target versions of PostgreSQL are the same.
- Install and integrate the **pglogical** extension with PostgreSQL on Amazon EC2.

Product versions

- PostgreSQL version 10 and later on Amazon RDS, with the features supported on Amazon RDS (see PostgreSQL on Amazon RDS in the AWS documentation). This pattern was tested by migrating PostgreSQL 9.5 to PostgreSQL version 10 on Amazon RDS, but it also applies to later versions of PostgreSQL on Amazon RDS.

Architecture

Data migration architecture



Tools

- **pglogical** extension
- PostgreSQL native utilities: **pg_dump** and **pg_restore**

Epics

Migrate data by using the pglogical extension

Task	Description	Skills required
Create an Amazon RDS PostgreSQL DB instance.	Set up a PostgreSQL DB instance in Amazon RDS. For instructions, see the Amazon RDS for PostgreSQL documentation.	DBA

Task	Description	Skills required
Obtain a schema dump from the source PostgreSQL database and restore it into the target PostgreSQL database.	1. Use the pg_dump utility with the `-s` option to generate a schema file from the source database. 2. Use the psql utility with the `-f` option to load the schema into the target database.	DBA
Turn on logical decoding.	In the Amazon RDS DB parameter group, set the `rds.logical_replication` static parameter to 1. For instructions, see the Amazon RDS documentation.	DBA

Task	Description	Skills required

Create the pglogical extension on the source and target databases.	1. Create the `pglogical` extension on the source PostgreSQL database:
	`psql -h <amazon-ec2-endpoint> -d target-dbname -U target-dbuser -c "create extension pglogical ;"`
	2. Create the `pglogical` extension on the target PostgreSQL database:
	`psql -h <amazon-rds-endpoint> -d source-dbname -U source-dbuser -c "create extension pglogical ;"`
		DBA

Create a publisher on the source PostgreSQL database.	To create a publisher, run: `psql -d dbname -p 5432 <<EOF SELECT pglogical.create_node( node_name := 'provider1', dsn := 'host=<ec2-endpoint> port=5432 dbname=source-dbname user=source-dbuser' ); EOF`	DBA

Task	Description	Skills required
Create a replication set, add tables and sequences.	To create a replication set on the source PostgreSQL database, and to add tables and sequences to the replicati on set, run: `psql -d dbname -p 5432 <<EOF SELECT pglogical .replication_set_a dd_all_tables('def ault', '{public} '::text[],synchron ize_data := true); EOF`	DBA
Create a subscriber.	To create a subscriber on the target PostgreSQL database, run: `psql -h <rds-endpoint> -d target-dbname -U target-dbuser <<EOF SELECT pglogical .create_node( node_name := 'subscriber1', dsn := 'host=<rd s-endpoint> port=5432 dbname=target-dbna me password=postgres user=target-dbuser' ); EOF`	DBA

Task	Description	Skills required
Create a subscription.	To create a subscription on the target PostgreSQL database, run: ```psql -h <rds-endpoint> -d target -U postgres <<EOF SELECT pglogical .create_subscription(subscription_name := 'subscription1', replication_sets := array['default'], provider_dsn := 'host=<ec2-endpoint> port=5432 dbname=<source-dbname> password=<password> user=source-dbuser');```	DBA

Validate your data

Task	Description	Skills required
Check source and target databases.	Check the source and target databases to confirm that data is being replicated successfully. You can perform basic validation by using `select count(1)` from the source and target tables.	DBA

Migrate an on-premises PostgreSQL database to Aurora PostgreSQL

Baji Shaik and Jitender Kumar, Amazon Web Services

Summary

Amazon Aurora PostgreSQL-Compatible Edition combines the performance and availability of high-end commercial databases with the simplicity and cost-effectiveness of open-source databases. Aurora provides these benefits by scaling storage across three Availability Zones in the same AWS Region, and supports up to 15 read replica instances for scaling out read workloads and providing high availability within a single Region. By using an Aurora global database, you can replicate PostgreSQL databases in up to five Regions for remote read access and disaster recovery in the event of a Region failure. This pattern describes the steps for migrating an on-premises PostgreSQL source database to an Aurora PostgreSQL-Compatible database. The pattern includes two migration options: using AWS Data Migration Service (AWS DMS) or using native PostgreSQL tools (such as pg_dump, pg_restore, and psql) or third-party tools.

The steps described in this pattern also apply to target PostgreSQL databases on Amazon Relational Database Service (Amazon RDS) and Amazon Elastic Compute Cloud (Amazon EC2) instances.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A PostgreSQL source database in an on-premises data center
- An Aurora PostgreSQL-Compatible DB instance or an Amazon RDS for PostgreSQL DB instance

Limitations

- Database size limits are 64 TB for Amazon RDS for PostgreSQL and 128 TB for Aurora PostgreSQL-Compatible.
- If you're using the AWS DMS migration option, review AWS DMS limitations on using a PostgreSQL database as a source.

Product versions

- For PostgreSQL major and minor version support in Amazon RDS, see [Amazon RDS for PostgreSQL updates] in the Amazon RDS documentation.
- For PostgreSQL support in Aurora, see [Amazon Aurora PostgreSQL updates] in the Aurora documentation.
- If you're using the AWS DMS migration option, see [supported PostgreSQL versions] in the AWS DMS documentation.

Architecture

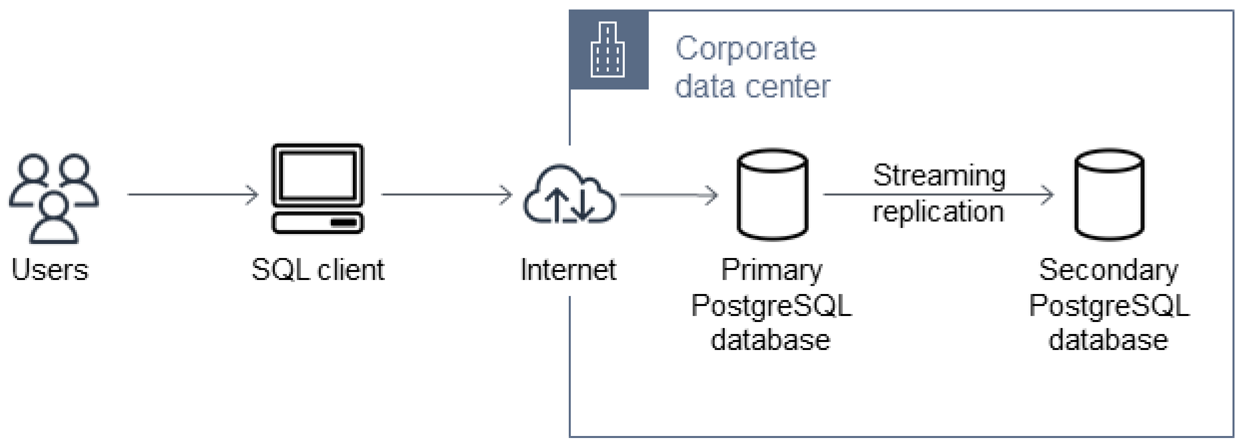
Source technology stack

- On-premises PostgreSQL database

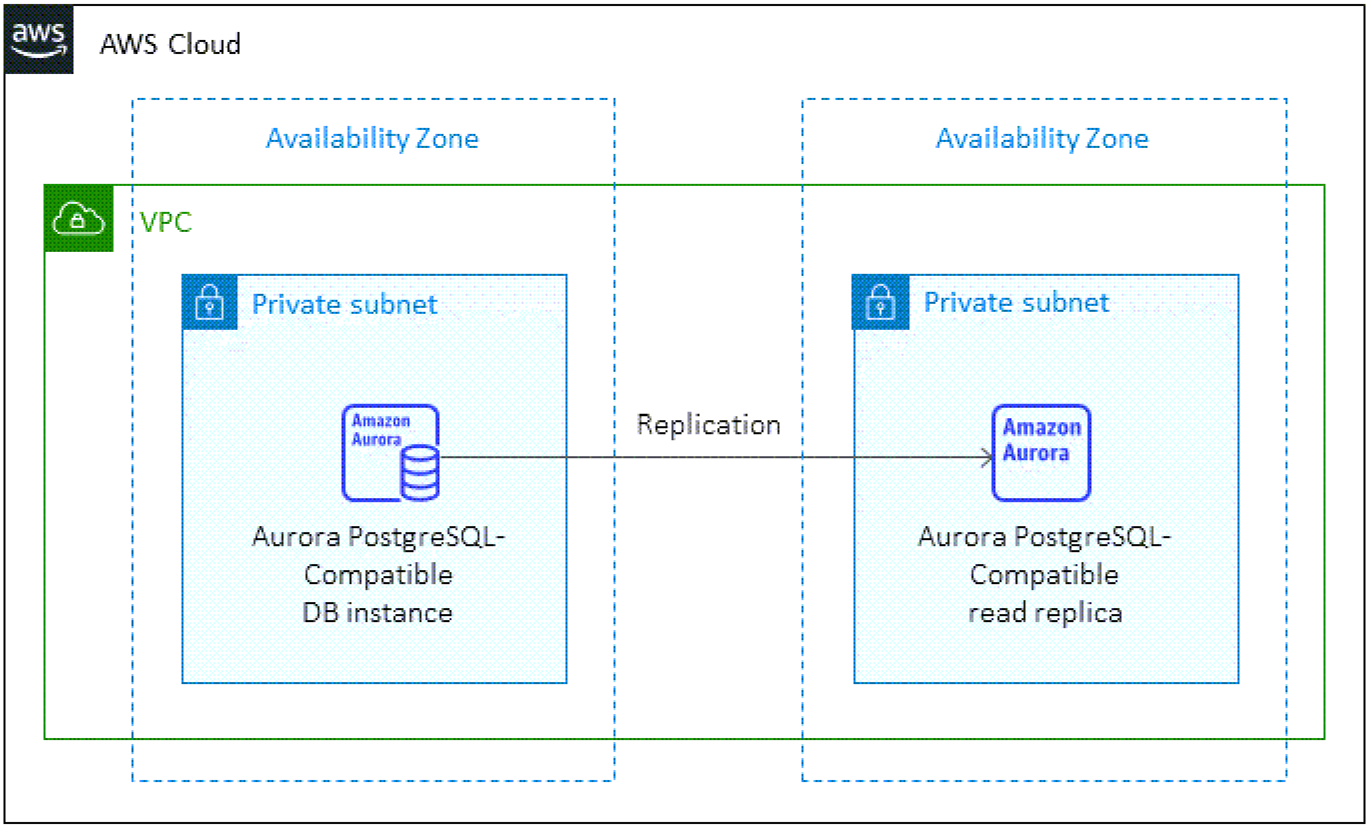
Target technology stack

- Aurora PostgreSQL-Compatible DB instance

Source architecture

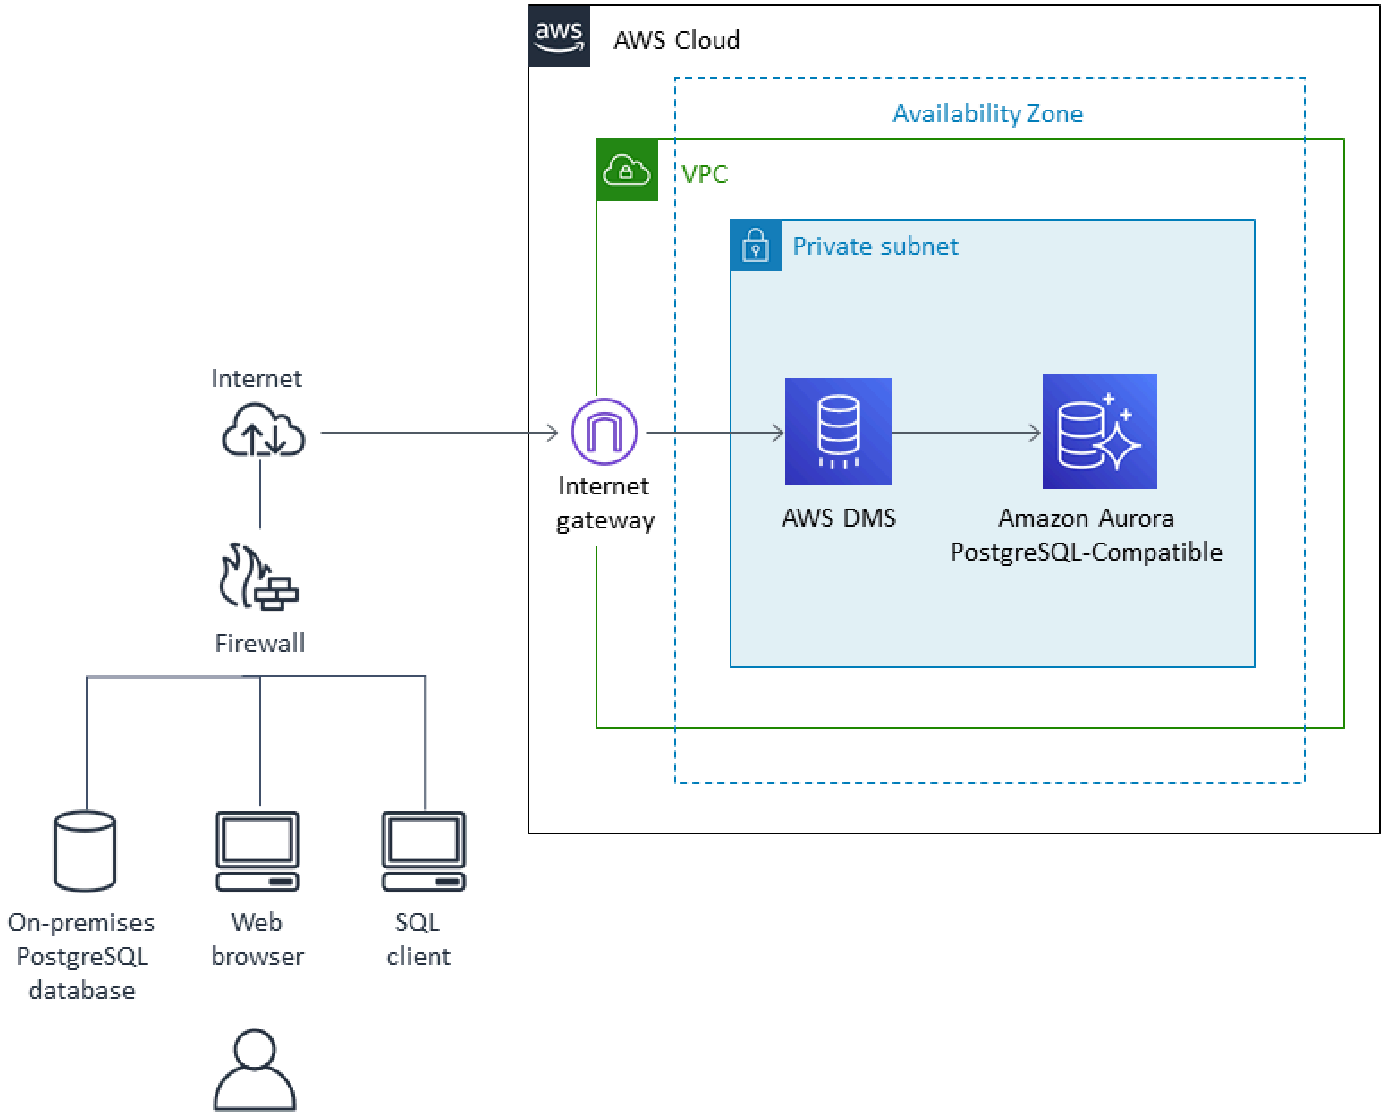


Target architecture

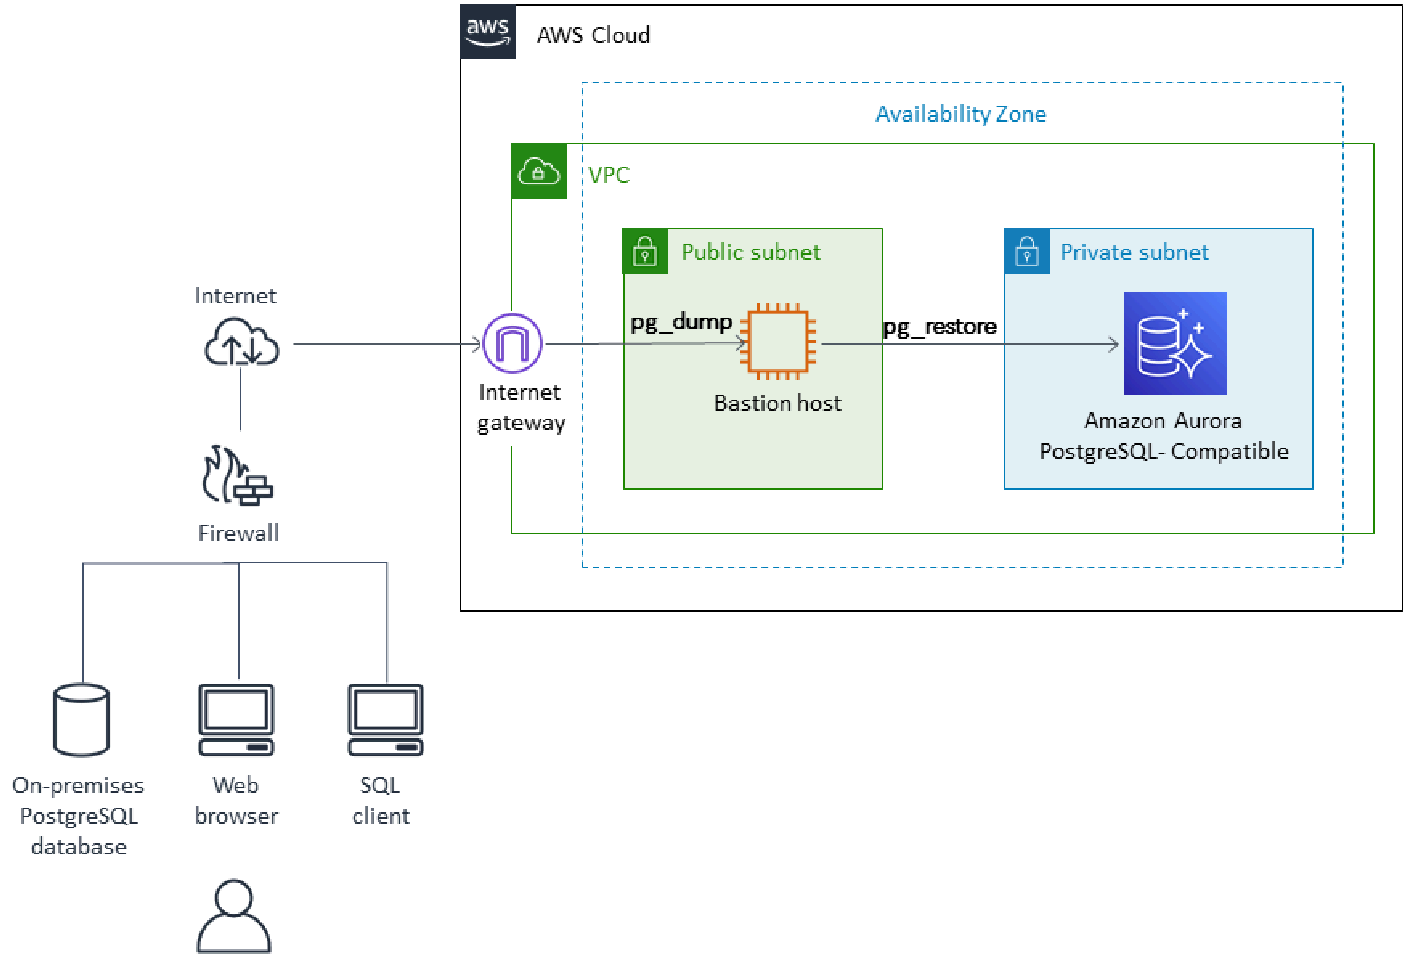


Data migration architecture

Using AWS DMS



Using native PostgreSQL tools



Tools

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises configurations. This service supports different sources and target databases. For information about how to validate the PostgreSQL source and target database versions and editions supported for use with AWS DMS, see Using a PostgreSQL database as an AWS DMS source. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- Native PostgreSQL tools include pg_dump, pg_restore, and psql.

Epics

Analyze the migration

Task	Description	Skills required
Validate the source and target database versions.	If you are using AWS DMS, make sure that you're using a supported version of PostgreSQL.	DBA
Identify the storage type and capacity requirements.	1. Calculate the storage allocated for the source database instance. 2. Gather the historical growth metrics for the source database instance. 3. Anticipate the future growth forecast for the target database instance. 4. Allocate storage by calculating the total number of read and write IOPS on the source database. A General Purpose SSD (gp2) volume provides 3 IOPS for each 1 GB of storage.	DBA, Systems administrator
Choose the proper instance type, capacity, storage features, and network features.	Determine the compute requirements of the target database instance. Review known performance issues that might need additiona l attention. Consider the following factors to	DBA, Systems administrator

Task	Description	Skills required
	determine the appropriate instance type: • CPU utilization of the source database instance • IOPS (read and write operations) for the source database instance • Memory footprint on the source database instance For more information, see Aurora DB instance classes in the Aurora documentation.	
Identify the network access security requirements for the source and target databases.	Determine the appropriate security groups that would enable the application to talk to the database.	DBA, Systems administrator
Identify the application migration strategy.	• Determine the migration cutover strategy based on the complexity of your application. • Determine the recovery time objective (RTO) and recovery point objective (RPO) for the application, and plan for the cutover accordingly.	DBA, App owner, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a VPC.	Create a new virtual private cloud (VPC) for the target database instance.	Systems administrator
Create security groups.	Create a security group within the VPC (as determined in the previous epic) to allow inbound connections to the database instance.	Systems administrator
Configure and start the Aurora DB cluster.	Create the target database instance with the new VPC and security group and start the instance.	Systems administrator

Migrate data – option 1 (using AWS DMS)

Task	Description	Skills required
Complete pre-migration steps.	1. Clean up the data in the source database. 2. Create a replication instance. 3. Create source and target endpoints. 4. Identify the number of available tables and objects to be migrated.	DBA
Complete migration steps.	1. Drop foreign key constrain ts and triggers on the target database.	DBA

Task	Description	Skills required
	2. Drop secondary indexes on the target database. 3. Use a full-load task to migrate data from the source to the target database. 4. Enable foreign keys. 5. If you're using flash-cut migration and your application requires minimal downtime, enable change data capture (CDC) to replicate ongoing changes 6. Enable triggers. 7. Update sequences. 8. Validate the source and target data.	
Validate data.	To ensure that your data was migrated accurately from the source to the target, follow the data validation steps in the AWS DMS documentation.	DBA

Migrate data – option 2 (using pg_dump and pg_restore)

Task	Description	Skills required
Prepare the source database.	1. Create a directory to store pg_dump backup if it doesn't already exist.	DBA

Task	Description	Skills required
	2. Create a migration user that has permissions to run pg_dump on database objects. 3. Connect to the EC2 instance and run pg_dump backup. For more information, see the pg_dump documentation and the walkthrough in the AWS DMS documentation.	
Prepare the target database.	1. Create a migration user that has permissions to use pg_restore on database objects. 2. Import the database dump by using pg_restore. For more information, see the pg_restore documentation and the walkthrough in the AWS DMS documentation.	DBA
Validate data.	1. Compare the database object counts between the source and the target databases. 2. Resolve any discrepancies found between object counts.	DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.	Implement the application migration strategy that you created in the first epic.	DBA, App owner, Systems administrator

Cut over to the target database

Task	Description	Skills required
Switch the application clients over to the new infrastru cture.	1. Stop all application services and client connections that point to the on-premises PostgreSQ L database. 2. Run the AWS DMS tasks. 3. Set up a rollback task (reverse CDC from Aurora PostgreSQL-Compatible to the on-premises PostgreSQ L database) if needed. 4. Validate data. 5. Start the application services on the new target by configuring Amazon Route 53 to the new Aurora PostgreSQL-Compatible DB instance. 6. Add Amazon CloudWatch and Performance Insights monitoring on your new Aurora PostgreSQL-Compatible DB instance.	DBA, App owner, Systems administrator

Task	Description	Skills required
If you need to roll back the migration.	1. Stop all application services that point to the Aurora PostgreSQL-Compatible database. 2. Roll back the changes to the source on-premises PostgreSQL database by using the AWS DMS task you created in the previous story. 3. Stop the AWS DMS tasks running from the on-premises PostgreSQL database to the Aurora PostgreSQL-Compatible database. 4. Configure the application so that it points back to the source on-premises PostgreSQL database. 5. Confirm that all rollback deployment is complete.	DBA, App owner

Close the project

Task	Description	Skills required
Shut down resources.	Shut down the temporary AWS resources.	DBA, Systems administrator
Validate documents.	Review and validate the project documents.	DBA, App owner, Systems administrator

Task	Description	Skills required
Gather metrics.	Gather metrics around time to migrate, percent of manual versus tool cost savings, and so on.	DBA, App owner, Systems administrator
Close the project.	Close the project and provide any feedback.	DBA, App owner, Systems administrator

Migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on Amazon EC2 running Linux

Tirumala Dasari, Amazon Web Services

Summary

This pattern describes how to migrate from an on-premises Microsoft SQL Server database running on Microsoft Windows, to Microsoft SQL Server on an Amazon Elastic Compute Cloud (Amazon EC2) Linux instance by using backup and restore utilities.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Amazon EC2 Linux AMI (Amazon Machine Image) with Microsoft SQL Server
- AWS Direct Connect between on-premises Windows and Microsoft SQL Server on the Linux EC2 instance

Architecture

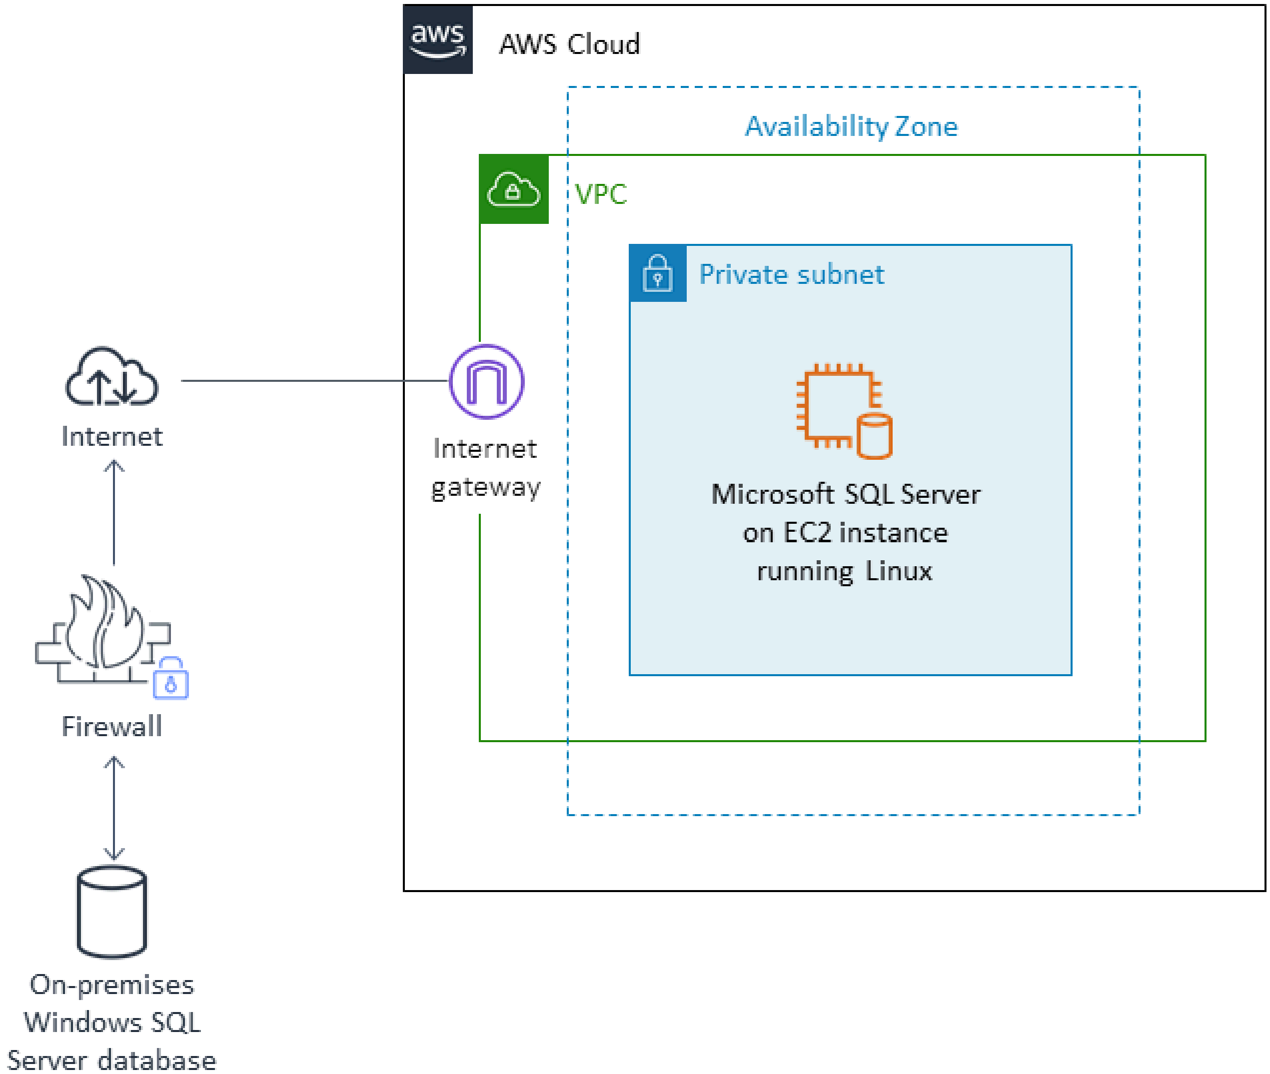
Source technology stack

- On-premises Microsoft SQL Server database

Target technology stack

- Linux EC2 instance with a Microsoft SQL Server database

Database migration architecture



Tools

- **WinSCP** - This tool enables Windows users to easily share files with Linux users.
- **Sqlcmd** - This command-line utility lets you submit T-SQL statements or batches to local and remote instances of SQL Server. The utility is extremely useful for repetitive database tasks such as batch processing or unit testing.

Epics

Prepare the EC2 Linux instance with SQL Server

Task	Description	Skills required
Select an AMI that provides the Linux operating system and includes Microsoft SQL Server.		Sysadmin
Configure the AMI to create an EC2 instance.		Sysadmin
Create inbound and outbound rules for security groups.		Sysadmin
Configure the Linux EC2 instance for a Microsoft SQL Server database.		DBA
Create users and provide permissions as in the source database.		Appowner, DBA
Install SQL Server tools and the sqlcmd utility on the Linux EC2 instance.		DBA

Back up the database and move backup file to Linux EC2 instance

Task	Description	Skills required
Back up the on-premises SQL Server database.		DBA
Install WinSCP on Microsoft SQL Server.		DBA

Task	Description	Skills required
Move the backup file to the Linux EC2 instance running Microsoft SQL Server.		DBA

Restore the database on Linux EC2 instance running SQL Server

Task	Description	Skills required
Restore the database from the database backup file by using the sqlcmd utility.		DBA
Validate database objects and data.		Developer, Test engineer

Cut over from Windows SQL Server to Windows SQL Server on Linux EC2 instance

Task	Description	Skills required
Validate database objects and data.		Developer, Test engineer
Cut over from the on-premis es Microsoft SQL Server database to the Linux EC2 instance running Microsoft SQL Server.		DBA

Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using linked servers

Kevin Yung, Viqash Adwani, and Vishal Singh, Amazon Web Services

Summary

Linked servers enable Microsoft SQL Server to run SQL statements on other instances of database servers. This pattern describes how you can migrate your on-premises Microsoft SQL Server database to Amazon Relational Database Service (Amazon RDS) for Microsoft SQL Server to achieve lower cost and higher availability. Currently, Amazon RDS for Microsoft SQL Server doesn't support connections outside an Amazon Virtual Private Cloud (Amazon VPC) network.

You can use this pattern to achieve the following objectives:

- To migrate Microsoft SQL Server to Amazon RDS for Microsoft SQL Server without breaking linked server capabilities.
- To prioritize and migrate linked Microsoft SQL Server in different waves.

Prerequisites and limitations

Prerequisites

- Check whether Microsoft SQL Server on Amazon RDS supports the features you require.
- Make sure that you can use either Amazon RDS for Microsoft SQL Server with default collations or collations set over database levels.

Architecture

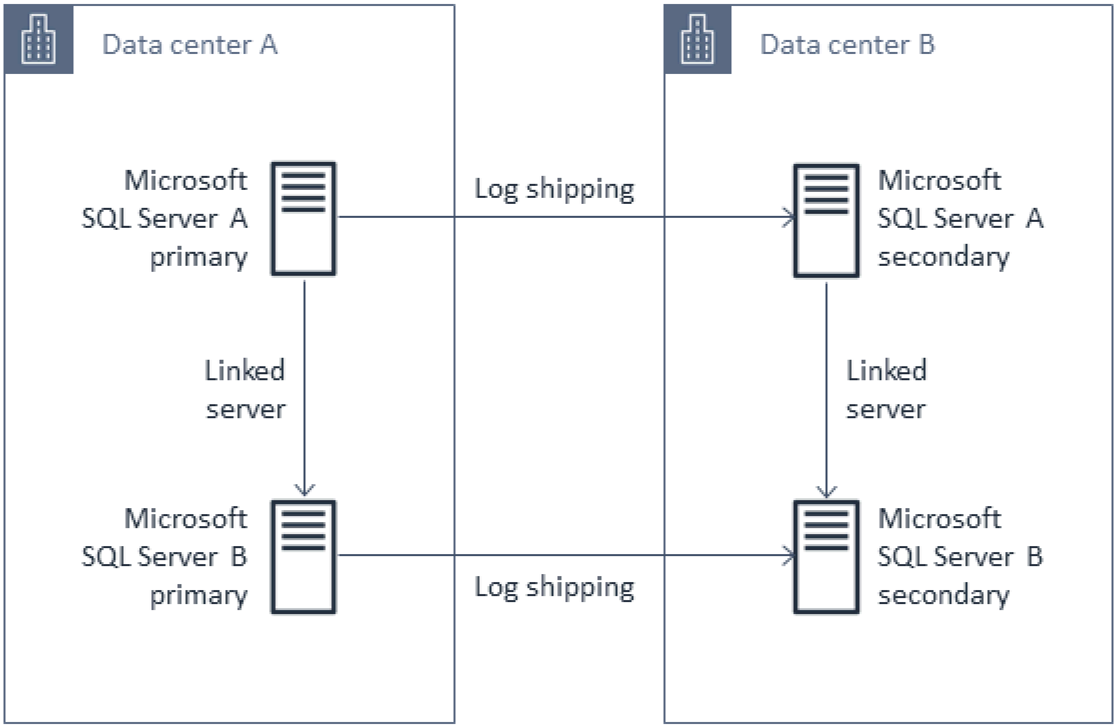
Source technology stack

- On-premises databases (Microsoft SQL Server)

Target technology stack

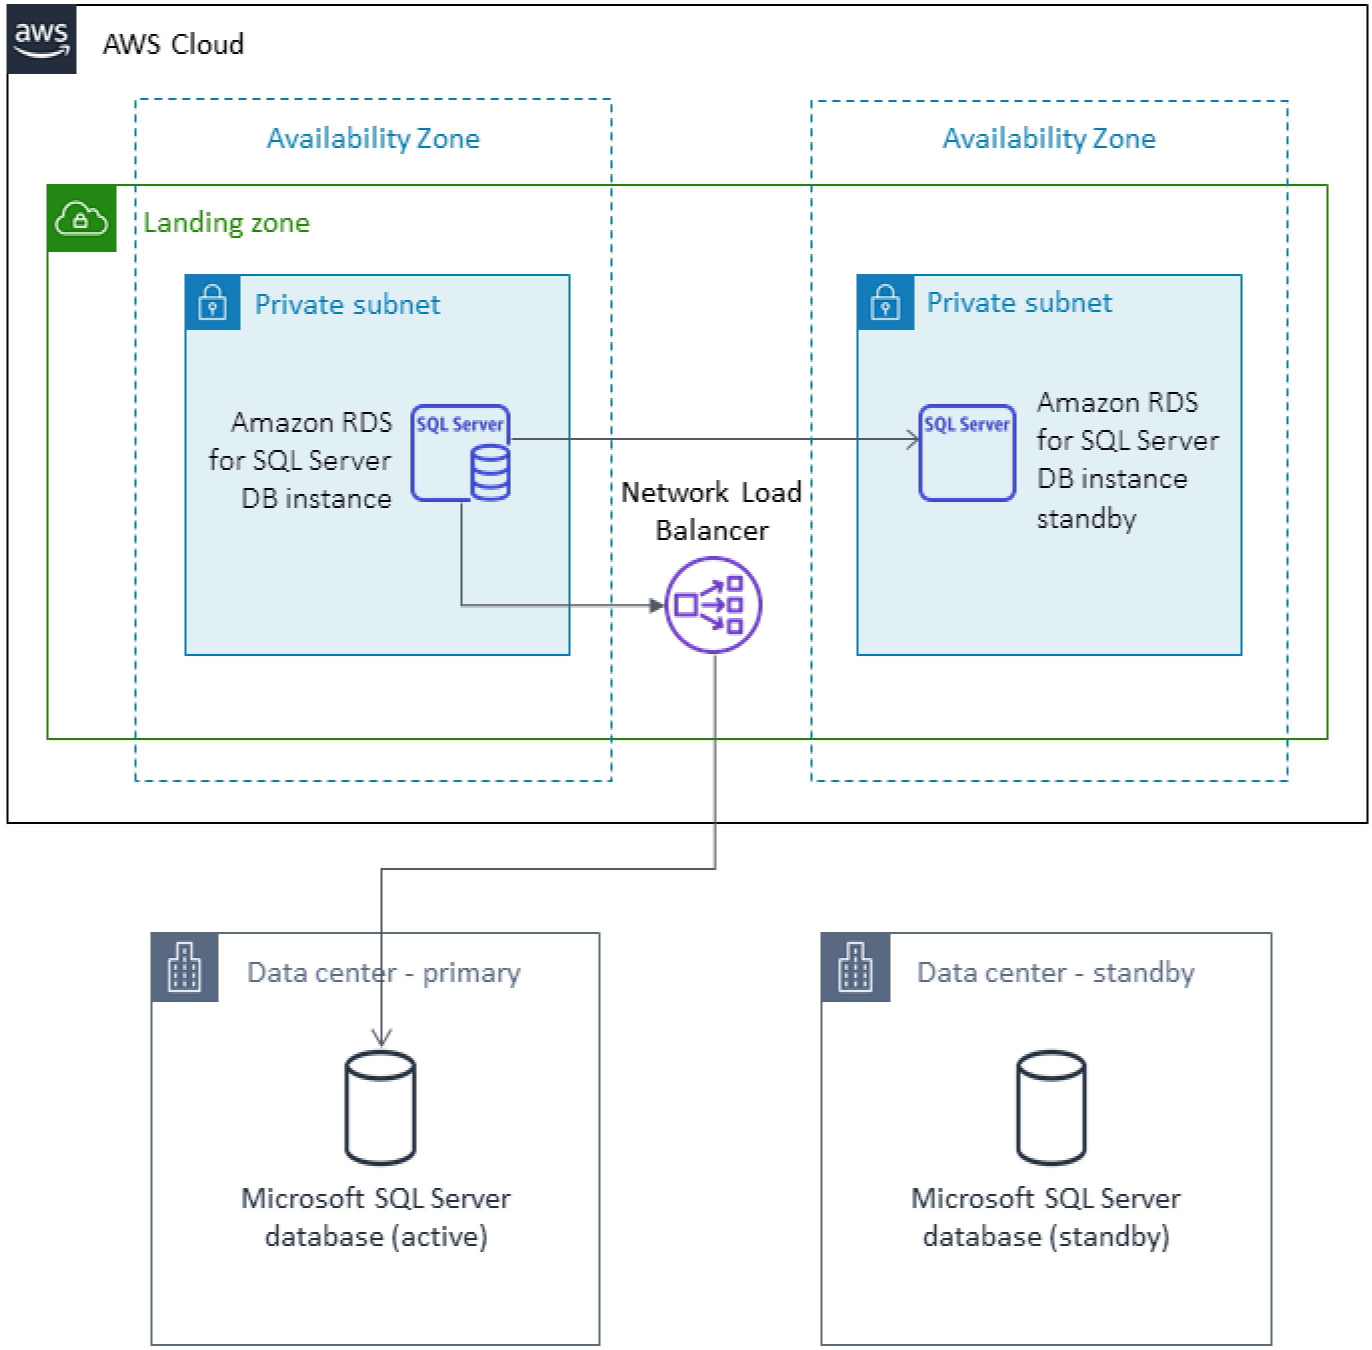
- Amazon RDS for SQL Server

Source state architecture



Target state architecture

In the target state, you migrate Microsoft SQL Server to Amazon RDS for Microsoft SQL Server by using linked servers. This architecture uses a Network Load Balancer to proxy the traffic from Amazon RDS for Microsoft SQL Server to on-premises servers running Microsoft SQL Server. The following diagram shows the reverse proxy capability for the Network Load Balancer.



Tools

- AWS CloudFormation
- Network Load Balancer
- Amazon RDS for SQL Server in multiple Availability Zones (Multi-AZs)

- AWS Database Migration Service (AWS DMS)

Epics

Create a landing zone VPC

Task	Description	Skills required
Create the CIDR allocation.		AWS SysAdmin
Create a virtual private cloud (VPC).		AWS SysAdmin
Create the VPC subnets.		AWS SysAdmin
Create the subnet access control lists (ACLs).		AWS SysAdmin
Create the subnet route tables.		AWS SysAdmin
Create a connection with AWS Direct Connect or AWS Virtual Private Network (VPN).		AWS SysAdmin

Migrate the database to Amazon RDS

Task	Description	Skills required
Create an Amazon RDS for Microsoft SQL Server DB instance.		AWS SysAdmin
Create an AWS DMS replicati on instance.		AWS SysAdmin

Task	Description	Skills required
Create the source and target database endpoints in AWS DMS.		AWS SysAdmin
Create the migration task and set continuous replication to ON after a full load.		AWS SysAdmin
Request a firewall change to allow Amazon RDS for Microsoft SQL Server to access the on-premises SQL Server databases.		AWS SysAdmin
Create a Network Load Balancer.		AWS SysAdmin
Create a target group that targets the database servers in your data center	We recommend that you use hostnames in the target setup to incorporate data center (DC) failover events.	AWS SysAdmin
Run the SQL statement for linked server setup.	Run the SQL statements for adding a linked server by using the Microsoft SQL management tool against the Amazon RDS for Microsoft SQL Server DB instance. In the SQL statement, set @datasrc to use the Network Load Balancer hostname. Add linked server login credentia ls by using the Microsoft SQL management tool against the Amazon RDS for Microsoft SQL Server DB instance.	AWS SysAdmin

Task	Description	Skills required
Test and validate the SQL Server functions.		AWS SysAdmin
Create a cutover.		AWS SysAdmin

Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using native backup and restore methods

Tirumala Dasari, David Queiroz, and Vishal Singh, Amazon Web Services

Summary

This pattern describes how to migrate an on-premises Microsoft SQL Server database to an Amazon Relational Database Service (Amazon RDS) for SQL Server DB instance (homogeneous migration). The migration process is based on native SQL Server backup and restore methods. It uses SQL Server Management Studio (SSMS) to create a database backup file, and an Amazon Simple Storage Service (Amazon S3) bucket to store the backup file before restoring it in Amazon RDS for SQL Server.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Identity and Access Management (IAM) role policies to access the S3 bucket and the Amazon RDS for SQL Server DB instance.

Limitations

- The process described in this pattern migrates only the database. SQL logins or database users, including any SQL Server Agent jobs, aren't migrated because they require additional steps.

Product versions

- SQL Server 2012-2017. For the latest list of supported versions and features, see Microsoft SQL Server on Amazon RDS in the AWS documentation.

Architecture

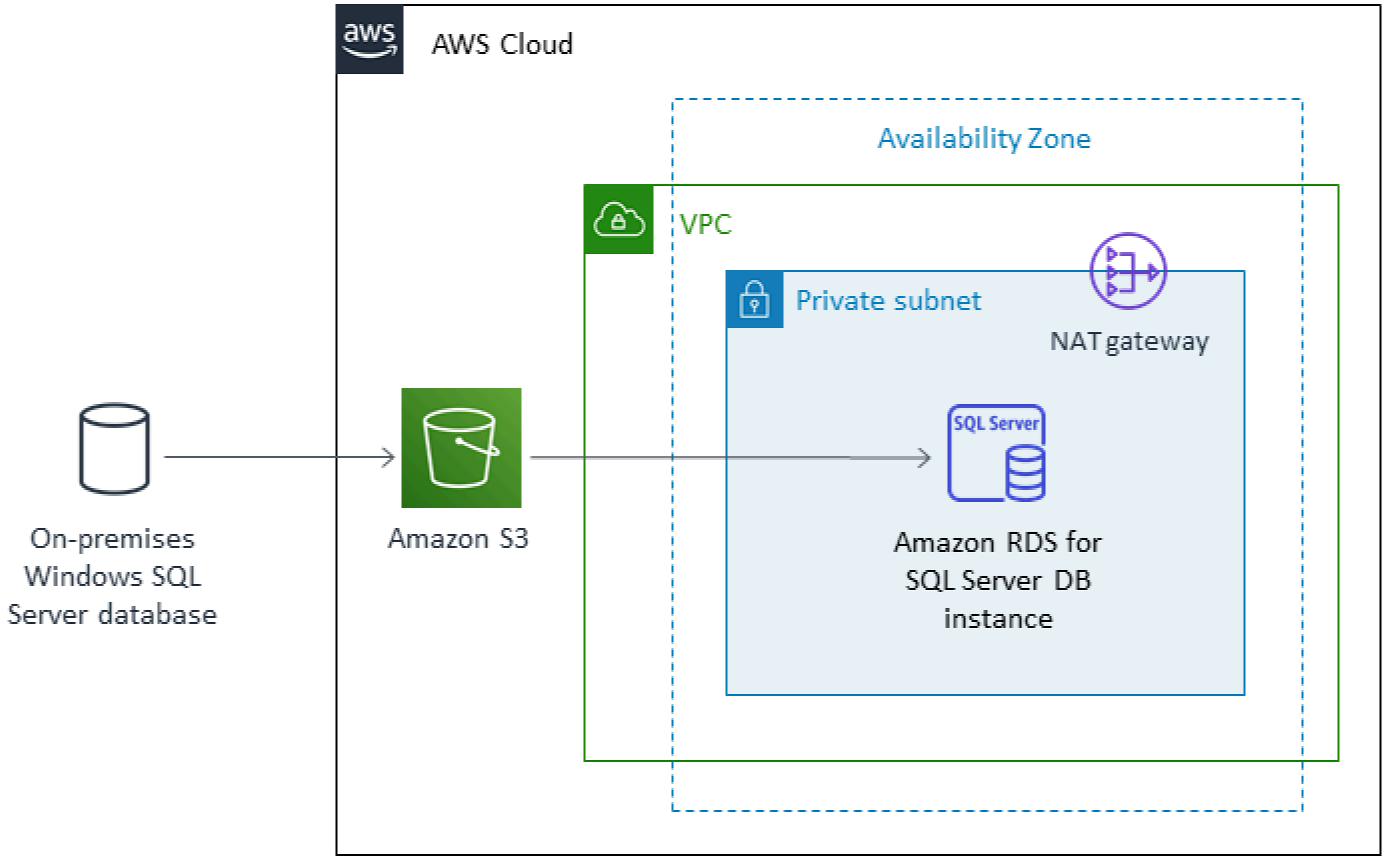
Source technology stack

- An on-premises Microsoft SQL Server database

Target technology stack

- Amazon RDS for SQL Server DB instance

Data migration architecture



Tools

- Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

Epics

Create an Amazon RDS for SQL Server DB instance

Task	Description	Skills required
Select SQL Server as the database engine in Amazon RDS for SQL Server.		DBA
Choose the SQL Server Express Edition.		DBA
Specify database details.	For more information about creating a DB instance, see the Amazon RDS documentation.	DBA, App owner

Create a backup file from the on-premises SQL Server database

Task	Description	Skills required
Connect to the on-premises SQL Server database through SSMS.		DBA
Create a backup of the database.	For instructions, see the SSMS documentation.	DBA, App owner

Upload the backup file to Amazon S3

Task	Description	Skills required
Create a bucket in Amazon S3.	For more information, see the Amazon S3 documentation.	DBA

Task	Description	Skills required
Upload the backup file to the S3 bucket.	For more information, see the [Amazon S3 documentation]().	SysOps administrator

Restore the database in Amazon RDS for SQL Server

Task	Description	Skills required
Add the option group to Amazon RDS.	1. Open the Amazon RDS console at https://console.aws.amazon.com/rds/. 2. In the navigation pane, choose **Option groups**, **Create group**. 3. Complete the information for the option group, and then choose **Create**. 4. Add the `SQLSERVER_BACKUP_RESTORE` option to the option group, and then choose **Add option**. For more information, see the [Amazon RDS documentation]().	SysOps administrator
Restore the database.	1. Connect to Amazon RDS for SQL Server through SSMS. 2. Call the `msdb.dbo.rds_restore_database` stored procedure to restore the database.	DBA

Validate the target database

Task	Description	Skills required
Validate objects and data.	Validate the objects and data between the source database and Amazon RDS for SQL Server. **Note** This task migrates the database only. Logins and jobs will not be migrated.	App owner, DBA

Cut over

Task	Description	Skills required
Redirect application traffic.	After validation, redirect application traffic to the Amazon RDS for SQL Server DB instance.	App owner, DBA

Migrate a Microsoft SQL Server database to Aurora MySQL by using AWS DMS and AWS SCT

Mark Szalkiewicz and Pavan Pusuluri, Amazon Web Services

Summary

This pattern describes how to migrate a Microsoft SQL Server database that is either on premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance to Amazon Aurora MySQL. The pattern uses AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT) for data migration and schema conversion.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Microsoft SQL Server source database in an on-premises data center or on an EC2 instance
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors, installed on either a local machine or an EC2 instance where AWS SCT is installed

Limitations

- Database size limit: 64 TB

Product versions

- Microsoft SQL Server 2008, 2008R2, 2012, 2014, 2016, and 2017 for the Enterprise, Standard, Workgroup, and Developer editions. The Web and Express editions aren't supported by AWS DMS. For the latest list of supported versions, see Using a Microsoft SQL Server Database as a Source for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Microsoft SQL Server versions supported by AWS SCT, see the AWS SCT documentation.
- MySQL versions 5.5, 5.6, and 5.7. For the latest list of supported versions, see Using a MySQL-Compatible Database as a Target for AWS DMS.

Architecture

Source technology stack

One of the following:

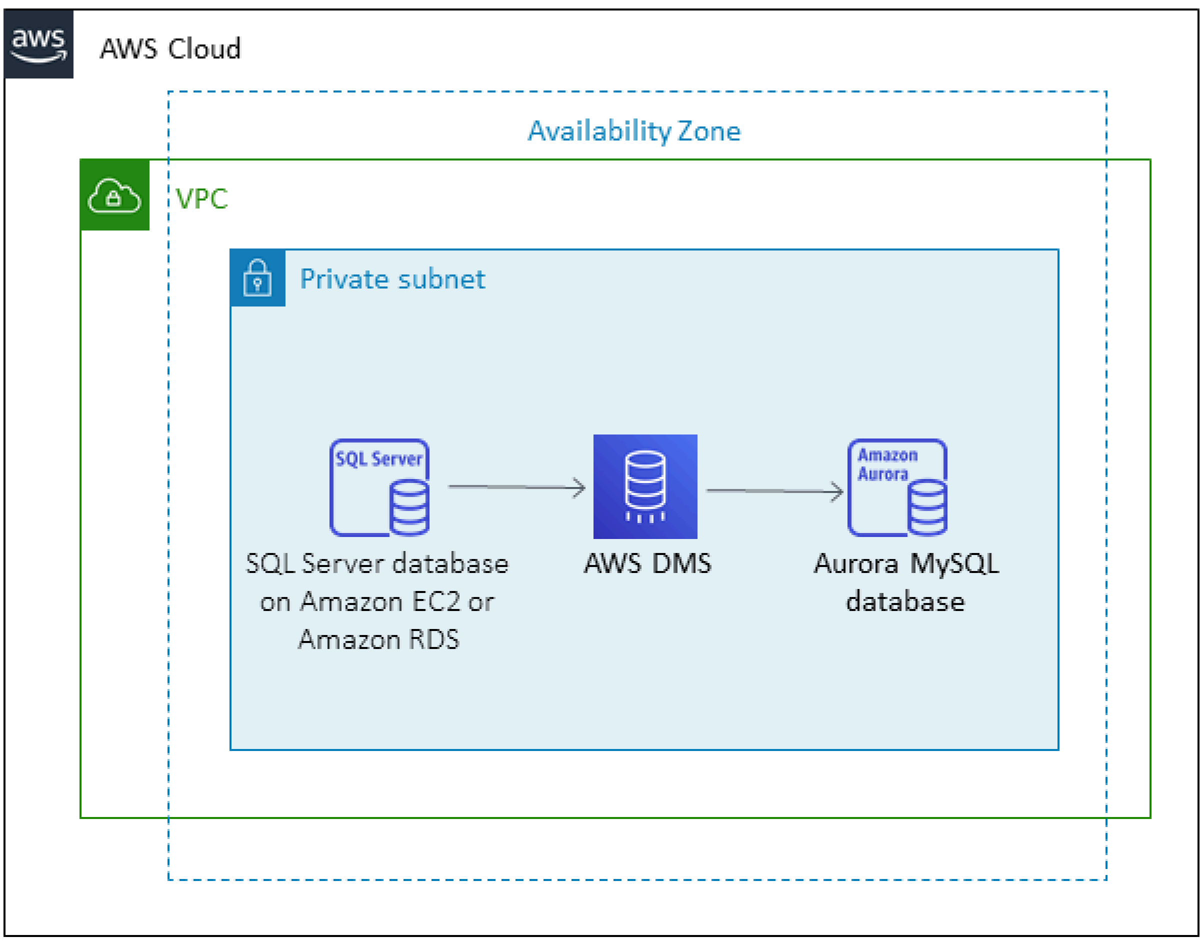
- An on-premises Microsoft SQL Server database
- A Microsoft SQL Server database on an EC2 instance

Target technology stack

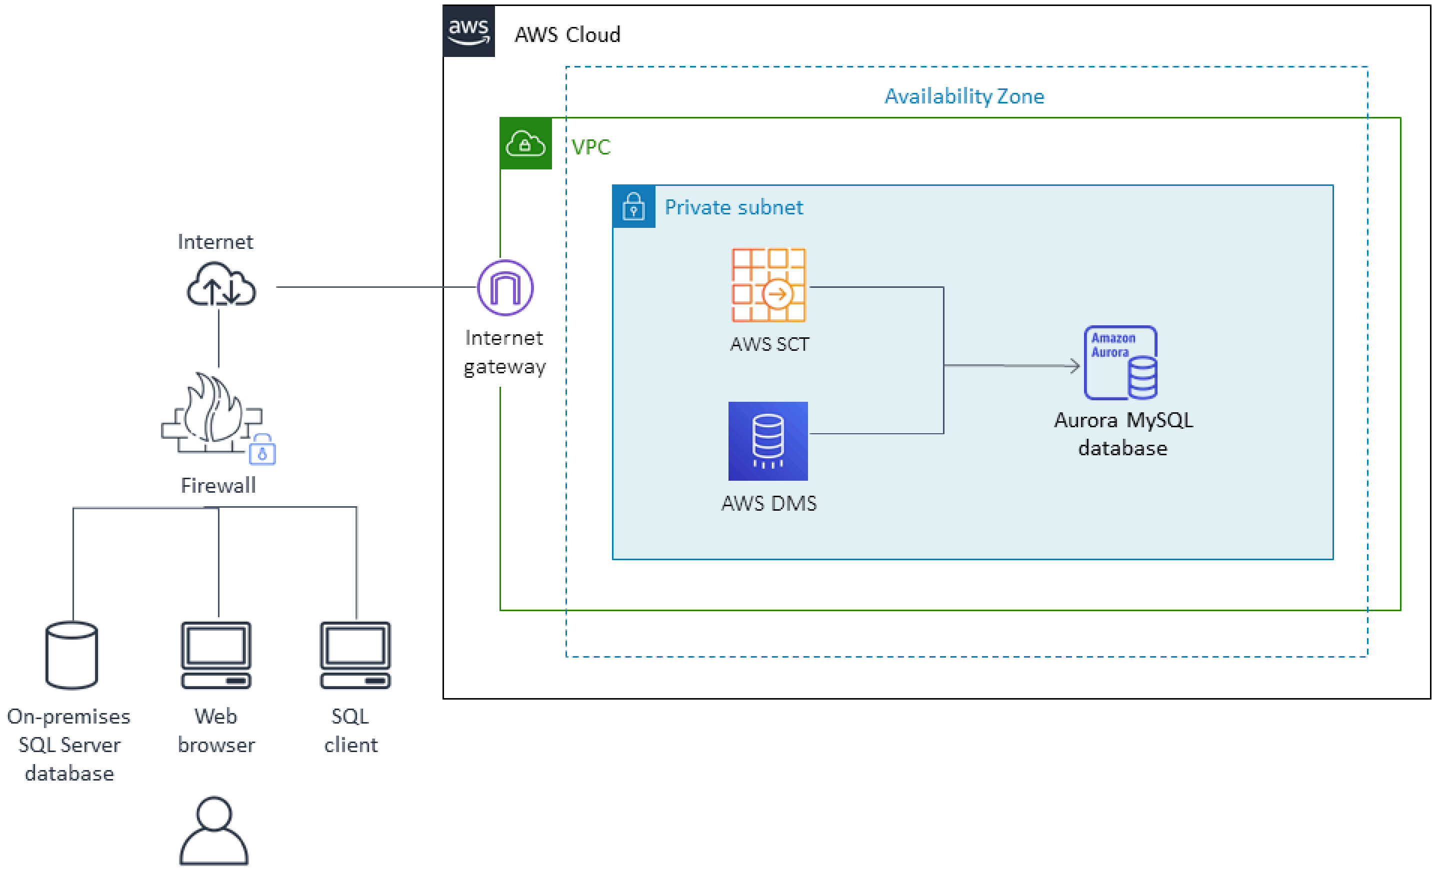
- Aurora MySQL

Data migration architecture

- From a Microsoft SQL Server database running in the AWS Cloud



- From a Microsoft SQL Server database running in an on-premises data center



Tools

- **AWS DMS** - [AWS Data Migration Service](https://docs.aws.amazon.com/dms/) (AWS DMS) helps you migrate your data to and from widely used commercial and open-source databases, including Oracle, SQL Server, MySQL, and PostgreSQL. You can use AWS DMS to migrate your data into the AWS Cloud, between on-premises instances (through an AWS Cloud setup), or between combinations of cloud and on-premises setups.
- **AWS SCT** - [AWS Schema Conversion Tool](https://docs.aws.amazon.com/SchemaConversionTool/) (AWS SCT) makes heterogeneous database migrations easy by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

Epics

Prepare for the migration

Task	Description	Skills required
Validate the source and target database version and engine.		DBA
Create an outbound security group for the source and target databases.		SysAdmin
Create and configure an EC2 instance for AWS SCT, if required.		DBA
Download the latest version of AWS SCT and associated drivers.		DBA
Add and validate the prerequisite users and grants in the source database.		DBA
Create an AWS SCT project for the workload and connect to the source database.		DBA
Generate an assessment report and evaluate feasibili ty.		DBA

Prepare the target database

Task	Description	Skills required
Create a target Amazon RDS DB instance, using Amazon Aurora as the database engine.		DBA
Extract the list of users, roles, and grants from the source.		DBA
Map the existing database users to the new database users.		App owner
Create users in the target database.		DBA
Apply roles from the previous step to the target database.		DBA
Review the database options, parameters, network files, and database links in the source database, and then evaluate their applicability to the target database.		DBA
Apply any relevant settings to the target.		DBA

Transfer objects

Task	Description	Skills required
Configure AWS SCT connectiv ity to the target database.		DBA

Task	Description	Skills required
Convert the schema using AWS SCT.	AWS SCT automatically converts the source database schema and most of the custom code to a format that is compatible with the target database. Any code that the tool cannot convert automatically is clearly marked so that you can convert it yourself.	DBA
Review the generated SQL report and save any errors and warnings.		DBA
Apply automated schema changes to the target or save them as a .sql file.		DBA
Validate that AWS SCT created the objects on the target.		DBA
Manually rewrite, reject, or redesign any items that failed to convert automatically.		DBA
Apply the generated role and user grants and review any exceptions.		DBA

Migrate the data

Task	Description	Skills required
Determine the migration method.		DBA
Create a replication instance from the AWS DMS console.	For detailed information on using AWS DMS, see the links in the "Related resources" section.	DBA
Create the source and target endpoints.		DBA
Create a replication task.		DBA
Start the replication task and monitor the logs.		DBA

Migrate the application

Task	Description	Skills required
Use AWS SCT to analyze and convert the SQL items within the application code.	When you convert your database schema from one engine to another, you also need to update the SQL code in your applications to interact with the new database engine instead of the old one. You can view, analyze, edit, and save the converted SQL code. For detailed information on using AWS SCT, see the links in the "Related resources" section.	App owner

Task	Description	Skills required
Create the new application servers on AWS.		App owner
Migrate the application code to the new servers.		App owner
Configure the application server for the target database and drivers.		App owner
Fix any code that's specific to the source database engine in the application.		App owner
Optimize the application code for the target engine.		App owner

Cut over

Task	Description	Skills required
Apply any new users, grants, and code changes to the target.		DBA
Lock the application for any changes.		App owner
Validate that all changes were propagated to the target database.		DBA
Point the new application server to the target database.		App owner
Recheck everything.		App owner

Task	Description	Skills required
Go live.		App owner

Close the project

Task	Description	Skills required
Shut down the temporary AWS resources (AWS DMS replication instance and EC2 instance used for AWS SCT).		DBA, App owner
Update feedback on the AWS DMS process for internal teams.		DBA, App owner
Revise the AWS DMS process and improve the template if necessary.		DBA, App owner
Review and validate the project documents.		DBA, App owner
Gather metrics around time to migrate, percent of manual versus tool cost savings, and so on.		DBA, App owner
Close the project and provide any feedback.		DBA, App owner

Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools

Shyam Sunder Rakhecha, Amazon Web Services

Summary

This pattern provides guidance for migrating an on-premises MariaDB database to Amazon Relational Database Service (Amazon RDS) for MariaDB by using native tools. If you have MySQL tools installed, you can use **mysql** and **mysqldump**. If you have MariaDB tools installed, you can use **mariadb** and **mariadb-dump**. MySQL and MariaDB tools have the same origin, but there are minor differences in MariaDB version 10.6 and later.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A MariaDB source database in an on-premises data center

Limitations

- Database size limit: 64 TB

Product versions

- MariaDB versions 10.0-10.6 (for the latest list of supported versions, see [MariaDB on Amazon RDS](#) in the AWS documentation)

Architecture

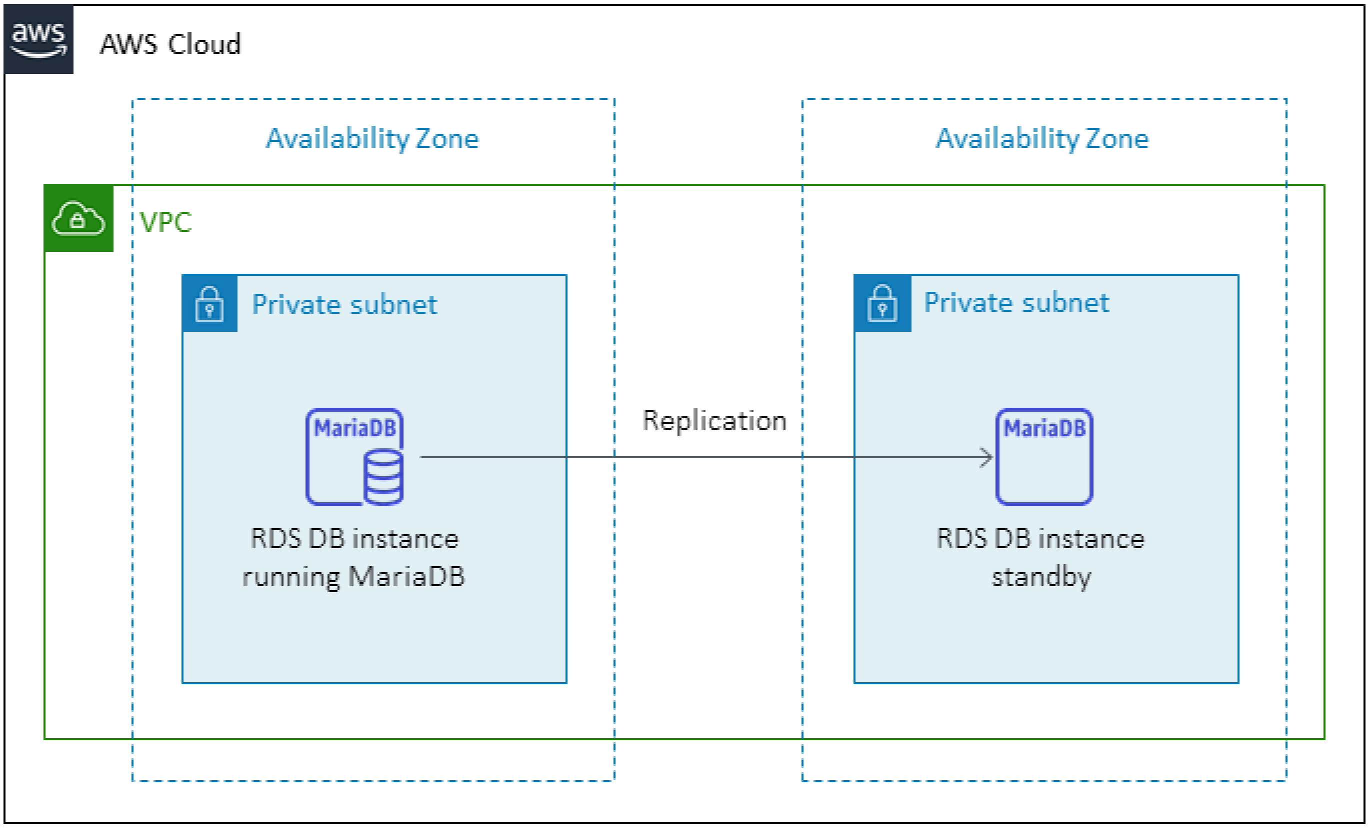
Source technology stack

- MariaDB database in an on-premises data center

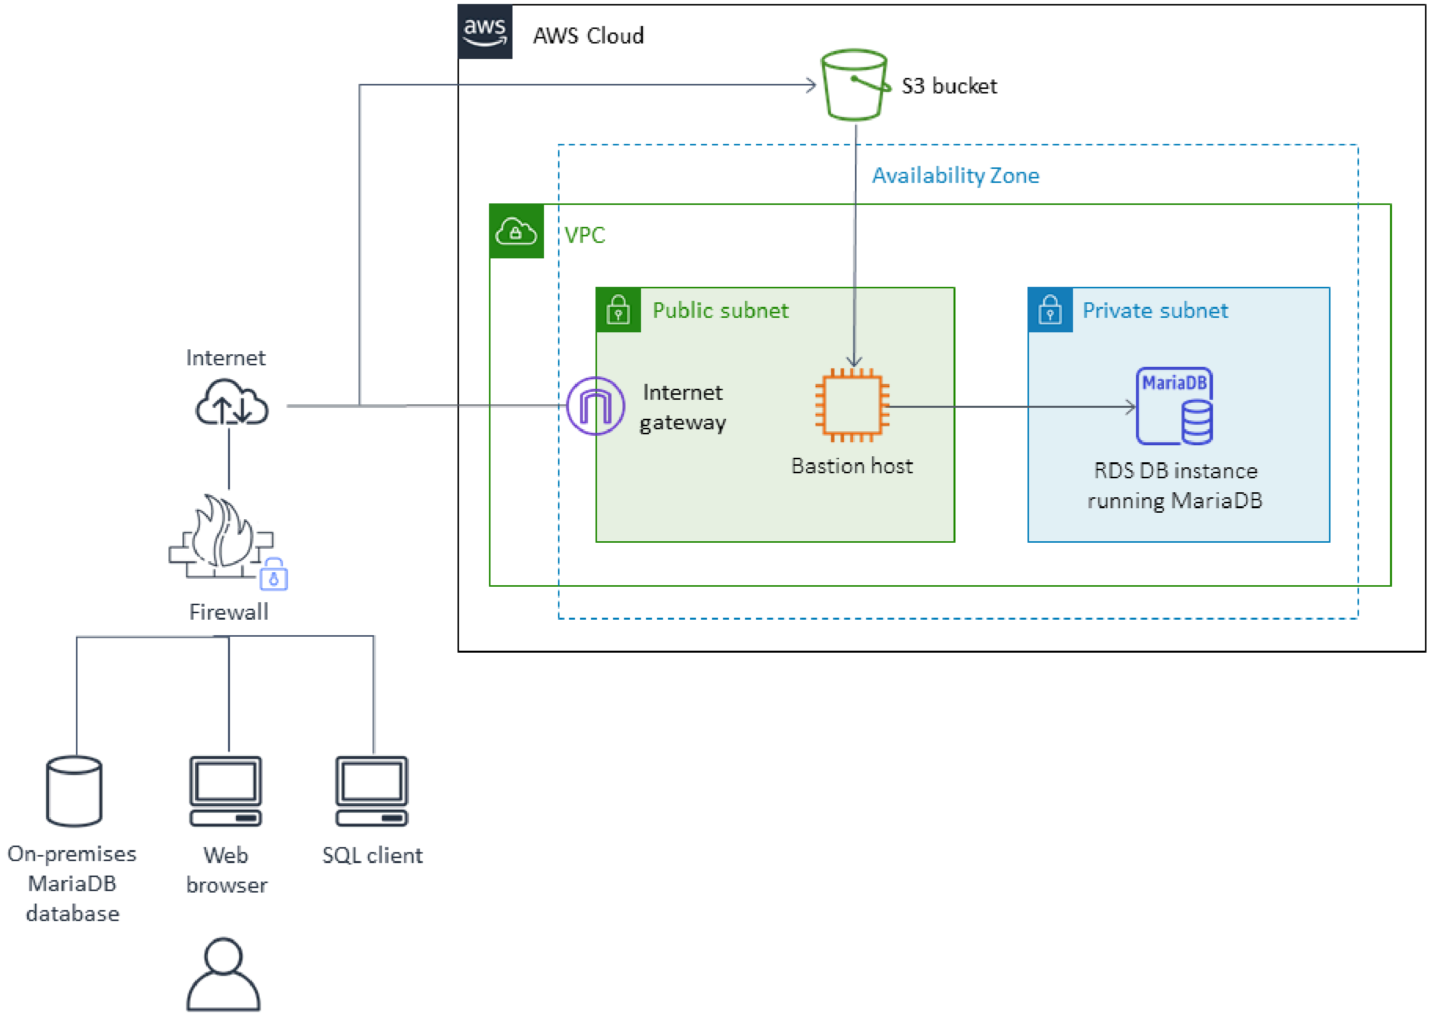
Target technology stack

- Amazon RDS for MariaDB DB instance

Target architecture



Data migration architecture



Tools

- Native MySQL tools: **mysql** and **mysqldump**
- Native MariaDB tools: **mariadb** and **mariadb-dump**

Epics

Plan the migration

Task	Description	Skills required
Validate source and target database versions and engines.		DBA

Task	Description	Skills required
Identify hardware requireme nts for the target server instance.		DBA, Systems administrator
Identify storage requirements (storage type and capacity).		DBA, Systems administrator
Choose the proper instance type based on capacity, storage features, and network features.		DBA, Systems administrator
Identify the network access security requirements for source and target databases.		DBA, Systems administrator
Identify the application migration strategy.		DBA, App owner, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).		Systems administrator
Create security groups.		Systems administrator
Configure and start an Amazon RDS DB instance running MariaDB.		Systems administrator

Migrate data

Task	Description	Skills required
Use native tools to migrate database objects and data.	In the source database, use **mysqldump** or **mariadb-dump** to create an output file that contains database objects and data. In the target database, use **mysql** or **mariadb** to restore the data.	DBA
Validate the data.	Check the source and target databases to confirm that the data migration was successfu l.	DBA

Migrate the application

Task	Description	Skills required
Follow the application migration strategy.		DBA, App owner, Systems administrator

Cut over

Task	Description	Skills required
Switch the application clients over to the new infrastru cture.		DBA, App owner, Systems administrator

Close the project

Task	Description	Skills required
Shut down the temporary AWS resources.		Systems administrator
Review and validate the project documents.		DBA, App owner, Systems administrator
Gather metrics around time to migrate, cost savings provided by tools, and so on.		DBA, App owner, Systems administrator
Close out the project and provide feedback.		DBA, App owner, Systems administrator

Migrate an on-premises MySQL database to Aurora MySQL

Igor Obradovic, Amazon Web Services

Summary

This pattern explains how to migrate an on-premises MySQL source database to Amazon Aurora MySQL-Compatible Edition. It describes two options for migration: using AWS Database Migration Service (AWS DMS) or using native MySQL tools such as **mysqldbcopy** and **mysqldump**.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source MySQL database in an on-premises data center

Limitations

- Database size limit: 128 TB

Product versions

- MySQL version 8.0 (Aurora MySQL version 3) is available under standard support.
- MySQL version 5.7 (Aurora MySQL version 2) is available under extended support, for an additional cost.

For the latest list of supported versions, see [Amazon Aurora versions] in the AWS documentation. If you're using AWS DMS, see also [Using a MySQL-Compatible Database as a Target for AWS DMS] for MySQL versions supported by AWS DMS.

Architecture

Source technology stack

- An on-premises MySQL database

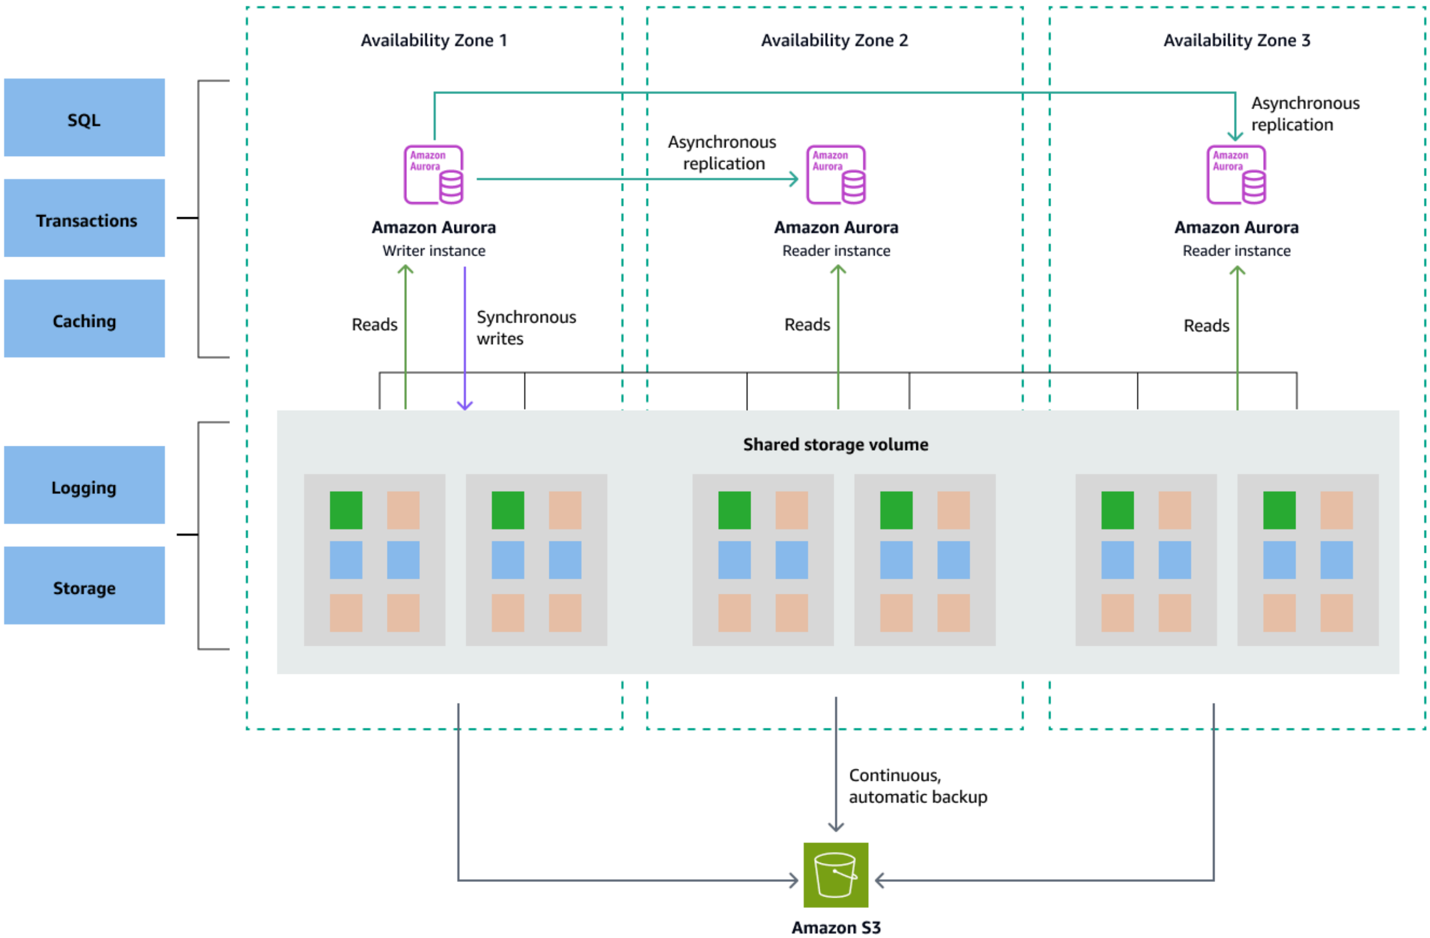
Target technology stack

- Amazon Aurora MySQL-Compatible Edition

Target architecture

Aurora data is stored in a cluster volume, which is a single, virtual volume that uses solid state drives (SSDs). A cluster volume consists of copies of the data across three Availability Zones in a single AWS Region. Because the data is automatically replicated across Availability Zones, it is highly durable with less possibility of data loss.

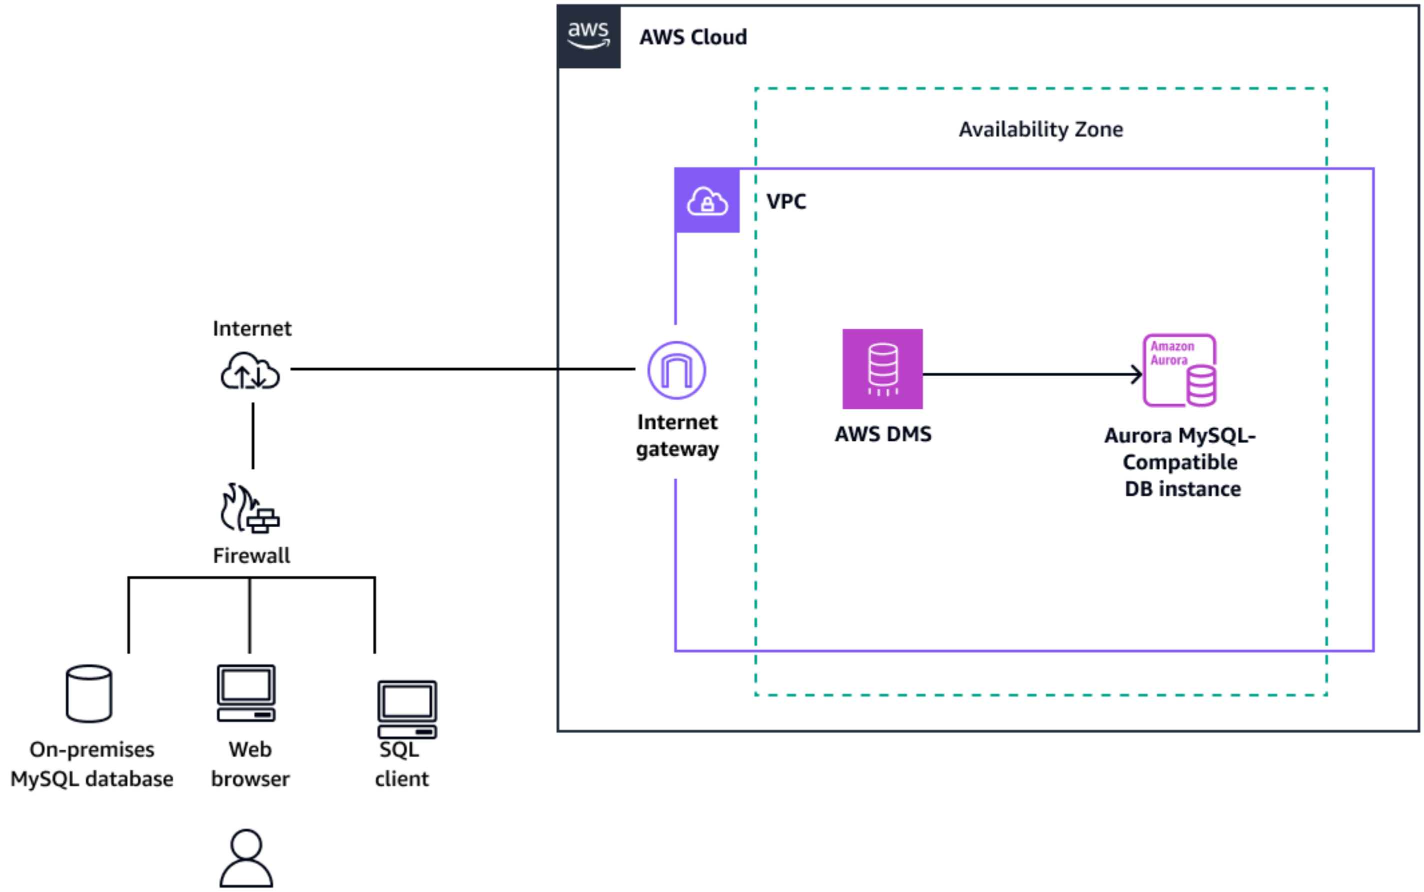
Aurora automatically divides your database volume into 10 GB segments spread across many disks. Each 10 GB chunk of your database volume is replicated six ways, across three Availability Zones. The following diagram illustrates the relationship between the cluster volume, the writer DB instance, and reader DB instances in an Aurora DB cluster, and the separation of compute capacity and storage. For more information about this architecture, see the [Aurora documentation](#) and [FAQ](#).



Data migration architecture

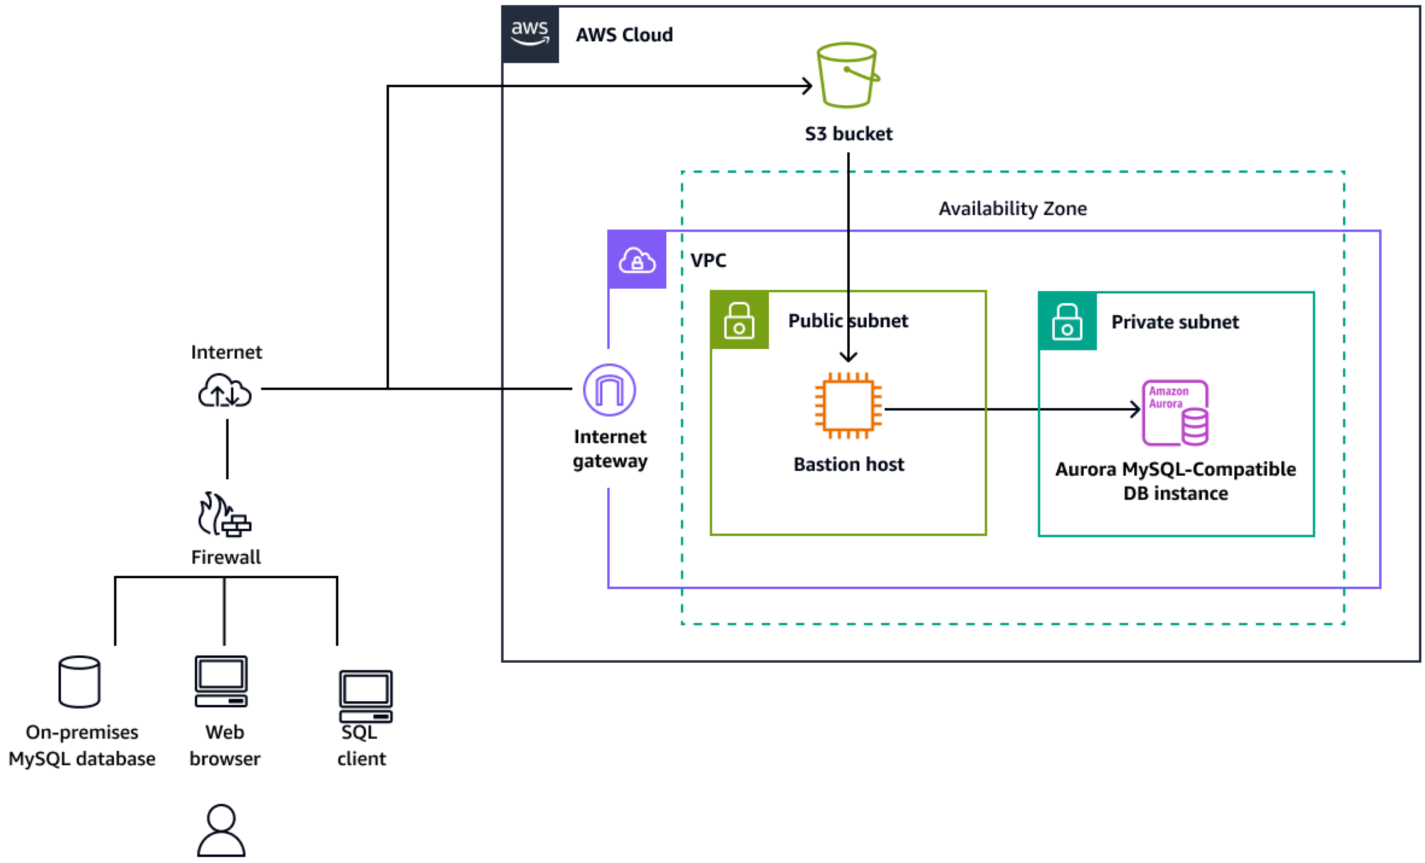
Using AWS DMS:

The following diagram illustrates the migration of an on-premises MySQL database to an Aurora MySQL-Compatible cluster in the AWS Cloud, using AWS DMS.



Using native MySQL tools:

The following diagram illustrates the migration of an on-premises MySQL database to an Aurora MySQL-Compatible cluster in the AWS Cloud, using native MySQL tools such as **mysqldbcopy** and **mysqldump**.



Tools

- [AWS Database Migration Service (AWS DMS)](#) supports several source and target database engines. For information about MySQL source and target databases supported by AWS DMS, see [Migrating MySQL-Compatible Databases to AWS](#). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- [mysqldbcopy](#) is a MySQL utility that copies a MySQL database on a single server or between servers.
- [mysqldump](#) is a MySQL utility that creates a dump file from a MySQL database for backup or migration purposes.

Epics

Plan the migration

Task	Description	Skills required
Validate the version and engine.	Validate the database version and engine for the source and target databases.	DBA
Identify hardware requireme nts.	Identify hardware requireme nts for the target server instance.	DBA, Systems administrator
Identify storage requireme nts.	Identify storage requirements (storage type and capacity).	DBA, Systems administrator
Choose the instance type.	Choose the proper instance type based on your compute, storage, and network requirements.	DBA, Systems administrator
Determine network access security requirements.	Identify the network access security requirements for the source and target databases.	DBA, Systems administrator
Determine strategy.	Identify the application migration strategy.	DBA, App owner, Systems administrator

Configure the infrastructure

Task	Description	Skills required
Create a virtual private cloud (VPC).	For instructions, see Create a VPC in the Amazon Virtual Private Cloud (Amazon VPC) documentation.	Systems administrator

Task	Description	Skills required
Create security groups.	For instructions, see Create a security group for your VPC in the Amazon VPC documenta tion.	Systems administrator
Configure and start an Aurora MySQL-Compatible DB cluster in your AWS account.	For instructions, see Creating an Amazon Aurora DB cluster in the Aurora documentation.	Systems administrator

Migrate data - option 1

Task	Description	Skills required
Use native MySQL tools or third-party tools to migrate database objects and data.	For instructions, see the documentation for MySQL tools such as mysqldbcopy and mysqldump.	DBA

Migrate data - option 2

Task	Description	Skills required
Migrate data with AWS DMS.	For instructions, see Using a MySQL-compatible database as a source and Using a MySQL-compatible database as a target in the AWS DMS documentation.	DBA

Migrate the application

Task	Description	Skills required
Follow the strategy.	Follow the application migration strategy.	DBA, App owner, Systems administrator

Cut over

Task	Description	Skills required
Switch application clients.	Switch the application clients over to connect to the new Aurora cluster endpoint.	DBA, App owner, Systems administrator

Close the project

Task	Description	Skills required
Shut down resources.	Shut down temporary AWS resources.	DBA, Systems administrator
Review documentation.	Review and validate the project documents.	DBA, App owner, Systems administrator
Collect metrics.	Gather metrics around time to migrate, percentage of manual steps versus tool usage, cost savings, and so on.	DBA, App owner, Systems administrator
Complete migration project.	Close out the project and provide feedback.	App owner, DBA, Systems administrator

Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3

Rohan Jamadagni, Udayasimha Theepireddy, and sajith menon, Amazon Web Services

Summary

This pattern describes how to migrate large, on-premises MySQL databases efficiently to Amazon Aurora MySQL by using Percona XtraBackup. Percona XtraBackup is an open-source, non-blocking backup utility for MySQL-based servers. The pattern shows how to use Amazon Elastic File System (Amazon EFS) to reduce the time to upload the backup to Amazon Simple Storage Service (Amazon S3) and to restore the backup to Amazon Aurora MySQL. The pattern also provides details on how to make incremental Percona backups to minimize the number of binary logs to be applied to the target Aurora MySQL database.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Permissions to create AWS Identity and Access Management (IAM) roles and policies
- Network connectivity between the on-premises MySQL database and the virtual private cloud (VPC) on AWS

Limitations

- The source servers must be Linux-based systems that can install a Network File System (NFS) client (nfs-utils/nfs-common).
- The S3 bucket used for uploading backup files supports server-side encryption (SSE-S3/SSE-KMS) only.
- Amazon S3 limits the size of the backup files to 5 TB. If your backup file exceeds 5 TB, you can split it into multiple, smaller files.
- The number of source files uploaded to the S3 bucket cannot exceed one million files.
- The pattern supports Percona XtraBackup full backup and incremental backup only. It doesn't support partial backups that use `--tables`, `--tables-exclude`, `--tables-file`, `--databases`, `--databases-exclude`, or `--databases-file`.

- Aurora doesn't restore users, functions, stored procedures, or time zone information from the source MySQL database.

Product versions

- The source database must be MySQL version 5.5, 5.6, or 5.7.
- For MySQL 5.7, you must use Percona XtraBackup 2.4.
- For MySQL 5.6 and 5.6, you must use Percona XtraBackup 2.3 or 2.4.

Architecture

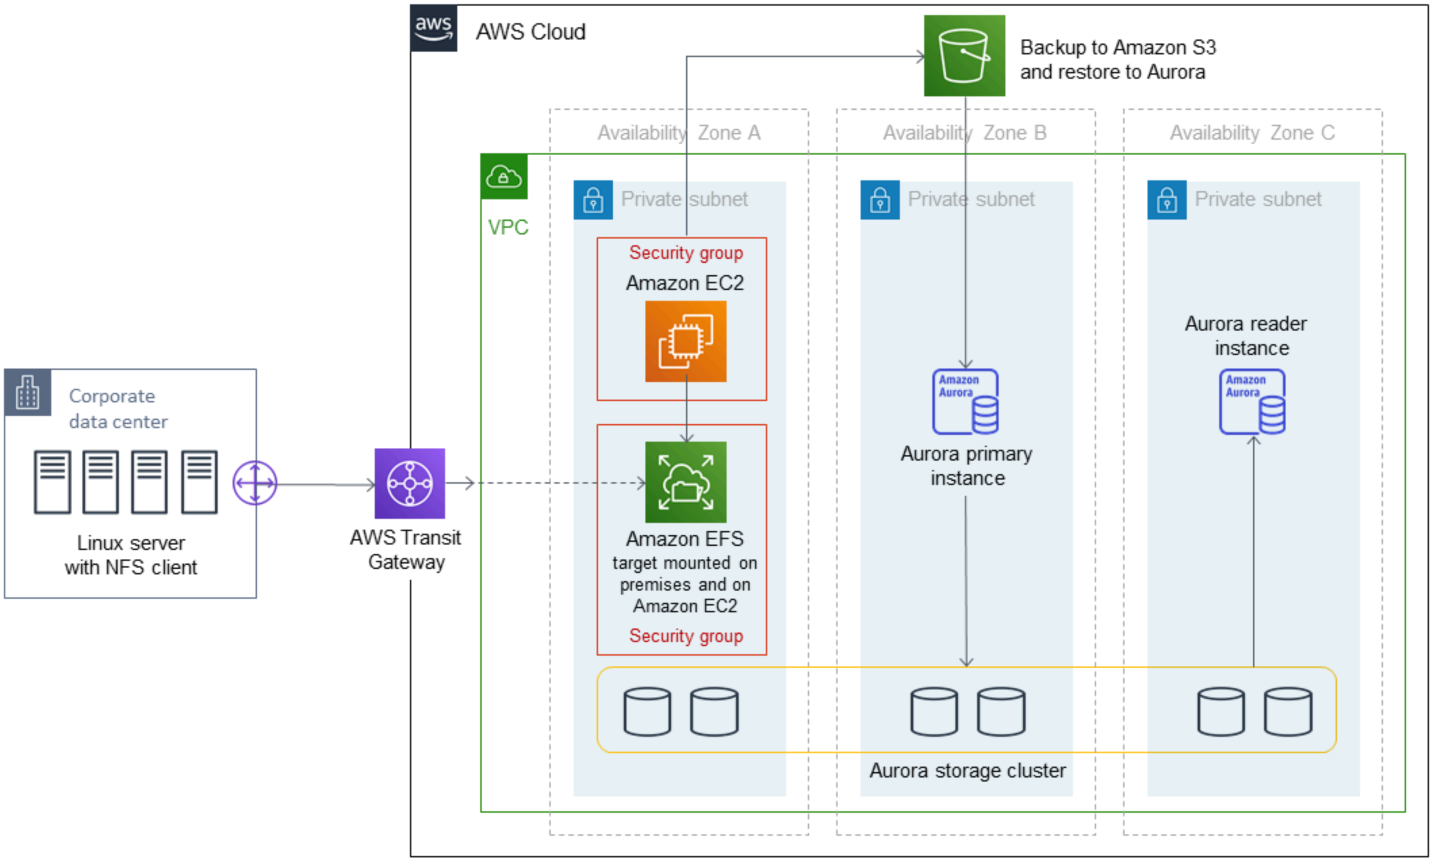
Source technology stack

- Linux-based operating system
- MySQL server
- Percona XtraBackup

Target technology stack

- Amazon Aurora
- Amazon S3
- Amazon EFS

Target architecture



Tools

AWS services

- [Amazon Aurora](#) is a fully managed relational database engine that makes it simple and cost-effective to set up, operate, and scale MySQL deployments. Aurora MySQL is a drop-in replacement for MySQL.
- [Amazon Elastic File System (Amazon EFS)](#) helps you create and configure shared file systems in the AWS Cloud.
- [Amazon Simple Storage Service (Amazon S3)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- [Percona XtraBackup](#) is an open-source utility that performs streaming, compressed, and incremental backups of MySQL databases without disrupting or blocking your databases.

Epics

Create an Amazon EFS file system

Task	Description	Skills required
Create a security group to associate with Amazon EFS mount targets.	Create a security group in the VPC that is configured with a VPN attachment to the on-premises database over AWS Transit Gateway. For more information about the commands and steps described in this and other stories, see the links in the "Related resources" section at the end of this pattern.	AWS DevOps/database administrator
Edit the security group rules.	Add an inbound rule, using type NFS, port 2049, and the IP range of the on-premises database server as the source. By default, the outbound rule allows all the traffic to leave. If this is not the case , add an outbound rule to open a connection for the NFS port. Add two more inbound rules: port 2049 (source: security group ID of this same security group) and port 22 (source: IP range from where you will connect to an EC2 instance).	AWS DevOps/database administrator
Create a file system.	In the mount targets, use the VPC and security group you created in the previous story. Choose the throughput	AWS DevOps/database administrator

Task	Description	Skills required
	mode and performance based on the I/O requirements of the on-premises database. Optionally, enable encryption at rest.	

Mount the file system

Task	Description	Skills required
Create an IAM instance profile role to be associated with an EC2 instance.	Create an IAM role that has permissions to upload and access objects in Amazon S3. Choose the S3 bucket where the backup will be stored as a policy resource.	AWS DevOps
Create an EC2 instance.	Launch an Linux-based EC2 instance and attach the IAM instance profile role that you created in the previous step, and the security group you created earlier.	AWS DevOps
Install the NFS client.	Install the NFS client on the on-premises database server and on the EC2 instance. For installation instructions, see the "Additional information" section.	DevOps
Mount the Amazon EFS file system.	Mount the Amazon EFS file system on premises and on the EC2 instance. On each server, create a directory	DevOps

Task	Description	Skills required
	for storing the backup, and mount the file system by using the mount target endpoint. For an example, see the "Additional information" section.	

Make a backup of the MySQL source database

Task	Description	Skills required
Install Percona XtraBackup.	Install Percona XtraBacku p 2.3 or 2.4 (depending on the version of your MySQL database) on the on-premises database server. For installat ion links, see the "Related resources" section.	Database administrator
Count the schemas and tables in the source database.	Gather and note the number of schemas and objects in the source MySQL database. You will use these counts to validate the Aurora MySQL database after migration.	Database administrator
(Optional) Note the latest binary log sequence from the source database.	Perform this step if you want to establish binary log replication between the source database and Aurora MySQL to minimize downtime. log-bin must be enabled, and server_id must be unique. Note the current binary log sequence from the	Database administrator

Task	Description	Skills required
	source database, just before initiating a backup. Perform this step just before full backup if you're planning to use only full backup. If you're planning to make increment al backups after a full backup, perform this step just before the final incremental backup that you will restore on the Aurora MySQL DB instance.	
Start a full backup of the source MySQL database.	Make a full backup of the MySQL source database using Percona XtraBackup. For example commands for full and incremental backups, see the "Additional information" section.	Database administrator

Task	Description	Skills required
(Optional) Make increment al backups using Percona XtraBackup.	Incremental backups can be used to reduce the amount of binary logs you need to apply to sync the source database with Aurora MySQL. Large-size and transaction-heavy databases might generate a large number of binary logs during backups. By taking incremental backups and storing them on a shared Amazon EFS file system, you can significantly reduce the time for backing up and uploading your database. For details, see the "Addition al information" section. Continue to make incremental backups until you're ready to begin the migration process to Aurora.	Database administrator

Task	Description	Skills required
Prepare backups.	In this step, transactional logs are applied to the backup for transactions that were in flight during the backup. Continue to apply transactional logs (--apply-log-only) to each incremental backup to merge the backups, except for the last backup. For examples, see the "Additional information" section. After this step, the complete, merged backup will be in ~/<efs_mount_name>/fullbackup.	Database administrator
Zip and split the final merged backup.	After you prepare the final, merged backup, use tar, zip, and split commands to create smaller zipped files of the backup. For examples, see the "Additional information" section.	Database administrator

Restore the backup to an Aurora MySQL DB cluster

Task	Description	Skills required
Upload the backup to Amazon S3.	The Amazon EFS file system where the backup files are stored is mounted on both the on-premises database and an EC2 instance, so the backup files are readily	AWS DevOps

Task	Description	Skills required
	available to the EC2 instance. Connect to the EC2 instance by using Secure Shell (SSH) and upload the zipped backup files to a new or existing S3 bucket; for example: aws s3 sync ~/ <efs_mount_name>/fullback up s3://<bucket_name>/ fullbackup. For additional details, see the links in the "Related resources" section.	
Create a service role for Aurora to access Amazon S3.	Create an IAM role with trust "rds.amazonaws.com" and a policy that will enable Aurora to access the S3 bucket where the backup files are stored. The required permissions are ListBucket, GetObject, and GetObjectVersion.	AWS DevOps

Task	Description	Skills required
Create the networking configuration for Aurora.	Create a cluster DB subnet group with at least two Availability Zones and a subnet route table configura tion that allows outbound connectivity to the source database. Create a security group that allows outbound connections to the on-premis es database, and allows administrators to connect to the Aurora DB cluster. For more information, see the links in the "Related resources " section.	AWS DevOps/database administrator
Restore the backup to an Aurora MySQL DB cluster.	Restore your data from the backup that you uploaded to Amazon S3. Specify the MySQL version of your source database, provide the S3 bucket name and folder path prefix where you uploaded the backup file (for example, "fullbackup" for the examples in the "Additional informati on" section), and provide the IAM role you created to authorize Aurora to access Amazon S3.	AWS DevOps/database administrator

Task	Description	Skills required
Validate the Aurora MySQL database.	Validate the count of schema and objects in the restored Aurora DB cluster against the count you obtained from the source database.	Database administrator
Set up binlog replication.	Use the binary log sequence that you noted earlier, before making the last backup that was restored to the Aurora DB cluster. Create a replication user on the source database, and follow the instructions in the "Additional informati on" section to provide the appropriate privileges, to enable replication on Aurora, and to confirm that the replication is in sync.	AWS DevOps/database administrator

Additional information

Installing an NFS client

- If you are using Red Hat or a similar Linux operating system, use the command:

```
$ sudo yum -y install nfs-utils
```

- If you are using Ubuntu or a similar Linux operating system, use the command:

```
$ sudo apt-get -y install nfs-common
```

For more information, see the walkthrough in the Amazon EFS documentation.

Mounting the Amazon EFS file system

Use the commands:

```
mkdir ~/<efs_mount_name>
$ sudo mount -t nfs -o
 nfsvers=4.1,rsize=1048576,wsize=1048576,hard,timeo=600,retrans=2,noresvport mount-target-IP:/ ~/<efs_mount_name>
```

For more information, see the walkthrough and Mounting EFS File Systems in the Amazon EFS documentation.

Making backups of the MySQL source database

Full backups

Use a command like the following, which takes the backup, zips it, and splits it into smaller chunks of 1 GB each:

```
xtrabackup --backup --user=dbuser --password=<password> --binlog-info=AUTO --stream=tar
 --target-dir=~/<efs_mount_name>/fullbackup | gzip - | split -d --bytes=1024MB - ~/
<efs_mount_name>/fullbackup/backup.tar.gz &
```

If you're planning to make subsequent incremental backups after the full backup, do not zip and split the backup. Instead, use a command similar to the following:

```
xtrabackup --backup --user=dbuser --password=<password> --target-dir=~/
<efs_mount_name>/fullbackup/
```

Incremental backups

Use the full backup path for the `--incremental-basedir` parameter; for example:

```
xtrabackup --backup --user=dbuser --password=<password> --target-dir=~/
<efs_mount_name>/incremental/backupdate --incremental-basedir=~/<efs_mount_name>/
fullbackup
```

where *basedir* is the path to the full backup and the xtrabackup_checkpoints file.

For more information about making backups, see Migrating Data from an External MySQL Database to an Amazon Aurora MySQL DB Cluster in the Aurora documentation.

Preparing backups

To prepare a full backup:

```
xtrabackup --prepare --apply-log-only --target-dir=~/<efs_mount_name>/fullbackup
```

To prepare an incremental backup:

```
xtrabackup --prepare --apply-log-only --target-dir=~/<efs_mount_name>/fullbackup --
incremental-dir=~/<efs_mount_name>/incremental/06062020
```

To prepare the final backup:

```
xtrabackup --prepare --target-dir=~/<efs_mount_name>/fullbackup --incremental-dir=~/
<efs_mount_name>/incremental/06072020
```

For more information, see Incremental backups in the Percona XtraBackup documentation.

Zipping and splitting the merged backup

To zip the merged backup at ~/<efs_mount_name>/fullbackup:

```
tar -zcvf <backupfilename.tar.gz> ~/<efs_mount_name>/fullbackup
```

To split the backup:

```
split -d -b1024M --verbose  <backupfilename.tar.gz> <backupfilename.tar.gz>
```

Setting up binlog replication

To create a replication user on the source database and provide the appropriate privileges:

```
CREATE USER 'repl_user'@'' IDENTIFIED BY ''; GRANT REPLICATION CLIENT, REPLICATION
 SLAVE ON *.* TO 'repl_user'@'';
```

To enable replication on Aurora by connecting to the Aurora DB cluster, enable binary logs in the DB cluster parameter group. Set `binlog_format = mixed` (mixed mode is preferred). This change requires that you restart the instance to apply the update.

```
CALL mysql.rds_set_external_master ('sourcedbinstanceIP', sourcedbport, 'repl_user',
 '', 'binlog_file_name', binlog_file_position, 0); CALL mysql.rds_start_replication;
```

To confirm that the replication is in sync:

```
SHOW Slave Status \G;
```

The **Seconds behind master** field shows how far behind Aurora is from the on-premises database.

Migrate on-premises Java applications to AWS using AWS App2Container

Dhananjay Karanjkar, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

AWS App2Container (A2C) is a command line tool that helps transform existing applications running in virtual machines into containers, without needing any code changes. A2C discovers applications running on a server, identifies dependencies, and generates relevant artifacts for seamless deployment to Amazon Elastic Container Service (Amazon ECS) and Amazon Elastic Kubernetes Service (Amazon EKS).

This pattern provides the steps for remotely migrating on-premises Java applications deployed on an application server to AWS Fargate or Amazon EKS by using App2Container through the worker machine.

The worker machine can be used in the following use cases:

- Docker installation is not allowed or not available on the application servers where the Java applications are running.
- You must manage the migration of multiple applications deployed on different physical or virtual servers.

This pattern uses AWS CodeCommit, AWS CodePipeline, and AWS CodeBuild.

Prerequisites and limitations

Prerequisites

- An application server with a Java application running on a Linux server
- A worker machine with a Linux operating system
- A worker machine with at least 20 GB of available disk space

Limitations

- Not all applications are supported. For more information, see Supported applications for Linux.

Architecture

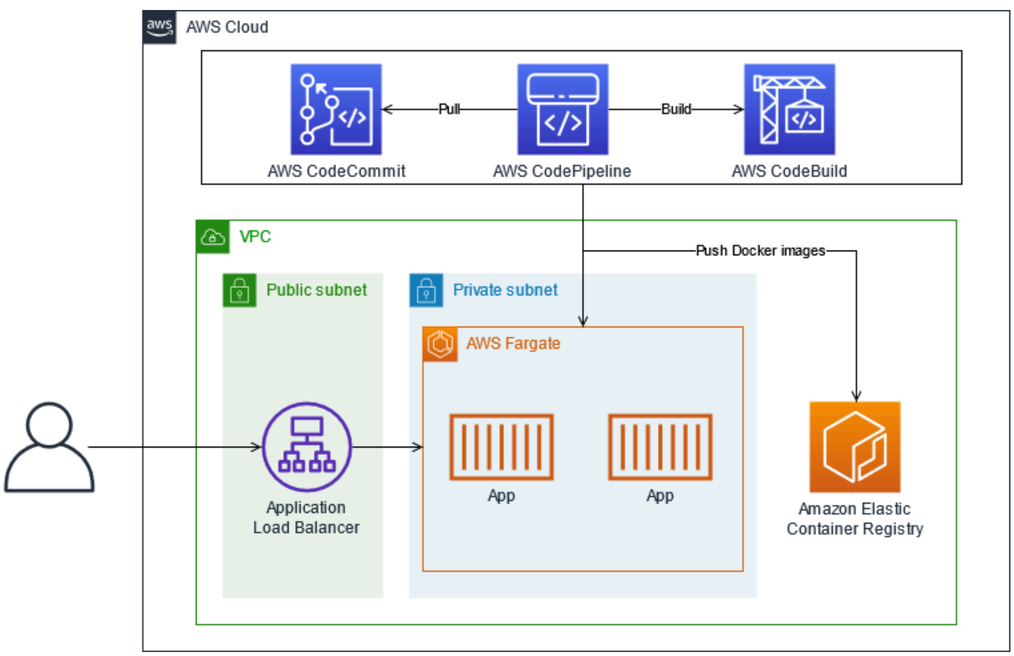
Source technology stack

- Java applications running on Linux server

Target technology stack

- AWS CodeBuild
- AWS CodeCommit
- AWS CodeDeploy
- AWS CodePipeline
- Amazon Elastic Container Registry
- AWS Fargate

Target architecture



Tools

Tools

- AWS App2Container – AWS App2Container (A2C) is a command line tool to help you lift and shift applications that run in your on-premises data centers or on virtual machines, so that they run in containers that are managed by Amazon ECS or Amazon EKS.
- AWS CodeBuild – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- AWS CodeCommit – AWS CodeCommit is a version control service hosted by Amazon Web Services that you can use to privately store and manage assets (such as documents, source code, and binary files) in the cloud.
- AWS CodePipeline – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that for running, stopping, and managing containers on a cluster.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- Amazon EKS – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.
- AWS Fargate – AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon Elastic Compute Cloud (Amazon EC2) instances. With Fargate, you no longer have to provision, configure, or scale clusters of virtual machines to run containers.

Epics

Set up credentials

Task	Description	Skills required
Create a secret to access the application server.	To access the application server remotely from the worker machine, create a secret in AWS Secrets Manager. For your secret, you can use either the SSH private key or the Certificate and the	DevOps, Developer

Task	Description	Skills required
	SSH private key. For more information, see [Manage secrets for AWS App2Container]().	

Set up the worker machine

Task	Description	Skills required
Install the tar file.	Run `sudo yum install -y tar`.	DevOps, Developer
Install the AWS CLI.	To install the Amazon Command Line Interface (AWS CLI), run `curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"` . Unzip `awscliv2.zip` . Run `sudo ./aws/install` .	DevOps, Developer
Install App2Container.	Run the following commands: `curl -o AWSApp2Container-installer-linux.tar.gz https://app2container-release-us-east-1.s3.us-east-1.amazonaws.com/latest/linux/AWSApp2Con`	DevOps, Developer

Task	Description	Skills required

	`tainer-installer-linux.tar.gz`
	
	`sudo tar xvf AWSApp2Container-installer-linux.tar.gz`
	
	`sudo ./install.sh`	

Configure the profiles.	To configure the AWS default profile, run `sudo aws configure` . To configure the named AWS default profile, run `sudo aws configure --profile <profile name>`.	DevOps, Developer

Install Docker.	Run the following commands.
	
	`sudo yum install -y docker`
	
	`sudo systemctl enable docker & sudo systemctl restart docker`	

Task	Description	Skills required
Initialize App2Container.	To initialize App2Container, you need the following information: • `workspace` : To store application containerization artifacts. We recommend providing a directory path that has at least 20 GB of free disk space. • `awsProfile` : AWS profile configured on the server. This is required to upload artifacts to Amazon S3, run the `containerize` command, and generate AWS artifacts for deployment on Amazon ECS or Amazon EKS. • `s3Bucket`: To extract and store AWS artifacts. • `metricsReportPermission` : To collect and store metrics reported. • `dockerContentTrust` : To sign the Docker image. Run `sudo app2container init`.	DevOps, Developer

Configure the worker machine

Task	Description	Skills required
Configure the worker machine to remotely connect and run App2Container commands on the application server.	To configure the worker machine, the following information is required: • `Server FQDN`: The fully qualified domain name of the application server. • `Server IP address`: The IP address of the applicati on server. Either the FQDN or the IP address is sufficien t. • `SecretARN` : The Amazon Resource Name (ARN) of the secret that is used to connect to the applicati on server and is stored in Secrets Manager. • `AuthMethod` : The `key` or `cert` authentication method. Run `sudo app2container remote configure` .	DevOps, Developer

Discover, analyze, and extract applications on the worker machine

Task	Description	Skills required
Discover the on-premises Java applications.	To remotely discover all the applications running on the	Developer, DevOps

Task	Description	Skills required
	application server, run the following command. `sudo app2container remote inventory --target <FQDN/IP of App server>` This command generates a list of deployed applications in `inventory.json` .	
Analyze the discovered applications.	To remotely analyze each application by using the application-id obtained in the inventory stage, run the following command. `sudo app2container remote analyze --application-id <java-app-id> --target <FQDN/IP of App Server>` This generates `analysis.json` file in the workspace location. After this file is generated, you can alter the containerization parameters based on your needs.	Developer, DevOps

Task	Description	Skills required
Extract the analyzed applicati ons.	To generate an applicati on archive for the analyzed application, remotely run the following command, which will generate the tar bundle in the workspace location. `sudo app2container remote extract --application-id <application id> --target <FQDN/IP of App Server>` Extracted artifacts can be generated on the local worker machine.	Developer, DevOps

Containerize the extracted artifacts on the worker machine

Task	Description	Skills required
Containerize the extracted artifacts.	Containerize the artifacts extracted in the previous step by running the following command. `sudo app2container containerize --input-archive <tar bundle location on worker machine>`	Developer, DevOps
Finalize the target.	To finalize the target, open `deployment.json` ,	Developer, DevOps

Task	Description	Skills required
	which is created when the `containerize` command runs. To specify AWS Fargate as the target, set `createEcsArtifacts` to `true`. To set Amazon EKS as the target, set `createEksArtifacts` to true.	

Generate and provision AWS artifacts

Task	Description	Skills required
Generate AWS deployment artifacts on the worker machine.	To generate deployment artifacts, run the following command. `sudo app2container generate app-deployment --application-id <application id>` This generates the `ecs-master.yml` AWS CloudFormation template in the workspace.	DevOps
Provision the artifacts.	To further provision the generated artifacts, deploy the AWS CloudFormation template by running the following command. `aws cloudformation deploy --template-`	DevOps

Task	Description	Skills required
	`file <path to ecs-master.yml> --capabilities CAPABILITY_NAMED_IAM --stack-name <application id>-ECS`	
Generate the pipeline.	Modify `pipeline.json` , which was created in the previous story, based on your needs. Then run the `generate pipeline` command to generate the pipeline deployment artifacts.	DevOps

Migrate shared file systems in an AWS large migration

Amit Rudraraju, Sam Apa, Bheemeswararao Balla, Wally Lu, and Sanjeev Prakasam, Amazon Web Services

Summary

Migrating 300 or more servers is considered a *large migration*. The purpose of a large migration is to migrate workloads from their existing, on-premises data centers to the AWS Cloud, and these projects typically focus on application and database workloads. However, shared file systems require focused attention and a separate migration plan. This pattern describes the migration process for shared file systems and provides best practices for migrating them successfully as part of a large migration project.

A *shared file system* (SFS), also known as a *network* or *clustered* file system, is a file share that is mounted to multiple servers. Shared file systems are accessed through protocols such as Network File System (NFS), Common Internet File System (CIFS), or Server Message Block (SMB).

These systems are not migrated with standard migration tools such as AWS Application Migration Service because they are neither dedicated to the host being migrated nor represented as a block device. Although most host dependencies are migrated transparently, the coordination and management of the dependent file systems must be handled separately.

You migrate shared file systems in the following phases: discover, plan, prepare, cut over, and validate. Using this pattern and the attached workbooks, you migrate your shared file system to an AWS storage service, such as Amazon Elastic File System (Amazon EFS), Amazon FSx for NetApp ONTAP, or Amazon FSx for Windows File Server. To transfer the file system, you can use AWS DataSync or a third-party tool, such as NetApp SnapMirror.

> Note: This pattern is part of an AWS Prescriptive Guidance series about large migrations to the AWS Cloud. This pattern includes best practices and instructions for incorporating SFSs into your wave plans for servers. If you are migrating one or more shared file systems outside of a large migration project, see the data transfer instructions in the AWS documentation for Amazon EFS, Amazon FSx for Windows File Server, and Amazon FSx for NetApp ONTAP.

Prerequisites and limitations

Prerequisites

Prerequisites can vary depending on your source and target shared file systems and your use case. The following are the most common:

- An active AWS account.
- You have completed application portfolio discovery for your large migration project and started developing wave plans. For more information, see Portfolio playbook for AWS large migrations.
- Virtual private clouds (VPCs) and security groups that allow ingress and egress traffic between the on-premises data center and your AWS environment. For more information, see Network-to-Amazon VPC connectivity options and AWS DataSync network requirements.
- Permissions to create AWS CloudFormation stacks or permissions to create Amazon EFS or Amazon FSx resources. For more information, see the CloudFormation documentation, Amazon EFS documentation, or Amazon FSx documentation.
- If you're using AWS DataSync to perform the migration, you need the following permissions:
  - Permissions for AWS DataSync to send logs to an AWS CloudWatch Logs log group. For more information, see Allowing DataSync to upload logs to CloudWatch log groups.
  - Permissions to access the CloudWatch Logs log group. For more information, see Overview of managing access permissions to your CloudWatch Logs resources.
  - Permissions to create agents and tasks in DataSync. For more information, see Required IAM permissions for using AWS DataSync.

Limitations

- This pattern is designed to migrate SFSs as part of a large migration project. It includes best practices and instructions for incorporating SFSs into your wave plans for migrating applications. If you are migrating one or more shared file systems outside of a large migration project, see the data transfer instructions in the AWS documentation for Amazon EFS, Amazon FSx for Windows File Server, and Amazon FSx for NetApp ONTAP.
- This pattern is based on commonly used architectures, services, and migration patterns. However, large migration projects and strategies can vary between organizations. You might need to customize this solution or the provided workbooks based on your requirements.

Architecture

Source technology stack

One or more of the following:

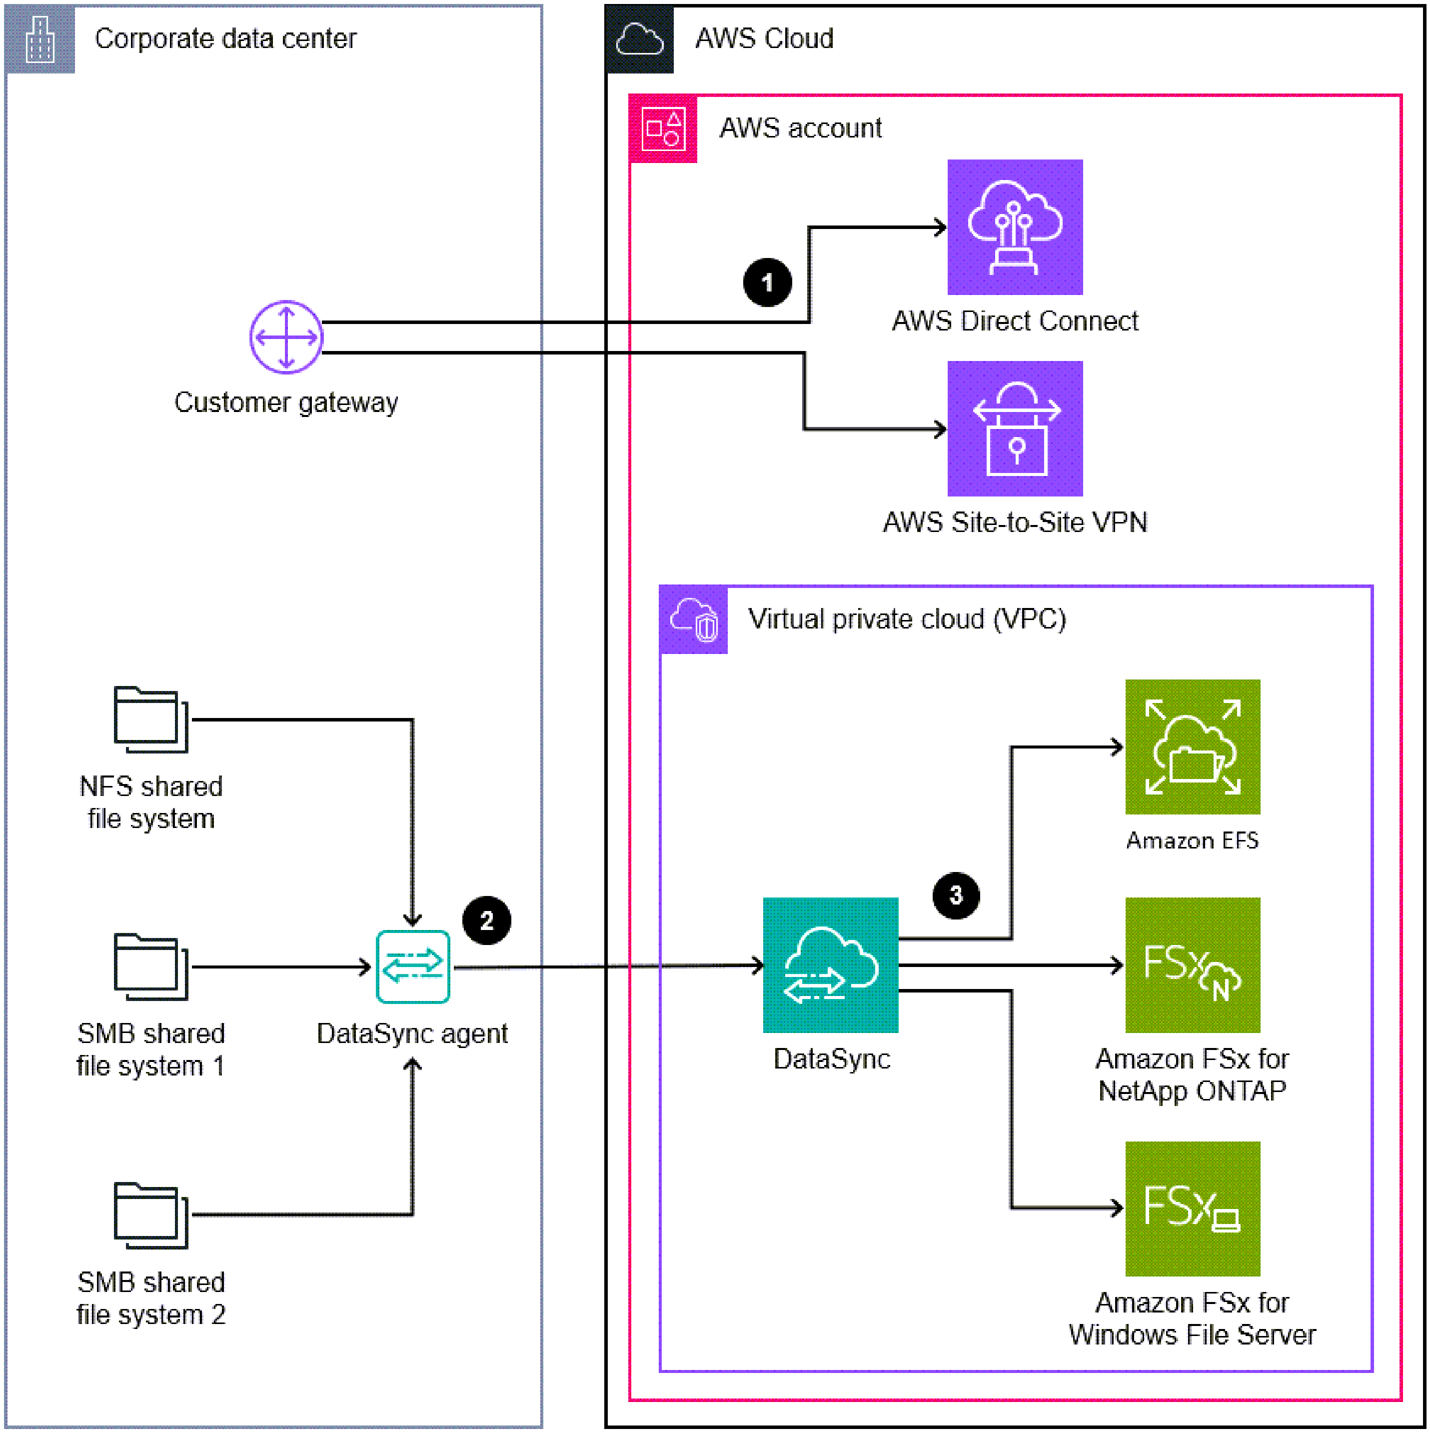
- Linux (NFS) file server
- Windows (SMB) file server
- NetApp storage array
- Dell EMC Isilon storage array

Target technology stack

One or more of the following:

- Amazon Elastic File System
- Amazon FSx for NetApp ONTAP
- Amazon FSx for Windows File Server

Target architecture



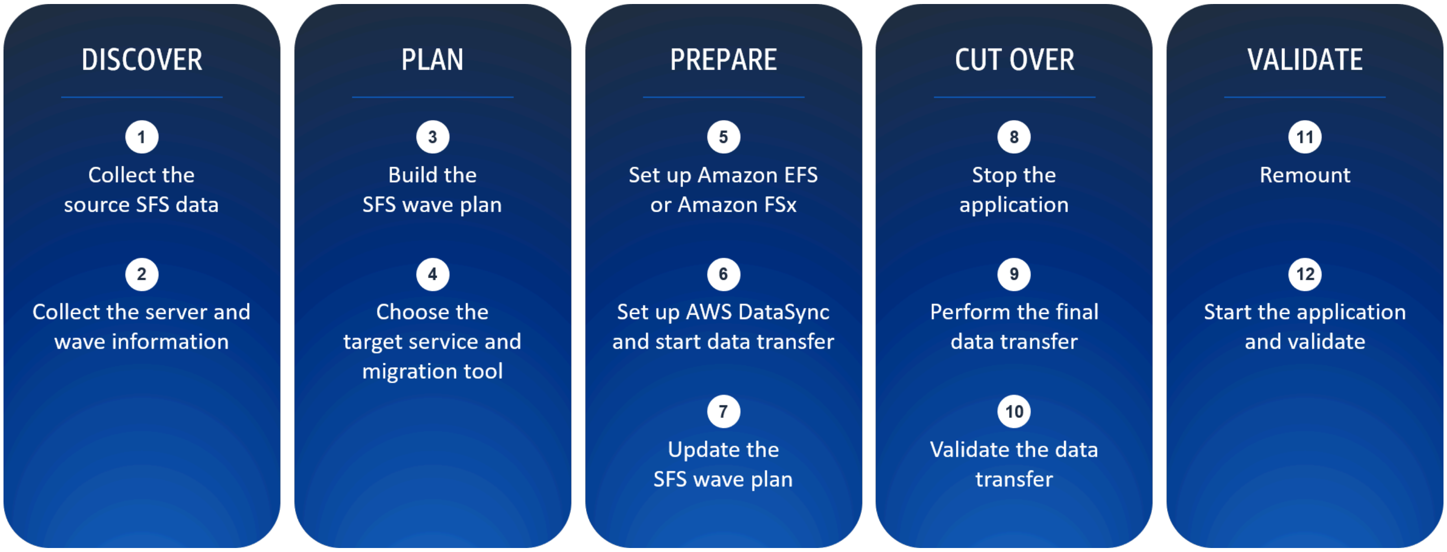
The diagram shows the following process:

1. You establish a connection between the on-premises data center and the AWS Cloud by using an AWS service such as AWS Direct Connect or AWS Site-to-Site VPN.
2. You install the DataSync agent in the on-premises data center.

3. According to your wave plan, you use DataSync to replicate data from the source shared file system to the target AWS file share.

Migration phases

The following image shows the phases and high-level steps for migrating an SFS in a large migration project.



The Epics section of this pattern contains detailed instructions for how to complete the migration and use the attached workbooks. The following is a high-level overview of the steps in this phased approach.

Phase	Steps
Discover	1. Using a discovery tool, you collect data about the shared file system, including servers, mount points, and IP addresses. 2. Using a configuration management database (CMDB) or your migration tool, you collect details about the server, including information about the migration wave, environment, application owner, IT service management (ITSM) service name, organizat ional unit, and application ID.

Plan	3. Using the collected information about the SFSs and the servers, create the SFS wave plan. 4. Using the information in the build worksheet, for each SFS, choose a target AWS service and a migration tool.
Prepare	5. Set up the target infrastructure in Amazon EFS, Amazon FSx for NetApp ONTAP, or Amazon FSx for Windows File Server. 6. Set up the data transfer service, such as DataSync, and then start the initial data sync. When the initial sync is complete, you can set up reoccurring syncs to run on a schedule, 7. Update the SFS wave plan with informati on about the target file share, such as the IP address or path.
Cut over	8. Stop applications that actively access the source SFS. 9. In the data transfer service, perform a final data sync. 10. When the sync is complete, validate that it was completely successfully by reviewing the log data in CloudWatch Logs.
Validate	11. On the servers, change the mount point to the new SFS path. 12. Restart and validate the applications.

Tools

AWS services

- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- AWS DataSync is an online data transfer and discovery service that helps you move files or object data to, from, and between AWS storage services.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.
- Amazon FSx provides file systems that support industry-standard connectivity protocols and offer high availability and replication across AWS Regions.

Other tools

- SnapMirror is a NetApp data replication tool that replicates data from specified source volumes or qtrees to target volumes or qtrees, respectively. You can use this tool to migrate a NetApp source file system to Amazon FSx for ONTAP.
- Robocopy, which is short for *Robust File Copy*, is a command-line directory and command for Windows. You can use this tool to migrate a Windows source file system to Amazon FSx for Windows File Server.

Best practices

Wave planning approaches

When planning waves for your large migration project, consider latency and application performance. When the SFS and dependent applications are operating in different locations, such as one in the cloud and one in the on-premises data center, this can increase latency and affect application performance. The following are the available options when creating wave plans:

1. **Migrate the SFS and all dependent servers within the same wave –** This approach prevents performance issues and minimizes rework, such as reconfiguring mount points multiple times. It is recommended when very low latency is required between the application and the SFS. However, wave planning is complex, and the goal is typically to remove variables from dependency groupings, not add to them. In addition, this approach isn't recommended if many servers access the same SFS because it makes the wave too large.
2. **Migrate the SFS after the last dependent server has been migrated –** For example, if an SFS is accessed by multiple servers and those servers are scheduled to migrate in waves 4, 6, and 7, schedule the SFS to migrate in wave 7.

This approach is often the most logical for large migrations and is recommended for latency-sensitive applications. It reduces costs associated with data transfer. It also minimizes the period of latency between the SFS and higher-tier (such as production) applications because higher-tier applications are typically scheduled to migrate last, after development and QA applications.

However, this approach still requires discovery, planning, and agility. You might need to migrate the SFS in an earlier wave. Confirm that the applications can withstand the additional latency for the period of time between the first dependent wave and the wave containing the SFS. Conduct a discovery session with the application owners and migrate the application in same wave the most latency-sensitive application. If performance issues are discovered after migrating a dependent application, be prepared to pivot quickly to migrate the SFS as quickly as possible.

3. **Migrate the SFS at the end of the large migration project –** This approach is recommended if latency is not a factor, such as when the data in the SFS is infrequently accessed or not critical to application performance. This approach streamlines the migration and simplifies cutover tasks.

You can blend these approaches based on the latency-sensitivity of the application. For example, you can migrate latency-sensitive SFSs by using approaches 1 or 2 and then migrate the rest of the SFSs by using approach 3.

Choosing an AWS file system service

AWS offers several cloud services for file storage. Each offers different benefits and limitations for performance, scale, accessibility, integration, compliance, and cost optimization. There are some logical default options. For example, if your current on-premises file system is operating Windows Server, then Amazon FSx for Windows File Server is the default choice. Or if the on-premises file system is operating NetApp ONTAP, then Amazon FSx for NetApp ONTAP is the default choice. However, you might choose a target service based on the requirements of your application or to realize other cloud operating benefits. For more information, see Choosing the right AWS file storage service for your deployment (AWS Summit presentation).

Choosing a migration tool

Amazon EFS and Amazon FSx support use of AWS DataSync to migrate shared file systems to the AWS Cloud. For more information about supported storage systems and services, benefits, and use cases, see What is AWS DataSync. For an overview of the process of using DataSync to transfer your files, see How AWS DataSync transfers work.

There are also several third-party tools that are available, including the following:

- If you choose Amazon FSx for NetApp ONTAP, you can use NetApp SnapMirror to migrate the files from the on-premises data center to the cloud. SnapMirror uses block-level replication, which can be faster than DataSync and reduce the duration of the data transfer process. For more information, see Migrating to FSx for ONTAP using NetApp SnapMirror.
- If you choose Amazon FSx for Windows File Server, you can use Robocopy to migrate files to the cloud. For more information, see Migrating existing files to FSx for Windows File Server using Robocopy.

Epics

Discover

Task	Description	Skills required
Prepare the SFS discovery workbook.	1. Download the workbooks in the Attachments section of this pattern. This contains two files, **SFS-Discovery-Workbook.xlsx** and **SFS-Wave-Plan-Workbook.xlsx**. 2. Open the **SFS-Discovery-Workbook** file in Microsoft Excel. 3. On the **Dashboard** worksheet, do the following: • In column **A**, update the environment name. • In column **B**, update the order of the environments to put them in order of lowest (1) priority to highest priority. • In columns **D–E**, update the wave schedule.	Migration engineer, Migration lead

Task	Description	Skills required
	• In columns **C** and **K**, update the AWS account names. • In column **L**, update the VPC IDs. • In columns **M–O**, update the subnet IDs. 4. Review the rest of the workbook template and update any other values necessary for your organization or use case. 5. Save the workbook.	

Task	Description	Skills required
Collect information about the source SFS.	1. Using your preferred discovery tool, identify all of the SFS mounts across all of the applicable storage devices, Linux servers, and Windows servers. Typically, you need to collect the following information: • Client devices • Client IP address • SFS details • Mount point **Note** You can add mount point details to your migration runbook for remounting the SFS after the migration. 2. Open the **SFS-Discovery-Workbook** file. 3. On the **Wave-Sheet** worksheet, do the following: • In the **Server location** (D) column, in the formula, confirm that the format	Migration engineer, Migration lead

Task	Description	Skills required
	of the CIDR range for the on-premises source works for your range. For example, if your CIDR range is `10.0.0.0/8` , enter `10.*.*.*`. • In the **SFS location** (E) column, in the formula, confirm that the format of the CIDR range for the target VPC works for your range. For example, if your CIDR range is `176.16.0.0/16` , enter `176.16.*.*` . 4. On the **SFS-Data** worksheet, do the following: • In the **Server name** (A) column, enter the name of the server where the SFS is mounted. • In the **SFS path** (B) column, enter the name of the SFS. • In the **IP address** (C) column, enter the IP address of the server. • Add any other relevant information that you collected during discovery, such as the mount point and SFS size. You can use this	

Task	Description	Skills required
	data later to modify the wave planning calculati ons. 5. Save the workbook.	

Task	Description	Skills required
Collect information about the servers.	1. Using your CMDB or the data recorded in your migration tool, identify all of the following informati on about the servers that have SFS mounts: • Server name • IP address • Wave • Organizational unit (OU) • Server environment, such as `DEV`, `QA`, or `PROD` • Application name • Application owner and contact information 2. Open the **SFS-Discovery-Workbook** file. 3. On the **Server-Data** worksheet, in columns **A–H**, enter the information that you collected about the source servers. Note the following: • In the **Wave #** (C) column, enter the wave name (such as `Wave1`), out-of-scope (`OOS`), or `Retire`. • If the **App owner contact** (H) column, verify the email address is correct. This email	Migration engineer, Migration lead

Task	Description	Skills required
	address is automatically generated based on the name you provided in the **App owner** (G) column. If necessary, manually update the value to reflect the correct email address. • Don't modify columns **I–J**, which contain formulas. 4. Save the workbook.	

Plan

Task	Description	Skills required
Build the SFS wave plan.	1. Open the **SFS-Discovery-Workbook** file. 2. Verify all of the information collected in the discovery phase is accurate and current. 3. On the **Wave-Sheet** worksheet, filter the **SFS wave** (K) column on the value 1. This is a list of all SFSs in the first wave. **Note** A value of `0` in this column indicates that the SFS is out	Build lead, Cutover lead, Migration engineer, Migration lead

Task	Description	Skills required
	of scope of the migration. This might be because the SFS is already hosted on AWS or because the servers that access the share are out of scope of the migration. 4. Verify that you want to migrate these SFSs in this wave. For more information about how to assign SFSs to waves, see *Wave planning approaches* in the [Best Practices](#) section. 5. Select and copy the cells containing the filtered values. Do not copy the header row containing the column titles. 6. Open the **SFS-Wave-Plan-Workbook** file that you previously downloaded. 7. On the **Export-from-Discovery** worksheet, select cell **A2**. 8. Paste the copied data. 9. Save the **SFS-Discovery-Workbook** and **SFS-Wave-Plan-Workbook** files.	

Task	Description	Skills required
Choose the target AWS service and migration tool.	1. In the **SFS-Wave-Plan-Workbook** file, on the **Exported-from-Discovery** worksheet, select and copy the values in the **Old path** (C) column. 2. On the **Build-Wave** worksheet, select cell **A2**. 3. Paste the copied data. Columns B–M in this worksheet automatically update to reflect other data associated with this path. 4. Remove any duplicate values in column **A**. For instructions, see [Remove duplicate values](#) (Microsoft Support website). 5. In the **Target pattern or service** (F) column, review the recommended target AWS service and update as needed. For more informati on, see *Choosing an AWS file system service* in the [Best practices](#) section of this pattern. 6. In the **Migration method** (G) column, review the recommended migration tool and update as needed. For more	Migration engineer, Migration lead

Task	Description	Skills required
	information, see *Choosing a migration tool* in the [Best practices](#) section of this pattern. 7. Save the **SFS-Discovery-Workbook** file. You have finished creating a wave plan for this wave. 8. Repeat these instructions to prepare a wave plan for each wave. Because wave plans are subject to change during the migration, we recommend that you plan no more than 5 waves in advance.	

Prepare

Task	Description	Skills required
Set up the target file system.	According to the details recorded in your wave plan, set up the target file systems in the target AWS account, VPC, and subnets. For instructions, see the following AWS documentation: • Amazon EFS • Amazon FSx for NetApp ONTAP	Migration engineer, Migration lead, AWS administrator

Task	Description	Skills required
	• Amazon FSx for Windows File Server	

Task	Description	Skills required

Set up the migration tool and transfer data.	1. If you're using AWS DataSync, configure logging for DataSync tasks. For instructions, see [Logging your AWS DataSync task activities]().
	2. Set up the migration tool and perform an initial data transfer according to the instructions for your selected tool:
	• For Amazon EFS, see the following:
	  ◦ [Transfer files to Amazon EFS using AWS DataSync]()
	• For Amazon FSx for ONTAP, see the following :
	  ◦ [Migrating to FSx for ONTAP using NetApp SnapMirror]()
	  ◦ [Migrating to FSx for ONTAP using AWS DataSync]()
	• For Amazon FSx for Windows File Server, see the following:
	  ◦ [Migrating existing files to FSx for Windows File Server using AWS DataSync]()
		AWS administrator, Cloud administrator, Migration engineer, Migration lead

Task	Description	Skills required
	- Migrating existing files to FSx for Windows File Server using Robocopy 3. Changes to the source SFS might occur during or after the initial transfer. Set up recurring data transfers between the source and target file systems to keep data synchronized: - If you're using DataSync, see Scheduling your AWS DataSync task. DataSync transfers only the modified or new files in the source SFS. - If you're using a third-party tool, see the documentation for your selected tool.	

Task	Description	Skills required
Update the wave plan.	1. Open the **SFS-Wave-Plan-Workbook** file for the current wave. 2. On the **Build–Wave** worksheet, in the **New path IP address** (N) column, enter the IP address of the target file system. Do one of the following to locate the IP address: • For FSx for Windows File Server, on the Amazon FSx console, choose **File systems**, choose your file system, and then view the **Network & Security** section. • For FSx for ONTAP, see Mounting volumes. • For Amazon EFS, see Mounting with an IP address. 3. In the **New path** (O) column, enter the new mount path. The mount path is the DNS name of the file system. Do one of the following to locate the mount path: • For FSx for Windows File Server, on the Amazon FSx console, choose **File**	Migration engineer, Migration lead

Task	Description	Skills required
	systems, choose your file system, and then choose **Attach**. • For FSx for ONTAP, see the **File system details** page. For instructions, see [Mounting volumes](#). • For Amazon EFS, see [Gather Information](#). 4. On the **Remount-Summary** worksheet, confirm that the **New path** (C) and **New path IP address** (D) columns reflect the updated values. 5. Confirm that your organization has prepared runbooks for remounting the Linux and Windows file systems after cutover. For general instructions, see the following: • [Mounting EFS file systems](#) • [Accessing FSx for Windows File Server file shares](#) • [Mounting FSx for ONTAP volumes](#) 6. If any dependent servers are not included in this wave, record them on the **App-Team-Communica**	

Task	Description	Skills required
	tion worksheet. Inform the respective application or server owners because they might not be included in the standard wave communications. 7. If SFSs are removed from the wave after completin g the wave plan, track these on the **Descoped** worksheet.	

Cut over

Task	Description	Skills required
Stop applications.	If applications or clients are actively performing read and write operations in the source SFS, stop them before you perform the final data sync. For instructions, see the application documenta tion or your internal processes for stopping read and write activities. For example, see Start or Stop the Web Server (IIS 8) (Microsoft documentation) or Managing system services with systemctl (Red Hat documentation).	App owner, App developer

Task	Description	Skills required
Perform the final data transfer.	1. In the migration tool, manually run a final data transfer task or job to synchronize the target file system with the source SFS. For instructions, see [Starting your DataSync task]() or see the documentation for your selected third-party migration tool. 2. Wait for the data transfer task to complete. For more information, see AWS [Monitoring AWS DataSync activity with Amazon CloudWatch]() and [Monitoring your DataSync task from the command line]().	Migration engineer, Migration lead

Task	Description	Skills required
Validate the data transfer.	If you're using AWS DataSync, do the following to validate the final data transfer completed successfully: 1. In the AWS DataSync console, make a note of the task and execution ID, such as `task-0000-exec-1111` . 2. Navigate to the **Task Logging** section of the DataSync task. 3. Choose the **CloudWatch log group** link. 4. In the logs, search for the task and execution ID. 5. Make note of any transfer errors. For more informati on, see [Common Errors](#) in the DataSync documenta tion. 6. Validate the following: • Compare the file lists from the source and target SFSs to confirm that all data has been transferred • Compare the file access permissions between the source and target SFSs.	Migration engineer, Migration lead

Task	Description	Skills required
	If you're using a third-party tool, see the data transfer validation instructions in the documentation for the selected migration tool.	

Validate

Task	Description	Skills required
Remount the file system and validate application function and performance.	1. If dependent servers were migrated in this wave, in the **SFS-Wave-Plan-Workbook** file, on the **Remount-Summary** worksheet, enter the new IP address of the server in the **New server IP address** (F) column. 2. On all servers, update the mount point for the file system from the old path to the new path. Use your organization's runbook for remounting previously discussed in the *Prepare* phase. 3. Confirm that the file system is mounted properly and accessible by checking the mounts and verifying files are present. The infrastructure team typically performs these activities.	AWS systems administrator, App owner

Task	Description	Skills required
	4. Restart the applications and engage the applicati on owners or QA team to complete functional and performance testing on the application, as needed for the application.	

Troubleshooting

Issue	Solution
Cell values in Microsoft Excel don’t update.	Copy the formulas in the sample rows by dragging the fill handle. For more informati on, see instructions for Windows or for Mac (Microsoft Support website).

Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters

Dhairya Jindani and Baji Shaik, Amazon Web Services

Summary

Oracle GoldenGate is a real-time data capture and replication service for heterogeneous databases and IT environments. However, this service doesn't currently support Amazon Relational Database Service (Amazon RDS) for Oracle. For a list of supported databases, see Oracle GoldenGate for Heterogeneous Databases (Oracle documentation). This pattern describes how to use Oracle GoldenGate and Oracle GoldenGate flat file adapters to generate flat files from the source Oracle database, which can be on-premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance. You can then import those flat files to an Amazon RDS for Oracle database instance.

In this pattern, you use Oracle GoldenGate to extract the trail files from your source Oracle database. The data pump copies the trail files to an integration server, which is an Amazon EC2 instance. On the integration server, Oracle GoldenGate uses the flat file adapter to generate a series of sequential flat files based on the transational data capture of the trail files.Oracle GoldenGate formats the data as either delimiter-separated values or length-delimited values. You then use Oracle SQL*Loader to import the flat files into the target Amazon RDS for Oracle database instance.

Intended audience

This pattern is intended for those who have experience with and knowledge of an Oracle GoldenGate's fundamental building blocks. For more information, see Overview of the Oracle GoldenGate Architecture (Oracle documentation).

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Oracle GoldenGate license.
- A separate license for an Oracle GoldenGate adapter.
- A source Oracle database, either running on-premises or on an Amazon EC2 instance.
- An Amazon EC2 Linux instance that is used as the integration server. For more information, see Get started with Amazon EC2 Linux instances (Amazon EC2 documentation).

- A target Amazon RDS for Oracle database instance. For more information, see [Creating an Oracle DB instance](#) (Amazon RDS documentation).

Product versions

- Oracle Database Enterprise Edition version 10g, 11g, 12c, or later
- Oracle GoldenGate version 12.2.0.1.1 or later

Architecture

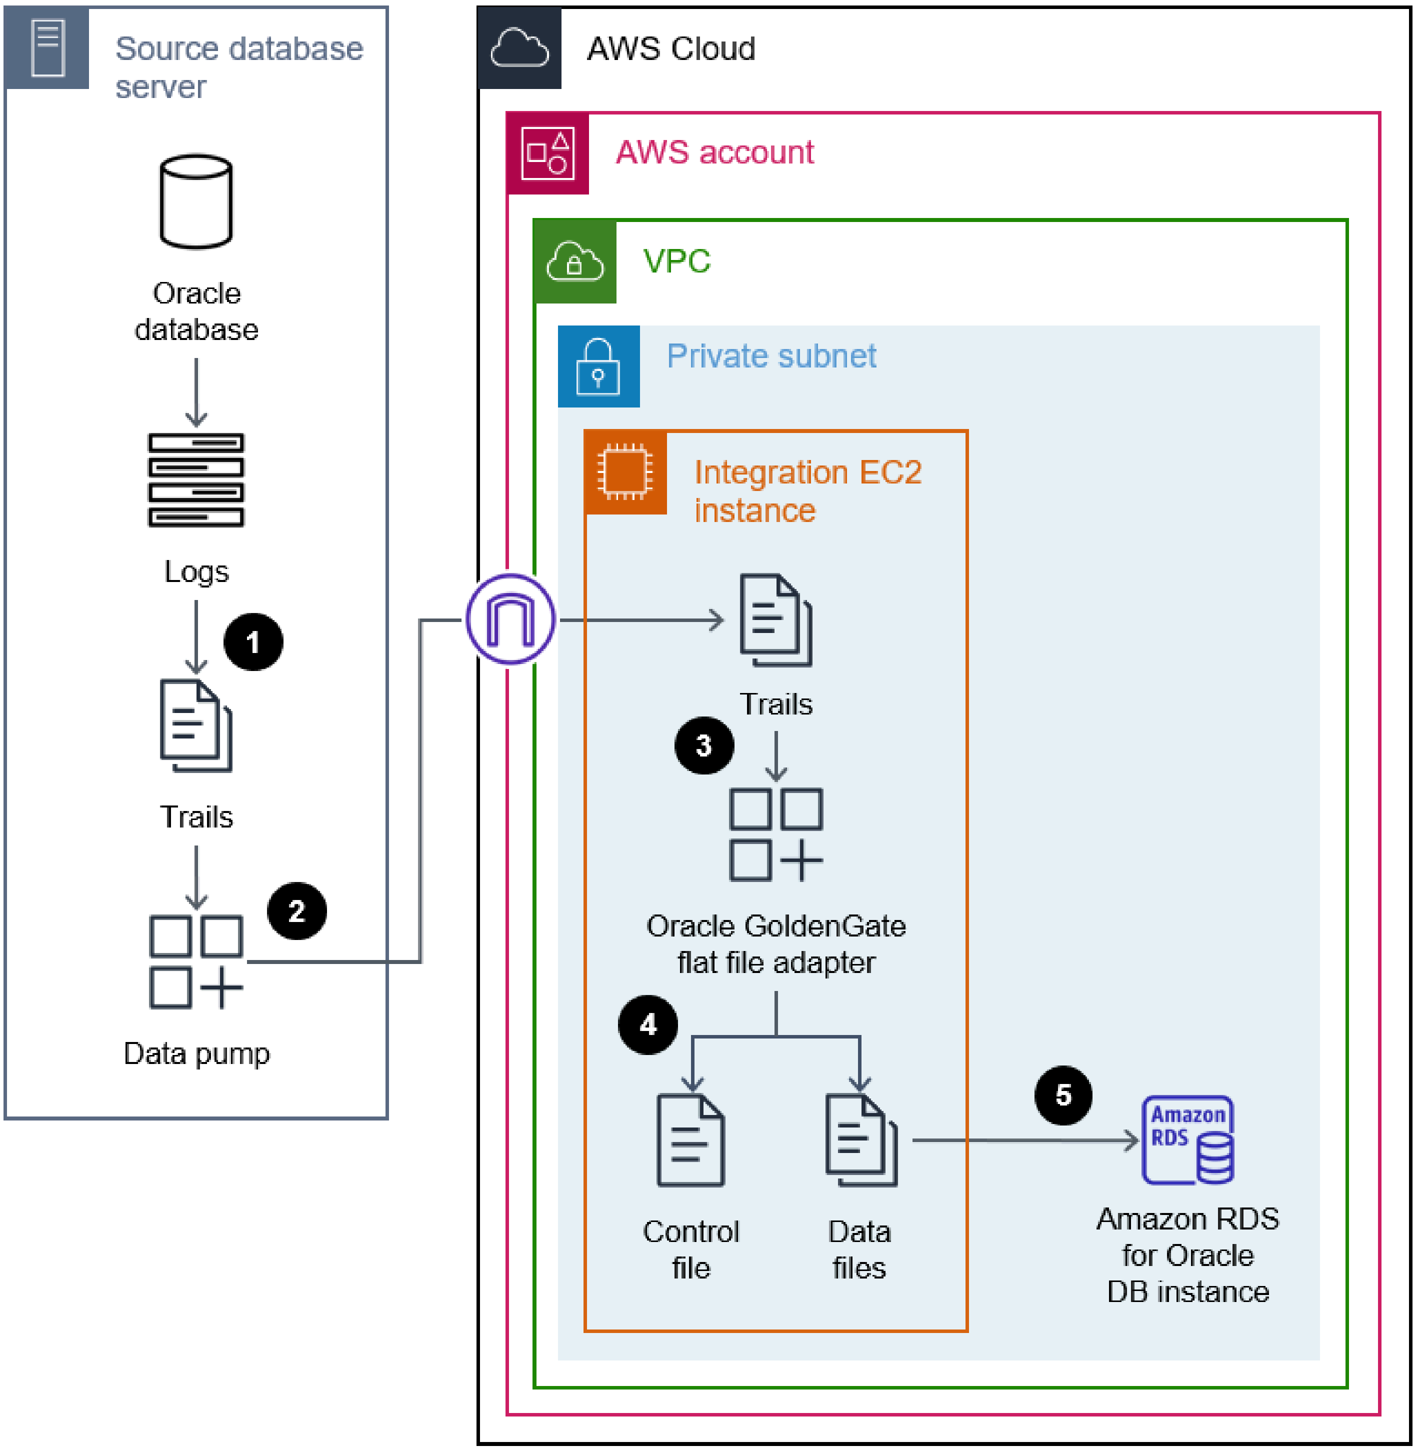
Source technology stack

An Oracle database (on premises or on an Amazon EC2 instance)

Target technology stack

Amazon RDS for Oracle

Source and target architecture



1. Oracle GoldenGate extracts trails from the source database logs.
2. The data pump extracts the trails and migrates them to an integration server.
3. The Oracle GoldenGate flat file adapter reads the trails, source definitions, and extract parameters.

4. You exit the extraction, which generates a control file and flat data files.
5. You migrate the flat data files to an Amazon RDS for Oracle database instance in the AWS Cloud.

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Relational Database Service (Amazon RDS) for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.

Other services

- Oracle GoldenGate is a service that helps you to replicate, filter, and transform data from one database to another heterogeneous database or to another target topology, such as flat files.
- Oracle GoldenGate application adapters enable Oracle GoldenGate to produce a series of sequential flat files and control files from transactional data captured in the trail files of a source database. These adapters are widely used for extract, transform, and load (ETL) operations in data warehouse applications and proprietary or legacy applications. Oracle GoldenGate performs this capture and applies it in near real-time across heterogeneous databases, platforms, and operating systems. The adapters support different formats for the output files, such as CSV or Apache Parquet. You can load these generated files in order to load the data into different heterogeneous databases.

Epics

Set up Oracle GoldenGate on the source database server

Task	Description	Skills required
Download Oracle GoldenGat e.	On the source database server, download Oracle GoldenGate version 12.2.0.1. 1 or later. For instructi ons, see Downloading	DBA

Task	Description	Skills required
	Oracle GoldenGate (Oracle documentation).	
Install Oracle GoldenGate.	For instructions, see Installing Oracle GoldenGate (Oracle documentation).	DBA
Set up Oracle GoldenGate.	For instructions, see Preparing the Database for Oracle GoldenGate (Oracle documentation).	DBA

Set up Oracle GoldenGate on the integration server

Task	Description	Skills required
Download Oracle GoldenGate.	On the integration server, download Oracle GoldenGate version 12.2.0.1.1 or later. For instructions, see Downloading Oracle GoldenGate (Oracle documentation).	DBA
Install Oracle GoldenGate.	Create directories, set up the manager process, and create the `defgen` file for a heterogeneous environment. For instructions, see Installing Oracle GoldenGate (Oracle documentation).	DBA

Change the Oracle GoldenGate data capture configuration

Task	Description	Skills required
Prepare the Oracle GoldenGate adapters.	On the integration server, set up the Oracle GoldenGate adapter software. Do the following: 1. From Oracle Software Delivery Cloud, download **ggs_Adapters_Linux_x64.zip**. 2. Unzip **ggs_Adapters_Linux_x64.zip**. 3. Run the following command to install the adapters: `tar -xvf ggs_Adapters_Linux_x64.tar`	DBA
Configure the data pump.	On the source server, configure the data pump to transfer the trail file from the source server to the integration server. Create the data pump parameter file and trails file directory. For instructions, see Configuring the Flat File Adapter (Oracle documentation).	DBA

Generate and migrate the flat files

Task	Description	Skills required
Generate the flat files.	Create the extract file and control file, and then start the extraction process on the integration server. This extracts the database changes and writes the source database to the flat files. For instructions, see Using the Flat File Adapter (Oracle documentation).	DBA
Load the flat files to the target database.	Load the flat files into the target Amazon RDS for Oracle database instance. For more information, see Importing using Oracle SQL*Loader (Amazon RDS documentation).	DBA

Troubleshooting

Issue	Solution
The Oracle GoldenGate flat file adapter generates an error.	For a description of the adapter errors, see Locating Error Messages (Oracle documentation). For troubleshooting instructions, see Troubleshooting the Flat File Adapter (Oracle documentation).

Change Python and Perl applications to support database migration from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition

Dwarika Patra and Deepesh Jayaprakash, Amazon Web Services

Summary

This pattern describes changes to application repositories that might be required when you migrate databases from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition. The pattern assumes that these applications are Python-based or Perl-based, and provides separate instructions for these scripting languages.

Migrating SQL Server databases to Aurora PostgreSQL-Compatible involves schema conversion, database object conversion, data migration, and data loading. Because of the differences between PostgreSQL and SQL Server (relating to data types, connection objects, syntax, and logic), the most difficult migration task involves making the necessary changes to the code base so that it works correctly with PostgreSQL.

For a Python-based application, connection objects and classes are scattered throughout the system. Also, the Python code base might use multiple libraries to connect to the database. If the database connection interface changes, the objects that run the application's inline queries also require changes.

For a Perl-based application, changes involve connection objects, database connection drivers, static and dynamic inline SQL statements, and how the application handles complex dynamic DML queries and results sets.

When you migrate your application, you can also consider possible enhancements on AWS, such as replacing the FTP server with Amazon Simple Storage Service (Amazon S3) access.

The application migration process involves the following challenges:

- Connection objects. If connection objects are scattered in the code with multiple libraries and function calls, you might have to find a generalized way to change them to support PostgreSQL.
- Error or exception handling during record retrieval or updates. If you have conditional create, read, update, and delete (CRUD) operations on the database that return variables, results sets, or data frames, any errors or exceptions might result in application errors with cascading effects. These should be handled carefully with proper validations and save points. One such save point is to call large inline SQL queries or database objects inside `BEGIN...EXCEPTION...END` blocks.

- Controlling transactions and their validation. These includes manual and automatic commits and rollbacks. The PostgreSQL driver for Perl requires you to always explicitly set the auto-commit attribute.
- Handling dynamic SQL queries. This requires a strong understanding of the query logic and iterative testing to ensure that queries work as expected.
- Performance. You should ensure that code changes don't result in degraded application performance.

This pattern explains the conversion process in detail.

Prerequisites and limitations

Prerequisites

- Working knowledge of Python and Perl syntax.
- Basic skills in SQL Server and PostgreSQL.
- Understanding of your existing application architecture.
- Access to your application code, SQL Server database, and PostgreSQL database.
- Access to Windows or Linux (or other Unix) development environment with credentials for developing, testing, and validating application changes.
- For a Python-based application, standard Python libraries that your application might require, such as **Pandas** to handle data frames, and **psycopg2** or **SQLAlchemy** for database connections.
- For a Perl-based application, required Perl packages with dependent libraries or modules. The Comprehensive Perl Archive Network (CPAN) module can support most application requirements.
- All required dependent customized libraries or modules.
- Database credentials for read access to SQL Server and read/write access to Aurora.
- PostgreSQL to validate and debug application changes with services and users.
- Access to development tools during application migration such as Visual Studio Code, Sublime Text, or **pgAdmin**.

Limitations

- Some Python or Perl versions, modules, libraries, and packages aren't compatible with the cloud environment.

- Some third-party libraries and frameworks used for SQL Server cannot be replaced to support PostgreSQL migration.
- Performance variations might require changes to your application, to inline Transact-SQL (T-SQL) queries, database functions, and stored procedures.
- PostgreSQL supports lowercase names for table names, column names, and other database objects.
- Some data types, such as UUID columns, are stored in lowercase only. Python and Perl applications must handle such case differences.
- Character encoding differences must be handled with the correct data type for the corresponding text columns in the PostgreSQL database.

Product versions

- Python 3.6 or later (use the version that supports your operating system)
- Perl 5.8.3 or later (use the version that supports your operating system)
- Aurora PostgreSQL-Compatible Edition 4.2 or later (see details)

Architecture

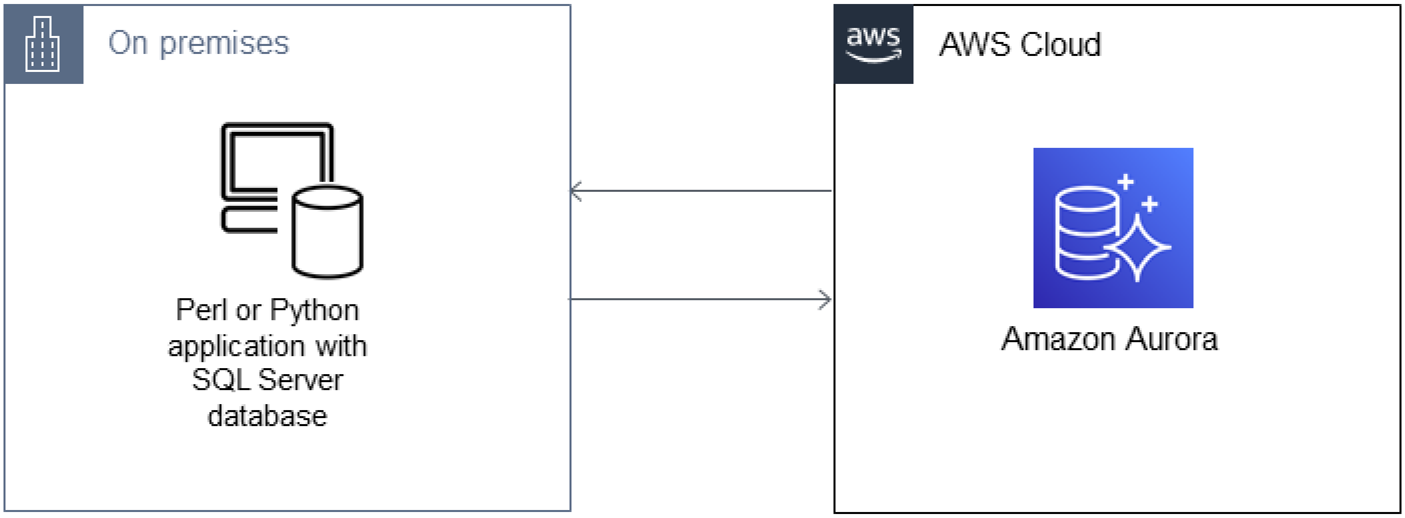
Source technology stack

- Scripting (application programming) language: Python 2.7 or later, or Perl 5.8
- Database: Microsoft SQL Server version 13
- Operating system: Red Hat Enterprise Linux (RHEL) 7

Target technology stack

- Scripting (application programming) language: Python 3.6 or later, or Perl 5.8 or later
- Database: Aurora PostgreSQL-Compatible 4.2
- Operating system: RHEL 7

Migration architecture



Tools

AWS services and tools

- Aurora PostgreSQL–Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases. Aurora PostgreSQL is a drop-in replacement for PostgreSQL and makes it easier and more cost-effective to set up, operate, and scale your new and existing PostgreSQL deployments.
- AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services by using commands in your command-line shell.

Other tools

- Python and PostgresSQL database connection libraries such as psycopg2 and SQLAlchemy
- Perl and its DBI modules
- PostgreSQL interactive terminal (psql)

Epics

Migrate your application repository to PostgreSQL – high-level steps

Task	Description	Skills required
Follow these code conversion steps to migrate your application to PostgreSQL.	1. Set database-specific ODBC drivers and libraries for PostgreSQL. For example, you can use one of the CPAN modules for Perl and **pyodbc**, **psycopg2**, or **SQLAlchemy** for Python. 2. Convert database objects by using these libraries to connect to Aurora PostgreSQL-Compatible. 3. Apply code changes in existing application modules to get compatible T-SQL statements. 4. Rewrite database-specific function calls and stored procedures in application code. 5. Handle changes to your application's variables and their data types that are used for inline SQL queries. 6. Handle incompatible database-specific functions. 7. Complete end-to-end testing of converted	App developer

Task	Description	Skills required
	application code for database migration. 8. Compare results from Microsoft SQL Server against the application you migrated to PostgreSQL. 9. Perform application performance benchmark ing between Microsoft SQL Server and PostgreSQL. 10Revise stored procedures or inline T-SQL statements called by the application to improve performance. The following epics provide detailed instructions for some of these conversion tasks for Python and Perl applications.	

Task	Description	Skills required
Use a checklist for each step of the migration.	Add the following to your checklist for each step of application migration, including the final step: • Review PostgreSQL documentation to ensure that all your changes are compatible with the PostgreSQL standard. • Check for integer and floating values for columns. • Identify the number of rows inserted, updated, and extracted, along with the column names and date/ time stamps. You can use a diff utility or write a script to automate these checks. • Complete performance checks for large inline SQL statements, and check the overall performance of the application. • Check for correct error handling for database operations and graceful program exit by using multiple try/catch blocks. • Check to ensure that proper logging processes are in place.	App developer

Analyze and update your application – Python code base

Task	Description	Skills required
Analyze your existing Python code base.	Your analysis should include the following to facilitate the application migration process: • Identify all connection objects in the code. • Identify all incompatible inline SQL queries (such as T-SQL statements and stored procedures) and analyze required changes. • Review the documentation for your code and track the control flow to understan d code functionality. This will be helpful later when you test the application for performance or load comparisons. • Understand the purpose of the application so you can test it effectively after database conversion. Most Python applications that are candidates for conversio n with database migration s are either feeds that load data from other sources into database tables, or extractors that retrieve data from the tables and transform them into	App developer

Task	Description	Skills required
	different output formats (such as CSV, JSON, or flat files) that are suitable for creating reports or for making API calls to perform validations.	

Task	Description	Skills required

Convert your database connections to support PostgreSQL.	Most Python applications use the **pyodbc** library to connect with SQL Server databases as follows.
	``
	import pyodbc
	....
	try:
	    conn_string =
	 "Driver=ODBC Driver 17
	 for SQL
	    Server;UID={};PWD=
	{};Server={};Datab
	ase={}".format
	 (conn_user, conn_pass
	word,
	    conn_server,
	 conn_database)
	    conn = pyodbc.co
	nnect(conn_string)
	    cur = conn.cursor()
	    result = cur.execu
	te(query_string)
	    for row in result:
	    print (row)
	except Exception as e:
	    print(str(e))
	``
	Convert the database connection to support PostgreSQL as follows.
	``
	import pyodbc
	import psycopg2
	....
	try:
	    conn_string =
	 'postgresql+psycop
	g2://'+
	``
		App developer

Task	Description	Skills required

	``
	    conn_user+':'+conn_password+'@'+conn_server+'/'+conn_database
	    conn = pyodbc.connect(conn_string, connect_args={'options':'-csearch_path=dbo'})
	    cur = conn.cursor()
	    result = cur.execute(query_string)
	    for row in result:
	    print (row)
	except Exception as e:
	    print(str(e))
	``	

Task	Description	Skills required

Change inline SQL queries to PostgreSQL.	Convert your inline SQL queries to a PostgreSQL-compatible format. For example, the following SQL Server query retrieves a string from a table.
	```dtype = "type1" stm = ‘"SELECT TOP 1 searchcode FROM TypesTable (NOLOCK) WHERE code="’ + "’" + str(dtype) + "’" # For Microsoft SQL Server Database Connection engine = create_engine(‘mssql+pyodbc:///?odbc_connect=%s’ % urllib.parse.quote_plus(conn_string), connect_args={‘connect_timeout’:login_timeout}) conn = engine_connect() rs = conn.execute(stm) for row in rs: print(row)```
	After conversion, the PostgreSQL-compatible inline SQL query looks like the following.
	```dtype = "type1" stm = ‘"SELECT searchcode FROM TypesTable```
		App developer

Task	Description	Skills required

	``
	WHERE code="' + "'" +
	 str(dtype) + "' LIMIT
	 1"
	# For PostgreSQL
	 Database Connection
	engine = create_en
	gine('postgres+psy
	copg2://%s' %conn_str
	ing, connect_a
	rgs={'connect_time
	out':login_timeout})
	conn = engine.connect()
	rs = conn.execute(stm)
	for row in rs:
	    print(row)
	``	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Handle dynamic SQL queries.</td><td>Dynamic SQL can be present in one script or in multiple Python scripts. Earlier examples showed how to use Python’s string replace function to insert variables for constructing dynamic SQL queries. An alternate approach is to append the query string with variables wherever applicable.

In the following example, the query string is constructed on the fly based on the values returned by a function.

<pre>query = ‘"SELECT id from
 equity e join issues i
 on e.permId=i.permId
 where e.id’"
query += get_id_fi
lter(ids) + " e.id is
 NOT NULL</pre>
These types of dynamic queries are very common during application migration . Follow these steps to handle dynamic queries:
Check the overall syntax (for example, the syntax for the <code>SELECT</code> statement with a <code>JOIN</code> clause).</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
	• Verify all variables or column names used in the query, such as `i` and `id`. • Check the functions, arguments, and return values used in the query (for example, `get_id_filter` and its argument `ids`).	

Task	Description	Skills required

Handle results sets, variables, and data frames.	For Microsoft SQL Server, you use Python methods such as `fetchone()` or `fetchall()` to retrieve the results set from the database. You can also use `fetchmany(size)` and specify the number of records to return from the results set. To do this, you can use the **pyodbc** connection object as shown in the following example.
	
	pyodbc (Microsoft SQL Server)
	
	`import pyodbc`
	`server = 'tcp:myserver.database.windows.net'`
	`database = 'exampledb'`
	`username = 'exampleusername'`
	`password = 'examplepassword'`
	`conn = pyodbc.connect('DRIVER={ODBC Driver 17 for SQL Server};SERVER='+server+';DATABASE='+database+';UID='+username+';PWD='+ password)`
	`cursor = conn.cursor()`
	`cursor.execute("SELECT * FROM ITEMS")`
	`row = cursor.fetchone()`
	`while row:`
		App developer

Task	Description	Skills required

	``
	    print(row[0])
	    row = cursor.fe
	tchone()
	``
	
	In Aurora, to perform similar tasks such as connectin g to PostgreSQL and fetching results sets, you can use either **psycopg2** or **SQLAlchemy**. These Python libraries provide the connection module and cursor object to traverse through the PostgreSQL database records, as shown in the following example.
	
	psycopg2 (Aurora PostgreSQ L-Compatible)
	
	``
	import psycopg2
	query = "SELECT * FROM
	 ITEMS;"
	//Initialize
	 variables
	host=dbname=user=
	password=port=sslm
	ode=connect_timeou
	t=""
	connstring = "host='{h
	ost}' dbname='{
	dbname}' user='{user}'
	 \
	password='{passw
	ord}'port='{port}'
	".format(host=host
	,dbname=dbname,\
	user=user,password=
	password,port=port)
	``	

Task	Description	Skills required

	``` conn = psycopg2. connect(connstring) cursor = conn.cursor() cursor.execute(query) column_names = [column[0] for column in cursor.description] print("Column Names: ", column_names) print("Column values: " for row in cursor: print("itemid :", row[0]) print("itemdescrpt ion :", row[1]) print("it emprice :", row[3])) ```
	 SQLAlchemy (Aurora PostgreSQL-Compatible)
	 ``` from sqlalchemy import create_engine from pandas import DataFrame conn_string = 'postgres ql://core:database @localhost:5432/ex ampledatabase' engine = create_en gine(conn_string) conn = engine.co nnect() dataid = 1001 result = conn.exec ute("SELECT * FROM ITEMS") df = DataFrame (result.fetchall()) ```	

Task	Description	Skills required
	``` df.columns = result.ke ys() df = pd.DataFrame() engine.connect() df = pd.read_sql_query(sql_query, engine, coerce_float=False) print("df=", df) ```	
Test your application during and after migration.	Testing the migrated Python application is an ongoing process. Because the migration includes connection object changes (**psycopg2** or **SQLAlchemy**), error handling, new features (data frames), inline SQL changes, bulk copy functionalities (`bcp` instead of `COPY`) and similar changes, it must be tested carefully during and after application migration. Check for: • Error conditions and handling • Any record mismatches after migration • Record updates or deletions • Time required to run the application	App developer

Analyze and update your application – Perl code base

Task	Description	Skills required
Analyze your existing Perl code base.	Your analysis should include the following to facilitate the application migration process. You should identify: • Any INI or configuration-based code • Database-specific standard Open Database Connectiv ity (ODBC) Perl drivers or any customized drivers • Code changes required for inline and T-SQL queries • Interactions among various Perl modules (for example, a single Perl ODBC connection object that is called or used by multiple functional components) • Dataset and results set handling • External, dependent Perl libraries • Any APIs that are used in the application • Perl version compatibility and driver compatibility with Aurora PostgreSQL-Compatible	App developer

Task	Description	Skills required

Convert the connections from the Perl application and DBI module to support PostgreSQL.	Perl-based applications generally use the Perl DBI module, which is a standard database access module for the Perl programming language. You can use the same DBI module with different drivers for SQL Server and PostgreSQL.
	
	For more information about required Perl modules, installations, and other instructions, see the [DBD::Pg documentation](). The following example connects to Aurora PostgreSQL-Compatible at `exampletest-aurorapg-database.cluster-sampleclusture.us-east-.rds.amazonaws.com` .
	
	`#!/usr/bin/perl`
	`use DBI;`
	`use strict;`
	`my $driver = "Pg";`
	`my $hostname = "exampletest-aurorapg-database-sampleclusture.us-east.rds.amazonaws.com"`
	`my $dsn = "DBI:$driver: dbname = $hostname ;host = 127.0.0.1;port = 5432";`
		App developer

Task	Description	Skills required

	<pre>my $username = "postgres
	";
	my $password = "pass123"
	;
	$dbh = DBI->conn
	ect("dbi:Pg:dbname
	=$hostname;host=$h
	ost;port=$port;opt
	ions=$options",
	      $username,
	      $password,
	      {AutoCommit =>
	 0, RaiseError => 1,
	 PrintError => 0}
	      );</pre>	

Task	Description	Skills required

Change Inline SQL queries to PostgreSQL.	Your application might have inline SQL queries with `SELECT`, `DELETE`, `UPDATE`, and similar statements that include query clauses that PostgreSQL doesn't support. For example, query keywords such as `TOP` and `NOLOCK` aren't supported in PostgreSQL. The following examples show how you can handle `TOP`, `NOLOCK`, and Boolean variables.
	
	In SQL Server:
	
	`$sqlStr = $sqlStr . "WHERE a.student_id in (SELECT TOP $numofRecords c_student_id \ FROM active_student_record b WITH (NOLOCK) \ INNER JOIN student_contributor c WITH (NOLOCK) on c.contributor_id = b.c_st)`
	
	For PostgreSQL, convert to:
	
	`$sqlStr = $sqlStr . "WHERE a.student_id in (SELECT TOP $numofRecords c_student_id \ FROM active_student_record b INNER JOIN`
		App developer

Task	Description	Skills required
	``` student_contributor c \ on c.contributor_id = b.c_student_contr_id WHERE b_current_1 is true \ LIMIT $numofRecords)" ```	

Task	Description	Skills required
Handle dynamic SQL queries and Perl variables.	Dynamic SQL queries are SQL statements that are built at application runtime. These queries are construct ed dynamically when the application is running, depending on certain conditions, so the full text of the query isn’t known until runtime. An example is a financial analytics applicati on that analyzes the top 10 shares on a daily basis, and these shares change every day. The SQL tables are created based on top performers, and the values aren’t known until runtime. Let’s say that the inline SQL queries for this example are passed to a wrapper function to get the results set in a variable, and then a variable uses a condition to determine whether the table exists: • If the table exists, don't create it; do some processin g. • If the table doesn’t exist, create the table and also do some processing.	App developer

Task	Description	Skills required

	Here’s an example of variable handling, followed by the SQL Server and PostgreSQL queries for this use case.
	`my $tableexists = db_read( arg 1, $sql_qry, undef, 'writer'); my $table_already_exists = $tableexists->[0]{table_exists}; if ($table_already_exists){ # do some thing } else { # do something else }`
	SQL Server:
	`my $sql_qry = "SELECT OBJECT_ID('$backendTable', 'U') table_exists", undef, 'writer')";`
	PostgreSQL:
	`my $sql_qry = "SELECT TO_REGCLASS('$backendTable', 'U') table_exists", undef, 'writer')";`
	The following example uses a Perl variable in	

Task	Description	Skills required

	inline SQL, which runs a `SELECT` statement with a `JOIN` to fetch the primary key of the table and position of the key column.
	
	SQL Server:
	
	`my $sql_qry = "SELECT column_name', character_maximum_length \ FROM INFORMATION_SCHEMA.COLUMNS \ WHERE TABLE_SCHEMA='$example_schemaInfo' \ AND TABLE_NAME='$example_table' \ AND DATA_TYPE IN ('varchar','nvarchar');";`
	
	PostgreSQL:
	
	`my $sql_qry = "SELECT c1.column_name, c1.ordinal_position \ FROM information_schema.key_column_usage AS c LEFT \ JOIN information_schema.table_constraints AS t1 \ ON t1.constraint_name = c1.constraint_name \ WHERE t1.table_name = $example_schemaInfo'.'$example_table’ \`	

Task	Description	Skills required
	`AND t1.constraint_type = 'PRIMARY KEY' ;";`	

Make additional changes to your Perl-based or Python-based application to support PostgreSQL

Task	Description	Skills required
Convert additional SQL Server constructs to PostgreSQL.	The following changes apply to all applications, regardless of programming language. • Qualify database objects that your application uses with new and appropriate schema names. • Handle LIKE operators for case-sensitive matching with the collation feature in PostgreSQL. • Handle unsupported database specific functions such as `DATEDIFF`, `DATEADD`, `GETDATE`, `CONVERT`, and `CAST` operators. For equivalent PostgreSQL-compatible functions, see *Native or built-in SQL functions* in the Additional information section. • Handle Boolean values in comparison statements.	App developer

Task	Description	Skills required
	• Handle return values from functions. These could be record sets, data frames, variables, and Boolean values. Handle these according to the requirements of your application and to support PostgreSQL. • Handle anonymous blocks (such as `BEGIN TRAN`) with new, user-defined PostgreSQL functions. • Convert bulk inserts for rows. The PostgreSQL equivalent of the SQL Server bulk copy (`bcp`) utility, which is called from inside the application, is `COPY`. • Convert column concatenation operators. SQL Server uses + for string concatenation, but PostgreSQL uses `||`.	

Improve performance

Task	Description	Skills required
Take advantage of AWS services to make performance enhancements.	When you migrate to the AWS Cloud, you can refine your application and database design to take advantage of AWS services. For example,	App developer, Cloud architect

Task	Description	Skills required
	if the queries from your Python application, which is connected to an Aurora PostgreSQL-Compatible database server, is taking more time than your original Microsoft SQL Server queries, you could consider creating a feed of historical data directly to an Amazon Simple Storage Service (Amazon S3) bucket from the Aurora server, and use Amazon Athena-based SQL queries to generate reports and analytic data queries for your user dashboards.

Additional information

Both Microsoft SQL Server and Aurora PostgreSQL-Compatible are ANSI SQL-complaint. However, you should still be aware of any incompatibilities in syntax, column data types, native database-specific functions, bulk inserts, and case sensitivity when you migrate your Python or Perl application from SQL Server to PostgreSQL.

The following sections provide more information about possible inconsistencies.

Data type comparison

Data type changes from SQL Server to PostgreSQL can lead to significant differences in the resulting data that applications operate on. For a comparison of data types, see the table on the Sqlines website.

Native or built-in SQL functions

The behavior of some functions differs between SQL Server and PostgreSQL databases. The following table provides a comparison.

Microsoft SQL Server	Description	PostgreSQL
`CAST`	Converts a value from one data type to another.	PostgreSQL `type :: operator`
`GETDATE()`	Returns the current database system date and time, in a `YYYY-MM-DD hh:mm:ss.mmm` format.	`CLOCK_TIMESTAMP`
`DATEADD`	Adds a time/date interval to a date.	`INTERVAL` expression
`CONVERT`	Converts a value to a specific data format.	`TO_CHAR`
`DATEDIFF`	Returns the difference between two dates.	`DATE_PART`
`TOP`	Limits the number of rows in a SELECT results set.	`LIMIT/FETCH`

Anonymous blocks

A structured SQL query is organized into sections such as declaration, executables, and exception handling. The following table compares the Microsoft SQL Server and PostgreSQL versions of a simple anonymous block. For complex anonymous blocks, we recommend that you call a custom database function within your application.

Microsoft SQL Server	PostgreSQL

`my $sql_qry1=`
`my $sql_qry2 =`
`my $sqlqry = "BEGIN TRAN`
`$sql_qry1 $sql_qry2`
`if @\@error !=0 ROLLBACK`
`TRAN`
`else COMIT TRAN";`
	`my $sql_qry1=`
	`my $sql_qry2 =`
	`my $sql_qry = " DO \$\$`
	`BEGIN`
	`$header_sql $content_sql`
	`END`
	`\$\$";`

Other differences

- **Bulk inserts of rows:** The PostgreSQL equivalent of the Microsoft SQL Server bcp utility is COPY.
- **Case sensitivity:** Column names are case-sensitive in PostgreSQL, so you have to convert your SQL Server column names to lowercase or uppercase. This becomes a factor when you extract or compare data, or place column names in results sets or variables. The following example identifies columns where values might be stored in uppercase or lowercase.

```
my $sql_qry = "SELECT $record_id FROM $exampleTable WHERE LOWER($record_name) =
 \'failed transaction\'";
```

- **Concatenation:** SQL Server uses + as an operator for string concatenation, whereas PostgreSQL uses ||.
- **Validation:** You should test and validate inline SQL queries and functions before you use them in application code for PostgreSQL.

- **ORM Library inclusion :** You can also look for including or replace existing database connection library with Python ORM libraries such as SQLAlchemy and PynomoDB. This will help to easily query and manipulate data from a database using an object-oriented paradigm.

Stream data from IBM Db2, SAP, Sybase, and other databases to MongoDB Atlas on AWS

Battulga Purevragchaa and Igor Alekseev, Amazon Web Services

Babu Srinivasan, MongoDB

Summary

This pattern describes the steps for migrating data from IBM Db2 and other databases such as mainframe databases and Sybase to MongoDB Atlas on the AWS Cloud. It uses AWS Glue to help accelerate the data migration to MongoDB Atlas.

The pattern accompanies the guide Migrating to MongoDB Atlas on AWS on the AWS Prescriptive Guidance website. It provides the implementation steps for one of the migration scenarios that are discussed in that guide. For additional migration scenarios, see the following patterns on the AWS Prescriptive Guidance website:

- Migrate a self-hosted MongoDB environment to MongoDB Atlas on AWS
- Migrate relational databases to MongoDB Atlas on AWS

The pattern is intended for AWS Managed Services Partners and AWS users.

Prerequisites and limitations

Prerequisites

- A source database such as SAP, Sybase, IBM Db2, and others to migrate to MongoDB Atlas.
- Familiarity with databases such as SAP, Sybase, IBM Db2, MongoDB Atlas, and AWS services.

Product versions

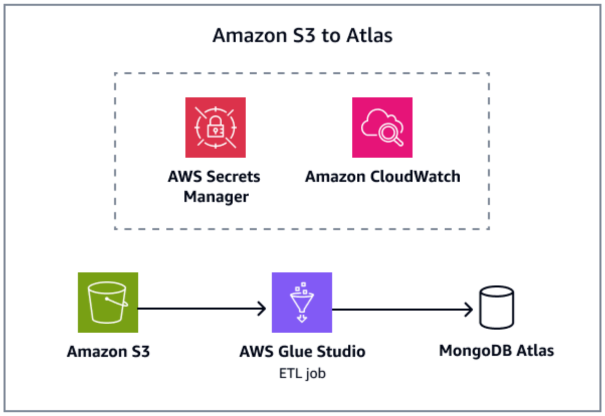
- MongoDB version 5.0 or later.

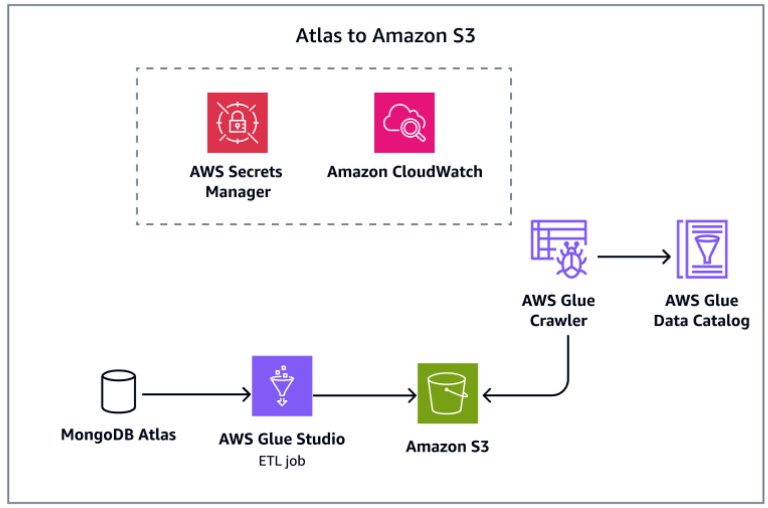
Architecture

The following diagram illustrates batch data load and data streaming by using AWS Glue Studio, Amazon Kinesis Data Streams, and MongoDB Atlas.

This reference architecture uses AWS Glue Studio to create extract, transform, and load (ETL) pipelines to migrate data to MongoDB Atlas. An AWS Glue crawler integrates with MongoDB Atlas to facilitate data governance. The data can be either ported in batch or streamed to MongoDB Atlas by using Amazon Kinesis Data Streams.

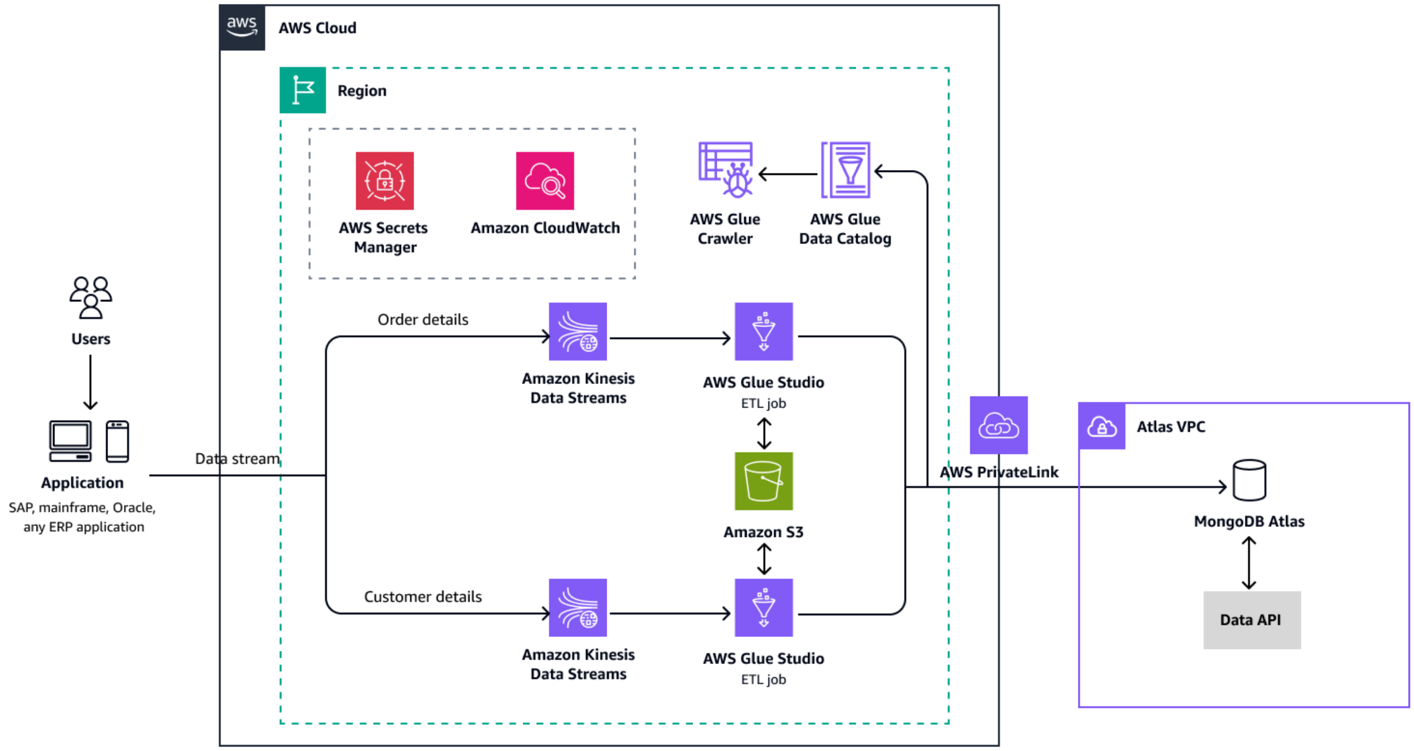
Batch data load





For more information about the batch data migration, see the AWS blog post [Compose your ETL jobs for MongoDB Atlas with AWS Glue](#).

Data streaming



For MongoDB Atlas reference architectures that support different usage scenarios, see [Migrating to MongoDB Atlas on AWS] on the AWS Prescriptive Guidance website.

Tools

- AWS Glue is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- Amazon Kinesis Data Streams helps you collect and process large streams of data records in real time.
- MongoDB Atlas is a fully managed database as a service (DbaaS) for deploying and managing MongoDB databases in the cloud.

Best practices

For guidelines, see Best Practices Guide for MongoDB in the MongoDB GitHub repository.

Epics

Discovery and assessment

Task	Description	Skills required
Determine the cluster size.	Estimate the working set size by using the information from `db.stats()` for the total index space. Assume that a percentage of your data space will be accessed frequentl y. Or, you can estimate your memory requirements based on your assumptions. This task should take approxima tely one week. For more information and examples for this and the other stories in this epic, see the links in the [Related resources](#) section.	MongoDB DBA, Application architect
Estimate network bandwidth requirements.	To estimate your network bandwidth requireme nts, multiply the average document size by the number of documents served per second. Consider the maximum traffic that any node on your cluster will bear as the basis. To calculate downstream data transfer rates from your cluster to client applications, use the sum of the total documents returned over a period of time. If your applications	MongoDB DBA

Task	Description	Skills required
	read from secondary nodes, divide this number of total documents by the number of nodes that can serve read operations. To find the average document size for a database, use the `db.stats().avgObjSize` command. This task will typically take one day.	
Select the Atlas tier.	Follow the instructions in the MongoDB documentation to select the correct Atlas cluster tier.	MongoDB DBA
Plan for cutover.	Plan for application cutover.	MongoDB DBA, Application architect

Set up a new MongoDB Atlas environment on AWS

Task	Description	Skills required
Create a new MongoDB Atlas cluster on AWS.	In MongoDB Atlas, choose **Build a Cluster**, and select AWS as the cloud provider.	MongoDB DBA
Select AWS Regions and global cluster configuration.	Select from the list of available AWS Regions for your Atlas cluster. Configure global clusters if required.	MongoDB DBA
Select the cluster tier.	Select your preferred cluster tier. Your tier selection determines factors such as	MongoDB DBA

Task	Description	Skills required
	memory, storage, and IOPS specification.	
Configure additional cluster settings.	Configure additional cluster settings such as MongoDB version, backup, and encryption options. For more information about these options, see the Related resources section.	MongoDB DBA

Configure security and compliance

Task	Description	Skills required
Configure the access list.	To connect to the Atlas cluster, you must add an entry to the project's access list. Atlas uses Transport Layer Security (TLS) / Secure Sockets Layer (SSL) to encrypt the connections to the virtual private cloud (VPC) for your database. To set up the access list for the project and for more information about the stories in this epic, see the links in the Related resources section.	MongoDB DBA
Authenticate and authorize users.	You must create and authenticate the database users who will access the MongoDB Atlas clusters. To access the clusters in a	MongoDB DBA

Task	Description	Skills required
	project, users must belong to that project, and they can belong to multiple projects. You can also enable authorization with AWS Identity and Access Management (IAM). For more information, see Set Up Authentication with IAM in the MongoDB documentation.	
Create custom roles.	(Optional) Atlas supports creating custom roles if the built-in Atlas database user privileges don't cover your desired set of privileges.	MongoDB DBA
Set up VPC peering.	(Optional) Atlas supports VPC peering with other AWS VPCs.	MongoDB DBA
Set up an AWS PrivateLink endpoint.	(Optional) You can set up private endpoints on AWS by using AWS PrivateLink.	MongoDB DBA
Enable two-factor authentic ation.	(Optional) Atlas supports two-factor authentication (2FA) to help users control access to their Atlas accounts.	MongoDB DBA
Set up user authentication and authorization with LDAP.	(Optional) Atlas supports performing user authentic ation and authorization with Lightweight Directory Access Protocol (LDAP).	MongoDB DBA

Task	Description	Skills required
Set up unified AWS access.	(Optional) Some Atlas features, including Atlas Data Lake and encryption at rest using customer key management, use IAM roles for authentication.	MongoDB DBA
Set up encryption at rest by using AWS KMS.	(Optional) Atlas supports using AWS Key Management Service (AWS KMS) to encrypt storage engines and cloud provider backups.	MongoDB DBA
Set up CSFLE.	(Optional) Atlas supports client-side field-level encryption (CSFLE), including automatic encryption of fields.	MongoDB DBA

Migrate data

Task	Description	Skills required
Launch your target replica set in MongoDB Atlas.	Launch your target replica set in MongoDB Atlas. In Atlas Live Migration Service, choose **I'm ready to migrate**.	MongoDB DBA
Establish the connection of AWS Glue with MongoDB Atlas.	Use an AWS Glue crawler to connect AWS Glue with MongoDB Atlas (target database). This step helps prepare the target environme nt for migration. For more	MongoDB DBA

Task	Description	Skills required
	information, see the [AWS Glue documentation]().	
Establish the connection of AWS Glue with the source database or source stream.	This helps prepare the target environment for migration.	MongoDB DBA
Set up the data transform ation.	Configure the transformation logic to migrate the data from the legacy structured schema to the flexible schema of MongoDB.	MongoDB DBA
Migrate the data.	Schedule the migration in AWS Glue Studio.	MongoDB DBA

Configure operational integration

Task	Description	Skills required
Connect to the cluster.	Connect to the MongoDB Atlas cluster.	App developer
Interact with data.	Interact with cluster data.	App developer
Monitor the clusters.	Monitor your MongoDB Atlas clusters.	MongoDB DBA
Back up and restore data.	Back up and restore cluster data.	MongoDB DBA

Troubleshooting

Issue	Solution
If you encounter issues	See Troubleshooting in the MongoDB Atlas CloudFormation Resources repository.

Migration patterns by workload

Topics

- IBM
- Microsoft
- N/A
- Open source
- Oracle
- SAP

IBM

- Migrate a Db2 database from Amazon EC2 to Aurora MySQL-Compatible by using AWS DMS
- Migrate Db2 for LUW to Amazon EC2 by using log shipping to reduce outage time
- Migrate Db2 for LUW to Amazon EC2 with high availability disaster recovery
- Migrate from IBM Db2 on Amazon EC2 to Aurora PostgreSQL-Compatible using AWS DMS and AWS SCT
- Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2
- Stream data from IBM Db2, SAP, Sybase, and other databases to MongoDB Atlas on AWS

Microsoft

- Accelerate the discovery and migration of Microsoft workloads to AWS
- Change Python and Perl applications to support database migration from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition
- Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel and Python
- Export a Microsoft SQL Server database to Amazon S3 by using AWS DMS
- Implement SHA1 hashing for PII data when migrating from SQL Server to PostgreSQL
- Ingest and migrate EC2 Windows instances into an AWS Managed Services account
- Migrate a messaging queue from Microsoft Azure Service Bus to Amazon SQS
- Migrate a Microsoft SQL Server database from Amazon EC2 to Amazon DocumentDB by using AWS DMS
- Migrate a Microsoft SQL Server database to Aurora MySQL by using AWS DMS and AWS SCT
- Migrate a .NET application from Microsoft Azure App Service to AWS Elastic Beanstalk
- Migrate an on-premises Microsoft SQL Server database to Amazon EC2
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using linked servers
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using native backup and restore methods
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents
- Migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on Amazon EC2 running Linux
- Migrate data from Microsoft Azure Blob to Amazon S3 by using Rclone
- Migrate an on-premises Microsoft SQL Server database to Amazon EC2 using Application Migration Service
- Migrate a relational database to MongoDB Atlas on AWS
- Migrate Windows SSL certificates to an Application Load Balancer using ACM
- Rehost on-premises workloads in the AWS Cloud: migration checklist
- Resolve connection errors after migrating Microsoft SQL Server to the AWS Cloud

- Set up Multi-AZ infrastructure for a SQL Server Always On FCI by using Amazon FSx

N/A

- Create an approval process for firewall requests during a rehost migration to AWS

Open source

- Create application users and roles in Aurora PostgreSQL-Compatible
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation
- Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools
- Migrate an on-premises MySQL database to Amazon EC2
- Migrate an on-premises MySQL database to Amazon RDS for MySQL
- Migrate an on-premises MySQL database to Aurora MySQL
- Migrate an on-premises PostgreSQL database to Aurora PostgreSQL
- Migrate a Couchbase Server database to Amazon EC2
- Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2 with Auto Scaling
- Migrate from Oracle GlassFish to AWS Elastic Beanstalk
- Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical
- Migrate on-premises Java applications to AWS using AWS App2Container
- Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3
- Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible
- Migrate Redis workloads to Redis Enterprise Cloud on AWS
- Restart the AWS Replication Agent automatically without disabling SELinux after rebooting a RHEL source server
- Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport

Oracle

- Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL
- Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database
- Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT
- Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL in SSL mode by using AWS DMS
- Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication
- Migrate an Amazon RDS for Oracle DB instance to another VPC
- Migrate an on-premises Oracle database to Amazon EC2 by using Oracle Data Pump
- Migrate an on-premises Oracle database to Amazon OpenSearch Service using Logstash
- Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT
- Migrate an on-premises Oracle database to Amazon RDS for Oracle
- Migrate an on-premises Oracle database to Amazon RDS for Oracle by using direct Oracle Data Pump Import over a database link
- Migrate an on-premises Oracle database to Amazon RDS for Oracle using Oracle Data Pump
- Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL by using an Oracle bystander and AWS DMS
- Migrate an on-premises Oracle database to Oracle on Amazon EC2
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for Oracle using AWS DMS
- Migrate an Oracle database to Amazon DynamoDB using AWS DMS
- Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters
- Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT
- Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT
- Migrate an Oracle JD Edwards EnterpriseOne database to AWS by using Oracle Data Pump and AWS DMS

- Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS
- Migrate an Oracle PeopleSoft database to AWS by using AWS DMS
- Migrate data from an on-premises Oracle database to Aurora PostgreSQL
- Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS
- Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate
- Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT
- Migrate from Oracle to Amazon DocumentDB using AWS DMS
- Migrate from Oracle WebLogic to Apache Tomcat (TomEE) on Amazon ECS
- Migrate function-based indexes from Oracle to PostgreSQL
- Migrate legacy applications from Oracle Pro*C to ECPG
- Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS
- Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database
- Migrate Oracle native functions to PostgreSQL using extensions
- Migrate Oracle PeopleSoft to Amazon RDS Custom
- Migrate Oracle ROWID functionality to PostgreSQL on AWS
- Migrate Oracle SERIALLY_REUSABLE pragma packages into PostgreSQL
- Migrate virtual generated columns from Oracle to PostgreSQL
- Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible
- Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL

SAP

- Migrate an on-premises SAP ASE database to Amazon EC2
- Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS
- Migrate SAP ASE on Amazon EC2 to Amazon Aurora PostgreSQL-Compatible using AWS SCT and AWS DMS
- Reduce homogeneous SAP migration cutover time by using Application Migration Service

More patterns

- Access AWS services from IBM z/OS by installing the AWS CLI
- Assess application readiness for migration to the AWS Cloud by using CAST Highlight
- Assess query performance for migrating SQL Server databases to MongoDB Atlas on AWS
- Automate cross-Region failover and failback by using DR Orchestrator Framework
- Automate database tasks in SQL Server Express edition running on Amazon EC2 by using AWS Lambda and Task Scheduler
- Build an advanced mainframe file viewer in the AWS Cloud
- Configure a data center extension to VMware Cloud on AWS using Hybrid Linked Mode
- Connect to Application Migration Service data and control planes over a private network
- Containerize mainframe workloads that have been modernized by Blu Age
- Convert JSON Oracle queries into PostgreSQL database SQL
- Convert the Teradata NORMALIZE temporal feature to Amazon Redshift SQL
- Convert the Teradata RESET WHEN feature to Amazon Redshift SQL
- Copy Amazon DynamoDB tables across accounts using AWS Backup
- Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing
- Deploy multiple-stack applications using AWS CDK with TypeScript
- Deploy SQL Server failover cluster instances on Amazon EC2 and Amazon FSx by using Terraform
- Emulate Oracle PL/SQL associative arrays in Amazon Aurora PostgreSQL and Amazon RDS for PostgreSQL
- Estimate the Amazon RDS engine size for an Oracle database by using AWR reports
- Generate data insights by using AWS Mainframe Modernization and Amazon Q in QuickSight
- Handle anonymous blocks in Dynamic SQL statements in Aurora PostgreSQL
- Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible
- Identify duplicate container images automatically when migrating to an Amazon ECR repository
- Integrate VMware vRealize Network Insight with VMware Cloud on AWS
- Migrate Apache Cassandra workloads to Amazon Keyspaces by using AWS Glue
- Migrate your container workloads from Azure Red Hat OpenShift (ARO) to Red Hat OpenShift Service on AWS (ROSA)

Analyze and visualize software architecture in CAST Imaging

Arpita Sinha, Amazon Web Services

James Hurrell, Cast Software

Summary

This pattern shows how you can use CAST Imaging to navigate a complex software system visually and perform a precise analysis of the software structure. By using CAST Imaging in this way, you can make more informed decisions about your application's architecture, especially for modernization purposes.

To view your application's architecture in CAST Imaging, you must first onboard your application's source code through the CAST Console. The console then publishes your application's data to CAST Imaging, where you can visualize and navigate your application architecture layer by layer.

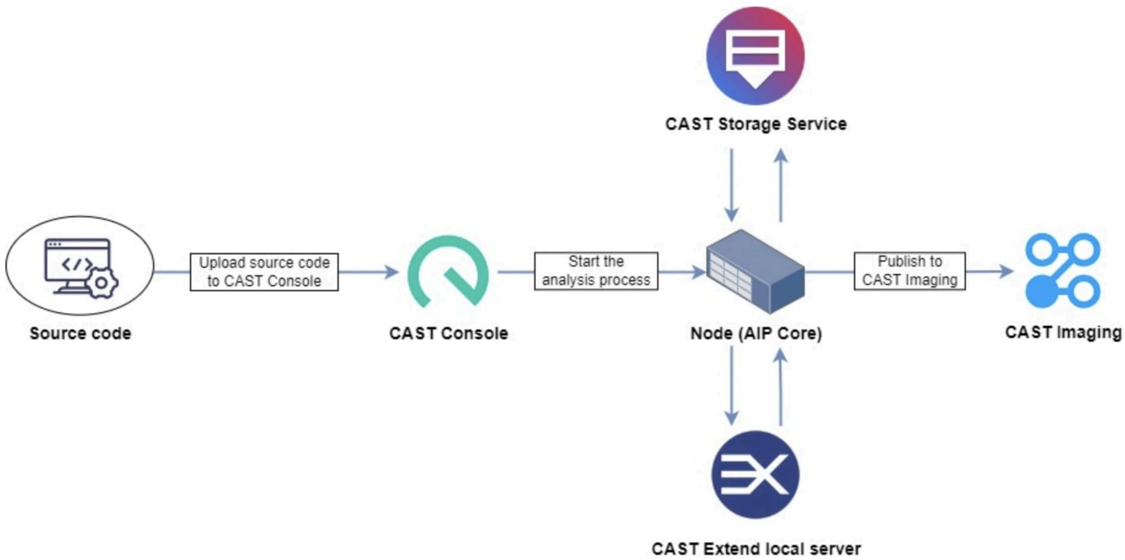
Prerequisites and limitations

Prerequisites

- An active AWS account
- The Amazon Machine Image (AMI) for CAST Imaging
- An Amazon Elastic Compute Cloud (Amazon EC2) instance that includes the following (a memory optimized **r5.xlarge** Amazon EC2 instance is recommended):
  - 4 vCPU
  - 32 GB RAM
  - 500 GB minimum General Purpose solid state drive (SSD) (gp3) volume
- CAST Console and CAST Imaging license keys (to get the required license keys, contact CAST at aws.contact-me@castsoftware.com)
- The complete source code of the application that you want to analyze in compressed (.zip) format
- Microsoft Edge, Mozilla Firefox, or Google Chrome

Architecture

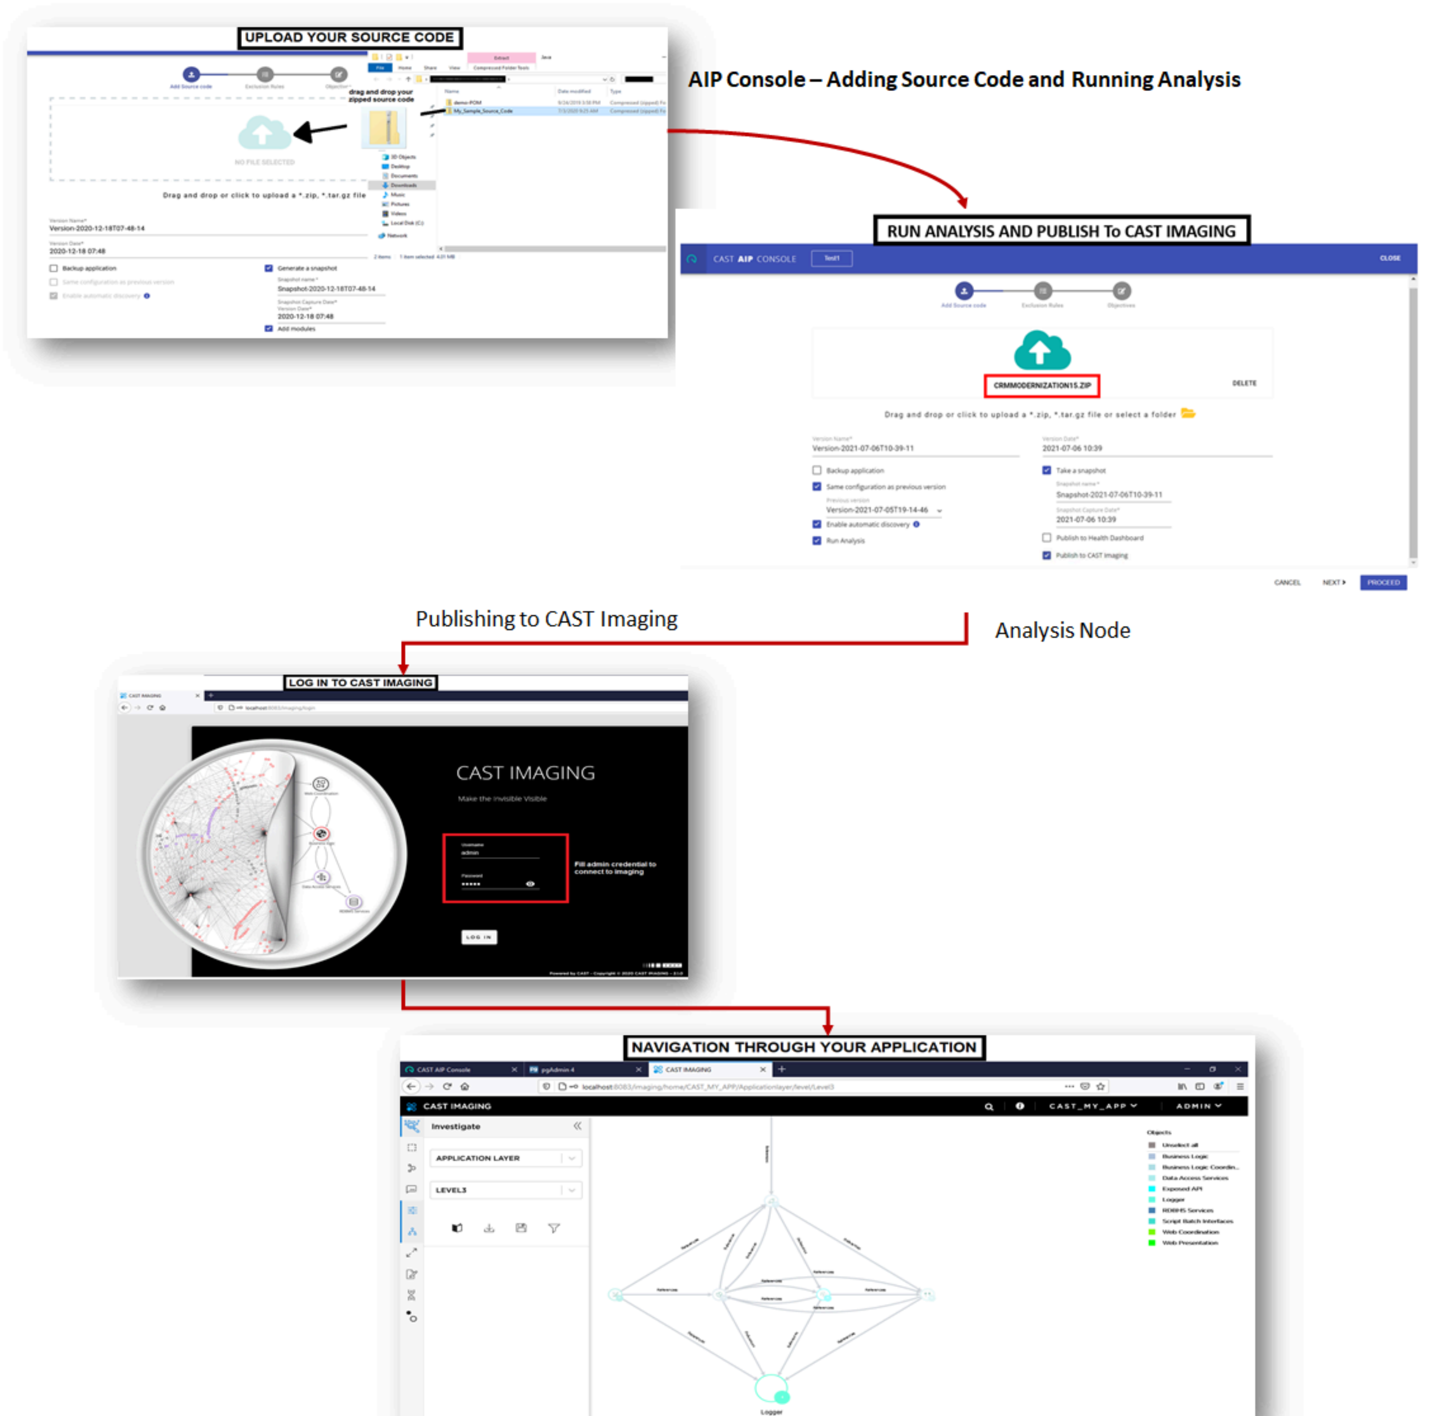
The following diagram shows an example workflow for onboarding an application's source code through the CAST Console and then viewing it in CAST Imaging:



The diagram shows the following workflow:

1. CAST generates application source code metadata by reverse-engineering front-end, middleware, and back-end code.
2. The application data that is generated by CAST is automatically imported into CAST Imaging, where it can be visualized and analyzed.

Here's a snapshot of how this process works:



CAST Imaging – Analyzing and Publishing Data, and Application visualization

Tools

- [CAST Imaging](#) is a browser-based application that helps you view and navigate your software system visually, so you can make informed decisions about its architecture.

- CAST Console is a browser-based application that helps you configure, run, and manage CAST AIP analyses.

> **Note**
>
> CAST Imaging and CAST Console are included in the AMI for CAST Imaging.

Epics

Set up the CAST Imaging environment

Task	Description	Skills required
Run the initial CAST Console configuration.	1. Open your web browser and connect to the CAST Console by entering the following URL: **http://localhost:8081** 2. When prompted, enter your **CAST Console license key**. Then, choose **Next**. 3. Review the configuration settings. If no changes are needed, choose **Save and Finish**.	Software architects, Developers, Technical leaders
Run the initial CAST Imaging configuration.	1. Open your web browser and connect to CAST Imaging by entering the following URL: **http://localhost:8083** 2. When prompted, log in by entering **admin** for both the username and password.	Software architects, Developers, Technical leaders

Task	Description	Skills required
	3. When prompted, enter your **CAST Imaging license key**. Then, choose **Update** to save the key.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Configure CAST Extend local server.</td><td>(Optional) By default, CAST Extend local server is configured to function in offline mode. If this is acceptable, no additional configuration is necessary. However, if you prefer to configure CAST Extend local server in online/proxy mode with a direct connection to CAST Extend, follow these steps.

Note
For CAST Extend credentials, see the CAST Extend registration page.

1. Use the CAST Extend Admin Center shortcut on the desktop to load your web browser and connect to CAST Extend local server.
2. Choose the Online option.
3. Enter your CAST Extend credentials (email and password), and choose Save to complete the process.</td><td>Software architects, Developers, Technical leaders</td></tr>
</table>

Onboard your application to CAST Imaging

Task	Description	Skills required
Prepare the source code for your application.	Save your application’s source code in a single, compresse d .zip file.	Software architects, Developers, Technical leaders
Add your application to the CAST Console.	1. Open your web browser and connect to the CAST Console by entering the following URL: **http://lo calhost:8081** 2. When prompted, log in by entering **admin** for both the username and password. 3. Choose **Add application**. Then, enter the application name and choose **Add**.	Software architects, Developers, Technical leaders
Open the source code delivery wizard.	Find the application that you created in the CAST Console. Then, choose **Add version**.	Software architects, Developers, Technical leaders
Upload the source code for your application.	Do one of the following: • Drag and drop the .zip file that contains your applicati on’s source code into the source code delivery wizard. −or− • Choose the **upload cloud icon**. Then, open the .zip file that contains your application’s source code.	Software architects, Developers, Technical leaders

Task	Description	Skills required
Start the analysis process.	1. In the delivery wizard, provide the version details and specify the configura tion options. For more information, see Standard onboarding for CAST Imaging in the CAST Imaging documentation. 2. Make sure that the **Publish to CAST Imaging** option is selected. Then, choose **Proceed**. **Note** Choosing **Proceed** starts the analysis process for the source code. The progress window in the CAST Console shows each step of the analysis process, and displays a notification when the analysis is complete.	Software architects, Developers, Technical leaders

Verify the analysis results and data published to CAST Imaging

Task	Description	Skills required
Check status and logs.	When all analysis actions are complete, verify that there's	Software architects, Developers, Technical leaders

Task	Description	Skills required
	a **success** message in the progress window. **Note** You can check the individual logs for each analysis action immediately after it's completed. To review the logs for a specific action, choose **View log** in the **Progress** window.	
Check the application details.	In the [Application details panel](), review the details about the analysis results. Make sure to look at the technologies that were discovered and the source code organization.	Software architects, Developers, Technical leaders

Task	Description	Skills required
Verify and access CAST Imaging.	1. In the **Application Management** pane in the CAST Console, verify that the version status of your application is [Imaging processed](). A CAST Imaging icon appears. 2. Choose the CAST Imaging icon to navigate directly to your application data in CAST Imaging. **Note** The *Imaging processed* status means that the source code has been analyzed and uploaded to your CAST Imaging instance.	Software architects, Developers, Technical leaders

Start analyzing your application with CAST Imaging

Task	Description	Skills required
Log in to CAST Imaging.	Open Cast Imaging and enter the default admin credentials (**admin/admin**). Your application's data appears.	Software architects, Developers, Technical leaders

Task	Description	Skills required
Explore your application's data in CAST Imaging.	Start viewing your software architecture by using CAST Imaging features. For a quick tutorial on how to use CAST Imaging's features, choose the **Help** icon to display the CAST Imaging Helper. For more information, see the CAST Imaging User Guide.	Software architects, Developers, Technical leaders

Assess application readiness for migration to the AWS Cloud by using CAST Highlight

Greg Rivera, Amazon Web Services

Summary

CAST Highlight is a software as a service (SaaS) solution for performing rapid application portfolio analysis. This pattern describes how to configure and use CAST Highlight to assess the cloud readiness of custom software applications across an organization's IT portfolio, and to plan for modernization or migration to the Amazon Web Services (AWS) Cloud.

CAST Highlight generates insights into an application's cloud readiness, identifies code blockers that need to be removed before a migration, estimates the effort to remove these blockers, and recommends AWS services that individual applications could use after the migration.

This pattern describes the procedure for setting up and using CAST Highlight, which consists of five steps: new user setup, application management, campaign management, source code analysis, and results analysis. You must complete all the steps in the *Epics* section of this pattern to ensure a successful application scan and analysis.

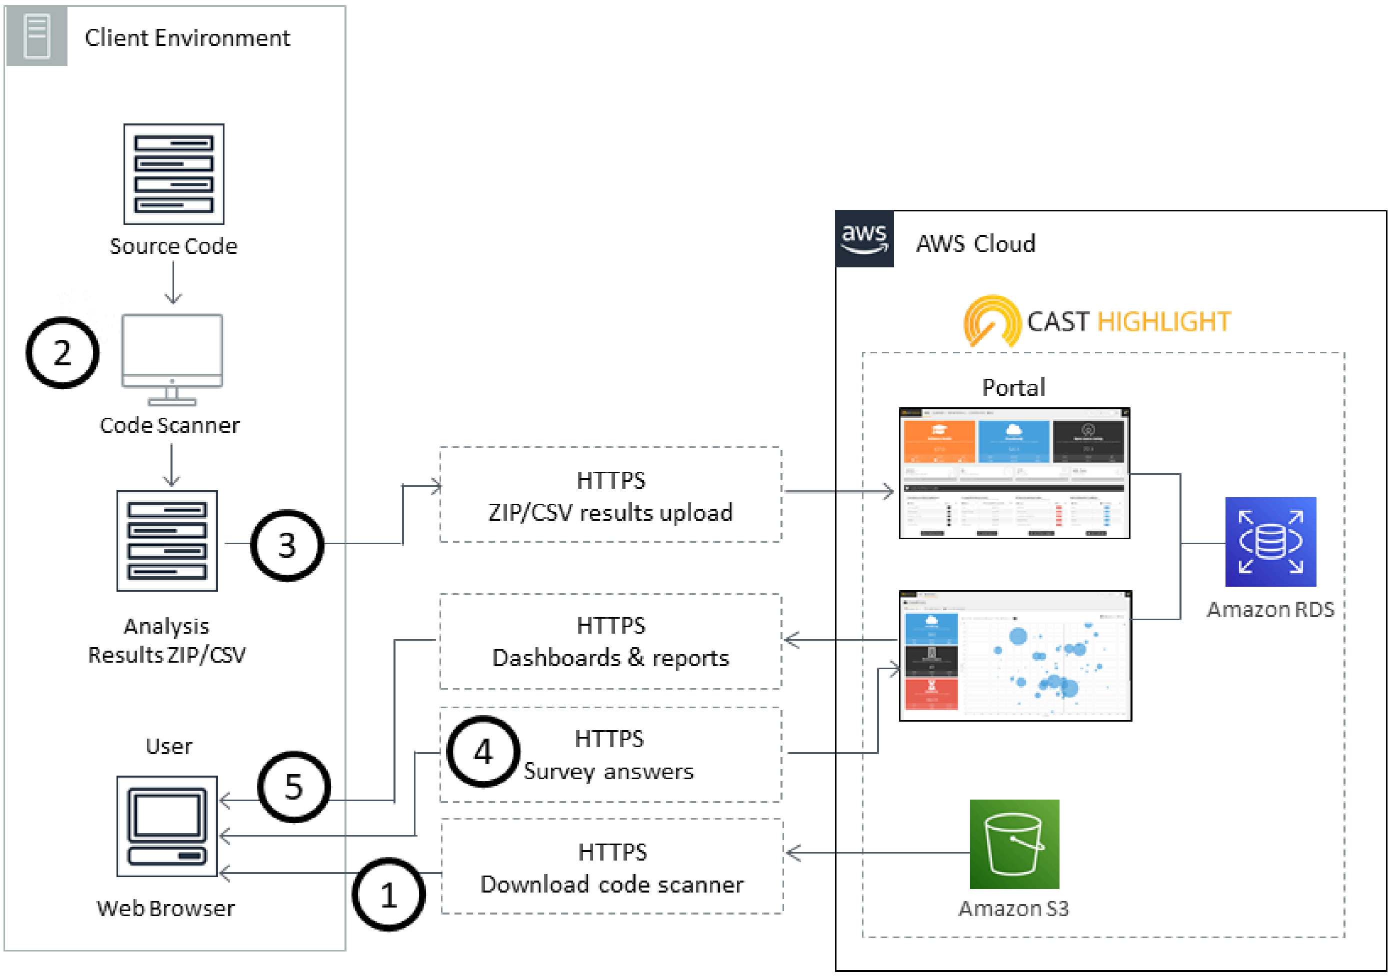
Prerequisites and limitations

Prerequisites

- An active CAST Highlight account with Portfolio Manager permissions.
- At least 300 MB free disk space and 4 GB memory on your local computer to install the CAST Highlight Local Agent.
- Microsoft Windows 8 or later.
- Your application source code must be stored in text files that are accessible from the machine where the Local Agent is installed. No source code leaves the premises and all code is locally scanned.

Architecture

The following diagram illustrates the workflow for using CAST Highlight.



The workflow consists of the following steps:

1. Log in to the CAST Highlight portal, download the Local Agent, and install it on your local computer. Amazon Simple Storage Service (Amazon S3) stores the Local Agent installation package.
2. Scan your source code files and produce a results file.
3. **Important**

   Upload the results file to the CAST Highlight portal. : No source code is included in the results file.
4. Answer survey questions for each application that you scanned.

5. View the dashboards and reports available in the CAST Highlight portal. Amazon Relational Database Service (Amazon RDS) stores the code scan, analysis results, and the CAST Highlight software data.

Technology stack

CAST Highlight supports the following technologies to analyze application cloud readiness:

- Java
- COBOL
- C#
- C++
- Clojure
- PHP
- JavaScript
- TypeScript
- Python
- Microsoft Transact-SQL
- VB.Net
- Kotlin
- Scala
- Swift

Automation and scale

- A CLI analyzer can be used to automate the CAST Highlight analysis process.

Tools

No tools are required for this pattern if all the prerequisites are met. However, you can choose to use optional tools, such as source code management (SCM) utilities, code extractors, or other tools to manage your source code files.

Epics

New user setup

Task	Description	Skills required
Activate your CAST Highlight account and choose your password.	All first-time CAST Highlight users receive an account activation email. Follow the activation link to activate your CAST Highlight account and enter a password to complete the activation process.	N/A
Log in to the CAST Highlight portal.	The CAST Highlight homepage appears after you enter your new password. Log in to the CAST Highlight portal with your user credentials.	N/A

Application management

Task	Description	Skills required
Create an application record.	In the CAST Highlight portal, navigate to the **Manage Application** tab in the **Manage Portfolio** section. In the **Applications** tile at the top of the screen, choose **Add**.	N/A
Choose an application name.	Enter a name for your application, and then choose **Save**. This name is used for	N/A

Task	Description	Skills required
	your application record in CAST Highlight.	
Repeat the steps for all applications.	Repeat these steps for each application that you want to scan.	N/A

Campaign management

Task	Description	Skills required
Create a campaign.	CAST Highlight uses "campaign" to describe a set of applications that will be analyzed at a specific time. In the CAST Highlight portal, navigate to the **Manage Campaigns** tab in the **Manage Portfolio** section. Choose **Create Campaign** to launch the campaign creation screen.	N/A
Enter a name and choose a closing date for the campaign.	Enter a name for your campaign and choose a closing date for it. **Important** Contributors cannot submit applicati on analysis results after the campaign's closing date.	N/A

Task	Description	Skills required
Decide to include source code scan, survey answers, and domain and application scope.	Choose one or more of the standard surveys that are used to enhance the source code analysis data with qualitative informati on. The survey categorie s are **Business impact**, **Software maintenan ce effort**, **CloudReady**, **Application properties**, and **Green Impact**. Choose the domain and applications that are analyzed during the campaign. **Important** Make sure that you add all applicati ons you want to scan in the **Manage Applications** section before you begin the campaign.	N/A
Customize the launch message.	Customize the launch message that will be sent by email to all contributors associated with the applicati ons in the campaign.	N/A
Launch the campaign.	Choose **Complete** to launch the campaign.	N/A

Source code analysis

Task	Description	Skills required
Download the CAST Highlight Local Agent.	In the CAST Highlight portal, choose **Application Scans** and download the Local Agent to your local computer.	N/A
Install the Local Agent.	Launch the CASTHighl ightSetup.exe installation program and follow the setup instructions that appear. After the Local Agent is installed, you are ready to analyze your applications.	N/A
Define the scope of the Local Agent code scan.	The code analysis is performed at the file level and doesn't consider the logical links or dependenc ies among files. All files are considered equal and part of the application. To provide accurate and consistent results, prepare your code scan scope by using the file or folder exclusion features available in the Local Agent.	N/A
Include open-source or COTS packages.	(Optional) If you want to include open-source or commercial off-the-shelf (COTS) packages, make sure they're included in the folders that you're planning	N/A

Task	Description	Skills required
	to scan. Typically, external libraries are grouped in a subfolder called "third-party" or something similar, and the main code is often located in the "src/main" file folder.	
Exclude test classes.	Test classes are typically excluded from the source code analysis because they are generally not part of the compiled application. However, you can choose to include them in the scan if required.	N/A
Exclude SCM, build, and deployment folders.	For more consistent results, you should avoid including SCM, build, or deploymen t folders (for example, .git or .svn files) in your scan.	N/A
Include dependency files.	If you want insights into frameworks and dependenc ies whose physical files are not part of the folder you're scanning, then make sure you include the dependency files (such as pom.xml, build.gra dle, package.json, or .vcsproj files).	N/A
Invoke the Local Agent.	Run the Local Agent on your local Windows machine.	N/A

Task	Description	Skills required
Choose the folder that contains your source code.	Choose the folder that contains your source code. You can add multiple folders to be discovered by the Local Agent. Although the Local Agent does support source discovery through network paths, you should make sure source folders are located on your local machine. **Important** We recommend running multiple scans if there are more than 10,000 files in your source folders.	N/A

Task	Description	Skills required
Start file discovery.	On the Local Agent dashboard, choose **Discover Files**. The Local Agent discovers files in your folders and subfolders, and detects their technologies. You can choose the **Cancel** button to cancel the discovery at any time. After the file discovery finishes, the Local Agent lists the folders and files that were found. The **Technologies** column shows associated technologies and file count. The **Path** column shows the location of the folders and files.	N/A

Task	Description	Skills required
Refine the source code scan configuration.	(Optional) To refine the Local Agent scan, you can deactivate one or more technologies for a specific folder or file. If all technologies are deactivated, your folder or file will be excluded from the scan's scope. To deactivate technologies, choose the yellow label of the technology you want to deactivate. You can also choose the filter icon when hovering over a file or a folder to associate a technology with a specific file or folder. These settings are saved and speed up the discovery process for the folder or file.	N/A
Start source code scan.	After you configure your scan, choose "Scan Files" to begin the scanning process.	N/A

Task	Description	Skills required
Check for green or grey labels.	After the source code scan is complete, a status label is shown at folder and file levels. A green label means that files were correctly scanned with the associated technology. A grey label means that files were not scanned and are excluded. The reason for their exclusion is shown when you hover over the label of each file. Possible reasons for file exclusion include binary files, unreadable files, missing files, external library, encoded files, generated files, syntax errors, content that isn't in the expected language, code that isn't compliant with enough analysis criteria, files that exceed the size limit (10 MB), timeout issues, or unavailability of the analyzer.	N/A
Modify the scan configuration and scan code again.	(Optional) You can modify your scan configuration settings and choose **Scan Files** to scan the files again.	N/A
Confirm scan results.	Choose **Confirm Results** if the scan results meet your requirements.	N/A

Task	Description	Skills required
View frameworks and software libraries found by the Local Agent.	View the frameworks and software libraries used or referenced by your applicati ons, and discovered by the Local Agent during the code scan. You can keep or ignore elements from these lists by choosing their individual switch button. Choose **Confirm dependenc ies** to proceed. **Important** If a framework is turned off, it is not listed in the CAST Highlight portal or attached to your application.	N/A

Task	Description	Skills required
Save code scan results.	The Local Agent displays a summary of your code scan results grouped by technology. Choose **Save** and specify the folder you want the results to be saved to. The Local Agent generates one .zip file per scan, which contains all the analysis results. Depending on the number of distinct technologies and root source folders, the Local Agent automatically generates one or several .csv files with the **FolderNam e.Technology.date.csv** naming structure.	N/A
Upload the code scan results to the CAST Highlight portal.	In the CAST Highlight portal, choose the applications you analyzed in the **Application Scans** section. Choose **Upload Results** and choose the .csv files. You can also upload the .csv files individually. After each file is uploaded, a record of the upload appears on your screen.	N/A

Task	Description	Skills required
Delete analysis result files, if required.	(Optional) An analysis results file can be deleted at any time during the upload process by choosing the trash can icon. **Important** Only users with Portfolio Manager privileges or the contributor who uploaded the results can delete the results.	N/A
Answer application survey.	A **Survey** button appears on applications that require a survey. Choose **Survey**, answer the questions for each section of the survey, and choose **Submit** after you finish. The progress of your survey is displayed at the top of your screen. You are able to submit your results after all mandatory information is submitted. However, you can enrich the data in your organization's CAST Highlight instance by answering all the questions.	N/A

Task	Description	Skills required
Submit code scan results.	After you upload all the .csv result files for the applicati on and complete the survey questions, choose **Submit** in the **Application Scans** section. This step is required to complete the process and ensure that the results are available in the CAST Highlight portal.	N/A

Results analysis

Task	Description	Skills required
View CAST Highlight portal homepage.	The CAST Highlight portal homepage includes tiles that have high-level informati on about your application portfolio, such as software health, CloudReady, and open-source safety scores for your entire portfolio. The homepage also includes the number of onboarded applications. For more information about the CAST Highlight metrics definitions and measurement methodolo gy, see [CAST Highlight – Metrics and methodolo gy (Microsoft PowerPoint presentation).]()	N/A

Task	Description	Skills required
View the CloudReady dashboard.	Choose the **CloudReady** tile to open the CloudReady dashboard. This is the primary portfolio-level dashboard for assessing the cloud readiness of your applications. It helps you plan and develop a portfolio roadmap for your cloud migration	N/A

Task	Description	Skills required
View the Portfolio Advisor for Cloud dashboard.	The Portfolio Advisor for Cloud dashboard automatically segments applications into recommended migration categories. Segmentation is based on the technical characteristics of each application. Factors include the source code analysis (cloud readiness, software resiliency, and more) and the business impact, which comes from the survey. In the upper right, choose **Compute** to generate the initial segmentation recommendations. The bubbles in the charts at the top of the dashboard represent each application in the portfolio, organized by the recommended segmentation. Each application is also listed in a data table below the charts, including relevant metrics for each application. The possible segments that are recommended include: • **Rehost** – A recommendation to change the infrastructure configuration of the application in order	N/A

Task	Description	Skills required
	to *lift and shift* it to the cloud by using an infrastructure as a service (IaaS) solution. • **Refactor** – A recommendation to perform modest modifications of the application code without changing the architecture or functionality so that it can be migrated by using a container as a service (CaaS) or platform as a service (PaaS) solution. • **Rearchitect** – A recommendation to dramatically modify the application code to improve the health of the application and to prepare it for migration by using a PaaS solution or deploy it as a serverless application by using a function as a service (FaaS) solution. • **Rebuild** – A recommendation to discard the code of the application and develop it again in the cloud by using a PaaS solution or develop it again as a serverless application by using a FaaS solution.	

Task	Description	Skills required
	• **Retire –** A recommendation to discard the application altogether or potentially replace it with a commercia l software as a service (SaaS) alternative.	
Modify segmentation recommendations.	In some cases, you might choose to change the segment recommended by CAST Highlight. You can do this by browsing to the application in the data table and selecting a different segment from the drop-down list next to the application name. Then choose **Save** in the upper right to save your changes. You can also export this data at any time by choosing **Export** in the upper right.	N/A

Task	Description	Skills required
Choose an application to analyze.	On the Portfolio Advisor for Cloud dashboard, choose an application bubble to analyze that application. Choose the name of the application in the table after the bubble chart to begin the deeper analysis. Different dashboards are available to analyze individua l applications, such as **Code Insights** (software health patterns), **Trends**, and **Software Composition** (open-source risks).	N/A

Task	Description	Skills required
Analyze the CloudRead y results of an individual application.	Choose the **CloudReady** tab, which shows the application's overall CloudReady score. This score is a weighted average based on a combination of the CloudReady survey answers and the CloudRead y code scan. The answers to the survey questions appear in the table below the tiles. Choose **CloudReady Code Scan** to view the code scan results. There is a list of CloudReady patterns that the application code was scanned for. This list includes the following columns: • **Cloud Requirement** is the specific code pattern. • **Technology** is the pattern's programming language. "Impact" is the pattern's impact on the application (C = code, F = framework, A = architecture). • **Criticality** is the level of importance of addressin g this pattern before migrating. • **Contribution** is how this pattern contributes to the overall CloudReady score.	N/A

Task	Description	Skills required
	If the pattern is green, it is a booster and increases the CloudReady score. If the pattern is red, it is a blocker and decreases the CloudReady score. If the pattern has no color, it is a blocker that was not detected and increases the CloudReady score. • **Roadblocks** are the number of individual occurrenc es of a blocker pattern. Choose the roadblock number to show a list of the source code files where the pattern was detected. • **Est. Effort** is an estimate of the number of days it will take to remediate the roadblocks in each row.	
Export data to Microsoft Excel.	(Optional) Choose **Export to Excel** to export the data for further analysis. The applicati on analysis results data can be used to further analyze the cloud readiness of an application and determine what code must to be updated before a migration.	N/A

Task	Description	Skills required
View recommendations.	Choose **Recommend ations** next to **CloudRead y Code Scan** to view the **Cloud Service Recommend ations** screen. This identifie s AWS services that the application could adopt based on its characteristics. Repeat this step to view recommendations for all the applications that you analyzed.	N/A

Automatically archive items to Amazon S3 using DynamoDB TTL

Tabby Ward, Amazon Web Services

Summary

This pattern provides steps to remove older data from an Amazon DynamoDB table and archive it to an Amazon Simple Storage Service (Amazon S3) bucket on Amazon Web Services (AWS) without having to manage a fleet of servers.

This pattern uses Amazon DynamoDB Time to Live (TTL) to automatically delete old items and Amazon DynamoDB Streams to capture the TTL-expired items. It then connects DynamoDB Streams to AWS Lambda, which runs the code without provisioning or managing any servers.

When new items are added to the DynamoDB stream, the Lambda function is initiated and writes the data to an Amazon Data Firehose delivery stream. Firehose provides a simple, fully managed solution to load the data as an archive into Amazon S3.

DynamoDB is often used to store time series data, such as webpage click-stream data or Internet of Things (IoT) data from sensors and connected devices. Rather than deleting less frequently accessed items, many customers want to archive them for auditing purposes. TTL simplifies this archiving by automatically deleting items based on the timestamp attribute.

Items deleted by TTL can be identified in DynamoDB Streams, which captures a time-ordered sequence of item-level modifications and stores the sequence in a log for up to 24 hours. This data can be consumed by a Lambda function and archived in an Amazon S3 bucket to reduce the storage cost. To further reduce the costs, Amazon S3 lifecycle rules can be created to automatically transition the data (as soon as it gets created) to lowest-cost storage classes, such as S3 Glacier Instant Retrieval or S3 Glacier Flexible Retrieval, or Amazon S3 Glacier Deep Archive for long-term storage.

Prerequisites and limitations

Prerequisites

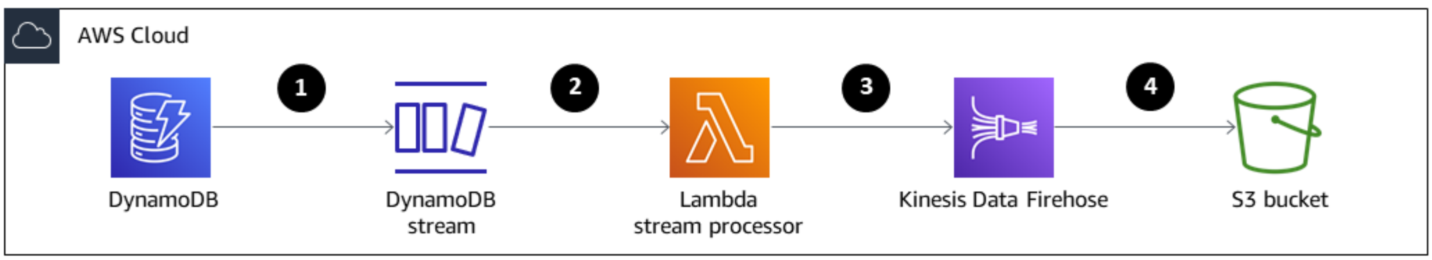
- An active AWS account.
- AWS Command Line Interface (AWS CLI) 1.7 or later, installed and configured on macOS, Linux, or Windows.
- Python 3.7 or later.

- [Boto3](), installed and configured. If Boto3 is not already installed, run the `python -m pip install boto3` command to install it.

Architecture

Technology stack

- Amazon DynamoDB
- Amazon DynamoDB Streams
- Amazon Data Firehose
- AWS Lambda
- Amazon S3



1. Items are deleted by TTL.
2. The DynamoDB stream trigger invokes the Lambda stream processor function.
3. The Lambda function puts records in the Firehose delivery stream in batch format.
4. Data records are archived in the S3 bucket.

Tools

- AWS CLI – The AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services.
- Amazon DynamoDB – Amazon DynamoDB is a key-value and document database that delivers single-digit millisecond performance at any scale.
- Amazon DynamoDB Time to Live (TTL) – Amazon DynamoDB TTL helps you define a per-item timestamp to determine when an item is no longer required.

- Amazon DynamoDB Streams – Amazon DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table and stores this information in a log for up to 24 hours.
- Amazon Data Firehose – Amazon Data Firehose is the easiest way to reliably load streaming data into data lakes, data stores, and analytics services.
- AWS Lambda – AWS Lambda runs code without the need to provision or manage servers. You pay only for the compute time you consume.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance.

Code

The code for this pattern is available in the GitHub Archive items to S3 using DynamoDB TTL repository.

Epics

Set up a DynamoDB table, TTL , and a DynamoDB stream

Task	Description	Skills required

Create a DynamoDB table.	Use the AWS CLI to create a table in DynamoDB called `Reservation` . Choose random read capacity unit (RCU) and write capacity unit (WCU), and give your table two attributes: `ReservationID` and `ReservationDate` .
	
	`aws dynamodb create-table \`
	`--table-name Reservation \`
	`--attribute-definitions AttributeName=ReservationID`
		Cloud architect, App developer

Task	Description	Skills required
	``` ,AttributeType=S AttributeName=Rese rvationDate,Attrib uteType=N \ --key-schema Attribute Name=ReservationID ,KeyType=HASH AttributeName=Rese rvationDate,KeyTyp e=RANGE \ --provisioned-th roughput ReadCapac ityUnits=100,Write CapacityUnits=100 ``` `ReservationDate` is an epoch timestamp that will be used to turn on TTL.	
Turn on DynamoDB TTL.	Use the AWS CLI to turn on DynamoDB TTL for the `ReservationDate` attribute. ``` aws dynamodb update-ti me-to-live \ --table-name Reservati on\ --time-to-live-spe cification Enabled=t rue,AttributeName= ReservationDate ```	Cloud architect, App developer

Task	Description	Skills required
Turn on a DynamoDB stream.	Use the AWS CLI to turn on a DynamoDB stream for the `Reservation` table by using the `NEW_AND_OLD_IMAGES` stream type. `aws dynamodb update-table \ --table-name Reservation \ --stream-specification StreamEnabled=true,StreamViewType=NEW_AND_OLD_IMAGES` This stream will contain records for new items, updated items, deleted items, and items that are deleted by TTL. The records for items that are deleted by TTL contain an additional metadata attribute to distinguish them from items that were deleted manually. The `userIdentity` field for TTL deletions indicates that the DynamoDB service performed the delete action. In this pattern, only the items deleted by TTL are archived, but you could archive only the records where `eventName` is `REMOVE` and `userIdent`	Cloud architect, App developer

Task	Description	Skills required
	`ity` contains `principal Id` equal to `dynamodb. amazonaws.com` .	

Create and configure an S3 bucket

Task	Description	Skills required
Create an S3 bucket.	Use the AWS CLI to create a destination S3 bucket in your AWS Region, replacing `us-east-1` with your Region and amzn-s3-demo-destination-bucket with the name of your bucket. `aws s3api create-bucket \ --bucket amzn-s3-demo-destination-bucket \ --region us-east-1` Make sure that your S3 bucket's name is globally unique, because the namespace is shared by all AWS accounts.	Cloud architect, App developer
Create a 30-day lifecycle policy for the S3 bucket.	1. Sign in to the AWS Management Console and open the Amazon S3 console. 2. Choose the S3 bucket that contains the data from Firehose.	Cloud architect, App developer

Task	Description	Skills required
	3. In the S3 bucket, choose the **Management** tab, and choose **Add lifecycle rule**. 4. Enter a name for your rule in the **Lifecycle rule** dialog box, and configure a 30-day lifecycle rule for your bucket.	

Create a Firehose delivery stream

Task	Description	Skills required
Create and configure a Firehose delivery stream.	Download and edit the `CreateFireHoseToS3.py` code example from the GitHub repository. This code is written in Python and shows you how to create a Firehose delivery stream and an AWS Identity and Access Management (IAM) role. The IAM role will have a policy that can be used by Firehose to write to the destination S3 bucket. To run the script, use the following command and command line arguments. Argument 1= `<Your_S3_bucket_ARN>` , which is the Amazon Resource Name	Cloud architect, App developer

Task	Description	Skills required
	(ARN) for the bucket that you created earlier Argument 2= Your Firehose name (This pilot is using `firehose_to_s3_stream` .) Argument 3= Your IAM role name (This pilot is using `firehose_to_s3` .) `python CreateFireHoseToS3.py <Your_S3_Bucket_ARN> firehose_to_s3_stream firehose_to_s3` If the specified IAM role does not exist, the script will create an assume role with a trusted relationship policy, as well as a policy that grants sufficient Amazon S3 permission. For examples of these policies, see the *Additional information* section.	

Task	Description	Skills required
Verify the Firehose delivery stream.	Describe the Firehose delivery stream by using the AWS CLI to verify that the delivery stream was successfully created. `aws firehose describe-delivery-stream --delivery-stream-name firehose_to_s3_stream`	Cloud architect, App developer

Create a Lambda function to process the Firehose delivery stream

Task	Description	Skills required
Create a trust policy for the Lambda function.	Create a trust policy file with the following information. `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Principal": { "Service": "lambda.amazonaws.com" }, "Action": "sts:AssumeRole" } ] }`	Cloud architect, App developer

Task	Description	Skills required
	This gives your function permission to access AWS resources.	
Create an execution role for the Lambda function.	To create the execution role, run the following code. `aws iam create-role --role-name lambda-ex --assume-role-policy-document file://TrustPolicy.json`	Cloud architect, App developer

Task	Description	Skills required

Add permission to the role.	To add permission to the role, use the `attach-policy-to-role` command.
	`aws iam attach-role-policy --role-name lambda-ex --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole`
	`aws iam attach-role-policy --role-name lambda-ex --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaDynamoDBExecutionRole`
	`aws iam attach-role-policy --role-name lambda-ex --policy-arn arn:aws:iam::aws:policy/AmazonKinesisFirehoseFullAccess`
	`aws iam attach-role-policy --role-name lambda-ex --policy-arn arn:aws:iam::aws:policy/IAMFullAccess`
		Cloud architect, App developer

Task	Description	Skills required

Create a Lambda function.	Compress the `LambdaStreamProcessor.py` file from the code repository by running the following command.
	`zip function.zip LambdaStreamProcessor.py`
	When you create the Lambda function, you will need the Lambda execution role ARN. To get the ARN, run the following code.
	`aws iam get-role \ --role-name lambda-ex`
	To create the Lambda function, run the following code.
	`# Review the environment variables and replace them with your values.`
	`aws lambda create-function --function-name LambdaStreamProcessor \ --zip-file fileb://function.zip --handler LambdaStreamProcessor.handler --runtime python3.8 \`
		Cloud architect, App developer

Task	Description	Skills required
	`--role {Your Lamda Execution Role ARN}\ --environment Variables="{firehose_name=firehose_to_s3_stream,bucket_arn = <Your_S3_bucket_ARN>,iam_role_name = firehose_to_s3, batch_size=400}"`	
Configure the Lambda function trigger.	Use the AWS CLI to configure the trigger (DynamoDB Streams), which invokes the Lambda function. The batch size of 400 is to avoid running into Lambda concurrency issues. `aws lambda create-event-source-mapping --function-name LambdaStreamProcessor \ --batch-size 400 --starting-position LATEST \ --event-source-arn <Your Latest Stream ARN From DynamoDB Console>`	Cloud architect, App developer

Test the functionality

Task	Description	Skills required
Add items with expired timestamps to the Reservation table.	To test the functionality, add items with expired epoch timestamps to the `Reservation` table. TTL will automatically delete items based on the timestamp. The Lambda function is initiated upon DynamoDB Stream activities, and it filters the event to identify `REMOVE` activity or deleted items. It then puts records in the Firehose delivery stream in batch format. The Firehose delivery stream transfers items to a destination S3 bucket with the `firehosetos3example/year=current year/month=current month/day=current day/hour=current hour/` prefix. **Important** To optimize data retrieval, configure Amazon S3 with the `Prefix` and `ErrorOutputPrefix` that	Cloud architect

Task	Description	Skills required
	are detailed in the *Additional information* section.	

Clean up the resources

Task	Description	Skills required
Delete all resources.	Delete all the resources to ensure that you aren't charged for any services that you aren't using.	Cloud architect, App developer

            }
        ]
    }
```

S3 permissions policy example

```
s3_access = {
        "Version": "2012-10-17",
        "Statement": [
            {
                "Sid": "",
                "Effect": "Allow",
                "Action": [
                    "s3:AbortMultipartUpload",
                    "s3:GetBucketLocation",
                    "s3:GetObject",
                    "s3:ListBucket",
                    "s3:ListBucketMultipartUploads",
                    "s3:PutObject"
                ],
                "Resource": [
                    "{your s3_bucket ARN}/*",
                    "{Your s3 bucket ARN}"
                ]
            }
        ]
    }
```

Test the functionality – Amazon S3 configuration

The Amazon S3 configuration with the following `Prefix` and `ErrorOutputPrefix` is chosen to optimize data retrieval.

Prefix

```
firehosetos3example/year=! {timestamp: yyyy}/month=! {timestamp:MM}/day=!
 {timestamp:dd}/hour=!{timestamp:HH}/
```

Firehose first creates a base folder called `firehosetos3example` directly under the S3 bucket. It then evaluates the expressions `!{timestamp:yyyy}`, `!{timestamp:MM}`, `!{timestamp:dd}`, and `!{timestamp:HH}` to year, month, day, and hour using the Java [DateTimeFormatter](https://docs.oracle.com/javase/8/docs/api/java/time/format/DateTimeFormatter.html) format.

For example, an approximate arrival timestamp of 1604683577 in Unix epoch time evaluates to `year=2020`, `month=11`, `day=06`, and `hour=05`. Therefore, the location in Amazon S3, where data records are delivered, evaluates to `firehosetos3example/year=2020/month=11/day=06/hour=05/`.

ErrorOutputPrefix

```
firehosetos3erroroutputbase/!{firehose:random-string}/!{firehose:error-output-type}/!
{timestamp:yyyy/MM/dd}/
```

The `ErrorOutputPrefix` results in a base folder called `firehosetos3erroroutputbase` directly under the S3 bucket. The expression `!{firehose:random-string}` evaluates to an 11-character random string such as `ztWxkdg3Thg`. The location for an Amazon S3 object where failed records are delivered could evaluate to `firehosetos3erroroutputbase/ztWxkdg3Thg/processing-failed/2020/11/06/`.

Build a multi-tenant serverless architecture in Amazon OpenSearch Service

Tabby Ward and Nisha Gambhir, Amazon Web Services

Summary

Amazon OpenSearch Service is a managed service that makes it easy to deploy, operate, and scale Elasticsearch, which is a popular open-source search and analytics engine. OpenSearch Service provides free-text search as well as near real-time ingestion and dashboarding for streaming data such as logs and metrics.

Software as a service (SaaS) providers frequently use OpenSearch Service to address a broad range of use cases, such as gaining customer insights in a scalable and secure way while reducing complexity and downtime.

Using OpenSearch Service in a multi-tenant environment introduces a series of considerations that affect partitioning, isolation, deployment, and management of your SaaS solution. SaaS providers have to consider how to effectively scale their Elasticsearch clusters with continually shifting workloads. They also need to consider how tiering and noisy neighbor conditions could impact their partitioning model.

This pattern reviews the models that are used to represent and isolate tenant data with Elasticsearch constructs. In addition, the pattern focuses on a simple serverless reference architecture as an example to demonstrate indexing and searching using OpenSearch Service in a multi-tenant environment. It implements the pool data partitioning model, which shares the same index among all tenants while maintaining a tenant's data isolation. This pattern uses the following AWS services: Amazon API Gateway, AWS Lambda, Amazon Simple Storage Service (Amazon S3), and OpenSearch Service.

For more information about the pool model and other data partitioning models, see the [Additional information](#) section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- [AWS Command Line Interface (AWS CLI) version 2.x](#), installed and configured on macOS, Linux, or Windows

- Python version 3.9
- pip3 – The Python source code is provided as a .zip file to be deployed in a Lambda function. If you want to use the code locally or customize it, follow these steps to develop and recompile the source code:
  1. Generate the `requirements.txt` file by running the the following command in the same directory as the Python scripts: `pip3 freeze > requirements.txt`
  2. Install the dependencies: `pip3 install -r requirements.txt`

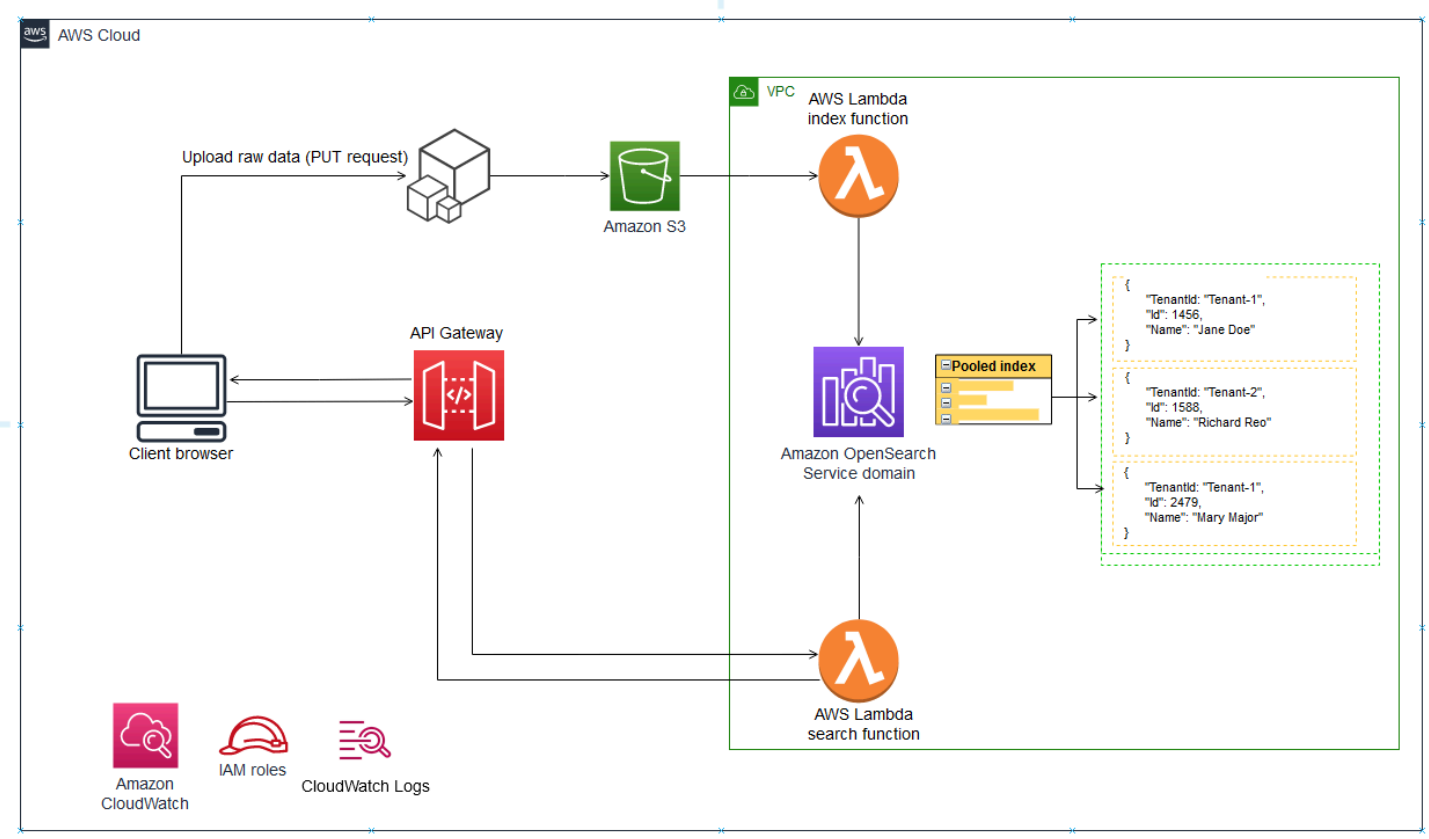
Limitations

- This code runs in Python, and doesn't currently support other programming languages.
- The sample application doesn't include AWS cross-Region or disaster recovery (DR) support.
- This pattern is intended for demonstration purposes only. It is not intended to be used in a production environment.

Architecture

The following diagram illustrates the high-level architecture of this pattern. The architecture includes the following:

- Lambda to index and query the content
- OpenSearch Service to perform search
- API Gateway to provide an API interaction with the user
- Amazon S3 to store raw (non-indexed) data
- Amazon CloudWatch to monitor logs
- AWS Identity and Access Management (IAM) to create tenant roles and policies



Automation and scale

For simplicity, the pattern uses AWS CLI to provision the infrastructure and to deploy the sample code. You can create an AWS CloudFormation template or AWS Cloud Development Kit (AWS CDK) scripts to automate the pattern.

Tools

AWS services

- [AWS CLI](#) is a unified tool for managing AWS services and resources by using commands in your command-line shell.
- [Lambda](#) is a compute service that lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [API Gateway](#) is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.
- [Amazon S3](#) is an object storage service that lets you store and retrieve any amount of information at any time, from anywhere on the web.

- [OpenSearch Service](https://docs.aws.amazon.com/opensearch-service/) is a fully managed service that makes it easy for you to deploy, secure, and run Elasticsearch cost-effectively at scale.

Code

The attachment provides sample files for this pattern. These include:

- `index_lambda_package.zip` – The Lambda function for indexing data in OpenSearch Service by using the pool model.
- `search_lambda_package.zip` – The Lambda function for searching for data in OpenSearch Service.
- `Tenant-1-data` – Sample raw (non-indexed) data for Tenant-1.
- `Tenant-2-data` – Sample raw (non-indexed) data for Tenant-2.

> **Important**
>
> The stories in this pattern include AWS CLI command examples that are formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) Unix continuation character at the end of each line with a caret (^).

> **Note**
>
> In AWS CLI commands, replace all values within the angle brackets (<>) with correct values.

Epics

Create and configure an S3 bucket

Task	Description	Skills required
Create an S3 bucket.	Create an S3 bucket in your AWS Region. This bucket will hold the non-indexed tenant data for the sample	Cloud architect, Cloud administrator

Task	Description	Skills required
	application. Make sure that the S3 bucket's name is globally unique, because the namespace is shared by all AWS accounts. To create an S3 bucket, you can use the AWS CLI [create-bucket](#) command as follows: `aws s3api create-bucket \ --bucket <tenantrawdata> \ --region <your-AWS-Region>` where `tenantrawdata` is the S3 bucket name. (You can use any unique name that follows [the bucket naming guidelines](#).)	

Create and configure an Elasticsearch cluster

Task	Description	Skills required
Create an OpenSearch Service domain.	Run the AWS CLI [create-elasticsearch-domain](#) command to create an OpenSearch Service domain: `aws es create-elasticsearch-domain \ --domain-name vpc-cli-example \`	Cloud architect, Cloud administrator

Task	Description	Skills required
	`--elasticsearch-ve rsion 7.10 \ --elasticsearch-cl uster-config InstanceT ype=t3.medium.elas ticsearch,Instance Count=1 \ --ebs-options EBSEnabled=true,Vo lumeType=gp2,Volum eSize=10 \ --domain-endpoint- options "{\"Enfor ceHTTPS\": true}" \ --encryption-at-re st-options "{\"Enabl ed\": true}" \ --node-to-node- encryption-options "{\"Enabled\": true}" \ --advanced-securit y-options "{\"Enabl ed\": true, \"Interna lUserDatabaseEnabled \": true, \ \"MasterUserOption s\": {\"MasterUserName \": \"KibanaUser\", \ \"MasterUserPasswo rd\": \"NewKiba naPassword@123\"}}" \ --vpc-options "{\"SubnetIds\": [\"<subnet-id>\"], \"SecurityGroupIds\": [\"<sg-id>\"]}" \ --access-policies "{\"Version\": \"2012-10-17\", \"Statement\":`	

Task	Description	Skills required

	``
	 [{ \"Effect\":
	 \"Allow\", \
	   \"Principal\":
	 {\"AWS\": \"*\" },
	 \"Action\":\"es:*\",
	 \
	   \"Resource\":
	 \"arn:aws:es:<regi
	on>:<account-id>:d
	omain\/vpc-cli-exa
	mple\/*\" }] }"
	``
	
	The instance count is set to 1 because the domain is for testing purposes. You need to enable fine-grained access control by using the `advanced-security-options` parameter, because the details cannot be changed after the domain has been created.
	
	This command creates a master user name (`KibanaUser`) and a password that you can use to log in to the Kibana console.
	
	Because the domain is part of a virtual private cloud (VPC), you have to make sure that you can reach the Elasticsearch instance by specifying the access policy to use.	

Task	Description	Skills required
	For more information, see Launching your Amazon OpenSearch Service domains within a VPC in the AWS documentation.	

Task	Description	Skills required
Set up a bastion host.	Set up a Amazon Elastic Compute Cloud (Amazon EC2) Windows instance as a bastion host to access the Kibana console. The Elasticsearch security group must allow traffic from the Amazon EC2 security group. For instructions, see the blog post [Controlling Network Access to EC2 Instances Using a Bastion Server](). When the bastion host has been set up, and you have the security group that is associated with the instance available, use the AWS CLI [authorize-security-group-ingress]() command to add permission to the Elasticsearch security group to allow port 443 from the Amazon EC2 (bastion host) security group. `aws ec2 authorize-security-group-ingress \ --group-id <SecurityGroupIdfElasticSearch> \ --protocol tcp \ --port 443 \`	Cloud architect, Cloud administrator

Task	Description	Skills required
	``` --source-group <SecurityGroupIdfB ashionHostEC2> ```	

Create and configure the Lambda index function

Task	Description	Skills required

Create the Lambda execution role.	Run the AWS CLI [create-role](https://docs.aws.amazon.com/cli/latest/reference/iam/create-role.html) command to grant the Lambda index function access to AWS services and resources:
	
	``
	aws iam create-role \
	  --role-name index-lambda-role \
	  --assume-role-policy-document file://lambda_assume_role.json
	``
	
	where `lambda_assume_role.json` is a JSON document that grants `AssumeRole` permissions to the Lambda function, as follows:
	
	``
	{
	     "Version": "2012-10-17",
	     "Statement": [
	         {
	             "Effect": "Allow",
	             "Principal": {
	``
		Cloud architect, Cloud administrator

Task	Description	Skills required

	``
	 "Service": "lambda.a
	mazonaws.com"
	                },
	              "Action":
	 "sts:AssumeRole"
	         }
	     ]
	 }
	``	

Task	Description	Skills required

Attach managed policies to the Lambda role.	Run the AWS CLI attach-role-policy command to attach managed policies to the role created in the previous step. These two policies give the role permissions to create an elastic network interface and to write logs to CloudWatch Logs.
	
	`aws iam attach-role-policy \ --role-name index-lambda-role \ --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole`
	
	`aws iam attach-role-policy \ --role-name index-lambda-role \ --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaVPCAccessExecutionRole`
		Cloud architect, Cloud administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr>
<td>Create a policy to give the Lambda index function permission to read the S3 objects.</td>
<td>

Run the AWS CLI [create-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/create-policy.html) command to to give the Lambda index function `s3:GetObject` permission to read the objects in the S3 bucket:

```
aws iam create-policy \
  --policy-name s3-permission-policy \
  --policy-document file://s3-policy.json
```

The file `s3-policy.json` is a JSON document shown below that grants `s3:GetObject` permissions to allow read access to S3 objects. If you used a different name when you created the S3 bucket, provide the correct bucket name in the `Resource` section:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::<tenantrawdata>/*"
        }
```

</td>
<td>Cloud architect, Cloud administrator</td>
</tr>
</table>

Task	Description	Skills required

	``
	    ]
	}
	``	

Attach the Amazon S3 permission policy to the Lambda execution role.	Run the AWS CLI [attach-role-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/attach-role-policy.html) command to attach the Amazon S3 permission policy you created in the previous step to the Lambda execution role:
	``
	aws iam attach-role-policy \
	  --role-name index-lambda-role \
	  --policy-arn <PolicyARN>
	``
	where `PolicyARN` is the Amazon Resource Name (ARN) of the Amazon S3 permission policy. You can get this value from the output of the previous command.
		Cloud architect, Cloud administrator

Task	Description	Skills required

Create the Lambda index function.	Run the AWS CLI [create-function](https://docs.aws.amazon.com/cli/latest/reference/lambda/create-function.html) command to create the Lambda index function, which will access OpenSearch Service:
	
	`aws lambda create-function \`
	`  --function-name index-lambda-function \`
	`  --zip-file fileb://index_lambda_package.zip \`
	`  --handler lambda_index.lambda_handler \`
	`  --runtime python3.9 \`
	`  --role "arn:aws:iam::account-id:role/index-lambda-role" \`
	`  --timeout 30 \`
	`  --vpc-config "{\"SubnetIds\": [\"<subnet-id1\>", \"<subnet-id2>\"], \`
	`    \"SecurityGroupIds\": [\"<sg-1>\"]}"`
		Cloud architect, Cloud administrator

Task	Description	Skills required
Allow Amazon S3 to call the Lambda index function.	Run the AWS CLI [add-permission](https://docs.aws.amazon.com/cli/latest/reference/lambda/add-permission.html) command to give Amazon S3 the permission to call the Lambda index function: `aws lambda add-permission \ --function-name index-lambda-function \ --statement-id s3-permissions \ --action lambda:InvokeFunction \ --principal s3.amazonaws.com \ --source-arn "arn:aws:s3:::<tenantrawdata>" \ --source-account "<account-id>"`	Cloud architect, Cloud administrator

Task	Description	Skills required
Add a Lambda trigger for the Amazon S3 event.	Run the AWS CLI put-bucket-notification-configuration command to send notifications to the Lambda index function when the Amazon S3 `ObjectCreated` event is detected. The index function runs whenever an object is uploaded to the S3 bucket. `aws s3api put-bucket-notification-configuration \ --bucket <tenantrawdata> \ --notification-configuration file://s3-trigger.json` The file `s3-trigger.json` is a JSON document in the current folder that adds the resource policy to the Lambda function when the Amazon S3 `ObjectCreated` event occurs.	Cloud architect, Cloud administrator

Create and configure the Lambda search function

Task	Description	Skills required
Create the Lambda execution role.	Run the AWS CLI create-role command to grant the Lambda search function	Cloud architect, Cloud administrator

Task	Description	Skills required

	access to AWS services and resources:
	```aws iam create-role \ --role-name search-lambda-role \ --assume-role-policy-document file://lambda_assume_role.json```
	 where `lambda_assume_role.json` is a JSON document in the current folder that grants `AssumeRole` permissions to the Lambda function, as follows:
	```{ "Version": "2012-10-17", "Statement": [{ "Effect": "Allow", "Principal": { "Service": "lambda.amazonaws.com" }, "Action": "sts:AssumeRole" }] }```	

Task	Description	Skills required

Attach managed policies to the Lambda role.	Run the AWS CLI [attach-role-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/attach-role-policy.html) command to attach managed policies to the role created in the previous step. These two policies give the role permissions to create an elastic network interface and to write logs to CloudWatch Logs.
	`aws iam attach-role-policy \ --role-name search-lambda-role \ --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaBasicExecutionRole`
	
	`aws iam attach-role-policy \ --role-name search-lambda-role \ --policy-arn arn:aws:iam::aws:policy/service-role/AWSLambdaVPCAccessExecutionRole`
		Cloud architect, Cloud administrator

Task	Description	Skills required
Create the Lambda search function.	Run the AWS CLI create-function command to create the Lambda search function, which will access OpenSearch Service: `aws lambda create-function \ --function-name search-lambda-function \ --zip-file fileb://search_lambda_package.zip \ --handler lambda_search.lambda_handler \ --runtime python3.9 \ --role "arn:aws:iam::account-id:role/search-lambda-role" \ --timeout 30 \ --vpc-config "{\"SubnetIds\": [\"<subnet-id1\>", \"<subnet-id2>\"], \ \"SecurityGroupIds\": [\"<sg-1>\"]}"`	Cloud architect, Cloud administrator

```
aws lambda create-function \
  --function-name search-lambda-function \
  --zip-file fileb://search_lambda_package.zip \
  --handler lambda_search.lambda_handler \
  --runtime python3.9 \
  --role "arn:aws:iam::account-id:role/search-lambda-role" \
  --timeout 30 \
  --vpc-config "{\"SubnetIds\": [\"<subnet-id1\>", \"<subnet-id2>\"], \
    \"SecurityGroupIds\": [\"<sg-1>\"]}"
```

Create and configure tenant roles

Task	Description	Skills required
Create tenant IAM roles.	Run the AWS CLI create-role command to create two tenant roles that will be used to test the search functionality:	Cloud architect, Cloud administrator

Task	Description	Skills required

	<pre>aws iam create-role \
	  --role-name Tenant-1-
	role \
	  --assume-role-poli
	cy-document file://as
	sume-role-policy.json</pre><pre>aws iam create-role \
	  --role-name Tenant-2-
	role \
	  --assume-role-poli
	cy-document file://as
	sume-role-policy.json</pre>The file `assume-role-policy.json` is a JSON document in the current folder that grants `AssumeRole` permissions to the Lambda execution role:<pre>{
	    "Version":
	 "2012-10-17",
	    "Statement": [
	        {
	            "Effect":
	 "Allow",
	            "Principa
	l": {
	                 "AWS":
	 "<Lambda execution role
	 for index function>",
	                 "AWS":
	 "<Lambda execution role
	 for search function>"
	             },
	            "Action":
	 "sts:AssumeRole"</pre>	

Task	Description	Skills required

	``
	        }
	    ]
	}
	``	

Task	Description	Skills required

Create a tenant IAM policy.	Run the AWS CLI [create-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/create-policy.html) command to create a tenant policy that grants access to Elasticsearch operations:
	
	`aws iam create-policy \ --policy-name tenant-policy \ --policy-document file://policy.json`
	
	The file `policy.json` is a JSON document in the current folder that grants permissions on Elasticsearch:
	
	`{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Action": [ "es:ESHttpDelete", "es:ESHttpGet", "es:ESHttpHead", "es:ESHttpPost", "es:ESHttpPut", "es:ESHttpPatch" ], "Resource": [`
		Cloud architect, Cloud administrator

Task	Description	Skills required

	``
	                "<ARN of
	 Elasticsearch domain
	 created earlier>"
	            ]
	        }
	    ]
	}
	``	

Attach the tenant IAM policy to the tenant roles.	Run the AWS CLI [attach-role-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/attach-role-policy.html) command to attach the tenant IAM policy to the two tenant roles you created in the earlier step:
	
	``
	aws iam attach-role-policy \
	  --policy-arn
	 arn:aws:iam::account-id:policy/tenant-policy \
	  --role-name Tenant-1-role
	
	aws iam attach-role-policy \
	  --policy-arn
	 arn:aws:iam::account-id:policy/tenant-policy \
	  --role-name Tenant-2-role
	``
	
	The policy ARN is from the output of the previous step.
		Cloud architect, Cloud administrator

Task	Description	Skills required

Create an IAM policy to give Lambda permissions to assume role.	Run the AWS CLI [create-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/create-policy.html) command to create a policy for Lambda to assume the tenant role:
	`aws iam create-policy \ --policy-name assume-tenant-role-policy \ --policy-document file://lambda_policy.json`
	The file `lambda_policy.json` is a JSON document in the current folder that grants permissions to `AssumeRole` :
	`{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Action": "sts:AssumeRole", "Resource": "<ARN of tenant role created earlier>" } ] }`
	For `Resource`, you can use a wildcard character to avoid
		Cloud architect, Cloud administrator

Task	Description	Skills required
	creating a new policy for each tenant.	

Create an IAM policy to give the Lambda index role permission to access Amazon S3.	Run the AWS CLI [create-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/create-policy.html) command to give the Lambda index role permission to access the objects in the S3 bucket:
	`aws iam create-policy \ --policy-name s3-permission-policy \ --policy-document file://s3_lambda_policy.json`
	The file `s3_lambda_policy.json` is the following JSON policy document in the current folder:
	`{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Action": "s3:GetObject", "Resource": "arn:aws:s3:::tenantrawdata/*" } ] }`
		Cloud architect, Cloud administrator

Task	Description	Skills required

Attach the policy to the Lambda execution role.	Run the AWS CLI [attach-role-policy](https://docs.aws.amazon.com/cli/latest/reference/iam/attach-role-policy.html) command to attach the policy created in the previous step to the Lambda index and search execution roles you created earlier:
	`aws iam attach-role-policy \`
	`  --policy-arn arn:aws:iam::account-id:policy/assume-tenant-role-policy \`
	`  --role-name index-lambda-role`
	
	`aws iam attach-role-policy \`
	`  --policy-arn arn:aws:iam::account-id:policy/assume-tenant-role-policy \`
	`  --role-name search-lambda-role`
	
	`aws iam attach-role-policy \`
	`  --policy-arn arn:aws:iam::account-id:policy/s3-permission-policy \`
	`  --role-name index-lambda-role`
	
	The policy ARN is from the output of the previous step.
		Cloud architect, Cloud administrator

Create and configure a search API

Task	Description	Skills required
Create a REST API in API Gateway.	Run the AWS CLI [create-rest-api](https://docs.aws.amazon.com/cli/latest/reference/apigateway/create-rest-api.html) command to create a REST API resource: `aws apigateway create-rest-api \ --name Test-Api \ --endpoint-configuration "{ \"types\": [\"REGIONAL\"] }"` For the endpoint configuration type, you can specify `EDGE` instead of `REGIONAL` to use edge locations instead of a particular AWS Region. Note the value of the `id` field from the command output. This is the API ID that you will use in subsequent commands.	Cloud architect, Cloud administrator
Create a resource for the search API.	The search API resource starts the Lambda search function with the resource name `search`. (You don't have to create an API for the Lambda index function, because it runs automatically when objects are uploaded to the S3 bucket.)	Cloud architect, Cloud administrator

Task	Description	Skills required

	1. Run the AWS CLI get-resources command to get the parent ID for the root path:
	`aws apigateway get-resources \ --rest-api-id <API-ID>`
	Note the value of the ID field. You will use this parent ID in the next command.
	`{ "items": [ { "id": "zpsri964ck", "path": "/" } ] }`
	2. Run the AWS CLI create-resource command to create a resource for the search API. For `parent-id` , specify the ID from the previous command.
	`aws apigateway create-resource \ --rest-api-id <API-ID> \ --parent-id <Parent-ID> \`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code> --path-part search</code></pre></td><td></td></tr>
<tr><td>Create a GET method for the search API.</td><td>Run the AWS CLI put-method command to create a <code>GET</code> method for the search API:<pre><code>aws apigateway put-method \
  --rest-api-id <API-ID> \

  --http-method GET \
  --authorization-type "NONE" \
  --no-api-key-required</code></pre>For <code>resource-id</code>, specify the ID from the output of the <code>create-resource</code> command.</td><td>Cloud architect, Cloud administrator</td></tr>
</table>

Task	Description	Skills required

Create a method response for the search API.	Run the AWS CLI put-method-response command to add a method response for the search API:
	`aws apigateway put-method-response \`
	`  --rest-api-id <API-ID> \`
	`  --resource-id  <ID from the create-resource command output> \`
	`  --http-method GET \`
	`  --status-code 200 \`
	`  --response-models "{\"application/json\": \"Empty\"}"`
	For `resource-id` , specify the ID from the output of the earlier `create-resource` command.
		Cloud architect, Cloud administrator

Task	Description	Skills required
Set up a proxy Lambda integration for the search API.	Run the AWS CLI [put-integration](https://docs.aws.amazon.com/cli/latest/reference/apigateway/put-integration.html) command to set up an integration with the Lambda search function: `aws apigateway put-integration \ --rest-api-id <API-ID> \ --resource-id <ID from the create-resource command output> \ --http-method GET \ --type AWS_PROXY \ --integration-http-method GET \ --uri arn:aws:apigateway:region:lambda:path/2015-03-31/functions/arn:aws:lambda:<region>:<account-id>:function:<function-name>/invocations` For `resource-id` , specify the ID from the earlier `create-resource` command.	Cloud architect, Cloud administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr>
<td>Grant API Gateway permission to call the Lambda search function.</td>
<td>

Run the AWS CLI [add-permission](https://docs.aws.amazon.com/cli/latest/reference/lambda/add-permission.html) command to give API Gateway permission to use the search function:

```
aws lambda add-permission \
  --function-name <function-name> \
  --statement-id apigateway-get \
  --action lambda:InvokeFunction \
  --principal apigateway.amazonaws.com \
  --source-arn "arn:aws:execute-api:<region>:<account-id>:api-id/*/GET/search
```

Change the `source-arn` path if you used a different API resource name instead of `search`.

</table>

Create and configure Kibana roles

Task	Description	Skills required
Log in to the Kibana console.	1. Find the link to Kibana on your domain dashboard on the OpenSearch Service console. The URL is in the form: `<domain-endpoint>/_plugin/kibana/` . 2. Use the bastion host you configured in the first epic to access the Kibana console. 3. Log in to the Kibana console by using the master user name and password from the earlier	Cloud architect, Cloud administrator

Task	Description	Skills required
	step, when you created the OpenSearch Service domain. 4. When prompted to select a tenant, choose **Private**.	

Task	Description	Skills required
Create and configure Kibana roles.	To provide data isolation and to make sure that one tenant cannot retrieve the data of another tenant, you need to use document security, which allows tenants to access only documents that contain their tenant ID. 1. On the Kibana console, in the navigation pane, choose **Security**, **Role**. 2. Create a new tenant role. 3. Set cluster permissions to `indices_all` , which gives create, read, update, and delete (CRUD) permissions on the OpenSearch Service index. 4. Restrict index permissions to the `tenant-data` index. (The index name should match the name in the Lambda search and index functions.) 5. Set index permissions to `indices_all` , to enable users to perform all index-related operations. (You can restrict operations for more granular access, depending on your requirements.)	Cloud architect, Cloud administrator

Task	Description	Skills required
	6. For document-level security, use the following policy to filter documents by tenant ID, to provide data isolation for tenants in a shared index: `{ "bool": { "must": { "match": { "TenantId": "Tenant-1" } } } }` The index name, properties, and values are case-sensitive.	

Task	Description	Skills required
Map users to roles.	1. Choose the **Mapped users** tab for the role, and then choose **Map users**. 2. In the **Backend roles** section, specify the ARN of the IAM tenant role that you created earlier, and then choose **Map**. This maps the IAM tenant role to the Kibana role so that tenant-specific search returns data for that tenant only. For example, if the IAM role name for Tenant-1 is `Tenant-1-Role` , specify the ARN for `Tenant-1-Role` (from the *Create and configure tenant roles* epic) in the **Backend roles** box for the Tenant-1 Kibana role. 3. Repeat steps 1 and 2 for Tenant-2. We recommend that you automate the creation of the tenant and Kibana roles at the time of tenant onboardin g.	Cloud architect, Cloud administrator

Task	Description	Skills required

Create the tenant-data index.	In the navigation pane, under **Management**, choose **Dev Tools**, and then run the following command. This command creates the `tenant-data` index to define the mapping for the `TenantId` property.
	`PUT /tenant-data`
	`{`
	`  "mappings": {`
	`    "properties": {`
	`      "TenantId":`
	` { "type": "keyword"}`
	`    }`
	`  }`
	`}`
		Cloud architect, Cloud administrator

Create VPC endpoints for Amazon S3 and AWS STS

Task	Description	Skills required

Create a VPC endpoint for Amazon S3.	Run the AWS CLI [create-vpc-endpoint](#) command to create a VPC endpoint for Amazon S3. The endpoint enables the Lambda index function in the VPC to access Amazon S3.
	`aws ec2 create-vpc-endpoint \`
	`  --vpc-id <VPC-ID> \`
	`  --service-name com.amazonaws.us-east-1.s3 \`
		Cloud architect, Cloud administrator

Task	Description	Skills required
	` --route-table-ids <route-table-ID>` For `vpc-id`, specify the VPC that you're using for the Lambda index function. For `service-name` , use the correct URL for the Amazon S3 endpoint. For `route-table-ids` , specify the route table that's associated with the VPC endpoint.	

Task	Description	Skills required
Create a VPC endpoint for AWS STS.	Run the AWS CLI [create-vpc-endpoint](https://docs.aws.amazon.com/cli/latest/reference/ec2/create-vpc-endpoint.html) command to create a VPC endpoint for AWS Security Token Service (AWS STS). The endpoint enables the Lambda index and search functions in the VPC to access AWS STS. The functions use AWS STS when they assume the IAM role. `aws ec2 create-vpc-endpoint \ --vpc-id <VPC-ID> \ --vpc-endpoint-type Interface \ --service-name com.amazonaws.us-east-1.sts \ --subnet-id <subnet-ID> \ --security-group-id <security-group-ID>` For `vpc-id`, specify the VPC that you're using for the Lambda index and search functions. For `subnet-id`, provide the subnet in which this endpoint should be created. For `security-group-id`, specify the security group to associate this endpoint with. (It could be the same as the security group Lambda uses.)	Cloud architect, Cloud administrator

Test multi-tenancy and data isolation

Task	Description	Skills required
Update the Python files for the index and search functions.	1. In the `index_lambda_package.zip` file, edit the `lamba_index.py` file to update the AWS account ID, AWS Region, and Elasticsearch endpoint information. 2. In the `search_lambda_package.zip` file, edit the `lambda_search.py` file to update the AWS account ID, AWS Region, and Elasticsearch endpoint information. You can get the Elasticsearch endpoint from the **Overview** tab of the OpenSearch Service console. It has the format `<AWS-Region>.es.amazonaws.com` .	Cloud architect, App developer
Update the Lambda code.	Use the AWS CLI [update-function-code](https://docs.aws.amazon.com/cli/latest/reference/lambda/update-function-code.html) command to update the Lambda code with the changes you made to the Python files: `aws lambda update-function-code \`	Cloud architect, App developer

Task	Description	Skills required

	`--function-name index-lambda-function \ --zip-file fileb://index_lambda_package.zip`
	
	`aws lambda update-function-code \ --function-name search-lambda-function \ --zip-file fileb://search_lambda_package.zip`	

Upload raw data to the S3 bucket.	Use the AWS CLI [cp](https://docs.aws.amazon.com/cli/latest/reference/s3/cp.html) command to upload data for the Tenant-1 and Tenant-2 objects to the `tenantrawdata` bucket (specify the name of the S3 bucket you created for this purpose):
	
	`aws s3 cp tenant-1-data s3://tenantrawdata`
	`aws s3 cp tenant-2-data s3://tenantrawdata`
	
	The S3 bucket is set up to run the Lambda index function whenever data is uploaded so that the document is indexed in Elasticsearch.
		Cloud architect, Cloud administrator

Task	Description	Skills required
Search data from the Kibana console.	On the Kibana console, run the following query: `GET tenant-data/_search` This query displays all the documents indexed in Elasticsearch. In this case, you should see two separate documents for Tenant-1 and Tenant-2.	Cloud architect, Cloud administrator

Task	Description	Skills required

Test the search API from API Gateway.	1. In the API Gateway console, open the search API, choose the GET method inside the search resource, and then choose **Test**.
	2. In the test window, provide the following query string (case-sensitive) for the tenant ID, and then choose **Test**.
	`TenantId=Tenant-1`
	The Lambda function sends a query to OpenSearch Service that filters the tenant document based on the document-level security. The method returns the document that belongs to Tenant-1.
	3. Change the query string to:
	`TenantId=Tenant-2`
	This query returns the document that belongs to Tenant-2.
	
	For screen illustrations, see the [Additional information](#) section.
		Cloud architect, App developer

Task	Description	Skills required
Clean up resources.	Clean up all the resources you created to prevent additional charges to your account.	AWS DevOps, Cloud architect, Cloud administrator

Additional information

Data partitioning models

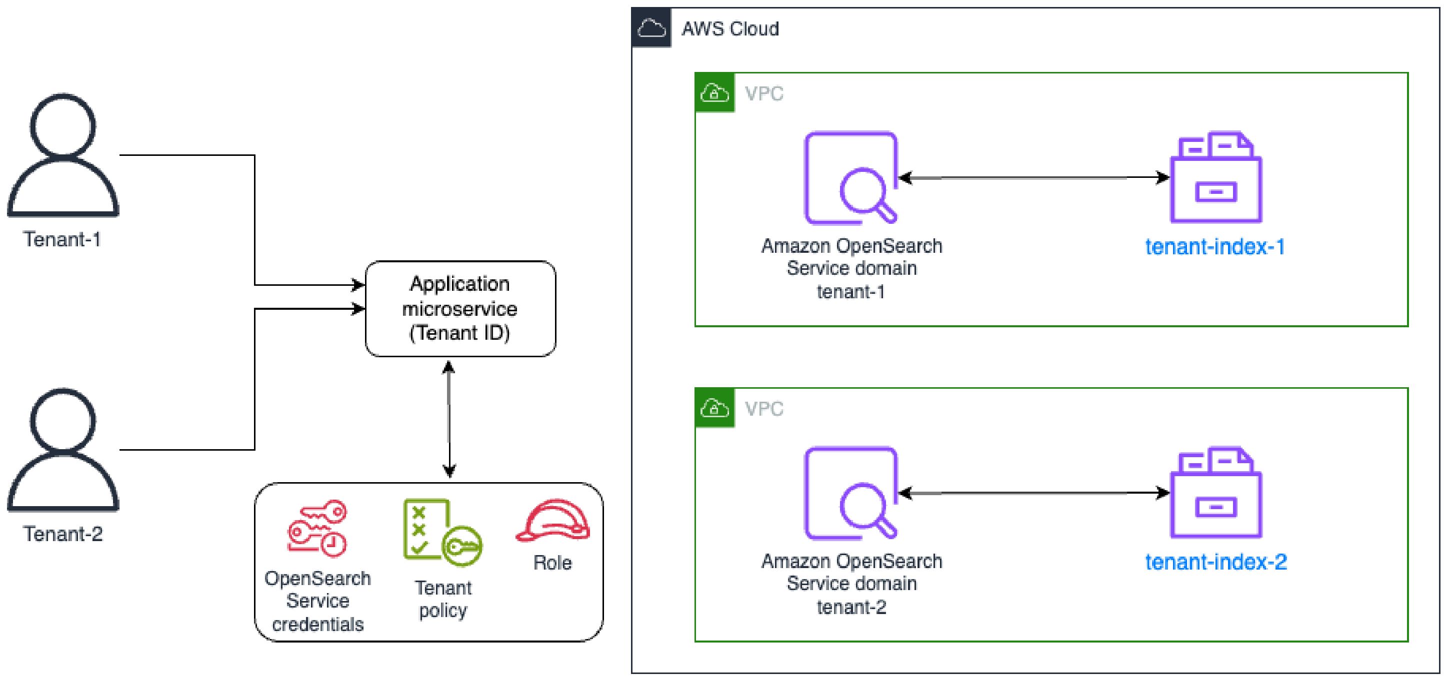
There are three common data partitioning models used in multi-tenant systems: silo, pool, and hybrid. The model you choose depends on the compliance, noisy neighbor, operations, and isolation needs of your environment.

Silo model

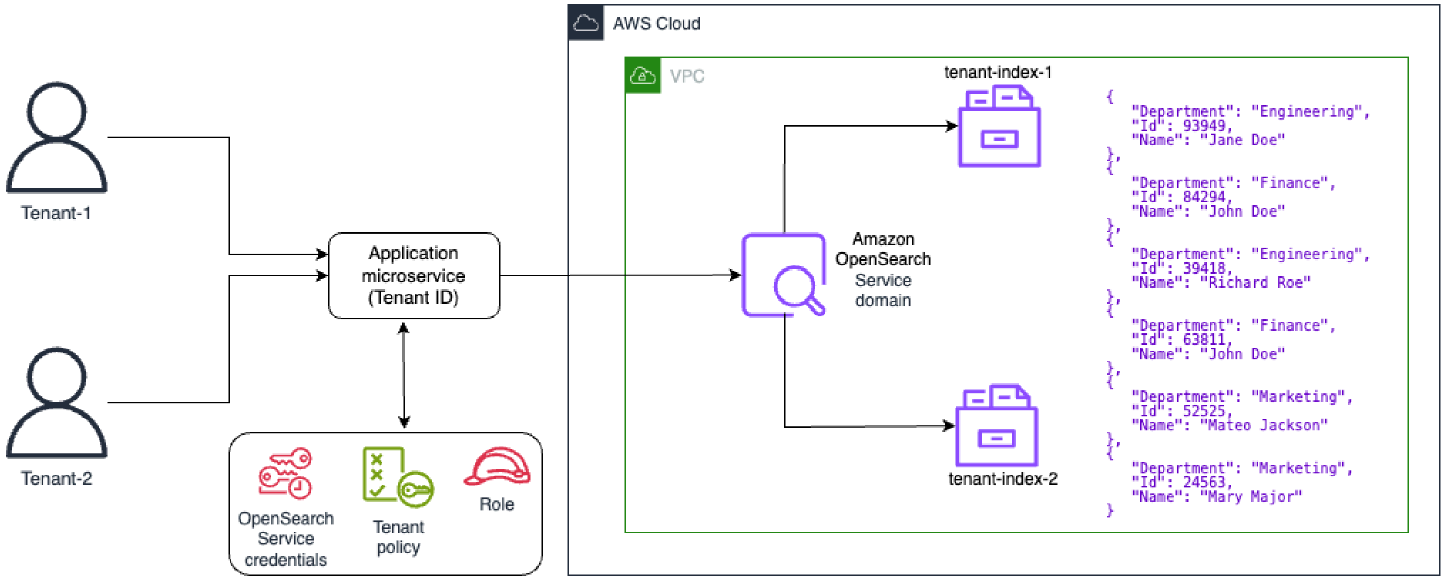
In the silo model, each tenant's data is stored in a distinct storage area where there is no commingling of tenant data. You can use two approaches to implement the silo model with OpenSearch Service: domain per tenant and index per tenant.

- **Domain per tenant** – You can use a separate OpenSearch Service domain (synonymous with an Elasticsearch cluster) per tenant. Placing each tenant in its own domain provides all the benefits associated with having data in a standalone construct. However, this approach introduces management and agility challenges. Its distributed nature makes it harder to aggregate and assess the operational health and activity of tenants. This is a costly option that requires each

OpenSearch Service domain to have three master nodes and two data nodes for production workloads at the minimum.



- **Index per tenant** – You can place tenant data in separate indexes within an OpenSearch Service cluster. With this approach, you use a tenant identifier when you create and name the index, by prepending the tenant identifier to the index name. The index per tenant approach helps you achieve your silo goals without introducing a completely separate cluster for each tenant. However, you might encounter memory pressure if the number of indexes grows, because this approach requires more shards, and the master node has to handle more allocation and rebalancing.



Isolation in the silo model – In the silo model, you use IAM policies to isolate the domains or indexes that hold each tenant's data. These policies prevent one tenant from accessing another tenant's data. To implement your silo isolation model, you can create a resource-based policy that controls access to your tenant resource. This is often a domain access policy that specifies which actions a principal can perform on the domain's sub-resources, including Elasticsearch indexes and APIs. With IAM identity-based polices, you can specify *allowed* or *denied* actions on the domain, indexes, or APIs within OpenSearch Service. The `Action` element of an IAM policy describes the specific action or actions that are allowed or denied by the policy, and the `Principal` element specifies the affected accounts, users, or roles.

The following sample policy grants Tenant-1 full access (as specified by `es:*`) to the sub-resources on the `tenant-1` domain only. The trailing `/*` in the `Resource` element indicates that this policy applies to the domain's sub-resources, not to the domain itself. When this policy is in effect, tenants are not allowed to create a new domain or modify settings on an existing domain.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::<aws-account-id>:user/Tenant-1"
         },
         "Action": "es:*",
         "Resource": "arn:aws:es:<Region>:<account-id>:domain/tenant-1/*"
```

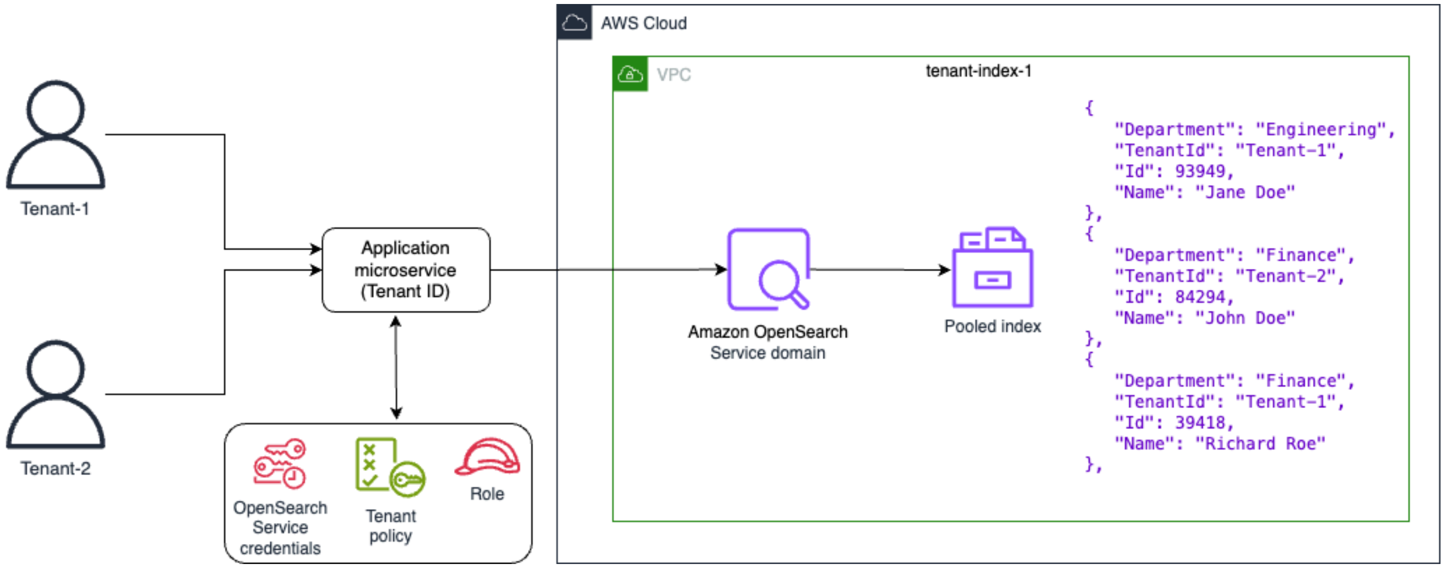
```
        }
    ]
}
```

To implement the tenant per index silo model, you would need to modify this sample policy to further restrict Tenant-1 to the specified index or indexes, by specifying the index name. The following sample policy restricts Tenant-1 to the `tenant-index-1` index.

```
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "AWS": "arn:aws:iam::123456789012:user/Tenant-1"
         },
         "Action": "es:*",
         "Resource": "arn:aws:es:<Region>:<account-id>:domain/test-domain/tenant-
index-1/*"
      }
   ]
}
```

Pool model

In the pool model, all tenant data is stored in an index within the same domain. The tenant identifier is included in the data (document) and used as the partition key, so you can determine which data belongs to which tenant. This model reduces the management overhead. Operating and managing the pooled index is easier and more efficient than managing multiple indexes. However, because tenant data is commingled within the same index, you lose the natural tenant isolation that the silo model provides. This approach might also degrade performance because of the noisy neighbor effect.



Tenant isolation in the pool model – In general, tenant isolation is challenging to implement in the pool model. The IAM mechanism used with the silo model doesn't allow you to describe isolation based on the tenant ID stored in your document.

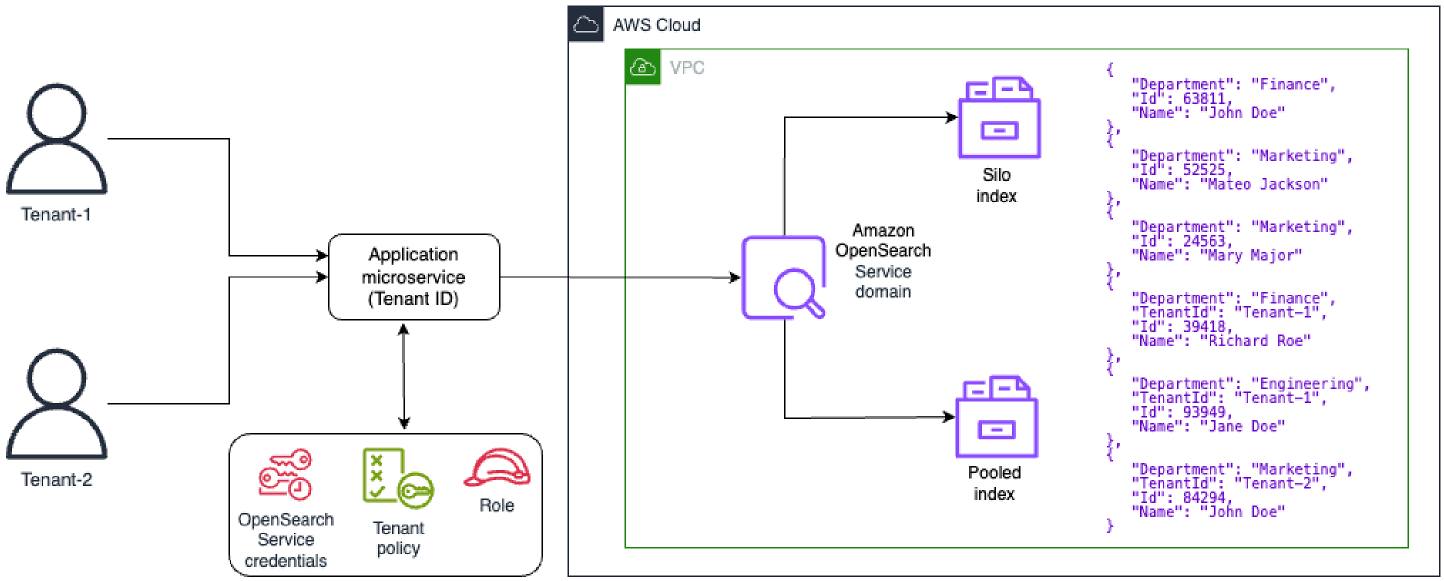
An alternative approach is to use the fine-grained access control (FGAC) support provided by the Open Distro for Elasticsearch. FGAC allows you to control permissions at an index, document, or field level. With each request, FGAC evaluates the user credentials and either authenticates the user or denies access. If FGAC authenticates the user, it fetches all roles mapped to that user and uses the complete set of permissions to determine how to handle the request.

To achieve the required isolation in the pooled model, you can use document-level security, which lets you restrict a role to a subset of documents in an index. The following sample role restricts queries to Tenant-1. By applying this role to Tenant-1, you can achieve the necessary isolation.

```
{
   "bool": {
     "must": {
       "match": {
         "tenantId": "Tenant-1"
       }
     }
   }
 }
```

Hybrid model

The hybrid model uses a combination of the silo and pool models in the same environment to offer unique experiences to each tenant tier (such as free, standard, and premium tiers). Each tier follows the same security profile that was used in the pool model.



Tenant isolation in the hybrid model – In the hybrid model, you follow the same security profile as in the pool model, where using the FGAC security model at the document level provided tenant isolation. Although this strategy simplifies cluster management and offers agility, it complicates other aspects of the architecture. For example, your code requires additional complexity to determine which model is associated with each tenant. You also have to ensure that single-tenant queries don't saturate the entire domain and degrade the experience for other tenants.

Deploy multiple-stack applications using AWS CDK with TypeScript

Dr. Rahul Sharad Gaikwad, Amazon Web Services

Summary

This pattern provides a step-by-step approach for application deployment on Amazon Web Services (AWS) using AWS Cloud Development Kit (AWS CDK) with TypeScript. As an example, the pattern deploys a serverless real-time analytics application.

The pattern builds and deploys nested stack applications. The parent AWS CloudFormation stack calls the child, or nested, stacks. Each child stack builds and deploys the AWS resources that are defined in the CloudFormation stack. AWS CDK Toolkit, the command line interface (CLI) command `cdk`, is the primary interface for the CloudFormation stacks.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Existing virtual private cloud (VPC) and subnets
- AWS CDK Toolkit installed and configured
- A user with administrator permissions and a set of access keys.
- Node.js
- AWS Command Line Interface (AWS CLI)

Limitations

- Because AWS CDK uses AWS CloudFormation, AWS CDK applications are subject to CloudFormation service quotas. For more information, see [AWS CloudFormation quotas].

Product versions

This pattern has been built and tested using the following tools and versions.

- AWS CDK Toolkit 1.83.0
- Node.js 14.13.0

- npm 7.0.14

The pattern should work with any version of AWS CDK or npm. Note that Node.js versions 13.0.0 through 13.6.0 are not compatible with the AWS CDK.

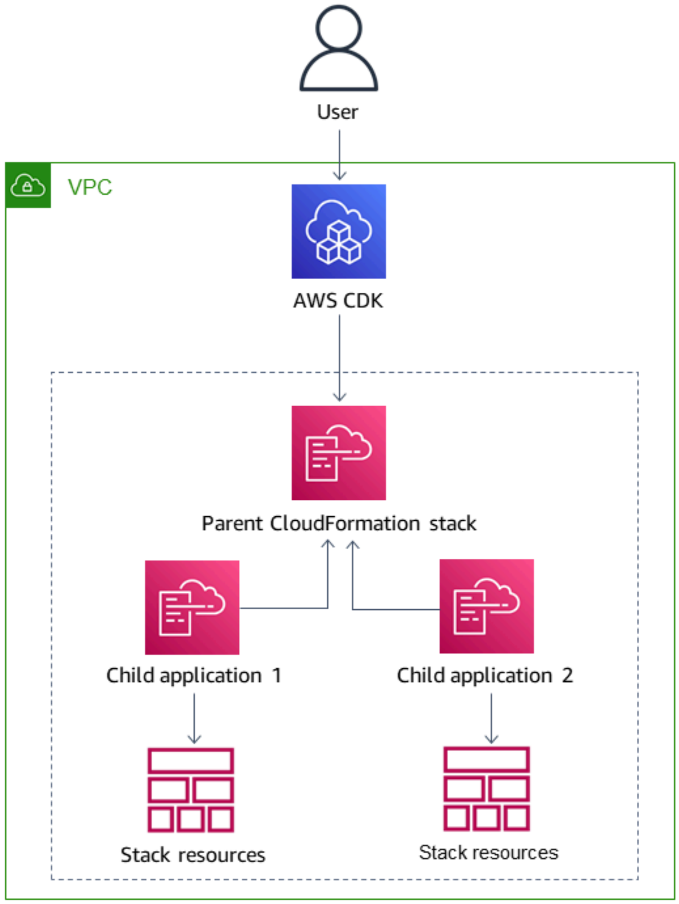
Architecture

Target technology stack

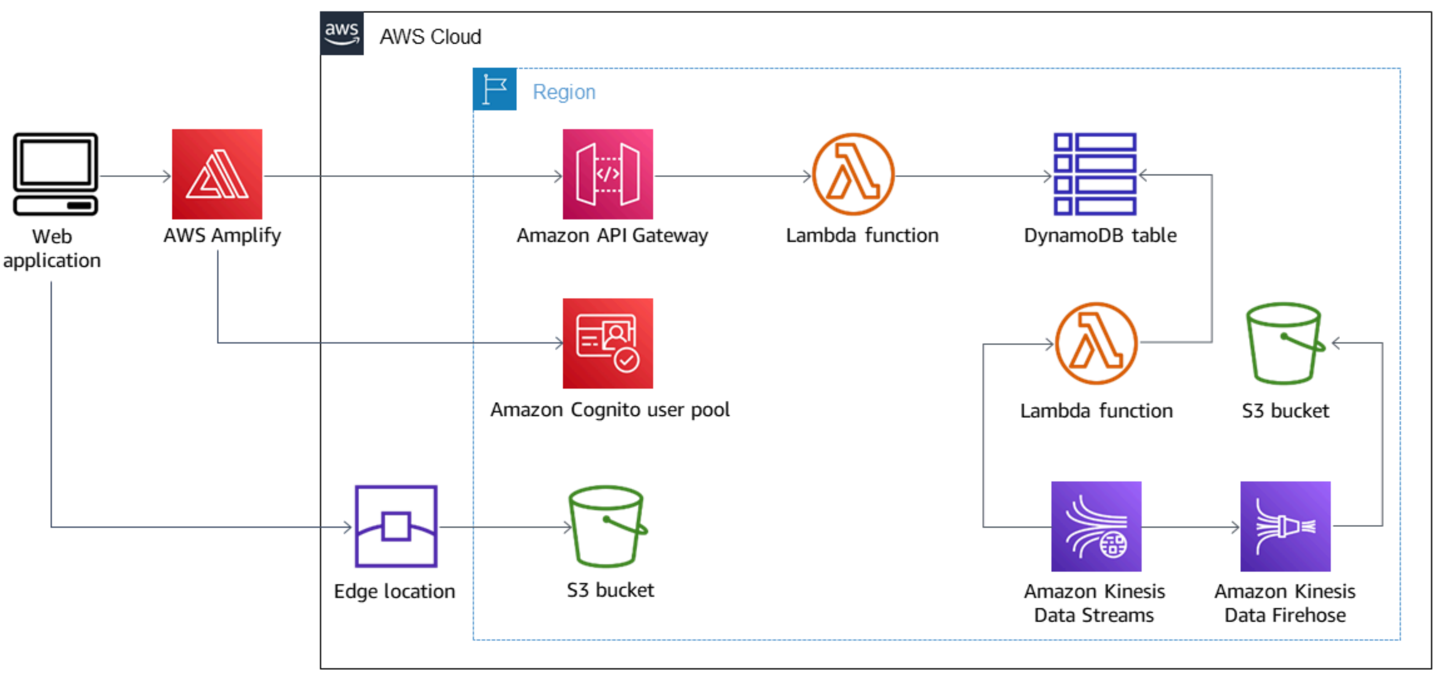
- AWS Amplify Console
- Amazon API Gateway
- AWS CDK
- Amazon CloudFront
- Amazon Cognito
- Amazon DynamoDB
- Amazon Data Firehose
- Amazon Kinesis Data Streams
- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)

Target architecture

The following diagram shows multiple-stack application deployment using AWS CDK with TypeScript.



The following diagram shows the architecture of the example serverless real-time application.



Tools

Tools

- AWS Amplify Console is the control center for fullstack web and mobile application deployments in AWS. Amplify Console hosting provides a git-based workflow for hosting fullstack serverless web apps with continuous deployment. The Admin UI is a visual interface for frontend web and mobile developers to create and manage app backends outside the AWS console.
- Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CDK Toolkit is a command line cloud development kit that helps you interact with your AWS CDK app. The `cdk` CLI command is the primary tool for interacting with your AWS CDK app. It runs your app, interrogates the application model you defined, and produces and deploys the AWS CloudFormation templates generated by the AWS CDK.
- Amazon CloudFront is a web service that speeds up distribution of static and dynamic web content, such as .html, .css, .js, and image files. CloudFront delivers your content through a worldwide network of data centers called edge locations for lower latency and improved performance.
- Amazon Cognito provides authentication, authorization, and user management for your web and mobile apps. Your users can sign in directly or through a third party.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- Amazon Data Firehose is a fully managed service for delivering real-time streaming data to destinations such as Amazon S3, Amazon Redshift, Amazon OpenSearch Service, Splunk, and any custom HTTP endpoint or HTTP endpoints owned by supported third-party service providers.
- Amazon Kinesis Data Streams is a service for collecting and processing large streams of data records in real time.
- AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code

The code for this pattern is attached.

Epics

Install AWS CDK Toolkit

Task	Description	Skills required
Install AWS CDK Toolkit.	To install AWS CDK Toolkit globally, run the following command. `npm install -g aws-cdk`	DevOps
Verify the version.	To verify the AWS CDK Toolkit version, run the following command. `cdk --version`	DevOps

Set up AWS credentials

Task	Description	Skills required

Set up credentials.	To set up credentials, run the `aws configure` command and follow the prompts.
	
	`$aws configure`
	`AWS Access Key ID [None]:`
	`AWS Secret Access Key [None]: your_secret_access_key`
	`Default region name [None]:`
		DevOps

Task	Description	Skills required
	`Default output format [None]:`	

Download the project code

Task	Description	Skills required
Download the attached project code.	For more information about the directory and file structure, see the *Additional information* section.	DevOps

Bootstrap the AWS CDK environment

Task	Description	Skills required
Bootstrap the environment.	To deploy the AWS CloudFormation template to the account and AWS Region that you want to use, run the following command. `cdk bootstrap <account>/<Region>` For more information, see the AWS documentation.	DevOps

Build and deploy the project

Task	Description	Skills required
Build the project.	To build the project code, run the `npm run build` command.	DevOps
Deploy the project.	To deploy the project code, run the `cdk deploy` command.	

Verify outputs

Task	Description	Skills required
Verify stack creation.	On the AWS Management Console, choose **CloudFormation**. In the stacks for the project, verify that a parent stack and two child stacks have been created.	DevOps

Test the application

Task	Description	Skills required
Send data to Kinesis Data Streams.	Configure your AWS Account to send data to Kinesis Data Streams using Amazon Kinesis Data Generator (KDG). For more information, see [Amazon Kinesis Data Generator]().	DevOps

Task	Description	Skills required
Create an Amazon Cognito user.	To create an Amazon Cognito user, download the cognito-setup.json CloudFormation template from the *Create an Amazon Cognito User* section on the [Kinesis Data Generator help page](). Initiate the template, and then enter your Amazon Cognito **Username** and **Password**. The **Outputs** tab lists the Kinesis Data Generator URL.	DevOps
Log in to Kinesis Data Generator	To log in to KDG, use the Amazon Cognito credentia ls that you provided and the Kinesis Data Generator URL.	DevOps
Test the application.	In KDG, in **Record template**, **Template 1**, paste the test code from the *Additiona l information* section, and choose **Send data**.	DevOps
Test API Gateway.	After the data has been ingested, test API Gateway by using the GET method to retrieve data.	DevOps

- Working with nested stacks
- AWS sample example - Serverless real-time analytics

Additional information

Directory and file details

This pattern sets up the following three stacks.

- `parent-cdk-stack.ts` – This stack acts as the parent stack and calls the two child applications as nested stacks.
- `real-time-analytics-poc-stack.ts` – This nested stack contains the infrastructure and application code.
- `real-time-analytics-web-stack.ts` – This nested stack contains only the static web application code.

Important files and their functionality

- `bin/real-time-analytics-poc.ts` – Entry point of the AWS CDK application. It loads all stacks defined under `lib/`.
- `lib/real-time-analytics-poc-stack.ts` – Definition of the AWS CDK application's stack (`real-time-analytics-poc`).
- `lib/real-time-analytics-web-stack.ts` – Definition of the AWS CDK application's stack (`real-time-analytics-web-stack`).
- `lib/parent-cdk-stack.ts` – Definition of the AWS CDK application's stack (`parent-cdk`).
- `package.json` – npm module manifest, which includes the application name, version, and dependencies.
- `package-lock.json` – Maintained by npm.
- `cdk.json` – Toolkit for running the application.
- `tsconfig.json` – The project's TypeScript configuration.
- `.gitignore` – List of files that Git should exclude from source control.
- `node_modules` – Maintained by npm; includes the project's dependencies.

The following section of code in the parent stack calls child applications as a nested AWS CDK stacks.

```
import * as cdk from '@aws-cdk/core';
import { Construct, Stack, StackProps } from '@aws-cdk/core';
import { RealTimeAnalyticsPocStack } from './real-time-analytics-poc-stack';
import { RealTimeAnalyticsWebStack } from './real-time-analytics-web-stack';

export class CdkParentStack extends Stack {
  constructor(scope: Construct, id: string, props?: StackProps) {
    super(scope, id, props);

    new RealTimeAnalyticsPocStack(this, 'RealTimeAnalyticsPocStack');
    new RealTimeAnalyticsWebStack(this, 'RealTimeAnalyticsWebStack');
  }
}
```

Code for testing

```
session={{date.now('YYYYMMDD')}}|sequence={{date.now('x')}}|
reception={{date.now('x')}}|instrument={{random.number(9)}}|
l={{random.number(20)}}|price_0={{random.number({"min":10000,
 "max":30000})}}|price_1={{random.number({"min":10000, "max":30000})}}|
price_2={{random.number({"min":10000, "max":30000})}}|
price_3={{random.number({"min":10000, "max":30000})}}|
price_4={{random.number({"min":10000, "max":30000})}}|
price_5={{random.number({"min":10000, "max":30000})}}|
price_6={{random.number({"min":10000, "max":30000})}}|
price_7={{random.number({"min":10000, "max":30000})}}|
price_8={{random.number({"min":10000, "max":30000})}}|
```

Testing API Gateway

On the API Gateway console, test API Gateway by using the GET method.

Automate deployment of nested applications using AWS SAM

Dr. Rahul Sharad Gaikwad, Ishwar Chauthaiwale, Dmitry Gulin, and Tabby Ward, Amazon Web Services

Summary

On Amazon Web Services (AWS), AWS Serverless Application Model (AWS SAM) is an open-source framework that provides shorthand syntax to express functions, APIs, databases, and event source mappings. With just a few lines for each resource, you can define the application you want and model it by using YAML. During deployment, SAM transforms and expands the SAM syntax into AWS CloudFormation syntax that you can use to build serverless applications faster.

AWS SAM simplifies the development, deployment, and management of serverless applications on the AWS platform. It provides a standardized framework, faster deployment, local testing capabilities, resource management, seamless Integration with Development Tools, and a supportive community. These features make it a valuable tool for building serverless applications efficiently and effectively.

This pattern uses AWS SAM templates to automate the deployment of nested applications. A nested application is an application within another application. Parent applications call their child applications. These are loosely coupled components of a serverless architecture.

Using nested applications, you can rapidly build highly sophisticated serverless architectures by reusing services or components that are independently authored and maintained but are composed using AWS SAM and the Serverless Application Repository. Nested applications help you to build applications that are more powerful, avoid duplicated work, and ensure consistency and best practices across your teams and organizations. To demonstrate nested applications, the pattern deploys an example AWS serverless shopping cart application.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An existing virtual private cloud (VPC) and subnets
- An integrated development environment such as Visual Studio Code (for more information, see Tools to Build on AWS)

- Python wheel library installed using pip install wheel, if it’s not already installed

Limitations

- The maximum number of applications that can be nested in a serverless application is 200.
- The maximum number of parameters for a nested application can have 60.

Product versions

- This solution is built on AWS SAM command line interface (AWS SAM CLI) version 1.21.1, but this architecture should work with later AWS SAM CLI versions.

Architecture

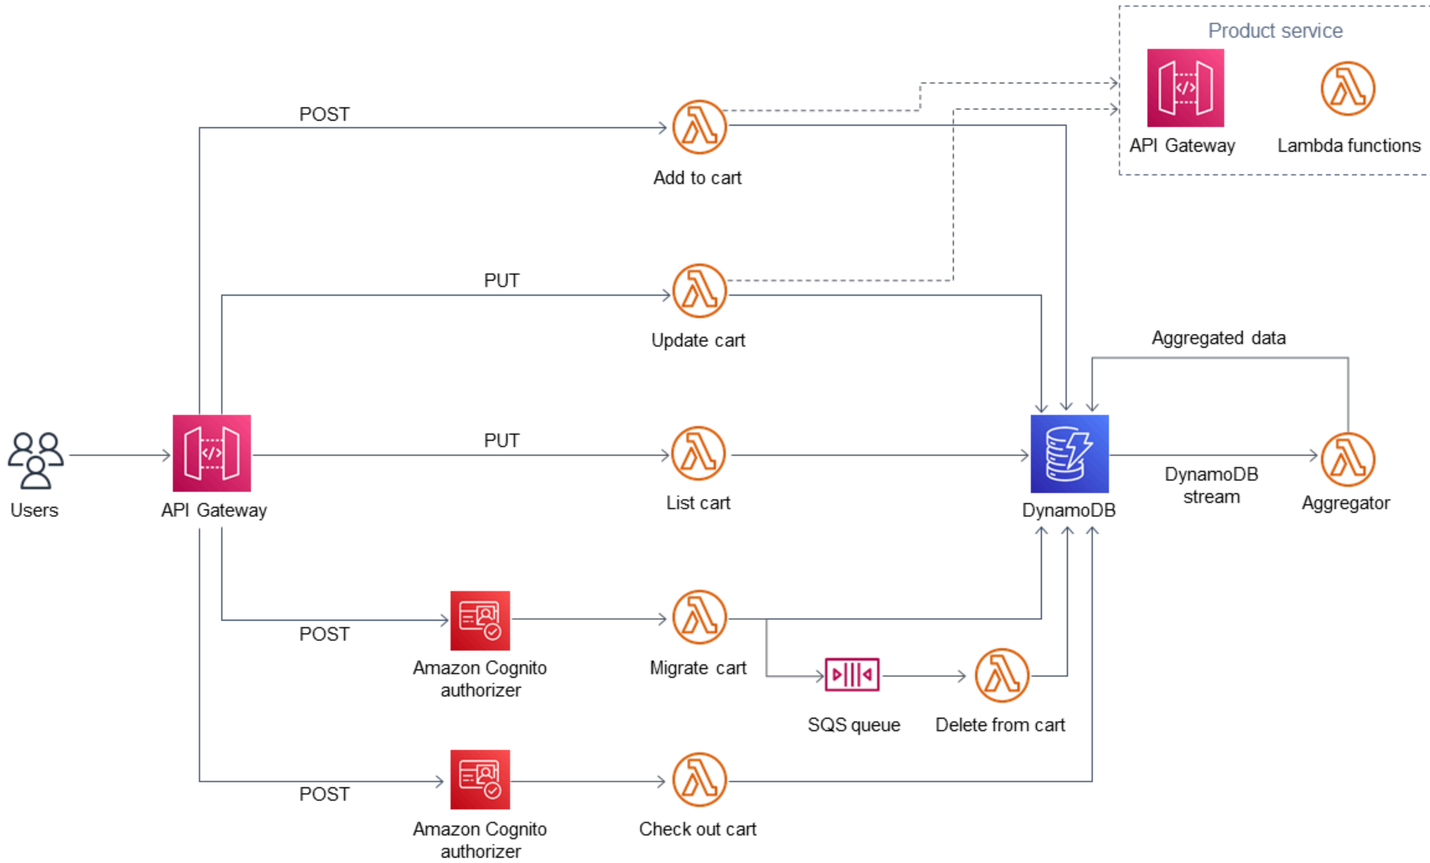
Target technology stack

- Amazon API Gateway
- AWS SAM
- Amazon Cognito
- Amazon DynamoDB
- AWS Lambda
- Amazon Simple Queue Service (Amazon SQS) queue

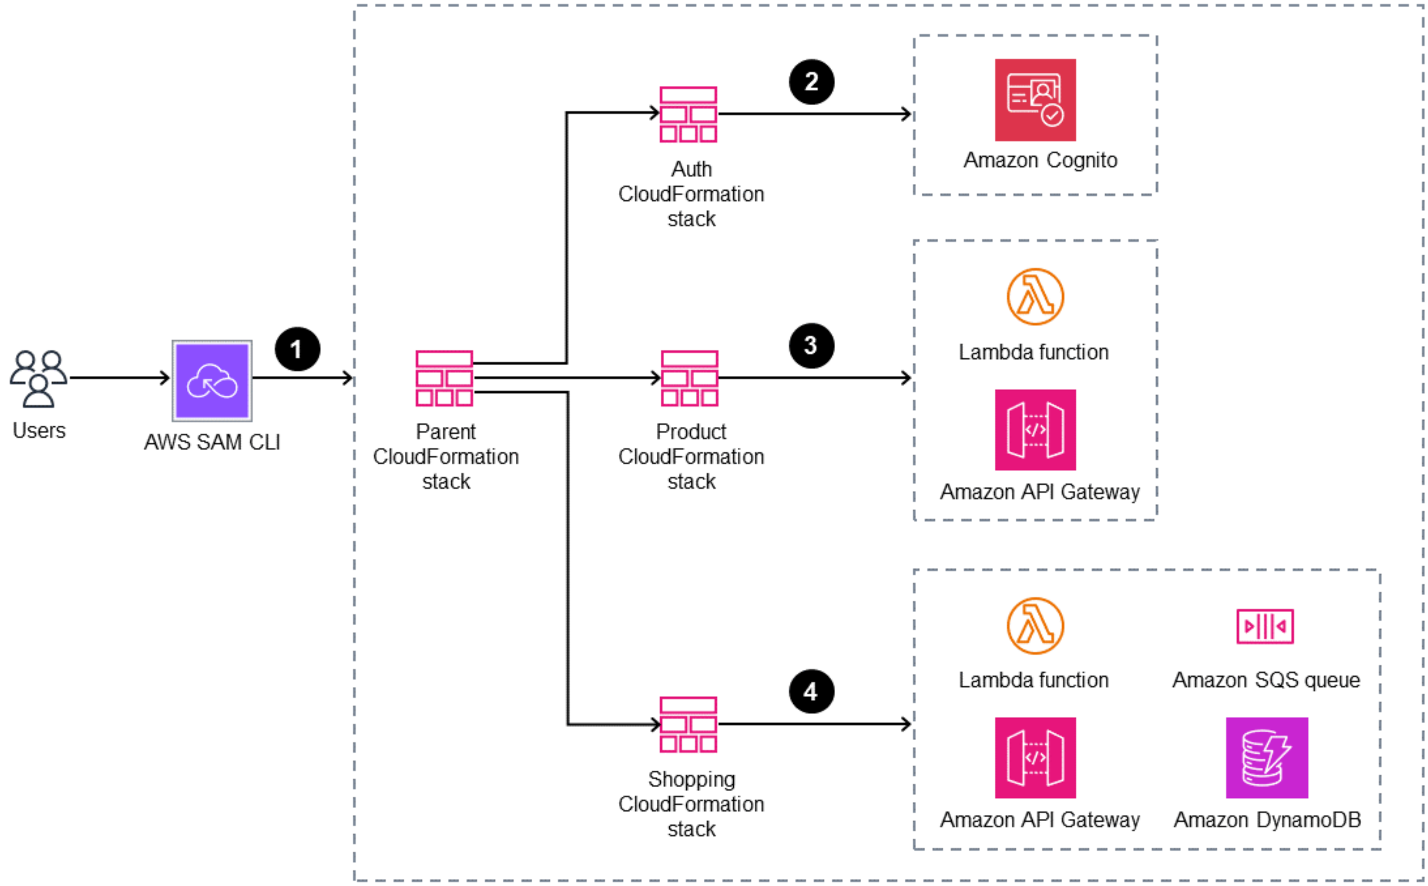
Target architecture

The following diagram shows how user requests are made to the shopping services by calling APIs. The user's request, including all necessary information, is sent to Amazon API Gateway and the Amazon Cognito authorizer, which performs authentication and authorization mechanisms for the APIs.

When an item is added, deleted, or updated in DynamoDB, an event is put onto DynamoDB Streams, which in turn initiates a Lambda function. To avoid immediate deletion of old items as part of a synchronous workflow, messages are put onto an SQS queue, which initiates a worker function to delete the messages.



In this solution setup, AWS SAM CLI serves as the interface for AWS CloudFormation stacks. AWS SAM templates automatically deploy nested applications. The parent SAM template calls the child templates, and the parent CloudFormation stack deploys the child stacks. Each child stack builds the AWS resources that are defined in the AWS SAM CloudFormation templates.



1. Build and deploy the stacks.
2. The Auth CloudFormation stack contains Amazon Cognito.
3. The Product CloudFormation stack contains an Lambda function and Amazon API Gateway
4. The Shopping CloudFormation stack contains a Lambda function, Amazon API Gateway, the SQS queue, and the Amazon DynamoDB database.

Tools

Tools

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- Amazon Cognito provides authentication, authorization, and user management for web and mobile apps.

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Serverless Application Model (AWS SAM) is an open-source framework that helps you build serverless applications in the AWS Cloud.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

Code

The code for this pattern is available in the GitHub AWS SAM Nested Stack Sample repository.

Epics

Install AWS SAM CLI

Task	Description	Skills required
Install AWS SAM CLI.	To install AWS SAM CLI, see the instructions in the AWS SAM documentation.	DevOps engineer

Set up AWS credentials.	To set AWS credentials so that the AWS SAM CLI can make calls to AWS services on your behalf, run the `aws configure` command and follow the prompts.
	`$aws configure`
	`AWS Access Key ID [None]: <your_access_key_id>`
	`AWS Secret Access Key [None]: your_secret_access_key`
		DevOps engineer

Task	Description	Skills required

	`Default region name [None]:`
	`Default output format [None]:`
	
	For more information on setting up your credentials, see Authentication and access credentials.	

Initialize the AWS SAM project

Task	Description	Skills required

Clone the AWS SAM code repository.	1. Clone the aws sam nested stack sample repository for this pattern by entering the following command.
	`git clone https://github.com/aws-samples/aws-sam-nested-stack-sample.git`
	2. Navigate into the cloned directory by entering the following command.
	`cd aws-sam-nested-stack-sample`
		DevOps engineer

Deploy templates to initialize the project.	To initialize the project, run the SAM `init` command. When prompted to choose a template source, choose	DevOps engineer

Task	Description	Skills required
	`Custom Template Location`.	

Compile and build the SAM template code

Task	Description	Skills required
Review the AWS SAM application templates.	Review the templates for the nested applications. This example uses the following nested application templates: • `auth.yaml` – This template sets up authentication-related resources, such as Amazon Cognito and AWS Systems Manager Parameter Store. • `product-mock.yaml` – This template deploys product-related resources, such as Lambda functions and Amazon API Gateway. • `shoppingcart-service.yaml` – This template sets up shopping cart–related resources, such as AWS Identity and Access Management (IAM), DynamoDB tables, and Lambda functions.	DevOps engineer
Review the parent template.	Review the template that will invoke the nested application	DevOps engineer

Task	Description	Skills required
	templates. In this example, the parent template is `template.yml` . All separate applications are nested in the single parent template `template.yml` .	
Compile and build the AWS SAM template code.	Using the AWS SAM CLI, run the following command. `sam build`	DevOps engineer

Deploy the AWS SAM template

Task	Description	Skills required
Deploy the applications.	To launch the SAM template code that creates the nested application CloudFormation stacks and deploys code in the AWS environment, run the following command. `sam deploy --guided --stack-name shopping-cart-nested-stack --capabilities CAPABILITY_IAM CAPABILITY_AUTO_EXPAND` The command will prompt with a few questions. Answer all questions with `y`.	DevOps engineer

Verify the deployment

Task	Description	Skills required
Verify the stacks.	To review the AWS CloudFormation stacks and AWS resources that were defined in the AWS SAM templates, do the following: 1. Log in to the AWS Management Console, and navigate to the **CloudFormation** console. 2. Verify that the parent and child stacks are listed. In this example, `sam-shopping-cart` is the parent stack that calls the nested Auth, Product and Shopping stacks. The product stack gives the Product API Gateway URL link as an output.	DevOps engineer

Additional information

After all the code is in place, the example has the following directory structure:

- sam_stacks – This folder contains the `shared.py` layer. A layer is a file archive that contains libraries, a custom runtime, or other dependencies. With layers, you can use libraries in your function without needing to include them in a deployment package.
- *product-mock-service* – This folder contains all product-related Lambda functions and files.
- *shopping-cart-service* – This folder contains all shopping-related Lambda functions and files.

Implement the serverless saga pattern by using AWS Step Functions

Tabby Ward, Joe Kern, and Rohan Mehta, Amazon Web Services

Summary

In a microservices architecture, the main goal is to build decoupled and independent components to promote agility, flexibility, and faster time to market for your applications. As a result of decoupling, each microservice component has its own data persistence layer. In a distributed architecture, business transactions can span multiple microservices. Because these microservices cannot use a single atomicity, consistency, isolation, durability (ACID) transaction, you might end up with partial transactions. In this case, some control logic is needed to undo the transactions that have already been processed. The distributed saga pattern is typically used for this purpose.

The saga pattern is a failure management pattern that helps establish consistency in distributed applications and coordinates transactions between multiple microservices to maintain data consistency. When you use the saga pattern, every service that performs a transaction publishes an event that triggers subsequent services to perform the next transaction in the chain. This continues until the last transaction in the chain is complete. If a business transaction fails, saga orchestrates a series of compensating transactions that undo the changes that were made by the preceding transactions.

This pattern demonstrates how to automate the setup and deployment of a sample application (which handles travel reservations) with serverless technologies such as AWS Step Functions, AWS Lambda, and Amazon DynamoDB. The sample application also uses Amazon API Gateway and Amazon Simple Notification Service (Amazon SNS) to implement a saga execution coordinator. The pattern can be deployed with an infrastructure as code (IaC) framework such as the AWS Cloud Development Kit (AWS CDK), the AWS Serverless Application Model (AWS SAM), or Terraform.

For more information about the saga pattern and other data persistence patterns, see the guide [Enabling data persistence in microservices] on the AWS Prescriptive Guidance website.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Permissions to create an AWS CloudFormation stack. For more information, see [Controlling access] in the CloudFormation documentation.

- IaC framework of your choice (AWS CDK, AWS SAM, or Terraform) configured with your AWS account so that you can use the framework CLI to deploy the application.
- NodeJS, used to build the application and run it locally.
- A code editor of your choice (such as Visual Studio Code, Sublime, or Atom).

Product versions

- NodeJS version 14
- AWS CDK version 2.37.1
- AWS SAM version 1.71.0
- Terraform version 1.3.7

Limitations

Event sourcing is a natural way to implement the saga orchestration pattern in a microservices architecture where all components are loosely coupled and don't have direct knowledge of one another. If your transaction involves a small number of steps (three to five), the saga pattern might be a great fit. However complexity increases with the number of microservices and the number of steps.

Testing and debugging can become difficult when you're using this design, because you have to have all services running in order to simulate the transaction pattern.

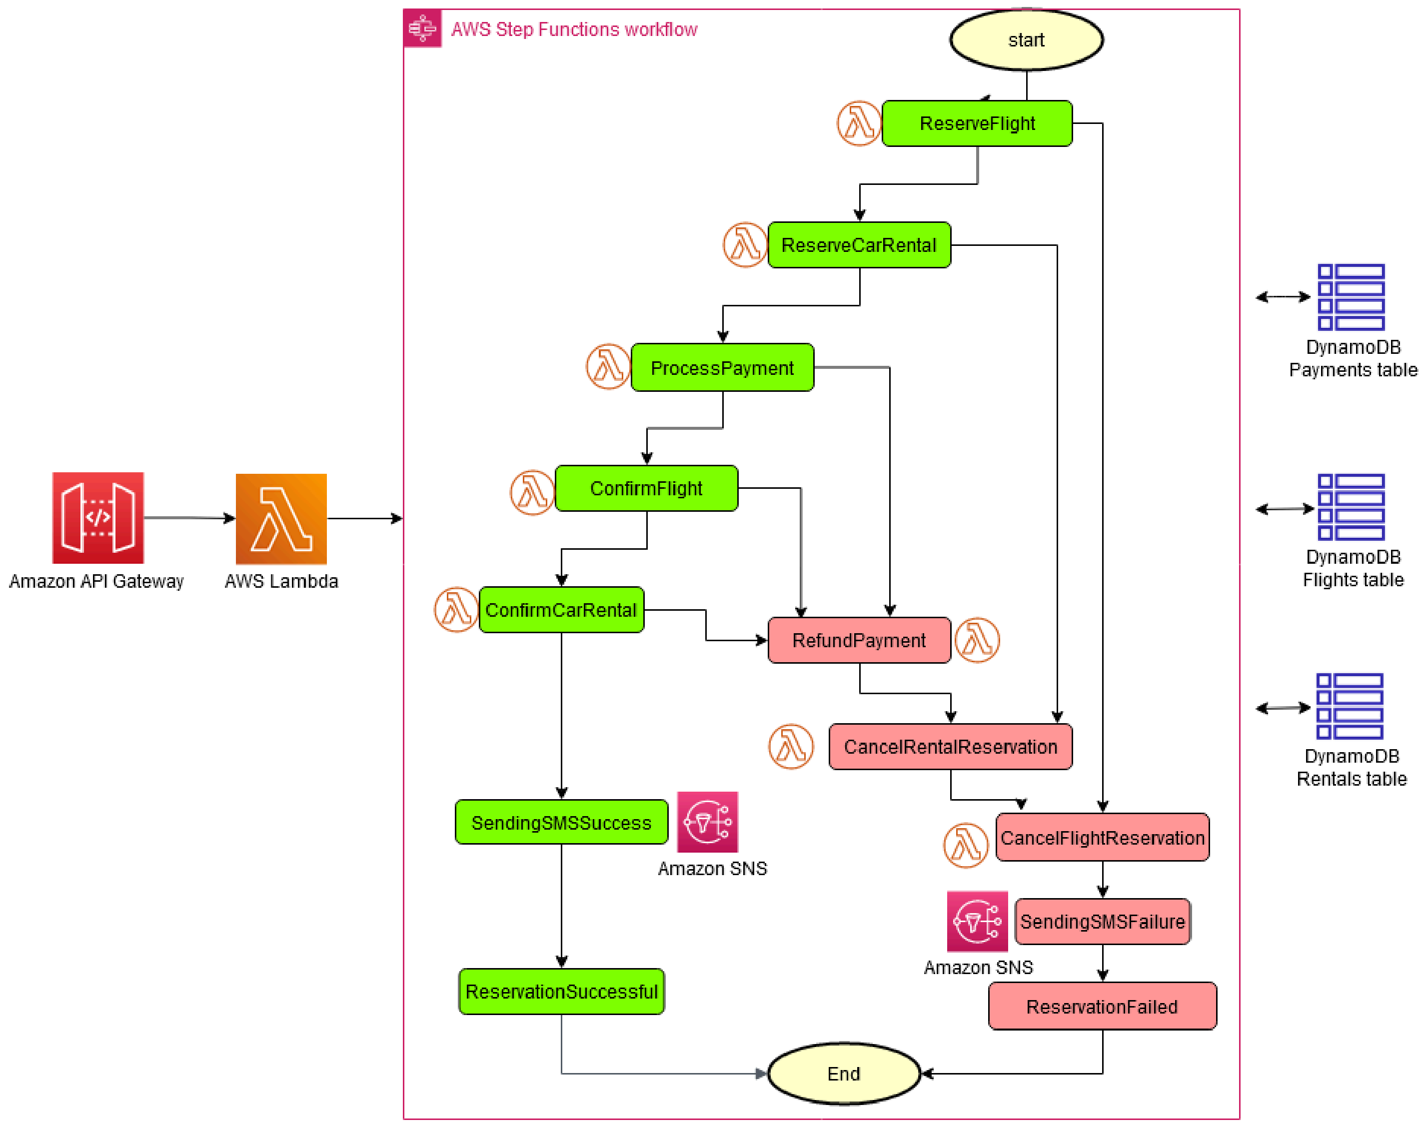
Architecture

Target architecture

The proposed architecture uses AWS Step Functions to build a saga pattern to book flights, book car rentals, and process payments for a vacation.

The following workflow diagram illustrates the typical flow of the travel reservation system. The workflow consists of reserving air travel ("ReserveFlight"), reserving a car ("ReserveCarRental"), processing payments ("ProcessPayment"), confirming flight reservations ("ConfirmFlight"), and confirming car rentals ("ConfirmCarRental") followed by a success notification when these steps are complete. However, if the system encounters any errors in running any of these transactions, it starts to fail backward. For example, an error with payment processing ("ProcessPayment") triggers a refund ("RefundPayment"), which then triggers a cancellation of the rental car and flight ("CancelRentalReservation" and "CancelFlightReservation"), which ends the entire transaction with a failure message.

This pattern deploys separate Lambda functions for each task that is highlighted in the diagram as well as three DynamoDB tables for flights, car rentals, and payments. Each Lambda function creates, updates, or deletes the rows in the respective DynamoDB tables, depending on whether a transaction is confirmed or rolled back. The pattern uses Amazon SNS to send text (SMS) messages to subscribers, notifying them of failed or successful transactions.



Automation and scale

You can create the configuration for this architecture by using one of the IaC frameworks. Use one of the following links for your preferred IaC.

- [Deploy with AWS CDK]
- [Deploy with AWS SAM]
- [Deploy with Terraform]

Tools

AWS services

- AWS Step Functions is a serverless orchestration service that lets you combine AWS Lambda functions and other AWS services to build business-critical applications. Through the Step Functions graphical console, you see your application's workflow as a series of event-driven steps.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability. You can use DynamoDB to create a database table that can store and retrieve any amount of data, and serve any level of request traffic.
- AWS Lambda is a compute service that lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.
- Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.
- AWS Cloud Development Kit (AWS CDK) is a software development framework for defining your cloud application resources by using familiar programming languages such as TypeScript, JavaScript, Python, Java, and C#/.Net.
- AWS Serverless Application Model (AWS SAM) is an open-source framework for building serverless applications. It provides shorthand syntax to express functions, APIs, databases, and event source mappings.

Code

The code for a sample application that demonstrates the saga pattern, including the IaC template (AWS CDK, AWS SAM, or Terraform), the Lambda functions, and the DynamoDB tables can be found in the following links. Follow the instructions in the first epic to install these.

- Deploy with AWS CDK

- Deploy with AWS SAM
- Deploy with Terraform

Epics

Install packages, compile, and build

Task	Description	Skills required
Install the NPM packages.	Create a new directory, navigate to that directory in a terminal, and clone the GitHub repository of your choice from the *Code* section earlier in this pattern. In the root folder that has the `package.json` file, run the following command to download and install all Node Package Manager (NPM) packages: `npm install`	Developer, Cloud architect
Compile scripts.	In the root folder, run the following command to instruct the TypeScrip t transpiler to create all necessary JavaScript files: `npm run build`	Developer, Cloud architect
Watch for changes and recompile.	In the root folder, run the following command in a separate terminal window to watch for code changes,	Developer, Cloud architect

Task	Description	Skills required
	and compile the code when it detects a change: ```npm run watch```	
Run unit tests (AWS CDK only).	If you're using the AWS CDK, in the root folder, run the following command to perform the Jest unit tests: ```npm run test```	Developer, Cloud architect

Deploy resources to the target AWS account

Task	Description	Skills required
Deploy the demo stack to AWS.	**Important** The application is AWS Region-agnostic. If you use a profile, you must declare the Region explicitly in either the [AWS Command Line Interface (AWS CLI) profile](#) or through [AWS CLI environment variables.](#) In the root folder, run the following command to create a deployment assembly and	Developer, Cloud architect

Task	Description	Skills required

	to deploy it to the default AWS account and Region.
	
	AWS CDK:
	
	`cdk bootstrap`
	`cdk deploy`
	
	AWS SAM:
	
	`sam build`
	`sam deploy --guided`
	
	Terraform:
	
	`terraform init`
	`terraform apply`
	
	This step might take several minutes to complete.
	This command uses the default credentials that were configured for the AWS CLI.
	
	Note the API Gateway URL that is displayed on the console after deployment is complete. You will need this information to test the saga execution flow.	

Task	Description	Skills required

Compare the deployed stack with the current state.	In the root folder, run the following command to compare the deployed stack with the current state after making changes to the source code:
	
	AWS CDK:
	
	`cdk diff`
	
	AWS SAM:
	
	`sam deploy`
	
	Terraform:
	
	`terraform plan`
		Developer, Cloud architect

Test the execution flow

Task	Description	Skills required
Test the saga execution flow.	Navigate to the API Gateway URL that you noted in the earlier step, when you deployed the stack. This URL triggers the state machine to start. For more information about how to manipulate the flow of the state machine by passing different URL parameters, see the Additional information section.	Developer, Cloud architect

Task	Description	Skills required
	To view the results, sign in to the AWS Management Console and navigate to the Step Functions console. Here, you can see every step of the saga state machine. You can also view the DynamoDB table to see the records inserted, updated, or deleted. If you refresh the screen frequently, you can watch the transaction status change from `pending` to `confirmed` . You can subscribe to the SNS topic by updating the code in the `stateMachine.ts` file with your cell phone number to receive SMS messages upon successful or failed reservations. For more information, see *Amazon SNS* in the [Additional information](#) section.	

Clean up

Task	Description	Skills required
Clean up resources.	To clean up the resources deployed for this application, you can use one of the following commands.	App developer, Cloud architect

Task	Description	Skills required
	AWS CDK: `cdk destroy` AWS SAM: `sam delete` Terraform: `terraform destroy`

Additional information

Code

For testing purposes, this pattern deploys API Gateway and a test Lambda function that triggers the Step Functions state machine. With Step Functions, you can control the functionality of the travel reservation system by passing a `run_type` parameter to mimic failures in "ReserveFlight," "ReserveCarRental," "ProcessPayment," "ConfirmFlight," and "ConfirmCarRental."

The `saga` Lambda function (`sagaLambda.ts`) takes input from the query parameters in the API Gateway URL, creates the following JSON object, and passes it to Step Functions for execution:

```
let input = {
"trip_id": tripID, //  value taken from query parameter, default is AWS request ID
"depart_city": "Detroit",
"depart_time": "2021-07-07T06:00:00.000Z",
"arrive_city": "Frankfurt",
"arrive_time": "2021-07-09T08:00:00.000Z",
"rental": "BMW",
"rental_from": "2021-07-09T00:00:00.000Z",
"rental_to": "2021-07-17T00:00:00.000Z",
"run_type": runType // value taken from query parameter, default is "success"
};
```

You can experiment with different flows of the Step Functions state machine by passing the following URL parameters:

- **Successful Execution** — https://{api gateway url}
- **Reserve Flight Fail** — https://{api gateway url}?**runType=failFlightsReservation**
- **Confirm Flight Fail** — https://{api gateway url}?**runType=failFlightsConfirmation**
- **Reserve Car Rental Fail** — https://{api gateway url}?**runType=failCarRentalReservation**
- **Confirm Car Rental Fail** — https://{api gateway url}?**runType=failCarRentalConfirmation**
- **Process Payment Fail** — https://{api gateway url}?**runType=failPayment**
- **Pass a Trip ID** — https://{api gateway url}?**tripID=**{by default, trip ID will be the AWS request ID}

IaC templates

The linked repositories include IaC templates that you can use to create the entire sample travel reservation application.

- [Deploy with AWS CDK]
- [Deploy with AWS SAM]
- [Deploy with Terraform]

DynamoDB tables

Here are the data models for the flights, car rentals, and payments tables.

```
Flight Data Model:
 var params = {
      TableName: process.env.TABLE_NAME,
      Item: {
        'pk' : {S: event.trip_id},
        'sk' : {S: flightReservationID},
        'trip_id' : {S: event.trip_id},
        'id': {S: flightReservationID},
        'depart_city' : {S: event.depart_city},
        'depart_time': {S: event.depart_time},
        'arrive_city': {S: event.arrive_city},
        'arrive_time': {S: event.arrive_time},
        'transaction_status': {S: 'pending'}
      }
    };

Car Rental Data Model:
var params = {
      TableName: process.env.TABLE_NAME,
      Item: {
        'pk' : {S: event.trip_id},
        'sk' : {S: carRentalReservationID},
        'trip_id' : {S: event.trip_id},
        'id': {S: carRentalReservationID},
        'rental': {S: event.rental},
        'rental_from': {S: event.rental_from},
        'rental_to': {S: event.rental_to},
        'transaction_status': {S: 'pending'}
      }
    };

Payment Data Model:
var params = {
      TableName: process.env.TABLE_NAME,
```

```
      Item: {
        'pk' : {S: event.trip_id},
        'sk' : {S: paymentID},
        'trip_id' : {S: event.trip_id},
        'id': {S: paymentID},
        'amount': {S: "750.00"}, // hard coded for simplicity as implementing any 
monetary transaction functionality is beyond the scope of this pattern
        'currency': {S: "USD"},
        'transaction_status': {S: "confirmed"}
      }
    };
```

Lambda functions

The following functions will be created to support the state machine flow and execution in Step Functions:

- **Reserve Flights**: Inserts a record into the DynamoDB Flights table with a `transaction_status` of `pending`, to book a flight.
- **Confirm Flight**: Updates the record in the DynamoDB Flights table, to set `transaction_status` to `confirmed`, to confirm the flight.
- **Cancel Flights Reservation**: Deletes the record from the DynamoDB Flights table, to cancel the pending flight.
- **Reserve Car Rentals**: Inserts a record into the DynamoDB CarRentals table with a `transaction_status` of `pending`, to book a car rental.
- **Confirm Car Rentals**: Updates the record in the DynamoDB CarRentals table, to set `transaction_status` to `confirmed`, to confirm the car rental.
- **Cancel Car Rentals Reservation:** Deletes the record from the DynamoDB CarRentals table, to cancel the pending car rental.
- **Process Payment**: Inserts a record into the DynamoDB Payment table for the payment.
- **Cancel Payment**: Deletes the record from the DynamoDB Payments table for the payment.

Amazon SNS

The sample application creates the following topic and subscription for sending SMS messages and notifying the customer about successful or failed reservations. If you want to receive text messages while testing the sample application, update the SMS subscription with your valid phone number in the state machine definition file.

AWS CDK snippet (add the phone number in the second line of the following code):

```
const topic = new  sns.Topic(this, 'Topic');
topic.addSubscription(new subscriptions.SmsSubscription('+11111111111'));
const snsNotificationFailure = new tasks.SnsPublish(this ,'SendingSMSFailure', {
topic:topic,
integrationPattern: sfn.IntegrationPattern.REQUEST_RESPONSE,
message: sfn.TaskInput.fromText('Your Travel Reservation Failed'),
});

const snsNotificationSuccess = new tasks.SnsPublish(this ,'SendingSMSSuccess', {
topic:topic,
integrationPattern: sfn.IntegrationPattern.REQUEST_RESPONSE,
message: sfn.TaskInput.fromText('Your Travel Reservation is Successful'),
});
```

AWS SAM snippet (replace the +1111111111 strings with your valid phone number):

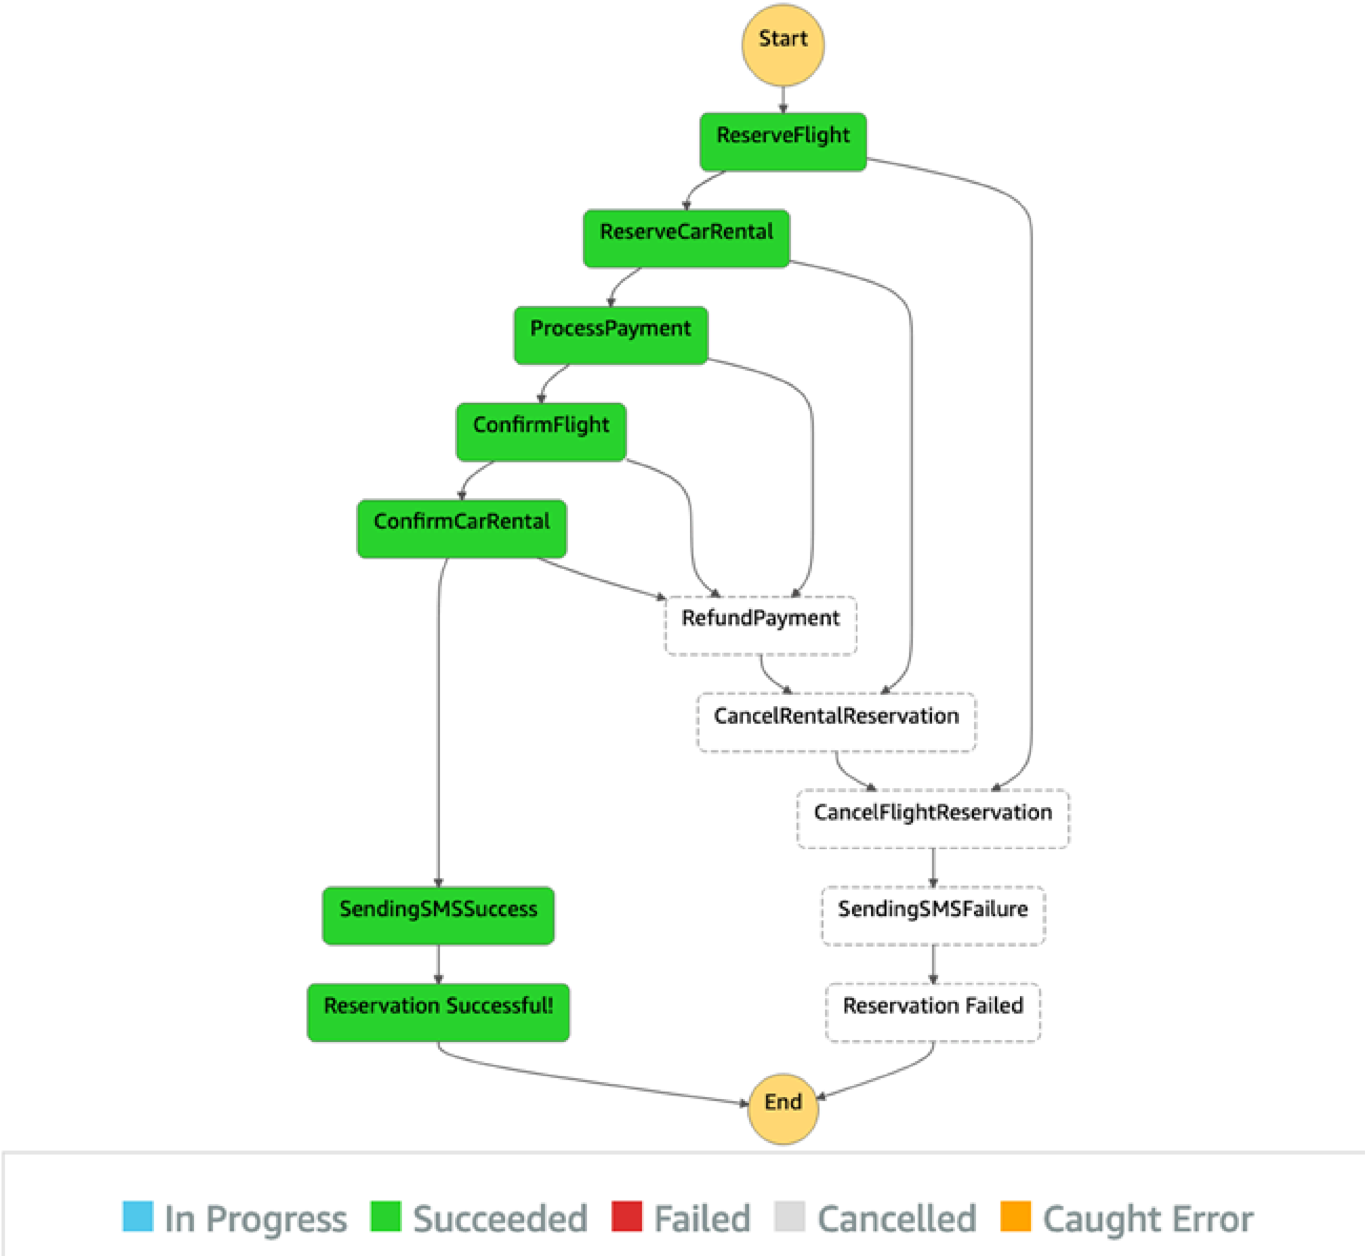
```
  StateMachineTopic11111111111:
    Type: 'AWS::SNS::Subscription'
    Properties:
      Protocol: sms
      TopicArn:
        Ref: StateMachineTopic
      Endpoint: '+11111111111'
    Metadata:
      'aws:sam:path': SamServerlessSagaStack/StateMachine/Topic/+11111111111/Resource
```

Terraform snippet (replace the +111111111 string with your valid phone number):

```
resource "aws_sns_topic_subscription" "sms-target" {
  topic_arn = aws_sns_topic.topic.arn
  protocol  = "sms"
  endpoint  = "+11111111111"
}
```

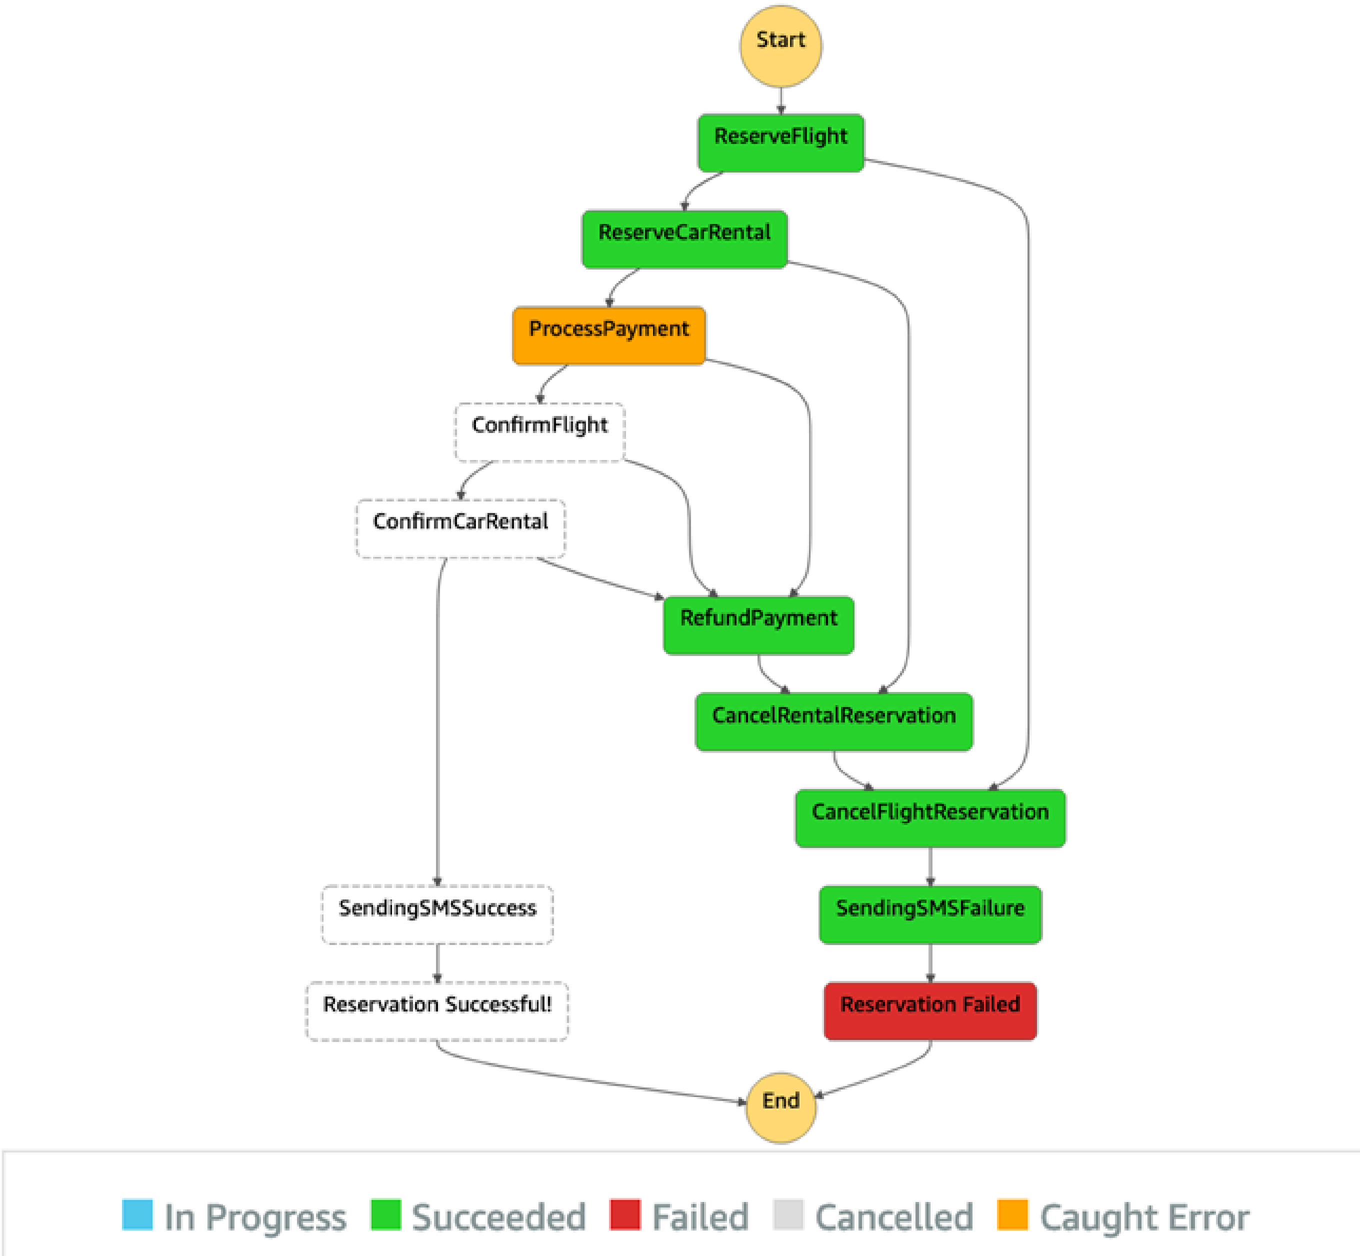
Successful reservations

The following flow illustrates a successful reservation with "ReserveFlight," "ReserveCarRental," and "ProcessPayment" followed by "ConfirmFlight" and "ConfirmCarRental." The customer is notified about the successful booking through SMS messages that are sent to the subscriber of the SNS topic.



Failed reservations

This flow is an example of failure in the saga pattern. If, after booking flights and car rentals, "ProcessPayment" fails, steps are canceled in reverse order. The reservations are released, and the customer is notified of the failure through SMS messages that are sent to the subscriber of the SNS topic.



Start
ReserveFlight
ReserveCarRental
ProcessPayment
ConfirmFlight
ConfirmCarRental
RefundPayment
CancelRentalReservation
CancelFlightReservation
SendingSMSSuccess
SendingSMSFailure
Reservation Successful!
Reservation Failed
End

Manage on-premises container applications by setting up Amazon ECS Anywhere with the AWS CDK

Dr. Rahul Sharad Gaikwad, Amazon Web Services

Summary

[Amazon ECS Anywhere](https://aws.amazon.com/ecs/anywhere/) is an extension of the Amazon Elastic Container Service (Amazon ECS). You can use ECS Anywhere to deploy native Amazon ECS tasks in an on-premises or customer-managed environment. This feature helps reduce costs and mitigate complex local container orchestration and operations. You can use ECS Anywhere to deploy and run container applications in both on-premises and cloud environments. It removes the need for your team to learn multiple domains and skill sets, or to manage complex software on their own.

This pattern demonstrates the steps to set up ECS Anywhere by using AWS Cloud Development Kit (AWS CDK) stacks.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. (See Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.)
- AWS CDK Toolkit, installed and configured. (See AWS CDK Toolkit in the AWS CDK documentation, and follow the instructions to install version 2 globally.)
- Node package manager (npm), installed and configured for the AWS CDK in TypeScript. (See Downloading and installing Node.js and npm in the npm documentation.)

Limitations

- For limitations and considerations, see External instances (Amazon ECS Anywhere) in the Amazon ECS documentation.

Product versions

- AWS CDK Toolkit version 2

- npm version 7.20.3 or later
- Node.js version 16.6.1 or later

Architecture

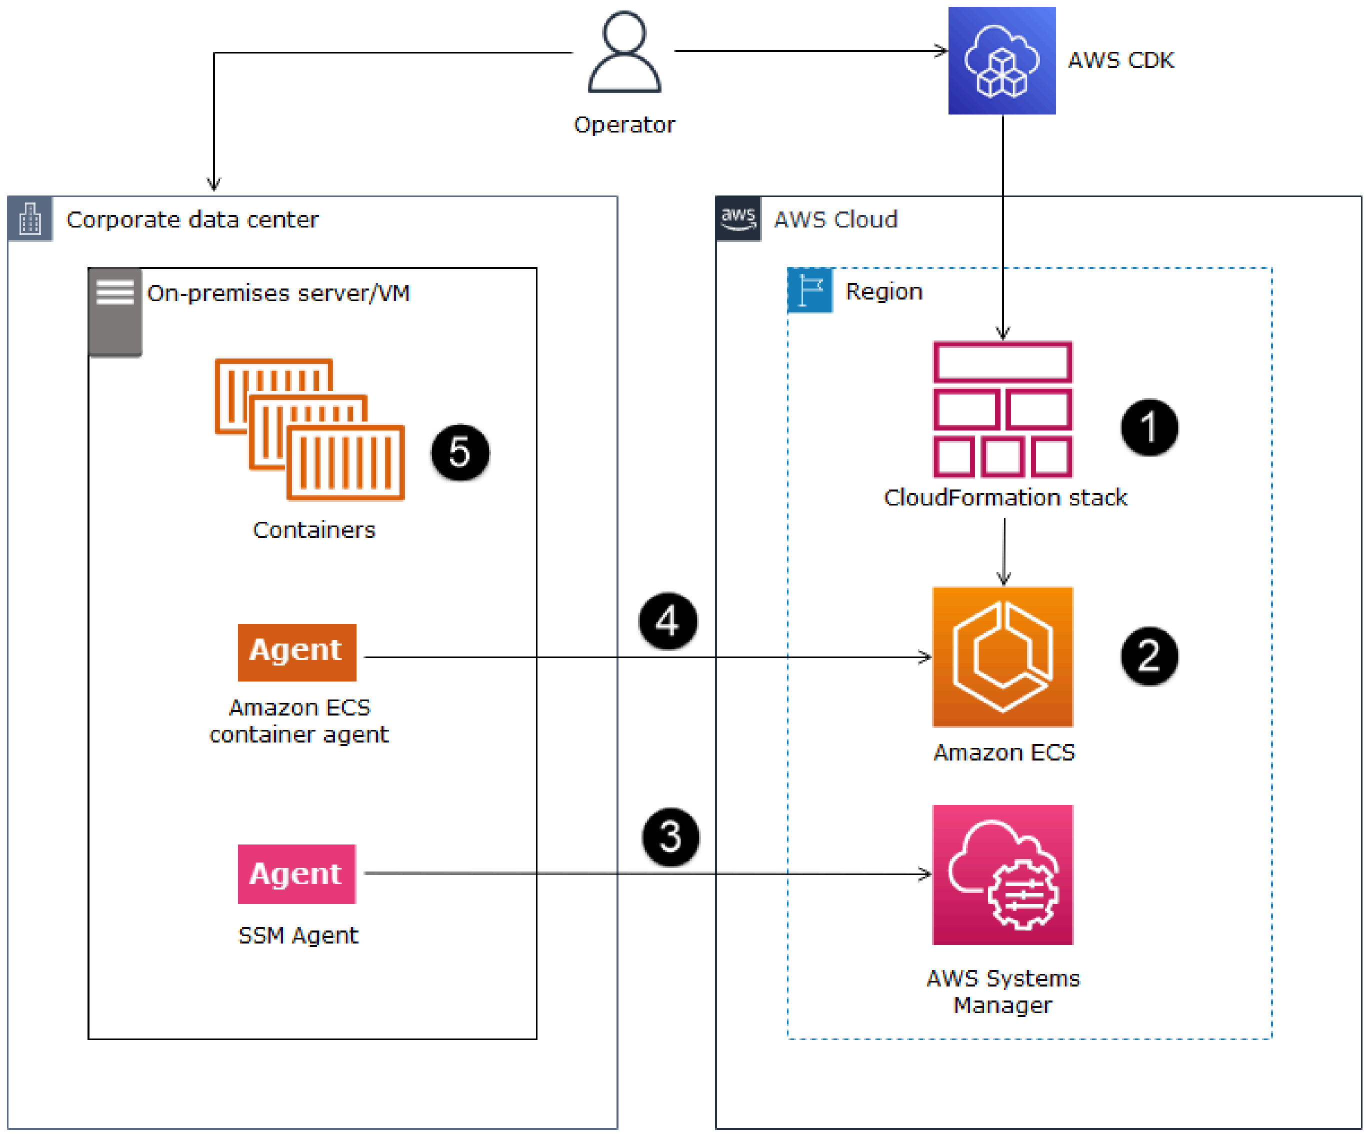
Target technology stack

- AWS CloudFormation
- AWS CDK
- Amazon ECS Anywhere
- AWS Identity and Access Management (IAM)

Target architecture

The following diagram illustrates a high-level system architecture of ECS Anywhere setup using the AWS CDK with TypeScript, as implemented by this pattern.

1. When you deploy the AWS CDK stack, it creates a CloudFormation stack on AWS.
2. The CloudFormation stack provisions an Amazon ECS cluster and related AWS resources.
3. To register an external instance with an Amazon ECS cluster, you must install AWS Systems Manager Agent (SSM Agent) on your virtual machine (VM) and register the VM as an AWS Systems Manager managed instance.
4. You must also install the Amazon ECS container agent and Docker on your VM to register it as an external instance with the Amazon ECS cluster.
5. When the external instance is registered and configured with the Amazon ECS cluster, it can run multiple containers on your VM, which is registered as an external instance.



Automation and scale

The [GitHub repository](https://github.com) that is provided with this pattern uses the AWS CDK as an infrastructure as code (IaC) tool to create the configuration for this architecture. AWS CDK helps you orchestrate resources and set up ECS Anywhere.

Tools

- [AWS Cloud Development Kit (AWS CDK)](https://aws.amazon.com/cdk/) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Code

The source code for this pattern is available on GitHub, in the Amazon ECS Anywhere CDK Samples repository. To clone and use the repository, follow the instructions in the next section.

Epics

Verify AWS CDK configuration

Task	Description	Skills required
Verify the AWS CDK version.	Verify the version of the AWS CDK Toolkit by running the following command: `cdk --version` This pattern requires AWS CDK version 2. If you have an earlier version of the AWS CDK, follow the instructions in the AWS CDK documentation to update it.	DevOps engineer

Set up AWS credentials.	To set up credentials, run the `aws configure` command and follow the prompts:
	`$aws configure`
	`AWS Access Key ID [None]: <your-access-key-ID>`
	`AWS Secret Access Key [None]: <your-secret-access-key>`
		DevOps engineer

Task	Description	Skills required
	`Default region name [None]: <your-Region-name>` `Default output format [None]:`	

Bootstrap the AWS CDK environment

Task	Description	Skills required
Clone the AWS CDK code repository.	Clone the GitHub code repository for this pattern by using the command: `git clone https://github.com/aws-samples/amazon-ecs-anywhere-cdk-samples.git`	DevOps engineer
Bootstrap the environment.	To deploy the AWS CloudFormation template to the account and AWS Region that you want to use, run the following command: `cdk bootstrap <account-number>/<Region>` For more information, see Bootstrapping in the AWS CDK documentation.	DevOps engineer

Build and deploy the project

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install package dependencies and compile TypeScript files.</td><td>Install the package dependencies and compile the TypeScript files by running the following commands:<pre><code>$cd amazon-ecs-anywhere-cdk-samples
$npm install
$npm fund</code></pre>These commands install all the packages from the sample repository.

Important
If you get any errors about missing packages, use one of the following commands:<pre><code>$npm ci</code></pre>—or—<pre><code>$npm install -g @aws-cdk/<package_name></code></pre></td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	For more information, see [npm ci](#) and [npm install](#) in the npm documentation.	
Build the project.	To build the project code, run the command: `npm run build` For more information about building and deploying the project, see [Your first AWS CDK app](#) in the AWS CDK documentation.	DevOps engineer
Deploy the project.	To deploy the project code, run the command: `cdk deploy`	DevOps engineer
Verify stack creation and output.	Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation, and choose the `EcsAnywhereStack` stack. The **Outputs** tab shows the commands to run on your external VM.	DevOps engineer

Set up an on-premises machine

Task	Description	Skills required
Set up your VM by using Vagrant.	For demonstration purposes, you can use [HashiCorp](#)	DevOps engineer

Task	Description	Skills required
	Vagrant to create a VM. Vagrant is an open-source utility for building and maintaining portable virtual software development environments. Create a Vagrant VM by running the `vagrant up` command from the root directory where Vagrantfile is placed. For more information, see the Vagrant documentation.	

Task	Description	Skills required

Register your VM as an external instance.	1. Log in to the Vagrant VM by using the `vagrant ssh` command. For more information, see the [Vagrant documentation]().
	
	 2. Create an activation code and ID that you can use to register your VM with AWS Systems Manager and to activate your external instance. The output from this command includes `ActivationId` and `ActivationCode` values:
	
	 `aws ssm create-activation --iam-role EcsAnywhereInstanceRole | tee ssm-activation.json`
	
	 3. Export the activation ID and code values:
	
	 `export ACTIVATION_ID=<activation-ID>`
	 `export ACTIVATION_CODE=<activation-code>`
	
	 4. Download the installation script to your on-premises server or VM:
		DevOps engineer

Task	Description	Skills required

	```curl -o "ecs-anywhere-install.sh" "https://amazon-ecs-agent.s3.amazonaws.com/ecs-anywhere-install-latest.sh" && sudo chmod +x ecs-anywhere-install.sh```
	
	5. Run the installation script on your on-premises server or VM:
	
	```sudo ./ecs-anywhere-install.sh \ --cluster test-ecs-anywhere \ --activation-id $ACTIVATION_ID \ --activation-code $ACTIVATION_CODE \ --region <Region>```
	
	For more information about setting up and registering your VM, see Registering an external instance to a cluster in the Amazon ECS documentation.	

Task	Description	Skills required

Verify the status of ECS Anywhere and the external VM.	To verify whether your virtual box is connected to the Amazon ECS control plane and running, use the following commands:
	`aws ssm describe-instance-information`
	`aws ecs list-container-instances --cluster $CLUSTER_NAME`
		DevOps engineer

Clean up

Task	Description	Skills required
Clean up and delete resources .	After you walk through this pattern, you should remove the resources you created to avoid incurring any further charges. To clean up, run the command: `cdk destroy`	DevOps engineer

Modernize ASP.NET Web Forms applications on AWS

Vijai Anand Ramalingam and Sreelaxmi Pai, Amazon Web Services

Summary

This pattern describes the steps for modernizing a legacy, monolith ASP.NET Web Forms application by porting it to ASP.NET Core on AWS.

Porting ASP.NET Web Forms applications to ASP.NET Core helps you take advantage of the performance, cost savings, and robust ecosystem of Linux. However, it can be a significant manual effort. In this pattern, the legacy application is modernized incrementally by using a phased approach, and then containerized in the AWS Cloud.

Consider a legacy, monolith application for a shopping cart. Let's assume that it was created as an ASP.NET Web Forms application and consists of .aspx pages with a code-behind (`aspx.cs`) file. The modernization process consists of these steps:

1. Break the monolith into microservices by using the appropriate decomposition patterns. For more information, see the guide [Decomposing monoliths into microservices] on the AWS Prescriptive Guidance website.
2. Port your legacy ASP.NET Web Forms (.NET Framework) application to ASP.NET Core in .NET 5 or later. In this pattern, you use Porting Assistant for .NET to scan your ASP.NET Web Forms application and identify incompatibilities with ASP.NET Core. This reduces the manual porting effort.
3. Redevelop the Web Forms UI layer by using React. This pattern doesn't cover UI redevelopment. For instructions, see [Create a New React App] in the React documentation.
4. Redevelop the Web Forms code-behind file (business interface) as an ASP.NET Core web API. This pattern uses NDepend reports to help identify required files and dependencies.
5. Upgrade shared/common projects, such as Business Logic and Data Access, in your legacy application to .NET 5 or later by using Porting Assistant for .NET.
6. Add AWS services to complement your application. For example, you can use [Amazon CloudWatch Logs] to monitor, store, and access your application's logs, and [AWS Systems Manager] to store your application settings.
7. Containerize the modernized ASP.NET Core application. This pattern creates a Docker file that targets Linux in Visual Studio and uses Docker Desktop to test it locally. This step assumes that your legacy application is already running on an on-premises or Amazon Elastic Compute Cloud

(Amazon EC2) Windows instance. For more information, see the pattern Run an ASP.NET Core web API Docker container on an Amazon EC2 Linux instance.

8. Deploy the modernized ASP.NET core application to Amazon Elastic Container Service (Amazon ECS). This pattern doesn't cover the deployment step. For instructions, see the Amazon ECS Workshop.

Note

This pattern doesn't cover UI development, database modernization, or container deployment steps.

Prerequisites and limitations

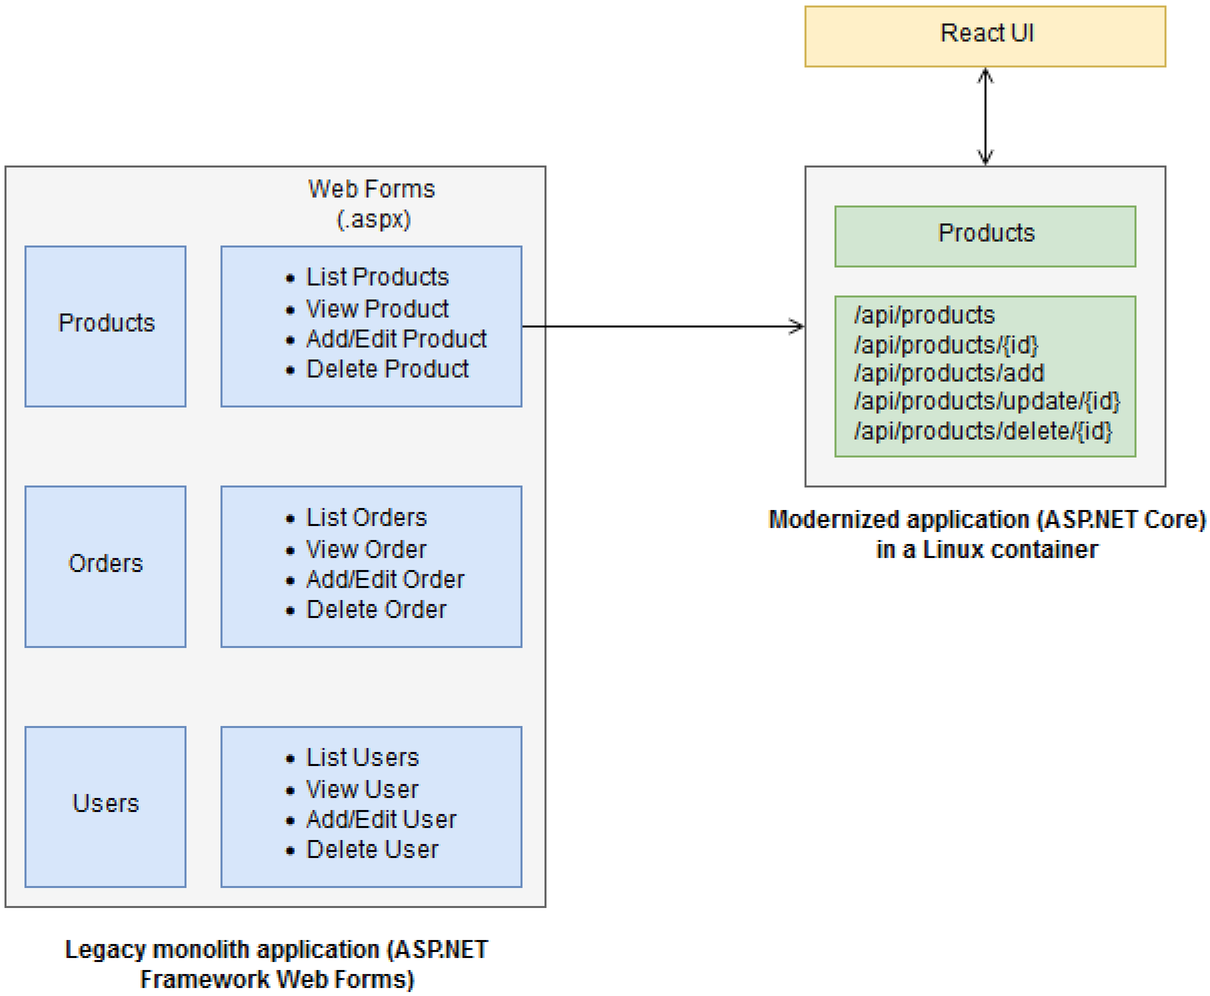
Prerequisites

- Visual Studio or Visual Studio Code, downloaded and installed.
- Access to an AWS account using the AWS Management Console and the AWS Command Line Interface (AWS CLI) version 2. (See the instructions for configuring the AWS CLI.)
- The AWS Toolkit for Visual Studio (see setup instructions).
- Docker Desktop, downloaded and installed.
- .NET SDK, downloaded and installed.
- NDepend tool, downloaded and installed. To install the NDepend extension for Visual Studio, run `NDepend.VisualStudioExtension.Installer` (see instructions). You can select Visual Studio 2019 or 2022, depending on your requirements.
- Porting Assistant for .NET, downloaded and installed.

Architecture

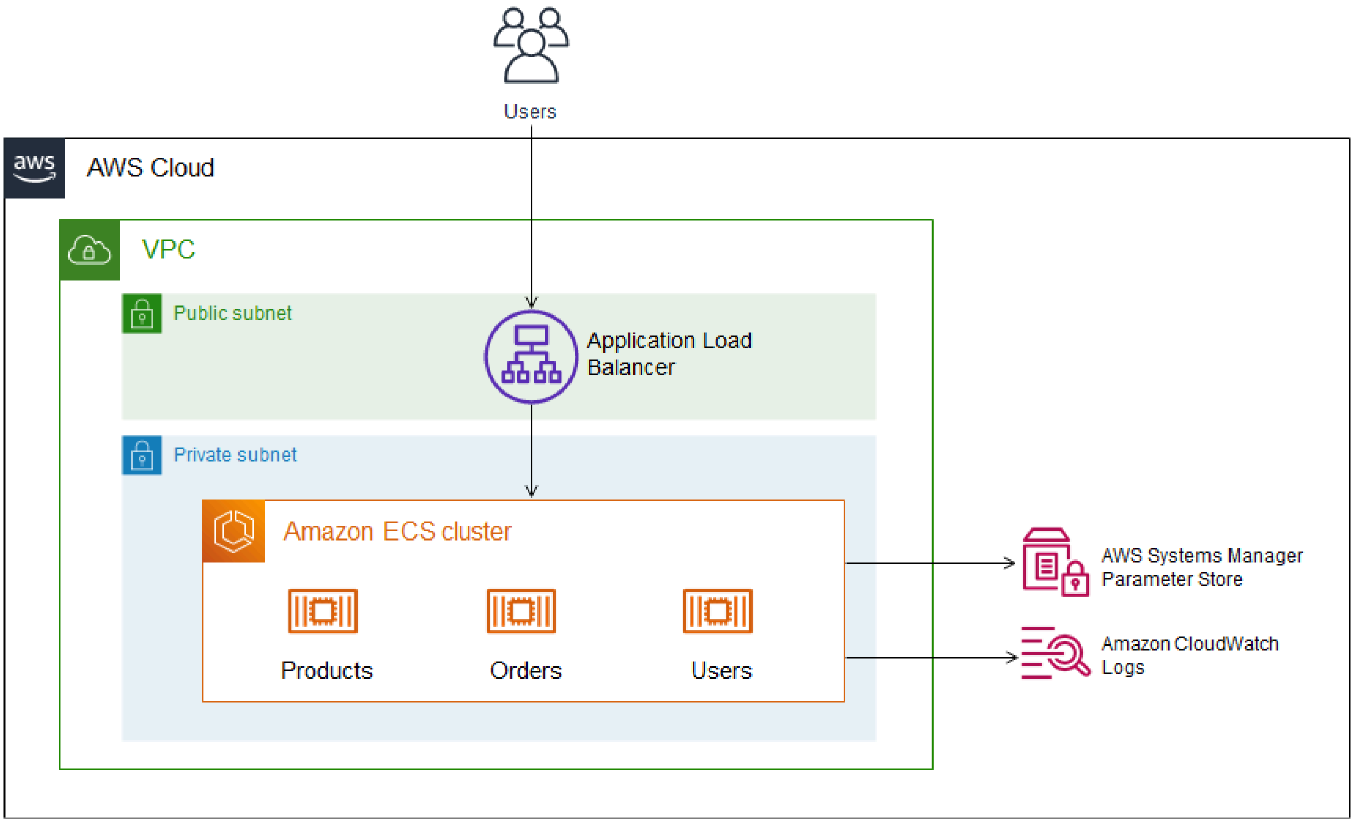
Modernizing the shopping cart application

The following diagram illustrates the modernization process for a legacy ASP.NET shopping cart application.



Target architecture

The following diagram illustrates the architecture of the modernized shopping cart application on AWS. ASP.NET Core web APIs are deployed to an Amazon ECS cluster. Logging and configuration services are provided by Amazon CloudWatch Logs and AWS Systems Manager.



Tools

AWS services

- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of EC2 instances that you manage.
- Amazon CloudWatch Logs – Amazon CloudWatch Logs centralizes the logs from all your systems, applications, and AWS services that you use. You can view and monitor the logs, search them for specific error codes or patterns, filter them based on specific fields, or archive them securely for future analysis.
- AWS Systems Manager — AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS

resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting (or taking corrective action) on any policy violations it detects.

Tools

- Visual Studio or Visual Studio Code – Tools for building .NET applications, web APIs, and other programs.
- AWS Toolkit for Visual Studio – An extension for Visual Studio that helps develop, debug, and deploy .NET applications that use AWS services.
- Docker Desktop – A tool that simplifies building and deploying containerized applications.
- NDepend – An analyzer that monitors .NET code for dependencies, quality issues, and code changes.
- Porting Assistant for .NET – An analysis tool that scans .NET code to identify incompatibilities with .NET Core and to estimate the migration effort.

Epics

Port your legacy application to .NET 5 or later version

Task	Description	Skills required
Upgrade your.NET Framework legacy application to .NET 5.	You can use Porting Assistant for .NET to convert your legacy ASP.NET Web Forms application to .NET 5 or later. Follow the instructions in the Porting Assistant for .NET documentation.	App developer
Generate NDepend reports.	When you modernize your ASP.NET Web Forms applicati on by decomposing it into microservices, you might not need all the .cs files from the legacy application. You can use NDepend to generate	App developer

Task	Description	Skills required
	a report for any code-behind (.cs) file, to get all the callers and callees. This report helps you identify and use only the required files in your microservices. After you install NDepend (see the [Prerequisites](#) section), open the solution (.sln file) for your legacy application in Visual Studio and follow these steps: 1. Build the legacy application in Visual Studio. 2. On the Visual Studio menu bar, choose **NDepend, Attach new NDepend project to current VS solution**. 3. Choose **Analyze .NET assemblies**. 4. When analysis is complete, navigate to the project in Solution Explorer. Right-click any code-behind file (for example, `listproducts.aspx.cs`) that you want to generate the report for, and then choose **Show on Dependency Graph**. 5. In the navigation bar, choose **Callers and callees,**	

Task	Description	Skills required
	and then choose **Edit code query**. 6. In the **Queries and Rules Edit pane**, choose the download arrow, and then choose **Export to Excel**. This process generates a report for the code-behind file that lists all callers and callees. For more information about the dependency graph, see the [NDepend documentation]().	

Task	Description	Skills required
Create a new .NET 5 solution.	To create a new .NET 5 (or later) structure for your modernized ASP.NET Core web APIs: 1. Open Visual Studio. 2. Create a new, blank solution. 3. Create new projects that target .NET 5 (or later), based on your legacy application. For examples of legacy and new projects for a shopping cart application, see the Additional information section. 4. Use the NDepend report from the previous step to identify all required files. Copy these files from the application you upgraded earlier and add them to the new solution. 5. Build the solution and fix all issues. For more information about creating projects and solutions, see the Visual Studio documentation.	App developer

Task	Description	Skills required
	Note As you build the solution and verify functionality, you might identify several additional files to be added to the solution, in addition to the files that NDepend identified.	

Update your application code

Task	Description	Skills required
Implement web APIs with ASP.NET Core.	Let's assume that one of the microservices that you identified in your legacy monolith shopping cart application is *Products*. You created a new ASP.NET Core web API project for *Products* in the previous epic. In this step, you identify and modernize all the web forms (.aspx pages) that are related to *Products*. Let's assume that *Products* consists of four web forms, as illustrated earlier in the [Architecture](#) section: • List Products • View Product	App developer

Task	Description	Skills required
	• Add/Edit Product • Delete Product You should analyze each web form, identify all the requests that are sent to the database to perform some logic, and get responses. You can implement each request as a web API endpoint. Given its web forms, *Products* can have the following possible endpoints: • `/api/products` • `/api/products/{id}` • `/api/products/add` • `/api/products/update/{id}` • `/api/products/delete/{id}` As mentioned previously, you can also reuse all the other projects that you upgraded to .NET 5, including Business Logic, Data Access, and shared/common projects.	

Task	Description	Skills required
Configure Amazon CloudWatc h Logs.	You can use Amazon CloudWatch Logs to monitor, store, and access your application's logs. You can log data into Amazon CloudWatc h Logs by using an AWS SDK. You can also integrate .NET applications with CloudWatc h Logs by using popular .NET logging frameworks such as NLog, Log4Net, and ASP.NET Core logging framework. For more information about this step, see the blog post Amazon CloudWatch Logs and .NET Logging Framework s.	App developer

Task	Description	Skills required
Configure AWS Systems Manager Parameter Store.	You can use AWS Systems Manager Parameter Store to store application settings such as connection strings separately from your application's code. The NuGet package Amazon.Extensions.Configuration.SystemsManager simplifies how your application loads these settings from the AWS Systems Manager Parameter Store into the .NET Core configuration system. For more information about this step, see the blog post .NET Core configuration provider for AWS Systems Manager.	App developer

Add authentication and authorization

Task	Description	Skills required
Use a shared cookie for authentication.	Modernizing a legacy monolith application is an iterative process and requires the monolith and its modernized version to co-exist. You can use a shared cookie to achieve seamless authentication between the two versions.	App developer

Task	Description	Skills required
	The legacy ASP.NET applicati on continues to validate user credentials and issues the cookie while the modernize d ASP.NET Core application validates the cookie. For instructions and sample code, see the [sample GitHub project]().	

Build and run the container locally

Task	Description	Skills required
Create a Docker image by using Visual Studio.	In this step, you create a Docker file by using the Visual Studio for .NET Core web API. 1. Open Visual Studio. 2. In Solution Explorer, from the context (right-click) menu of your project, choose **Add, Docker Support.** 3. Select **Linux** as the target operating system**.** Visual Studio creates a Docker file for your project. For a sample Docker file, see [Visual Studio Container Tools for Docker]() on the Microsoft website.	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Build and run the container by using Docker Desktop.</td><td>Now you can build, create and run the container in Docker Desktop.

1. Open a Command Prompt window. Navigate to the solution folder where the Docker file is located. Run the following command to create the Docker image:

<pre>docker build -t aspnetcorewebapiimage -f Dockerfile .</pre>
2. Run the following command to view all Docker images:

<pre>docker images</pre>
3. Run the following command to create and run a container:

<pre>docker run -d -p 8080:80 --name aspnetcorewebapicontainer aspnetcorewebapiimage</pre>
4. Open Docker Desktop, and then choose Containers/Apps. You can see a new container named <code>aspnetcorewebapicontainer</code> running.</td><td>App developer</td></tr>
</table>

Additional information

The following tables provide examples of sample projects for a legacy shopping cart application and the equivalent projects in your modernized ASP.NET Core application.

Legacy solution:

Project name	Project template	Target framework
Business Interface	Class Library	.NET Framework
BusinessLogic	Class Library	.NET Framework
WebApplication	ASP.NET Framework Web Application	.NET Framework
UnitTests	NUnit Test Project	.NET Framework
Shared ->Common	Class Library	.NET Framework
Shared ->Framework	Class Library	.NET Framework

New solution:

Project name	Project template	Target framework
BusinessLogic	Class Library	.NET 5.0

<WebAPI>	ASP.NET Core Web API	.NET 5.0
<WebAPI>.UnitTests	NUnit 3 Test Project	.NET 5.0
Shared ->Common	Class Library	.NET 5.0
Shared ->Framework	Class Library	.NET 5.0

Run event-driven and scheduled workloads at scale with AWS Fargate

HARI OHM PRASATH RAJAGOPAL, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern describes how to run scheduled and event-driven workloads at scale on the Amazon Web Services (AWS) Cloud by using AWS Fargate.

In the use case that this pattern sets up, code is scanned for AWS sensitive information, such as the AWS account number and credentials, whenever a pull request is submitted. The pull request initiates a Lambda function. The Lambda function invokes a Fargate task that takes care of the code scan. Lambda is initiated whenever a new pull request is raised. If the scan finds any sensitive information, Amazon Simple Notification Service (Amazon SNS) sends the scan results in an email message.

This pattern is helpful in the following business use cases:

- If your business must run many scheduled and event-driven workloads that cannot be run by AWS Lambda because of limitations around runtime (a 15-minute limit) or memory
- If you want AWS to manage the instances provisioned for these workloads

When you use this pattern, you have the option of creating a new virtual private cloud (VPC). This pattern also uses AWS CodeCommit.

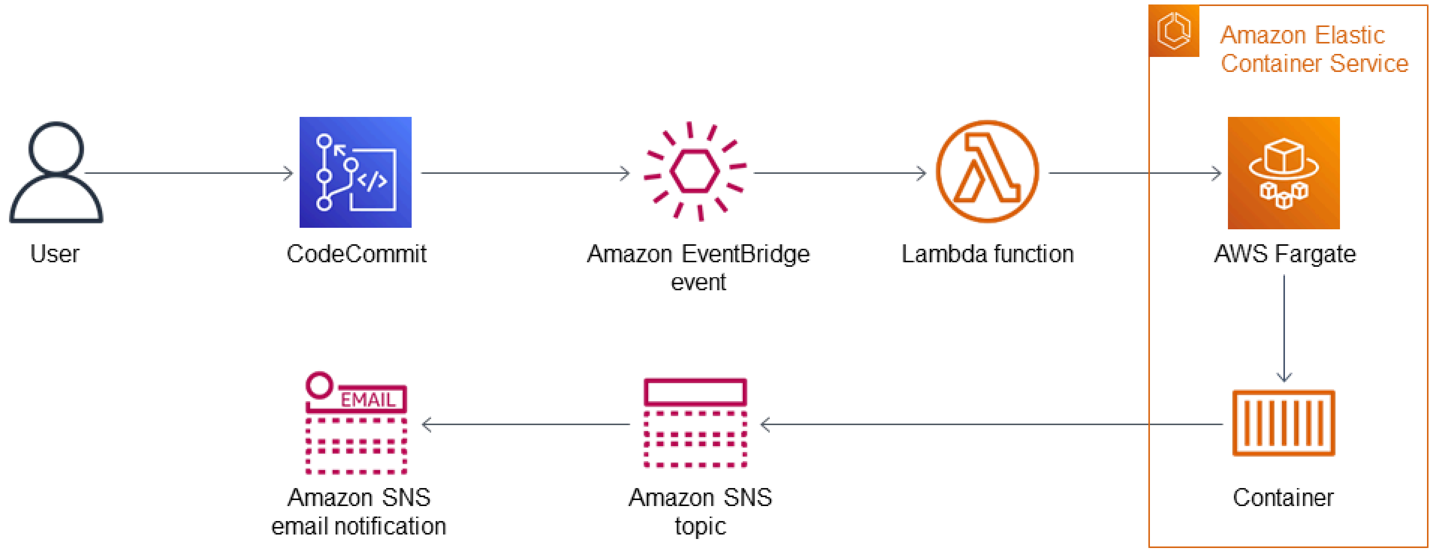
Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS CodeCommit for hosting the code base and creating pull requests
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows
- Workloads running in containers

- Apache Maven executable set up in classpath

Architecture



The overall flow includes the following steps.

1. Whenever a new pull request is submitted in CodeCommit, a Lambda function is initiated. The Lambda function listens through the `CodeCommit Pull Request State Change` event through Amazon EventBridge.
2. The Lambda function submits a new Fargate task with the following environment parameters for checking out the code and scanning it.

```
RUNNER # <<TaskARN>>
SNS_TOPIC # <<SNSTopicARN>>
SUBNET # <<Subnet in which Fargate task gets launched>>
```

   If the scan finds sensitive information in the code, Fargate pushes a new message to the Amazon SNS topic.
3. An SNS subscriber reads the message from the topic and sends an email message.

Technology

- AWS CodeCommit
- Amazon Elastic Container Registry (Amazon ECR)

- Amazon Elastic Container Service (Amazon ECS)
- Amazon EventBridge
- AWS Fargate
- AWS Lambda
- Amazon SNS
- Docker

Tools

Tools

- AWS CLI – AWS Command Line Interface (CLI) is a unified tool to manage your AWS services.
- AWS CodeCommit – AWS CodeCommit is a fully managed source control service that hosts secure Git-based repositories. Using CodeCommit, teams can collaborate on code in a secure and highly scalable environment.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that developers can use to store, manage, and deploy Docker container images.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service. You can use Amazon ECS to run, stop, and manage containers on a cluster.
- AWS Fargate – AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon EC2 instances.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers). Publishers communicate asynchronously with subscribers by sending messages to a topic, which is a logical access point and communication channel. Clients that subscribe to the SNS topic receive published messages using a supported protocol, such Lambda, email, mobile push notifications, and mobile text messages (SMS).
- Docker – Docker helps you build, test, and deliver applications in packages called containers.
- Git client – Command line or desktop tool to check out the required artifacts
- Maven – Apache Maven is a project management tool for centrally managing a project's build, reporting, and documentation.

Epics

Set up the local repository

Task	Description	Skills required
Download the code.	In the **Attachments** section, download the .zip file and extract the files.	Developer, AWS system administrator
Set up the repo.	Run `mvn clean install` on the root folder.	Developer, AWS system administrator

Create an Amazon ECR image and push the image

Task	Description	Skills required
Create an Amazon ECR repository and log in.	Open the Amazon ECR console. In the navigatio n pane, choose **Repositor ies**, and then choose **Create repository**. For help with this and other stories, see the **Related resources** section.	Developer, AWS system administrator
Push your container image.	Open the repository, choose **View push commands**, and log in to Docker. After you are logged in, run the commands, with the required substitut ions, that are under **Push the container image** in the **Additional information** section. This uploads the Docker container image that is used to perform code scanning. After the upload	Developer, AWS system administrator

Task	Description	Skills required
	is complete, copy the URL of the latest build in the Amazon ECR repository.	

Create the CodeCommit repository

Task	Description	Skills required
Create the CodeCommit repository.	To create a new AWS CodeCommit repository, run the command under **Create the CodeCommit repository** in the **Additional informati on** section.	Developer, AWS system administrator

Create the VPC (optional)

Task	Description	Skills required
Create a VPC.	If you want to use a new VPC rather than an existing one, run the commands under **Create a VPC** in the **Additional information** section. The AWS Cloud Development Kit (AWS CDK) script will output the IDs of the VPC and subnet that were created.	Developer, AWS system administrator

Create the Amazon ECS cluster and Fargate task

Task	Description	Skills required
Create the cluster and the task.	To create an Amazon ECS cluster and Fargate task definition, run the commands under **Create the cluster and task** in the **Additional information** section. Make sure that the correct VPC ID and Amazon ECR repo URI are passed in as a parameter while running the shell script. The script creates a Fargate task definition that points to the Docker image (responsible for scanning). The script then creates a job and an associate d execution role.	Developer, AWS system administrator
Verify the Amazon ECS cluster.	Open the Amazon ECS console. In the navigation pane, choose **Clusters**, and choose the newly created Amazon ECS cluster named **Fargate-Job-Cluster**. After this, choose **Task definition** in the navigation pane, and confirm that there is a new task definition with the prefix `awscdkfargateecsTa skDef` .	Developer, AWS system administrator

Create the SNS topic and subscriber

Task	Description	Skills required
Create an SNS topic.	To create an SNS topic, run the command under **Create the SNS topic** in the **Additional informati on** section. After creation is successful, note the `SNS ARN`, which is used in the next step.	Developer, AWS system administrator
Create the SNS subscriber.	To create an email subscribe r for the SNS topic, run the command under **Create the SNS subscriber** in the **Additional information** section. Make sure to replace `TopicARN` and `Email address` used in the CLI command. To receive email notifications, make sure to confirm the email address that is used as a subscriber.	Developer, AWS system administrator

Create the Lambda function and CodeCommit trigger

Task	Description	Skills required
Create the function and the trigger.	To create a Lambda function with a CodeCommit trigger, run the command under **Lambda function and CodeCommit trigger** in the **Additional information** section. Make sure to replace	Developer, AWS system administrator

Task	Description	Skills required
	the parameters with the corresponding values before running the command. The script creates the Lambda function and configures it to be invoked when a new pull request is made.	

Test the application

Task	Description	Skills required
Test the application.	If you check in any AWS sensitive information to CodeCommit repo, the Lambda function should be initiated. The Lambda function initiates the Fargate task, which scans the code and sends the scan results in an email notification.	Developer, AWS system administrator

Tenant onboarding in SaaS architecture for the silo model using C# and AWS CDK

Tabby Ward, Susmitha Reddy Gankidi, and Vijai Anand Ramalingam, Amazon Web Services

Summary

Software as a service (SaaS) applications can be built with a variety of different architectural models. The *silo model* refers to an architecture where tenants are provided dedicated resources.

SaaS applications rely on a frictionless model for introducing new tenants into their environment. This often requires the orchestration of a number of components to successfully provision and configure all the elements needed to create a new tenant. This process, in SaaS architecture, is referred to as tenant on-boarding. On-boarding should be fully automated for every SaaS environment by utilizing infrastructure as code in your on-boarding process.

This pattern guides you through an example of creating a tenant and provisioning a basic infrastructure for the tenant on Amazon Web Services (AWS). The pattern uses C# and the AWS Cloud Development Kit (AWS CDK).

Because this pattern creates a billing alarm, we recommend deploying the stack in the US East (N. Virginia), or us-east-1, AWS Region. For more information, see the AWS documentation.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS Identity and Access Management (IAM) principal with sufficient IAM access to create AWS resources for this pattern. For more information, see IAM roles.
- Install Amazon Command Line Interface (AWS CLI) and configure AWS CLI to perform AWS CDK deployment.
- Visual Studio 2022 downloaded and installed or Visual Studio Code downloaded and installed.
- AWS Toolkit for Visual Studio set up.
- .NET Core 3.1 or later (required for C# AWS CDK applications)
- Amazon.Lambda.Tools installed.

Limitations

- AWS CDK uses AWS CloudFormation, so AWS CDK applications are subject to CloudFormation service quotas. For more information, see AWS CloudFormation quotas.
- The tenant CloudFormation stack is created with a CloudFormation service role `infra-cloudformation-role` with wildcard characters on actions (`sns*` and `sqs*`) but with resources locked down to the `tenant-cluster` prefix. For a production use case, evaluate this setting and provide only required access to this service role. The `InfrastructureProvision` Lambda function also uses a wildcard character (`cloudformation*`) to provision the CloudFormation stack but with resources locked down to the `tenant-cluster` prefix.
- This example code's docker build uses `--platform=linux/amd64` to force `linux/amd64` based images. This is to ensure that the final image artifacts will be suitable for Lambda, which by default uses x86-64 architecture. If you need to change the target Lambda architecture, be sure to change both the Dockerfiles and the AWS CDK codes. For more information, see the blog post Migrating AWS Lambda functions to Arm-based AWS Graviton2 processors.
- The stack deletion process will not clean up CloudWatch Logs (log groups and logs) generated by the stack. You must manually clean up the logs through the AWS Management Console Amazon CloudWatch console or the through the API.

This pattern is set up as an example. For production use, evaluate the following setups and make changes based on your business requirements:

- The AWS Simple Storage Service (Amazon S3) bucket in this example does not have versioning enabled for simplicity. Evaluate and update the setup as needed.
- This example sets up Amazon API Gateway REST API endpoints without authentication, authorization, or throttling for simplicity. For production use, we recommend integrating the system with the business security infrastructure. Evaluate this setting and add required security settings as needed.
- For this tenant infrastructure example, Amazon Simple Notification Service (Amazon SNS) and Amazon Simple Queue Service (Amazon SQS) have only minimum setups. The AWS Key Management Service (AWS KMS) for each tenant opens to Amazon CloudWatch and Amazon SNS services in the account to consume based on the AWS KMS key policy. The setup is only an example placeholder. Adjust the setups as needed based on your business use case.
- The entire setup, which includes but isn't limited to API endpoints and backend tenant provisioning and deletion by using AWS CloudFormation, covers only the basic happy path case. Evaluate and update the setup with the necessary retry logic, additional error handling logic, and security logic based on your business needs.

- The example code is tested with up-to-date cdk-nag to check for policies at the time of this writing. New policies might be enforced in the future. These new policies might require you to manually modify the stack based on the recommendations before the stack can be deployed. Review the existing code to ensure that it aligns with your business requirements.
- The code relies on the AWS CDK to generate a random suffix instead of relying on static assigned physical names for most created resources. This setup is to ensure that these resources are unique and do not conflict with other stacks. For more information, see the AWS CDK documentation. Adjust this based on your business requirements.
- This example code packages .NET Lambda artifacts into Docker based images and runs with the Lambda provided Container image runtime. The container image runtime has advantages for standard transfer and store mechanisms (container registries) and more accurate local test environments (through the container image). You can switch the project to use Lambda provided .NET runtimes to reduce the build time of the Docker images, but you will then need to set up transfer and store mechanisms and ensure that the local setup matches the Lambda setup. Adjust the code to align with users' business requirements.

Product versions

- AWS CDK version 2.45.0 or later
- Visual Studio 2022

Architecture

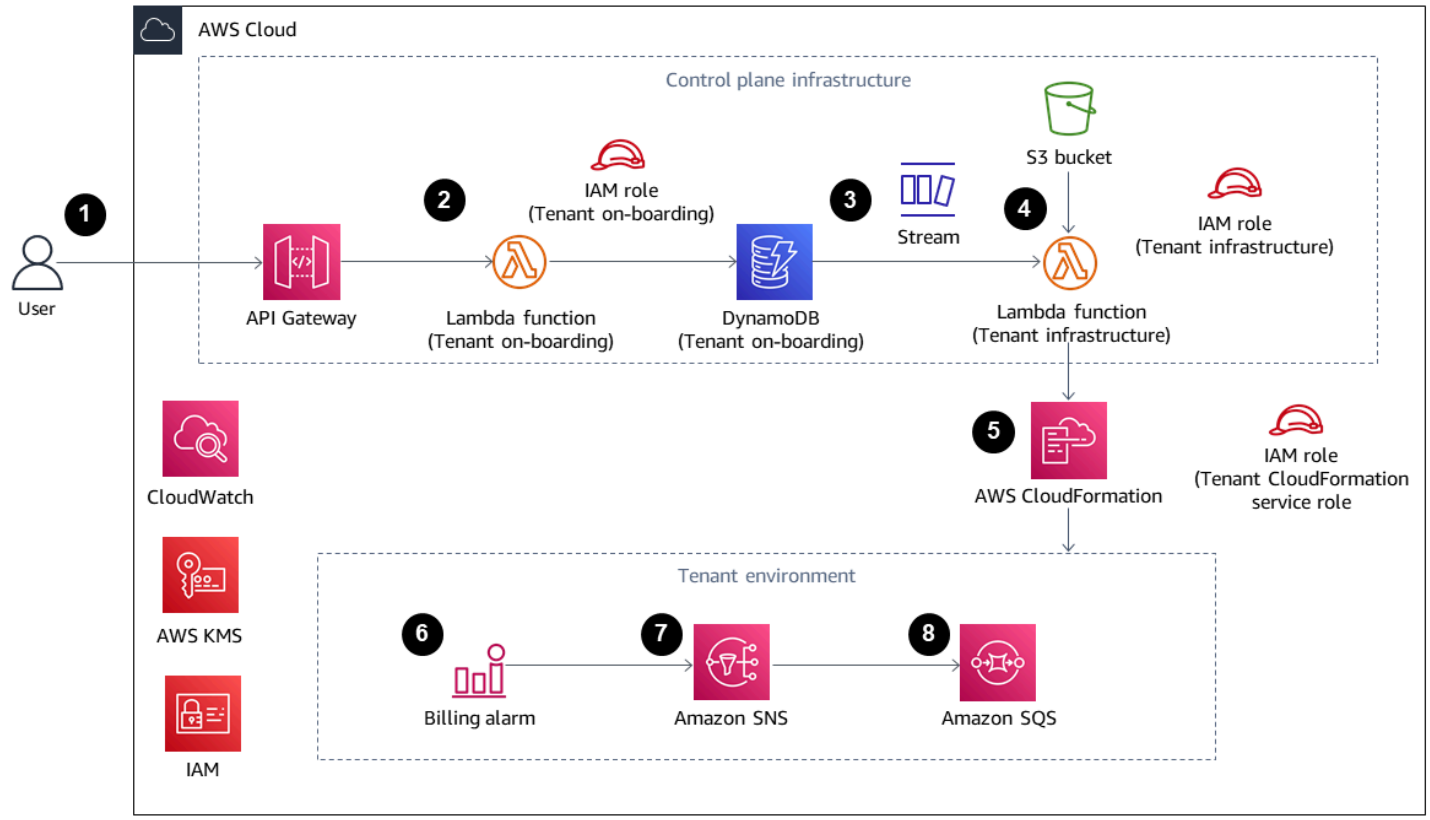
Technology stack

- Amazon API Gateway
- AWS CloudFormation
- Amazon CloudWatch
- Amazon DynamoDB
- AWS Identity and Access Management (IAM)
- AWS KMS
- AWS Lambda
- Amazon S3
- Amazon SNS

- Amazon SQS

Architecture

The following diagram shows the tenant stack creation flow. For more information about the control-plane and tenant technology stacks, see the *Additional information* section.



Tenant stack creation flow

1. User sends a POST API request with new tenant payload (tenant name, tenant description) in JSON to a REST API hosted by Amazon API Gateway. The API Gateway processes the request and forwards it to the backend Lambda Tenant On-boarding function. In this example, there is no authorization or authentication. In a production setup, this API should be integrated with the SaaS infrastructure security system.
2. The Tenant On-boarding function verifies the request. Then it attempts to store the tenant record, which includes the tenant name, generated tenant universally unique identifier (UUID), and tenant description, into the Amazon DynamoDB Tenant On-boarding table.
3. After DynamoDB stores the record, a DynamoDB stream initiates the downstream Lambda Tenant Infrastructure function.

4. The Tenant Infrastructure Lambda function acts based the on received DynamoDB stream. If the stream is for the INSERT event, the function uses the stream's NewImage section (latest update record, Tenant Name field) to invoke CloudFormation to create a new tenant infrastructure using the template that is stored in the S3 bucket. The CloudFormation template requires the Tenant Name parameter.
5. AWS CloudFormation creates the tenant infrastructure based on the CloudFormation template and input parameters.
6. Each tenant infrastructure setup has a CloudWatch alarm, a billing alarm, and an alarm event.
7. The alarm event becomes a message to an SNS topic, which is encrypted by the tenant's AWS KMS key.
8. The SNS topic forwards the received alarm message to the SQS queue, which is encrypted by the tenant's AWS KMS for encryption key.

Other systems can be integrated with Amazon SQS to perform actions based on messages in queue. In this example, to keep the code generic, incoming messages remain in queue and require manual deletion.

Tenant stack deletion flow

1. User sends a DELETE API request with new tenant payload (tenant name, tenant description) in JSON to the REST API hosted by Amazon API Gateway, which will process the request and forward to Tenant On-boarding function. In this example, there is no authorization or authentication. In a production setup, this API will be integrated with the SaaS infrastructure security system.
2. The Tenant On-boarding function will verify the request and then attempt to delete the tenant record (tenant name) from the Tenant On-boarding table.
3. After DynamoDB deletes the record successfully (the record exists in the table and is deleted), a DynamoDB stream initiates the downstream Lambda Tenant Infrastructure function.
4. The Tenant Infrastructure Lambda function acts based on the received DynamoDB stream record. If the stream is for the REMOVE event, the function uses the record's OldImage section (record information and Tenant Name field, before the latest change, which is delete) to initiate deletion of an existing stack based on that record information.
5. AWS CloudFormation deletes the target tenant stack according to the input.

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CDK Toolkit is a command line cloud development kit that helps you interact with your AWS Cloud Development Kit (AWS CDK) app.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- AWS Toolkit for Visual Studio is a plugin for the Visual Studio integrated development environment (IDE). The Toolkit for Visual Studio supports developing, debugging, and deploying .NET applications that use AWS services.

Other tools

- Visual Studio is an IDE that includes compilers, code completion tools, graphical designers, and other features that support software development.

Code

The code for this pattern is in the Tenant onboarding in SaaS Architecture for Silo Model APG Example repository.

Epics

Set up AWS CDK

Task	Description	Skills required
Verify Node.js installation.	To verify that Node.js is installed on your local machine, run the following command. `node --version`	AWS administrator, AWS DevOps
Install AWS CDK Toolkit.	To install AWS CDK Toolkit on your local machine, run the following command. `npm install -g aws-cdk` If npm is not installed, you can install it from the Node.js site.	AWS administrator, AWS DevOps
Verify the AWS CDK Toolkit version.	To verify that the AWS CDK Toolkit version is installed correctly on your machine, run the following command.	AWS administrator, AWS DevOps

Task	Description	Skills required
	`cdk --version`	

Review the code for the tenant onboarding control plane

Task	Description	Skills required
Clone the repository.	Clone the [repository](), and navigate to the `\tenant-onboarding-in-saas-architecture-for-silo-model-apg-example` folder. In Visual Studio 2022, open the `\src\TenantOnboardingInfra.sln` solution. Open the `TenantOnboardingInfraStack.cs` file and review the code. The following resources are created as part of this stack: • DynamoDB table • S3 bucket (Upload the CloudFormation template to the S3 bucket.) • Lambda execution role • Lambda function • API Gateway API • Event source to Lambda function	AWS administrator, AWS DevOps

Task	Description	Skills required
Review the CloudFormation template.	In the `\tenant-onboarding-in-saas-architecture-for-silo-model-apg-example\template` folder, open `infra.yaml`, and review the CloudFormation template. This template will be hydrated with the tenant name retrieved from the tenant onboarding DynamoDB table. The template provisions the tenant-specific infrastructure. In this example, it provisions the AWS KMS key, Amazon SNS , Amazon SQS, and the CloudWatch alarm.	App developer, AWS DevOps

Task	Description	Skills required
Review the tenant onboardin g function.	Open `Function.cs` , and review the code for the tenant onboarding function, which is created with the Visual Studio AWS Lambda Project (.NET Core- C#) template with the .NET 6 (Container Image) blueprint. Open the `Dockerfile` , and review the code. The `Dockerfile` is a text file that consists of instructions for building the Lambda container image. Note that the following NuGet packages are added as dependencies to the `TenantOnboardingFunction` project: • `Amazon.Lambda.APIGatewayEvents` • `AWSSDK.DynamoDBv2` • `Newtonsoft.Json`	App developer, AWS DevOps

Task	Description	Skills required
Review the Tenant InfraProvisioning function.	Navigate to `\tenant-onboarding-in-saas-architecture-for-silo-model-apg-example\src\InfraProvisioningFunction` . Open `Function.cs` , and review the code for the tenant infrastructure provisioning function, which is created with the Visual Studio AWS Lambda Project (.NET Core- C#) template with the .NET 6 (Container Image) blueprint. Open the `Dockerfile` , and review the code. Note that the following NuGet packages are added as dependencies to the `InfraProvisioningFunction` project: • `Amazon.Lambda.DynamoDBEvents` • `AWSSDK.DynamoDBv2` • `AWSSDK.Cloudformation`	App developer, AWS DevOps

Deploy the AWS resources

Task	Description	Skills required
Build the solution.	To build the solution, perform the following steps: 1. In Visual Studio 2022, open the `\tenant-onboarding-in-saas-architecture-for-silo-model-apg-example\src\TenantOnboardingInfra.sln` solution. 2. Open the context (right-click) menu for the solution, and choose **Build solution**. **Note** Make sure that you update the `Amazon.CDK.Lib` `NuGet` package to the latest version in `\tenant-onboarding-in-saas-architecture-for-silo-model-apg-example\src\TenantOnboardingInfra`	App developer

Task	Description	Skills required
	project before you build the solution.	

Bootstrap the AWS CDK environment.	Open the Windows command prompt and navigate to the AWS CDK app root folder where the `cdk.json` file is available (`\tenant-onboarding-in-saas-architecture-for-silo-model-apg-example`). Run the following command for bootstrapping.
	`cdk bootstrap`
	If you have created an AWS profile for the credentials, use the command with your profile.
	`cdk bootstrap --profile <profile name>`
		AWS administrator, AWS DevOps

Task	Description	Skills required

List the AWS CDK stacks.	To list all the stacks to be created as part of this project, run the following command.
	`cdk ls`
	`cdk ls --profile <profile name>`
	If you have created an AWS profile for the credentials, use the command with your profile.
	`cdk ls --profile <profile name>`
		AWS administrator, AWS DevOps

Review which AWS resources will be created.	To review all the AWS resources that will be created as part of this project, run the following command.
	`cdk diff`
	If you have created an AWS profile for the credentials, use the command with your profile.
	`cdk diff --profile <profile name>`
		AWS administrator, AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Deploy all the AWS resources by using AWS CDK.</td><td>To deploy all the AWS resources run the following command.

```
cdk deploy --all --require-approval never
```

If you have created an AWS profile for the credentials, use the command with your profile.

```
cdk deploy --all --require-approval never --profile <profile name>
```

After the deployment is complete, copy the API URL from the outputs section in the command prompt, which is shown in the following example.

```
Outputs:
TenantOnboardingInfraStack.TenantOnboardingAPIEndpoint42E526D7 = https://j2qmp8ds21i1i.execute-api.us-west-2.amazonaws.com/prod/
```
</td><td>AWS administrator, AWS DevOps</td></tr>
</table>

Verify the functionality

Task	Description	Skills required

Create a new tenant.	To create the new tenant, send the following curl request.
	`curl -X POST <TenantOnboardingAPIEndpoint* from CDK Output>tenant -d '{"Name":"Tenant123", "Description":"Stack for Tenant123"}'`
	Change the place holder `<TenantOnboardingAPIEndpoint* from CDK Output>` to the actual value from AWS CDK, as shown in the following example.
	`curl -X POST https://j2qmp8ds21i1i.execute-api.us-west-2.amazonaws.com/prod/tenant -d '{"Name":"Tenant123", "Description":"test12"}'`
	The following example shows the output.
	`{"message": "A new tenant added - 5/4/2022 7:11:30 AM"}`
		App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
Verify the newly created tenant details in DynamoDB.	To verify the newly created tenant details in DynamoDB, perform the following steps. 1. Open AWS Management Console, and navigate to the Amazon DynamoDB service. 2. In the left navigation, choose **Explore items**, and choose the `TenantOnboarding` table. **Note** The tenant name will be prepended with `tenantcluster-`. For more information, see the *Additional information* section. 3. Verify that a new item is created with the tenant details.	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
Verify the stack creation for the new tenant.	Verify that the new stack was successfully created and provisioned with infrastru cture for the newly created tenant according to the CloudFormation template. 1. Open the CloudFormation console. 2. In the left navigation, choose **Stacks**, and verify that a stack with the tenant name was successfu lly created. 3. Choose the newly created tenant stack, and then choose the **Resources** tab. Note the alarm resource and the Amazon SQS resource. 4. Open a new terminal with AWS credentials configure d, and point to the correct Region. To raise a test alarm, enter the following code, replacing `<alarm resource name>` with the alarm resource name noted in step 3. `aws cloudwatch set-alarm-state --alarm-name <alarm resource name> --state-value`	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required

	<pre>ALARM --state-reason
	'Test setup'</pre>
	The following example shows the code with an alarm resource name.
	<pre>aws cloudwatch set-
	alarm-state --alarm-
	name tenantcluster-
	tenant123-alarm --
	state-value ALARM --
	state-reason 'Test
	 setup'</pre>
	5. Open the console and navigate to the Amazon SQS console. Choose the Amazon SQS resource name identified in step 3. Follow the [AWS documentation instructions](#) to receive and delete the test message from the alarm that was raised in step 4.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Delete the tenant stack.</td><td>

To delete the tenant stack, send the following curl request.

```
curl -X DELETE <TenantOnboardingAPIEndpoint* from CDK Output>tenant/<Tenant Name from previous step>
```

Change the place holder `<TenantOnboardingAPIEndpoint* from CDK Output>` to the actual value from AWS CDK, and change `<Tenant Name from previous step>` to the actual value from the previous tenant creation step, as shown in the following example.

```
curl -X DELETE https://j2qmp8ds21i1i.execute-api.us-west-2.amazonaws.com/prod/tenant/Tenant123
```

The following example shows the output.

```
{"message": "Tenant destroyed - 5/4/2022 7:14:48 AM"}
```

</td><td>App developer, AWS DevOps, AWS administrator</td></tr>
</table>

Task	Description	Skills required
Verify the stack deletion for the existing tenant.	To verify that the existing tenant stack got deleted, perform the following steps: 1. Open console and navigate to the CloudFormation console. 2. In the left navigation, verify that the existing stack with the tenant name is no longer in console (if the CloudFormation console is set up to show only **Active** stacks) or is in the process of being deleted. If the stack is no longer in the CloudForm ation console, use the dropdown list to change the console's setting from **Active** to **Deleted** to see the deleted stack and verify that the stack was deleted successfully.	App developer, AWS administrator, AWS DevOps

Clean up

Task	Description	Skills required
Destroy the environment.	Before the stack clean up, ensure the following: • All records in DynamoDB are removed either through	AWS administrator, AWS DevOps

Task	Description	Skills required
	the previous tenant deletion operation or through the DynamoDB console or API. Each tenant record deletion will initiate the cleanup of its AWS CloudFormation counterpa rt. • All tenant-based AWS CloudFormation stacks are cleaned up (in case the DynamoDB trigger cleanup logic fails) on the AWS CloudFormation console. After testing is done, AWS CDK can be used to destroy all the stacks and related resources by running the following command. `cdk destroy --all;` If you created an AWS profile for the credentials, use the profile. Confirm the stack deletion prompt to delete the stack.	

Task	Description	Skills required
Clean up Amazon CloudWatch Logs.	The stack deletion process will not clean up CloudWatc h Logs (log groups and logs) that were generated by the stack. Manually clean up the CloudWatch resources by using the CloudWatch console or the API.	App developer, AWS DevOps, AWS administrator

Additional information

Control-plane technology stack

The CDK code written in .NET is used to provision the control-plane infrastructure, which consists of the following resources:

1. **API Gateway**

   Serves as the REST API entry point for the control-plane stack.

2. **Tenant on-boarding Lambda function**

   This Lambda function is initiated by API Gateway using the m method.

   A POST method API request results in (`tenant name`, `tenant description`) being inserted into the DynamoDB `Tenant Onboarding` table.

   In this code example, the tenant name is also used as part of the tenant stack name and the names of resources within that stack. This is to make these resources easier to identify. This tenant name must be unique across the setup to avoid conflicts or errors. Detailed input validation setup is explained in the IAM roles documentation and the *Limitations* section.

The persistence process to the DynamoDB table will succeed only if the tenant name is not used in any other record in the table.

The tenant name in this case is the partition key for this table, because only the partition key can be used as a `PutItem` condition expression.

If the tenant name was never recorded before, the record will be saved into the table successfully.

However, if the tenant name is already used by an existing record in the table, the operation will fail and initiate a DynamoDB `ConditionalCheckFailedException` exception. The exception will be used to return a failure message (`HTTP BadRequest`) indicating that the tenant name already exists.

A `DELETE` method API request will remove the record for a specific tenant name from the `Tenant Onboarding` table.

The DynamoDB record deletion in this example will succeed even if the record does not exist.

If the target record exists and is deleted, it will create a DynamoDB stream record. Otherwise, no downstream record will be created.

3. **Tenant on-boarding DynamoDB, with Amazon DynamoDB Streams enabled**

   This records the tenant metadata information, and any record save or deletion will send a stream downstream to the `Tenant Infrastructure` Lambda function.

4. **Tenant infrastructure Lambda function**

   This Lambda function is initiated by the DynamoDB stream record from the previous step. If the record is for an `INSERT` event, it invokes AWS CloudFormation to create a new tenant infrastructure with the CloudFormation template that is stored in an S3 bucket. If the record is for `REMOVE`, it initiates deletion of an existing stack based on the stream record's `Tenant Name` field.

5. **S3 bucket**

   This is for storing the CloudFormation template.

6. **IAM roles for each Lambda function and a service role for CloudFormation**

Each Lambda function has its unique IAM role with least-privilege permissions to achieve its task. For example, the `Tenant On-boarding` Lambda function has read/write access to DynamoDB, and the `Tenant Infrastructure` Lambda function can only read the DynamoDB stream.

A custom CloudFormation service role is created for tenant stack provisioning. This service role contains additional permissions for CloudFormation stack provisioning (for example, the AWS KMS key). This divides roles between Lambda and CloudFormation to avoid all permissions on a single role (Infrastructure Lambda role).

Permissions that allow powerful actions (such as creating and deleting CloudFormation stacks) are locked down and allowed only on resources that start with `tenantcluster-`. The exception is AWS KMS, because of its resource naming convention. The ingested tenant name from the API will be prepended with `tenantcluster-` along with other validation checks (alphanumeric with dash only, and limited to less than 30 characters to fit into most AWS resource naming). This ensures that the tenant name will not accidentally result in disruption of core infrastructure stacks or resources.

Tenant technology stack

A CloudFormation template is stored in the S3 bucket. The template provisions the tenant-specific AWS KMS key, a CloudWatch alarm, an SNS topic, an SQS queue, and an SQS policy.

The AWS KMS key is used for data encryption by Amazon SNS and Amazon SQS for their messages. The security practices for AwsSolutions-SNS2 and AwsSolutions-SQS2 recommend that you set up Amazon SNS and Amazon SQS with encryption. However, CloudWatch alarms don't work with Amazon SNS when using an AWS managed key, so you must use a customer managed key in this case. For more information, see the AWS Knowledge Center.

The SQS policy is used on the Amazon SQS queue to allow the created SNS topic to deliver the message to the queue. Without the SQS policy, the access will be denied. For more information, see the Amazon SNS documentation.

Decompose monoliths into microservices by using CQRS and event sourcing

Rodolfo Jr. Cerrada, Dmitry Gulin, and Tabby Ward, Amazon Web Services

Summary

This pattern combines two patterns, using both the command query responsibility separation (CQRS) pattern and the event sourcing pattern. The CQRS pattern separates responsibilities of the command and query models. The event sourcing pattern takes advantage of asynchronous event-driven communication to improve the overall user experience.

You can use CQRS and Amazon Web Services (AWS) services to maintain and scale each data model independently while refactoring your monolith application into microservices architecture. Then you can use the event sourcing pattern to synchronize data from the command database to the query database.

This pattern uses example code that includes a solution (*.sln) file that you can open using the latest version of Visual Studio. The example contains Reward API code to showcase how CQRS and event sourcing work in AWS serverless and traditional or on-premises applications.

To learn more about CQRS and event sourcing, see the Additional information section.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Amazon CloudWatch
- Amazon DynamoDB tables
- Amazon DynamoDB Streams
- AWS Identity and Access Management (IAM) access key and secret key; for more information, see the video in the *Related resources* section
- AWS Lambda
- Familiarity with Visual Studio
- Familiarity with AWS Toolkit for Visual Studio; for more information, see the *AWS Toolkit for Visual Studio demo* video in the *Related resources* section

Product versions

- Visual Studio 2019 Community Edition.
- AWS Toolkit for Visual Studio 2019.
- .NET Core 3.1. This component is an option in the Visual Studio installation. To include .NET Core during installation, select **NET Core cross-platform development**.

Limitations

- The example code for a traditional on-premises application (ASP.NET Core Web API and data access objects) does not come with a database. However, it comes with the `CustomerData` in-memory object, which acts as a mock database. The code provided is enough for you to test the pattern.

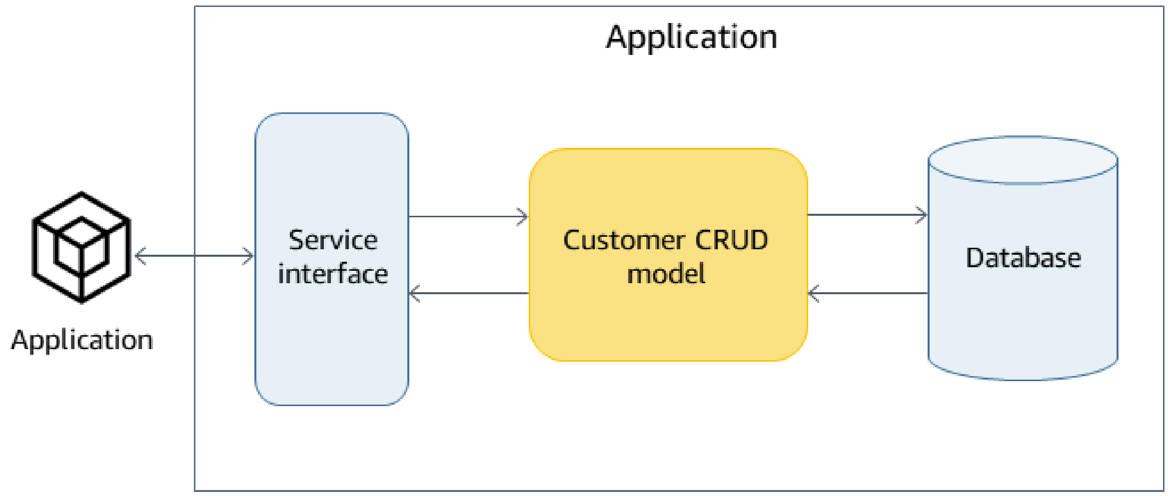
Architecture

Source technology stack

- ASP.NET Core Web API project
- IIS Web Server
- Data access object
- CRUD model

Source architecture

In the source architecture, the CRUD model contains both command and query interfaces in one application. For example code, see `CustomerDAO.cs` (attached).

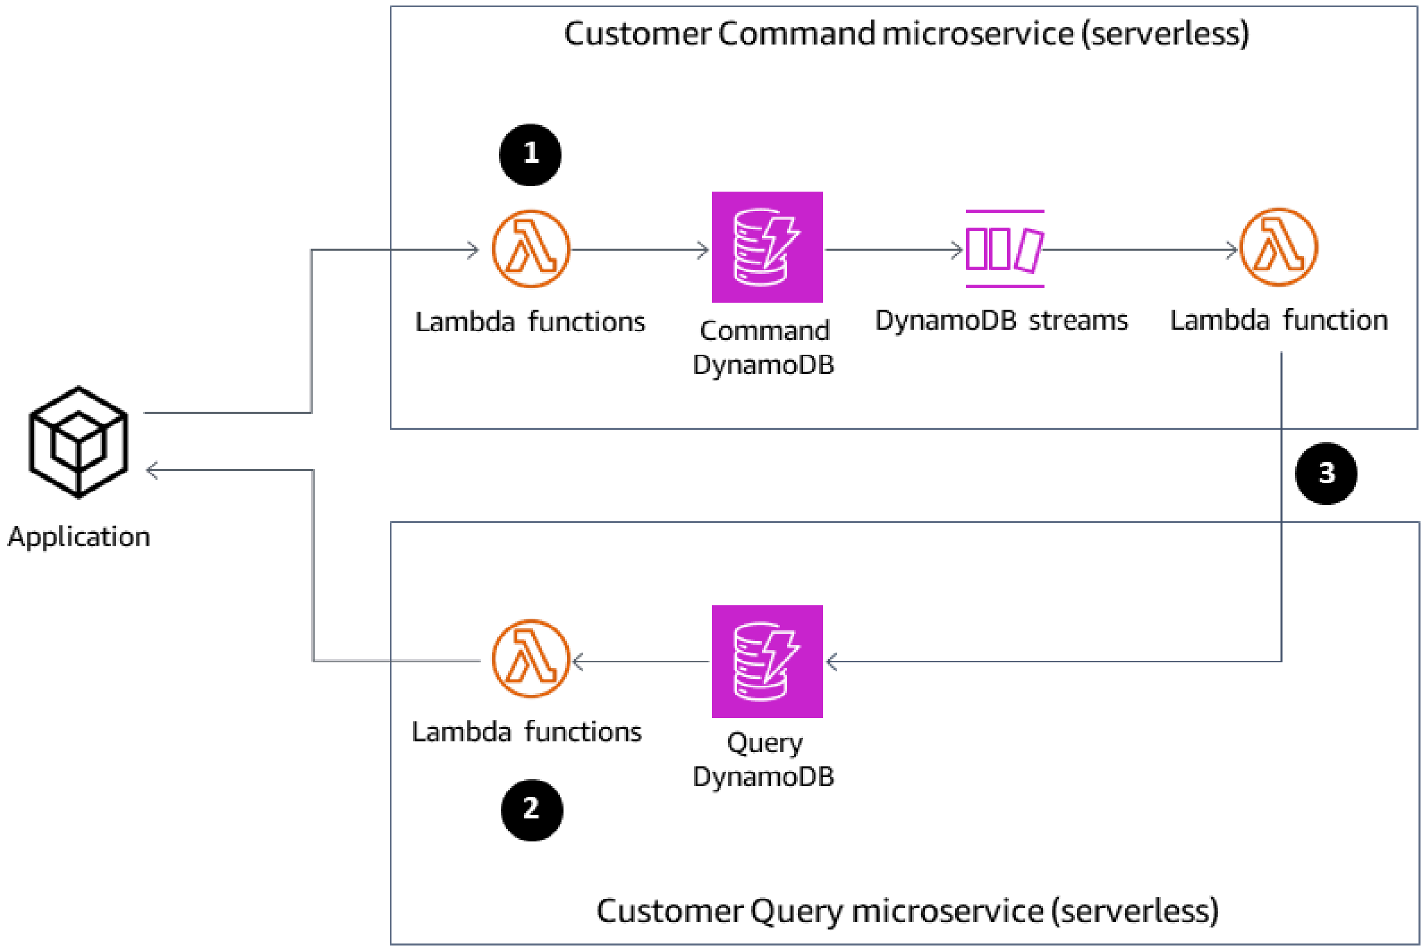


Target technology stack

- Amazon DynamoDB
- Amazon DynamoDB Streams
- AWS Lambda
- (Optional) Amazon API Gateway
- (Optional) Amazon Simple Notification Service (Amazon SNS)

Target architecture

In the target architecture, the command and query interfaces are separated. The architecture shown in the following diagram can be extended with API Gateway and Amazon SNS. For more information, see the Additional information section.



1. Command Lambda functions perform write operations, such as create, update, or delete, on the database.
2. Query Lambda functions perform read operations, such as get or select, on the database.
3. This Lambda function processes the DynamoDB streams from the Command database and updates the Query database for the changes.

Tools

Tools

- Amazon DynamoDB – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
- Amazon DynamoDB Streams – DynamoDB Streams captures a time-ordered sequence of item-level modifications in any DynamoDB table. It then stores this information in a log for up to 24 hours. Encryption at rest encrypts the data in DynamoDB streams.

- [AWS Lambda](#) – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- [AWS Management Console](#) – The AWS Management Console is a web application that comprises a broad collection of service consoles for managing AWS services.
- [Visual Studio 2019 Community Edition](#) – Visual Studio 2019 is an integrated development environment (IDE). The Community Edition is free for open-source contributors. In this pattern, you will use Visual Studio 2019 Community Edition to open, compile, and run example code. For viewing only, you can use any text editor or [Visual Studio Code](#).
- [AWS Toolkit for Visual Studio](#) – The AWS Toolkit for Visual Studio is a plugin for the Visual Studio IDE. The AWS Toolkit for Visual Studio makes it easier for you to develop, debug, and deploy .NET applications that use AWS services.

Code

The example code is attached. For instructions on deploying the example code, see the *Epics* section.

Epics

Open and build the solution

Task	Description	Skills required
Open the solution.	1. Download the example source code (`CQRS-ES Code.zip`) from the *Attachments* section, and extract the files. 2. In the Visual Studio IDE, choose **File**, **Open**, **Project Solution**, and navigate to the folder where you extracted the source code. 3. Choose **AWS.APG.CQRSES.sln**, and then	App developer

Task	Description	Skills required
	choose **Open**. The entire solution is loaded into Visual Studio.	
Build the solution.	Open the context (right-click) menu for the solution, and then choose **Build Solution**. This will build and compile all the projects in the solution. It should compile successfully. Visual Studio Solution Explorer should show the directory structure. • `CQRS On-Premises Code Sample` contains an example of using CQRS on premises. • `CQRS AWS Serverless` contains all the CQRS and event-sourcing example code using AWS serverless services.	App developer

Build the DynamoDB tables

Task	Description	Skills required
Provide credentials.	If you don't have an access key yet, see the video in the *Related resources* section. 1. In Solution Explorer, expand **CQRS AWS**	App developer, Data engineer, DBA

Task	Description	Skills required
	Serverless, and then expand the **Build** solution folder. 2. Expand the **AwS.APG.CQRSES.Build** project and view the `Program.cs` file. 3. Scroll to the top of `Program.cs` and look for `Program()` . 4. Replace `YOUR ACCESS KEY` with your account access key, and replace `YOUR SECRET KEY`with your account secret key. Note that in a production environment, you would not hardcode your keys. Instead, you could use [AWS Secrets Manager](https://aws.amazon.com/secrets-manager/) to store and retrieve the credentials.	
Build the project.	To build the project, open the context (right-click) menu for the **AwS.APG.CQRSES.Build** project, and then choose **Build**.	App developer, Data engineer, DBA

Task	Description	Skills required
Build and populate the tables.	To build the tables and populate them with seed data, open the context (right-click) menu for the **AwS.APG.CQRSES.Build** project, and then choose **Debug**, **Start New Instance**.	App developer, Data engineer, DBA
Verify the table construction and the data.	To verify, navigate to **AWS Explorer**, and expand **Amazon DynamoDB**. It should display the tables. Open each table to display the example data.	App developer, Data engineer, DBA

Run local tests

Task	Description	Skills required
Build the CQRS project.	1. Open the solution, and navigate to the **CQRS AWS Services/CQRS/Tests** solution folder. 2. In the **AWS.APG.CQRSES.CQRSLambda.Tests** project, open **BaseFunctionTest.cs**, and replace *AccessKey* and *SecretKey* with the IAM keys that you created. 3. Save the changes. 4. To compile and build the test project, open the context (right-click) menu	App developer, Test engineer

Task	Description	Skills required
	for the project, and then choose **Build**.	
Build the event-sourcing project.	1. Navigate to the **CQRS AWS Services/Event Source/Tests** solution folder. 2. In the **AWS.APG.CQRSES.EventSourceLambda.Tests** project, open **BaseFunctionTest.cs**, and replace *AccessKey* and *SecretKey* with the IAM keys that you created. 3. Save the changes. 4. To compile and build the test project, open the context (right-click) menu for the project, and then choose **Build**.	App developer, Test engineer
Run the tests.	To run all tests, choose **View**, **Test Explorer**, and then choose **Run All Tests In View**. All tests should pass, which is indicated by a green check mark icon.	App developer, Test engineer

Publish the CQRS Lambda functions to AWS

Task	Description	Skills required
Publish the first Lambda function.	1. In Solution Explorer, open the context (right-click) menu for the AWS.APG.C	App developer, DevOps engineer

Task	Description	Skills required
	QRSES.CommandCreateLambda project, and then choose **Publish to AWS Lambda**. 2. Select the profile that you want to use and the AWS Region where you want to deploy the Lambda function, and the function name. 3. For the remaining fields, keep the default values, and choose **Next**. 4. In **Role Name** dropdown list, select **AWSLambdaFullAccess**. 5. To provide your account keys, choose **Add**, and enter `AcessKey` as the variable and your access key as the value. Then choose **Add** again, enter `SecretKey` as the variable and your secret key as the value. 6. For the remaining fields, keep the default values, and choose **Upload**. After the Lambda test function uploads, it appears in Visual Studio automatically. 7. Repeat steps 1-6 for the following projects:	

Task	Description	Skills required
	• AWS.APG.CQRSES.CommandDeleteLambda • AWS.APG.CQRSES.CommandUpdateLambda • AWS.APG.CQRSES.CommandAddRewardLambda • AWS.APG.CQRSES.CommandRedeemRewardLambda • AWS.APG.CQRSES.QueryCustomerListLambda • AWS.APG.CQRSES.QueryRewqardLambda	
Verify the function upload.	(Optional) You can verify that the function was successfully loaded by navigating to AWS Explorer and expanding **AWS Lambda**. To open the test window, choose the Lambda function (double-click).	App developer, DevOps engineer

Task	Description	Skills required
Test the Lambda function.	1. Enter the request data, or copy an example request data from **Test data** in the [Additional information](#) section. Make sure that you select data that is for the function you are testing. 2. To run the test, choose **Invoke**. The response and any errors are displayed in the **Response** text box, and logs are shown in the **Logs** text box or in CloudWatch Logs. 3. To verify the data, in AWS Explorer, choose the DynamoDB table (double-click). All CQRS Lambda projects are found under the `CQRS AWS Serverless\CQRS\Command Microservice` and `CQRS AWS Serverless\CQRS\Command Microservice` solution folders. For the solution directory and projects, see **Source code directory** in the [Additional information](#) section.	App developer, DevOps engineer

Task	Description	Skills required
Publish the remaining functions.	Repeat the previous steps for the following projects: • AWS.APG.CQRSES.CommandDeleteLambda • AWS.APG.CQRSES.CommandUpdateLambda • AWS.APG.CQRSES.CommandAddRewardLambda • AWS.APG.CQRSES.CommandRedeemRewardLambda • AWS.APG.CQRSES.QueryCustomerListLambda • AWS.APG.CQRSES.QueryRewqardLambda	App developer, DevOps engineer

Set up the Lambda function as an event listener

Task	Description	Skills required
Publish the Customer and Reward Lambda event handlers.	To publish each event handler, follow the steps in the preceding epic. The projects are under the `CQRS AWS Serverless\Event Source\Customer Event` and `CQRS AWS Serverless\Event Source\Reward Event` solution folders. For more information, see *Source code*	App developer

Task	Description	Skills required
	directory in the Additional information section.	

Task	Description	Skills required
Attach the event-sourcing Lambda event listener.	1. Log in to the AWS Management Console using the same account you use when you publish the Lambda projects. 2. For the **Region**, select **US East 1** or the Region where you deployed the Lambda functions in the previous epic. 3. Navigate to the **Lambda** service. 4. Select the `EventSourceCustomer` Lambda function. 5. Choose **Add Trigger**. 6. In the **Trigger configuration** dropdown list, select **DynamoDB**. 7. In the **DynamoDB table** dropdown list, select **cqrses-customer-cmd**. 8. In the **Starting position** dropdown list, select *Trim horizon* from . Trim horizon means that the DynamoDB trigger will start reading at the last (untrimmed) stream record, which is the oldest record in the shard. 9. Select the **Enable trigger** check box.	App developer

Task	Description	Skills required
	10For the remaining fields, keep the default values, and choose **Add**. After the listener is successfully attached to the DynamoDB table, it will be displayed on the Lambda designer page.	
Publish and attach the EventSourceReward Lambda function.	To publish and attach the `EventSourceReward` Lambda function, repeat the steps in the previous two stories, selecting **cqrses-reward-cmd** from the **DynamoDB table** dropdown list.	App developer

Test and validate the DynamoDB streams and Lambda trigger

Task	Description	Skills required
Test the stream and the Lambda trigger.	1. In Visual Studio, navigate to AWS Explorer. 2. Expand AWS Lambda, and choose the **CommandRedeemReward** function (double-click). In the function window that opens, you can test the function. 3. In the **Request** text box, enter the request data in JavaScript Object Notation	App developer

Task	Description	Skills required
	(JSON) format. For an example request, see **Test data** in the [Additional information](#) section. 4. Choose **Invoke**.	
Validate, using the DynamodDB reward query table.	1. Open the **cqrses-reward-query** table. 2. Check the points of the customer that redeemed the reward. The redeemed points should be subtracted from the customer's total aggregated points.	App developer
Validate, using CloudWatch Logs.	1. Navigate to CloudWatch and choose **Log groups**. 2. The **/aws/lambda/EventSourceReward** log group contains the logs for the `EventSourceReward` trigger. All Lambda calls are logged, including the messages you placed in `context.Logger.LogLine` and `Console.Writeline` in the Lambda code.	App developer

Task	Description	Skills required
Validate the EventSourceCustomer trigger.	To validate the `EventSourceCustomer` trigger, repeat the steps in this epic, using the `EventSourceCustomer` trigger's respective customer table and CloudWatch logs.	App developer

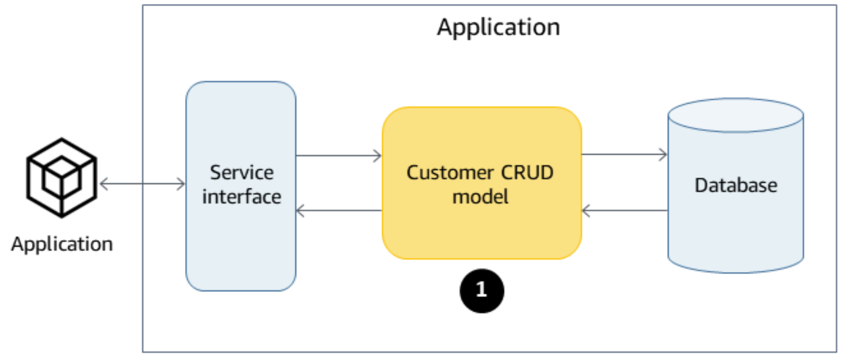
Additional information

CQRS and event sourcing

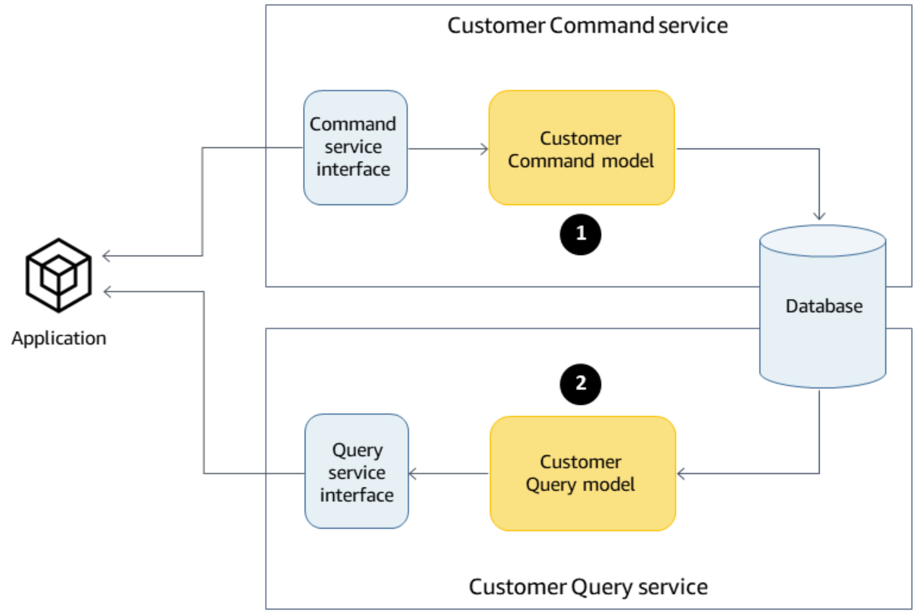
CQRS

The CQRS pattern separates a single conceptual operations model, such as a data access object single CRUD (create, read, update, delete) model, into command and query operations models. The command model refers to any operation, such as create, update, or delete, that changes the state. The query model refers to any operation that returns a value.



1. The Customer CRUD model includes the following interfaces:
   - `Create Customer()`
   - `UpdateCustomer()`
   - `DeleteCustomer()`
   - `AddPoints()`
   - `RedeemPoints()`
   - `GetVIPCustomers()`
   - `GetCustomerList()`
   - `GetCustomerPoints()`

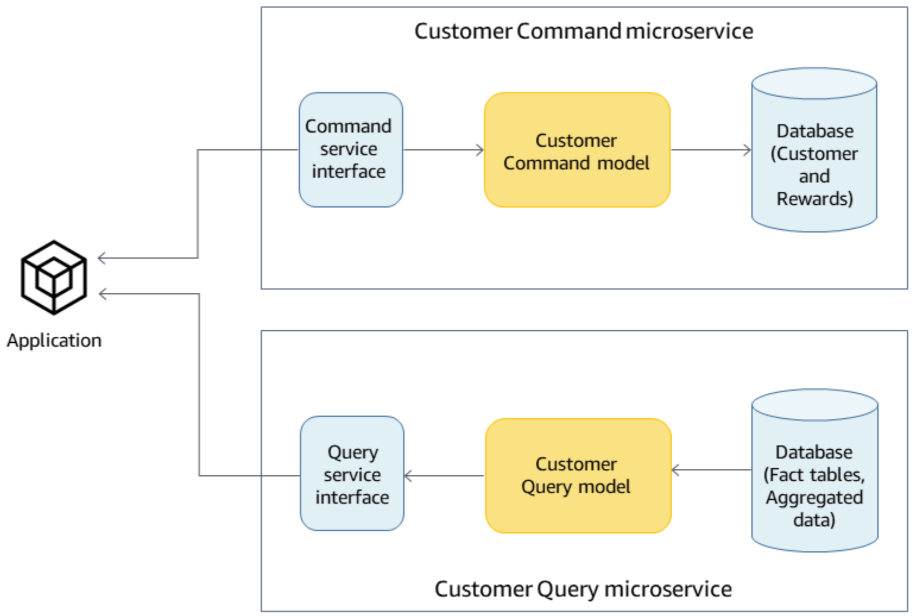
As your requirements become more complex, you can move from this single-model approach. CQRS uses a command model and a query model to separate the responsibility for writing and reading data. That way, the data can be independently maintained and managed. With a clear separation of responsibilities, enhancements to each model do not impact the other. This separation improves maintenance and performance, and it reduces the complexity of the application as it grows.



1. Interfaces in the Customer Command model:
   - `Create Customer()`
   - `UpdateCustomer()`
   - `DeleteCustomer()`
   - `AddPoints()`
   - `RedeemPoints()`
2. Interfaces in the Customer Query model:
   - `GetVIPCustomers()`
   - `GetCustomerList()`
   - `GetCustomerPoints()`
   - `GetMonthlyStatement()`

For example code, see *Source code directory*.

The CQRS pattern then decouples the database. This decoupling leads to the total independence of each service, which is the main ingredient of microservice architecture.



Using CQRS in the AWS Cloud, you can further optimize each service. For example, you can set different compute settings or choose between a serverless or a container-based microservice. You can replace your on-premises caching with Amazon ElastiCache. If you have an on-premises publish/subscribe messaging, you can replace it with Amazon Simple Notification Service (Amazon SNS). Additionally, you can take advantage of pay-as-you-go pricing and the wide array of AWS services that you pay only for what you use.

CQRS includes the following benefits:

- Independent scaling – Each model can have its scaling strategy adjusted to meet the requirements and demand of the service. Similar to high-performance applications, separating read and write enables the model to scale independently to address each demand. You can also add or reduce compute resources to address the scalability demand of one model without affecting the other.
- Independent maintenance – Separation of query and command models improves the maintainability of the models. You can make code changes and enhancements to one model without affecting the other.
- Security – It's easier to apply the permissions and policies to separate models for read and write.
- Optimized reads – You can define a schema that is optimized for queries. For example, you can define a schema for the aggregated data and a separate schema for the fact tables.
- Integration – CQRS fits well with event-based programming models.

- Managed complexity – The separation into query and command models is suited to complex domains.

When using CQRS, keep in mind the following caveats:

- The CQRS pattern applies only to a specific portion of an application and not the whole application. If implemented on a domain that does not fit the pattern, it can reduce productivity, increase risk, and introduce complexity.
- The pattern works best for frequently used models that have an imbalance read and write operations.
- For read-heavy applications, such as large reports that take time to process, CQRS gives you the option to select the right database and create a schema to store your aggregated data. This improves the response time of reading and viewing the report by processing the report data only one time and dumping it in the aggregated table.
- For the write-heavy applications, you can configure the database for write operations and allow the command microservice to scale independently when the demand for write increases. For examples, see the `AWS.APG.CQRSES.CommandRedeemRewardLambda` and `AWS.APG.CQRSES.CommandAddRewardLambda` microservices.

Event sourcing

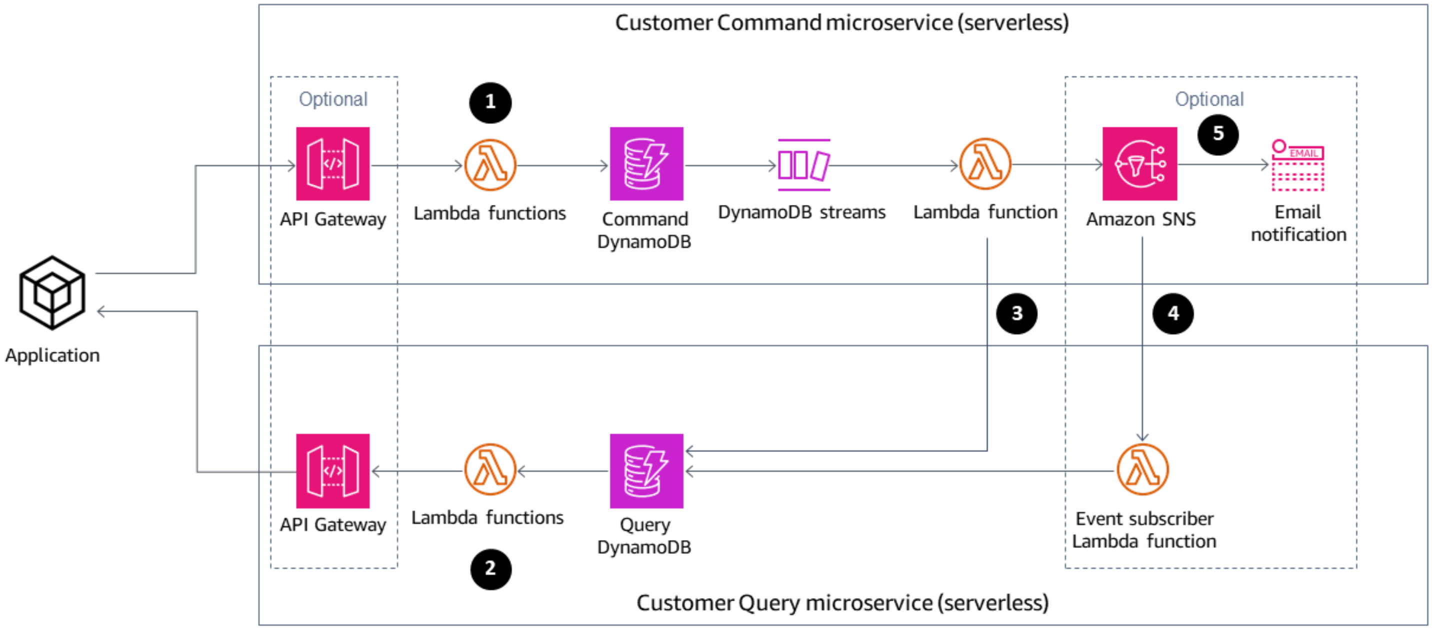
The next step is to use event sourcing to synchronize the query database when a command is run. For example, consider the following events:

- A customer reward point is added that requires the customer total or aggregated reward points in the query database to be updated.
- A customer's last name is updated in the command database, which requires the surrogate customer information in the query database to be updated.

In the traditional CRUD model, you ensure consistency of data by locking the data until it finishes a transaction. In event sourcing, the data are synchronized through publishing a series of events that will be consumed by a subscriber to update its respective data.

The event-sourcing pattern ensures and records a full series of actions taken on the data and publishes it through a sequence of events. These events represent a set of changes to the data that subscribers of that event must process to keep their record updated. These events are consumed by the subscriber, synchronizing the data on the subscriber's database. In this case, that's the query database.

The following diagram shows event sourcing used with CQRS on AWS.



1. Command Lambda functions perform write operations, such as create, update, or delete, on the database.
2. Query Lambda functions perform read operations, such as get or select, on the database.
3. This Lambda function processes the DynamoDB streams from the Command database and updates the Query database for the changes. You can also use this function also to publish a message to Amazon SNS so that its subscribers can process the data.
4. (Optional) The Lambda event subscriber processes the message published by Amazon SNS and updates the Query database.
5. (Optional) Amazon SNS sends email notification of the write operation.

On AWS, the query database can be synchronized by DynamoDB Streams. DynamoDB captures a time-ordered sequence of item-level modifications in a DynamobDB table in near-real time and durably stores the information within 24 hours.

Activating DynamoDB Streams enables the database to publish a sequence of events that makes the event sourcing pattern possible. The event sourcing pattern adds the event subscriber. The event subscriber application consumes the event and processes it depending on the subscriber's responsibility. In the previous diagram, the event subscriber pushes the changes to the Query

DynamoDB database to keep the data synchronized. The use of Amazon SNS, the message broker, and the event subscriber application keeps the architecture decoupled.

Event sourcing includes the following benefits:

- Consistency for transactional data
- A reliable audit trail and history of the actions, which can be used to monitor actions taken in the data
- Allows distributed applications such as microservices to synchronize their data across the environment
- Reliable publication of events whenever the state changes
- Reconstructing or replaying of past states
- Loosely coupled entities that exchange events for migration from a monolithic application to microservices
- Reduction of conflicts caused by concurrent updates; event sourcing avoids the requirement to update objects directly in the data store
- Flexibility and extensibility from decoupling the task and the event
- External system updates
- Management of multiple tasks in a single event

When using event sourcing, keep in mind the following caveats:

- Because there is some delay in updating data between the source subscriber databases, the only way to undo a change is to add a compensating event to the event store.
- Implementing event sourcing has a learning curve since its different style of programming.

Test data

Use the following test data to test the Lambda function after successful deployment.

CommandCreate Customer

```
{  "Id":1501,  "Firstname":"John",  "Lastname":"Done",  "CompanyName":"AnyCompany",
 "Address": "USA",  "VIP":true }
```

CommandUpdate Customer

```
{  "Id":1501,  "Firstname":"John",  "Lastname":"Doe",  "CompanyName":"Example Corp.",
 "Address": "Seattle, USA",  "VIP":true }
```

CommandDelete Customer

Enter the customer ID as request data. For example, if the customer ID is 151, enter 151 as request data.

```
151
```

QueryCustomerList

This is blank. When it is invoked, it will return all customers.

CommandAddReward

This will add 40 points to customer with ID 1 (Richard).

```
{
  "Id":10101,
  "CustomerId":1,
  "Points":40
}
```

CommandRedeemReward

This will deduct 15 points to customer with ID 1 (Richard).

```
{
  "Id":10110,
  "CustomerId":1,
  "Points":15
}
```

QueryReward

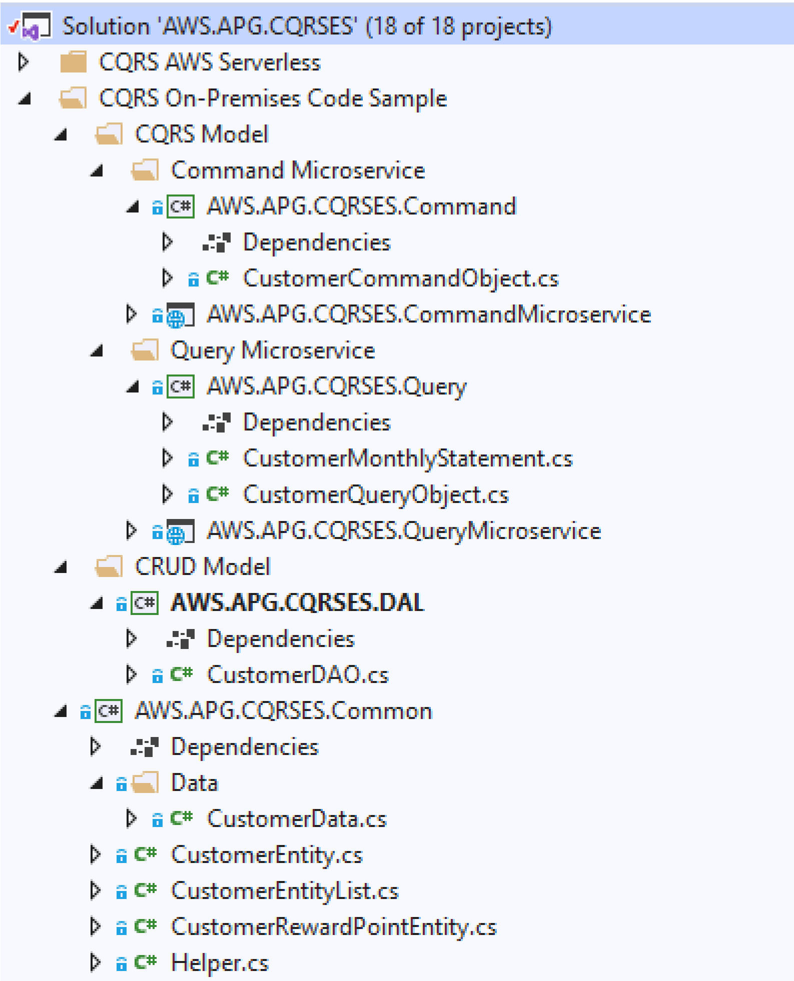
Enter the ID of the customer. For example, enter 1 for Richard, 2 for Arnav, and 3 for Shirley.

```
2
```

Source code directory

Use the following table as a guide to the directory structure of the Visual Studio solution.

CQRS On-Premises Code Sample solution directory



Customer CRUD model

CQRS On-Premises Code Sample\CRUD Model\AWS.APG.CQRSES.DAL project

CQRS version of the Customer CRUD model

- Customer command: `CQRS On-Premises Code Sample\CQRS Model\Command Microservice\AWS.APG.CQRSES.Command`project
- Customer query: `CQRS On-Premises Code Sample\CQRS Model\Query Microservice \AWS.APG.CQRSES.Query` project

Command and Query microservices

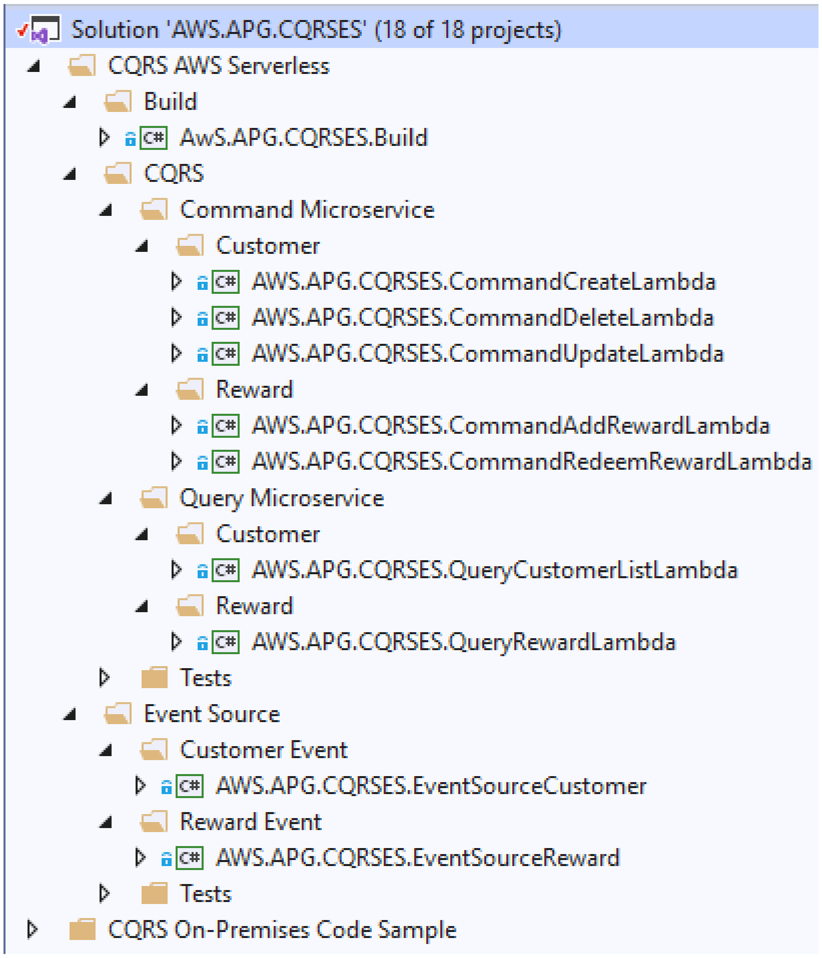
The Command microservice is under the solution folder `CQRS On-Premises Code Sample\CQRS Model\Command Microservice`:

- `AWS.APG.CQRSES.CommandMicroservice` ASP.NET Core API project acts as the entry point where consumers interact with the service.
- `AWS.APG.CQRSES.Command` .NET Core project is an object that hosts command-related objects and interfaces.

The query microservice is under the solution folder `CQRS On-Premises Code Sample\CQRS Model\Query Microservice`:

- `AWS.APG.CQRSES.QueryMicroservice` ASP.NET Core API project acts as the entry point where consumers interact with the service.
- `AWS.APG.CQRSES.Query` .NET Core project is an object that hosts query-related objects and interfaces.

CQRS AWS Serverless code solution directory



This code is the AWS version of the on-premises code using AWS serverless services.

In C# .NET Core, each Lambda function is represented by one .NET Core project. In this pattern's example code, there is a separate project for each interface in the command and query models.

CQRS using AWS services

You can find the root solution directory for CQRS using AWS serverless services is in the `CQRS AWS Serverless\CQRS`folder. The example includes two models: Customer and Reward.

The command Lambda functions for Customer and Reward are under `CQRS\Command Microservice\Customer` and `CQRS\Command Microservice\Reward` folders. They contain the following Lambda projects:

- Customer command: `CommandCreateLambda`, `CommandDeleteLambda`, and `CommandUpdateLambda`
- Reward command: `CommandAddRewardLambda` and `CommandRedeemRewardLambda`

The query Lambda functions for Customer and Reward are found under the `CQRS\Query Microservice\Customer` and `CQRS\QueryMicroservice\Reward`folders. They contain the `QueryCustomerListLambda` and `QueryRewardLambda` Lambda projects.

CQRS test project

The test project is under the `CQRS\Tests` folder. This project contains a test script to automate testing the CQRS Lambda functions.

Event sourcing using AWS services

The following Lambda event handlers are initiated by the Customer and Reward DynamoDB streams to process and synchronize the data in query tables.

- The `EventSourceCustomer` Lambda function is mapped to the Customer table (`cqrses-customer-cmd`) DynamoDB stream.
- The `EventSourceReward` Lambda function is mapped to the Reward table (`cqrses-reward-cmd`) DynamoDB stream.

Access AWS services from IBM z/OS by installing the AWS CLI

Souma Ghosh, Paulo Vitor Pereira, and Phil de Valence, Amazon Web Services

Summary

The AWS Command Line Interface (AWS CLI) is an open source tool for managing multiple AWS services by using commands in a command line shell. With minimal configuration, you can run commands from command line sessions such as the command prompt, terminal, and bash shell to implement functionality that's equivalent to that provided by the browser-based AWS Management Console.

All AWS infrastructure as a service (IaaS) administration, management, and access functions in the AWS Management Console are available in the AWS API and AWS CLI. You can install the AWS CLI on an IBM z/OS mainframe to directly access, manage, and interact with AWS services from z/OS. The AWS CLI enables users and applications to perform various tasks, such as:

- Transferring files or datasets between z/OS and Amazon Simple Storage Service (Amazon S3) object storage and viewing content of buckets
- Starting and stopping different AWS resources; for example, starting a batch job in an AWS Mainframe Modernization environment
- Calling an AWS Lambda function to implement common business logic
- Integrating with artificial intelligence and machine learning (AI/ML) and analytics services

This pattern describes how to install, configure, and use the AWS CLI on z/OS. You can install it globally, so it's available to all z/OS users, or at a user level. The pattern also details how to use the AWS CLI in an interactive command line session from z/OS Unix System Services (USS) or as a batch job.

Prerequisites and limitations

Prerequisites

- **Network communication from z/OS to AWS**

  By default, the AWS CLI sends requests to AWS services by using HTTPS on TCP port 443. To use the AWS CLI successfully, you must be able to make outbound connections on TCP port 443. You can use any of the following z/OS USS commands (some of these might not be installed in your environment) to test network connectivity from z/OS to AWS:

```
ping amazonaws.com
dig amazonaws.com
traceroute amazonaws.com
curl -k https://docs.aws.amazon.com/cli/v1/userguide/cli-chap-welcome.html
```

- **AWS credentials**

  In order to communicate with AWS Cloud services from z/OS, the AWS CLI requires you to configure some credentials with privileges to access the target AWS account. For programmatic commands to AWS, you can use access keys, which consist of an access key ID and secret access key. If you don't have access keys, you can create them from the AWS Management Console. As a best practice, do not use the access keys for the AWS account root user for any task unless the root user is required. Instead, create a new administrator IAM user and prepare for least-privilege permissions to set up the user with access keys. After you create the user, you can create an access key ID and secret access key for this user.

  > **Warning**
  >
  > AWS Identity and Access Management (IAM) users have long-term credentials that present a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

- **IBM Python for z/OS**

  The AWS CLI requires Python 3.8 or later. IBM has enabled Python to run on z/OS with IBM Open Enterprise Python for z/OS. IBM Open Enterprise Python is available at no charge through Shopz SMP/E, or you can download the PAX file from the IBM website. For instructions, see the installation and configuration documentation for IBM Open Enterprise Python for z/OS.

Limitations

- The installation instructions provided in this pattern are applicable to **AWS CLI version 1 only**. The latest version of the AWS CLI is version 2. However, this pattern uses the older version because the installation methods are different for version 2, and the binary executables available for version 2 aren't compatible with the z/OS system.

Product versions

- AWS CLI version 1
- Python 3.8 or later

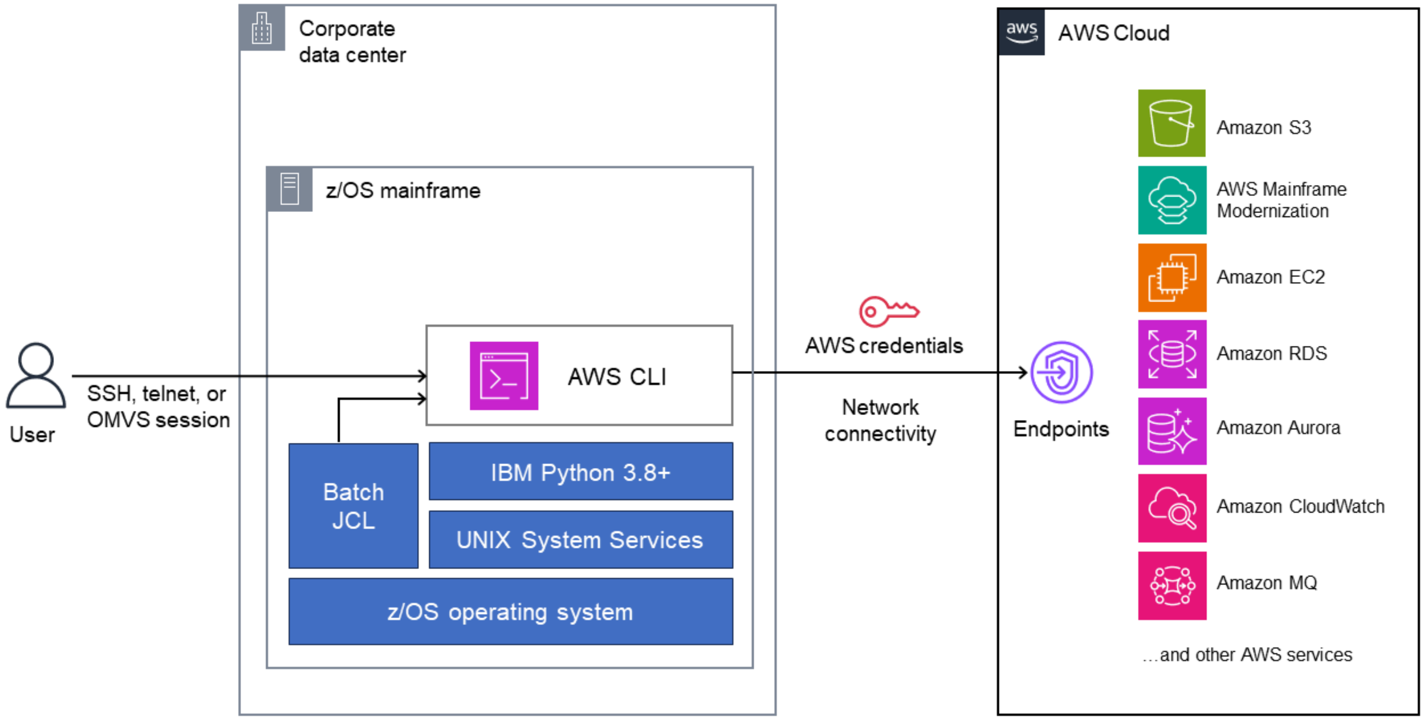
Architecture

Technology stack

- Mainframe running z/OS
- Mainframe z/OS UNIX System Services (USS)
- Mainframe Open MVS (OMVS) – z/OS UNIX shell environment command interface
- Mainframe disk, such as a direct-access storage device (DASD)
- AWS CLI

Target architecture

The following diagram shows an AWS CLI deployment on IBM z/OS. You can invoke the AWS CLI from an interactive user session, such as SSH, and telnet sessions. You can also invoke it from a batch job by using job control language (JCL), or from any program that can call a z/OS Unix shell command.



The AWS CLI communicates with AWS service endpoints over a TCP/IP network. This network connection can happen over the internet or through a private AWS Direct Connect connection from the customer data center to AWS Cloud data centers. The communication is authenticated with AWS credentials and encrypted.

Automation and scale

You can explore the capabilities of an AWS service with the AWS CLI and develop USS shell scripts to manage your AWS resources from z/OS. You can also run AWS CLI commands and shell scripts from the z/OS batch environment, and you can automate batch jobs to run on a specific schedule by integrating with mainframe schedulers. AWS CLI commands or scripts can be coded inside parameters (PARMs) and procedures (PROCs), and can be scaled by following the standard approach of calling the PARM or PROC from different batch jobs with different parameters.

Tools

- [AWS Command Line Interface (AWS CLI)](#) is an open source tool that helps you interact with AWS services through commands in your command-line shell.

Best practices

- For security reasons, restrict the access permissions to the USS directory where the AWS access key details are stored. Allow access to only the users or programs that use the AWS CLI.
- Do not use the AWS account root user access keys for any task. Instead, create a new administrator IAM user for yourself and set it up with access keys.

> **Warning**
>
> IAM users have long-term credentials that present a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.

Epics

Install AWS CLI version 1 on z/OS USS

Task	Description	Skills required
Install Python 3.8 or later.	1. Log in to the z/OS USS command prompt interface by using one of these methods: • Use a Time Sharing Option (TSO) OMVS command from the Interactive System Productivity Facility (ISPF) panel, or • Use SSH or telnet to connect to the IP of the mainframe logical partition (LPAR).	Mainframe z/OS administr ator

Task	Description	Skills required
	This pattern assumes that `cliuser` is the userid used to log in to the USS environment and `/u/cliuser/` is the home directory for the user. You can set the user home directory differently in your z/OS environment depending on your installation requirements. 2. Follow the installation guide for IBM Open Enterprise Python for z/OS to install Python 3.8 or later if it isn't already installed.	

Task	Description	Skills required

Set USS environment variables.	Add environment variables to the profile. You can add these either to the `/u/cliuser/.profile` file for an individual user (`cliuser`) or to the `/etc/profile` file for all users.
	
	Note
	This pattern assumes that Python has been installed in the `/u/awscli/python` directory. If your installation directory is different, update the code accordingly.
	
	`# Python configuration`
	`export BPXKAUTOC`
	`VT='ON'`
	`export CEERUNOPT`
	`S='FILETAG(AUTOCVT`
	`,AUTOTAG) POSIX(ON)'`
	`export TAGREDIR_ERR=txt`
	`export TAGREDIR_IN=txt`
	`export TAGREDIR_`
	`OUT=txt`
	
	`# AWS CLI configura`
	`tion`
	`export PATH=/u/c`
	`liuser/python/bin:`
	`$PATH`
		Mainframe z/OS administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre>export PYTHONPATH=/u/cliuser/python:$PYTHONPATH</pre></td><td></td></tr>
<tr><td>Test the Python installation.</td><td>Run the python command:<pre>python --version</pre>The output should confirm that you have Python 3.8 or later installed correctly.</td><td>Mainframe z/OS administrator</td></tr>
<tr><td>Verify or install pip.</td><td>1. The pip command is usually installed automatically when you install Python from the IBM website. To verify, run the command:<pre>pip ––version</pre>If pip is installed, this command should show the installed version.
2. If the pip command isn't found, install pip by running the following command:<pre>python -m ensurepip --upgrade</pre>For more installation options, see the pip documentation.</td><td>Mainframe z/OS administrator</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install AWS CLI version 1.</td><td>

1. To install the AWS CLI, run the command:

```
python -m pip install
 awscli
```

The output should be similar to the following.

```
Successfully
 installed PyYAML-6.
0.1 awscli-1.32.23
 botocore-1.34.23
 colorama-0.4.4
 docutils-0.16
 jmespath-1.0.1
pyasn1-0.5.1 python-
dateutil-2.8.2
 rsa-4.7.2 s3transfe
r-0.10.0 urllib3-2
.0.7
```

2. Change the permission of the **aws** executable by running the following command. Make sure to update the placeholder directory `<python_installation_dir>` with your Python installation path.

```
chmod 744 <python_i
nstallation_dir>/b
in/aws
```

</td><td>Mainframe z/OS administrator</td></tr>
</table>

Task	Description	Skills required

	3. Run the following command to test the AWS CLI installation:
	`aws --version`
	The output should show the versions of the AWS CLI, Python, and botocore, similar to the following.
	`aws-cli/1.32.3 Python/3.9.5 OS/390/27.00 botocore/1.34.3`	

Configure AWS CLI access from z/OS

Task	Description	Skills required
Configure the AWS access keys, default Region, and output.	The AWS CLI documentation describes different options for setting up AWS access. You can choose a configuration according to your organizat ion's standards. This example uses the short-term credentia l configuration. 1. Configure the AWS CLI with the following command: `aws configure`	AWS administrator, Mainframe z/OS administr ator, Mainframe z/OS developer

Task	Description	Skills required

	2. Provide the details for the following items when prompted. The access key ID and secret access key values are from the keys you obtained when you set AWS credentials in the [Prerequisites](#) steps.
	
	`AWS Access Key ID [None]: ASIAIOSFODNN7EXAMPLE`
	`AWS Secret Access Key [None]: wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY`
	`Default region name [None]: us-east-1`
	`Default output format [None]:`
	`aws configure set aws_session_token IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZ2luX2IQoJb3JpZVERYLONGSTRINGEXAMPLE`
	
	This configuration, including access keys, is stored in the `/u/cliuser/.aws` folder. For security reasons, restrict this folder to allow access only to the users or programs that use the AWS CLI.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Test the AWS CLI.</td><td>1. Run the following command at the command prompt to test the AWS CLI with a simple command:

<code>aws s3 ls</code>

The output should list all the S3 buckets for the configured AWS account without any errors.
2. Follow the instructions in the next two epics to transfer data from USS to Amazon S3. You can choose one of these two options:
• Option 1 (next epic): Interactively transfer an EBCDIC comma-separated value (CSV) file to Amazon S3 and query the file from Amazon Athena.
• Option 2: Transfer an EBCDIC fixed-length dataset to Amazon S3 as a batch job.</td><td>Mainframe z/OS administrator, Mainframe z/OS developer</td></tr>
</table>

Option 1 – Transfer data from USS to Amazon S3 interactively from a USS session

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Download and transfer the sample CSV file.</td><td>1. Download <code>sales-records.csv</code> from the Attachments section. This file provides a sample CSV file with sales records.
2. Transfer the file to z/OS USS.
3. Verify that the <code>/u/cliuser/sales-records.csv</code> file is readable in EBCDIC format in USS by using a text editor of your choice.</td><td>App developer, Mainframe z/OS developer</td></tr>
<tr><td>Create an S3 bucket and upload the CSV file.</td><td>1. Create an S3 bucket to store the CSV file.
<pre>aws s3 mb s3://<s3_bucket_name></pre>where <code><s3_bucket_name></code> is the unique name for a bucket; for example:
<pre>aws s3 mb s3://DOC-EXAMPLE-BUCKET1</pre>2. Upload the CSV file from z/OS USS to the S3 bucket:</td><td>App developer, Mainframe z/OS developer</td></tr>
</table>

Task	Description	Skills required
	``` aws s3 cp <csv_file_path> s3://<s3_bucket_name> ``` For example: ``` aws s3 cp /u/cliuser/sales-records.csv s3://DOC-EXAMPLE-BUCKET1 ``` 3. List the contents of the S3 bucket and confirm that they include the uploaded file: ``` aws s3 ls s3://<s3_bucket_name> ``` For example: ``` aws s3 ls s3://DOC-EXAMPLE-BUCKET1 ```	

Task	Description	Skills required
View the S3 bucket and uploaded file.	1. Sign in to the AWS Management Console and open the Amazon S3 console. 2. Navigate to see the new S3 bucket and the uploaded object. For more information about uploading objects, see Getting started with Amazon S3 in the Amazon S3 documentation.	General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Run a SQL query on an Amazon Athena table.</td><td>
1. Open the Amazon Athena console.
2. Create a new table (for example, <code>DOC-EXAMPLE-BUCKET</code>) by using the CSV data from Amazon S3. For more information, see Querying Amazon S3 Inventory with Amazon Athena in the Amazon S3 documentation.
3. Run the <code>SELECT</code> query against the table to view the data.
<pre>SELECT * FROM
 <table_name>;</pre>
For example:
<pre>SELECT * FROM DOC-
EXAMPLE-BUCKET;</pre>
The output of the SQL query will display the contents of your CSV file.</td><td>General AWS, App developer</td></tr>
</table>

Option 2 – Transfer data from USS to Amazon S3 by using batch JCL

Task	Description	Skills required
Upload the sample file.	1. Download `sales-records-fixed.txt` from	Mainframe z/OS developer

Task	Description	Skills required
	the Attachments section. This is a sample file with sales records. Rename the text file; for example, to `USER.DATA.FIXED` . 2. Transfer the file to z/OS as a fixed-blocked (FB), 256 record length (LRECL), physical sequential (PS) dataset. 3. Use the dataset list utility to verify that the `USER.DATA.FIXED` dataset is readable in EBCDIC format under ISPF option 3.4. See the Additional information section for example output.	

Task	Description	Skills required

Create batch JCL.	Code the batch JCL as follows to create the destination S3 bucket, upload the dataset, and list the bucket content. Make sure to replace the directory name, file names, and bucket name to your own values.
	
	`//AWSCLICP JOB ACTINFO1,'IBMUSER' ,CLASS=A,MSGCLASS= H,MSGLEVEL=(1,1), // NOTIFY=&SYSUID,TIM E=1440`
	`//*---------------------------------------------------`
	`//* Sample job for AWS CLI`
	`//*---------------------------------------------------`
	`//USSCMD EXEC PGM=BPXBA TCH`
	`//STDERR  DD SYSOUT=*`
	`//STDOUT  DD SYSOUT=*`
	`//STDENV  DD *`
	`export PATH=/u/c liuser/python/bin: $PATH`
	`//STDPARM DD *`
	`SH`
	`export _BPXK_AUT OCVT=ON;`
	`aws s3 mb s3://DOC- EXAMPLE-BUCKET2;`
		Mainframe z/OS developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

```
 cp "//'USER.DATA.FIXE
D'" /tmp/tmpfile;
 aws s3 cp /tmp/tmpf
ile s3://DOC-EXAMPLE-
BUCKET2/USER.DATA.F
IXED;
 rm /tmp/tmpfile;
 aws s3 ls s3://DOC-
EXAMPLE-BUCKET2;
/*
```

</td><td></td></tr>
<tr><td>Submit the batch JCL job.</td><td>

1. Submit the JCL job that you coded in the previous step.
2. Check the status of the job in System Display and Search Facility (SDSF). If successful, the job should end with return code 0.
3. The standard output (STDOUT) from the job log shows the successful bucket creation, dataset upload, and list of bucket contents. For a sample screen illustration, see the [Additional information](#) section.

</td><td>Mainframe z/OS developer</td></tr>
</table>

Task	Description	Skills required
View the dataset uploaded to the S3 bucket.	1. Sign in to the AWS Management Console and open the [Amazon S3 console](). 2. Navigate to see the uploaded file in the test bucket. 3. You can further process the `USER.DATA.FIXED` file or analyze it by using analytics services such as Amazon Redshift.	General AWS

Back up and archive mainframe data to Amazon S3 using BMC AMI Cloud Data

Santosh Kumar Singh, Gilberto Biondo, and Maggie Li, Amazon Web Services

Mikhael Liberman, Model9 Mainframe Software

Summary

This pattern demonstrates how to back up and archive mainframe data directly to Amazon Simple Storage Service (Amazon S3), and then recall and restore that data to the mainframe by using BMC AMI Cloud Data (previously known as Model9 Manager). If you are looking for a way to modernize your backup and archive solution as part of a mainframe modernization project or to meet compliance requirements, this pattern can help meet those goals.

Typically, organizations that run core business applications on mainframes use a virtual tape library (VTL) to back up data stores such as files and logs. This method can be expensive because it consumes billable MIPS, and the data stored on tapes outside the mainframe is inaccessible. To avoid these issues, you can use BMC AMI Cloud Data to quickly and cost-effectively transfer operational and historical mainframe data directly to Amazon S3. You can use BMC AMI Cloud Data to back up and archive data over TCP/IP to AWS while taking advantage of IBM z Integrated Information Processor (zIIP) engines to reduce cost, parallelism, and transfer times.

Prerequisites and limitations

Prerequisites

- An active AWS account
- BMC AMI Cloud Data with a valid license key
- TCP/IP connectivity between the mainframe and AWS
- An AWS Identity and Access Management (IAM) role for read/write access to an S3 bucket
- Mainframe security product (RACF) access in place to run BMC AMI Cloud processes
- A BMC AMI Cloud z/OS agent (Java version 8 64-bit SR5 FP16 or later) that has available network ports, firewall rules permitting access to S3 buckets, and a dedicated z/FS file system
- Requirements met for the BMC AMI Cloud management server

Limitations

- BMC AMI Cloud Data stores its operational data in a PostgreSQL database that runs as a Docker container on the same Amazon Elastic Compute Cloud (Amazon EC2) instance as the management server. Amazon Relational Database Service (Amazon RDS) is not currently supported as a backend for BMC AMI Cloud Data. For more information about the latest product updates, see What's New? in the BMC documentation.
- This pattern backs up and archives z/OS mainframe data only. BMC AMI Cloud Data backs up and archives only mainframe files.
- This pattern doesn’t convert data into standard open formats such as JSON or CSV. Use an additional transformation service such as BMC AMI Cloud Analytics (previously known as Model9 Gravity) to convert the data into standard open formats. Cloud-native applications and data analytics tools can access the data after it's is written to the cloud.

Product versions

- BMC AMI Cloud Data version 2.x

Architecture

Source technology stack

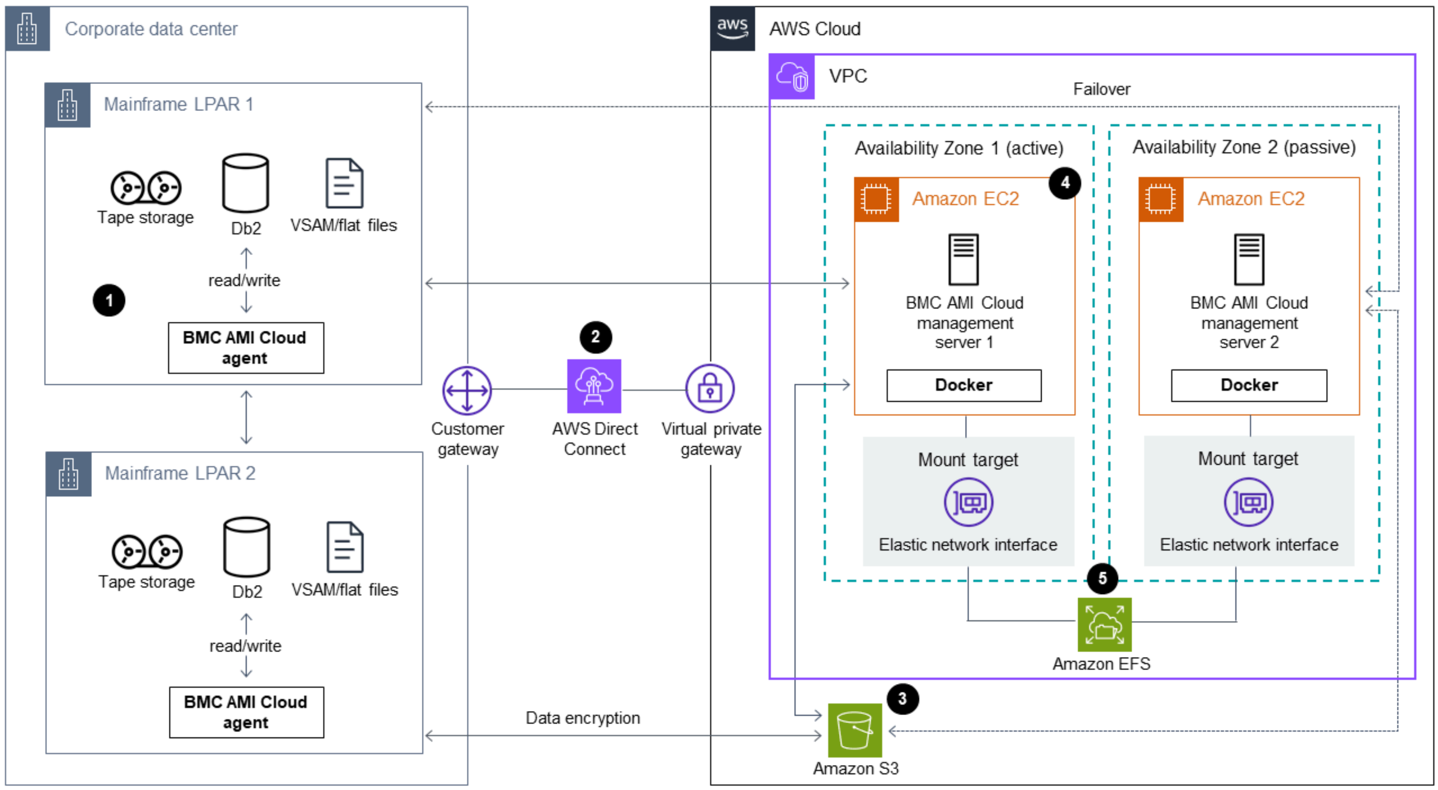
- Mainframe running z/OS
- Mainframe files such as datasets and z/OS UNIX System Services (USS) files
- Mainframe disk, such as a direct-access storage device (DASD)
- Mainframe tape (virtual or physical tape library)

Target technology stack

- Amazon S3
- Amazon EC2 instance in a virtual private cloud (VPC)
- AWS Direct Connect
- Amazon Elastic File System (Amazon EFS)

Target architecture

The following diagram shows a reference architecture where BMC AMI Cloud Data software agents on a mainframe drive the legacy data backup and archive processes that store the data in Amazon S3.



The diagram shows the following workflow:

1. BMC AMI Cloud Data software agents run on mainframe logical partitions (LPARs). The software agents read and write mainframe data from DASD or tape directly to Amazon S3 over TCP/IP.
2. AWS Direct Connect sets up a physical, isolated connection between the on-premises network and AWS. For enhanced security, run a site-to-site VPN on top of AWS Direct Connect to encrypt data in transit.
3. The S3 bucket stores mainframe files as object storage data, and BMC AMI Cloud Data agents directly communicate with the S3 buckets. Certificates are used for HTTPS encryption of all communications between the agent and Amazon S3. Amazon S3 data encryption is used to encrypt and protect the data at rest.
4. BMC AMI Cloud Data management servers run as Docker containers on EC2 instances. The instances communicate with agents running on mainframe LPARs and S3 buckets.
5. Amazon EFS is mounted on both active and passive EC2 instances to share the Network File System (NFS) storage. This is to make sure that metadata related to a policy created on the

management server isn't lost in the event of a failover. In the event of a failover by the active server, the passive server can be accessed without any data loss. If the passive server fails, the active server can be accessed without any data loss.

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve nearly any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- AWS Direct Connect links your internal network to a AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

BMC tools

- BMC AMI Cloud management server is a GUI application that runs as a Docker container on an Amazon Linux Amazon Machine Image (AMI) for Amazon EC2. The management server provides the functionality to manage BMC AMI Cloud activities such as reporting, creating and managing policies, running archives, and performing backups, recalls, and restores.
- BMC AMI Cloud agent runs on an on-premises mainframe LPAR that reads and writes files directly to object storage by using TCP/IP. A started task runs on a mainframe LPAR and is responsible for reading and writing backup and archive data to and from Amazon S3.
- BMC AMI Cloud Mainframe Command Line Interface (M9CLI) provides you with a set of commands to perform BMC AMI Cloud actions directly from TSO/E or in batch operations, without the dependency on the management server.

Epics

Create an S3 bucket and IAM policy

Task	Description	Skills required
Create an S3 bucket.	Create an S3 bucket to store the files and volumes that you want to back up and archive from your mainframe environment.	General AWS

Create an IAM policy.	All BMC AMI Cloud management servers and agents require access to the S3 bucket that you created in the previous step.
	
	To grant the required access, create the following IAM policy:
	
	`{`
	`    "Version":`
	` "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Sid":`
	` "Listfolder",`
	`            "Action": [`
	
	` "s3:ListBucket",`
	
	` "s3:GetBucketLocat`
	`ion",`
	
	` "s3:ListBucketVers`
	`ions"`
	`            ],`
	`            "Effect":`
	` "Allow",`

Get the BMC AMI Cloud software license and download the software

Task	Description	Skills required
Get a BMC AMI Cloud software license.	To get a software license key, contact the [BMC AMI Cloud team](). The output of the z/OS `D M=CPU` command is required for generating a license.	Build lead
Download the BMC AMI Cloud software and license key.	Obtain the installation files and license key by following the instructions in the [BMC documentation]().	Mainframe infrastructure administrator

Install the BMC AMI Cloud software agent on the mainframe

Task	Description	Skills required
Install the BMC AMI Cloud software agent.	1. Before you start the installation process, verify that [minimum software and hardware requirements]() for the agent have been met. 2. To install the agent, follow the instructions in the [BMC documentation](). 3. After the agent starts running on the mainframe LPAR, check for the `ZM91000I MODEL9 BACKUP AGENT INITIALIZED` message in the spool. Verify that the	Mainframe infrastructure administrator

Task	Description	Skills required
	connectivity is successfully established between the agent and the S3 bucket by looking for the `Object store connectivity has been established successfully` message in the agent's STDOUT.	

Set up a BMC AMI Cloud management server on an EC2 instance

Task	Description	Skills required
Create Amazon EC2 Linux 2 instances.	Launch two Amazon EC2 Linux 2 instances in different Availability Zones by following the instructions from [Step 1: Launch an instance](#) in the Amazon EC2 documentation. The instance must meet the following recommended hardware and software requirements: • CPU – Minimum 4 cores • RAM – Minimum 8 GB • Drive – 40 GB • Recommended EC2 instance – C5.xlarge • OS – Linux	Cloud architect, Cloud administrator

Task	Description	Skills required
	• Software – Docker, unzip, vi/VIM • Network bandwidth – Minimum 1 GB For more information, see the BMC documentation.	
Create an Amazon EFS file system.	Create an Amazon EFS file system by following the instructions from Step 1: Create your Amazon EFS file system in the Amazon EFS documentation. When creating the file system, do the following: • Choose the Standard storage class. • Choose the same VPC that you used to launch your EC2 instances.	Cloud administrator, Cloud architect

Task	Description	Skills required

Install Docker and configure the management server.	**Connect to your EC2 instances:**
	
	Connect to your EC2 instances by following the instructions from Connect to your Linux instance in the Amazon EC2 documentation.
	
	Configure your EC2 instances :
	
	For each EC2 instance, do the following:
	
	1. To install Docker, run the command:
	`sudo yum install docker`
	2. To start Docker, run the command:
	`sudo service docker start`
	3. To validate the status of Docker, run the command:
	`sudo service docker status`
	4. In the `/etc/selinux` folder, change the `config` file to `SELINUX=permissive` .
		Cloud architect, Cloud administrator

Task	Description	Skills required
	5. Upload the `model9-v2.x.y_build_build-id-server.zip` and `VerificationScripts.zip` files (that you downloaded earlier) to a temporary folder in one of the EC2 instances (for example, into the `/var/tmp` folder in your instance). 6. To go to the `tmp` folder, run the command: `cd/var/tmp` 7. To unzip the verification script, run the command: `unzip VerificationScripts.zip` 8. To change the directory, run the command: `cd /var/tmp/sysutils/PrereqsScripts` 9. To run the verification script, run the command: `./M9VerifyPrereqs.sh` 10After the verification script prompts for the input,	

Task	Description	Skills required
	enter the Amazon S3 URL and port number. Then, enter the z/OS IP/DNS and port number. **Note** The script runs a check to confirm that EC2 instance can connect with the S3 bucket and agent that's running on the mainframe. If a connection is established, a success message is displayed.	

Task	Description	Skills required

Install the management server software.	1. Create a folder and subfolder in the root directory (for example, `/data/model9`) in the EC2 instance that you plan to make the active server.
	2. To install the `amazon-efs-utils` package and to mount the Amazon EFS file system created earlier, run the following commands:
	`sudo yum install -y amazon-efs-utils`
	`sudo mount -t efs -o tls <File System ID>:/ /data/model9`
	3. To update the EC2 instance's `/etc/fstab` file with an entry for the Amazon EFS file system (so that Amazon EFS is automatically remounted when Amazon EC2 reboots), run the command:
	`<Amazon-EFS-file-system-id>:/ /data/model9 efs defaults,_netdev 0 0`
	4. To define the path to the BMC AMI Cloud installation files and the target
		Cloud architect, Cloud administrator

Task	Description	Skills required

	installation location, run the following commands to export variables:
	`export MODEL9_HOME=/data/model9`
	`export M9INSTALL=/var/tmp`
	Note: We recommend that you add these EXPORT commands to your `.bashrc` script.
	5. To change the directory, run the `cd $MODEL9_HOME` command, and then create another subdirectory by running the `mkdir diag` command.
	6. To unzip the installation file, run the command:
	`unzip $M9INSTALL/model9-<v2.x.y>_build_<build-id>-server.zip`
	Note: Replace `x.y` (the version) and	

Task	Description	Skills required

	`build-id` with your values.
	
	7. To deploy the application, run the following commands:
	
	`docker load -i $MODEL9_HOME/model9-<v2.x.y>_build_<build-id>.docker`
	`docker load -i $MODEL9_HOME/postgres-12.10-x86.docker.gz`
	
	Note
	Replace `v2.x.y` (the version) and `build-id` with your values.
	
	8. In the `$MODEL9_HOME/conf` folder, update the `model9-local.yml` file.
	
	Note
	Some of the parameters have default values and others can be updated as necessary. For more	

Task	Description	Skills required

	information, see the instructions in the `model9-local.yml` file.
	9. Create a file called `$MODEL9_HOME/conf`, and then add the following parameters to the file:
	`TZ=America/New_York EXTRA_JVM_ARGS=-Xmx2048m`
	10. To create a Docker network bridge, run the command:
	`docker network create -d bridge model9network`
	11. To start the PostgreSQL database container for BMC AMI Cloud, run the following command:
	`docker run -p 127.0.0.1:5432:5432 \ -v $MODEL9_HOME/db/data:/var/lib/postgresql/data:z \ --name model9db --restart unless-stopped \ --network model9network \`	

Task	Description	Skills required

```
-e POSTGRES_PASSWORD=
model9 -e POSTGRES_
DB=model9 -d
 postgres:12.10
```

12. After the PostgreSQL container starts running, run the following command to start the application server:

```
docker run -d -p
 0.0.0.0:443:443 -p
 0.0.0.0:80:80 \
--sysctl net.ipv4.
tcp_keepalive_time
=600 \
--sysctl net.ipv4.
tcp_keepalive_intv
l=30 \
--sysctl net.ipv4.
tcp_keepalive_prob
es=10 \
-v $MODEL9_HOME:/mode
l9:z -h $(hostname)
 --restart unless-st
opped \
--env-file $MODEL9_H
OME/conf/model9.env
 \
--network model9net
work \
--name model9-v2.x.y
 model9:<v2.x.y>.<b
uild-id>
```

Note

Replace `v2.x.y` (the version) and

Task	Description	Skills required
	build-id with your values. 13. To check the health status of both containers, run the command: `docker ps -a` 14. To install a management server on the passive EC2 instances, repeat steps 1–4, 7, and 10–13. **Note** To troubleshoot issues, go to the logs stored in the `/data/model9/logs/` folder. For more information, see the [BMC documentation]().	

Add an agent and define a backup or archive policy on the BMC AMI Cloud management server

Task	Description	Skills required
Add a new agent.	Before you add a new agent, confirm the following: • A BMC AMI Cloud agent is running on the mainframe LPAR and has been	Mainframe storage administrator or developer

Task	Description	Skills required
	initialized completely. Identify the agent by looking for the `ZM91000I MODEL9 BACKUP AGENT INITIALIZED` initialization message in the spool. • A Docker container for the management server is fully initialized and running. You must create an agent on the management server before you define any backup and archive policies. To create the agent, do the following: 1. Use a web browser to access the management server that's deployed on your Amazon EC2 machine, and then log in with your mainframe credentials. 2. Choose the **AGENTS** tab, and then choose **ADD NEW AGENT**. 3. For **Name**, enter the agent name. 4. For **Hostname/IP Address**, enter the host name or IP address of your mainframe. 5. For **Port**, enter your port number. 6. Choose **TEST CONNECTION**. You can see	

Task	Description	Skills required
	a **success** message if the connectivity is successfully established. 7. Choose **CREATE**. After the agent is created, you'll see the **connected** status against the object storage and mainframe agent in a new window that appears in the table.	
Create a backup or archive policy.	1. Choose **POLICIES**. 2. Choose **CREATE POLICY**. 3. On the **CREATE A NEW POLICY** page, enter your policy specifications. **Note** For more information about the available specifications, see [Creating a new policy]() in the BMC documentation. 4. Choose **FINISH**. 5. The new policy is now listed as a table. To see this table, choose the **POLICIES** tab.	Mainframe storage administrator or developer

Run the backup or archive policy from the management server

Task	Description	Skills required
Run the backup or archive policy.	Run the data backup or archive policy that you created earlier from the management server either manually or automatically (based on a schedule). To run the policy manually: 1. Choose the **POLICIES** tab from the navigation menu. 2. On the right side of the table for the policy that you want to run, choose the three-dot menu. 3. Choose **Run Now**. 4. In the pop-up confirmation window, choose **YES, RUN POLICY NOW**. 5. After the policy runs, verify the run status in the policy activity section. 6. For the policy that ran, choose the three-dot menu, and then choose **View Run Log** to see the logs. 7. To verify that the backup was created, check the S3 bucket.	Mainframe storage administrator or developer
Restore the backup or archive policy.	1. On the navigation menu, choose the **POLICIES** tab.	Mainframe storage administrator or developer

Task	Description	Skills required
	2. Choose the policy to run your restore process on. This will list all the backup or archive activities that ran in the past for that specific policy. 3. To select the backups that you want to restore, choose the **Date-time** column. The `file/Volume/Storage` group name shows the run details of the policy. 4. On the right side of the table, choose the three-dot menu, and then choose **RESTORE**. 5. In the pop-up window, enter your target name, volume, and storage group, and then choose **RESTORE**. 6. Enter your mainframe credentials, and then choose **RESTORE** again. 7. To verify that the restore was successful, check the logs or the mainframe.	

Run the backup or archive policy from the mainframe

Task	Description	Skills required
Run the backup or archive policy by using M9CLI.	Use the M9CLI to perform backup and restore processes from TSO/E, REXX, or through JCLs without setting up rules on the BMC AMI Cloud management server. **Using TSO/E:** If you use TSO/E, make sure that `M9CLI REXX` is concatenated to `TSO`. To back up a dataset through TSO/E, use the `TSO M9CLI BACKDSN <DSNAME>` command. **Note** For more informati on about M9CLI commands, see CLI reference in the BMC documentation. **Using JCLs:** To run the backup and archive policy by using JCLs, run the `M9CLI` command. **Using batch operations:**	Mainframe storage administr ator or developer

Task	Description	Skills required

	The following example shows you how to archive a dataset by running the `M9CLI` command in batch:
	`//JOBNAME JOB …`
	`//M9CLI EXEC PGM=IKJEFT01`
	`//STEPLIB DD DISP=SHR, DSN=<MODEL9 LOADLIB>`
	`//SYSEXEC DD DISP=SHR, DSN=<MODEL9 EXEC LIB>`
	`//SYSTSPRT DD SYSOUT=*`
	`//SYSPRINT DD SYSOUT=*`
	`//SYSTSIN DD TSO M9CLI ARCHIVE`
	`M9CLI ARCHIVE <DSNNAME OR DSN PATTERN>`
	`/`	

Task	Description	Skills required
Run the backup or archive policy in JCL batch.	BMC AMI Cloud provides a sample JCL routine called **M9SAPIJ**. You can customize **M9SAPIJ** to run a specific policy created on the management server with a JCL. This job can also be part of a batch scheduler for running backup and restore processes automatically. The batch job expects the following mandatory values: • Management server IP address/host name • Port number • Policy ID or policy name (which is created on the management server) **Note** You can also change other values by following the instructions on the sample job.	Mainframe storage administrator or developer

Build COBOL Db2 programs by using AWS Mainframe Modernization and AWS CodeBuild

Luis Gustavo Dantas and Eduardo Zimelewicz, Amazon Web Services

Summary

This pattern explains how to create a simple AWS CodeBuild project to precompile and bind COBOL Db2 programs by using the AWS Mainframe Modernization Replatform tools. This enables the deployment and execution of these programs in the AWS Mainframe Modernization Replatform runtime environment.

COBOL, a business-oriented programming language, powers many critical applications due to its reliability and readability. IBM Db2, a relational database management system, manages large volumes of data efficiently and integrates with COBOL programs through SQL. Together, COBOL and Db2 form the backbone of mission-critical operations in industries such as finance and government, despite the emergence of newer technologies.

Migrating COBOL and Db2 components from the mainframe environment to other platforms leads to challenges such as platform compatibility, integration complexity, data migration, and performance optimization. Moving these critical components requires careful planning, technical expertise, and resources to ensure a smooth migration while maintaining reliability and functionality.

The AWS Mainframe Modernization service provides tools and resources to replatform mainframe applications and databases to run on AWS infrastructure, such as Amazon Elastic Compute Cloud (Amazon EC2) instances. This involves moving mainframe workloads to the cloud without major code changes.

The Db2 precompile and bind process is essential for optimizing the performance and reliability of database applications. Precompilation transforms embedded SQL statements into executable code, which reduces runtime overhead and enhances efficiency. The bind process links the precompiled code with database structures, facilitating access paths and query optimization. This process ensures data integrity, improves application responsiveness, and guards against security vulnerabilities. Properly precompiled and bound applications minimize resource consumption, enhance scalability, and mitigate the risks of SQL injection attacks.

Prerequisites and limitations

Prerequisites

- An AWS account and administrative-level console access.
- An IBM Db2 database system, such as IBM Db2 for z/OS or Db2 for Linux, Unix, and Windows (LUW).
- The IBM Data Server Client software, which is available for download from the IBM website. For more information, see IBM Data Server Client and Data Server Driver types.
- A COBOL Db2 program to be compiled and bound. Alternatively, this pattern provides a basic sample program that you can use.
- A virtual private cloud (VPC) on AWS with a private network. For information about creating a VPC, see the Amazon Virtual Private Cloud (Amazon VPC) documentation.
- A source control repository such as GitHub or GitLab.

Limitations

- For AWS CodeBuild quotas, see Quotas for AWS CodeBuild.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

Source technology stack

The source stack includes:

- COBOL programs that use a Db2 database to store data
- IBM COBOL compiler and Db2 for z/OS precompiler
- Other parts of the mainframe setup, such as the file system, transaction manager, and spool

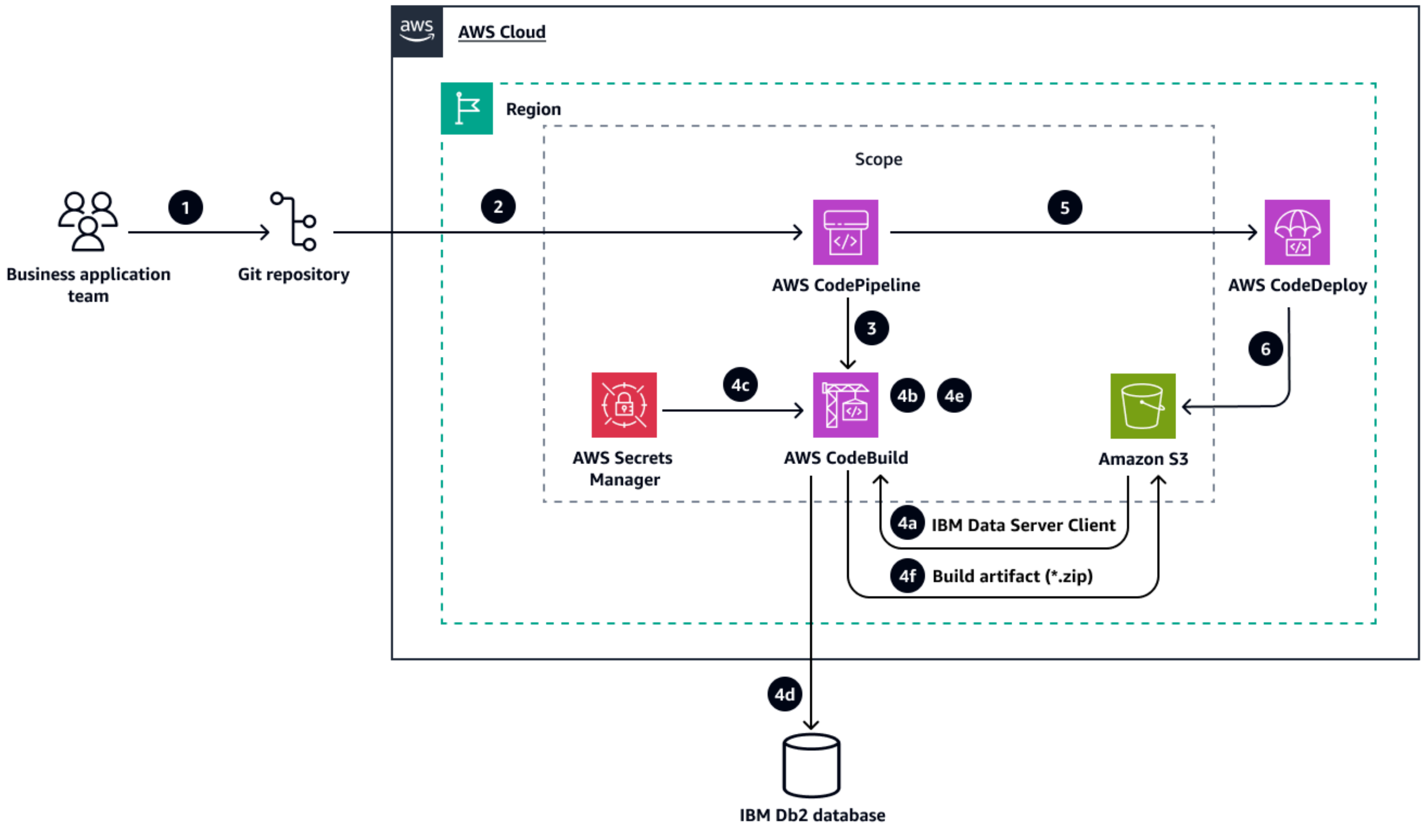
Target technology stack

This pattern's approach works for two options: moving data from Db2 for z/OS to Db2 for LUW, or staying on Db2 for z/OS. The target architecture includes:

- COBOL programs that use a Db2 database to store data
- AWS Mainframe Modernization Replatform compilation tools

- AWS CodeBuild as the infrastructure to build the application
- Other AWS Cloud resources such as Amazon Linux

Target architecture



The diagram illustrates the following:

1. The user uploads their code to a source control repository such as GitHub or GitLab.
2. AWS CodePipeline notices the change and gets the code from the repository.
3. CodePipeline starts AWS CodeBuild and sends the code.
4. CodeBuild follows the instructions in the `buildspec.yml` template (provided in the [Additional information](#) section) to:
   a. Get the IBM Data Server Client from an Amazon Simple Storage Service (Amazon S3) bucket.
   b. Install and set up the IBM Data Server Client.
   c. Retrieve Db2 credentials from AWS Secrets Manager.
   d. Connect to the Db2 server.
   e. Precompile, compile, and bind the COBOL program.

    f. Save the finished products in an S3 bucket for AWS CodeDeploy to use.

5. CodePipeline starts CodeDeploy.
6. CodeDeploy coordinates its agents, which are already installed in the runtime environments. The agents fetch the application from Amazon S3 and install it based on the instructions in `appspec.yml`.

To keep things simple and focused on the build, the instructions in this pattern cover steps 1 through 4 but don't include the deployment of the COBOL Db2 program.

Automation and scale

For simplicity, this pattern describes how to provision resources manually. However, there are numerous automation options available, such as AWS CloudFormation, AWS Cloud Development Kit (AWS CDK), and HashiCorp Terraform, which automate these tasks. For more information, see the AWS CloudFormation and AWS CDK documentation.

Tools

AWS services

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeDeploy automates deployments to Amazon EC2 or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS Mainframe Modernization provides tools and resources to help you plan and implement migration and modernization from mainframes to AWS managed runtime environments.

Other tools

- **Amazon ECR image for AWS Mainframe Modernization Replatform tools**. To compile a COBOL application, you'll need to initiate CodeBuild by using an Amazon Elastic Container Registry (Amazon ECR) image that contains the AWS Mainframe Modernization Replatform tools:

```
673918848628.dkr.ecr.<your-region>.amazonaws.com/m2-enterprise-build-tools:9.0.7.R1
```

For more information about the ECR image available, see the tutorial in the *AWS Mainframe Modernization User Guide*.

- IBM Data Server Client software is essential for precompiling and binding COBOL Db2 programs in CodeBuild. It acts as a bridge between the COBOL compiler and Db2.

Best practices

- Not every COBOL program relies on Db2 as its data persistence layer. Make sure that compilation directives for accessing Db2 are applied only to COBOL programs that are specifically designed to interact with Db2. Implement a logic to distinguish between COBOL Db2 programs and COBOL programs that do not use Db2.
- We recommend that you avoid compiling programs that haven't been modified. Implement a process to identify which programs require compilation.

Epics

Create the cloud infrastructure

Task	Description	Skills required
Create an S3 bucket to host the IBM Data Server Client and pipeline artifacts.	You need to set up an S3 bucket to (a) upload the IBM Data Server Client, (b) store your code from the repository, and (c) store the results of the build process. 1. Sign in to the AWS Management Console, and open the Amazon S3 console. 2. Choose an existing S3 bucket or create a new bucket. Note the bucket's	General AWS

Task	Description	Skills required
	Amazon Resource Name (ARN) for future use. For ways to create an S3 bucket, see the [Amazon S3 documentation.]()	
Upload the IBM Data Server Client to the S3 bucket.	1. On the [Amazon S3 console](), choose the bucket to open it. 2. Choose **Create folder**, specify its name as **client**, and then choose **Create folder**. 3. Open the **client** folder, choose **Upload**, **Add files**. 4. Choose the **IBM Data Server Client** file that you previously downloaded from the [IBM website]() to your local file system. The file name should be similar to `v11.5.8_linuxx64_client.tar.gz` or `v11.5.9_linuxx64_client.tar.gz` . 5. Choose **Open**, **Upload** and wait for the upload to complete. 6. On the **Files and folders** tab, choose the Data Server Client and note its S3 URI.	General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create an AWS Secrets Manager secret for your Db2 credentials.</td><td>

To create a secret to securely store your DB2 credentials:

1. On the [Secrets Manager console](https://console.aws.amazon.com/secretsmanager/), choose **Store a new secret**.
2. In the **Choose secret type** pane, choose **Another type of secret** and **Plaintext**.
3. In the **Plaintext** box, type your Db2 credentials by using the following JSON structure.

```
{
    "username": "<your-db2-user-name>",
    "password": "<your-db2-password>",
    "db2node": "db2dev",
    "db2host": "<your-db2-hostname-or-IP>",
    "db2port": <your-db2-port>,
    "db2name": "<your-db2-location>",
    "qualifier": "<your-db2-qualifier>"
}
```

</td><td>General AWS</td></tr>
</table>

Task	Description	Skills required
	4. Choose **Next** and give the secret a name such as `dev-db2-cred` . 5. Choose **Next**, **Next**, and **Store**. For more information about creating secrets, see the [Secrets Manager documentation].	

Task	Description	Skills required
Verify that Db2 is accessible from the VPC subnet.	AWS CodeBuild needs a connection to the Db2 server so that the Data Server Client can perform precompilation and bind operations. Make sure that CodeBuild can reach the Db2 server through a secure connection. 1. Open the [Amazon VPC console](https://console.aws.amazon.com/vpc/). 2. On the navigation pane, choose **Subnets** and write down the IDs and **IPv4 CIDRs** of the **private subnets** where CodeBuild will work. 3. Update the current network access control settings for your Db2 system by introducing an inbound rule. This rule should enable custom TCP access to the Db2 port exclusively from the subnet CIDRs that are associate d with your CodeBuild project.	Network administrator, General AWS

Create the application artifacts

Task	Description	Skills required

Create the COBOL Db2 asset.	1. If you want to use a simple COBOL Db2 example, save the following source code as `CDB2SMP.cbl` . Or, you can replace this example with a program that you already own.
	``
	       IDENTIFICATION DIVISION.
	       PROGRAM-ID. CDB2SMP.
	       DATA DIVISION.
	       WORKING-STORAGE SECTION.
	       01 WS-NAME PIC X(100).
	       PROCEDURE DIVISION.
	           EXEC SQL
	             SELECT NAME INTO :WS-NAME
	             FROM SYSIBM.SYSTABLES
	           END-EXEC
	           GOBACK.
	``
	2. Commit the changes and push the file to your repository.
		App developer

Create the `buildspec.yml` file.	1. Generate the `buildspec.yml` file based on the example that's provided in	AWS DevOps

Task	Description	Skills required
	the [Additional information](#) section. 2. Commit the changes and push the file to your repository.	
Connect your repository to CodePipeline.	1. Open the [AWS Developer Tools console](#). 2. In the navigation pane, choose **Settings, Connections**. 3. Follow the [instructions](#) in the Developer Tools console documentation for the source provider of your choice. You will need the Amazon Resource Name (ARN) for the connection when you create the AWS Identity and Access Management (IAM) policy for CodePipeline in a later step.	AWS DevOps

Configure permissions

Task	Description	Skills required
Create an IAM policy for CodeBuild.	The CodeBuild project requires access to some resources, including Secrets Manager and Amazon S3.	General AWS

Task	Description	Skills required
	To set up the necessary permissions: 1. Open the IAM console. 2. In the navigation pane, choose **Policies**, **Create Policy**, and then select the CodeBuild service. 3. Switch the formatting from **Visual** to **JSON**, and copy the **CodeBuild policy** that's provided in the Additional information section to the **Policy editor** field. 4. Name and save this policy for future reference in the next step. For more information about creating IAM policies, see the IAM documentation.	

Task	Description	Skills required
Create an IAM role for CodeBuild.	To make the security policies available for CodeBuild, you need to configure an IAM role. To create this role: 1. On the [IAM console](), in the navigation pane, choose **Roles**, **Create Role**. 3. For **Trusted entity type**, keep the default **AWS service** setting. 4. For **Use case**, select the CodeBuild service, and then choose **Next**. 4. In the list of available IAM policies, locate the policy you created for CodeBuild, and then choose **Next** to attach it to the role. 5. Specify a name for the role, and choose **Create role** to save it for future reference in CodeBuild. For more information about creating an IAM role for an AWS service, see the [IAM documentation]().	General AWS

Task	Description	Skills required
Create an IAM policy for CodePipeline.	The AWS CodePipeline pipeline requires access to some resources, including your code repository and Amazon S3. Repeat the steps provided previously for CodeBuild to create an IAM policy for CodePipeline (in step 2, choose **CodePipeline** instead of **CodeBuild**).	AWS DevOps

Task	Description	Skills required

Create an IAM role for CodePipeline.	To make the security policies available for CodePipeline, you need to configure an IAM role.
	
	To create this role:
	
	1. On the [IAM console](https://console.aws.amazon.com/iam/), choose **Roles**, **Create Role**.
	2. For **Trusted entity type**, choose **Custom trust policy**.
	
	A policy with an empty `Principal` element will be displayed.
	3. On the `Principal` line, between the braces, add:
	
	`"Service": "codepipeline.amazonaws.com"`
	
	The trust policy will look like this:
	
	`{ "Version": "2012-10-17", "Statement": [ { "Sid": "Statement1", "Effect": "Allow", "Principal": {`
		AWS DevOps

Task	Description	Skills required

	``
	          "Service":
	  "codepipeline.amaz
	onaws.com"
	        },
	        "Action":
	  "sts:AssumeRole"
	     }
	    ]
	}
	``
	4. Choose **Next**.
	5. In the list of available IAM policies, locate the policy you created for CodePipeline, and then choose **Next** to attach it to the role.
	6. Specify a name for the role, and choose **Create role** to save it for future reference in CodePipeline.	

Compile and bind the COBOL Db2 program

Task	Description	Skills required
Create a CodePipeline pipeline and CodeBuild project.	To create a CodePipeline pipeline and the CodeBuild project that compiles and binds the COBOL Db2 program: 1. Open the [CodePipeline console](), and choose **Create Pipeline**, **Build custom pipeline**.	AWS DevOps

Task	Description	Skills required
	2. Specify a name for the pipeline. 3. For **Service role**, choose **Existing service role** and choose specify the ARN for the IAM role you created for CodePipeline. 4. Expand **Advanced settings**, choose **Custom location**, choose the S3 bucket you previously created, and then choose **Next**. 5. For **Source provider**, select your third-party source provider, and provide the relevant information for the provider:. a. For **Connection,** select the connection that was created for the source provider. b. For **Repository name**, select your repository. c. For **Default branch**, select the branch that stores your COBOL program and `buildspec.yml` . d. Choose **Next**. 6. For **Build provider**, choose **Other build providers**, **AWS CodeBuild**.	

Task	Description	Skills required
	7. For **Project name**, choose **Create project**. The console displays a CodeBuild window where you can create a build project. In this window: a. Enter a name for the project. b. For **Environment image**, choose **Custom image**. c. For **Environment type**, choose **Linux Container**. d. For **ECR account**, choose **Other ECR account**. e. For **Amazon ECR repository URI**, enter: `673918848628.dkr.ecr.<your-region>.amazonaws.com/m2-enterprise-build-tools:8.0.9.R1` . f. For **Service role**, choose **Existing service role** and select the role you created for CodeBuild. g. Expand the **Additional configuration** section, and then choose the VPC, private subnets,	

Task	Description	Skills required
	and security group for this project. h. In the **Buildspec** section, choose **Use a buildspec file**. i. At the end of the window, choose **Continue to** CodePipeline. The CodeBuild window will close so you can go back to the CodePipeline console. 8. Back in the CodePipeline console, choose **Next**. 9. In the **Add deploy stage** pane, choose **Skip deploy stage**, and confirm. 10Review the pipeline parameters and then choose **Create pipeline**.	
Review the output.	Verify the success of the build by reviewing the CodePipeline build logs.	AWS DevOps

Task	Description	Skills required

Check results in Db2.	Verify the package version on the SYSPLAN table.
	`select CAST(NAME AS VARCHAR(10)) as name, VALIDATE, LAST_BIND_TIME, LASTUSED, CAST(PKGVERSION AS VARCHAR(10)) as PKGVERSION from SYSIBM.SYSPLAN where NAME = 'CDB2SMP' order by LAST_BIND_TIME desc`
	The version must match the CodeBuild build ID, which is CDB2SMP in our example:
	`NAME       VALIDATE LAST_BIND_TIME             LASTUSED PKGVERSION`
	`---------- -------- -------------------------- -------- ----------`
	`CDB2SMP    B        2024-05-18-11.53.11.503738 01/01/0001 19`	

Troubleshooting

Issue	Solution
Occasionally, the AWS console switches Regions when you move between services.	Make sure to verify the selected AWS Region whenever you switch between services.

Issue	Solution
	The AWS Region selector is in the upper-right corner of the console window.
It can be difficult to identify Db2 connectivity issues from CodeBuild.	To troubleshoot connectivity problems, add the following DB2 connect command to the `buildspec.yml` file. This addition helps you debug and resolve connectivity issues. `db2 connect to $DB_NAME user $DB2USER using $DB2PASS`
Occasionally, the role pane in the IAM console doesn't immediately show the IAM policy you've created.	If you encounter a delay, refresh the screen to display the latest information.

Build a Micro Focus Enterprise Server PAC with Amazon EC2 Auto Scaling and Systems Manager

Kevin Yung and Krithika Palani Selvam, Amazon Web Services

Peter Woods, None

Abraham Rondon, Micro Focus

Summary

This pattern introduces a scalable architecture for mainframe applications using Micro Focus Enterprise Server in Scale-Out Performance and Availability Cluster (PAC) and an Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group on Amazon Web Services (AWS). The solution is fully automated with AWS Systems Manager and Amazon EC2 Auto Scaling lifecycle hooks. By using this pattern, you can set up your mainframe online and batch applications to achieve high resiliency by automatically scaling in and out based on your capacity demands.

Note

This pattern was tested with Micro Focus Enterprise Server version 6.0. For version 8, see Set up Micro Focus Runtime (on Amazon EC2).

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Micro Focus Enterprise Server software and license. For details, contact Micro Focus sales.
- An understanding of the concept of rebuilding and delivering a mainframe application to run in Micro Focus Enterprise Server. For a high-level overview, see Micro Focus Enterprise Server Data Sheet.
- An understanding of the concepts in Micro Focus Enterprise Server scale-out Performance and Availability Cluster. For more information, see the Micro Focus Enterprise Server documentation.
- An understanding of the overall concept of mainframe application DevOps with continuous integration (CI). For an AWS Prescriptive Guidance pattern that was developed by AWSand Micro Focus, see Mainframe modernization: DevOps on AWS with Micro Focus.

> **Note**
>
> This pattern was tested with Micro Focus Enterprise Server version 6. For version 8, see Set up Micro Focus Runtime (on Amazon EC2).

Limitations

- For a list of platforms that are supported by Micro Focus Enterprise Server, see the Micro Focus Enterprise Server Data Sheet.
- The scripts and tests used in this pattern are based on Amazon EC2 Windows Server 2019; other Windows Server versions and operating systems were not tested for this pattern.
- The pattern is based on Micro Focus Enterprise Server 6.0 for Windows; earlier or later releases were not tested in the development of this pattern.

Product versions

- Micro Focus Enterprise Server 6.0
- Windows Server 2019

Architecture

In the conventional mainframe environment, you must provision hardware to host your applications and corporate data. To cater for and meet the spikes in seasonal, monthly, quarterly, or even unprecedented or unexpected demands, mainframe users must *scale out* by purchasing additional storage and compute capacity. Increasing the number of storage and compute capacity resources improves overall performance, but the scaling is not linear.

This is not the case when you start adopting an on-demand consumption model on AWS by using Amazon EC2 Auto Scaling and Micro Focus Enterprise Servers. The following sections explain detail how to build a fully automated, scalable mainframe application architecture using Micro Focus Enterprise Server Scale-Out Performance and Availability Cluster (PAC) with an Amazon EC2 Auto Scaling group.

Micro Focus Enterprise Server automatic scaling architecture

First, it is important to understand the basic concepts of Micro Focus Enterprise Server. This environment provides a mainframe-compatible, x86 deployment environment for applications that have traditionally run on the IBM mainframe. It delivers both online and batch runs and a transaction environment that supports the following:

- IBM COBOL
- IBM PL/I
- IBM JCL batch jobs
- IBM CICS and IMS TM transactions
- Web services
- Common batch utilities, including SORT

Micro Focus Enterprise Server enables mainframe applications to run with minimal changes. Existing mainframe workloads can be moved to x86 platforms and modernized to take advantage of AWS Cloud native extensions for rapid expansion to new markets or geographies.

The AWS Prescriptive Guidance pattern Mainframe modernization: DevOps on AWS with Micro Focus introduced the architecture to accelerate the development and testing of mainframe applications on AWS using Micro Focus Enterprise Developer and Enterprise Test Server with AWS CodePipeline and AWS CodeBuild. This pattern focuses on the deployment of mainframe applications to the AWS production environment to achieve high availability and resiliency.

In a mainframe production environment, you might have set up IBM Parallel Sysplex in the mainframe to achieve high performance and high availability. To create a scale-out architecture similar to Sysplex, Micro Focus introduced the Performance and Availability Cluster (PAC) to Enterprise Server. PACs support mainframe application deployment onto multiple Enterprise Server regions managed as a single image and scaled out in Amazon EC2 instances. PACs also support predictable application performance and system throughput on demand.

In a PAC, multiple Enterprise Server instances work together as a single logical entity. Failure of one Enterprise Server instance, therefore, will not interrupt business continuity because capacity is shared with other regions while new instances are automatically started using industry standard functionality such as an Amazon EC2 Auto Scaling group. This removes single points of failure, improving resilience to hardware, network, and application issues. Scaled-out Enterprise Server instances can be operated and managed by using the Enterprise Server Common Web Administration (ESCWA) APIs, simplifying the operational maintenance and serviceability of Enterprise Servers.

> **Note**
>
> Micro Focus recommends that the Performance and Availability Cluster (PAC) should consist of at least three Enterprise Server regions so that availability is not compromised in the event an Enterprise Server region fails or requires maintenance.

PAC configuration requires a supported relational database management service (RDBMS) to manage the region database, a cross-region database, and optional data store databases. A data store database should be used to managed Virtual Storage Access Method (VSAM) files using the Micro Focus Database File Handler support to improve availability and scalability. Supported RDBMSs include the following:

- Microsoft SQL Server 2009 R2 and later
- PostgreSQL 10.x, including Amazon Aurora PostgreSQL-Compatible Edition
- DB2 10.4 and later

For details of supported RDBMS and PAC requirements, see Micro Focus Enterprise Server - Prerequisites and Micro Focus Enterprise Server - Recommended PAC Configuration.

The following diagram shows a typical AWS architecture setup for a Micro Focus PAC.

	Component	Description
1	Enterprise Server instances automatic scaling group	Set up an automatic scaling group deployed with Enterprise Server instances in a PAC. The number of instances can be scaled out

		or in initiated by Amazon CloudWatch alarms using CloudWatch metrics.
2	Enterprise Server ESCWA instances automatic scaling group	Set up an automatic scaling group deployed with Enterprise Server Common Web Administration (ESCWA). ESCWA provides cluster management APIs. The ESCWA servers act as a control plane to add or remove Enterprise Servers and start or stop Enterpris e Server regions in the PAC during the Enterprise Server instance automatic scaling events. Because the ESCWA instance is used only for the PAC management, its traffic pattern is predictable, and its automatic scaling desired capacity requirement can be set to 1.
3	Amazon Aurora instance in a Multi-AZ setup	Set up a relational database management system (RDBMS) to host both user and system data files to be shared across the Enterprise Server instances.

4	Amazon ElastiCache (Redis OSS) instance and replica	Set up an ElastiCache (Redis OSS) primary instance and at least one replica to host user data and act as a scale-out repository (SOR) for the Enterprise Server instances . You can configure one or more scale-out repository to store specific types of user data. Enterprise Server uses a Redis NoSQL database as an SOR, a requirement to maintain PAC integrity.
5	Network Load Balancer	Set up a load balancer, providing a hostname for applications to connect to the services provided by Enterprise Server instances (for example, accessing the application through a 3270 emulator).

These components form the minimum requirement for a Micro Focus Enterprise Server PAC cluster. The next section covers cluster management automation.

Using AWS Systems Manager Automation for scaling

After the PAC cluster is deployed on AWS, the PAC is managed through the Enterprise Server Common Web Administration (ESCWA) APIs.

To automate the cluster management tasks during automatic scaling events, you can use Systems Manager Automation runbooks and Amazon EC2 Auto Scaling with Amazon EventBridge. The architecture of these automations is shown in the following diagram.

	Component	Description
1	Automatic scaling lifecycle hook	Set up automatic scaling lifecycle hooks and send notifications to Amazon EventBridge when new instances are launched and existing instances are terminated in the automatic scaling group.
2	Amazon EventBridge	Set up an Amazon EventBrid ge rule to route automatic scaling events to Systems

		Manager Automation runbook targets.
3	Automation runbooks	Set up Systems Manager Automation runbooks to run Windows PowerShell scripts and invoke ESCWA APIs to manage the PAC. For examples, see the *Additional information* section.
4	Enterprise Server ESCWA instance in an automatic scaling group	Set up an Enterprise Server ESCWA instance in an automatic scaling group. The ESCWA instance provides APIs to manage the PAC.

Tools

- Micro Focus Enterprise Server – Micro Focus Enterprise Server provides the run environment for applications created with any integrated development environment (IDE) variant of Enterprise Developer.
- Amazon EC2 Auto Scaling – Amazon EC2 Auto Scaling helps you ensure that you have the correct number of Amazon EC2 instances available to handle the load for your application. You create collections of EC2 instances, called Auto Scaling groups, and specify minimum and maximum numbers of instances.
- Amazon ElastiCache (Redis OSS) – Amazon ElastiCache is a web service for setting up, managing, and scaling a distributed in-memory data store or cache environment in the cloud. It provides a high-performance, scalable, and cost-effective caching solution.
- Amazon RDS – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks.
- AWS Systems Manager – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS

resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting on (or taking corrective action on) any policy violations it detects.

Epics

Create an Amazon Aurora instance

Task	Description	Skills required
Create an AWS CloudFormation template for an Amazon Aurora instance.	Use the AWS example code snippet to make a CloudFormation template that will create an Amazon Aurora PostgreSQL-Compatible Edition instance.	Cloud architect
Deploy a CloudFormation stack to create the Amazon Aurora instance.	Use the CloudFormation template to create an Aurora PostgreSQL-Compatible instance that has Multi-AZ replication enabled for production workloads.	Cloud architect
Configure database connection settings for Enterprise Server.	Follow the instructions in the Micro Focus documentation to prepare the connection strings and database configuration for Micro Focus Enterprise Server.	Data engineer, DevOps engineer

Create an Amazon ElastiCache cluster for the Redis instance

Task	Description	Skills required
Create a CloudFormation template for the Amazon	Use the AWS example code snippet to make a CloudForm	Cloud architect

Task	Description	Skills required
ElastiCache cluster for the Redis instance.	ation template that will create an Amazon ElastiCache cluster for the Redis instance.	
Deploy the CloudFormation stack to create an Amazon ElastiCache cluster for the Redis instance.	Create the Amazon ElastiCache cluster for the Redis instance that has Multi-AZ replication enabled for production workloads.	Cloud architect
Configure Enterprise Server PSOR connection settings.	Follow the instructions in the [Micro Focus documentation](#) to prepare the PAC Scale-Out Repository (PSOR) connection configuration for Micro Focus Enterprise Server PAC.	DevOps engineer

Create a Micro Focus Enterprise Server ESCWA automatic scaling group

Task	Description	Skills required
Create a Micro Focus Enterprise Server AMI.	Create an Amazon EC2 Windows Server instance and install the Micro Focus Enterprise Server binary in the EC2 instance. Create an Amazon Machine Image (AMI) of the EC2 instance. For more information, see the [Enterprise Server installation documentation](#).	Cloud architect
Create a CloudFormation template for Enterprise Server ESCWA.	Use the [AWS example code snippet](#) to make a template for creating a custom stack of	Cloud architect

Task	Description	Skills required
	Enterprise Server ESCWA in an automatic scaling group.	
Deploy the CloudForm ation stack to create an Amazon EC2 scaling group for Enterprise Server ESCWA.	Use the CloudFormation template to deploy the automatic scaling group with the Micro Focus Enterprise Server ESCWA AMI created in the previous story.	Cloud architect

Create an AWS Systems Manager Automation runbook

Task	Description	Skills required
Create a CloudFormation template for a Systems Manager Automation runbook.	Use the example code snippets in the *Additional information* section to make a CloudFormation template that will create a Systems Manager Automation runbook for automating PAC creation, Enterprise Server scale in, and Enterprise Server scale out.	Cloud architect
Deploy the CloudFormation stack that contains the Systems Manager Automation runbook.	Use the CloudFormation template to deploy a stack that contains the Automatio n runbook for PAC creation, Enterprise Server scale in, and Enterprise Server scale out.	Cloud architect

Create an automatic scaling group for Micro Focus Enterprise Server

Task	Description	Skills required
Create a CloudFormation template for setting up an automatic scaling group for Micro Focus Enterprise Server.	Use the AWS example code snippet to make a CloudFormation template that will create an automatic scaling group. This template will reuse the same AMI that was created for the Micro Focus Enterprise Server ESCWA instance. Then use an AWS example code snippet to create the automatic scaling lifecycle event and set up Amazon EventBridge to filter for scale-out and scale-in events in the same CloudFormation template.	Cloud architect
Deploy the CloudFormation stack for the automatic scaling group for Micro Focus Enterprise Servers.	Deploy the CloudFormation stack that contains the automatic scaling group for Micro Focus Enterprise Servers.	Cloud architect

- Running automations with triggers using EventBridge

Additional information

The following scenarios must be automated for scaling in or scaling out the PAC clusters.

Automation for starting or recreating a PAC

At the start of a PAC cluster, Enterprise Server requires ESCWA to invoke APIs to create a PAC configuration. This starts and adds Enterprise Server regions into the PAC. To create or recreate a PAC, use the following steps:

1. Configure a PAC Scale-Out Repository (PSOR) in ESCWA with a given name.

```
POST /server/v1/config/groups/sors
```

2. Create a PAC with a given name and attach the PSOR to it.

```
POST /server/v1/config/groups/pacs
```

3. Configure the region database and cross-region database if this is the first time you are setting up a PAC.

> **Note**
>
> This step uses SQL queries and the Micro Focus Enterprise Suite command line **dbhfhadmin** tool to create the database and import initial data.

4. Install the PAC definition into the Enterprise Server regions.

```
POST /server/v1/config/mfds
POST /native/v1/config/groups/pacs/${pac_uid}/install
```

5. Start Enterprise Server regions in the PAC.

```
POST /native/v1/regions/${host_ip}/${port}/${region_name}/start
```

The previous steps can be implemented by using a Windows PowerShell script.

The following steps explain how to build an automation for creating a PAC by reusing the Windows PowerShell script.

1. Create an Amazon EC2 launch template that downloads or creates the Windows PowerShell script as part of the bootstrap process. For example, you can use EC2 user data to download the script from an Amazon Simple Storage Service (Amazon S3) bucket.
2. Create an AWS Systems Manager Automation runbook to invoke the Windows PowerShell script.
3. Associate the runbook to the ESCWA instance by using the instance tag.
4. Create an ESCWA automatic scaling group by using the launch template.

You can use the following example AWS CloudFormation snippet to create the Automation runbook.

Example CloudFormation snippet for a Systems Manager Automation runbook used for PAC creation

```
PACInitDocument:
   Type: AWS::SSM::Document
   Properties:
     DocumentType: Command
     Content:
       schemaVersion: '2.2'
       description: Operation Runbook to create Enterprise Server PAC
       mainSteps:
       - action: aws:runPowerShellScript
         name: CreatePAC
         inputs:
           onFailure: Abort
           timeoutSeconds: "1200"
           runCommand:
           - |
             C:\Scripts\PAC-Init.ps1
PacInitAutomation:
   Type: AWS::SSM::Document
   Properties:
     DocumentType: Automation
     Content:
       description: Prepare Micro Focus PAC Cluster via ESCWA Server
       schemaVersion: '0.3'
       assumeRole: !GetAtt SsmAssumeRole.Arn
       mainSteps:
         - name: RunPACInitDocument
           action: aws:runCommand
           timeoutSeconds: 300
           onFailure: Abort
```

```
            inputs:
              DocumentName: !Ref PACInitDocument
              Targets:
                - Key: tag:Enterprise Server - ESCWA
                  Values:
                    - "true"
  PacInitDocumentAssociation:
    Type: AWS::SSM::Association
    Properties:
      DocumentVersion: "$LATEST"
      Name: !Ref PACInitDocument
      Targets:
        - Key: tag:Enterprise Server - ESCWA
          Values:
            - "true"
```

For more information, see [Micro Focus Enterprise Server - Configuring a PAC](#).

Automation for scaling out with a new Enterprise Server instance

When an Enterprise Server instance is scaled out, its Enterprise Server region must be added to the PAC. The following steps explain how to invoke ESCWA APIs and add the Enterprise Server region into the PAC.

1. Install the PAC definition into the Enterprise Server regions.

```
POST '/server/v1/config/mfds'
POST /native/v1/config/groups/pacs/${pac_uid}/install
```

2. Warm Start the region in the PAC.

```
POST /native/v1/regions/${host_ip}/${port}/${region_name}/start
```

3. Add the Enterprise Server instance to the load balancer by associating the automatic scaling group to the load balancer.

The previous steps can be implemented by using a Windows PowerShell script. For more information, see [Micro Focus Enterprise Server - Configuring a PAC](#).

The following steps can be used to build an event driven automation to add a newly launched Enterprise Server instance into a PAC by reusing the Windows PowerShell script.

1. Create an Amazon EC2 launch template for Enterprise Server instance that provisions an Enterprise Server Region during its bootstrap. For example, you can use the Micro Focus Enterprise Server command mfds to import a region configuration. For further details and options available for this command, see the Enterprise Server Reference.
2. Create an Enterprise Server automatic scaling group that uses the launch template created in the previous step.
3. Create a Systems Manager Automation runbook to invoke the Windows PowerShell script.
4. Associate the runbook to the ESCWA instance by using the instance tag.
5. Create an Amazon EventBridge rule to filter for the EC2 Instance Launch Successful event for the Enterprise Server automatic scaling group, and create the target to use the Automation runbook.

You can use the following example CloudFormation snippet to create the Automation runbook and the EventBridge rule.

Example CloudFormation snippet for Systems Manager used for scaling out Enterprise Server instances

```
ScaleOutDocument:
   Type: AWS::SSM::Document
   Properties:
     DocumentType: Command
     Content:
       schemaVersion: '2.2'
       description: Operation Runbook to Adding MFDS Server into an existing PAC
       parameters:
         MfdsPort:
           type: String
         InstanceIpAddress:
           type: String
           default: "Not-Available"
         InstanceId:
           type: String
           default: "Not-Available"
       mainSteps:
       - action: aws:runPowerShellScript
         name: Add_MFDS
         inputs:
           onFailure: Abort
           timeoutSeconds: "300"
```

```
            runCommand:
            - |
              $ip = "{{InstanceIpAddress}}"
              if ( ${ip} -eq "Not-Available" ) {
                $ip = aws ec2 describe-instances --instance-id {{InstanceId}} --output
 text --query "Reservations[0].Instances[0].PrivateIpAddress"
              }
              C:\Scripts\Scale-Out.ps1 -host_ip ${ip} -port {{MfdsPort}}

  PacScaleOutAutomation:
    Type: AWS::SSM::Document
    Properties:
      DocumentType: Automation
      Content:
        parameters:
          MfdsPort:
            type: String
          InstanceIpAddress:
            type: String
            default: "Not-Available"
          InstanceId:
            type: String
            default: "Not-Available"
        description: Scale Out 1 New Server in Micro Focus PAC Cluster via ESCWA
 Server
        schemaVersion: '0.3'
        assumeRole: !GetAtt SsmAssumeRole.Arn
        mainSteps:
          - name: RunScaleOutCommand
            action: aws:runCommand
            timeoutSeconds: 300
            onFailure: Abort
            inputs:
              DocumentName: !Ref ScaleOutDocument
              Parameters:
                InstanceIpAddress: "{{InstanceIpAddress}}"
                InstanceId: "{{InstanceId}}"
                MfdsPort: "{{MfdsPort}}"
              Targets:
                - Key: tag:Enterprise Server - ESCWA
                  Values:
                    - "true"
```

Automation for scaling in an Enterprise Server instance

Similar to scaling out, when an Enterprise Server instance is *scaled in*, the event EC2 Instance-terminate Lifecycle Action is initiated, and the following process and API calls are needed to remove a Micro Focus Enterprise Server instance from the PAC.

1. Stop the region in the terminating Enterprise Server instance.

```
POST "/native/v1/regions/${host_ip}/${port}/${region_name}/stop"
```

2. Remove the Enterprise Server Instance from the PAC.

```
DELETE "/server/v1/config/mfds/${uid}"
```

3. Send signal to continue terminating the Enterprise Server instance.

The previous steps can be implemented in a Windows PowerShell script. For additional details of this process, see Micro Focus Enterprise Server document - Administering a PAC.

The following steps explain how to build an event-driven automation to terminate an Enterprise Server instance from a PAC by reusing the Windows PowerShell script.

1. Create a Systems Manager Automation runbook to invoke the Windows PowerShell script.
2. Associate the runbook to the ESCWA instance by using the instance tag.
3. Create an automatic scaling group lifecycle hook for EC2 instance termination.
4. Create an Amazon EventBridge rule to filter EC2 Instance-terminate Lifecycle Action event for the Enterprise Server automatic scaling group, and create the target to use the Automation runbook.

You can use the following example CloudFormation template for creating a Systems Manager Automation runbook, lifecycle hook, and EventBridge rule.

Example CloudFormation snippet for a Systems Manager Automation runbook used for scaling in an Enterprise Server instance

```
ScaleInDocument:
   Type: AWS::SSM::Document
   Properties:
     DocumentType: Command
```

```
      Content:
        schemaVersion: '2.2'
        description: Operation Runbook to Remove MFDS Server from PAC
        parameters:
          MfdsPort:
            type: String
          InstanceIpAddress:
            type: String
            default: "Not-Available"
          InstanceId:
            type: String
            default: "Not-Available"
        mainSteps:
        - action: aws:runPowerShellScript
          name: Remove_MFDS
          inputs:
            onFailure: Abort
            runCommand:
            - |
              $ip = "{{InstanceIpAddress}}"
              if ( ${ip} -eq "Not-Available" ) {
                $ip = aws ec2 describe-instances --instance-id {{InstanceId}} --output
 text --query "Reservations[0].Instances[0].PrivateIpAddress"
              }
              C:\Scripts\Scale-In.ps1 -host_ip ${ip} -port {{MfdsPort}}

  PacScaleInAutomation:
    Type: AWS::SSM::Document
    Properties:
      DocumentType: Automation
      Content:
        parameters:
          MfdsPort:
            type: String
          InstanceIpAddress:
            type: String
            default: "Not-Available"
          InstanceId:

                InstanceId: "{{ InstanceId }}"
                LifecycleActionResult: CONTINUE
                LifecycleHookName: !Ref ScaleInLifeCycleHook
```

Automation for an Amazon EC2 automatic scaling trigger

The process of setting up a scaling policy for Enterprise Server instances requires an understanding of the application behavior. In most cases, you can set up target tracking scaling policies. For example, you can use the average CPU utilization as the Amazon CloudWatch metric to set for the automatic scaling policy. For more information, see Target tracking scaling policies for Amazon EC2 Auto Scaling. For applications that have regular traffic patterns, consider using a predictive scaling policy. For more information, see Predictive scaling for Amazon EC2 Auto Scaling.

Build an advanced mainframe file viewer in the AWS Cloud

Boopathy GOPALSAMY and Jeremiah O'Connor, Amazon Web Services

Summary

This pattern provides code samples and steps to help you build an advanced tool for browsing and reviewing your mainframe fixed-format files by using AWS serverless services. The pattern provides an example of how to convert a mainframe input file to an Amazon OpenSearch Service document for browsing and searching. The file viewer tool can help you achieve the following:

- Retain the same mainframe file structure and layout for consistency in your AWS target migration environment (for example, you can maintain the same layout for files in a batch application that transmits files to external parties)
- Speed up development and testing during your mainframe migration
- Support maintenance activities after the migration

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a subnet that's reachable by your legacy platform
- > **Note**
  >
  > An input file and its corresponding common business-oriented language (COBOL) copybook (: For input file and COBOL copybook examples, see gfs-mainframe-solutions on the GitHub repository. For more information about COBOL copybooks, see the Enterprise COBOL for z/OS 6.3 Programming Guide on the IBM website.)

Limitations

- Copybook parsing is limited to no more than two nested levels (OCCURS)

Architecture

Source technology stack

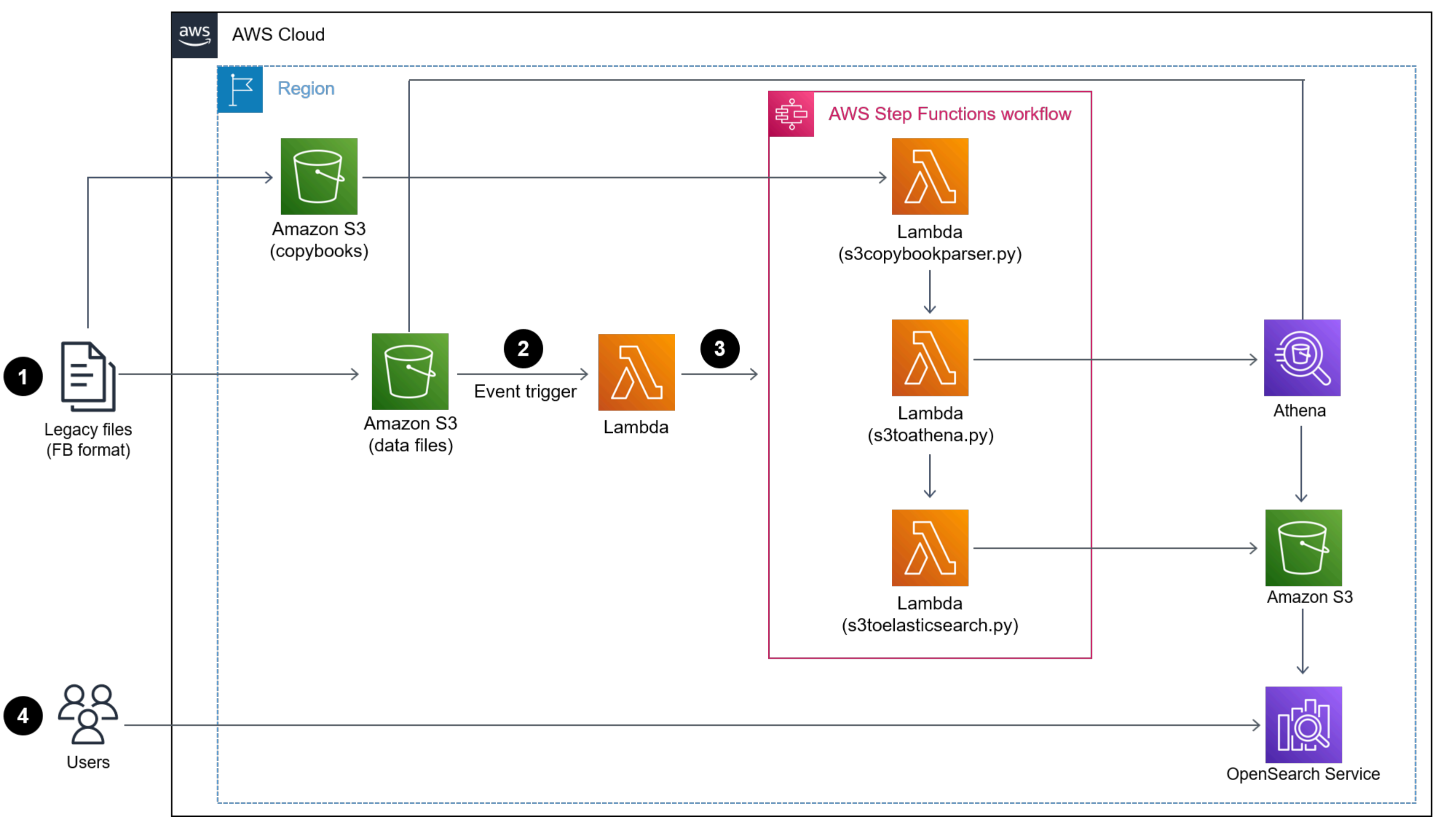
- Input files in FB (Fixed Blocked) format
- COBOL copybook layout

Target technology stack

- Amazon Athena
- Amazon OpenSearch Service
- Amazon Simple Storage Service (Amazon S3)
- AWS Lambda
- AWS Step Functions

Target architecture

The following diagram shows the process of parsing and converting a mainframe input file to an OpenSearch Service document for browsing and searching.



The diagram shows the following workflow:

1. An admin user or application pushes input files to one S3 bucket and COBOL copybooks to another S3 bucket.
2. > **Note**
   >
   > The S3 bucket with the input files invokes a Lambda function that kicks off a serverless Step Functions workflow. : The use of an S3 event trigger and Lambda function to drive the Step Functions workflow in this pattern is optional. The GitHub code samples in this pattern don't include the use of these services, but you can use these services based on your requirements.
3. The Step Functions workflow coordinates all the batch processes from the following Lambda functions:
   - The `s3copybookparser.py` function parses the copybook layout and extracts field attributes, data types, and offsets (required for input data processing).
   - The `s3toathena.py` function creates an Athena table layout. Athena parses the input data that's processed by the `s3toathena.py` function and converts the data to a CSV file.
   - The `s3toelasticsearch.py` function ingests the results file from the S3 bucket and pushes the file to OpenSearch Service.
4. Users access OpenSearch Dashboards with OpenSearch Service to retrieve the data in various table and column formats and then run queries against the indexed data.

Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, you use Lambda to implement core logic, such as parsing files, converting data, and loading data into OpenSearch Service for interactive file access.
- Amazon OpenSearch Service is a managed service that helps you deploy, operate, and scale OpenSearch Service clusters in the AWS Cloud. In this pattern, you use OpenSearch Service to index the converted files and provide interactive search capabilities for users.

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Step Functions is a serverless orchestration service that helps you combine Lambda functions and other AWS services to build business-critical applications. In this pattern, you use Step Functions to orchestrate Lambda functions.

Other tools

- GitHub is a code-hosting service that provides collaboration tools and version control.
- Python is a high-level programming language.

Code

The code for this pattern is available in the GitHub gfs-mainframe-patterns repository.

Epics

Prepare the target environment

Task	Description	Skills required
Create the S3 bucket.	Create an S3 bucket for storing the copybooks, input files, and output files. We recommend the following folder structure for your S3 bucket: • `copybook/` • `input/` • `output/` • `query/`	General AWS

Task	Description	Skills required
	• `results/`	
Create the s3copybookparser function.	1. Create a Lambda function called `s3copybookparser` and upload the source code (`s3copybookparser.py` and `copybook.py`) from the GitHub repository. 2. Attach the IAM policy `S3ReadOnly` to the Lambda function.	General AWS
Create the s3toathena function.	1. Create a Lambda function called `s3toathena` and upload the source code (`s3toathena.py`) from the GitHub repository. Configure the Lambda timeout to > 60 seconds. 2. To provide access to the required resources, attach the IAM policies `AmazonAthenaFullAccess` and `S3FullAccess` to the Lambda function.	General AWS

Task	Description	Skills required
Create the s3toelasticsearch function.	1. **Important** [Add a Python dependency to your Lambda environment](). : To use the `s3toelasticsearch` function, you must add the Python dependency because the Lambda function uses Python Elasticsearch client dependencies (`Elasticsearch==7.9.0` and `requests_aws4auth`). 2. Create a Lambda function called `s3toelasticsearch` and upload the source code (`s3toelasticsearch.py`) from the [GitHub]() repository. 3. Import the Python dependency as a Lambda layer. 4. Attach the IAM policies `S3ReadOnly` and `AmazonOpenSearchSe`	General AWS

Task	Description	Skills required
	`rviceReadOnlyAccess` to the Lambda function.	

Task	Description	Skills required
Create the OpenSearch Service cluster.	**Create the cluster** 1. Create an OpenSearch Service cluster. When you create the cluster, do the following: • **Note** Create a master user and password for the cluster that you can use for signing in to OpenSearch Dashboards. : This step is not required if you use authentication through Amazon Cognito. • Choose fine-grained access control. This give you additional ways of controlling access to your data in OpenSearch Service. 2. Copy the domain URL and pass it as the environment variable **'HOST'** to the Lambda function `s3toelasticsearch` .	General AWS

Task	Description	Skills required
	Grant access to the IAM role To provide fine-grained access to the Lambda function's IAM role (`arn:aws:iam::**:role/service-role/s3toelasticsearch-role-**`), do the following: 1. Sign in to OpenSearch Dashboards as the master user. 2. Choose the **Security** tab, and then choose **Roles**, **all_access**, **Map user**, **Backend roles**. 3. Add the Amazon Resource Name (ARN) of the Lambda function's IAM role, and then choose **Save**. For more information, see [Mapping roles to users](#) in the OpenSearch Service documentation.	

Task	Description	Skills required
Create Step Functions for orchestration.	1. [Create a Step Functions state machine](#) with the standard flow. The definitio n is included in the [GitHub](#) repository. 2. In the JSON script, replace the Lambda function’s ARNs with the ARNs from the Lambda function in your environment.	General AWS

Deploy and run

Task	Description	Skills required
Upload the input files and copybooks to the S3 bucket.	Download sample files from the [GitHub](#) repository sample folder and upload the files to the S3 bucket that you created earlier. 1. Upload `Mockedcopy.cpy` and `acctix.cpy` to the `<S3_Bucket>/copybook` folder. 2. Upload the `Modedupdate.txt` and `acctindex.cpy` sample input files to the `<S3_Bucket>/input` folder.	General AWS
Invoke the Step Functions.	1. Sign in to the AWS Management Console and	General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

open the [Step Functions console](#).

2. In the navigation pane, choose **State machines**.
3. Choose your state machine, and then choose **Start execution**.
4. In the **Input** box, enter the following copybook/file path as a JSON variable to the S3 bucket, and then choose **Start execution**.

```
{
  "s3_copybook_bucket_name": "<BUCKET NAME>",
  "s3_copybook_bucket_key": "<COPYBOOK PATH>",
  "s3_source_bucket_name": "<BUCKET NAME",
  "s3_source_bucket_key": "INPUT FILE PATH"
}
```

For example:

```
{
  "s3_copybook_bucket_name": "fileaidtest",
  "s3_copybook_bucket_key": "copybook/acctix.cpy",
  "s3_source_bucket_name": "fileaidtest",
```

</td><td></td></tr>
</table>

Task	Description	Skills required
	``` "s3_source_bucket_key": "input/acctindex" } ```	
Validate the workflow execution in Step Functions.	In the [Step Functions console](), review the workflow execution in the **Graph inspector**. The execution run states are color coded to represent execution status. For example, blue indicates **In Progress**, green indicates **Succeeded**, and red indicates **Failed**. You can also review the table in the **Execution event history** section for more detailed information about the execution events. For an example of a graphical workflow execution, see *Step Functions graph* in the *Additional information* section of this pattern.	General AWS

Task	Description	Skills required
Validate the delivery logs in Amazon CloudWatch.	1. Sign in to the AWS Management Console and open the [CloudWatch console](). 2. In the navigation pane, expand **Logs**, and then choose **Log groups**. 3. In the search box, search for the `s3toelasticsearch` function's log group. For an example of successful delivery logs, see *CloudWatch delivery logs* in the *Additional information* section of this pattern.	General AWS

Task	Description	Skills required
Validate the formatted file in OpenSearch Dashboards and perform file operations.	1. Sign in to the AWS Management Console. Under **Analytics**, choose **Amazon OpenSearch Service**. 2. In the navigation pane, choose **Domains**. 3. In the search box, enter the URL for your domain in [OpenSearch Dashboards](#). 4. Choose your dashboard , and then [sign in as the master user](#). 5. Browse the indexed data in table format. 6. Compare the input file against the formatted output file (indexed document) in OpenSearc h Dashboards. The dashboard view shows the added column headers for your formatted files. Confirm that the source data from your unformatt ed input files matches the target data in the dashboard view. 7. Perform actions such as search (for example, by using field names, values, or expressions), filter, and [DQL](#) (Dashboard Query	General AWS

Task	Description	Skills required
	Language) operations against the indexed file.

Containerize mainframe workloads that have been modernized by Blu Age

Richard Milner-Watts, Amazon Web Services

Summary

This pattern provides a sample container environment for running mainframe workloads that have been modernized by using the Blu Age tool. Blu Age converts legacy mainframe workloads into modern Java code. This pattern provides a wrapper around the Java application so you can run it by using container orchestration services such as Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic Kubernetes Service (Amazon EKS).

For more information about modernizing your workloads by using Blu Age and AWS services, see these AWS Prescriptive Guidance publications:

- Running modernized Blu Age mainframe workloads on serverless AWS infrastructure
- Deploy an environment for containerized Blu Age applications by using Terraform

For assistance with using Blu Age to modernize your mainframe workloads, contact the Blu Age team by choosing **Contact our experts** on the Blu Age website. For assistance with migrating your modernized workloads to AWS, integrating them with AWS services, and moving them into production, contact your AWS account manager or fill out the AWS Professional Services form.

Prerequisites and limitations

Prerequisites

- A modernized Java application that was created by Blu Age. For testing purposes, this pattern provides a sample Java application that you can use as a proof of concept.
- A Docker environment that you can use to build the container.

Limitations

Depending on the container orchestration platform that you use, the resources that can be made available to the container (such as CPU, RAM, and storage) might be limited. For example, if you're using Amazon ECS with AWS Fargate, see the Amazon ECS documentation for limits and considerations.

Architecture

Source technology stack

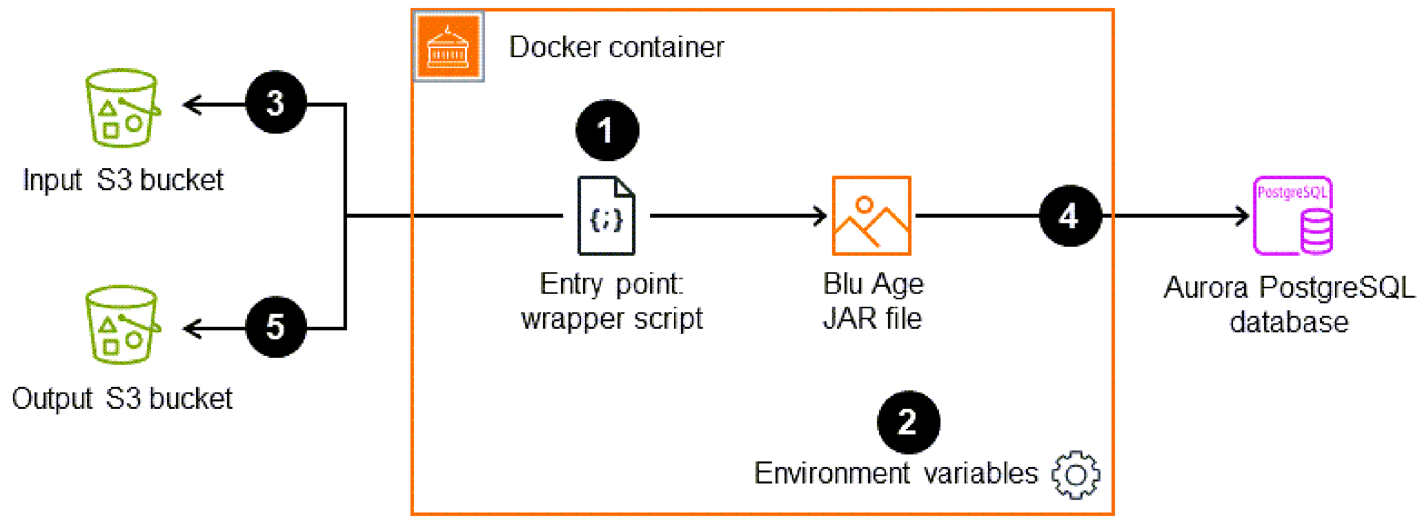
- Blu Age
- Java

Target technology stack

- Docker

Target architecture

The following diagram shows the architecture of the Blu Age application within a Docker container.



1. The entry point for the container is the wrapper script. This bash script is responsible for preparing the runtime environment for the Blu Age application and processing outputs.
2. Environment variables within the container are used to configure variables in the wrapper script, such as the Amazon Simple Storage Service (Amazon S3) bucket names and database credentials. Environment variables are supplied by either AWS Secrets Manager or Parameter Store, a capability of AWS Systems Manager. If you're using Amazon ECS as your container orchestration service, you can also hardcode the environment variables in the Amazon ECS task definition.
3. The wrapper script is responsible for pulling any input files from the S3 bucket into the container before you run the Blu Age application. The AWS Command Line Interface (AWS CLI) is

installed within the container. This provides a mechanism for accessing objects that are stored in Amazon S3 through the gateway virtual private cloud (VPC) endpoint.

4. The Java Archive (JAR) file for the Blu Age application might need to communicate with other data sources, such as Amazon Aurora.
5. After completion, the wrapper script delivers the resulting output files into an S3 bucket for further processing (for example, by Amazon CloudWatch logging services). The pattern also supports delivering zipped log files to Amazon S3, if you're using an alternative to standard CloudWatch logging.

Tools

AWS services

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.

Tools

- Docker is a software platform for building, testing, and deploying applications. Docker packages software into standardized units called containers, which have everything the software needs to run, including libraries, system tools, code, and runtime. You can use Docker to deploy and scale applications into any environment.
- Bash is a command language interface (shell) for the GNU operating system.
- Java is the programming language and development environment used in this pattern.
- Blu Age is an AWS mainframe modernization tool that converts legacy mainframe workloads, including application code, dependencies, and infrastructure, into modern workloads for the cloud.

Code repository

The code for this pattern is available in the GitHub Blu Age sample container repository.

Best practices

- Externalize the variables for altering your application's behavior by using environment variables. These variables enable the container orchestration solution to alter the runtime environment without rebuilding the container. This pattern includes examples of environment variables that can be useful for Blu Age applications.
- Validate any application dependencies before you run your Blu Age application. For example, verify that the database is available and credentials are valid. Write tests in the wrapper script to verify dependencies, and fail early if they are not met.
- Use verbose logging within the wrapper script. Interacting directly with a running container can be challenging, depending on the orchestration platform and how long the job takes. Make sure that useful output is written to `STDOUT` to help diagnose any issues. For example, output might include the contents of the application's working directory both before and after you run the application.

Epics

Obtain a Blu Age application JAR file

Task	Description	Skills required
Option 1 - Work with Blu Age to obtain your application's JAR file.	The container in this pattern requires a Blu Age applicati on. Alternatively, you can use the sample Java applicati on that's provided with this pattern for a prototype. Work with the Blu Age team to obtain a JAR file for your application that can be baked into the container. If the JAR file isn't available, see the next task to use the sample application instead.	Cloud architect

Task	Description	Skills required
Option 2 - Build or use the supplied sample application JAR file.	This pattern provides a prebuilt sample JAR file. This file outputs the application's environment variables to `STDOUT` before sleeping for 30 seconds and exiting. This file is named `bluAgeSample.jar` and is located in the docker folder of the GitHub repository. If you want to alter the code and build your own version of the JAR file, use the source code located at ./java_sample/src/sample_java_app.java in the GitHub repository. You can use the build script at ./java_sample/build.sh to compile the Java source and build a new JAR fie.	App developer

Build the Blu Age container

Task	Description	Skills required
Clone the GitHub repository.	Clone the sample code repository by using the command: `git clone https://github.com/aws-samp`	AWS DevOps

Task	Description	Skills required
	`les/aws-blu-age-sa mple-container`	
Use Docker to build the container.	Use Docker to build the container before you push it to a Docker registry such as Amazon ECR: 1. From your chosen terminal, navigate to the `docker` folder within your local GitHub repository. 2. Use this command to build the container: `docker build -t <tag> .` where `<tag>` is the container name you want to use.	AWS DevOps
Test the Blu Age container.	(Optional) If necessary, test the container locally by using the command: `docker run -it <tag> /bin/bash`	AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Authenticate to your Docker repository.</td><td>If you plan to use Amazon ECR, follow the instructions in the Amazon ECR documentation to install and configure the AWS CLI and authenticate the Docker CLI to your default registry.

We recommend that you use the get-login-password command for authentication.

Note
The Amazon ECR console provides a pre-populated version of this command if you use the View push commands button. For more information, see the Amazon ECR documentation.

<pre><code>aws ecr get-login
-password --region
 <region> | docker
 login --username
 AWS --password-stdin
 <account>.dkr.ecr.
<region>.amazonaws
.com</code></pre></td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	If you don't plan to use Amazon ECR, follow the instructions provided for your container registry system.	
Create a container repository.	Create a repository in Amazon ECR. For instructions, see the pattern [Deploy an environment for containerized Blu Age applications by using Terraform](). If you're using another container registry system, follow the instructions provided for that system.	AWS DevOps

Task	Description	Skills required

Tag and push your container to the target repository.	If you're using Amazon ECR:
	1. Tag the local Docker image with the Amazon ECR registry and repository, so you can push it to your remote repository:
	`docker tag <tag>:latest <account>.dkr.ecr.<region>.amazonaws.com/<repository>:<versionNumber>`
	2. Push the image to the remote repository:
	`docker push <account>.dkr.ecr.<region>.amazonaws.com/<repository>:<versionNumber>`
	For more information, see Pushing a Docker image in the *Amazon ECR User Guide*.

Convert and unpack EBCDIC data to ASCII on AWS by using Python

Luis Gustavo Dantas, Amazon Web Services

Summary

Because mainframes typically host critical business data, modernizing data is one of the most important tasks when migrating data to the Amazon Web Services (AWS) Cloud or other American Standard Code for Information Interchange (ASCII) environment. On mainframes, data is typically encoded in extended binary-coded decimal interchange code (EBCDIC) format. Exporting database, Virtual Storage Access Method (VSAM), or flat files generally produces packed, binary EBCDIC files, which are more complex to migrate. The most commonly used database migration solution is change data capture (CDC), which, in most cases, automatically converts data encoding. However, CDC mechanisms might not be available for these database, VSAM, or flat files. For these files, an alternative approach is required to modernize the data.

This pattern describes how to modernize EBCDIC data by converting it to ASCII format. After conversion, you can load the data into distributed databases or have applications in the cloud process the data directly. The pattern uses the conversion script and sample files in the mainframe-data-utilities GitHub repository.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An EBCDIC input file and its corresponding common business-oriented language (COBOL) copybook. A sample EBCDIC file and COBOL copybook are included in the mainframe-data-utilities GitHub repository. For more information about COBOL copybooks, see Enterprise COBOL for z/OS 6.4 Programming Guide on the IBM website.

Limitations

- File layouts defined inside COBOL programs are not supported. They must be made available separately.

Product versions

- Python version 3.8 or later

Architecture

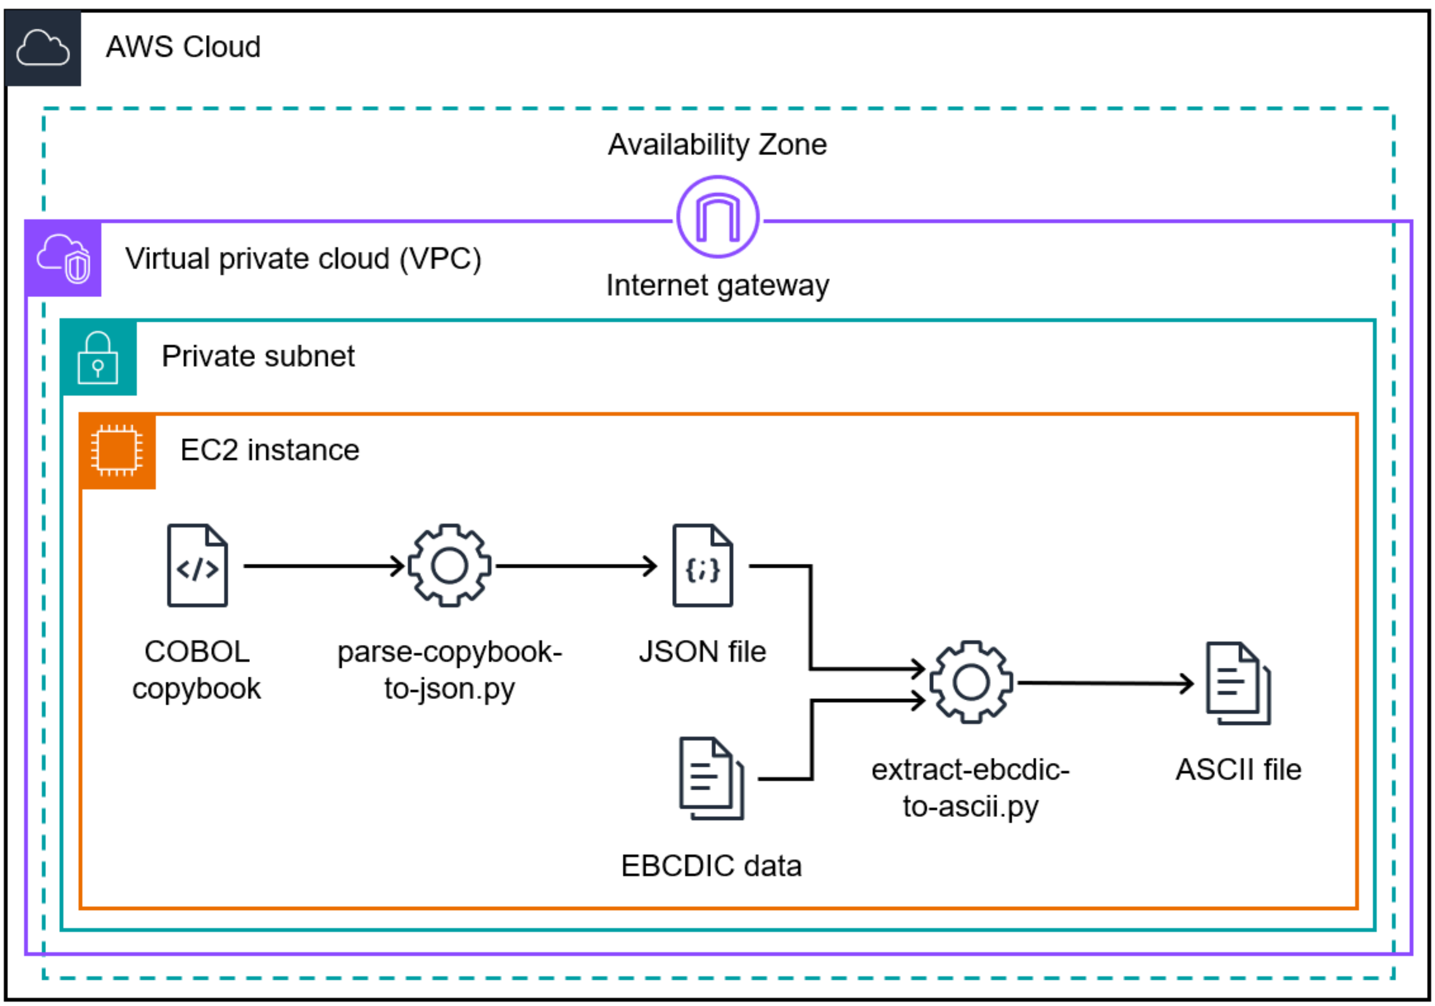
Source technology stack

- EBCDIC data on a mainframe
- COBOL copybook

Target technology stack

- Amazon Elastic Compute Cloud (Amazon EC2) instance in a virtual private cloud (VPC)
- Amazon Elastic Block Store (Amazon EBS)
- Python and its required packages, JavaScript Object Notation (JSON), sys, and datetime
- ASCII flat file ready to be read by a modern application or loaded in a relational database table

Target architecture



The architecture diagram shows the process of converting an EBCDIC file to an ASCII file on an EC2 instance:

1. Using the **parse_copybook_to_json.py** script, you convert the COBOL copybook to a JSON file.
2. Using the JSON file and the **extract_ebcdic_to_ascii.py** script, you convert the EBCDIC data to an ASCII file.

Automation and scale

After the resources needed for the first manual file conversions are in place, you can automate file conversion. This pattern doesn't include instructions for automation. There are multiple ways to automate the conversion. The following is an overview of one possible approach:

1. Encapsulate the AWS Command Line Interface (AWS CLI) and Python script commands into a shell script.
2. Create an AWS Lambda function that asynchronously submits the shell script job into an EC2 instance. For more information, see [Scheduling SSH jobs using AWS Lambda](https://aws.amazon.com/blogs/compute/scheduling-ssh-jobs-using-aws-lambda/).
3. Create an Amazon Simple Storage Service (Amazon S3) trigger that invokes the Lambda function every time a legacy file is uploaded. For more information, see [Using an Amazon S3 trigger to invoke a Lambda function](https://docs.aws.amazon.com/lambda/latest/dg/with-s3-example.html).

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Other tools

- GitHub is a code-hosting service that provides collaboration tools and version control.
- Python is a high-level programming language.

Code repository

The code for this pattern is available in the mainframe-data-utilities GitHub repository.

Epics

Prepare the EC2 instance

Task	Description	Skills required
Launch an EC2 instance.	The EC2 instance must have outbound internet access. This allows the instance to access the Python source code available on GitHub. To create the instance: 1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2. 2. Launch an EC2 Linux instance. Use a public IP address and allow inbound access through port 22. Ensure that the storage size of the instance is at least twice the size of the EBCDIC data file. For instructions, see the Amazon EC2 documentation.	General AWS
Install Git.	1. Using a secure shell (SSH) client, connect to the EC2	General AWS, Linux

Task	Description	Skills required
	instance you just launched. For more information, see [Connect to your Linux instance](). 2. In the Amazon EC2 console, run the following command. This installs Git on the EC2 instance. `sudo yum install git` 3. Run the following command and confirm that Git has been successfully installed. `git --version`	

Task	Description	Skills required

Install Python.	1. In the Amazon EC2 console, run the following command. This installs Python on the EC2 instance.
	`sudo yum install python3`
	2. In the Amazon EC2 console, run the following command. This installs Pip3 on the EC2 instance.
	`sudo yum install python3-pip`
	3. In the Amazon EC2 console, run the following command. This installs AWS SDK for Python (Boto3) on the EC2 instance.
	`sudo pip3 install boto3`
	4. In the Amazon EC2 console, run the following command, where `<us-east-1>` is the code for your AWS Region. For a complete list of Region codes, see Available Regions in the Amazon EC2 documentation.
		General AWS, Linux

Task	Description	Skills required
	`export AWS_DEFAULT_REGION=<us-east-1>`	
Clone the GitHub repository.	1. In the Amazon EC2 console, run the following command. This clones the **mainframe-data-utilities** repository from GitHub and opens the default copy location, the home folder. `git clone https://github.com/aws-samples/mainframe-data-utilities.git` 2. In the home folder, confirm that the `mainframe-data-utilities` folder is present.	General AWS, GitHub

Create the ASCII file from the EBCDIC data

Task	Description	Skills required
Parse the COBOL copybook into the JSON layout file.	Inside the `mainframe-data-utilities` folder, run the **parse_copybook_to_json.py** script. This automation module reads the file layout from a COBOL copybook and creates a JSON file. The JSON file contains the informati	General AWS, Linux

Task	Description	Skills required

	on required to interpret and extract the data from the source file. This creates the JSON metadata from the COBOL copybook.
	
	The following command converts the COBOL copybook to a JSON file.
	
	`python3 parse_copybook_to_json.py \ -copybook LegacyReference/COBPACK2.cpy \ -output sample-data/cobpack2-list.json \ -dict sample-data/cobpack2-dict.json \ -ebcdic sample-data/COBPACK.OUTFILE.txt \ -ascii sample-data/COBPACK.ASCII.txt \ -print 10000`
	
	The script prints the received arguments.
	
	`------------------------------------------------------------------------------------ Copybook file...............| LegacyReference/COBPACK2.cpy Parsed copybook (JSON List).| sample-data/cobpack2-list.json`	

Task	Description	Skills required
	``` JSON Dict (document ation)...| sample-da ta/cobpack2-dict.json ASCII file..... ....| sample- data/COBPACK.ASCII.t xt EBCDIC file..... ....| sample- data/COBPACK.OUTFILE .txt Print each..... ....| 10000 --------------------- ------------------ ------------------ -------------- ``` For more information about the arguments, see the README file in the GitHub repository.	

Task	Description	Skills required

Inspect the JSON layout file.	1. Navigate to the output path defined in the **parse_copybook_to_json.py** script.
	2. Check the creation time of the **sample-data/cobpack2-list.json** file to confirm that you have selected the appropriate JSON layout file.
	3. Examine the JSON file and confirm that the contents are similar to the following.
	
	`"input": "extract-ebcdic-to-ascii/COBPACK.OUTFILE.txt",`
	`"output": "extract-ebcdic-to-ascii/COBPACK.ASCII.txt",`
	`"max": 0,`
	`"skip": 0,`
	`"print": 10000,`
	`"lrecl": 150,`
	`"rem-low-values": true,`
	`"separator": "|",`
	`"transf": [`
	`{`
	`"type": "ch",`
	`"bytes": 19,`
	`"name": "OUTFILE-TEXT"`
	`}`
	
	The most important attributes of the JSON layout file are:
		General AWS, JSON

Task	Description	Skills required
	• `input` – Contains the path of the EBCDIC file to be converted • `output` – Defines the path where the ASCII file will be generated • `lrecl` – Specifies the size in bytes of the logical record length • `transf` – Lists all fields and their size in bytes For more information about the JSON layout file, see the README file in the GitHub repository.	

Task	Description	Skills required

Create the ASCII file.	Run the **extract_ebcdic_to_ascii.py** script, which is included in the cloned GitHub repository. This script reads the EBCDIC file and writes a converted and readable ASCII file.
	`python3 extract_ebcdic_to_ascii.py -local-json sample-data/cobpack2-list.json`
	As the script processes the EBCDIC data, it prints a message for every batch of 10,000 records. See the following example.
	`------------------------------------------------------------------------------------------------`
	`2023-05-15 21:21:46.322253 | Local Json file   | -local-json | sample-data/cobpack2-list.json`
	`2023-05-15 21:21:47.034556 | Records processed | 10000`
	`2023-05-15 21:21:47.736434 | Records processed | 20000`
	`2023-05-15 21:21:48.441696 | Records processed | 30000`
		General AWS

Task	Description	Skills required
	``` 2023-05-15 21:21:49. 173781 | Records processed | 40000 2023-05-15 21:21:49. 874779 | Records processed | 50000 2023-05-15 21:21:50. 705873 | Records processed | 60000 2023-05-15 21:21:51. 609335 | Records processed | 70000 2023-05-15 21:21:52. 292989 | Records processed | 80000 2023-05-15 21:21:52. 938366 | Records processed | 89280 2023-05-15 21:21:52. 938448 Seconds 6.616232 ``` For information about how to change the print frequency, see the README file in the GitHub repository.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Examine the ASCII file.</td><td>

Check the creation time of the extract-ebcdic-to-ascii/COBPACK.ASCII.txt file to verify that it was recently created.
In the Amazon EC2 console, enter the following command. This opens the first record of the ASCII file.
<pre><code>head sample-data/
COBPACK.ASCII.txt -n
 1| xxd</code></pre>
Examine the contents of the first record. Because EBCDIC files are usually binary, they don't have carriage return and line feed (CRLF) special characters. The extract_ebcdic_to_ascii.py script adds a pipe character as a column separator, which is defined in the script parameters.

If you used the sample EBCDIC file provided, the following is the first record in the ASCII file.
</td><td>General AWS, Linux</td></tr>

Convert mainframe files from EBCDIC format to character-delimited ASCII format in Amazon S3 using AWS Lambda

Luis Gustavo Dantas, Amazon Web Services

Summary

This pattern shows you how to launch an AWS Lambda function that automatically converts mainframe EBCDIC (Extended Binary Coded Decimal Interchange Code) files to character-delimited ASCII (American Standard Code for Information Interchange) files. The Lambda function runs after the ASCII files are uploaded to an Amazon Simple Storage Service (Amazon S3) bucket. After the file conversion, you can read the ASCII files on x86-based workloads or load the files into modern databases.

The file conversion approach demonstrated in this pattern can help you overcome the challenges of working with EBCDIC files on modern environments. Files encoded in EBCDIC often contain data represented in a binary or packed decimal format, and fields are fixed-length. These characteristics create obstacles because modern x86-based workloads or distributed environments generally work with ASCII-encoded data and can't process EBCDIC files.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An S3 bucket
- An AWS Identity and Access Management (IAM) user with administrative permissions
- AWS CloudShell
- Python 3.8.0 or later
- A flat file encoded in EBCDIC and its corresponding data structure in a common business-oriented language (COBOL) copybook

> **Note**
>
> This pattern uses a sample EBCDIC file (CLIENT.EBCDIC.txt) and its corresponding COBOL copybook (COBKS05.cpy). Both files are available in the GitHub mainframe-data-utilities repository.

Limitations

- COBOL copybooks usually hold multiple layout definitions. The [mainframe-data-utilities] project can parse this kind of copybook but can't infer which layout to consider on data conversion. This is because copybooks don't hold this logic (which remains on COBOL programs instead). Consequently, you must manually configure the rules for selecting layouts after you parse the copybook.
- This pattern is subject to [Lambda quotas].

Architecture

Source technology stack

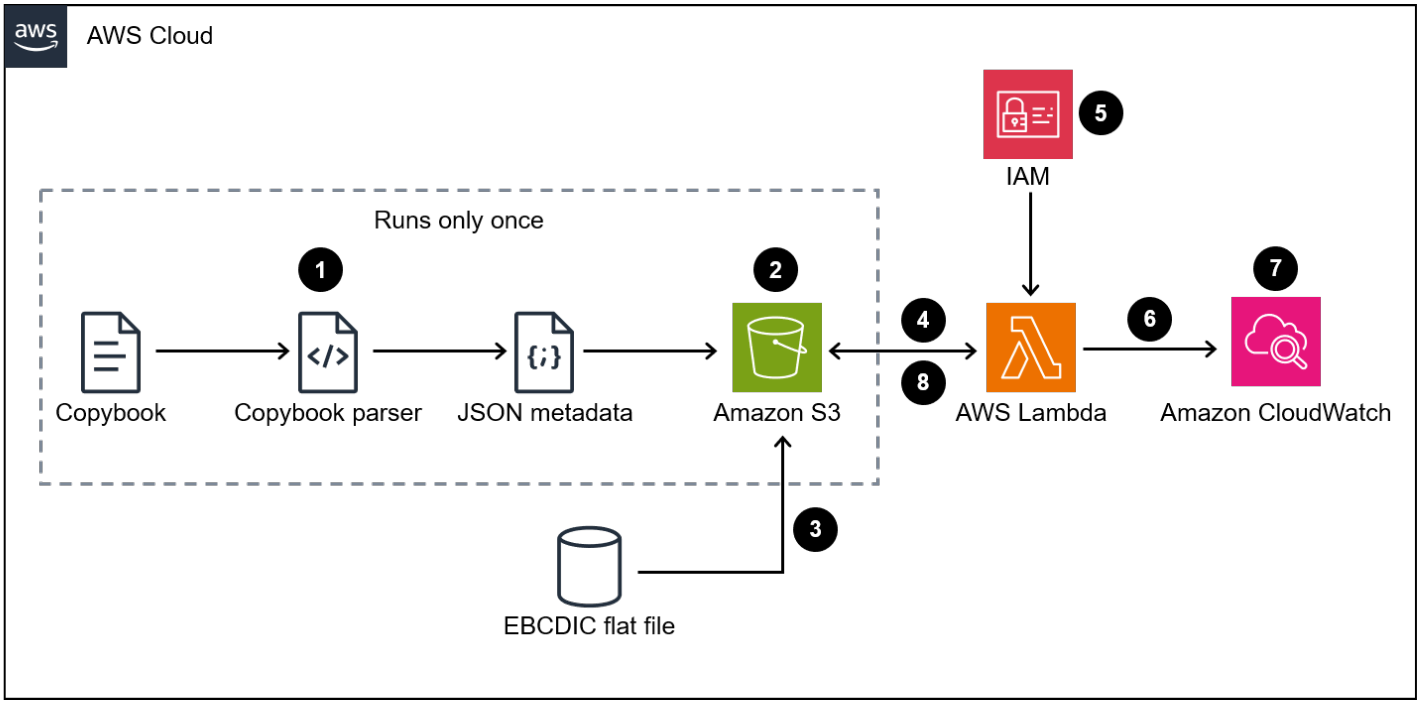
- IBM z/OS, IBM i, and other EBCDIC systems
- Sequential files with data encoded in EBCDIC (such as IBM Db2 unloads)
- COBOL copybook

Target technology stack

- Amazon S3
- Amazon S3 event notification
- IAM
- Lambda function
- Python 3.8 or later
- Mainframe Data Utilities
- JSON metadata
- Character-delimited ASCII files

Target architecture

The following diagram shows an architecture for converting mainframe EBCDIC files to ASCII files.



The diagram shows the following workflow:

1. The user runs the copybook parser script to convert the COBOL copybook into a JSON file.
2. The user uploads the JSON metadata to an S3 bucket. This makes the metadata readable by the data conversion Lambda function.
3. The user or an automated process uploads the EBCDIC file to the S3 bucket.
4. The S3 notification event triggers the data conversion Lambda function.
5. AWS verifies the S3 bucket read-write permissions for the Lambda function.
6. Lambda reads the file from the S3 bucket and locally converts the file from EBCDIC to ASCII.
7. Lambda logs the process status in Amazon CloudWatch.
8. Lambda writes the ASCII file back to Amazon S3.

Note

The copybook parser script runs only once, after it converts the metadata to JSON and then uploads that data to an S3 bucket. After the initial conversion, any EBCDIC file that uses the same JSON file that's uploaded to the S3 bucket will use the same metadata.

Tools

AWS tools

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS CloudShell is a browser-based shell that you can use to manage AWS services by using the AWS Command Line Interface (AWS CLI) and a range of preinstalled development tools.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Other tools

- GitHub is a code-hosting service that provides collaboration tools and version control.
- Python is a high-level programming language.

Code

The code for this pattern is available in the GitHub mainframe-data-utilities repository.

Best practices

Consider the following best practices:

- Set the required permissions at the Amazon Resource Name (ARN) level.
- Always grant least-privilege permissions for IAM policies. For more information, see Security best practices in IAM in the IAM documentation.

Epics

Create environment variables and a working folder

Task	Description	Skills required

Create the environment variables.	Copy the following environment variables to a text editor, and then replace the <placeholder> values in the following example with your resource values:
	`bucket=<your_bucket_name>`
	`account=<your_account_number>`
	`region=<your_region_code>`
	Note
	You will create references to your S3 bucket, AWS account, and AWS Region later.
	To define environment variables, open the [CloudShell console](), and then copy and paste your updated environment variables onto the command line.
		General AWS

Task	Description	Skills required
	Note You must repeat this step every time the CloudShell session restarts.	
Create a working folder.	To simplify the resource clean-up process later on, create a working folder in CloudShell by running the following command: `mkdir workdir; cd workdir` **Note** You must change the directory to the working directory (`workdir`) every time you lose a connectio n to your CloudShell session.	General AWS

Define an IAM role and policy

Task	Description	Skills required
Create a trust policy for the Lambda function.	The EBCDIC converter runs in a Lambda function. The function must have an IAM	General AWS

Task	Description	Skills required

	role. Before you create the IAM role, you must define a trust policy document that enables resources to assume that policy.
	
	From the CloudShell working folder, create a policy document by running the following command:
	
	`E2ATrustPol=$(cat <<EOF`
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Effect": "Allow",`
	`            "Principal": {`
	`                "Service": "lambda.amazonaws.com"`
	`            },`
	`            "Action": "sts:AssumeRole"`
	`        }`
	`    ]`
	`}`
	`EOF`
	`)`
	`printf "$E2ATrustPol" > E2ATrustPol.json`	

Task	Description	Skills required
Create the IAM role for Lambda conversion.	To create an IAM role, run the following AWS CLI command from the CloudShell working folder: `aws iam create-role --role-name E2AConvLambdaRole --assume-role-policy-document file://E2ATrustPol.json`	General AWS

Task	Description	Skills required

Create the IAM policy document for the Lambda function.	The Lambda function must have read-write access to the S3 bucket and write permissions for Amazon CloudWatch Logs.
	
	To create an IAM policy, run the following command from the CloudShell working folder:
	
	`E2APolicy=$(cat <<EOF`
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Sid": "Logs",`
	`            "Effect": "Allow",`
	`            "Action": [`
	`                "logs:PutLogEvents",`
	`                "logs:CreateLogStream",`
	`                "logs:CreateLogGroup"`
	`            ],`
	`            "Resource": [`
	`                "arn:aws:logs:*:*:log-group:*",`
	`                "arn:aws:logs:*:*:log-group:*:log-stream:*"`
	`            ]`
		General AWS

Task	Description	Skills required

	``
	        },
	        {
	            "Sid": "S3",
	            "Effect":
	 "Allow",
	            "Action": [
	
	 "s3:GetObject",
	
	 "s3:PutObject",
	
	 "s3:GetObjectVersion"
	            ],
	            "Resource":
	 [
	
	 "arn:aws:s3:::%s/*",
	
	 "arn:aws:s3:::%s"
	            ]
	        }
	    ]
	}
	EOF
	)
	printf "$E2APolicy"
	 "$bucket" "$bucket"
	 > E2AConvLambdaPolic
	y.json
	``	

Task	Description	Skills required
Attach the IAM policy document to the IAM role.	To attach the IAM policy to the IAM role, run the following command from your CloudShell working folder: `aws iam put-role-policy --role-name E2AConvLambdaRole --policy-name E2AConvLambdaPolicy --policy-document file://E2AConvLambdaPolicy.json`	General AWS

Create the Lambda function for EBCDIC conversion

Task	Description	Skills required
Download the EBCDIC conversion source code.	From the CloudShell working folder, run the following command to download the mainframe-data-utilities source code from GitHub: `git clone https://github.com/aws-samples/mainframe-data-utilities.git mdu`	General AWS
Create the ZIP package.	From the CloudShell working folder, run the following command to create the ZIP package that creates the Lambda function for EBCDIC conversion:	General AWS

Task	Description	Skills required
	`cd mdu; zip ../mdu.zip *.py; cd ..`	
Create the Lambda function.	From the CloudShell working folder, run the following command to create the Lambda function for EBCDIC conversion: `aws lambda create-function \ --function-name E2A \ --runtime python3.9 \ --zip-file fileb://mdu.zip \ --handler extract_ebcdic_to_ascii.lambda_handler \ --role arn:aws:iam::$account:role/E2AConvLambdaRole \ --timeout 10 \ --environment "Variables={layout=$bucket/layout/}"` **Note** The environment variable layout tells the Lambda function where the JSON metadata resides.	General AWS

Task	Description	Skills required
Create the resource-based policy for the Lambda function.	From the CloudShell working folder, run the following command to allow your Amazon S3 event notificat ion to trigger the Lambda function for EBCDIC conversio n: ```aws lambda add-permi ssion \ --function-name E2A \ --action lambda:In vokeFunction \ --principal s3.amazon aws.com \ --source-arn arn:aws:s 3:::$bucket \ --source-account $account \ --statement-id 1```	General AWS

Create the Amazon S3 event notification

Task	Description	Skills required
Create the configuration document for the Amazon S3 event notification.	The Amazon S3 event notification initiates the EBCDIC conversion Lambda function when files are placed in the input folder. From the CloudShell working folder, run the following command to create the JSON document for the Amazon S3 event notification:	General AWS

Task	Description	Skills required

	``
	{
	"LambdaFunctionC
	onfigurations": [
	    {
	      "Id": "E2A",
	      "LambdaFu
	nctionArn": "arn:aws:
	lambda:%s:%s:funct
	ion:E2A",
	      "Events":
	 ["s3:ObjectCreated:
	Put"],
	      "Filter": {
	        "Key": {
	          "FilterRu
	les": [
	            {
	              "Name":
	 "prefix",
	              "Value":
	 "input/"
	            }
	          ]
	        }
	      }
	    }
	  ]
	}
	EOF
	)
	printf "$S3E2AEvent"
	 "$region" "$account" >
	 S3E2AEvent.json
	``	

Task	Description	Skills required
Create the Amazon S3 event notification.	From the CloudShell working folder, run the following command to create the Amazon S3 event notification: ```aws s3api put-bucket-notification-configuration --bucket $bucket --notification-configuration file://S3E2AEvent.json```	General AWS

Create and upload the JSON metadata

Task	Description	Skills required
Parse the COBOL copybook.	From the CloudShell working folder, run the following command to parse a sample COBOL copybook into a JSON file (which defines how to read and slice the data file properly): ```python3 mdu/parse_copybook_to_json.py \ -copybook mdu/LegacyReference/COBKS05.cpy \ -output CLIENT.json \ -output-s3key CLIENT.ASCII.txt \ -output-s3bkt $bucket \ -output-type s3 \```	General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>-print   25</code></pre></td><td></td></tr>
<tr><td>Add the transformation rule.</td><td>The sample data file and its corresponding COBOL copybook is a multi-layout file. This means that the conversion must slice data based on certain rules. In this case, bytes on position 3 and 4 in each row define the layout.

From the CloudShell working folder, edit the <code>CLIENT.json</code> file and change the contents from <code>"transf-rule": [],</code> to the following:
<pre><code>"transf-rule": [
{
"offset": 4,
"size": 2,
"hex": "0002",
"transf": "transf1"
},
{
"offset": 4,
"size": 2,
"hex": "0000",
"transf": "transf2"
}
],</code></pre></td><td>General AWS, IBM Mainframe, Cobol</td></tr>
</table>

Task	Description	Skills required
Upload the JSON metadata to the S3 bucket.	From the CloudShell working folder, run the following AWS CLI command to upload the JSON metadata to your S3 bucket: `aws s3 cp CLIENT.json s3://$bucket/layout/CLIENT.json`	General AWS

Convert the EBCDIC file

Task	Description	Skills required
Send the EBCDIC file to the S3 bucket.	From the CloudShell working folder, run the following command to send the EBCDIC file to the S3 bucket: `aws s3 cp mdu/sample-data/CLIENT.EBCDIC.txt s3://$bucket/input/` **Note** We recommend that you set different folders for input (EBCDIC) and output (ASCII) files to avoid calling the Lambda conversion function again when the ASCII	General AWS

Task	Description	Skills required
	file is uploaded to the S3 bucket.	

Check the output.	From the CloudShell working folder, run the following command to check if the ASCII file is generated in your S3 bucket:
	`awss3 ls s3://$bucket/`
	Note
	The data conversion can take several seconds to happen. We recommend that you check for the ASCII file a few times.
	After the ASCII file is available, run the following command to download the file from the S3 bucket to the current folder:
	`aws s3 cp s3://$bucket/ CLIENT.ASCII.txt .`
	Check the ASCII file content:
	`head CLIENT.ASCII.txt`
		General AWS

Clean the environment

Task	Description	Skills required

(Optional) Prepare the variables and folder.	If you lose connection with CloudShell, reconnect and then run the following command to change the directory to the working folder:
	`cd workdir`
	Ensure that the environment variables are defined:
	`bucket=<your_bucket_name>`
	`account=<your_account_number>`
	`region=<your_region_code>`
		General AWS

Remove the notification configuration for the bucket.	From the CloudShell working folder, run the following command to remove the Amazon S3 event notification configuration:
	`aws s3api put-bucket-notification-configuration \`
	`--bucket=$bucket \`
	`--notification-configuration="{}"`
		General AWS

Delete the Lambda function.	From the CloudShell working folder, run the following	General AWS

Task	Description	Skills required
	command to delete the Lambda function for the EBCDIC converter: `awslambdadelete-function--function-nameE2A`	

Delete the IAM role and policy.	From the CloudShell working folder, run the following command to remove the EBCDIC converter role and policy:
	`aws iam delete-role-policy --role-name E2AConvLambdaRole --policy-name E2AConvLambdaPolicy`
	
	`aws iam delete-role --role-name E2AConvLambdaRole`
		General AWS

Delete the files generated in the S3 bucket.	From the CloudShell working folder, run the following command to delete the files generated in the S3 bucket:
	`aws s3 rm s3://$bucket/layout --recursive`
	`aws s3 rm s3://$bucket/input --recursive`
	`aws s3 rm s3://$bucket/CLIENT.ASCII.txt`
		General AWS

Task	Description	Skills required
Delete the working folder.	From the CloudShell working folder, run the following command to remove `workdir` and its contents: `cd ..; rm -Rf workdir`	General AWS

Convert mainframe data files with complex record layouts using Micro Focus

Peter West, Amazon Web Services

Summary

This pattern shows you how to convert mainframe data files with non-text data and complex record layouts from EBCDIC (Extended Binary Coded Decimal Interchange Code) character encoding to ASCII (American Standard Code for Information Interchange) character encoding by using a Micro Focus structure file. To complete the file conversion, you must do the following:

1. Prepare a single source file that describes all the data items and record layouts in your mainframe environment.
2. Create a structure file that contains the record layout of the data by using the Micro Focus Data File Editor as part of the Micro Focus Classic Data File Tools or Data File Tools. The structure file identifies the non-text data so that you can correctly convert your mainframe files from EBCDIC to ASCII.
3. Test the structure file by using the Classic Data File Tools or Data File Tools.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Micro Focus Enterprise Developer for Windows, available through AWS Mainframe Modernization

Product versions

- Micro Focus Enterprise Server 7.0 and later

Tools

- Micro Focus Enterprise Developer provides the run environment for applications created with any integrated development environment (IDE) variant of Enterprise Developer.
- Micro Focus Classic Data File Tools help you convert, navigate, edit, and create data files. The Classic Data File Tools include Data File Converter, Record Layout Editor, and Data File Editor.

- Micro Focus Data File Tools help you create, edit, and move data files. The Data File Tools include Data File Editor, File Conversion Utilities, and the Data File Structure Command Line Utility.

Epics

Prepare the source file

Task	Description	Skills required
Identify source components.	Identify all possible record layouts for the file, including any redefinitions that contain non-text data. If you have layouts that contain redefinitions, you must factor these layouts down to unique layouts that describe each possible permutation of the data structure. Typically, a data file's record layouts can be described by the following archetypes: • Record layout with only text data • Record layout with non-text data • Record layout with non-text data subordinate to a REDEFINES clause For more information on creating flattened record layouts for files that contain complex record layouts, see	App developer

Task	Description	Skills required
	Rehosting EBCDIC applications on ASCII environments for mainframe migrations.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Identify record layout conditions.</td><td>For files with multiple record layouts or files that contain complex layouts with a REDEFINES clause, identify the data and conditions within a record that you can use to define which layout to use during conversion. We recommend that you discuss this task with a subject matter expert (SME) who understan ds the programs that process these files.

For example, a file might contain two record types that contain non-text data. You can inspect the source and possibly find code similar to the following:

<pre>MOVE "M" TO PART-TYPE
 MOVE "MAIN ASSEMBLY" TO
 PART-NAME
MOVE "S" TO PART-TYPE
 MOVE "SUB ASSEMBLY 1"
 TO PART-NAME</pre>
The code helps you identify the following:

• The "PART-TYPE" field is used to determine the record type
• The value "M" is used for the "M-PART-RECORD"</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
	• The value "S" is used for the "S-PART-RECORD" You can document the values that are used by this field to associate the record layouts with the correct data records in the file.	
Build the source file.	If the file is described over multiple source files or if the record layout contains non-text data that's subordina te to a REDEFINES clause, then create a new source file that contains the record layouts. The new program doesn't need to describe the file using SELECT and FD statements. The program can simply contain the record descriptions as 01 levels within Working-Storage. **Note** You can create a source file for each data file or create a master source file that describes all the data files.	App developer

Task	Description	Skills required
Compile the source file.	Compile the source file to build the data dictionary. We recommend that you compile the source file by using the EBCDIC character set. If the IBMCOMP directive or ODOSLIDE directives are being used, then you must use these directives in the source file too. **Note** IBMCOMP affects the byte storage of COMP fields and ODOSLIDE affects padding on OCCURS VARYING structures. If these directives are set incorrectly, then the conversion tool won't read the data record correctly. This results in bad data in the converted file.	App developer

(Option A) Create the structure file using Classic Data File Tools

Task	Description	Skills required
Start the tool and load the dictionary.	1. Choose the Windows Start menu icon, search for and choose **Micro Focus**	App developer

Task	Description	Skills required
	Enterprise Developer, and then choose **Classic Data File Tools**. 2. Choose **File**, and then choose **Record Layout**. 3. In the **Select a file to construct the layouts from** dialog box, for **File name**, select the IDY (`.idy`) file that was created when you compiled the source file earlier. Then, choose **Open**. 4. To confirm that Classic Data File Tools is using EBCDIC, in the **Data File Tools** dialog box, choose **YES** if the IDY file is set to **EBCDIC** and **Datatools** is set to **ANSI**.	

Task	Description	Skills required
Create the default record layout.	Use the default record layout for all records that don't match any conditional layouts. 1. In the **Layout** window, expand the data structure , and then locate the 01 level used for the default layout. 2. Right-click the 01 item, and then choose **New Layout**. 3. In the **New Record Layout Wizard** dialog box, choose **Default Layout**, and then choose **Next**. 4. Choose **Finish**. The default layout appears in the **Layouts** pane and can be identified by the red folder icon.	App developer

Task	Description	Skills required
Create a conditional record layout.	Use the conditional record layout when there is more than one record layout in a file. 1. In the **Layouts** pane, expand the data structure , and then locate the 01 level used for the condition al layout. 2. Right-click the 01 item, and then choose **New Layout**. 3. In the **New Record Layout Wizard** dialog box, choose **Conditional Layout**, and then choose **Next**. 4. Choose **Finish**. The conditional layout appears in the **Layouts** pane and can be identified by the yellow folder icon. 5. Expand the conditional layout, right-click the field where you must place a condition, and then choose **Properties**. 6. In the **Field Propertie s** dialog box, enter the condition. Confirm that the character set is set to **EBCDIC**, and then choose **OK**. A checkmark appears	App developer

Task	Description	Skills required
	next to the field that has a condition set. 7. Repeat steps 5–6 for any other fields that require conditions for this layout. 8. Repeat steps 1–6 for any other conditional layouts that must be added. 9. Choose **File**, choose **Save As**, and then save the structure file to disk.	

(Option B) Create the structure file using Data File Tools

Task	Description	Skills required
Start the tool and load the dictionary.	1. Choose the Windows Start menu icon, search for and choose **Micro Focus Enterprise Developer**, and then choose **Data File Tools**. 2. Choose **File**, **New**, **Structure File**. 3. In the **Open** dialog box, for **File name**, select the IDY (`.idy`) file that was created when you compiled the source file earlier. Then, choose **Open**. 4. To confirm that Data File Tools is using EBCDIC, confirm that the drop-	App developer

Task	Description	Skills required
	down menu in the **Debug File** section is set to **EBCDIC**.	
Create the default record layout.	Use the default record layout for all records that do not match any conditional layouts. 1. In the **Available Layouts** section on the left pane, expand the data structure , and then locate the 01 level used for the default layout. 2. Right-click the 01 item, and then choose **Create Default Layout**. The default layout appears in the **Layouts** pane and can be identified by the blue "D" icon.	App developer

Task	Description	Skills required
Create a conditional record layout.	Use the conditional record layout when there is more than one record layout in a file. 1. In the **Selected Layouts** section on the right pane, expand the data structure , and then locate the 01 level used for the condition al layout. 2. Right-click the 01 item, and then choose **Create Conditional Layout**. The conditional layout appears in the **Layouts** pane on the right side and can be identified by the green "C" icon. 3. Expand the conditional layout, right-click the field where you must place a condition, and then choose **Properties**. 4. In the **Field Propertie s** dialog box, enter the condition. Confirm that the character set is set to **EBCDIC**, and then choose **OK**. A red "IF" icon appears next to the field that has a condition set.	App developer

Task	Description	Skills required
	5. Repeat steps 3–4 for any other fields that require conditions for this layout. 6. Repeat steps 1–4 for any other conditional layouts that must be added. 7. Choose **File**, choose **Save As**, and then save the structure file to disk.	

(Option A) Test the structure file using Classic Data File Tools

Task	Description	Skills required
Test an EBCDIC data file.	Confirm that you can use your structure file to view an EBCDIC test data file correctly . 1. Choose the Windows Start menu icon, find and choose **Micro Focus Enterpris e Developer**, and then choose **Classic Data Tools**. 2. Choose **File**, and then choose **Open**. 3. In the **Open** dialog box, for **File name**, select the EBCDIC dataset, and then choose **Open**. 4. Choose **File**, **Data File Editor**, **Load Record Layouts**.	App developer

Task	Description	Skills required
	5. In the **Open** dialog box, for **File name**, select the structure file, and then choose **Open**. 6. To confirm that the character set mode is set to EBCDIC, confirm that the drop-down menu is set to **EBCDIC**. You can see the raw record data in the left pane and the formatted data in the right pane. 7. Choose various records to ensure that all formats are rendered with the correct layout.	

(Option B) Test the structure file using Data File Tools

Task	Description	Skills required
Test an EBCDIC data file.	Confirm that you can use your structure file to view an EBCDIC test data file correctly . 1. Choose the Windows Start menu icon, find and select **Micro Focus Enterprise Developer**, and then choose **Data File Tools**. 2. Choose **File**, **Open**, **Data File**.	App developer

Task	Description	Skills required
	3. In the **Open Data File** dialog box, on the **Local** tab, for **Filename**, choose **Browse** to find the location of the EBCDIC test file. 4. For **Structure File (optional)**, choose **Browse** to find the location of the structure file. 5. In the **File Details** section, enter the details of the file and confirm that **Encoding** is set to **EBCDIC**. 6. Choose either **Open Shared** or **Open Exclusive** mode depending on your requirements. 7. Confirm that the drop-down menu in the **Appearance** section of the toolbar is set to **EBCDIC**. You will see the raw record data in the left pane and the formatted data in the right pane. 8. Choose various records to ensure that all formats are rendered with the correct layout.	

Test data file conversion

Task	Description	Skills required
Test the conversion of an EBCDIC file.	1. Choose the Windows Start menu icon, find and select **Micro Focus Enterpris e Developer**, and then choose **Classic Data Tools**. 2. Choose **Tools**, and then choose **Convert**. 3. In the **Data File Convert** dialog box, in the **Input file** section, for **Filename**, choose **Browse** to find and select the EBCDIC input file. Confirm that **Character set** is set to **EBCDIC**. 4. In the **Character Set Conversion** section, select the **Convert character set** and **Records contain non-text data items** check boxes. Choose **Select layout for conversion**, and then choose **Browse** to find and select the structure file. 5. In the **New file** section, for **Filename**, enter the path and file name of the ASCII output file that you want to create. By default, the conversion tool defaults to the same format as the	App developer

Task	Description	Skills required
	input file. For testing, leave the options set to their default values. 6. Choose **Convert**. 7. Follow the steps in either the *(Option A) Test the structure file using Classic Data File Tools* or *(Option B) Test the structure file using Data File Tools* section, but load the ASCII output file instead of the EBCDIC file. 8. Load both the EBCDIC and ASCII files into the Data File Editor, and then compare the files side by side to check the accuracy of the conversion.

Deploy an environment for containerized Blu Age applications by using Terraform

Richard Milner-Watts, Amazon Web Services

Summary

Migrating legacy mainframe workloads into modern cloud architectures can eliminate the costs of maintaining a mainframe—costs that only increase as the environment ages. However, migrating jobs from a mainframe can pose unique challenges. Internal resources might not be familiar with the job logic, and the high performance of mainframes at these specialized tasks can be difficult to replicate when compared to commodity, generalized CPUs. Rewriting these jobs can be a large undertaking and require significant effort.

Blu Age converts legacy mainframe workloads into modern Java code, which you can then run as a container.

This pattern provides a sample serverless architecture for running a containerized application that has been modernized with the Blu Age tool. The included HashiCorp Terraform files will build a secure architecture for the orchestration of Blu Age containers, supporting both batch tasks and real-time services.

For more information about modernizing your workloads by using Blu Age and AWS services, see these AWS Prescriptive Guidance publications:

- Running mainframe workloads that have been modernized with Blu Age on AWS serverless infrastructure
- Containerize mainframe workloads that have been modernized by Blu Age

For assistance with using Blu Age to modernize your mainframe workloads, contact the Blu Age team by choosing **Contact our experts** on the Blu Age website. For assistance with migrating your modernized workloads to AWS, integrating them with AWS services, and moving them into production, contact your AWS account manager or fill out the AWS Professional Services form.

Prerequisites and limitations

Prerequisites

- The sample containerized Blu Age application provided by the [Containerize mainframe workloads that have been modernized by Blu Age] pattern. The sample application provides the logic to handle the processing of input and output for the modernized application, and it can integrate with this architecture.
- Terraform is required to deploy these resources.

Limitations

- Amazon Elastic Container Service (Amazon ECS) places limits on the task resources that can be made available to the container. These resources include CPU, RAM, and storage. For example, when using Amazon ECS with AWS Fargate, the [task resource limits apply].

Product versions

This solution was tested with the following versions:

- Terraform 1.3.6
- Terraform AWS Provider 4.46.0

Architecture

Source technology stack

- Blu Age
- Terraform

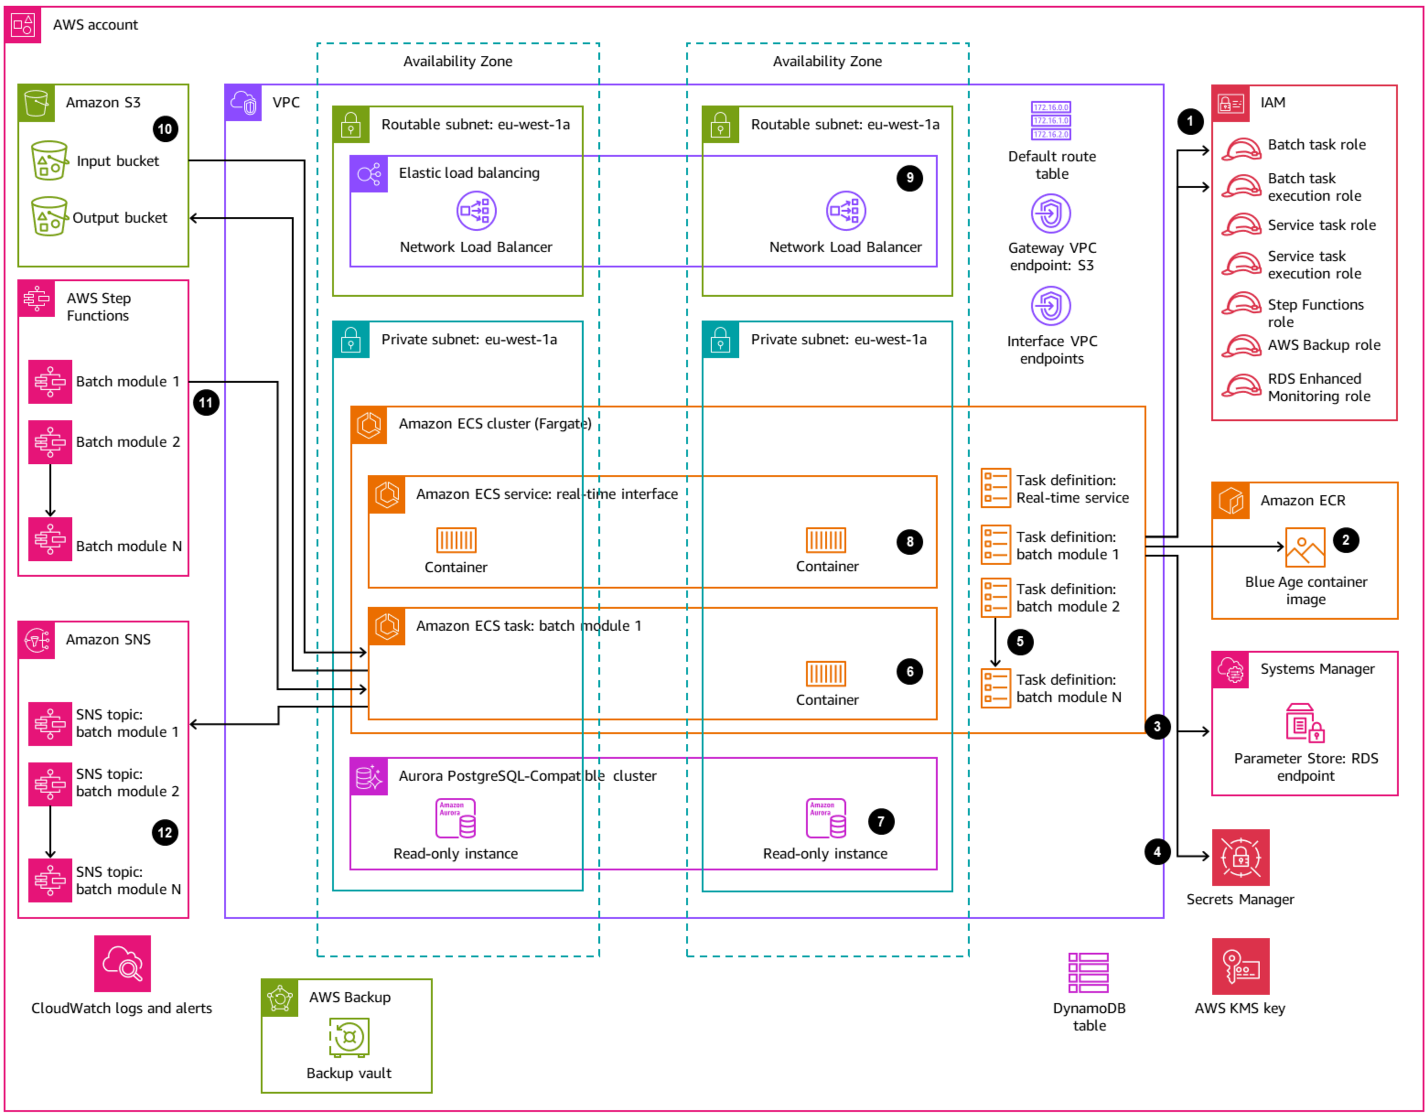
Target technology stack

- Amazon Aurora PostgreSQL-Compatible Edition
- AWS Backup
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- AWS Identity and Access Management Service (IAM)
- AWS Key Management Server (AWS KMS)
- AWS Secrets Manager

- Amazon Simple Notification Service (Amazon SNS)
- Amazon Simple Storage Service (Amazon S3)
- AWS Step Functions
- AWS Systems Manager

Target architecture

The following diagram shows the solution architecture.



1. The solution deploys the following IAM roles:
   - Batch task role
   - Batch task execution role

- Service task role
- Service task execution role
- Step Functions role
- AWS Backup role
- RDS Enhanced Monitoring role.

The roles conform to least-privileged access principles.

2. Amazon ECR is used to store the container image that is orchestrated by this pattern.
3. AWS Systems Manager Parameter Store provides configuration data about each environment to the Amazon ECS task definition at runtime.
4. AWS Secrets Manager provides sensitive configuration data about the environment to the Amazon ECS task definition at runtime. The data has been encrypted by AWS KMS.
5. The Terraform modules create Amazon ECS task definitions for all real-time and batch tasks.
6. Amazon ECS runs a batch task by using AWS Fargate as the compute engine. This is a short-lived task, initiated as required by AWS Step Functions.
7. Amazon Aurora PostgreSQL-Compatible provides a database to support the modernized application. This replaces mainframe databases such as IBM Db2 or IBM IMS DB.
8. Amazon ECS runs a long-lived service to deliver a modernized real-time workload. These stateless applications run permanently with containers spread across Availability Zones.
9. A Network Load Balancer is used to grant access to the real-time workload. The Network Load Balancer supports earlier protocols, such as IBM CICS. Alternatively, you can use an Application Load Balancer with HTTP-based workloads.
10. Amazon S3 provides object storage for job inputs and outputs. The container should handle pull and push operations into Amazon S3 to prepare the working directory for the Blu Age application.
11. The AWS Step Functions service is used to orchestrate running the Amazon ECS tasks to process batch workloads.
12. SNS topics for each batch workload are used to integrate the modernized application with other systems, such as email, or to initiate additional actions, such as delivering output objects from Amazon S3 into FTP.

Note

By default, the solution has no access to the internet. This pattern assumes that the virtual private cloud (VPC) will be connected to other networks using a service such as AWS Transit Gateway. As such, multiple interface VPC endpoints are deployed to grant access to the AWS services used by the solution. To turn on direct internet access, you can use the toggle in the Terraform module to replace the VPC endpoints with an internet gateway and the associated resources.

Automation and scale

The use of serverless resources throughout this pattern helps to ensure that, by scaling out, there are few limits on the scale of this design. This reduces *noisy neighbor concerns*, such as the competition for compute resources that might be experienced on the original mainframe. Batch tasks can be scheduled to run simultaneously as needed.

Individual containers are limited by the maximum sizes supported by Fargate. For more information, see the *Task CPU and memory* section in the Amazon ECS documentation.

To scale real-time workloads horizontally, you can add containers.

Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- AWS Backup is a fully managed service that helps you centralize and automate data protection across AWS services, in the cloud, and on premises.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.

- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- AWS Systems Manager Parameter Store provides secure, hierarchical storage for configuration data management and secrets management.

Other services

- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses Terraform to create the sample architecture.

Code repository

The source code for this pattern is available in the GitHub Blu Age Sample ECS Infrastructure (Terraform) repository.

Best practices

- For test environments, use features such as the `forceDate` option to configure the modernized application to generate consistent test results by always running for a known time period.
- Tune each task individually to consume the optimal amount of resources. You can use Amazon CloudWatch Container Insights to obtain guidance on potential bottlenecks.

Epics

Prepare the environment for deployment

Task	Description	Skills required
Clone the solution source code.	Clone the solution code from the [GitHub project]().	DevOps engineer
Bootstrap the environment by deploying resources to store the Terraform state.	1. Open a terminal window, and confirm that Terraform is installed and that AWS credentials are available. 2. Navigate to the `bootstrap-terraform` folder. 3. Edit the file `main.tf` if you want to change the names of the S3 bucket (`<accountId>-terraform-backend`) and Amazon DynamoDB table (`terraform-lock`). 4. Run the `terraform apply` command to deploy the resources. Make a note of the S3 bucket and DynamoDB table names.	DevOps engineer

Deploy the solution infrastructure

Task	Description	Skills required
Review and update the Terraform configuration.	In the root directory, open the file `main.tf`, review the contents, and consider	DevOps engineer

Task	Description	Skills required
	making the following updates: 1. Update the AWS Region by searching for and replacing the string `eu-west-1` with the desired Region that you want to use. 2. Update the bucket name in the `Terraform Backend` block if the default was altered in the previous epic. 3. Update the `dynamodb_table` value if the default was altered in the previous epic. 4. Update the value of the `stack_prefix` variable to the string that you want. This string will be prepended to the names of all resources created by this pattern. 5. Update the value of the `vpc_cidr` This should be at least a `/24` address range. 6. Review the `Locals` section. This is used to define the Blu Age tasks that will be deployed. The solution will iterate over the list object `bluage_ba`	

Task	Description	Skills required
	`tch_modules` , creating the associated resources (Step Functions state machine, task definition, and SNS topic) for each element of the list. In some cases, you might want to adjust variables for different environments. For example, to force the runtime in test environments, you can change value of the `force_execution_time` variable. 7. To turn on internet access, change the value for `direct_internet_access_required` from `false` to `true`. This will deploy an internet gateway, along with the NAT gateways and route tables that turn on public internet access for the infrastructure. By default, the solution will deploy interface VPC endpoints into a VPC without direct internet access. 8. To grant access to any client-server workloads that are served through Elastic Load Balancing , update the values of	

Task	Description	Skills required
	`additional_nlb_ingress_cidrs` with the CIDR networks that should be allowed.	
Deploy the Terraform file.	From your terminal, run the `terraform apply` command to deploy all resources. Review the changes generated by Terraform, and enter **yes** to initiate the build. Note that it can take over 15 minutes to deploy this infrastructure.	DevOps engineer

(Optional) Deploy a valid Blu Age containerized application

Task	Description	Skills required
Push the Blu Age container image to Amazon ECR.	Push the container into the Amazon ECR repository that you created in the previous epic. For instructions, see the [Amazon ECR documentation](https://docs.aws.amazon.com/AmazonECR/latest/userguide/docker-push-ecr-image.html). Make a note of the container image URI.	DevOps engineer
Update the Terraform to reference the Blu Age container image.	Update the file `main.tf` to reference the container image that you uploaded.	DevOps engineer
Redeploy the Terraform file.	From your terminal, run `terraform apply` to deploy all resources. Review the	DevOps engineer

Task	Description	Skills required
	suggested updates from Terraform, and then enter **yes** to proceed with the deployment.

Generate Db2 z/OS data insights by using AWS Mainframe Modernization and Amazon Q in QuickSight

Shubham Roy, Roshna Razack, and Santosh Kumar Singh, Amazon Web Services

Summary

If your organization is hosting business-critical data in an IBM Db2 mainframe environment, gaining insights from that data is crucial for driving growth and innovation. By unlocking mainframe data, you can build faster, secure, and scalable business intelligence to accelerate data-driven decision-making, growth, and innovation in the Amazon Web Services (AWS) Cloud.

This pattern presents a solution for generating business insights and creating sharable narratives from mainframe data in IBM Db2 for z/OS tables. Mainframe data changes are streamed to Amazon Managed Streaming for Apache Kafka (Amazon MSK) topic using AWS Mainframe Modernization Data Replication with Precisely. Using Amazon Redshift streaming ingestion, Amazon MSK topic data is stored in Amazon Redshift Serverless data warehouse tables for analytics in Amazon QuickSight.

After the data is available in QuickSight, you can use natural language prompts with Amazon Q in QuickSight to create summaries of the data, ask questions, and generate data stories. You don't have to write SQL queries or learn a business intelligence (BI) tool.

Business context

This pattern presents a solution for mainframe data analytics and data insights use cases. Using the pattern, you build a visual dashboard for your company's data. To demonstrate the solution, this pattern uses a health care company that provides medical, dental, and vision plans to its members in the US. In this example, member demographics and plan information are stored in the IBM Db2 for z/OS data tables. The visual dashboard shows the following:

- Member distribution by region
- Member distribution by gender
- Member distribution by age
- Member distribution by plan type
- Members who have not completed preventive immunization

For examples of member distribution by region and members who have not completed preventive immunization, see the Additional information section.

After you create the dashboard, you generate a data story that explains the insights from the previous analysis. The data story provides recommendations for increasing the number of members who have completed preventive immunizations.

Prerequisites and limitations

Prerequisites

- An active AWS account. This solution was built and tested on Amazon Linux 2 on Amazon Elastic Compute Cloud (Amazon EC2).
- An virtual private cloud (VPC) with a subnet that can be accessed by your mainframe system.
- A mainframe database with business data. For the example data used to build and test this solution, see the *Attachments* section.
- Change data capture (CDC) enabled on the Db2 z/OS tables. To enable CDC on Db2 z/OS, see the IBM documentation.
- Precisely Connect CDC for z/OS installed on the z/OS system that's hosting the source databases. The Precisely Connect CDC for z/OS image is provided as a zip file within the AWS Mainframe Modernization - Data Replication for IBM z/OS Amazon Machine Image (AMI). To install Precisely Connect CDC for z/OS on the mainframe, see the Precisely installation documentation.

Limitations

- Your mainframe Db2 data should be in a data type that's supported by Precisely Connect CDC. For a list of supported data types, see the Precisely Connect CDC documentation.
- Your data at Amazon MSK should be in a data type that's supported by Amazon Redshift. For a list of supported data types, see the Amazon Redshift documentation.
- Amazon Redshift has different behaviors and size limits for different data types. For more information, see the Amazon Redshift documentation.
- The near real-time data in QuickSight depends on the refresh interval set for the Amazon Redshift database.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. Amazon Q in QuickSight is currently not available in every Region that supports

QuickSight. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

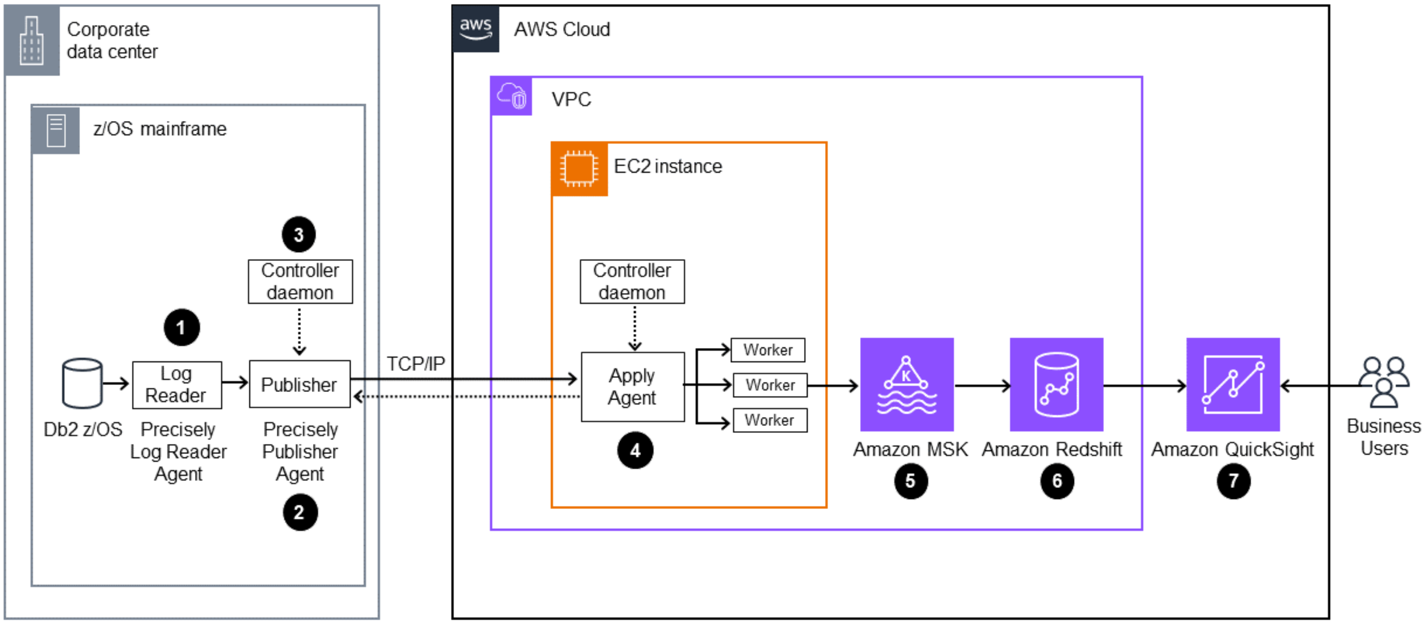
Product versions

- AWS Mainframe Modernization Data Replication with Precisely version 4.1.44
- Python version 3.6 or later
- Apache Kafka version 3.5.1

Architecture

Target architecture

The following diagram shows an architecture for generating business insights from mainframe data by using AWS Mainframe Modernization Data Replication with Precisely and Amazon Q in QuickSight.



The diagram shows the following workflow:

1. The Precisely Log Reader Agent reads data from Db2 logs and writes the data into transient storage on an OMVS file system on the mainframe.
2. The Publisher Agent reads the raw Db2 logs from transient storage.

3. The on-premises controller daemon authenticates, authorizes, monitors, and manages operations.
4. The Apply Agent is deployed on Amazon EC2 by using the preconfigured AMI. It connects with the Publisher Agent through the controller daemon by using TCP/IP. The Apply Agent pushes data to Amazon MSK using multiple workers for high-throughput.
5. The workers write the data to the Amazon MSK topic in JSON format. As the intermediate target for the replicated messages, Amazon MSK provides the highly available and automated failover capabilities.
6. Amazon Redshift streaming ingestion provides low-latency, high-speed data ingestion from Amazon MSK to an Amazon Redshift Serverless database. A stored procedure in Amazon Redshift performs the mainframe change data (insert/update/deletes) reconciliation into Amazon Redshift tables. These Amazon Redshift tables serves as the data analytics source for QuickSight.
7. Users access the data in QuickSight for analytics and insights. You can use Amazon Q in QuickSight to interact with the data by using natural language prompts.

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them out or in.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- Amazon Managed Streaming for Apache Kafka (Amazon MSK) is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard. This pattern uses the generative BI capabilities of Amazon Q in QuickSight.
- Amazon Redshift Serverless is a serverless option of Amazon Redshift that makes it more efficient to run and scale analytics in seconds without the need to set up and manage data warehouse infrastructure.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.

Other tools

- Precisely Connect CDC collects and integrates data from legacy systems into cloud and data platforms.

Code repository

The code for this pattern is available in the GitHub Mainframe_DataInsights_change_data_reconciliation repository. The code is a stored procedure in Amazon Redshift. This stored procedure reconciles mainframe data changes (inserts, updates, and deletes) from Amazon MSK into the Amazon Redshift tables. These Amazon Redshift tables serve as the data analytics source for QuickSight.

Best practices

- Follow best practices while setting up your Amazon MSK cluster.
- Follow Amazon Redshift data parsing best practices for improving performance.
- When you create the AWS Identity and Access Management (IAM) roles for the Precisely setup, follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Set up AWS Mainframe Modernization Data Replication with Precisely on Amazon EC2

Task	Description	Skills required
Set up a security group.	To connect to the controlle r daemon and the Amazon MSK cluster, create a security group for the EC2 instance. Add the following inbound and outbound rules: • **Inbound rule 1:**	DevOps engineer, AWS DevOps

Task	Description	Skills required
	- For **Type**,choose **Custom TCP**. - For **Protocol**, choose **TCP**. - For **Port range**, choose **2626** (default port for the Precisely controlle r daemon) or the port number of the controlle r daemon running on the mainframe. - For **Source**, choose CIDR block. **Inbound rule 2:** - For **Type**, choose **Custom TCP**. - For **Protocol**, choose **SSH**. - For **Port range**, choose **22**. - For **Source**, choose **IP address** or **prefix list**. **Inbound rule 3:** - For **Type**, choose **Custom TCP**. - For **Protocol**, choose **TCP**. - For **Port range**, choose **9092-9098**. - For **Source**, choose **CIDR block**. **Outbound rule 1:**	

Task	Description	Skills required
	- For **Type**, choose **Custom TCP**. - For **Protocol**, choose **TCP**. - For **Port range**, choose **9092-9098**. - For **Source**, choose **CIDR block**. • **Outbound rule 2:** - For **Type**, choose **Custom TCP**. - For **Protocol**, choose **TCP**. - For **Port range**, choose **2626** (default port for the Precisely controlle r daemon) or the port number of the controlle r daemon running on the mainframe. - For **Source**, choose **CIDR block**. Note the name of the security group. You will need to reference the name when you launch the EC2 instance and configure the Amazon MSK cluster.	

Task	Description	Skills required
Create an IAM policy and an IAM role.	1. To create an IAM policy and an IAM role, follow the instructions in the [AWS documentation](). The IAM policy grants access to create topics on the Amazon MSK cluster and to send data to those topics. 2. After you create the IAM role, associate the policy with it. Note the IAM role name. This role will be used as the IAM instance profile when you launch the EC2 instance.	DevOps engineer, AWS systems administrator

Task	Description	Skills required
Provision an EC2 instance.	To provision an EC2 instance to run Precisely CDC and connect to Amazon MSK, do the following: 1. Sign in to AWS Marketplace, and subscribe to AWS Mainframe Modernization – Data Replication for IBM z/OS. 2. Select the AMI from the managed subscriptions, and choose on **Launch new instance.** 3. Provide other configuration details, such as the instance name, instance type, key pair, VPC, and subnets. For more information, see the Amazon EC2 documentation. 4. In the dropdown list, choose the security group that you created earlier. 5. Under **Advanced details**, **IAM instance profile**, you must select the role that you created earlier. 6. Choose **Launch instance**.	AWS administrator, DevOps engineer

Set up Amazon MSK

Task	Description	Skills required
Create the Amazon MSK cluster.	To create an Amazon MSK cluster, do the following : 1. Sign in to the AWS Management Console, and open the Amazon MSK console at https://console.aws.amazon.com/msk/. 2. Choose **Create cluster**. 3. For the cluster creation method, choose **Custom create**, and for the cluster type, choose **Provisioned**. 4. Provide a name for the cluster. 5. Update **Cluster settings** as needed, and keep the defaults for the other settings. 6. Note the **<Kafka version>**. You will need it during Kafka client setup. 7. Choose **Next**. 8. Choose the same VPC and subnets that you used for the Precisely EC2 instance, and choose the security group that you created earlier.	AWS DevOps, Cloud administrator

Task	Description	Skills required
	9. In the **Security settings** section, enable both **SASL/ SCRAM** and **IAM role-base d authentication**. Precisely Connect CDC uses SASL/ SCRAM (Simple Authentic ation and Security Layer/ Salted Challenge Response Mechanism), and IAM is needed for connecting to Amazon Redshift. 10. Choose **Next**. 11. For reviewing, choose **Monitoring** and **Broker log delivery method.** 12. Choose **Next**, and then choose **Create the cluster**. A typical provisioned cluster takes up to 15 minutes to create. After the cluster is created, its status changes from **Creating** to **Active**.	

Task	Description	Skills required
Set up SASL/SCRAM authentication.	To set up SASL/SCRAM authentication for an Amazon MSK cluster, do the following: 1. To set up a secret in Secrets Manager, follow the instructions in the AWS documentation. 2. Open the Amazon MSK console, and select the Amazon MSK cluster that you created previously. 3. Choose the **Properties** tab. 4. Choose **Associate secrets**, **Choose the secrets**, select the secrets key that you created, and then choose **Associate secrets**. You will see a success message similar to the following: `Successfully associated 1 secret for cluster <chosen cluster name>` 5. Choose the cluster name. 6. In the cluster summary, choose **View client information**. 7. Note the private endpoint connection string for the	Cloud architect

Task	Description	Skills required
	authentication type SASL/ SCRAM.	

Task	Description	Skills required

Create the Amazon MSK topic.	To create the Amazon MSK topic, do the following:
	
	1. Connect to the EC2 instance that you created earlier, and install the latest updates by running the following command:
	`sudo yum update -y`
	2. Install the Java and Kafka library by running the following command:
	`sudo yum install -y java-11 librdkafka librdkafka-devel`
	3. To create a folder named `kafka` in `/home/ec2-user`, navigate to that folder, and run the following command:
	`mkdir kafka;cd kafka`
	4. Download the `kafka` client library to the `kafka` folder, replacing `<YOUR MSK VERSION>` with the Kafka version that you noted during the Amazon MSK cluster creation:
	`wget https://archive.apache.org/`
		Cloud administrator

Task	Description	Skills required
	``` dist/kafka//kafka_ 2.13-<YOUR MSK VERSION>.tgz ``` 5. To extract the downloaded file, run the following command, replacing `YOUR MSK VERSION>`: ``` tar -xzf kafka_2.13- <YOUR MSK VERSION>. tgz ``` 6. To navigate to the `kafka libs` directory and download the Java IAM authentication Java Archive (JAR) file, run the following commands, replacing `<YOUR MSK VERSION>`: ``` cd kafka_2.13-<YOUR MSK VERSION>/libs wget https://g ithub.com/aws/aws- msk-iam-auth/relea ses/download/v1.1. 1/aws-msk-iam-auth -1.1.1-all.jarkafka ``` 7. To navigate to the Kafka `bin` directory and create the `client.properties` file, run the following commands:	

Task	Description	Skills required

	`cd /home/ec2-user/kafka/kafka_2.13-<YOUR MSK VERSION>/bin`
	`cat >client.properties`
	
	8. Update the `client.properties` file with the following contents:
	
	`security.protocol=SASL_SSL`
	`sasl.mechanism=AWS_MSK_IAM`
	`sasl.jaas.config=software.amazon.msk.auth.iam.IAMLoginModule required;`
	`sasl.client.callback.handler.class=software.amazon.msk.auth.iam.IAMClientCallbackHandler`
	
	9. To create a Kafka topic, navigate to the Kafka bin and run the following command, replacing `<kafka broker>` with the IAM bootstrap server private endpoint that you noted during Amazon MSK cluster creation:
	
	`./kafka-topics.sh --bootstrap-server <kafka broker> --command-config`	

Task	Description	Skills required
	`client.properties --create --replication-factor 3 —partitions 6 --topic <topic name>` 10. When the message `Created topic <topic name>` appears, note the topic name.	

Configure the Precisely Apply Engine on Amazon EC2

Task	Description	Skills required
Set up the Precisely scripts to replicate data changes.	To set up the Precisely Connect CDC scripts to replicate changed data from the mainframe to the Amazon MSK topic, do the following: 1. To create a folder name precisely and change to that folder, run the following command: `mkdir /home/ec2-user/precisely;cd /home/ec2-user/precisely` 2. To create two folders inside precisely called `scripts` and `ddls`, and then change to the `scripts` folder, run the following command:	App developer, Cloud architect

Task	Description	Skills required
	``` mkdir scripts;mkdir ddls;cd scripts ``` 3. To create a file named `sqdata_kafka_producer.conf` in the `scripts` folder, run the following command: ``` cat >sqdata_k afka_producer.conf ``` 4. Update `sqdata_kafka_producer.conf` file with the following content: ``` builtin.features=S ASL_SCRAM security.protocol =SASL_SSL sasl.mechanism=SC RAM-SHA-512 sasl.username=<User Name> sasl.passwor d=<Password> metadata.broke r.list=<SASL/SCRAM Bootstrap servers> ``` **Note** Update `<SASL/SCRAM Bootstrap servers>` with the Amazon MSK	

Task	Description	Skills required

	SASL/SCRAM broker list that you previously configured. Update `<User Name>` and `<Password>` with the username and password that you set up previously in Secrets Manager.
	
	5. Create a `script.sqd` file in the `scripts` folder.
	
	`cat >script.sqd`
	
	The Apply Engine uses `script.sqd` to process source data and replicate the source data to the target. For an example Apply Engine script, see the Additional information section.
	
	6. To change to the `ddls` folder and create a .ddl file for each Db2 table, run the following commands:
	
	`cd /home/ec2-user/precisely/ddls`
	`cat >mem_details.ddl`
	`cat >mem_plans.ddl`	

Task	Description	Skills required
	For example .ddl files, see the Additional information section.	

Task	Description	Skills required

Generate the network ACL key.	To generate the network access control list (network ACL) key, do the following:
	1. To export the `sqdata` installation path, run the following command:
	`export PATH=$PATH:/usr/sbin:/opt/precisely/di/sqdata/bin`
	2. To change to the `/home/ec2-user` directory and generate the network ACL key, run the following commands:
	`cd /home/ec2-user`
	`sqdutil keygen --force`
	After the public and private keys are generated, the following message is displayed:
	`SQDUT04I Generating a private key in file /home/ec2-user/.nacl/id_nacl`
	`SQDC017I sqdutil(pid=27344) terminated successfully`
		Cloud architect, AWS DevOps

Task	Description	Skills required
	3. Note the generated public key that is stored in the `.nacl` folder.	

Prepare the mainframe source environment

Task	Description	Skills required
Configure defaults in the ISPF screen.	To configure default settings in the Interactive System Productivity Facility (ISPF), follow the instructions in the [Precisely documentation]().	Mainframe system administr ator
Configure the controller daemon.	To configure the controller daemon, do the following: 1. On the **SQData z/OS Main Menu** screen, choose option 2. 2. On the **Add Daemon to List** screen, in the **Daemon Name** field, enter a name for the daemon, and then press **Enter**.	Mainframe system administr ator
Configure the publisher.	To configure the publisher, do the following: 1. On the **SQData z/OS Main Menu** screen, choose option 3. This takes you to the **Capture/Publisher Summary** screen.	Mainframe system administr ator

Task	Description	Skills required
	2. Choose the option to add a CAB file. This will take you to the **Add CAB File to List** screen. 3. In the **Name** field, enter a name for the CAB file. For **Db2**, enter the **Type** as D. 4. Press **Enter**. This takes you to the **Create New Db2 Capture CAB File** screen. 5. In the **zFS Dir** field, specify the storage mount point. 6. Press **Enter** to save and continue.	

Task	Description	Skills required

Update the daemon configuration file.	To update the publisher details in the controller daemon configuration file, do the following:
	
	1. On the **SQData z/OS Main Menu** screen, choose option 2.
	2. Enter S near the daemon that you created to see the daemon details.
	3. Enter 1, and then press **Enter** to edit the agents file.
	4. Add your CAB file details. The following example shows the details for a CAB file named `DB2ZTOMSK` . Use your mainframe user ID instead of `<userid>`.
	
	`ÝDB2ZTOMSK¨`
	`type=capture`
	`cab=/u/<userid>/sqdata/DB2ZTOMSK.cab`
	
	5. Press **F3**.
	6. Enter 2 to edit the ACL file. Add your `userid` to the `acl` configuration file as shown in the following example:
	
	`Ýacls¨`
	`prod=admin,<userid>`
		Mainframe system administrator

Task	Description	Skills required
	7. Press **F3** to save and exit.	
Create the job to start the controller daemon.	To create the job, do the following: 1. In **Options**, enter `G`. 2. Enter the JOB Card, job and proc libraries, and `Db2 load` library details. 3. Enter the network ACL file details, and enter option 2 to generate the job control language (JCL) file in the specified job library.	Mainframe system administr ator

Task	Description	Skills required
Generate the capture publisher JCL file.	To generation the capture publisher JCL file, do the following: 1. On the **SQData z/OS Main Menu** screen, choose option 3. This takes you to the **Capture/Publisher Summary** screen. 2. Enter S next to the CAB file to select it. This takes you to the **Db2 Capture/Publisher Detail** screen. 3. In **Options**, enter G in options to generate the `capture/publisher` job. 4. Enter the JOB card, job, and procedure libraries , and Db2 load library details. 5. To create the job, choose option 4. The job is created in the job library specified in job library.	Mainframe system administr ator

Task	Description	Skills required

Check and update CDC.	1. Check the `DATACAPTURE` flag for the Db2 table by running the following query, changing `<table name>` to your Db2 table name:
	`SELECT DATACAPTURE FROM SYSIBM.SYSTABLES WHERE NAME='<table name>';`
	Confirm that the result shows `DATACAPTURE` as Y.
	2. If `DATACAPTURE` is not Y, run the following query to enable CDC on the Db2 table, changing `<table name>` to your Db2 table name:
	`ALTER TABLE <table name> DATA CAPTURE CHANGES;`
		Mainframe system administrator

Task	Description	Skills required
Submit the JCL files.	Submit the following JCL files that you configured in the previous steps: • JCL file to start the controller daemon • JCL file to start capture and publish After you submit the JCL files, you can start the Apply Engine in Precisely on the EC2 instance.	Mainframe system administr ator

Run and validate CDC

Task	Description	Skills required
Start the Apply Engine and validate the CDC.	To start the Apply Engine on the EC2 instance and validate the CDC, do the following: 1. To connect to the EC2 instance, follow the instructions in the AWS documentation. 2. Change to the directory that contains the `script.sqd` file: `cd /home/ec2-user/pre cisely/scripts`	Cloud architect, App developer

Task	Description	Skills required
	3. To start the Apply Engine, run the following `sqdeng` start command: `sqdeng -s script.sqd --identity=/home/ec2-user/.nacl/id_nacl` The Apply Engine will start waiting for updates from the mainframe source. 4. To test CDC, make some record inserts or updates in the Db2 table. 5. Validate that the Apply Engine log shows the number of records captured and written to the target.	

Task	Description	Skills required

Validate the records on the Amazon MSK topic.	To read the message from the Kafka topic, do the following:
	
	1. To change to the `bin` directory of the Kafka client installation path on the EC2 instance, run the following command, replacing `<Kafka version>` with your version:
	`cd /home/ec2-user/kafka/kafka_2.13-<Kafka version>/bin`
	2. To validate the Db2 CDC written as messages in the Kafka topic, run the following command, replacing `<kafka broker>` and `<Topic Name>` with the topic that you created earlier:
	`./kafka-console-consumer.sh --bootstrap-server <kafka broker>:9098 --topic <Topic Name> --from-beginning --consumer.config client.properties`
	3. Validate that the messages match the number of
		App developer, Cloud architect

Task	Description	Skills required
	records updated in the Db2 table.	

Store mainframe change data in an Amazon Redshift Serverless data warehouse

Task	Description	Skills required
Set up Amazon Redshift Serverless.	To create an Amazon Redshift Serverless data warehouse, follow the instructions in the [AWS documentation](). On the Amazon Redshift Serverless dashboard, validate that the namespace and workgroup were created and are available. For this example pattern, the process might take 2‒5 minutes.	Data engineer
Set up the IAM role and trust policy required for streaming ingestion.	To set up Amazon Redshift Serverless streaming ingestion from Amazon MSK, do following: 1. Create an IAM policy for Amazon Redshift to access Amazon MSK. Replacing `[region]` with the AWS Region for Amazon MSK, `[account-id]` with your AWS account ID, and `[msk-cluster-name]` with	Data engineer

Task	Description	Skills required
	Amazon MSK cluster name, run the following code: `{"Version": "2012-10-17","Statement": [{"Sid": "MSKIAMpolicy","Effect": "Allow","Action": ["kafka-cluster:ReadData","kafka-cluster:DescribeTopic","kafka-cluster:Connect"], "Resource": ["arn:aws:kafka:[region]:[account-id]:cluster/[msk-cluster-name]/*","arn:aws:kafka:[region]:[account-id]:topic/[msk-cluster-name]/*"]},{"Effect": "Allow","Action": ["kafka-cluster:AlterGroup","kafka-cluster:DescribeGroup"],"Resource": ["arn:aws:kafka:[region]:[account-id]:group/[msk-cluster-name]/*"]}]}` You can find the cluster name and the Amazon	

Task	Description	Skills required
	Resource Name (ARN) on the Amazon MSK console. On the console, choose **Cluster summary**, and then choose **ARN**. 2. To create an IAM role and attach the policy, follow the instructions in the AWS documentation. 3. To attach the IAM role to the Amazon Redshift Serverless namespace, do following: a. Sign in to the console, and open the Amazon Redshift console at https://console.aws.amazon.com/redshiftv2/. b. Choose the **Serverless** dashboard. c. Choose **Namespace**. d. Choose the **Security and encryption** tab. e. Choose **Permission**, and attach the IAM role that you created. 4. In your Amazon Redshift Serverless security group, create an inbound rule with the following details: • For **Type**, choose **Custom TCP**.	

Task	Description	Skills required
	• For **Protocol**, choose **TCP**. • For **Port range**, choose **9098, 9198**. • For **Source**, choose **Amazon MSK security group**. 5. In your Amazon MSK security group, create an inbound rule with following details: • For **Type**, choose **Custom TCP**. • For **Protocol**, choose **TCP**. • For **Port range**, choose **9098, 9198**. • For **Source**, choose **Amazon Redshift security group**. This pattern uses the port for IAM authentication for both Amazon Redshift and Amazon MSK configura tion. For more information, see the AWS documenta tion (step 2). 6. Turn on enhanced VPC routing for the Amazon Redshift Serverless workgroup. For more	

Task	Description	Skills required
	information, see the [AWS documentation]().	

Connect Amazon Redshift Serverless to Amazon MSK.	To connect to the Amazon MSK topic, create an external schema in Amazon Redshift Serverless. In Amazon Redshift query editor v2, run the following SQL command, replacing `'iam_role_arn'` with the role that you created previously and replacing `'MSK_cluster_arn '`with the ARN for your cluster.
	`CREATE EXTERNAL SCHEMA member_schema`
	`FROM MSK`
	`IAM_ROLE 'iam_role_arn'`
	`AUTHENTICATION iam`
	`URI 'MSK_cluster_arn';`
		Migration engineer

Task	Description	Skills required

Create a materialized view.	To consume the data from the Amazon MSK topic in Amazon Redshift Serverless, create a materialized view. In Amazon Redshift query editor v2, run the following SQL commands, replacing `<MSK_Topic_name>` with the name of your Amazon MSK topic.
	`CREATE MATERIALIZED VIEW member_view`
	`AUTO REFRESH YES`
	`AS SELECT`
	`kafka_partition,`
	`kafka_offset,`
	`refresh_time,`
	`json_parse(kafka_value) AS Data`
	`FROM member_schema.<MSK_Topic_name>`
	`WHERE CAN_JSON_PARSE(kafka_value);`
		Migration engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create target tables in Amazon Redshift.</td><td>Amazon Redshift tables provide the input for QuickSight. This pattern uses the tables <code>member_dtls</code> and <code>member_plans</code> , which match the source Db2 tables on the mainframe.

To create the two tables in Amazon Redshift, run the following SQL commands in Amazon Redshift query editor v2:

<pre>-- Table 1: members_d
tls
CREATE TABLE members_d
tls (
 memberid INT ENCODE
 AZ64,
 member_name VARCHAR(1
00) ENCODE ZSTD,
 member_type VARCHAR(5
0) ENCODE ZSTD,

Create a stored procedure in Amazon Redshift.	This pattern uses a stored procedure to sync-up change data (`INSERT`, `UPDATE`, `DELETE`) from the source mainframe to the target Amazon Redshift data warehouse table for analytics in QuickSight. To create the stored procedure in Amazon Redshift, use query editor v2 to run the stored procedure code that's in the GitHub repository.	Migration engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Read from the streaming materialized view and load to the target tables.</td><td>The stored procedure reads data change from the streaming materialized view and loads the data changes to the target tables. To run the stored procedure, use the following command:
<pre><code>call SP_Members_Load();</code></pre>
You can use Amazon EventBridge to schedule the jobs in your Amazon Redshift data warehouse to call this stored procedure based on your data latency requireme nts. EventBridge runs jobs at fixed intervals. To monitor whether the previous call to the procedure completed , you might need to use a mechanism such as an AWS Step Functions state machine. For more information, see the following resources:
Creating an Amazon EventBridge rule that runs on a schedule
Accelerate orchestration of an ELT process using AWS Step Functions and Amazon Redshift Data API.</td><td>Migration engineer</td></tr>
</table>

Task	Description	Skills required
	Another option is to use Amazon Redshift query editor v2 to schedule the refresh. For more information, see [Scheduling a query with query editor v2]().	

Connect QuickSight to data in Amazon Redshift

Task	Description	Skills required
Set up QuickSight.	To set up QuickSight, follow the instructions in the [AWS documentation]().	Migration engineer
Set up a secure connectio n between QuickSight and Amazon Redshift.	To set up secure a connectio n between QuickSight and Amazon Redshift, do the following 1. To authorize connectio ns from QuickSight to Amazon Redshift, open the Amazon Redshift console, and add an inbound rule in the Amazon Redshift security group. The rule should allow traffic to port 5439 (the default Redshift port) from the CIDR range where you set up QuickSight. For a list of AWS Regions and their IP addresses, see [Supported]()	Migration engineer

Task	Description	Skills required
	[AWS Regions for QuickSight](#). 2. On the Amazon Redshift console, choose **Workgroup**, **Data access**, **Network and security**, and enable **Publicly accessible**.	

Task	Description	Skills required
Create a dataset for QuickSight.	To create a dataset for QuickSight from Amazon Redshift, do following: 1. On the QuickSight console, in the navigation pane, choose **Datasets**. 2. On the **Datasets** page, choose **New data set**. 3. Choose **Redshift Manual connect**. 4. In the **New Redshift data source** window, enter the connection information: • For **Data source name**, enter a name for the Amazon Redshift data source. • For **Database server**, enter the endpoint of the Amazon Redshift cluster. You can get the endpoint value from the **Endpoint** field in the **General information** section for the cluster workgroup on the Amazon Redshift Serverless dashboard. The server address is the first part of the endpoint before the colon, as shown in the following example:	Migration engineer

Task	Description	Skills required
	`mfdata-insights.NNNNNNNNN.us-east-1.redshift-serverless.amazonaws.com:5439/dev` • For the port, enter 5439 (the default port for Amazon Redshift). • Enter the name of the database (after the slash in the endpoint). In this case, the database name is dev. • For **Username** and **Password**, enter the username and password for the Amazon Redshift database. 5. Choose **Validate Connection**. If successful, you should see a green check mark, which indicates validation. If validation fails, see the Troubleshooting section. 6. Choose **Create data source**.	

Task	Description	Skills required
Join the dataset.	To create analytics in QuickSight, join the two tables by following the instructions in the [AWS documentation](). In the **Join Configuration** pane, choose **Left** for **Join type**. Under **Join clauses**, use `memberid from member_plans = memberid from members_details .`	Migration engineer

Get business insights from the mainframe data by using Amazon Q in QuickSight

Task	Description	Skills required
Set up Amazon Q in QuickSight.	To set up the Amazon Q in QuickSight Generative BI capability, follow the instructions in the [AWS documentation]().	Migration engineer
Analyze mainframe data and build a visual dashboard.	To analyze and visualize your data in QuickSight, do the following: 1. To create the mainframe data analysis, follow the instructions in the [AWS documentation](). For the dataset, choose the dataset that you created.	Migration engineer

Task	Description	Skills required
	2. On the analysis page choose **Build visual**. 3. In the **Create topic for analysis** window, choose **Update existing topic**. 4. In the **Select a topic** dropdown list, choose the topic that you created previously. 5. Choose **Topic linking**. 6. After you link the topic, choose **Build visual** to open the Amazon Q **Build a Visual** window. 7. In the prompt bar. write your analysis questions . The example questions used for this pattern are the following: • Show member distribution by region • Show member distribution by age • Show member distribution by gender • Show member distribution by plan type • Show members not completed preventive immunization After you enter your questions, choose **Build**.	

Task	Description	Skills required
	Amazon Q in QuickSight creates the visuals. 8. To add the visuals to your visual dashboard, choose **ADD TO ANALYSIS**. When you're finished, you can publish your dashboard to share with others in your organization. For examples, see *Mainframe visual dashboard* in the [Additional information](#) section.	

Create a data story with Amazon Q in QuickSight from mainframe data

Task	Description	Skills required
Create a data story.	Create a data story to explain insights from the previous analysis, and generate a recommendation to increase preventive immunization for members: 1. To create the data story, follow the instructions in the [AWS documentation](#). 2. For the data story prompt, use the following: `Build a data story about Region with`	Migration engineer

Task	Description	Skills required
	`most numbers of members. Also show the member distribution by medical plan, vision plan, dental plan. Recommend how to motivate members to complete immunizat ion. Include 4 points of supportin g data for this pattern.` You can also build your own prompt to generate data stories for other business insights. 3. Choose **Add visuals**, and add the visuals that are relevant to the data story. For this pattern, use the visuals that you created previously. 4. Choose **Build**. 5. For example data story output, see *Data story output* in the [Additional information](#) section.	
View the generated data story.	To view the generated data story, choose that story on the **Data stories** page.	Migration engineer

Task	Description	Skills required
Edit a generated data story.	To change the formatting, layout, or visuals in a data story, follow the instructions in the [AWS documentation]().	Migration engineer
Share a data story.	To share a data story, follow the instructions in the [AWS documentation]().	Migration engineer

Troubleshooting

Issue	Solution
For QuickSight to Amazon Redshift dataset creation, `Validate Connection` has faled.	1. Confirm that the security group attached to the Amazon Redshift Serverless instance allows inbound traffic from the IP address range associated with the Region where you set up QuickSight. 2. Confirm that the VPC where Amazon Redshift Serverless is deployed is publicly available. 3. Confirm that you are using the correct username and password for Amazon Redshift. You can reset the username and password on the Amazon Redshift console.
Trying to start the Apply engine on the EC2 instance returns the following error: `-bash: sqdeng: command not found`	Export the `sqdata` installation path by running following command: `export PATH=$PATH:/usr/sbin:/opt/precisely/di/sqdata/bin`
Trying to start the Apply Engine returns one of the following connection errors:	Check the mainframe spool to make sure that the controller daemon jobs are running.

Issue	Solution
• `SQDD018E Cannot connect to transfer socket(rc==0x18468). Agent:<Agent Name > Socket:/u/./sqdata/.DB2ZTOMSK.cab.data` • `SQDUR06E Error opening url cdc://<VPC end point name>:2626/DB2ZTOMSK/DB2ZTOMSK : errno:1128 (Unknown error 1128)`

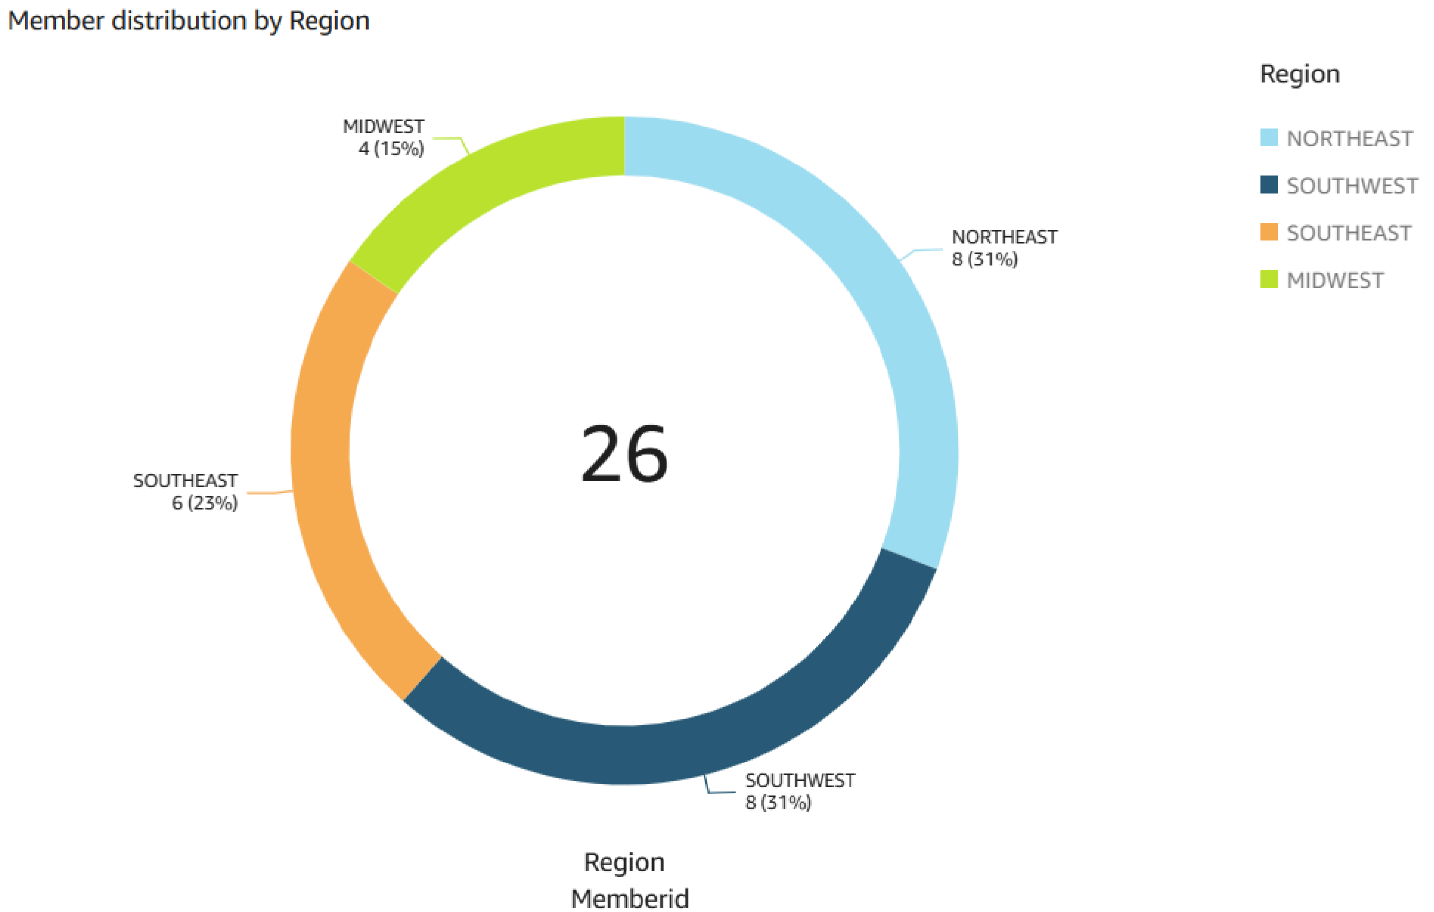
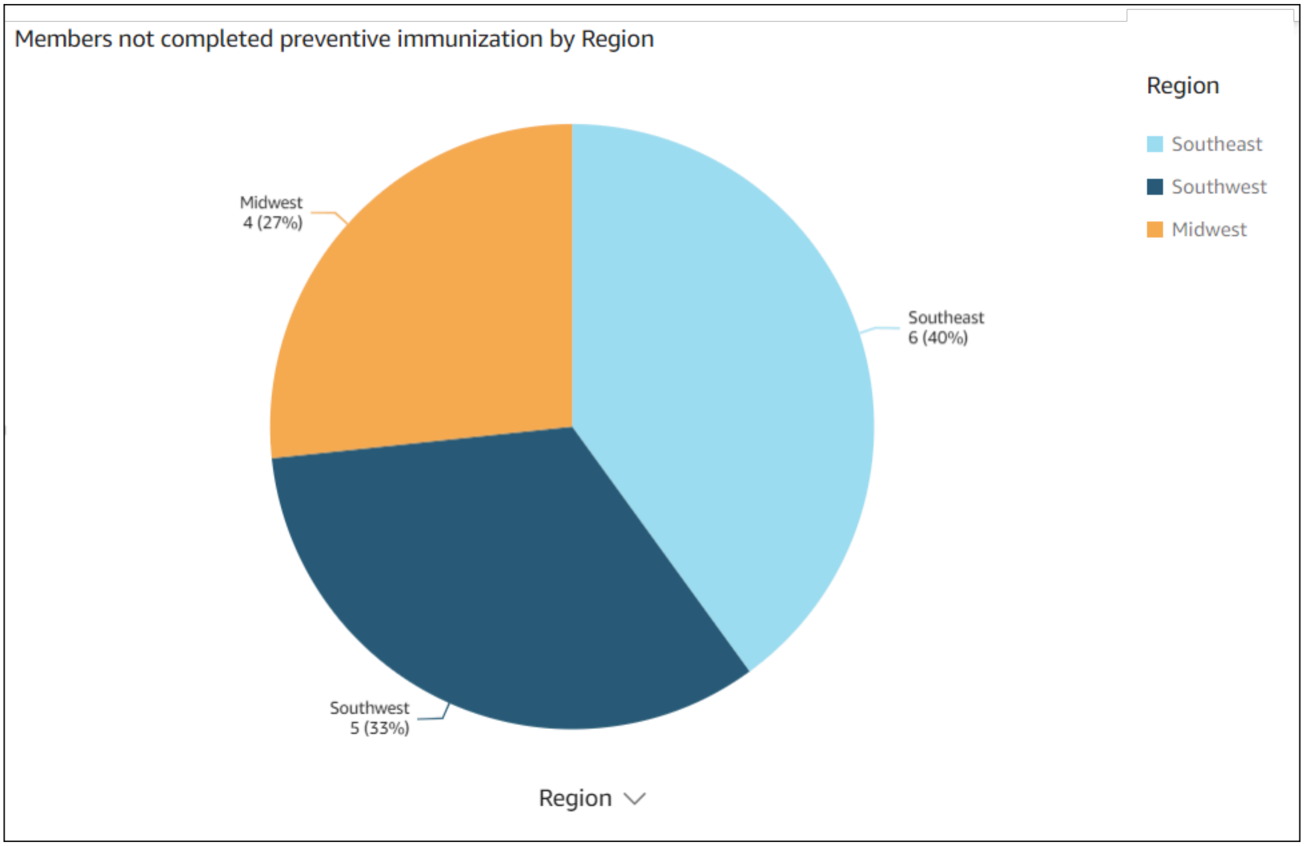
Mainframe visual dashboard

The following data visual was created by Amazon Q in QuickSight for the analysis question `show member distribution by region`.



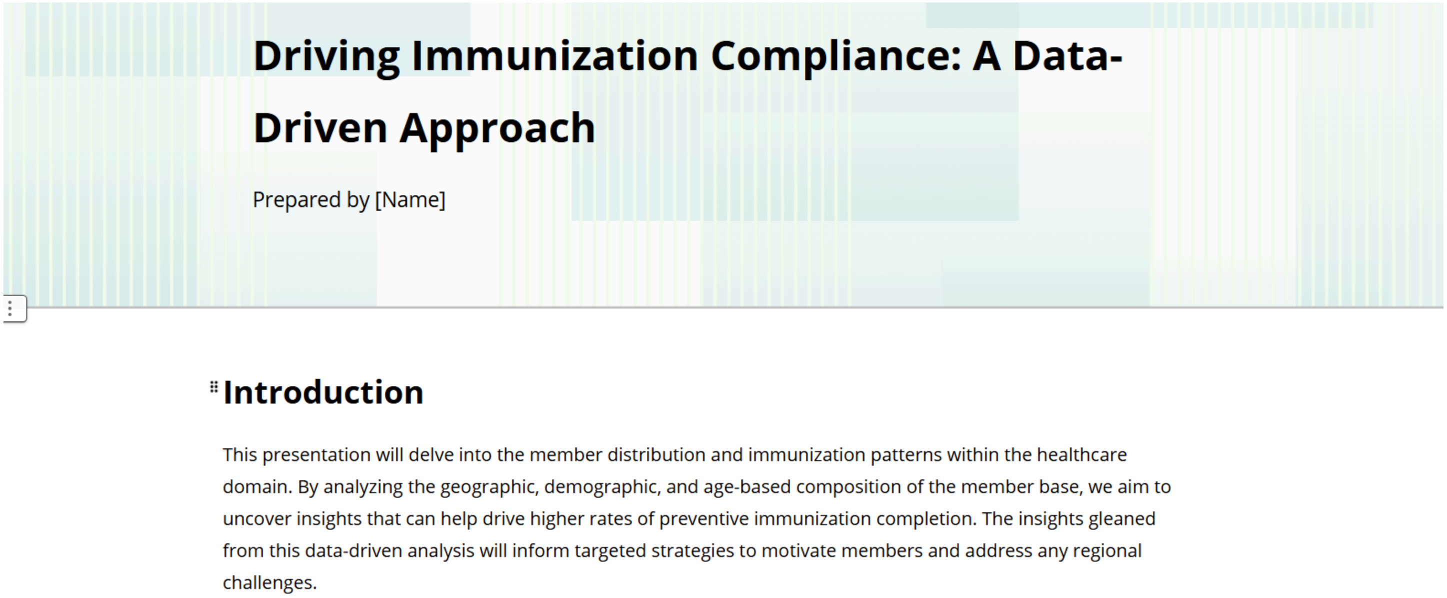
The following data visual was created by Amazon Q in QuickSight for the question `show member distribution by Region who have not completed preventive immunization, in pie chart`.



Data story output

The following screenshots show sections of the data story created by Amazon Q in QuickSight for the prompt `Build a data story about Region with most numbers of members. Also show the member distribution by age, member distribution by gender. Recommend how to motivate members to complete immunization. Include 4 points of supporting data for this pattern.`

In the introduction, the data story recommends choosing the region with the most members to gain the greatest impact from immunization efforts.



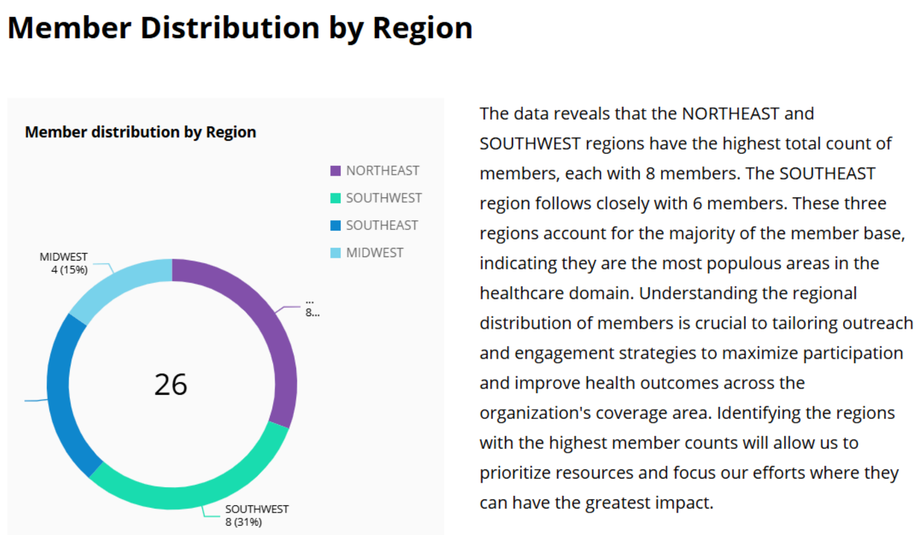
Driving Immunization Compliance: A Data-Driven Approach

Prepared by [Name]

Introduction

This presentation will delve into the member distribution and immunization patterns within the healthcare domain. By analyzing the geographic, demographic, and age-based composition of the member base, we aim to uncover insights that can help drive higher rates of preventive immunization completion. The insights gleaned from this data-driven analysis will inform targeted strategies to motivate members and address any regional challenges.

The data story provides an analysis of member numbers for the four regions. The Northeast, Southwest, and Southeast regions have the most members.

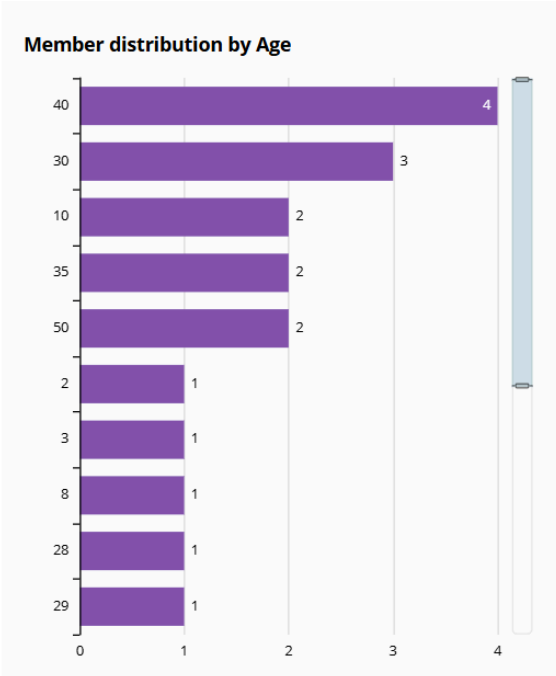


Member Distribution by Region

The data reveals that the NORTHEAST and SOUTHWEST regions have the highest total count of members, each with 8 members. The SOUTHEAST region follows closely with 6 members. These three regions account for the majority of the member base, indicating they are the most populous areas in the healthcare domain. Understanding the regional distribution of members is crucial to tailoring outreach and engagement strategies to maximize participation and improve health outcomes across the organization's coverage area. Identifying the regions with the highest member counts will allow us to prioritize resources and focus our efforts where they can have the greatest impact.

The data story presents an analysis of members by age.

Member Distribution by Age



The age distribution of the member base reveals some interesting trends. According to the graph data, the top three ages with the highest total distinct count of member IDs are 40 with 4 members, 30 with 3 members, and 10 with 2 members. Conversely, the bottom three ages with the lowest distinct member counts are 55, 45, and 28, each with only 1 member. This suggests that the healthcare organization's member base skews towards younger and middle-aged adults, with fewer senior and adolescent members. Understanding this age distribution can help the organization tailor its outreach and engagement strategies to better meet the needs of its target demographics.

The data story focuses on immunization efforts in the Midwest.

Personalized Outreach Campaigns

By leveraging the detailed member distribution insights, we can craft personalized outreach campaigns that resonate with our target audience. Tailoring the messaging and resources to address the unique needs and concerns of members in different age groups and genders will enhance the impact of our immunization promotion efforts. Deploying these targeted outreach initiatives across the regions identified as having the lowest immunization rates will help drive increased member engagement and completion of preventive care.

Addressing Regional Challenges

The Midwest region presents unique challenges in driving higher immunization rates among members. This area is characterized by a diverse population with varying socioeconomic backgrounds and access to healthcare resources. To address these regional nuances, we will develop targeted educational initiatives that resonate with the local community. Our outreach efforts will leverage partnerships with trusted community organizations to improve awareness and accessibility of preventive care services. By tailoring our approach to the specific needs of the Midwest, we can empower members to prioritize their health and complete recommended immunizations.

Anticipated Outcomes

By leveraging the proposed gamification strategies, personalized outreach campaigns, and targeted regional interventions, we expect to see a significant improvement in the overall immunization rates across the healthcare organization. This will enable us to enhance the health and well-being of our members, leading to better healthcare outcomes and potential cost savings. The implementation of these strategies will serve as a crucial step in ensuring our members receive the necessary preventive care and protection against potential health risks.

Conclusion

The insights gleaned from this comprehensive analysis of member distribution and immunization patterns within the healthcare domain provide a solid foundation for strategic interventions. By understanding the demographic composition of the member base and identifying regional variations in preventive care completion, we can develop tailored outreach campaigns and leverage gamification techniques to effectively motivate members to prioritize their health. These targeted efforts will not only improve individual wellness but also strengthen the overall member engagement and loyalty within the organization.

Generate data insights by using AWS Mainframe Modernization and Amazon Q in QuickSight

Shubham Roy, Roshna Razack, and Santosh Kumar Singh, Amazon Web Services

Summary

If your organization is hosting business-critical data in a mainframe environment, gaining insights from that data is crucial for driving growth and innovation. By unlocking mainframe data, you can build faster, secure, and scalable business intelligence to accelerate data-driven decision-making, growth, and innovation in the Amazon Web Services (AWS) Cloud.

This pattern presents a solution for generating business insights and creating sharable narratives from mainframe data by using AWS Mainframe Modernization File Transfer with BMC and Amazon Q in QuickSight. Mainframe datasets are transferred to Amazon Simple Storage Service (Amazon S3) by using AWS Mainframe Modernization File Transfer with BMC. An AWS Lambda function formats and prepares mainframe data file for loading into Amazon QuickSight.

After the data is available in QuickSight, you can use natural language prompts with Amazon Q in QuickSight to create summaries of the data, ask questions, and generate data stories. You don't have to write SQL queries or learn a business intelligence (BI) tool.

Business context

This pattern presents a solution for mainframe data analytics and data insights use cases. Using the pattern, you build a visual dashboard for your company's data. To demonstrate the solution, this pattern uses a health care company that provides medical, dental, and vision plans to its members in the US. In this example, member demographics and plan information are stored in the mainframe datasets. The visual dashboard shows the following:

- Member distribution by region
- Member distribution by gender
- Member distribution by age
- Member distribution by plan type
- Members who have not completed preventive immunization

After you create the dashboard, you generate a data story that explains the insights from the previous analysis. The data story provides recommendations for increasing the number of members who have completed preventive immunizations.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Mainframe datasets with business data
- Access to install a file transfer agent on the mainframe

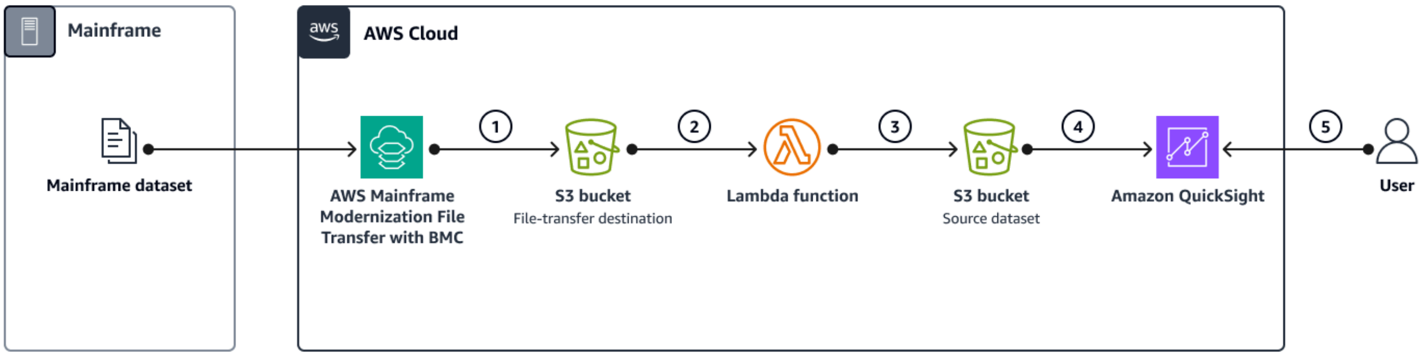
Limitations

- Your mainframe data file should be in one of the file formats supported by QuickSight. For a list supported file formats, see the Amazon QuickSight documentation.

  This pattern uses a Lambda function to convert the mainframe file into a format supported by QuickSight.

Architecture

The following diagram shows an architecture for generating business insights from mainframe data by using AWS Mainframe Modernization File Transfer with BMC and Amazon Q in QuickSight.



The diagram shows the following workflow:

1. A mainframe dataset containing business data is transferred to Amazon S3 by using AWS Mainframe Modernization File Transfer with BMC.

2. The Lambda function converts the file that's in the file-transfer destination S3 bucket to comma-separated values (CSV) format.
3. The Lambda function sends the converted file to the source dataset S3 bucket.
4. The data in the file is ingested by QuickSight.
5. Users access the data in QuickSight. You can use Amazon Q in QuickSight to interact with the data by using natural language prompts.

Tools

AWS services

- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Mainframe Modernization File Transfer with BMC converts and transfers mainframe datasets to Amazon S3 for mainframe modernization, migration, and augmentation use cases.
- Amazon QuickSight is a cloud-scale BI service that helps you visualize, analyze, and report your data in a single dashboard. This pattern uses the generative BI capabilities of Amazon Q in QuickSight.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Best practices

- When you create the AWS Identity and Access Management (IAM) roles for AWS Mainframe Modernization File Transfer with BMC and the Lambda function, follow the principle of least privilege.
- Ensure that your source dataset has supported data types for QuickSight. If your source dataset contains unsupported data types, convert them to supported data types. For information about unsupported mainframe data types and how to convert them to data types supported by Amazon Q in QuickSight, see the Related resources section.

Epics

Set up AWS Mainframe Modernization File Transfer with BMC

Task	Description	Skills required
Install the file transfer agent.	To install AWS Mainframe Modernization File Transfer Agent on your mainframe, follow the instructions in the AWS documentation.	Mainframe system administr ator
Create an S3 bucket for mainframe file transfer.	Create an S3 bucket to store the output file from AWS Mainframe Modernization File Transfer with BMC. In the architecture diagram, this is the file-transfer destination bucket.	Migration engineer
Create the data transfer endpoint.	1. Create an S3 bucket to stage the input mainframe file for AWS Mainframe Modernization File Transfer with BMC. 2. To create the mainframe data transfer endpoint, follow the instructions in the AWS documentation.	AWS Mainframe Moderniza tion specialist

Convert the mainframe file name extension for QuickSight integration

Task	Description	Skills required
Create an S3 bucket.	Create an S3 bucket for the Lambda function to copy the converted mainframe file	Migration engineer

Task	Description	Skills required
	from the source to the final destination bucket.	

Task	Description	Skills required
Create a Lambda function.	To create a Lambda function that changes the file extension and copies the mainframe file to the destination bucket, do the following: 1. Sign in to the AWS Management Console, and navigate to the AWS Lambda console. 2. Choose **Create function**, and then choose **Author from scratch**. 3. For **Function name**, enter a name for your function. 4. In the **Runtime** dropdown list, choose **Python.3.X**. 5. Expand **Change default execution role**, and then choose **Create a new role with basic Lambda permissions**. 6. Choose **Create function**. 7. Choose the **Code** tab, and then paste the `S3CopyLambda.py` Python code that's provided in the [Additional information](#) section. The Python code was generated by using [Amazon Q Developer](#) in the Microsoft Visual Studio	Migration engineer

Task	Description	Skills required
	integrated development environment (IDE). 8. Edit the `destination_bucket_name` to the name of the S3 bucket that you created previously, and change `destination_file_key` to the mainframe file name. 9. Deploy the Lambda function.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create an Amazon S3 trigger to invoke the Lambda function.</td><td>To configure a trigger that invokes the Lambda function, do the following:

1. On the Lambda console, open the Functions page.
2. Choose the Lambda function.
3. In Function overview, choose Add trigger.
4. In the Trigger configura tion dropdown list, choose S3.
5. In the Bucket field, enter the name of your source bucket.
6. In the Event type dropdown list, choose All object create events.
7. Select the I acknowledge that using the same S3 bucket for both input and output is not recommend ed check box, and then choose Add.

For more information, see Tutorial: Using an Amazon S3 trigger to invoke a Lambda function.</td><td>Migration lead</td></tr>
</table>

Task	Description	Skills required
Provide IAM permissions for the Lambda function.	IAM permissions are required for the Lambda function to access the file-transfer destination and source dataset S3 buckets. Update the policy associated with the Lambda function execution role by allowing `s3:GetObject` and `s3:DeleteObject` permissions for the file-transfer destination S3 bucket and `s3:PutObject` access for the source dataset S3 bucket. For more information, see the [Create a permissions policy](#) section in *Tutorial: Using an Amazon S3 trigger to invoke a Lambda function*.	Migration lead

Define a mainframe data transfer task

Task	Description	Skills required
Create a transfer task to copy the mainframe file to the S3 bucket.	To create a mainframe file transfer task, follow the instructions in the [AWS Mainframe Modernization documentation.](#) **Note** Specify **Source code page** encoding as	Migration engineer

Task	Description	Skills required
	IBM1047 and **Target code page** encoding as **UTF-8**.	
Verify the transfer task.	To verify that the data transfer is successful, follow the instructions in the [AWS Mainframe Modernization documentation](). Confirm that the mainframe file is in the file-transfer destination S3 bucket.	Migration lead
Verify the Lambda copy function.	Verify that the Lambda function is initiated and that the file is copied with a .csv extension to the source dataset S3 bucket. The .csv file created by the Lambda function is the input data file for QuickSight. For example data, see the `Sample-data-member-healthcare-APG` file in the [Attachments]() section.	Migration lead

Connect QuickSight to the mainframe data

Task	Description	Skills required
Set up QuickSight.	To set up QuickSight, follow the instructions in the [AWS documentation]().	Migration lead

Task	Description	Skills required
Create a dataset for QuickSight.	To create a dataset for QuickSight, follow the instructions in the AWS documentation. The input data file is the converted mainframe file that was created when you defined the mainframe data transfer task.	Migration lead

Get business insights from the mainframe data by using Amazon Q in QuickSight

Task	Description	Skills required
Set up Amazon Q in QuickSight.	This capability requires Enterprise Edition. To set up Amazon Q in QuickSight, do the following: 1. To get the Amazon Q add-on, follow the instructions Step 1: Get the Q add-on in the AWS documentation. 2. To use the generative BI capabilities in Amazon Q, upgrade your users' accounts. Follow the instructions in the AWS documentation. 3. Create an Amazon Q topic by using the dataset that you created previously. Follow the instructions in the AWS documentation.	Migration lead

Task	Description	Skills required
	4. To configure the topic metadata so that it's natural language–friendly, follow the instructions in the [AWS documentation]().	

Task	Description	Skills required
Analyze mainframe data and build a visual dashboard.	To analyze and visualize your data in QuickSight, do the following: 1. To create the mainframe data analysis, follow the instructions in the [AWS documentation](). For the dataset, choose the dataset created in the previous step. 2. On the analysis page choose **Build visual**. 3. In the **Create topic for analysis** window, choose **Update existing topic**. 4. In the **Select a topic** dropdown list, choose the topic that you created previously. 5. Choose **Topic linking**. 6. After you link the topic, choose **Build visual** to open the Amazon Q **Build a Visual** window. 7. In the prompt bar. write your analysis questions . The example questions used for this pattern are the following: • Show member distribut ion by region	Migration engineer

Task	Description	Skills required
	• Show members distribution by age • Show member distribution by gender • Show member distribution by plan type • Show member not completed preventive immunization After you enter your questions, choose **Build**. Amazon Q in QuickSight creates the visuals. 8. To add the visuals to your visual dashboard, choose **ADD TO ANALYSIS**. When you're finished, you can publish your dashboard to share with others in your organization. For examples, see *Mainframe visual dashboard* in the [Additional information](#) section.	

Create a data story with Amazon Q in QuickSight from the mainframe data

Task	Description	Skills required
Create a data story.	Create a data story to explain insights from the previous	Migration engineer

Task	Description	Skills required
	analysis, and generate a recommendation to increase preventive immunization for members: 1. To create the data story, follow the instructions in the [AWS documentation](#). 2. For the data story prompt, use the following: `Build a data story about Region with most numbers of members. Also show the member distribution by medical plan, vision plan, dental plan. Recommend how to motivate members to complete immunizat ion. Include 4 points of supportin g data for this pattern.` You can also build your own prompt to generate data stories for other business insights. 3. Choose **Add visuals**, and add the visuals that are relevant to the data story. For this pattern, use the	

Task	Description	Skills required
	visuals that you created previously. 4. Choose **Build**. 5. For example data story output, see *Data story output* in the [Additional information](#) section.	
View the generated data story.	To view the generated data story, follow the instructions in the [AWS documentation](#).	Migration lead
Edit a generated data story.	To change the formatting, layout, or visuals in a data story, follow the instructions in the [AWS documentation](#).	Migration lead
Share a data story.	To share a data story, follow the instructions in the [AWS documentation](#).	Migration engineer

Troubleshooting

Issue	Solution
Unable to discover the mainframe files or datasets entered in **Data sets search criteria** for **Create transfer task** in AWS Mainframe Modernization File Transfer with BMC.	1. First, check the connection by choosing **Data transfer endpoints** on the AWS Mainframe Modernization Transfer with BMC console. If the last heartbeat time is greater than two minutes, the connectio n for file transfer hasn't been establish ed. If the last heartbeat time is less than 2 minutes for the agent running on the mainframe, the connection to the agent is successful. Proceed to step 2.

Issue	Solution
	2. Check the AWS Secrets Manager setup. A secret key must be configured in Secrets Manager with a **key** of `userId` (uppercase I) with a **value** of the mainframe's user ID and a **key** of `password` with the **value** of the mainframe password. The `userId` and `password` secret keys are case-sensitive and must be entered as is.

Related resources

To convert mainframe data types such as PACKED-DECIMAL (COMP-3) or BINARY (COMP or COMP-4) to a data type supported by QuickSight, see the following patterns:

- Convert and unpack EBCDIC data to ASCII on AWS by using Python
- Convert mainframe files from EBCDIC format to character-delimited ASCII format in Amazon S3 using AWS Lambda

Additional information

S3CopyLambda.py

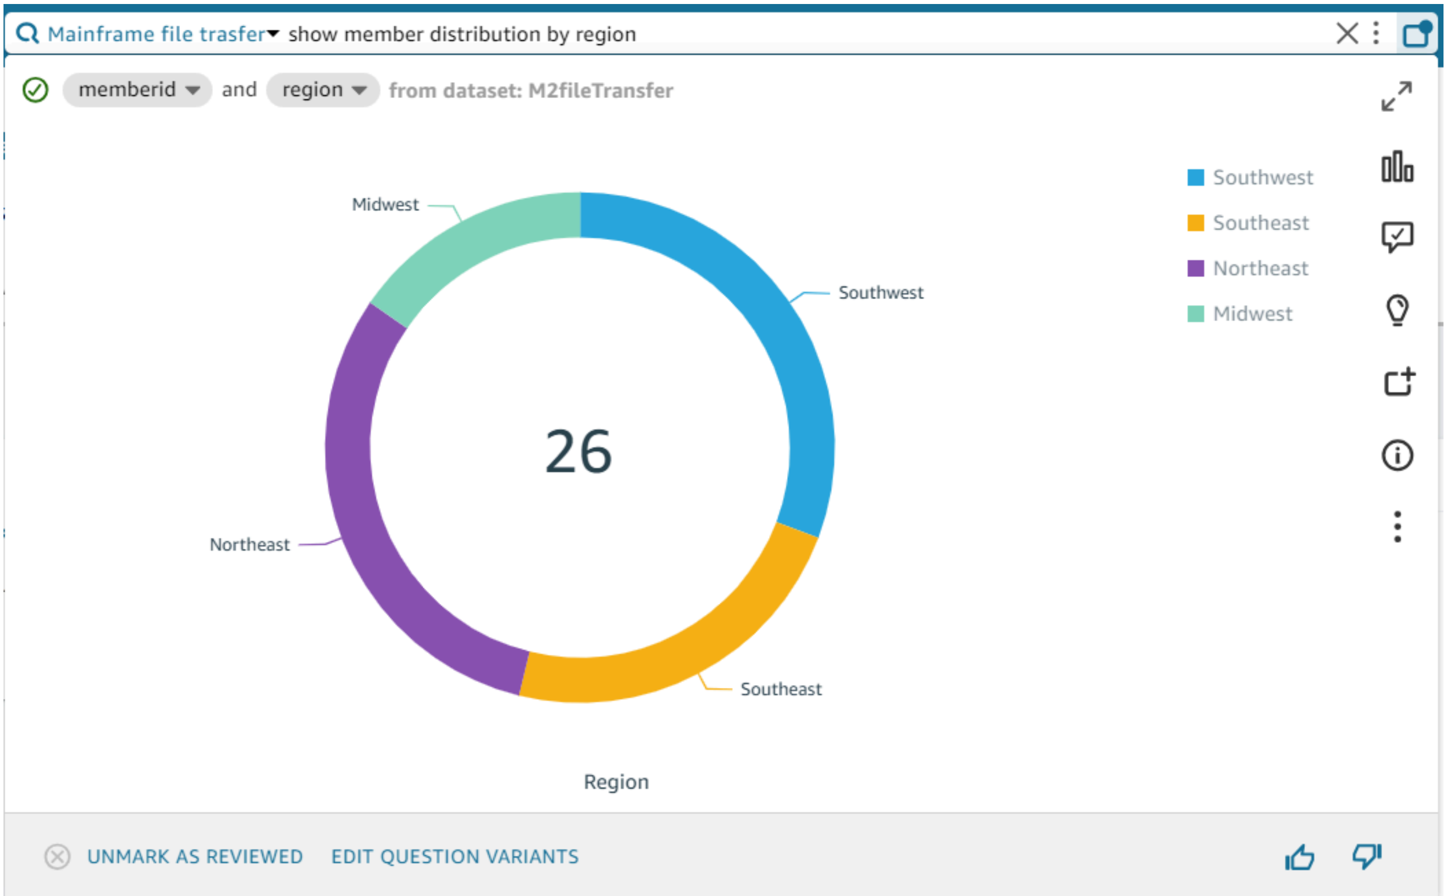
The following Python code was generated by using a prompt with Amazon Q Developer in an IDE:

```
#Create a lambda function triggered by S3. display the S3 bucket name and key
import boto3
s3 = boto3.client('s3')
def lambda_handler(event, context):
print(event)
bucket = event['Records'][0]['s3']['bucket']['name']
key = event['Records'][0]['s3']['object']['key']
print(bucket, key)
#If key starts with object_created, skip copy, print "copy skipped". Return lambda with
 key value.
if key.startswith('object_created'):
print("copy skipped")
return {
```

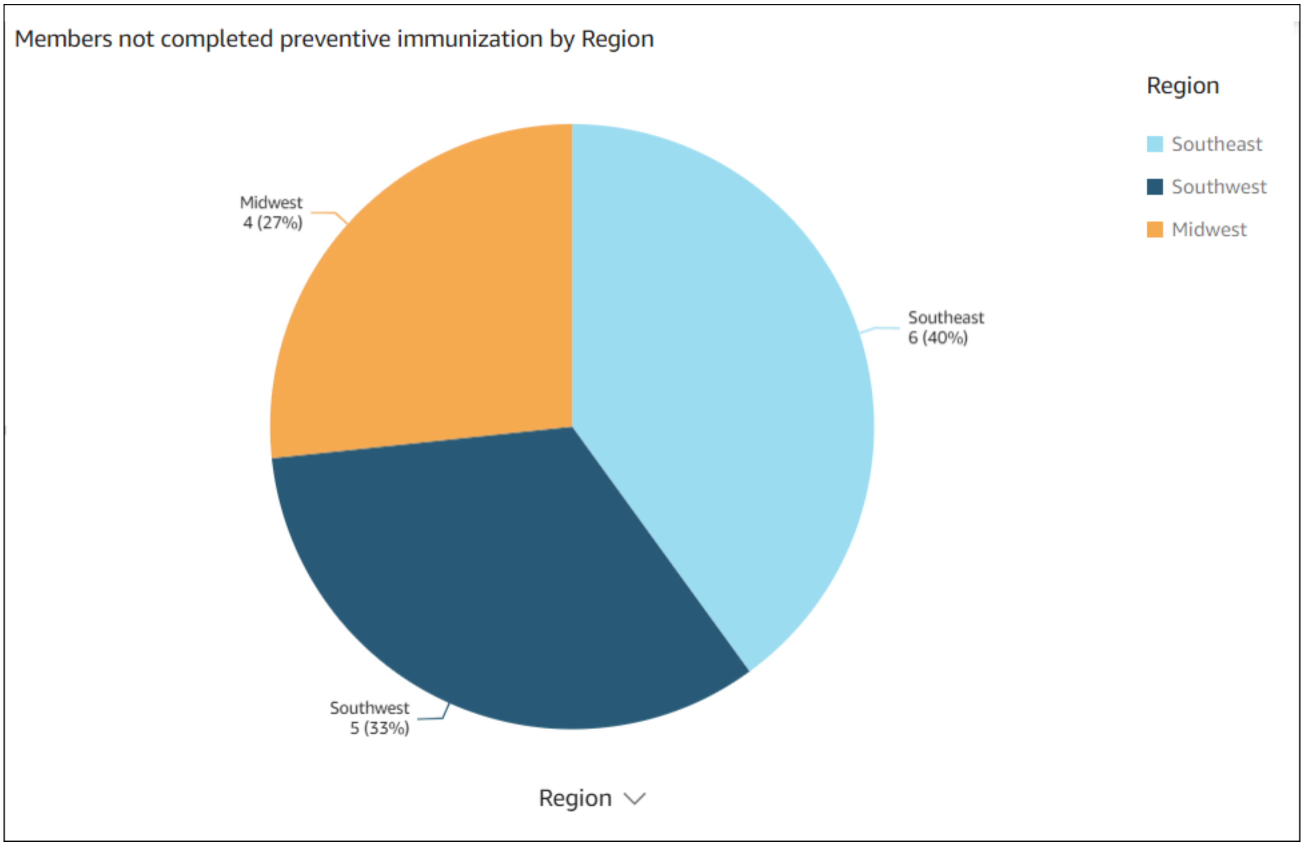
```
'statusCode': 200,
'body': key
}
# Copy the file from the source bucket to the destination bucket.
 Destination_bucket_name = 'm2-filetransfer-final-opt-bkt'. Destination_file_key =
 'healthdata.csv'
copy_source = {'Bucket': bucket, 'Key': key}
s3.copy_object(Bucket='m2-filetransfer-final-opt-bkt', Key='healthdata.csv',
 CopySource=copy_source)
print("file copied")
#Delete the file from the source bucket.
s3.delete_object(Bucket=bucket, Key=key)
return {
'statusCode': 200,
'body': 'Copy Successful'
}
```

Mainframe visual dashboard

The following data visual was created by Amazon Q in QuickSight for the analysis question `show member distribution by region`.



The following data visual was created by Amazon Q in QuickSight for the question `show member distribution by Region who have not completed preventive immunization, in pie chart`.

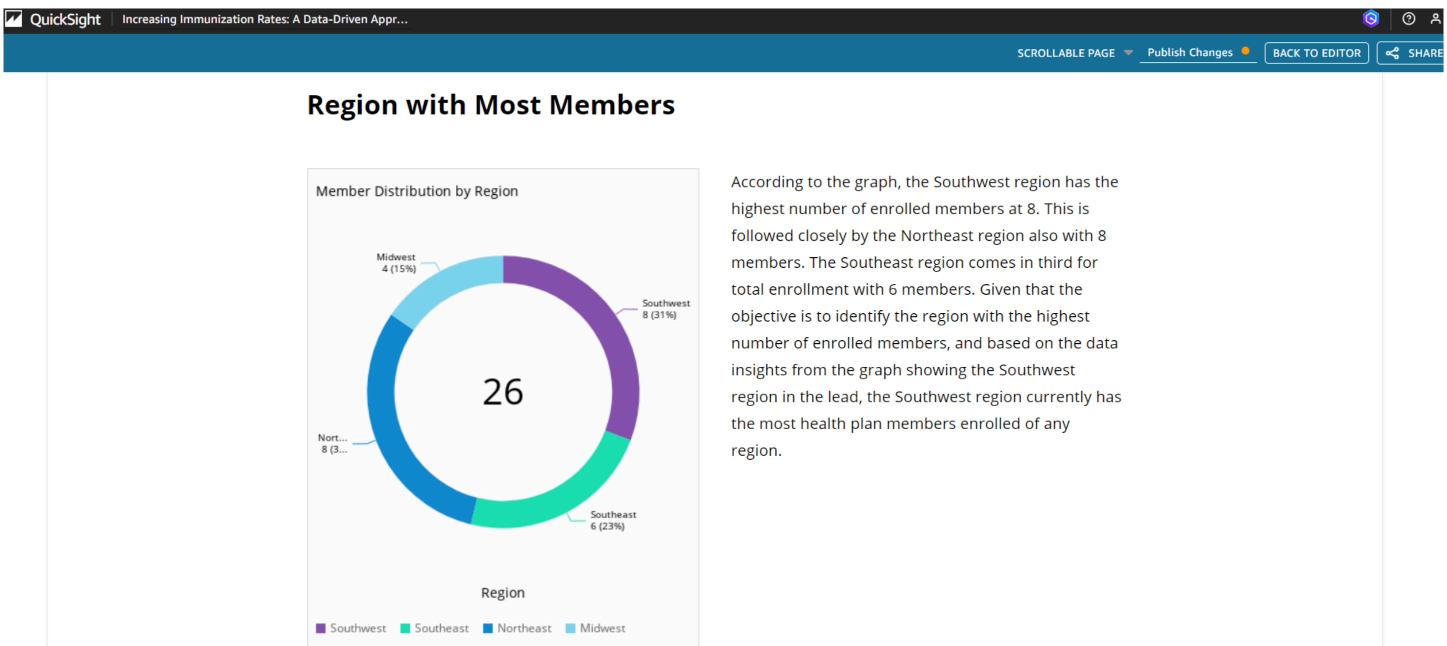


Data story output

The following screenshots show sections of the data story created by Amazon Q in QuickSight for the prompt `Build a data story about Region with most numbers of members. Also show the member distribution by medical plan, vision plan, dental plan. Recommend how to motivate members to complete immunization. Include 4 points of supporting data.`

In the introduction, the data story recommends choosing the region with the most members to gain the greatest impact from immunization efforts.

The data story provides an analysis of member numbers for the top three regions, and names the Southwest as the leading region for focusing on immunization efforts.



Note

The Southwest and Northeast regions each have eight members. However, the Southwest has more members that aren't fully vaccinated, so it has more potential to benefit from initiatives to increase immunization rates.

Implement Microsoft Entra ID-based authentication in an AWS Blu Age modernized mainframe application

Vishal Jaswani and Rimpy Tewani, Amazon Web Services

Summary

Mainframe applications that are modernized by using refactoring patterns, such as those by AWS Mainframe Modernization Refactor with AWS Blu Age, require careful integration of authentication mechanisms into the new application architecture. This integration is typically addressed as a post-modernization activity. The task can be complex and often involves the migration or externalization of existing authentication systems to align with modern security standards and cloud-native practices. Developers need to consider how to implement authentication effectively while they work within the constraints of the modernized application's runtime environment and libraries. After modernization, AWS provides ways to make it easier for you to integrate your AWS Blu Age modern code with identity and access management systems such as Amazon Cognito and Microsoft Entra ID (formerly known as Azure AD).

This pattern explains how to implement an authentication mechanism in your modernized application when the authentication provider is Microsoft Entra ID, without spending time on research and trials. The pattern provides:

- Field-tested and relevant Angular libraries from the Microsoft Authentication Library (MSAL) and other Microsoft Entra ID documentation that are essential to the authentication implementation.
- Configurations required on the AWS Blu Age Runtime to enable Spring Security by using OAuth 2.0.
- A library that captures authenticated users' identities and passes them to the AWS Blu Age Runtime.
- Security measures that we recommend implementing.
- Troubleshooting tips for commonly encountered problems with the Microsoft Entra ID setup.

> **Note**
>
> This pattern uses the AWS Blu Age OAuth extension library, which is provided to customers as part of their AWS Professional Services engagement. This library isn't part of the AWS Blu Age Runtime.

Prerequisites and limitations

Prerequisites

- A modernized application that was produced by AWS Blu Age mainframe modernization refactoring tools. This pattern uses CardDemo as a sample open source mainframe application.
- The AWS Blu Age OAuth extension library, which is provided by the AWS Blu Age team during your engagement with AWS Professional Services.
- An active AWS account to deploy and test the modernized application.
- Familiarity with AWS Blu Age configuration files and Microsoft Entra ID fundamentals.

Limitations

- This pattern covers OAuth 2.0 authentication and basic token-based authorization flows. Advanced authorization scenarios and fine-grained access control mechanisms are not in scope.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

This pattern was developed by using:

- AWS Blu Age Runtime version 4.1.0 (the pattern also works with later versions that are backward compatible)
- MSAL library version 3.0.23
- Java Development Kit (JDK) version 17
- Angular version 16.1

Architecture

Source technology stack

In typical mainframe environments, authentication is implemented through user profiles. These profiles identify users to the system, define who can sign in, and specify which functions users can perform on system resources. User profiles are managed by security officers or security administrators.

Target technology stack

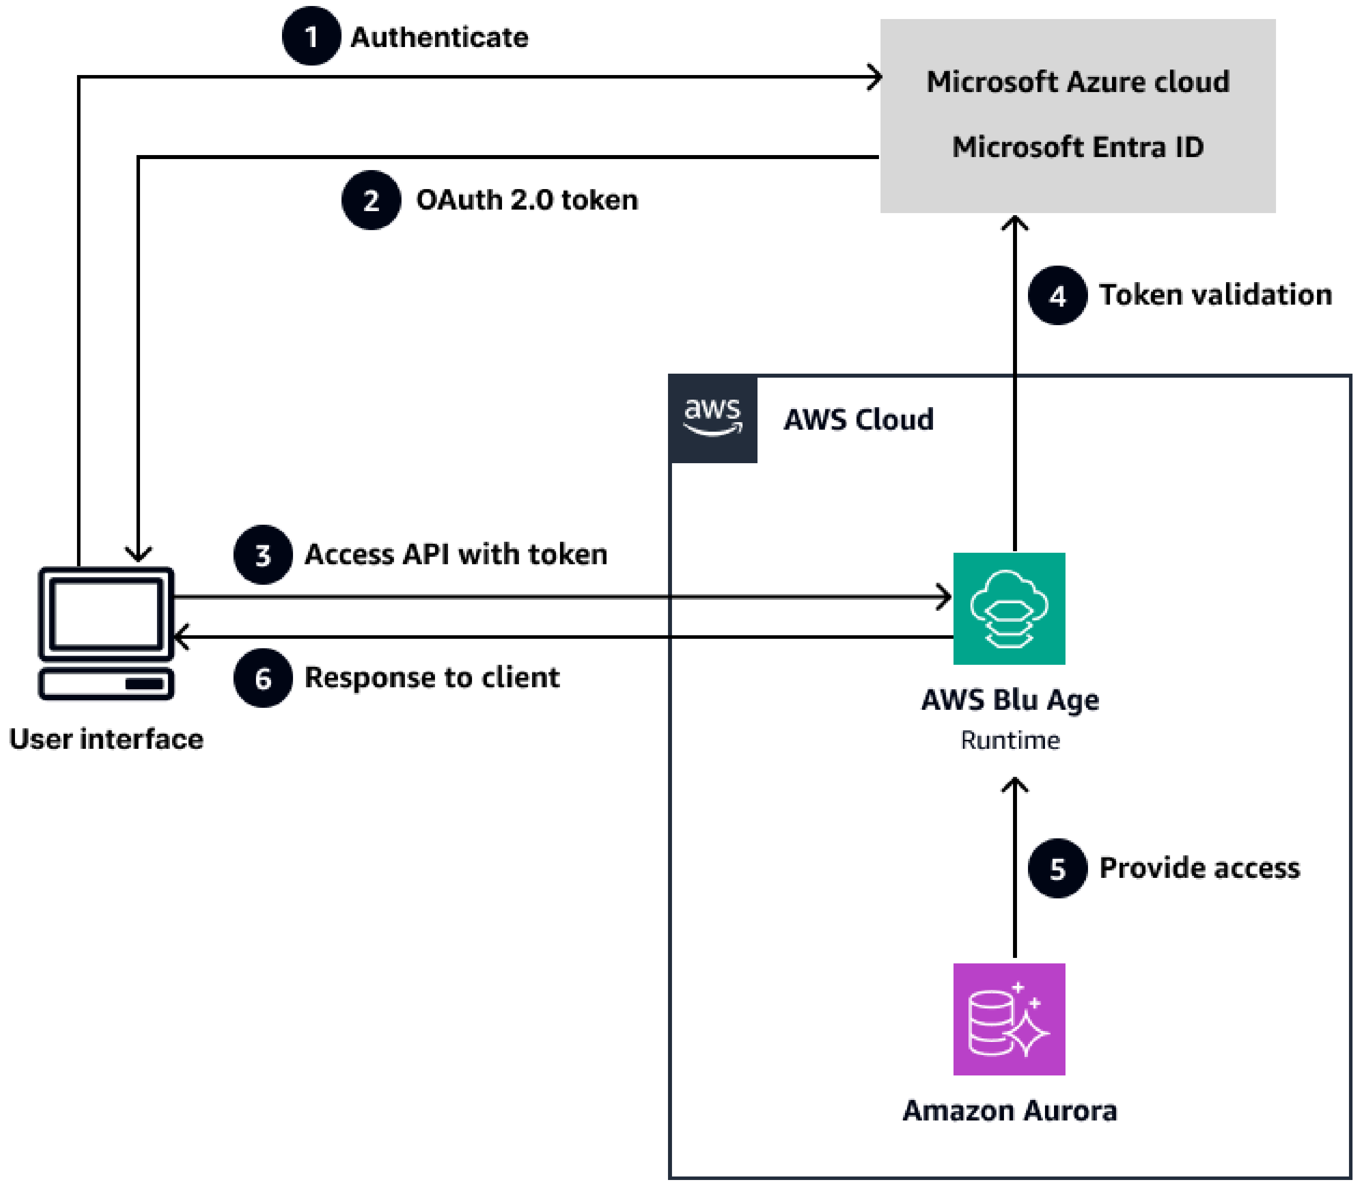
- Microsoft Entra ID
- Modernized Java Spring Boot-based backend
- AWS Blu Age Runtime
- Spring Security with OAuth 2.0
- Angular single-page application (SPA)

Target architecture

AWS Blu Age runtime supports OAuth 2.0-based authentication by default, so the pattern uses that standard to protect backend APIs.

The following diagram illustrates the process flow.

> **Note**
>
> The diagram includes Amazon Aurora as an example of database modernization although Aurora isn't included in the steps for this pattern.



where:

1. A user tries to authenticate with Microsoft Entra ID.
2. Microsoft Entra ID returns refresh, access, and ID tokens that the application uses in subsequent calls.
3. The MSAL interceptor includes the access token in the `Authorization` header of an HTTPS request to call the AWS Blu Age Runtime.

4. The AWS Blu Age `extension-oauth` library extracts the user information from the header by using an AWS Blu Age Runtime configuration file (`application-main.yml`) and places this information in a `SharedContext` object so that the business logic can consume it.

> **Note**
>
> `SharedContext` is a runtime component provided by AWS Blu Age that manages application context and state information across the modernized application. For more information about AWS Blu Age Runtime components and updates, see [AWS Blu Age release notes] in the AWS Mainframe Modernization documentation. For more information about the `application-main.yml` file, see [Set up configuration for AWS Blu Age Runtime] in the AWS Mainframe Modernization documentation.

5. The AWS Blu Age Runtime checks if the token is present.
   a. If the token is present, it checks the validity of the token by communicating with Microsoft Entra ID.
   b. If the token isn't present, the AWS Blu Age Runtime returns an error with HTTP status code 403.
6. If the token is valid, the AWS Blue Age Runtime allows the business logic to continue. If the token is invalid, the AWS Blu Age Runtime returns an error with HTTP status code 403.

OAuth 2.0 workflow

For a high-level diagram of the OAuth 2.0 workflow, see the Microsoft Entra documentation.

Tools

AWS services

- AWS Mainframe Modernization provides tools and resources to help you plan and implement migration and modernization from mainframes to AWS managed runtime environments. You can use this service's refactoring features, which are provided by AWS Blu Age, to convert and modernize your legacy mainframe applications.

Code repository

The CardDemo application has been updated to demonstrate integration with Microsoft Entra ID. You can access the code from the GitHub repository for this pattern.

Backend configuration

This pattern requires changes to the `application-main.yml` configuration file to enable Spring Security by using OAuth 2.0 on the backend application. The `.yml` file looks like this:

```
gapwalk-application.security: enabled
gapwalk-application:
  security:
    identity: oauth
    issuerUri: ${issuerUrl}
    claim:
      claims:
        -
          claimName: upn
          claimMapValue: username
spring:
  autoconfigure:
    exclude:
     -
 org.springframework.boot.autoconfigure.security.oauth2.client.servlet.OAuth2ClientAutoConfigur
     -
 org.springframework.boot.autoconfigure.security.oauth2.resource.servlet.OAuth2ResourceServerAu
  security:
    oauth2:
      client:
        registration:
          azure:
            client-id: {clientId}
            client-secret: ${clientSecret}
            provider: azure
            authorization-grant-type: authorization_code
            redirect-uri: ${redirectUri}
            scope: openid

        provider:
          azure:
            authorization-uri: ${gapwalk-application.security.issuerUri}/oauth2/v2.0/
authorize
            token-uri:  ${gapwalk-application.security.issuerUri}/oauth2/v2.0/token
            jwk-set-uri: ${gapwalk-application.security.issuerUri}/discovery/v2.0/keys
      resourceserver:
        jwt:
          jwk-set-uri: ${gapwalk-application.security.issuerUri}/discovery/v2.0/keys
```

AWS Blu Age OAuth extension filter library

The AWS Blu Age OAuth extension library is provided by the AWS Blu Age team during your engagement with [AWS Professional Services](https://aws.amazon.com/professional-services/).

This library reads the `claim.claims` configuration in the `application-main.yml` fie that's shown in the previous code block. This configuration is a list. Each item in the list provides two values: `claimName` and `claimMapValue`. `claimName` represents a key name in a JSON Web Token (JWT) sent by the frontend, and `claimMapValue` is the name of the key in `SharedContext`. For example, if you want to capture the user ID on the backend, set `claimName` to the key name in the JWT that holds the `userId` that's provided by Microsoft Entra ID, and set `claimMapValue` to the key name to fetch the user ID in the backend code.

For example, if you set `UserId` in `claimMapValue`, you can use the following code to extract the user ID:

```
SharedContext.get().getValue("userId", [UserId]);
```

Best practices

In your implementation of this pattern, take the following important security considerations into account.

> **Important**
>
> This pattern provides a foundation for authentication integration. We recommend that you implement security measures in addition to those discussed in this section based on your business requirements before you deploy it to production.

- **AWS configuration security.** Move sensitive configuration values from `application-main.yml` to AWS Secrets Manager. For example, configure the following properties by using Secrets Manager:

```
security:
    oauth2:
      client:
        registration:
          azure:
```

```
            client-id: {clientId}
            client-secret: ${clientSecret}
```

For more information about how you can use Secrets Manager to configure AWS Blu Age parameters, see AWS Blu Age Runtime secrets in the AWS Mainframe Modernization documentation.

- **Runtime environment protection.** Configure the modernized application environment with proper AWS security controls:

```
server:
  tomcat:
    remoteip:
     protocol-header: X-Forwarded-Proto
     remote-ip-header: X-Forwarded-For
  forward-headers-strategy: NATIVE
```

- **Amazon CloudWatch logging.** Consider adding the file `logback-spring.xml to src/main/resources`:

```
<configuration>
 <appender name="CLOUDWATCH"
 class="com.amazonaws.services.logs.logback.CloudWatchAppender">
   <logGroup>/aws/bluage/application</logGroup>
   <logStream>${AWS_REGION}-${ENVIRONMENT}</logStream>
   <layout>
    <pattern>%d{yyyy-MM-dd HH:mm:ss} [%thread] %-5level %logger{36} - %msg%n</
pattern>
   </layout>
 </appender>

 <root level="INFO">
 <appender-ref ref="CLOUDWATCH"/>
 </root>
</configuration>
```

For information about enabling tracing with CloudWatch, see Enable trace to log correlation in the CloudWatch documentation.

- **Token configuration and handling.** Configure token lifetimes in Microsoft Entra ID to align with your security requirements. Set access tokens to expire within 1 hour and refresh tokens to expire within 24 hours. In the AWS Blu Age Runtime configuration (`application-main.yml`), make sure that JWT validation is configured properly with the exact issuer URI and audience values from your Entra ID application registration.

When a token expires and is refreshed:

1. The Angular application's error interceptor handles the 401 response by obtaining a new token through MSAL.
2. The new token is sent with the subsequent request.
3. The AWS Blu Age Runtime's OAuth filter validates the new token and automatically updates `SharedContext` with the current user information. This ensures that business logic continues to have access to valid user context through `SharedContext.get().getValue()` calls.

For more information about the AWS Blu Age Runtime components and their updates, see AWS Blu Age release notes.

- **AWS Blu Age Runtime security.** The `oauth2-ext` library provided by AWS Blu Age must be placed in the correct shared directory location (`{app-server-home}/shared/`) with proper file permissions. Verify that the library successfully extracts user information from JWTs by checking the `SharedContext` object population in your logs.
- **Specific claims configuration.** In `application-main.yml`, define the claims that you need from Microsoft Entra ID explicitly. For example, to capture the user's email and roles, specify:

```
gapwalk-application:
  security:
    claim:
      claims:
        - claimName: upn
          claimMapValue: username
        - claimName: roles
          claimMapValue: userRoles
        - claimName: email
          claimMapValue: userEmail
```

- **Error handling.** Add error handling to address authentication failures in your Angular application; for example:

```
@Injectable()
export class AuthErrorInterceptor implements HttpInterceptor {
  intercept(request: HttpRequest<any>, next: HttpHandler): Observable<HttpEvent<any>>
 {
    return next.handle(request).pipe(
```

```
      catchError((error: HttpErrorResponse) => {
        if (error.status === 401) {
          // Handle token expiration
          this.authService.login();
        }
        if (error.status === 403) {
          // Handle unauthorized access
          this.router.navigate(['/unauthorized']);
        }
        return throwError(() => error);
      })
    );
  }
}
```

- **Session timeout configuration.** Configure session timeout settings in both the AWS Blu Age Runtime and Microsoft Entra ID. For example, add the following code to your `application-main.yml` file:

```
server:
  servlet:
    session:
      timeout: 3600 # 1 hour in seconds
```

- **MsalGuard.** You must implement the MsalGuard feature for all protected routes to prevent unauthorized access. For example:

```
const routes: Routes = [
    { path: '', redirectTo: '/transaction-runner', pathMatch: 'full' },
    { path: 'transaction-runner', component: TransactionRunnerComponent,
 canActivate:guards },
    { path: 'user-info', component: UserInfoComponent, canActivate:guards },
    { path: 'term/:transid/:commarea', component: TermComponent,
 canActivate:guards },
 { path: 'code', component: TransactionRunnerComponent  }
];
```

  Routes that don’t have MsalGuard protection will be accessible without authentication, potentially exposing sensitive functionality. Make sure that all routes that require authentication include the guards in their configuration.

Epics

Set up a Microsoft Entra ID

Task	Description	Skills required
Set up a Microsoft Azure account to create an Entra ID.	For options and instructi ons, see the Microsoft Azure website.	App developer
Set up a Microsoft Entra ID in your application.	To learn how to add Microsoft Entra ID B2C (Azure AD B2C) authentication to your Angular SPA, see the Microsoft documentation. Specifically: 1. Register your application and record identifiers. 2. Expose the AWS Blu Age transaction endpoint by adding and exposing a custom scope. 3. After you define the scope and the API URL, configure these values in the `apiUri` and `apiScope` properties of the `environment.ts` file in the code repository.	App developer

Clone the repository and deploy your AWS Blu Age code

Task	Description	Skills required
Clone the GitHub repositor y to get the Angular code required for authentication.	Run the following command to clone the GitHub repositor y that's provided with this	App developer

Task	Description	Skills required
	pattern into your local current working directory: `git clone https://github.com/aws-samples/sample-microsoft-entra-id-based-auth-in-aws-bluage-modernized-mainframe-app.git`	
Deploy the AWS Blu Age modernized code on a Tomcat server to implement authentication.	To set up the local environment that includes Tomcat and the Angular development server, follow the installation steps provided by the AWS Blu Age team as part of your customer engagement with AWS Professional Services.	App developer

Build the authentication solution

Task	Description	Skills required
Enable AWS Blu Age Runtime security to protect the AWS Blu Age REST API endpoints.	Configure the `application-main.yml` file that the AWS Blu Age Runtime uses as follows. For an example of this file, see the Code repository section earlier in this pattern. • `spring:security:oauth2:client:*` enables Spring Security OAuth 2.0 client support.	App developer

Task	Description	Skills required
	Replace the settings with values that are specific to your Microsoft Entra ID setup. • `spring:security:oauth2:resourceserver` enables Spring Security OAuth 2.0 resource server support. • `gapwalk-application.security.issuerUri` specifies the URL of the identity provider for fetching configuration information such as the authorization endpoint, the token endpoint, and so on. • `gapwalk-application.security.identity` should be set to `oauth`. • `gapwalk-application.security.claim.claims` specifies the list of claims required to capture user IDs and user names. For an example, see the [Code repository] section earlier in this pattern. • `gapwalk-application.security` should be set to `enabled`. • `spring.autoconfigure.exclude` should	

Task	Description	Skills required
	be removed to enable authentication.	
Incorporate the example code from your local environment into your Blu Age modernized Angular code base.	For information about how to incorporate the example into your AWS Blu Age modernized Angular code base, see the [Code repository](#) section earlier in this pattern.	App developer

Place the `oauth2-ext` library in the shared directory.	Place the `oauth2-ext` library in the shared directory of the application server so that your AWS Blu Age modernized application can use it. Run the following commands:
	`cd oauth2-ext/target`
	`cp extension-oauth-filter-<version>.jar /{app-server-home}/shared/`
		App developer

Deploy the authentication solution

Task	Description	Skills required

Deploy the frontend application.	Run the following commands to start the frontend application locally:
	`npm install`
	`ng serve --ssl`
	`npm start`
		App developer

Task	Description	Skills required
	Note Adding the `--ssl` flag to the `ng serve` command ensures that the developme nt server uses HTTPS, which is more secure than other protocols and provides a better simulation of a production environme nt.	
Start the backend application.	Start Tomcat server in Eclipse.	App developer

Test the application

Task	Description	Skills required
Test login functionality.	Access the locally deployed application at `http://localhost:4200` to verify that users are asked to confirm their identity. **Note** HTTP is used here for demonstra tion purposes. In a production or other publicly accessible environment, you	App developer

Task	Description	Skills required
	must use HTTPS for security. Even for local development, we recommend that you set up HTTPS when possible. The Microsoft login prompt should appear, and users who are configured in Microsoft Entra ID should be allowed to access the application.	

Task	Description	Skills required
Test the authorization header in the request.	**Note** The following steps use the [CardDemo](#) application as an example. Testing steps for other modern applications will vary. 1. Launch transaction `CC00` in the CardDemo application. 2. Sign in with user credentia ls. For example, if you're using the [AWS Blu Age level 3 self-paced workshop](#), you can use the name `USER0001` and password `PASSWORD` for credentials. 3. Open the **Developer Tools** window in the same tab of your browser. 4. Open the **Network** tab and check the request sent to the backend `http://localhost:8080/gapwalk-application/transaction` . 5. Check the request header and verify that you see an authorization header with the value `Bearer`	App developer

Task	Description	Skills required
	`<token>` where `<token>` is a value that's generated by Microsoft Entra ID.	
Test the logout functionality.	Choose **Quit** to log out, and try to access the application again. It should present a new login prompt.	App developer

Troubleshooting

Issue	Solution
The token issued by Microsoft Entra ID isn't compatible with Spring Boot OAuth 2.0 security.	For a resolution to the issue, see Microsoft Entra ID OAuth Flow on the OAuth blog.
General token-related questions.	To decode and view the contents of a JWT token, use the https://jwt.io/ website.

Integrate Stonebranch Universal Controller with AWS Mainframe Modernization

Vaidy Sankaran and Pablo Alonso Prieto, Amazon Web Services

Robert Lemieux and Huseyin Gomleksizoglu, Stonebranch

Summary

This pattern explains how to integrate Stonebranch Universal Automation Center (UAC) workload orchestration with Amazon Web Services (AWS) Mainframe Modernization service. AWS Mainframe Modernization service migrates and modernizes mainframe applications to the AWS Cloud. It offers two patterns: AWS Mainframe Modernization Replatform with Micro Focus Enterprise technology and AWS Mainframe Modernization Automated Refactor with AWS Blu Age.

Stonebranch UAC is a real-time IT automation and orchestration platform. UAC is designed to automate and orchestrate jobs, activities, and workflows across hybrid IT systems, from on-premises to AWS. Enterprise clients using mainframe systems are transitioning to cloud-centric modernized infrastructures and applications. Stonebranch's tools and professional services facilitate the migration of existing schedulers and automation capabilities to the AWS Cloud.

When you migrate or modernize your mainframe programs to the AWS Cloud using AWS Mainframe Modernization service, you can use this integration to automate batch scheduling, increase agility, improve maintenance, and decrease costs.

This pattern provides instructions for integrating Stonebranch scheduler with mainframe applications migrated to the AWS Mainframe Modernization service Micro Focus Enterprise runtime. This pattern is for solutions architects, developers, consultants, migration specialists, and others working in migrations, modernizations, operations, or DevOps.

Targeted outcome

This pattern focuses on providing the following target outcomes:

- The ability to schedule, automate, and run mainframe batch jobs running in AWS Mainframe Modernization service (Microfocus runtime) from Stonebranch Universal Controller.
- Monitor the application's batch processes from the Stonebranch Universal Controller.
- Start/Restart/Rerun/Stop batch processes automatically or manually from the Stonebranch Universal Controller.

- Retrieve the results of the AWS Mainframe Modernization batch processes.
- Capture the AWS CloudWatch logs of the batch jobs in Stonebranch Universal Controller.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Micro Focus Bankdemo application with job control language (JCL) files, and a batch process deployed in a AWS Mainframe Modernization service (Micro Focus runtime) environment
- Basic knowledge of how to build and deploy a mainframe application that runs on Micro Focus Enterprise Server
- Basic knowledge of Stonebranch Universal Controller
- Stonebranch trial license (contact Stonebranch)
- Windows or Linux Amazon Elastic Compute Cloud (Amazon EC2) instances (for example, xlarge) with a minimum of four cores, 8 GB memory, and 2 GB disk space
- Apache Tomcat version 8.5.x or 9.0.x
- Oracle Java Runtime Environment (JRE) or OpenJDK version 8 or 11
- Amazon Aurora MySQL–Compatible Edition
- Amazon Simple Storage Service (Amazon S3) bucket for export repository
- Amazon Elastic File System (Amaon EFS) for agent Stonebranch Universal Message Service (OMS) connections for high availability (HA)
- Stonebranch Universal Controller 7.2 Universal Agent 7.2 Installation Files
- AWS Mainframe Modernization task scheduling template (latest released version of the .zip file)

Limitations

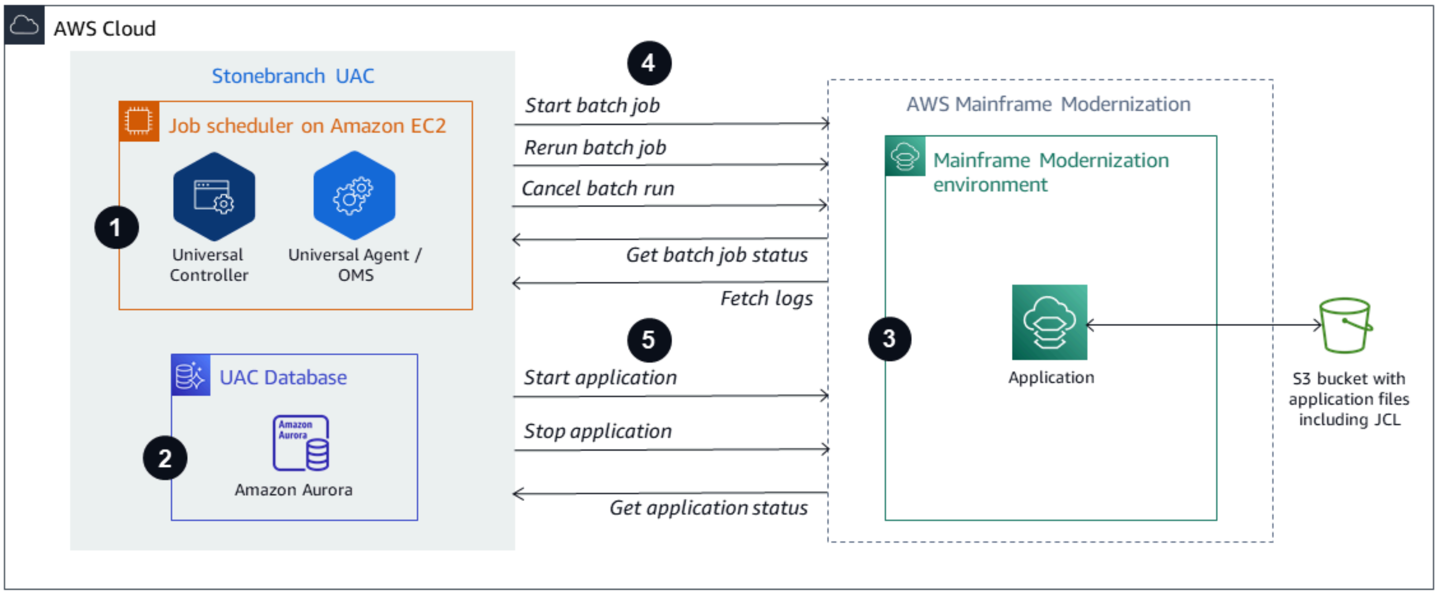
- The product and solution has been tested and compatibility validated only with OpenJDK 8 and 11.
- The aws-mainframe-modernization-stonebranch-integration task scheduling template will work only with AWS Mainframe Modernization service.
- This task scheduling template will work on only a Unix, Linux, or Windows edition of Stonebranch agents.

- Some AWS services aren't available in all AWS Regions. For Region availability, see [AWS services by Region](). For specific endpoints, see the [Service endpoints and quotas]() page, and choose the link for the service.

Architecture

Target state architecture

The following diagram shows the example AWS environment that is required for this pilot.



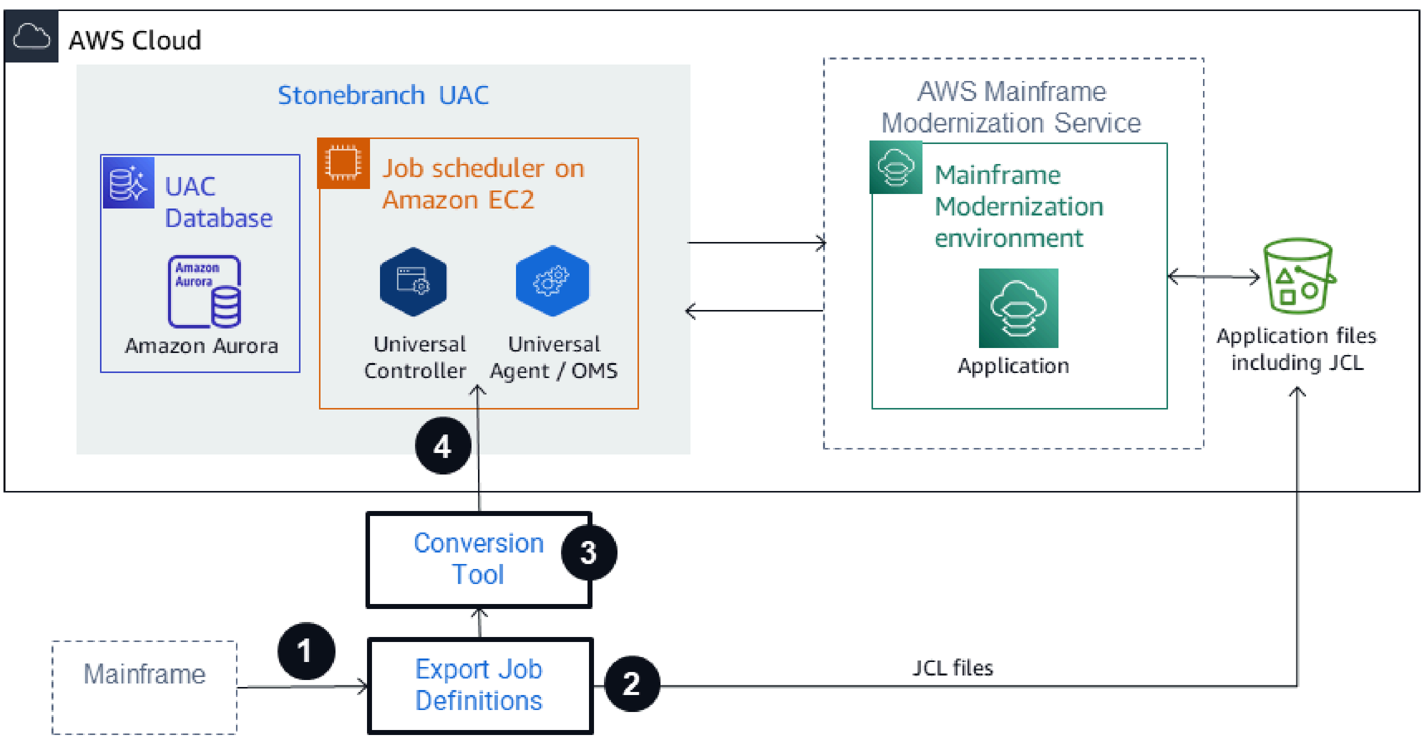
1. Stonebranch Universal Automation Center (UAC) includes two main components: Universal Controller and Universal Agents. Stonebranch OMS is used as a message bus between the controller and individual agents.
2. Stonebranch UAC Database is used by Universal Controller. The database can be MySQL, Microsoft SQL Server, Oracle, or Aurora MySQL–Compatible.
3. AWS Mainframe Modernization service – Micro Focus runtime environment with the [BankDemo application deployed](). The BankDemo application files will be stored in an S3 bucket. This bucket also contains the mainframe JCL files.
4. Stonebranch UAC can run the following functions for the batch run:
   a. Start a batch job using the JCL file name that exists in the S3 bucket linked to the AWS mainframe modernization service.
   b. Get the status of the batch job run.
   c. Wait until the batch job run is completed.

   d. Fetch logs of the batch job run.
   e. Rerun the failed batch jobs.
   f. Cancel the batch job while the job is running.

5. Stonebranch UAC can run the following functions for the application:
   a. Start Application
   b. Get Status of the Application
   c. Wait until the Application is started or stopped
   d. Stop Application
   e. Fetch Logs of Application operation

Stonebranch jobs conversion

The following diagram represents Stonebranch's job conversion process during the modernization journey. It describes how the job schedules and tasks definitions are converted into a compatible format that can run AWS Mainframe Modernization batch tasks.

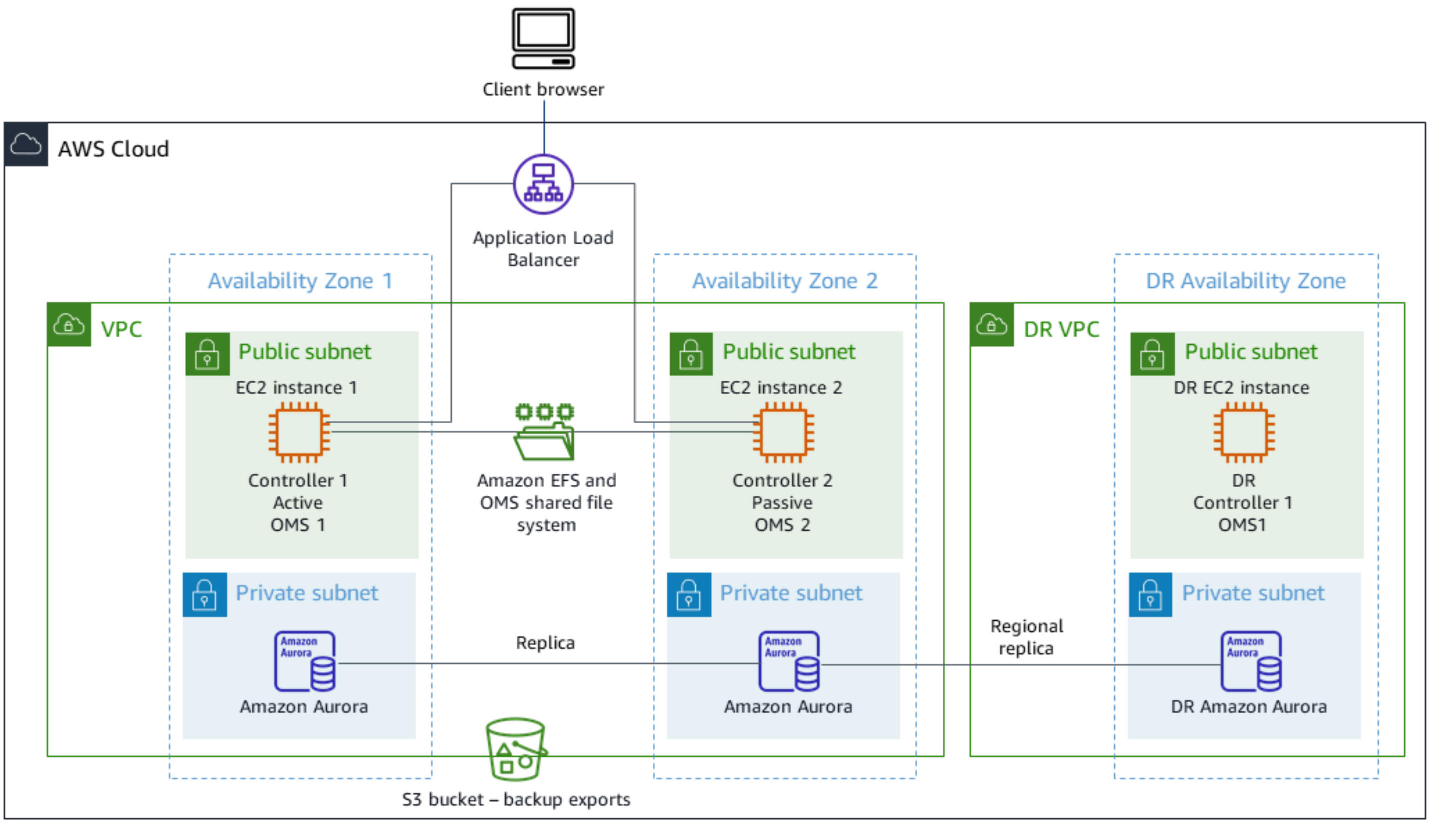


1. For the conversion process, the job definitions are exported from the existing mainframe system.
2. JCL files can be uploaded to the S3 bucket for the Mainframe Modernization application so that these JCL files can be deployed by the AWS Mainframe Modernization service.

3. The conversion tool converts the exported job definitions to UAC tasks.
4. After all the task definitions and job schedules are created, these objects will be imported to the Universal Controller. The converted tasks then run the processes in the AWS Mainframe Modernization service instead of running them on the mainframe.

Stonebranch UAC architecture

The following architecture diagram represents an active-active-passive model of high availability (HA) Universal Controller. Stonebranch UAC is deployed in multiple Availability Zones to provide high availability and support disaster recovery (DR).



Universal Controller

Two Linux servers are provisioned as Universal Controllers. Both connect to the same database endpoint. Each server houses a Universal Controller application and OMS. The most recent version of Universal Controller is used at the time it is provisioned.

The Universal Controllers are deployed in the Tomcat webapp as the document ROOT and are served on port 80. This deployment eases the configuration of the frontend load balancer.

HTTP over TLS or HTTPS is enabled using the Stonebranch wildcard certificate (for example, `https://customer.stonebranch.cloud`). This secures communication between the browser and the application.

OMS

A Universal Agent and OMS (Opswise Message Service) reside on each Universal Controller server. All deployed Universal Agents from the customer end are set up to connect to both OMS services. OMS acts as a common messaging service between the Universal Agents and the Universal Controller.

Amazon EFS mounts a spool directory on each server. OMS uses this shared spool directory to keep the connection and task information from controllers and agents. OMS works in a high-availability mode. If the active OMS goes down, the passive OMS has access to all the data, and it resumes active operations automatically. Universal Agents detect this change and automatically connect to the new active OMS.

Database

Amazon Relational Database Service (Amazon RDS) houses the UAC database, with Amazon Aurora MySQL–Compatible as its engine. Amazon RDS is helps in managing and offering scheduled backups at regular intervals. Both Universal Controller instances connect to the same database endpoint.

Load balancer

An Application Load Balancer is set-up for each instance. The load balancer directs traffic to the active controller at any given moment. Your instance domain names point to the respective load balancer endpoints.

URLs

Each of your instances has a URL, as shown in the following example.

Environment	Instance
Production	`customer.stonebranch.cloud`
Development (non-production)	`customerdev.stonebranch.cloud`
Testing (non-production)	`customertest.stonebranch.cloud`

> **Note**
>
> Non-production instance names can be set based on your needs.

High availability

High availability (HA) is the ability of a system to operate continuously without failure for a designated period of time. Such failures include, but are not limited to, storage, server communication response delays caused by CPU or memory issues, and networking connectivity.

To meet HA requirements:

- All EC2 instances, databases, and other configurations are mirrored across two separate Availability Zones within the same AWS Region.
- The controller is provisioned through an Amazon Machine Image (AMI) on two Linux servers in the two Availability Zones. For example, if you are provisioned in the Europe eu-west-1 Region, you have a Universal Controller in Availability Zone eu-west-1a and Availability Zone eu-west-1c.
- No jobs are allowed to run directly on the application servers and no data is allowed to be stored on these servers.
- The Application Load Balancer runs health checks on each Universal Controller to identify the active one and direct traffic to it. In the event that one server incurs issues, the load balancer automatically promotes the passive Universal Controller to an active state. The load balancer then identifies the new active Universal Controller instance from the health checks and starts directing traffic. The failover happens within four minutes with no job loss, and the frontend URL remains the same.
- The Aurora MySQL–Compatible database service stores Universal Controller data. For production environments, a database cluster is built with two database instances in two different Availability Zones within a single AWS Region. Both Universal Controllers use a Java Database Connectivity (JDBC) interface that points to a single database cluster endpoint. In the event that one database instance incurs issues, the database cluster endpoint dynamically points to the healthy instance. No manual intervention is required.

Backup and purge

Stonebranch Universal Controller is set to back up and purge old data following the schedule shown in the table.

Type	Schedule
Activity	7 days
Audit	90 days
History	60 days

Backup data older than the dates shown is exported to .xml format and stored in the file system. After the backup process is complete, older data is purged from the database and archived in an S3 bucket for up to one year for production instances.

You can adjust this schedule in your Universal Controller interface. However, increasing these time-frames might cause a longer downtime during maintenance.

Tools

AWS services

- AWS Mainframe Modernization is an AWS cloud-native platform that helps you modernize your mainframe applications to AWS managed runtime environments. It provides tools and resources to help you plan and implement migration and modernization.
- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon EC2 instances.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon Aurora MySQL–Compatible Edition.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon EC2 instances, containers, and IP addresses in one or more Availability Zones. This pattern uses an Application Load Balancer.

Stonebranch

- Universal Automation Center (UAC) is a system of enterprise workload automation products. This pattern uses the following UAC components:
  - Universal Controller, a Java web application running in a Tomcat web container, is the enterprise job scheduler and workload automation broker solution of Universal Automation Center. The Controller presents a user interface for creating, monitoring, and configuring Controller information; handles the scheduling logic; processes all messages to and from Universal Agents; and synchronizes much of the high availability operation of Universal Automation Center.
  - Universal Agent is a vendor-independent scheduling agent that collaborates with existing job scheduler on all major computing platforms, both legacy and distributed. All schedulers that run on z/Series, i/Series, Unix, Linux, or Windows are supported.
- Universal Agent is a vendor-independent scheduling agent that collaborates with existing job scheduler on all major computing platforms, both legacy and distributed. All schedulers that run on z/Series, i/Series, Unix, Linux, or Windows are supported.
- Stonebranch aws-mainframe-modernization-stonebranch-integration AWS Mainframe Modernization Universal Extension is the integration template to run, monitor and rerun batch jobs in AWS Mainframe Modernization platform.

Code

The code for this pattern is available in the aws-mainframe-modernization-stonebranch-integration GitHub repository.

Epics

Install Universal Controller and Universal Agent on Amazon EC2

Task	Description	Skills required
Download the installation files.	Download the installation from Stonebranch servers. To get the installation files, contact with Stonebranch.	Cloud architect
Launch the EC2 instance.	You will need about 3 GB of extra space for the Universal Controller and Universal	Cloud architect

Task	Description	Skills required
	Agent installations. So provide at least 30 GB of disk space for the instance. Add port 8080 to the security group so that it’s accessible.	

Task	Description	Skills required

Check prerequisites.	Before the installation, do the following:
	
	1. Install Java as described in [Downloading Java Runtime Environment]().
	`$ sudo yum -y update`
	`$ sudo yum install java-11-amazon-corretto`
	
	Be sure to use one of the supported JAVA versions. The previous command should install java-11. Check the Java version and be sure you are using version 11 before continuing.
	2. As described in [Installing Apache Tomcat](), run the following commands.
	`$ sudo yum install tomcat tomcat-admin-webapps`
	`$ sudo systemctl enable tomcat`
	`$ sudo systemctl start tomcat`
	3. Create an Amazon Aurora database as described in [Creating and connecting to an Aurora MySQL DB cluster](). Use Amazon
		Cloud administrator, Linux administrator

Task	Description	Skills required
	Aurora MySQL-Compatible Edition. Choose a Master username and Master password. Keep the default values for the rest of the settings.	

Task	Description	Skills required

Install Universal Controller.	1. Upload the `universal-controller-7.2.0.0.tar` installation file to the EC2 instance.
	2. Unarchive the installation files to a `temp` folder.
	`$ tar -xvf universal-controller-7.2.0.0.tar`
	3. Give the installation script run permission.
	`$ chmod a+x install-controller.sh`
	4. Install the controller. This example uses the following command to install Universal Controller under `/usr/share/tomcat`. Use the Amazon Aurora database that you created in the previous steps.
	`$ sudo ./install-controller.sh --tomcat-dir /usr/share/tomcat/ --controller-file universal-controller-7.2.0.0-build.145.war --dbuser admin --dbpass "****" --dbname uc --rdbms mysql --dburl`
		Cloud architect, Linux administrator

Task	Description	Skills required

	``` jdbc:mysql://database-2-instance-1.cih63miincgy.us-east-1.rds.amazonaws.com:3306/ ```
	The last line of the output of the script should be "Installation complete."
	5. Navigate to the following URL in the EC2 instance.
	``` http://<public_ip>:8080/uc ```
	6. On the login screen, enter **ops.admin** in the **Username** section, and keep the **Password** field empty.
	7. Set a new password for the `ops.admin` user.	

Task	Description	Skills required

Install Universal Agent.	1. Upload the `sb-7.2.0.1-linux-3.10-x86_64.tar.Z` installation file to the EC2 instance.
	2. Log in to the EC2 instance.
	3. Unarchive the Universal Agent installation package.
	`$ zcat sb-7.2.0.1-linux-3.10-x86_64.tar.Z | tar xvf -`
	4. Run the following command.
	`$ sudo ./unvinst --oms_servers 7878@localhost --oms_autostart yes --python yes`
	5. Create a PAM file.
	`$ cp /etc/pam.d/login /etc/pam.d/ucmd`
	6. Enable Autostart for Universal Agent.
	`$ /sbin/restorecon -v /etc/rc.d/init.d/ubrokerd`
		Cloud administrator, Linux administrator

Task	Description	Skills required
Add OMS to Universal Controller.	1. Log in to Universal Controller with the `ops.admin` user. 2. Choose the **Services** menu at the top left corner of the screen, and then choose the **OMS Servers** menu in the **System** 3. In the OMS Server Address field, type `localhost`, and then save. 4. You will see the status of the OMS server as **Connected** and the **Session Status** as **Operational**.	Universal Controller administrator

Import AWS Mainframe Modernization Universal Extension and create a task

Task	Description	Skills required
Import Integration Template.	For this step, you need the [AWS Mainframe Modernization Universal Extension](). Ensure the latest released version of the .zip file is downloaded. 1. Log in to the Universal Controller with the `ops.admin` user.	Universal Controller administrator

Task	Description	Skills required
	2. Navigate to **Services**, **Import Integration Template**. 3. Select the Integrati on Template .zip file (`aws_mainframe_mode rnization_stonebra nch_extension.zip`), and choose **Import**. After the Integration Template is imported, you will see **AWS Mainframe Modernization Tasks** under **Available Services**.	

Task	Description	Skills required
Enable resolvable credentials.	1. Navigate to **Services**, **AWS Mainframe Modernization Tasks**. 2. On the right panel, fill in the required fields: • **Name**: New Mainframe Modernization Task • **Agent**: Select the only agent (AGNT0001). Under **AWS Mainframe Modernization Details**: • **Action**: List Environme nts • **AWS Credentials**: If you have an AWS Identity and Access Managemen t (IAM) role added to the EC2 instance, you can keep this field empty. If you will use `AWSAccess KeyID` and `AWSSecret Key` , choose the icon **()** next to the field. In the **Credential Details** window that opens, enter the following information and then save. • **Name**: AWS Mainframe Modernization Credentia ls	Universal Controller administr ator

Task	Description	Skills required
	• **Runtime User**: Write the AWS access key ID in this field. • **Runtime Password**: Write the AWS secret key in this field. • **End Point**: Be sure that the endpoint has the correct AWS Region. The default is `https://m2.us-east-1.amazonaws.com` . • **Region**: Enter the Region of the AWS Mainframe Modernization service. The default is `us-east-1` . 3. Keep the default values in the rest of the fields, and save the task.	

Task	Description	Skills required
Launch the task.	1. At the top of the right panel, choose **Launch Task**. 2. In the **Confirm** window, choose **Launch**. After that, the Universal Controller Console will display a message similar to the following message. *2022-08-24 10:11:49 AM* *Successfully launched the Universal task "New Mainframe Modernization Task" with task instance sys_id 1661291493634146313NC8E38DB8OZJY.* 3. Navigate to the **Instances** If you don't see the **Instances** tab, choose the right arrow to scroll right. 4. Open the context (right-click) menu for the task instance in the list, choose **Retrieve Output**, and then choose **Submit** in the **Retrieve Output** 5. In the **Retrieve Output** window, you will see the list of environments in STDOUT.	Universal Controller administrator

Test starting a batch job

Task	Description	Skills required
Create a task for the batch job.	1. Navigate to **Services**, **AWS Mainframe Modernization Tasks**. 2. On the right panel, fill in the required fields: • **Name**: New Mainframe Modernization Task • **Agent**: Select the only agent (AGNT0001). Under **AWS Mainframe Modernization Details**: • **Action**: Start Batch (or Start Batch and Wait to run the batch job and wait until the task completes in AWS) • **AWS Credentials**: If you have an IAM role added to the EC2 instance, you can keep this field empty. If you will use `AWSAccessKeyID` and `AWSSecretKey`, choose the icon **()** next to the field. • **End Point**: Be sure that the endpoint has the correct AWS Region. The default is https://m2.us-east-1.amazonaws.com.	Universal Controller administrator

Task	Description	Skills required
	• **Region**: Enter the Region of the AWS Mainframe Modernization service. The default is `us-east-1` . • **Application**: Choose the icon next to the field **()**, and choose **Submit** in the **Refresh Applicati on Choices**. This will connect to the AWS Mainframe Moderniza tion service and return the list of applications. Now you can select the application from the dropdown list. Select the application you want to run the batch job. • **JCL File Name**: `RUNHELLO.jcl` • **Wait for Success or Failure**: If this option is selected, the task will wait until the status of the batch job is success or failure. • **Polling Interval**: This is the amount of time between each polling. • **Fetch Execution Logs**: If selected, logs will be fetched automatically	

Task	Description	Skills required
	when the batch job has completed. • **Log Format**: This is the format of the logs to be printed out. It can be Text or JSON format. 3. Keep the default values in the rest of the fields, and save the task.	

Task	Description	Skills required
Launch the task.	1. At the top of the right panel, choose **Launch Task**. 2. In the **Confirm** window, choose **Launch**. After that, the Universal Controlle r Console will display a message similar to the following message. *2022-08-24 11:11:59 AM* *Successfully launched the Universal task "Mainframe Modernization Start Batch" with task instance sys_id <sys id>.* 3. Navigate to the **Instances** If you don’t see the **Instances** tab, choose the right arrow to scroll right. 4. Open the context (right-click) menu for the task instance in the list, choose **Retrieve Output**, and then choose **Submit** in the **Retrieve Output** 5. In the **Retrieve Output** window, you will see the list of environments in STDOUT.	Universal Controller administr ator

Create a workflow for multiple tasks

Task	Description	Skills required
Copy the tasks.	1. Open the context (right click) menu for the task that you want to create copies of, and choose **Copy**. 2. In the **Copy AWS Mainframe Modernization Task** window enter the following new name for the new task: Mainframe Modernization Start Batch - *RUNAWS2.* 3. Copy the task again, using the following name: Mainframe Modernization Start Batch - *RUNAWS3.* 4. Copy with the task again, using the following name: Mainframe Modernization Start Batch - *RUNAWS4.* 5. Copy the task a final time, using the following name: Mainframe Modernization Start Batch - *FOOBAR.*	Universal Controller administrator
Update tasks.	1. Open (double-click) the Mainframe Modernization Start Batch - RUNAWS2 task, change the **JCL File Name** field to `RUNAWS2.jcl` , and save. 2. Open (double-click) the Mainframe Modernization	Universal Controller administrator

Task	Description	Skills required
	Start Batch - RUNAWS3 task, change the **JCL File Name** field to `RUNAWS3.jcl`, and save. 3. Open (double-click) the Mainframe Modernization Start Batch - RUNAWS4 task, change the **JCL File Name** field to `RUNAWS4.jcl`, and save. 4. Open (double-click) the Mainframe Modernization Start Batch - FOOBAR task, change the **JCL File Name** field to `MISSING.jcl`, and save. **This task will fail because the JCL File Name value is incorrect.**	

Task	Description	Skills required
Create a workflow.	1. Navigate to **Services**, **Workflows**. 2. On the right panel, enter **Mainframe Modernization Workflow** in the **Name** field, and save. 3. In the right panel, choose **Edit Workflow**. 4. On the **Workflow Editor Tab**, the **Add Task** button **(+)**. 5. In the **Task Find** window, choose **Search** to see all the tasks in the Universal Controller. 6. Click the icon next to Mainframe Modernization Start Batch Task, and drag the icon into an empty place in the **Workflow Editor**. 7. Repeat the same action for the other Mainframe Modernization tasks and place them as shown in the *Additional information* section. 8. Choose the **Connect** button **()**, and connect the tasks together. To connect a task with another, click in the middle of a task, and drag it to the target task.	Universal Controller administr ator

Task	Description	Skills required
	9. Connect the tasks as shown in the *Additional informati on* section, and save the workflow. 10Right-click an empty place in the Workflow Editor, choose **Launch Workflow**, and then choose **OK**.	
Check the status of the workflow.	1. On the left menu, choose the **Activity** 2. In the middle of the window, choose **Start**. You will see the list of task instances in the list. 3. Open (double-click) Mainframe Moderniza tion Workflow in the list, or open the context (right-click) menu and choose **Workflow Task Commands**, **View Workflow**. You will see the tasks as shown in the Additional information section. The second task was expected to fail because you used a missing JCL file.	Univeral Controller administr ator

Troubleshoot failed batch jobs and rerun

Task	Description	Skills required
Fix the failed task and rerun.	1. Open (double-click) the failed task to see the error for the task. 2. You have two options for fixing the failed task. • Fix the JCL file name, and set it to `FOOBAR.jcl` . • Add the correct JCL file name to the **JCL File Name (Temp)**. This field will overwrite the **JCL File Name** field. For this pilot, choose the second option, and save the task instance. 3. In the **Workflow Monitor**, open the context (right-click) menu for the failed task, and choose **Commands**, **Re-run**. 4. After that, all the tasks will complete successfully.	Universal Controller administrator

Create Start Application and Stop Application tasks

Task	Description	Skills required
Create the Start Application action.	1. Navigate to **Services**, **AWS Mainframe Modernization Tasks**. 2. On the right panel, fill in the required fields. • **Name**: Mainframe Modernization Start Application • **Agent**: Select the only agent (AGNT0001) Under **AWS Mainframe Modernization Details**: • **Action**: Start Application • **AWS Credentials**: If you have an IAM role added to the EC2 instance, you can keep this field empty. If you will use `AWSAccessKeyID` and `AWSSecretKey`, select the credential that you created before. • **End Point**: Be sure that the endpoint has the correct Region. The default is `https://m2.us-east-1.amazonaws.com`. • **Region**: Enter the Region of the AWS Mainframe	Universal Controller administrator

Task	Description	Skills required
	Modernization service. The default is `us-east-1` . • **Application**: Choose the icon next to the field **()**, and choose **Submit** in the **Refresh Application Choices**. This will connect to the AWS Mainframe Modernization service and return the list of applications. Now you can select the application from the dropdown list. Select the application you want to run the batch job. • **Wait for Success or Failure**: If this option is selected, the task will wait until the status of the batch job is success or failure. • **Polling Interval**: This is the amount of time between each polling. • **Fetch Execution Logs**: If selected, logs will be fetched automatically when the batch job has completed. • **Log Format:** This is the format of the logs to be	

Task	Description	Skills required
	printed out. It can be Text or JSON format. 3. Keep the default values in the rest of the fields, and save the task. 4. Now copy this task and create a task for Stop Application. Change the name to **Mainframe Moderinization Stop Application**, and change the action to **Stop Application**.	

Create a Cancel Batch Execution task

Task	Description	Skills required
Create the Cancel Batch action.	1. Navigate to **Services**, **AWS Mainframe Modernization Tasks**. 2. On the right panel, fill in the required fields. • **Name**: Mainframe Modernization Cancel Batch Execution • **Agent**: Select the only agent (AGNT0001) Under **AWS Mainframe Modernization Details**: • **Action**: Cancel Batch Execution	

Task	Description	Skills required
	• **AWS Credentials**: If you have an IAM role added to the EC2 instance, you can keep this field empty. If you will use `AWSAccessKeyID` and `AWSSecretKey` , select the credential that you created before. • **End Point**: Be sure that the endpoint has the correct Region. The default is `https://m2.us-east-1.amazonaws.com` . • **Region**: Enter the Region of the AWS Mainframe Modernization service. The default is `us-east-1` . • **Application**: Choose the icon next to the field **()**, and choose **Submit** in the **Refresh Application Choices**. This will connect to the AWS Mainframe Modernization service and return the list of applications. Now you can select the application from the dropdown list. Select the application you want to run the batch job.	

Task	Description	Skills required
	• **Wait for Success or Failure**: If this option is selected, the task will wait until the status of the batch job is success or failure. • **Polling Interval**: This is the amount of time between each polling. • **Fetch Execution Logs**: If selected, logs will be fetched automatically when the batch job has completed. • **Log Format**: This is the format of the logs to be printed out. It can be Text or JSON format. 3. Keep the default values in the rest of the fields, and save the task.

Migrate and replicate VSAM files to Amazon RDS or Amazon MSK using Connect from Precisely

Prachi Khanna and Boopathy GOPALSAMY, Amazon Web Services

Summary

This pattern shows you how to migrate and replicate Virtual Storage Access Method (VSAM) files from a mainframe to a target environment in the AWS Cloud by using Connect from Precisely. The target environments covered in this pattern include Amazon Relational Database Service (Amazon RDS) and Amazon Managed Streaming for Apache Kafka (Amazon MSK). Connect uses change data capture (CDC) to continuously monitor updates to your source VSAM files and then transfer these updates to one or more of your AWS target environments. You can use this pattern to meet your application modernization or data analytics goals. For example, you can use Connect to migrate your VSAM application files to the AWS Cloud with low latency, or migrate your VSAM data to an AWS data warehouse or data lake for analytics that can tolerate synchronization latencies that are higher than required for application modernization.

Prerequisites and limitations

Prerequisites

- IBM z/OS V2R1 or later
- CICS Transaction Server for z/OS (CICS TS) V5.1 or later (CICS/VSAM data capture)
- IBM MQ 8.0 or later
- Compliance with z/OS security requirements (for example, APF authorization for SQData load libraries)
- VSAM recovery logs turned on
- (Optional) CICS VSAM Recovery Version (CICS VR) to automatically capture CDC logs
- An active AWS account
- An Amazon Virtual Private Cloud (VPC) with a subnet that's reachable by your legacy platform
- A VSAM Connect license from Precisely

Limitations

- Connect doesn't support automatic target table creation based on source VSAM schemas or copybooks. You must define the target table structure for the first time.

- For non-streaming targets such as Amazon RDS, you must specify the conversion source to target mapping in the Apply Engine configuration script.
- Logging, monitoring, and alerting functions are implemented through APIs and require external components (such as Amazon CloudWatch) to be fully operational.

Product versions

- SQData 40134 for z/OS
- SQData 4.0.43 for the Amazon Linux Amazon Machine Image (AMI) on Amazon Elastic Compute Cloud (Amazon EC2)

Architecture

Source technology stack

- Job Control Language (JCL)
- z/OS Unix shell and Interactive System Productivity Facility (ISPF)
- VSAM utilities (IDCAMS)

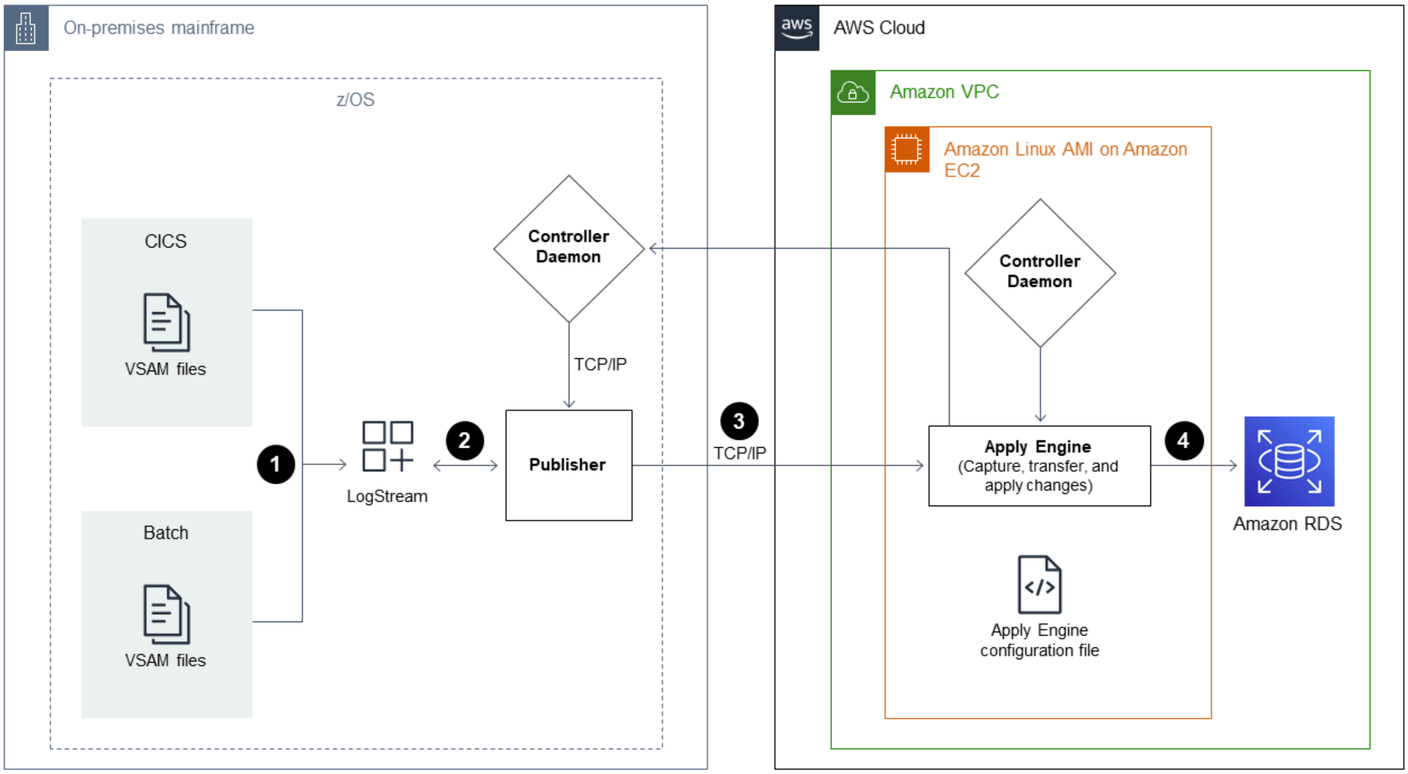
Target technology stack

- Amazon EC2
- Amazon MSK
- Amazon RDS
- Amazon VPC

Target architecture

Migrating VSAM files to Amazon RDS

The following diagram shows how to migrate VSAM files to a relational database, such as Amazon RDS, in real time or near real time by using the CDC agent/publisher in the source environment (on-premises mainframe) and the Apply Engine in the target environment (AWS Cloud).



The diagram shows the following batch workflow:

1. Connect captures changes to a file by comparing VSAM files from backup files to identify changes and then sends the changes to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to a target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Apply Engine in the target environment receives the changes from the Publisher agent and applies them to a relational or non-relational database.

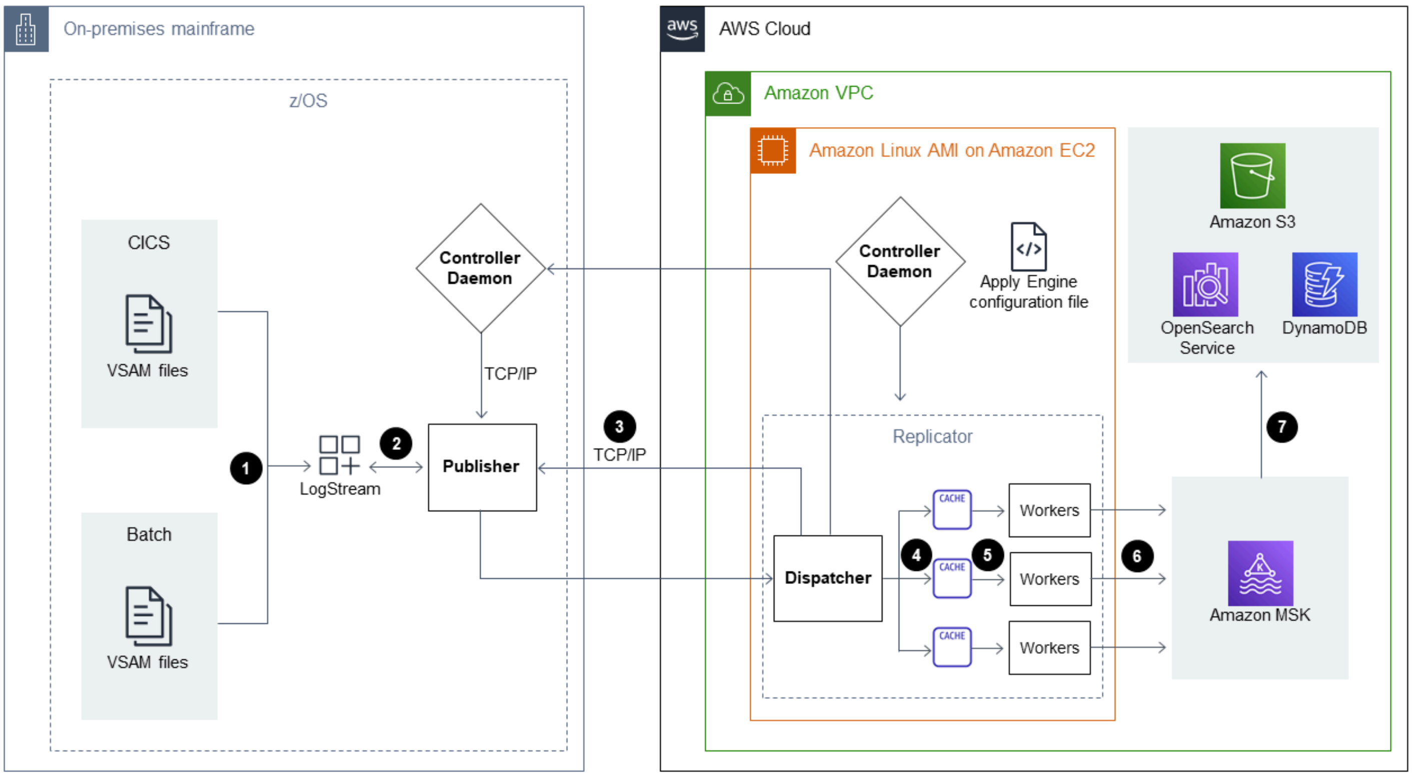
The diagram shows the following online workflow:

1. Connect captures changes in the online file by using a log replicate and then streams captured changes to a logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.

4. The Apply Engine in the target environment receives the changes from the Publisher agent and then applies them to a relational or non-relational database.

Migrating VSAM files to Amazon MSK

The following diagram shows how to stream VSAM data structures from a mainframe to Amazon MSK in high-performance mode and automatically generate JSON or AVRO schema conversions that integrate with Amazon MSK.



The diagram shows the following batch workflow:

1. Connect captures changes to a file by using CICS VR or by comparing VSAM files from backup files to identify changes. Captured changes are sent to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Replicator Engine that's operating in parallel processing mode splits the data to a unit of work cache.
5. Worker threads capture the data from the cache.

6. Data is published to Amazon MSK topics from the worker threads.
7. Users apply changes from Amazon MSK to targets such as Amazon DynamoDB, Amazon Simple Storage Service (Amazon S3), or Amazon OpenSearch Service by using connectors.

The diagram shows the following online workflow:

1. Changes in the online file are captured by using a log replicate. Captured changes are streamed to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Replicator Engine that's operating in parallel processing mode splits the data to a unit of work cache.
5. Worker threads capture the data from the cache.
6. Data is published to Amazon MSK topics from the worker threads.
7. Users apply changes from Amazon MSK to targets such as DynamoDB, Amazon S3, or OpenSearch Service by using connectors.

Tools

- Amazon Managed Streaming for Apache Kafka (Amazon MSK) is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.

Epics

Prepare the source environment (mainframe)

Task	Description	Skills required
Install Connect CDC 4.1.	1. Contact the Precisely Support team to obtain a license and installation packages.	IBM Mainframe Developer/ Admin

Task	Description	Skills required
	2. Use example JCLs to install Connect CDC 4.1. For instructions, see [Install Connect CDC (SQData) using JCL](#) in the Precisely documentation. 3. Run the `SETPROG APF` command to authorize the Connect load libraries SQDATA.V4nnn.LOADLIB.	
Set up the zFS directory.	To set up a zFS directory, follow the instructions from [zFS variable directories](#) in the Precisely documentation. **Note** Controller Daemon and Capture/Publisher agent configurations are stored in the z/OS UNIX Systems Services file system (referred to as zFS). The Controller Daemon, Capture, Storage, and Publisher agents require a predefined zFS directory structure for storing a small number of files.	IBM Mainframe Developer/Admin

Task	Description	Skills required
Configure TCP/IP ports.	To configure TCP/IP ports, follow the instructions from [TCP/IP ports](#) in the Precisely documentation. **Note** The Controller Daemon requires TCP/IP ports on source systems. The ports are referenced by the engines on the target systems (where captured change data is processed).	IBM Mainframe Developer/Admin

Task	Description	Skills required
Create a z/OS logstream.	To create a z/OS logstream, follow the instructions from Create z/OS system logStreams in the Precisely documentation. **Note** Connect uses the logstream to capture and stream data between your source environment and target environment during migration. For an example JCL that creates a z/OS LogStream, see Create z/OS system logStreams in the Precisely documentation.	IBM Mainframe Developer
Identify and authorize IDs for zFS users and started tasks.	Use RACF to grant access to the OMVS zFS file system. For an example JCL, see Identify and authorize zFS user and started task IDs in the Precisely documentation.	IBM Mainframe Developer/ Admin

Task	Description	Skills required
Generate z/OS public/private keys and the authorized key file.	Run the JCL to generate the key pair. For an example, see *Key pair example* in the *Additional information* section of this pattern. For instructions, see Generate z/OS public and private keys and authorized key file in the Precisely documentation.	IBM Mainframe Developer/ Admin

Activate the CICS VSAM Log Replicate and attach it to the logstream.	Run the following JCL script:
	
	`//STEP1 EXEC PGM=IDCAMS`
	`//SYSPRINT DD SYSOUT=*`
	`//SYSIN DD *`
	`ALTER SQDATA.CICS.FILEA -`
	`LOGSTREAMID(SQDATA.VSAMCDC.LOG1) -`
	`LOGREPLICATE`
		IBM Mainframe Developer/ Admin

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Activate the VSAM File Recovery Log through an FCT.</td><td>Modify the File Control Table (FCT) to reflect the following parameter changes:

<tr><td>Set up CDCzLog for the Publisher agent.</td><td>1. Create the CDCzLog Publisher CAB file.
2. Encrypt the published data.
3. Prepare the CDCzLog Publisher Runtime JCL.</td><td>IBM Mainframe Developer/ Admin</td></tr>
</table>

Task	Description	Skills required
Activate the Controller Daemon.	1. Open the ISPF panel and run the following command to open the Precisely menu: `EXEC 'SQDATA.V4nnnnn.ISPFLIB(SQDC$STA)' 'SQDATA.V4nnnnn'` 2. To set up the Controller Daemon, choose option 2 from the menu.	IBM Mainframe Developer/Admin
Activate the publisher.	1. Open the ISPF panel and run the following command to open the Precisely menu: `EXEC 'SQDATA.V4nnnnn.ISPFLIB(SQDC$STA)' 'SQDATA.V4nnnnn'` 2. To set up the publisher, choose option 3 from the menu and **I** for insert.	IBM Mainframe Developer/Admin

Task	Description	Skills required
Activate the logstream.	1. Open the ISPF panel and run the following command to open the Precisely menu: `EXEC 'SQDATA.V4nnnnn.ISPFLIB(SQDC$STA)' 'SQDATA.V4nnnnn'` 2. To set up the logstream, choose option 4 from the menu and **I** for insert. Then, enter the name of the logstream created in the preceding steps.	IBM Mainframe Developer/Admin

Prepare the target environment (AWS)

Task	Description	Skills required
Install Precisely on an EC2 instance.	To install Connect from Precisely on the Amazon Linux AMI for Amazon EC2, follow the instructions from [Install Connect CDC (SQData) on UNIX](#) in the Precisely documentation.	General AWS
Open TCP/IP ports.	To modify the security group to include the Controller Daemon ports for inbound and outbound access, follow the instructions from [TCP/IP](#) in the Precisely documentation.	General AWS

Task	Description	Skills required
Create file directories.	To create file directories, follow the instructions from [Prepare target apply environment](#) in the Precisely documentation.	General AWS

Create the Apply Engine configuration file.	Create the Apply Engine configuration file in the working directory of the Apply Engine. The following example configuration file shows Apache Kafka as the target:
	`builtin.features=SASL_SCRAM`
	`  security.protocol=SASL_SSL`
	`  sasl.mechanism=SCRAM-SHA-512`
	`  sasl.username=`
	`  sasl.password=`
	`  metadata.broker.list=`
	Note
	For more information, see [Security](#) in the Apache Kafka documentation.
		General AWS

Task	Description	Skills required
Create scripts for Apply Engine processing.	Create the scripts for the Apply Engine to process source data and replicate source data to the target. For more information, see Create an apply engine script in the Precisely documentation.	General AWS
Run the scripts.	Use the `SQDPARSE` and `SQDENG` commands to run the script. For more information, see Parse a script for zOS in the Precisely documentation.	General AWS

Validate the environment

Task	Description	Skills required
Validate the list of VSAM files and target tables for CDC processing.	1. Validate VSAM files, including replication logs, recovery logs, FCT parameters, and the logstream. 2. Validate target database tables, including whether the tables are created as per the required schema definition, table access, and other criteria.	General AWS, Mainframe
Verify that the Connect CDC SQData product is linked.	Run a testing job and verify that the return code from this job is 0 (Successful).	General AWS, Mainframe

Task	Description	Skills required
	Note Connect CDC SQData Apply Engine status messages should show active connectio n messages.	

Run and validate test cases (Batch)

Task	Description	Skills required
Run the batch job in the mainframe.	Run the batch application job using a modified JCL. Include steps in the modified JCL that do the following: 1. Take a backup of the data files. 2. Compare the backup file with the modified data files, generate the delta file, and then note the delta record count from the messages. 3. Push the delta file to the z/ OS logstream. 4. Run the JCL. For an example JCL, see [Prepare file compare capture JCL](#) in the Precisely documenta tion.	General AWS, Mainframe

Task	Description	Skills required
Check the logstream.	Check the logstream to confirm that you can see the change data for the completed mainframe batch job.	General AWS, Mainframe
Validate the counts for the source delta changes and target table.	To confirm the records are tallied, do the following: 1. Gather the source delta count from the batch JCL messages. 2. Monitor the Apply Engine for record level counts of the number of records inserted, updated, or deleted in the VSAM file. 3. Query the target table for record counts. 4. Compare and tally all the different record counts.	General AWS, Mainframe

Run and validate test cases (Online)

Task	Description	Skills required
Run the online transaction in a CICS region.	1. Run the online transaction to validate the test case. 2. Validate the transaction execution code (RC=0 – Success).	IBM Mainframe Developer

Task	Description	Skills required
Check the logstream.	Confirm that the logstream is populated with specific record level changes.	AWS Mainframe Developer
Validate the count in the target database.	Monitor the Apply Engine for record level counts.	Precisely, Linux
Validate the record counts and data records in the target database.	Query the target database to validate the record counts and data records.	General AWS

Additional information

Configuration file example

This is an example configuration file for a logstream where the source environment is a mainframe and the target environment is Amazon MSK:

```
 -- JOBNAME -- PASS THE SUBSCRIBER NAME
 -- REPORT  progress report will be produced after "n" (number) of Source records
processed.

 JOBNAME VSMTOKFK;
 --REPORT EVERY 100;
 -- Change Op has been ‘I’ for insert, ‘D’ for delete , and ‘R’ for Replace. For RDS
it is 'U' for update
 -- Character Encoding on z/OS is Code Page 1047, on Linux and UNIX it is Code Page
819 and on Windows, Code Page 1252
```

```
 OPTIONS
 CDCOP('I', 'U', 'D'),
 PSEUDO NULL = NO,
 USE AVRO COMPATIBLE NAMES,
 APPLICATION ENCODING SCHEME = 1208;

 --       SOURCE DESCRIPTIONS

 BEGIN GROUP VSAM_SRC;
 DESCRIPTION COBOL ../copybk/ACCOUNT AS account_file;
 END GROUP;

Key pair example

This an example of how to run the JCL to generate the key pair:

```
//SQDUTIL EXEC PGM=SQDUTIL //SQDPUBL DD DSN=&USER..NACL.PUBLIC, //
 DCB=(RECFM=FB,LRECL=80,BLKSIZE=21200), // DISP=(,CATLG,DELETE),UNIT=SYSDA, //
 SPACE=(TRK,(1,1)) //SQDPKEY DD DSN=&USER..NACL.PRIVATE, //
 DCB=(RECFM=FB,LRECL=80,BLKSIZE=21200), // DISP=(,CATLG,DELETE),UNIT=SYSDA, //
 SPACE=(TRK,(1,1)) //SQDPARMS DD  keygen //SYSPRINT DD SYSOUT= //SYSOUT DD SYSOUT=* //
SQDLOG DD SYSOUT=* //*SQDLOG8 DD DUMMY
```

Modernize the CardDemo mainframe application by using AWS Transform

Santosh Kumar Singh and Cheryl du Preez, Amazon Web Services

Summary

AWS Transform is designed to accelerate the modernization of mainframe applications. It uses generative AI to streamline the mainframe modernization process. It automates complex tasks, such as: legacy code analysis, mainframe documentation, business rules extraction, monolithic applications decomposition into business domain, and code refactoring. It accelerates modernization projects by automating complex tasks, such as application analysis and migration sequence planning. When decomposing monolithic applications, AWS Transform intelligently sequences the mainframe application transformation, which helps you to transform business functions in parallel. AWS Transform can accelerate decision making and enhance operational agility and migration efficiency.

This pattern offers step-by-step instructions to help you test the mainframe modernization capabilities of AWS Transform by using CardDemo, which is a sample open source mainframe application.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS IAM Identity Center, enabled
- Permissions that allow administrators to enable AWS Transform
- Permissions that allow administrators to accept Amazon Simple Storage Service (Amazon S3) connection requests for the AWS Transform web application

Limitations

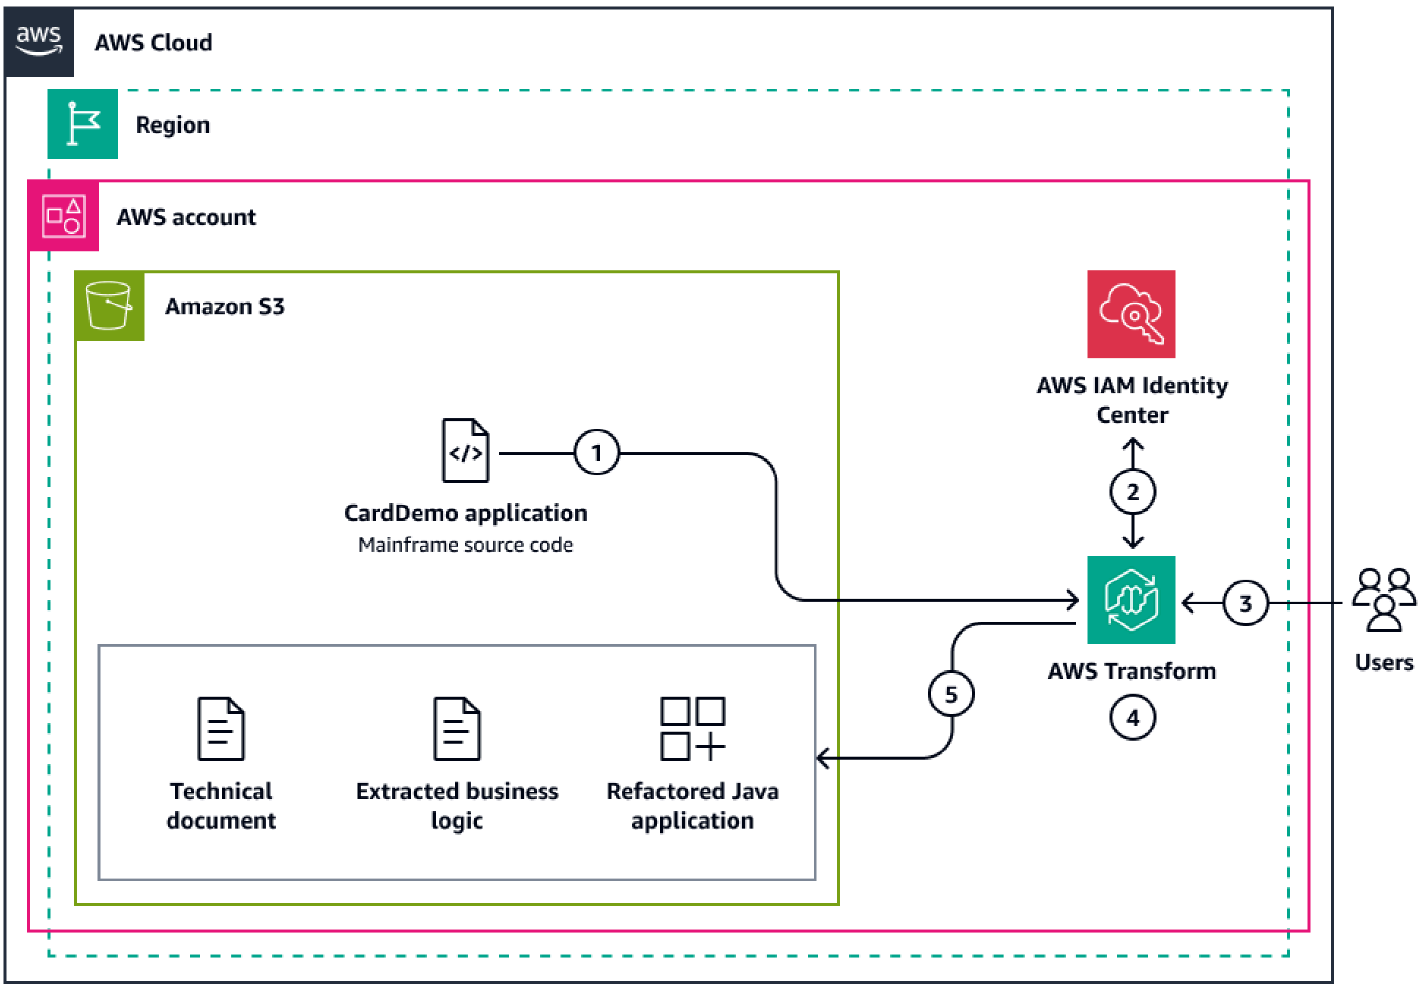
- AWS Transform is available only in some AWS Regions. For a complete list of supported Regions, see Supported Regions for AWS Transform.
- AWS Transform supports code analysis, document generation, business rules extraction, decomposition, and refactoring from Common Business-Oriented Language (COBOL) to Java. For

more information, see Capabilities and key features and Supported file types for transformation of mainframe applications.

- There is a service quota for mainframe transformation capabilities in AWS Transform. For more information, see Quotas for AWS Transform.
- In order to collaborate on a shared workspace, all users must be registered users of the same instance of AWS IAM Identity Center that is associated with your instance of the AWS Transform web application.
- The Amazon S3 bucket and AWS Transform must be in the same AWS account and Region.

Architecture

The following diagram shows the architecture that you set up in this pattern.



The diagram shows the following workflow:

1. AWS Transform uses a connector to access the CardDemo mainframe application, which is stored in an Amazon S3 bucket.
2. AWS Transform uses AWS IAM Identity Center to manage user access and authentication. The system implements multiple layers of security controls for authentication, authorization, encryption, and access management to help protect code and artifacts during processing. Users interact with the AWS Transform agent through a chat interface. You can provide instructions to the AI agent for specific tasks in English. For more information, see Human in the loop (HITL) in the AWS Transform documentation.
3. The AI agent interprets the user's instructions, creates a job plan, divides the job into executable tasks, and actions it autonomously. Users can review and approve the transformation. Transformation tasks include the following:
   - **Code analysis –** AWS Transform analyzes the code in each file for details such as file name, file type, lines of code, and their paths. The agent analyzes the source code, runs classifications, creates dependency mappings, and identifies any missing artifacts. It also identifies duplicate components.
   - **Document generation** – AWS Transform generates documentation for the mainframe application. By analyzing the code, it can automatically create detailed documentation of the application programs, including descriptions of the business logic, flows, integrations, and dependencies present in your legacy systems.
   - **Business logic extraction**– AWS Transform analyzes COBOL programs to document their core business logic, to help you understand the fundamental business logic.
   - **Code decomposition** – AWS Transform decomposes the code into domains that account for dependencies between programs and components. Grouping related files and programs within the same domain improves organization and helps preserve the application's logical structure when breaking it down into smaller components.
   - **Migration wave planning –** Based on the domains you created during the decomposition phase, AWS Transform generates a migration wave plan with recommended modernization order.
   - **Code refactoring –** AWS Transform refactors the code in all or selected domain files into Java code. The goal of this step is to preserve the critical business logic of the application while refactoring it to a modernized, cloud-optimized Java application.
4. AWS Transform stores the refactored code, generated documents, associated artifacts, and runtime libraries in your Amazon S3 bucket. You can do the following:
   - Access the runtime folder in your Amazon S3 bucket.

- Build and deploy the application by following the Build and deploy your modernized application post-refactoring in the AWS Transform documentation.
- Through the chat interface, request and download a sample AWS CloudFormation, AWS Cloud Development Kit (AWS CDK), or Hashicorp Terraform template. These templates can help you deploy the AWS resources that are necessary to support the refactored application.
- Use Reforge to improve the quality of refactored code by using large language models (LLMs). The refactoring engine preserves the functional equivalence of COBOL while transforming it into Java code. Reforge is an optional step that is available after the transformation. This step uses LLMs to restructure the code to closely resemble native Java, which can improve readability and maintainability. Reforge also adds human-readable comments to help you understand the code, and it implements modern coding patterns and best practices.

Tools

AWS services

- AWS Transform uses agentic AI to help you accelerate the modernization of legacy workloads, such as .NET, mainframe, and VMware workloads.
- AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to your AWS accounts and cloud applications.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code repository

You can use the open source AWS CardDemo mainframe application as a sample application to get started with mainframe modernization.

Best practices

- **Start small –** Begin with small, less complex code (15,000–20,000 lines of code) to get an understanding of how AWS Transform analyzes and transforms mainframe applications.
- **Combine with human expertise –** Use AWS Transform as an accelerator while applying human expertise for optimal results.
- **Review and test thoroughly –** Always review the transformed code carefully and run comprehensive tests to validate the functional equivalency after transformation.

- **Provide feedback** – To provide feedback and suggestions for improvement, use the **Send feedback** button in the AWS Management Console or create a case with AWS Support. For more information, see Creating a support case. Your input is valuable for service enhancements and future development.

Epics

Prepare the mainframe application

Task	Description	Skills required
Create a bucket.	Create an Amazon S3 bucket in the same AWS account and Region where AWS Transform is enabled. You use this bucket to store the mainframe application code, and AWS Transform uses this bucket to store the generated documents, refactored code and other files associated with the transformation. For instructions, see Creating a bucket in the Amazon S3 documentation.	General AWS
Prepare the sample mainframe application.	1. Enter the following command to clone the CardDemo repository to your local workstation: `git clone https://github.com/aws-samples/aws-mainframe-modernization-carddemo.git`	App developer, DevOps engineer

Task	Description	Skills required
	2. Create a new folder named `carddemo`. 3. Copy the `app` folder, which contains the mainframe source code, from the cloned repository into the `carddemo` folder. 4. Compress the `cardemo` folder into a ZIP file. 5. Upload the ZIP file to the Amazon S3 bucket that you created. For instructions, see [Uploading objects](#) in the Amazon S3 documenta tion.	

Configure IAM Identity Center and AWS Transform

Task	Description	Skills required
Add users to IAM Identity Center.	Add your prospective users to IAM Identity Center. Follow the instructions in [Adding users in IAM Identity Center](#) in the AWS Transform documentation.	AWS administrator
Enable AWS Transform and add users.	1. Enable AWS Transform. Follow the instructions in [Enable AWS Transform](#). 2. Add users to AWS Transform. Follow the	AWS administrator

Task	Description	Skills required
	instructions in [Adding users to AWS Transform]().	
Configure user access to the AWS Transform web applicati on.	Each user must accept the invitation to access the AWS Transform web application. Follow the instructions in [Accepting the invitation]() in the AWS Transform documenta tion.	App developer, App owner
Log in to the AWS Transform web application.	Follow the instructions in [Signing in to AWS Transform]().	App developer, App owner
Set up a workspace.	Set up a workspace where users can collaborate in the AWS Transform web applicati on. Follow the instructions in [Setting up your workspace]() in the AWS Transform documentation.	AWS administrator

Transform the mainframe application

Task	Description	Skills required
Create a transformation job.	Create a transformation job to modernize the CardDemo mainframe application. For instructions, see [Create and start a job]() in the AWS Transform documentation. When you are asked to set the objectives in the AWS Transform chat interface,	App developer, App owner

Task	Description	Skills required
	choose **Perform mainframe modernization (IBM z/OS to AWS)** and then choose **Analyze code, Generate technical documentation, Business logic, Decompose code, Plan Migration sequence and Transform code to Java**.	
Set up the connector.	Establish a connector to the Amazon S3 bucket that contains the CardDemo mainframe application. This connector allows AWS Transform to access resources in the bucket and perform consecutive transformation functions. For instructions, see Set up a connector in the AWS Transform documentation.	AWS administrator

Task	Description	Skills required
Perform code analysis.	1. On the **Specify asset location** page, enter the Amazon S3 bucket path for the `carddemo` ZIP file that you uploaded. 2. Choose **Approve and send to AWS Transform**. It starts analyzing the code. 3. Monitor the status on the **Worklog** tab. 4. When the analysis is complete, under **Analyze code** in the left navigatio n pane, choose **View code analysis results**. 5. (Optional) Choose **Download** to download the complete asset list, missing source code, and dependency file. For more information, see Code analysis in the AWS Transform documentation.	App developer, App owner

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Generate technical documentation.</td><td>In the left navigation pane, under Generate technical documentation, choose Select files and configure settings.
Expand COBOL or JCL, and then select one or multiple files.
Choose the documentation detail level:
Summary – Provides a high-level overview of each file in the scope. Also, gives a one-line summary of each file.
Detailed functional specification – Provides comprehensive details for each file in the mainframe application transformation scope. Some details include logic and flow, identified business rules, data flow, dependencies, input and output processing, and various transaction details.
Choose Send to AWS Transform.
Monitor the progress in the Worklog tab.</td><td>App developer, App owner</td></tr>
</table>

Task	Description	Skills required
	Note Document generation time varies from minutes to hours, depending on the number of files and lines of code. 6. When complete, choose **Review documentation results**. 7. Access the generated document through the web application or download it. The generated documenta tion is also stored in the Amazon S3 bucket. 8. Explore the generated documentation by asking specific questions in the chat interface. For example, you can say "Tell me the features of CBACT01C." For more information, see Generate technical documentation in the AWS Transform documentation.	

Task	Description	Skills required
Extract the business logic.	1. In the left navigation pane, expand **Extract business logic**, and then choose **Select files for business logic extraction**. 2. Expand **COBOL** or **JCL**, and then select one or multiple files. 3. Choose **Send to AWS Transform**. 4. Monitor the progress in the **Worklog** tab. **Note** Business logic extraction time varies from minutes to hours, depending on the number of files and lines of code. 5. When extraction is complete, choose **Review business logic extraction results**. 6. Select a COBOL or JCL file, and then choose **View**. 7. Change the scope in **Flow diagram and functional rules** to review different levels of the flow charts,	App developer, App owner

Task	Description	Skills required
	including the supporting code. 8. (Optional) Review the generated business logic, which is stored in JSON format in your Amazon S3 bucket. For more information, see Extract business logic in the AWS Transform documenta tion.	

Task	Description	Skills required
Decompose the code.	1. In the left navigation pane, expand **Decompose code**, and then choose **Decompose into domains**. 2. In the **Actions** list, choose **Create domain**. 3. Enter a name for the new domain, such as `Bill payment`. 4. (Optional) Provide a description. 5. In the **Find files** search bar, search for `CB00`, and then select the file. 6. Choose **Mark as seed**. 7. Verify that the seed flag changes from **No** to **Yes**. 8. Choose **Create**. 9. Choose **Save**. 10. Choose **Decompose**. 11. Review the decomposition output by choosing the domain name. 12. When the decomposition is complete, choose **Send to AWS Transform**. For more information about decomposition and seeds, see Decomposition in the AWS Transform documentation.	App developer, App owner

Task	Description	Skills required
Plan the migration waves.	Plan the migration waves for the CardDemo application. Follow the instructions in [Migration wave planning](#) in the AWS Transform documentation to review and edit the wave plan.	App developer, App owner
Refactor the code.	1. Refactor the CardDemo mainframe application into Java code in all or selected domain files. Follow the instructions in [Refactor code](#) in the AWS Transform documentation. 2. After the refactoring process is complete, build and deploy the modernized Java application. Follow the instructions in [Build and deploy your modernized application post-refactoring](#) in the AWS Transform documentation.	App developer, App owner

Task	Description	Skills required
(Optional) Use Reforge to improve the Java code.	1. Create a new job, and then enter an objective of `Reforge the code`. 2. Enter the of a project that has been modernized through AWS Transform. This project should be in your Amazon S3 bucket. 3. Enter the Java class list that specifies which service classes to reforge. 4. Review the generated output in the Amazon S3 bucket. For more information, see Reforge in the AWS Transform documentation.	App developer, App owner

Task	Description	Skills required
Streamline the deployment.	AWS Transform can provide infrastructure as code (IaC) templates for CloudFormation, AWS CDK, or Terraform. These templates help you deploy core components, including compute, database, storage, and security resources. 1. In the AWS Transform chat interface, request the templates by entering `Share the mainframe refactor <service> templates` , where `<service>` is one of the supported IaC services. 2. Deploy the template by using your preferred service. For example, see the following resources: • Create a stack from the CloudFormation console (CloudFormation documentation) • Deploy AWS CDK applications (AWS CDK documentation) • Build infrastructure (Terraform documentation)	App developer, App owner

Task	Description	Skills required
	For more information, see Deployment capabilities in the AWS Transform documentation.	

Troubleshooting

Issue	Solution
You are unable to view the source code or generated document in the AWS Transform web application.	Add a policy to the CORS permission for the Amazon S3 bucket to allow AWS Transform as an origin. For more information, see S3 bucket CORS permissions in the AWS Transform documentation.

Modernize mainframe output management on AWS by using Rocket Enterprise Server and LRS PageCenterX

Shubham Roy, Amazon Web Services

Abraham Rondon, Micro Focus

Guy Tucker, Levi, Ray and Shoup Inc

Summary

By modernizing your mainframe output management, you can achieve cost savings, mitigate the technical debt of maintaining legacy systems, and improve resiliency and agility through DevOps and Amazon Web Services (AWS) cloud-native technologies. This pattern shows you how to modernize your business-critical mainframe output-management workloads on the AWS Cloud. The pattern uses Rocket Enterprise Server as a runtime for a modernized mainframe application, with Levi, Ray & Shoup, Inc. (LRS) VPSX/MFI (Micro Focus Interface) as a print server and LRS PageCenterX as an archive server. LRS PageCenterX provides output-management solutions for viewing, indexing, searching, archiving, and securing access to business outputs.

The pattern is based on the replatform mainframe modernization approach. Mainframe applications are migrated by AWS Mainframe Modernization on Amazon Elastic Compute Cloud (Amazon EC2). Mainframe output-management workloads are migrated to Amazon EC2, and a mainframe database, such as IBM Db2 for z/OS, is migrated to Amazon Relational Database Service (Amazon RDS). The LRS Directory Integration Server (LRS/DIS) works with AWS Directory Service for Microsoft Active Directory for output-management workflow authentication and authorization.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A mainframe output-management workload.
- Basic knowledge of how to rebuild and deliver a mainframe application that runs on Rocket Enterprise Server. For more information, see the Rocket Enterprise Server data sheet in the Rocket Software documentation.
- Basic knowledge of LRS cloud printing solutions and concepts. For more information, see *Output Modernization* in the LRS documentation.

- Rocket Enterprise Server software and license. For more information, contact [Rocket Software](#).
- LRS VPSX/MFI, LRS PageCenterX, LRS/Queue, and LRS/DIS software and licenses. For more information, [contact LRS](#). You must provide the hostnames of the EC2 instances where the LRS products will be installed.

Note: For more information about configuration considerations for mainframe output-ma nagement workloads, see *Considerations* in the [Additional information](#) section of this pattern.

Product versions

- [Rocket Enterprise Server 10.0](#)
- [LRS VPSX/MFI](#)
- [LRS PageCenterX](#) V1R3 or later

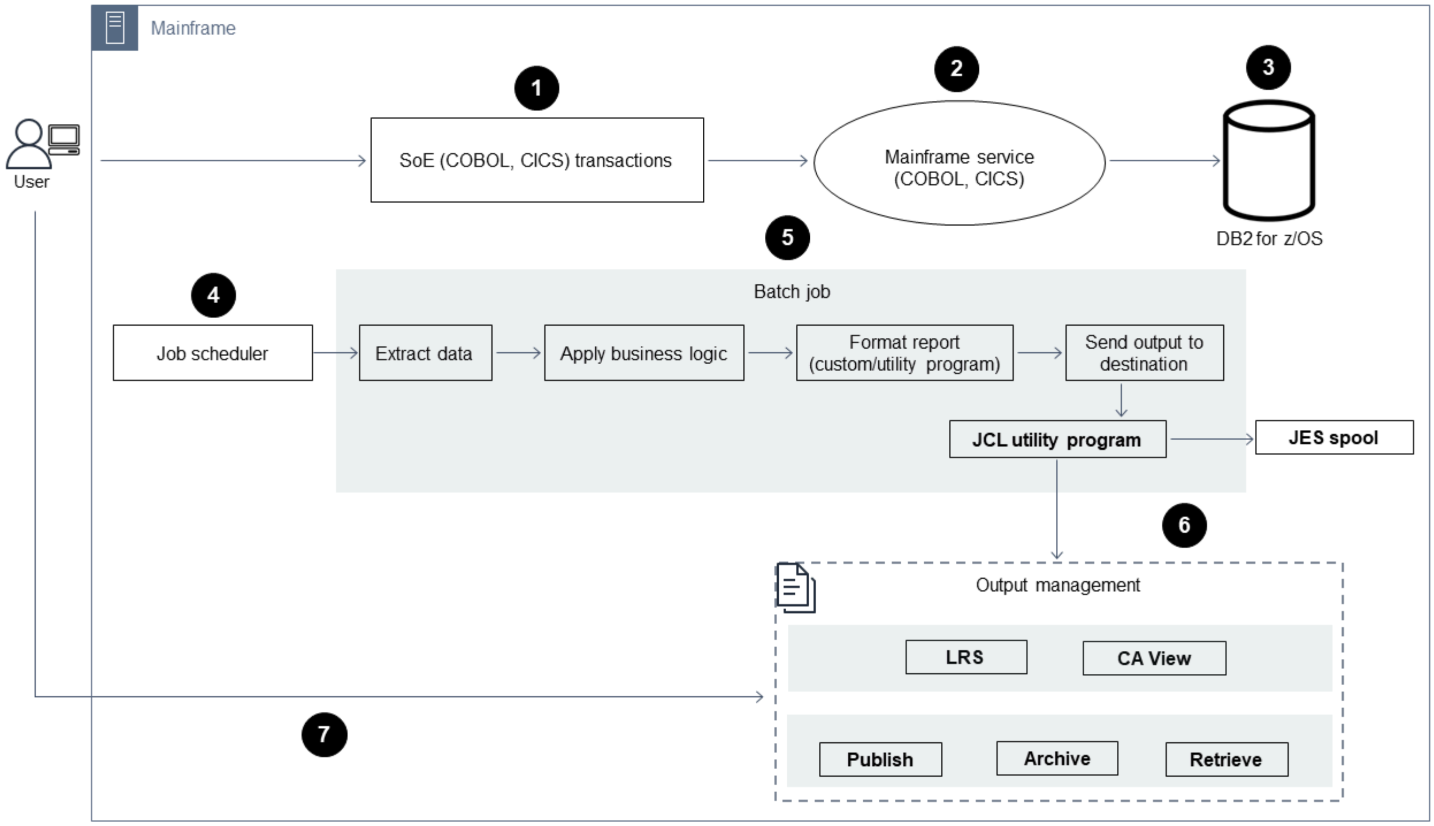
Architecture

Source technology stack

- Operating system – IBM z/OS
- Programming language – Common business-oriented language (COBOL), job control language (JCL), and Customer Information Control System (CICS)
- Database – IBM Db2 for z/OS, IBM Information Management System (IMS) database, and Virtual Storage Access Method (VSAM)
- Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
- Print and archive solutions – IBM mainframe z/OS output and printing products (IBM Infoprint Server for z/OS, LRS, and CA Deliver) and archiving solutions (CA Deliver, ASG Mobius, or CA Bundle)

Source architecture

The following diagram shows a typical current state architecture for a mainframe output-management workload.



The diagram shows the following workflow:

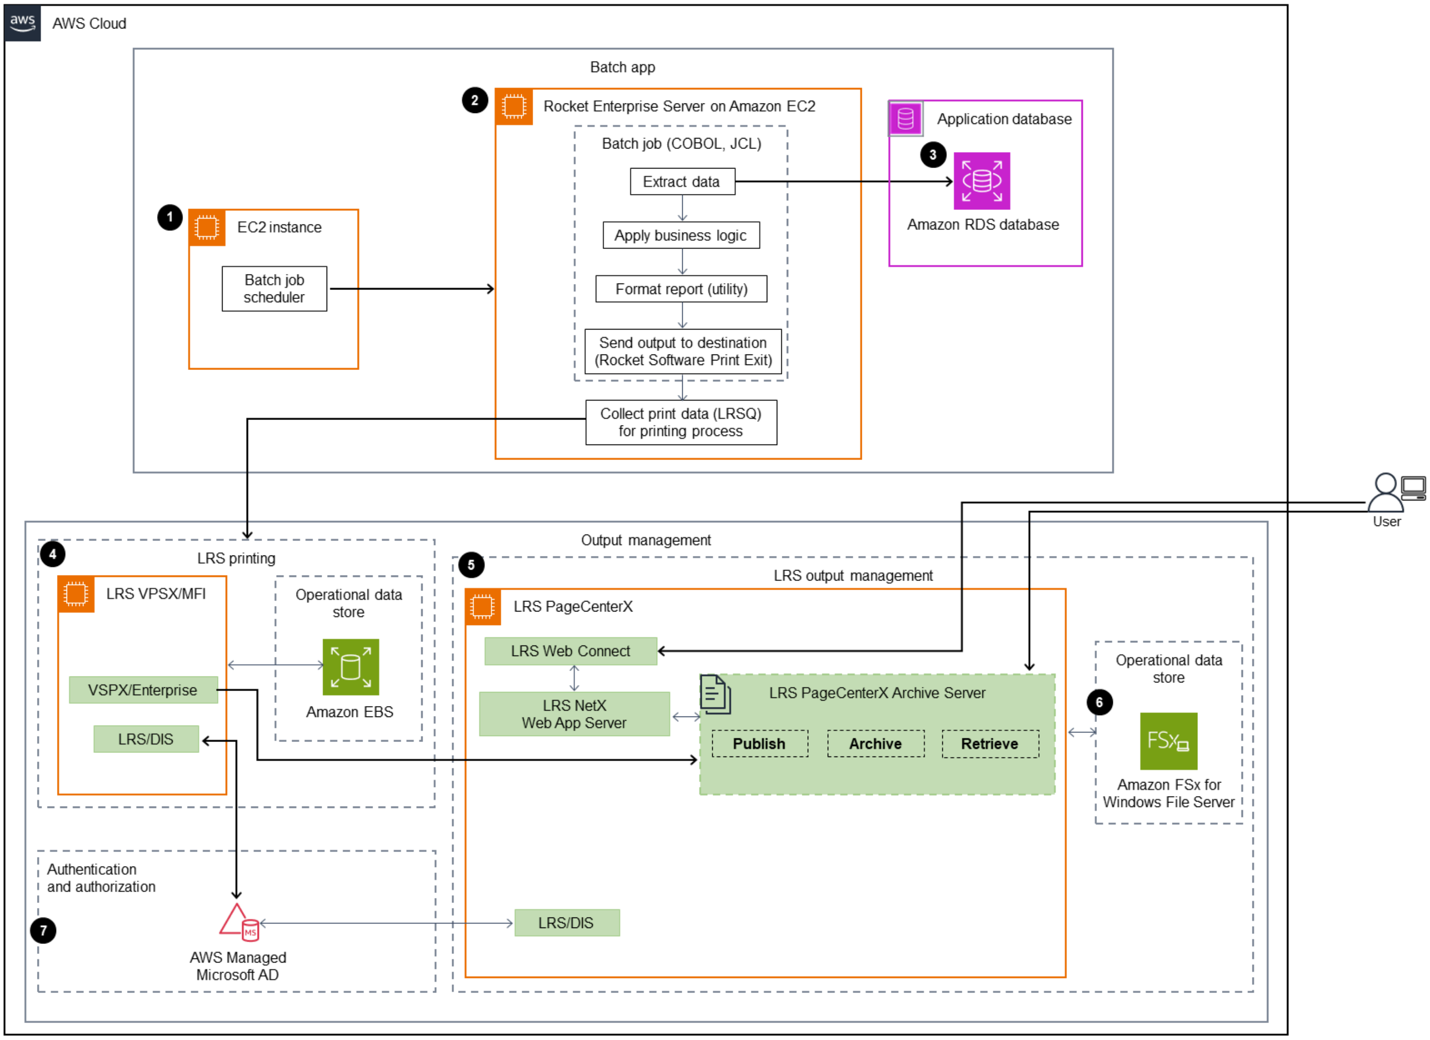
1. Users perform business transactions on a system of engagement (SoE) that's built on an IBM CICS application written in COBOL.
2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM Db2 for z/OS.
3. The SoR persists the business data from the SoE.
4. The batch job scheduler initiates a batch job to generate print output.
5. The batch job extracts data from the database. It formats the data according to business requirements, and then it generates business output such as billing statements, ID cards, or loan statements. Finally, the batch job routes the output to output management for format, publish, and storage of the output based on the business requirements.
6. Output management receives output from the batch job. Output management indexes, arranges, and publishes the output to a specified destination in the output-management system, such as LRS PageCenterX solutions (as demonstrated in this pattern) or CA View.
7. Users can view, search, and retrieve the output.

Target technology stack

- Operating system – Windows Server running on Amazon EC2
- Compute – Amazon EC2
- Storage – Amazon Elastic Block Store (Amazon EBS) and Amazon FSx for Windows File Server
- Programming language – COBOL, JCL, and CICS
- Database – Amazon RDS
- Security – AWS Managed Microsoft AD
- Printing and archiving – LRS printing (VPSX) and archiving (PageCenterX) solution on AWS
- Mainframe runtime environment – Rocket Enterprise Server

Target architecture

The following diagram shows an architecture for a mainframe output-management workload that's deployed in the AWS Cloud.



The diagram shows the following workflow:

1. The batch job scheduler initiates a batch job to create output, such as billing statements, ID cards, or loan statements.
2. The mainframe batch job (replatformed to Amazon EC2) uses the Rocket Enterprise Server runtime to extract data from the application database, apply business logic to the data, and format the data. It then sends the data to an output destination by using the Rocket Software printer exit module (OpenText Micro Focus documentation).
3. The application database (an SoR that runs on Amazon RDS) persists data for print output.
4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2, and its operational data is stored in Amazon EBS. LRS VPSX/MFI uses the TCP/IP-based LRS/Queue transmission agent to collect output data through the Rocket Software JES Print Exit API.

LRS VPSX/MFI does data preprocessing, such as EBCDIC to ASCII translation. It also does more complex tasks, including converting mainframe-exclusive data streams such as IBM Advanced Function Presentation (AFP) and Xerox Line Conditioned Data Stream (LCDS) into more common viewing and printing data streams such as Printer Command Language (PCL) and PDF.

During the maintenance window of LRS PageCenterX, LRS VPSX/MFI persists the output queue and serves as backup for the output queue. LRS VPSX/MFI connects and sends output to LRS PageCenterX by using the LRS/Queue protocol. LRS/Queue performs an exchange of both readiness and completion for the jobs to help ensure that the data transfer occurs.

Notes:

For more information on print data passed from Rocket Software Print Exit to LRS/Queue and LRS VPSX/MFI supported mainframe batch mechanisms, see *Print data capture* in the Additional information section.

LRS VPSX/MFI can perform health checks at the printer-fleet level. For more information, see *Printer-fleet health checks* in the Additional information section of this pattern.

5. The LRS PageCenterX output-management solution is deployed on Amazon EC2, and its operational data is stored in Amazon FSx for Windows File Server. LRS PageCenterX provides a central report management system of all files imported into LRS PageCenterX along with all users able to access the files. Users can view specific file content or perform searches across multiple files for matching criteria.

   The LRS/NetX component is a multi-threaded web application server that provides a common runtime environment for the LRS PageCenterX application and other LRS applications. The LRS/Web Connect component is installed on your web server and provides a connector from the web server to the LRS/NetX web application server.

6. LRS PageCenterX provides storage for file system objects. The operational data of LRS PageCenterX is stored in Amazon FSx for Windows File Server.

7. Output-management authentication and authorization are performed by AWS Managed Microsoft AD with LRS/DIS.

> **Note**
>
> The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM AFP or Xerox LCDS.

AWS infrastructure architecture

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe output-management workload.

The diagram shows the following workflow:

1. The batch scheduler initiates the batch process and is deployed on Amazon EC2 across multiple Availability Zones for high availability (HA).

> **Note**
>
> This pattern doesn't cover the implementation of the batch scheduler. For more information about implementation, see the software vendor documentation for your scheduler.

2. The mainframe batch job (written in a programming language such as JCL or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The batch job is deployed on Amazon EC2 across two Availability Zones for HA. It uses the Rocket Software Print Exit API to route print output to LRS VPSX/MFI for data preprocessing.
3. The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA (active-standby redundant pair). It uses Amazon EBS as an operational data store. The Network Load Balancer performs a health check on the LRS VPSX/MFI EC2 instances. If an active instance is in an unhealthy state, the load balancer routes traffic to hot standby instances in the other Availability Zone. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of a failure, a failed instance must be restarted before the LRS services can resume processing the print request.

> **Note**
>
> LRS VPSX/MFI can also perform health checks at the printer-fleet level. For more information, see *Printer-fleet health checks* in the Additional information section of this pattern.

4. LRS PageCenterX output management is deployed on Amazon EC2 across two Availability Zones for HA (active-standby redundant pair). It uses Amazon FSx for Windows File Server as an operational data store. If an active instance is in an unhealthy state, the load balancer performs a health check on the LRS PageCenterX EC2 instances and routes traffic to standby instances in the other Availability Zone.
5. A Network Load Balancer provides a DNS name to integrate the LRS VPSX/MFI Server with LRS PageCenterX.

> **Note**
>
> LRS PageCenterX supports a Layer 4 load balancer.

6. LRS PageCenterX uses Amazon FSx for Windows File Server as an operational data store deployed across two Availability Zones for HA. LRS PageCenterX understands only files that are in the file share, not in an external database.
7. AWS Managed Microsoft AD is used with LRS/DIS to perform output-management workflow authentication and authorization. For more information, see *Print output authentication and authorization* in the Additional information section.

Tools

AWS services

- AWS Directory Service for Microsoft Active Directory enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon EC2 instances, containers, and IP addresses in one or more Availability Zones. This pattern uses a Network Load Balancer.
- Amazon FSx provides file systems that support industry-standard connectivity protocols and offer high availability and replication across AWS Regions. This pattern uses Amazon FSx for Windows File Server.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.

Other tools

- LRS PageCenterX software provides a scalable document and report content management solution that helps users obtain maximum value from information through automated indexing, encryption, and advanced search features.

- [LRS VPSX/MFI (Micro Focus Interface)](), codeveloped by LRS and Rocket Software, captures output from a Rocket Software JES spool and reliably delivers it to a specified print destination.
- LRS/Queue is a transmission agent that's TCP/IP based. LRS VPSX/MFI uses LRS/Queue to collect or capture print data through the Rocket Software JES Print Exit programming interface.
- LRS Directory Integration Server (LRS/DIS) is used for authentication and authorization during the print workflow.
- [Rocket Enterprise Server]() is an application deployment environment for mainframe applications. It provides the runtime environment for mainframe applications that are migrated or created by using any version of Rocket Enterprise Developer.

Epics

Set up the Rocket runtime and deploy a mainframe batch application

Task	Description	Skills required
Set up the runtime and deploy a demo application.	To set up Rocket Enterprise Server on Amazon EC2 and deploy the Rocket Software BankDemo demonstra tion application, follow the instructions in AWS Mainframe Modernization [user-guide](). The BankDemo application is a mainframe batch applicati on that creates and then initiates print output.	Cloud architect

Set up an LRS print server on Amazon EC2

Task	Description	Skills required
Create an Amazon EC2 Windows instance.	To launch an Amazon EC2 Windows instance, follow	Cloud architect

Task	Description	Skills required
	the instructions in [Launch an Amazon EC2 instance](#) in the Amazon EC2 documentation. Use the same hostname that you used for your LRS product license. Your instance must meet the following hardware and software requirements for LRS VPSX/MFI: • CPU – Dual Core • RAM – 16 GB • Drive – 500 GB • Minimum EC2 instance – `m5.xlarge` • OS – Windows • Software – Internet Information Services (IIS) or Apache **Note** The preceding hardware and software requireme nts are intended for a small printer fleet (around 500-1000) . To get the full requirements, consult	

Task	Description	Skills required
	with your LRS and AWS contacts. 1. When you create your Windows instance, confirm that the EC2 hostname is the same hostname used for the LRS product license. 2. Connect to your EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 3. On the Windows **Start** menu, find and open **Server Manager**. 4. In Server Manager, choose **Dashboard**, **Quick Start**, **Add roles and features**, and then choose **Server roles**. 5. In Server roles, choose **WebServer (IIS)**, and then choose **Application Development**. 6. In Application Developme nt, select the **CGI** check box. 7. To install CGI, follow the instructions in the Windows Server Manger	

Task	Description	Skills required
	Add roles and features wizard. 8. Open port 5500 in the Windows firewall of the EC2 instance for LRS/ Queue communication.	

Task	Description	Skills required
Install LRS VPSX/MFI on the EC2 instance.	1. Connect to your EC2 instance. 2. Open the link to the product download page from the LRS email message that you should have received. **Note** LRS products are distributed by electronic file transfer (EFT). 3. Download LRS VPSX/MFI, and unzip the file (default folder: `c:\LRS`). 4. To install LRS VPSX/MFI, launch the LRS Product Installer from the unzipped folder. 5. On the **Select Features** menu, select **VPSX® Server**, and then choose **Next** to start the installat ion process. You will receive a success message when installation is complete.	Cloud architect

Task	Description	Skills required
Install LRS/Queue.	1. Connect to your Rocket Enterprise Server EC2 instance. 2. Open the link to the LRS product download page from the LRS email message that you should have received, download LRS/Queue, and then unzip the file. 3. Navigate to the location where you downloaded the files, and then launch the LRS Product Installer to install LRS/Queue. 4. Follow the instructions in the LRS Product Installer to complete the installation process.	Cloud architect

Task	Description	Skills required
Install LRS/DIS.	The LRS/DIS product often is included in LRS VPSX installation. However, if LRS/DIS wasn't installed along with LRS VPSX, use the following steps to install it: 1. Connect to your LRS VPSX/MFI EC2 instance. 2. Open the link to the LRS product download page from the LRS email message that you should have received, download LRS/DIS, and then unzip the file. 3. Navigate to the location where you downloaded the files, and then launch the LRS Product Installer. 4. In the LRS Product Installer, expand **LRS Misc Tools**, select **LRS DIS**, and then choose **Next**. 5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.	Cloud architect

Task	Description	Skills required
Create a target group.	Create a target group by following the instructions in [Create a target group for your Network Load Balancer](). When you create the target group, register the LRS VPSX/MFI EC2 instance as the target: 1. On the **Specify group details** page, for **Choose a Target Type**, choose **Instances**. 2. For **Protocol**, choose **TCP**. 3. For **Port**, choose **5500**. 4. On the **Register targets** page, in the **Available instances** section, select the LRS VPSX/MFI EC2 instance.	Cloud architect

Task	Description	Skills required
Create a Network Load Balancer.	To create the Network Load Balancer, follow the instructions in the [Elastic Load Balancing documentation](). Your Network Load Balancer routes traffic from Rocket Enterprise Server to the LRS VPSX/MFI EC2 instance. When you create the Network Load Balancer, choose the following values on the **Listeners and Routing** page: 1. For **Protocol**, choose **TCP**. 2. For **Port**, choose **5500**. 3. For **Default action**, choose **Forward to** for the target group that you created earlier.	Cloud architect

Integrate Rocket Enterprise Server with LRS/Queue and LRS VPSX/MFI

Task	Description	Skills required
Configure Rocket Enterprise Server for LRS/Queue integration.	1. Connect to your Rocket Enterprise Server EC2 instance by following the instructions in the [Amazon EC2 documentation](). 2. On the Windows **Start** menu, open the Rocket Enterprise Server Administration UI.	Cloud architect

Task	Description	Skills required
	3. In the menu bar, choose **NATIVE**. 4. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO** for your Enterprise Server region. 5. From **General** in the left navigation pane, scroll down to the **Additional** section to configure the environment variables (`LRSQ_ADDRESS` , `LRSQ_PORT` , `LRSQ_COMMAND`) to point to LRSQ. • For **LRSQ_ADDRESS**, enter the IP address or DNS name of the Network Load Balancer that you created earlier. • For **LRSQ_PORT**, enter **VPSX LRSQ Listener Port (5500)**. • For **LRSQ_COMMAND**, enter the path location of the LRSQ executable. **Note** LRS currently supports a maximum character limit of 50 for DNS names.	

Task	Description	Skills required
	If your DNS name is longer than 50 characters, you can use the IP address of the Network Load Balancer as an alternative.	

Task	Description	Skills required
Configure Rocket Enterprise Server for LRS VPSX/MFI integration.	1. Copy the `VPSX_MFI_R2` folder from the LRS VPSX/MFI installer to the Rocket Enterprise Server location at `C\BANKDEMO\print`. 2. Connect to your Rocket Enterprise Server EC2 instance by following the instructions in the [Amazon EC2 documentation](https://docs.aws.amazon.com/AWSEC2/latest/WindowsGuide/connecting_to_windows_instance.html). 3. On the Windows **Start** menu, open the Rocket Enterprise Server Administration UI. 4. On the menu bar, choose **NATIVE**. 5. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO**. 6. Under BANKDEMO, choose **JES**. 7. Under **JES Program Path**, add the `DLL(VPSX_MFI_R2)` path from `C\BANKDEMO\print`.	Cloud architect

Set up the print queue and the print users

Task	Description	Skills required
Associate the Rocket Software Print Exit module	1. Connect to your Rocket Enterprise Server EC2	Cloud architect

Task	Description	Skills required
with the Rocket Enterprise Server batch printer Server Execution Process.	instance by following the instructions in the [Amazon EC2 documentation](). 2. On the Windows **Start** menu, open the Rocket Focus Enterprise Server Administration UI. 3. On the menu bar, choose **NATIVE**. 4. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO**. 5. Under BANKDEMO, choose **JES**, and scroll down to **Printers**. 6. In Printers, associate the Rocket Software Print Exit module (**LRSPRTE6 for Batch**) to the Rocket Enterprise Server batch printer **Server Execution Process (SEP)**. This enables print output routing to LRS VPSX/MFI. For more information about configuration, see [Using the Exit]() in the OpenText Micro Focus documentation.	

Task	Description	Skills required
Create a print output queue in LRS VPSX/MFI and integrate it with LRS PageCenterX.	1. Connect to your LRS VPSX/ MFI EC2 instance. 2. On the Windows **Start** menu, open **VPSX Web Interface**. 3. In the navigation pane, choose **Printers**. 4. Choose **Add**, and then choose **Add Printer**. 5. On the **Printer Configuration** page, for **Printer Name**, enter **Local**. 6. For **VPSX ID**, enter **VPS1**. 7. For **CommType**, select **TCPIP/LRSQ**. 8. For **Host/IP Address**, enter the IP address of the Network Load Balancer fronting the LRS PageCenterX EC2 instances. 9. For **Remote port**, enter 5800. 10. For **Remote queue,** enter the name of the LRS PageCenterX document folder where output will be stored. 11. Choose **Add**.	Cloud architect

Task	Description	Skills required
Create a print user in LRS VPSX/MFI.	1. Connect to your LRS VPSX/ MFI EC2 instance. 2. On the Windows **Start** menu, open **VPSX Web Interface**. 3. In the navigation pane, choose **Security**, and then choose **Users**. 4. In the **User Name** column, choose **admin**, and then choose **Copy**. 5. In the **User Profile Maintenance** window, for **User Name**, enter a username (for example, **PrintUser**). 6. For **Description**, enter a brief description (for example, **User for test print**). 7. Choose **Update**. This creates a print user (for example, **PrintUser**). 8. In the navigation pane, under **User**, choose the new user that you created. 9. On the **Command** menu, choose **Security**. 10. On the **Security Rules** page, choose all the applicable printer security and job security options, and then choose **Save**.	Cloud architect

Task	Description	Skills required
	11. To add your new print user to the **Administrator** group, on the navigation pane, choose **Security**, and then choose **Configure**. 12. In the **Security configuration** window, add your new print user to the **Administrator** column.	

Set up an LRS PageCenterX server on Amazon EC2

Task	Description	Skills required
Create an Amazon EC2 Windows instance.	Launch an Amazon EC2 Windows instance by following the instructions from [Step 1: Launch an instance](#) in the Amazon EC2 documentation. Use the same hostname that you used for your LRS product license. Your instance must meet the following hardware and software requirements for LRS PageCenterX: • CPU – Dual Core • RAM – 16 GB • Drive – 500 GB • Minimum EC2 instance – `m5.xlarge` • OS – Windows	Cloud architect

Task	Description	Skills required
	• Software –IIS or Apache **Note** The preceding hardware and software requirements are intended for a small printer fleet (around 500–1000). To get the full requirements, consult with your LRS and AWS contacts. 1. When you create your Windows instance, confirm that the EC2 hostname is the same hostname used for the LRS product license. 2. Connect to your EC2 instance by following the instructions in the [Amazon EC2 documentation](#). 3. On the Windows **Start** menu, find and open **Server Manager**. 4. In Server Manager, choose **Dashboard**, **Quick Start**, **Add roles and features**, then choose **Server roles**. 5. In Server roles, choose **WebServer (IIS)**, and	

Task	Description	Skills required
	then choose **Application Development**. 6. In Application Developme nt, select the **CGI** check box. 7. To install CGI, follow the instructions in the Windows Server Manger **Add roles and features** wizard. 8. Open port 5800 for inbound TCP/IP traffic in the Windows firewall of the EC2 instance. LRS VPSX uses the TCPIP/LRS Q protocol on 5800 port to communicate to LRS PageCenterX.	

Task	Description	Skills required
Install LRS PageCenterX on the EC2 instance.	1. Connect to your EC2 instance. 2. Open the link to the product download page from the LRS email message that you should have received. **Note** LRS products are distributed by electronic file transfer (EFT). 3. Download LRS PageCenterX, and unzip the file (default folder: `c:\LRS`). 4. To install LRS PageCenterX, launch the LRS Product Installer from the unzipped folder. 5. On the **Select Features** menu, select **PageCenterX**, and then choose **Next** to start the installation process. You will receive a success message when installation is complete.	Cloud architect

Task	Description	Skills required
Install LRS/DIS.	The LRS/DIS product often is included in LRS VPSX installat ion. However, if LRS/DIS wasn't installed along with LRS VPSX, use the following steps to install it: 1. Connect to your LRS PageCenterX EC2 instance. 2. Open the link to the LRS product download page from the LRS email that you should have received, download LRS/DIS, and then unzip the file. 3. Navigate to the location where you downloaded the files, and then launch the LRS Product Installer. 4. In the LRS Product Installer , expand **LRS Misc Tools**, select **LRS DIS**, and then choose **Next**. 5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.	Cloud architect

Task	Description	Skills required
Create a target group.	Create a target group by following the instructions in [Create a target group for your Network Load Balancer](). When you create the target group, register the LRS PageCenterX EC2 instance as the target: 1. On the **Specify group details** page, for **Choose a Target Type**, choose **Instances**. 2. For **Protocol**, choose **TCP**. 3. For **Port**, choose **5800**. 4. On the **Register targets** page, in the **Available instances** section, select the LRS PageCenterX EC2 instance.	Cloud architect

Task	Description	Skills required
Create a Network Load Balancer.	To create the Network Load Balancer, follow the instructions in the [Elastic Load Balancing documentation](). Your Network Load Balancer routes traffic from LRS VPSX/MFI to the LRS PageCenterX EC2 instance. When you create the Network Load Balancer, choose the following values on the **Listeners and Routing** page: 1. For **Protocol**, choose **TCP**. 2. For **Port**, choose **5800**. 3. For **Default action**, choose **Forward to** for the target group that you created earlier.	Cloud architect

Set up output-management features in LRS PageCenterX

Task	Description	Skills required
Enable the Import function in LRS PageCenterX.	You can use the LRS PageCenterX Import function to recognize the outputs landing on LRS PageCenterX by criteria such as Job name or Form ID. You can then route the outputs to specific folders in LRS PageCenterX.	Cloud architect

Task	Description	Skills required
	To enable the Import function, do the following: 1. Connect to your LRS PageCenterX EC2 instance by following the instructions in the [Amazon EC2 documentation](https://docs.aws.amazon.com/AWSEC2/latest/WindowsGuide/connecting_to_windows_instance.html). 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**. 4. On the **Configuration** page, choose **Advanced**, **Import parameter**. 5. In the **Import parameter section**, select the **Advanced Import** check box. 6. To commit the changes, choose **Update**.	

Task	Description	Skills required
Configure the document retention policy.	LRS PageCenterX uses a document retention policy to decide how long to keep a document in LRS PageCente rX. To configure the document retention policy, do the following: 1. Connect to your LRS PageCenterX EC2 instance. 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**. 4. On the Admin page, choose **Archive Group List/General admin**, and then choose **Retention policy**. 5. In the Retention policy section, choose **Add** to create a retention policy. 6. On the **Retention Policy Information** page, enter a **Retention policy name**, **Description**, and **Document retention** period. 7. To save your changes and create the policy, choose **Ok**.	Cloud architect

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a rule to route the output document to a specific folder in LRS PageCenterX.</td><td>In LRS PageCenterX, Destination determines the folder path where output will be sent when this destination is invoked by Report Definition. For this example, create a folder based on the Form ID folder in the report definition, and save the output to that folder.

1. Connect to your LRS PageCenterX EC2 instance.
2. On the Windows Start menu, open PCX Web Interface.
3. In Folder Explorer, choose Admin, Advance Import, Destination.
4. In the Destination section, choose Add to open the Destination Maintenance form.
5. On the Destination Maintenance form, enter the following values:
• Destination name – Form
• Description – Description of the destination, such as Form-based folder structure</td><td>Cloud architect</td></tr>
</table>

Task	Description	Skills required
	Destination type – Folder **Folder Parameters** – Import folder path (the folder path that will be created in PageCenterX when the document arrives; for example, the path `/Test/&FORM/&IMPORTDATE/&IMPORTTIME` will create a base `Test` folder, a subfolder based on **Form-Id** named `STD`, a subfolder based on **Import date**, and then a subfolder based on **Import time**) **Document name** – Dynamic name assigned to a document when it's stored in the folder. 6. In the dropdown list, choose a retention policy. For example, choose **Year1** to retain the document for 1 year. 7. To save the changes, choose **Ok**.	

Task	Description	Skills required
Create a report definition.	1. Connect to your LRS PageCenterX EC2 instance. 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**, **Advance Import**, **Report Definition**, and then choose **Add**. 4. On the **Report definitio n maintenance** page, on the **General** tab, enter the **Report Definition name.** 5. On the **General** tab, under **Fields**, you can specify selection criteria such as **Job Name**, **Form**, **Class**, and **Author**. For example, you could enter a **Job Name** of **MFIDEMO**. The **Job Name** value will be the name of the batch job that will generate print output. 6. On the **Destination** tab, under **Available Destinati on**, choose the previously created destination (**Form**). 7. Choose **Add** to add the **Form** destination as **Assigned destination**.	Cloud architect

Task	Description	Skills required
	Note This example includes a report definition where an output generated by the MFIDEMO and routed to LRS PageCenterX is saved in the folder structure defined in the destination definition.	

Set up authentication and authorization for output management

Task	Description	Skills required
Create an AWS Managed Microsoft AD domain with users and groups.	1. To create a directory on AWS Managed Microsoft AD, follow the instructions in [Create your AWS Managed Microsoft AD directory](). 2. To deploy an EC2 instance (Active Directory manager) and install Active Directory tools to manage your AWS Managed Microsoft AD, follow the instructions in [Step 3: Deploy an EC2 instance to manage your]()	Cloud architect

Task	Description	Skills required
	AWS Managed Microsoft AD. 3. To connect to your EC2 instance, follow the instructions in the Amazon EC2 documentation. **Note** When you connect to the EC2 instance, in the **Windows Security** window, enter the administr ator credentials for the directory that you created in step 1. 4. On the Windows **Start** menu, under **Windows Administrative Tools**, choose **Active Directory Users and Computers**. 5. To create a print user in the Active Directory domain, follow the instructions in Create a user.	

Task	Description	Skills required
Join the EC2 instances to an AWS Managed Microsoft AD domain.	Join the LRS VPSX/MFI and LRS PageCenterX EC2 instances to your AWS Managed Microsoft AD domain automatically (AWS Knowledge Center documentation) or manually (AWS Directory Service documentation).	Cloud architect

Task	Description	Skills required
Configure and integrate LRS/DIS with AWS Managed Microsoft AD for the LRS PageCenterX EC2 instance.	1. Connect to your LRS PageCenterX EC2 instance. 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**. 4. On the **Configuration** page, in the **Security Parameters** section, for **Security Type**, select **LRS/DIS**. 5. Enter your preferences for the rest of the options in the Security Parameters section. 6. On the Windows **Start** menu, open the **PageCenterX** folder, choose **Server Start**, and then choose **Server Stop**. 7. Log in to LRS PageCenterX with your Active Directory username and password.	Cloud architect

Task	Description	Skills required
Configure an Import group to import output from LRS VPSX to LRS PageCenterX.	1. Connect to your LRS PageCenterX EC2 instance. 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**, **Security admin**, **Groups**. 4. In the Groups section, choose **Add** to open the **Group preference** form. 5. In the Group preferenc e form, enter values for **Group name** and **Descripti on**. 6. Expand **General options,** and then select the **Import** check box. 7. To save the changes, choose **Ok**.	Cloud architect
Add a security rule to the Import group.	1. Open the context (right-click) menu for **Import group**. 2. Choose **Advance**, and then choose **Security**. 3. In the Security section, choose **Import**, and select the **Subfolder** check box. 4. To save the changes, choose **Apply**.	Cloud architect

Task	Description	Skills required
Create a user in LRS PageCenterX to perform output import from LRS VPSX/MFI.	When you create a user in LRS PageCenterX to perform output import, the username should be the same as the **VPSX ID** of the print output queue in LRS VPSX/MFI. In this example, the VPSX ID is **VPS1**. 1. Connect to your LRS PageCenterX EC2 instance. 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**, **Security admin**, **User.** 4. Choose **Add** to open the **User profile maintenance** form. 5. In User profile maintenan ce, for **User name**, enter **VPS1**.	Cloud architect

Task	Description	Skills required
Add the LRS PageCenterX Import user to the Import only group.	To provide necessary permission for document import from LRS VPSX to LRS PageCenterX, do the following: 1. Connect to your LRS PageCenterX EC2 instance. 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**, **Security admin**, **Groups**. 4. In the Groups section, open the context (right-click) menu for the **Import only** group, and then choose **Advance**, **Security**. 5. On the **Folder Security Records (ImportOnly)** page, choose the **User** tab. 6. On the User tab, under **Name**, select user **VPS1** from the dropdown list, and choose **Apply**.	Cloud architect

Task	Description	Skills required
Configure LRS/DIS with AWS Managed Microsoft AD for the LRS VPSX/MFI EC2 instance.	1. Connect to your LRS VPSX/MFI EC2 instance. 2. On the Windows **Start** menu, open **VPSX Web Interface**. 3. In the navigation pane, choose **Security**, and then choose **Configure**. 4. On the **Security Configura tion** page, in the **Security Parameters** section, for **Security Type**, select **LRS/DIS (External)**. 5. Enter your preferences for the rest of the options in the Security Parameters section. 6. On the Windows **Start** menu, open the **LRS Output Management** folder, choose **Server Start**, and then choose **Server Stop**. 7. Log in to LRS VPSX/MFI with your Active Directory username and password.	Cloud architect

Configure Amazon FSx for Windows File Server as the operational data store for LRS PageCenterX

Task	Description	Skills required
Create a file system for LRS PageCenterX.	To use Amazon FSx for Windows File Server as an operational data store for LRS PageCenterX in a Multi-AZ environment, follow the instructions in [Step 1: Create your file system]().	Cloud architect
Map the file share to the LRS PageCenterX EC2 instance.	To map the file share created in previous step to the LRS PageCenterX EC2 instance, follow the instructions in [Step 2: Map your file share to an EC2 instance running Windows Server]().	Cloud architect
Map LRS PageCenterX Control Directory and Master Folder Directory to the Amazon FSx network share drive.	1. Connect to your LRS PageCenterX EC2 instance by following the instructi ons in the [Amazon EC2 documentation](). 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In **Folder Explorer**, choose **Admin**, **Configuration**. 4. On the Configuration page, choose **Directories**, and then choose **Control Directory**.	Cloud architect

Task	Description	Skills required
	5. In **Control Directories**, enter `\\FSx file share DNS name\share\cntl` . 6. In **Master Folder Directory**, enter `\\FSx file share DNS name\share\mstr` .	

Test an output-management workflow

Task	Description	Skills required
Initiate a batch print request from the Rocket Software BankDemo app.	1. Open the 3270-terminal emulator in your Rocket Enterprise Server EC2 instance. 2. Connect to the BankDemo app by running the command `connect 127.0.0.1:9278` . 3. On the BankDemo command line interface, for **User id**, enter **B0001**. For **Password**, enter a non-blank key. 4. For the **Request printed statement(s)** option, enter **X** on the blank line. 5. In the **Send statement by** section, for **Mail**, enter **Y**, and then press F10.	Test engineer
Check the print output in LRS PageCenterX.	1. Connect to your LRS PageCenterX EC2 instance	Test engineer

Task	Description	Skills required
	by following the instructions in the [Amazon EC2 documentation](). 2. On the Windows **Start** menu, open **PCX Web Interface**. 3. In the navigation pane, open the **Test** folder, open the **STD** folder, and then open the folder with the job run date, such as `08-03-2023` (MM-DD-YYYY). **Note** This is the same folder structure as defined in the story *Create a rule to route the output document to a specific folder in LRS PageCenterX*. 4. Open the `formtest-STD.txt` file. You can now see the print output of an account statement with columns for **Account No.**, **Description**, **Date**, **Amount**, and **Balance**. For an example, see the `batch_pri`	

Task	Description	Skills required
	nt_output attachment for this pattern.

- Modernize your mainframe batch printing workloads on AWS (AWS Prescriptive Guidance)

Additional information

Considerations

During your modernization journey, you might consider a wide variety of configurations for mainframe batch and online processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform might incorporate the IBM AFP data stream or Xerox LCDS into the current workflow. Additionally, mainframe carriage control characters and channel command words can affect the look of the printed page and might need special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

Print data capture

Rocket Software Print Exit passes the necessary information for LRS VPSX/MFI to effectively process the spool file. The information consists of fields passed in the relevant control blocks, such as the following:

- JOBNAME
- OWNER (USERID)
- DESTINATION

- FORM
- FILENAME
- WRITER

LRS VPSX/MFI supports the following mainframe batch mechanisms for capturing data from Rocket Enterprise Server:

- BATCH COBOL print/spool processing using standard z/OS JCL SYSOUT DD/OUTPUT statements.
- BATCH COBOL print/spool processing using standard z/OS JCL CA-SPOOL SUBSYS DD statements.
- IMS/COBOL print/spool processing using the CBLTDLI interface. For a full list of supported methods and programming examples, see the LRS documentation that's included with your product license.

Printer-fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep-dive health checks for printer fleets, see the LRS documentation that's included with your product license.

Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or a Lightweight Directory Access Protocol (LDAP) server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks—for example, command-level security such as hold or release, purge, modify, copy, and reroute. Security can be set up by either the user-ID or the group, similar to an Active Directory security group or an LDAP group.

Modernize mainframe batch printing workloads on AWS by using Rocket Enterprise Server and LRS VPSX/MFI

Shubham Roy and Kevin Yung, Amazon Web Services

Abraham Rondon, Micro Focus

Guy Tucker, Levi, Ray and Shoup Inc

Summary

This pattern shows you how to modernize your business-critical mainframe batch printing workloads on the Amazon Web Services (AWS) Cloud by using Rocket Enterprise Server as a runtime for a modernized mainframe application and LRS VPSX/MFI (Micro Focus Interface) as a print server. The pattern is based on the [replatform](#) mainframe modernization approach. In this approach, you migrate your mainframe batch jobs to Amazon Elastic Compute Cloud (Amazon EC2) and migrate your mainframe database, such as IBM DB2 for z/OS, to Amazon Relational Database Service (Amazon RDS). The authentication and authorization for the modernized print workflow is performed by AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD. The LRS Directory Information Server (LRS/DIS) is integrated with AWS Managed Microsoft AD. By modernizing your batch printing workloads, you can reduce IT infrastructure costs, mitigate the technical debt of maintaining legacy systems, remove data silos, increase agility and efficiency with a DevOps model, and take advantage of on-demand resources and automation in the AWS Cloud.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A mainframe printing or output management workload
- Basic knowledge of how to rebuild and deliver a mainframe application that runs on Rocket Enterprise Server (For more information, see the Rocket Enterprise Server data sheet in the Rocket documentation.)
- Basic knowledge of LRS cloud printing solutions and concepts
- Rocket Enterprise Server software and license (For more information, contact Rocket sales.)
- LRS VPSX/MFI, LRS/Queue, and LRS/DIS software and licenses (For more information, contact LRS sales.)

Note

For more information about configuration considerations for mainframe batch printing workloads, see *Considerations* in the Additional information section of this pattern.

Product versions

- Rocket Enterprise Server 6.0 (product update 7)
- LRS VPSX/MFI V1R3 or higher

Architecture

Source technology stack

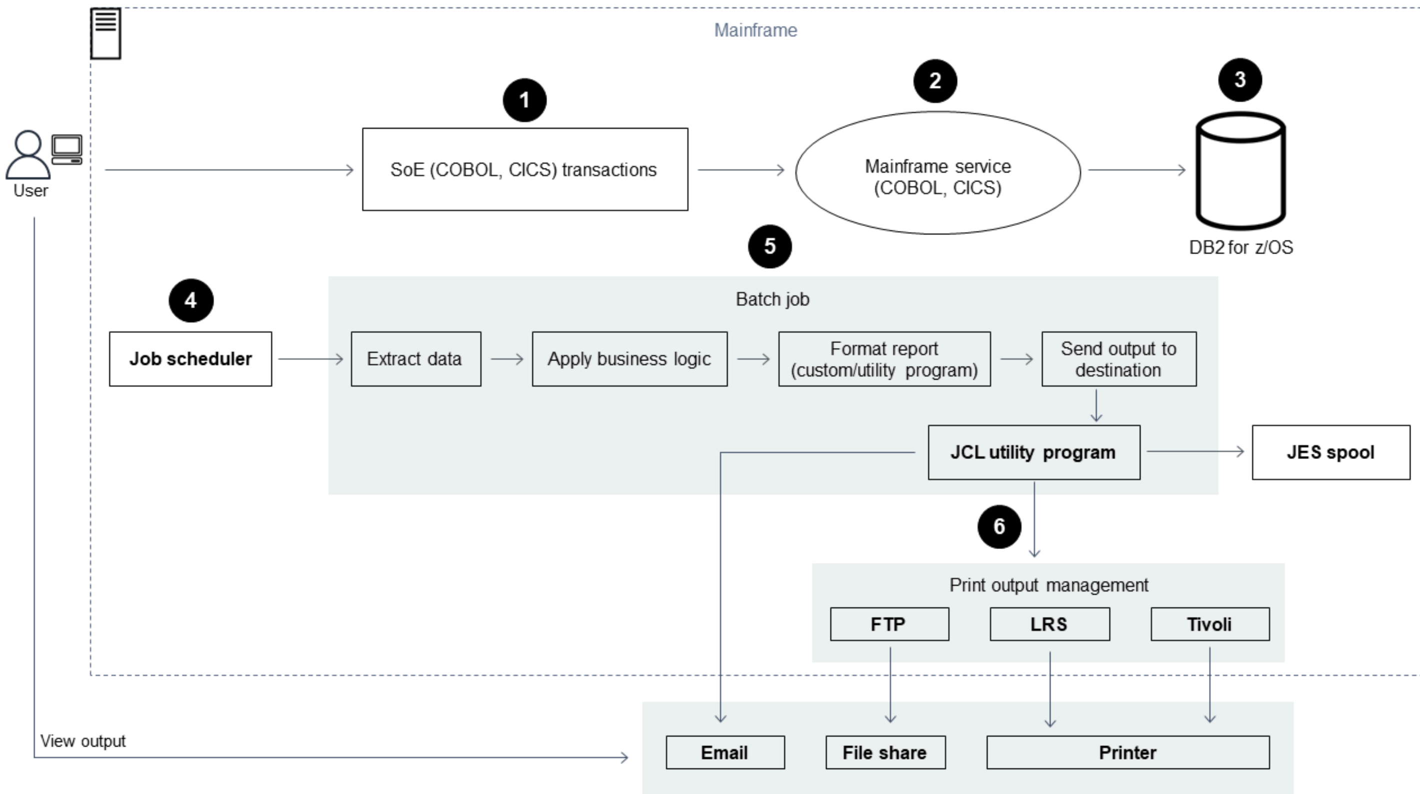
- Operating system – IBM z/OS
- Programming language – Common Business-Oriented Language (COBOL), job control language (JCL), and Customer Information Control System (CICS)
- Database – IBM DB2 for z/OS and Virtual Storage Access Method (VSAM)
- Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
- Printing and output management – IBM mainframe z/OS printing products (IBM Tivoli Output Manager for z/OS, LRS, and CA View)

Target technology stack

- Operating system – Microsoft Windows Server running on Amazon EC2
- Compute – Amazon EC2
- Programming language – COBOL, JCL, and CICS
- Database – Amazon RDS
- Security – AWS Managed Microsoft AD
- Printing and output management – LRS printing solution on AWS
- Mainframe runtime environment – Rocket Enterprise Server

Source architecture

The following diagram shows a typical current state architecture for a mainframe batch printing workload:

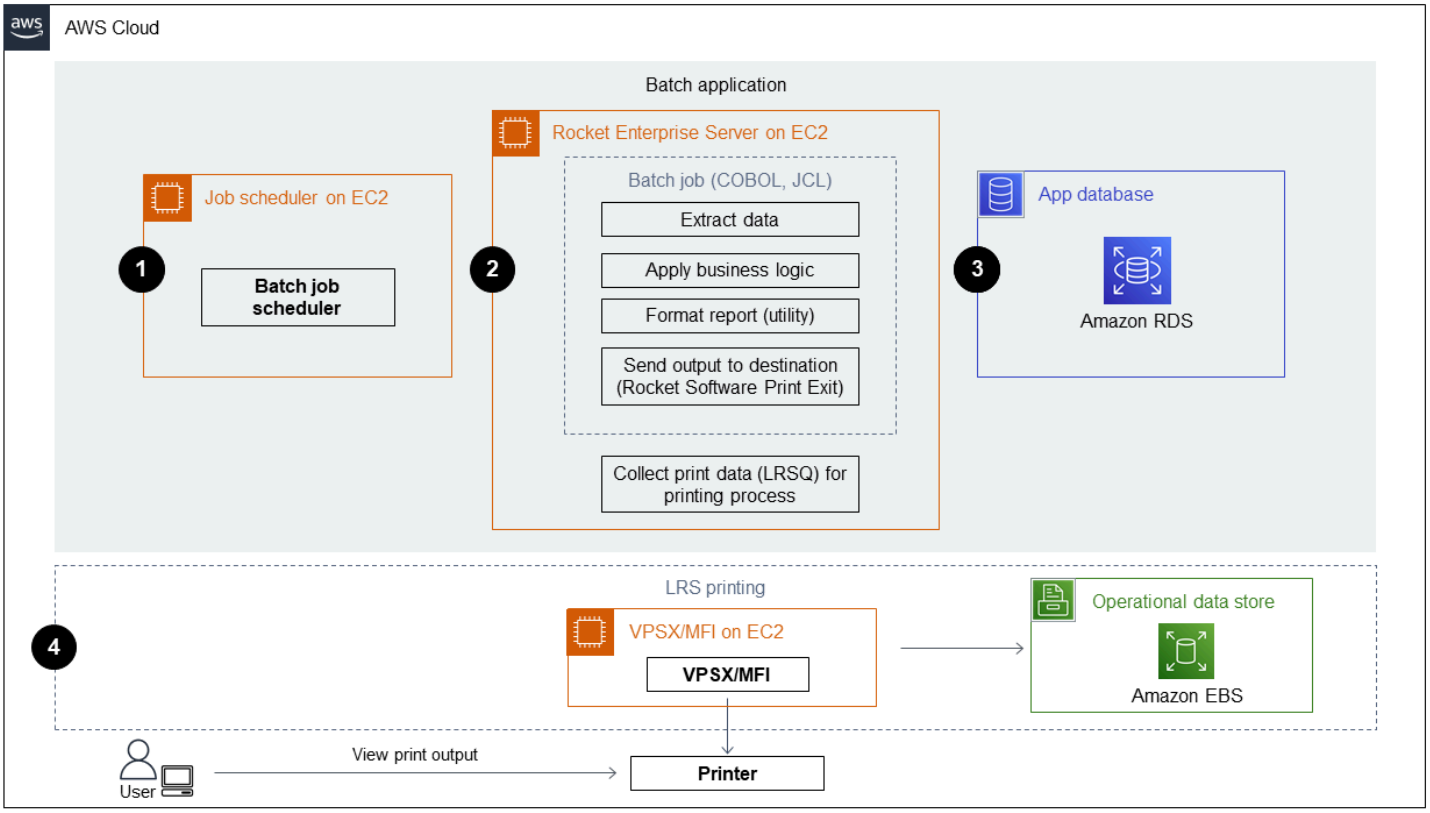


The diagram shows the following workflow:

1. Users perform business transactions on a system of engagement (SoE) that's built on an IBM CICS application written in COBOL.
2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM DB2 for z/OS.
3. The SoR persists the business data from the SoE.
4. The batch job scheduler initiates a batch job to generate print output.
5. The batch job extracts data from the database, formats the data according to business requirements, and then generates business output such as billing statements, ID cards, or loan statements. Finally, the batch job routes the output to printing output management for processing and output delivery, based on the business requirements.
6. Printing output management receives print output from the batch job, and then delivers that output to a specified destination, such as email, a file share that uses secure FTP, a physical printer that uses LRS printing solutions (as demonstrated in this pattern), or IBM Tivoli.

Target architecture

The following diagram shows an architecture for a mainframe batch printing workload that's deployed in the AWS Cloud:



The diagram shows the following workflow:

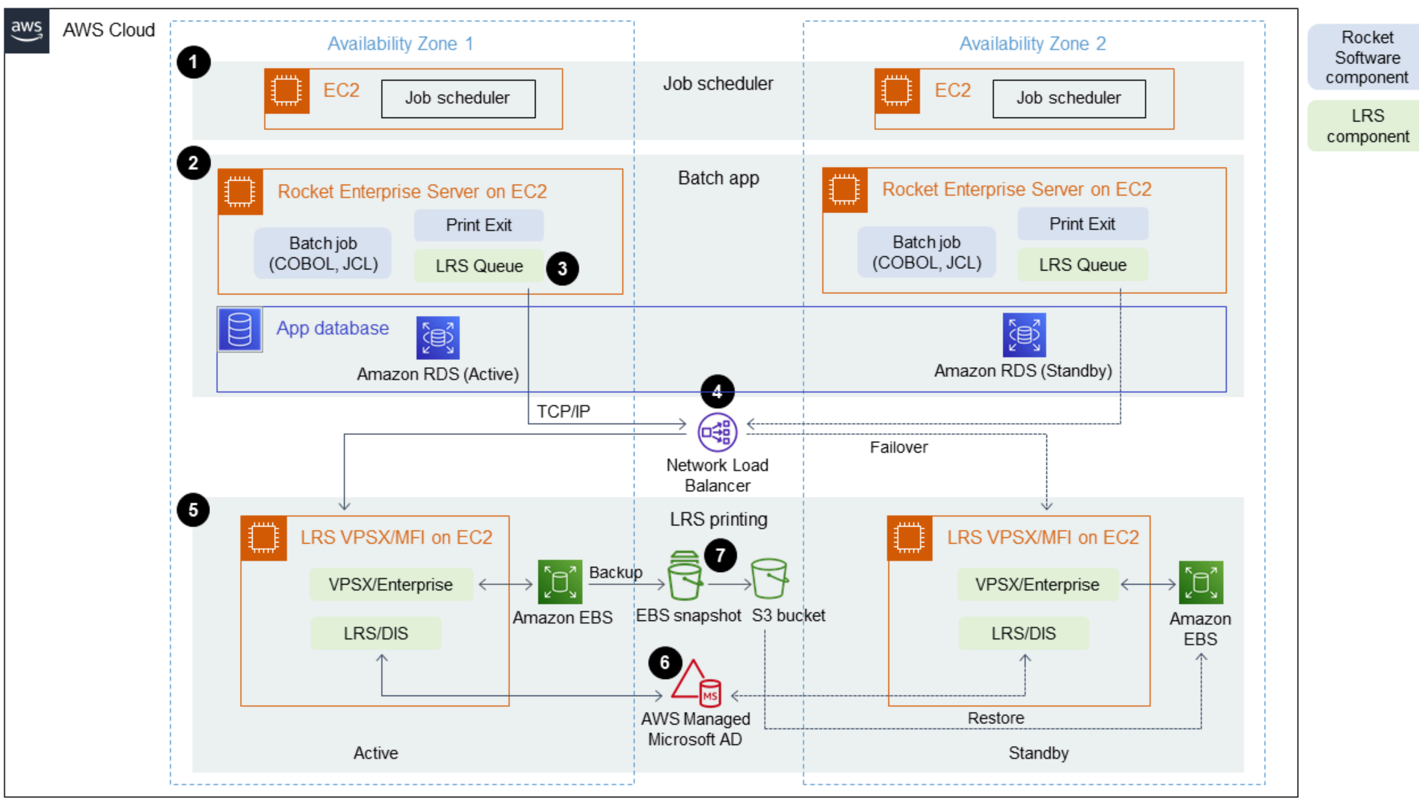
1. The batch job scheduler initiates a batch job to create print output, such as billing statements, ID cards, or loan statements.
2. The mainframe batch job (replatformed to Amazon EC2) uses the Rocket Enterprise Server runtime to extract data from the application database, apply business logic to the data, format the data, and then send the data to a print destination by using Rocket Software Print Exit (Micro Focus documentation).
3. The application database (an SoR that runs on Amazon RDS) persists data for print output.
4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2 and its operational data is stored in Amazon Elastic Block Store (Amazon EBS). LRS VPSX/MFI uses the TCP/IP-based LRS/Queue transmission agent to collect print data through the Rocket Software JES Print Exit API and deliver the data to a specified printer destination.

Note

The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM Advanced Function Presentation (AFP) or Xerox Line Condition Data Stream (LCDS). For more information about using Rocket Software for mainframe application migration and modernization on AWS, see the Empowering Enterprise Mainframe Workloads on AWS with Micro Focus blog post.

AWS infrastructure architecture

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe batch printing workload:



The diagram shows the following workflow:

1. The batch scheduler initiates the batch process and is deployed on Amazon EC2 across multiple Availability Zones for high availability (HA).

> **Note**
>
> This pattern doesn't cover the implementation of the batch scheduler. For more information about implementation, see the software vendor documentation for your scheduler.

2. The mainframe batch job (written on a programming language such as JCL or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The job is deployed on Amazon EC2 across two Availability Zones for HA and uses Rocket Software Print Exit to route print output to LRS VPSX/MFI for end-user printing.
3. LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data from the Rocket Software JES Print Exit programming interface. Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the spool file and dynamically build LRS/Queue commands. The commands are then run using a standard built-in function from Rocket Software.

> **Note**
>
> For more information on print data passed from Rocket Software Print Exit to LRS/Queue and LRS VPSX/MFI supported mainframe batch mechanisms, see *Print data capture* in the Additional information section of this pattern.

4. > **Note**
   >
   > A Network Load Balancer provides a DNS name to integrate Rocket Enterprise Server with LRS VPSX/MFI. : LRS VPSX/MFI supports a Layer 4 load balancer. The Network Load Balancer also does a basic health check on LRS VPSX/MFI and routes traffic to the registered targets that are healthy.

5. > **Note**
   >
   > The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA and uses Amazon EBS as an operational data store. LRS VPSX/MFI supports both the active-active and active-passive service modes. This architecture uses multiple AZs in an active-passive pair as an active and hot standby. The Network Load Balancer performs a health check on LRS VPSX/MFI EC2 instances and routes traffic to hot

standby instances in the other AZ if an active instance is in an unhealthy state. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of recovery, a failed instance has to be restarted for the LRS services to resume processing the print request. : LRS VPSX/MFI can also perform health checks at the printer fleet level. For more information, see *Printer fleet health checks* in the Additional information section of this pattern.

6. AWS Managed Microsoft AD integrates with LRS/DIS to perform print workflow authentication and authorization. For more information, see *Print authentication and authorization* in the Additional information section of this pattern.
7. LRS VPSX/MFI uses Amazon EBS for block storage. You can back up Amazon EBS data from active EC2 instances to Amazon S3 as point-in-time snapshots and restore them to hot standby EBS volumes. To automate the creation, retention, and deletion of Amazon EBS volume snapshots, you can use Amazon Data Lifecycle Manager to set the frequency of automated snapshots and restore them based on your RTO/RPO requirements.

Tools

AWS services

- Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for a relational database and manages common database administration tasks.
- AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD, enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.

Other tools

- LRS VPSX/MFI (Micro Focus Interface), co-developed by LRS and Rocket Software, captures output from a Rocket Enterprise Server JES spool and reliably delivers it to a specified print destination.
- LRS Directory Information Server (LRS/DIS) is used for authentication and authorization during the print workflow.
- TCP/IP-based LRS/Queue transmission agent is used by LRS VPSX/MFI to collect or capture print data through the Rocket Software JES Print Exit programming interface.
- Rocket Enterprise Server is an application deployment environment for mainframe applications. It provides the execution environment for mainframe applications that are migrated or created by using any version of Rocket Software Enterprise Developer.

Epics

Set up Rocket Enterprise Server on Amazon EC2 and deploy a mainframe batch application

Task	Description	Skills required
Set up Rocket Enterprise Server and deploy a demo application.	Set up Rocket Enterpris e Server on Amazon EC2, and then deploy the Rocket Software BankDemo demonstration application on Amazon EC2. The BankDemo application is a mainframe batch applicati on that creates and then initiates print output.	Cloud architect

Set up an LRS print server on Amazon EC2

Task	Description	Skills required
Get an LRS product license for printing.	To get an LRS product license for LRS VPSX/MFI, LRS/ Queue, and LRS/DIS, contact	Build lead

Task	Description	Skills required
	the LRS Output Management team. You must provide the host names of the EC2 instances where the LRS products will be installed.	

Task	Description	Skills required
Create an Amazon EC2 Windows instance to install LRS VPSX/MFI.	Launch an Amazon EC2 Windows instance by following the instructions from [Launch an Amazon EC2 instance](#) in the Amazon EC2 documentation. Your instance must meet the following hardware and software requirements for LRS VPSX/MFI: • CPU – Dual Core • RAM – 16 GB • Drive – 500 GB • Minimum EC2 instance – m5.xlarge • OS – Windows/Linux • Software – Internet Information Service (IIS) or Apache **Note** The preceding hardware and software requirements are intended for a small printer fleet (around 500–1000). To get the full requirements, consult with your LRS and AWS contacts.	Cloud architect

Task	Description	Skills required
	When you create your Windows instance, do the following: 1. Confirm that the EC2 host name is the same host name used for the LRS product license. 2. Enable CGI in Amazon EC2 by completing the following: a. Connect to your EC2 instance by following the instructions from	

Task	Description	Skills required
Install LRS VPSX/MFI on the EC2 instance.	1. Connect to your EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. **Note** Open the link to the product download page from the LRS email that you should receive. : LRS products are distributed by electronic file transfer (EFT). 3. Download LRS VPSX/MFI and unzip the file (default folder: `c:\LRS`). 4. Launch the LRS Product Installer from the unzipped folder to install LRS VPSX/MFI. 5. In the **Select Features** menu, select **VPSX® Server (V1R3.022)**, and then choose **Next** to start the installation process. You will receive a success message when installation is complete.	Cloud architect

Task	Description	Skills required
Install LRS/Queue.	1. Connect to your Rocket Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/Queue, and then unzip the file. 3. Go to the location where you downloaded the files, and then launch the LRS product installer to install LRS/Queue.	Cloud architect

Task	Description	Skills required
Install LRS/DIS.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructi ons from [Step 2: Connect to your instance](#) in the Amazon EC2 documenta tion. 2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/DIS, and then unzip the file. 3. Go to the location where you downloaded the files, and then launch the LRS Product Installer. 4. In the LRS Product Installer , expand **LRS Misc Tools**, select **LRS DIS**, and then choose **Next**. 5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.	Cloud architect

Task	Description	Skills required
Create a target group and register LRS VPSX/MFI EC2 as the target.	Create a target group by following the instructions from [Create a target group for your Network Load Balancer](#) in the Elastic Load Balancing documentation. When you create the target group, do the following: 1. On the **Specify group details** page, for **Choose a Target Type**, choose **Instances**. 2. For **Protocol**, choose **TCP**. 3. For **Port**, choose **5500**. 4. On the **Register targets** page, in the **Available instances** section, select the LRS VPSX/MFI EC2 instances.	Cloud architect

Task	Description	Skills required
Create a Network Load Balancer.	Follow the instructions from [Create a Network Load Balancer](#) in the Elastic Load Balancing documentation. Your Network Load Balancer routes traffic from Rocket Enterprise Server to LRS VPSX/MFI EC2. When you create the Network Load Balancer, do the following on the **Listeners and Routing** page: 1. For **Protocol**, choose **TCP**. 2. For **Port**, choose **5500**. 3. For **Default action**, choose **Forward to** for the target group that you created earlier.	Cloud architect

Integrate Rocket Enterprise Server with LRS VPSX/MFI and LRS/Queue

Task	Description	Skills required
Configure Rocket Enterpris e Server for LRS/Queue integration.	1. Connect to your Rocket Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. In the Windows Start menu, open the Rocket	Cloud architect

Task	Description	Skills required
	Enterprise Server Administration UI. 3. In the menu bar, choose **NATIVE**. 4. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO**. 5. From **General** in the left navigation pane, scroll down to the **Additional** section to configure the environment variables (LRSQ_ADDRESS, LRSQ_PORT, LRSQ_COMMAND) to point to LRSQ. 6. For **LRSQ_ADDRESS**, enter the IP address or DNS name of the Network Load Balancer that you created earlier. 7. For **LRSQ_PORT**, enter **VPSX LRSQ Listener Port (5500)**. 8. For **LRSQ_COMMAND**, enter the path location of the LRSQ executable. **Note** LRS currently supports a maximum character limit of	

Task	Description	Skills required
	50 for DNS names, but this is subject to change in the future. If your DNS name is greater than 50, then you can use the IP address of the Network Load Balancer as an alternative.	

Task	Description	Skills required
Configure Rocket Enterpris e Server for LRS VPSX/MFI integration.	1. Copy the `VPSX_MFI_R2` folder from the LRS VPSX/MFI installer to the Rocket Enterprise Server location at `C\BANKDEMO\print` . 2. Connect to your Rocket Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 3. In the Windows Start menu, open the Rocket Enterprise Server Administr ation UI. 4. In the menu bar, choose **NATIVE**. 5. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO**. 6. Under **BANKDEMO**, choose **JES**. 7. Under **JES Program Path**, add the `DLL(VPSX_ MFI_R2)` path from the `C\BANKDEMO\print` location.	Cloud architect

Set up printers and print users in Rocket Enterprise Server and LRS VPSX/MFI

Task	Description	Skills required
Associate the Rocket Software Print Exit module to the Rocket Enterprise Server batch printer Server Execution Process.	1. Connect to your Rocket Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. In the Windows Start menu, open the Rocket Enterprise Server Administration UI. 3. In the menu bar, choose **NATIVE**. 4. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO**. 5. Under **BANKDEMO**, choose **JES**, and scroll down to **Printers**. 6. In **Printers**, associate the Rocket Software Print Exit module (LRSPRTE6 for Batch) to the Rocket Enterprise Server batch printer Server Execution Process (SEP). This allows print output routing to LRS VPSX/MFI. 7. Sign in to the Enterprise Server Administration UI.	Cloud architect

Task	Description	Skills required
	For more information about configuration, see Using the Exit in the Micro Focus documentation.	

Task	Description	Skills required
Add a printer in LRS VPSX/MFI.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. Open the VPSX Web Interface from the Windows Start menu. 3. In the navigation pane, choose **Printers**. 4. Choose **Add**, and then choose **Add Printer**. 5. On the **Printer Configuration** page, for **Printer Name**, enter **Local**. 6. For **VPSX ID**, enter **VPS1**. 7. For **CommType**, select **TCPIP/LRSQ**. 8. For **Host/IP Address**, enter the IP address of the physical printer that you want to add. 9. For **Device**, enter the name of your device. 10. Choose either **Windows Driver** or **Linux/Mac Driver**. 11. Choose **Add**.	Cloud architect

Task	Description	Skills required
Create a print user in LRS VPSX/MFI.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. Open the VPSX Web Interface from the Windows Start menu. 3. In the navigation pane, choose **Security**, and then choose **Users**. 4. In the **User Name** column, choose **admin**, and then choose **Copy**. 5. In the **User Profile Maintenance** window, for **User Name**, enter a user name (for example, **PrintUser**). 6. For **Description**, enter a brief description (for example, **User for test print**). 7. Choose **Update**. This creates a print user (for example, **PrintUser**). 8. In the navigation pane, under **User**, choose the new user that you created. 9. From the **Command** menu, choose **Security**.	Cloud architect

Task	Description	Skills required
	10. On the **Security Rules** page, choose all the applicable printer security and job security options, and then choose **Save**. 11. To add your new print user to the **Administrator** group, go to the navigation pane, choose **Security**, and then choose **Configure**. 12. In the **Security configuration** window, add your new print user to the **Administrator** column.	

Set up print authentication and authorization

Task	Description	Skills required
Create an AWS Managed Microsoft AD domain with users and groups.	1. Create an Active Directory on AWS Managed Microsoft AD by following the instructions from [Create your AWS Managed Microsoft AD directory](#) in the AWS Directory Service documentation. 2. Deploy an EC2 instance (Active Directory manager) and install Active Directory tools to manage your AWS Managed Microsoft AD by following the instructions from [Step 3: Deploy an EC2](#)	Cloud architect

Task	Description	Skills required
	[instance to manage your AWS Managed Microsoft AD](#) in the AWS Directory Service documentation. 3. **Note** Connect to your EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documenta tion. : When you connect to the EC2 instance, enter your administrator credentials (for the directory that you created in step one) in the Windows Security window. 4. In the Windows Start menu, under **Windows Administrative Tools**, choose **Active Directory Users and Computers**. 5. Create a print user in the Active Directory domain by following the steps from [Create a user](#) in the	

Task	Description	Skills required
	AWS Directory service documentation.	
Join LRS VPSX/MFI EC2 to an AWS Managed Microsoft AD domain.	Join LRS VPSX/MFI EC2 to your AWS Managed Microsoft AD domain automatically (AWS Knowledge Center documentation) or manually (AWS Directory Service documentation).	Cloud architect

Task	Description	Skills required
Configure and integrate LRS/DIS with AWS Managed Microsoft AD.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. In the Windows Start menu, open the VPSX Web Interface. 3. In the navigation pane, choose **Security**, and then choose **Configure**. 4. On the **Security Configuration** page, in the **Security Parameters** section, for **Security Type**, select **Internal**. 5. Enter your preferences for the rest of the options in the **Security Parameters** section. 6. Open the **LRS Output Management** folder from the Microsoft Windows Start menu, choose **Server Start**, and then choose **Server Stop**. 7. Log in to LRS VPSX/MFI with your Active Directory user name and password.	Cloud architect

Test a print workflow

Task	Description	Skills required
Initiate a batch print request from the Rocket Software BankDemo app.	1. Open the 3270 terminal emulator in your Rocket Enterprise Server EC2 instance. 2. Connect to the BankDemo app by running the following command: `connect 127.0.0.1:9278` 3. On the BankDemo command line interface, for **User id**, enter **B0001**. For **Password**, enter a non-blank key. 4. For the **Request printed statement(s)** option, enter **X** on the blank line. 5. In the **Send statement by** section, for **Mail**, enter **Y**, and then press F10.	Test engineer
Check the print output in LRS VPSX/MFI.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. In Windows Start menu, open the VPSX Web Interface.	Test engineer

Task	Description	Skills required
	3. In the navigation pane, choose **Printers**, and then choose **Output Queue**. 4. In the **Spool ID** column, choose the spool ID for the request in the printer queue. 5. On the **Actions** tab, in the **COMMAND** column, choose **Browse**. You can now see the print output of an account statement with columns for **Account No.**, **Descripti on**, **Date**, **Amount**, and **Balance**. For an example, see the **batch_print_output** attachment for this pattern.	

Related resources

- LRS Output Modernization (LRS documentation)
- ANSI and machine carriage controls (IBM documentation)
- Channel command words (IBM documentation)

- Line Conditioned Data Stream (LCDS) (Compart documentation)

Additional information

Considerations

During your modernization journey, you may consider a wide variety of configurations for both mainframe batch processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform may incorporate the IBM Advanced Function Presentation (AFP) or the Xerox Line Condition Data Stream (LCDS) into the current workflow. Additionally, mainframe carriage control characters and channel command words can affect the look of the printed page and may need special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

Print data capture

Rocket Software Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the spool file. The information consists of fields passed in the relevant control blocks, such as:

- JOBNAME
- OWNER (USERID)
- DESTINATION
- FORM
- FILENAME
- WRITER

LRS VPSX/MFI supports the following mainframe batch mechanisms for capturing data from Rocket Enterprise Server.

- BATCH COBOL print/spool processing using standard z/OS JCL SYSOUT DD/OUTPUT statements
- BATCH COBOL print/spool processing using standard z/OS JCL CA-SPOOL SUBSYS DD statements
- IMS/COBOL print/spool processing using the CBLTDLI interface (For a full list of supported methods and programming examples, see the LRS documentation that's included with your product license.)

Printer fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep dive health checks for printer fleets, see the LRS documentation that's included with your product license.

Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or an LDAP server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks. For example, command-level security such as hold/release, purge, modify, copy, and reroute. Security can be set up by either the User-ID or Group (similar to AD group or LDAP group).

Mainframe modernization: DevOps on AWS with Rocket Software Enterprise Suite

Kevin Yung, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

Customer challenges

Organizations that run core applications on mainframe hardware usually encounter a few challenges when the hardware needs to scale up to meet the demands of digital innovations. These challenges include the following constraints.

- Mainframe development and test environments are unable to scale due to the inflexibility of mainframe hardware components and the high cost of changing.
- Mainframe development is facing skill shortages, because new developers are not familiar and not interested in the traditional mainframe development tools. Modern technology such as containers, continuous integration/continuous delivery (CI/CD) pipelines, and modern test frameworks are not available in mainframe development.

Pattern outcomes

To address these challenges, Amazon Web Services (AWS) and Rocket Software Micro Focus, an AWS Partner Network (APN) Partner, have collaborated to create this pattern. The solution is designed to help you achieve the following outcomes.

- Improved developer productivity. Developers can be given new mainframe development instances within minutes.
- Use of the AWS Cloud to create new mainframe test environments with virtually unlimited capacity.
- Rapid provisioning of new mainframe CI/CD infrastructure. Provisioning on AWS can be completed within an hour by using AWS CloudFormation and AWS Systems Manager.
- Native use of AWS DevOps tools for mainframe development, including AWS CodeBuild, AWS CodeCommit, AWS CodePipeline, AWS CodeDeploy, and Amazon Elastic Container Registry (Amazon ECR).

- Transform traditional waterfall development to agile development in mainframe projects.

Technologies summary

In this pattern, the target stack contains the following components.

Logical components	Implementation solutions	Description
Source code repositories	Rocket Software AccuRev Server, CodeCommit, Amazon ECR	Source code management – The solution uses two types of source code: • Mainframe source code, for example, COBOL and JCL. • AWS infrastructure templates and automation scripts Both types of source code need version control, but they are managed in different SCMs. Source code deployed into mainframe or Rocket Software Enterprise Servers is managed in Rocket Software Micro Focus AccuRev Server. AWS templates and automation scripts are managed in CodeCommit. Amazon ECR is used for the Docker image repositories.
Enterprise developer instances	Amazon Elastic Compute Cloud (Amazon EC2), Rocket Software Enterprise Developer for Eclipse	Mainframe developers can develop code in Amazon EC2 by using Rocket Software Enterprise Developer for Eclipse. This eliminates the

		need to rely on mainframe hardware to write and test code.
Rocket Software Enterprise Suite license management	Rocket Software Enterprise Suite License Manager	For centralized Rocket Software Enterprise Suite license management and governance, the solution uses Rocket Software Enterprise Suite License Manager to host the required license.
CI/CD pipelines	CodePipeline, CodeBuild, CodeDeploy, Rocket Software Enterprise Developer in a container, Rocket Software Enterprise Test Server in a container, Rocket Software Micro Focus Enterprise Server	Mainframe developme nt teams need CI/CD pipelines to perform code compilation, integration tests, and regression tests. In AWS, CodePipeline and CodeBuild can work with Rocket Software Enterprise Developer and Enterprise Test Server in a container natively.

Prerequisites and limitations

Prerequisites

Name	Description
py3270	py3270 is a Python interface to x3270, an IBM 3270 terminal emulator. It provides an API to a x3270 or s3270 subprocess.
x3270	x3270 is an IBM 3270 terminal emulator for the X Window System and Windows. This can be used by developer for unit testing locally.

Robot-Framework-Mainframe-3270-Library	Mainframe3270 is a library for Robot Framework based on py3270 project.
Rocket Software Verastream	Rocket Software Verastream is an integrati on platform that enables testing mainframe assets the way that mobile apps, web applicati ons, and SOA web services are tested.
Rocket Software Unified Functional Testing (UFT) installer and license	Rocket Software Unified Functional Testing is software that provides functional and regression test automation for software applications and environments.
Rocket Software Enterprise Server installer and license	Enterprise Server provides the runtime environment for mainframe applications.
Rocket Software Enterprise Test Server installer and license	Rocket Software Enterprise Test Server is an IBM mainframe application test environment.
Rocket Software AccuRev installer and license for Server, and Rocket Software Micro Focus AccuRev installer and license for Windows and Linux operating systems	AccuRev provides source code management (SCM). The AccuRev system is designed for use by a team of people who are developing a set of files.
Rocket Software Enterprise Developer for Eclipse installer, patch and license	Enterprise Developer provide mainframe developer a platform to develop and maintain the core mainframe online and batch applicati ons.

Limitations

- Building a Windows Docker image is not supported in CodeBuild. This reported issue needs support from Windows Kernel/HCS and Docker teams. The work-around is to create a Docker image build runbook by using Systems Manager. This pattern uses the work-around to build Rocket Software Enterprise Developer for Eclipse and Rocket Software Micro Focus Enterprise Test Server Container images.

- Virtual private cloud (VPC) connectivity from CodeBuild is not supported in Windows yet, so the pattern does not use Rocket Software License Manager to manage licenses in OpenText Rocket Software Enterprise Developer and Rocket Software Enterprise Test Server containers.

Product versions

- Rocket Software Enterprise Developer 5.5 or later
- Rocket Software Enterprise Test Server 5.5 or later
- Rocket Software Enterprise Server 5.5 or later
- Rocket Software AccuRev 7.x or later
- Windows Docker base image for Rocket Software Enterprise Developer and Enterprise Test Server: **microsoft/dotnet-framework-4.7.2-runtime**
- Linux Docker base image for AccuRev client: **amazonlinux:2**

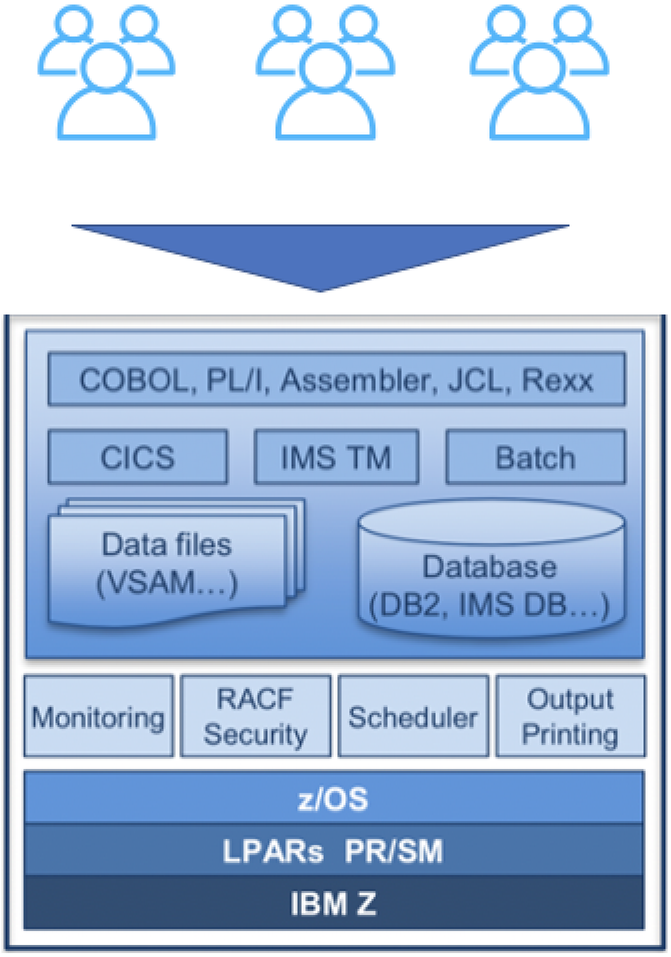
Architecture

Mainframe environment

In conventional mainframe development, the developers need to use mainframe hardware to develop and test programs. They face capacity limitations, for example restricted million instructions per second (MIPS) for the dev/test environment, and they must rely on the tools that are available on the mainframe computers.

In many organizations, mainframe development follows the waterfall development methodology, with teams relying on long cycles to release changes. These release cycles are usually longer than digital product development.

The following diagram shows multiple mainframe projects sharing mainframe hardware for their development. In mainframe hardware, it is expensive to scale out a development and test environment for more projects.



AWS **architecture**

This pattern extends mainframe development to the AWS Cloud. First, it uses AccuRev SCM to host the mainframe source code on AWS. Then it makes Enterprise Developer and Enterprise Test Server available for building and testing the mainframe code on AWS.

The following sections describe the pattern's three major components.

1. SCM

In AWS, the pattern uses AccuRev to create a set of SCM workspaces and version control for the mainframe source code. Its stream-based architecture enables parallel mainframe development for multiple teams. To merge a change, AccuRev uses the promote concept. To add that change to other workspaces, AccuRev uses the update concept.

At the project level, each team can create one or more streams in AccuRev to track project level changes. These are called project streams. These project streams are inherited from the same parent stream. The parent stream is used to merge the changes from different project streams.

Each project stream can promote code to AccuRev, and a promote post trigger is set up to initiate the AWS CI/CD pipeline. The successful build for a project stream change can be promoted to its parent stream for more regression tests.

Usually, the parent stream is called the system integration stream. When there is a promotion from a project stream to a system integration stream, a post promotion trigger initiates another CI/CD pipeline to run regression tests.

In addition to mainframe code, this pattern includes AWS CloudFormation templates, Systems Manager Automation documents, and scripts. Following infrastructure-as-code best practices, they are version-controlled in CodeCommit.

If you need to synchronize mainframe code back to a mainframe environment for deployment, Rocket Software provides the Enterprise Sync solution, which synchronizes code from the AccuRev SCM back to the mainframe SCM.

2. Developer and test environments

In a large organization, scaling more than a hundred or even more than a thousand mainframe developers is challenging. To address this constraint, the pattern uses Amazon EC2 Windows instances for development. On the instances, Enterprise Developer for Eclipse tools are installed. The developer can perform all mainframe code test and debugging locally on the instance.

AWS Systems Manager State Manager and Automation documents are used to automate the developer instance provisioning. The average time to create a developer instance is within 15 minutes. The following software and configurations are prepared:

- AccuRev Windows client for checking out and committing source code into AccuRev
- Enterprise Developers for Eclipse tool, for writing, testing, and debugging mainframe code locally
- Open source testing frameworks Python behavior-driven development (BDD) test framework Behave, py3270, and the x3270 emulator for creating scripts to test applications
- A Docker developer tool for building the Enterprise Test Server Docker image and testing the application in the Enterprise Test Server Docker container

In the development cycle, developers use the EC2 instance to develop and test mainframe code locally. When the local changes are tested successfully, developers promote the change into the AccuRev server.

3. CI/CD pipelines

In the pattern, CI/CD pipelines are used for integration tests and regression tests before deployment to the production environment.

As explained in the SCM section, AccuRev uses two types of streams: a project stream and an integration stream. Each stream is hooked up with CI/CD pipelines. To perform the integration between the AccuRev server and AWS CodePipeline, the pattern uses AccuRev post promotion script to create an event to initiate CI/CD.

For example, when a developer promotes a change to a project stream in AccuRev, it initiates a post promotion script to run in AccuRev Server. Then the script uploads the metadata of the change into an Amazon Simple Storage Service (Amazon S3) bucket to create an Amazon S3 event. This event will initiate a CodePipeline configured pipeline to run.

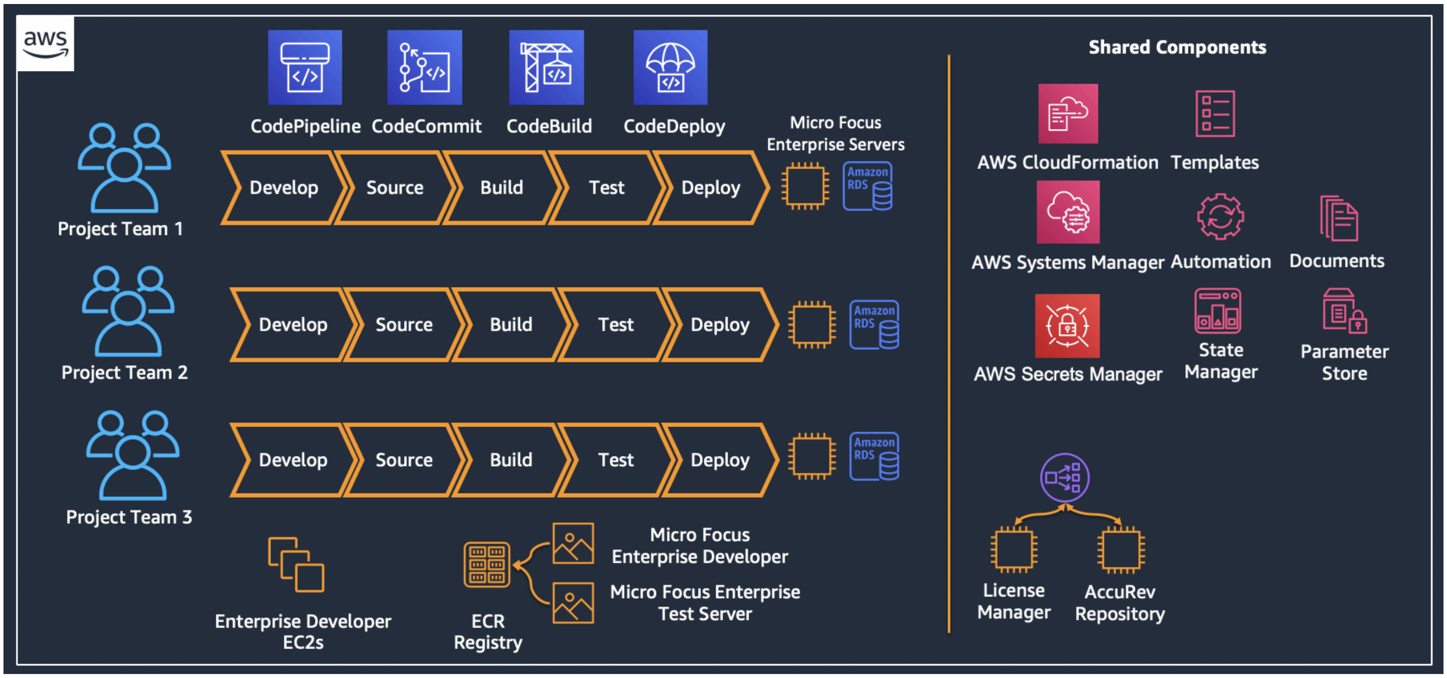
The same event-initiating mechanism is used for the integration stream and its associated pipelines.

In the CI/CD pipeline, CodePipeline uses CodeBuild with the AccuRev Linux client container to check out the latest code from the AccuRev streams. Then the pipeline starts CodeBuild to use the Enterprise Developer Windows container to compile the source code, and to use the Enterprise Test Server Windows container in CodeBuild to test mainframe applications.

The CI/CD pipelines are built using CloudFormation templates, and the blueprint will be used for new projects. By using the templates, it takes less than an hour for a project to create a new CI/CD pipeline in AWS.

To scale your mainframe test capability on AWS, the pattern builds out the Rocket Software DevOps test suite, Verastream and UFT server. By using the modern DevOps tools, you can run as many tests on AWS as you need.

An example mainframe development environment with Rocket Software on AWS is shown in the following diagram.



Target technology stack

This section provides a closer look at the architecture of each component in the pattern.

1. Source code repository – AccuRev SCM

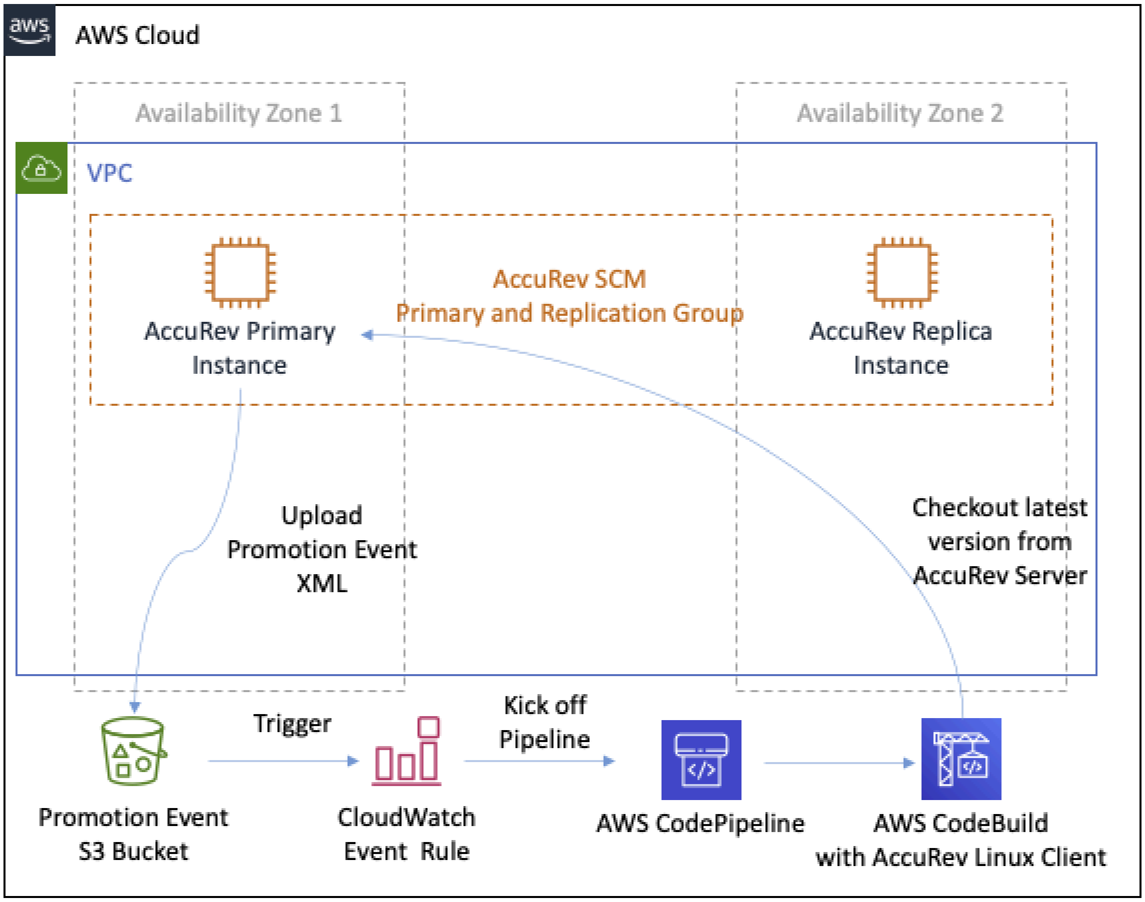
AccuRev SCM is set up to manage mainframe source code versions. For high availability, AccuRev supports primary and replica modes. Operators can fail over to the replica when performing maintenance on the primary node.

To speed up the response of the CI/CD pipeline, the pattern uses Amazon CloudWatch Events to detect source code changes and initiate the start of the pipeline.

1. The pipeline is set up to use an Amazon S3 source.
2. A CloudWatch Events rule is set up to capture S3 events from a source S3 bucket.
3. The CloudWatch Events rule sets a target to the pipeline.
4. AccuRev SCM is configured to run a post promotion script locally after promotion is complete.
5. AccuRev SCM generates an XML file that contains the metadata of the promotion, and the script uploads the XML file to the source S3 bucket.
6. After the upload, the source S3 bucket sends events to match the CloudWatch Events rule, and the CloudWatch Events rule initiates the pipeline to run.

When the pipeline runs, it kicks off a CodeBuild project to use an AccuRev Linux client container to check out the latest mainframe code from an associated AccuRev stream.

The following diagram shows an AccuRev Server setup.



2. Enterprise Developer template

The pattern uses Amazon EC2 templates to simplify creation of the developer instance. By using State Manager, it can apply software and license settings to EC2 instances consistently.

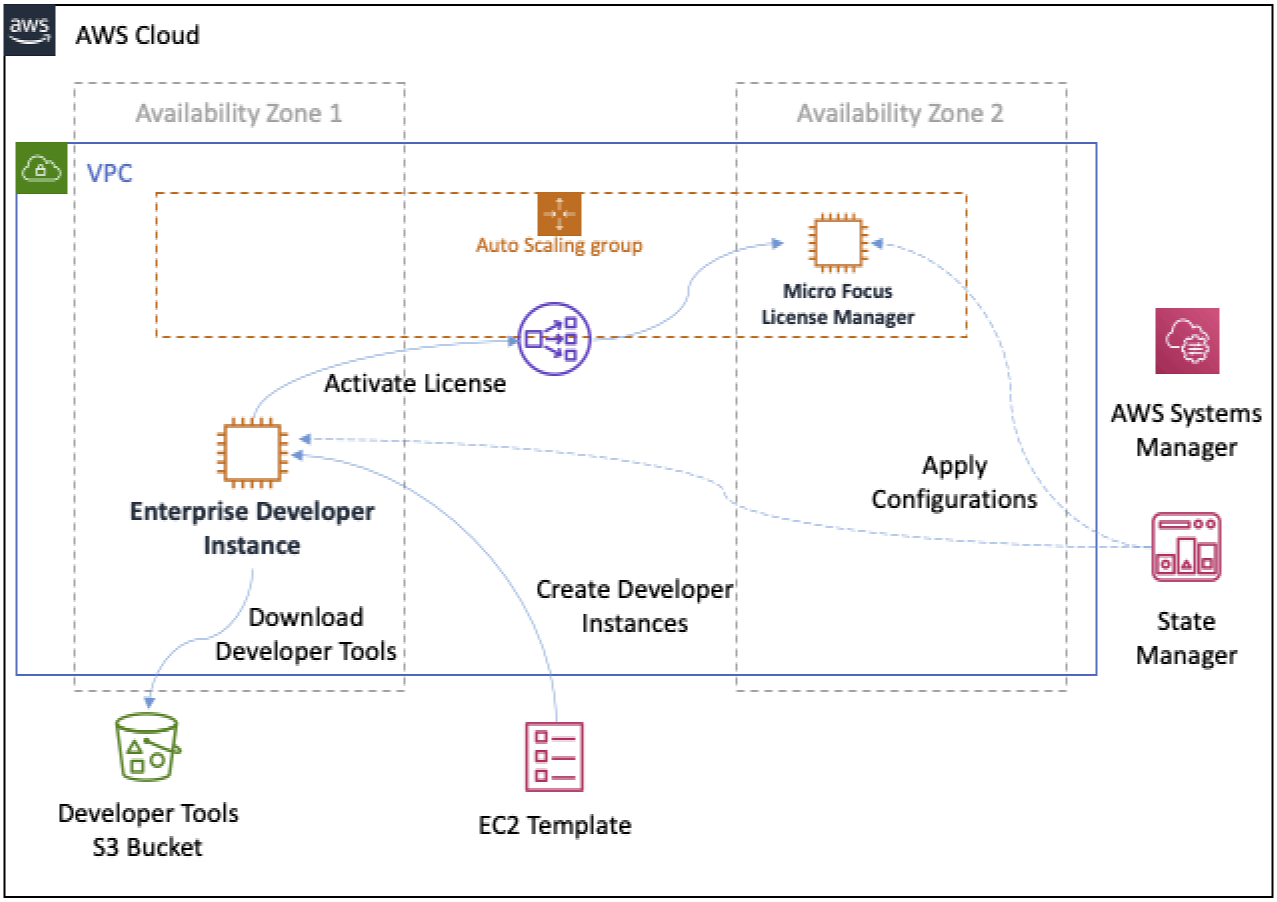
The Amazon EC2 template builds in its VPC context settings and default instance settings, and it follows enterprise tagging requirements. By using a template, a team can create their own new development instances.

When a developer instance starts, by associating with tags, Systems Manager uses State Manager to apply automation. The automation includes the following general steps.

1. Install Enterprise Developer software and install patches.
2. Install the AccuRev client for Windows.

3. Install the pre-configured script for developers to join the AccuRev stream. Initialize Eclipse workspaces.
4. Install development tools, including x3270, py3270, and Docker.
5. Configure license settings to point to a License Manager load balancer.

The following diagram shows an Enterprise developer instance created by the Amazon EC2 template, with software and configuration applied to the instance by State Manager. Enterprise developer instances connect to AWS License Manager to activate their license.



3. CI/CD pipelines

As explained in the AWS architecture section, in the pattern, there are project-level CI/CD pipelines and system integration pipelines. Each mainframe project team creates a pipeline or multiple CI/CD pipelines for building the programs that they are developing in a project. These project CI/CD pipelines check out source code from an associated AccuRev stream.

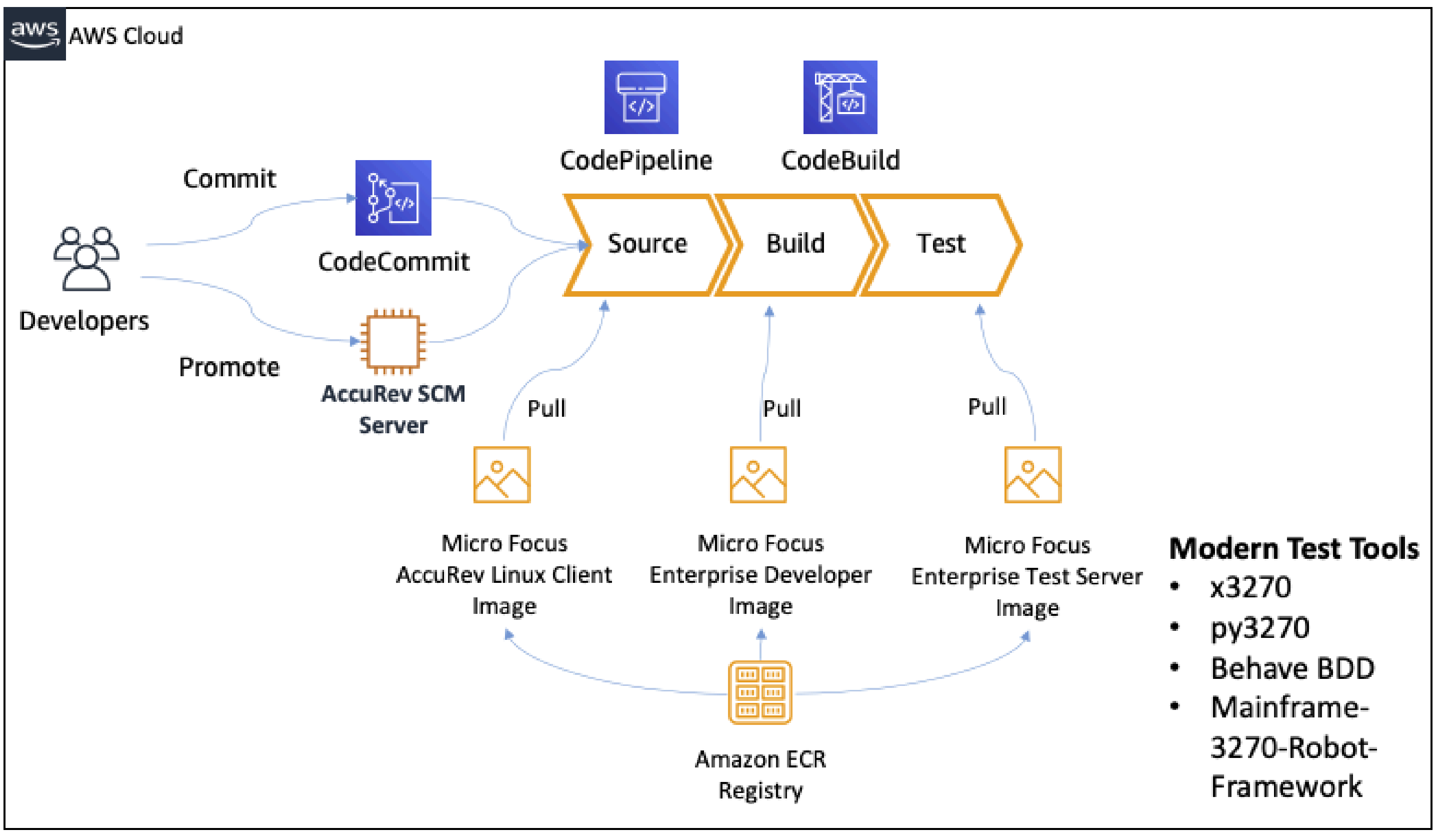
In a project team, developers promote their code in the associated AccuRev stream. Then the promotion initiates the project pipeline to build the code and run integration tests.

Each project CI/CD pipeline uses CodeBuild projects with the Enterprise Developer tool Amazon ECR image and Enterprise Test Server tool Amazon ECR image.

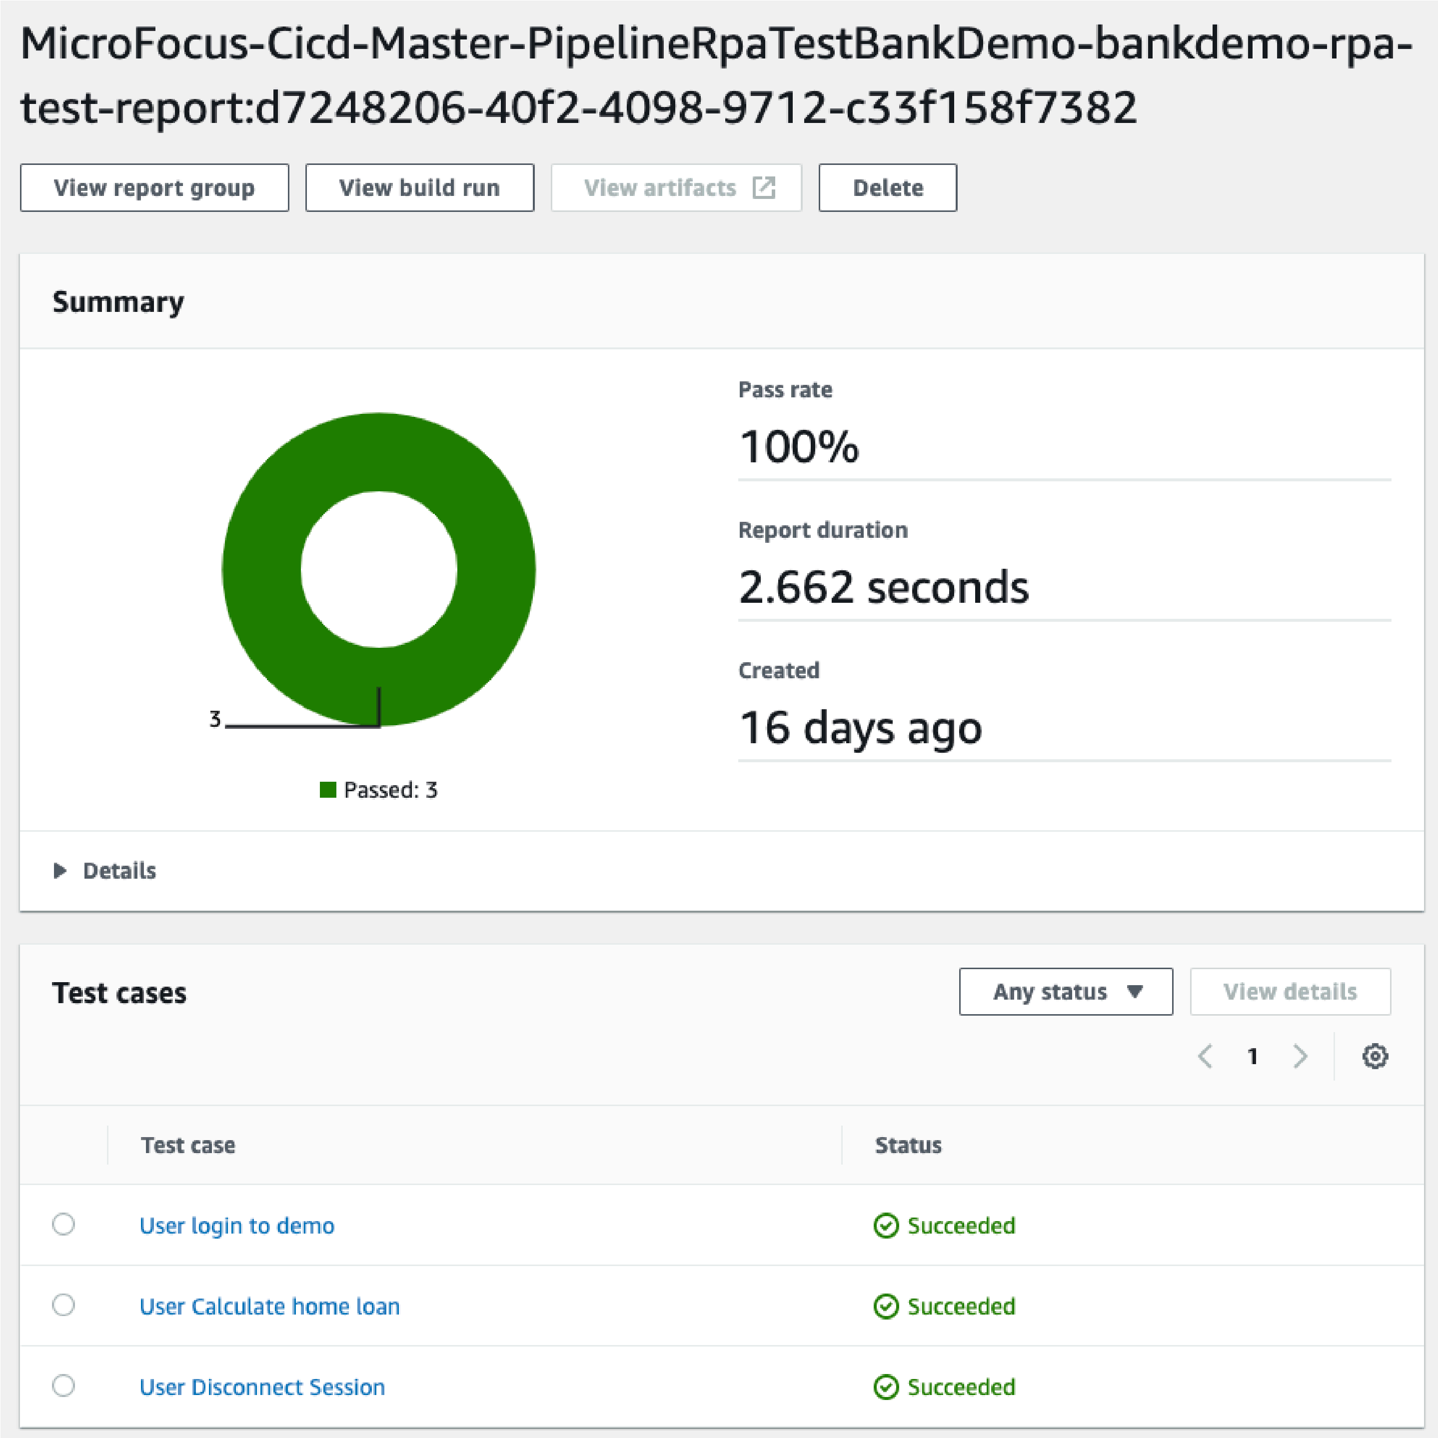
CodePipeline and CodeBuild are used to create the CI/CD pipelines. Because CodeBuild and CodePipeline have no upfront fees or commitments, you pay only for what you use. Compared to mainframe hardware, the AWS solution greatly reduces hardware provisioning lead time and lowers the cost of your testing environment.

In modern development, multiple test methodologies are used. For example, test-driven development (TDD), BDD, and Robot Framework. With this pattern, developers can use these modern tools for mainframe testing. For example, by using x3270, py3270 and the Behave python test tool, you can define an online application's behavior. You can also use build mainframe 3270 robot framework in these CI/CD pipelines.

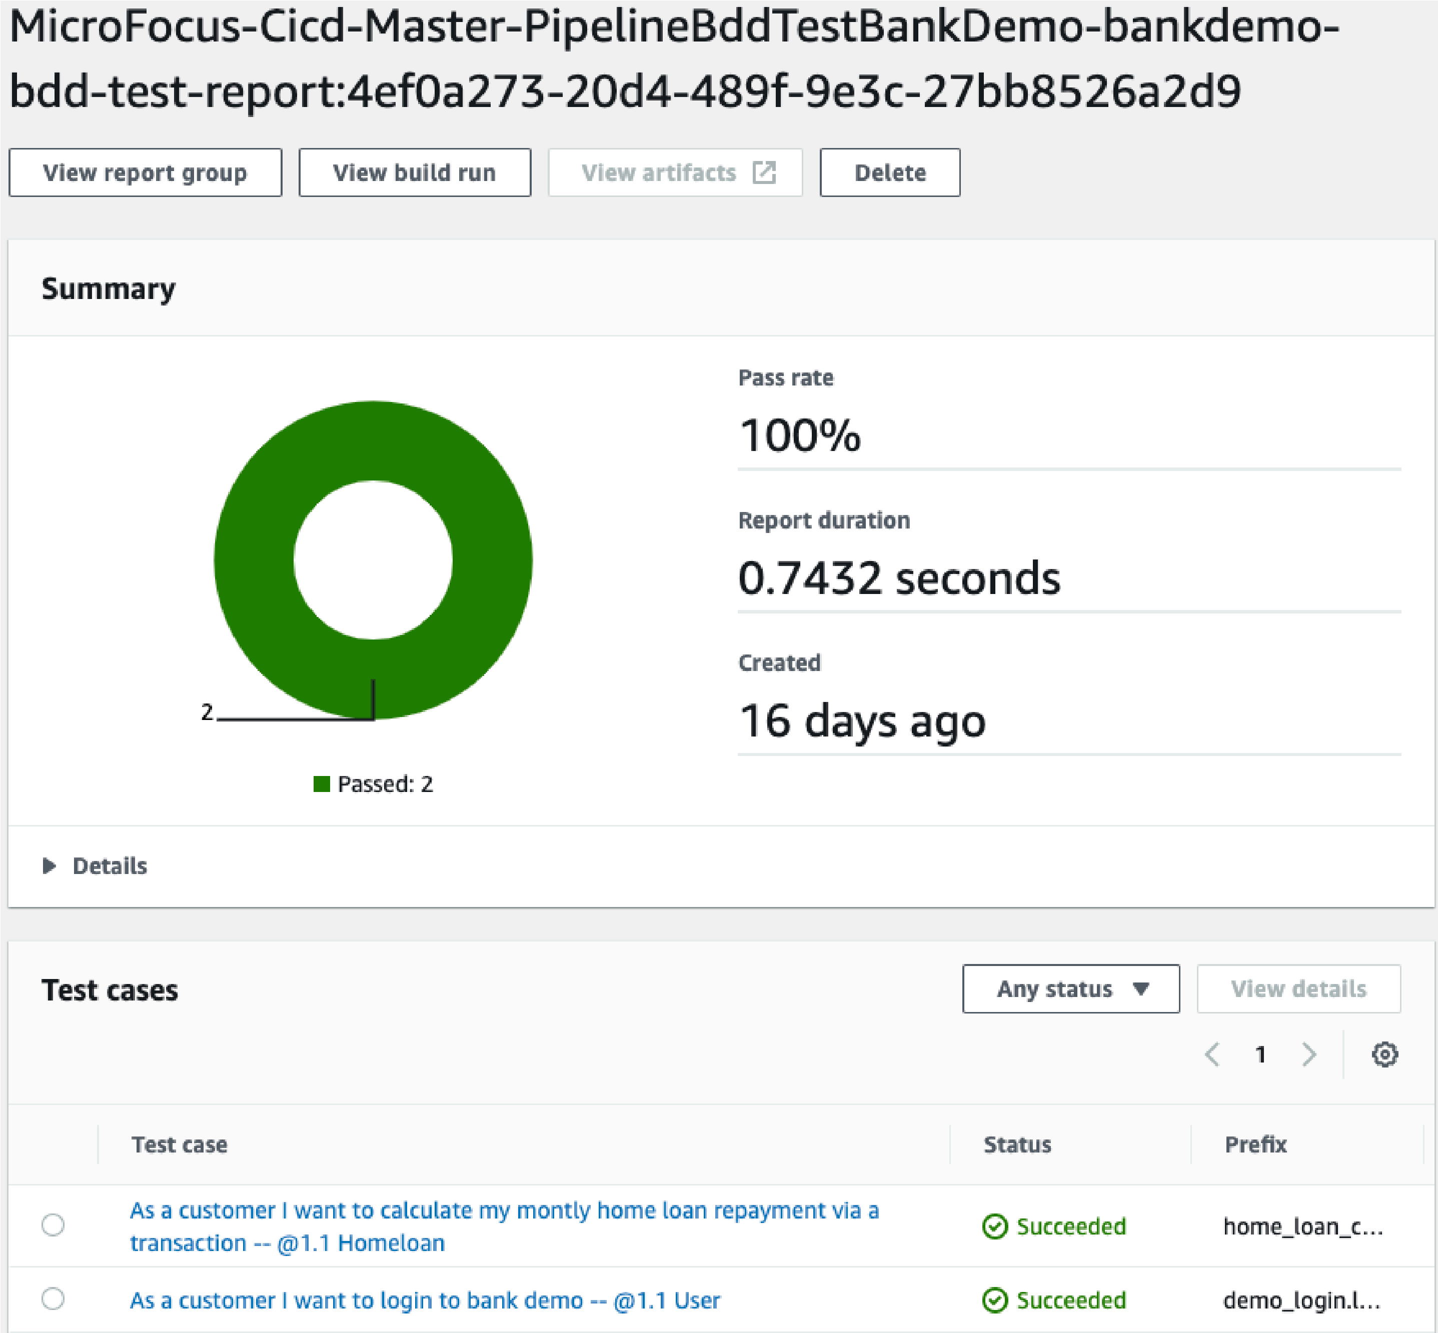
The following diagram shows the team stream CI/CD pipeline.



The following diagram shows the project CI/CD test report produced by CodePipeline in Mainframe3270 Robot Framework.



The following diagram shows the project CI/CD test report produced by CodePipeline in Py3270 and Behave BDD.



After project level tests are passed successfully, the tested code is manually promoted to the integration stream in AccuRev SCM. You can automate this step after the teams have a confidence on the tests coverage of their project pipeline.

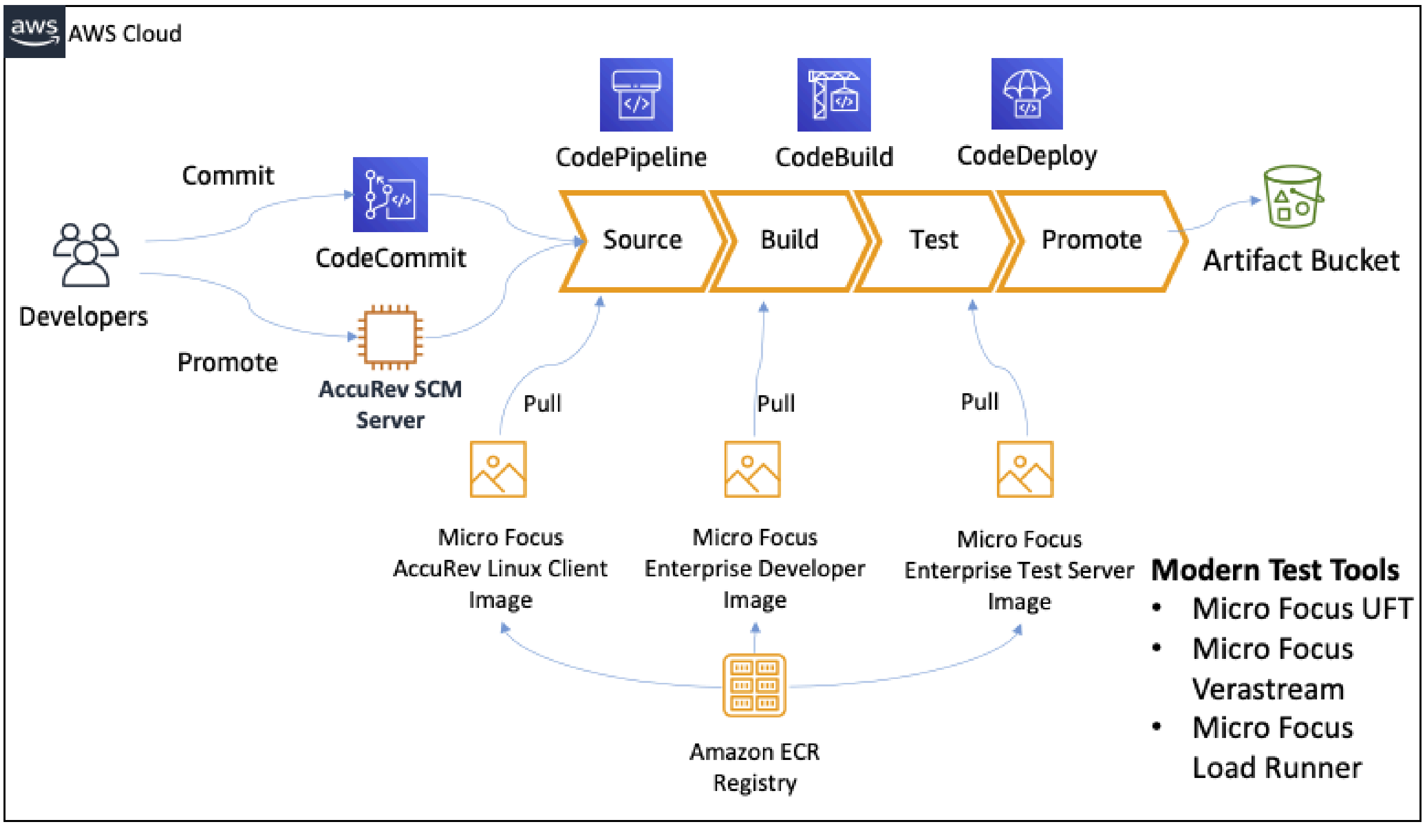
When code is promoted, the system integration CI/CD pipeline checks out the merged code and performs regression tests. The merged code is promoted from all parallel project streams.

Depending on how fine grain the test environment is required, customers can have more system integration CI/CD pipelines in a different environment, for example UAT, Pre-Production.

In the pattern, the tools used in the system integration pipeline are Enterprise Test Server, UFT Server, and Verastream. All these tools can be deployed into the Docker container and used with CodeBuild.

After successfully testing of the mainframe programs, the artifact is stored, with version control, in an S3 bucket.

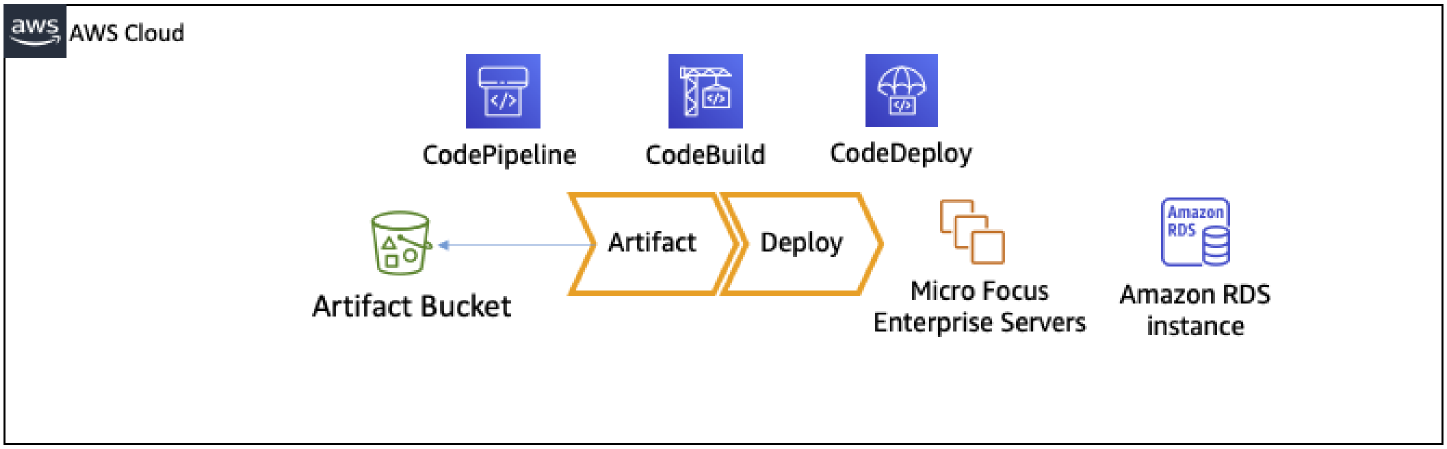
The following diagram shows a system integration CI/CD pipeline.



After the artifact has been successfully tested in the system integration CI/CD pipelines, it can be promoted for production deployment.

If you need to deploy source code back to the mainframe, Rocket Software offers the Enterprise Sync solution to synchronize source code from AccuRev back to Mainframe Endeavour.

The following diagram shows a production CI/CD pipeline deploying the artifact into Enterprise Servers. In this example, CodeDeploy orchestrates the deployment of the tested mainframe artifact into Enterprise Server.



In addition to the architecture walkthrough of the CI/CD pipeline, see the AWS DevOps blog post Automate thousands of mainframe tests on AWS with the Micro Focus Enterprise Suite for more information on testing mainframe applications in CodeBuild and CodePipeline. (Micro Focus is now Rocket Software.) Refer to the blog post for the best practices and details of doing mainframe tests on AWS.

Tools

AWS automation tools

- AWS CloudFormation
- Amazon CloudWatch Events
- AWS CodeBuild
- AWS CodeDeploy
- AWS CodePipeline
- Amazon ECR
- Amazon S3
- AWS Secrets Manager
- AWS Systems Manager

Rocket Software tools

- Rocket Enterprise Developer for Eclipse

- Rocket Enterprise Test Server
- Rocket Enterprise Server (production deployment)
- Rocket Software AccuRev
- Rocket Software Enterprise Suite License Manager
- Rocket Software Verastream Host Integrator
- Rocket Software UFT One

Other tools

- x3270
- py3270
- Robot-Framework-Mainframe-3270-Library

Epics

Create the AccuRev SCM infrastructure

Task	Description	Skills required
Deploy a primary AccuRev SCM server by using CloudFormation.		AWS CloudFormation
Create the AccuRev Administr ator user.	Log in to AccuRev SCM Server, and run the CLI command to create an Administrator user.	AccuRev SCM Server Administrator
Create AccuRev streams.	Create AccuRev streams that inherit from upper streams in sequence: Production, System Integration, Team streams.	AccuRev SCM Administrator
Create the developer AccuRev login accounts.	Use AccuRev SCM CLI commands to create AccuRev users login accounts for mainframe developers.	AccuRev SCM Administrator

Create the Enterprise Developer Amazon EC2 launch template

Task	Description	Skills required
Deploy the Amazon EC2 launch template by using CloudFormation.	Use CloudFormation to deploy an Amazon EC2 launch template for Enterprise Developer instances. The template includes a Systems Manager Automation document for the Rocket Enterprise Developer instance.	AWS CloudFormation
Create the Enterprise Developer instance from the Amazon EC2 template.		AWS Console Login and Mainframe Developer Skills

Create the Enterprise Developer tool Docker image

Task	Description	Skills required
Create the Enterprise Developer tool Docker image.	Use the Docker command and the Enterprise Developer tool Dockerfile to create the Docker image.	Docker
Create the Docker repository in Amazon ECR.	On the Amazon ECR console, create the repository for the Enterprise Developer Docker image.	Amazon ECR
Push the Enterprise Developer tool Docker image to Amazon ECR.	Run the Docker push command to push the Enterprise Developer tool Docker image to save it in the	Docker

Task	Description	Skills required
	Docker repository in Amazon ECR.	

Create the Enterprise Test Server Docker image

Task	Description	Skills required
Create the Enterprise Test Server Docker image.	Use the Docker command and the Enterprise Test Server Dockerfile to create the Docker image.	Docker
Create the Docker repository in Amazon ECR.	On the Amazon ECR console, create the Amazon ECR repository for the Enterprise Test Server Docker image.	Amazon ECR
Push the Enterprise Test Server Docker image to Amazon ECR.	Run the Docker push command to push and save the Enterprise Test Server Docker image in Amazon ECR.	Docker

Create the team stream CI/CD pipeline

Task	Description	Skills required
Create the CodeCommit repository.	On the CodeCommit console, create a Git-based repositor y for infrastructure and CloudFormation code.	AWS CodeCommit
Upload the CloudFormation template and the automatio	Run the Git push command to upload CloudFormation	Git

Modernize mainframe online printing workloads on AWS by using Micro Focus Enterprise Server and LRS VPSX/MFI

Shubham Roy and Kevin Yung, Amazon Web Services

Abraham Rondon, Micro Focus

Guy Tucker, Levi, Ray and Shoup Inc

Summary

This pattern shows you how to modernize your business-critical mainframe online printing workloads on the Amazon Web Services (AWS) Cloud by using Micro Focus Enterprise Server as a runtime for a modernized mainframe application and LRS VPSX/MFI (Micro Focus Interface) as a print server. The pattern is based on the replatform mainframe modernization approach. In this approach, you migrate your mainframe online application to Amazon Elastic Compute Cloud (Amazon EC2) and migrate your mainframe database, such as IBM DB2 for z/OS, to Amazon Relational Database Service (Amazon RDS). The authentication and authorization for the modernized print workflow is performed by AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD. The LRS Directory Information Server (LRS/DIS) is integrated with AWS Managed Microsoft AD for print workflow authentication and authorization. By modernizing your online printing workloads, you can reduce IT infrastructure costs, mitigate the technical debt of maintaining legacy systems, remove data silos, increase agility and efficiency with a DevOps model, and take advantage of on-demand resources and automation in the AWS Cloud.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A mainframe online printing or output management workload
- Basic knowledge of how to rebuild and deliver a mainframe application that runs on Micro Focus Enterprise Server (For more information, see the Enterprise Server data sheet in the Micro Focus documentation.)
- Basic knowledge of LRS cloud printing solutions and concepts (For more information, see Output Modernization in the LRS documentation.)
- Micro Focus Enterprise Server software and license (For more information, contact Micro Focus sales.)

- LRS VPSX/MFI, LRS/Queue, and LRS/DIS software and licenses (For more information, contact LRS sales.)

> **Note**
>
> For more information about configuration considerations for mainframe online printing workloads, see *Considerations* in the *Additional information* section of this pattern.

Product versions

- Micro Focus Enterprise Server 8.0 or later
- LRS VPSX/MFI V1R3 or later

Architecture

Source technology stack

- Operating system – IBM z/OS
- Programming language – Common Business-Oriented Language (COBOL) and Customer Information Control System (CICS)
- Database – IBM DB2 for z/OS IBM Information Management System (IMS) and Virtual Storage Access Method (VSAM)
- Security – Resource Access Control Facility (RACF), CA Top Secret for z/OS, and Access Control Facility 2 (ACF2)
- Printing and output management – IBM mainframe z/OS printing products (IBM Infoprint Server for z/OS, LRS, and CA View)

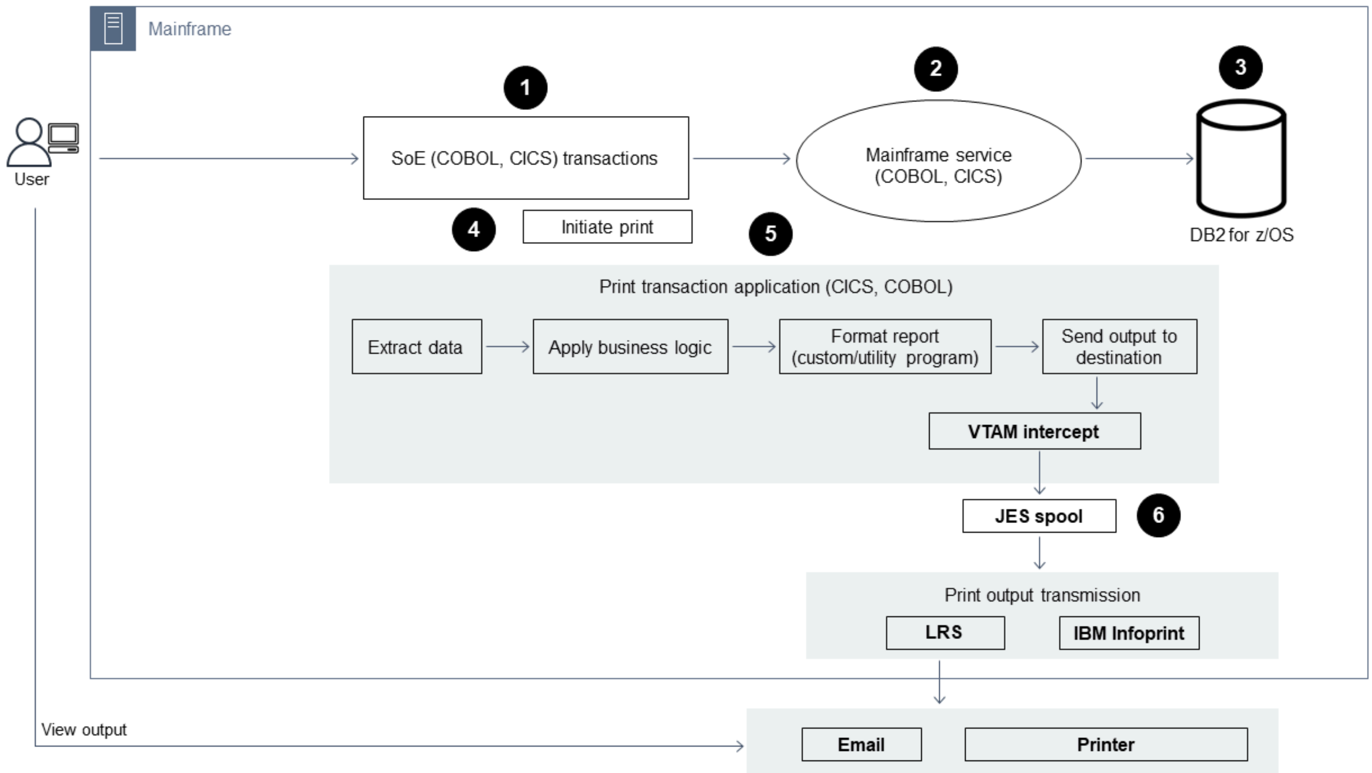
Target technology stack

- Operating system – Microsoft Windows Server running on Amazon EC2
- Compute – Amazon EC2
- Programming language – COBOL and CICS
- Database – Amazon RDS
- Security – AWS Managed Microsoft AD

- Printing and output management – LRS printing solution on AWS
- Mainframe runtime environment – Micro Focus Enterprise Server

Source architecture

The following diagram shows a typical current state architecture for a mainframe online printing workload.



The diagram shows the following workflow:

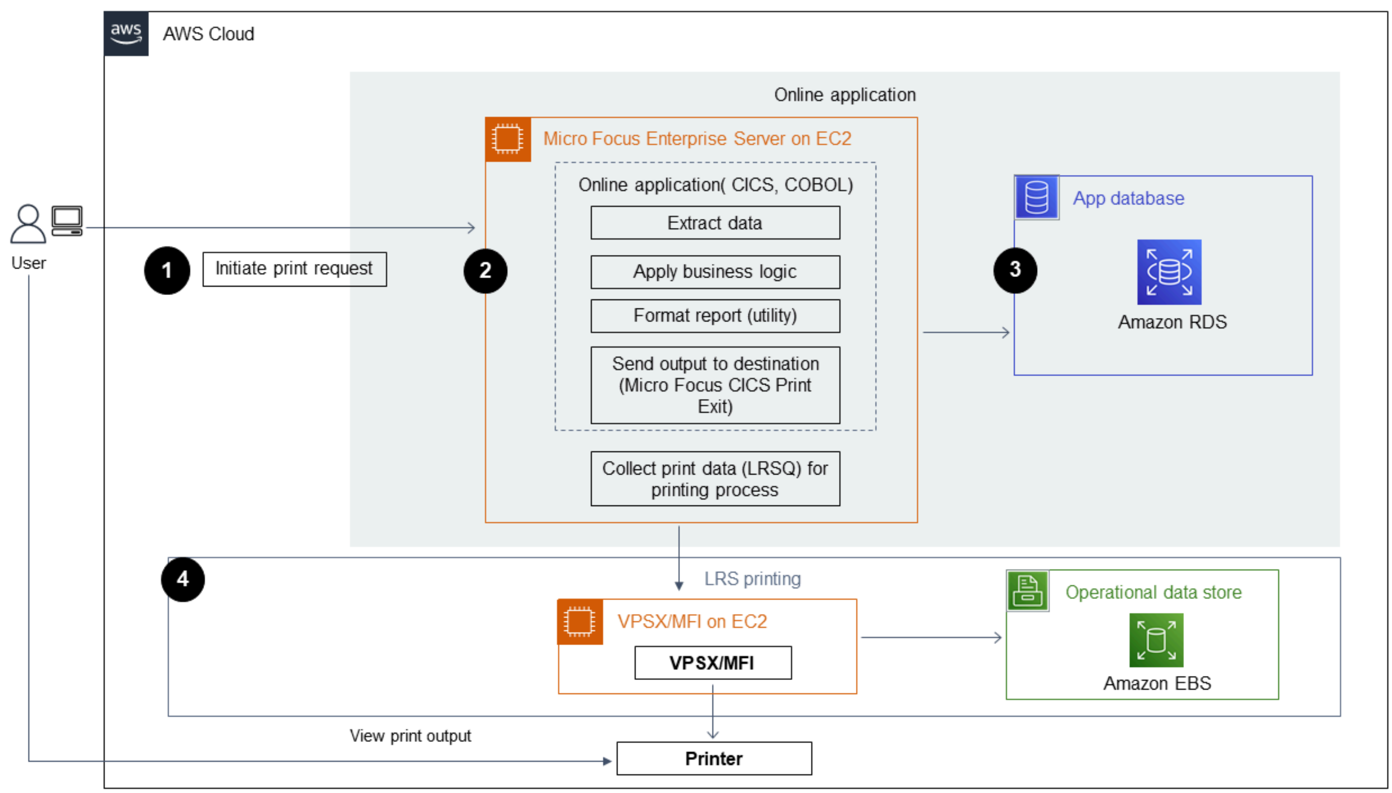
1. Users perform business transactions on a system of engagement (SoE) that's built on an IBM CICS application written in COBOL.
2. The SoE invokes the mainframe service, which records the business transaction data in a system-of-records (SoR) database such as IBM DB2 for z/OS.
3. The SoR persists the business data from the SoE.
4. A user initiates a request to generate print output from the CICS SoE, which initiates a print transaction application to process the print request.
5. The print transaction application (such as a CICS and COBOL program) extracts data from the database, formats the data according to business requirements, and generates business output

(print data) such as billing statements, ID cards, or loan statements. Then, the application sends a print request by using Virtual Telecommunications Access Method (VTAM). A z/OS print server (such as IBM Infoprint Server) uses NetSpool or a similar VTAM component to intercept the print requests, and then creates print output datasets on the JES spool by using JES output parameters. The JES output parameters specify routing information that the print server uses to transmit the output to a particular network printer. The term *VTAM* refers to the z/OS Communications Server and the System Network Architecture (SNA) services element of z/OS.

6. The printing output transmission component transmits the output print datasets from the JES spool to remote printers or print servers, such as LRS (as demonstrated in this pattern), IBM Infoprint Server, or email destinations.

Target architecture

The following diagram shows an architecture for a mainframe online printing workload that's deployed in the AWS Cloud:



The diagram shows the following workflow:

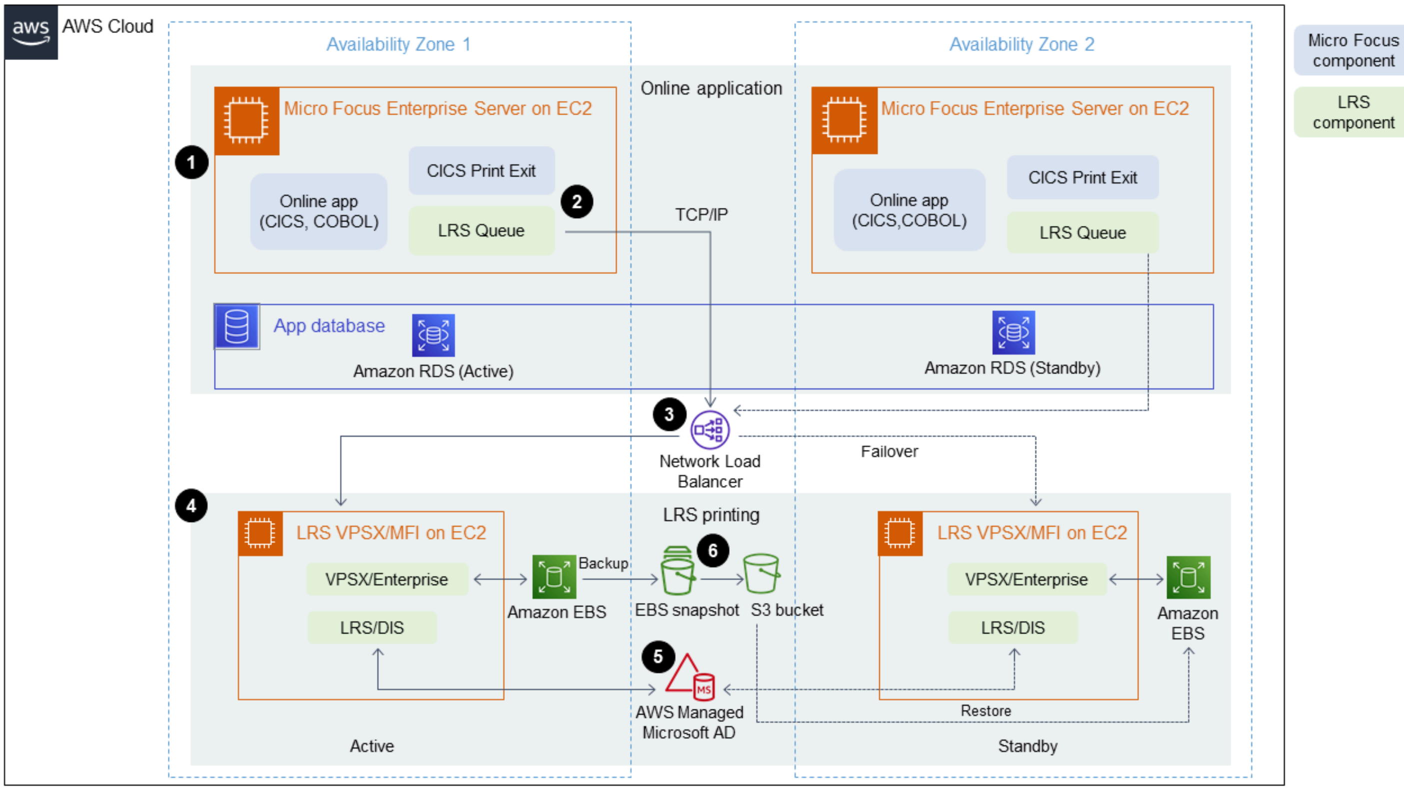
1. A user initiates a print request from an online (CICS) user-interface to create print output, such as billing statements, ID cards, or loan statements.

2. The mainframe online application (replatformed to Amazon EC2) uses the Micro Focus Enterprise Server runtime to extract data from the application database, apply business logic to the data, format the data, and then send the data to a print destination by using Micro Focus CICS Print Exit (DFHUPRNT).
3. The application database (an SoR that runs on Amazon RDS) persists data for print output.
4. The LRS VPSX/MFI printing solution is deployed on Amazon EC2, and its operational data is stored in Amazon Elastic Block Store (Amazon EBS). LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect print data through the Micro Focus CICS Print Exit API (DFHUPRNT) and deliver the data to a specified printer destination. The original TERMID (TERM) that's used in the modernized CICS application is used as the VPSX/MFI Queue name.

> **Note**
>
> The target solution typically doesn't require application changes to accommodate mainframe formatting languages, such as IBM Advanced Function Presentation (AFP) or Xerox Line Condition Data Stream (LCDS). For more information about using Micro Focus for mainframe application migration and modernization on AWS, see Empowering Enterprise Mainframe Workloads on AWS with Micro Focus in the AWS documentation.

AWS infrastructure architecture

The following diagram shows a highly available and secure AWS infrastructure architecture for a mainframe online printing workload:



The diagram shows the following workflow:

1. The mainframe online application (written on a programming language such as CICS or COBOL) uses core business logic to process and generate print output, such as billing statements, ID cards, and loan statements. The online application is deployed on Amazon EC2 across two Availability Zones (AZ) for high availability (HA) and uses Micro Focus CICS Print Exit to route print output to LRS VPSX/MFI for end-user printing.
2. LRS VPSX/MFI uses a TCP/IP-based LRS/Queue transmission agent to collect or capture print data from the Micro Focus online Print Exit programming interface. Online Print Exit passes the necessary information to enable LRS VPSX/MFI to effectively process the print file and dynamically build LRS/Queue commands.

> **Note**
>
> For more information on various CICS application programing methods for print and how they are supported in Micro Focus Enterprise server and LRS VPSX/MFI, see *Print data capture* in the *Additional information* section of this pattern.

3. > **Note**
   >
   > A Network Load Balancer provides a DNS name to integrate Micro Focus Enterprise Server with LRS VPSX/MFI. : LRS VPSX/MFI supports a Layer 4 load balancer. The Network Load Balancer also does a basic health check on LRS VPSX/MFI and routes traffic to the registered targets that are healthy.

4. The LRS VPSX/MFI print server is deployed on Amazon EC2 across two Availability Zones for HA and uses Amazon EBS as an operational data store. LRS VPSX/MFI supports both the active-active and active-passive service modes. This architecture uses multiple Availability Zones in an active-passive pair as an active and hot standby. The Network Load Balancer performs a health check on LRS VPSX/MFI EC2 instances and routes traffic to hot standby instances in another Availability Zone if an active instance is in an unhealthy state. The print requests are persisted in the LRS Job Queue locally in each of the EC2 instances. In the event of recovery, a failed instance has to be restarted for the LRS services to resume processing the print request.

   > **Note**
   >
   > LRS VPSX/MFI can also perform health checks at the printer fleet level. For more information, see *Printer fleet health checks* in the *Additional information* section of this pattern.

5. AWS Managed Microsoft AD integrates with LRS/DIS to perform print workflow authentication and authorization. For more information, see *Print authentication and authorization* in the *Additional information* section of this pattern.
6. LRS VPSX/MFI uses Amazon EBS for block storage. You can back up Amazon EBS data from active EC2 instances to Amazon S3 as point-in-time snapshots and restore them to hot standby EBS volumes. To automate the creation, retention, and deletion of Amazon EBS volume snapshots, you can use Amazon Data Lifecycle Manager to set the frequency of automated snapshots and restore them based on your RTO/RPO requirements.

Tools

AWS services

- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- AWS Directory Service for Microsoft Active Directory (AD), also known as AWS Managed Microsoft Active Directory, enables your directory-aware workloads and AWS resources to use managed Active Directory in AWS.

Other tools

- LRS VPSX/MFI (Micro Focus Interface), co-developed by LRS and Micro Focus, captures output from a Micro Focus Enterprise Server JES spool and reliably delivers it to a specified print destination.
- LRS Directory Information Server (LRS/DIS) is used for authentication and authorization during the print workflow.
- LRS/Queue is a TCP/IP-based LRS/Queue transmission agent, used by LRS VPSX/MFI, to collect or capture print data through the Micro Focus online Print Exit programming interface.
- Micro Focus Enterprise Server is an application deployment environment for mainframe applications. It provides the execution environment for mainframe applications that are migrated or created by using any version of Micro Focus Enterprise Developer.

Epics

Set up Micro Focus Enterprise Server on Amazon EC2 and deploy a mainframe online application

Task	Description	Skills required
Set up Micro Focus Enterprise Server and deploy a demo online application.	Set up Micro Focus Enterprise Server on Amazon EC2, and then deploy the Micro Focus Account Demo application	Cloud architect

Task	Description	Skills required
	(ACCT Demo) on Amazon EC2 by following the instructions from Tutorial: CICS Support in the Micro Focus documenta tion. The ACCT Demo application is a mainframe online (CICS) application that creates and then initiates print output.	

Set up an LRS print server on Amazon EC2

Task	Description	Skills required
Get an LRS product license for printing.	To get an LRS product license for LRS VPSX/MFI, LRS/Queue, and LRS/DIS, contact the LRS Output Managemen t team. You must provide the host names of the EC2 instances where the LRS products will be installed.	Build lead
Create an Amazon EC2 Windows instance to install LRS VPSX/MFI.	Launch an Amazon EC2 Windows instance by following the instructions from Step 1: Launch an instance in the Amazon EC2 documentation. Your instance must meet the following hardware and software requirements for LRS VPSX/MFI:	Cloud architect

Task	Description	Skills required
	• CPU – Dual Core • RAM – 16 GB • Drive – 500 GB • Minimum EC2 instance – m5.xlarge • OS – Windows/Linux • Software – Internet Information Service (IIS) or Apache **Note** The preceding hardware and software requirements are intended for a small printer fleet (around 500–1000). To get the full requirements, consult with your LRS and AWS contacts. When you create your Windows instance, do the following: 1. Confirm that the EC2 host name is the same host name used for the LRS product license.	

Task	Description	Skills required
	2. Enable CGI in Amazon EC2 by completing the following: a. Connect to your EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. b. In the Windows Start menu, find and open Server Manager. c. In Server Manager, choose **Dashboard**, **Quick Start**, **Add roles and features**. Then, choose **Server roles**. d. In **Server roles**, choose **WebServer (IIS)**, and then choose **Application Development**. e. In **Application Development**, select the **CGI** check box. f. Follow the instructions on the Windows Server Manager **Add roles and features** wizard to install CGI. g. Open port 5500 in the Windows firewall of the EC2 instance for LRS/ Queue communication.	

Task	Description	Skills required
Install LRS VPSX/MFI on the EC2 instance.	1. Connect to your EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. **Note** Open the link to the product download page from the LRS email that you should receive. : LRS products are distributed by electronic file transfer (EFT). 3. Download LRS VPSX/MFI and unzip the file (default folder: `c:\LRS`). 4. Launch the LRS Product Installer from the unzipped folder to install LRS VPSX/MFI. 5. In the **Select Features** menu, select **VPSX® Server (V1R3.022)**, and then choose **Next** to start the installation process. You will receive a success message when installation is complete.	Cloud architect

Task	Description	Skills required
Install LRS/Queue.	1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/Queue, and then unzip the file. 3. Go to the location where you downloaded the files, and then launch the LRS product installer to install LRS/Queue.	Cloud architect

Task	Description	Skills required
Install LRS/DIS.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructi ons from [Step 2: Connect to your instance](#) in the Amazon EC2 documenta tion. 2. Open the link to the LRS product download page from the LRS email that you should receive, download LRS/DIS, and then unzip the file. 3. Go to the location where you downloaded the files, and then launch the LRS Product Installer. 4. In the LRS Product Installer , expand **LRS Misc Tools**, select **LRS DIS**, and then choose **Next**. 5. Follow the rest of the instructions in the LRS Product Installer to complete the installation process.	Cloud architect

Task	Description	Skills required
Create a target group and register LRS VPSX/MFI EC2 as the target.	Create a target group by following the instructions from [Create a target group for your Network Load Balancer](#) in the Elastic Load Balancing documentation. When you create the target group, do the following: 1. On the **Specify group details** page, for **Choose a Target Type**, choose **Instances**. 2. For **Protocol**, choose **TCP**. 3. For **Port**, choose **5500**. 4. On the **Register targets** page, in the **Available instances** section, select the LRS VPSX/MFI EC2 instances.	Cloud architect

Task	Description	Skills required
Create a Network Load Balancer.	Follow the instructions from [Create a Network Load Balancer](#) in the Elastic Load Balancing documentation. Your Network Load Balancer routes traffic from Micro Focus Enterprise Server to LRS VPSX/MFI EC2. When you create the Network Load Balancer, do the following on the **Listeners and Routing** page: 1. For **Protocol**, choose **TCP**. 2. For **Port**, choose **5500**. 3. For **Default action**, choose **Forward to** for the target group that you created earlier.	Cloud architect

Integrate Micro Focus Enterprise Server with LRS VPSX/MFI and LRS/Queue

Task	Description	Skills required
Configure Micro Focus Enterprise Server for LRS/Queue integration.	1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. In the Windows Start menu, open the Micro	Cloud architect

Task	Description	Skills required
	Focus Enterprise Server Administration UI. 3. In the menu bar, choose **NATIVE**. 4. In the navigation pane, choose **Directory Server**, and then choose **BANKDEMO** or your Enterprise server region. 5. From **General** in the left navigation pane, scroll down to the **Additional** section to configure the environment variables (LRSQ_ADDRESS, LRSQ_PORT, LRSQ_COMMAND) to point to LRSQ. 6. For **LRSQ_ADDRESS**, enter the IP address or DNS name of the Network Load Balancer that you created earlier. 7. For **LRSQ_PORT**, enter **VPSX LRSQ Listener Port (5500)**. 8. For **LRSQ_COMMAND**, enter the path location of the LRSQ executable. 9. **Note** LRS currently supports a maximum	

Task	Description	Skills required
	character limit of 50 for DNS names, but this is subject to change in the future. If your DNS name is greater than 50, then you can use the IP address of the Network Load Balancer as an alternative.	

Task	Description	Skills required
Make CICS Print Exit (DFHUPRNT) available to Micro Focus Enterprise Server initialization.	1. Connect to your Micro Focus Enterprise Server EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. **Note** Copy CICS Print Exit (DFHUPRNT) from the LRS VPSX/MFI executable folder (named `VPSX_MFI_R2`) to the Micro Focus Enterprise Server EC2 instance location. For 32 bit systems, the location is `C:\Program Files (x86)\Micro Focus\Enterprise Server\bin` . For 64 bit systems, the location is `C:\Program Files (x86)\Micro Focus\Enterprise Server\bin64` .: The DFHUPRNT_	Cloud architect

Task	Description	Skills required
	`64.dll` file must be renamed to `DFHUPRNT.dll` when copied. **Validate that Micro Focus Enterprise Server has detected CICS Print Exit (DFHUPRNT)** 1. Stop and start Micro Focus Enterprise Server. 2. In the Administration panel of Micro Focus Enterpris e Server, open **Monitor**, **Logs**, **Console logs**. 3. Check the console logs for the following message: "3270 printer user exit DFHUPRNT installed successfully."	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Define the CICS printer's terminal ID (TERMIDs) as Micro Focus Enterprise Server.</td><td>Enable 3270 printing in Micro Focus Enterprise Server

1. In the Administration panel of Micro Focus Enterpris e Server, open CICS, Resources, By Group.
2. From the left navigation panel, choose SIT (System Initialization Table), and then choose BNKCICV.
3. In the General section, scroll down to 3270, and then select the 3270 Print check box.

Define the CICS printer's terminal in Micro Focus Enterprise Server

1. In the Administration panel of Micro Focus Enterpris e Server, open CICS, Resources, By Type.
2. From the left navigation panel, choose Term, and then choose New. The Create Terminal Resource form opens.
3. For Name, enter the name of the LRS Print Queue. (Note: This pattern uses "P275" as the CICS</td><td>Cloud architect</td></tr>
</table>

Task	Description	Skills required
	printer's terminal ID and LRS VPSX Print Queue.) 4. For **Group**, enter **BANKTERM**. 5. For **Auto Install – Model**, enter **NO**. 6. For **Terminal Identifiers - Terminal type**, enter **DFHPRT32**. 7. For **Net name**, enter **VTAMP275**. 8. For **Terminal Usage**, select the **In Service** check box. 9. Scroll at the top of the page, and then chose **Save**. 10. Choose **Install**. A pop-up message displays a successful installation message.	

Set up printers and print users in Micro Focus Enterprise Server and LRS VPSX/MFI

Task	Description	Skills required
Create a print queue in the LRS VPSX.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation.	Cloud architect

Task	Description	Skills required
	2. Open the VPSX Web Interface from the Windows Start menu. 3. In the navigation pane, choose **Printers**. 4. Choose **Add**, and then choose **Add Printer**. 5. On the **Printer Configuration** page, for **Printer Name**, enter **P275**. 6. For **VPSX ID**, enter **VPS1**. 7. For **CommType**, select **TCPIP/LRSQ**. 8. For **Host/IP Address**, enter the IP address of the physical printer that you want to add. 9. For **Device**, enter the name of your device. 10. Choose either **Windows Driver** or **Linux/Mac Driver**. 11. Choose **Add**. **Note** The print queue must be equivalent to the Print TERMIDs created in Micro Focus Enterprise Server.	

Task	Description	Skills required
Create a print user in LRS VPSX/MFI.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from [Step 2: Connect to your instance](#) in the Amazon EC2 documentation. 2. Open the VPSX Web Interface from the Windows Start menu. 3. In the navigation pane, choose **Security**, and then choose **Users**. 4. In the **User Name** column, choose **admin**, and then choose **Copy**. 5. In the **User Profile Maintenance** window, for **User Name**, enter a user name (for example, **PrintUser**). 6. For **Description**, enter a brief description (for example, **User for test print**). 7. Choose **Update**. This creates a print user (for example, **PrintUser**). 8. In the navigation pane, under **User**, choose the new user that you created. 9. From the **Command** menu, choose **Security**.	Cloud architect

Task	Description	Skills required
	10. On the **Security Rules** page, choose all the applicable printer security and job security options, and then choose **Save**. 11. To add your new print user to the **Administrator** group, go to the navigation pane, choose **Security**, and then choose **Configure**. 12. In the **Security configura tion** window, add your new print user to the **Administr ator** column.	

Set up print authentication and authorization

Task	Description	Skills required
Create an AWS Managed Microsoft AD domain with users and groups.	1. Create an Active Directory on AWS Managed Microsoft AD by following the instructions from [Create your AWS Managed Microsoft AD directory](#) in the AWS Directory Service documentation. 2. Deploy an EC2 instance (Active Directory manager) and install Active Directory tools to manage your AWS Managed Microsoft AD by following the instructions from [Step 3: Deploy an EC2](#)	Cloud architect

Task	Description	Skills required
	instance to manage your AWS Managed Microsoft AD in the AWS Directory Service documentation. 3. **Note** Connect to your EC2 instance by following the instructions from Step 2: Connect to your instance in the Amazon EC2 documenta tion. : When you connect to the EC2 instance, enter your administrator credentials (for the directory that you created in step one) in the Windows Security window. 4. In the Windows Start menu, under **Windows Administrative Tools**, choose **Active Directory Users and Computers**. 5. Create a print user in the Active Directory domain by following the steps from Create a user in the	

Task	Description	Skills required
	AWS Directory service documentation.	
Join LRS VPSX/MFI EC2 to an AWS Managed Microsoft AD domain.	Join LRS VPSX/MFI EC2 to your AWS Managed Microsoft AD domain automatically (AWS Knowledge Center documentation) or manually (AWS Directory Service documentation).	Cloud architect

Task	Description	Skills required
Configure and integrate LRS/DIS with AWS Managed Microsoft AD.	1. Connect to your LRS VPSX/MFI EC2 instance by following the instructions from [Step 2: Connect to your instance] in the Amazon EC2 documentation. 2. In the Windows Start menu, open the **VPSX Web Interface**. 3. In the navigation pane, choose **Security**, and then choose **Configure**. 4. On the **Security Configuration** page, in the **Security Parameters** section, for **Security Type**, select **Internal**. 5. Enter your preferences for the rest of the options in the **Security Parameters** section. 6. Open the **LRS Output Management** folder from the Microsoft Windows Start menu, choose **Server Start**, and then choose **Server Stop**. 7. Log in to LRS VPSX/MFI with your Active Directory user name and password.	Cloud architect

Test an online print workflow

Task	Description	Skills required
Initiate an online print request from the Micro Focus ACCT Demo app.	1. **Note** Open the TN3270 terminal emulator in your Micro Focus Enterprise Server EC2 instance. (: This pattern uses 3270 terminal emulators .) 2. Connect to the TN3270 terminal emulator (Rumba). For **Host name address**, use **127.0.0.1**. For **Telnet Port**, use **9270**. 3. After connecting to the 3270 screen, press CTL +SHIFT+Z to clear the screen. 4. To start the ACCT Demo application, in clear screen, enter **ACCT**. This opens the ACCT Demo online (CICS) application main screen. **Note**: The main screen includes menu options such as **Account file**, **To search by name**, **enter**, **Request type**, **Account**, and **Printer**.	Cloud architect

Task	Description	Skills required
	5. To submit a print request from the ACCT Demo online (CICS) application, enter **P** in the **request type** field, **11111** in the **account** field, and **P275** in the **printer** field. Be sure to set the value in the **printer** field to the value of the CICS printer's terminal ID. 6. Press **Enter**. The "Print Request Scheduled " message appears at the bottom of the screen. This confirms that an online print request was generated from the ACCT Demo application and sent to LRS VPS/MFI for print processing.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Check the print output in LRS VPSX/MFI.</td><td>Connect to your LRS VPSX/MFI EC2 instance by following the instructions from Step 2: Connect to your instance in the Amazon EC2 documentation.
In the Windows Start menu, open the VPSX Web Interface.
In the navigation pane, choose Printers, and then choose Output Queue. Find the P275 print queue that you created for online printing earlier.
For the print queue (P275), in the Spool ID column, choose the spool ID for the request in the printer queue.
On the Actions tab, in the COMMAND column, choose Browse.
You can now see the print output of an account statement with columns for Account No., SURNAME, FIRST, ADDRESS, TELEPHONE, No. Cards Issued, Date issued, Amount, and Balance.</td><td>Test engineer</td></tr>
</table>

Task	Description	Skills required
	For an example, see the **online_print_output** attachment for this pattern.

Additional information

Considerations

During your modernization journey, you may consider a wide variety of configurations for mainframe online processes and the output they generate. The mainframe platform has been customized by every customer and vendor that uses it with particular requirements that directly affect print. For example, your current platform may incorporate the IBM Advanced Function Presentation (AFP) or the Xerox Line Condition Data Stream (LCDS) into the current workflow. Additionally, mainframe carriage control characters and channel command words can affect the look of the printed page and may need special handling. As part of the modernization planning process, we recommend that you assess and understand the configurations in your specific print environment.

Print data capture

This section summarizes the CICS application programming methods that you can use in an IBM mainframe environment for printing. LRS VPSX/MFI components provide techniques to allow the same application programs to create data in the same way. The following table describes how each application programming method is supported in a modernized CICS application running in AWS and Micro Focus Enterprise Server with an LRS VPSX/MFI print server.

Method	Description	Support for the method in a modernized environment
EXEC CICS SEND TEXT.. or EXEC CICS SEND MAP..	These CICS and VTAM methods are responsible for creating and delivering 3270/SCS print data streams to LUTYPE0, LUTYPE1, and LUTYPE3 print devices.	A Micro Focus online Print Exit (DFHUPRNT) applicati on program interface (API) enables print data to be processed by VPSX/MFI when 3270/SCS print data streams are created by using either of these methods.
EXEC CICS SEND TEXT.. or EXEC CICS SEND MAP.. (with third-party IBM mainframe software)	The CICS and VTAM methods are responsible for creating and delivering 3270/SCS print data streams to LUTYPE0, LUTYPE1, and LUTYPE3 print devices. Third-party software products intercept the print data, convert the data to standard print format data with an ASA/MCH control character, and place the data on the JES spool to be processed by mainframe-based printing systems that use JES.	A Micro Focus online Print Exit (DFHUPRNT) API enables print data to be processed by VPSX/MFI when 3270/SCS print data streams are created by using either of these methods.
EXEC CICS SPOOLOPEN	This method is used by CICS application programs to write data directly to the JES	Micro Focus Enterprise Server spools the data to the Enterprise Server spool where

	spool. The data then becomes available to be processed by mainframe-based printing systems that use JES.	it can be processed by the VPSX/MFI Batch Print Exit (LRSPRTE6) that spools the data to VPSX.
DRS/API	An LRS-supplied programma tic interface is used for writing print data to JES.	VPSX/MFI supplies a replacement interface that spools the print data directly to VPSX.

Printer fleet health checks

LRS VPSX/MFI (LRS LoadX) can perform deep dive health checks, including device management and operational optimization. Device management can detect failure in a printer device and route the print request to a healthy printer. For more information about deep dive health checks for printer fleets, see the LRS documentation that's included with your product license.

Print authentication and authorization

LRS/DIS enables LRS applications to authenticate user IDs and passwords by using Microsoft Active Directory or an LDAP server. In addition to basic print authorization, LRS/DIS can also apply granular-level print security controls in the following use cases:

- Manage who can browse the printer job.
- Manage the browsing level of other user's jobs.
- Manage operational tasks. For example, command-level security such as hold/release, purge, modify, copy, and reroute. Security can be set up by either the User-ID or Group (similar to AD group or LDAP group).

Move mainframe files directly to Amazon S3 using Transfer Family

Luis Gustavo Dantas, Amazon Web Services

Summary

As part of the modernization journey, you can face the challenge of transferring files between your on-premises servers and the Amazon Web Services (AWS) Cloud. Transferring data from mainframes can be a significant challenge because mainframes typically can't access modern data stores like Amazon Simple Storage Service (Amazon S3), Amazon Elastic Block Store (Amazon EBS), or Amazon Elastic File System (Amazon EFS).

Many customers use intermediate staging resources, such as on-premises Linux, Unix, or Windows servers, to transfer files to the AWS Cloud. You can avoid this indirect method by using AWS Transfer Family with the Secure Shell (SSH) File Transfer Protocol (SFTP) to upload mainframe files directly to Amazon S3.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a subnet that's reachable by your legacy platform
- A Transfer Family endpoint for your VPC
- Mainframe Virtual Storage Access Method (VSAM) files converted to sequential, fixed-length files (IBM documentation)

Limitations

- SFTP transfers files in binary mode by default, which means that files are uploaded to Amazon S3 with EBCDIC encoding preserved. If your file doesn't contain binary or packed data, then you can use the **sftp** ascii subcommand (IBM documentation) to convert your files to text during the transfer.
- You must unpack mainframe files (AWS Prescriptive Guidance) that contain packed and binary content to use these files in your target environment.
- Amazon S3 objects can range in size from a minimum of 0 bytes to a maximum of 5 TB. For more information about Amazon S3 capabilities, see Amazon S3 FAQs.

Architecture

Source technology stack

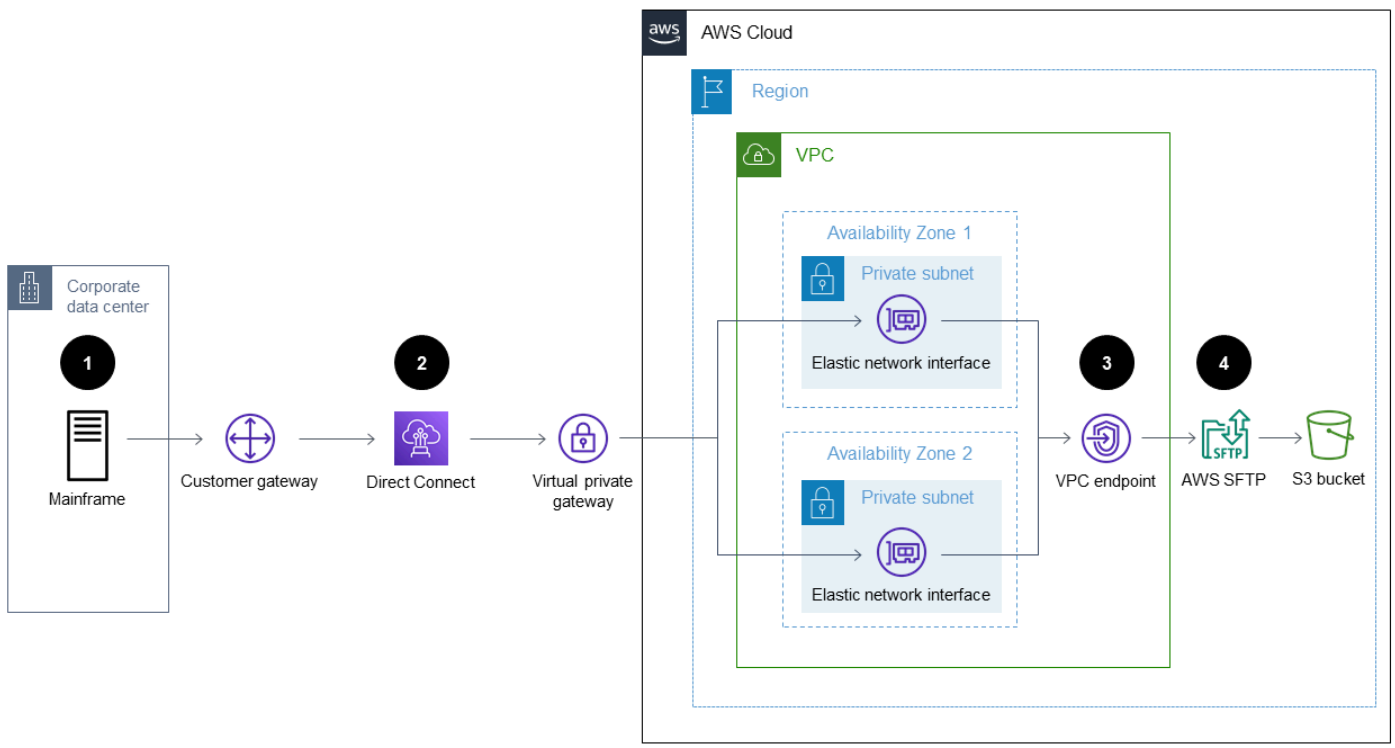
- Job control language (JCL)
- z/OS Unix shell and ISPF
- SFTP
- VSAM and flat files

Target technology stack

- Transfer Family
- Amazon S3
- Amazon Virtual Private Cloud (Amazon VPC)

Target architecture

The following diagram shows a reference architecture for using Transfer Family with SFTP to upload mainframe files directly to an S3 bucket.



The diagram shows the following workflow:

1. You use a JCL job to transfer your mainframe files from the legacy mainframe to the AWS Cloud through Direct Connect.
2. Direct Connect enables your network traffic to remain on the AWS global network and bypass the public internet. Direct Connect also enhances the network speed, starting at 50 Mbps and scaling up to 100 Gbps.
3. The VPC endpoint enables connections between your VPC resources and the supported services without using the public internet. Access to Transfer Family and Amazon S3 achieves high availability by taking place through the elastic network interfaces located in two private subnets and Availability Zones.
4. Transfer Family authenticates users and uses SFTP to receive your files from the legacy environment and move them to an S3 bucket.

Automation and scale

After the Transfer Family service is in place, you can transfer an unlimited number of files from the mainframe to Amazon S3 by using a JCL job as the SFTP client. You can also automate the file transfer by using a mainframe batch job scheduler to run the SFTP jobs when you're ready to transfer the mainframe files.

Tools

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- AWS Transfer Family enables you to securely scale your recurring business-to-business file transfers to Amazon S3 and Amazon EFS by using SFTP, FTPS, and FTP protocols.

Epics

Create the S3 bucket and the access policy

Task	Description	Skills required
Create the S3 bucket.	Create an S3 bucket to host the files that you transfer from your legacy environme nt.	General AWS
Create the IAM role and policy.	Transfer Family uses your AWS Identity and Access Management (IAM) role to grant access to the S3 bucket that you created earlier. Create an IAM role that includes the following IAM policy: `{ "Version": "2012-10-17", "Statement": [ { "Sid": "UserFolderListing", "Action": [ "s3:ListBucket", "s3:GetBucketLocat ion" ], "Effect": "Allow", "Resource": [`	General AWS

Task	Description	Skills required

	``
	 "arn:aws:s3:::<your-
	bucket-name>"
	            ]
	        },
	        {
	            "Sid":
	 "HomeDirObjectAcce
	ss",
	            "Effect":
	 "Allow",
	            "Action": [
	
	 "s3:PutObject",
	
	 "s3:GetObjectAcl",
	
	 "s3:GetObject",
	
	 "s3:DeleteObjectVe
	rsion",
	
	 "s3:DeleteObject",
	
	 "s3:PutObjectAcl",
	
	 "s3:GetObjectVersion"
	            ],
	            "Resource":
	 "arn:aws:s3:::<your-
	bucket-name>/*"
	        }
	    ]
	}
	``
	
	Note
	
	You must choose the Transfer use case	

Task	Description	Skills required
	when you create the IAM role.	

Define the transfer service

Task	Description	Skills required
Create the SFTP server.	1. Sign in to the AWS Management console, open the [Transfer Family console](), and then choose **Create server**. 2. Choose only **SFTP (SSH File Transfer Protocol) - file transfer over Secure Shell protocol** and then choose **Next**. 3. For **Identity provider**, choose **Service managed** and then choose **Next**. 4. For **Endpoint type**, choose **VPC hosted**. 5. For **Access**, choose **Internal**. 6. For **VPC**, choose your VPC. 7. In the **Availability Zones** section, choose your Availability Zones and subnets. 8. In the **Security Groups** section, choose your	General AWS

Task	Description	Skills required
	security group, and then choose **Next**. 9. For **Domain**, choose **Amazon S3** and then choose **Next**. 10. Leave the default options on the **Configure additional details** page and then choose **Next**. 11. Choose **Create server**. **Note** For more information about how to set up an SFTP server, see Create an SFTP-enabled server (AWS Transfer Family User Guide).	

Task	Description	Skills required
Get the server address.	1. Open the Transfer Family console and choose your server ID in the **Server ID** column. 2. In the **Endpoint details** section, for **Endpoint type**, choose the endpoint ID. This takes you to the Amazon VPC console. 3. On the **Details** tab of the Amazon VPC console, find the DNS names next to **DNS names**.	General AWS
Create the SFTP client key pair.	Create an SSH key pair for either Microsoft Windows or macOS/Linux/UNIX.	General AWS, SSH

Task	Description	Skills required
Create the SFTP user.	1. Open the [Transfer Family console](), choose **Servers** from the navigation pane, and then select your server. 2. In the **Server ID** column, choose the server ID for your server and then choose **Add user**. 3. For **Username**, enter a user name that matches your SSH key pair user name. 4. For **Role**, choose the IAM role that you created earlier. 5. For **Home directory** , choose the S3 bucket that you created earlier. 6. For **SSH public keys**, enter the key pair that you created earlier. 7. Choose **Add**.	General AWS

Transfer the mainframe file

Task	Description	Skills required
Send the SSH private key to the mainframe.	Use SFTP or SCP to send the SSH private key to the legacy environment. SFTP example:	Mainframe, z/OS Unix shell, FTP, SCP

Task	Description	Skills required

	<pre>sftp [USERNAME@mainframeIP]
	[password]
	cd [/u/USERNAME]
	put [your-key-pair-file]</pre> SCP example: <pre>scp [your-key-pair-file] [USERNAME@MainframeIP]:/[u/USERNAME]</pre> Next, store the SSH key in the z/OS Unix file system under the user name that will later run the file transfer batch job (for example, `/u/CONTROLM`). **Note** For more information about z/OS Unix shell, see An introduction to the z/OS shells (IBM documentation).	

Task	Description	Skills required

Create the JCL SFTP client.	Because mainframes don't have a native SFTP client, you must use the BPXBATCH utility to run the SFTP client from the z/OS Unix shell.
	
	In the ISPF editor, create the JCL SFTP client. For example:
	
	`//JOBNAM JOB ...`
	`//*************************************************************`
	`//SFTP EXEC PGM=BPXBATCH,REGION=0M`
	`//STDPARM DD *`
	`SH cp "//'MAINFRAME.FILE.NAME'" filename.txt;`
	`echo 'put filename.txt' > uplcmd;`
	`sftp -b uplcmd -i ssh_private_key_file ssh_username@<transfer service ip or DNS>;`
	`//SYSPRINT DD SYSOUT=*`
	`//STDOUT DD SYSOUT=*`
	`//STDENV DD *`
	`//STDERR DD SYSOUT=*`
	
	Note
	For more information about how to run a command in the z/OS Unix shell, see
		JCL, Mainframe, z/OS Unix shell

Task	Description	Skills required
	The BPXBATCH utility (IBM documentation). For more information about how to create or edit JCL jobs in z/OS, see What is ISPF? and The ISPF editor (IBM documentation).	
Run the JCL SFTP client.	1. In the ISPF editor, enter **SUB**, and then press the ENTER key after the JCL job is created. 2. Monitor the mainframe's file transfer batch job activity in SDSF. **Note** For more information about how to check the activity of batch jobs, see z/OS SDSF User's Guide (IBM documentation).	Mainframe, JCL, ISPF

Task	Description	Skills required
Validate the file transfer.	1. Sign in to the AWS Management console, open the Amazon S3 console, and then choose **Buckets** from the navigation pane. 2. Choose the bucket that's associated with your Transfer Family. 3. In the **Objects** section of the **Objects** tab, find the file that you transferred from the mainframe.	General AWS
Automate the JCL SFTP client.	Use job scheduler to automatically trigger the JCL SFTP client. **Note** You can use mainframe job schedulers, such as BMC Control-M or CA Workload Automation, to automate batch jobs for file transfers based on time and other batch job dependencies.	Job scheduler

Secure and streamline user access in a Db2 federation database on AWS by using trusted contexts

Sai Parthasaradhi, Amazon Web Services

Summary

Many companies are migrating their legacy mainframe workloads to Amazon Web Services (AWS). This migration includes shifting IBM Db2 for z/OS databases to Db2 for Linux, Unix, and Windows (LUW) on Amazon Elastic Compute Cloud (Amazon EC2). During a phased migration from on premises to AWS, users might need to access data in IBM Db2 z/OS and in Db2 LUW on Amazon EC2 until all applications and databases are fully migrated to Db2 LUW. In such remote data-access scenarios, user authentication can be challenging because different platforms use different authentication mechanisms.

This pattern covers how to set up a federation server on Db2 for LUW with Db2 for z/OS as a remote database. The pattern uses a trusted context to propagate a user's identity from Db2 LUW to Db2 z/OS without re-authenticating on the remote database. For more information about trusted contexts, see the Additional information section.

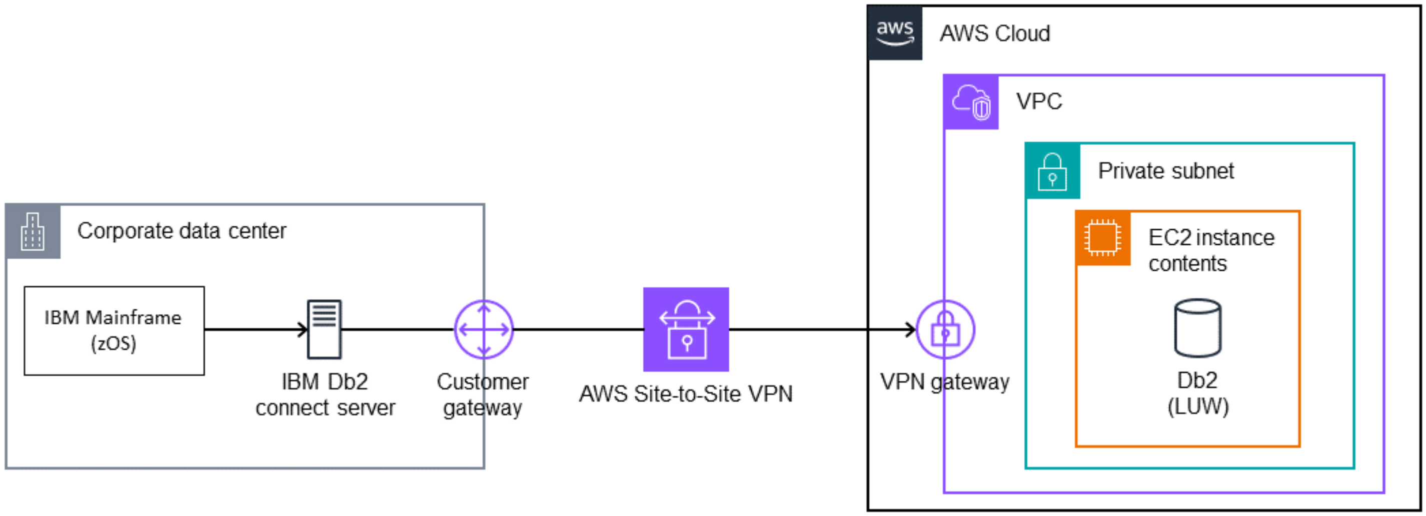
Prerequisites and limitations

Prerequisites

- An active AWS account
- A Db2 instance running on an Amazon EC2 instance
- A remote Db2 for z/OS database running on premises
- The on-premises network connected to AWS through AWS Site-to-Site VPN or AWS Direct Connect

Architecture

Target architecture



Tools

AWS services

- [Amazon Elastic Compute Cloud (Amazon EC2)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Site-to-Site VPN](#) helps you pass traffic between instances that you launch on AWS and your own remote network.

Other tools

- [db2cli](#) is the Db2 interactive command line interface (CLI) command.

Epics

Enable federation on the Db2 LUW database running on AWS

Task	Description	Skills required
Enable federation on the DB2 LUW DB.	To enable federation on DB2 LUW, run the following command. `update dbm cfg using federated YES`	DBA

Task	Description	Skills required

Restart the database.	To restart the database, run the following command.
	`db2stop force;`
	`db2start;`
		DBA

Catalog the remote database

Task	Description	Skills required
Catalog the remote Db2 z/OS subsystem.	To catalog the remote Db2 z/OS database on Db2 LUW running on AWS, use the following example command. `catalog TCPIP NODE tcpnode REMOTE mainframehost SERVER mainframeport`	DBA
Catalog the remote database.	To catalog the remote database, use the following example command. `catalog db dbnam1 as ndbnam1 at node tcpnode`	DBA

Create the remote server definition

Task	Description	Skills required
Collect user credentials for the remote Db2 z/OS database.	Before proceeding with the next steps, gather the following information:	DBA

Task	Description	Skills required
	- Db2 z/OS subsystem name – The cataloged Db2 z/OS name on LUW from the previous step (for example, `ndbnam1`) - Db2 z/OS version – The Db2 z/OS subsystem version (for example, `12`) - Db2 z/OS user ID – The user with the BIND privilege, which is needed to create only the server definition (for example, `dbuser1`) - Db2 z/OS password – The password for `dbuser1` (for example, `dbpasswd`) - Db2 z/OS proxy user – The ID of the proxy user, which will be used to establish trusted connection (for example, `zproxy`) - Db2 z/OS proxy password – The password for the `zproxy` user (for example, `zproxy`)	
Create the DRDA wrapper.	To create the DRDA wrapper, run the following command. `CREATE WRAPPER DRDA;`	DBA

Task	Description	Skills required
Create the server definition.	To create the server definitio n, run the following example command. `CREATE SERVER ndbserver TYPE DB2/ZOS VERSION 12 WRAPPER DRDA AUTHORIZATION "dbuser1" PASSWORD "dbpasswd " OPTIONS ( DBNAME 'ndbnam1',FED_PROX Y_USER 'ZPROXY' );` In this definition, `FED_PROXY _USER` specifies the proxy user that will be used for establishing trusted connectio ns to the Db2 z/OS database. The authorization user ID and password are required only for creating the remote server object in the Db2 LUW database. They won't be used later during runtime.	DBA

Create user mappings

Task	Description	Skills required
Create a user mapping for the proxy user.	To create a user mapping for proxy user, run the following command. `CREATE USER MAPPING FOR ZPROXY SERVER ndbserver OPTIONS (REMOTE_AUTHID`	DBA

Task	Description	Skills required
	``` 'ZPROXY', REMOTE_PA SSWORD 'zproxy'); ```	
Create user mappings for each user on Db2 LUW.	Create user mappings for all the users on the Db2 LUW database on AWS who need to access remote data through the proxy user. To create the user mappings, run the following command. ``` CREATE USER MAPPING FOR PERSON1 SERVER ndbserver OPTIONS (REMOTE_AUTHID 'USERZID', USE_TRUST ED_CONTEXT 'Y'); ``` The statement specifies that a user on Db2 LUW (`PERSON1`) can establish a trusted connection to the remote Db2 z/OS database (`USE_TRUSTED_CONTEXT 'Y'`). After the connection is established through the proxy user, the user can access the data by using the Db2 z/OS user ID (`REMOTE_AUTHID 'USERZID'`).	DBA

Create the trusted context object

Task	Description	Skills required
Create the trusted context object.	To create the trusted context object on the remote Db2 z/OS database, use the following example command. `CREATE TRUSTED CONTEXT CTX_LUW_ZOS BASED UPON CONNECTION USING SYSTEM AUTHID ZPROXY ATTRIBUTES ( ADDRESS '10.10.10.10' ) NO DEFAULT ROLE ENABLE WITH USE FOR PUBLIC WITHOUT AUTHENTICATION;` In this definition, `CTX_LUW_ZOS` is an arbitrary name for the trusted context object. The object contains the proxy user ID and the IP address of the server from which the trusted connection must originate. In this example, the server the Db2 LUW database on AWS. You can use the domain name instead of the IP address. The clause `WITH USE FOR PUBLIC WITHOUT AUTHENTICATION` indicates that switching the user ID on a trusted connection is	DBA

Task	Description	Skills required
	allowed for every user ID. A password doesn't need to be provided.

- IBM Resource Access Control Facility (RACF)
- IBM Db2 LUW Federation
- Trusted contexts

Additional information

Db2 trusted contexts

A trusted context is a Db2 database object that defines a trust relationship between a federated server and a remote database server. To define a trusted relationship, the trusted context specifies trust attributes. There are three types of trust attributes:

- The system authorization ID that makes the initial database connection request
- The IP address or domain name from which the connection is made
- The encryption setting for data communications between the database server and the database client

A trusted connection is established when all attributes of a connection request match the attributes specified in any trusted context object defined on the server. There are two types of trusted connections: implicit and explicit. After an implicit trusted connection is established, a user inherits a role that isn't available to them outside the scope of that trusted connection definition. After an explicit trusted connection is established, users can be switched on the same physical connection, with or without authentication. In addition, Db2 users can be granted roles that specify privileges that are for use only within the trusted connection. This pattern uses an explicit trusted connection.

Trusted context in this pattern

After the pattern is complete, PERSON1 on Db2 LUW accesses remote data from Db2 z/OS by using a federated trusted context. The connection for PERSON1 is established through a proxy user if the connection originates from the IP address or domain name that is specified in the trusted context definition. After the connection is established, PERSON1's corresponding Db2 z/OS user ID is switched without re-authentication, and the user can access the data or objects based on the Db2 privileges set up for that user.

Benefits of federated trusted contexts

- This approach maintains the principle of least privilege by eliminating the use of a common user ID or application ID that would need a superset of all the privileges required by all users.
- The real identity of the user who performs the transaction on both the federated and remote database is always known and can be audited.
- Performance improves because the physical connection is being reused across the users without the need for the federated server to re-authenticate.

Transfer large-scale Db2 z/OS data to Amazon S3 in CSV files

Bruno Sahinoglu, Abhijit Kshirsagar, and Ivan Schuster, Amazon Web Services

Summary

A mainframe is still a system of record in many enterprises, containing a massive amount of data including master data entities with records of current as well as the historical business transactions. It is often siloed and not easily accessed by the distributed systems within the same enterprise. With the emergence of cloud technology and big data democratization, enterprises are interested in using the insights hidden in the mainframe data to develop new business capabilities.

With that objective, enterprises are looking to open their mainframe Db2 data to their Amazon Web Services (AWS) Cloud environment. The business reasons are several and the transfer methods differ from case to case. You might prefer to connect your application directly to the mainframe, or you might prefer to replicate your data in near real time. If the use case is to feed a data warehouse or a data lake, having an up-to-date copy is no longer a concern, and the procedure described in this pattern might suffice, especially if you want to avoid any third-party product licensing costs. Another use case might be the mainframe data transfer for a migration project. In a migration scenario, data is required for performing the functional equivalence testing. The approach described in this post is a cost effective way to transfer the Db2 data to the AWS Cloud environment.

Because Amazon Simple Storage Service (Amazon S3) is one of the most integrated AWS services, you can access the data from there and gather insights directly by using other AWS services such as Amazon Athena, AWS Lambda functions, or Amazon QuickSight . You can also load the data to Amazon Aurora or Amazon DynamoDB by using AWS Glue or AWS Database Migration Service (AWS DMS). With that aim in mind, this describes how to unload Db2 data in CSV files in ASCII format on the mainframe and transfer the files to Amazon S3.

For this purpose, [mainframe scripts](#) have been developed to help to generate job control languages (JCLs) to unload and transfer as many Db2 tables as you need.

Prerequisites and limitations

Prerequisites

- An IBM z/OS operating system user with authorization to run Restructured Extended Executor (REXX) and JCL scripts.

- Access to z/OS Unix System Services (USS) to generate SSH (Secure Shell) private and public keys.
- A writable S3 bucket. For more information, see [Create your first S3 bucket] in the Amazon S3 documentation.
- An AWS Transfer Family SSH File Transfer Protocol (SFTP)-enabled server using **Service managed** as the identity provider and Amazon S3 as the AWS storage service. For more information, see [Create an SFTP-enabled server] in the AWS Transfer Family documentation.

Limitations

- This approach isn't suitable for near real-time or real-time data synchronization.
- Data can be moved only from Db2 z/OS to Amazon S3, not the other way around.

Architecture

Source technology stack

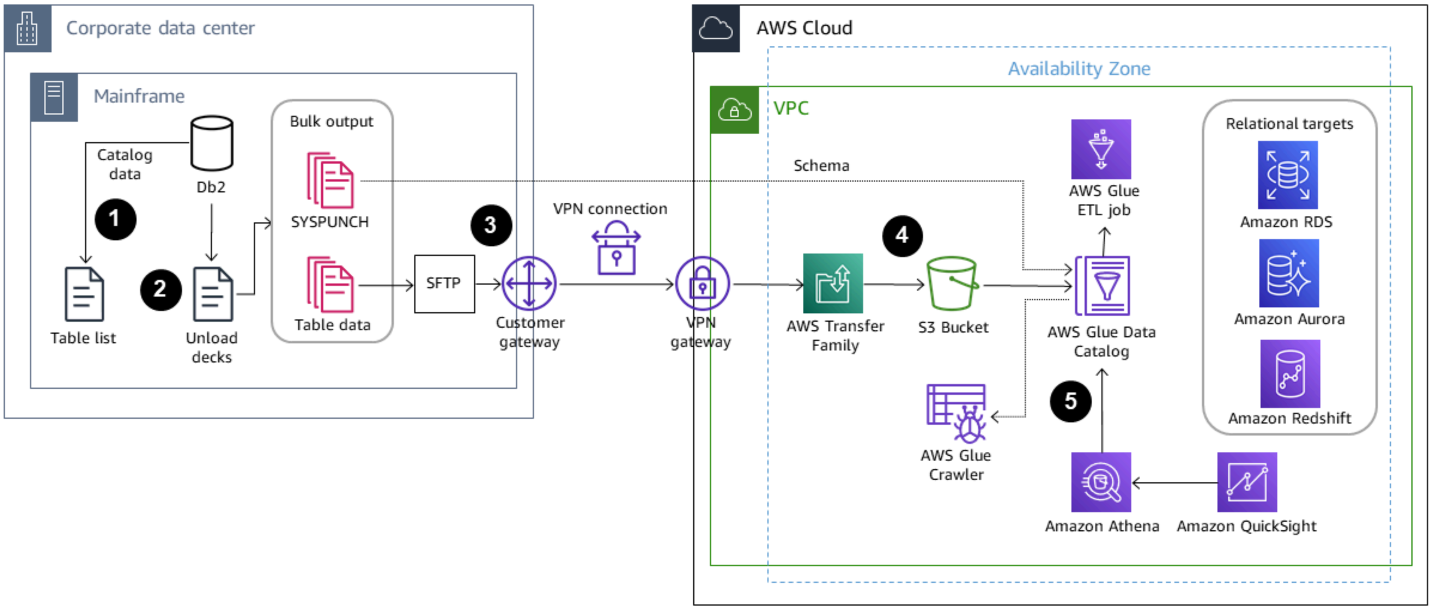
- Mainframe running Db2 on z/OS

Target technology stack

- AWS Transfer Family
- Amazon S3
- Amazon Athena
- Amazon QuickSight
- AWS Glue
- Amazon Relational Database Service (Amazon RDS)
- Amazon Aurora
- Amazon Redshift

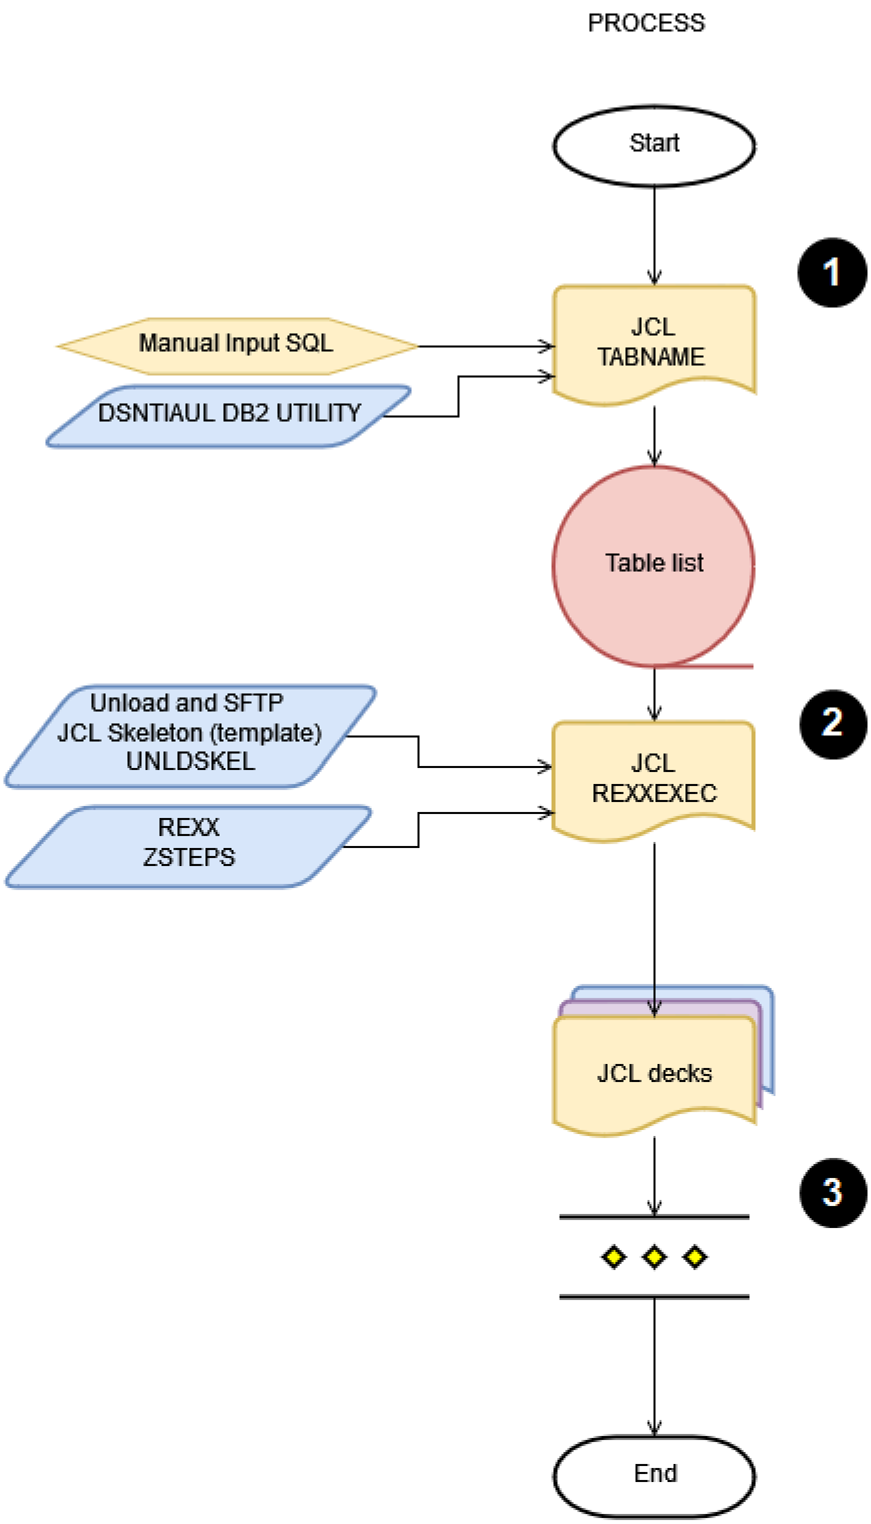
Source and target architecture

The following diagram shows the process for generating, extracting, and transferring Db2 z/OS data in ASCII CSV format to an S3 bucket.



1. A list of tables is selected for data migration from the Db2 catalog.
2. The list is used to drive the generation of unload jobs with the numeric and data columns in the external format.
3. The data is then transferred over to Amazon S3 by using AWS Transfer Family.
4. An AWS Glue extract, transform, and load (ETL) job can transform the data and load it to a processed bucket in the specified format, or AWS Glue can feed the data directly into the database.
5. Amazon Athena and Amazon QuickSight can be used to query and render the data to drive analytics.

The following diagram shows a logical flow of the entire process.



1. The first JCL, called TABNAME, will use the Db2 utility DSNTIAUL to extract and generate the list of tables that you plan to unload from Db2. To choose your tables, you must manually adapt the SQL input to select and add filter criteria to include one or more Db2 schemas.

2. The second JCL, called REXXEXEC, will use the a JCL skeleton and the REXX program that is provided to process the Table list created by the JCL TABNAME and generate one JCL per table name. Each JCL will contain one step for unloading the table and another step for sending the file to the S3 bucket by using the SFTP protocol.
3. The last step consists of running the JCL to unload the table and transferring the file to AWS. The entire process can be automated using a scheduler on premises or on AWS.

Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon Simple Storage Service (Amazon S3) by using standard SQL.
- Amazon Aurora is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- Amazon Redshift is a managed petabyte-scale data warehouse service in the AWS Cloud.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Transfer Family is a secure transfer service that enables you to transfer files into and out of AWS storage services.

Mainframe tools

- SSH File Transfer Protocol (SFTP) is a secure file transfer protocol that allows remote login to and file transfer between servers. SSH provides security by encrypting all traffic.
- DSNTIAUL is a sample program provided by IBM for unloading data.
- DSNUTILB is a utilities batch program provided by IBM for unloading data with different options from DSNTIAUL.

- z/OS OpenSSH is a port of Open Source Software SSH running on the Unix System Service under the IBM operating system z/OS. SSH is a secure, encrypted connection program between two computers running on a TCP/IP network. It provides multiple utilities, including ssh-keygen.
- REXX (Restructured Extended Executor) script is used to automate JCL generation with the Db2 Unload and SFTP steps.

Code

The code for this pattern is available in the GitHub unloaddb2 repository.

Best practices

For the first unload, the generated JCLs should unload the entire table data.

After the first full unload, perform incremental unloads for better performance and cost savings. pdate the SQL query in the template JCL deck to accommodate any changes to the unload process.

You can convert the schema manually or by using a script on Lambda with the Db2 SYSPUNCH as an input. For an industrial process, AWS Schema Conversion Tool (SCT) is the preferred option.

Finally, use a mainframe-based scheduler or a scheduler on AWS with an agent on the mainframe to help manage and automate the entire process.

Epics

Set up the S3 bucket

Task	Description	Skills required
Create the S3 bucket.	For instructions, see Create your first S3 bucket.	General AWS

Set up the Transfer Family server

Task	Description	Skills required
Create an SFTP-enabled server.	To open and create an SFTP server on the AWS Transfer	General AWS

Task	Description	Skills required
	Family console, do the following: 1. On the Choose protocols, page, select the **SFTP (SSH File Transfer Protocol) – file transfer over Secure Shell** check box. 2. For the identity provider, choose **Service managed**. 3. For the endpoint, choose **Publicly accessible**. 4. For the domain, choose **Amazon S3**. 5. On the **Configure additional details** page, keep the default settings. 6. Create the server.	
Create an IAM role for Transfer Family.	To create an AWS Identity and Access Management (IAM) role for Transfer Family to access Amazon S3, follow the instructions in Create an IAM role and policy.	AWS administrator
Add an Amazon S3 service-m anaged user.	To add the Amazon S3 service-managed user, follow the instructions in the AWS documentation, and use your mainframe user ID.	General AWS

Secure the communication protocol

Task	Description	Skills required
Create the SSH key.	Under your mainframe USS environment, run the following command. `ssh-keygen -t rsa` **Note** When prompted for a passphrase, keep it empty.	Mainframe developer

Give the right authorization levels to the SSH folder and key files.	By default, the public and private keys will be stored in the user directory `/u/home/username/.ssh` .
	You must give the authorization 644 to the key files and 700 to the folder.
	`chmod 644 .ssh/id_rsa`
	`chmod 700 .ssh`
		Mainframe developer

Copy the public key content to your Amazon S3 service-managed user.	To copy the USS-generated public key content, open the [AWS Transfer Family console](https://console.aws.amazon.com/transfer/). 1. In the navigation pane, choose **Servers**. 2. Choose the identifier in the **Server ID** column to see the **Server details**	Mainframe developer

Task	Description	Skills required
	3. Under **Users**, choose a user name to see the **User details** 4. Under **SSH public keys**, choose **Add SSH public key** to add the public key to a user. For the SSH public key, enter your public key.Your key is validated by the service before you can add your new user. 5. Choose **Add key**.	

Generate the JCLs

Task	Description	Skills required
Generate the in-scope Db2 table list.	Provide input SQL to create a list of the tables that are scoped for data migration . This step requires you to specify selection criteria quering the Db2 catalog table SYSIBM.SYSTABLES using a SQL where clause. Filters can be customized to include a specific schema or table names that start with a particular prefix or based on a timestamp for incremental unload. Output is captured in a physical sequential (PS) dataset on the mainframe.	Mainframe developer

Task	Description	Skills required
	This dataset will act as input for the next phase of JCL generation. Before you use the JCL TABNAME (You can rename it if necessary), make the following changes: 1. Substitute <Jobcard> with a job class and a user that is authorized to run Db2 utilities. 2. Substitute <HLQ1> or customize the output dataset names to meet your site standards. 3. Update the STEPLIB stack of PDSEs (partitioned data set extended) according to your site standards. The example in this pattern uses the IBM defaults. 4. Substitute the PLAN name and LIB with your installat ion-specific values. 5. Substitute <Schema> and <Prefix> with your selection criteria for the Db2 catalog. 6. Save the resultant JCL in a PDS (partitioned data set) library. 7. Submit the JCL.	

Task	Description	Skills required

Task	Description	Skills required
Modify the JCL templates.	The JCL templates that are provided with this pattern contain a generic job card and library names. However, most mainframe sites will have their own naming standards for dataset names, library names, and job cards. For example, a specific job class might be required to run Db2 jobs. The Job Entry Subsytem implementations JES2 and JES3 can impose additional changes. Standard load libraries might have a different first qualifier than SYS1, which is IBM default. Therefore, customize the templates to account for your site-specific standards before you run them. Make the following changes in the skeleton JCL UNLDSKEL: 1. Modify the job card with a job class and user that is authorized to run Db2 utilities. 2. Customize output dataset names to meet your site standards. 3. Update the STEPLIB stack of PDSEs according to	Mainframe developer

Task	Description	Skills required

	your site standards. The example in this pattern uses the IBM defaults.
	4. Substitute <DSN> with your Db2 subsystem name and correlation ID.
	5. Save the resultant JCL in a PDS library that is part of your ISPSLIB stack, which is the standard skeleton template library for ISPF.

Task	Description	Skills required
Generate the Mass Unload JCL.	This step involves running a REXX script under an ISPF environment by using JCL. Provide the list of in-scope tables created on the first step as input for mass JCL generation against the `TABLIST DD` name. The JCL will generate one new JCL per table name in a user-specified partitioned dataset specified against the `ISPFILE DD` name. Allocate this library beforehand. Each new JCL will have two steps: one step to unload the Db2 table into a file, and one step to send the file to the S3 bucket. Make the following changes in the JCL REXXEXEC (you can change the name): 1. Substitute `Job card user ID` with a mainframe user ID that has unload authority on the tables. Substitute `SYSPROC`, `ISPPLIB`, `ISPSLIB`, `ISPMLIB`, and `ISPTLIB` `<HLQ1>` value or customize the `DSN` to meet your site standards. To find out your installation-specific values,	Mainframe developer

Task	Description	Skills required
	you use the command `TSO ISRDDN`. 2. Substitute `<MFUSER>` with a user ID that has job-running privileges in your installation. 3. Substitute `<FTPUSER>` with a user ID that has the USS and FTP privilege in your installation.. It is assumed that this user ID and its SSH security keys are in place in the appropriate Unix Systems Services directory on the mainframe. 4. Substitute `<AWS TransferFamily IP>` with the AWS Transfer Family IP address or the domain name. This address will be used for the SFTP step. 5. Submit the JCL after applying the site standard accommodation and updating the REXX program as described below. **Mass JCL generation job** `//RUNREXX JOB (CREATEJCL),'RUNS ISPF TABLIST',`

	``	

Task	Description	Skills required
	Before you use the REXX script, make the following changes: 1. Save the REXX script in a PDS library defined under the `SYSEXEC` stack in the JCL REXXEXEC edited in the previous step with ZSTEPS as the member name. If you want to rename it, you should update the JCL to accommodate your needs. 2. This script uses the trace option to print additiona l information in case there are errors. You can instead add error handling code after the `EXECIO`, `ISPEXEC`, and `TSO` statements, and remove the trace line. 3. This script generates member names by using the `LOD`nnnnn naming convention, which can support up to 100,000 members. If you have more than 100,000 tables, use a shorter prefix, and adjust the numbers in the `tempjob` statement.	

Task	Description	Skills required

	ZSTEPS REXX script

	``	

Run the JCLs

Task	Description	Skills required
Perform the Db2 Unload step.	After the JCL generation, you will have as many JCLs as you have tables that need to be unloaded. This story uses a JCL-generated example to explain the structure and the most important steps. No action is required on your part. The following information is for reference only. If your intention is to submit the JCLs that you have generated in the previous step, skip to the *Submit the LODnnnnn JCLs* task. When unloading Db2 data using a JCL with the IBM	Mainframe developer, System engineer

Task	Description	Skills required

	provided DSNUTILB Db2 utility, you must make sure that the unloaded data does not contain compressed numeric data. To accomplis h this, use the DSNUTILB `DELIMITED` parameter.
	
	The `DELIMITED` parameter supports unloading the data in CSV format by adding a character as the delimiter and double quotation marks for the text field, removing the padding in the VARCHAR column, and converting all the numeric fields into EXTERNAL FORMAT, including the DATE fields.
	
	The following example shows what the unload step in the generated JCL looks like, using the comma character as a delimiter.
	
	`UNLOAD`
	`DELIMITED COLDEL ','`
	`FROM TABLE SCHEMA_NA ME.TBNAME`
	`UNLDDN SYSREC01`
	`PUNCHDDN SYSPUN01`
	`SHRLEVEL CHANGE`
	`ISOLATION UR;`	

Task	Description	Skills required

Perform the SFTP step.	To use the SFTP protocol from a JCL, use the BPXBATCH utility.
	
	The SFTP utility can't access the MVS datasets directly. You can use the copy command (`cp`) to copy the sequential file `&USRPFX..DB2.UNLOAD.&JOBNAME` to the USS directory, where it becomes `&TABNAME..csv` .
	
	Run the `sftp` command using the private key (`id_rsa`) and using the RACF user ID as the user name to connect to the AWS Transfer Family IP address.
	
	`SH cp "//'&USRPFX..DB2.UNLOAD.&JOBNAME'" &TABNAME..csv;`
	`echo "ascii " >> uplcmd;`
	`echo "PUT &TABNAME..csv " >>>> uplcmd;`
	`sftp -b uplcmd -i .ssh/id_rsa &FTPUSER.@&FTP_TF_SITE;`
	`rm &TABNAME..csv;`
		Mainframe developer, System engineer

Task	Description	Skills required
Submit the LODnnnnn JCLs.	The prior JCL has generated all LODnnnnn JCL tables that need to be unloaded, transformed into CSV, and transferred to the S3 bucket. Run the `submit` command on all the JCLs that have been generated.	Mainframe developer, System engineer

Additional information

After you have your Db2 data on Amazon S3, you have many ways to develop new insights. Because Amazon S3 integrates with AWS data analytics services, you can freely consume or expose this data on the distributed side. For example, you can do the following:

- Build a data lake on Amazon S3, and extract valuable insights by using query-in-place, analytics, and machine learning tools without moving the data.
- Initiate a Lambda function by setting up a post-upload processing workflow that is integrated with AWS Transfer Family.
- Develop new microservices for accessing the data in Amazon S3 or in fully managed database by using AWS Glue, which is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development.

In a migration use case, because you can transfer any data from the mainframe to S3, you can do the following:

- Retire physical infrastructure, and create a cost-effective data archival strategy with Amazon S3 Glacier and S3 Glacier Deep Archive.
- Build scalable, durable, and secure backup and restore solutions with Amazon S3 and other AWS services, such as S3 Glacier and Amazon Elastic File System (Amazon EFS), to augment or replace existing on-premises capabilities.

More patterns

- Deploy the Security Automations for AWS WAF solution by using Terraform
- Replicate mainframe databases to AWS by using Precisely Connect

Create detailed cost and usage reports for AWS Glue jobs by using AWS Cost Explorer

Parijat Bhide and Aromal Raj Jayarajan, Amazon Web Services

Summary

This pattern shows how to track the usage costs of AWS Glue data integration jobs by configuring user-defined cost allocation tags. You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for jobs across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level.

Prerequisites and limitations

Prerequisites

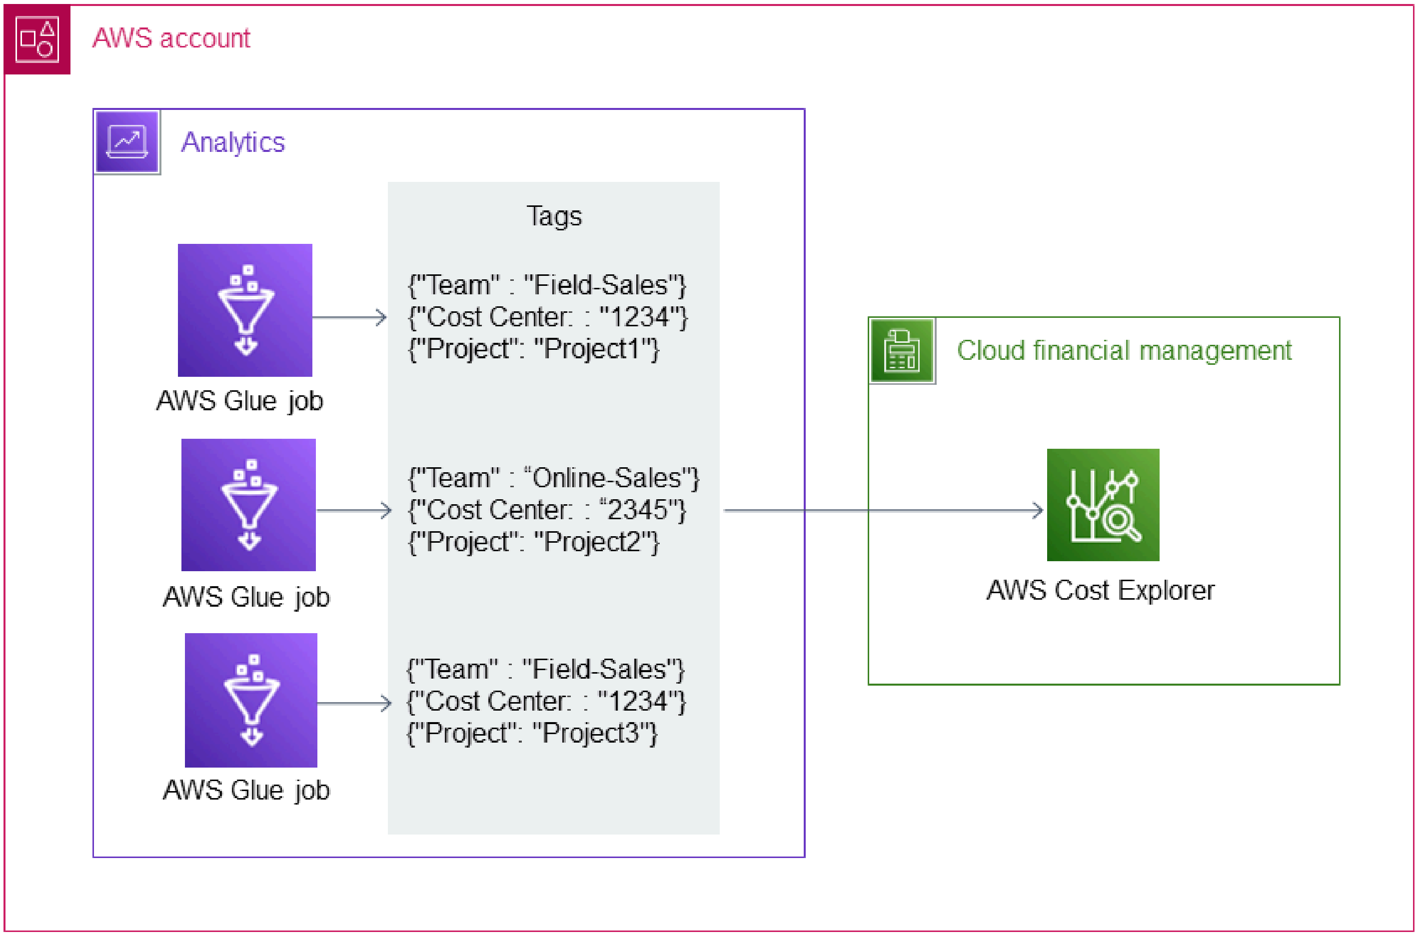
- An active AWS account
- One or more AWS Glue jobs that have user-defined tags activated

Architecture

Target technology stack

- AWS Glue
- AWS Cost Explorer

The following diagram shows how you can apply tags to track usage costs for AWS Glue jobs.



The diagram shows the following workflow:

1. A data engineer or AWS administrator creates user-defined cost allocation tags for the AWS Glue jobs.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.

Tools

- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- AWS Cost Explorer helps you view and analyze your AWS costs and usage.

Epics

Create and activate tags for your AWS Glue jobs

Task	Description	Skills required
Create user-defined cost allocation tags for your AWS Glue jobs.	**To add tags to an existing AWS Glue job** 1. Sign in to the AWS Management console, and then open the [AWS Glue console](https://console.aws.amazon.com/glue/). 2. In the left navigation pane, under **ETL**, choose **Jobs**. 3. In the **Your jobs** section, choose the name of the job that you're tagging. 4. Choose the **Job details** tab. Then, expand the **Advanced properties** section. 5. For **Tags**, choose **Add new tag**. 6. For **Key**, enter a name for your tag. 7. (Optional) For **Value**, enter a value that you want associated with the key. 8. (Optional) Repeat steps 5-7 for each tag that you want to create for the job. 9. Choose **Save**.	Data engineer

Task	Description	Skills required
	To add tags to a new AWS Glue job 1. Create a new AWS Glue job based on your use case requirements. For instructions, see [Working with jobs on the AWS Glue Console]() in the *AWS Glue Developer Guide*. 2. When you configure the **Job details** settings, follow steps 4-9 of the **To add tags to an existing AWS Glue job** section of this task. **Note** For more information, see [AWS tags in AWS Glue]() in the *AWS Glue Developer Guide.*	
Activate the user-defined cost allocation tags.	Follow the instructions in [Activating user-defined cost allocation tags]() in the *AWS Billing User Guide*.	AWS administrator

Create cost and usage reports for your AWS Glue jobs

Task	Description	Skills required
Create cost and usage reports for your AWS Glue jobs by using tag filters in AWS Cost Explorer.	1. Sign in to the AWS Management Console and open the [AWS Cost Management console](https://console.aws.amazon.com/cost-management/home). 2. In the left navigation pane, choose **Reports**. 3. Choose **Create new report**. 4. For **Select a report type**, choose **Cost and usage (recommended)**. Then, choose **Create Report**. 5. For **Filters**, choose **Service**. The **Service** dropdown appears. 6. Select the check boxes next to **Glue**. Then, choose **Apply filters**. 7. For **Filters**, choose **Tag**. The **Tag** dropdown appears. 8. Choose **Team**. Then, select the check boxes next to the teams that you've assigned tags to. Exclude any teams that you haven't assigned tags to. Then, choose **Apply filters**. 9. At the top of the chart, choose **Tag**. Then, choose the tags for the AWS Glue	General AWS, AWS administrator

Task	Description	Skills required
	jobs that you want to create a report for. 10. At the top of the chart, choose the **Last 3 Months** dropdown and choose the timeframe that you want the report to cover. Then, choose the **Monthly** dropdown and choose how you want the line items in the report to be aggregated based on timeframe. 11. Choose **Save as**. Then, enter a title for your report. 12. Choose **Save Report**. For more information, see Exploring your data using Cost Explorer in the *AWS Cost Management User Guide*.	

Create detailed cost and usage reports for Amazon EMR clusters by using AWS Cost Explorer

Parijat Bhide and Aromal Raj Jayarajan, Amazon Web Services

Summary

This pattern shows how to track the usage costs of Amazon EMR clusters by configuring user-defined cost allocation tags. You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for clusters across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level.

Prerequisites and limitations

Prerequisites

- An active AWS account
- One or more EMR clusters that have user-defined tags activated

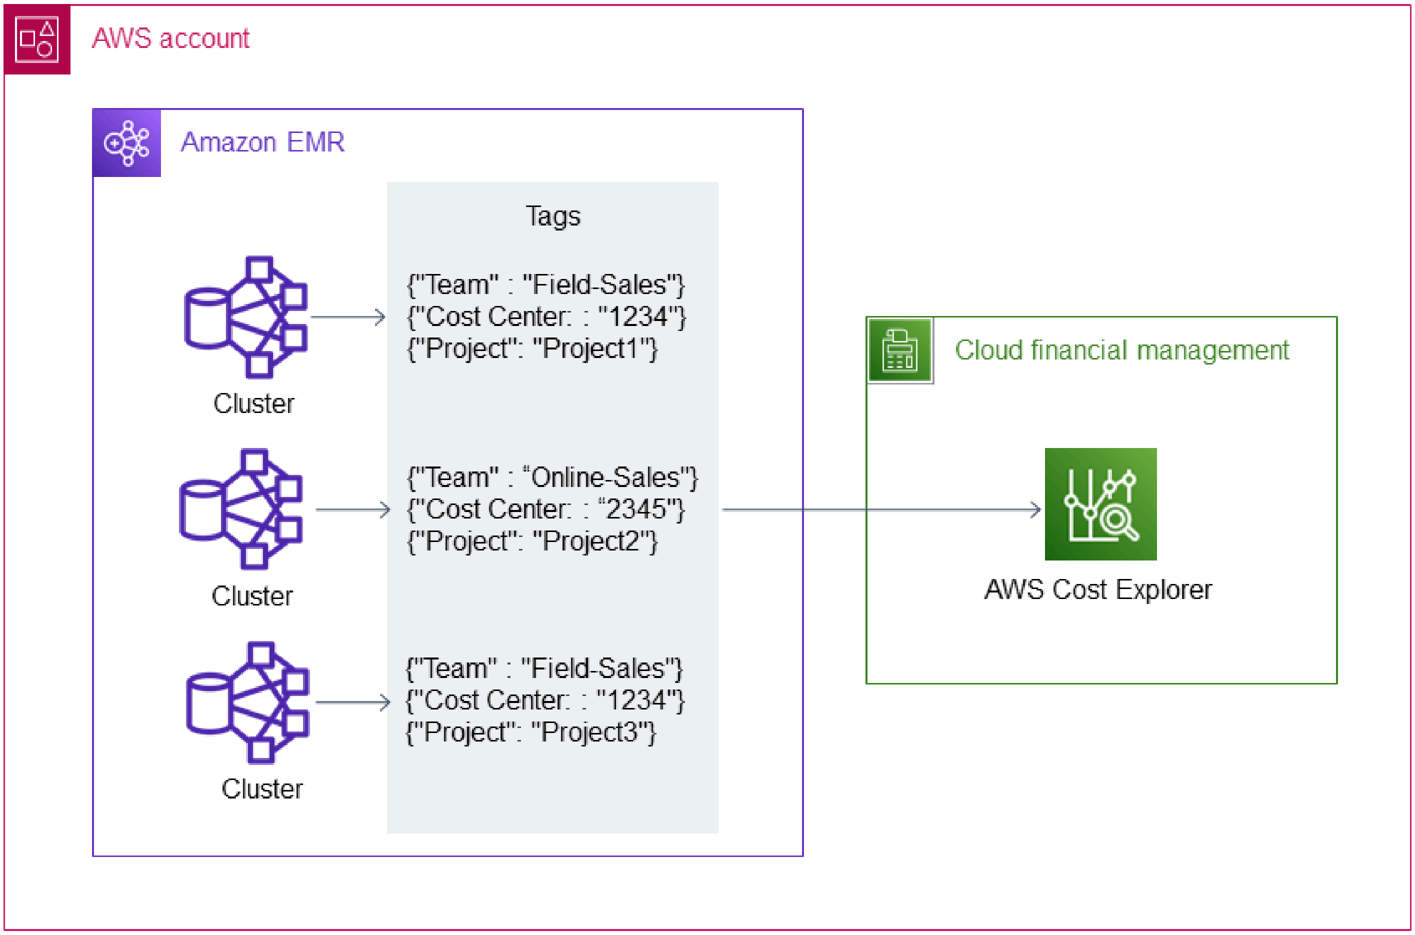
Architecture

Target technology stack

- Amazon EMR
- AWS Cost Explorer

Target architecture

The following diagram shows how you can apply tags to track usage costs for specific Amazon EMR clusters.



The diagram shows the following workflow:

1. A data engineer or AWS administrator creates user-defined cost allocation tags for the Amazon EMR clusters.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.

Tools

Tools

- Amazon EMR is a managed cluster platform that simplifies running big data frameworks on AWS to process and analyze large amounts of data.
- AWS Cost Explorer helps you view and analyze your AWS costs and usage.

Epics

Create and activate tags for your Amazon EMR clusters

Task	Description	Skills required
Create user-defined cost allocation tags for your Amazon EMR clusters.	**To add tags to an existing Amazon EMR cluster** Follow the instructions in Adding tags to an existing cluster in the *Amazon EMR Management Guide*. **To add tags to a new Amazon EMR cluster** Follow the instructions in Add tags to a new cluster in the *Amazon EMR Management Guide*. For more information about how to set up an Amazon EMR cluster, see Plan and configure clusters in the *Amazon EMR Management Guide*.	Data engineer
Activate the user-defined cost allocation tags.	Follow the instructions in Activating user-defined cost allocation tags in the *AWS Billing User Guide*.	AWS administrator

Create cost and usage reports for your Amazon EMR clusters

Task	Description	Skills required
Create cost and usage reports for your Amazon EMR clusters by using tag filters in AWS Cost Explorer.	1. Sign in to the AWS Management Console and open the [AWS Cost Management console](https://console.aws.amazon.com/cost-management/home). 2. In the left navigation pane, choose **Reports**. 3. Choose **Create new report**. 4. For **Select a report type**, choose **Cost and usage (recommended)**. Then, choose **Create Report**. 5. For **Filters**, choose **Service**. The **Service** dropdown appears. 6. Select the check boxes next to **EMR (Elastic MapReduce)** and **EC2-Instances (Elastic Compute Cloud – Compute)**. Then, choose **Apply filters**. 7. For **Filters**, choose **Tag**. The **Tag** dropdown appears. 8. Choose **Team**. Then, select the check boxes next to the teams that you've assigned tags to. Exclude any teams that you haven't assigned tags to. Then, choose **Apply filters**.	General AWS, AWS administrator

Task	Description	Skills required
	9. At the top of the chart, choose **Tag**. Then, choose the tags for the Amazon EMR clusters that you want to create a report for. 10. At the top of the chart, choose the **Last 3 Months** dropdown and choose the timeframe that you want the report to cover. Then, choose the **Monthly** dropdown and choose how you want the line items in the report to be aggregate d based on timeframe. 11. Choose **Save as**. Then, enter a title for your report. 12. Choose **Save Report**. For more information, see Exploring your data using Cost Explorer in the *AWS Cost Management User Guide*.

Implement SAML 2.0 authentication for Amazon WorkSpaces by using Auth0 and AWS Managed Microsoft AD

Siva Vinnakota and Shantanu Padhye, Amazon Web Services

Summary

This pattern explores how you can integrate Auth0 with AWS Directory Service for Microsoft Active Directory to create a robust SAML 2.0 authentication solution for your Amazon WorkSpaces environment. It explains how to establish federation between these AWS services to enable advanced features such as multi-factor authentication (MFA) and custom login flows while preserving seamless desktop access through AWS Managed Microsoft AD. Whether you're managing only a handful of users or thousands, this integration helps provide flexibility and security for your organization. This pattern provides the steps for the setup process so you can implement this solution in your own environment.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Managed Microsoft AD
- A provisioned desktop in Amazon WorkSpaces Personal that is associated with AWS Managed Microsoft AD
- An Amazon Elastic Compute Cloud (Amazon EC2) instance
- An Auth0 account

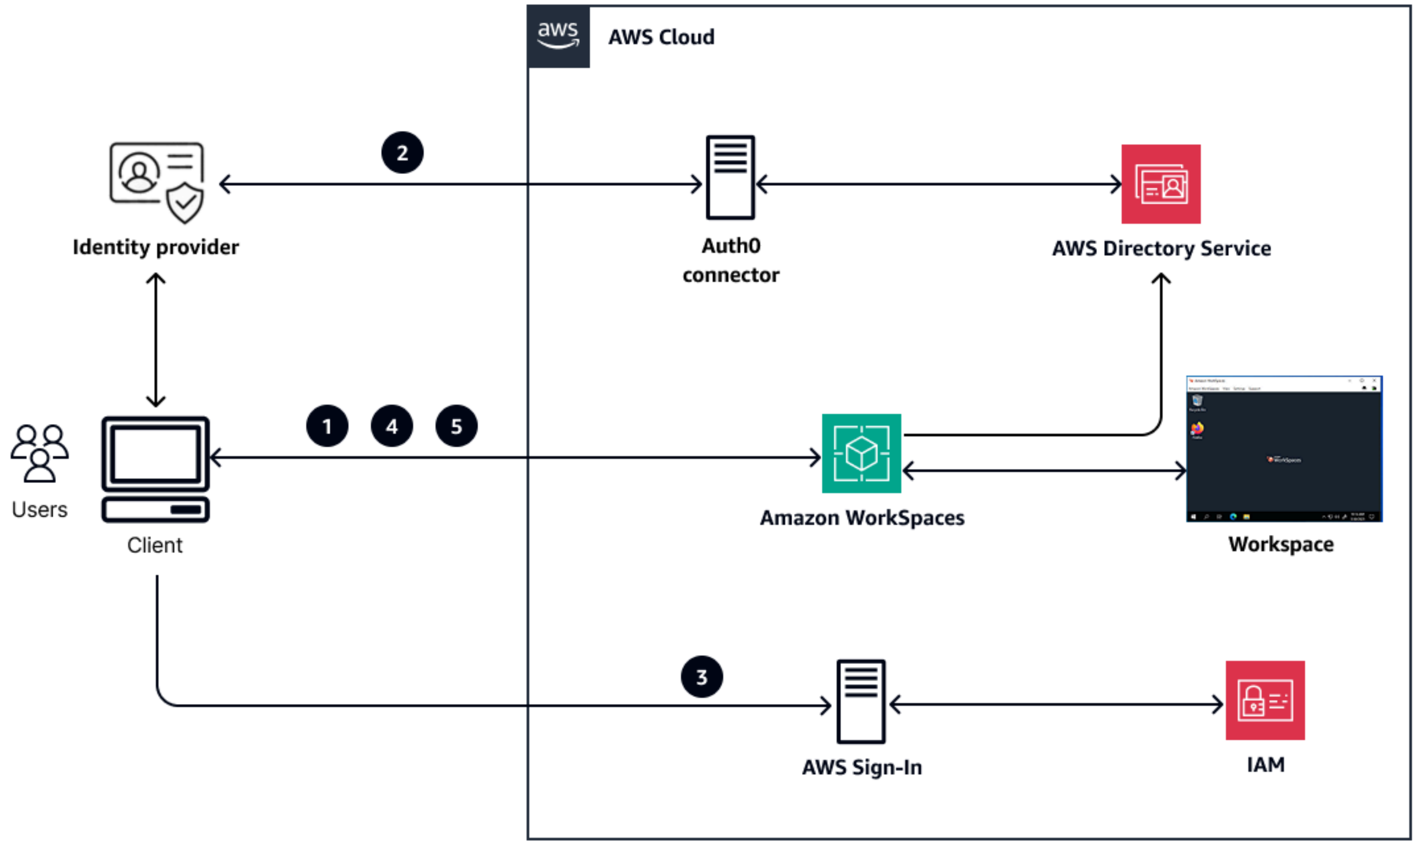
Limitations

Some AWS services aren’t available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

The SAML 2.0 authentication process for a WorkSpaces client application consists of five steps that are illustrated in the following diagram. These steps represent a typical workflow for logging in.

You can use this distributed approach to authentication after you follow the instructions in this pattern, to help provide a structured and secure method for user access.



Workflow:

1. **Registration**. The user launches the client application for WorkSpaces and enters the WorkSpaces registration code for their SAML-enabled WorkSpaces directory. WorkSpaces returns the Auth0 identity provider (IdP) URL to the client application.
2. **Login.** The WorkSpaces client redirects to the user's web browser by using the Auth0 URL. The user authenticates with their username and password. Auth0 returns a SAML assertion to the client browser. The SAML assertion is an encrypted token that asserts the user's identity.
3. **Authenticate**. The client browser posts the SAML assertion to the AWS Sign-In endpoint to validate it. AWS Sign-In allows the caller to assume an AWS Identity and Access Management (IAM) role. This returns a token that contains temporary credentials for the IAM role.
4. **WorkSpaces login**. The WorkSpaces client presents the token to the WorkSpaces service endpoint. WorkSpaces exchanges the token for a session token and returns the session token to the WorkSpaces client with a login URL. When the WorkSpaces client loads the login page. the username value is populated by the `NameId` value that's passed in the SAML response.

5. **Streaming**. The user enters their password and authenticates against the WorkSpaces directory. After authentication, WorkSpaces returns a token to the client. The client redirects back to the WorkSpaces service and presents the token. This brokers a streaming session between the WorkSpaces client and the WorkSpace.

> **Note**
>
> To set up a seamless single sign-on experience that doesn't require a password prompt, see the Certificate-based authentication and WorkSpaces Personal in the WorkSpaces documentation.

Tools

AWS services

- Amazon WorkSpaces is a fully managed virtual desktop infrastructure (VDI) service that provides users with cloud-based desktops without having to procure and deploy hardware or install complex software.
- AWS Directory Service for Microsoft Active Directory enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.

Other tools

- Auth0 is an authentication and authorization platform that helps you manage access to your applications.

Epics

Configure the Active Directory LDAP Connector in Auth0

Task	Description	Skills required
Install the Active Directory LDAP connector in Auth0 with AWS Managed Microsoft AD.	1. Log in to the Auth0 dashboard and choose **Authentication**, **Enterprise**, **Active Directory / LDAP**.	Cloud administrator, Cloud architect

Task	Description	Skills required
	Choose **Create a connection**. 2. Provide the name for your Active Directory connection, and then choose **Create**. 3. On the **Setup** tab, download the agent for your operating system. When the installation is complete, your default browser displays a prompt for the ticket URL. 4. Enter the provisioning ticket URL, which should be unique for your connection string, and then choose **Continue**. 5. In the **AD LDAP Configuration** dialog box, for **Username** and **Password**, enter your administrator credentials, and then choose **Save**. When the connection to Auth0 has been established, the configuration log is displayed with a reporting status of **OK** for all checks.	

Task	Description	Skills required

Create an application in Auth0 to generate the SAML metadata manifest file.	1. Log in to the Auth0 dashboard and create a new application by following the instructions in the [Auth0 documentation]().
	 2. On the Auth0 dashboard, choose the application name to access its configuration settings. On the **AddOns** tab, choose **SAML2 Web App**.
	 3. On the **Settings** tab for the add-on, for **Application Callback URL**, enter **https://signin.aws.amazon.com/saml**. This is where the SAML token will send the POST request.
	 4. On the **Settings** tab, in the **Settings** box, paste the following SAML configuration code in JSON format:
	 `{`
	 `  "audience": "https://signin.aws.amazon.com/saml",`
	 `  "mappings": {`
	 `    "email": "http://schemas.xmlsoap.org/ws/2005/05/identity/claims/sAMAccountName",`
	 `    "name": "http://schemas.xmlsoap.org/`
		Cloud administrator, Cloud architect

Task	Description	Skills required

	``
	ws/2005/05/identity/
	claims/name"
	  },
	  "createUpnClaim":
	 false,
	  "passthroughClaims
	WithNoMapping":
	 false,
	  "mapUnknownClaimsA
	sIs": false,
	  "mapIdentities":
	 false,
	  "nameIdentifierFor
	mat": "urn:oasi
	s:names:tc:SAML:2.
	0:nameid-format:pe
	rsistent",
	  "nameIdentifierPro
	bes": [
	    "http://s
	chemas.auth0.com/s
	AMAccountName"
	  ]
	}
	``
	5. Save, and then choose **Enable**.
	6. Choose the **Usage** tab, and download the metadata manifest file for the identity provider. This information is required for the next steps.
	7. Close the **SAML2 Web App** window.
	8. On the applications screen, choose **Connections**. Under **Enterprise**, select the correct Active Directory	

Task	Description	Skills required
	/LDAP connector and enable it.	

Set up IdP, role, and policy for SAML 2.0 in IAM

Task	Description	Skills required
Create a SAML 2.0 IdP in IAM.	To set up SAML 2.0 as an IdP, follow the steps that are outlined in [Create a SAML identity provider in IAM](#) in the IAM documentation.	Cloud administrator
Create an IAM role and policy for SAML 2.0 federation.	1. Create an IAM role for SAML 2.0 federation. For instructions, see [step 2](#) in the instructions for setting up SAML 2.0 for WorkSpaces Personal in the WorkSpaces documentation. 2. Create an IAM policy and associate it with the role you created in the previous step. For instructions, see [step 3](#) in the instructions for setting up SAML 2.0 for WorkSpaces Personal in the WorkSpaces documentation.	Cloud administrator

Configure assertions in Auth0

Task	Description	Skills required
Configure Auth0 and SAML assertions.	You can use Auth0 actions to configure assertions in SAML 2.0 responses. A SAML assertion is an encrypted token that asserts the user's identity. 1. Sign in to the Auth0 dashboard. Choose **Actions**, **Library**, **Create Action**, **Build from scratch**. 2. Provide the following values and then choose **Create**. **Name: Specify a name for the action** **Trigger: Choose Login/Post Login** **Runtime: Choose Node 18** 3. On the next screen, enter the following code: `exports.onExecutePostLogin = async (event, api) => {   if (event.client.name === "Workspace_Saml") {     const awsRole = 'arn:aws:iam::030784294031:role/Workspace_Auth0,arn:aw`	Cloud administrator

Task	Description	Skills required

	``
	s:iam::03078429403
	1:saml-provider/Au
	th0';
	     const awsRoleSe
	ssion = event.use
	r.sAMAccountName;
	     const email =
	 event.user.emails[
	0];
	     api.samlR
	esponse.setDestina
	tion('https://sign
	in.aws.amazon.com/
	saml');
	     api.samlR
	esponse.setAttribu
	te('https://aws.am
	azon.com/SAML/
	Attributes/Role',
	 awsRole)
	     api.samlR
	esponse.setAttribu
	te('https://aws.am
	azon.com/SAML/Attr
	ibutes/RoleSession
	Name', awsRoleSe
	ssion)
	     api.samlR
	esponse.setAttribu
	te('https://aws.am
	azon.com/SAML/Attr
	ibutes/PrincipalTa
	g:Email', email)
	   } return;
	};
	``
	4. Choose **Deploy**.
	
	This completes the setup of SAML 2.0 authentication for WorkSpaces Personal	

Task	Description	Skills required
	desktops. The Architect ure section illustrates the authentication process after setup.	

Troubleshooting

Issue	Solution
SAML 2.0 authentication issues in WorkSpaces	If you encounter any issues when you implement SAML 2.0 authentication for WorkSpaces Personal, follow the steps and links outlined in the AWS re:Post article on troubleshooting SAML 2.0 authentication. For additional information about investigating SAML 2.0 errors while accessing WorkSpaces, see: • How do I create a HAR file and Console logs from my browser for an AWS Support case? (AWS re:Post) • View a SAML response in your browser (IAM documentation)

Deploy a Lustre file system for high-performance data processing by using Terraform and DRA

Arun Bagal and Ishwar Chauthaiwale, Amazon Web Services

Summary

This pattern automatically deploys a Lustre file system on AWS and integrates it with Amazon Elastic Compute Cloud (Amazon EC2) and Amazon Simple Storage Service (Amazon S3).

This solution helps you quickly set up a high performance computing (HPC) environment with integrated storage, compute resources, and Amazon S3 data access. It combines Lustre's storage capabilities with the flexible compute options provided by Amazon EC2 and the scalable object storage in Amazon S3, so you can tackle data-intensive workloads in machine learning, HPC, and big data analytics.

The pattern uses a HashiCorp Terraform module and Amazon FSx for Lustre to streamline the following process:

- Provisioning a Lustre file system
- Establishing a data repository association (DRA) between FSx for Lustre and an S3 bucket to link the Lustre file system with Amazon S3 objects
- Creating an EC2 instance
- Mounting the Lustre file system with the Amazon S3-linked DRA on the EC2 instance

The benefits of this solution include:

- Modular design. You can easily maintain and update the individual components of this solution.
- Scalability. You can quickly deploy consistent environments across AWS accounts or Regions.
- Flexibility. You can customize the deployment to fit your specific needs.
- Best practices. This pattern uses preconfigured modules that follow AWS best practices.

For more information about Lustre file systems, see the Lustre website.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A least privilege AWS Identity and Access Management (IAM) policy (see instructions)

Limitations

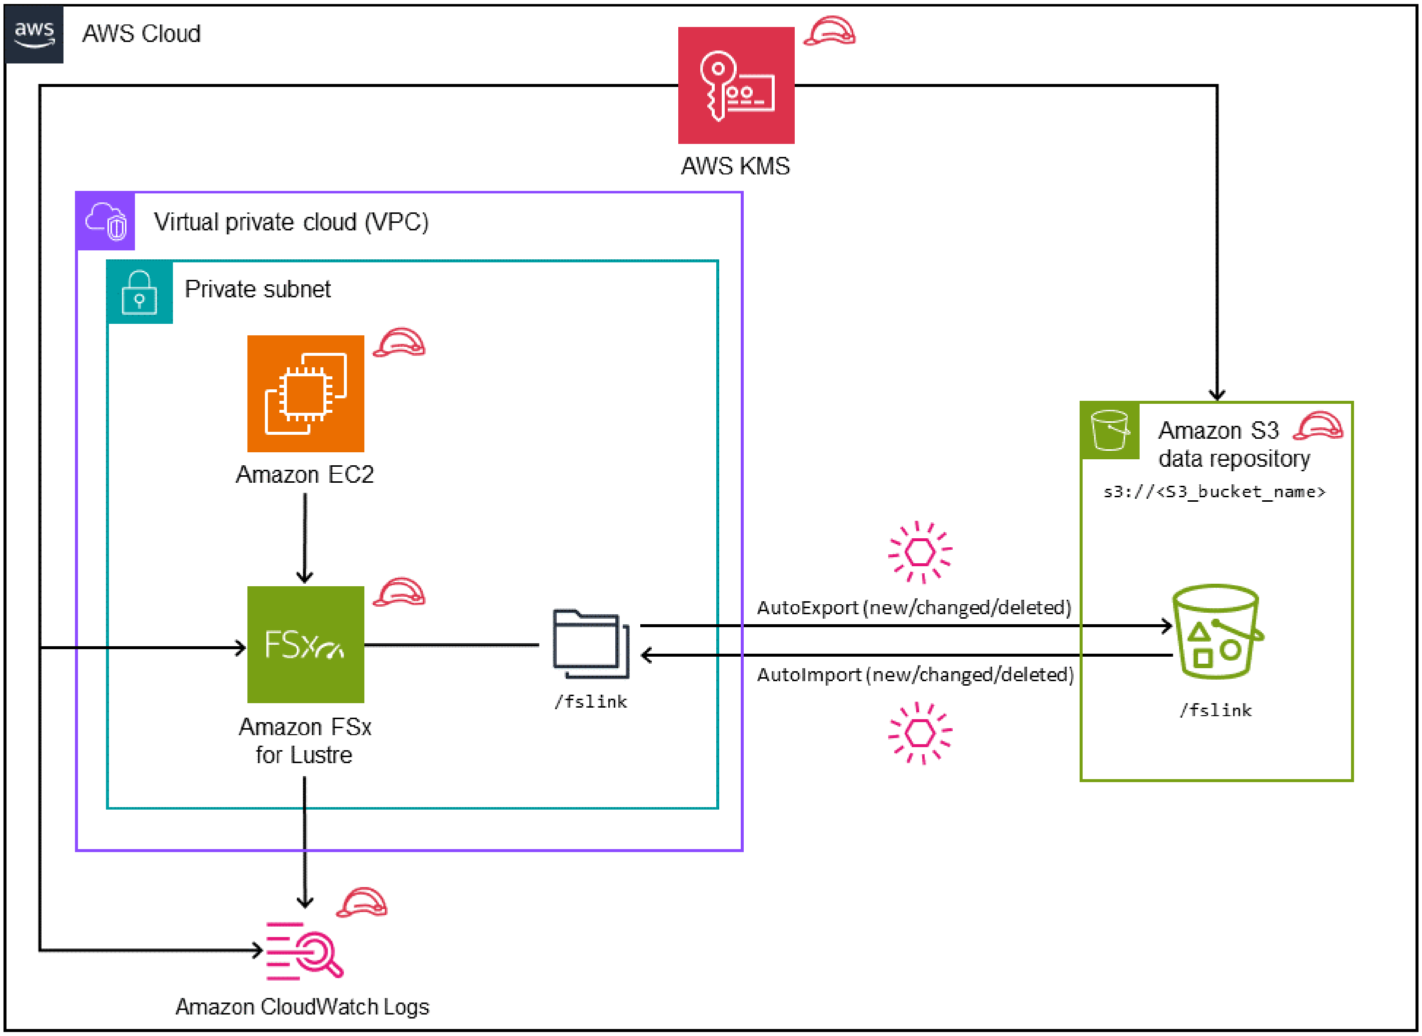
FSx for Lustre limits the Lustre file system to a single Availability Zone, which could be a concern if you have high availability requirements. If the Availability Zone that contains the file system fails, access to the file system is lost until recovery. To achieve high availability, you can use DRA to link the Lustre file system with Amazon S3, and transfer data between Availability Zones.

Product versions

- Terraform version 1.9.3 or later
- HashiCorp AWS Provider version 4.0.0 or later

Architecture

The following diagram shows the architecture for FSx for Lustre and complementary AWS services in the AWS Cloud.



The architecture includes the following:

- An S3 bucket is used as a durable, scalable, and cost-effective storage location for data. The integration between FSx for Lustre and Amazon S3 provides a high-performance file system that is seamlessly linked with Amazon S3.
- FSx for Lustre runs and manages the Lustre file system.
- Amazon CloudWatch Logs collects and monitors log data from the file system. These logs provide insights into the performance, health, and activity of your Lustre file system.
- Amazon EC2 is used to access Lustre file systems by using the open source Lustre client. EC2 instances can access file systems from other Availability Zones within the same virtual private cloud (VPC). The networking configuration allows for access across subnets within the VPC. After the Lustre file system is mounted on the instance, you can work with its files and directories just as you would use a local file system.

- AWS Key Management Service (AWS KMS) enhances the security of the file system by providing encryption for data at rest.

Automation and scale

Terraform makes it easier to deploy, manage, and scale your Lustre file systems across multiple environments. In FSx for Lustre, a single file system has size limitations, so you might need to horizontally scale by creating multiple file systems. You can use Terraform to provision multiple Lustre file systems based on your workload needs.

Tools

AWS services

- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon FSx for Lustre makes it easy and cost-effective to launch, run, and scale a high-performance Lustre file system.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code repository

The code for this pattern is available in the GitHub Provision FSx for Lustre Filesystem using Terraform repository.

Best practices

- The following variables define the Lustre file system. Make sure to configure these correctly based on your environment, as instructed in the Epics section.
  - `storage_capacity` – The storage capacity of the Lustre file system, in GiBs. The minimum and default setting is 1200 GiB.

- deployment_type – The deployment type for the Lustre file system. For an explanation of the two options, PERSISTENT_1 and PERSISTENT_2 (default), see the FSx for Lustre documentation.
- per_unit_storage_throughput – The read and write throughput, in MBs per second per TiB.
- subnet_id – The ID of the private subnet where you want to deploy FSx for Lustre.
- vpc_id – The ID of your virtual private cloud on AWS where you want to deploy FSx for Lustre.
- data_repository_path – The path to the S3 bucket that will be linked to the Lustre file system.
- iam_instance_profile – The IAM instance profile to use to launch the EC2 instance.
- kms_key_id – The Amazon Resource Name (ARN) of the AWS KMS key that will be used for data encryption.

- Ensure proper network access and placement within the VPC by using the security_group and vpc_id variables.
- Run the terraform plan command as described in the Epics section to preview and verify changes before applying them. This helps catch potential issues and ensures that you are aware of what will be deployed.
- Use the terraform validate command as described in the Epics section to check for syntax errors and to confirm that your configuration is correct.

Epics

Set up your environment

Task	Description	Skills required
Install Terraform.	To install Terraform on your local machine, follow the instructions in the Terraform documentation.	AWS DevOps, DevOps engineer
Set up AWS credentials.	To set up the AWS Command Line Interface (AWS CLI) profile for the account, follow	AWS DevOps, DevOps engineer

Task	Description	Skills required
	the instructions in the [AWS documentation]().	
Clone the GitHub repository.	To clone the GitHub repositor y, run the command: `git clone https://github.com/aws-samples/provision-fsx-lustre-with-terraform.git`	AWS DevOps, DevOps engineer

Configure and deploy FSx for Lustre

Task	Description	Skills required
Update the deployment configuration.	1. In the cloned repositor y on your local machine, navigate to the `fsx_deployment` directory: `cd fsx_deployment` 2. Open the `terraform .tfvars` file, and update the values of the following variables: • `vpc_id` • `subnet_id` • `data_repository_path` • `iam_instance_profile`	AWS DevOps, DevOps engineer

Task	Description	Skills required
	• `kms_key_id` For descriptions of these variables, see the Best practices section. 3. In the same directory, open the `locals.tf` file and update the CIDR ranges for the `fsx_inress` and `fsx_egress` security group variables. 4. If needed, open the `variables.tf` file and update the default values of these variables: • `storage_capacity` • `deployment_type` • `per_unit_storage_throughput` For descriptions of these variables, see the Best practices section.	
Initialize the Terraform environment.	To initialize your environment to run the Terraform `fsx_deployment` module, run: `terraform init`	AWS DevOps, DevOps engineer

Task	Description	Skills required
Validate the Terraform syntax.	To check for syntax errors and to confirm that your configuration is correct, run: `terraform validate`	AWS DevOps, DevOps engineer
Validate the Terraform configuration.	To create a Terraform execution plan and preview the deployment, run: `terraform plan -var-file terraform.tfvars`	AWS DevOps, DevOps engineer
Deploy the Terraform module.	To deploy the FSx for Lustre resources, run: `terraform apply -var-file terraform.tfvars`	AWS DevOps, DevOps engineer

Clean up AWS resources

Task	Description	Skills required
Remove AWS resources.	After you finish using your FSx for Lustre environment, you can remove the AWS resources deployed by Terraform to avoid incurring unnecessary charges. The Terraform module provided in the code repository automates this cleanup.	AWS DevOps, DevOps engineer

Task	Description	Skills required

	1. In your local repository, navigate to the `fsx_deployment` directory:
	`cd fsx_deployment`
	2. Run the command:
	`terraform destroy -var-file terraform.tfvars`	

Troubleshooting

Issue	Solution
FSx for Lustre returns errors.	For help with FSx for Lustre issues, see Troubleshooting Amazon FSx for Lustre in the FSx for Lustre documentation.

Set up a Grafana monitoring dashboard for AWS ParallelCluster

Dario La Porta and William Lu, Amazon Web Services

Summary

AWS ParallelCluster helps you deploy and manage high performance computing (HPC) clusters. It supports AWS Batch and Slurm open source job schedulers. Although AWS ParallelCluster is integrated with Amazon CloudWatch for logging and metrics, it doesn't provide a monitoring dashboard for the workload.

The Grafana dashboard for AWS ParallelCluster (GitHub) is a monitoring dashboard for AWS ParallelCluster. It provides job scheduler insights and detailed monitoring metrics at the operating system (OS) level. For more information about the dashboards included in this solution, see Example Dashboards in the GitHub repository. These metrics help you better understand the HPC workload and its performance. However, the dashboard code is not updated for the latest versions of AWS ParallelCluster or the open source packages that are used in solution. This pattern enhances the solution to provide the following benefits:

- Supports AWS ParallelCluster v3
- Uses the latest version of open source packages, including Prometheus, Grafana, Prometheus Slurm Exporter, and NVIDIA DCGM-Exporter
- Increases the number of CPU cores and GPUs that the Slurm jobs use
- Adds a job monitoring dashboard
- Enhances the GPU node monitoring dashboard for nodes with 4 or 8 graphics processing units (GPUs)

This version of the enhanced solution has been implemented and verified in an AWS customer's HPC production environment.

Prerequisites and limitations

Prerequisites

- AWS ParallelCluster CLI, installed and configured.
- A supported network configuration for AWS ParallelCluster. This pattern uses the AWS ParallelCluster using two subnets configuration, which requires a public subnet, private subnet, internet gateway, and NAT gateway.

- All AWS ParallelCluster cluster nodes must have internet access. This is required so that the installation scripts can download the open source software and Docker images.
- A key pair in Amazon Elastic Compute Cloud (Amazon EC2). Resources that have this key pair have Secure Shell (SSH) access to the head node.

Limitations

- This pattern is designed to support Ubuntu 20.04 LTS. If you're using a different version of Ubuntu or if you use Amazon Linux or CentOS, then you need to modify the scripts provided with this solution. These modifications are not included in this pattern.

Product versions

- Ubuntu 20.04 LTS
- ParallelCluster 3.X

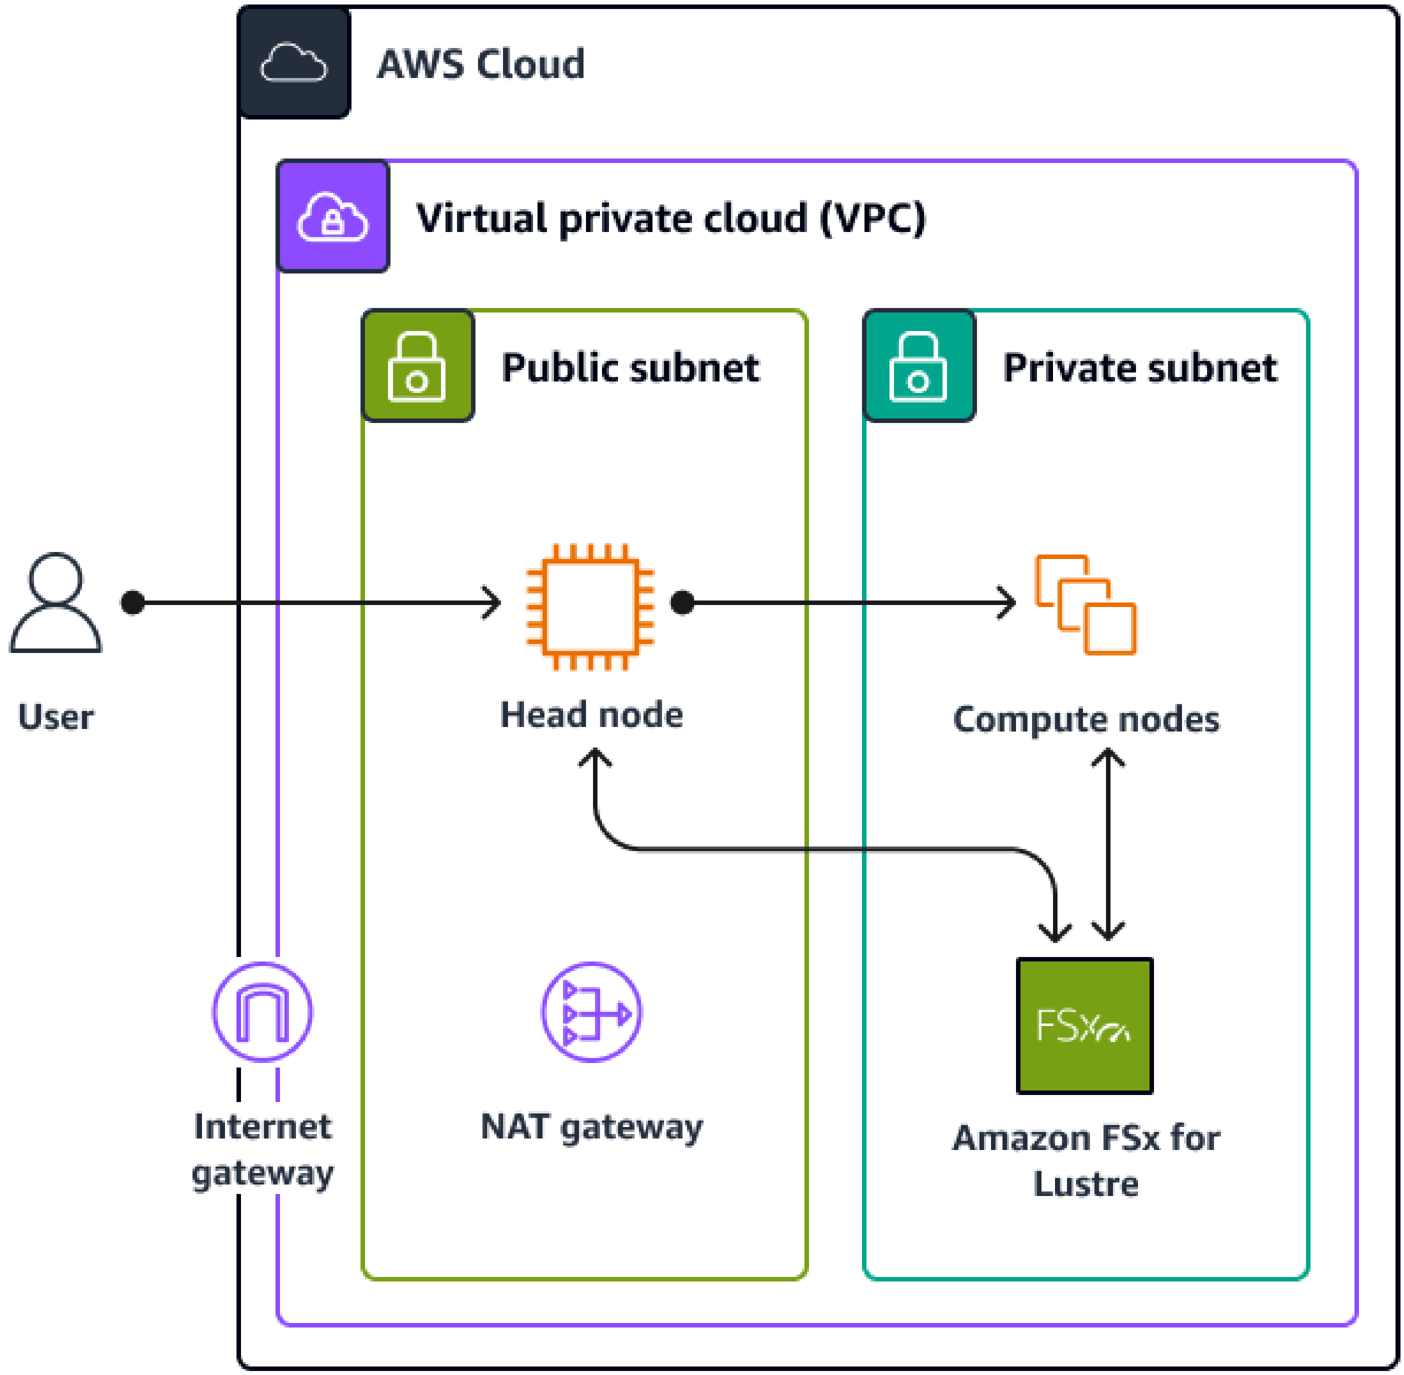
Billing and cost considerations

- The solution deployed in this pattern is not covered by the free tier. Charges apply for Amazon EC2, Amazon FSx for Lustre, the NAT gateway in Amazon VPC, and Amazon Route 53.

Architecture

Target architecture

The following diagram shows how a user can access the monitoring dashboard for AWS ParallelCluster on the head node. The head node runs NICE DCV, Prometheus, Grafana, Prometheus Slurm Exporter, Prometheus Node Exporter, and NGINX Open Source. The compute nodes run Prometheus Node Exporter, and they also run NVIDIA DCGM-Exporter if the node contains GPUs. The head node retrieves information from the compute nodes and displays that data in the Grafana dashboard.



In most cases, the head node is not heavily loaded because the job scheduler doesn't require a significant amount of CPU or memory. Users access the dashboard on the head node by using SSL on port 443.

All authorized viewers can anonymously view the monitoring dashboards. Only the Grafana administrator can modify dashboards. You configure a password for the Grafana administrator in the `aws-parallelcluster-monitoring/docker-compose/docker-compose.head.yml` file.

Tools

AWS services

- NICE DCV is a high-performance remote display protocol that helps you deliver remote desktops and application streaming from any cloud or data center to any device, over varying network conditions.
- AWS ParallelCluster helps you deploy and manage high performance computing (HPC) clusters. It supports AWS Batch and Slurm open source job schedulers.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- Grafana is an open source software that helps you query, visualize, alert on, and explore metrics, logs, and traces.
- NGINX Open Source is an open source web server and reverse proxy.
- NVIDIA Data Center GPU Manager (DCGM) is a suite of tools for managing and monitoring NVIDIA data center graphics processing units (GPUs) in cluster environments. In this pattern, you use DCGM-Exporter, which helps you export GPU metrics from Prometheus.
- Prometheus is an open source system-monitoring toolkit that collects and stores its metrics as time-series data with associated key-value pairs, which are called *labels*. In this pattern, you also use Prometheus Slurm Exporter to collect and export metrics, and you use Prometheus Node Exporter to export metrics from the compute nodes.
- Ubuntu is an open source, Linux-based operating system that is designed for enterprise servers, desktops, cloud environments, and IoT.

Code repository

The code for this pattern is available in the GitHub [pcluster-monitoring-dashboard](https://github.com/aws-samples/parallelcluster-monitoring-dashboard) repository.

Epics

Create the required resources

Task	Description	Skills required
Create an S3 bucket.	Create an Amazon S3 bucket. You use this bucket to store the configuration scripts. For instructions, see [Creating a bucket](#) in the Amazon S3 documentation.	General AWS
Clone the repository.	Clone the GitHub [pcluster-monitoring-dashboard](#) repo by running the following command. `git clone https://github.com/aws-samples/parallelcluster-monitoring-dashboard.git`	DevOps engineer
Create an admin password.	1. Choose the `aws-parallelcluster-monitoring` folder, choose the `docker-compose` folder, and then open the **docker-compose.head.yml** file. 2. In the `GF_SECURITY_ADMIN_PASSWORD` variable, replace `Grafana4PC!` with a password of your choice. This is the administrative	Linux Shell scripting

Task	Description	Skills required
	password that you use to manage the Grafana account. 3. Save and close the **docker-compose.head.yml** file.	
Copy the required files into the S3 bucket.	Copy the post_install.sh script and the aws-parallelcluster-monitoring folder into the S3 bucket you created. For instructions, see Uploading objects in the Amazon S3 documentation.	General AWS

Task	Description	Skills required
Configure an additional security group for the head node.	1. Create a security group for the head node. This security group will allow inbound traffic to the monitoring dashboards on the head node. For instructions, see [Create a security group](#) in the Amazon VPC documentation. 2. Add an inbound rule to the security group. For instructions, see [Add rules to a security group](#) in the Amazon VPC documentation. Use the following parameters for the rule: • **Type** – HTTPS • **Protocol** – TCP • **Port range** – 443 • **Source** – Enter your IP address • **Description** – Allow users to access the monitoring dashboard	AWS administrator

Task	Description	Skills required
Configure an IAM policy for the head node.	Create an identity-based policy for the head node. This policy allows the node to retrieve metric data from Amazon CloudWatch. The GitHub repo contains an example policy. For instructions, see Creating IAM policies in the AWS Identity and Access Management (IAM) documentation.	AWS administrator
Configure an IAM policy for the compute nodes.	Create an identity-based policy for the compute nodes. This policy allows the node to create the tags that contain the job ID and job owner. The GitHub repo contains an example policy. For instructions, see Creating IAM policies in the IAM documentation. If you use the provided example file, replace the following values: • **<REGION>** – The AWS Region where the cluster is hosted • **<ACCOUNT_ID>** – The AWS account ID	AWS administrator

Create the cluster

Task	Description	Skills required
Modify the provided cluster template file.	Create the AWS ParallelC luster cluster. Use the provided cluster.yaml AWS CloudFormation template file as a starting point to create the cluster. Replace the following values in the provided template: • **<REGION>** – The AWS Region where the cluster is hosted. • **<HEADNODE_SUBNET>** – The public subnet of the VPC. • **<ADDITIONAL_HEAD_N ODE_SG>** – The name of the security group that you created for the head node. • **<KEY_NAME>** – Enter the name of an existing Amazon EC2 key pair. Resources that have this key pair have Secure Shell (SSH) access to the head node. • **<ALLOWED_IPS>** -–Enter the CIDR-formatted IP address range that is allowed to make SSH connections to the head node.	AWS administrator

Task	Description	Skills required
	• **<ADDITIONAL_HEAD_NODE_POLICY>** – Enter the name of the IAM policy that you created for the head node. • **<BUCKET_NAME>** – Enter the name of the S3 bucket you created. • **<COMPUTE_SUBNET>** – Enter the name of the private subnet in the VPC. • **<ADDITIONAL_COMPUTE_NODE_POLICY>** – Enter the name of the IAM policy that you created for the compute node.	
Create the cluster.	In the AWS ParallelCluster CLI, enter the following command. This deploys the CloudFormation template and creates the cluster. For more information about this command, see [pcluster create-cluster](https://docs.aws.amazon.com/parallelcluster/latest/ug/pcluster.create-cluster-v3.html) in the AWS ParallelCluster documentation. `pcluster create-cluster -n <cluster_name> -c cluster.yaml`	AWS administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Monitor the cluster creation.</td><td>Enter the following command to monitor the cluster creation. For more informati on about this command, see pcluster describe-cluster in the AWS ParallelCluster documentation.<pre><code>pcluster describe-cluster -n <cluster_name></code></pre></td><td>AWS administrator</td></tr>
</table>

Using the Grafana dashboards

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Access to the Grafana portal.</td><td>1. Enter the following command to retrieve the public IP address of the head node.<pre><code>pcluster describe-cluster -n <cluster_name> --query headNode.publicIpAddress</code></pre>2. In a web browser, navigate to the following URL in order to access the Grafana dashboard.

https://<head_node_public_ip_address></td><td>AWS administrator</td></tr>
</table>

Task	Description	Skills required
	3. On the Grafana front page, choose the 4-square **Dashboard** icon on the left menu, and then choose **General**. This shows a list of configured dashboards. The following dashboards are available in Grafana: • **Cluster Cost** – Contains information about the cost of the cluster • **Cluster Logs** – Contains information about the logs of the cluster • **Compute Node Details** – Contains information about usage statistics of the compute nodes • **Compute Node List** – Contains the list of the compute nodes of the cluster • **GPU Nodes** – Contains information about usage statistics of the GPU nodes • **Jobs Details** – Contains information about the jobs resources utilization • **Head Node Details** – Contains information about usage statistics of the head node	

Task	Description	Skills required
	• **ParallelCluster Summary** – Contains information about cluster usage	

Clean up the solution to stop incurring associated costs

Task	Description	Skills required
Delete the cluster.	Enter the following command to delete the cluster. For more information about this command, see [pcluster delete-cluster](#) in the AWS ParallelCluster documentation. `pcluster delete-cluster -n <cluster_name>`	AWS administrator
Delete the IAM policies.	Delete the policies that you created for the head node and compute node. For more information about deleting policies, see [Deleting IAM policies](#) in the IAM documentation.	AWS administrator
Delete the security group and rule.	Delete the security group that you created for the head node. For more information, see [Delete security group rules](#) and [Delete a security](#)	AWS administrator

Task	Description	Skills required
	group in the Amazon VPC documentation.	
Delete the S3 bucket.	Delete the S3 bucket that you created to store the configuration scripts. For more information, see Deleting a bucket in the Amazon S3 documentation.	General AWS

Troubleshooting

Issue	Solution
The head node is not accessible in the browser.	Check the security group and confirm that the inbound port 443 is open.
Grafana doesn't open.	On the head node, check the container log for `docker logs Grafana`.
Some metrics have no data.	On the head node, check the container logs of all containers.

Configure a data center extension to VMware Cloud on AWS using Hybrid Linked Mode

Deepak Kumar, Amazon Web Services

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how you can use Hybrid Linked Mode to view and manage inventories in an on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC) by using a single VMware vSphere Client interface.

By configuring Hybrid Linked Mode, you can migrate your on-premises virtual machines (VMs) and applications to the cloud SDDC. Your IT teams can then manage your cloud-based resources with familiar VMware tools and without requiring any new tools. You can also ensure consistent operations and simplified administration by using the VMware Cloud Gateway Appliance.

This pattern provides two options for configuring Hybrid Linked Mode, but you can only use one option at a time. The first option installs the Cloud Gateway Appliance and uses it to link from the on-premises vCenter Server to the cloud SDDC. The second option configures Hybrid Linked Mode from the cloud SDDC.

Prerequisites and limitations

Prerequisites (both options)

- An existing on-premises data center and a cloud SDDC.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN, or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn't exceed 100ms.

- Cloud administrators with access to your on-premises environment.
- The vCenter Server’s fully qualified domain name (FQDN) must resolve to a private IP address.

Prerequisites for Option 1

- The on-premises environment should run on vSphere 6.5.0d or later.
- The Cloud Gateway Appliance and vCenter Server can communicate over AWS Direct Connect, a VPN, or both.
- The Cloud Gateway Appliance meets hardware requirements.
- Firewall ports are open.

Prerequisites for Option 2

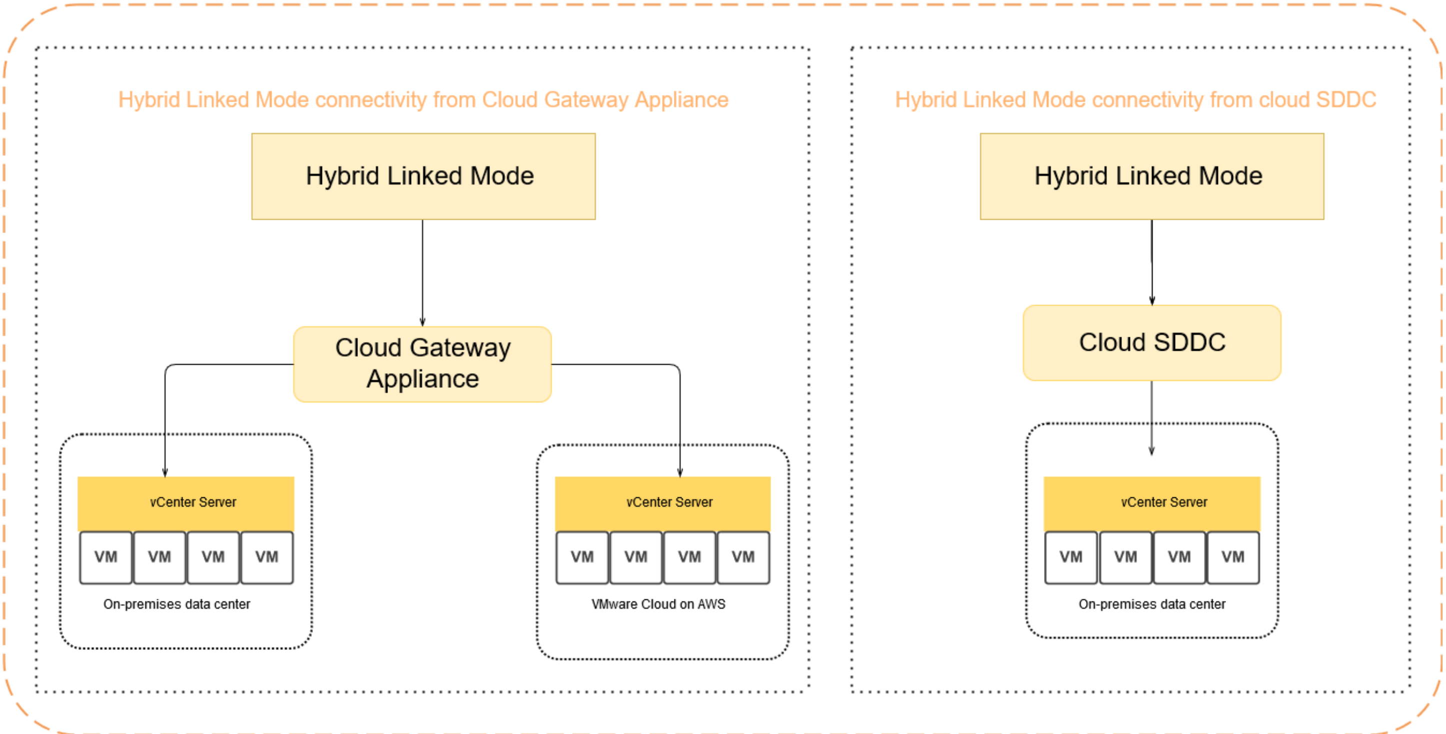
- The on-premises vCenter Server runs on vSphere 6.0 Update 3 or later, or on vSphere 6.5.0d or later .
- Login credentials are available for the on-premises vSphere single sign-on (SSO) domain.
- Users in the on-premises environment have read-only access to the base distinguished name (Base DN).
- The on-premises Domain Name System (DNS) server is configured for VMware Management Gateway.
- Implement network connectivity tests using the VMware Connectivity Validator.
- Firewall ports are open.

Limitations

- Hybrid Linked Mode can only connect one on-premises vCenter Sever Enhanced Linked Mode domain.
- Hybrid Linked Mode only supports on-premises vCenter Server running version 6.7 or later.

Architecture

The following diagram shows both options for configuring Hybrid Linked Mode.

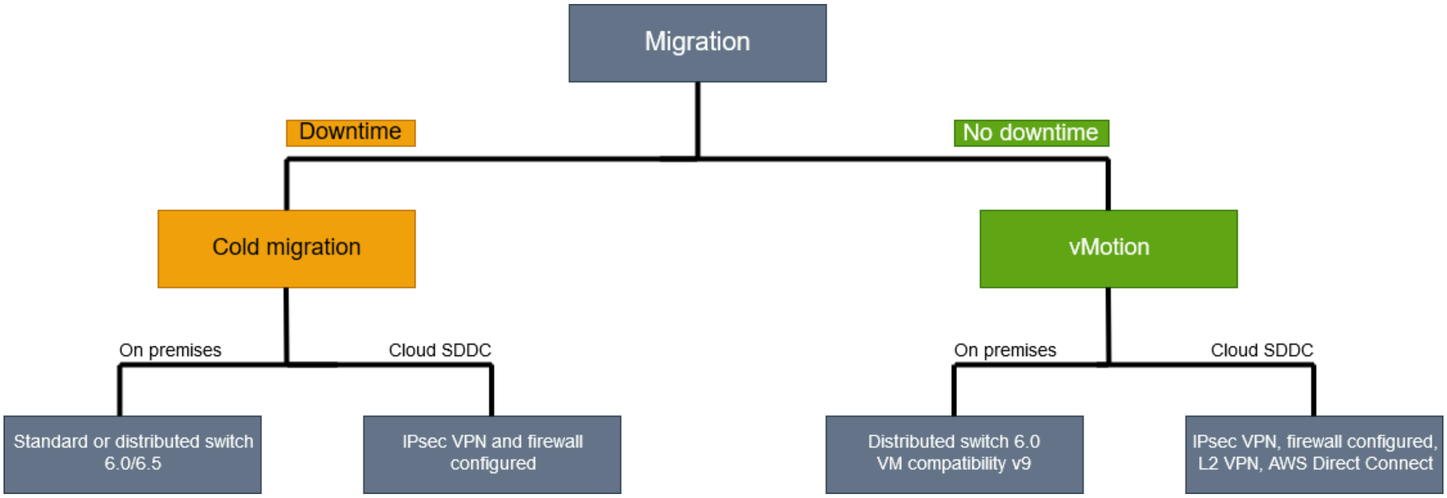


Migrating different workload types using Hybrid Linked Mode

Hybrid Linked Mode supports migrating workloads between an on-premises data center and a cloud SDDC by using either a [cold migration](#) or a live migration with [VMware vSphere vMotion](#). Factors that must be considered when choosing the migration method include the virtual switch type and version, the connection type to the cloud SDDC, and the virtual hardware version.

A cold migration is appropriate for VMs that experience downtime. You can shut down the VMs, migrate them, and then turn them back on. The migration time is faster because there is no need to copy active memory. We recommend using a cold migration for applications that accept downtime (for example, tier 3 applications or development and testing workloads). If your VMs cannot experience downtime, you should consider a live migration using vMotion for your mission-critical applications.

The following diagram provides an overview of the different workload migration types using Hybrid Linked Mode.



Tools

- VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.
- VMware Cloud Gateway Appliance enables a number of hybrid cloud use cases where on-premises resources are connected to cloud resources.
- VMware vSphere is VMware's virtualization platform, which transforms data centers into aggregated computing infrastructures that include CPU, storage, and networking resources.

Epics

Option 1 - Use Hybrid Linked Mode with the Cloud Gateway Appliance

Task	Description	Skills required
Configure the Cloud Gateway Appliance.	1. Log in to the VMware Cloud on AWS console and download the Cloud Gateway Appliance. 2. Install the Cloud Gateway Appliance in your on-premises environment with the following two steps: • Choose **Start to configure** and then	Cloud administrator

Task	Description	Skills required
	deploy the Cloud Gateway Appliance. • Configure Hybrid Linked Mode. For more information and detailed steps, see [Configuring Hybrid Linked Mode using the vCenter Cloud Gateway Appliance] in the VMware documentation.	

Option 2 - Use Hybrid Linked Mode from the cloud SDDC

Task	Description	Skills required
Configure Hybrid Linked Mode from the cloud SDDC.	1. Log in to the VMware Cloud on AWS console and use the Connectivity Validator to check all required network connectivity. For more information about this, see [Validate network connectivity for Hybrid Linked Mode] in the VMware documentation. 2. Log in to the vSphere Client of the cloud SDDC, choose **Menu**, choose **Administration**, and then choose **Domains**. 3. In the **Hybrid Cloud** section, choose **Linked**	Cloud administrator

Task	Description	Skills required
	Domains and then connect to your on-premises vCenter Server. 4. Add an identity source to the cloud SDDC Lightweig ht Directory Access Protocol (LDAP) domain. For more information about this, see Add an Identity Source to the SDDC LDAP Domain in the VMware documentation.

Configure VMware vRealize Automation to provision VMs on VMware Cloud on AWS

Deepak Kumar, Amazon Web Services

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

[VMware vRealize Automation](#) is automation software that you can use to request and manage IT resources. By choosing to configure vRealize Automation with VMware Cloud on AWS, you can automate the delivery of virtual machines (VMs), applications, and IT services across multiple data centers and cloud environments.

Your IT teams can then create catalog items to configure service provisioning and operational capabilities that your users can request and use with their existing vRealize Automation tools. You can also improve your IT agility and efficiency by integrating VMware Cloud on AWS with vRealize Automation Cloud Assembly.

This pattern describes how to configure VMware vRealize Automation to automatically build VMs or application capabilities on VMware Cloud on AWS.

Prerequisites and limitations

Prerequisites

- An existing on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC). For more information about the cloud SDCC, see About Software-Defined Data Centers in the VMware documentation.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN (route or policy-based), or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn’t exceed 100ms.

- The vCenter Server's fully qualified domain name (FQDN) must resolve to a private IP address.
- Cloud SDDC users with access to your on-premises environment.
- Organization owner access in the vRealize Automation Cloud Assembly service role.
- End users with permission in vRealize Automation Service Broker to consume service.
- The on-premises data center's Classless Inter-Domain Routing (CIDR) range must be open for the generating of API tokens from the VMware Cloud on AWS console. The following list provides the minimum roles required to generate API tokens:
  - Organization member
  - Organization owner
  - Service Roles - VMware Cloud on AWS
  - Administrator
  - NSX Cloud Administrator
  - NSX Cloud Auditor

For more information about this, see Connectivity Options for VMware Cloud on AWS SDDCs from the AWS Partner Network Blog.

Limitations

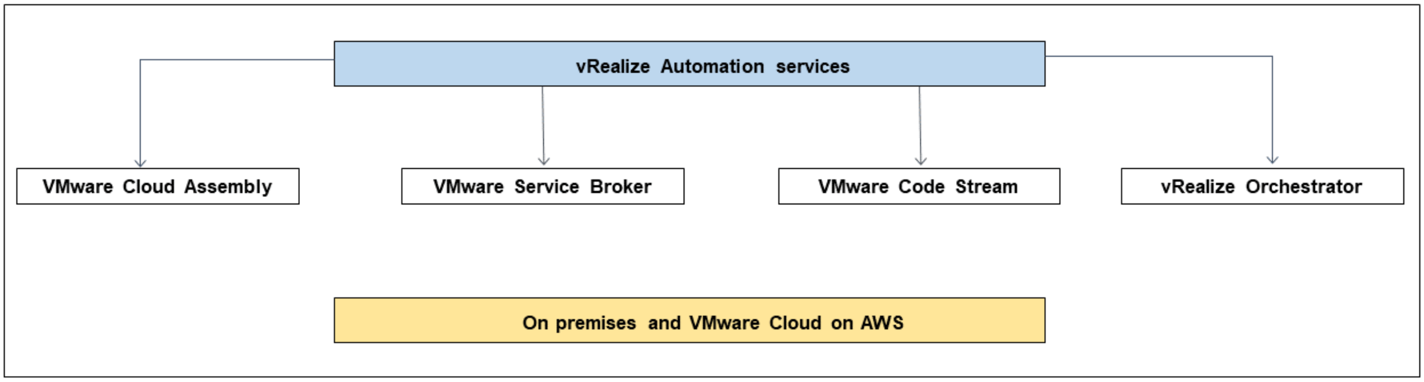
- You can only configure 20 VMware Cloud accounts with public endpoints in one vRealize Automation. For more information about this, see Scalability and concurrency maximums in the VMware documentation.

Product versions

- vRealize Automation version 8.x or later
- VMware vRealize Identity Manager version 3.x or later
- VMware vRealize Suite Lifecycle Manager version 8.x or later

Architecture

The following diagram shows the vRealize Automation services that can use infrastructure from both on-premises and VMware Cloud on AWS environments.



VMware Cloud Assembly components

VMware Cloud Assembly is a core component of vRealize Automation and you can use it to deploy and provision VMs and compute resources. The following table describes VMware Cloud Assembly components that must be configured for provisioning VMs on VMware Cloud on AWS.

Components	Definition
Cloud Account	The Cloud Account provides connection details (for example, server name, user name and password, access key, and API token). VMware Cloud Assembly uses the Cloud Account to collect an inventory of your resources.
Cloud zones	Cloud zones identify resource boundaries in the Cloud Account (for example, AWS Regions and the cloud SDDC). Cloud zones associate compute resources with the Cloud Assembly project.
Projects	A project is a logical entity that consists of users and resources such as cloud zones. It also consists of resource quotas and VM naming policies that are used when building the VM.
Flavor mappings	Flavor mapping provides information about the VM's capacity (for example, number of CPUs and amount of memory) that are used in the Cloud Template.

Image mappings	Image mapping maps the VMware vSphere VM template and Amazon Web Services (AWS) image that are used in the Cloud Template. For more information about this, see Learn more about image mappings in vRealize Automation in the VMware documentation.
Network profile	Network profile controls the placement decision to choose a network during VM provisioning.
Storage profile	Storage profile controls the placement decision to choose storage during VM provisioning.
Cloud Templates	VMware Cloud Templates are an important component of vRealize Automation because they define cloud infrastructure provisioning and orchestration. The Cloud Templates are specifications for the resources and include the resource type, resource properties, and input to be collected from users.

Tools

- VMware vRealize Automation – vRealize Automation is an infrastructure automation platform with event-driven state management and compliance. It is designed to help organizations control and secure self-service clouds, multi-cloud automation with governance, and DevOps-based infrastructure delivery.
- VMware Cloud on AWS – VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.

Epics

Generate the API tokens

Task	Description	Skills required
Generate the API tokens from your VMware Cloud on AWS account.	1. Sign in to the VMware Cloud Console. 2. On the VMware Cloud Services toolbar, choose **My Account** and then choose **API Token**. 3. Enter a name for your API token, provide the required lifespan, and define the scopes for the token. 4. Choose the **Open ID** check box and then choose **Generate**. 5. Record the API token's credentials. For more information about this, see [How do I generate API tokens](#) in the VMware documentation.	Cloud administrator

Install vRealize Automation in your on-premises data center

Task	Description	Skills required
Download the required software.	Download the VMware vRealize Suite ISO file from the My VMware Portal. This package contains vRealize	Cloud administrator

Task	Description	Skills required
	Suite Lifecycle Manager, VMware Identity Manager, and vRealize Automation.	
Install the software.	Install the software and connect to your cloud SDCC by following the instructi ons from [Installing vRealize Suite Lifecycle Manager with Easy Installer for vRealize Automationand VMware Identity Manager]() in the VMware documentation. **Important** Make sure that the following are available for your installation: • The on-premises VMware vCenter Server setup and login credentials • The network details for the vRealize Automation IP and subnet • The vRealize Automation license key	Cloud administrator, Cloud architect

Connect VMware Cloud on AWS with VMware Cloud Assembly

Task	Description	Skills required
Configure your Cloud Accounts.	1. On the VMware Cloud Console, open the **Infrastructure** tab, choose **Manage – Cloud Accounts**, and then choose **Add Cloud Accounts**. 2. Choose **VMware Cloud on AWS** as the type. 3. Paste the API token information that you recorded earlier. This populates all available cloud SDDCs in your VMware Cloud on AWS organization. 4. Choose the required cloud SDCC and then provide the vCenter user name and password for the SDDC. 5. After you are successfu lly authenticated, you can view the integrated VMware Cloud on AWS account with an **OK** status. For more information about this, see [Create a VMware Cloud on AWS cloud account in vRealize Automation]() in the VMware documentation.	Cloud architect, Cloud administrator

Task	Description	Skills required
Configure the project.	1. On the VMware Cloud Console, open the **Projects** tab and then choose **New project**. 2. Enter the name of your project. 3. Open the **Cloud Zones** tab and choose **default VMware Cloud on AWS Cloud Account**.	Cloud administrator
Configure cloud zone.	1. On the VMware Cloud Console, open **Cloud Zones** and choose the cloud zone for your SDDC data center. 2. By default, `cloudadmin@vmc.local` (this is the default local user ID for the cloud SDDC's vCenter) only has access to provision in the `Compute-ResourcePool` . 3. Open the **Compute** tab under **Cloud Zones** and then choose **Compute-ResourcePool**.	Cloud administrator

Task	Description	Skills required
Configure flavor mapping.	1. Open the **Flavor Mappings** tab and create a new flavor mapping. 2. Enter the flavor name, choose the VMware Cloud on AWS account, and then provide the number of vCPUs and amount of memory.	Cloud administrator
Configure image mapping.	1. Open **Image Mappings** and create a new image mapping. 2. Enter the image name. 3. Choose the VMware Cloud on AWS account and provide the Cloud Account templates that are required.	Cloud administrator
Configure network profile.	1. Open **Network Profile** and create a new network profile. 2. Enter the network profile name. 3. Open the **Network** tab and choose the existing network that you want to use for provisioning.	Cloud administrator

Task	Description	Skills required
Configure storage profile.	1. Open **Storage Profile** and choose **New Storage Profile**. 2. Enter the storage profile's name. 3. In the **Policies** section, create a new policy. 4. Choose **Workload Datastore**. By default `cloudadmin@vmc.local` only has access to provision in the workload's datastore.	Cloud administrator

Task	Description	Skills required
Create the Cloud Template.	1. Open the **Design** tab, choose **Cloud Templates** , and then choose **New From** and **Blank Canvas**. 2. Provide the name and description of the Cloud Template. 3. Choose the project that you created earlier. 4. From the Cloud Template resources design page, drag components into the blank canvas according to your requirements. 5. Choose **Test** to test the template and fix any issues. 6. Choose **Deployment** and provide the deployment name to deploy the VMs. For more information about this, see [Create a basic cloud template] in the VMware documentation.	Cloud administrator

Integrate VMware vRealize Network Insight with VMware Cloud on AWS

Deepak Kumar, Piotr Pitera, and Sachin Trivedi, Amazon Web Services

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to integrate VMware vRealize Network Insight with VMware Cloud on AWS and inspect traffic flow from your virtual machines. This integration also helps you plan application migrations to VMware Cloud on AWS.

vRealize Network Insight offers visibility into your network infrastructure. It provides network monitoring and analytics features to improve security, mitigate migration risks, and optimize performance. You can use this tool to monitor traffic flows from your virtual machines and view recommended security rules based on the observed traffic. For more information about vRealize Network Insight, see the VMware documentation.

VMware Cloud on AWS is a pay-as-you-go (on-demand) service that enables enterprises of all sizes to run workloads across VMware vSphere-based cloud environments by using a wide range of AWS services. You can start with a minimum of 2 hosts per SDDC cluster and scale up to 16 hosts per cluster in your production environment. For more information, see the VMware Cloud on AWS website. To learn more about SDDCs, see About Software-Defined Data Centers in the VMware documentation.

Prerequisites and limitations

Prerequisites

- VMware Cloud on AWS SDDC, deployed

Limitations

- For known limitations, see the VMware documentation.

Product versions

- vRealize Network Insight version 5.0.0
- VMware Cloud on AWS SDDC version 1.24

Architecture

Source technology stack

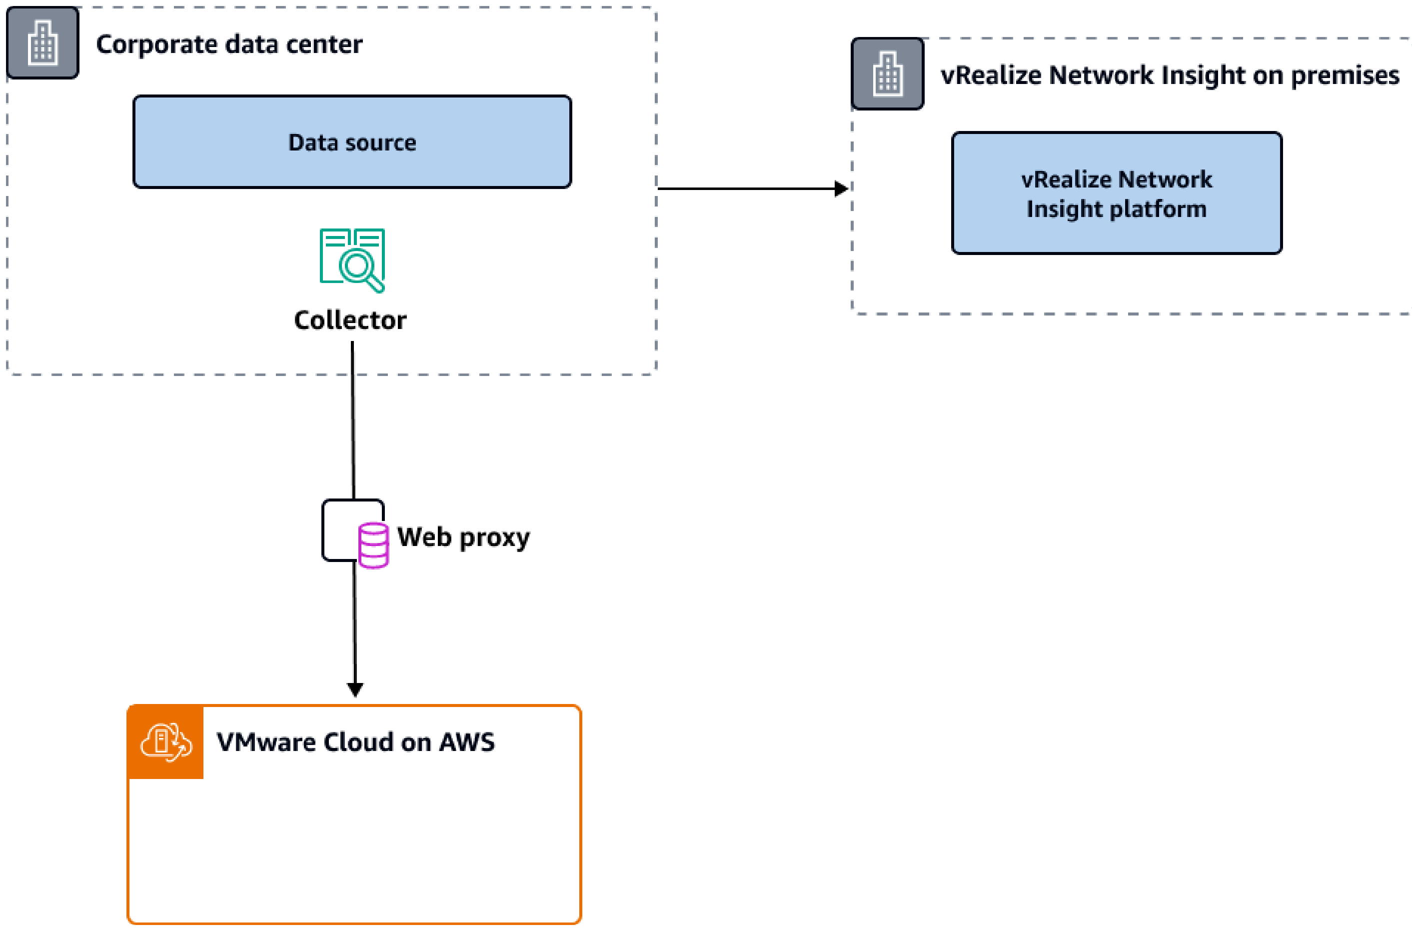
- vRealize Network Insight

Target technology stack

- VMware Cloud on AWS

Target architecture

The following diagram shows the connectivity between VMware Cloud on AWS and vRealize Network Insight on premises.



Tools

- VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.
- VMware vRealize Network Insight is a monitoring and analytics tool that provides visibility into the network infrastructure for security planning and troubleshooting.

Epics

Set up your environment for vRealize Network Insight

Task	Description	Skills required
Create a VMware user account.	Create a VMware user account or log in to your existing VMware account.	Cloud administrator

Task	Description	Skills required
	To open a new account: 1. Sign up for a VMware Customer Connect account by completing the registrat ion form. New users will receive an email to activate their accounts. 2. Enter the authentication code from the email. 3. Log in to Customer Connect.	
Download the OVA files for vRealize Network Insight.	Download the OVA files for vRealize Network Insight:. 1. Navigate to the VMware product download page at https://my.vmware.com/group/vmware/home. 2. Search for vRealize Network Insight. 3. Download the latest vRealize Network Insight version 5.0.0 platform and collector OVA files.	Cloud administrator
Deploy vRealize Network Insight.	For deployment instructions, see the VMware documenta tion.	Cloud administrator

Add a data source and collector

Task	Description	Skills required
Add a data source.	1. Log in to vRealize Network Insight. 2. Choose **Settings**, **Accounts and Data Sources**, **Add Source**. 3. For **Type**, choose **On-premise vCenter server**. For more information, see the [VMware documentation].	Cloud administrator
Set up a collector for the data source.	For instructions, see the [VMware documentation].	Cloud administrator

Analyze application dependencies

Task	Description	Skills required
Create an application.	If you don't have an existing application in vRealize Network Insight, follow the steps in the [VMware documentation] to create one.	Cloud administrator
Discover and analyze your application.	1. Use vRealize Network Insight to discover your application. For instructi ons, see the [VMware documentation].	Cloud administrator

Task	Description	Skills required
	2. Analyze your application. For instructions, see the VMware documentation.

Migrate VMs to VMware Cloud on AWS by using HCX OS Assisted Migration

Deepak Kumar and Himanshu Gupta, Amazon Web Services

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to migrate a virtual machine (VM) from a non-vSphere environment to VMware Cloud on Amazon Web Services (AWS) by using OS Assisted Migration (OSAM).

OSAM is part of VMware Hybrid Cloud Extension (HCX), which is included with VMware Cloud on AWS. You can use OSAM to migrate a non-vSphere environment such as VMware KVM or Hyper-V to VMware Cloud on AWS. OSAM uses Sentinel software, which you install on a Windows or Linux guest VM to assist in replicating the VM from your on-premises environment to a Software-Defined Data Center (SDDC) on VMware Cloud on AWS.

This pattern explains how to enable OSAM, install Sentinel software on a Windows VM, connect and register with an HCX Sentinel Gateway (SGW) appliance at the source site, and establish a forwarding connection with an HCX Sentinel Data Receiver (SDR) appliance at the destination site to initiate migration.

For more information about OSAM, see the VMware documentation.

Prerequisites and limitations

Prerequisites

- Install HCX in your source and target environments. For HCX prerequisites, see Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX in the AWS Prescriptive Guidance documentation.
- For OSAM prerequisites, see the installation checklist in the VMware documentation.
- For OSAM port information, see VMware HCX port requirements on the VMware Ports and Protocols website.

Limitations

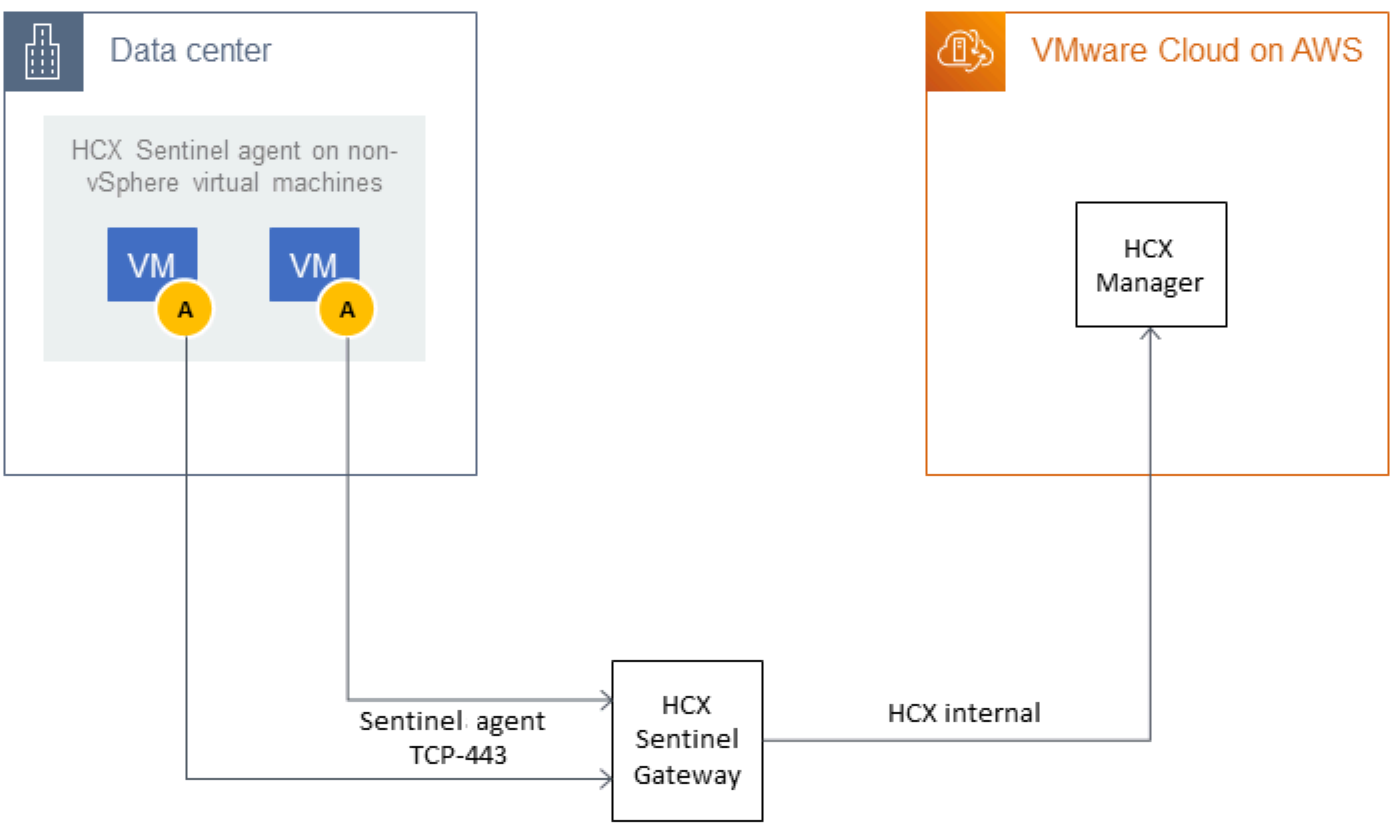
- [VMware HCX 4.2.0 Configuration Limits]
- [Considerations for OSAM Deployment]
- [Supported Guest Operating Systems]
- [Guest Operating System Considerations]

Product versions

- VMware HCX 4.2.0
- VMware SDDC 1.12

Architecture

The following diagram shows how HCX OSAM works with the Sentinel software to replicate non-vSphere VMs from your on-premises environment to VMware Cloud on AWS.



OSAM consists of three components:

- The Sentinel Gateway (SGW) appliance, which is used to connect and forward workloads and applications in the source VMware-based environment
- The Sentinel Data Receiver (SDR), which is used in the destination VMware Cloud on AWS environment to receive migrated workloads from the source
- Sentinel software, which must be installed on each guest VM that you want to migrate

OSAM uses the Sentinel software that is installed on Windows or Linux guest VMs to assist in replicating a VM from on premises to a VMware SDDC. The Sentinel software that you install on guest VMs collects the system configurations from the guest VM and assists with the data replication. This information is also used to create the inventory of guest VMs for migration and helps prepare the disks on the replica VM for replication and migration purposes.

Tools

- VMware HCX 4.2.0
- VMware Cloud on AWS SDDC

Epics

Configure HCX

Task	Description	Skills required
Deploy HCX Cloud and HCX Connector.	Follow the instructions in [HCX Connector and HCX Cloud Installations]() in the VMware documentation.	Cloud administrator, Systems administrator

Configure OSAM and migrate VMs

Task	Description	Skills required
Install HCX Sentinel.	To install Sentinel on Linux: 1. In the vCenter Server for the HCX Connector, choose	Cloud administrator

Task	Description	Skills required
	Interconnect, **Multi-Site Service Mesh**, **Sentinel Management**. 2. Choose **Download Linux Bundle**. 3. Install the Sentinel agent on a Linux machine. For more information, see Downloading and Installing HCX Sentinel Agent software in the VMware documentation.	

Task	Description	Skills required

Migrate VMs.	To migrate your VMs in groups (called *mobility groups*), follow these steps:
	
	1. In the vSphere Client, from the HCX plug-in, choose **Services**, **Migration**.
	2. Choose **Migrate**.
	3. Choose **Non vSphere Inventory**, **Remote connections**. This will show the list VMs that you installed HCX Sentinel on.
	4. For **Group name**, enter the name of the mobility group you want to create for the VMs.
	5. Choose the VMs you want to migrate, and then choose **Add** to add them to the mobility group.
	6. For each VM:
	  a. Select the destination compute container.
	  b. Select the destination storage.
	  c. Select the migration profile.
	  d. Select the destination folder.
	7. To start the migration process, choose **Go**.
		Cloud administrator

Task	Description	Skills required
	HCX validates your VM selections before migration starts. For more information, see Migrating Virtual Machines with Mobility Groups and Monitoring and Estimating Migration with Mobility Groups in the VMware documentation.

Send logs from VMware Cloud on AWS to Splunk by using VMware Aria Operations for Logs

Deepak Kumar and Piotr Pitera, Amazon Web Services

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

This pattern describes how to forward VMware Cloud on AWS events or logs to a syslog or an HTTP endpoint such as Splunk by using VMware Aria Operations for Logs.

VMware Aria Operations for Logs is a log analysis tool that offers enhanced visibility and accelerated troubleshooting in the VMware Cloud on AWS environment. You can configure this tool to send either all or a portion of logs or events in VMware Cloud on AWS to a syslog or HTTP endpoint. The endpoint can be either a software as a service (SaaS) endpoint or an on-premises endpoint such as Splunk. (This pattern provides the instructions for Splunk.) To learn more about VMware Aria Operations for Logs, see the VMware documentation.

VMware Cloud on AWS is a pay-as-you-go (on-demand) service that enables enterprises of all sizes to run workloads across VMware vSphere-based cloud environments by using a wide range of AWS services. You can start with a minimum of 2 hosts per Software-Defined Data Center (SDDC) cluster and scale up to 16 hosts per cluster in your production environment. For more information, see the VMware Cloud on AWS website. To learn more about SDDCs, see About Software-Defined Data Centers in the VMware documentation.

Prerequisites and limitations

Prerequisites

- Splunk, configured on premises

Limitations

You can sign up for a free trial subscription to VMware Aria Operations for Logs. This subscription is valid for 30 days and has the following limitations:

- Maximum size of logs you can forward: 50 GB logs per day
- Maximum number of log forwarding configurations you can create: 10
- Maximum number of log forwarding configurations you can activate: 5

To access all service features, you must upgrade to a premium subscription.

For more information about trial and premium subscriptions, see VMware Aria Operations for Logs (SaaS) Subscriptions and Billing in the VMware documentation. For more information about usage limits, see Usage Limitations for Features in the VMware documentation.

Product versions

- VMware Cloud on AWS SDDC version 1.24
- VMware Aria Operations for Logs version 8.10
- On-premises Splunk version 9.x

Architecture

Source technology stack

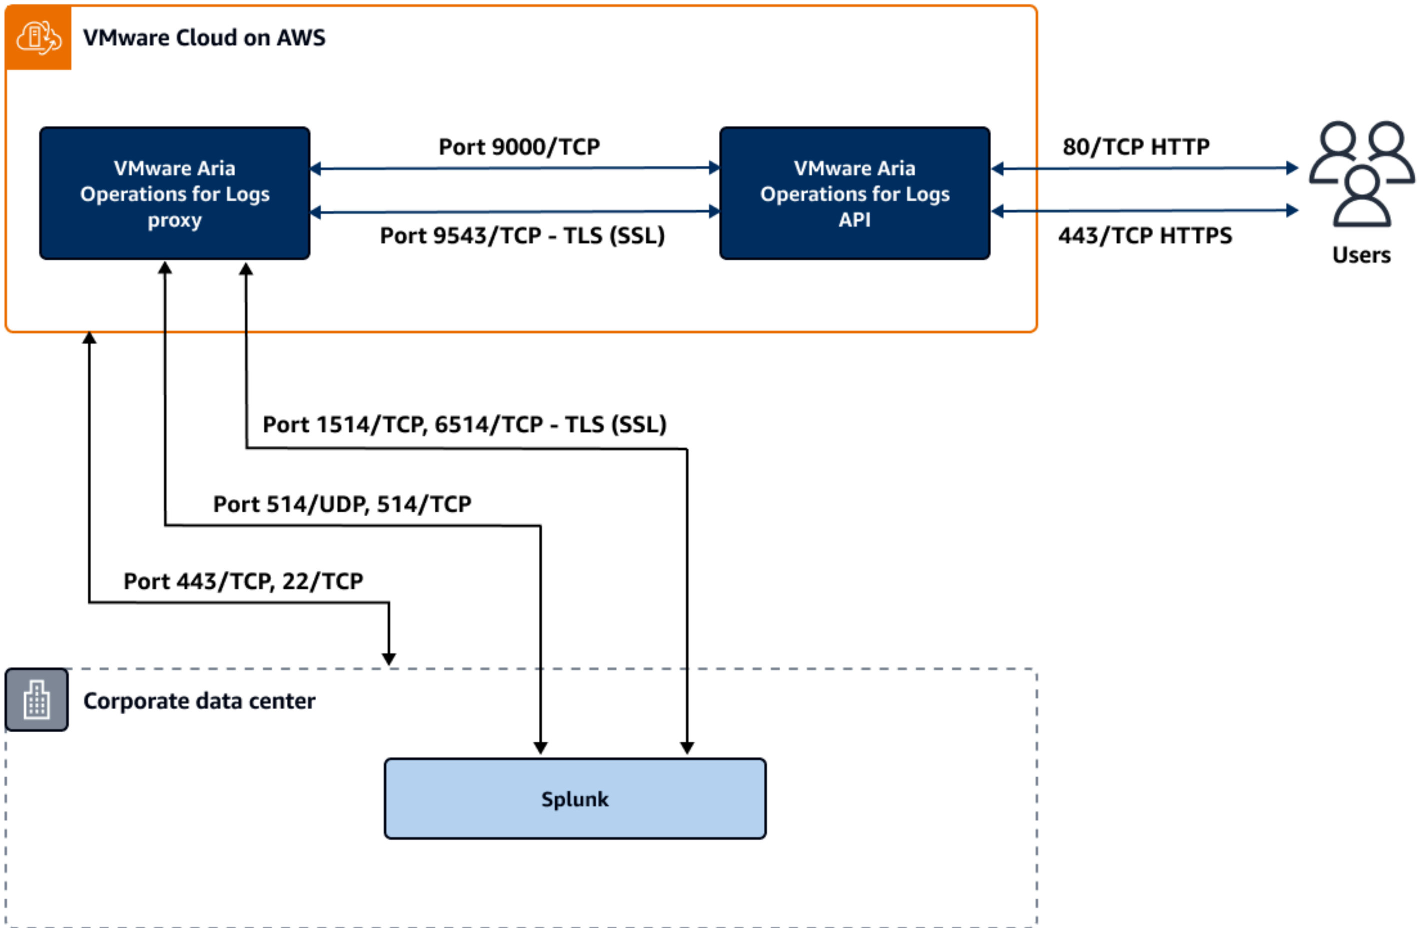
- VMware Cloud on AWS
- VMware Aria Operations for Logs

Target technology stack

- On-premises Splunk

Target architecture

The following diagram shows the connectivity between a corporate data center and VMware Aria Operations for Logs in VMware Cloud on AWS.



Tools

- VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.
- VMware Aria Operations for Logs is a log analysis and troubleshooting tool for VMware Cloud on AWS.

Epics

Deploy an SDDC and enable VMware Aria Operation for Logs

Task	Description	Skills required
Deploy a VMware Cloud on AWS SDDC.	Follow the instructions in Deploy a VMware SDDC on AWS by using VMware Cloud	Cloud architect, Cloud administrator

Task	Description	Skills required
	on AWS in AWS Prescriptive Guidance.	
Sign up for VMware Aria Operations for Logs.	For instructions, see the VMware documentation.	Cloud architect

Deploy a cloud proxy

Task	Description	Skills required
Deploy a cloud proxy.	To forward logs to an on-premises instance of Splunk, you must add a cloud proxy for VMware Aria Operations for Logs. This proxy receives information from the on-premises data center and sends it to VMware Aria Operations for Logs for analysis. To download and install the cloud proxy: 1. Make sure that ports 443, 22, and 514 are open between your on-premises environment and VMware Cloud on AWS. For additional ports, you can use 1514/TCP or 6514/TCP. For more information about ports, see VMware Aria Operations for Logs Firewall Recommendations	Cloud administrator, Cloud architect

Task	Description	Skills required
	in the VMware documentation. 2. Log in to VMware Aria Operations for Logs. 3. On the home page, choose **Add Collector** in the widget. 4. On the **Cloud Proxy Virtual Appliance** screen, copy the token key. You must use this key within 24 hours to finish the following steps. 5. Choose the download link for the OVA file. 6. Navigate to VMware vSphere web client, choose your cluster, and then select **Deploy OVF template**. 7. When you're prompted for the key, paste the token key that you copied in step 4. 8. Choose **Finish** to install the cloud proxy.	

Forward logs to an on-premises Splunk endpoint

Task	Description	Skills required
Configure log forwarding.	To forward logs to the Splunk endpoint:	

Task	Description	Skills required
	1. Log in to VMware Aria Operations for Logs. 2. Navigate to **Log Management**. 3. Choose **Log Forwarding**. 4. Choose **New Configuration**, and complete the following settings: • Provide a name for the log forwarding configuration. • For **Destination**, choose **On Premises**. • For **Cloud Proxy**, select the cloud proxy that you installed earlier. • For **Endpoint Type**, choose **TCP**. • For **Endpoint URL**, provide your on-premises Splunk URL in the format: `tcp://x.x.x.x (your Splunk IP address):514` • (Optional) For **Tags**, you can specify tag names and values to facilitate querying. • Choose **Apply to all logs** or **Apply to specific logs**. If you want to send all	

Task	Description	Skills required
	VMware Cloud on AWS logs to Splunk, choose **Apply to all logs**. 5. Choose **Verify**. 6. Choose **Save**. For more information, see Forward Logs from VMware Aria Operations for Logs in the VMware documentation.

Set up a CI/CD pipeline for hybrid workloads on Amazon ECS Anywhere by using AWS CDK and GitLab

Dr. Rahul Sharad Gaikwad, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more.

Amazon ECS Anywhere is an extension of the Amazon Elastic Container Service (Amazon ECS). It provides support for registering an *external instance*, such as an on-premises server or virtual machine (VM), to your Amazon ECS cluster. is feature helps reduce costs and mitigate complex local container orchestration and operations. You can use ECS Anywhere to deploy and run container applications in both on-premises and cloud environments. It removes the need for your team to learn multiple domains and skill sets, or to manage complex software on their own.

This pattern describes a step-by-step approach to provision an Amazon ECS cluster with Amazon ECS Anywhere instances by using Amazon Web Services (AWS) Cloud Development Kit (AWS CDK) stacks. You then use AWS CodePipeline to set up a continuous integration and continuous deployment (CI/CD) pipeline. Then, you replicate your GitLab code repository to AWS CodeCommit and deploy your containerized application on the Amazon ECS cluster.

This pattern is designed to help those who use on-premises infrastructure to run container applications and use GitLab to manage the application code base. You can manage those workloads by using AWS Cloud services, without disturbing your existing, on-premises infrastructure.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A container application running on on-premises infrastructure.
- A GitLab repository where you manage your application code base. For more information, see Repository (GitLab).
- AWS Command Line Interface (AWS CLI), installed and configured. For more information, see Installing or updating the latest version of the AWS CLI (AWS CLI documentation).

- AWS CDK Toolkit, installed and configured globally. For more information, see Install the AWS CDK (AWS CDK documentation).
- npm, installed and configured for the AWS CDK in TypeScript. For more information, see Downloading and installing Node.js and npm (npm documentation).

Limitations

- For limitations and considerations, see External instances (Amazon ECS Anywhere) in the Amazon ECS documentation.

Product versions

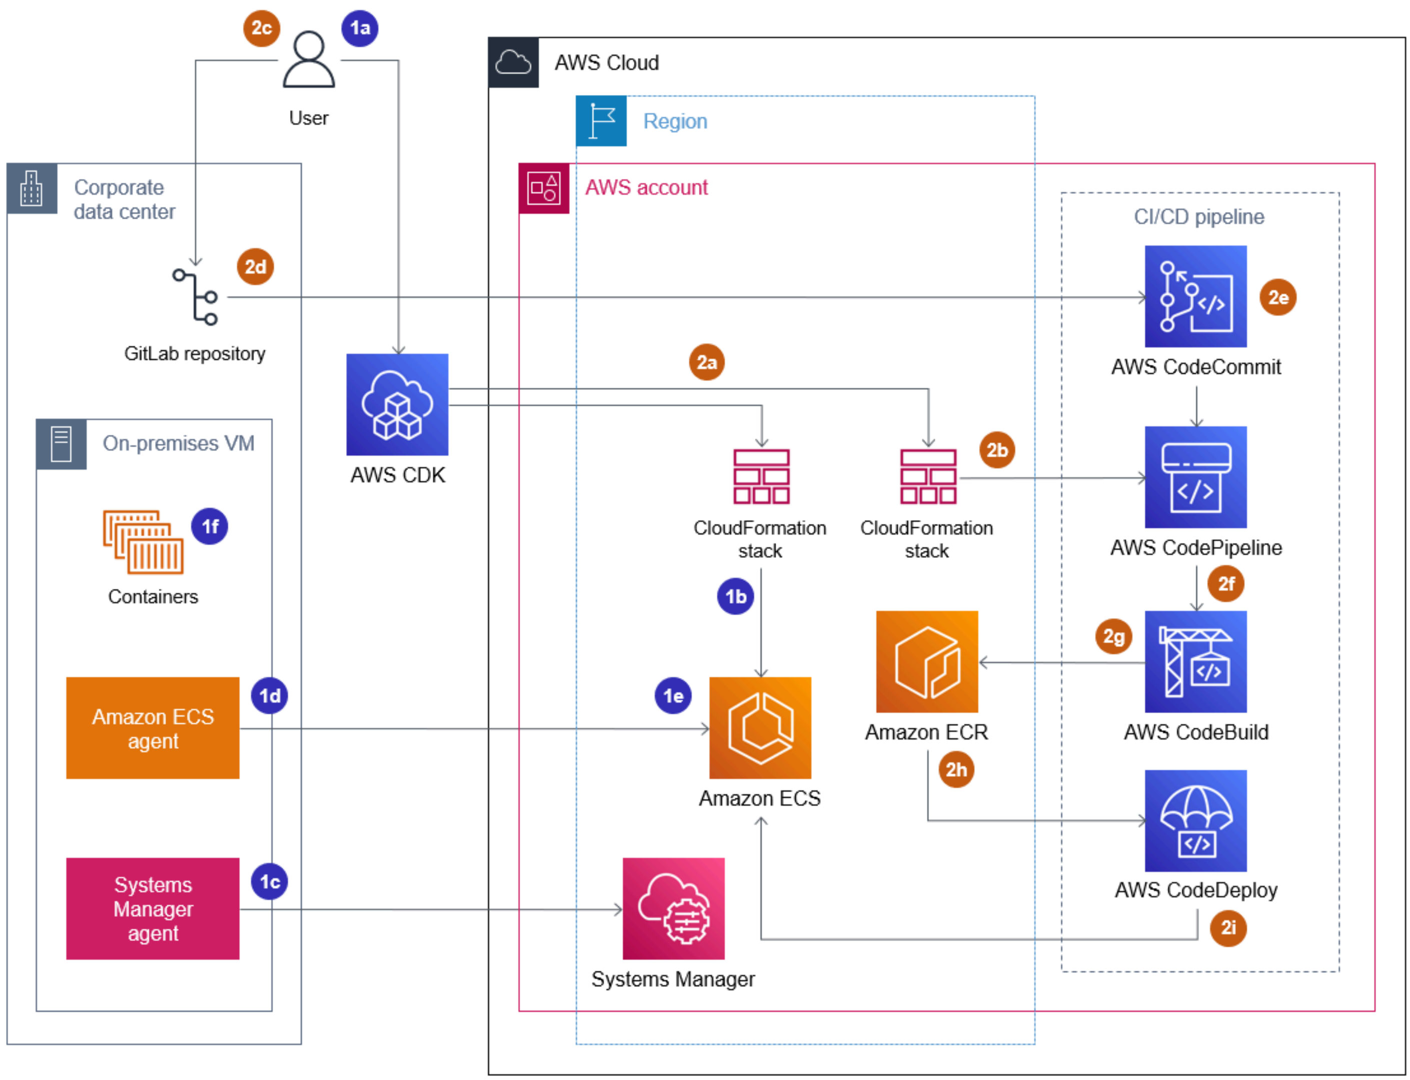
- AWS CDK Toolkit version 2.27.0 or later
- npm version 7.20.3 or later
- Node.js version 16.6.1 or later

Architecture

Target technology stack

- AWS CDK
- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- Amazon ECS Anywhere
- Amazon Elastic Container Registry (Amazon ECR)
- AWS Identity and Access Management (IAM)
- AWS System Manager
- GitLab repository

Target architecture



This diagram represents two primary workflows described in this pattern, provisioning the Amazon ECS cluster and setting up the CI/CD pipeline that sets up and deploys the CI/CD pipeline, as follows:

1. **Provisioning the Amazon ECS cluster**
   a. When you deploy the first AWS CDK stack, it creates a CloudFormation stack on AWS.
   b. This CloudFormation stack provisions an Amazon ECS cluster and related AWS resources.
   c. To register an external instance with an Amazon ECS cluster, you must install AWS Systems Manager Agent (SSM Agent) on your VM and register the VM as an AWS Systems Manager managed instance.
   d. You must also install the Amazon ECS container agent and Docker on your VM to register it as an external instance with the Amazon ECS cluster.

e. When the external instance is registered and configured with the Amazon ECS cluster, it can run multiple containers on your VM, which is registered as an external instance.

f. The Amazon ECS cluster is active and can run the application workloads through containers. The Amazon ECS Anywhere container instance runs in on-premises environment but is associated with the Amazon ECS cluster in the cloud.

2. **Setting up and deploying the CI/CD pipeline**

   a. When you deploy the second AWS CDK stack, it creates another CloudFormation stack on AWS.

   b. This CloudFormation stack provisions a pipeline in CodePipeline and related AWS resources.

   c. You push and merge application code changes to an on-premises GitLab repository.

   d. The GitLab repository is automatically replicated to the CodeCommit repository.

   e. The updates to the CodeCommit repo automatically starts CodePipeline.

   f. CodePipeline copies code from CodeCommit and creates the deployable application build in CodeBuild.

   g. CodePipeline creates a Docker image of the CodeBuild build environment and pushes it to the Amazon ECR repo.

   h. CodePipeline initiates CodeDeploy actions that pull the container image from the Amazon ECR repo.

   i. CodePipeline deploys the container image on the Amazon ECS cluster.

Automation and scale

This pattern uses the AWS CDK as an infrastructure as code (IaC) tool to configure and deploy this architecture. AWS CDK helps you orchestrate the AWS resources and set up Amazon ECS Anywhere and the CI/CD pipeline.

Tools

AWS services

- [AWS Cloud Development Kit (AWS CDK)]() is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- [AWS CodeCommit]() is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster. This pattern also uses Amazon ECS Anywhere, which provides support for registering an on-premises server or VM to your Amazon ECS cluster.

Other tools

- Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.
- Vagrant is an open-source utility for building and maintaining portable virtual software development environments. For demonstration purposes, this pattern uses Vagrant to create an on-premises VM.

Code repository

The code for this pattern is available in the GitHub CI/CD pipeline for Amazon ECS Anywhere using AWS CDK repository.

Best practices

Consider the following best practices when deploying this pattern:

- Best practices for developing and deploying cloud infrastructure with the AWS CDK
- Best practices for developing cloud applications with AWS CDK (AWS blog post)

Epics

Verify the AWS CDK configuration

Task	Description	Skills required
Verify the AWS CDK version.	Verify the version of the AWS CDK Toolkit by entering the following command. `cdk --version` This pattern requires version 2.27.0 or later. If you have an earlier version, follow the instructions in the AWS CDK documentation to update it.	DevOps engineer
Verify the npm version.	Verify the version of npm by entering the following command. `npm --version` This pattern requires version 7.20.3 or later. If you have an earlier version, follow the instructions in the npm documentation to update it.	DevOps engineer
Set up AWS credentials.	Set up AWS credentials by entering the `aws configure` command and following the prompts. `$aws configure`	DevOps engineer

Task	Description	Skills required
	```AWS Access Key ID [None]: <your-access-key-ID> AWS Secret Access Key [None]: <your-secret-access-key> Default region name [None]: <your-Region-name> Default output format [None]:```	

Bootstrap the AWS CDK environment

Task	Description	Skills required

Clone the AWS CDK code repository.	1. Clone the [CI/CD pipeline for Amazon ECS Anywhere using AWS CDK]() repository for this pattern by entering the following command.
	`git clone https://github.com/aws-samples/amazon-ecs-anywhere-cicd-pipeline-cdk-sample.git`
	2. Navigate into the cloned directory by entering the following command.
	`cd amazon-ecs-anywhere-cicd-pipeline-cdk-sample`
		DevOps engineer

Task	Description	Skills required
Bootstrap the environment.	Deploy the CloudFormation template to the account and AWS Region that you want to use by entering the following command. `cdk bootstrap <account-number>/<Region>` For more information, see [Bootstrapping](#) in the AWS CDK documentation.	DevOps engineer

Build and deploy the infrastructure for Amazon ECS Anywhere

Task	Description	Skills required

Install the package dependencies and compile the TypeScript files.	Install the package dependencies and compile the TypeScript files by entering the following commands.
	`$cd EcsAnywhereCdk`
	`$npm install`
	`$npm fund`
	These commands install all the packages from the sample repository. For more informati on, see npm ci and npm install in the npm documenta tion. If you get any errors about missing packages when
		DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>you enter these commands, see the Troubleshooting section of this pattern.</td><td></td></tr>
<tr><td>Build the project.</td><td>To build the project code, enter the following command.
<pre>npm run build</pre>For more information about building and deploying the project, see Your first AWS CDK app in the AWS CDK documentation.</td><td>DevOps engineer</td></tr>
<tr><td>Deploy the Amazon ECS Anywhere infrastructure stack.</td><td>1. List the stacks by entering the following command.
<pre>$cdk list</pre>2. Confirm that the output returns the <code>EcsAnywhereInfraStack</code> and <code>ECSAnywherePipelineStack</code> stacks.
3. Deploy the <code>EcsAnywhereInfraStack</code> stack by entering the following command.
<pre>$cdk deploy EcsAnywhereInfraStack</pre></td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
Verify stack creation and output.	1. Sign in to the AWS Management Console and open the CloudFormation console at https://console.aws.amazon.com/cloudformation/. 2. On the **Stacks** page, select the `EcsAnywhereInfraStack` stack. 3. Confirm that the stack status is either `CREATE_IN_PROGRESS` or `CREATE_COMPLETE` . Setting up the Amazon ECS cluster can take some time. Do not proceed until the stack creation is complete.	DevOps engineer

Set up an on-premises VM

Task	Description	Skills required
Set up your VM.	Create a Vagrant VM by entering the `vagrant up` command from the root directory where Vagrantfile is located. For more information, see the [Vagrant documentation](https://www.vagrantup.com/docs).	DevOps engineer
Register your VM as an external instance.	1. Log in to the Vagrant VM by using the `vagrant ssh` command. For more	DevOps engineer

Task	Description	Skills required
	information, see the [Vagrant documentation](). 2. Install AWS CLI on the VM by following [AWS CLI installation instructions]() and entering the following commands. `$ curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" \` `> -o "awscliv2.zip"` `$sudo apt install unzip` `$unzip awscliv2.zip` `$sudo ./aws/install` `$aws configure` `AWS Access Key ID [None]: <your-access-key-ID>` `AWS Secret Access Key [None]: <your-secret-access-key>` `Default region name [None]: <your-Region-name>` `Default output format [None]:` 1. Create an activation code and ID that you can use to register your VM with AWS Systems Manager and to activate your external instance. The output from this command includes the	

Task	Description	Skills required

	activation ID and activation code values.
	`aws ssm create-activation \ > --iam-role EcsAnywhereInstanceRole \ > | tee ssm-activation.json`
	If you receive an error when you run this command, see the Troubleshooting section.
	2. Export the activation ID and code values.
	`export ACTIVATION_ID=<activation-ID>`
	`export ACTIVATION_CODE=<activation-code>`
	3. Download the installation script to your VM.
	`curl --proto "https" -o "ecs-anywhere-install.sh" \ > "https://amazon-ecs-agent.s3.amazonaws.com/ecs-anywhere-install-latest.sh"`
	4. Run the installation script on your VM.	

Task	Description	Skills required

	<pre>sudo bash ecs-anywh
	ere-install.sh \
	--cluster EcsAnywhe
	reCluster \
	--activation-id
	 $ACTIVATION_ID \
	--activation-code
	 $ACTIVATION_CODE \
	--region <region-n
	ame></pre> This sets up your VM was an Amazon ECS Anywhere external instance and registers the instance in the Amazon ECS cluster. For more information, see [Registering an external instance to a cluster]() in the Amazon ECS documentation. If you experience any issues, see the [Troubleshooting]() section.	

Verify the status of Amazon ECS Anywhere and the external VM.	To verify whether your VM is connected to the Amazon ECS control plane and running, use the following commands. <pre>$aws ssm describe-
	instance-information
	$aws ecs list-cont
	ainer-instances --
	cluster $CLUSTER_NAME</pre>
		DevOps engineer

Deploy the CI/CD pipeline

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a branch in the CodeCommit repo.</td><td>Create a branch named <code>main</code> in the CodeCommit repo by creating the first commit for the repository. You can follow AWS documentation to Create a commit in CodeCommit. The following command is an example.<pre>aws codecommit put-file \
  --repository-name EcsAnywhereRepo \
  --branch-name main \
  --file-path README.md \
  --file-content "Test" \
  --name "Dev Ops" \
  --email "devops@example.com" \
  --commit-message "Adding README."</pre></td><td>DevOps engineer</td></tr>
<tr><td>Set up repo mirroring.</td><td>You can mirror a GitLab repository to and from external sources. You can select which repository serves as the source. Branches, tags, and commits are synced automatically. Set up a push mirror between the GitLab repository that hosts your application and the CodeCommit repository.</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	For instructions, see [Set up a push mirror from GitLab to CodeCommit](#) (GitLab documentation). **Note** By default, mirroring automatically syncs the repository. If you want to manually update the repositories, see [Update a mirror](#) (GitLab documentation).	
Deploy the CI/CD pipeline stack.	Deploy the `EcsAnywherePipelineStack` stack by entering the following command. `$cdk deploy EcsAnywherePipelineStack`	DevOps engineer

Task	Description	Skills required
Test the CI/CD pipeline.	1. Make application code changes and push it to the source, on-premises GitLab repo. For more informati on, see [Push Options](#) (GitLab documentation). For example, edit the `../application/index.html` file to update the application version value. 2. When the code is replicate d to the CodeCommit repo, this starts the CI/CD pipeline. Do one of the following: • If you are using automatic mirroring to synchronize the GitLab repo with the CodeCommit repo, continue to the next step. • If you are using manual mirroring, push the application code changes to the CodeCommit repo by following the instructi ons in [Update a mirror](#) (GitLab documentation). 3. On your local machine, in a web browser, enter http://localhost:80. This opens the NGINX web	DevOps engineer

Task	Description	Skills required
	page because port 80 is forwarded to localhost in Vagrantfile. Confirm that you can view the updated application version value. This validates the pipeline and image deployment. 4. (Optional) If you want to verify the deployment in the AWS Management Console, do the following: a. Open the Amazon ECS console at https://console.aws.amazon.com/ecs/. b. From the navigation bar, select the Region to use. c. In the navigation pane, choose **Clusters**. d. On the **Clusters** page, select the **EcsAnywhereCluster** cluster. e. Choose **Task Definitions**. f. Confirm the container is running.	

Clean up

Task	Description	Skills required
Clean up and delete the resources.	After you walk through this pattern, you should	DevOps engineer

Task	Description	Skills required

	remove the proof-of-concept resources you created. To clean up, enter the following commands.
	`$cdk destroy EcsAnywherePipelineStack`
	`$cdk destroy EcsAnywhereInfraStack`	

Troubleshooting

Issue	Solution

Errors about missing packages when installing package dependencies.	Enter one of the following commands to resolve missing packages.
	`$npm ci`
	or
	`$npm install -g @aws-cdk/<package_name>`

When you run the `aws ssm create-activation` command on the VM, you receive the following error. `An error occurred (ValidationException) when calling the CreateActivation operation: Nonexistent role or missing ssm service principal in trust policy:`	The `EcsAnywhereInfraStack` stack isn't fully deployed, and the IAM role necessary to run this command hasn't been created yet. Check the stack status in the CloudFormation console. Retry the command after the status changes to `CREATE_COMPLETE`.

Issue	Solution
`arn:aws:iam::000000000000:role/EcsAnywhereInstanceRole`	

An Amazon ECS health check returns `UNHEALTHY` , and you see the following error in the **Services** section of the cluster in the Amazon ECS console.
 	
`service EcsAnywhereService was unable to place a task because no container instance met all of its requirements. Reason: No Container Instances were found in your cluster.`
	Restart the Amazon ECS agent on your Vagrant VM by entering the following commands.
	
	`$vagrant ssh`
	`$sudo systemctl restart ecs`
	`$sudo systemctl status ecs`

Identify and alert when Amazon Data Firehose resources are not encrypted with an AWS KMS key

Ram Kandaswamy, Amazon Web Services

Summary

For compliance, some organizations must have encryption enabled on data delivery resources such as Amazon Data Firehose. This pattern shows a way to monitor, detect, and notify when resources are out of compliance.

To maintain the encryption requirement, this pattern can be used on AWS to provide automated monitoring and detection of Amazon Data Firehose delivery resources that aren't encrypted with an AWS Key Management Service (AWS KMS) key. The solution sends alert notifications, and it can be extended to perform automatic remediation. This solution can be applied to an individual account or a multiple-account environment, such as an environment that uses an AWS landing zone or AWS Control Tower.

Prerequisites and limitations

Prerequisites

- Amazon Data Firehose delivery stream
- Sufficient permissions and familiarity with AWS CloudFormation, which is used in this infrastructure automation

Limitations

- The solution is not real time because it uses AWS CloudTrail events for detection, and there is a delay between the time an unencrypted resource is created and the notification is sent.

Architecture

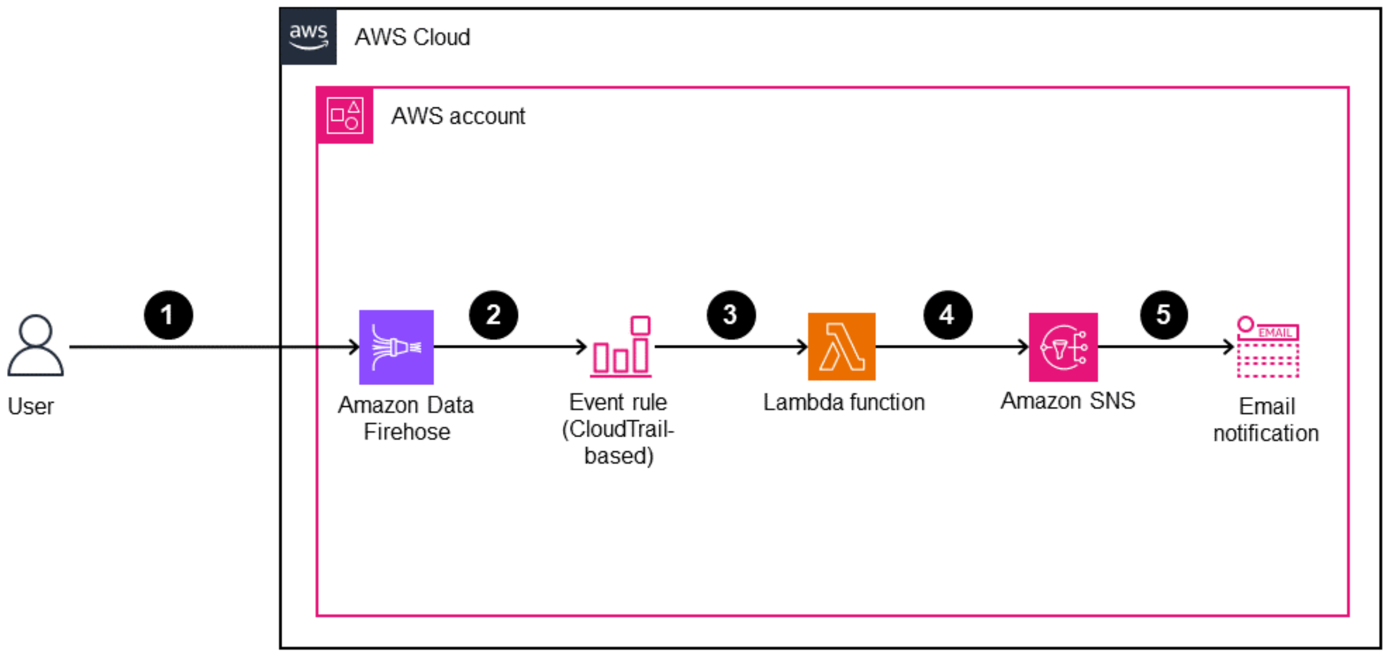
Target technology stack

The solution uses serverless technology and the following services:

- AWS CloudTrail
- Amazon CloudWatch

- AWS Command Line Interface (AWS CLI)
- AWS Identity and Access Management (IAM)
- Amazon Data Firehose
- AWS Lambda
- Amazon Simple Notification Service (Amazon SNS)

Target architecture



The diagram illustrates these steps:

1. A user creates or modifies Amazon Data Firehose.
2. A CloudTrail event is detected and matched.
3. Lambda is invoked.
4. Non-compliant resources are identified.
5. Email notification is sent.

Automation and scale

You can use AWS CloudFormation StackSets to apply this solution to multiple AWS Regions or accounts with a single command.

Tools

- AWS CloudTrail is an AWS service that helps you enable governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail. Events include actions taken in the AWS Management Console, AWS CLI, AWS SDKs, and API operations.
- Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS Command Line Interface (AWS CLI) is an open source tool that enables you to interact with AWS services by using commands in your command line shell.
- AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- Amazon Data Firehose is a fully managed service for delivering real-time streaming data. With Firehose, you don't have to write applications or manage resources. You configure your data producers to send data to Firehose, and it automatically delivers the data to the destination that you specified.
- AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code isn’t running.
- Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).

Epics

Enforce encryption for compliance

Task	Description	Skills required
Deploy AWS CloudFormation StackSets.	In the AWS CLI, use the `firehose-encryption-checker.yaml` template (attached) to create the stack set by running the following	Cloud architect, Systems administrator

Task	Description	Skills required
	command. Provide a valid Amazon SNS topic Amazon Resource Name (ARN) for the parameter. The deploymen t should successfully create CloudWatch Events rules, the Lambda function, and an IAM role with the necessary permissions, as described in the template. `aws cloudformation create-stack-set --stack-set-name my-stack-set --template-body file://firehose-encryption-checker.yaml`	

Task	Description	Skills required
Create stack instances.	Stacks can be created in the AWS Regions of your choice as well as in one or more accounts. To create stack instances, run the following command. Replace the stack name, account numbers, and Regions with your own. `aws cloudformation create-stack-instances --stack-set-name my-stack-set --accounts 123456789012 223456789012 --regions us-east-1 us-east-2 us-west-1 us-west-2 --operation-preferences FailureToleranceCount=1`	Cloud architect, Systems administrator

Automate adding or updating Windows registry entries using AWS Systems Manager

Appasaheb Bagali, Amazon Web Services

Summary

AWS Systems Manager is a remote management tool for Amazon Elastic Compute Cloud (Amazon EC2) instances. Systems Manager provides visibility and control over your infrastructure on Amazon Web Services. This versatile tool can be used to fix Windows registry changes that are identified as vulnerabilities by the security vulnerability scan report.

This pattern covers the steps to keep your EC2 instances that are running Windows operating system secure by automating registry changes that are recommended for the safety of your environment. The pattern uses the Run command to run a Command document. The code is attached, and a portion of it is included in the *Code* section.

Prerequisites and limitations

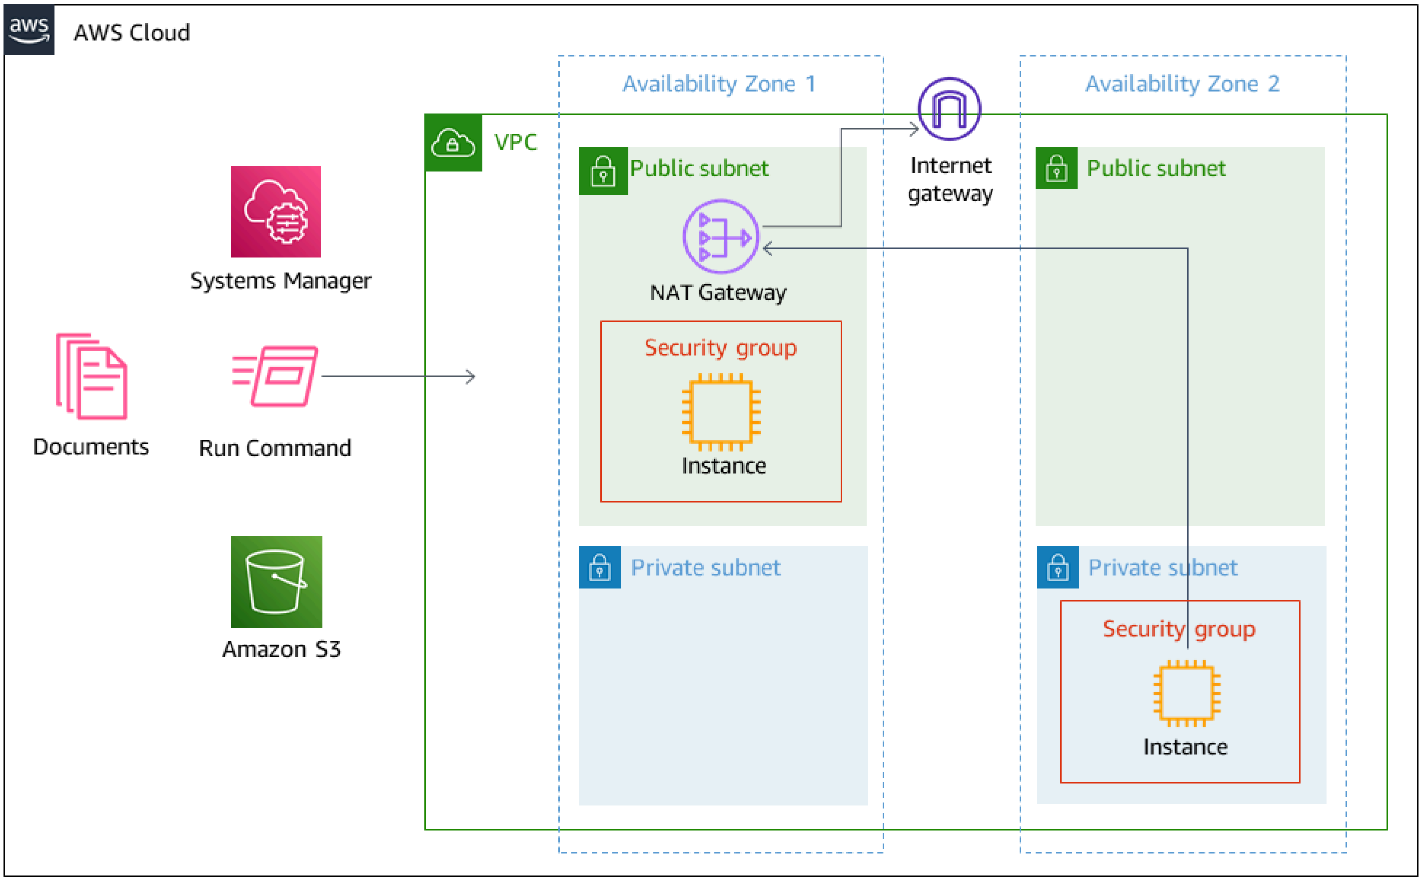
- An active AWS account
- Permissions to access the EC2 instance and Systems Manager

Architecture

Target technology stack

- A virtual private cloud (VPC), with two subnets and a network address translation (NAT) gateway
- A Systems Manager Command document to add or update the registry name and value
- Systems Manager Run Command to run the Command document on the specified EC2 instances

Target architecture



Tools

Tools

- [IAM policies and roles](#) – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- [Amazon Simple Storage Service](#) – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers. In this pattern, an S3 bucket is used to store the Systems Manager logs.
- [AWS Systems Manager](#) – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Systems Manager helps you maintain security and compliance by scanning your *managed instances* and reporting (or taking corrective action on) any policy violations it detects.

- [AWS Systems Manager Command document](#) – AWS Systems Manager Command documents are used by Run Command. Most Command documents are supported on all Linux and Windows Server operating systems supported by Systems Manager.
- [AWS Systems Manager Run Command](#) – AWS Systems Manager Run Command gives you a way to manage the configuration of your managed instances remotely and securely. Using Run Command, you can automate common administrative tasks and perform one-time configuration changes at scale.

Code

You can use the following example code to add or update a Microsoft Windows registry name to `Version`, registry path to `HKCU:\Software\ScriptingGuys\Scripts`, and value to 2.

```
#Windows registry path which needs to add/update
$registryPath ='HKCU:\\Software\\ScriptingGuys\\Scripts'
#Windows registry Name  which needs to add/update
$Name = 'Version'
#Windows registry value  which needs to add/update
$value = 2
# Test-Path cmdlet to see if the registry key exists.
IF(!(Test-Path $registryPath))
        {
           New-Item -Path $registryPath -Force | Out-Null
           New-ItemProperty -Path $registryPath -Name $name -Value     $value ` -
PropertyType DWORD -                 Force | Out-        Null
        } ELSE {
                      New-ItemProperty -Path $registryPath -Name $name -Value $value `
 -PropertyType            DWORD        -Force | Out-Null
            }
echo 'Registry Path:'$registryPath
 echo 'Registry Name:'$registryPath
 echo 'Registry Value:'(Get-ItemProperty -Path $registryPath -Name $Name).version
```

The full Systems Manager Command document JavaScript Object Notation (JSON) code example is attached.

Epics

Set up a VPC

Task	Description	Skills required
Create a VPC.	On the AWS Managemen t Console, create a VPC that has public and private subnets and a NAT gateway. For more information, see the [AWS documentation]().	Cloud administrator
Create security groups.	Ensure that each security group allows access for Remote Desktop Protocol (RDP) from the source IP address.	Cloud administrator

Create an IAM policy and an IAM role

Task	Description	Skills required
Create an IAM policy.	Create an IAM policy that provides access to Amazon S3, Amazon EC2, and Systems Manager.	Cloud administrator
Create an IAM role.	Create an IAM role, and attach the IAM policy that provides access to Amazon S3, Amazon EC2, and Systems Manager.	Cloud administrator

Run the automation

Task	Description	Skills required
Create the Systems Manager Command document.	Create a Systems Manager Command document that will deploy the Microsoft Windows registry changes to add or update.	Cloud administrator
Run the Systems Manager Run Command.	Run the Systems Manager Run Command, selecting the Command document and the Systems Manager target instances. This pushes the Microsoft Windows registry change in the selected Command document to the target instances.	Cloud administrator

Automatically create an RFC in AMS using Python

Gnanasekaran Kailasam, Amazon Web Services

Summary

AWS Managed Services (AMS) helps you to operate your cloud-based infrastructure more efficiently and securely by providing ongoing management of your Amazon Web Services (AWS) infrastructure. To make a change to your managed environment, you need to create and submit a new request for change (RFC) that includes a change type (CT) ID for a particular operation or action.

However, manually creating an RFC can take around five minutes and teams in your organization might need to submit multiple RFCs every day. This pattern helps you to automate the RFC creation process, reduce the creation time for each RFC, and eliminate manual errors.

This pattern describes how to use Python code to automatically create the `Stop EC2 instance` RFC that stops Amazon Elastic Compute Cloud (Amazon EC2) instances in your AMS account. You can then apply this pattern's approach and the Python automation to other RFC types.

Prerequisites and limitations

Prerequisites

- An AMS Advanced account. For more information about this, see [AMS operations plans](#) in the AWS Managed Services documentation.
- At least one existing EC2 instance in your AMS account.
- An understanding of how to create and submit RFCs in AMS.
- Familiarity with Python.

Limitations

- You can only use RFCs for changes in your AMS account. Your AWS account uses different processes for similar changes.

Architecture

Technology stack

- AMS
- AWS Command Line Interface (AWS CLI)
- AWS SDK for Python (Boto3)
- Python and its required packages (JSON and Boto3)

Automation and scale

This pattern provides sample code to automate the `Stop EC2 instance` RFC, but you can use this pattern's sample code and approach for other RFCs.

Tools

- AWS Managed Services – AMS helps you to operate your AWS infrastructure more efficiently and securely.
- AWS CLI – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. In AMS, the change management API provides operations to create and manage RFCs.
- AWS SDK for Python (Boto3) – SDK for Python makes it easy to integrate your Python application, library, or script with AWS services.

Code

The `AMS Stop EC2 Instance.zip` file (attached) contains the Python code for creating a `Stop EC2 instance` RFC. You can also configure this code to submit a single RFC for multiple EC2 instances.

Epics

Option 1 – Set up environment for macOS or Linux

Task	Description	Skills required
Install and validate Python.	1. Open a terminal window and run the `brew install python3` command. 2. Validate that Python is correctly installed by	AWS systems administrator

Task	Description	Skills required
	running the `python --version` command. 3. Validate that `pip` is correctly installed by running the `pip --version` command.	
Install AWS CLI.	Run the `pip install awscli --upgrade –user` command to install AWS CLI.	AWS systems administrator
Install Boto3.	Run the `pip install boto3` command to install Boto3.	AWS systems administrator
Install JSON.	Run the `pip install json` command to install JSON.	AWS systems administrator
Set up AMS CLI.	Sign in to the AWS Management Console, open the AMS console, and then choose **Documentation**. Download the .zip file that contains the AMS CLI, unzip it, and then install it on your local machine. After you install AMS CLI, run the `aws amscm help` command. The output provides information about the AMS change managemen t process.	AWS systems administrator

Option 2 – Set up environment for Windows

Task	Description	Skills required
Install and validate Python.	1. Open the [Python releases for Windows](#) page, download the latest version, and then install Python. 2. Validate that Python is correctly installed by running the `python --version` command. 3. Validate that `pip` is correctly installed by running the `pip --version` command.	AWS systems administrator
Install AWS CLI.	Run the `pip install awscli --upgrade –user` command to install AWS CLI.	AWS systems administrator
Install Boto3.	Run the `pip install boto3` command to install Boto3.	AWS systems administrator
Install JSON.	Run the `pip install json` command to install JSON.	AWS systems administrator
Set up AMS CLI.	Sign in to the AWS Management Console, open the AMS console, and then choose **Documentation**. Download the .zip file that contains the AMS CLI, unzip it, and then install it on your local machine.	AWS systems administrator

Task	Description	Skills required
	After you install AMS CLI, run the `aws amscm help` command. The output provides information about the AMS change managemen t process	

Extract the CT ID and execution parameters for the RFC

Task	Description	Skills required
Extract the CT ID, version, and execution parameters for the RFC.	Each RFC has a different CT ID, version, and execution parameters. You can extract this information by using one of the following options: 1. Follow the instructions from the *Finding a request for change (RFC) with the CLI* section in [RFC use examples](#) from the AWS Managed Services documentation. 2. Open an existing RFC of a similar type or create new RFC as a test through the AMS console. Use the RFC's CT ID and execution parameters. For more information about this, see [Finding an RFC with the console](#) in the	AWS systems administrator

Task	Description	Skills required
	AWS Managed Services documentation. **Note** To adapt this pattern's Python automation for other RFCs, replace the CT type and parameter values in the `ams_stop_ec2_instance` Python code file from the `AMS Stop EC2 Instance.zip` file (attached) with those that you extracted.	

Run the Python automation

Task	Description	Skills required
Run the Python automation.	1. Download the `AMS Stop EC2 Instance.zip` file (attached) to your local machine and extract the file. 2. Update `input_instances` with your EC2 instance information. 3. Open a terminal and navigate to the path for your extracted code	AWS systems administrator

Task	Description	Skills required
	4. Run the `pythonams_stop_ec2_instance.py` command.

Automatically stop and start an Amazon RDS DB instance using AWS Systems Manager Maintenance Windows

Ashita Dsilva, Amazon Web Services

Summary

This pattern demonstrates how to automatically stop and start an Amazon Relational Database Service (Amazon RDS) DB instance on a specific schedule (for example, shutting down a DB instance outside of business hours to reduce costs) by using AWS Systems Manager Maintenance Windows. For this purpose, Systems Manager is cost-effective for typical use cases.

AWS Systems Manager Automation provides the `AWS-StopRdsInstance` and `AWS-StartRdsInstance` runbooks to stop and start Amazon RDS DB instances. This means that you don't need to write custom logic with AWS Lambda functions or create an Amazon CloudWatch Events rule.

Systems Manager provides two capabilities for scheduling tasks: [State Manager] and [Maintenance Windows]. State Manager sets and maintains the required state configuration for resources in your Amazon Web Services (AWS) account one time or on a specific schedule. Maintenance Windows runs tasks on the resources in your account during a specific time window. Although you can use this pattern's approach with State Manager or Maintenance Windows, we recommend that you use Maintenance Windows because it can run one or more tasks based on assigned priority and can also run AWS Lambda functions and AWS Step Functions tasks. For more information about State Manager and Maintenance Windows, see [Choosing between State Manager and Maintenance Windows] in the Systems Manager documentation.

This pattern provides detailed steps to configure two separate maintenance windows that use cron expressions to stop and then start an Amazon RDS DB instance.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon RDS DB instance that you want to stop and start on a specific schedule.
- Cron expressions for your required schedule. For example, the expression `cron(0 9 ? * MON-FRI *)` runs the task at 09:00 on every Monday, Tuesday, Wednesday, Thursday, and Friday.

For more information, see Cron and rate expressions for maintenance windows in the Systems Manager documentation.

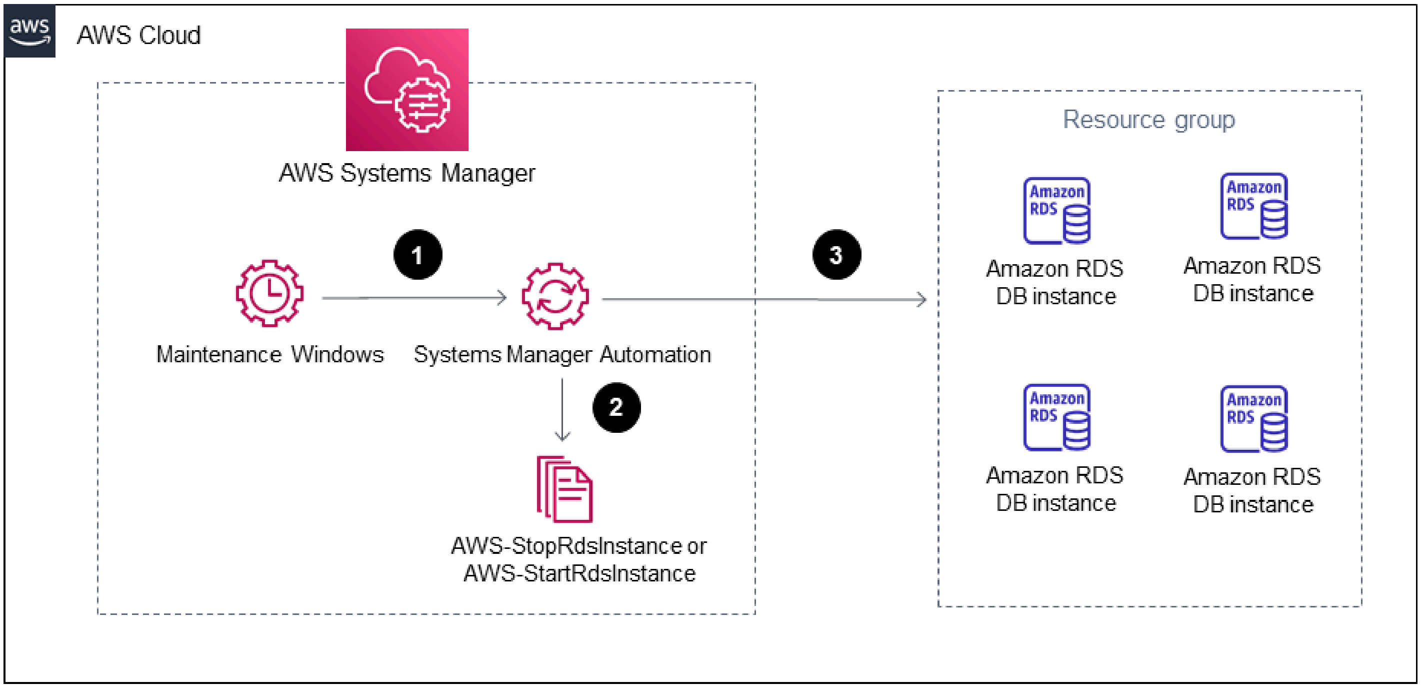
- Familiarity with Systems Manager.
- Permissions to start and stop the RDS instance. For more information, see the Epics section.

Limitations

- An Amazon RDS DB instance can be stopped for up to seven days at one time. After seven days, the DB instance automatically restarts to ensure that it receives any required maintenance updates.
- You can't stop a DB instance that is a read replica or that has a read replica.
- You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.
- Service quotas apply to Maintenance Windows and Systems Manager Automation. For more information about service quotas, see AWS Systems Manager endpoints and quotas in the AWS General Reference documentation.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

The following diagram shows the workflow to automatically stop and start an Amazon RDS DB instance.



The workflow has the following steps:

1. Create a maintenance window and use cron expressions to define the stop and start schedule for your Amazon RDS DB instances.

2. Register a Systems Manager Automation task to the maintenance window by using the `AWS-StopRdsInstance` or `AWS-StartRdsInstance` runbook.

3. Register a target with the maintenance window by using a tag-based resource group for your Amazon RDS DB instances.

Technology stack

- AWS CloudFormation
- AWS Identity and Access Management (IAM)
- Amazon RDS
- Systems Manager

Automation and scale

You can stop and start multiple Amazon RDS DB instances at the same time by tagging the required Amazon RDS DB instances, creating a resource group that includes all the tagged DB instances, and registering this resource group as a target for the maintenance window.

Tools

- AWS CloudFormation is a service that helps you model and set up your AWS resources.
- AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources.
- Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- AWS Resource Groups helps you organize AWS resources into groups, tag resources, and manage, monitor, and automate tasks on grouped resources.
- AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. This pattern uses the following features of Systems Manager:
  - AWS Systems Manager Automation simplifies common maintenance and deployment tasks of Amazon Elastic Compute Cloud (Amazon EC2) instances and other AWS resources.
  - AWS Systems Manager Maintenance Windows helps you define a schedule for when to perform potentially disruptive actions on your instances.

Epics

Create and configure the IAM service role for Systems Manager Automation

Task	Description	Skills required
Configure the IAM service role for Systems Manager Automation.	Sign in to the AWS Management Console and create a service role for Systems Manager Automatio n. You can use one of the following two methods to create this service role: • Use AWS CloudFormation to configure a service	AWS administrator

Task	Description	Skills required

	role for Systems Manager Automation
	• Use IAM to configure roles for Systems Manager Automation
	
	The Systems Manager Automation workflow invokes Amazon RDS by using a service role to perform start and stop actions on the Amazon RDS DB instance.
	
	The service role must be configured with the following inline policy that has permissions to start and stop the Amazon RDS DB instance:
	
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Sid": "RdsStartStop",`
	`            "Effect": "Allow",`
	`            "Action": [`
	`                "rds:StopDBInstance",`
	`                "rds:StartDBInstance"`
	`            ],`
	`            "Resource": "<RDS_Instance_ARN>"`	

Task	Description	Skills required

	``
	        },
	        {
	            "Sid":
	 "RdsDescribe",
	            "Effect":
	 "Allow",
	            "Action":
	 "rds:DescribeDBIns
	tances",
	            "Resource":
	 "*"
	        }
	    ]
	}
	``
	
	Make sure that you replace `<RDS_Instance_ARN>` with the Amazon Resource Name (ARN) of your Amazon RDS DB instance.
	
	If you are unfamiliar with using IAM policies and roles, follow the instructions in the *Solution Overview* section of the [Schedule Amazon RDS stop and start using AWS Systems Manager](#) blog post.
	
	Important
	Make sure that you record the ARN of the service role.	

Create a resource group

Task	Description	Skills required
Tag the Amazon RDS DB instances.	Open the [Amazon RDS console](#) and tag the Amazon RDS DB instances that you want to add to the resource group. A tag is metadata assigned to an AWS resource and consists of a key-value pair. We recommend that you use *Action* as the **Tag key** and *StartStop* as the **Value**. For more information about this, see [Adding, listing, and removing tags](#) in the Amazon RDS documentation.	AWS administrator
Create a resource group for your tagged Amazon RDS DB instances.	Open the [AWS Resource Groups console](#) and create a resource group based on the tag that you created for your Amazon RDS instances. Under **Grouping Criteria**, make sure that you choose **AWS::RDS::DBInstance** for the resource type and then provide the tag's key-value pair (for example, "Action-StartStop"). This ensures that the service only checks for Amazon RDS DB instances and not other resources that have this tag. Make sure	AWS administrator

Task	Description	Skills required
	that you record the resource group's name. For more information and detailed steps, see [Build a tag-based query and create a group](#) in the AWS Resource Groups documentation.	

Configure a maintenance window to stop the Amazon RDS DB instances

Task	Description	Skills required
Create a maintenance window.	1. Open the [Systems Manager console](#), choose **Maintenance Windows**, and then choose **Create a maintenance window**. Provide a name for your maintenance window (for example, "StopRdsI nstance"), enter a descripti on, and then uncheck **Allow unregistered targets**. 2. Choose **CRON/Rate expression** and provide the schedule expressio n to define when the Amazon RDS DB instances should be stopped. Enter **1** for the **Duration** and **0** for **Stop initiating tasks**. By default, the **Time**	AWS administrator

Task	Description	Skills required
	zone shows UTC. You can change the time zone to initiate the maintenance window based on the timestamp defined in your cron expression. 3. Choose **Create maintenance window**. The system returns you to the maintenance window page and the state of your maintenance window is **Enabled**. **Important** The task to stop the DB instance runs almost instantly when initiated and doesn't span the entire duration of the maintenance window. This pattern provides the minimum values for **Duration** and **Stop initiating tasks** because they are the required parameters for a maintenance window.	

Task	Description	Skills required
	For more information and detailed steps, see [Create a maintenance window (console)]() in the Systems Manager documentation.	
Assign a target to the maintenance window.	1. On the [Systems Manager console](), choose **Maintenance Windows**, choose **Actions**, and then choose **Register targets**. 2. In the **Targets** area, specify **Choose a resource group** and then choose the name of an existing resource group in your account. 3. For **Resource types**, choose **AWS::RDS::DBInstance** and then choose **Register target**. For more information and detailed steps, see [Assign targets to a maintenance window (console)]() in the Systems Manager documentation.	AWS administrator

Task	Description	Skills required
Assign a task to the maintenance window.	1. On the [Systems Manager console](), choose **Maintenance Windows**, and then choose your maintenance window. Choose **Actions**, and then choose **Register Automation task**. 2. For **Document**, choose **AWS-StopRdsInstance**. 3. In the **Targets** section, choose **Selecting registered target groups**, and then choose the maintenance window target that you registered with the current maintenance window. 4. For **Rate control**, specify 100 percent for **Concurrency** and **Error threshold**. You can change the **Rate control** values according to your requirements for task concurrency and error threshold. For more information about this, see [About concurrency and error thresholds]() in the Systems Manager documentation. 5. In the **IAM service role** section, for **Service role**, leave this box blank or create your own custom role. If you leave the box	AWS administrator

Task	Description	Skills required
	blank, Systems Manager automatically creates the service-linked role **AWSServiceRoleForAmazonSSM** and then associates the role with the task. To create your own custom role, see [Create a custom service role for maintenance windows (console)](), and then associate that custom role with the task. 6. In the **Input Parameters** section, specify the following parameters for the runbook: • **InstanceId**: `{{RESOURCE_ID}}` **Note** For **InstanceId**, a pseudo parameter is used to extract the Amazon RDS DB resource ID from the ARN. To learn more about pseudo parameters, see [About pseudo parameters]() in the Systems	

Task	Description	Skills required
	Manager documentation. • **AutomationAssumeRole**: Provide the ARN of the service role that you created for Systems Manager Automation. 7. Choose **Register Automation task**. **Important** The **Service role** option defines the service role required for the maintenance window to run tasks. However, this role is not identical to the service role that you created earlier for Systems Manager Automation. For more information and detailed steps, see Assign tasks to a maintenance window (console) in the Systems Manager documentation.	

Configure a maintenance window to start the Amazon RDS DB instances

Task	Description	Skills required
Configure a maintenance window to start the Amazon RDS DB instances.	Repeat the steps from the *Configure a maintenance window to stop the Amazon RDS DB instances* epic to configure another maintenance window to start the Amazon RDS DB instances at a scheduled time. **Important** You must make the following changes when you configure the maintenance window to start the DB instances: • Use a new name for the maintenance window (for example, "StartRdsInstance"). • Replace the cron expression with the cron expression that you want to use to start the DB instances. • Replace the `AWS-StopRdsInstance` runbook with `AWS-StartRdsInstance` in **Task**.	AWS administrator

Centralize software package distribution in AWS Organizations by using Terraform

Pradip kumar Pandey, Chintamani Aphale, T.V.R.L.Phani Kumar Dadi, Pratap Kumar Nanda, Aarti Rajput, and Mayuri Shinde, Amazon Web Services

Summary

Enterprises often maintain multiple AWS accounts that are spread across multiple AWS Regions in order to create a strong isolation barrier between workloads. To stay secure and compliant, their administration teams install agent-based tools such as CrowdStrike, SentinelOne, or TrendMicro tools for security scanning, and the Amazon CloudWatch agent, Datadog Agent, or AppDynamics agents for monitoring. These teams often face challenges when they want to centrally automate software package management and distribution across this large landscape.

Distributor, a capability of AWS Systems Manager, automates the process of packaging and publishing software to managed Microsoft Windows and Linux instances across the cloud and on-premises servers through a single simplified interface. This pattern demonstrates how you can use Terraform to further simplify the process of managing the installation of software and to run scripts across a large number of instances and member accounts within AWS Organizations with minimal effort.

This solution works for Amazon, Linux, and Windows instances that are managed by Systems Manager.

Prerequisites and limitations

- A Distributor package that has the software to be installed
- Terraform version 0.15.0 or later
- Amazon Elastic Compute Cloud (Amazon EC2) instances that are managed by Systems Manager and have basic permissions to access Amazon Simple Storage Service (Amazon S3) in the target account
- A landing zone for your organization that's set up by using AWS Control Tower
- (Optional) Account Factory for Terraform (AFT)

Architecture

Resource details

This pattern uses [Account Factory for Terraform (AFT)](#) to create all required AWS resources and the code pipeline to deploy the resources in a deployment account. The code pipeline runs in two repositories:

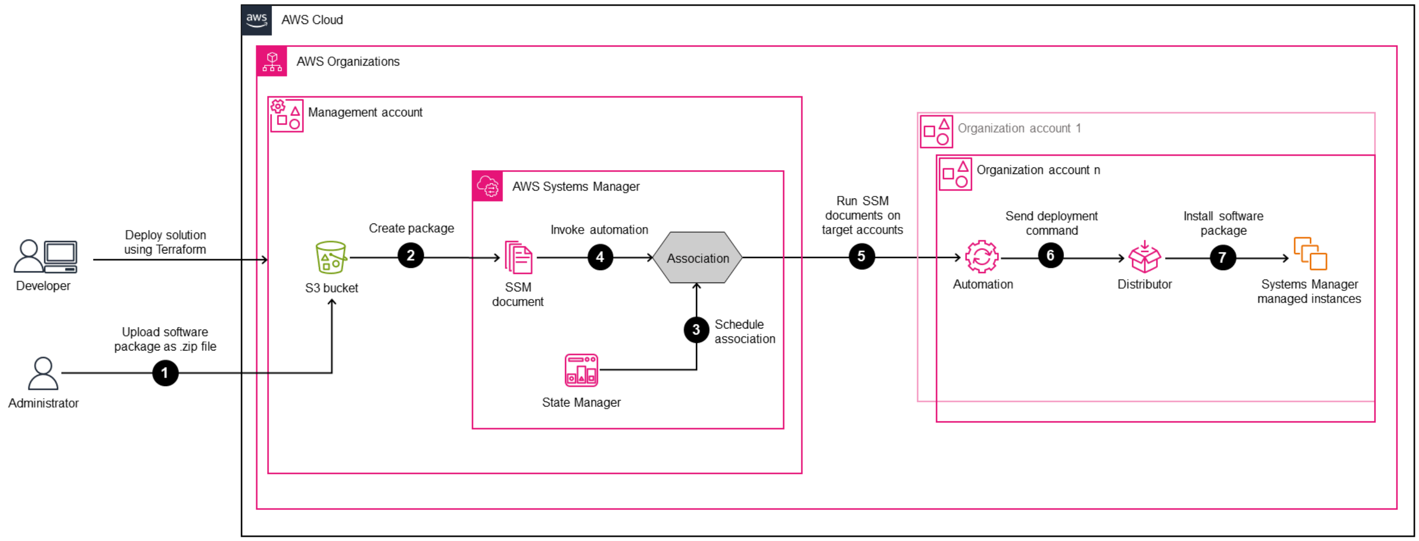
- **Global customization** contains Terraform code that will run across all accounts registered with AFT.
- **Account customizations** contains Terraform code that will run in the deployment account.

You can also deploy this solution without using AFT, by running [Terraform](#) commands in the account customizations folder.

The Terraform code deploys the following resources:

- AWS Identity and Access Management (IAM) role and policies
  - [SystemsManager-AutomationExecutionRole](#) grants the user permissions to run automations in the target accounts.
  - [SystemsManager-AutomationAdministrationRole](#) grants the user permissions to run automations in multiple accounts and organizational units (OUs).
- Compressed files and manifest.json for the package
  - In Systems Manager, a [package](#) includes at least one .zip file of software or installable assets.
  - The JSON manifest includes pointers to your package code files.
- S3 bucket
  - The distributed package that is shared across the organization is securely stored in an Amazon S3 bucket.
- AWS Systems Manager documents (SSM documents)
  - `DistributeSoftwarePackage` contains the logic to distribute the software package to every target instance in the member accounts.
  - `AddSoftwarePackageToDistributor` contains the logic to package the installable software assets and add it to Automation, a capability of AWS Systems Manager.
- Systems Manager association
  - A Systems Manager association is used to deploy the solution.

Architecture and workflow



The diagram illustrates the following steps:

1. To run the solution from a centralized account, you upload your packages or software along with deployment steps to an S3 bucket.
2. Your customized package becomes available in the Systems Manager console [Documents](#) section, in the **Owned by me** tab.
3. State Manager, a capability of Systems Manager, creates, schedules, and runs an association for the package across the organization. The association specifies that the software package must be installed and running on a managed node before it can be installed on the target node.
4. The association instructs Systems Manager to install the package on the target node.
5. For any subsequent installations or changes, users can run the same association periodically or manually from a single location to perform deployments across accounts.
6. In member accounts, Automation sends deployment commands to Distributor.
7. Distributor distributes software packages across instances.

This solution uses the management account within AWS Organizations, but you can also designate an account (delegated administrator) to manage this on behalf of the organization.

Tools

AWS services

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. This pattern uses Amazon S3 to centralize and securely store the distributed package.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses the following Systems Manager capabilities:
  - Distributor helps you package and publish software to Systems Manager managed instances.
  - Automation simplifies common maintenance, deployment, and remediation tasks for many AWS services.
  - Documents performs actions on your Systems Manager managed instances across your organization and accounts.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The instructions and code for this pattern are available in the GitHub Centralized package distribution repository.

Best practices

- To assign tags to an association, use the AWS Command Line Interface (AWS CLI) or the AWS Tools for PowerShell. Adding tags to an association by using the Systems Manager console isn't supported. For more information, see Tagging Systems Manager resources in the Systems Manager documentation.
- To run an association by using a new version of a document shared from another account, set the document version to `default`.
- To tag only the target node, use one tag key. If you want to target your nodes by using multiple tag keys, use the resource group option.

Epics

Configure source files and accounts

Task	Description	Skills required

Clone the repository.	1. Clone the GitHub [Centralized package distribution](https://github.com/aws-samples/aws-organization-centralised-package-distribution) repository:
	`git clone https://github.com/aws-samples/aws-organization-centralised-package-distribution`
	2. The Terraform code repository requires two customization folders that are managed by AFT. Confirm that your local copy of the repository contains these folders:
	`$ cd centralised-package-distribution`
	`$ ls`
	`global-customization account-customization`
		DevOps engineer

Update global variables.	Update the following input parameters in the `global-customization/variables.tf` file. These variables apply to all accounts that are created and managed by AFT.	DevOps engineer

Task	Description	Skills required
	• `account_id` : The ID of the account where the Distributor solution will be deployed. • `aws_region` : The AWS Region where the associati on will be deployed.	
Update account variables.	Update the following input parameters in the `account-customizat ion/variables.tf` file. These variables apply only to specific accounts that are created and managed by AFT. • `package_bucket_nam e` : The name of the S3 bucket that contains the package distribution file. • `package_name` : The name of the package distribution file. • `package_version` : The package version of the installer.	DevOps engineer

Customize parameters and deployment files

Task	Description	Skills required
Update input parameters for the State Manager associati on.	Update the following input parameters in the `account- customization/assoc`	DevOps engineer

Task	Description	Skills required

	`iation.tf` file to define the state you want to maintain on your instances . You can use the default parameter values if they support your use case.
	
	• `targetAccounts` : The organizational unit (OU) IDs within AWS Organizations that represent accounts with the target instances for distribution. OU IDs start with "ou".
	• `targetRegions` : The AWS Regions (for example, "us-east-1” or "ap-south east-2") where the target instances are running.
	• `action`: Specify whether to install or uninstall the package.
	• `installationType` : One of the following installation types:
	  • `uninstall` : The package is uninstalled.
	  • `reinstall` : The application is taken offline until the reinstall ation process is complete.
	  • `In-place update`: The application is available while new or updated	

Task	Description	Skills required
	files are added to the installation. • `name`: The name of the package to install or uninstall. • `version`: The version of the package to install or uninstall. If no version of the package is installed, the system returns an error. • `bucketName` : The S3 bucket name the package has been deployed to. This bucket should consist of the packages and the manifest file only. • `bucketPrefix` : The S3 prefix where the package assets are stored. • `AutomationAssumeRole` : The Amazon Resource Name (ARN) of `SystemsManager-AutomationAdministrationRole` .	

Task	Description	Skills required
Prepare compressed files and the `manifest.json` file for the package.	This pattern provides sample PowerShell installable files (.msi for Windows and .rpm for Linux) with install and uninstall scripts in the `account-customization/package` folder. 1. Replace the PowerShell installable files with your own files, or provide your installable file, install and uninstall scripts, and manifest file to create a package in the `account-customization` folder in your account. 2. Customize the default `manifest.json` file that Terraform generates in the `account-customization` folder according to your requirements.	DevOps engineer

Run Terraform commands to provision resources

Task	Description	Skills required
Initialize the Terraform configuration.	To deploy the solution automatically with AFT, push the code to AWS CodeCommit: `$ git add *`	DevOps engineer

Task	Description	Skills required

	`$ git commit -m "message"`
	`$ git push`
	
	You can also deploy this solution without using AFT by running a Terraform command from the `account-customization` folder. To initialize the working directory that contains the Terraform files, run:
	
	`$ terraform init`	

Preview changes.	To preview the changes that Terraform will make to the infrastructre, run the command: `$ terraform plan` This command evaluates the Terraform configuration to determine the desired state of the resources that have been declared. It also compares the desired state with the actual infrastructure to provision within the workspace.	DevOps engineer

Task	Description	Skills required
Apply changes.	Run the following command to implement the changes that you made to the `variables.tf` files: `$ terraform apply`	DevOps engineer

Validate resources

Task	Description	Skills required
Validate the creation of SSM documents.	1. On the [Systems Manager console](https://console.aws.amazon.com/systems-manager/), in the left navigation pane, choose **Documents**. 2. Choose the **Owned by me** tab. You should see the `DistributeSoftwarePackage` and `AddSoftwarePackageToDistributor` packages.	DevOps engineer
Validate the successful deployment of automations.	1. On the Systems Manager console, in the left navigation pane, choose **Automation**. 2. In the **Automation executions** list, you should see the most recent `DistributeSoftwarePackage` and `AddSoftwa`	DevOps engineer

Task	Description	Skills required
	`rePackageToDistributor` deployments. 3. Choose **Execution ID** to validate that they completed successfully.	
Validate that the package deployed to the targeted member account instances.	1. On the Systems Manager console, in the navigation pane, choose **Run Command**. 2. In **Command history**, you will see each invocation and its status. 3. Choose any **Command ID** to see the deployment history for each target instance. 4. Choose the **Instance ID** and check the **Output** section for the distribution.	DevOps engineer

Troubleshooting

Issue	Solution
The State Manager association failed or is stuck in pending status.	See the troubleshooting information in the AWS Knowledge Center.
A scheduled association failed to run.	Your schedule specification might be invalid. State Manager doesn't currently support specifying months in cron expressions for associations. Use cron or rate expressions to confirm the schedule.

Configure logging for .NET applications in Amazon CloudWatch Logs by using NLog

Bibhuti Sahu and Rob Hill (AWS), Amazon Web Services

Summary

This pattern describes how to use the NLog open-source logging framework to log .NET application usage and events in Amazon CloudWatch Logs. In the CloudWatch console, you can view the application's log messages in near real time. You can also set up metrics and configure alarms to notify you if a metric threshold is exceeded. Using CloudWatch Application Insights, you can view automated or custom dashboards that show potential problems for the monitored applications. CloudWatch Application Insights is designed to help you quickly isolate ongoing issues with your applications and infrastructure.

To write log messages to CloudWatch Logs, you add the `AWS.Logger.NLog` NuGet package to the .NET project. Then, you update the `NLog.config` file to use CloudWatch Logs as a target.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A .NET web or console application that:
  - Uses supported .NET Framework or .NET Core versions. For more information, see *Product versions*.
  - Uses NLog to send log data to Application Insights.
- Permissions to create an IAM role for an AWS service. For more information, see Service role permissions.
- Permissions to pass a role to an AWS service. For more information, see Granting a user permissions to pass a role to an AWS service.

Product versions

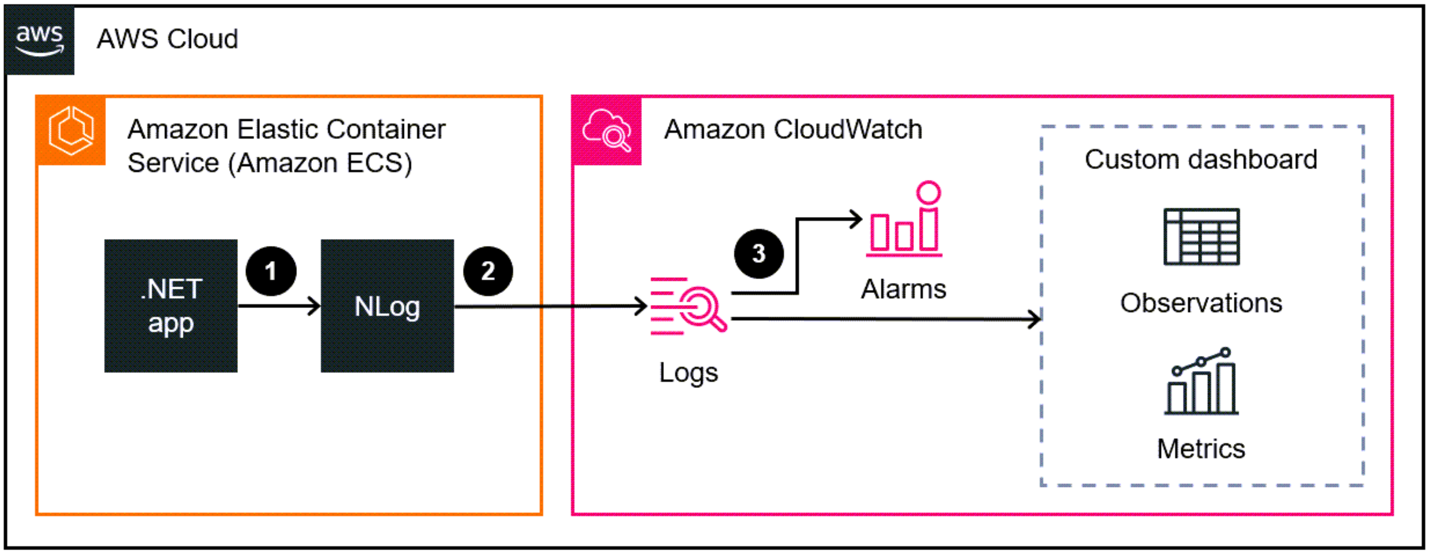
- .NET Framework version 3.5 or later
- .NET Core versions 1.0.1, 2.0.0, or later

Architecture

Target technology stack

- NLog
- Amazon CloudWatch Logs

Target architecture



1. The .NET application writes log data to the NLog logging framework.
2. NLog writes the log data to CloudWatch Logs.
3. You use CloudWatch alarms and custom dashboards to monitor the .NET application.

Tools

AWS services

- [Amazon CloudWatch Application Insights](#) helps you observe the health of your applications and underlying AWS resources.
- [Amazon CloudWatch Logs](#) helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- AWS Tools for PowerShell are a set of PowerShell modules that help you script operations on your AWS resources from the PowerShell command line.

Other tools

- Logger.NLog is an NLog target that records log data to CloudWatch Logs.
- NLog is an open-source logging framework for .NET platforms that helps you write log data to targets, such as databases, log files, or consoles.
- PowerShell is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.
- Visual Studio is an integrated development environment (IDE) that includes compilers, code completion tools, graphical designers, and other features that support software development.

Best practices

- Set a retention policy for the target log group. This must be done outside of the NLog configuration. By default, log data is stored in CloudWatch Logs indefinitely.
- Adhere to the Best practices for managing AWS access keys.

Epics

Set up access and tools

Task	Description	Skills required
Create an IAM policy.	Follow the instructions in Creating policies using the JSON editor in the IAM documentation. Enter the following JSON policy, which has the least-privilege permissions necessary to allow CloudWatch Logs to read and write logs. `{`	AWS administrator, AWS DevOps

Task	Description	Skills required

	``
	    "Version":
	 "2012-10-17",
	    "Statement": [
	        {
	            "Effect":
	 "Allow",
	            "Action": [
	
	 "logs:CreateLogGro
	up",
	
	 "logs:CreateLogStr
	eam",
	
	 "logs:GetLogEvents",
	
	 "logs:PutLogEvents",
	
	 "logs:DescribeLogG
	roups",
	
	 "logs:DescribeLogS
	treams",
	
	 "logs:PutRetention
	Policy"
	            ],
	            "Resource":
	 [
	                "*"
	            ]
	        }
	    ]
	}
	``	

Task	Description	Skills required
Create an IAM role.	Follow the instructions in [Creating a role to delegate permissions to an AWS service](#) in the IAM documentation. Select the policy that you created previously. This is the role CloudWatch Logs assumes to perform logging actions.	AWS administrator, AWS DevOps
Set up AWS Tools for PowerShell.	1. Follow the instructions for your operating system in [Installing the AWS Tools for PowerShell](#). 2. Use the AWS Tools for PowerShell cmdlets to store your access key and secret key in a profile. For instructions, see [Managing Profiles](#) in the AWS Tools for PowerShell documenta tion.	General AWS

Configure NLog

Task	Description	Skills required
Install the NuGet package.	1. In Visual Studio, choose **File**, and then choose **Open a project or solution**. 2. Choose the project where you want to install NLog.	App developer

Task	Description	Skills required
	3. In Visual Studio, choose **Tools**, **NuGet Package Manager**, **Package Manager Console**. 4. Install the `AWS.Logger.NLog` NuGet package by entering the following command. `Install-Package AWS.Logger.NLog -Version 3.1.0`	

Task	Description	Skills required
Configure the logging target.	1. Open the `NLog.config` file. 2. For the target `type`, enter `AWSTarget` . 3. For the target `logGroup`, enter the name of the [log group](https://docs.aws.amazon.com/AmazonCloudWatch/latest/logs/Working-with-log-groups-and-streams.html) that you want to use. If the log group doesn't already exist, a new log group with the provided name is automatically created. 4. For the target `region`, enter the AWS Region where CloudWatch Logs is configured. 5. For the target `profile`, enter the name of the profile that you created previously to store to store the access key and secret key. 6. Save and close the `NLog.config` file. For a sample configuration file, see the Additional information section of this pattern. When you run your application, NLog will write the log messages and send them to CloudWatch Logs.	App developer

Validate and monitor logs

Task	Description	Skills required
Validate logging.	Follow the instructions in View log data sent to CloudWatch Logs in the CloudWatch Logs documenta tion. Validate that log events are being recorded for the .NET application. If log events are not being recorded, see the Troublesh ooting section in this pattern.	General AWS
Monitor the .NET application stack.	Configure monitoring in CloudWatch as needed for your use case. You can use CloudWatch Logs Insights, CloudWatch Metrics Insights, and CloudWatch Application Insights to monitor your .NET workload. You can also configure alarms so that you can receive alerts, and you can create a custom dashboard for monitoring the workload from a single view.	General AWS

Troubleshooting

Issue	Solution
Log data doesn't appear in CloudWatch Logs.	Make sure that the IAM policy is attached to the IAM role that CloudWatch Logs assumes.

Issue	Solution
	For instructions, see the *Set up access and tools* section in the Epics section.

Additional information

The following is a sample `NLog.config` file.

```
<?xml version="1.0" encoding="utf-8" ?>
<configuration>
  <configSections>
    <section name="nlog" type="NLog.Config.ConfigSectionHandler, NLog" />
  </configSections>
  <startup>
    <supportedRuntime version="v4.0" sku=".NETFramework,Version=v4.7.2" />
  </startup>
  <nlog>
    <extensions>
      <add assembly="NLog.AWS.Logger" />
    </extensions>
    <targets>
      <target name="aws" type="AWSTarget" logGroup="NLog.TestGroup" region="us-east-1"
 profile="demo"/>
    </targets>
    <rules>
      <logger name="*" minlevel="Info" writeTo="aws" />
    </rules>
  </nlog>
</configuration>
```

Copy AWS Service Catalog products across different AWS accounts and AWS Regions

Sachin Vighe and Santosh Kale, Amazon Web Services

Summary

AWS Service Catalog is a Regional service and this means that AWS Service Catalog portfolios and products are only visible in the AWS Region where they are created. If you set up an AWS Service Catalog hub in a new Region, you must recreate your existing products and this can be a time-consuming process.

This pattern's approach helps simplify this process by describing how to copy products from an AWS Service Catalog hub in a source AWS account or Region to a new hub in a destination account or Region. For more information about the AWS Service Catalog hub and spoke model, see AWS Service Catalog hub and spoke model: How to automate the deployment and management of AWS Service Catalog to many accounts on the AWS Management and Governance Blog.

The pattern also provides the separate code packages required to copy AWS Service Catalog products across accounts or to other Regions. By using this pattern, your organization can save time, make existing and previous product versions available in a new AWS Service Catalog hub, minimize the risk of manual errors, and scale the approach across multiple accounts or Regions.

> **Note**
>
> This pattern's *Epics* section provides two options for copying products. You can use Option 1 to copy products across accounts or choose Option 2 to copy products across Regions.

Prerequisites and limitations

Prerequisites

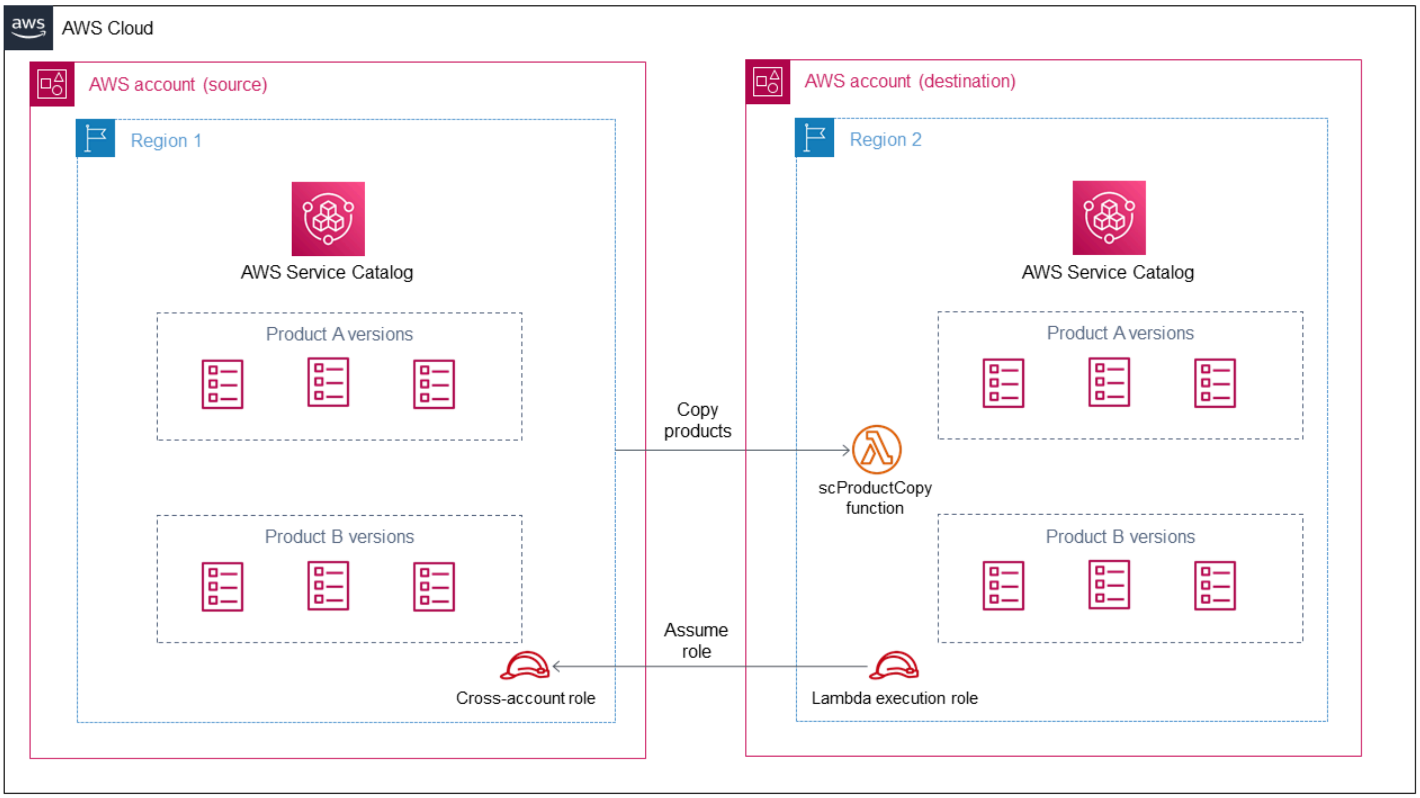
- An active AWS account.
- Existing AWS Service Catalog products in a source account or Region.
- An existing AWS Service Catalog hub in a destination account or Region.
- If you want to copy products across accounts, you must share and then import the AWS Service Catalog portfolio containing the products into your destination account. For more information about this, see Sharing and importing portfolios in the AWS Service Catalog documentation.

Limitations

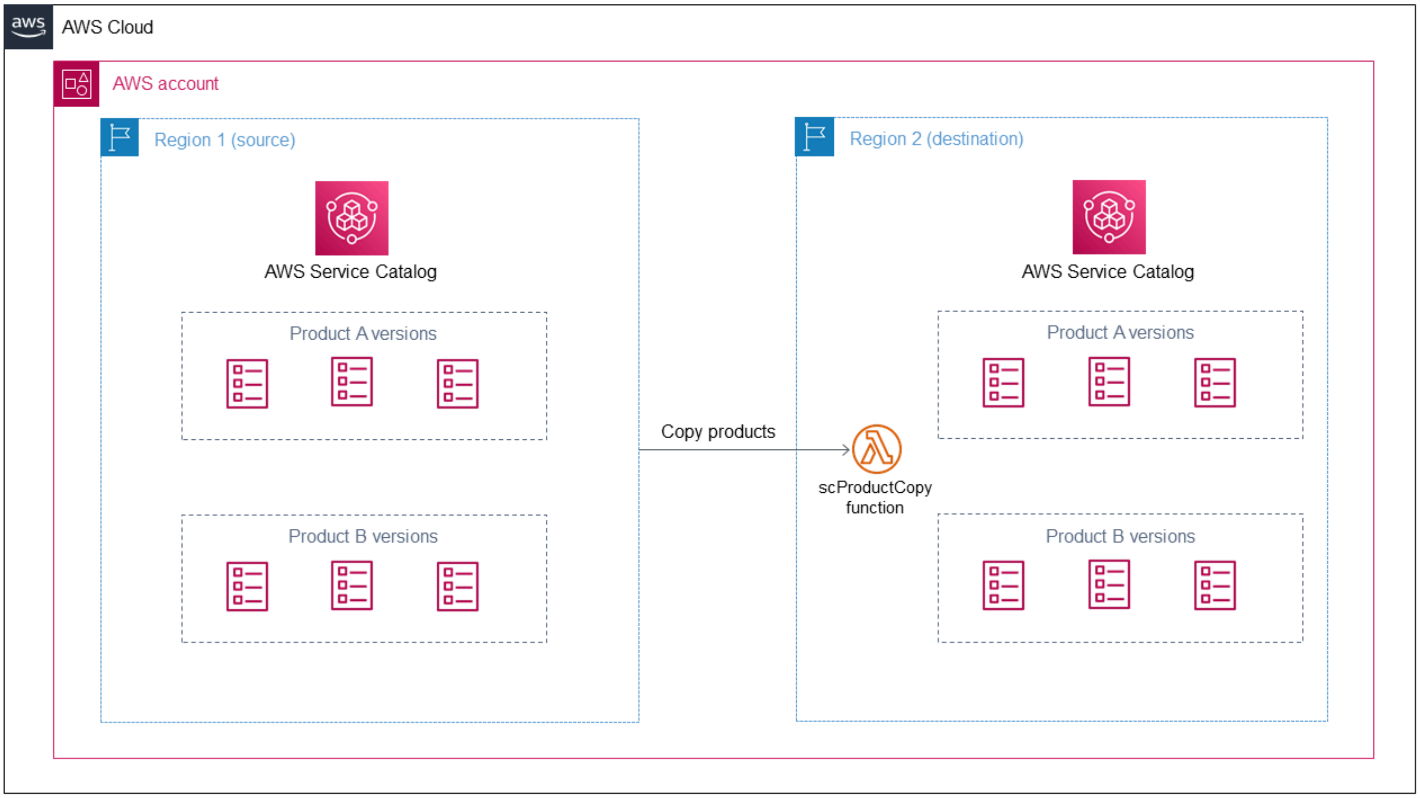
- AWS Service Catalog products that you want to copy across Regions or accounts cannot belong to more than one portfolio.

Architecture

The following diagram shows the copying of AWS Service Catalog products from a source account to a destination account.



The following diagram shows the copying of AWS Service Catalog products from a source Region to a destination Region.



Technology stack

- Amazon CloudWatch
- AWS Identity and Access Management (IAM)
- AWS Lambda
- AWS Service Catalog

Automation and scale

You can scale this pattern's approach by using a Lambda function that can be scaled depending on the number of requests received or how many AWS Service Catalog products you need to copy. For more information about this, see [Lambda function scaling](#) in the AWS Lambda documentation.

Tools

- [AWS Command Line Interface (AWS CLI)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Service Catalog](#) helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

Code

You can use the `cross-account-copy` package (attached) to copy AWS Service Catalog products across accounts or the `cross-region-copy` package (attached) to copy products across Regions.

The `cross-account-copy` package contains the following files:

- `copyconf.properties` – The configuration file that contains the Region and AWS account ID parameters for copying products across accounts.
- `scProductCopyLambda.py` – The Python function for copying products across accounts.
- `createDestAccountRole.sh` – The script to create an IAM role in the destination account.
- `createSrcAccountRole.sh` – The script to create an IAM role in the source account.
- `copyProduct.sh` – The script to create and invoke the Lambda function for copying products across accounts.

The `cross-region-copy` package contains the following files:

- `copyconf.properties` – The configuration file that contains the Region and AWS account ID parameters for copying products across Regions.
- `scProductCopyLambda.py` – The Python function for copying products across Regions.
- `copyProduct.sh` – The script to create an IAM role and create and invoke the Lambda function for copying products across Regions.

Epics

Option 1 – Copy AWS Service Catalog products across accounts

Task	Description	Skills required
Update the configuration file.	1. Download the `cross-account-copy` package (attached) to your local machine. 2. Update the `copyconf.properties` configuration file with the following values: • `srcRegion` – Provide the source Region that contains the products. • `destRegion` – Provide the destination Region for the products. • `sourceAccountId` – Provide the AWS account ID for your source account. • `destAccountId` – Provide the AWS account ID for your destination account.	AWS administrator, AWS systems administrator, Cloud administrator
Configure your credentials for AWS CLI in the destination account.	Configure your credentials to access AWS CLI in your destination account by running the `aws configure` command and providing the following values :	AWS administrator, AWS systems administrator, Cloud administrator

Task	Description	Skills required

	`$aws configure`
	`AWS Access Key ID [None]: <your_access_key_id>`
	`AWS Secret Access Key [None]: <your_secret_access_key>`
	`Default region name [None]: Region`
	`Default output format [None]:`
	
	For more information about this, see Configuration basics in the AWS Command Line Interface documentation.	

Task	Description	Skills required

Configure your credentials for AWS CLI in the source account.	Configure your credentials to access AWS CLI in your source account by running the `aws configure` command and providing the following values:
	`$aws configure`
	`AWS Access Key ID [None]: <your_access_key_id>`
	`AWS Secret Access Key [None]: <your_secret_access_key>`
	`Default region name [None]: Region`
	`Default output format [None]:`
	For more information about this, see [Configuration basics] in the AWS Command Line Interface documentation.
		AWS administrator, AWS systems administrator, Cloud administrator

Create a Lambda execution role in your destination account.	Run the `createDestAccountRole.sh` script in your destination account. The script implements the following actions: • Creates a Lambda execution role in your destination account • Creates and attaches the IAM policy for the Lambda execution role	AWS administrator, AWS systems administrator, Cloud administrator

Task	Description	Skills required
Create the cross-account IAM role in your source account.	Run the `createSrcAccountRole.sh` script in your source account. The script implements the following actions: • Creates a cross-account IAM role in your source account that is assumed by the Lambda execution role in the destination account to copy products • Creates and attaches an IAM policy for the cross-account role in your source account	AWS administrator, AWS systems administrator, Cloud administrator
Run the copyProduct script in the destination account.	Run the `copyProduct.sh` script in your destination account. The script implements the following actions: • Creates and invokes the Lambda function to copy products from the source account to the destination account	AWS administrator, AWS systems administrator, Cloud administrator

Option 2 – Copy AWS Service Catalog products from a source Region to a destination Region

Task	Description	Skills required
Update the configuration file.	1. Download the `cross-region-copy` package (attached) to your local machine. 2. Update the `copyconf.properties` configuration file with the following values: • `srcRegion` – Provide the source Region that contains the products. • `destRegion` – Provide the destination Region for the products. • `accountId` – Provide your AWS account ID.	AWS systems administrator, Cloud administrator, AWS administrator

Configure your credentials for AWS CLI.	Configure your credentials to access AWS CLI in your environment by running the `aws configure` command and providing the following values:
	
	`$aws configure`
	`AWS Access Key ID [None]: <your_access_key_id>`
	`AWS Secret Access Key [None]: <your_secret_access_key>`
	`Default region name [None]: Region`
		AWS administrator, AWS systems administrator, Cloud administrator

Task	Description	Skills required
	`Default output format [None]:` For more information about this, see Configuration basics in the AWS Command Line Interface documentation.	
Run the copyProduct script.	Run the `copyProduct.sh` script in your destination Region. The script implements the following actions: • Creates a Lambda execution role • Creates and attaches the IAM policy for the Lambda execution role • Creates and invokes the Lambda function to copy products from the source Region to the destination Region	AWS administrator, AWS systems administrator, Cloud administrator

Create a RACI or RASCI matrix for a cloud operating model

Teddy Germade, Jerome Descreux, Florian Leroux, and Josselin LE MINEUR, Amazon Web Services

Summary

The Cloud Center of Excellence (CCoE) or CEE (Cloud Enablement Engine) is an empowered and accountable team that is focused on operational readiness for the cloud. Their key focus is to transform the information IT organization from an on-premises operating model to a cloud operating model. The CCoE should be a cross-functional team that includes representation from infrastructure, applications, operations, and security.

One of the key components of a cloud operating model is a *RACI matrix* or *RASCI matrix*. This is used to define the roles and responsibilities for all parties involved in migration activities and cloud operations. The matrix name is derived from the responsibility types defined in the matrix: responsible (R), accountable (A), support (S), consulted (C), and informed (I). The support type is optional. If you include it, it's called a *RASCI matrix*, and if you exclude it, it's called a *RACI matrix*.

By starting with the attached template, your CCoE team can create a RACI or RASCI matrix for your organization. The template contains teams, roles, and tasks that are common in cloud operating models. The foundation of this matrix is the tasks related to operations integration and CCoE capabilities. However, you can customize this template to meet the needs of your organization's structure and use case.

There are no limits to the implementation of a RACI matrix. This approach works for large organizations, start-ups, and everything in between. For small organizations, the same resource can fill several roles.

Epics

Create the matrix

Task	Description	Skills required
Identify key stakeholders.	Identify key service and team managers that are linked to the strategic objectives of your cloud operating model.	Project manager

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Customize the matrix template.</td><td>Download the template in the Attachments section, and then update the RACI or RASCI matrix as follows:
On the Cloud Teams worksheet, update the CCoE stream names, team names, and team descripti ons as needed for your organization.
On the Cloud Roles worksheet, update the roles, team names, and role descriptions as needed for your organization.
On the RASCI worksheet , update the following as needed for your organizat ion:
In row 1 and column A, update the CCoE streams.
In row 2, update the team names.
In row 3, update the role names.
In columns D and E, update the general fields and activities that you want to include in your RASCI chart.</td><td>Project manager</td></tr>
</table>

Task	Description	Skills required
Plan meetings.	1. Communicate the RASCI objectives to all stakehold ers. 2. Plan one or more meetings so that an empowered representative from each team can attend.	Project manager

Task	Description	Skills required

Complete the matrix.	In the meeting with all stakeholders, do the following:
	
	1. Confirm that a represent ative from each team is present. Team participa tion is mandatory so that you can accurately assign responsibility types for each task.
	2. Review the what a RASCI matrix is and the objectives with the participants.
	3. Review the [shared responsibility model](https://aws.amazon.com/compliance/shared-responsibility-model/) with the participants so that they understand the scope of their organization’s responsibilities for security in the cloud.
	4. On the **RASCI** worksheet , for each task or activity, complete columns F through AN to assign the following responsibility types:
	    • **Responsible (R)** – This role is responsible for performing the work to complete the task.
	    • **Accountable (A)** – This role is held accountab le for making sure the
		Project manager

Task	Description	Skills required
	task is completed. This role is also responsible for ensuring the prerequisites are met and delegating the task to those who are responsible. • **Support (S)** – This role helps those who are responsible complete the task. This responsibility type is optional, and you can choose to exclude it in order to create a more traditional RACI matrix. • **Consulted (C)** – This role should be consulted for opinions or expertise on the task. Depending on the task, this responsibility type might not be required. • **Informed (I)** – This role should be kept up to date on the progress of the task and notified when the task is completed. • **Blank** – This role is not involved in the activity or task.	

Task	Description	Skills required
Share the RASCI matrix.	When the RACI or RASCI matrix is complete, have it approved by leadership. Save it in a shared repositor y or central location where all stakeholders can access it. We recommend that you use standard document control processes to record and approve revisions to the matrix.	Project manager

Create alarms for custom metrics using Amazon CloudWatch anomaly detection

Ram Kandaswamy and Raheem Jiwani, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, you can use Amazon CloudWatch to create alarms that monitor metrics and send notifications or automatically make changes if a threshold is breached.

To avoid being limited by static thresholds, you can create alarms based on past patterns and that notify you if specific metrics are outside the normal operating window. For example, you could monitor your API's response times from Amazon API Gateway and receive notifications about anomalies that prevent you from meeting a service-level agreement (SLA).

This pattern describes how to use CloudWatch anomaly detection for custom metrics. The pattern shows you how to create a custom metric in Amazon CloudWatch Logs Insights or publish a custom metric with an AWS Lambda function, and then set up anomaly detection and create notifications using Amazon Simple Notification Service (Amazon SNS).

Prerequisites and limitations

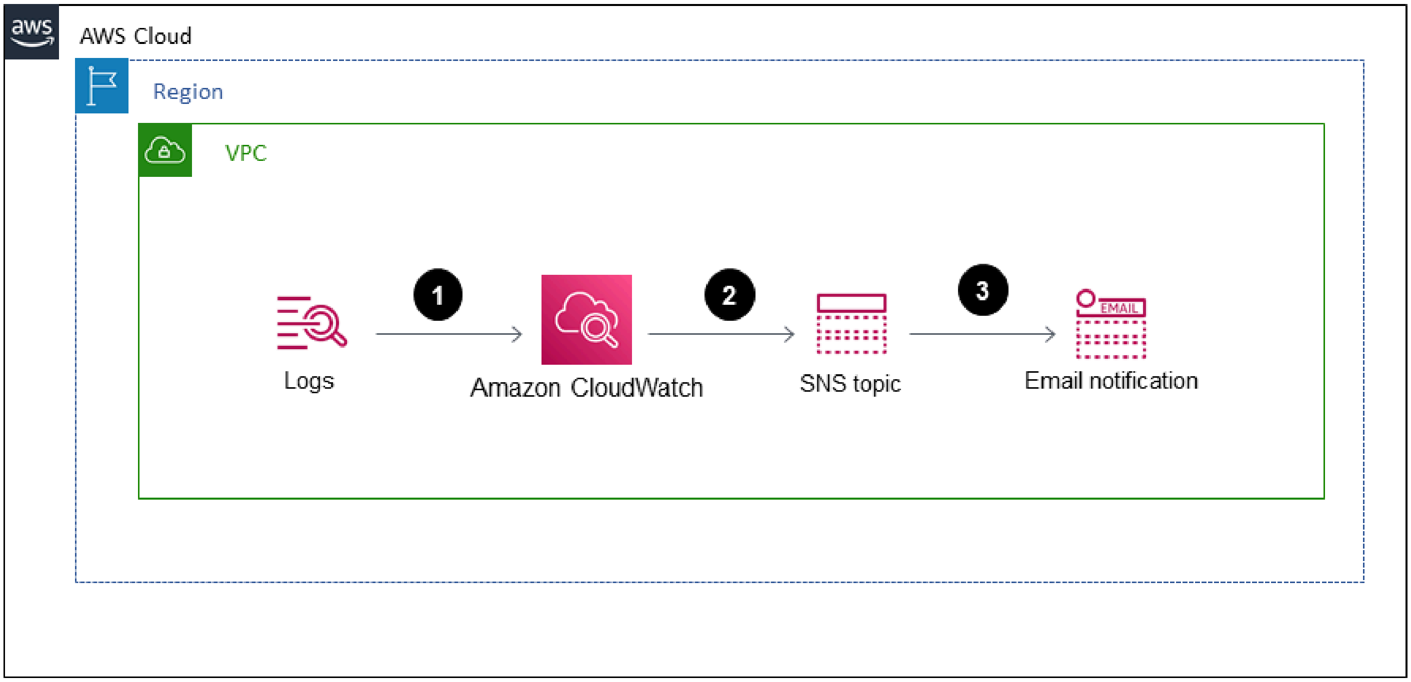
Prerequisites

- An active AWS account.
- An existing SNS topic, configured to send email notifications. For more information about this, see Getting started with Amazon SNS in the Amazon SNS documentation.
- An existing application, configured with CloudWatch Logs.

Limitations

- CloudWatch metrics don't support millisecond time intervals. For more information about the granularity of regular and custom metrics, see the Amazon CloudWatch FAQs.

Architecture



The diagram shows the following workflow:

1. Logs that use metrics created and updated by CloudWatch Logs are streamed to CloudWatch.
2. An alarm initiates based on thresholds and sends an alert to an SNS topic.
3. Amazon SNS sends you an email notification.

Technology stack

- CloudWatch
- AWS Lambda
- Amazon SNS

Tools

- Amazon CloudWatch provides a reliable, scalable, and flexible monitoring solution.
- AWS Lambda is a compute service that helps you run code without provisioning or managing servers.
- Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.

Epics

Set up anomaly detection for a custom metric

Task	Description	Skills required
Option 1 - Create a custom metric with a Lambda function.	Download the `lambda_function.py` file (attached) and then replace the sample `lambda_function.py` file in the [aws-lambda-developer-guide](https://github.com/awsdocs/aws-lambda-developer-guide) repository on the AWS Documentation GitHub. This provides you with a sample Lambda function that sends custom metrics to CloudWatch Logs. The Lambda function uses the Boto3 API to integrate with CloudWatch. After you run the Lambda function, you can sign in to the AWS Management Console, open the CloudWatch console, and the published metric is available under your published namespace.	DevOps engineer, AWS DevOps
Option 2 – Create custom metrics from CloudWatch log groups.	Sign in to the AWS Management Console, open the CloudWatch console, and then choose **Log groups**. Choose the log group that you want to create a metric for.	DevOps engineer, AWS DevOps

Task	Description	Skills required
	Choose **Actions** and then choose **Create metric filter**. For **Filter pattern**, enter the filter pattern that you want to use. For more informati on, see [Filter and pattern syntax](#) in the CloudWatch documentation. To test your filter pattern, enter one or more log events under **Test Pattern**. Each log event must be within one line, because line breaks are used to separate log events in the **Log event** messages box. After you test the pattern, you can enter a name and value for your metric under **Metric details**. For more information and steps to create a custom metric, see [Create a metric filter for a log group](#) in the CloudWatch documentation.	

Task	Description	Skills required
Create an alarm for your custom metric.	On the CloudWatch console, choose **Alarms** and then choose **Create Alarm**. Choose **Select metric** and enter the name of the metric that you created earlier into the search box. Choose the **Graphed metrics** tab and configure the options according to your requirements. Under **Conditions**, choose **Anomaly detection** instead of **Static thresholds**. This shows you a band based on two standard default deviations. You can set up thresholds and adjust them according to your requireme nts. Choose **Next.** **Note** The band is dynamic and depends on the quality of the datapoints. When you begin aggregati ng more data, the band and threshold s are automatically updated.	DevOps engineer, AWS DevOps

Task	Description	Skills required
Set up SNS notifications.	Under **Notification**, choose the SNS topic to notify when the alarm is in `ALARM` state, `OK` state, or `INSUFFICIENT_DATA` state. To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose **Add notification**. Choose **Next**. Enter a name and description for the alarm. The name must only contain ASCII characters. Then choose **Next**. Under **Preview and create**, confirm that the information and conditions are correct, and then choose **Create alarm**.	DevOps engineer, AWS DevOps

Create an AWS Cloud9 IDE that uses Amazon EBS volumes with default encryption

Janardhan Malyala and Dhrubajyoti Mukherjee, Amazon Web Services

Summary

Notice: AWS Cloud9 is no longer available to new customers. Existing customers of AWS Cloud9 can continue to use the service as normal. Learn more

You can use encryption by default to enforce the encryption of your Amazon Elastic Block Store (Amazon EBS) volumes and snapshot copies on the Amazon Web Services (AWS) Cloud.

You can create an AWS Cloud9 integrated development environment (IDE) that uses EBS volumes encrypted by default. However, the AWS Identity and Access Management (IAM) service-linked role for AWS Cloud9 requires access to the AWS Key Management Service (AWS KMS) key for these EBS volumes. If access is not provided, the AWS Cloud9 IDE might fail to launch and debugging might be difficult.

This pattern provides the steps to add the service-linked role for AWS Cloud9 to the AWS KMS key that is used by your EBS volumes. The setup described by this pattern helps you successfully create and launch an IDE that uses EBS volumes with encryption by default.

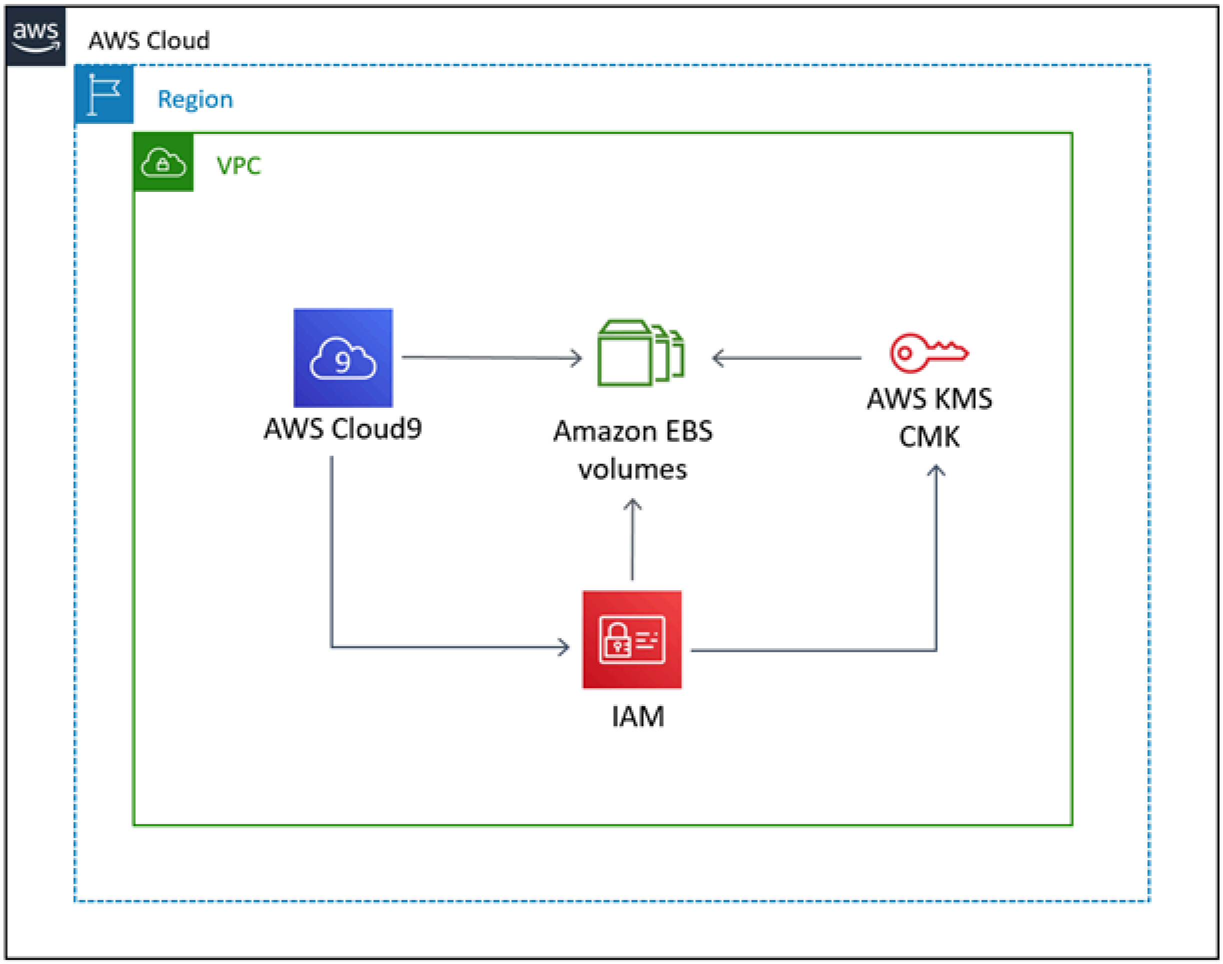
Prerequisites and limitations

Prerequisites

- An active AWS account.
- Default encryption turned on for EBS volumes. For more information about encryption by default, see Amazon EBS encryption in the Amazon Elastic Compute Cloud (Amazon EC2) documentation.
- An existing customer managed KMS key for encrypting your EBS volumes.

> **Note**
>
> You don't need to create the service-linked role for AWS Cloud9. When you create an AWS Cloud9 development environment, AWS Cloud9 creates the service-linked role for you.

Architecture



Technology stack

- AWS Cloud9
- IAM
- AWS KMS

Tools

- [AWS Cloud9](https://docs.aws.amazon.com/cloud9/latest/user-guide/welcome.html) is an integrated development environment (IDE) that helps you code, build, run, test, and debug software. It also helps you release software to the AWS Cloud.
- [Amazon Elastic Block Store (Amazon EBS)](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/AmazonEBS.html) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.

- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service (AWS KMS)](#) helps you create and control cryptographic keys to help protect your data.

Epics

Find the default encryption key value

Task	Description	Skills required
Record the default encryptio n key value for the EBS volumes.	Sign in to the AWS Management Console and open the Amazon EC2 console. Choose **EC2 dashboard**, and then choose **Data protection and security** in **Account attributes**. In **EBS encryption** section, copy and record the value in **Default encryption key**.	Cloud architect, DevOps engineer

Provide access to the AWS KMS key

Task	Description	Skills required
Provide AWS Cloud9 with access to the KMS key for EBS volumes.	1. Open the AWS KMS console, and then choose **Customer managed keys**. Select the AWS KMS key used for Amazon EBS encryption, and then choose **View key**. 2. On the **Key policy** tab, confirm that you can see the text form of the key	Cloud architect, DevOps engineer

Task	Description	Skills required
	policy. If you cannot see the text form, choose **Switch to policy view**. 3. Choose **Edit**. Add the code in the [Additional information](#) section to the policy, and then choose **Save changes**. The policy changes permit the service-linked role for AWS Cloud9, `AWSServiceRoleForAWSCloud9` , to access the key. For more information about updating a key policy, see [How to change a key policy](#) (AWS KMS documentation). **Important** The service-linked role for AWS Cloud9 is automatically created when you launch your first IDE. For more information, see [Creating a service-linked role](#) in the AWS Cloud9 documentation.	

Create and launch the IDE

Task	Description	Skills required
Create and launch the AWS Cloud9 IDE.	Open the AWS Cloud9 console and choose **Create environment**. Configure IDE according to your requirements by following the steps from [Creating an EC2 environment](#) in the AWS Cloud9 documentation.	Cloud architect, DevOps engineer

Related resources

- [Encrypt EBS volumes used by AWS Cloud9](#)
- [Create a service-linked role for AWS Cloud9](#)
- [Create an EC2 environment in AWS Cloud9](#)

Additional information

AWS KMS key policy updates

Replace <aws_accountid> with your AWS account ID.

```
{
            "Sid": "Allow use of the key",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::<aws_accountid>:role/aws-service-role/
cloud9.amazonaws.com/AWSServiceRoleForAWSCloud9"
            },
            "Action": [
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
```

```
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow attachment of persistent resources",
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::<aws_accountid>:role/aws-service-role/
cloud9.amazonaws.com/AWSServiceRoleForAWSCloud9"
            },
            "Action": [
                "kms:CreateGrant",
                "kms:ListGrants",
                "kms:RevokeGrant"
            ],
            "Resource": "*",
            "Condition": {
                "Bool": {
                    "kms:GrantIsForAWSResource": "true"
                }
            }
        }
```

Using a cross-account key

If you want to use a cross-account KMS key, you must use a grant in combination with the KMS key policy. This enables cross-account access to the key. In the same account that you used to create the Cloud9 environment, run the following command in the terminal.

```
aws kms create-grant \
 --region <Region where Cloud9 environment is created> \
 --key-id <The cross-account KMS key ARN> \
 --grantee-principal arn:aws:iam::<The account where Cloud9 environment is
 created>:role/aws-service-role/cloud9.amazonaws.com/AWSServiceRoleForAWSCloud9 \
 --operations "Encrypt" "Decrypt" "ReEncryptFrom" "ReEncryptTo" "GenerateDataKey"
 "GenerateDataKeyWithoutPlaintext" "DescribeKey" "CreateGrant"
```

After you run this command, you can create Cloud9 environments by using EBS encryption with a key in a different account.

Create tag-based Amazon CloudWatch dashboards automatically

Janak Vadaria, Vinodkumar Mandalapu, and RAJNEESH TYAGI, Amazon Web Services

Summary

Creating different Amazon CloudWatch dashboards manually can be time-consuming, particularly when you have to create and update multiple resources to automatically scale your environment. A solution that creates and updates your CloudWatch dashboards automatically can save you time. This pattern helps you deploy a fully automated AWS Cloud Development Kit (AWS CDK) pipeline that creates and updates CloudWatch dashboards for your AWS resources based on tag change events, to display Golden Signals metrics.

In site reliability engineering (SRE), Golden Signals refers to a comprehensive set of metrics that offer a broad view of a service from a user or consumer perspective. These metrics consist of latency, traffic, errors, and saturation. For more information, see [What is Site Reliability Engineering (SRE)?](#) on the AWS website.

The solution provided by this pattern is event-driven. After it's deployed, it continuously monitors the tag change events and automatically updates the CloudWatch dashboards and alarms.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), installed and configured
- Prerequisites for the AWS CDK v2
- A bootstrapped environment on AWS
- Python version 3
- AWS SDK for Python (Boto3), installed
- Node.js version 18 or later
- Node package manager (npm), installed and configured for the AWS CDK
- Moderate (level 200) familiarity with the AWS CDK and AWS CodePipeline

Limitations

This solution currently creates automated dashboards for the following AWS services only:

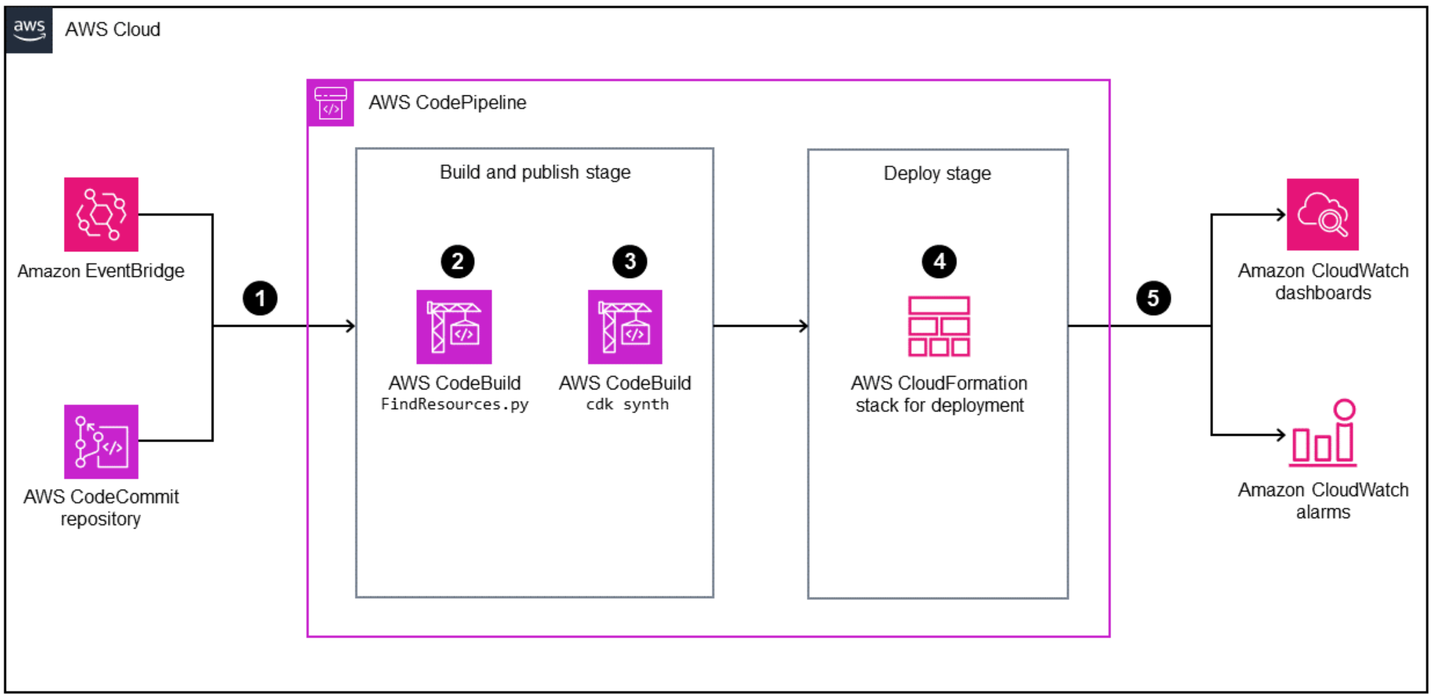
- Amazon Relational Database Service (Amazon RDS)
- AWS Auto Scaling
- Amazon Simple Notification Service (Amazon SNS)
- Amazon DynamoDB
- AWS Lambda

Architecture

Target technology stack

- CloudWatch dashboards
- CloudWatch alarms

Target architecture



1. An AWS tag change event for the configured application tags or code changes initiates a pipeline in AWS CodePipeline to build and deploy updated CloudWatch dashboards.
2. AWS CodeBuild runs a Python script to find the resources that have configured tags and stores the resource IDs in a local file in a CodeBuild environment.

3. CodeBuild runs **cdk synth** to generate AWS CloudFormation templates that deploy CloudWatch dashboards and alarms.
4. CodePipeline deploys the AWS CloudFormation templates to the specified AWS account and Region.
5. When the AWS CloudFormation stack has been deployed successfully, you can view the CloudWatch dashboards and alarms.

Automation and scale

This solution has been automated by using the AWS CDK. You can find the code in the GitHub Golden Signals Dashboards on Amazon CloudWatch repository. For additional scaling and to create custom dashboards, you can configure multiple tag keys and values.

Tools

Amazon services

- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources, including AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Best practices

As a security best practice, you can use encryption and authentication for the source repositories that connect to your pipelines. For additional best practices, see CodePipeline best practices and use cases in the CodePipeline documentation.

Epics

Configure and deploy the sample application

Task	Description	Skills required
Configure and deploy the sample application.	1. Clone the GitHub [sample code repository](#) by using the command: `git clone https://github.com/aws-samples/golden-signals-dashboards-sample-app` 2. Navigate to the cloned repository on your computer and open the `src/project-settings.ts` file with the editor of your choice. 3. Change the `projectSettings` constant value according to your AWS resource tags and application mappings. 4. Set the `AWS_ACCOUNT`, `AWS_REGION`, and `GS_DASHBOARD_INSTANCE` environment variables: • Set `AWS_ACCOUNT` to the account ID of your AWS account. • Set `AWS_REGION` to the Region where you want	AWS DevOps

Task	Description	Skills required
	to deploy the sample application. • Set `GS_DASHBOARD_INSTANCE` to `dev`, `test`, or `prod`, depending on your development environment. (We recommend `test` for the testing procedure described in this pattern.) 5. Set up the AWS CLI with your AWS credentials. For more information, see [Set and view configuration settings using commands](#) in the AWS CLI documentation. 6. Run the following command to deploy the Golden Signals dashboard sample application: `sh deploy.sh`	

Task	Description	Skills required
Automatically create dashboards and alarms.	After you deploy the sample application, you can create any of the resources that this solution supports with expected tag values, which will automatically create the specified dashboards and alarms. To test this solution, create an AWS Lambda function: 1. Sign in to the AWS Management Console in the AWS Region where you deployed the sample application. 2. Open the Lambda console at https://console.aws.amazon.com/lambda/. 3. Choose **Create a function**, and then enter a function name. 4. In the **Advanced settings** pane, select **Enable tags**, and then choose **Add new tag**. Enter the following key and value: • Key: `AutoDashboard` • Value: `True` 5. Choose **Create function**. The Lambda function immediately starts a code	AWS DevOps

Task	Description	Skills required
	pipeline, which creates the dashboards and alarms for that particular Lambda function automatically. 6. To view the automated dashboards and alarms, open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/. You can view the custom dashboards and alarms for the function you specified in the `projectSettings` constant (**APP1-lambda** by default). 7. Select the dashboard for the Lambda function to view additional automated dashboards that were created as part of this solution. 8. Repeat these steps for other services, such as Amazon RDS, Amazon SNS, AWS Auto Scaling, and DynamoDB, to generate the associated dashboards. For an example for Amazon RDS, see the [Additional information](#) section.	

Remove the sample application

Task	Description	Skills required
Remove the `golden-signals-dashboard` construct.	1. To remove all the AWS CloudFormation stacks created by the sample application, you have to reconfigure the `AWS_ACCOUNT` , `AWS_REGION` , and `GS_DASHBOARD_INSTANCE` environment variables. The `destroy.sh` command requires these configurations. • `AWS_ACCOUNT` is the account ID of your AWS account. • `AWS_REGION` is the Region where you deployed your sample application. • `GS_DASHBOARD_INSTANCE` is `dev`, `test`, or `prod`, based on your previous settings. 2. Set up AWS CLI with your AWS credentials. 3. Run the following command to remove the sample application and all associated AWS CloudFormation stacks:	AWS DevOps

Task	Description	Skills required
	`sh destroy.sh`	

Troubleshooting

Issue	Solution
Python command not found (referring to `findresources.sh` , line 8).	Check the version of your Python installat ion. If you have installed Python version 3, replace `python` with `python3` on line 8 of the `resources.sh` file, and run the `sh deploy.sh` command again to deploy the solution.

Document your AWS landing zone design

Michael Daehnert, Florian Langer, and Michael Lodemann, Amazon Web Services

Summary

A *landing zone* is a well-architected, multi-account environment that's based on security and compliance best practices. It is the enterprise-wide container that holds all of your organizational units (OUs), AWS accounts, users, and other resources. A landing zone can scale to fit the needs of an enterprise of any size. AWS has two options for creating your landing zone: a service-based landing zone using AWS Control Tower or a customized landing zone that you build. Each option requires a different level of AWS knowledge.

AWS created AWS Control Tower to help you save time by automating the setup of a landing zone. AWS Control Tower is managed by AWS and uses best practices and guidelines to help you create your foundational environment. AWS Control Tower uses integrated services, such as AWS Service Catalog and AWS Organizations, to provision accounts in your landing zone and manage access to those accounts.

AWS landing zone projects vary in requirements, implementation details, and operational action items. There are customization aspects that need to be handled with every landing zone implementation. This includes (but is not limited to) how access management is handled, which technology stack is used, and what the monitoring requirements are for operational excellence. This pattern provides a template that helps you document your landing zone project. By using the template, you can document your project more quickly and help your development and operations teams understand your landing zone.

Prerequisites and limitations

Limitations

This pattern does not describe what a landing zone is or how to implement one. For more information about these topics, see the Related resources section.

Epics

Create the design document

Task	Description	Skills required
Identify key stakeholders.	Identify key service and team managers that are linked to your landing zone.	Project manager
Customize the template.	Download the template in the [Attachments](#) section, and then update the template as follows: 1. Remove any sections that don't apply to your organization's landing zone or processes. 2. Add any sections that are unique to your organizat ion.	Project manager
Complete the template.	In meetings with the stakeholders or by using a write-and-review process, complete the template as follows: 1. Use the guidance and information in the blue boxes to complete each section. 2. Replace or remove any yellow fields with custom values for your organizat ion.	Project manager

Task	Description	Skills required
	3. Replace or remove any image fields with your custom architecture or flow diagrams. 4. Complete the *Revision history* and *Contributors* section of the template.	
Share the design document.	When your landing zone design documentation is complete, save it in a shared repository or central location where all stakeholders can access it. We recommend that you use standard document control processes to record and approve revisions to the design document.	Project manager

Improve operational performance by enabling Amazon DevOps Guru across multiple AWS Regions, accounts, and OUs with the AWS CDK

Dr. Rahul Sharad Gaikwad, Amazon Web Services

Summary

This pattern demonstrates the steps to enable the Amazon DevOps Guru service across multiple Amazon Web Services (AWS) Regions, accounts, and organizational units (OUs) by using the AWS Cloud Development Kit (AWS CDK) in TypeScript. You can use AWS CDK stacks to deploy AWS CloudFormation StackSets from the administrator (primary) AWS account to enable Amazon DevOps Guru across multiple accounts, instead of logging into each account and enabling DevOps Guru individually for each account.

Amazon DevOps Guru provides artificial intelligence operations (AIOps) features to help you improve the availability of your applications and resolve operational issues faster. DevOps Guru reduces your manual effort by applying machine learning (ML) powered recommendations, without requiring any ML expertise. DevOps Guru analyzes your resources and operational data. If it detects any anomalies, it provides metrics, events, and recommendations to help you address the issue.

This pattern describes three deployment options for enabling Amazon DevOps Guru:

- For all stack resources across multiple accounts and Regions
- For all stack resources across OUs
- For specific stack resources across multiple accounts and Regions

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. (See Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.)
- AWS CDK Toolkit, installed and configured. (See AWS CDK Toolkit in the AWS CDK documentation.)
- Node Package Manager (npm), installed and configured for the AWS CDK in TypeScript. (See Downloading and installing Node.js and npm in the npm documentation.)

- Python3 installed and configured, for running a Python script to inject traffic into the sample serverless application. (See Python Setup and Usage in the Python documentation.)
- Pip, installed and configured to install the Python requests library. (See the pip installation instructions on the PyPl website.)

Product versions

- AWS CDK Toolkit version 1.107.0 or later
- npm version 7.9.0 or later
- Node.js version 15.3.0 or later

Architecture

Technologies

The architecture for this pattern includes the following services:

- Amazon DevOps Guru
- AWS CloudFormation
- Amazon API Gateway
- AWS Lambda
- Amazon DynamoDB
- Amazon CloudWatch
- AWS CloudTrail

AWS CDK stacks

The pattern uses the following AWS CDK stacks:

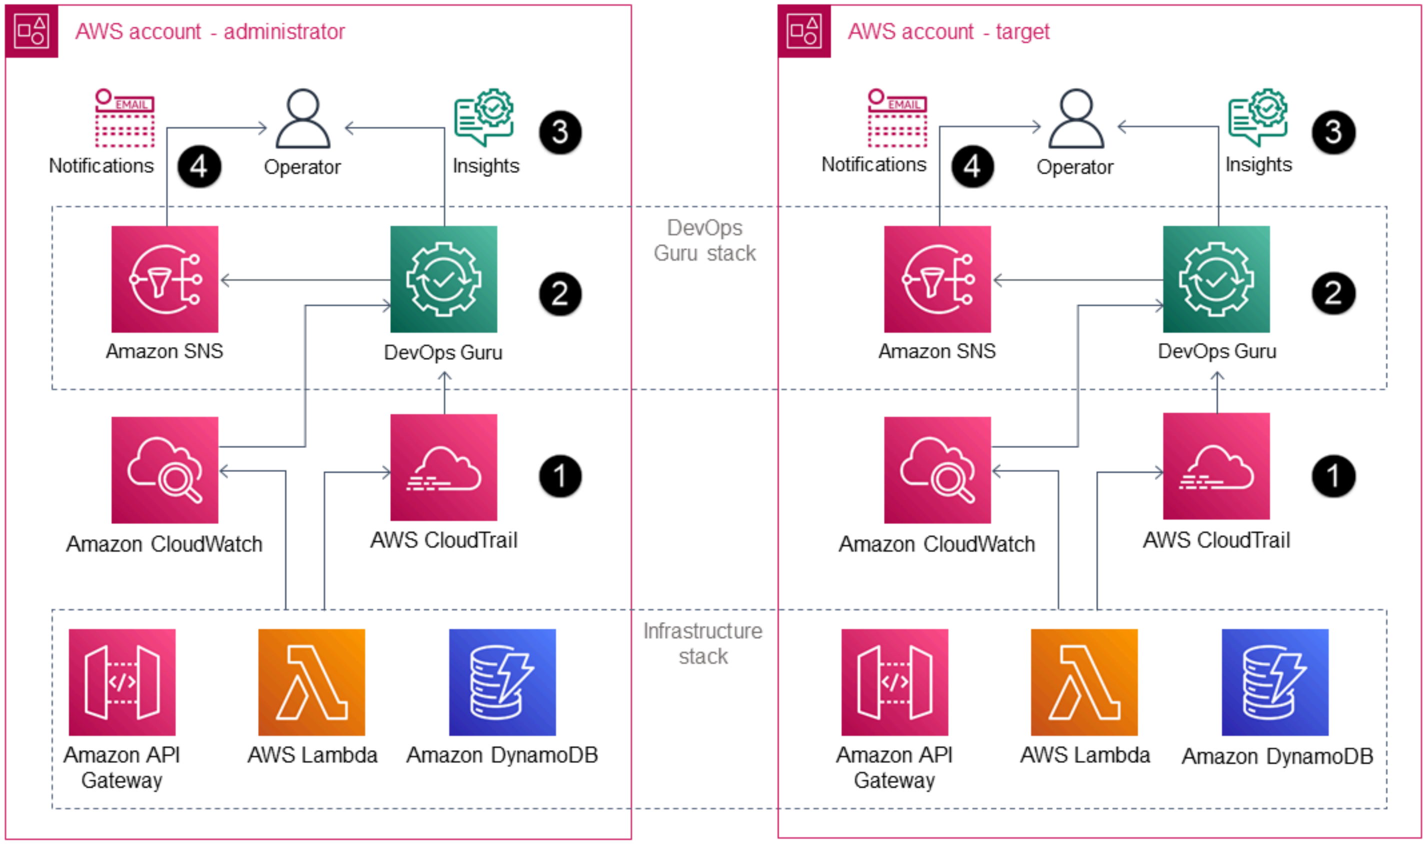
- `CdkStackSetAdminRole` – Creates an AWS Identity and Access management (IAM) administrator role to establish a trust relationship between the administrator and target accounts.
- `CdkStackSetExecRole` – Creates an IAM role to trust the administrator account.

- `CdkDevopsGuruStackMultiAccReg` – Enables DevOps Guru across multiple AWS Regions and accounts for all stacks, and sets up Amazon Simple Notification Service (Amazon SNS) notifications.
- `CdkDevopsGuruStackMultiAccRegSpecStacks` – Enables DevOps Guru across multiple AWS Regions and accounts for specific stacks, and sets up Amazon SNS notifications.
- `CdkDevopsguruStackOrgUnit` – Enables DevOps Guru across OUs, and sets up Amazon SNS notifications.
- `CdkInfrastructureStack` – Deploys sample serverless application components such as API Gateway, Lambda, and DynamoDB in the administrator account to demonstrate fault injection and insights generation.

Sample application architecture

The following diagram illustrates the architecture of a sample serverless application that has been deployed across multiple accounts and Regions. The pattern uses the administrator account to deploy all the AWS CDK stacks. It also uses the administrator account as one of the target accounts for setting up DevOps Guru.

1. When DevOps Guru is enabled, it first baselines each resource's behavior and then ingests operational data from CloudWatch vended metrics.
2. If it detects an anomaly, it correlates it with the events from CloudTrail, and generates an insight.
3. The insight provides a correlated sequence of events along with prescribed recommendations to enable the operator to identify the culprit resource.
4. Amazon SNS sends notification messages to the operator.



Automation and scale

The [GitHub repository](#) provided with this pattern uses the AWS CDK as an infrastructure as code (IaC) tool to create the configuration for this architecture. AWS CDK helps you orchestrate resources and enable DevOps Guru across multiple AWS accounts, Regions, and OUs.

Tools

AWS services

- [AWS CDK](#) – AWS Cloud Development Kit (AWS CDK) helps you define your cloud infrastructure as code in one of five supported programming languages: TypeScript, JavaScript, Python, Java, and C#.
- [AWS CLI](#) – AWS Command Line Interface (AWS CLI) is a unified tool that provides a consistent command-line interface for interacting with AWS services and resources.

Code

The source code for this pattern is available on GitHub, in the [Amazon DevOps Guru CDK Samples] repository. The AWS CDK code is written in TypeScript. To clone and use the repository, follow the instructions in the next section.

> **Important**
>
> Some of the stories in this pattern include AWS CDK and AWS CLI command examples that are formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) continuation character at the end of each line with a caret (^).

Epics

Prepare the AWS resources for deployment

Task	Description	Skills required

Configure AWS named profiles.	Set up your AWS named profiles as follows to deploy stacks in a multi-account environment.
	
	For the administrator account:
	
	`$aws configure --profile administrator`
	`AWS Access Key ID [****]: <your-administrator-access-key-ID>`
	`AWS Secret Access Key [****]: <your-administrator-secret-access-key>`
	`Default region name [None]: <your-administrator-region>`
	`Default output format [None]: json`
		DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>For the target account:
<pre>$aws configure --profile
 target
AWS Access Key ID
 [****: <your-target-
access-key-ID>
AWS Secret Access Key
 [****]: <your-target-
secret-access-key>
Default region name
 [None]: <your-target-
region>
Default output format
 [None]: json</pre>For more information, see Using named profiles in the AWS CLI documentation.</td><td></td></tr>
<tr><td>Verify AWS profile configurations.</td><td>(Optional) You can verify your AWS profile configurations in the <code>credentials</code> and <code>config</code> files by following the instructions in Set and view configuration settings in the AWS CLI documentation.</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
Verify the AWS CDK version.	Verify the version of the AWS CDK Toolkit by running the following command: `$cdk --version` This pattern requires version 1.107.0 or later. If you have an earlier version of the AWS CDK, follow the instructions in the [AWS CDK documentation](https://docs.aws.amazon.com/cdk/) to update it.	DevOps engineer
Clone the project code.	Clone the GitHub repository for this pattern by using the command: `$git clone https://github.com/aws-samples/amazon-devopsguru-cdk-samples.git`	DevOps engineer

Task	Description	Skills required

Install package dependencies and compile the TypeScript files.	Install the package dependencies and compile the TypeScript files by running the following commands:
	`$cd amazon-devopsguru-cdk-samples`
	`$npm install`
	`$npm fund`
	These commands install all the packages from the sample repository.
	Important
	If you get any errors about missing packages, use one of the following commands:
	`$npm ci`
	—or—
	`$npm install -g @aws-cdk/<package-name>`
	You can find the list of package names and versions in the `Dependencies` section of the `/amazon-d`
		DevOps engineer

Task	Description	Skills required
	`evopsguru-cdk-samples/package.json` file. For more information, see [npm ci] and [npm install] in the npm documentation.	

Build (synthesize) the AWS CDK stacks

Task	Description	Skills required
Configure an email address for Amazon SNS notifications.	Follow these steps to provide an email address for Amazon SNS notifications: 1. Edit the files `/amazon-devopsguru-cdk-samples/lib/cdk-devopsguru-multi-acc-reg-stack.ts` and `/amazon-devopsguru-cdk-samples/lib/cdk-devopsguru-org-uni-stack.ts` . 2. In the `DevOpsGuruTopic` , `Subscription` section, update the `Endpoint` parameter with your email address. 3. Save and close the files.	DevOps engineer
Build the project code.	Build the project code and synthesize the stacks by running the command:	DevOps engineer

Task	Description	Skills required
	```npm run build && cdk synth``` You should see output similar to the following: ```$npm run build && cdk synth > cdk-devopsguru@0.1.0 build > tsc Successfully synthesized to ~/amazon-devopsguru-cdk-samples/cdk.out Supply a stack id (CdkDevopsGuruStackMultiAccReg,CdkDevopsGuruStackMultiAccRegSpecStacks, CdkDevopsguruStackOrgUnit, CdkInfrastructureStack, CdkStackSetAdminRole, CdkStackSetExecRole) to display its template.``` For more information and steps, see [Your first AWS CDK app](#) in the AWS CDK documentation.	

Task	Description	Skills required

List the AWS CDK stacks.	Run the following command to list all AWS CDK stacks:
	`$cdk list`
	The command displays the following list:
	`CdkDevopsGuruStackMultiAccReg`
	`CdkDevopsGuruStackMultiAccRegSpecStacks`
	`CdkDevopsguruStackOrgUnit`
	`CdkInfrastructureStack`
	`CdkStackSetAdminRole`
	`CdkStackSetExecRole`
		DevOps engineer

Option 1 - Enable DevOps Guru for all stack resources across multiple accounts

Task	Description	Skills required
Deploy the AWS CDK stacks for creating IAM roles.	This pattern uses [AWS CloudFormation StackSets](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/what-is-cfnstacksets.html) to perform stack operations across multiple accounts. If you are creating your first stack set, you must create the following IAM roles to get the required permissions set up in your AWS accounts:	DevOps engineer

Task	Description	Skills required
	• `AWSCloudFormationStackSetAdministrationRole` • `AWSCloudFormationStackSetExecutionRole` **Note** The roles must have these exact names. 1. Create the IAM `AWSCloudFormationStackSetAdministrationRole` role in the administrator (primary) account by running the following CLI command: `$cdk deploy CdkStackSetAdminRole --profile administrator` 2. Create the IAM `AWSCloudFormationStackSetExecutionRole` role in all target accounts where you want to run the stack instances. To create this role, run these CLI commands:	

Task	Description	Skills required

	<pre>$cdk deploy CdkStackSetExecRole \
	  --parameters AdministratorAccountId=<administrator-account-ID> \
	  --profile administrator
	
	$cdk deploy CdkStackSetExecRole \
	  --parameters AdministratorAccountId=<administrator-account-ID> \
	  --profile target</pre>
	For more information, see Grant self-managed permissions in the AWS CloudFormation documentation.	

Task	Description	Skills required
Deploy the AWS CDK stack for enabling DevOps Guru across multiple accounts.	The AWS CDK `CdkDevopsGuruStackMultiAccReg` stack creates stack sets to deploy stack instances across multiple accounts and Regions. To deploy the stack, run the following CLI command with the specified parameters: `$cdk deploy CdkDevopsGuruStackMultiAccReg \ --profile administrator \ --parameters AdministratorAccountId=<administrator-account-ID> \ --parameters TargetAccountId=<target-account-ID> \ --parameters RegionIds="<region-1>,<region-2>"` Currently Amazon DevOps Guru is available in the AWS Regions listed in the [DevOps Guru FAQ]().	DevOps engineer

Option 2 - Enable DevOps Guru for all stack resources across OUs

Task	Description	Skills required
Extract OU IDs.	On the AWS Organizations console, identify the IDs of the organizational units where you want to enable DevOps Guru.	DevOps engineer
Enable service-managed permissions for OUs.	If you're using AWS Organizations for account management, you must grant service-managed permissions to enable DevOps Guru. Instead of creating the IAM roles manually, use organization-based trusted access and service-linked roles (SLRs).	DevOps engineer
Deploy the AWS CDK stack for enabling DevOps Guru across OUs.	The AWS CDK `CdkDevopsguruStackOrgUnit` stack enables DevOps Guru service across OUs. To deploy the stack, run the following command with the specified parameters: `$cdk deploy CdkDevopsguruStackOrgUnit \ --profile administrator \ --parameters RegionIds="<region-1>,<region-2>" \ --parameters OrganizationalUnitIds="<OU-1>,<OU-2>"`	DevOps engineer

Option 3 - Enable DevOps Guru for specific stack resources across multiple accounts

Task	Description	Skills required

Deploy the AWS CDK stacks for creating IAM roles.	If you haven't already created the required IAM roles shown in the first option, do that first:
	
	1. Create the IAM `AWSCloudFormationStackSetAdministrationRole` role in the administrator (primary) account by running the following CLI command:
	
	`$cdk deploy CdkStackSetAdminRole --profile administrator`
	
	2. Create the IAM `AWSCloudFormationStackSetExecutionRole` role in all target accounts where you want to run the stack instances. To create this role, run the CLI commands:
	
	`$cdk deploy CdkStackSetExecRole \ --parameters AdministratorAccountId=<administrator-account-ID> \ --profile administrator`
		DevOps engineer

Task	Description	Skills required
	```$cdk deploy CdkStackSetExecRole \ --parameters AdministratorAccountId=<administrator-account-ID> \ --profile target``` For more information, see [Grant self-managed permissions](#) in the AWS CloudFormation documentation.	
Delete existing stacks.	If you already used the first option to enable DevOps Guru for all stack resources, you can delete the old stack by using the following command: ```$cdk destroy CdkDevopsGuruStackMultiAccReg --profile administrator``` Or, you can change the `RegionIds` parameter when you redeploy the stack to avoid a *Stacks already exist* error.	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Update the AWS CDK stack with a stack list.</td><td>1. Edit the file <code>/amazon-devopsguru-cdk-samples/lib/cdk-devopsguru-multi-acc-reg-spec-stack.ts</code> .
2. Under <code>Resources</code> , <code>CloudFormation</code> , <code>StackNames</code> , list the stacks for which you want to enable DevOps Guru. For demonstration purposes, the parameter specifies the <code>CdkInfrastructureStack</code> stack, but you can edit this entry based on your requirements.
3. Save and close the file.
4. To synthesize and update the stack template, run:
<pre>$cdk synth</pre></td><td>Data engineer</td></tr>
</table>

Task	Description	Skills required
Deploy the AWS CDK stack for enabling DevOps Guru for specific stack resources across multiple accounts.	The AWS CDK `CdkDevopsGuruStackMultiAccRegSpecStacks` stack enables DevOps Guru for specific stack resources across multiple accounts. To deploy the stack, run the following command: `$cdk deploy CdkDevopsGuruStackMultiAccRegSpecStacks \ --profile administrator \ --parameters AdministratorAccountId=<administrator-account-ID> \ --parameters TargetAccountId=<target-account-ID> \ --parameters RegionIds="<region-1>,<region-2>"` **Note** If you previously deployed this stack for option 1, change the `RegionIds` parameter (making sure to choose from [available Regions](https://)) to avoid a *Stacks already exist* error.	DevOps engineer

Deploy the AWS CDK infrastructure stack

Task	Description	Skills required
Deploy the sample serverless infrastructure stack.	The AWS CDK `CdkInfrastructureStack` stack deploys serverless components such as API Gateway, Lambda, and a DynamoDB table to demonstrate DevOps Guru insights. To deploy the stack, run the following command: `$cdk deploy CdkInfrastructureStack --profile administrator`	DevOps engineer
Insert sample records in DynamoDB.	Run the following command to populate the DynamoDB table with sample records. Provide the correct path for the `populate-shops-dynamodb-table.json` script. `$aws dynamodb batch-write-item \ --request-items file://scripts/populate-shops-dynamodb-table.json \ --profile administrator` The command displays the following output:	DevOps engineer

Task	Description	Skills required
	`{ "UnprocessedItems" : {} }`	

Task	Description	Skills required

Verify inserted records in DynamoDB.	To verify that the DynamoDB table includes the sample records from the `populate-shops-dynamodb-table.json` file, access the URL for the `ListRestApiEndpointMonitorOperator` API, which is published as an output of the AWS CDK stack. You can also find this URL in the **Outputs** tab of the AWS CloudFormation console for the `CdkInfrastructureStack` stack. The AWS CDK output would look similar to the following:
	`CdkInfrastructureStack.CreateRestApiMonitorOperatorEndpointD1D00045 = https://oure17c5vob.execute-api.<your-region>.amazonaws.com/prod/`
	
	`CdkInfrastructureStack.ListRestApiMonitorOperatorEndpointABBDB8D8 = https://cdff8icfrn4.execute-api.<your-region>.amazonaws.com/prod/`
		DevOps engineer

Task	Description	Skills required
Wait for resources to complete baselining.	This serverless stack has a few resources. We recommend that you wait for 2 hours before you carry out the next steps. If you deployed this stack in a production environment, it might take up to 24 hours to complete baselining, depending on the number of resources you selected to monitor in DevOps Guru.	DevOps engineer

Generate DevOps Guru insights

Task	Description	Skills required
Update the AWS CDK infrastructure stack.	To try out DevOps Guru insights, you can make some configuration changes to reproduce a typical operational issue. 1. Edit the file `/amazon-devopsguru-cdk-samples/lib/infrastructure-stack.ts` . 2. In the `DDB Table` section, change the read capacity for the DynamoDB table from 5 to 1. 3. Save and close the file. 4. Run the following commands to synthesize	DevOps engineer

Task	Description	Skills required

	and deploy the updated AWS CDK infrastructure stack:
	`$cdk synth`
	`$cdk deploy CdkInfras tructureStack -- profile administrator`	

Task	Description	Skills required
Inject HTTP requests on the API.	Inject ingress traffic in the form of HTTP requests on the `ListRestApiMonitorOperatorEndpointxxxx` API: 1. Edit the Python script `/amazon-devopsguru-cdk-samples/scripts/sendAPIRequest.py`. 2. Update the `url` variable with the API link for `ListRestApiMonitorOperatorEndpointxxxx`. You can find this URL in the output of the AWS CDK **deploy** command or on the AWS Cloudformation console, in the **Outputs** tab for the stack. 3. Save and close the file. 4. Run the Python script by using the command: `$python sendAPIRequest.py` 5. Make sure that you get a 200 status code. 6. You might need to run the script through multiple (preferably four) terminals	DevOps engineer

Task	Description	Skills required
	to inject traffic at a high rate. 7. After the script runs approximately 10 minutes in a loop, you can see an operational insight on the [DevOps Guru console]().	
Review DevOps Guru insights.	Under standard conditions, the DevOps Guru dashboard displays zero in the ongoing insights counter. If it detects an anomaly, it raises an alert in the form of an insight. In the navigation pane, choose **Insights** to see the details of the anomaly, including an overview, aggregated metrics, relevant events, and recommendations. For more information about reviewing insights, see the [Gaining operational insights with AIOps using Amazon DevOps Guru]() blog post.	DevOps engineer

Clean up

Task	Description	Skills required
Clean up and delete resources .	After you walk through this pattern, you should remove the resources you created to avoid incurring any	DevOps engineer

Task	Description	Skills required

	further charges. Run these commands:
	`$cdk destroy CdkDevopsGuruStackMultiAccReg --profile administrator`
	`$cdk destroy CdkDevopsguruStackOrgUnit --profile administrator`
	`$cdk destroy CdkDevopsGuruStackMultiAccRegSpecStacks --profile administrator`
	`$cdk destroy CdkInfrastructureStack --profile administrator`
	`$cdk destroy CdkStackSetAdminRole --profile administrator`
	`$cdk destroy CdkStackSetExecRole --profile administrator`
	`$cdk destroy CdkStackSetExecRole --profile target`

Govern permission sets for multiple accounts by using Account Factory for Terraform

Anand Krishna Varanasi and Siamak Heshmati, Amazon Web Services

Summary

This pattern helps you integrate AWS Control Tower Account Factory Terraform (AFT) with AWS IAM Identity Center in order to configure permissions for multiple AWS accounts at scale. This approach uses custom AWS Lambda functions to automate permission set assignments to AWS accounts that are managed as an organization. This streamlines the process because it doesn't require manual intervention from your platform engineering team. This solution can enhance operational efficiency, security and consistency. It promotes a secure and standardized onboarding process for AWS Control Tower, making it indispensable for enterprises that prioritize agility and reliability for their cloud infrastructure.

Prerequisites and limitations

Prerequisites

- AWS accounts, managed through AWS Control Tower. For more information, see Getting started with AWS Control Tower.
- Account Factory for Terraform, deployed in a dedicated account in your environment. For more information, see Deploy AWS Control Tower Account Factory for Terraform.
- An IAM Identity Center instance, set up in your environment. For more information, see Getting started with IAM Identity Center.
- An active IAM Identity Center group, configured. For more information, see Add groups to your IAM Identity Center directory.
- Python version 3.9 or later, installed

Limitations

- This solution can be used only with accounts that are managed through AWS Control Tower. This solution is deployed by using Account Factory for Terraform.
- This pattern does not include instructions for setting up identity federation with an identity source. For more information about how to complete this set up, see IAM Identity Center identity source tutorials in the IAM Identity Center documentation.

Architecture

AFT overview

AFT sets up a Terraform pipeline that helps you provision and customize your accounts in AWS Control Tower. AFT follows a GitOps model that automates the processes of account provisioning in AWS Control Tower. You create an *account request Terraform file* and commit it to repository. This initiates the AFT workflow for account provisioning. After account provisioning is complete, AFT can automatically run additional customization steps. For more information, see AFT architecture in the AWS Control Tower documentation.

AFT provides the following main repositories:

- `aft-account-request` – This repository contains Terraform code to create or update AWS accounts.
- `aft-account-customizations` – This repository contains Terraform code to create or customize resources on a per-account basis.
- `aft-global-customizations` – This repository contains Terraform code to create or customize resources for all accounts, at scale.
- `aft-account-provisioning-customizations` – This repository manages customizations that are applied only to specific accounts created by and managed with AFT. For example, you might use this repository to customize user or groups assignments in IAM Identity Center or to automate account closures.

Solution overview

This custom solution includes an AWS Step Functions state machine and an AWS Lambda function that assign permission sets to users and groups for multiple accounts. The state machine deployed through this pattern operates in conjunction with pre-existing AFT `aft_account_provisioning_customizations` state machine. A user submits a request to update IAM Identity Center user and group assignments either when a new AWS account is created or after the account is created. They do this by pushing a change to the `aft-account-request` repository. The request to create or update an account initiates a stream in Amazon DynamoDB Streams. This starts the Lambda function, which updates IAM Identity Center users and groups for the target AWS accounts.

The following is an example of the parameters you can provide in the Lambda function for permission set assignments to target users and groups:

```
custom_fields = {
    "InstanceArn"          = "<Organization ID>",
    "PermissionSetArn"     = "<Permission set ARN>",
    "PrincipalId"          = "<Principal ID>",
  }
```

The following are the parameters in this statement:

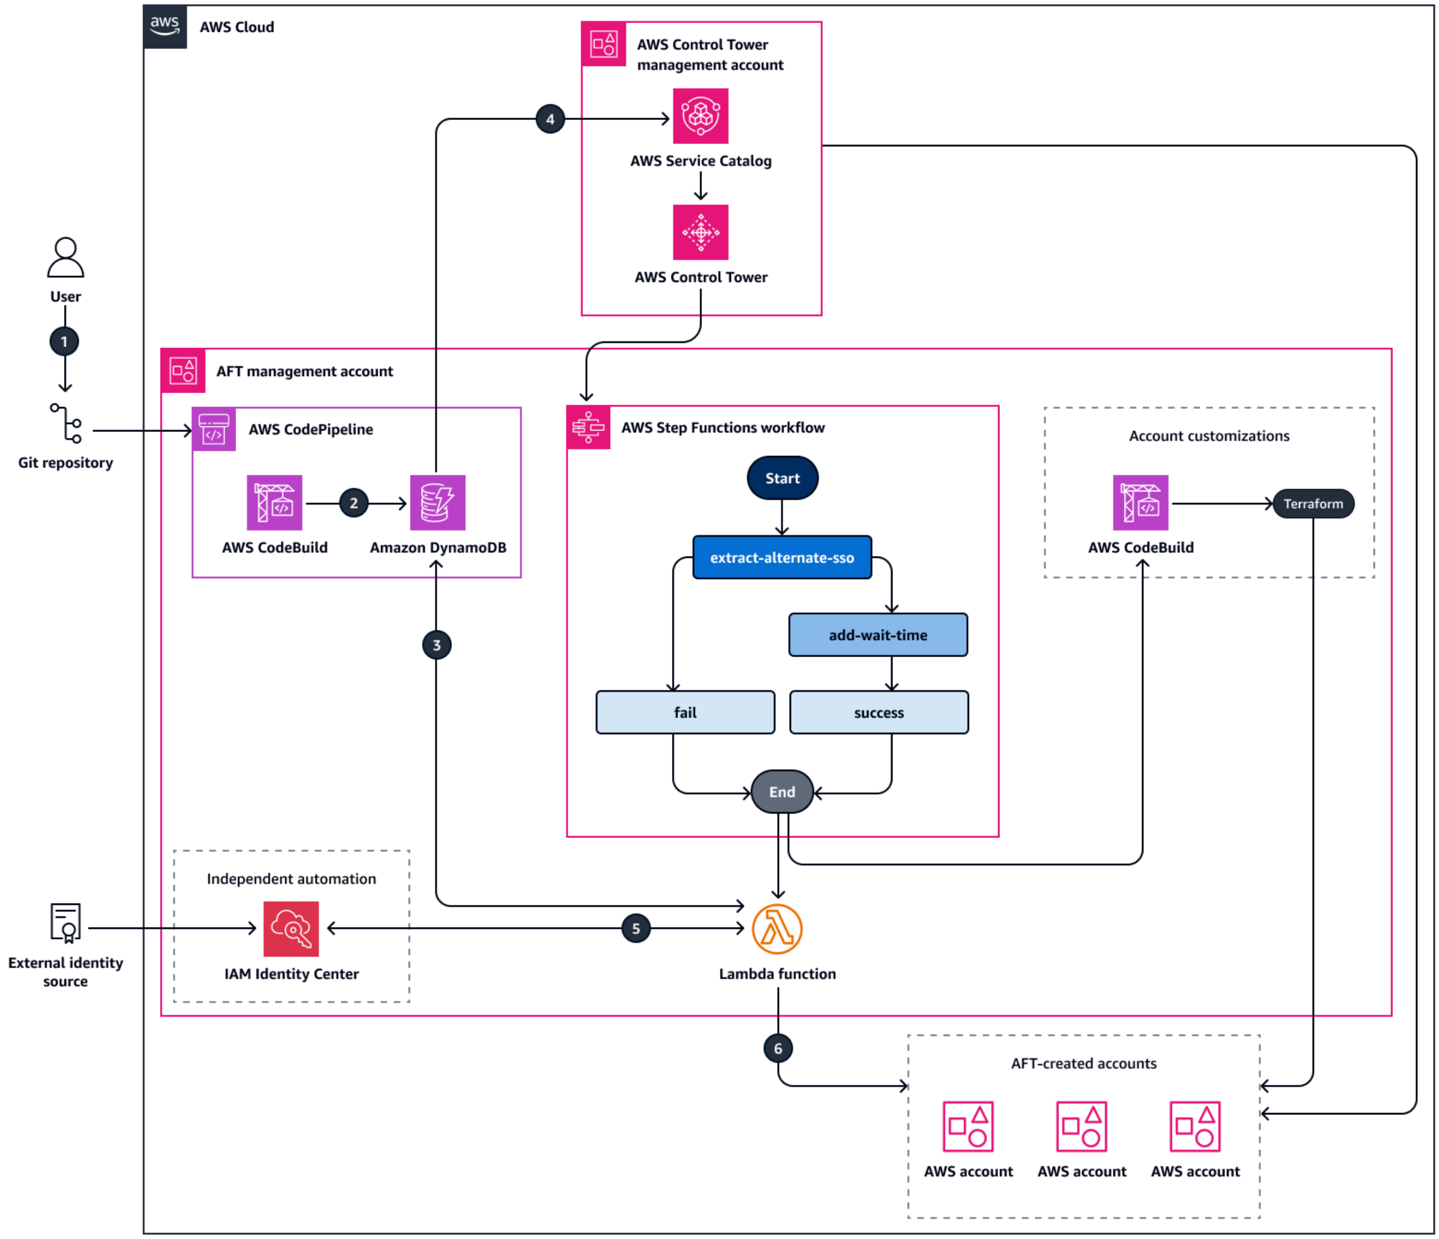
- `InstanceArn` – The Amazon Resource Name (ARN) of the organization
- `PermissionSetArn` – The ARN of the permission set
- `PrincipalId` – The identifier of a user or group in IAM Identity Center to which the permission set will be applied

> **Note**
>
> You must create the target permission set, users, and groups before running this solution.

While the `InstanceArn` value must remain consistent, you can modify the Lambda function to assign multiple permission sets to multiple target identities. The parameters for permission sets must end in `PermissionSetArn`, and the parameters for users and groups must end in `PrincipalId`. You must define both attributes. The following is an example of how to define multiple permission sets and target users and groups:

```
custom_fields = {
    "InstanceArn"                      = "<Organization ID>",
    "AdminAccessPermissionSetArn"      = "<Admin privileges permission set ARN>",
    "AdminAccessPrincipalId"           = "<Admin principal ID>",
    "ReadOnlyAccessPermissionSetArn"  = "<Read-only privileges permission set ARN>",
    "ReadOnlyAccessPrincipalId"        = "<Read-only principal ID>",
  }
```

The following diagram shows a step-by-step workflow of how the solution updates permissions sets for users and groups in the target AWS accounts at scale. When the user initiates an account creation request, AFT initiates the `aft-account-provisioning-framework` Step Functions state machine. This state machine starts the `extract-alternate-sso` Lambda function. The Lambda function assigns permissions sets to users and groups in the target AWS accounts. These users or groups can be from any configured identity source in IAM Identity Center. Examples of identity sources include Okta, Active Directory, or Ping Identity.



The diagram shows the following workflow when new accounts are created:

1. A user pushes a `custom_fields` change to the `aft-account-request` repository.
2. AWS CodePipeline starts an AWS CodeBuild job that records the user-defined metadata into the `aft-request-audit` Amazon DynamoDB table. This table has attributes to record user-defined metadata. The `ddb_event_name` attribute defines the type of AFT operation:

  - If the value is `INSERT`, then the solution assigns the permissions set to the target identities when the new AWS account is created.
  - If the value is `UPDATE`, then the solution assigns the permissions set to the target identities after the AWS account is created.
3. Amazon DynamoDB Streams initiates the `aft_alternate_sso_extract` Lambda function.
4. The `aft_alternate_sso_extract` Lambda function assumes an AWS Identity and Access Management (IAM) role in the AWS Control Tower management account.
5. The Lambda function assigns the permissions sets to the target users and groups by making an AWS SDK for Python (Boto3) [create_account_assignment](#) API call to IAM Identity Center. It retrieves the permission set and identity assignments from the `aft-request-audit` Amazon DynamoDB table.
6. When the Step Functions workflow completes, the permission sets are assigned to the target identities.

Automation and scale

AFT operates at scale by using AWS services such as CodePipeline, AWS CodeBuild, DynamoDB, and Lambda, which are highly scalable. For additional automation, you can integrate this solution with a ticket or issue management system, such as Jira. For more information, see the [Additional information](#) section of this pattern.

Tools

AWS services

- [Account Factory for Terraform (AFT)](#) is the main tool in this solution. The `aft-account-provisioning-customizations` repository contains the Terraform code for creating customizations for AWS accounts, such as custom IAM Identity Center user or group assignments.
- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

Other tools

- Python is a general-purpose computer programming language.
- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code repository for AFT is available in the GitHub AWS Control Tower Account Factory for Terraform repository. The code for this pattern is available in the Govern SSO Assignments for AWS accounts using Account Factory for Terraform (AFT) repository.

Best practices

- Understand the AWS shared responsibility model.
- Follow the security recommendations for AWS Control Tower. For more information, see Security in AWS Control Tower.
- Follow the principle of least privilege. For more information, see Apply least-privilege permissions.
- Build specific and focused permission sets and IAM roles for groups and business units.

Epics

Deploy the solution

Task	Description	Skills required
Create an IAM role.	In the AWS Control Tower management account, use Terraform to create an IAM role. This role has cross-acc ount access and a trust policy that allows federated access from the identity provider. It also has permissions to grant access to other accounts through AWS Control Tower.	AWS DevOps, Cloud architect

Task	Description	Skills required

	The Lambda function will assume this role. Do the following:
	
	1. Download the `AFTCrossAccountRole.tf` file from the GitHub code repository.
	2. Modify the `AFTCrossAccountRole.tf` file as necessary for your AWS environment.
	3. In Terraform, enter the following commands to create this IAM role:
	
	`terraform init`
	`terraform plan`
	`terraform apply`
	
	4. Validate that the role was successfully deployed and has the expected cross-account access.	

Task	Description	Skills required
Customize the solution for your environment.	1. Enter the following command to clone the [Govern SSO Assignments for AWS accounts using Account Factory for Terraform (AFT)](https://github.com/aws-samples/aft-custom-sso-assignment) repository to your local workstation. `git clone https://github.com/aws-samples/aft-custom-sso-assignment.git` 2. In the `aft-account-provisioning-customizations/terraform` folder, open the `variables.tf` file. 3. Modify the variables as needed for your environment. 4. Save and close the `variables.tf` file. 5. Open the `account-request.tf` file in your `aft-account-request` repository. 6. Modify the `custom_fields` parameters to define the permission sets and target users and groups. For more information, see the [Architecture](#) section of this pattern.	AWS DevOps, Cloud architect

Task	Description	Skills required
	7. Save and close the `account-request.tf` file.	
Deploy the solution.	1. In the cloned repository, copy the contents of `terraform` folder, and then paste them into the `terraform` folder in the `aft-account-provisioning-customizations` repository. 2. In the AFT management account, start the `ct-aft-account-provisioning-customizations` pipeline. This deploys the custom solution. For instructions, see [Start a pipeline in CodePipeline](#). 3. Validate that the resources were successfully deployed in the AFT management account.	AWS DevOps, Cloud architect
Set up a code repository connection.	Set up a connection between the code repository where you will store the configuration files and your AWS account. For instructions, see the [Add third-party source providers to pipelines using CodeConnections](#) in the AWS CodePipeline documentation.	AWS DevOps, Cloud architect

Use the solution

Task	Description	Skills required
Start AFT pipeline to deploy a new account.	Follow the instructions in [Provision a new account with AFT](#) in order to start the pipeline that creates a new AWS account in your AWS Control Tower environment. Wait for the account creation process to complete.	AWS DevOps, Cloud architect
Validate the changes.	1. Open the [AWS IAM Identity Center console](#). 2. In the list of accounts, choose the newly created account. 3. Validate that permission sets have been assigned to grant access to the target users and groups.	AWS DevOps, Cloud architect

Troubleshooting

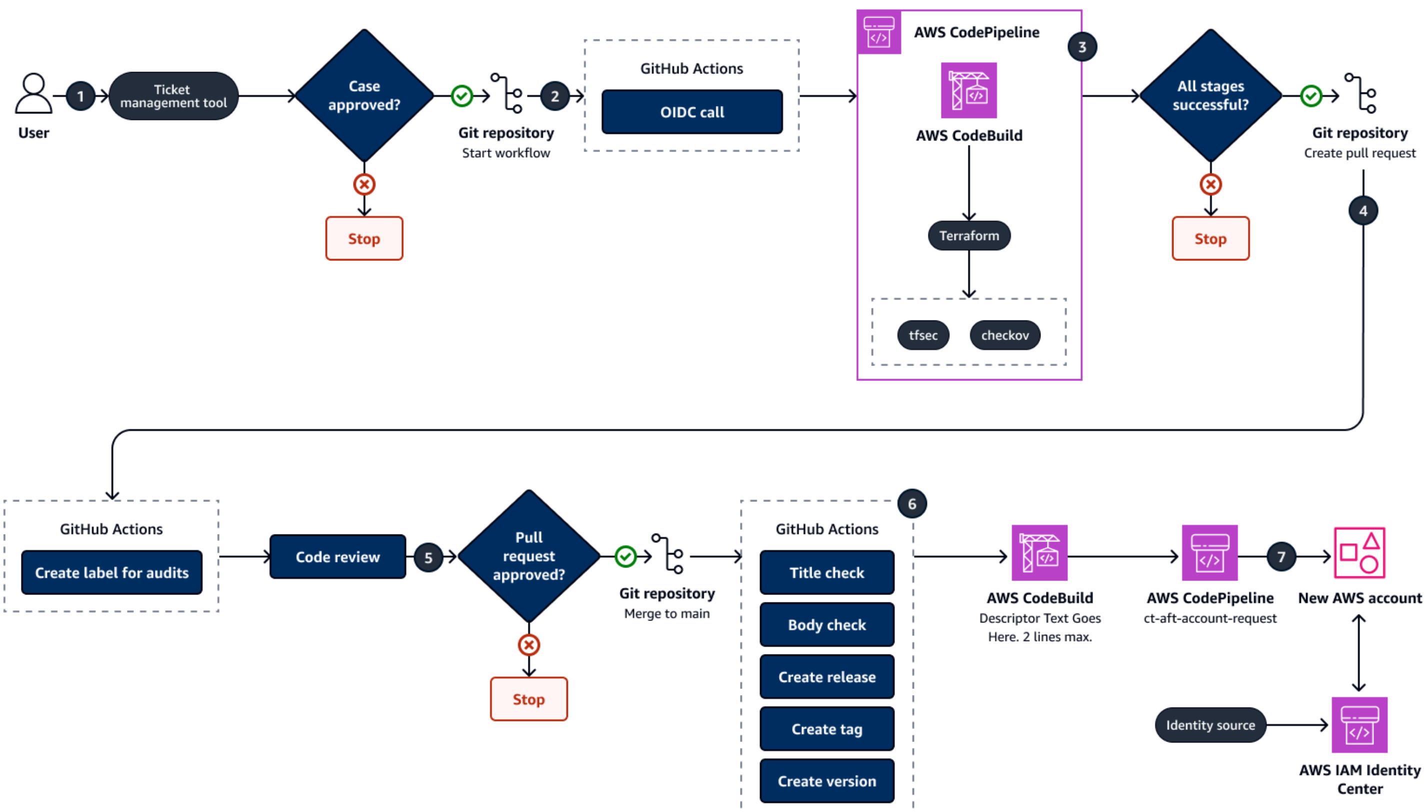
Issue	Solution
Permission set assignment is not working.	Make sure the group ARN, organization id, and Lambda parameters are correct. For examples, see the *Solution overview* section of this pattern.
Updating code in the repository does not start the pipeline.	This issue is related to the connectivity between your AWS account and the repository. In the AWS Management Console, validate that the connection is active. For more

Issue	Solution
	information, see GitHub connections in the AWS CodePipeline documentation.

Additional information

Integrating with a ticket management tool

You can choose to integrate this solution with a ticket or issue management tool, such as Jira or ServiceNow. The following diagram shows an example workflow for this option. You can integrate the ticket management tool with the AFT solution repositories by using your tool's connectors. For Jira connectors, see Integrate Jira with GitHub. For ServiceNow connectors, see Integrating with GitHub. You can even build custom solutions that require users to provide a ticket ID as part of the pull request approval. If a request to create a new AWS account by using AFT is approved, that event could initiate a workflow that adds custom fields to the `aft-account-request` GitHub repository. You can design any custom workflow that meets the requirements of your use case.



The diagram shows the following workflow:

1. Users request a custom permission set assignment in a ticket management tool, such as Jira.
2. After the case is approved, a workflow begins to update the permission set assignment. (Optional) You can use plugins for custom automation of this step.
3. Operators send the Terraform code with the updated permission set parameters to the `aft-account-request` repository into a development or feature branch.
4. GitHub Actions initiates AWS CodeBuild by using an OpenID Connect (OIDC) call. CodeBuild performs infrastructure as code (IaC) security scans by using tools such as [tfsec] and [checkov]. It warns the operators of any security violations.
5. If no violations are found, GitHub Actions creates an automated pull request and assigns a code review to the code owners. It also creates a tag for the pull request.
6. If the code owner approves the code review, another GitHub Actions workflow starts. It checks pull request standards, including:
   - If the pull request title meets requirements.
   - If pull request body contains approved case numbers.
   - If the pull request is properly tagged.
7. If the pull requests meets standards, GitHub Actions starts the AFT product workflow. It uses starts the `ct-aft-account-request` pipeline in AWS CodePipeline. This pipeline starts the `aft-account-provisioning-framework` custom state machine in Step Functions. This state machine works as previously described in the *Solution overview* section of this pattern.

Implement Account Factory for Terraform (AFT) by using a bootstrap pipeline

Vinicius Elias and Edgar Costa Filho, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern provides a simple and secure method for deploying AWS Control Tower Account Factory for Terraform (AFT) from the management account of AWS Organizations. The core of the solution is an AWS CloudFormation template that automates the AFT configuration by creating a Terraform pipeline, which is structured to be easily adaptable for initial deployment or subsequent updates.

Security and data integrity are top priorities at AWS, so the Terraform state file, which is a critical component that tracks the state of the managed infrastructure and configurations, is securely stored in an Amazon Simple Storage Service (Amazon S3) bucket. This bucket is configured with several security measures, including server-side encryption and policies to block public access, to help ensure that your Terraform state is safeguarded against unauthorized access and data breaches.

The management account orchestrates and oversees the entire environment, so it is a critical resource in AWS Control Tower. This pattern follows AWS best practices and ensures that the deployment process is not only efficient but also aligns with security and governance standards, to offer a comprehensive, secure, and efficient way to deploy AFT in your AWS environment.

For more information about AFT, see the AWS Control Tower documentation.

Prerequisites and limitations

Prerequisites

- A basic AWS multi-account environment with the following accounts at the minimum: management account, Log Archive account, Audit account, and one additional account for AFT management.
- An established AWS Control Tower environment. The management account should be properly configured, because the CloudFormation template will be deployed within it.

- The necessary permissions in the AWS management account. You'll need sufficient permissions to create and manage resources such as S3 buckets, AWS Lambda functions, AWS Identity and Access Management (IAM) roles, and AWS CodePipeline projects.
- Familiarity with Terraform. Understanding Terraform's core concepts and workflow is important because the deployment involves generating and managing Terraform configurations.

Limitations

- Be aware of the AWS resource quotas in your account. The deployment might create multiple resources, and encountering service quotas could impede the deployment process.
- The template is designed for specific versions of Terraform and AWS services. Upgrading or changing versions might require template modifications.
- The template doesn't support self-managed version control system (VCS) services such as GitHub Enterprise.

Product versions

- Terraform version 1.6.6 or later
- AFT version 1.11 or later

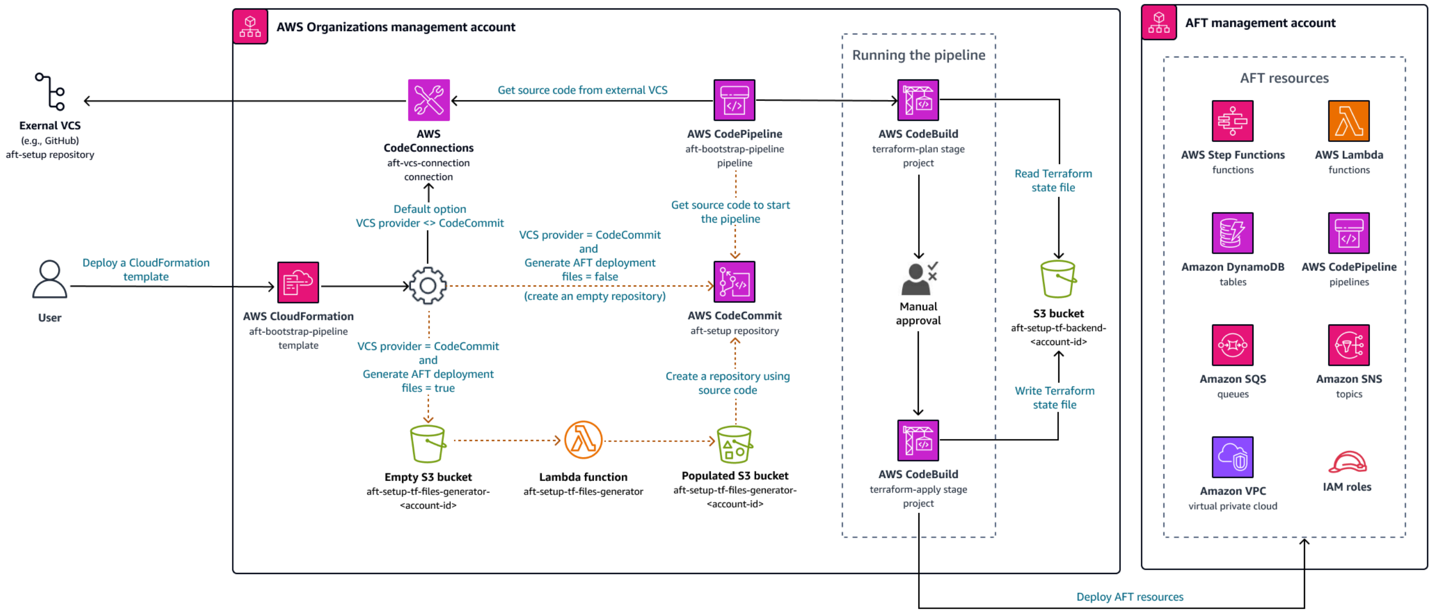
Architecture

Target technology stack

- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- Amazon EventBridge
- IAM
- AWS Lambda
- Amazon S3

Target architecture

The following diagram illustrates the implementation discussed in this pattern.



The workflow consists of three main tasks: creating the resources, generating the content, and running the pipeline.

Creating the resources

The [CloudFormation template that's provided with this pattern] creates and sets up all required resources, depending on the parameters you select when you deploy the template. At the minimum, the template creates the following resources:

- A CodePipeline pipeline to implement the AFT
- An S3 bucket to store the Terraform state file that's associated with the AFT implementation
- Two CodeBuild projects to implement the Terraform plan and apply commands in different stages of the pipeline
- IAM roles for CodeBuild and CodePipeline services
- A second S3 bucket to store pipeline runtime artifacts

Depending on the VCS provider you select (CodeCommit or external VCS), the template creates the following resources.

- For **CodeCommit**:
  - A CodeCommit repository to store the AFT Terraform bootstrap code

  - An EventBridge rule to capture CodeCommit repository changes on the `main` branch
  - Another IAM role for the EventBridge rule
- For any other **external VCS provider**, such as GitHub:
  - An AWS CodeConnections connection

Additionally, when you select CodeCommit as the VCS provider, if you set the `Generate AFT Files` parameter to `true`, the template creates these additional resources to generate the content:

- An S3 bucket to store the generated content and to be used as the source of the CodeCommit repository
- A Lambda function to process the given parameters and generate the appropriate content
- An IAM function to run the Lambda function
- A CloudFormation custom resource that runs the Lambda function when the template is deployed

Generating the content

To generate the AFT bootstrap files and their content, the solution uses a Lambda function and an S3 bucket. The function creates a folder in the bucket, and then creates two files inside the folder: `main.tf` and `backend.tf`. The function also processes the provided CloudFormation parameters and populates these files with predefined code, replacing the respective parameter values.

To view the code that's used as a template to generate the files, see the solution's [GitHub repository](). Basically, the files are generated as follows.

main.tf

```
module "aft" {
  source = "github.com/aws-ia/terraform-aws-control_tower_account_factory?
ref=<aft_version>"

  # Required variables
  ct_management_account_id  = "<ct_management_account_id>"
  log_archive_account_id    = "<log_archive_account_id>"
  audit_account_id          = "<audit_account_id>"
  aft_management_account_id = "<aft_management_account_id>"
  ct_home_region            = "<ct_home_region>"
```

```
  # Optional variables
  tf_backend_secondary_region = "<tf_backend_secondary_region>"
  aft_metrics_reporting       = "<false|true>"

  # AFT Feature flags
  aft_feature_cloudtrail_data_events      = "<false|true>"
  aft_feature_enterprise_support          = "<false|true>"
  aft_feature_delete_default_vpcs_enabled = "<false|true>"

  # Terraform variables
  terraform_version      = "<terraform_version>"
  terraform_distribution = "<terraform_distribution>"

  # VCS variables (if you have chosen an external VCS)
  vcs_provider                                  = "<github|githubenterprise|gitlab|
gitlabselfmanaged|bitbucket>"
  account_request_repo_name                     = "<org-name>/aft-account-request"
  account_customizations_repo_name              = "<org-name>/aft-account-
customizations"
  account_provisioning_customizations_repo_name = "<org-name>/aft-account-provisioning-
customizations"
  global_customizations_repo_name               = "<org-name>/aft-global-
customizations"

}
```

backend.tf

```
terraform {
  backend "s3" {
    region = "<aft-main-region>"
    bucket = "<s3-bucket-name>"
    key    = "aft-setup.tfstate"
  }
}
```

During the CodeCommit repository creation, if you set the `Generate AFT Files` parameter to `true`, the template uses the S3 bucket with the generated content as the source of the `main` branch to automatically populate the repository.

Running the pipeline

After the resources have been created and the bootstrap files have been configured, the pipeline runs. The first stage (*Source*) fetches the source code from the main branch of the repository, and the second stage (*Build*) runs the Terraform plan command and generates the results to be reviewed. In the third stage (*Approval*), the pipeline waits for a manual action to approve or reject the last stage (*Deploy*). At the last stage, the pipeline runs the Terraform `apply` command by using the result of the previous Terraform `plan` command as input. Finally, a cross-account role and the permissions in the management account are used to create the AFT resources in the AFT management account.

> **Note**
>
> If you select an external VCS provider, you will need to authorize the connection with your VCS provider credentials. To complete the setup, follow the steps in [Update a pending connection](#) in the AWS Developer Tools console documentation.

Tools

AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories without needing to manage your own source control system.
- [AWS CodePipeline](#) helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- [AWS CodeConnections](#) enables AWS resources and services, such as CodePipeline, to connect to external code repositories, such as GitHub.
- [AWS Lambda](#) is a compute service that runs your code in response to events and automatically manages compute resources, providing a fast way to create a modern, serverless application for production.
- [AWS SDK for Python (Boto3)](#) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

Other tools

- Terraform is an infrastructure as code (IaC) tool that lets you build, change, and version infrastructure safely and efficiently. This includes low-level components such as compute instances, storage, and networking; and high-level components such as DNS entries and SaaS features.
- Python is an easy to learn, powerful programming language. It has efficient high-level data structures and provides a simple but effective approach to object-oriented programming.

Code repository

The code for this pattern is available in the GitHub AFT bootstrap pipeline repository.

For the official AFT repository, see AWS Control Tower Account Factory for Terraform in GitHub.

Best practices

When you deploy AFT by using the provided CloudFormation template, we recommend that you follow best practices to help ensure a secure, efficient, and successful implementation. Key guidelines and recommendations for implementing and operating the AFT include the following.

- **Thorough review of parameters**: Carefully review and understand each parameter in the CloudFormation template. Accurate parameter configuration is crucial for the correct setup and functioning of AFT.
- **Regular template updates**: Keep the template updated with the latest AWS features and Terraform versions. Regular updates help you take advantage of new functionality and maintain security.
- **Versioning**: Pin your AFT module version and use a separate AFT deployment for testing if possible.
- **Scope**: Use AFT only to deploy infrastructure guardrails and customizations. Do not use it to deploy your application.
- **Linting and validation**: The AFT pipeline requires a linted and validated Terraform configuration. Run lint, validate, and test before pushing the configuration to AFT repositories.
- **Terraform modules**: Build reusable Terraform code as modules, and always specify the Terraform and AWS provider versions to match your organization's requirements.

Epics

Set up and configure the AWS environment

Task	Description	Skills required
Prepare the AWS Control Tower environment.	Set up and configure AWS Control Tower in your AWS environment to ensure centralized management and governance for your AWS accounts. For more information, see [Getting started with AWS Control Tower](#) in the AWS Control Tower documentation.	Cloud administrator
Launch the AFT management account.	Use the AWS Control Tower Account Factory to launch a new AWS account to serve as your AFT management account. For more information, see [Provision accounts with AWS Service Catalog Account Factory](#) in the AWS Control Tower documentation.	Cloud administrator

Deploy the CloudFormation template in the management account

Task	Description	Skills required
Launch the CloudFormation template.	In this epic, you deploy the CloudFormation template provided with this solution to set up the AFT bootstrap pipeline in your AWS	Cloud administrator

Task	Description	Skills required
	management account. The pipeline deploys the AFT solution in the AFT management account that you set up in the previous epic. **Step 1: Open the AWS CloudFormation console** • Sign in to the AWS Management Console and open the [AWS CloudFormation console](). Make sure that you are operating within the correct AWS Control Tower main Region. **Step 2: Create a new stack** 1. Choose to create a new stack. 2. Select the option to upload a template file, and upload the [CloudFormation template]() that's provided with this pattern. **Step 3: Configure stack parameters** • `VCS Provider`: Select the version control system (VCS) provider to use. You can select an external	

Task	Description	Skills required
	VCS such as GitHub, or use CodeCommit if your account is allowed to use the service. • `Repository Name` : Specify the repository name for storing the AFT bootstrap module. For external VCS providers, use the full path, including the organization name (for example, `my-github-org/my-repo`). • `Branch Name`: Specify the source repository branch. • `CodeBuild Docker Image`: Choose the file to use as the CodeBuild Docker base image. • If you set the VCS provider to an option other than CodeCommit, go to step 8. **Step 4: Decide on file generation** • If you selected CodeCommit as your VCS provider, you can use the `Generate AFT Files` parameter to control the generation of default AFT deployment files. Set this parameter to:	

Task	Description	Skills required
	`true` to automatically create and store AFT deployment files in the specified repository. `false` if you want to manually handle the file creation or already have the files in place. - If you selected `false`, go to step 8; otherwise, follow steps 5–7 first. **Step 5: Fill in AWS Control Tower and AFT account details** - If you set the `Generate AFT Files` parameter to `true`, provide the following AWS Control Tower and AFT account-specific information. `Log Archive Account ID`: The ID of the Log Archive account ID in AWS Control Tower. `Audit Account ID`: The ID of the Audit account in AWS Control Tower. `AFT Management Account ID`: The ID of the AFT management	

Task	Description	Skills required

	account that you created in the first epic.
	• `AFT Main Region` and `AFT Secondary Region`: The main and secondary AWS Regions for AFT deployment.
	
	Step 6: Configure AFT options
	
	• Set up metrics reporting:
	  • `AFT Enable Metrics Reporting` : Enable or disable AFT metrics reporting. For more information, see [Operational metrics](#) in the AWS Control Tower documentation.
	
	• Set AFT feature options:
	  • `Enable AFT CloudTrail Data Events`: Enable CloudTrail data events in all AFT managed accounts. For more information, see [AWS CloudTrail data events](#) in the AWS Control Tower documentation.
	  • `Enable AFT Enterprise Support` :	

Task	Description	Skills required
	Enable Enterprise Support in all AFT managed accounts. For more information, see [AWS Enterprise Support plan](#) in the AWS Control Tower documentation. • `Enable AFT Delete Default VPC`: Delete all VPCs in the AFT management account only. For more information, see [Delete the AWS default VPC](#) in the AWS Control Tower documentation. **Step 7: Specify versions** • `AFT Terraform Version`: Choose the version of Terraform to use in AFT pipelines. • `AFT Version`: Define the AFT version for deployment. Keep the default setting (`latest`) to use the most current AFT version. **Step 8: Review and create the stack** • Review all the parameters and settings. If everythin	

Task	Description	Skills required
	g is in order, proceed to create the stack. **Step 9: Monitor stack creation** • AWS CloudFormation provisions and configures the resources you defined. Monitor the stack creation process on the CloudFormation console. This process might take several minutes. **Step 10: Verify the deployment** • When the stack status shows **CREATE_COMPLETE**, verify that all resources have been correctly created. • In the **Outputs** section, note the `TerraformBackendBucketName` value.	

Populate and validate the AFT bootstrap repository and pipeline

Task	Description	Skills required
Option 1: Populate the AFT bootstrap repository for an external VCS.	If you set the VCS provider to an external VCS (not to	Cloud administrator

Task	Description	Skills required
	CodeCommit), follow these steps. (Optional) After you deploy the CloudFormation template, you can populate or validate the content in the newly created AFT bootstrap repository, and test whether the pipeline has run successfully. **Step 1: Update the connection** 1. On the [CodePipeline console](https://console.aws.amazon.com/codesuite/codepipeline/home), in the navigation pane, choose **Settings**, **Connections**. 2. Select the `aft-vcs-connection` connection. It should be in `Pending` status. 3. Choose **Update pending connection** and follow the instructions in [Update a pending connection](https://docs.aws.amazon.com/dtconsole/latest/userguide/connections-update.html) in the Developer Tools console documentation. 4. When the connection is in `Available` status, move to the next step. **Step 2: Populate the repository**	

Task	Description	Skills required

	1. Use your external VCS credentials to clone the repository that you specified in the template to your local machine. If you kept the default name, the repository is called `aft-setup` .
	2. In the repository, create a folder called `terraform` with two empty files inside it: `backend.tf` and `main.tf`.
	3. Open the `backend.tf` file and add this code snippet:
	
	`terraform {`
	`  backend "s3" {`
	`    region = "<aft-main-region>"`
	`    bucket = "<s3-bucket-name>"`
	`    key    = "aft-setup"`
	`  }`
	`}`
	
	In the file:
	• Replace `<aft-main-region>` with the main AFT Region. This should match the AWS Control Tower main Region.	

Task	Description	Skills required
	- Replace `<s3-bucket-name>` with the name of the Terraform backend bucket. You can find this in the `TerraformBackendBucketName` output generated by the CloudFormation template you deployed earlier. 4. Open the `main.tf` file and use one of the examples available in the [AFT repository] to deploy AFT. For example, you can work with your preferred VCS provider (CodeCommit, GitHub, or Bitbucket) or customize the AFT VPC. For more AFT input options, see the [README file] in the AFT repository. **Step 2: Commit and push your changes** - After you have created and populated the folder and files, confirm your changes, and upload the code to the repository. The pipeline starts automatically, runs through the Source and Build stages, and then waits	

Task	Description	Skills required
	for an Approval action before the Deploy stage.	

Task	Description	Skills required
Option 2: Populate the AFT bootstrap repository for CodeCommit.	If you set the VCS provider to CodeCommit, follow these steps. (Optional) After you deploy the CloudFormation template, you can populate or validate the content in the newly created AFT bootstrap repository, and test whether the pipeline has run successfully. If you set the `Generate AFT Files` parameter to `true`, skip to the next story (validating the pipeline). **Step 1: Populate the repository** 1. Open the [AWS CodeCommit console](#) and select the newly created repository. If you kept the default name, the repository name should be `aft-setup` . 2. Clone the repository to your local machine by using SSH, HTTPS, or HTTPS (GRC), and open it in an editor. 3. Create a folder called `terraform` and two empty files inside it:	Cloud administrator

Task	Description	Skills required

	`backend.tf` and `main.tf`.
	4. Open the `backend.tf` file and add this code snippet:
	`terraform {`
	`  backend "s3" {`
	`    region = "<aft-main-region>"`
	`    bucket = "<s3-bucket-name>"`
	`    key    = "aft-setup"`
	`  }`
	`}`
	In the file:
	• Replace `<aft-main-region>` with the main AFT Region. This should match the AWS Control Tower main Region.
	• Replace `<s3-bucket-name>` with the name of the Terraform backend bucket. You can find this in the `TerraformBackendBucketName` output generated by the CloudFormation template you deployed earlier.
	5. Open the `main.tf` file and use one of the examples	

Task	Description	Skills required
	available in the AFT repository to deploy AFT. For example, you can work with your preferred version control system (VCS) provider (CodeCommit, GitHub, or Bitbucket) or customize the AFT VPC. For more AFT input options, see the README file in the AFT repository. **Step 2: Commit and push your changes** • After you have created and populated the folder and files, confirm your changes, and upload the code to the repository. The pipeline starts automatically, runs through the Source and Build stages, and then waits for an Approval action before the Deploy stage.	

Task	Description	Skills required
Validate the AFT bootstrap pipeline.	**Step 1: View the pipeline** • Open the [CodePipeline console](https://console.aws.amazon.com/codepipeline/) and check whether the `aft-bootstrap-pipeline` pipeline was started successfully. It should be running a Terraform plan or waiting for a manual approval action. **Step 2: Approve the Terraform plan results** • You can review the results of the Terraform plan by looking at the execution logs of the Build stage, and then approve or reject the execution on the Approval stage. If you approve, the pipeline starts deploying AFT resources in the provided AFT management account. **Step 3: Wait for the deployment** • Wait for the pipeline to run successfully. This should take around 30 minutes. Any failures you might encounter are often caused	Cloud administrator

Task	Description	Skills required
	by API quotas. In these cases, you can rerun the pipeline to continue the deployment. **Step 4: Check created resources** • Access the AFT managemen t account and confirm that the resources have been created.	

Troubleshooting

Issue	Solution
The custom Lambda function included in the CloudFormation template fails during deployment.	Check the Amazon CloudWatch logs for the Lambda function to identify the error. The logs provide detailed information and can help pinpoint the specific issue. Confirm that the Lambda function has the necessary permissions and that the environment variables have been set correctly.
You encounter failures in resource creation or management caused by inadequate permissio ns.	Review the IAM roles and policies that are attached to the Lambda function, CodeBuild, and other services involved in the deploymen t. Confirm that they have the necessary permissions. If there are permission issues, adjust the IAM policies to grant the required access.

Issue	Solution
You're using an outdated version of the CloudFormation template with newer AWS services or Terraform versions.	Regularly update the CloudFormation template to be compatible with the latest AWS and Terraform releases. Check the release notes or documentation for any version-s pecific changes or requirements.
You reach AWS service quotas during deployment.	Before you deploy the pipeline, check AWS service quotas for resources such as S3 buckets, IAM roles, and Lambda functions . Request increases if necessary. For more information, see [AWS service quotas](#) on the AWS website.
You encounter errors due to incorrect input parameters in the CloudFormation template.	Double-check all input parameters for typos or incorrect values. Confirm that resource identifiers, such as account IDs and Region names, are accurate.

AWS service quotas:

- AWS service quotas provides information about how to view AWS service quotas and how to request increases.

Manage AWS Service Catalog products in multiple AWS accounts and AWS Regions

Ram Kandaswamy, Amazon Web Services

Summary

Amazon Web Services (AWS) Service Catalog simplifies and accelerates the governance and distribution of infrastructure as code (IaC) templates for enterprises. You use AWS CloudFormation templates to define a collection of AWS resources (*stacks*) required for a product. AWS CloudFormation StackSets extends this functionality by enabling you to create, update, or delete stacks across multiple accounts and AWS Regions with a single operation.

AWS Service Catalog administrators create products by using CloudFormation templates that are authored by developers, and publish them. These products are then associated with a portfolio, and constraints are applied for governance. To make your products available to users in other AWS accounts or organizational units (OUs), you typically share your portfolio with them. This pattern describes an alternative approach for managing AWS Service Catalog product offerings that is based on AWS CloudFormation StackSets. Instead of sharing portfolios, you use stack set constraints to set AWS Regions and accounts where your product can be deployed and used. By using this approach, you can provision your AWS Service Catalog products in multiple accounts, OUs, and AWS Regions, and manage them from a central location, while meeting your governance requirements.

Benefits of this approach:

- The product is provisioned and managed from the primary account, and not shared with other accounts.
- This approach provides a consolidated view of all provisioned products (stacks) that are based on a specific product.
- Configuration with AWS Service Management Connector is easier, because it targets only one account.
- It's easier to query and use products from AWS Service Catalog.

Prerequisites and limitations

Prerequisites

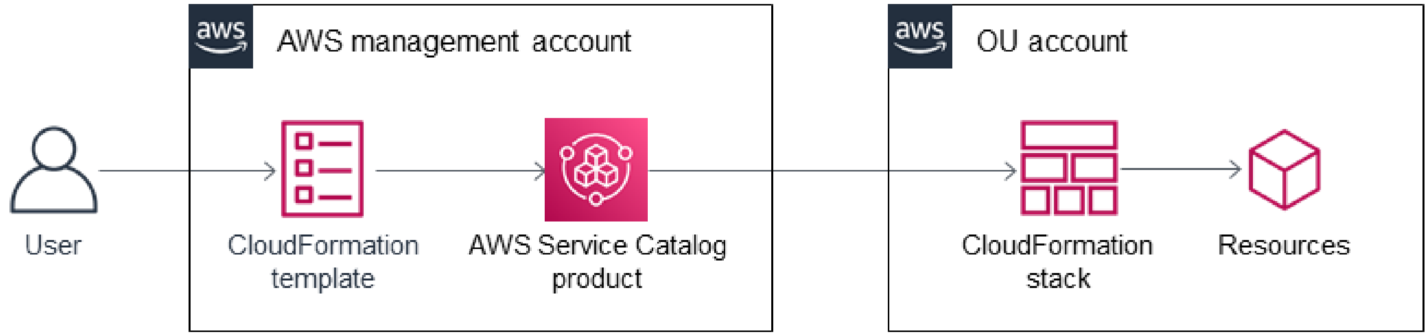
- AWS CloudFormation templates for IaC and versioning
- Multi-account setup and AWS Service Catalog for provisioning and managing AWS resources

Limitations

- This approach uses AWS CloudFormation StackSets, and the limitations of StackSets apply:
  - StackSets doesn't support CloudFormation template deployment through macros. If you're using a macro to preprocess the template, you won't be able to use a StackSets-based deployment.
  - StackSets provides the ability to disassociate a stack from the stack set, so you can target a specific stack to fix an issue. However, a disassociated stack cannot be re-associated with the stack set.
- AWS Service Catalog autogenerates StackSet names. Customization isn't currently supported.

Architecture

Target architecture



1. The user creates an AWS CloudFormation template to provision AWS resources, in JSON or YAML format.
2. The CloudFormation template creates a product in AWS Service Catalog, which is added to a portfolio.
3. The user creates a provisioned product, which creates CloudFormation stacks in the target accounts.
4. Each stack provisions the resources specified in the CloudFormation templates.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Service Catalog helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

Epics

Provision products across accounts

Task	Description	Skills required
Create a portfolio.	A portfolio is a container that includes one or more products that are grouped together based on specific criteria. Using a portfolio for your products helps you apply common constraints across your product set. To create a portfolio, follow the instructions in the AWS Service Catalog documentation. If you're using the AWS CLI, here's an example command:	AWS Service Catalog, IAM

Task	Description	Skills required
	`aws servicecatalog create-portfolio --provider-name my-provider --display-name my-portfolio` For more information, see the [AWS CLI documentation]().	
Create a CloudFormation template.	Create a CloudFormation template that describes the resources. Resource property values should be parameterized where applicable.	AWS CloudFormation, JSON/ YAML

Task	Description	Skills required
Create a product with version information.	The CloudFormation template becomes a product when you publish it in the AWS Service Catalog. Provide values for the optional version detail parameters, such as version title and description; this will be helpful for querying for the product later. To create a product, follow the instructions in the [AWS Service Catalog documentation](). If you're using the AWS CLI, an example command is: `aws servicecatalog create-product --cli-input-json file://create-product-input.json` where `create-product-input.json` is the file that passes the parameters for the product. For an example of this file, see the *Additional information* section. For more information, see the [AWS CLI documentation]().	AWS Service Catalog

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Apply constraints.</td><td>Apply stack set constraints to the portfolio, to configure product deployment options such as multiple AWS accounts, Regions, and permissions. For instructions, see the AWS Service Catalog documentation.</td><td>AWS Service Catalog</td></tr>
<tr><td>Add permissions.</td><td>Provide permissions to users so that they can launch the products in the portfolio. For console instructions, see the AWS Service Catalog documentation. If you're using the AWS CLI, here's an example command:

<pre><code>aws servicecatalog
 associate-principal-
with-portfolio \
    --portfolio-id
 port-2s6abcdefwdh4 \
    --principal-arn
 arn:aws:iam::44445
5556666:role/Admin \
    --principal-type
 IAM</code></pre>

For more information, see the AWS CLI documentation.</td><td>AWS Service Catalog, IAM</td></tr>
</table>

Task	Description	Skills required
Provision the product.	A provisioned product is a resourced instance of a product. Provisioning a product based on a CloudFormation template launches a CloudFormation stack and its underlying resources. Provision the product by targeting the applicable AWS Regions and accounts, based on stack set constraints. In the AWS CLI, here's an example command: `aws servicecatalog provision-product \ --product-id prod-abcdfz3syn2rg \ --provisioning-artifact-id pa-abc347pcsccfm \ --provisioned-product-name "mytestppname3"` For more information, see the [AWS CLI documentation]().	AWS Service Catalog

Additional information

When you use the `create-product` command, the `cli-input-json` parameter points to a file that specifies information such as product owner, support email, and CloudFormation template details. Here's an example of such a file:

```
{
   "Owner": "Test admin",
      "SupportDescription": "Testing",
         "Name": "SNS",
            "SupportEmail": "example@example.com",
            "ProductType": "CLOUD_FORMATION_TEMPLATE",
               "AcceptLanguage": "en",
                  "ProvisioningArtifactParameters": {
                     "Description": "SNS product",
                        "DisableTemplateValidation": true,
                           "Info": {
                              "LoadTemplateFromURL": "<url>"
                     },
                           "Name": "version 1"
}
```

Migrate an AWS member account from AWS Organizations to AWS Control Tower

Rodolfo Jr. Cerrada, Amazon Web Services

Summary

This pattern describes how to migrate an Amazon Web Services (AWS) account from AWS Organizations, where it is a member account that's governed by a management account, to AWS Control Tower. By enrolling the account in AWS Control Tower, you can take advantage of preventive and detective guardrails and features that streamline your account governance. You might also want to migrate your member account if your AWS Organizations management account has been compromised, and you want to move member accounts to a new organization that is governed by AWS Control Tower.

AWS Control Tower provides a framework that combines and integrates the capabilities of several other AWS services, including AWS Organizations, and ensures consistent compliance and governance across your multi-account environment. With AWS Control Tower, you can follow a set of prescribed rules and definitions that extend the capabilities of AWS Organizations. For example, you can use guardrails to ensure that security logs and necessary cross-account access permissions are created, and not altered.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Control Tower set up in your target organization in AWS Organizations (for instructions, see Setting up in the AWS Control Tower documentation)
- Administrator credentials for AWS Control Tower (member of the **AWSControlTowerAdmins** group)
- Administrator credentials for the source AWS account

Limitations

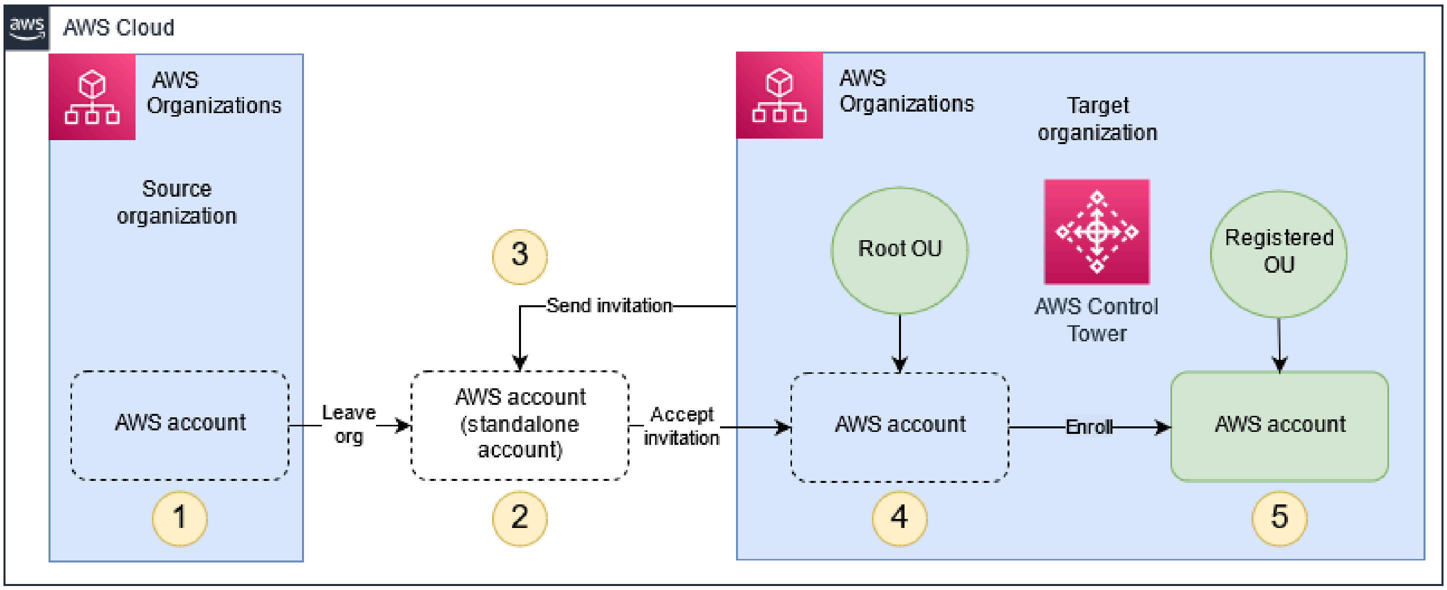
- The source management account in AWS Organizations must be different from the target management account in AWS Control Tower.

Product versions

- AWS Control Tower version 2.3 (February 2020) or later (see release notes)

Architecture

The following diagram illustrates the migration process and reference architecture. This pattern migrates the AWS account from the source organization to a target organization that is governed by AWS Control Tower.



The enrollment process consists of these steps:

1. The account leaves the source organization in AWS Organizations.
2. The account becomes a standalone account. This means that it doesn't belong to any organization, so governance and billing are managed independently by account administrators.
3. The target organization sends an invitation for the account to join the organization.
4. The standalone account accepts the invitation and becomes a member of the target organization.
5. The account is enrolled in AWS Control Tower and moved to a registered organizational unit (OU). (We recommend that you check the AWS Control Tower dashboard to confirm the enrollment.) At this point, all guardrails that are enabled in the registered OU take effect.

Tools

AWS services

- AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into a single entity (an *organization*) that you create and centrally manage.
- AWS Control Tower integrates the capabilities of other services, including AWS Organizations, AWS IAM Identity Center (successor to AWS Single Sign-On), and AWS Service Catalog, to help you enforce and manage governance rules for security, operations, and compliance at scale across all your organizations and accounts in the AWS Cloud.

Epics

Remove the member account from the source organization

Task	Description	Skills required
Verify that the member account can run as a stand-alone account.	Confirm that the member account that will leave the source organization has the information that is required for it to operate as a standalone account. For example, if the member account doesn't have billing information, it can't operate as a standalone account, because AWS uses the payment information to charge for any billable AWS activity that occurs while the account isn't attached to an organization. Typically, if you created the member account by using the AWS Organizations console,	Account administrator

Task	Description	Skills required
	API, or AWS Command Line Interface (CLI) commands, the information required of standalone accounts isn't automatically collected. To add this information, sign in to the account, and specify a support plan, contact information, and a payment method. For more information about what you need to know before removing an account from an organization, see [Before removing an account from organization](#) in the AWS Organizations documenta tion.	

Task	Description	Skills required
Remove the member account from its source organization.	Follow the instructions in the AWS Organizations documentation to remove a member account from an organization. You can sign in to the organizat ion's management account and remove the member account, or sign in to the member account and leave the organization. If you don't have administr ator-level credentials to remove or leave the account, ask for assistance from your organization's administrator. If the member account is missing a support plan, contact information, or payment information, you will be prompted to provide and verify that information. When you leave the organizat ion, you are redirected to the **Getting Started** page of the AWS Organizations console, where you can view invitatio ns for your account to join other organizations.	Management account administrator or account administrator

Task	Description	Skills required
	Important At this point, your account is a standalone account. If you are running workloads that aren't covered by AWS Free Tier, you will be charged according to the payment and billing information you provided for the account.	
Verify that the member account is no longer part of the source organization.	In the AWS Organizations console, you should no longer see the **Leave organization** button. Instead. you should see pending invitations, if any, from other organizations.	Account administrator

Task	Description	Skills required
Remove the IAM roles that grant access to your account from the organization you left.	When you remove the account from the source organization, AWS Identity and Access Management (IAM) roles created by AWS Organizations or by administrators aren't automatically deleted. To terminate access from the source organization's management account, you must manually delete the IAM roles. For more information, see [Deleting roles or instance profiles](#) in the IAM documentation. When a member account leaves an organization, all tags that were attached to the account are deleted. Standalone accounts do not support tags.	Account administrator

Invite the account to join the new organization with AWS Control Tower

Task	Description	Skills required
Sign in to AWS Control Tower.	Sign in to the AWS Control Tower console as an administrator. Currently, there is no direct way to move an AWS account from a source organization to an organization in an	AWS Control Tower administrator

Task	Description	Skills required
	OU that's governed by AWS Control Tower. However, you can extend AWS Control Tower governance to an existing AWS account when you enroll it into an OU that's already governed by AWS Control Tower. That's why you have to log in to AWS Control Tower for this step.	

Task	Description	Skills required
Invite the member account.	1. Sign in to the AWS Organizations console, and navigate to the **AWS Accounts** page. 2. On the **Add an AWS account** page, choose **Invite an existing AWS account**. 3. Complete the account information, including the 12-digit account number (without dashes) and the optional description and tags, and then choose **Send invitation**. **Important** Verify that no applications or network connectivity will be affected by the account transfer. This action sends an invitation email with a link to the member account. When the account administrator follows the link and accepts the invitation, the member account appears in the **AWS accounts** page. For more information, see [Inviting an	AWS Control Tower administrator

Task	Description	Skills required
	AWS account to join your organization in the AWS Organizations documentation.	
Test applications and connectivity.	When the member account has been registered into the new organization, it appears in the OU within a root. It also appears in the AWS Control Tower console, flagged as not enrolled in accounts, because it hasn't yet been enrolled in the AWS Control Tower registered OU. Verify the following: • Check the AWS Control Tower dashboard to see if there are any guardrail violations. • Check network connectivity (VPN or AWS Direct Connect) to make sure it wasn't affected by the transfer. • (Application owners) Test the applications that are associated with this account to verify that they run as expected, and that dependencies weren't affected by the account transfer.	AWS Control Tower administrator, Member account administrator, Application owners

Prepare the account for enrollment

Task	Description	Skills required
Review guardrails and fix any violations.	Review the guardrails that are defined in the target OU, especially the preventive guardrails, and fix any violations. A number of [mandatory, preventive guardrails]() are enabled by default when you set up your AWS Control Tower landing zone. These can't be disabled. You must review these mandatory guardrails and fix the member account (manually or by using a script) before you enroll the account. **Note** Preventive guardrails keep AWS Control Tower registered accounts compliant and prevent policy violations. Any violation of preventive guardrails might affect enrollment. Detective guardrail violations appear in the AWS Control Tower dashboard	AWS Control Tower administrator, Member account administrator

Task	Description	Skills required
	, if detected, after successful enrollment. They do not affect the enrollment process. For more information, see [Guardrails in AWS Control Tower](#) in the AWS documentation.	
Check for connectivity issues after fixing guardrail violation s.	In some cases, you might have to close specific ports or disable services to fix guardrail violations. Make sure that applications that use those ports and services are remediated before you enroll the account.	Application owner

Enroll the account into AWS Control Tower

Task	Description	Skills required
Sign in to the AWS Control Tower console.	Use sign-in credentials that have administrative permissio ns for AWS Control Tower. Do not use the root user (management account) credentials to enroll an AWS Organizations account. This will display an error message.	AWS Control Tower administr ator
Enroll the account.	1. From the Account Factory page in AWS Control	AWS Control Tower administr ator

Task	Description	Skills required
	Tower, choose **Enroll account**. 2. Fill in the details, including the email address associated with the account you want to enroll, the display name that will appear in AWS Control Tower, the IAM Identity Center email address, the first and last name of the account owner, and the OU in which you would like to enroll the account. The IAM Identity Center email address is your preferred user email address. You can use the same email address as the account email. 3. Choose **Enroll account**. For more information, see [Enroll an existing account](#) in the AWS Control Tower documentation.	

Verify the account after enrollment

Task	Description	Skills required
Verify the account.	From AWS Control Tower, choose **Accounts**. The account that you just enrolled has an initial state of **Enrolling**.	AWS Control Tower administrator, Member account administrator

Task	Description	Skills required
	When enrollment is complete, its state changes to **Enrolled**.	
Check for guardrail violations.	Guardrails defined in the OU will automatically apply to the enrolled member account. Monitor the AWS Control Tower dashboard for violations and fix them accordingly. For more information, see [Guardrails in AWS Control Tower](#) in the AWS documentation.	AWS Control Tower administrator, Member account administrator

Troubleshooting

Issue	Solution
You receive the error message: **An unknown error occurred. Try again later, or contact AWS Support.**	This error occurs when you use root user credentials (management account) in AWS Control Tower to enroll a new account. AWS Service Catalog can't map the Account Factory Portfolio or product to the root user, which results in the error message. To remediate this error, use non-root, full-access user (administrator) credentials to enroll the new account. For more information about how to assign administrative access to an administrative user, see [Getting started](#) in the AWS IAM Identity Center (successor to AWS Single Sign-On) documentation.

Issue	Solution
The AWS Control Tower **Activities** page displays a **Get Catastrophic Drift** action.	This action reflects a drift check of the service and does not indicate any issues with the AWS Control Tower setup. No action is required.

Monitor SAP RHEL Pacemaker clusters by using AWS services

Harsh Thoria, Randy Germann, and RAVEENDRA Voore, Amazon Web Services

Summary

This pattern outlines the steps for monitoring and configuring alerts for a Red Hat Enterprise Linux (RHEL) Pacemaker cluster for SAP applications and SAP HANA database services by using Amazon CloudWatch and Amazon Simple Notification Service (Amazon SNS).

The configuration enables you to monitor SAP SCS or ASCS, Enqueue Replication Server (ERS), and SAP HANA cluster resources when they are in a "stopped" state with the help of CloudWatch log streams, metric filters, and alarms. Amazon SNS sends an email to the infrastructure or SAP Basis team about the stopped cluster status.

You can create the AWS resources for this pattern by using AWS CloudFormation scripts or the AWS service consoles. This pattern assumes that you're using the consoles; it doesn't provide CloudFormation scripts or cover infrastructure deployment for CloudWatch and Amazon SNS. Pacemaker commands are used to set the cluster alerting configuration.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Amazon SNS set up to send email or mobile notifications.
- An SAP ASCS/ERS for ABAP or SCS/ERS for Java, and SAP HANA Database RHEL Pacemaker cluster. For instructions, see the following:
  - SAP HANA cluster setup
  - SAP Netweaver ABAP/Java cluster setup

Limitations

- This solution currently works for RHEL version 7.3 and later Pacemaker-based clusters. It hasn’t been tested on SUSE operating systems.

Product versions

- RHEL 7.3 and later

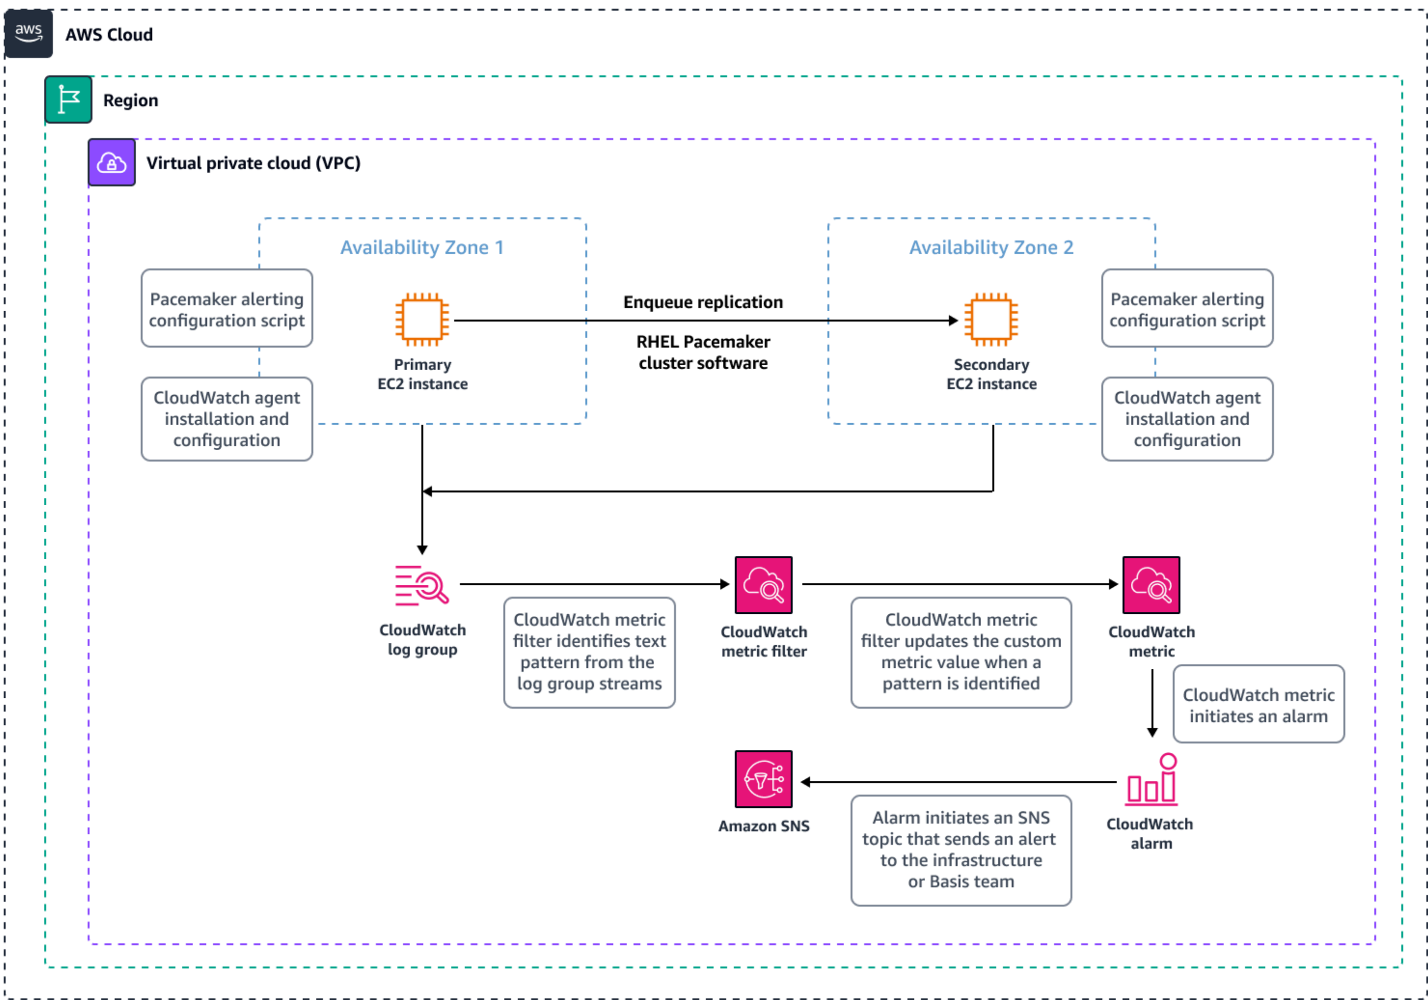
Architecture

Target technology stack

- RHEL Pacemaker alert event-driven agent
- Amazon Elastic Compute Cloud (Amazon EC2)
- CloudWatch alarm
- CloudWatch log group and metric filter
- Amazon SNS

Target architecture

The following diagram illustrates the components and workflows for this solution.



Automation and scale

- You can automate the creation of AWS resources by using CloudFormation scripts. You can also use additional metric filters to scale and cover multiple clusters.

Tools

AWS services

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

Tools

- CloudWatch agent (unified) is a tool that collects system-level metrics, logs, and traces from EC2 instances, and retrieves custom metrics from your applications.
- Pacemaker alert agent (for RHEL 7.3 and later) is a tool that initiates an action when there's a change, such as when a resource stops or restarts, in a Pacemaker cluster.

Best practices

- For best practices for using SAP workloads on AWS, see the SAP Lens for the AWS Well-Architected Framework.
- Consider the costs involved in setting up CloudWatch monitoring for SAP HANA clusters. For more information, see the CloudWatch documentation.
- Consider using a pager or ticketing mechanism for Amazon SNS alerts.
- Always check for RHEL high availability (HA) versions of the RPM package for **pcs**, Pacemaker, and the AWS fencing agent.

Epics

Set up Amazon SNS

Task	Description	Skills required
Create an SNS topic.	1. Sign in to the AWS Management Console and open the Amazon SNS console at https://console.aws.amazon.com/sns/v3/home. 2. On the Amazon SNS dashboard, under **Common actions**, choose **Create Topic**. 3. In the **Create new topic** dialog box, for **Type**, choose **Standard**. 4. For **Topic name**, enter a name for the topic (for example, `my-topic`). 5. Choose **Create topic**. This creates an SNS topic with a resource policy that lets you publish notificat ions. 6. Copy the **Topic ARN** (for example, `arn:aws:sns:us-east-1:111122223333:my-topic`). You will use this ARN in a later step.	AWS administrator
Modify the access policy for the SNS topic.	1. On the Amazon SNS console, in the navigation	AWS systems administrator

Task	Description	Skills required
	pane, choose **Topics**, and then choose the topic you created. 2. Choose **Edit** and go to the **Access policy** section. 3. Make sure that the access policy includes CloudWatch as one of the service principals that are allowed to publish to this topic. For example: `{ "Sid": "Allow AWS CloudWatch to Publish to this SNS topic", "Effect": "Allow", "Principal": { "Service": [ "cloudwatch.amazonaws.com" ] }, "Action": "SNS:Publish", "Resource": "arn:aws:sns:us-east-1:111122223333:my-topic" }` 4. Choose **Save changes**.	

Task	Description	Skills required
Subscribe to the SNS topic.	1. On the Amazon SNS console, in the navigatio n pane, choose **Subscript ions**, **Create subscription**. 2. For **Topic ARN**, paste the ARN that you created in the first task. 3. For **Protocol**, choose **Email**. 4. For **Endpoint**, enter an email address for the person or team that is responsible for the SAP Pacemaker cluster and should receive notificat ions. For example, this can be the email address for the SAP Basis or infrastru cture team's distribution list. 5. Choose **Create subscript ion**. 6. From your email applicati on, open the message from AWS Notifications and confirm your subscription. Your web browser displays a confirmation response from Amazon SNS.	AWS systems administrator

Confirm the setup of the cluster

Task	Description	Skills required
Check cluster status.	Use the **pcs status** command to confirm that the resources are online.	SAP Basis administrator

Configure Pacemaker alerts

Task	Description	Skills required

Configure the Pacemaker alert agent on the primary cluster instance.	Log in to the EC2 instance in the pimary cluster and run the following commands:
	`install --mode=0755 /usr/share/pacemaker/alerts/alert_file.sh.sample`
	`touch /var/lib/pacemaker/alert_file.sh`
	`touch /var/log/pcmk_alert_file.log`
	`chown hacluster:haclient /var/log/pcmk_alert_file.log`
	`chmod 600 /var/log/pcmk_alert_file.log`
	`pcs alert create id=alert_file description="Log events to a file." path=/var/lib/pacemaker/alert_file.sh`
	`pcs alert recipient add alert_file id=my-alert_logfile value=/va`
		SAP Basis administrator

Task	Description	Skills required
	`r/log/pcmk_alert_f` `ile.log`	

Configure the Pacemaker alert agent on the secondary cluster instance.	Log in to the secondary cluster EC2 instance in the secondary cluster and run the following commands:
	
	`install --mode=0755 /`
	`usr/share/pacemak`
	`er/alerts/alert_fi`
	`le.sh.sample`
	`touch /var/lib/`
	`pacemaker/alert_fi`
	`le.sh`
	`touch /var/log/`
	`pcmk_alert_file.log`
	`chown hacluster`
	`:haclient /var/log/`
	`pcmk_alert_file.log`
	`chmod 600 /var/log/`
	`pcmk_alert_file.log`
		SAP Basis administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Confirm that the RHEL alert resource was created.</td><td>Use the following command to confirm that the alert resource was created:

<pre>pcs alert</pre>

The output of the command will look like this:

<pre>[root@xxxxxxx ~]# pcs
 alert
Alerts:
 Alert: alert_file
 (path=/var/lib/pac
emaker/alert_file.sh)
  Description: Log
 events to a file.
  Recipients:
   Recipient: my-
alert_logfile (value=/
var/log/pcmk_alert_
file.log)</pre></td><td>SAP Basis administrator</td></tr>
</table>

Configure the CloudWatch agent

Task	Description	Skills required
Install the CloudWatch agent.	There are several ways to install the CloudWatch agent on an EC2 instance. To use the command line: 1. Download the CloudWatch agent package:	AWS systems administrator

Task	Description	Skills required

	`wget https://s3.<region>.amazonaws.com/amazoncloudwatch-agent-region/redhat/amd64/latest/amazon-cloudwatch-agent.rpm`
	
	where `<region>` is the AWS Region where the EC2 instance is located (for example, `us-west-2`).
	
	2. Optional) Verify the package signature. For instructions, see [Verifying the signature of the CloudWatch agent package](#) in the CloudWatch documentation.
	
	3. Install the package on the first instance:
	
	`sudo rpm -U ./amazon-cloudwatch-agent.rpm`
	
	4. Repeat for the secondary instance.
	
	For more information, see the [CloudWatch documentation](#).	

Task	Description	Skills required
Attach an IAM role to the EC2 instance.	To enable the CloudWatch agent to send data from the instances, you must attach the IAM **CloudWatchAgentServerRole** role to each instance. Or, you can add a policy for the CloudWatch agent to your existing IAM role. For more information, see the [CloudWatch documentation]().	AWS administrator

Task	Description	Skills required
Configure the CloudWatch agent to monitor the Pacemaker alert agent log file on the primary cluster instance.	1. Configure the primary cluster instance by running the command: `sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-config-wizard` 2. Choose **1** for Linux, and then select the options for your monitoring strategy. 3. For the question **"Do you want to monitor any log files,"** choose **Yes** and provide the path of the Pacemaker log file from the **pcs alert** command. In our case, it is `var/log/pcmk_alert_file.log` . 4. Provide the name of the log group and log stream. If you don't specify a log stream, the AWS instance ID is used as the default. 5. Repeat steps 1-4 for the secondary cluster instance.	AWS administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Start the CloudWatch agent on the primary and secondary cluster instances.</td><td>To start the agent, run the following command on the EC2 instances in the primary and secondary clusters:
<pre><code>sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m
ec2 -s -c file:/opt/aws/amazon-cloudwatch-agent/bin/config.json</code></pre></td><td>AWS administrator</td></tr>
</table>

Set up CloudWatch resources

Task	Description	Skills required
Set up CloudWatch log groups.	1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/ 2. In the navigation pane, choose **Log groups, Create log group**. 3. Enter a name for the log group,and then choose **Create log group**. The CloudWatch agent will transfer the Pacemaker alert file to the CloudWatch log group as a log stream.	AWS administrator

Task	Description	Skills required
Set up CloudWatch metric filters.	Metric filters help you search for a pattern such as `stop <cluster-resource-name>` in the CloudWatch log streams. When this pattern is identified, the metric filter updates a custom metric. 1. On the CloudWatch console, in the navigation pane, choose **Log groups**. 2. Choose the name of the log group you created in the previous task. 3. Choose **Actions**, **Create metric filter**. 4. For **Filter pattern**, enter the filter pattern to use, such as `stop ABC_scs`, to match the stop event for an SAP SCS cluster resource named `ABC_scs`. For more information, see [Filter pattern syntax](#) in the CloudWatch documentation. 5. (Optional) To test your filter pattern, under **Test Pattern**, enter one or more log events to use to test the pattern. Each log event must be specified on a	AWS administrator, SAP Basis administrator

Task	Description	Skills required
	separate line, because line breaks are used to separate log events in the **Log event messages** box. 6. Choose **Next**, and then enter a name for the filter. 7. Under **Metric details**, for **Metric namespace**, enter a name for the CloudWatch namespace where the metric will be published (for example, `sapcluster_monitoring`). If this namespace doesn't already exist, select **Create new**. 8. For **Metric name**, enter a name for the new metric (for example, `sapcluster_<sid>` , where `<sid>` is the SAP system identification name). 9. For **Metric value**, enter **1**. Alternatively, you can enter a token such as `$size`. This increments the metric by the value of the number in the `size` field for every log event that contains a `size` field. 10. For **Default value**, enter **0**. 11. Choose **Create metric filter**.	

Task	Description	Skills required
	When the metric filter identifies the pattern in step 4, it updates the value of the CloudWatch custom metric `sapcluster_abc` to **1**. The CloudWatch alarm `SAP-Cluster-QA1-ABC` monitors the metric `sapcluster_abc` and sends out an SNS notification when the value of the metric changes to **1**. This indicates that the cluster resource has stopped and action needs to be taken.	

Task	Description	Skills required

Set up a CloudWatch metric alarm for the SAP ASCS/SCS and ERS metric.	To create an alarm based on a single metric:
	
	1. On the CloudWatch console, in the navigation pane, choose **Alarms**, **All alarms**.
	2. Choose **Create alarm**.
	3. Choose **Select Metric**.
	4. Search for the custom metric `sapcluster_monitoring` that was created in the previous task.
	5. Choose the metric name for SAP SCS (for example, `sapcluster_<abc>`), which was also created in the previous task.
	6. On the **Graphed metrics** tab, set the following:
	  • For **Statistic**, choose **Maximum**.
	  • For **Period**, choose **1 minute**.
	  • For **Threshold type**, choose **Static** and set the threshold for `sapcluster_<sid>` to a value that's greater than or equal to 1.
	7. Choose **Next**.
		AWS administrator

Task	Description	Skills required
	8. For **Notification**, select the SNS topic you created in the first epic. 9. For **Name** and **Description**, provide the alarm name and a brief description, and then choose **Next**. 10.Choose **Create Alarm**.	
Set up a CloudWatch metric alarm for the SAP HANA metric.	Repeat the steps for setting up a CloudWatch metric alarm from the previous task, with these changes: • For step 5, choose the metric name for SAP HANA (for example, `sapcluster_db_<abc>`). • For step 6, set the threshold for `sapcluster_<sid>` to a value that's greater than 0.	AWS administrator

Monitor application activity by using CloudWatch Logs Insights

Ram Kandaswamy, Amazon Web Services

Summary

This pattern provides a solution for automatically detecting and alerting on application exceptions by using Amazon CloudWatch Logs Insights. By implementing automated log analysis and alerting, you can quickly identify and respond to application issues in your production environment.

Logs play a crucial role in monitoring system behavior, identifying issues, and ensuring optimal performance. During a migration process, log files are invaluable for validating the system's functioning in the new environment, detecting compatibility problems, and identifying any unexpected behaviors. Issues could be related to operations or security. For security-related issues, enabling the detection of unauthorized access attempts or suspicious activities early is essential for maintaining security and regulatory compliance. This capability is especially important when dealing with sensitive data or critical systems.

This pattern is particularly valuable for teams that need to maintain high application availability and quickly respond to production issues. It’s relevant across various industries and use cases. For example, in telecommunications, it enables quick identification of network misconfigurations or outages and detection of suboptimal routing paths to pinpoint potential congestion. In the Internet of Things (IoT) domain, Greengrass components can publish logs to CloudWatch, allowing this technique to extract relevant log details and present them in a comprehensive dashboard.

Prerequisites and limitations

Prerequisites

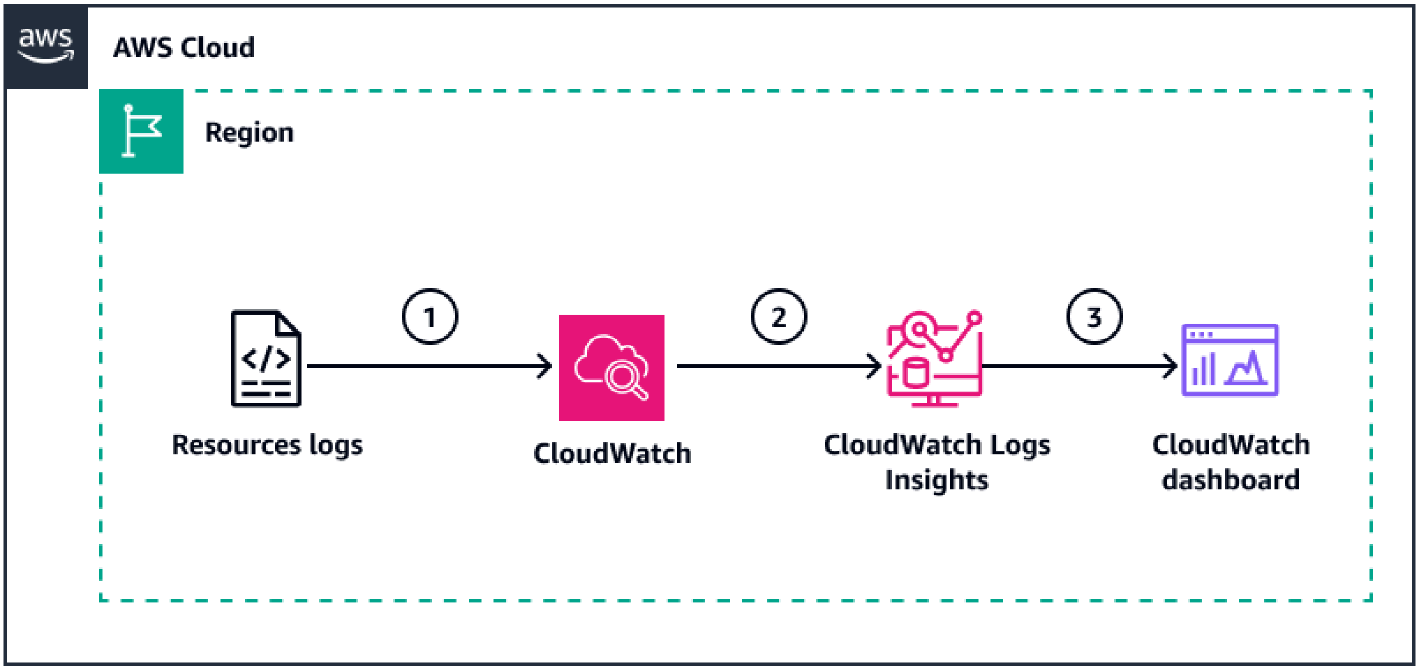
- A production application deployed in active AWS account
- Basic understanding of the production application's logging format and exception patterns
- Application logs configured to stream to Amazon CloudWatch Logs

Limitations

- Some AWS services aren’t available in all AWS Regions. For Region availability, see [AWS Services by Region]. For specific endpoints, see [Service endpoints and quotas], and choose the link for the service.

Architecture

The following diagram shows how CloudWatch Logs Insights evaluates resource logs and sends a relevant data visualization to a CloudWatch dashboard.



The diagram shows the following workflow:

1. The resources publish logs to CloudWatch Logs. Resources can include AWS resources such as Amazon Elastic Compute Cloud (Amazon EC2) instances or Amazon Simple Storage Service (Amazon S3) buckets. Another example includes on-premises systems with CloudWatch Agent installed that can publish logs to CloudWatch.
2. CloudWatch Logs Insights filters for the relevant pattern string. Examples of search pattern strings include "error", "exception", or a specific regular expression.
3. Typically, the production support team or developers add the pattern visualization to the CloudWatch dashboard.

Automation and scale

Developers can automate this pattern’s solution by using the AWS Cloud Development Kit (AWS CDK), AWS CloudFormation, or AWS SDKs to handle multiple string patterns. Teams can incorporate this automation into their continuous integration and deployment (CI/CD) DevOps processes.

Tools

AWS services

- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.

Best practices

- Define and configure log groups to analyze relevant log data.
- Use field explorers to understand the structure and fields available in your log data.
- Write efficient queries by using CloudWatch Logs Insights query syntax.
- Adapt sample queries to your specific requirements for quicker analysis.
- Monitor queries to identify potential performance issues or bottlenecks.
- Set query limits to avoid excessive costs or resource consumption.
- Save queries for future use to save time and ensure consistent analysis.
- Apply appropriate IAM policies to control access to CloudWatch Logs Insights and log groups. Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.
- Enable log data encryption using AWS KMS for sensitive log data.

Epics

Create log group and configure logs to view in dashboard.

Task	Description	Skills required
Configure IAM permissions.	To configure IAM permissions, do the following:	AWS administrator, AWS DevOps, AWS systems administrator, Cloud

Task	Description	Skills required
	1. Identify the IAM roles used by your application for writing logs and by users or services that will create dashboards, queries, and alarms. 2. For the application role, add the following API actions and resource to a policy: `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Action": [ "logs:CreateLogGroup", "logs:CreateLogStream", "logs:PutLogEvents" ], "Resource": [ "arn:aws:logs:*:*:*" ] } ] }`	administrator, Cloud architect , DevOps engineer

Task	Description	Skills required
	3. For managing CloudWatch resources, add the following to a policy: ```{ "Version": "2012-10-17", "Statement": [{ "Effect": "Allow", "Action": ["cloudwatch:PutDashboard", "cloudwatch:GetDashboard", "logs:StartQuery", "logs:StopQuery", "logs:GetQueryResults", "cloudwatch:PutMetricAlarm"], "Resource": "*" }] }``` For information about how to create IAM policies or to add permissions to	

Task	Description	Skills required
	existing policies, see Define custom IAM permissions with customer managed policies and Edit IAM policies in the *IAM User Guide*. For more information, see Identity and access management for Amazon CloudWatch Logs and CloudWatch Logs permissions reference in the *Amazon CloudWatch Logs User Guide*.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a log group.</td><td>To create a log group, use any of the following options:
Create or open a CloudFormation template file (YAML or JSON format) with a <code>.yaml</code> or <code>.json</code> extension. (The following code uses YAML format.) Add the following resource definition to the Resources section of your template:<pre><code>MyLogGroup:
  Type: AWS::Logs
::LogGroup
  Properties:
    LogGroupName: my-
log-group</code></pre>For more information, see Quick Start: Use AWS CloudFormation to get started with CloudWatch Logs in the Amazon CloudWatch Logs User Guide.
Use the CloudWatch console, as described in Create a log group in CloudWatch Logs in the Amazon CloudWatch Logs User Guide.</td><td>AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	• Use the CreateLogGroup operation in the CloudWatch Logs API.	
Generate a CloudWatch Logs Insights query.	To create and save a CloudWatch Logs Insights query: 1. Open the CloudWatch console. 2. Navigate to **Logs Insights**. 3. Create your query by using one of the following methods: • Start with a sample query from the **Queries** section. • Write a custom query. • Modify the following example query: `fields @timestamp, @message | filter @message like /(?i)exception/|stats count() by bin(30s)` This query checks the log file, extracts the timestamp and message content, filters for the word "exception" (case-insensitive), and counts occurrences in 30-second intervals.	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Task	Description	Skills required
Create visualization in a CloudWatch dashboard.	To use a CloudWatch dashboard to create a visualization, do the following : 1. Open the CloudWatch console, and create a CloudWatch dashboard (if you don't have one already) or open an existing dashboard. 2. Add your exception monitoring visualization. Bar, line, and pie charts are available, depending on your business need. For more information, see Using widgets on CloudWatch dashboards in the *Amazon CloudWatch Logs User Guide*. For real-time data visualizations, you can customize a widget to meet your requirements. For more information about dashboard options and capabilities, see Using Amazon CloudWatch dashboards and Creating flexible CloudWatch dashboards with dashboard variables in the *Amazon CloudWatch Logs User Guide*.	AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect , DevOps engineer

Troubleshooting

Issue	Solution
Unable to see query results or query seems broken	Start with a working query that was modified from a sample query. Perform small incremental changes to parts of the query (such as a filter or field), and take advantage of the CloudWatch Logs query generator feature.
Log groups not creating log streams	In the IAM policy, make sure that the resource for the CreateLogStream and the CreateLogGroup operations is provided with a wildcard character (`*`) value. The `create` operation will not succeed without this wildcard permission.

Monitor use of a shared Amazon Machine Image across multiple AWS accounts

Naveen Suthar and Sandeep Gawande, Amazon Web Services

Summary

[Amazon Machine Images (AMIs)] are used to create Amazon Elastic Compute Cloud (Amazon EC2) instances in your Amazon Web Services (AWS) environment. You can create AMIs in a separate, centralized AWS account, which is called a *creator account* in this pattern. You can then share the AMI across multiple AWS accounts that are in the same AWS Region, which are called *consumer accounts* in this pattern. Managing AMIs from a single account provides scalability and simplifies governance. In the consumer accounts, you can reference the shared AMI in Amazon EC2 Auto Scaling launch templates and Amazon Elastic Kubernetes Service (Amazon EKS) node groups.

When a shared AMI is deprecated, deregistered, or unshared, AWS services that refer to the AMI in the consumer accounts cannot use this AMI to launch new instances. Any auto scaling event or relaunch of the same instance fails. This can lead to issues in the production environment, such as application downtime or performance degradation. When AMI sharing and usage events occur in multiple AWS accounts, it can be difficult to monitor this activity.

This pattern helps you monitor shared AMI usage and status across accounts in the same Region. It uses serverless AWS services, such as Amazon EventBridge, Amazon DynamoDB, AWS Lambda, and Amazon Simple Email Service (Amazon SES). You provision the infrastructure as code (IaC) by using HashiCorp Terraform. This solution provides alerts when a service in a consumer account references a deregistered or unshared AMI.

Prerequisites and limitations

Prerequisites

- Two or more active AWS accounts: one creator account and one or more consumer accounts
- One or more AMIs that are shared from the creator account to a consumer account
- Terraform CLI, installed (Terraform documentation)
- Terraform AWS Provider, configured (Terraform documentation)
- (Optional, but recommended) Terraform backend, configured (Terraform documentation)
- Git, installed

Limitations

- This pattern monitors AMIs that have been shared to specific accounts by using the account ID. This pattern does not monitor AMIs that have been shared to an organization by using the organization ID.
- AMIs can only be shared to accounts that are within the same AWS Region. This pattern monitors AMIs within a single, target Region. To monitor use of AMIs in multiple Regions, you deploy this solution in each Region.
- This pattern doesn't monitor any AMIs that were shared before this solution was deployed. If you want to monitor previously shared AMIs, you can unshare the AMI and then reshare it with the consumer accounts.

Product versions

- Terraform version 1.2.0 or later
- Terraform AWS Provider version 4.20 or later

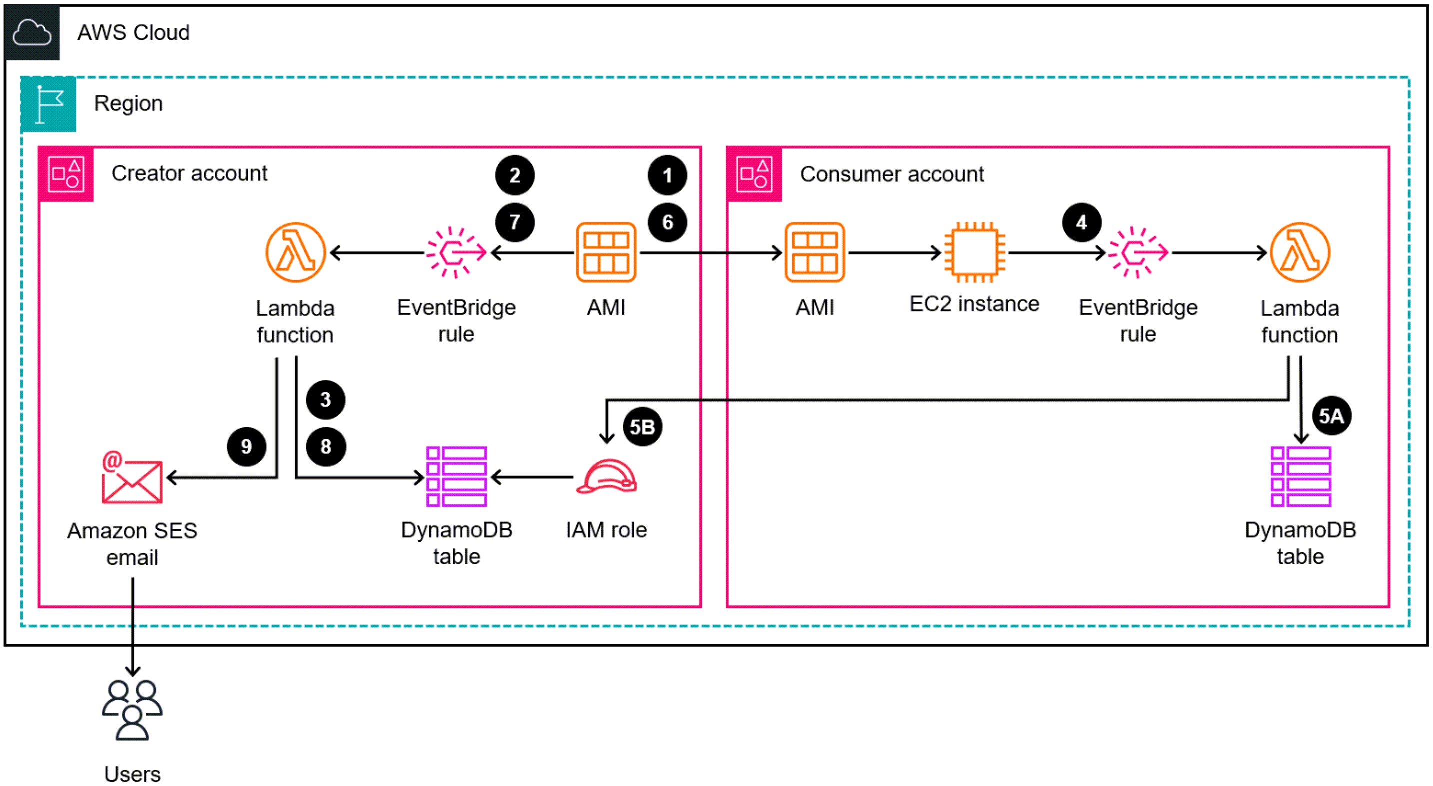
Architecture

Target technology stack

The following resources are provisioned as IaC through Terraform:

- Amazon DynamoDB tables
- Amazon EventBridge rules
- AWS Identity and Access Management (IAM) role
- AWS Lambda functions
- Amazon SES

Target architecture



The diagram shows the following workflow:

1. An AMI in the creator account is shared with a consumer account in the same AWS Region.
2. When the AMI is shared, an EventBridge rule in the creator account captures the `ModifyImageAttribute` event and initiates a Lambda function in the creator account.
3. The Lambda function stores data related to the AMI in a DynamoDB table in the creator account.
4. When an AWS service in the consumer account uses the shared AMI to launch an Amazon EC2 instance or when the shared AMI is associated with a launch template, an EventBridge rule in the consumer account captures use of the shared AMI.
5. The EventBridge rule initiates a Lambda function in the consumer account. The Lambda function does the following:
    a. The Lambda function updates the AMI-related data in a DynamoDB table in the consumer account.
    b. The Lambda function assumes an IAM role in the creator account and updates the Lambda table in the creator account. In the `Mapping` table, it creates an item that maps the instance ID or launch template ID to its respective AMI ID.
6. The AMI that is centrally managed in the creator account is deprecated, deregistered, or unshared.

7. The EventBridge rule in the creator account captures the `ModifyImageAttribute` or `DeregisterImage` event with the `remove` action and initiates the Lambda function.
8. The Lambda function checks the DynamoDB table to determine whether the AMI is used in any of the consumer accounts. If there are no instance IDs or launch template IDs associated with the AMI in the `Mapping` table, then the process is complete.
9. If any instance IDs or launch template IDs are associated with the AMI in the `Mapping` table, then the Lambda function uses Amazon SES to send an email notification to the configured subscribers.

Tools

AWS services

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Email Service (Amazon SES) helps you send and receive emails by using your own email addresses and domains.

Other tools

- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub cross-account-ami-monitoring-terraform-samples repository.

Best practices

- Follow the Best practices for working with AWS Lambda functions.
- Follow the Best practices for building AMIs.
- When creating the IAM role, follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.
- Set up monitoring and alerting for the AWS Lambda functions. For more information, see Monitoring and troubleshooting Lambda functions.

Epics

Customize the Terraform configuration files

Task	Description	Skills required
Create the AWS CLI named profiles.	For the creator account and each consumer account, create an AWS Command Line Interface (AWS CLI) named profile. For instructions, see Set up the AWS CLI in the AWS Getting Started Resources Center.	DevOps engineer
Clone the repository.	Enter the following command. This clones the cross-account-ami-monitoring-terraform-samples repository from GitHub by using SSH. `git clone git@github.com:aws-samples/`	DevOps engineer

Task	Description	Skills required
	`cross-account-ami-monitoring-terraform-samples.git`	

Task	Description	Skills required
Update the provider.tf file.	1. Enter the following command to navigate into the `terraform` folder in the cloned repository. `cd cross-account-ami-monitoring/terraform` 2. Open the `provider.tf` file. 3. Update the Terraform AWS Provider configurations for the creator account and consumer account as follows: • For `alias`, enter a name for the provider configuration. • For `region`, enter the target AWS Region where you want to deploy this solution. • For `profile`, enter the AWS CLI named profile for accessing the account. 4. If you are configuring more than one consumer account, create a profile for each additional consumer account. 5. Save and close the `provider.tf` file.	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>For more information about configuring the providers, see Multiple provider configurations in the Terraform documentation.</td><td></td></tr>
<tr><td>Update the terraform.tfvars file.</td><td>Open the <code>terraform.tfvars</code> file.
In the <code>account_email_mapping</code> parameter, configure alerts for the creator account and consumer account as follows:
For <code>account</code>, enter the account ID.
For <code>email</code>, enter the email address where you want to send alerts. You can enter only one email address for each account.
If you are configuring more than one consumer account, enter an account and email address for each additional consumer account.
Save and close the <code>terraform.tfvars</code> file.</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
Update the main.tf file.	Complete these steps only if you are deploying this solution to more than one consumer account. If you are deploying this solution to only one consumer account, no modification of this file is necessary. 1. Open the `main.tf` file. 2. For each additional consumer account, create a new module that is based off the `consumer_account_A` module in the template. For each consumer account, for `provider`, the value should match the alias you entered in the `provider.tf` file. 3. Save and close the `main.tf` file.	DevOps engineer

Deploy the solution by using Terraform

Task	Description	Skills required
Deploy the solution.	In the Terraform CLI, enter the following commands to deploy the AWS resources in the creator and consumer accounts:	DevOps engineer

Task	Description	Skills required

	1. Enter the following command to initialize Terraform.
	`terraform init`
	2. Enter the following command to validate the Terraform configurations.
	`terraform validate`
	3. Enter the following command to create a Terraform execution plan.
	`terraform plan`
	4. Review the configuration changes in the Terraform plan and confirm that you want to implement these changes.
	5. Enter the following command to deploy the resources.
	`terraform apply`	

Task	Description	Skills required
Verify the email address identity.	When you deployed the Terraform plan, Terraform created an email address identity for each consumer account in Amazon SES. Before notifications can be sent to that email address, you must verify the email address. For instructions, see [Verifying an email address identity](#) in the Amazon SES documentation.	General AWS

Validate resource deployment

Task	Description	Skills required
Validate deployment in the creator account.	1. Sign in to the creator account. 2. In the navigation bar, confirm that are viewing the target AWS Region. If you're in a different Region, choose the name of the currently displayed Region, and then choose the target Region. 3. Open the [DynamoDB console](#). 4. In the navigation pane, choose **Tables**.	DevOps engineer

Task	Description	Skills required
	5. In the list of tables, validate that the `AmiShare` table is present. 6. Open the [Lambda console](https://console.aws.amazon.com/lambda/). 7. In the navigation pane, choose **Functions**. 8. In the list of functions , validate that the `ami-share` function is present. 9. Open the [IAM console](https://console.aws.amazon.com/iam/). 10. In the navigation pane, choose **Roles**. 11. In the list of roles, validate that the `external-ddb-role` role is present. 12. Open the [EventBridge console](https://console.aws.amazon.com/events/). 13. In the navigation pane, choose **Rules**. 14. In the list of rules, validate that the `modify_image_attribute_event` rule is present. 15. Open the [Amazon SES console](https://console.aws.amazon.com/ses/). 16. In the navigation pane, choose **Verified Identities**. 17. In the list of identities, validate that an email address identity has been	

Task	Description	Skills required
	registered and verified for each consumer account.	

Task	Description	Skills required
Validate deployment in the consumer account.	1. Sign in to the consumer account. 2. In the navigation bar, confirm that are viewing the target AWS Region. If you're in a different Region, choose the name of the currently displayed Region, and then choose the target Region. 3. Open the [DynamoDB console](https://console.aws.amazon.com/dynamodb/). 4. In the navigation pane, choose **Tables**. 5. In the list of tables, validate that the `Mapping` table is present. 6. Open the [Lambda console](https://console.aws.amazon.com/lambda/). 7. In the navigation pane, choose **Functions**. 8. In the list of functions , validate that the `ami-usage-function` and `ami-deregister-function` functions are present. 9. Open the [EventBridge console](https://console.aws.amazon.com/events/). 10. In the navigation pane, choose **Rules**. 11. In the list of rules, validate that the `ami_usage`	DevOps engineer

Task	Description	Skills required
	`_events` and `ami_dereg ister_events` rules are present.	

Validate monitoring

Task	Description	Skills required
Create an AMI in the creator account.	1. In the creator account, create a private AMI. For instructions, see Create an AMI from an Amazon EC2 instance. 2. Share the new AMI with one of the consumer accounts. For instructions, see Share an AMI with specific AWS accounts.	DevOps engineer
Use the AMI in the consumer account.	In the consumer account, use the shared AMI to create an Amazon EC2 instance or launch template. For instructi ons, see How do I launch an Amazon EC2 instance from a custom AMI (AWS re:Post Knowledge Center) or Create a launch template for an Auto Scaling group (Amazon EC2 Auto Scaling documentation).	DevOps engineer
Validate monitoring and alerting.	1. Sign in to the creator account.	DevOps engineer

Task	Description	Skills required
	2. Open the [Amazon EC2 console](). 3. In the navigation pane, choose **AMIs**. 4. Select the AMI in the list, and then choose **Actions**, **Edit AMI permissions**. 5. In the **Shared accounts** section, select the consumer account, and then choose **Remove selected**. 6. Choose **Save changes**. 7. Validate that the target email address you defined for the consumer account receives a notification that the sharing was canceled for the AMI.	

(Optional) Stop monitoring shared AMIs

Task	Description	Skills required
Delete the resources.	1. Enter the following command to remove the resources deployed by this pattern and stop monitorin g shared AMIs. `terraform destroy`	DevOps engineer

Task	Description	Skills required
	2. Confirm the `destroy` command by entering `yes`.	

Troubleshooting

Issue	Solution
I did not receive an email alert.	There could be multiple reasons why the Amazon SES email was not sent. Check the following: 1. In the Epics section, use the *Validate resource deployment* epic to confirm that the infrastructure was provisioned properly in all AWS accounts. 2. Validate the Lambda function events in Amazon CloudWatch Logs. For instructions, see Using the CloudWatch console in the Lambda documentation. Confirm that there are no permissions issues, such an explicit deny in any identity-based or resource-based policies. For more information, see Policy evaluation logic in the IAM documentation. 3. In Amazon SES, validate that the status of the email address identity is **Verified**. For more information, see Verifying an email address identity.

Set up alerts for programmatic account closures in AWS Organizations

Richard Milner-Watts, Debojit Bhadra, and Manav Yadav, Amazon Web Services

Summary

The CloseAccount API for AWS Organizations enables you to close member accounts within an organization programmatically, without having to log in to the account with root credentials. The RemoveAccountFromOrganization API pulls an account out from an organization in AWS Organizations, so it becomes a standalone account.

These APIs potentially increase the number of operators who can close or remove an AWS account. All users who have access to the organization through AWS Identity and Access Management (IAM) in the AWS Organizations management account can call these APIs, so access isn't limited to the owner of the account's root email with any associated multi-factor authentication (MFA) device.

This pattern implements alerts when the `CloseAccount` and `RemoveAccountFromOrganization` APIs are called, so you can monitor these activities. For alerts, it uses an Amazon Simple Notification Service (Amazon SNS) topic. You can also set up Slack notifications through a webhook.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An organization in AWS Organizations
- Access to the organization management account, under the organization's root, to create the required resources

Limitations

- As described in the AWS Organizations API reference, the `CloseAccount` API allows only 10 percent of active member accounts to be closed within a rolling 30-day period.
- When an AWS account is closed, its status is changed to SUSPENDED. For 90 days after this status transition, AWS Support can reopen the account. After 90 days the account is permanently deleted.

- Users who have access to the AWS Organizations management account and APIs might also have permissions to disable these alerts. If the primary concern is malicious behavior instead of accidental deletion, consider protecting the resources created by this pattern with an IAM permissions boundary.
- The API calls for `CloseAccount` and `RemoveAccountFromOrganization` are processed in the US East (N. Virginia) Region (`us-east-1`). Therefore, you must deploy this solution in `us-east-1` in order to observe the events.

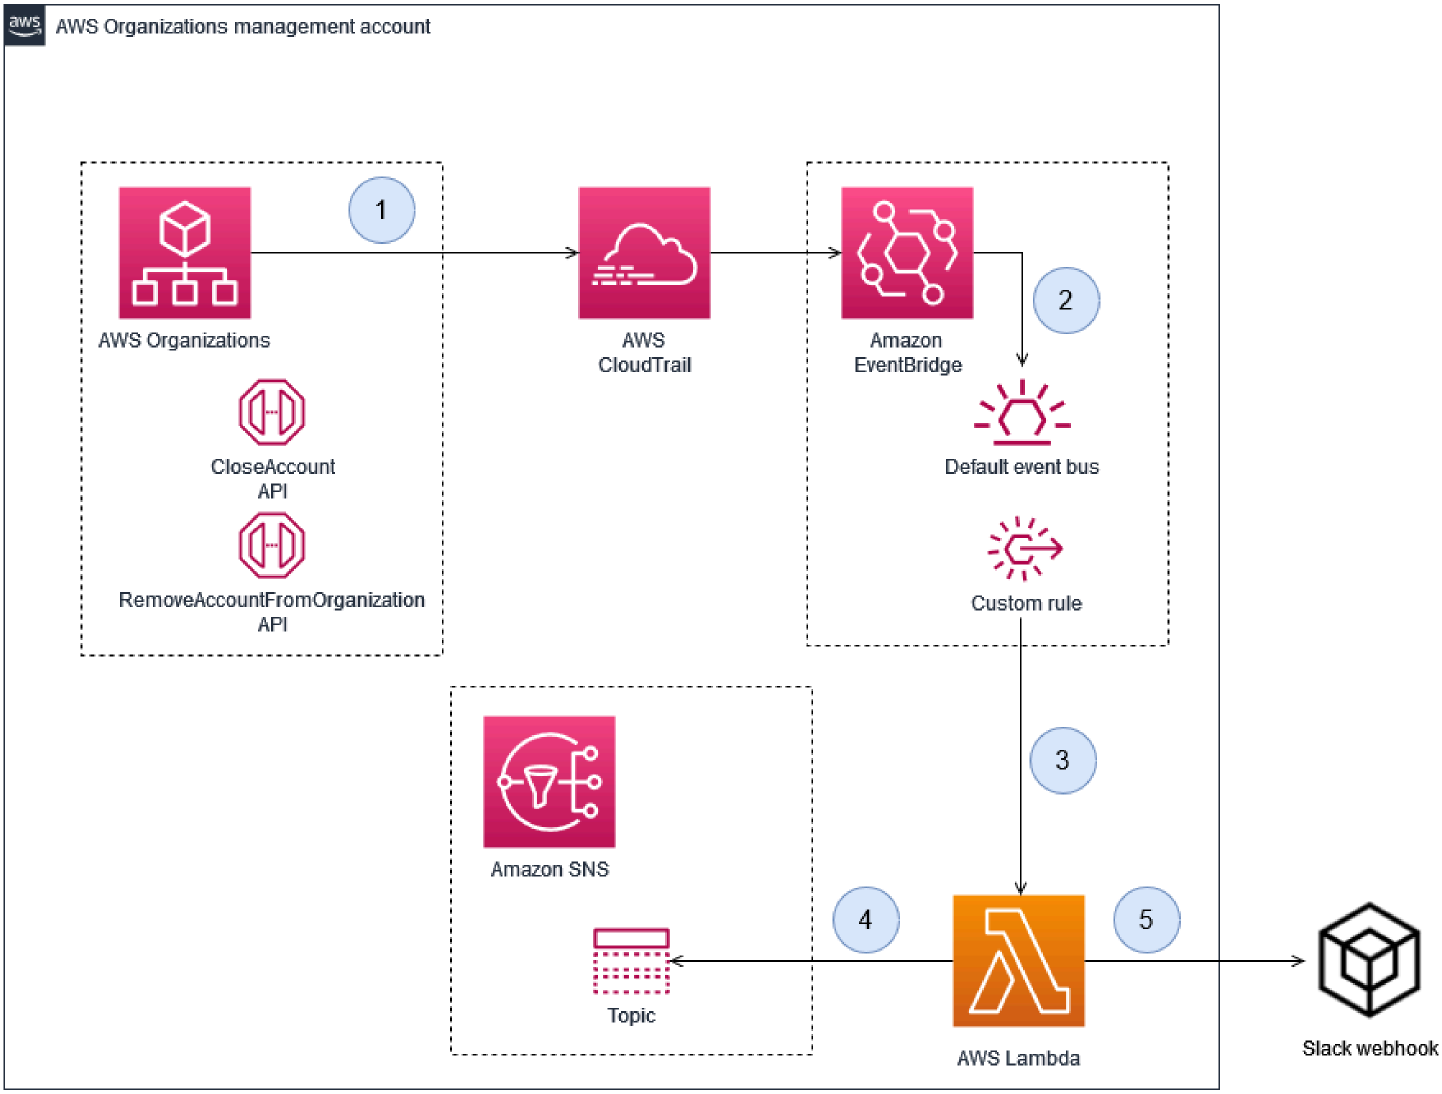
Architecture

Target technology stack

- AWS Organizations
- AWS CloudTrail
- Amazon EventBridge
- AWS Lambda
- Amazon SNS

Target architecture

The following diagram shows the solution architecture for this pattern.



1. AWS Organizations processes a `CloseAccount` or `RemoveAccountFromOrganization` request.
2. Amazon EventBridge is integrated with AWS CloudTrail to deliver these events to the default event bus.
3. A custom Amazon EventBridge rule matches the AWS Organizations requests and calls an AWS Lambda function.
4. The Lambda function delivers a message to an SNS topic, which users can subscribe to for email alerts or further processing.
5. If Slack notifications are enabled, the Lambda function delivers a message to a Slack webhook.

Tools

AWS services

- AWS CloudFormation provides a way to model a collection of related AWS and third-party resources, provision them quickly and consistently, and manage them throughout their lifecycles, by treating infrastructure as code.
- Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge receives an event, an indicator of a change in environment, and applies a rule to route the event to a target. Rules match events to targets based on either the structure of the event, called an *event pattern*, or on a schedule.
- AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests each day to thousands each second. You pay only for the compute time that you consume. There is no charge when your code is not running.
- AWS Organizations helps you centrally manage and govern your environment as you grow and scale your AWS resources. Using AWS Organizations, you can programmatically create new AWS accounts and allocate resources, group accounts to organize your workflows, apply policies to accounts or groups for governance, and simplify billing by using a single payment method for all your accounts.
- AWS CloudTrail monitors and records account activity across your AWS infrastructure, and gives you control over storage, analysis, and remediation actions.
- Amazon Simple Notification Service (Amazon SNS) is a fully managed messaging service for both application-to-application (A2A) and application-to-person (A2P) communication.

Other tools

- AWS Lambda Powertools for Python library is a set of utilities that provide tracing, logging, metrics, and event handling features for Lambda functions.

Code

The code for this pattern is located in the GitHub AWS Account Closer Notifier repository.

The solution includes a CloudFormation template that deploys the architecture for this pattern. It uses the AWS Lambda Powertools for Python library to provide logging and tracing.

Epics

Deploy the architecture

Task	Description	Skills required
Launch the CloudFormation template for the solution stack.	The CloudFormation template for this pattern is in the main branch of the [GitHub repository](). It deploys the IAM roles, EventBridge rules, Lambda functions, and the SNS topic. To launch the template: 1. Clone the [GitHub repository]() to obtain a copy of the solution code. 2. Open the AWS Management Console for the AWS Organizations management account. 3. Choose the US East (N. Virginia) Region (`us-east-1`), and then open the [CloudFormation console](). 4. Create the stack by using the `account-closure-notifier.yml` template and specifying the following values: • Stack name: `aws-account-closure-notifier-stack`	AWS administrator

Task	Description	Skills required
	• `ResourcePrefix` parameter: `aws-account-closure-notifier` • `SlackNotification` parameter: If Slack notifications are required, change this setting to `true`. • `SlackWebhookEndpoint` parameter: If Slack notifications are required, specify the webhook URL. For more information about launching a CloudFormation stack, see the [AWS documentation].	
Verify that the solution has launched successfully.	1. Wait for the CloudFormation stack to reach a status of CREATE_COMPLETE. 2. Open the [EventBridge console] in `us-east-1` . 3. Verify that a new rule has been created with the name `aws-account-closure-notifier-event-rule` .	AWS administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Subscribe to the SNS topic.</td><td>(Optional) If you want to subscribe to the SNS topic:

1. Open the Amazon SNS console in <code>us-east-1</code> , and find the topic named <code>aws-account-closure-notifier-sns-topic</code> .
2. Choose the topic name, and then choose Create subscription.
3. For Protocol, choose Email.
4. For Endpoint, specify the email address that should receive the notification, and then choose Create subscription.
5. Check your email inbox for a message from AWS Notifications. Use the link in this email to confirm the subscription.

For more information about setting up SNS notifications, see the Amazon SNS documentation.</td><td>AWS administrator</td></tr>
</table>

Verify the solution

Task	Description	Skills required
Send a test event to the default event bus.	The [GitHub repository](#) provides a sample event that you can send to the EventBridge default event bus for testing. The EventBridge rule also reacts to events that use the custom event source `account.closure.notifier` . **Note** You can't use the CloudTrail event source to send this event, because it's not possible to send an event as an AWS service. To send a test event: 1. Open the [EventBridge console](#) in `us-east-1` . 2. In the navigation pane, under **Buses**, choose **Event buses**, and then select the default event bus. 3. Choose **Send events**. 4. For **Event source**, enter `account.closure.notifier` .	AWS administrator

Task	Description	Skills required
	5. For **Detail type**, enter `AWS API Call via CloudTrail` . 6. For **Event detail**, copy and paste the contents of `tests/dummy-event.json` from the GitHub repository into the text box. 7. Choose **Send** to initiate the notification workflow.	
Verify that the email notificat ion was received.	Check the mailbox that subscribed to the SNS topic for notifications. You should receive an email with details of the account that was closed and the principal that performed the API call.	AWS administrator
Verify that the Slack notificat ion was received.	(Optional) If you specified a webhook URL for the `SlackWebhookEndpoint` parameter when you deployed the CloudFormation template, check the Slack channel that is mapped to the webhook. It should display a message with details of the account that was closed and the principal that performed the API call.	AWS administrator

View EBS snapshot details for your AWS account or organization

Arun Chandapillai and Parag Nagwekar, Amazon Web Services

Summary

This pattern describes how you can automatically generate an on-demand report of all Amazon Elastic Block Store (Amazon EBS) snapshots in your Amazon Web Services (AWS) account or organizational unit (OU) in AWS Organizations.

Amazon EBS is an easy-to-use, scalable, high-performance block- storage service designed for Amazon Elastic Compute Cloud (Amazon EC2). An EBS volume provides durable and persistent storage that you can attach to your EC2 instances. You can use EBS volumes as primary storage for your data and take a point-in-time backup of your EBS volumes by creating a snapshot. You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to view the details of specific EBS snapshots. This pattern provides a programmatic way to retrieve information about all EBS snapshots in your AWS account or OU.

You can use the script provided by this pattern to generate a comma-separated values (CSV) file that has the following information about each snapshot: account ID, snapshot ID, volume ID and size, the date the snapshot was taken, instance ID, and description. If your EBS snapshots are tagged, the report also includes the owner and team attributes.

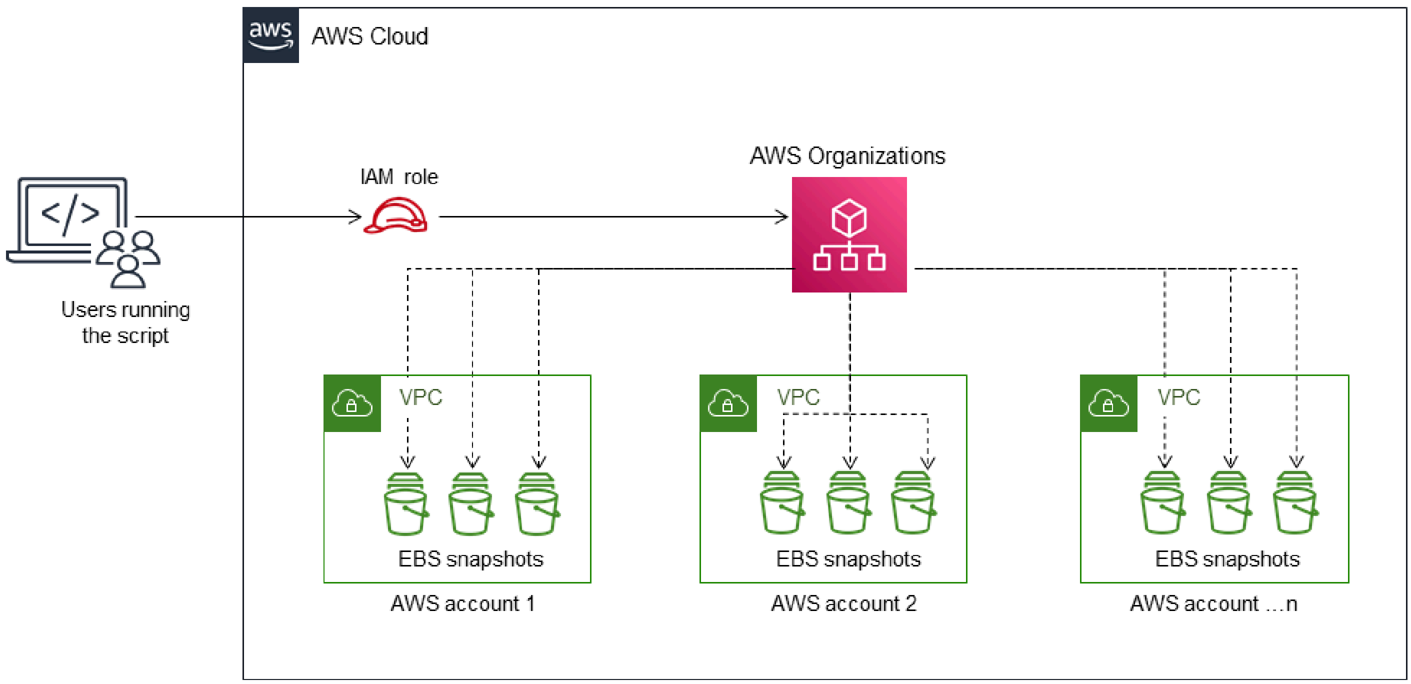
Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS CLI version 2 installed and configured
- AWS Identity and Access Management (IAM) role with the appropriate permissions (access permissions for a specific account or for all accounts in an OU if you're planning to run the script from AWS Organizations)

Architecture

The following diagram shows the script workflow that generates an on-demand report of EBS snapshots that are spread across multiple AWS accounts in an OU.



Tools

AWS services

- [AWS Command Line Interface (AWS CLI)](https://docs.aws.amazon.com/cli/latest/userguide/cli-chap-welcome.html) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with EC2 instances.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

Code

The code for the sample application used in this pattern is available on GitHub, in the aws-ebs-snapshots-awsorganizations repository. Follow the instructions in the next section to use the sample files.

Epics

Download the script

Task	Description	Skills required
Download the Python script.	Download the script [GetSnapshotDetailsAllAccountsOU.py]() from the [GitHub repository]().	General AWS

Get EBS snapshot details for an AWS account

Task	Description	Skills required

Run the Python script.	Run the command:
	`python3 getsnapshotinfo.py --file <output-file>.csv --region <region-name>`
	where `<output-file>` refers to the CSV output file where you want information about the EBS snapshots placed, and `<region-name>` is the AWS Region where the snapshots are stored. For example:
	`python3 getsnapshotinfo.py --file snapshots.csv --region us-east-1`
		General AWS

Get EBS snapshot details for an organization

Task	Description	Skills required
Run the Python script.	Run the command: `python3 getsnapshotinfo.py --file <output-file>.csv --role <IAM-role> --region <region-name>` where `<output-file>` refers to the CSV output file where you want information about the EBS snapshots placed, `<IAM-role>` is a role that provides permissions to access AWS Organizations, and `<region-name>` is the AWS Region where the snapshots are stored. For example: `python3 getsnapshotinfo.py --file snapshots.csv --role <IAM role> --region us-west-2`	General AWS

Additional information

EBS snapshot types

Amazon EBS provides three types of snapshots, based on ownership and access:

- **Owned by you –** By default, only you can create volumes from snapshots that you own.
- **Public snapshots –** You can share snapshots publicly with all other AWS accounts. To create a public snapshot, you modify the permissions for a snapshot to share it with the AWS accounts that you specify. Users that you will authorize can then use the snapshots you share by creating their own EBS volumes, while your original snapshot remains unaffected. You can also make your unencrypted snapshots available publicly to all AWS users. However, you can't make your encrypted snapshots available publicly for security reasons. Public snapshots pose a significant security risk because of the possibility of exposing personal and sensitive data. We strongly recommend against sharing your EBS snapshots with all AWS accounts. For more information about sharing snapshots, see the AWS documentation.
- **Private snapshots –** You can share snapshots privately with individual AWS accounts that you specify. To share the snapshot privately with specific AWS accounts, follow the instructions in the AWS documentation, and choose **Private** for the permissions setting. Users that you have authorized can use the snapshots that you share to create their own EBS volumes, while your original snapshot remains unaffected.

Overviews and procedures

The following table provides links to more information about EBS snapshots, including how you can lower EBS volume costs by finding and deleting unused snapshots, and archive rarely accessed snapshots that do not require frequent or fast retrieval.

For information about	See
Snapshots, their features, and limitations	Create Amazon EBS snapshots
How to create a snapshot	Console: Create a snapshot

FAQ

What is the minimum archive period?

The minimum archive period is 90 days.

How long would it take to restore an archived snapshot?

It can take up to 72 hours to restore an archived snapshot from the archive tier to the standard tier, depending on the size of the snapshot.

Are archived snapshots full snapshots?

Archived snapshots are always full snapshots.

Which snapshots can a user archive?

You can archive only snapshots that you own in your account.

Can you archive a snapshot of the root device volume of a registered Amazon Machine Image (AMI)?

No, you can’t archive a snapshot of the root device volume of a registered AMI.

What are security considerations for sharing a snapshot?

When you share a snapshot, you are giving others access to all the data on the snapshot. Share snapshots only with people that you trust with your data.

How do you share a snapshot with another AWS Region?

Snapshots are constrained to the Region in which they were created. To share a snapshot with another Region, copy the snapshot to that Region and then share the copy.

Can you share snapshots that are encrypted?

You can't share snapshots that are encrypted with the default AWS managed key. You can share snapshots that are encrypted with a customer managed key only. When you share an encrypted snapshot, you must also share the customer managed key that was used to encrypt the snapshot.

What about unencrypted snapshots?

You can share unencrypted snapshots publicly.

- More patterns

Automate RabbitMQ configuration in Amazon MQ

Yogesh Bhatia and Afroz Khan, Amazon Web Services

Summary

[Amazon MQ](https://aws.amazon.com/amazon-mq/) is a managed message broker service that provides compatibility with many popular message brokers. Using Amazon MQ with RabbitMQ provides a robust RabbitMQ cluster managed in the Amazon Web Services (AWS) Cloud with multiple brokers and configuration options. Amazon MQ provides a highly available, secure, and scalable infrastructure, and can process a large number of messages per second with ease. Multiple applications can use the infrastructure with different virtual hosts, queues, and exchanges. However, managing these configuration options or creating the infrastructure manually can require time and effort. This pattern describes a way to manage configurations for RabbitMQ in one step, through a single file. You can embed the code provided with this pattern within any continuous integration (CI) tool such as Jenkins or Bamboo.

You can use this pattern to configure any RabbitMQ cluster. All it requires is connectivity to the cluster. Although there are many other ways to manage RabbitMQ configurations, this solution creates entire application configurations in one step, so you can manage queues and other details easily.

Prerequisites and limitations

Prerequisites

- AWS Command Line Interface (AWS CLI) installed and configured to point to your AWS account (for instructions, see [AWS CLI documentation](https://docs.aws.amazon.com/cli/))
- Ansible installed, so you can run playbooks to create the configuration
- **rabbitmqadmin** installed (for instructions, see the [RabbitMQ documentation](https://www.rabbitmq.com/management-cli.html))
- A RabbitMQ cluster in Amazon MQ, created with healthy Amazon CloudWatch metrics

Additional requirements

- Make sure to create the configurations for virtual hosts and users separately and not as part of JSON.
- Make sure that the configuration JSON is part of the repository and is version-controlled.
- The version of the **rabbitmqadmin** CLI must be the same as the version of the RabbitMQ server, so the best option is to download the CLI from the RabbitMQ console.

- As part of the pipeline, make sure that JSON syntax is validated before each run.

Product versions

- AWS CLI version 2.0
- Ansible version 2.9.13
- **rabbitmqadmin** version 3.9.13 (must be the same as the RabbitMQ server version)

Architecture

Source technology stack

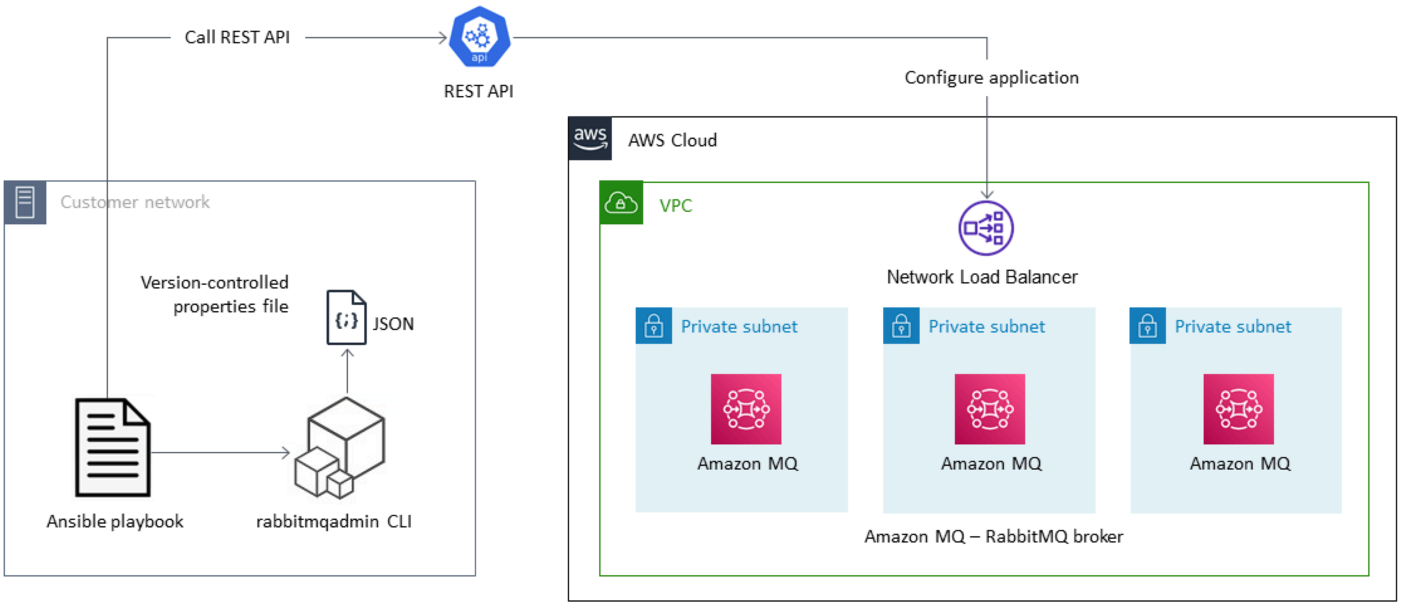
- An RabbitMQ cluster running on an existing on-premises virtual machine (VM) or a Kubernetes cluster (on premises or in the cloud)

Target technology stack

- Automated RabbitMQ configurations on Amazon MQ for RabbitMQ

Target architecture

There are many ways to configure RabbitMQ. This pattern uses the import configuration functionality, where a single JSON file contains all the configurations. This file applies all settings and can be managed by a version-control system such as Bitbucket or Git. This pattern uses Ansible to implement the configuration through the **rabbitmqadmin** CLI.



Tools

Tools

- rabbitmqadmin is a command-line tool for the RabbitMQ HTTP-based API. It is used to manage and monitor RabbitMQ nodes and clusters.
- Ansible is an open-source tool for automating applications and IT infrastructure.
- AWS CLI enables you to interact with AWS services by using commands in a command-line shell.

AWS services

- Amazon MQ is a managed message broker service that makes it easy to set up and operate message brokers in the cloud.
- AWS CloudFormation helps you set up your AWS infrastructure and speed up cloud provisioning with infrastructure as code.

Code

The JSON configuration file used in this pattern and a sample Ansible playbook are provided in the attachment.

Epics

Create your AWS infrastructure

Task	Description	Skills required
Create a RabbitMQ cluster on AWS.	If you don't already have a RabbitMQ cluster, you can use [AWS CloudFormation](https://aws.amazon.com/cloudformation/) to create the stack on AWS. Or, you can use the [Cloudformation module in Ansible](https://docs.ansible.com/ansible/latest/collections/amazon/aws/cloudformation_module.html) to create the stack. With the latter approach, you can use Ansible for both tasks: to create the RabbitMQ infrastructure and to manage configurations.	AWS CloudFormation, Ansible

Create the Amazon MQ for RabbitMQ configuration

Task	Description	Skills required
Create a properties file.	Download the JSON configuration file (`rabbitmqconfig.json`) in the attachment, or export it from the RabbitMQ console. Modify it to configure queues, exchanges, and bindings. This configuration file demonstrates the following: - Creates two queues: `sample-queue1` and `sample-queue2`	JSON

Task	Description	Skills required
	- Creates two exchanges: `sample-exchange1` and `sample-exchange2` - Implements the binding between the queues and exchanges These configurations are performed under the root (/) virtual host, as required by **rabbitmqadmin**.	

Task	Description	Skills required
Retrieve the details of the Amazon MQ for RabbitMQ infrastructure.	Retrieve the following details for the RabbitMQ infrastru cture on AWS: • Broker name • RabbitMQ host • RabbitMQ user name (the administrator user created during cluster creation) • RabbitMQ password You can use the AWS Management Console or the AWS CLI to retrieve this information. These details enable the Ansible playbook to connect to your AWS account and use the RabbitMQ cluster to run commands. **Important** The computer that runs the Ansible playbook must be able to access your AWS account, and AWS CLI must already be configured, as described in the *Prerequisites* section.	AWS CLI, Amazon MQ

Task	Description	Skills required

Create the hosts_var file.	Create the `hosts_var` file for Ansible and make sure that all the variables are defined in the file. Consider using Ansible Vault to store the password. You can configure the `hosts_var` file as follows (replace the asterisks with your informati on):
	`RABBITMQ_HOST: "***********.mq.us-east-2.amazonaws.com"`
	`RABBITMQ_VHOST: "/"`
	`RABBITMQ_USERNAME: "admin"`
	`RABBITMQ_PASSWORD: "*******"`
		Ansible

Task	Description	Skills required
Create an Ansible playbook.	For a sample playbook, see `ansible-rabbit-config.yaml` in the attachment. Download and save this file. The Ansible playbook imports and manages all RabbitMQ configurations, such as queues, exchanges, and bindings, that applications require. Follow best practices for Ansible playbooks, such as securing passwords. Use Ansible Vault for password encryption, and retrieve the RabbitMQ password from the encrypted file.	Ansible

Deploy the configuration

Task	Description	Skills required
Run the playbook.	Run the Ansible playbook that you created in the previous epic. `ansible-playbook ansible-rabbit-config.yaml` You can verify the new configurations on the RabbitMQ console.	RabbitMQ, Amazon MQ, Ansible

Improve call quality on agent workstations in Amazon Connect contact centers

Ernest Ozdoba, Amazon Web Services

Summary

Call quality issues are some of the most difficult problems to troubleshoot in contact centers. To avoid voice quality issues and complex troubleshooting procedures, you must optimize your agents' work environment and workstation settings. This pattern describes voice quality optimization techniques for agent workstations in Amazon Connect contact centers. It provides recommendations in the following areas:

- Work environment adjustments. Agents' surroundings don't affect how voice is transmitted over the network, but they do have an effect on call quality.
- Agent workstation settings. Hardware and network configurations for contact center workstations have significant effects on call quality.
- Browser settings. Agents use a web browser to access the Amazon Connect Contact Control Panel (CCP) website and communicate with customers, so browser settings can affect call quality.

The following components can also affect call quality, but they fall outside the scope of the workstation and aren't covered in this pattern:

- Traffic flows to the Amazon Web Services (AWS) Cloud over AWS Direct Connect, a full-tunnel VPN, or a split-tunnel VPN
- Network conditions when working in or outside the corporate office
- Public switched telephone network (PSTN) connectivity
- The customer's device and telephony carrier
- Virtual desktop infrastructure (VDI) setup

For more information relating to these areas, see Common Contact Control Panel (CCP) Issues and Use the Endpoint Test Utility in the Amazon Connect documentation.

Prerequisites and limitations

Prerequisites

- Headsets and workstations must comply with the requirements specified in the Amazon Connect Administrator Guide.

Limitations

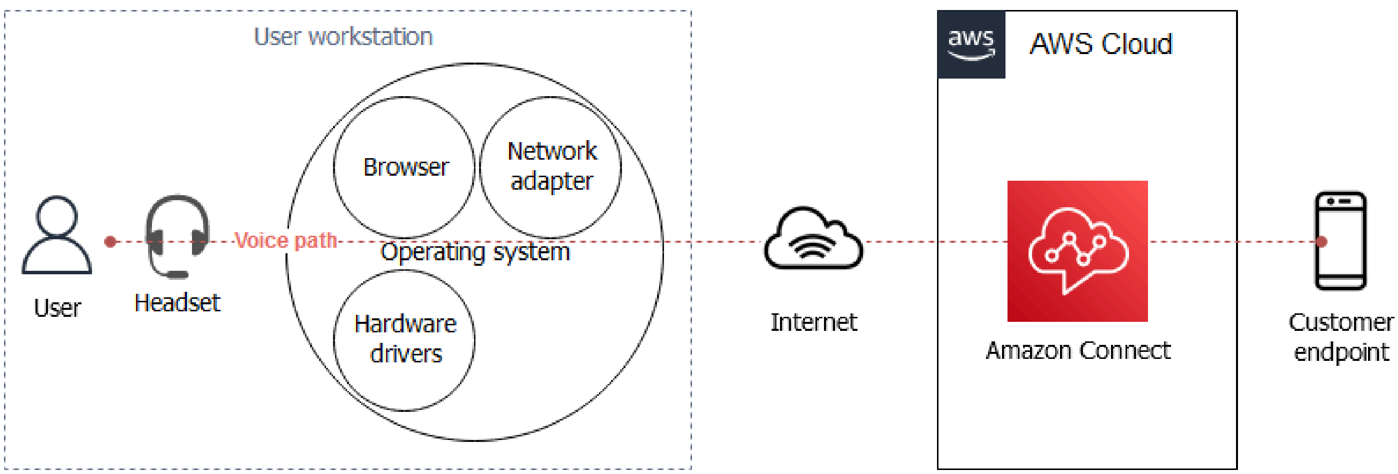
- The optimization techniques in this pattern apply to soft phone voice quality. They do not apply when you configure the Amazon Connect CCP in desk phone mode. However, you can use desk phone mode if your soft phone setup doesn't provide acceptable voice quality for the call.

Product versions

- For supported browsers and versions, see the Amazon Connect Administrator Guide.

Architecture

This pattern is architecture-agnostic because it targets agent workstation settings. As the following diagram shows, the voice path from the agent to the customer is affected by the agent's headset, browser, operating system, workstation hardware, and network.



In Amazon Connect contact centers, the user's audio connectivity is established with WebRTC. Voice is encoded with the Opus interactive audio codec and encrypted with the Secure Real-time Transport Protocol (SRTP) in transit. Other network architectures are possible, including VPN, private WAN/LAN, and ISP networks.

Tools

- [Amazon Connect Endpoint Test Utility](#) – This utility checks network connectivity and browser settings.
- Browser configuration editors for WebRTC settings:
  - For Firefox: **about:config**
  - For Chrome: **chrome://flags**
- [CCP Log Parser](#) – This tool helps you analyze CCP logs for troubleshooting purposes.

Epics

Adjust the work environment

Task	Description	Skills required
Reduce background noise.	Avoid noisy environments. If this is not possible, optimize the environment with these soundproofing tips: • Absorb noise by using sound-dissipating surfaces such as curtains, carpets, and soft furnishings. • Block noise by putting barriers between desks. • Consider an active noise cancellation (ANC) solution such as a white noise generator to help concentra tion and ensure privacy, or use noise-canceling headsets. • Prevent echo on your calls. Big, empty spaces might create echo effects or	Agent, Manager

Task	Description	Skills required
	amplify noises. Covering surfaces that can bounce sounds will help reduce echoes.	

Optimize agent workstation settings

Task	Description	Skills required
Choose the right headset.	• If the environment is noisy, choose a stereo headset. Directing sound to both ears helps agents focus and hear the customer better, and reduces the overall noise by making it less likely for agents to raise their voices. • Avoid using loud speakers or built-in computer audio. For best quality, use a wired headset that’s dedicated to contact center use. Wireless headsets are convenient, but they might be a source of additional audio delay and reduced audio quality because of radio interfere nce and transcoding.	Agent, Manager
Use the headset as intended.	• Enable the active noise canceling and speech enhancement features of your headset if they are	Agent

Task	Description	Skills required
	available. Look for settings such as ANC or ANR. For instructions on activating these settings, see the user manual for your headset. • Adjust your microphone so you can speak directly into it. The best position for your microphone is just below your chin. Correct placement can make a difference of 10 decibels (dB) in the sound level. Most headsets allow you to rotate or bend the microphone arm (boom), so it is important to keep it in the right place when you are talking. • Some headsets are equipped with multiple microphones and advanced features such as voice beamforming, which helps capture speech without a boom. To make sure that you're using the main microphone as intended by the manufacturer, see the user manual for your device.	

Task	Description	Skills required
Check workstation resources.	Make sure that your agents' computers are performan t. If they use third-party applications that consume resources, their computers might not meet the minimum [hardware requirements](#) to run CCP. If agents experienc e call quality issues, make sure that they have enough processing power (CPU), disk space, network bandwidth , and memory available for CCP. Agents should close any unnecessary applicati ons and tabs to improve CCP performance and call quality.	Administrator

Task	Description	Skills required
Configure the operating system's sound settings.	The default settings for microphone level and boost usually work fine. If you find that outbound voice is quiet or the microphone is picking up too much, it might help to adjust these settings. Microphone settings can be found in your computer's system sound configuration (**Sound**, **Input** on MacOS, **Microphone Properties** in Windows). You can access advanced settings that might affect voice quality through system tools or third-party applications. Here are some of the settings you can check: • Sample rate – This value determines how many times the sound is probed per second. The default setting is usually 44 or 48 kilohertz (kHz). The optimal value for Amazon Connect is 48 kHz. You can use your browser settings to override the default value. For more information, see the troubleshooting section of the *Amazon Connect Administrator Guide*. • Gain – This value determine s how much the microphon	Agent, Administrator

Task	Description	Skills required
	e amplifies the sound. If you turn the gain up, your microphone might pick up more background noise. • Bit depth – This digital resolution value describes how many levels of sound amplitude are being recognized. The higher the bit depth, the smoother the voice sounds. However, many traditional telephony networks use the pulse-code modulation (PCM) standard, which supports only 8-bit resolution. • Open threshold – This is the minimal sound amplitude that a microphone picks up. If you’re experiencing voice quality issues, try restoring these values to their default settings before investigating further. For more information about these and other adjustabl e settings, see your device manual.	

Task	Description	Skills required
Use a wired network.	Typically, wired ethernet has lower latency, so it is easier to provide the consistent transmission quality required for voice data transmission. We recommend 100 KB bandwidth per call at the minimum. • If agents are working from home, we recommend wired over wireless connections. It shouldn't take more than 150 milliseconds to hear the customer. You can access Amazon Connect's latency test from the [Amazon Connect Endpoint Test Utility](). However, this utility measures the delay from the browser to Amazon Connect Regions, not to customers. The 150-millisecond one-way delay recommendation prevents the agent and customer from talking over each other. The value is measured from end to end, and each element adds a delay, including the part of the call between the Amazon Connect Region and the customer.	Network administrator, Agent

Task	Description	Skills required
	• If agents are working from the office, corporate Wi-Fi is acceptable as long as parameters are in the recommended range, and Real-time Transport Protocol (RTP) traffic is prioritized.	
Update hardware drivers.	When you use a USB or other type of headset that has its own firmware, we recommend that you keep it updated with the latest version. Simple headsets that use an auxiliary port use the computer’s built-in audio device, so make sure that the operating system hardware driver is up to date. In rare cases, an audio driver update can cause audio issues, and you might need to roll it back. For more information about changing firmware and driver versions, see your device manual.	Administrator

Task	Description	Skills required
Avoid USB hubs and dongles.	When you connect your headset, avoid additional devices such as dongles, port type converters, hubs, and extension cables. These devices might affect call quality. Connect your device directly to the port in your computer instead.	Agent

Task	Description	Skills required
Check CCP logs.	The CCP Log Parser provides an easy way to check applicati on logs. 1. Download the CCP logs after a call. 2. Open the CCP Log Parser. 3. Drag and drop the log file to upload the log for analysis. 4. When the log has been analyzed, the **Snapshots & Logs** tab will be selected by default. Choose the **Metrics** tab next to it to check insights. 5. In the **WebRTC Metrics - audio_input** section, check the following: • The **Audio Level** graph, to see if your received audio level is above 0. This indicates that audio was received from your caller. • The **Packets** graph for any lost packets. If this chart shows significant increases, contact your IT support team. 6. In the **WebRTC Metrics - audio_output** section, check the following:	Agent (advanced skills)

Task	Description	Skills required
	- The **Audio Level** graph, to confirm that audio was sent out from your device. - The **Packets** graph. If you see a packet loss spike, report it to your IT support team. - The **Jitter Buffer & RTT** graph. Round trip time (RTT) values above 300 will affect the call experience. Report these to your IT support team.	

Optimize browser settings

Task	Description	Skills required
Restore default WebRTC settings.	WebRTC has to be enabled to make soft phone calls with CCP. We recommend that you keep the default settings for WebRTC-related features. - In Chrome, you can set flags by navigating to the URL **chrome://flags**. Type **WebRTC** in the search box to find settings that can interfere with CCP, and set these to **Default**. - In Firefox, type **about:config** in the address bar, and	Administrator

Task	Description	Skills required
	then type **WebRTC** in the search box on the configura tion page. Non-default settings appear in bold text and can be changed to **Default**.	
Disable browser extensions when troubleshooting.	Some browser extension s might affect call quality or even prevent calls from connecting properly. Use the incognito window or private mode in your browser, and disable all extensions. If that solves the problem, review your browser extensions and look for suspicious add-ons, or disable them individually.	Agent, Administrator
Check the browser sample rate.	Confirm that your microphon e input is set to the optimal 48 kHz sample rate. For instructions, see the Amazon Connect Administrator Guide.	Agent, Administrator

Related resources

If you've followed the steps in this pattern but you're still encountering problems with call quality, see the following resources for troubleshooting tips.

- Review common Contact Control Panel (CCP) issues.
- Check the connection with the Endpoint Test Utility.
- Follow the troubleshooting guide for any other issues.

If your troubleshooting and adjustments don't solve the call quality issue, the root cause might be external to your workstation. For further troubleshooting, contact your IT support team.

Access AWS services from an ASP.NET Core app using Amazon Cognito identity pools

Bibhuti Sahu and Marcelo Barbosa, Amazon Web Services

Summary

This pattern discusses how you can configure Amazon Cognito user pools and identity pools, and then enable an ASP.NET Core app to access AWS resources after successful authentication.

Amazon Cognito provides authentication, authorization, and user management for your web and mobile apps. The two main components of Amazon Cognito are user pools and identity pools.

A user pool is a user directory in Amazon Cognito. With a user pool, your users can sign in to your web or mobile app through Amazon Cognito. Your users can also sign in through social identity providers such as Google, Facebook, Amazon, or Apple, and through SAML identity providers.

Amazon Cognito identity pools (federated identities) enable you to create unique identities for your users and federate them with identity providers. With an identity pool, you can obtain temporary, limited-privilege AWS credentials to access other AWS services. Before you can begin using your new Amazon Cognito identity pool, you must assign one or more AWS Identity and Access Management (IAM) roles to determine the level of access you want your application users to have to your AWS resources. Identity pools define two types of identities: authenticated and unauthenticated. Each identity type can be assigned its own role in IAM. Authenticated identities belong to users who are authenticated by a public login provider (Amazon Cognito user pools, Facebook, Google, SAML, or any OpenID Connect providers) or a developer provider (your own backend authentication process), whereas unauthenticated identities typically belong to guest users. When Amazon Cognito receives a user request, the service determines whether the request is authenticated or unauthenticated, determines which role is associated with that authentication type, and then uses the policy attached to that role to respond to the request.

Prerequisites and limitations

Prerequisites

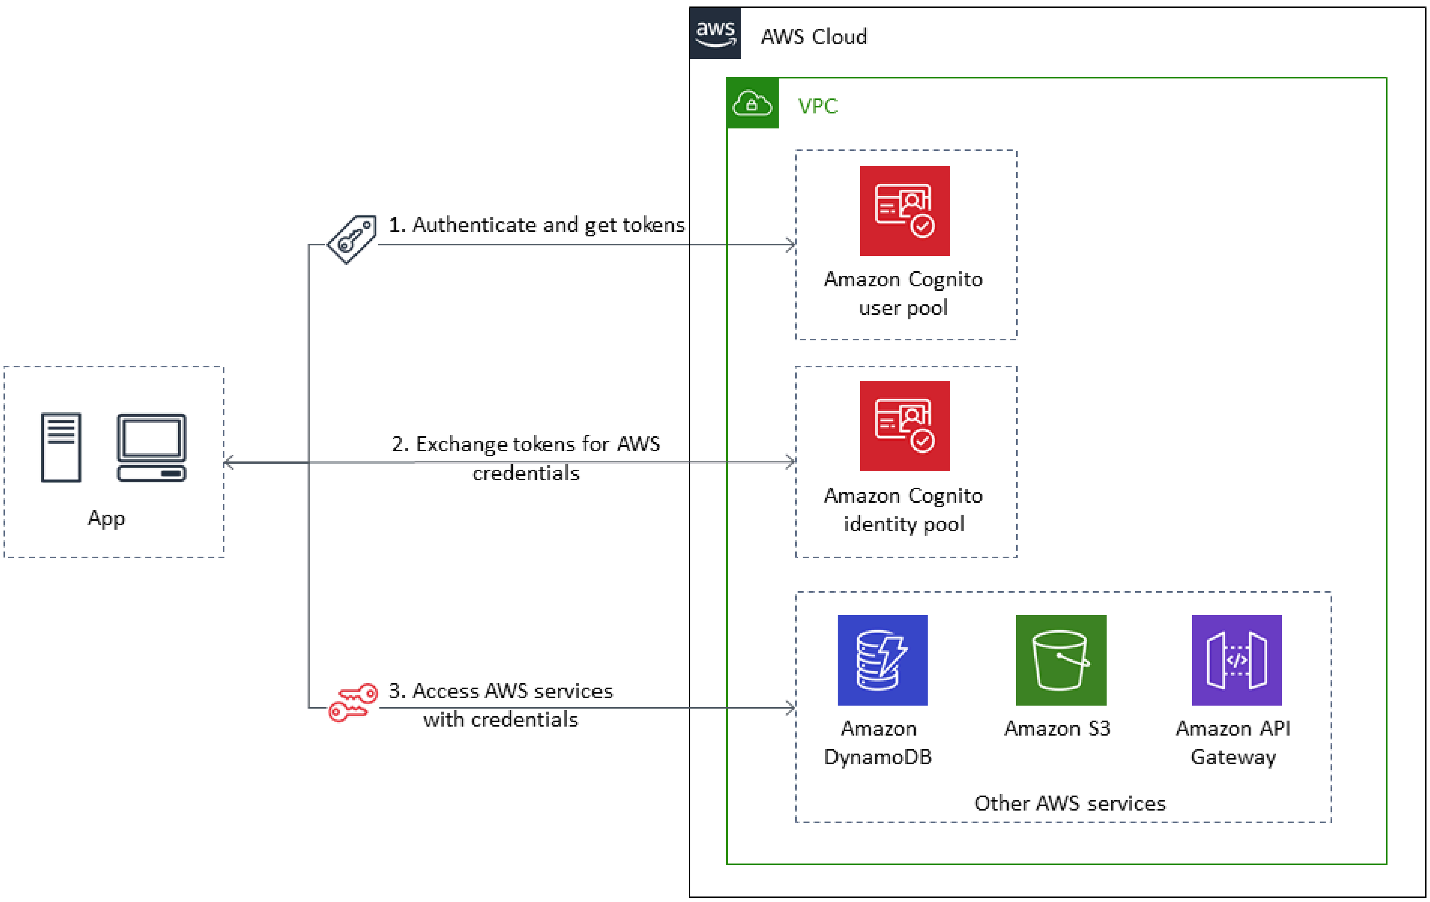
- An AWS account with Amazon Cognito and IAM permissions
- Access to the AWS resources you want to use
- ASP.NET Core 2.0.0 or later

Architecture

Technology stack

- Amazon Cognito
- ASP.NET Core

Target architecture



Tools

Tools, SDKs, and AWS services

- Visual Studio or Visual Studio Code
- Amazon.AspNetCore.Identity.Cognito (1.0.4) – NuGet package
- AWSSDK.S3 (3.3.110.32) – NuGet package
- Amazon Cognito

Code

The attached .zip file includes sample files that illustrate the following:

- How to retrieve an access token for the logged in user
- How to exchange an access token for AWS credentials
- How to access the Amazon Simple Storage Service (Amazon S3) service with AWS credentials

IAM role for authenticated identities

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "mobileanalytics:PutEvents",
        "cognito-sync:*",
        "cognito-identity:*",
        "s3:ListAllMyBuckets*"
      ],
      "Resource": [
        "*"
      ]
    }
  ]
}

Epics

Create an Amazon Cognito user pool

Task	Description	Skills required
Create a user pool.	1. Sign in to the AWS Management Console and open the Amazon Cognito console. 2. Choose **Manage User Pools**.	Developer

Task	Description	Skills required
	3. In the top-right corner of the page, choose **Create a user pool**. 4. Provide a name for your user pool, choose **Review defaults**, and then choose **Create pool**. 5. Note the pool ID.	
Add an app client.	You can create an app to use the built-in webpages for signing up and signing in your users. 1. On the navigation bar on the left side of the user pool page, choose **App clients** under **General settings**, and then choose **Add an app client**. 2. Give your app a name, and then choose **Create app client**. 3. Note the app client ID and the client secret (choose **Show Details** to see the client secret).	Developer

Create an Amazon Cognito identity pool

Task	Description	Skills required
Create an identity pool.	1. On the Amazon Cognito console, choose **Manage**	Developer

Task	Description	Skills required
	Identity Pools, and then choose **Create new identity pool**. 2. Type a name for the identity pool. 3. If you want to enable unauthenticated identities, select that option from the **Unauthenticated identities** section. 4. In the **Authentication providers** section, configure the Amazon Cognito identity pool by setting the user pool ID and the app client ID, and then choose **Create Pool**.	
Assign IAM roles for the identity pool.	You can edit the IAM roles for authenticated and unauthenticated users, or keep the defaults, and then choose **Allow**. For this pattern, we will edit the authenticated IAM role and provide access for `s3:ListAllMyBuckets` . For sample code, see the IAM role provided earlier in the [Tools](#) section.	Developer

Task	Description	Skills required
Copy the identity pool ID.	When you choose **Allow** in the previous step, the **Getting started with Amazon Cognito** page is displayed. On this page, you can either copy the identity pool ID from the **Get AWS Credentials** section or choose **Edit identity pool** in the upper right and copy the identity pool ID from the screen that's displayed.	Developer

Configure your sample app

Task	Description	Skills required
Clone the sample ASP.NET Core web app.	1. Clone the sample .NET core web app from https://github.com/aws/aws-aspnet-cognito-identity-provider.git. 2. Navigate to the `samples` folder and open the solution. In this project, you'll configure the `appsettings.json` file and add a new page that will render all S3 buckets after successful sign in.	Developer
Add dependencies.	Add a NuGet dependency for `Amazon.AspNetCore.Identity.Cognito` to	Developer

Task	Description	Skills required
	your ASP.NET Core applicati on.	
Add the configuration keys and values to `appsettin gs.json` .	Include the code from the attached `appsettin gs.json` file in your `appsettings.json` file, and then replace the placeholders with the values from the previous steps.	Developer
Create a new user and sign in.	Create a new user in the Amazon Cognito user pool, and verify that the user exists under **Users and Groups** in the user pool.	Developer
Create a new Razor Page called `MyS3Buckets` .	Add a new ASP.NET Core Razor Page to your sample app, and replace the content for `MyS3Bucket.cshtml` and `MyS3Bucket.cshtml. cs` from the attached sample. Add the new **MyS3Bucket** page under navigation in the `_Layout.c shtml` page.	Developer

Troubleshooting

Issue	Solution
After you open the sample application from the GitHub repository, you get an error when	In the `src` folder, make sure to remove from the reference to the `Amazon.AspNetCore. Identity.Cognito` project from the

Issue	Solution
you try to add the NuGet package to the Samples project.	`Samples.sln` file. You can then add the NuGet package to the Samples project without any issues.

Authenticate Microsoft SQL Server on Amazon EC2 using AWS Directory Service

Jagadish Kantubugata and Oludahun Bade Ajidahun, Amazon Web Services

Summary

This pattern describes how to create an AWS Directory Service directory and use it to authenticate Microsoft SQL Server on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

AWS Directory Service provides multiple ways to use Amazon Cloud Directory and Microsoft Active Directory (AD) with other AWS services. Directories store information about users, groups, and devices, and administrators use them to manage access to information and resources. AWS Directory Service provides multiple directory choices for users who want to use their existing Microsoft AD or Lightweight Directory Access Protocol (LDAP)–aware applications in the cloud. It also offers those same choices to developers who need a directory to manage users, groups, devices, and access.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a minimum of two private subnets and two public subnets
- An AWS Identity and Access Management (IAM) role to join the server into the domain

Architecture

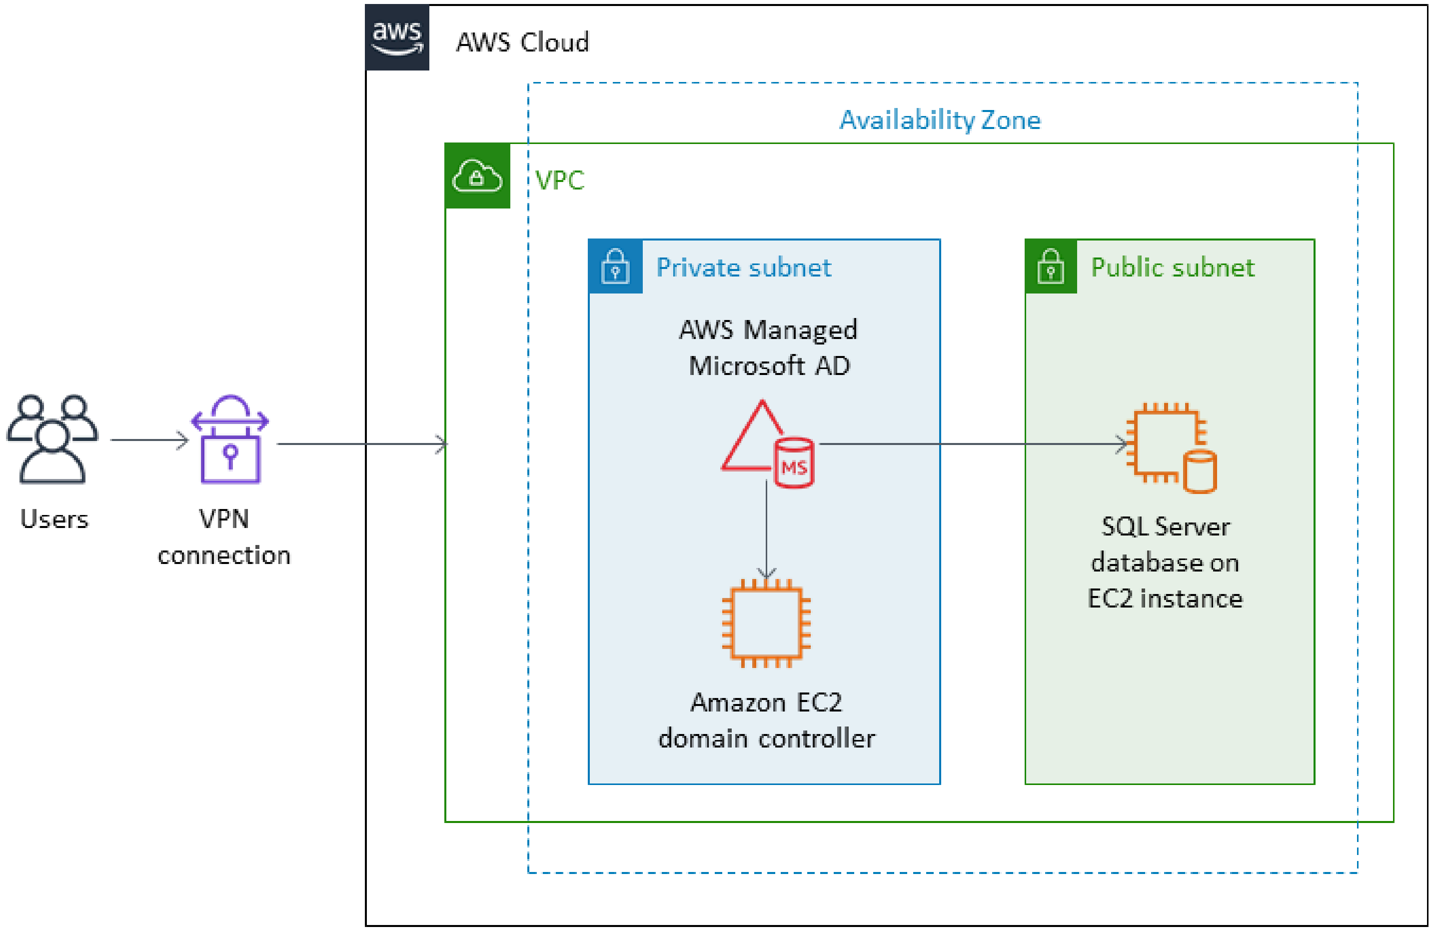
Source technology stack

- The source can be an on-premises Active Directory

Target technology stack

- AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD)

Target architecture



Tools

- SQL Server Management Studio (SSMS) is a tool for managing Microsoft SQL Server, including accessing, configuring, and administering SQL Server components.

Epics

Set up a directory

Task	Description	Skills required
Select AWS Managed Microsoft AD as the directory type.	On the [AWS Directory Service console](), choose **Directori es**, **Set up directory**, **AWS Managed Microsoft AD**, **Next**.	DevOps

Task	Description	Skills required
Select edition.	From the available editions for AWS Managed Microsoft AD, choose **Standard Edition**.	DevOps
Specify the directory DNS name.	Use a fully qualified domain name. This name will resolve inside your VPC only. It does not need to be publicly resolvable.	DevOps
Set the administrator password.	Set the password for the default administrative user, which is named **Admin**.	DevOps
Choose the VPC and subnets.	Choose the VPC that will contain your directory and the subnets for the domain controllers. If you do not have a VPC with at least two subnets, you must create one.	DevOps
Review and launch the directory.	Review the edition and price information for the directory , and then choose **Create directory**.	DevOps

Launch an EC2 instance for SQL Server in the domain

Task	Description	Skills required
Select an AMI for SQL Server.	The steps in this epic seamlessly join a Windows EC2 instance to your AWS Managed Microsoft AD directory.	DevOps, DBA

Task	Description	Skills required
	On the [Amazon EC2 console](https://console.aws.amazon.com/ec2/), choose **Launch instance**, and then select the appropriate Amazon Machine Image (AMI) for SQL Server.	
Configure instance details.	Configure the Windows instance to meet your requirements for SQL Server.	DevOps, DBA
Select the key pair name.	Select a key pair, and then launch the instance.	DevOps, DBA
Add a network.	You can choose the VPC that your directory was created in.	DevOps, DBA
Select an IAM role.	In **Advanced settings**, select an IAM profile that has the AWS managed policies `AmazonSSMManagedInstanceCore` and `AmazonSSMDirectoryServiceAccess` attached to it.	DevOps, DBA
Add a subnet.	Choose one of the public subnets in your VPC. The subnet that you choose must have all external traffic routed to an internet gateway. If this is not the case, you won't be able to connect to the instance remotely.	DevOps, DBA

Task	Description	Skills required
Choose your domain.	Choose the domain that you created from the **Domain join** directory list.	DevOps, DBA
Launch the instance.	Choose **Launch instance**.	DBA

Authenticate SQL Server using Directory Service

Task	Description	Skills required
Log in as a Windows administrator.	Log in to the Windows EC2 instance by using Windows administrator credentials.	DBA
Log in to SQL Server.	Launch SQL Server Management Studio (SSMS) and log in to SQL Server by using the Windows authentic ation method.	DBA
Create a login for the directory user.	In SSMS, choose **Security**, and then choose **New Login**.	DBA
Search for a login name.	Choose the search button next to the login text box.	DBA
Select a location.	In the **Select User or Group** dialog box, choose **Locations**.	DBA
Enter network credentials.	Enter the fully qualified network credentials you used when you created the directory service; for example: `test.com\admin` .	DBA

Task	Description	Skills required
Select the directory.	Choose the AWS directory name, and then choose **OK**.	DBA
Select an object name.	Select the user for which you want to create the login. Select the location, choose the entire directory, search for the user, and add the login.	DBA
Log in to the SQL Server instance.	Log in to the Windows EC2 instance for SQL Server by using your domain credentia ls.	DBA
Log in to SQL Server as a domain user.	Launch SSMS and connect to the database engine by using the Windows authentication method.	DBA

Automate incident response and forensics

Lucas Kauffman and Tomek Jakubowski, Amazon Web Services

Summary

This pattern deploys a set of processes that use AWS Lambda functions to provide the following:

- A way to initiate the incident-response process with minimum knowledge
- Automated, repeatable processes that are aligned with the *AWS Security Incident Response Guide*
- Separation of accounts to operate the automation steps, store artifacts, and create forensic environments

The Automated Incident Response and Forensics framework follows a standard digital forensic process consisting of the following phases:

1. Containment
2. Acquisition
3. Examination
4. Analysis

You can perform investigations on static data (for example, acquired memory or disk images) and on dynamic data that is live but on separated systems.

For more details, see the Additional information section.

Prerequisites and limitations

Prerequisites

- Two AWS accounts:
  - Security account, which can be an existing account, but is preferably new
  - Forensics account, preferably new
- AWS Organizations set up
- In the Organizations member accounts:

  - The Amazon Elastic Compute Cloud (Amazon EC2) role must have Get and List access to Amazon Simple Storage Service (Amazon S3) and be accessible by AWS Systems Manager. We recommend using the `AmazonSSMManagedInstanceCore` AWS managed role. Note that this role will automatically be attached to the Amazon EC2 instance when incident response is initiated. After the response has finished, AWS Identity and Access Management (IAM) will remove all rights to the instance.
  - Virtual private cloud (VPC) endpoints in the AWS member account and in the Incident Response and Analysis VPCs. Those endpoints are: S3 Gateway, EC2 Messages, SSM, and SSM Messages.
- AWS Command Line Interface (AWS CLI) installed on the Amazon EC2 instances. If the Amazon EC2 instances don't have AWS CLI installed, internet access will be required for the disk snapshot and memory acquisition to work. In this case, the scripts will reach out to the internet to download the AWS CLI installation files and will install them on the instances.

Limitations

- This framework does not intend to generate artifacts that can be considered as electronic evidence, submissible in court.
- Currently, this pattern supports only Linux based instances running on x86 architecture.

Architecture

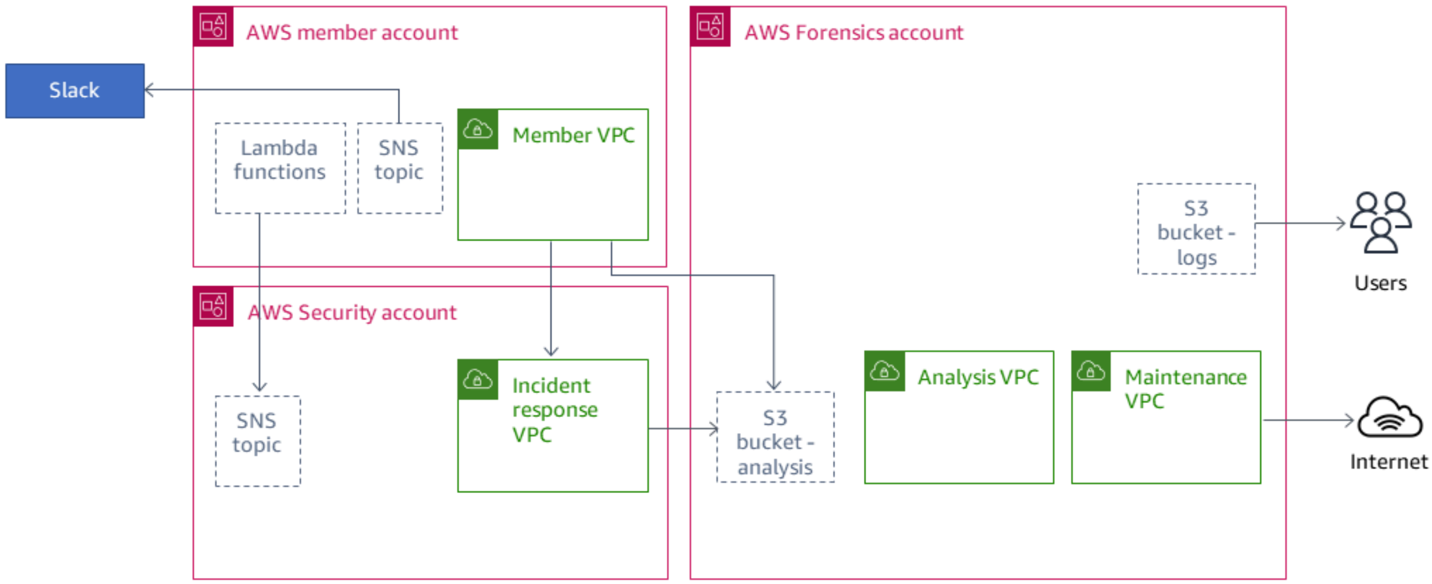
Target architecture

In addition to the member account, the target environment consists of two main accounts: a Security account and a Forensics account. Two accounts are used for the following reasons:

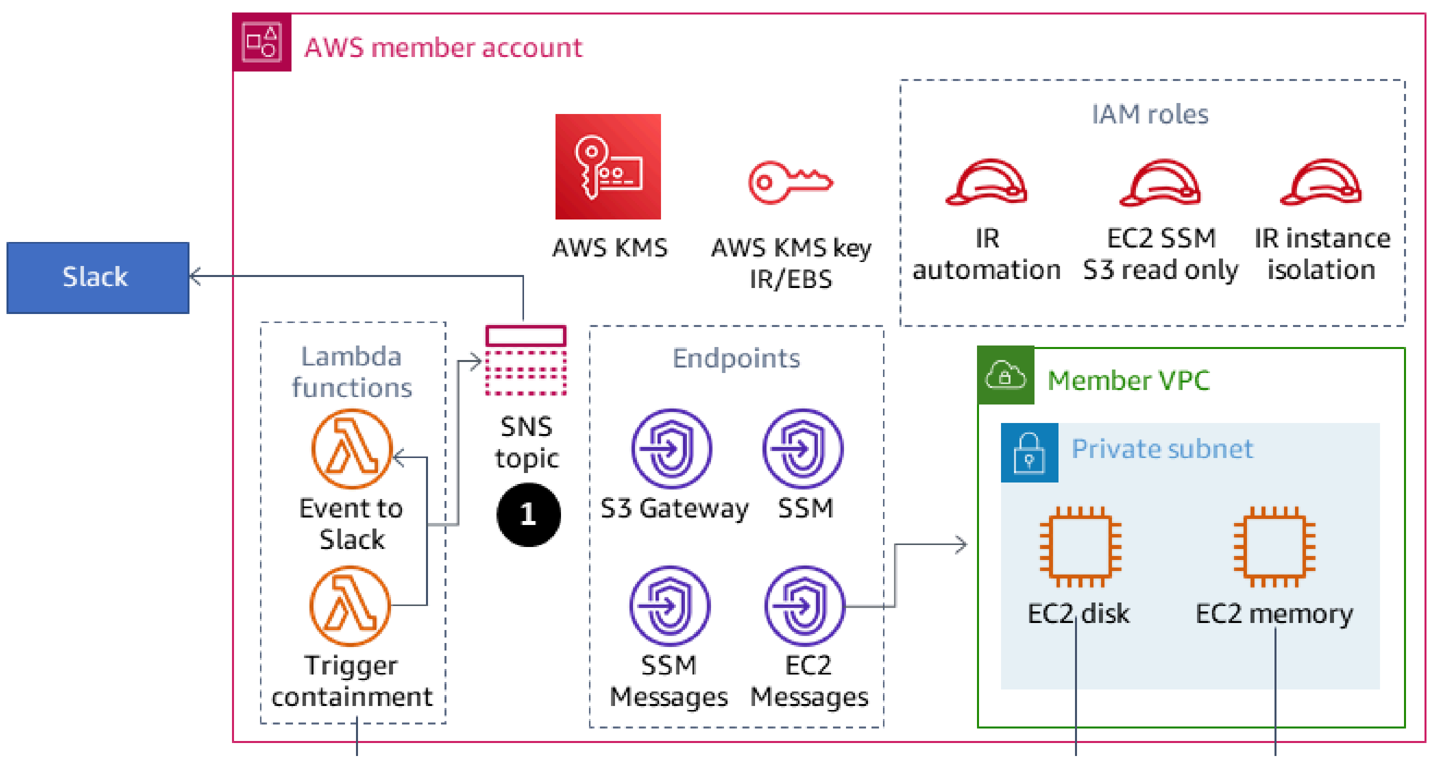
- To separate them from any other customer accounts to reduce blast radius in case of a failed forensic analysis
- To help ensure the isolation and protection of the integrity of the artifacts being analyzed
- To keep the investigation confidential
- To avoid situations where the threat actors might have used all the resources immediately available to your compromised AWS account by hitting service quotas and so preventing you from instantiating an Amazon EC2 instance to perform investigations.

Also, having separate Security and Forensics accounts allows for creating separate roles—a Responder for acquiring evidence and an Investigator for analyzing it. Each role would have access to its separate account.

The following diagram shows only the interaction between the accounts. Details of each account are shown in subsequent diagrams, and a complete diagram is attached.

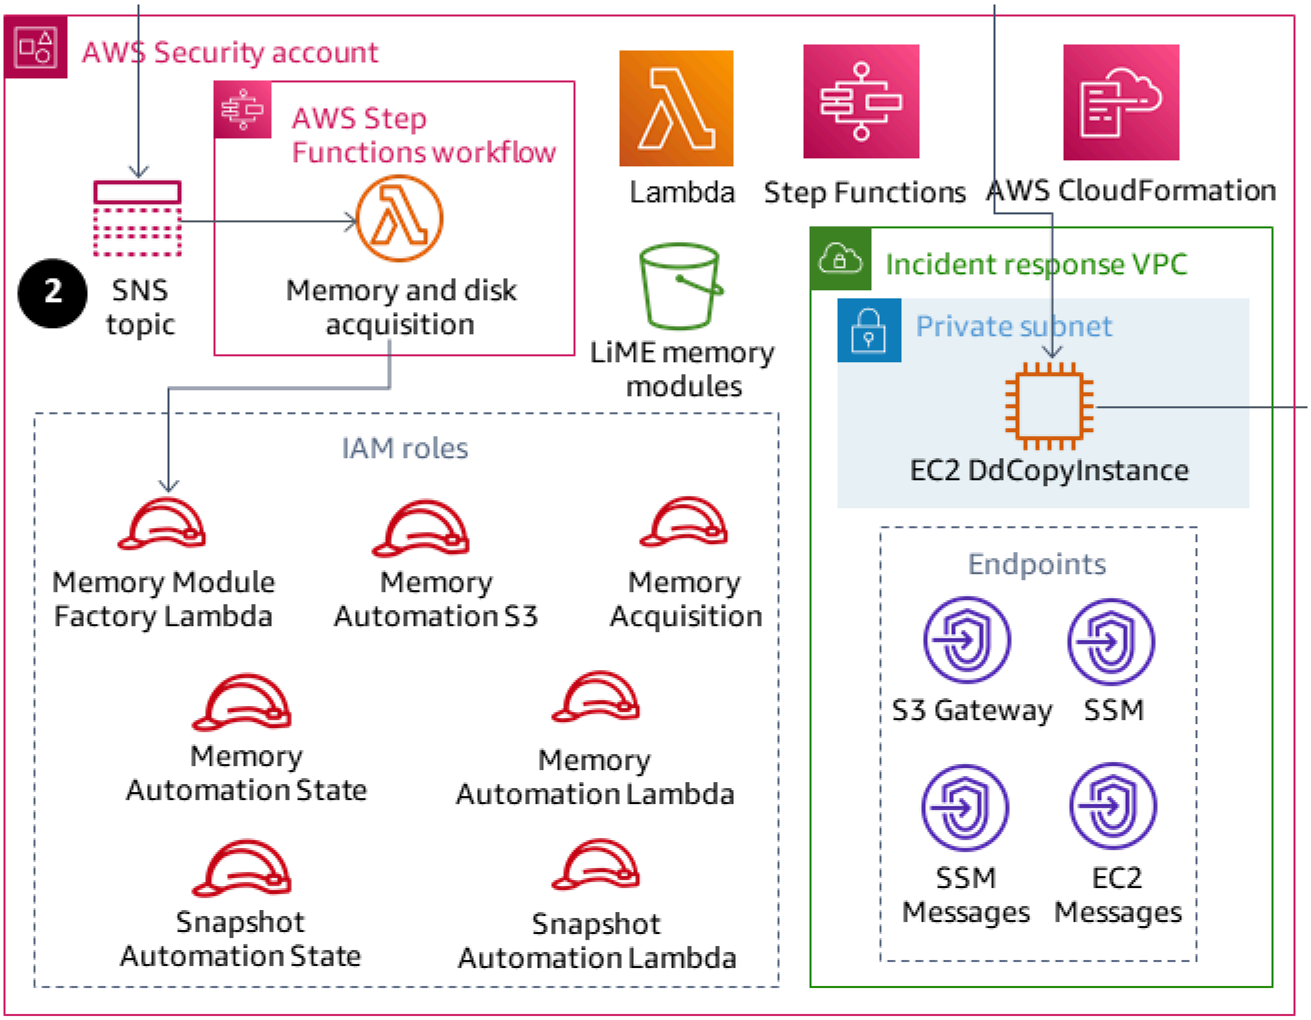


The following diagram shows the member account.



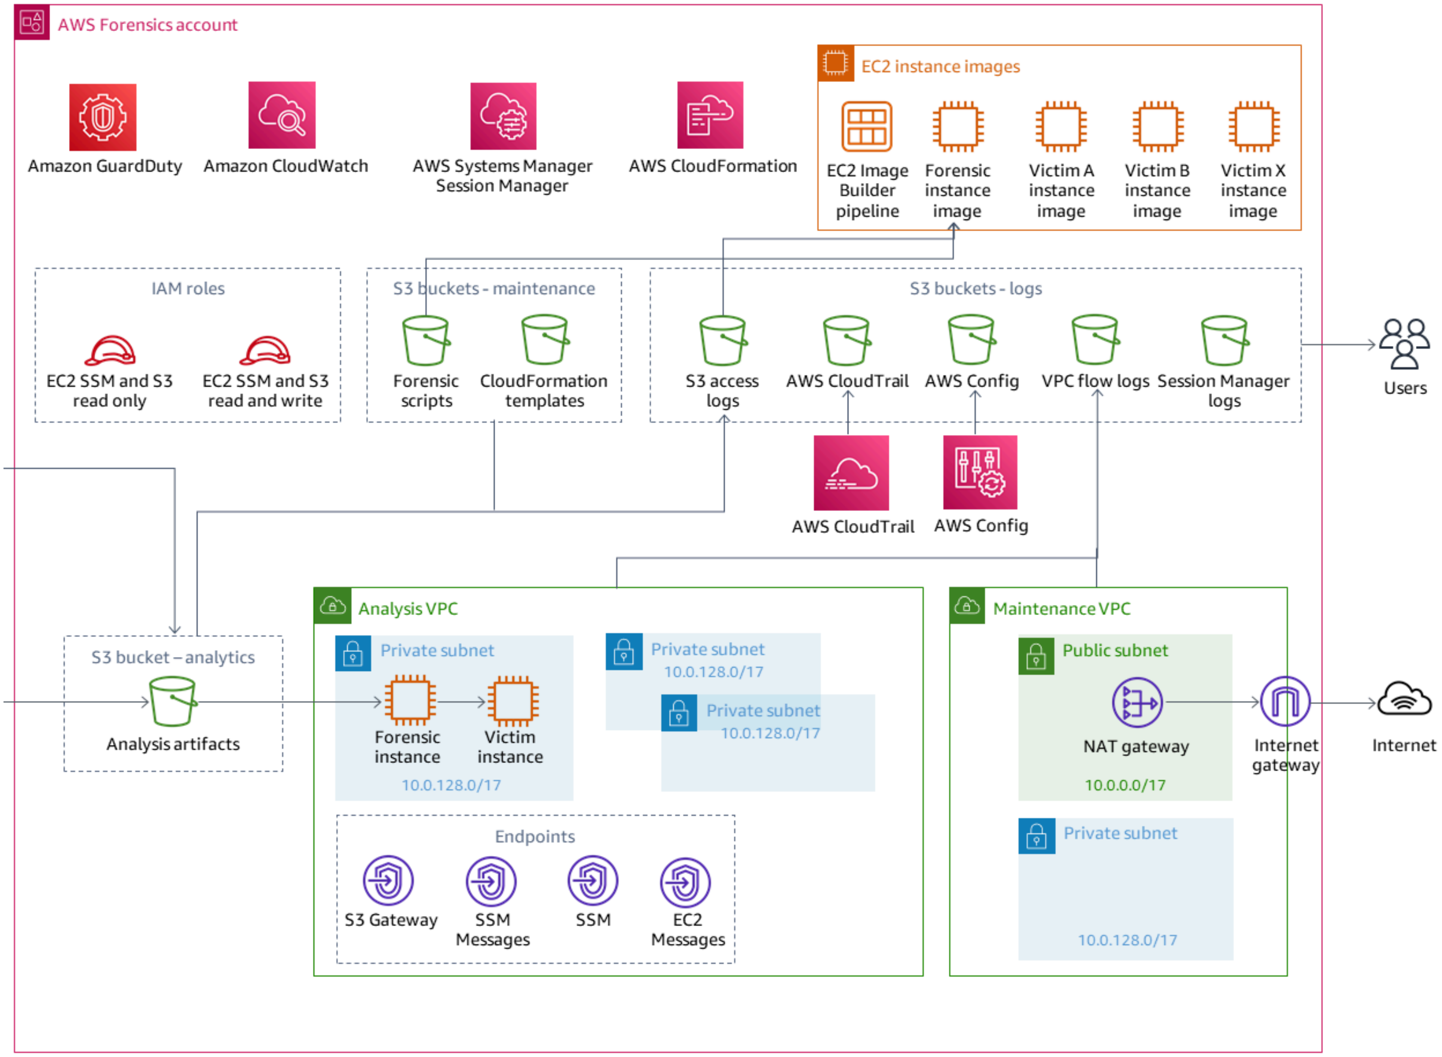
1. An event is sent to the Slack Amazon Simple Notification Service (Amazon SNS) topic.

The following diagram shows the Security account.



2. The Amazon SNS topic in the Security account initiates Forensics events.

The following diagram shows the Forensics account.



The Security account is where the two main AWS Step Functions workflows are created for memory and disk image acquisition. After the workflows are running, they access the member account that has the Amazon EC2 instances involved in an incident, and they initiate a set of Lambda functions that will gather a memory dump or a disk dump. Those artifacts are then stored in the Forensics account.

The Forensics account will hold the artifacts gathered by the Step Functions workflow in the Analysis artifacts Amazon S3 bucket. The Forensics account will also have an Amazon EC2 Image Builder pipeline that builds an Amazon Machine Image (AMI) of a Forensics instance. Currently, the image is based on SANS SIFT Workstation.

The build process uses the Maintenance VPC, which has connectivity to the internet. The image can be later used for spinning up the Amazon EC2 instance for analysis of the gathered artifacts in the Analysis VPC.

The Analysis VPC does not have internet connectivity. By default, the pattern creates three private analysis subnets. You can create up to 200 subnets, which is the quota for the number of subnets in a VPC, but the VPC endpoints need to have those subnets added for AWS Systems Manager Session Manager to automate running commands in them.

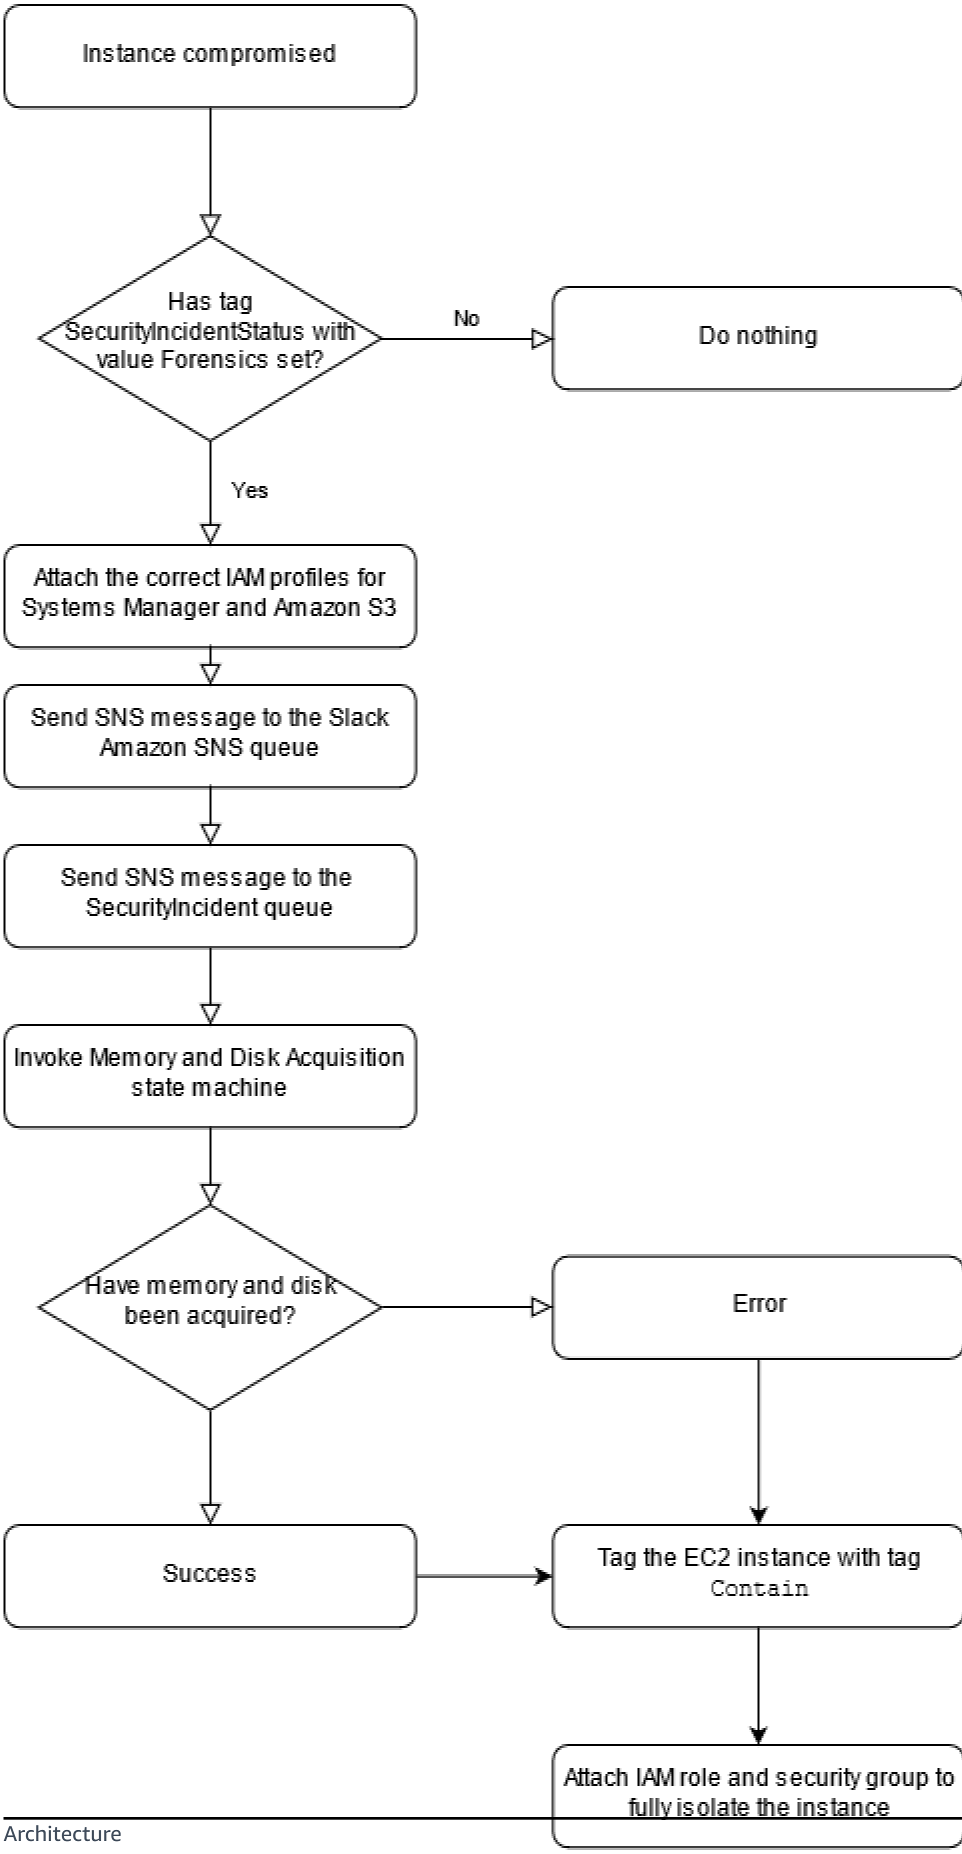
From a best-practices perspective, we recommend using AWS CloudTrail and AWS Config to do the following:

- Track changes made in your Forensics account
- Monitor access and integrity of the artifacts that are stored and analyzed

Workflow

The following diagram shows the key steps of a workflow that includes the process and decision tree from when an instance is compromised until it is analyzed and contained.

1. Has the `SecurityIncidentStatus`tag been set with the value Analyze? If yes, do the following:
   a. Attach the correct IAM profiles for AWS Systems Manager and Amazon S3.
   b. Send an Amazon SNS message to the Amazon SNS queue in Slack.
   c. Send an Amazon SNS message to the `SecurityIncident` queue.
   d. Invoke the Memory and Disk Acquisition state machine.
2. Have memory and disk been acquired? If no, there is an error.
3. Tag the Amazon EC2 instance with the `Contain` tag.
4. Attach the IAM role and security group to fully isolate the instance.



Instance compromised
Has tag SecurityIncidentStatus with value Forensics set?
No
Do nothing
Yes
Attach the correct IAM profiles for Systems Manager and Amazon S3
Send SNS message to the Slack Amazon SNS queue
Send SNS message to the SecurityIncident queue
Invoke Memory and Disk Acquisition state machine
Have memory and disk been acquired?
Error
Success
Tag the EC2 instance with tag Contain
Attach IAM role and security group to fully isolate the instance

Automation and scale

The intent of this pattern is to provide a scalable solution to perform incident response and forensics across several accounts within a single AWS Organizations organization.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Security Hub provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

Code

For the code and specific implementation and usage guidance, see the GitHub Automated Incident Response and Forensics Framework repository.

Epics

Deploy the CloudFormation templates

Task	Description	Skills required
Deploy CloudFormation templates.	The CloudFormation templates are marked 1 through 7 with the first word of the script name indicating in which account the template needs to be deployed. Note that the order of launching the CloudFormation templates is important. • `1-forensic-AnalysisVPCnS3Buckets.yaml` : Deployed in the forensics account. It creates the Amazon S3 buckets and the Analysis VPC, and it activates CloudTrail. • `2-forensic-MaintenanceVPCnEC2ImageBuilderPipeline.yaml` : Deploys the maintenance VPC and image builder pipeline based on SANS SIFT. • `3-security_IR-Disk_Mem_automation.yaml` : Deploys the functions in the security account that	AWS administrator

Task	Description	Skills required
	enable disk and memory acquisition. • `4-security_LiME_Volatility_Factory.yaml` : Initiates a build function to start creating the memory modules based on the given AMI IDs. Note that AMI IDs are different across AWS Regions. Whenever you need new memory modules, you can rerun this script with the new AMI IDs. Consider integrating this with your golden image AMI builder pipelines (if used in your environment). • `5-member-IR-automation.yaml` : Creates the member incident-response automation function, which initiates the incident-response process. It allows sharing Amazon Elastic Block Store (Amazon EBS) volumes across accounts, automated posting to Slack channels during the incident-response process, initiating the forensics process, and isolating the instances after the process finishes.	

Task	Description	Skills required
	• `6-forensic-artifact-s3-policies.yaml` : After all the scripts have been deployed this script fixes the permissions required for all the cross-account interactions. • `7-security-IR-vpc.yaml` : Configures a VPC used for incident response volume processing. To initiate the incident response framework for a specific Amazon EC2 instance, create a tag with the key `SecurityIncidentStatus` and the value `Analyze`. This will initiate the member Lambda function that will automatically start isolation and memory as well as disk acquisition.	

Task	Description	Skills required
Operate the framework.	The Lambda function will also retag the asset at the end (or on failure) with `Contain`. This initiates the containment, which fully isolates the instance with a no INBOUND/OUTBOUND security group and with an IAM role that disallows all access. Follow the steps in the [GitHub repository]().	AWS administrator

Deploy custom Security Hub actions

Task	Description	Skills required
Deploy the custom Security Hub actions by using a CloudFormation template.	To create a custom action so that you can use the dropdown list from Security Hub, deploy the `Modules/SecurityHub Custom Actions/SecurityHubCustomActions.yaml` CloudFormation template. Then modify the `IRAutomation` role in each of the member accounts to allow the Lambda function that runs the action to assume the `IRAutomation` role. For more information, see the [GitHub repository]().	AWS administrator

Related resources

- AWS Security Incident Response Guide

Additional information

By using this environment, a Security Operations Center (SOC) team can improve their security incident response process through the following:

- Having the ability to perform forensics in a segregated environment to avoid accidental compromise of production resources
- Having a standardized, repeatable, automated process to do containment and analysis.
- Giving any account owner or administrator the ability to initiate the incident-response process with the minimal knowledge of how to use tags
- Having a standardized, clean environment for performing incident analysis and forensics without the noise of a larger environment
- Having the ability to create multiple analysis environments in parallel
- Focusing SOC resources on incident response instead of on maintenance and documentation of a cloud forensics environment
- Moving away from a manual process toward an automated one to achieve scalability
- Using CloudFormation templates for consistency and to avoid repeatable tasks

Additionally, you avoid using persistent infrastructure, and you pay for resources when you need them.

Automate remediation for AWS Security Hub standard findings

Chandini Penmetsa and Aromal Raj Jayarajan, Amazon Web Services

Summary

With AWS Security Hub, you can enable checks for standard best practices such as the following:

- AWS Foundational Security Best Practices
- CIS AWS Foundations Benchmark
- Payment Card Industry Data Security Standard (PCI DSS)

Each of these standards has predefined controls. Security Hub checks for the control in a given AWS account and reports the findings.

AWS Security Hub sends all findings to Amazon EventBridge by default. This pattern provides a security control that deploys an EventBridge rule to identify AWS Foundational Security Best Practices standard findings. The rule identifies the following findings for automatic scaling, virtual private clouds (VPCs), Amazon Elastic Block Store (Amazon EBS), and Amazon Relational Database Service (Amazon RDS) from the AWS Foundational Security Best Practices standard:

- [AutoScaling.1] Auto Scaling groups associated with a load balancer should use load balancer health checks
- [EC2.2] The VPC default security group should not allow inbound and outbound traffic
- [EC2.6] VPC flow logging should be enabled in all VPCs
- [EC2.7] EBS default encryption should be enabled
- [RDS.1] RDS snapshots should be private
- [RDS.6] Enhanced monitoring should be configured for RDS DB instances and clusters
- [RDS.7] RDS clusters should have deletion protection enabled

The EventBridge rule forwards these findings to an AWS Lambda function, which remediates the finding. The Lambda function then sends a notification with remediation information to an Amazon Simple Notification Service (Amazon SNS) topic.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An email address where you want to receive the remediation notification
- Security Hub and AWS Config enabled in the AWS Region where you intend to deploy the control
- An Amazon Simple Storage Service (Amazon S3) bucket in same Region as the control to upload the AWS Lambda code

Limitations

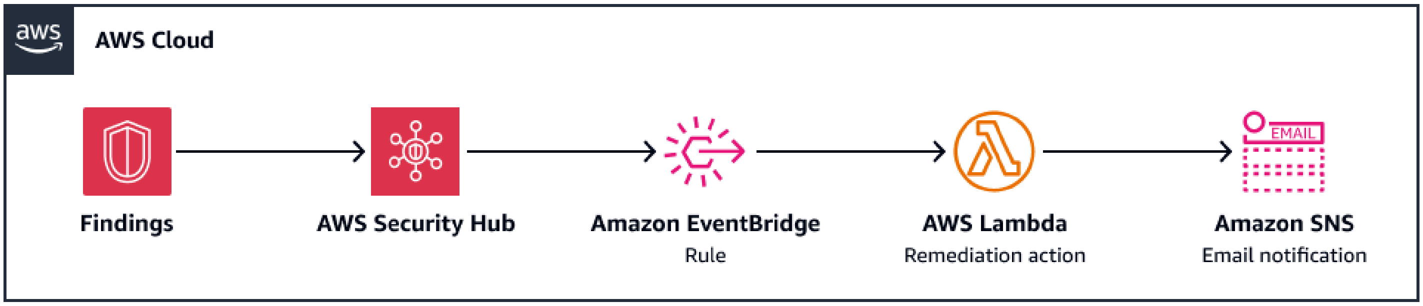
- This security control automatically remediates new findings reported after the security control deployment. To remediate existing findings, select the findings manually on the Security Hub console. Then, under **Actions**, select the **AFSBPRemedy** custom action that was created as part of the deployment by AWS CloudFormation.
- This security control is regional and must be deployed in the AWS Regions that you intend to monitor.
- For the EC2.6 remedy, to enable VPC Flow Logs, an Amazon CloudWatch Logs log group will be created with `/VpcFlowLogs/vpc_id` format. If a log group exists with same name, the existing log group will be used.
- For the EC2.7 remedy, to enable Amazon EBS default encryption, the default AWS Key Management Service (AWS KMS) key is used. This change prevents the use of certain instances that do not support encryption.

Architecture

Target technology stack

- Lambda function
- Amazon SNS topic
- EventBridge rule
- AWS Identity and Access Management (IAM) roles for the Lambda function, VPC Flow Logs, and Amazon RDS Enhanced Monitoring

Target architecture



Automation and scale

If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts that you want this to monitor.

Tools

- AWS CloudFormation is a service that helps you model and set up AWS resources by using infrastructure as code.
- Amazon EventBridge delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services, routing that data to targets such as Lambda functions.
- AWS Lambda supports running code without provisioning or managing servers.
- Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Best practices

- Nine AWS Security Hub best practices
- AWS Foundational Security Best Practices standard

Epics

Deploy the security control

Task	Description	Skills required
Define the Amazon S3 bucket.	On the Amazon S3 console, choose or create an Amazon S3 bucket with a unique name that does not contain leading slashes. An Amazon S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. Your Amazon S3 bucket must be in the same Region as the Security Hub findings that are being evaluated.	Cloud Architect
Upload the Lambda code to the Amazon S3 bucket.	Upload the Lambda code .zip file that's provided in the "Attachments" section to the defined Amazon S3 bucket.	Cloud Architect
Deploy the AWS CloudFormation template.	Deploy the AWS CloudFormation template that's provided as an attachment to this pattern. In the next epic, provide the values for the parameters.	Cloud Architect

Complete the parameters in the AWS CloudFormation template

Task	Description	Skills required
Provide the Amazon S3 bucket name.	Enter the name of the Amazon S3 bucket that you created in the first epic.	Cloud Architect
Provide the Amazon S3 prefix.	Provide the location of the Lambda code .zip file in your Amazon S3 bucket, without leading slashes (for example, `<directory>/<file-name>.zip`).	Cloud Architect
Provide the ARN of the Amazon SNS topic.	If you want to use an existing Amazon SNS topic for remediation notifications, provide the Amazon Resource Name (ARN) of the Amazon SNS topic. If you want to use a new Amazon SNS topic, keep the value as None (the default value).	Cloud Architect
Provide an email address.	Provide an email address where you want to receive the remediation notifications (needed only when you want AWS CloudFormation to create the Amazon SNS topic).	Cloud Architect
Define the logging level.	Define the logging level and frequency for your Lambda function. `Info` designates detailed informational messages on the application's	Cloud Architect

Task	Description	Skills required
	progress. `Error` designates error events that could still allow the application to continue running. `Warning` designates potentially harmful situations.	
Provide the ARN of the IAM role for VPC Flow Logs.	Provide the ARN of the IAM role to be used for VPC Flow Logs. If you enter `None`, AWS CloudFormation creates an IAM role and uses it.	Cloud Architect
Provide the ARN of the IAM role for Amazon RDS Enhanced Monitoring.	Provide the ARN of the IAM role to be used for Amazon RDS Enhanced Monitoring. If you enter `None`, AWS CloudFormation creates an IAM role and uses it.	Cloud Architect

Confirm the subscription

Task	Description	Skills required
Confirm the Amazon SNS subscription.	When the template successfully deploys, if a new Amazon SNS topic was created, a subscription message is sent to the email address that you provided. To receive remediation notifications, you must confirm this subscription email message.	Cloud Architect

Automate security scans for cross-account workloads using Amazon Inspector and AWS Security Hub

Ramya Pulipaka and Mikesh Khanal, Amazon Web Services

Summary

This pattern describes how to automatically scan for vulnerabilities in cross-account workloads on the Amazon Web Services (AWS) Cloud.

The pattern helps create a schedule for host-based scans of Amazon Elastic Compute Cloud (Amazon EC2) instances that are grouped by tags or for network-based Amazon Inspector scans. An AWS CloudFormation stack deploys all the required AWS resources and services to your AWS accounts.

The Amazon Inspector findings are exported to AWS Security Hub and provide insights into vulnerabilities across your accounts, AWS Regions, virtual private clouds (VPCs), and Amazon EC2 instances. You can receive these findings by email or you can create an Amazon Simple Notification Service (Amazon SNS) topic that uses an HTTP endpoint to send the findings to ticketing tools, security information and event management (SIEM) software, or other third-party security solutions.

Prerequisites and limitations

Prerequisites

- Active AWS accounts that host cross-account workloads, including a central audit account.
- An existing email address to receive email notifications from Amazon SNS.
- An existing HTTP endpoint used by ticketing tools, SIEM software, or other third-party security solutions.
- Security Hub, enabled and configured. You can use this pattern without Security Hub, but we recommend using Security Hub because of the insights it generates. For more information, see [Setting up Security Hub] in the Security Hub documentation.
- An Amazon Inspector agent must be installed on each EC2 instance that you want to scan. You can install the Amazon Inspector agent on multiple EC2 instances by using [AWS Systems Manager Run Command].

Skills

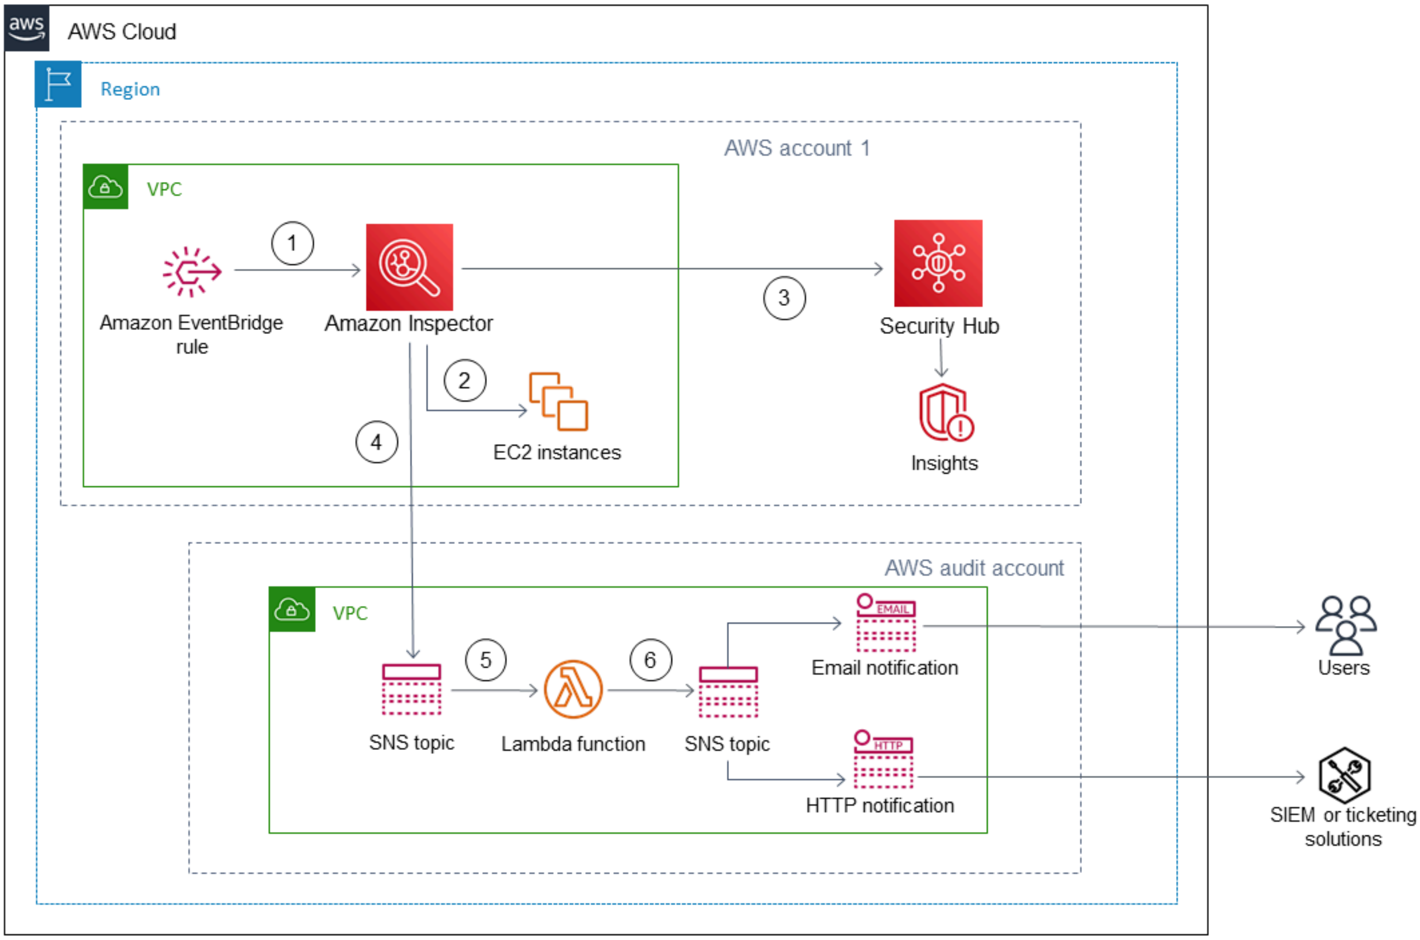
- Experience using `self-managed` and `service-managed` permissions for stack sets in CloudFormation. If you want to use `self-managed` permissions to deploy stack instances to specific accounts in specific Regions, you must create the required AWS Identity and Access Management (IAM) roles. If you want to use `service-managed` permissions to deploy stack instances to accounts managed by AWS Organizations in specific Regions, you don't need to create the required IAM roles. For more information, see [Create a stack set](#) in the CloudFormation documentation.

Limitations

- If no tags are applied to Amazon EC2 instances in an account, then Amazon Inspector scans all the instances in that account.
- The CloudFormation stack sets and the `onboard-audit-account.yaml` file (attached) must be deployed in the same Region.
- This pattern's approach can scale under the publish quota of 30,000 transactions per second (TPS) for an Amazon SNS topic in the US East (N. Virginia) Region (`us-east-1`), although limits vary by Region. To scale more effectively and avoid data loss, we recommend using Amazon Simple Queue Service (Amazon SQS) in front of the Amazon SNS topic.

Architecture

The following diagram illustrates the workflow for automatically scanning Amazon EC2 instances.



The workflow consists of the following steps:

1. An Amazon EventBridge rule uses a cron expression to self-initiate on a specific schedule and initiates Amazon Inspector.
2. Amazon Inspector scans the tagged Amazon EC2 instances in the account.
3. Amazon Inspector sends the findings to Security Hub, which generates insights for workflow, prioritization, and remediation.
4. Amazon Inspector also sends the assessment's status to an Amazon SNS topic in the audit account. An AWS Lambda function is invoked if a `findings reported` event is published to the Amazon SNS topic.
5. The Lambda function fetches, formats, and sends the findings to another Amazon SNS topic in the audit account.
6. Findings are sent to the email addresses that are subscribed to the Amazon SNS topic. The full details and recommendations are sent in JSON format to the subscribed HTTP endpoint.

Tools

- [AWS CloudFormation] helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications.
- AWS CloudFormation StackSets extends the functionality of stacks by enabling you to create, update, or delete stacks across multiple accounts and Regions with a single operation.
- AWS Control Tower creates an abstraction or orchestration layer that combines and integrates the capabilities of several other AWS services, including AWS Organizations.
- Amazon EventBridge is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources.
- AWS Lambda is a compute service that helps you run code without provisioning or managing servers.
- AWS Security Hub provides you with a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices.
- Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.

Epics

Deploy the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template in the audit account.	Download and save the `onboard-audit-account.yaml` file (attached) to a local path on your computer. Sign in to the AWS Management Console for your audit account, open the CloudFormation console, and then choose **Create stack**.	Developer, Security engineer

Task	Description	Skills required
	Choose **Prepare template** in the **Prerequisites** section, and then choose **Template is ready**. Choose **Template source** in the **Specify template** section, and then choose **Template is ready**. Upload the `onboard-audit-account.yaml` file and then configure the remaining options according to your requirements. Make sure that you configure the following input parameters: • `DestinationEmailAddress` – Enter an email address to receive findings. • `HTTPEndpoint` – Provide an HTTP endpoint for your ticketing or SIEM tools. **Note** You can also deploy the CloudFormation template by using AWS Command Line Interface (AWS CLI). For more information about this, see [Creating a stack](#) in	

Task	Description	Skills required
	the CloudFormation documentation.	
Confirm the Amazon SNS subscription.	Open your email inbox and choose **Confirm subscription** in the email that you receive from Amazon SNS. This opens a web browser window and displays the subscription confirmation.	Developer, Security engineer

Create CloudFormation stack sets to automate the Amazon Inspector scan schedule

Task	Description	Skills required
Create stack sets in the audit account.	Download the `vulnerability-management-program.yaml` file (attached) to a local path on your computer. On the [CloudFormation console](https://console.aws.amazon.com/cloudformation/), choose **View stacksets** and then choose **Create StackSet**. Choose **Template is ready**, choose **Upload a template file**, and then upload the `vulnerability-management-program.yaml` file. If you want to use `self-managed` permissions,	Developer, Security engineer

Task	Description	Skills required
	follow the instructions from Create a stack set with self-managed permissions in the CloudFormation documentation. This creates stack sets in individual accounts. If you want to use `service-managed` permissions, follow the instructions from Create a stack set with service-managed permissions in the CloudFormation documentation. This creates stack sets in your entire organization or specified organizational units (OUs). Make sure that the following input parameters are configured for your stack sets: • `AssessmentSchedule` – The schedule for EventBridge using cron expressions. • `Duration` – The duration of the Amazon Inspector assessment run in seconds. • `CentralSNSTopicArn` – The Amazon Resource Name (ARN) for the central Amazon SNS topic.	

Task	Description	Skills required
	• `Tagkey` – The tag key that is associated with the resource group. • `Tagvalue` – The tag value that is associated with the resource group. If you want to scan Amazon EC2 instances in the audit account, you must run the `vulnerability-management-program.yaml` file as a CloudFormation stack in the audit account.	
Validate the solution.	Check that you receive findings by email or HTTP endpoint on the schedule that you specified for Amazon Inspector.	Developer, Security engineer

Automatically audit AWS security groups that allow access from public IP addresses

Eugene Shifer and Stephen DiCato, Amazon Web Services

Summary

As a security best practice, it's crucial to minimize the exposure of AWS resources to only what is absolutely necessary. For example, web servers that serve the general public need to allow inbound access from the internet, but access to other workloads should be restricted to specific networks to reduce unnecessary exposure. Security groups in Amazon Virtual Private Cloud (Amazon VPC) are an effective control to help you limit resource access. However, evaluating security groups can be a cumbersome task, especially in multi-account architectures. AWS Config rules and AWS Security Hub controls can help you identify security groups that permit access from the public internet (0.0.0.0/0) to specific network communication protocols, such as Secure Shell (SSH), HTTP, HTTPS, and Windows remote desktop protocol (RDP). However, these rules and controls are not applicable if services run on non-standard ports or if access is restricted to certain public IP addresses. For instance, this might occur when a web service is associated with TCP port 8443 instead of the standard TCP port 443. This might also occur when developers have access to the server from their home networks, such as for testing purposes.

To address this, you can use the infrastructure as code (IaC) solution provided in this pattern to identify security groups that allow access from any non-private (RFC 1918 noncompliant) IP addresses to any workload in your AWS account or AWS organization. The AWS CloudFormation template provisions a custom AWS Config rule, an AWS Lambda function, and the necessary permissions. You can deploy it as a stack in a single account or as a stack set across the entire organization, managed through AWS Organizations.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Experience using GitHub
- If you're deploying into a single AWS account:
  - Permissions to create CloudFormation stacks

  - AWS Config set up in the target account
  - (Optional) Security Hub set up in the target account
- If you're deploying into an AWS organization:
  - Permissions to create CloudFormation stack sets
  - Security Hub set up with AWS Organizations integration
  - AWS Config set up in the accounts where you are deploying this solution
  - Designate an AWS account to be the delegated administrator for AWS Config and Security Hub

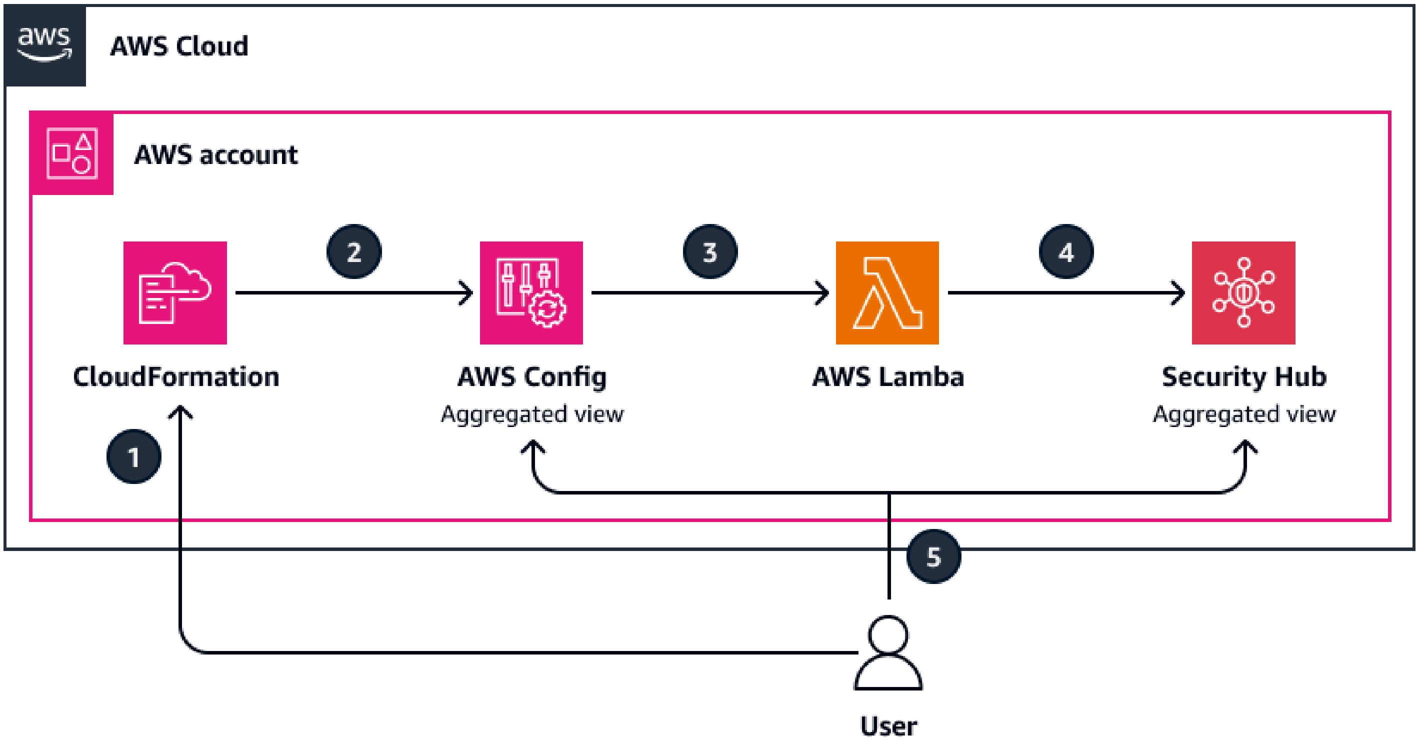
Limitations

- If you're deploying to an individual account that doesn't have Security Hub enabled, you can use AWS Config to evaluate the findings.
- If you're deploying to an organization that doesn't have a delegated administrator for AWS Config and Security Hub, you must log into the individual member accounts to view the findings.
- If you use AWS Control Tower to manage and govern the accounts in your organization, deploy the IaC in this pattern by using Customizations for AWS Control Tower (CfCT). Using the CloudFormation console would create configuration drift from AWS Control Tower guardrails and require that you re-enroll the organizational units (OUs) or managed accounts.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

Deploying into an individual AWS account

The following architecture diagram shows the deployment of the AWS resources within a single AWS account. You provision the resources by using a CloudFormation template directly through the CloudFormation console. If Security Hub is enabled, you can view the results in either AWS Config or Security Hub. If Security Hub is not enabled, you can view the results only in AWS Config.

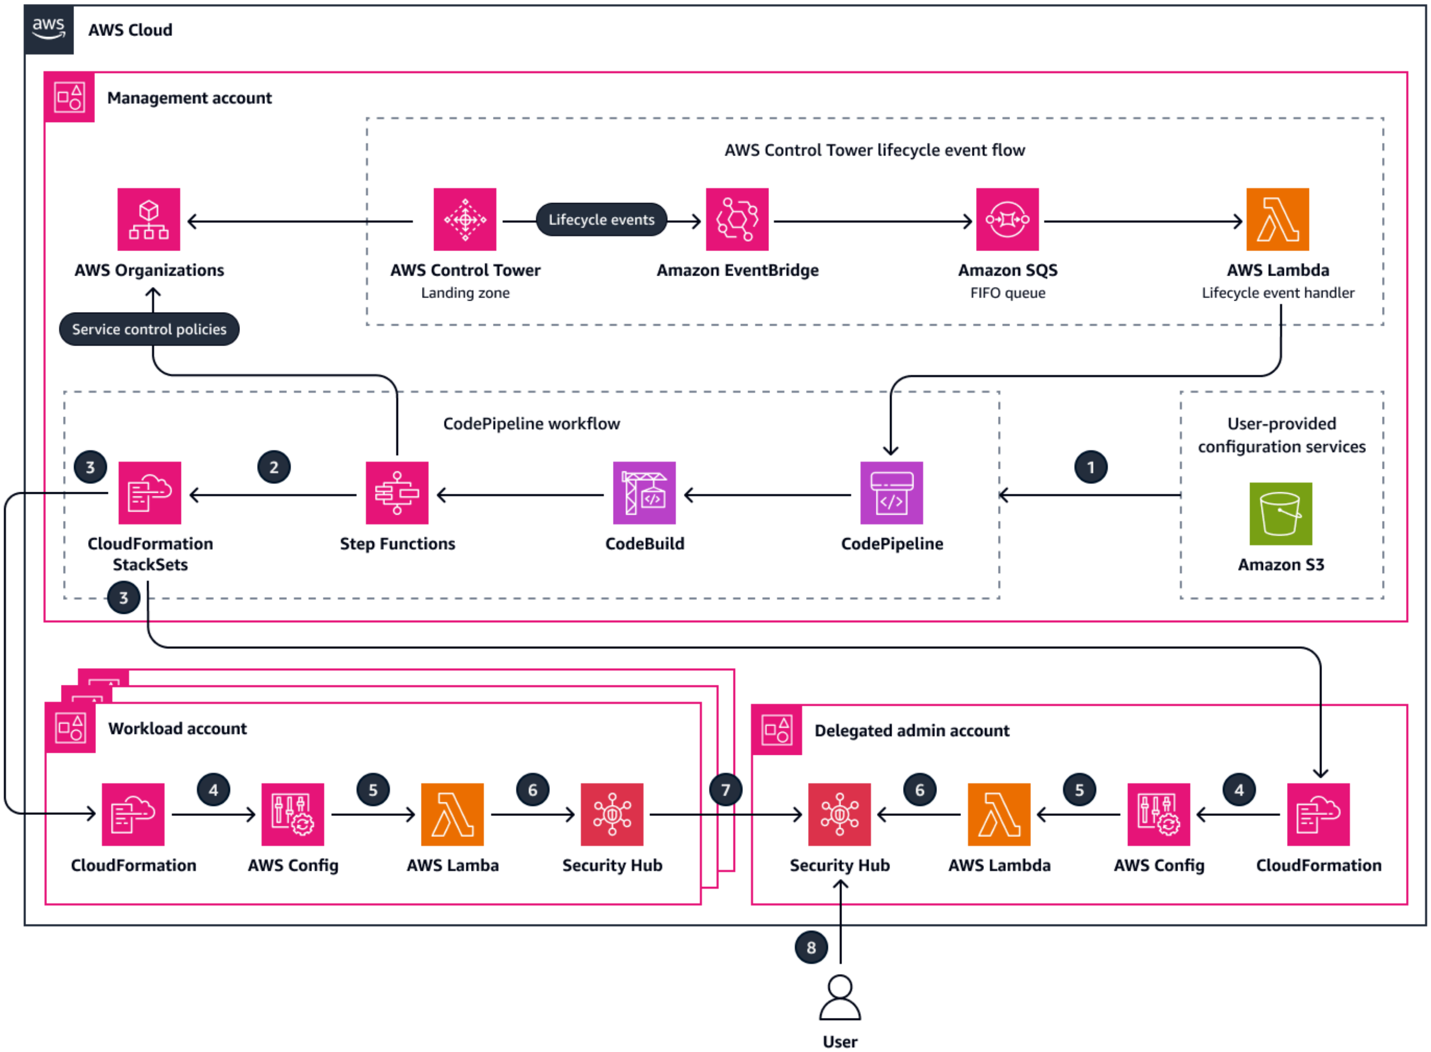


The diagram shows the following workflow:

1. You create a CloudFormation stack. This deploys a Lambda function and an AWS Config rule. Both the rule and function are set up with the AWS Identity and Access Management (IAM) permissions that are required to publish resource evaluations in AWS Config and logs.
2. The AWS Config rule operates in [detective evaluation mode](#) and invokes the Lambda function every 24 hours.
3. The Lambda function assesses the security groups and sends updates to AWS Config.
4. Security Hub receives all of the AWS Config findings.
5. You can view the findings in Security Hub or in AWS Config, depending on the services that you have set up in the account.

Deploying into an AWS organization

The following diagram shows deployment of the pattern across multiple accounts that are managed through AWS Organizations and AWS Control Tower. You deploy the CloudFormation template through CfCT. The assessment outcomes are centralized in Security Hub in the delegated administrator account. The AWS CodePipeline workflow section of the diagram shows the background steps that occur during CfCT deployment.



The diagram shows the following workflow:

1. In the management account, you upload a compressed (ZIP) file of the IaC template to an Amazon Simple Storage Service (Amazon S3) bucket that is deployed by CfCT.
2. The CfCT pipeline unzips the file, runs cfn-nag (GitHub) checks, and deploys the template as a CloudFormation stack set.
3. Depending on the configuration you specify in the CfCT manifest file, CloudFormation StackSets deploys stacks into individual accounts or specified OUs. This deploys a Lambda function and an AWS Config rule in the target accounts. Both the rule and function are set up with the IAM permissions that are required to publish resource evaluations in AWS Config and logs.
4. The AWS Config rule operates in detective evaluation mode and invokes the Lambda function every 24 hours.
5. The Lambda function assesses the security groups and sends updates to AWS Config.

6. AWS Config forwards all of the findings to Security Hub.
7. The Security Hub findings are aggregated in the delegated administrator account.
8. You can view the aggregated findings in Security Hub in the delegated administrator account.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time. An AWS Config rule defines your ideal configuration settings for a resource, and AWS Config can evaluate whether your AWS resources comply with the conditions in the rule.
- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices. Customizations for AWS Control Tower (CfCT) helps you customize your AWS Control Tower landing zone and stay aligned with AWS best practices. Customizations for this solution are implemented through CloudFormation templates and AWS Organizations service control policies (SCPs).
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Security Hub provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.

Other tools

- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub Detect vulnerable security groups repository.

Best practices

We recommend that you adhere to the best practices in the following resources:

- Best Practices for Organizational Units with AWS Organizations (AWS Cloud Operations & Migrations Blog)
- Guidance for Establishing an Initial Foundation using AWS Control Tower on AWS (AWS Solutions Library)
- Guidance for creating and modifying AWS Control Tower resources (AWS Control Tower documentation)
- CfCT deployment considerations (AWS Control Tower documentation)
- Apply least-privilege permissions (IAM documentation)

Epics

Review the CloudFormation template

Task	Description	Skills required
Determine your deployment strategy.	Review the solution and code to determine the deploymen t strategy for your AWS environment. Determine whether you are deploying into a single account or an AWS organization.	App owner, General AWS
Clone the repository.	Enter the following command to clone the Detect vulnerabl e security groups repository: `git clone https://github.com/aws-samples/detect-public-security-groups.git`	App developer, App owner

Task	Description	Skills required
Validate the Python version.	1. Navigate into the top-level directory in the cloned repository: `cd detect-public-security-groups` 2. Open **Security-Group-Public-Assessment.yaml**. 3. In the `SgPublicAccessCheckLambdaFunction` resource, confirm that the Python version is compatible with your target AWS Regions. By default, this function uses Python 3.12. For more information, see [AWS Lambda adds support for Python 3.12](). If necessary, update the Python version. 4. Save and close **Security-Group-Public-Assessment.yaml**.	AWS administrator, App developer

Deploy the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	Deploy the CloudFormation template into your AWS environment. Do one of the following:	App developer, AWS administrator, General AWS

Task	Description	Skills required
	• If you're deploying to a single AWS account, follow the instructions in Creating a stack. • If you're deploying to an organization that isn't managed by AWS Control Tower, follow the instructions in Create a stack set. • If you're deploying to an organization that is managed by AWS Control Tower, see the instructions in the Build your own customizations.	
Verify the deployment.	In the CloudFormation console, verify that the stack or stack set has deployed successfully.	AWS administrator, App owner

Review the findings

Task	Description	Skills required
View the AWS Config rule findings.	In Security Hub, do the following to view a list of individual findings: 1. Open the Security Hub console. 2. In the navigation pane, choose **Findings**.	AWS administrator, AWS systems administrator, Cloud administrator

Task	Description	Skills required
	3. In the **Add filters** box, add the following filters: • **Compliance Status** is `FAILED` • **Title** is `SgPublicAccessCheck` 4. Choose **Apply**. In Security Hub, do the following to view a list of total findings grouped by AWS account: 1. Open the [Security Hub console](https://console.aws.amazon.com/securityhub/). 2. In the navigation pane, choose **Insights**. 3. Choose **Create insight**. 4. To select the grouping attribute for the insight: a. Choose the search box to display the filter options. b. Choose **Group by**. c. Select **AwsAccountId**. d. Choose **Apply**. 5. In the **Add filters** box, add the following filters: • **Title** is `SgPublicAccessCheck` • **Compliance Status** is `FAILED`	

Task	Description	Skills required
	6. Choose **Create insight**. 7. Enter an **Insight name**, and then choose **Create insight**. In AWS Config, to view a list of findings, follow the instructions in [Viewing Compliance Information and Evaluation Results]() in the AWS Config documentation.	

Troubleshooting

Issue	Solution
The CloudFormation stack set creation or deletion fails.	When AWS Control Tower is deployed, it enforces necessary guardrails and assumes control over AWS Config aggregators and rules. This includes preventing any direct alterations through CloudFormation. To properly deploy or remove this CloudFormation template, including all associated resources, you must use CfCT.
CfCT fails to delete the CloudFormation template.	If the CloudFormation template persists even after making necessary changes in the manifest file and removing the template files, confirm that the manifest file contains the `enable_stack_set_deletion` parameter and that the value is set to `false`. For more information, see [Delete a stack set]() in the CfCT documentation.

Automatically re-enable AWS CloudTrail by using a custom remediation rule in AWS Config

Manigandan Shri, Amazon Web Services

Summary

Visibility over activity in your Amazon Web Services (AWS) account is an important security and operational best practice. AWS CloudTrail helps you with the governance, compliance, and operational and risk auditing of your account.

To ensure that CloudTrail remains enabled in your account, AWS Config provides the `cloudtrail-enabled` managed rule. If CloudTrail is turned off, the `cloudtrail-enabled` rule automatically re-enables it by using automatic remediation.

However, you must make sure that you follow security best practices for CloudTrail if you use automatic remediation. These best practices include enabling CloudTrail in all AWS Regions, logging read and write workloads, enabling insights, and encrypting log files with server-side encryption using AWS Key Management Service (AWS KMS) managed keys (SSE-KMS).

This pattern helps you follow these security best practices by providing a custom remediation action to automatically re-enable CloudTrail in your account.

Important

We recommend using service control policies (SCPs) to prevent any tampering with CloudTrail. For more information about this, see the *Prevent tampering with AWS CloudTrail* section of How to use AWS Organizations to simplify security at enormous scale on the AWS Security Blog.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Permissions to create an AWS Systems Manager Automation runbook

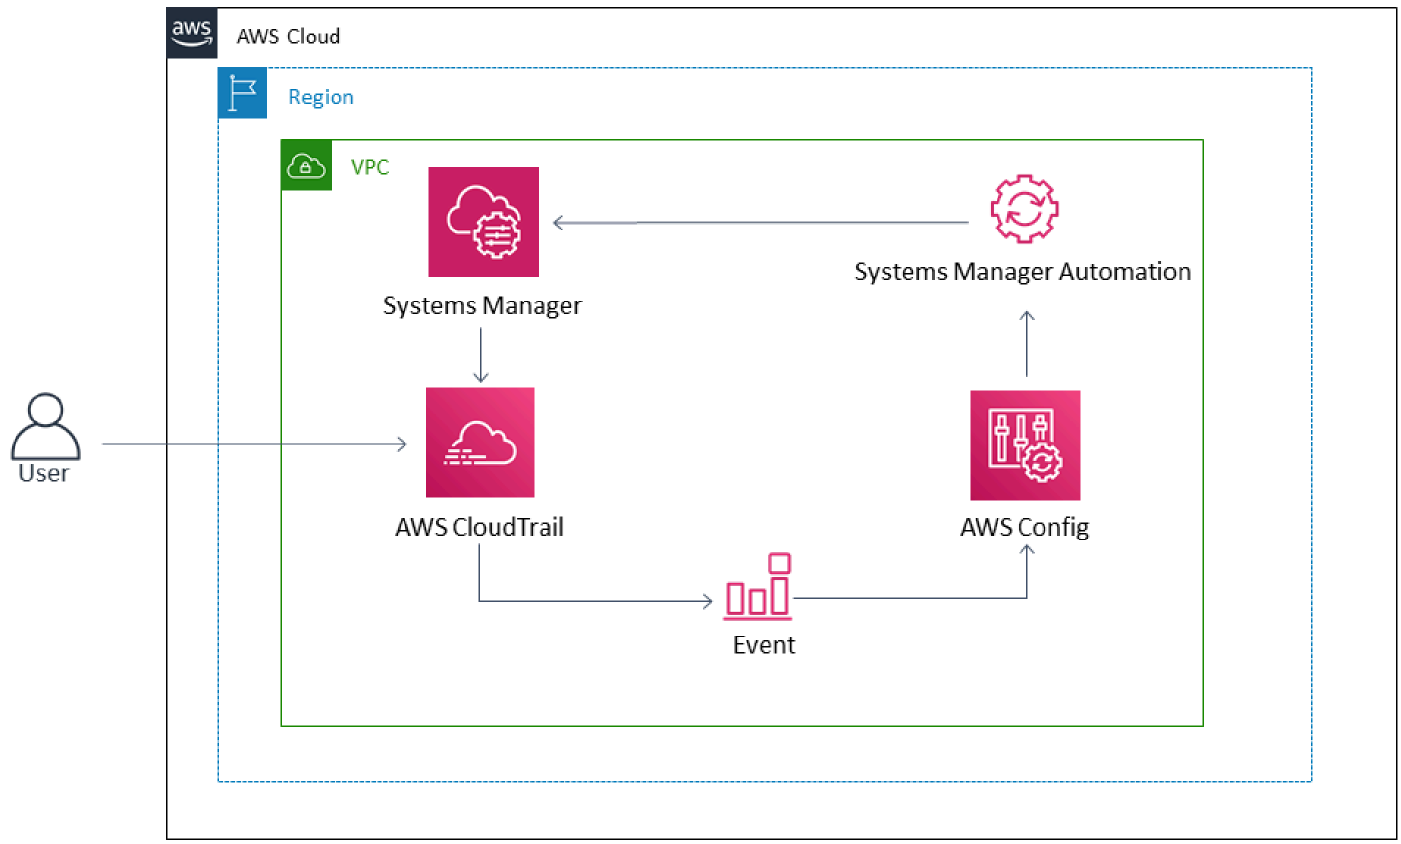
- An existing trail for your account

Limitations

This pattern doesn't support the following actions:

- Setting an Amazon Simple Storage Service (Amazon S3) prefix key for the storage location
- Publishing to an Amazon Simple Notification Service (Amazon SNS) topic
- Configuring Amazon CloudWatch Logs to monitor your CloudTrail logs

Architecture



Technology stack

- AWS Config
- CloudTrail
- Systems Manager

- Systems Manager Automation

Tools

- AWS Config provides a detailed view of the configuration of AWS resources in your account.
- AWS CloudTrail helps you enable governance, compliance, and operational and risk auditing of your account.
- AWS Key Management Service (AWS KMS) is an encryption and key management service.
- AWS Systems Manager helps you view and control your infrastructure on AWS.
- AWS Systems Manager Automation simplifies common maintenance and deployment tasks of Amazon Elastic Compute Cloud (Amazon EC2) instances and other AWS resources.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code

The **cloudtrail-remediation-action.yml** file (attached) helps you create a Systems Manager Automation runbook to set up and re-enable CloudTrail using security best practices.

Epics

Configure CloudTrail

Task	Description	Skills required
Create an S3 bucket.	Sign in to the AWS Management Console, open the Amazon S3 console, and then create an S3 bucket to store the CloudTrail logs. For more information, see Create an S3 bucket in the Amazon S3 documentation.	Systems administrator

Task	Description	Skills required
Add a bucket policy to allow CloudTrail to deliver log files to the S3 bucket.	CloudTrail must have the required permissions to deliver log files to your S3 bucket. On the Amazon S3 console, choose the S3 bucket that you created earlier and then choose **Permissions**. Create an S3 bucket policy by using the Amazon S3 bucket policy for CloudTrail from the CloudTrail documentation. For steps on how to add a policy to an S3 bucket, see Adding a bucket policy using the Amazon S3 console in the Amazon S3 documentation. **Important** If you specified a prefix when you created your trail in CloudTrail, make sure that you include it in the S3 bucket policy. The prefix is an optional addition to the S3 object key that creates a folder-like organization in your S3 bucket. For more information about this, see Creating a	Systems administrator

Task	Description	Skills required
	trail in the CloudTrail documentation.	
Create a KMS key.	Create an AWS KMS key for CloudTrail to encrypt objects before adding them to the S3 bucket. For help with this story, see Encrypting CloudTrail log files with AWS KMS managed keys (SSE-KMS) in the CloudTrail documentation.	Systems administrator
Add a key policy to the KMS key.	Attach a KMS key policy to allow CloudTrail to use the KMS key. For help with this story, see Encrypting CloudTrail log files with AWS KMS–managed keys (SSE-KMS) in the CloudTrail documentation. **Important** CloudTrail doesn't require `Decrypt` permissions.	Systems administrator

Task	Description	Skills required
Create AssumeRole for Systems Manager runbook	Create an `AssumeRole` for Systems Manager Automation to run the runbook. For instructions and more information about this, see [Setting up automation](#) in the Systems Manager documentation.	Systems administrator

Create and test the Systems Manager Automation runbook

Task	Description	Skills required
Create the Systems Manager Automation runbook.	Use the `cloudtrail-remediation-action.yml` file (attached) to create the Systems Manager Automation runbook. For more information about this, see [Creating Systems Manager documents](#) in the Systems Manager documentation.	Systems administrator
Test the runbook.	On the Systems Manager console, test the Systems Manager Automation runbook that you created earlier. For more information about this, see [Running a simple automation](#) in the Systems Manager documentation.	Systems administrator

Set up the automatic remediation rule in AWS Config

Task	Description	Skills required
Add the CloudTrail-enabled rule.	On the AWS Config console, choose **Rules** and then choose **Add rule**. On the **Add rule** page, choose **Add custom** rule. On the **Configure rule** page, enter a name and description, and add the `cloudtrail-enabled` rule. For more information, see [Managing your AWS Config rules](#) in the AWS Config documentation.	Systems administrator
Add the automatic remediation action.	From the **Actions** dropdown list, choose **Manage remediation**. Choose **Auto remediation** and then choose the Systems Manager runbook that you created earlier. The following are the required input parameters for CloudTrail: • `CloudTrailName` • `CloudTrailS3BucketName` • `CloudTrailKmsKeyId` • `AssumeRole` (optional)	Systems administrator

Task	Description	Skills required
	The following input parameters are set to **true** by default: • `IsMultiRegionTrail` • `IsOrganizationTrail` • `IncludeGlobalServiceEvents` • `EnableLogFileValidation` Retain the default values for the **Rate Limits parameter** and **Resource ID parameter**. Choose **Save**. For more information, see Remediating noncompliant AWS resources with AWS Config rules in the AWS Config documentation.	

Task	Description	Skills required
Test the automatic remediati on rule.	To test the automatic remediation rule, open the CloudTrail console, choose **Trails**, and then choose the trail. Choose **Stop logging** to turn off logging for the trail. When you are prompted to confirm, choose **Stop logging**. CloudTrail stops logging activity for that trail. Follow the instructions from Evaluating your resources in the AWS Config documenta tion to make sure that CloudTrail was automatically re-enabled.	Systems administrator

Automatically remediate unencrypted Amazon RDS DB instances and clusters

Ajay Rawat and Josh Joy, Amazon Web Services

Summary

This pattern describes how to automatically remediate unencrypted Amazon Relational Database Service (Amazon RDS) DB instances and clusters on Amazon Web Services (AWS) by using AWS Config, AWS Systems Manager runbooks, and AWS Key Management Service (AWS KMS) keys.

Encrypted RDS DB instances provide an additional layer of data protection by securing your data from unauthorized access to the underlying storage. You can use Amazon RDS encryption to increase data protection of your applications deployed in the AWS Cloud, and to fulfill compliance requirements for encryption at rest. You can enable encryption for an RDS DB instance when you create it, but not after it's created. However, you can add encryption to an unencrypted RDS DB instance by creating a snapshot of your DB instance, and then creating an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot to get an encrypted copy of your original DB instance.

This pattern uses AWS Config Rules to evaluate RDS DB instances and clusters. It applies remediation by using AWS Systems Manager runbooks, which define the actions to be performed on noncompliant Amazon RDS resources, and AWS KMS keys to encrypt the DB snapshots. It then enforces service control policies (SCPs) to prevent the creation of new DB instances and clusters without encryption.

The code for this pattern is provided in GitHub.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Files from the GitHub source code repository for this pattern downloaded to your computer
- An unencrypted RDS DB instance or cluster
- An existing AWS KMS key for encrypting RDS DB instances and clusters
- Access to update the KMS key resource policy

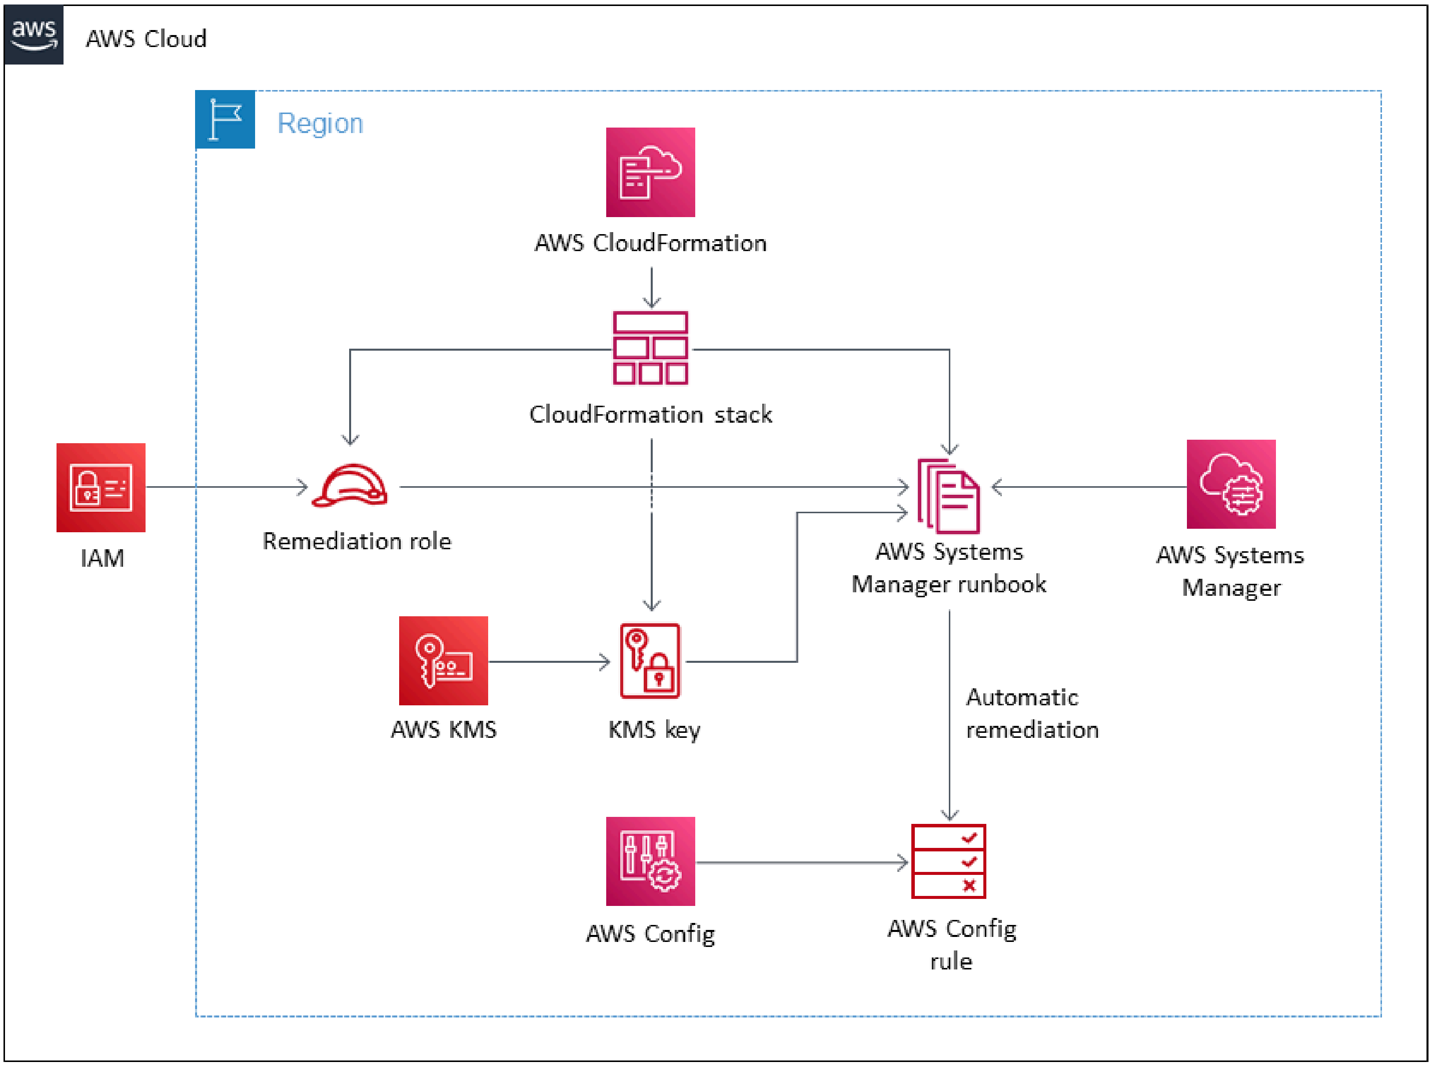
- AWS Config enabled in your AWS account (see Getting Started with AWS Config in the AWS documentation)

Limitations

- You can enable encryption for an RDS DB instance only when you create it, not after it has been created.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- Amazon RDS encryption is available for most DB instance classes. For a list of exceptions, see Encrypting Amazon RDS resources in the Amazon RDS documentation.
- To copy an encrypted snapshot from one AWS Region to another, you must specify the KMS key in the destination AWS Region. This is because KMS keys are specific to the AWS Region that they are created in.
- The source snapshot remains encrypted throughout the copy process. Amazon RDS uses envelope encryption to protect data during the copy process. For more information, see Envelope encryption in the AWS KMS documentation.
- You can't unencrypt an encrypted DB instance. However, you can export data from an encrypted DB instance and import the data into an unencrypted DB instance.
- You should delete a KMS key only when you are sure that you don't need to use it any longer. If you aren't sure, consider disabling the KMS key instead of deleting it. You can reenable a disabled KMS key if you need to use it again later, but you cannot recover a deleted KMS key.
- If you don't choose to retain automated backups, your automated backups that are in the same AWS Region as the DB instance are deleted. They can't be recovered after you delete the DB instance.
- Your automated backups are retained for the retention period that is set on the DB instance at the time you delete it. This set retention period occurs whether or not you choose to create a final DB snapshot.
- If automatic remediation is enabled, this solution encrypts all databases that have the same KMS key.

Architecture

The following diagram illustrates the architecture for the AWS CloudFormation implementation. Note that you can also implement this pattern by using the AWS Cloud Development Kit (AWS CDK).



Tools

Tools

- [AWS CloudFormation](#) helps you automatically set up your AWS resources. It enables you to use a template file to create and delete a collection of resources together as a single unit (a stack).
- [AWS Cloud Development Kit (AWS CDK)](#) is a software development framework for defining your cloud infrastructure in code and provisioning it by using familiar programming languages.

AWS services and features

- AWS Config keeps track of the configuration of your AWS resources and their relationships to your other resources. It can also evaluate those AWS resources for compliance. This service uses rules that can be configured to evaluate AWS resources against desired configurations. You can use a set of AWS Config managed rules for common compliance scenarios, or you can create your own rules for custom scenarios. When an AWS resource is found to be noncompliant, you can specify a remediation action through an AWS Systems Manager runbook and optionally send an alert through an Amazon Simple Notification Service (Amazon SNS) topic. In other words, you can associate remediation actions with AWS Config Rules and choose to run them automatically to address noncompliant resources without manual intervention. If a resource is still noncompliant after automatic remediation, you can set the rule to try automatic remediation again.
- Amazon Relational Database Service (Amazon RDS) makes it easier to set up, operate, and scale a relational database in the cloud. The basic building block of Amazon RDS is the DB instance, which is an isolated database environment in the AWS Cloud. Amazon RDS provides a selection of instance types that are optimized to fit different relational database use cases. Instance types comprise various combinations of CPU, memory, storage, and networking capacity and give you the flexibility to choose the appropriate mix of resources for your database. Each instance type includes several instance sizes, allowing you to scale your database to the requirements of your target workload.
- AWS Key Management Service (AWS KMS) is a managed service that makes it easy for you to create and control AWS KMS keys, which encrypt your data. A KMS key is a logical representation of a root key. The KMS key includes metadata, such as the key ID, creation date, description, and key state.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Service control policies (SCPs) offer central control over the maximum available permissions for all accounts in your organization. SCPs help you ensure that your accounts stay within your organization’s access control guidelines. SCPs don't affect users or roles in the management account. They affect only the member accounts in your organization. We strongly recommend that you don't attach SCPs to the root of your organization without thoroughly testing the impact that the policy has on accounts. Instead, create an organizational unit (OU) that you can move your accounts into one at a time, or at least in small numbers, to ensure that you don't inadvertently lock users out of key services.

Code

The source code and templates for this pattern are available in a GitHub repository. The pattern provides two implementation options: You can deploy an AWS CloudFormation template to create the remediation role that encrypts RDS DB instances and clusters, or use the AWS CDK. The repository has separate folders for these two options.

The Epics section provides step-by-step instructions for deploying the CloudFormation template. If you want to use the AWS CDK, follow the instructions in the `README.md` file in the GitHub repository.

Best practices

- Enable data encryption both at rest and in transit.
- Enable AWS Config in all accounts and AWS Regions.
- Record configuration changes to all resource types.
- Rotate your IAM credentials regularly.
- Leverage tagging for AWS Config, which makes is easier to manage, search for, and filter resources.

Epics

Create the IAM remediation role and Systems Manager runbook

Task	Description	Skills required
Download the CloudFormation template.	Download the `unencrypted-to-encrypted-rds.template.json` file from the GitHub repository.	DevOps engineer
Create the CloudFormation stack.	1. Sign in to the AWS Management Console and open the CloudFormation console. 2. Launch the `unencrypted-to-encrypted-`	DevOps engineer

Task	Description	Skills required
	`rds.template.json` template to create a new stack. For more information about deploying templates, see the [AWS CloudFormation documentation]().	
Review CloudFormation parameters and values.	1. Review stack details and update values based on your environment requirements. 2. Choose **Create stack** to deploy the template.	DevOps engineer
Review the resources.	When the stack has been created, its status changes to **CREATE_COMPLETE**. Review the created resources (IAM role, Systems Manager runbook) in the CloudFormation console.	DevOps engineer

Update the AWS KMS key policy

Task	Description	Skills required
Update your KMS key policy.	1. Make sure that the key alias `alias/RDSEncryptionAtRestKMSAlias` exists. 2. The key policy statement should include the IAM	DevOps engineer

Task	Description	Skills required
	remediation role. (Check the resources created by the CloudFormation template you deployed in the previous epic.) 3. In the following key policy, update the portions that are in bold to match your account and the IAM role that was created. `{ "Sid": "Allow access through RDS for all principals in the account that are authorized to use RDS", "Effect": "Allow", "Principal": { "AWS": "arn:aws:iam:: <your-AWS-account-ID>":role/<your-IAM-remediation-role>" }, "Action": ["kms:Encrypt", "kms:Decrypt", "kms:ReEncrypt*", "kms:GenerateDataKey*", "kms:CreateGrant", "kms:ListGrants",`	

Task	Description	Skills required

	``
	        "kms:Desc
	ribeKey"
	    ],
	    "Resource": "*",
	    "Condition": {
	        "StringEquals":
	 {
	            "kms:ViaS
	ervice": "rds.us-e
	ast-1.amazonaws.com",
	            "kms:Call
	erAccount": "<your-AW
	S-account-ID>"
	        }
	    }
	}
	``	

Find and remediate noncompliant resources

Task	Description	Skills required
View noncompliant resources.	1. To view a list of noncompli ant resources, open the [AWS Config console](https://console.aws.amazon.com/config/). 2. In the navigation pane, choose **Rules**, and then choose the `rds-stora ge-encrypted` rule. The noncompliant resources listed in the AWS Config console will be instances, not clusters. The remediati on automation encrypts instances and clusters, and creates either a newly	DevOps engineer

Task	Description	Skills required
	encrypted instance or a newly created cluster. However, be sure not to simultaneously remediate multiple instances that belong to the same cluster. Before you remediate any RDS DB instances or volumes, make sure that the RDS DB instance is not in use. Confirm that there are no write operations occurring while the snapshot is being created, to ensure that the snapshot contains the original data. Consider enforcing a maintenance window during which the remediation will run.	

Task	Description	Skills required
Remediate noncompliant resources.	1. When you are ready and the maintenance window is in effect, choose the resource to remediate, and then choose **Remediate**. The **Action status** column should now display **Action execution queued**. 2. View the progress and status of the remediation in Systems Manager. Open the [Systems Manager console](). In the navigation pane, choose **Automation**, and then select the execution ID of the corresponding automation to view further details.	DevOps engineer
Verify that the RDS DB instance is available.	After the automation completes, the newly encrypted RDS DB instance will become available. The encrypted RDS DB instance will have the prefix `encrypted` followed by the original name. For example, if the unencrypted RDS DB instance name was `database-1` , the newly encrypted RDS DB instance would be `encrypted-database-1` .	DevOps engineer

Task	Description	Skills required
Terminate the unencrypted instance.	After remediation is complete and the newly encrypted resource has been validated, you can terminate the unencrypted instance. Make sure to confirm that the newly encrypted resource matches the unencrypted resource before you terminate any resources.	DevOps engineer

Enforce SCPs

Task	Description	Skills required
Enforce SCPs.	Enforce SCPs to prevent DB instances and clusters from being created without encryption in the future. Use the `rds_encrypted.json` file that's provided in the GitHub repository for this purpose, and follow the instructions in the AWS documentation.	Security engineer

Additional information

How does AWS Config work?

When you use AWS Config, it first discovers the supported AWS resources that exist in your account and generates a configuration item for each resource. AWS Config also generates configuration items when the configuration of a resource changes, and it maintains historical records of the configuration items of your resources from the time you start the configuration recorder. By default, AWS Config creates configuration items for every supported resource in the AWS Region. If you don't want AWS Config to create configuration items for all supported resources, you can specify the resource types that you want it to track.

How are AWS Config and AWS Config Rules related to AWS Security Hub?

AWS Security Hub is a security and compliance service that provides security and compliance posture management as a service. It uses AWS Config and AWS Config Rules as its primary mechanism to evaluate the configuration of AWS resources. AWS Config Rules can also be used to evaluate resource configuration directly. Other AWS services, such AWS Control Tower and AWS Firewall Manager, also use AWS Config Rules.

Automatically rotate IAM user access keys at scale with AWS Organizations and AWS Secrets Manager

Tracy Hickey, Michael Davie, Arvind Patel, Laura Seletos, and Gaurav Verma, Amazon Web Services

Summary

Important: As a best practice, AWS recommends that you use AWS Identity and Access Management (IAM) roles instead of IAM users with long-term credentials such as access keys. The approach documented in this pattern is intended only for legacy implementations that require long-lived AWS API credentials. For these implementations, we still recommend that you consider options for using short-term credentials, such as using Amazon Elastic Compute Cloud (Amazon EC2) instance profiles or IAM Roles Anywhere. The approach in this article is only for cases where you are unable to change to using short-term credentials immediately, and you require long-term credentials to be rotated on a schedule. With this approach, you are responsib le for periodically updating your legacy application code or configuration to use the rotated API credentials.

Access keys are long-term credentials for an IAM user. Regularly rotating your IAM credentials helps prevent a compromised set of IAM access keys from accessing components in your AWS account. Rotating IAM credentials is also an important part of security best practices in IAM.

This pattern helps you automatically rotate IAM access keys by using AWS CloudFormation templates, which are provided in the GitHub IAM key rotation repository.

The pattern supports deployment in a single account or multiple accounts. If you're using AWS Organizations, this solution identifies all AWS account IDs within your organization and dynamically scales as accounts are removed or new accounts are created. The centralized AWS Lambda function uses an assumed IAM role to locally run the rotation functions across multiple accounts that you select.

- New IAM access keys are generated when existing access keys are 90 days old.
- The new access keys are stored as a secret in AWS Secrets Manager. A resource-based policy allows only the specified IAM principal to access and retrieve the secret. If you choose to store keys in the management account, the keys for all accounts are stored in the management account.

- The email address assigned to the owner of the AWS account where the new access keys were created receives a notification.
- The previous access keys are deactivated at 100 days old, and then deleted at 110 days old.
- A centralized email notification is sent to the AWS account owner.

Lambda functions and Amazon CloudWatch automatically perform these actions. You can then retrieve the new access key pair and replace them in your code or applications. The rotation, deletion, and deactivation periods can be customized.

Prerequisites and limitations

- At least one active AWS account.
- AWS Organizations, configured and set up (see tutorial).
- Permissions to query AWS Organizations from your management account. For more information, see AWS Organizations and service-linked roles in the AWS Organizations documentation.
- An IAM principal that has permissions to launch the AWS CloudFormation template and associated resources. For more information, see Grant self-managed permissions in the AWS CloudFormation documentation.
- An existing Amazon Simple Storage Service (Amazon S3) bucket to deploy the resources.
- Amazon Simple Email Service (Amazon SES) moved out of the sandbox. For more information, see Moving out of the Amazon SES sandbox in the Amazon SES documentation.
- If you choose to run Lambda in a virtual private cloud (VPC), the following resources, which should be created before you run the main CloudFormation template:
  - A VPC.
  - A subnet.
  - Endpoints for Amazon SES, AWS Systems Manager, AWS Security Token Service (AWS STS), Amazon S3, and AWS Secrets Manager. (You can run the endpoint template that's provided in the GitHub IAM key rotation repository to create these endpoints.)
- The Simple Mail Transfer Protocol (SMTP) user and password stored in AWS Systems Manager parameters (SSM parameters). Parameters must match the main CloudFormation template parameters.

Architecture

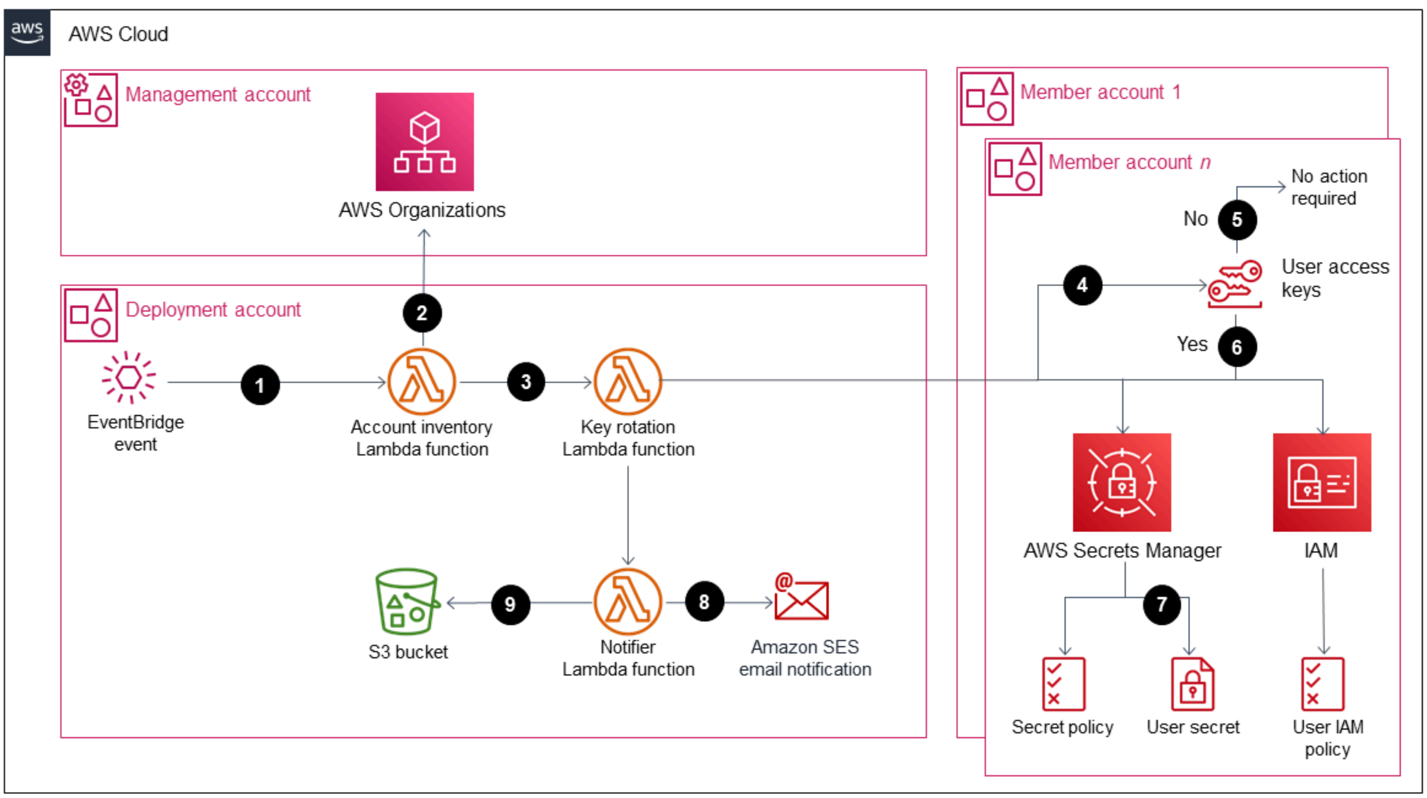
Technology stack

- Amazon CloudWatch
- Amazon EventBridge
- IAM
- AWS Lambda
- AWS Organizations
- Amazon S3

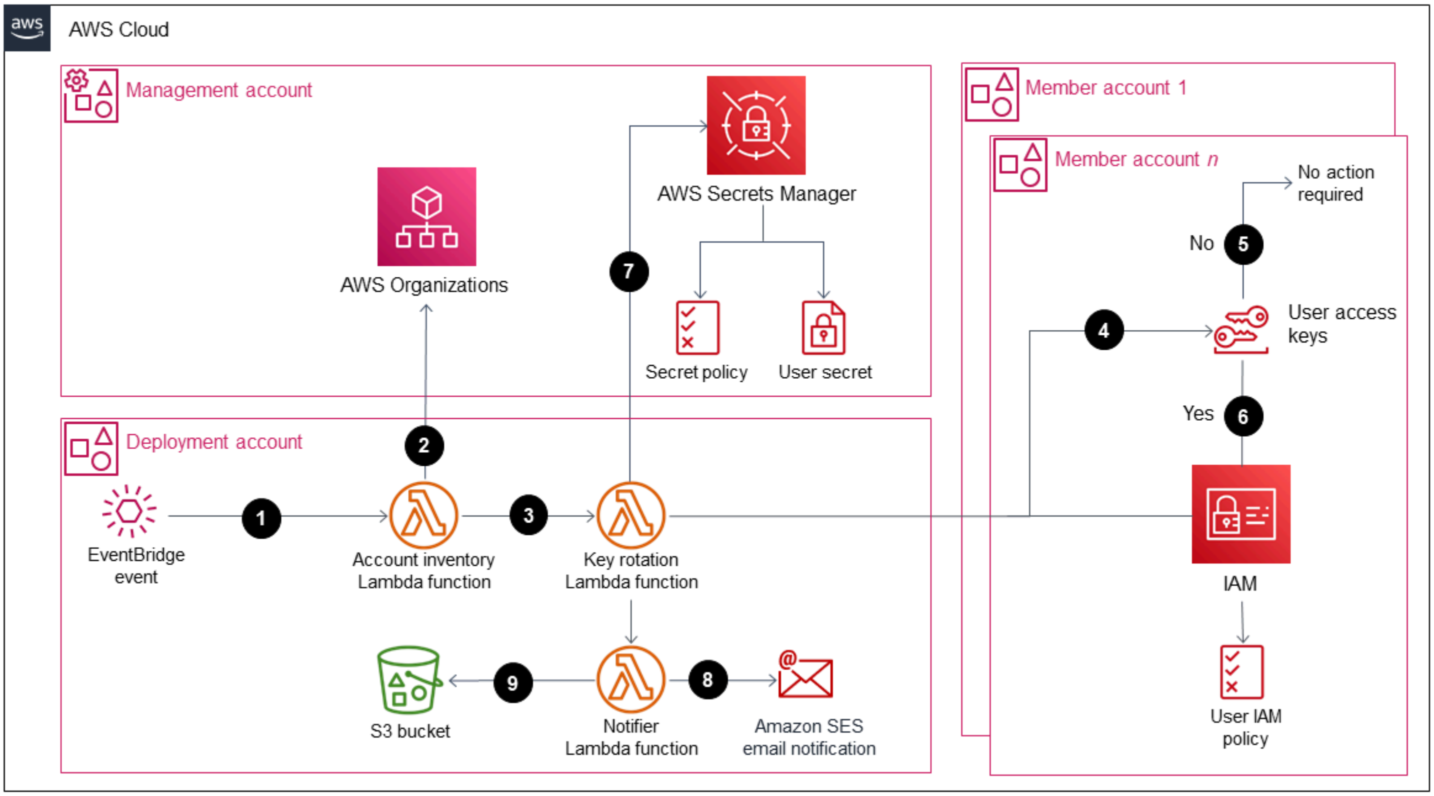
Architecture

The following diagrams show the components and workflows for this pattern. The solution supports two scenarios for storing the credentials: in a member account and in the management account.

Option 1: Store the credentials in a member account



Option 2: Store the credentials in the management account



The diagrams show the following workflow:

1. An EventBridge event initiates an `account_inventory` Lambda function every 24 hours.
2. This Lambda function queries AWS Organizations for a list of all AWS account IDs, account names, and account emails.
3. The `account_inventory` Lambda function initiates an `access_key_auto_rotation` Lambda function for each AWS account ID and passes the metadata to it for additional processing.
4. The `access_key_auto_rotation` Lambda function uses an assumed IAM role to access the AWS account ID. The Lambda script runs an audit against all users and their IAM access keys in the account.
5. If the IAM access key's age hasn't exceeded the best practice threshold, the Lambda function takes no further action.
6. If the IAM access key's age has exceeded the best practice threshold, the `access_key_auto_rotation` Lambda function determines which rotation action to perform.
7. When action is required, the `access_key_auto_rotation` Lambda function creates and updates a secret in AWS Secrets Manager if a new key is generated. A resource-based policy is also created that allows only the specified IAM principal to access and retrieve the secret. In the

case of option 1, the credentials are stored in Secrets Manager in the respective account. In the case of option 2 (if the `StoreSecretsInCentralAccount` flag is set to **True**), the credentials are stored in Secrets Manager in the management account.

8. A `notifier` Lambda function is initiated to notify the account's owner of the rotation activity. This function receives the AWS account ID, account name, account email, and the rotation actions that were performed.
9. The `notifier` Lambda function queries the deployment S3 bucket for an email template and dynamically updates it with the relevant activity metadata. The email is then sent to the account owner's email address.

Notes:

- This solution supports resiliency in multiple Availability Zones. However, it doesn't support resiliency in multiple AWS Regions. For support in multiple Regions, you can deploy the solution in the second Region and keep the key rotation EventBridge rule disabled. You can then enable the rule when you want to run the solution in the second Region.
- You can run this solution in audit mode. In audit mode, IAM access keys aren't modified, but an email is sent to notify users. To run the solution in audit mode, set the `DryRunFlag` flag to **True** when you run the key rotation template or in the environment variable for the `access_key_auto_rotation` Lambda function.

Automation and scale

The CloudFormation templates that automate this solution are provided in the GitHub [IAM key rotation] repository and listed in the *Code* section. In AWS Organizations, you can use [CloudFormation StackSets] to deploy the `ASA-iam-key-auto-rotation-iam-assumed-roles.yaml` CloudFormation template in multiple accounts instead of deploying the solution individually to each member account.

Tools

AWS services

- [Amazon CloudWatch] helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [AWS Identity and Access Management (IAM)] helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Simple Email Service (Amazon SES) helps you send and receive emails by using your own email addresses and domains.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- Amazon VPC endpoints provide an interface to connect to services powered by AWS PrivateLink, including many AWS services. For each subnet that you specify from your VPC, an endpoint network interface is created in the subnet and assigned a private IP address from the subnet address range.

Code

The required AWS CloudFormation templates, Python scripts, and runbook documentation are available in the GitHub IAM key rotation repository. The templates are deployed as follows.

Template	Deploy in	Notes
`ASA-iam-key-auto-rotation-and-notifier-solution.yaml`	Deployment account	This is the main template for the solution.
`ASA-iam-key-auto-rotation-iam-assumed-roles.yaml`	Single or multiple member accounts where you want to rotate the credentials	You can use CloudFormation stack sets to deploy

		this template in multiple accounts.
`ASA-iam-key-auto-rotation-list-accounts-role.yaml`	Central/management account	Use this template to keep an inventory of accounts in AWS Organizations.
`ASA-iam-key-auto-rotation-vpc-endpoints.yaml`	Deployment account	Use this template to automate the creation of endpoints only if you want to run the Lambda functions in a VPC (set the `RunLambdaInVPC` parameter to **True** in the main template).

Epics

Set up the solution

Task	Description	Skills required
Choose your deployment S3 bucket.	Sign in to the AWS Management Console for your account, open the [Amazon S3 console](), and then choose the S3 bucket for your deployment. If you want to implement the solution for multiple accounts in AWS Organizations, sign in to the management account for your organization.	Cloud architect
Clone the repository.	Clone the GitHub [IAM key rotation]() repository to your local desktop.	Cloud architect

Task	Description	Skills required
Upload the files to the S3 bucket.	Upload the cloned files to your S3 bucket. Use the following default folder structure to copy and paste all cloned files and directories: `asa/asa-iam-rotation` **Note** You can customize this folder structure in the CloudFormation templates.	Cloud architect
Modify the email template.	Modify the `iam-auto-key-rotation-enforcement.html` email template (located in the `template` folder) according to your requirements. Replace `[Department Name Here]` at the end of the template with your department's name.	Cloud architect

Deploy the solution

Task	Description	Skills required
Launch the CloudFormation template for key rotation.	1. Launch the `ASA-iam-key-auto-rotation-and-notifier-solution.yaml` template in	Cloud architect

Task	Description	Skills required
	the deployment account. For more information, see [Selecting a stack template](#) in the CloudFormation documentation. 2. Specify values for parameters, including: • **CloudFormation S3 Bucket Name** (`S3BucketName`) – The name of the deploymen t S3 bucket that contains your Lambda code. • **CloudFormation S3 Bucket Prefix** (`S3BucketPrefix`) – The S3 bucket's prefix. • **Assumed IAM Role Name** (`IAMRoleName`) – The role name that the `key-rotation` Lambda function will assume to rotate the keys. • **IAM Execution Role Name** (`Execution RoleName`) – The name of the IAM execution role that's used by the `key-rotation` Lambda function. • **Inventory Execution Role Name** (`Inventory`	

Task	Description	Skills required
	`ExecutionRoleName`) – The name of the IAM execution role that's used by the `account_inventory` Lambda function. • **Dry Run Flag (Audit Mode)** (`DryRunFlag`) – Set to **True** to turn on audit mode (default). Set to **False** to turn on enforcement mode. • **Account to List Organization Accounts** (`OrgListAccount`) – The account ID of the central/management account that will be used to list the accounts in the organization. • **List Accounts Role Name** (`OrgListRole`) – The role name that will be used to list the accounts in the organization. • **Secrets Store flag for central account** (`StoreSecretsInCentralAccount`) – Set to **True** to store secrets in the central account. Set to **False** to store	

Task	Description	Skills required
	secrets in the respective account. • **Regions to replicate the credentials** (`CredentialReplicationRegions`) – The AWS Regions where you want to replicate the credentials (Secrets Manager), separated by commas; for example, `us-east-2,us-west-1,us-west-2` . Skip the Region where you are creating the stack. • **Run Lambda in VPC** (`RunLambdaInVpc`) – Set to **True** to run Lambda functions in a specified VPC. You must have VPC endpoints created and attach a NAT gateway to the subnet that contains the Lambda function. For more information, see the re:Post article that covers this option. • **VPC Id for Lambda functions** (`VpcId`), **VPC CIDR for Security Group Rule** (`VpcCidr`), and **Subnet Id for Lambda functions** (`SubnetId`)	

Task	Description	Skills required
	– Provide information about the VPC, CIDR, and subnet if you set `RunLambdaInVpc` to **True**. • **Admin Email Address** (`AdminEmailAddress`) – A valid email address to send notifications to. • **AWS Organization ID** (`AWSOrgID`) – The unique ID of your organization. This ID begins with `o-` and is followed by 10-32 lowercase letters or digits. • **Email Template File name [Audit Mode]** (`EmailTemplateAudit`) and **[Enforce Mode]** (`EmailTemplateEnforce`) – The filename of the email HTML template to be sent out by the `notifier` module for audit mode and enforce mode. • **SMTP User SSM Parameter Name** (`SMTPUserParamName`) and **SMTP Password**	

Task	Description	Skills required
	SSM Parameter Name (`SMTPPasswordParamName`) – User and password information for Simple Mail Transfer Protocol (SMTP).	

Task	Description	Skills required
Launch the CloudFormation template for assumed roles.	1. In the [AWS CloudFormation console](), launch the `ASA-iam-key-auto-rotation-iam-assumed-roles.yaml` template for each account where you want to rotate keys. If you have more than one account, you can deploy the main CloudFormation template in your management account as a stack and deploy the `ASA-iam-key-auto-rotation-iam-assumed-roles.yaml` template with CloudFormation stack sets to all required accounts. For more information, see [Working with AWS CloudFormation StackSets]() in the CloudFormation documentation. 2. Specify values for the following parameters: • **Assumed IAM Role Name** (`IAMRoleName`) – IAM role name that will be assumed by the Lambda `access_key_auto_rotation` function. You can keep the default value.	Cloud architect

Task	Description	Skills required
	• **IAM Execution Role Name** (`ExecutionRoleName`) – The IAM role that will assume the sub-account role to run the Lambda function. • **Primary AWS Account ID** (`PrimaryAccountID`) – The AWS account ID where the main template will be deployed. • **IAM Exemption Group** (`IAMExemptionGroup`) – The IAM group name being used to facilitate IAM accounts that you want to exclude from automatic key rotation.	

Task	Description	Skills required
Launch the CloudFormation template for account inventory.	1. Launch the `ASA-iam-key-auto-rotation-list-accounts-role.yaml` template in the management/central account 2. Specify values for the following parameters: • **Assumed IAM Role Name** (`IAMRoleName`) – IAM role name that the Lambda `access_key_auto_rotation` function will assume. • **IAM Execution Role Name for Account Lambda** (`AccountExecutionRoleName`) – The name of the IAM role that the Lambda `notifier` function will assume. • **IAM Execution Role Name for rotation Lambda** (`RotationExecutionRoleName`) – The name of the IAM role that the Lambda `access_key_auto_rotation` function will assume. • **Primary AWS Account ID** (`PrimaryAc`	Cloud architect

Task	Description	Skills required
	`countID`) – The AWS account ID where the main template will be deployed.	
Launch the CloudFormation template for VPC endpoints.	This task is optional. 1. Launch the `ASA-iam-key-auto-rotation-vpc-endpoints.yaml` template in the deployment account. 2. Specify values for the following parameters: • **VPC ID** (`pVpcId`), **Subnet Id** (`pSubnetId`), and **CIDR range for VPC** (`pVPCCidr`) – Provide information about the VPC, CIDR, and subnet. • Set the parameter for each VPC endpoint to **True**. If you already have endpoints, you can choose **False**.	Cloud architect

Automatically validate and deploy IAM policies and roles by using CodePipeline, IAM Access Analyzer, and AWS CloudFormation macros

Helton Ribeiro and Guilherme Simoes, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more.

This pattern describes the steps and provides code to create a deployment pipeline that allows your development teams to create AWS Identity and Access Management (IAM) policies and roles in your Amazon Web Services (AWS) accounts. This approach helps your organization reduce overhead for your operational teams and speed up the deployment process. It also helps your developers to create IAM roles and policies that are compatible with your existing governance and security controls.

This pattern's approach uses AWS Identity and Access Management Access Analyzer to validate the IAM policies that you want to attach to IAM roles and uses AWS CloudFormation to deploy the IAM roles. However, instead of directly editing the AWS CloudFormation template file, your development team creates JSON-formatted IAM policies and roles. An AWS CloudFormation macro transforms these JSON-formatted policy files into AWS CloudFormation IAM resource types before beginning the deployment.

The deployment pipeline (`RolesPipeline`) has source, validation, and deployment stages. During the source stage, your development team pushes the JSON files that contain the definition of the IAM roles and policies to an AWS CodeCommit repository. AWS CodeBuild then runs a script to validate those files and copies them to an Amazon Simple Storage Service (Amazon S3) bucket. Because your development teams don't have direct access to the AWS CloudFormation template file stored in a separate S3 bucket, they must follow the JSON file creation and validation process.

Finally, during the deployment phase, AWS CodeDeploy uses an AWS CloudFormation stack to update or delete the IAM policies and roles in an account.

> **Important**
>
> This pattern's workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern's approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Prerequisites and limitations

Prerequisites

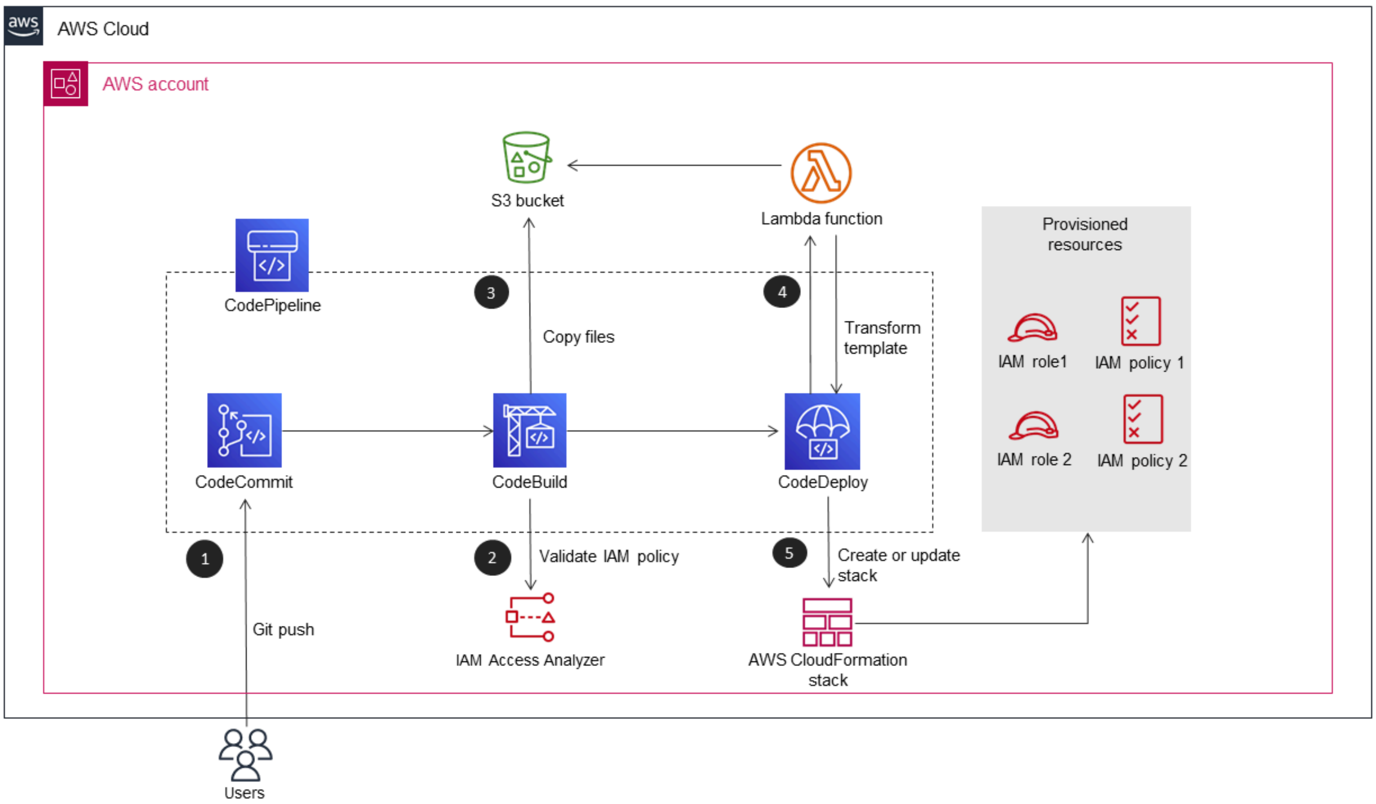
- An active AWS account.
- A new or existing S3 bucket for the `RolesPipeline` pipeline. Make sure that the access credentials you're using have permissions to upload objects to this bucket.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- AWS Serverless Application Model (AWS SAM) CLI, installed and configured. For more information about this, see Installing the AWS SAM CLI in the AWS SAM documentation.
- Python 3, installed on your local machine. For more information about this, see the Python documentation.
- A Git client, installed and configured.
- The GitHub `IAM roles pipeline` repository, cloned to your local machine.
- Existing JSON-formatted IAM policies and roles. For more information about this, see the ReadMe file in the Github `IAM roles pipeline` repository.
- Your developer team must not have permissions to edit this solution's AWS CodePipeline, CodeBuild, and CodeDeploy resources.

Limitations

- This pattern's workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern's approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Architecture

The following diagram shows you how to automatically validate and deploy IAM roles and policies to an account by using CodePipeline, IAM Access Analyzer, and AWS CloudFormation macros.



The diagram shows the following workflow:

1. A developer writes JSON files that contain the definitions for the IAM policies and roles. The developer pushes the code to a CodeCommit repository and CodePipeline then initiates the `RolesPipeline` pipeline.
2. CodeBuild validates the JSON files by using IAM Access Analyzer. If there are any security or error-related findings, the deployment process is stopped.
3. If there are no security or error-related findings, the JSON files are sent to the `RolesBucket` S3 bucket.
4. An AWS CloudFormation macro implemented as an AWS Lambda function then reads the JSON files from the `RolesBucket` bucket and transforms them into AWS CloudFormation IAM resources types.
5. A predefined AWS CloudFormation stack installs, updates, or deletes the IAM policies and roles in the account.

Automation and scale

AWS CloudFormation templates that automatically deploy this pattern are provided in the GitHub IAM roles pipeline repository.

Tools

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- IAM Access Analyzer helps you identify the resources in your organization and accounts, such as S3 buckets or IAM roles, that are shared with an external entity. This helps you to identify unintended access to your resources and data.
- AWS Serverless Application Model (AWS SAM) is an open-source framework that helps you build serverless applications in the AWS Cloud.

Code

The source code and templates for this pattern are available in the GitHub IAM roles pipeline repository.

Epics

Clone the repository

Task	Description	Skills required
Clone the sample repository.	Clone the GitHub IAM roles pipeline repository to your local machine.	App developer, General AWS

Deploy the RolesPipeline pipeline

Task	Description	Skills required
Deploy the pipeline.	1. Navigate to the directory that contains the cloned repository. 2. **Important** Run the `make deploy bucket=<bucket_name>` command. : you must replace `<bucket_name>` with the bucket name for your existing S3 bucket. 3. Run the `aws codepipeline get-pipeline –name RolesPipeline` command to check if your deployment is successful.	App developer, General AWS
Clone the pipeline's repository.	1. The `RolesPipeline` AWS CloudFormation stack creates the `roles-pipeline-repo` CodeCommit repository. 2. Sign in to the AWS Management Console, open the AWS CodeCommit console, and then copy the CodeCommit repository's URL to clone it to your	App developer, General AWS

Task	Description	Skills required
	local machine. For more information about this, see [Connect to an AWS CodeCommit repository](#) in the AWS CodeCommit documentation.	

Test the RolesPipeline pipeline

Task	Description	Skills required
Test the RolesPipeline pipeline with valid IAM policies and roles.	1. Create JSON files for your IAM policies and roles. You can use the samples in the `role-example` directory from the GitHub `IAM roles pipeline` repository. 2. **Important** Define your IAM policies and roles with the required configurations. : Make sure that you follow the format described in the `ReadMe` file from the GitHub `IAM roles pipeline` repository. 3. Push the modifications into the `roles-pipeline-`	App developer, General AWS

Task	Description	Skills required
	`repo` CodeCommit repository. 4. Verify the implementation of the `RolesPipeline` pipeline. 5. Make sure that the IAM policies and roles are correctly deployed in the account. 6. Validate if there is a permissions boundary associated to the IAM policies or roles. For more information about this, see [Permissions boundaries for IAM entities](#) in the IAM documentation.	
Test the RolesPipeline pipeline with invalid IAM policies and roles.	1. Modify the `roles-pipeline-repo` CodeCommit repository and include invalid IAM roles or policies. For example, you can use an action that doesn't exist or an invalid IAM policy version. 2. Verify the pipeline implementation. IAM Access Analyzer stops the pipeline during the validation stage if it detects invalid IAM policies or roles.	App developer, General AWS

Clean up your resources

Task	Description	Skills required
Prepare for cleanup.	Empty the S3 buckets and then run the `destroy` command.	App developer, General AWS
Delete the RolesStack stack.	1. The `RolesPipeline` pipeline creates a `RolesStack` AWS CloudFormation stack that deploys the IAM policies and roles. You must delete this stack before deleting the `RolesPipeline` pipeline. 2. Sign in to the AWS Management Console, open the AWS CloudFormation console, and then choose the `RolesStack` stack and choose **Delete**.	App developer, General AWS
Delete the RolesPipeline stack.	To delete the `RolesPipeline` AWS CloudFormation stack, follow the instructions from the ReadMe file in the Github `IAM roles pipeline` repository.	App developer, General AWS

Bidirectionally integrate AWS Security Hub with Jira software

Joaquin Rinaudo, Amazon Web Services

Summary

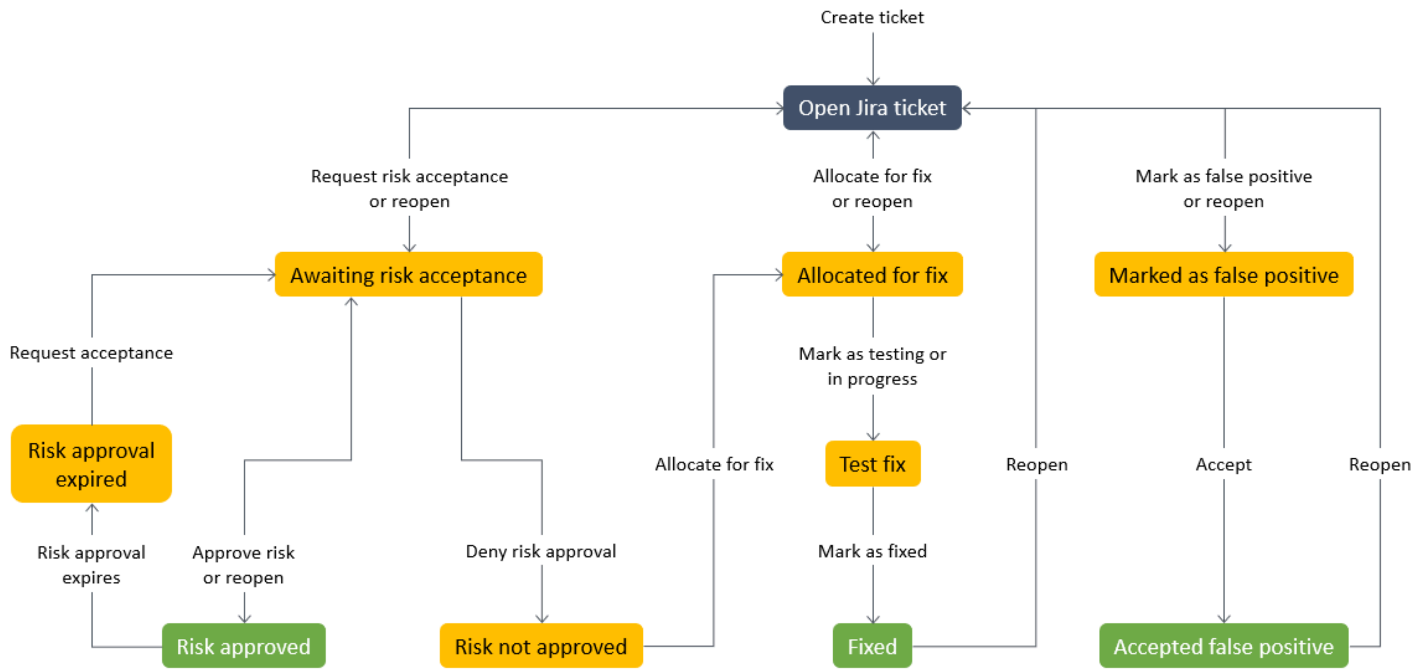
This solution supports a bidirectional integration between AWS Security Hub and Jira. Using this solution, you can automatically and manually create and update Jira tickets from Security Hub findings. Security teams can use this integration to notify developer teams of severe security findings that require action.

The solution allows you to:

- Select which Security Hub controls automatically create or update tickets in Jira.
- In the Security Hub console, use Security Hub custom actions to manually escalate tickets in Jira.
- Automatically assign tickets in Jira based on the AWS account tags defined in AWS Organizations. If this tag is not defined, a default assignee is used.
- Automatically suppress Security Hub findings that are marked as false positive or accepted risk in Jira.
- Automatically close a Jira ticket when its related finding is archived in Security Hub.
- Reopen Jira tickets when Security Hub findings reoccur.

Jira workflow

The solution uses a custom Jira workflow that allows developers to manage and document risks. As the issue moves through the workflow, bidirectional integration ensures that the status of the Jira ticket and Security Hub finding is synchronized across the workflows in both services. This workflow is a derivative of *SecDevOps Risk Workflow* by Dinis Cruz, licensed licensed under [Apache License version 2.0](). We recommend adding a Jira workflow condition so that only members of your security team can change the ticket status.



For an example of a Jira ticket automatically generated by this solution, see the Additional information section of this pattern.

Prerequisites and limitations

Prerequisites

- If you want to deploy this solution across a multi-account AWS environment:
  - Your multi-account environment is active and managed by AWS Organizations.
  - Security Hub is enabled on your AWS accounts.
  - In AWS Organizations, you have designated a Security Hub administrator account.
  - You have a cross-account AWS Identity and Access Management (IAM) role that has `AWSOrganizationsReadOnlyAccess` permissions to the AWS Organizations management account.
  - (Optional) You have tagged your AWS accounts with `SecurityContactID`. This tag is used to assign Jira tickets to the defined security contacts.
- If you want to deploy this solution within a single AWS account:
  - You have an active AWS account.
  - Security Hub is enabled on your AWS account.
- A Jira Data Center instance

> **Important**
>
> This solution supports use of Jira Cloud. However, Jira Cloud does not support importing XML workflows, so you need to manually re-create the workflow in Jira. You can find of the transitions and status in the GitHub repository.

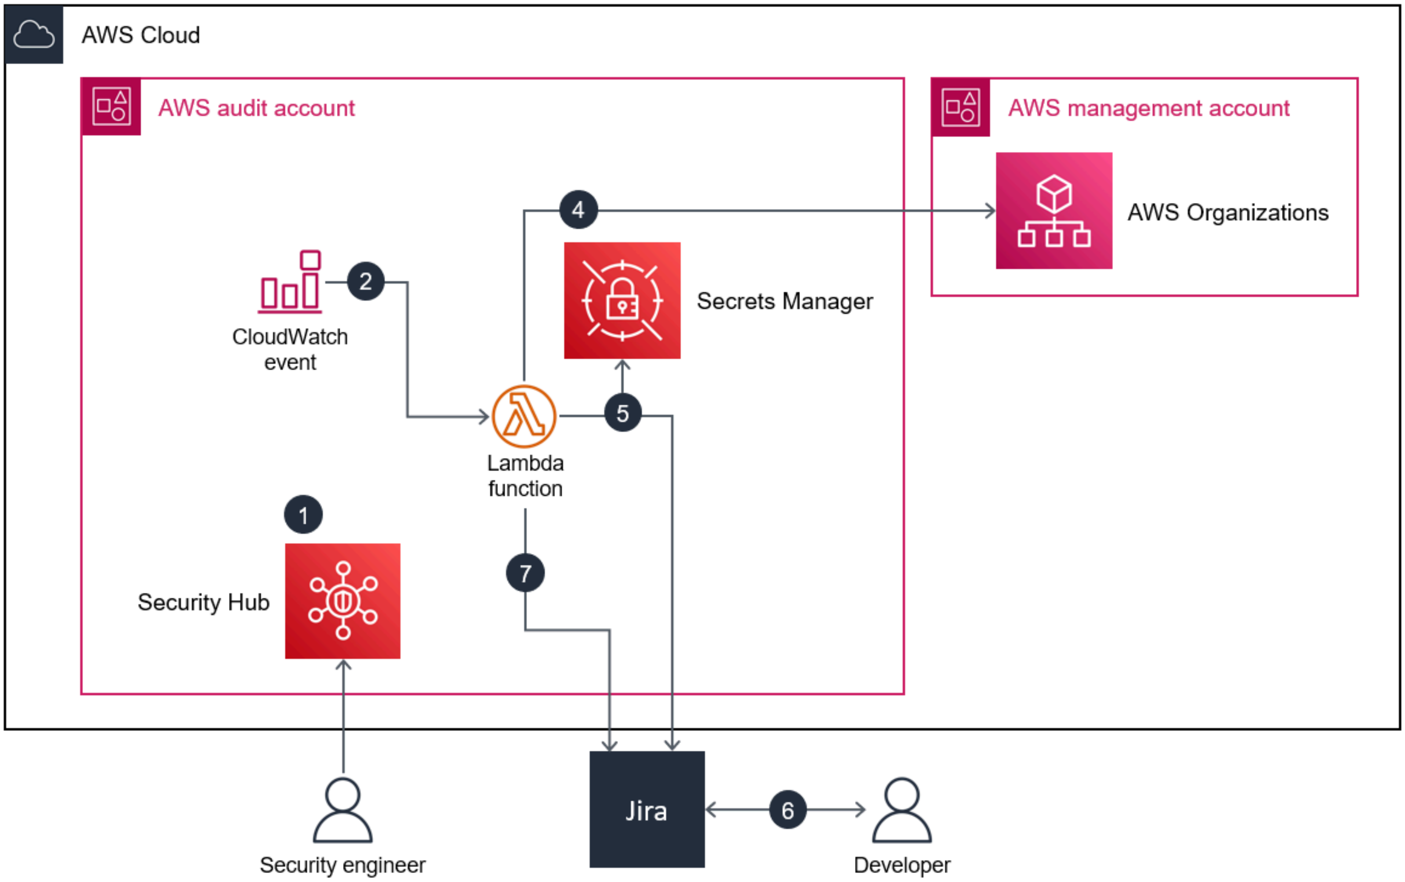
- Administrator permissions in Jira
- One of the following Jira tokens:
  - For Jira Enterprise, a personal access token (PAT). For more information, see Using Personal Access Tokens (Atlassian support).
  - For Jira Cloud, a Jira API token. For more information, see Manage API tokens (Atlassian support).

Architecture

This section illustrates the architecture of the solution in various scenarios, such as when the developer and security engineer decide to accept the risk or decide to fix the issue.

Scenario 1: Developer addresses the issue

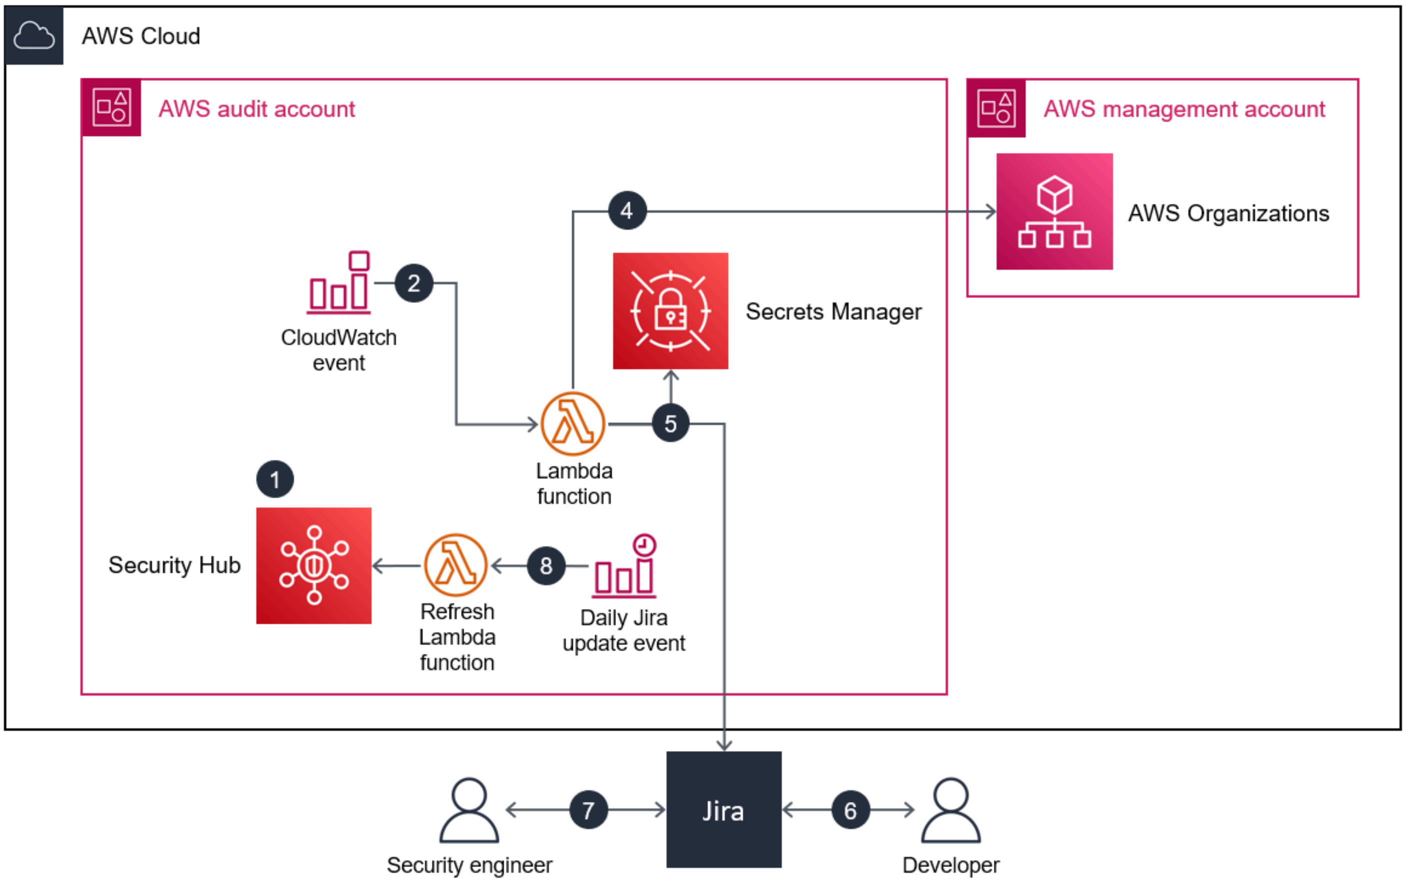
1. Security Hub generates a finding against a specified security control, such as those in the AWS Foundational Security Best Practices standard.
2. An Amazon CloudWatch event associated with the finding and the `CreateJIRA` action initiates an AWS Lambda function.
3. The Lambda function uses its configuration file and the finding's `GeneratorId` field to evaluate whether it should escalate the finding.
4. The Lambda function determines the finding should be escalated, it obtains the `SecurityContactID` account tag from AWS Organizations in the AWS management account. This ID is associated with the developer and is used as the assignee ID for the Jira ticket.
5. The Lambda function uses the credentials stored in AWS Secrets Manager to create a ticket in Jira. Jira notifies the developer.
6. The developer addresses the underlying security finding and, in Jira, changes the status of the ticket to `TEST FIX`.
7. Security Hub updates the finding as `ARCHIVED`, and a new event is generated. This event causes the Lambda function to automatically close the Jira ticket.



Scenario 2: Developer decides to accept the risk

1. Security Hub generates a finding against a specified security control, such as those in the [AWS Foundational Security Best Practices standard](https://docs.aws.amazon.com/securityhub/latest/userguide/securityhub-standards-fsbp.html).
2. A CloudWatch event associated with the finding and the `CreateJIRA` action initiates a Lambda function.
3. The Lambda function uses its configuration file and the finding's `GeneratorId` field to evaluate whether it should escalate the finding.
4. The Lambda function determines the finding should be escalated, it obtains the `SecurityContactID` account tag from AWS Organizations in the AWS management account. This ID is associated with the developer and is used as the assignee ID for the Jira ticket.
5. The Lambda function uses the credentials stored in Secrets Manager to create a ticket in Jira. Jira notifies the developer.
6. The developer decides to accept the risk and, in Jira, changes the status of the ticket to `AWAITING RISK ACCEPTANCE`.

7. The security engineer reviews the request and finds the business justification appropriate. The security engineer changes the status of the Jira ticket to `ACCEPTED RISK`. This closes the Jira ticket.
8. A CloudWatch daily event initiates the refresh Lambda function, which identifies closed Jira tickets and updates their related Security Hub findings as `SUPPRESSED`.



Tools

AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [Amazon CloudWatch Events](#) helps you monitor system events for your AWS resources by using rules to match events and route them to functions or streams.

- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- AWS Security Hub provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.

Code repository

The code for this pattern is available on GitHub, in the aws-securityhub-jira-software-integration repository. It includes the sample code and Jira workflow for this solution.

Epics

Configure Jira

Task	Description	Skills required
Import the workflow.	As an administrator in Jira, import the `issue-workflow.xml` file to your Jira Data Center instance. If you use Jira Cloud, you need to create the workflow according to the `assets/jira-cloud-transitions.png` and `assets/jira-cloud-status.png` files. Files can be found in the aws-securityhub-jira-software-integration repository in GitHub. For instructions,	Jira administrator

Task	Description	Skills required
	see Using XML to create a workflow (Jira documenta tion).	
Activate and assign the workflow.	Workflows are inactive until you assign them to a workflow scheme. You then assign the workflow scheme to a project. 1. For your project, make sure you have identified an issue type scheme for the project. You can create a new issue type or select from an existing one, such as Bug. 2. Assign the imported workflow to a workflow scheme according to the instructions in Activate a workflow (Jira documenta tion). 3. Assign the workflow scheme to a project according to the instructi ons in Associate a workflow scheme with a project (Jira documentation).	Jira administrator

Set up the solution parameters

Task	Description	Skills required
Configure the solution parameters.	1. In the **conf** folder, open `params_prod.shfile`. 2. Provide values for the following parameters: • `ORG_ACCOUNT_ID` – The account ID for your AWS Organizations management account. The solution reads account tags and assigns tickets to the specific security contacts defined in those AWS account tags. • `ORG_ROLE` – The name of the IAM role used to access the AWS Organizations management account. This role must have `OrganizationsReadOnlyAccess` permissions. • `EXTERNAL_ID` – An optional parameter if you are using an external ID to assume the IAM role defined in `ORG_ROLE`. For more information, see [How to use an external ID](#) (IAM documentation).	AWS systems administrator

Task	Description	Skills required
	• JIRA_DEFAULT_ASSIGNEE – This is the Jira default assignee for all security issues. This default assignee is used in case account is not tagged properly or role cannot be assumed. • JIRA_INSTANCE – The HTTPS address for your Jira endpoint in the following format: team-<team-id>.atlassian.net/ • JIRA_PROJECT_KEY – The name of the Jira project key used to create tickets, such as SEC or TEST. This project must already exist in Jira. • ISSUE_TYPE – The name of the issue type scheme assigned to the project in Jira, such as Bug or Security Issue. • REGIONS – List of AWS Region codes where you want to deploy this solution, such as eu-west-1 .	

Task	Description	Skills required
	3. Save and close the solution parameter file.	
Identify the findings you want to automate.	1. Open the [Security Hub console](). 2. In the Security Hub navigation pane, choose **Findings**. 3. Choose the finding title. 4. Choose the finding ID. This displays the complete JSON for the finding. 5. In the JSON, copy the string in the `Generator Id` field. This value is in [AWS Security Finding Format (ASFF)](). For example, `aws-foundational-security-best-practices/v/1.0.0/S3.1` corresponds to findings from the security control *S3.1 S3 Block Public Access setting should be enabled*. 6. Repeat these steps until you have copied all of the `GeneratorID` values for any findings you want to automate.	

Task	Description	Skills required

Add the findings to the configuration file.	1. In **src/code**, open the `config.jsonconfig` file.
	2. Paste the `GeneratorID` values you retrieved in the previous story into the `default` parameter, and use commas to separate each ID.
	3. Save and close the configuration file.
	
	The following code example shows automating the `aws-foundational-security-best-practices/v/1.0.0/SNS.1` and `aws-foundational-security-best-practices/v/1.0.0/S3.1` findings.
	
	`{`
	`    "Controls" : {`
	`        "eu-west-1": [`
	`         "arn:aws:securityhub:::ruleset/cis-aws-foundations-benchmark/v/1.2.0/rule/1.22"`
	`     ],`
	`        "default": [`
	`aws-foundational-security-best-practices/v/1.0.0/SNS.1,`
		AWS systems administrator

Task	Description	Skills required
	``` aws-foundational-security-best-practices/v/1.0.0/S3.1] } } ``` **Note** You can choose to automate different findings for each AWS Region. A good practice to help prevent duplicated findings is to select a single Region to automate creation of controls related to IAM.	

Deploy the integration

Task	Description	Skills required
Deploy the integration.	In a command line terminal, enter the following command: `./deploy.sh prod`	AWS systems administrator
Upload Jira credentials to Secrets Manager.	1. Open the [Secrets Manager console]().	AWS systems administrator

Task	Description	Skills required
	2. Under **Secrets**, choose **Store a new secret**. 3. For **Secret type**, choose **Other type of secret**. 4. If you are using Jira Enterprise, for **Key/value pairs**, do the following: • In the first row, enter `auth` in the key box, and then enter `token_auth` in the value box. • Add a second row, enter `token` in the key box, and then enter your personal access token in the value box. If you are using Jira Cloud, for **Key/value pairs**, do the following: • In the first row, enter `auth` in the key box, and then enter `basic_auth` in the value box. • Add a second row, enter `token` in the key box, and then enter your API token in the value box. • Add a third row, enter `email` in the key box, and then enter your email address in the value box.	

Task	Description	Skills required
	5. Choose **Next**. 6. For **Secret name**, enter `Jira-Token` , and then at the bottom of the page, choose **Next**. 7. On the **Secret rotation** page, keep **Disable automatic rotation**, and then at the bottom of the page, choose **Next**. 8. On the **Review** page, review the secret details, and then choose **Store**.	

Task	Description	Skills required
Create the Security Hub custom action.	1. For each AWS Region, in the AWS Command Line Interface (AWS CLI), use the [create-action-target](#) command to create a Security Hub custom action named `CreateJiraIssue`. `aws securityhub create-action-target --name "CreateJiraIssue" \ --description "Create ticket in JIRA" \ --id "CreateJiraIssue" --region $<aws-region>` 2. Open the [Security Hub console](#). 3. In the Security Hub navigation pane, choose **Findings**. 4. In the list of findings, select the findings you want to escalate. 5. In the **Actions** menu, choose `CreateJiraIssue`.	AWS systems administrator

Related resources

- AWS Service Management Connector for Jira Service Management
- AWS Foundational Security Best Practices standard

Additional information

Example of a Jira ticket

When a specified Security Hub finding occurs, this solution automatically creates a Jira ticket. The ticket includes the following information:

- **Title** – The title identifies the security issue in the following format:

```
AWS Security Issue :: <AWS account ID> :: <Security Hub finding title>
```

- **Description** – The description section of the ticket describes the security control associated with the finding, includes a link to the finding in the Security Hub console, and provides a short description of how to handle the security issue in the Jira workflow.

The following is an example of an automatically generated Jira ticket.

Title	AWS Security Issue :: 012345678912 :: Lambda.1 Lambda function policies should prohibit public access.
Description	**What is the problem?** We detected a security finding within the AWS account 012345678 912 you are responsible for. This control checks whether the AWS Lambda function policy attached to the Lambda resource prohibits public access. If the Lambda function policy allows public access, the control fails. <Link to Security Hub finding>

What do I need to do with the ticket?

- Access the account and verify the configura tion. Acknowledge working on ticket by moving it to "Allocated for Fix". Once fixed, moved to test fix so security validates the issue is addressed.
- If you think risk should be accepted, move it to "Awaiting Risk acceptance". This will require review by a security engineer.
- If you think is a false positive, transitio n it to "Mark as False Positive". This will get reviewed by a security engineer and reopened/closed accordingly.

Build a pipeline for hardened container images using EC2 Image Builder and Terraform

Mike Saintcross and Andrew Ranes, Amazon Web Services

Summary

This pattern builds an EC2 Image Builder pipeline that produces a hardened Amazon Linux 2 base container image. Terraform is used as an infrastructure as code (IaC) tool to configure and provision the infrastructure that is used to create hardened container images. The recipe helps you deploy a Docker-based Amazon Linux 2 container image that has been hardened according to Red Hat Enterprise Linux (RHEL) 7 STIG Version 3 Release 7 – Medium. (See STIG-Build-Linux-Medium version 2022.2.1 in the *Linux STIG components* section of the EC2 Image Builder documentation.) This is referred to as a *golden* container image.

The build includes two Amazon EventBridge rules. One rule starts the container image pipeline when the Amazon Inspector finding is **High** or **Critical** so that non-secure images are replaced. This rule requires both Amazon Inspector and Amazon Elastic Container Registry (Amazon ECR) enhanced scanning to be enabled. The other rule sends notifications to an Amazon Simple Queue Service (Amazon SQS) queue after a successful image push to the Amazon ECR repository, to help you use the latest container images.

> **Note**
>
> Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs.

Prerequisites and limitations

Prerequisites

- An AWS account that you can deploy the infrastructure in.
- AWS Command Line Interface (AWS CLI) installed for setting your AWS credentials for local deployment.
- Terraform downloaded and set up by following the instructions in the Terraform documentation.
- Git (if you're provisioning from a local machine).

- A role within the AWS account that you can use to create AWS resources.
- All variables defined in the .tfvars file. Or, you can define all variables when you apply the Terraform configuration.

Limitations

- This solution creates an Amazon Virtual Private Cloud (Amazon VPC) infrastructure that includes a NAT gateway and an internet gateway for internet connectivity from its private subnet. You cannot use VPC endpoints, because the bootstrap process by AWS Task Orchestrator and Executor (AWSTOE) installs AWS CLI version 2 from the internet.

Product versions

- Amazon Linux 2
- AWS CLI version 1.1 or later

Architecture

Target technology stack

This pattern creates 43 resources, including:

- Two Amazon Simple Storage Service (Amazon S3) buckets: one for the pipeline component files and one for server access and Amazon VPC flow logs
- An Amazon ECR repository
- A virtual private cloud (VPC) that contains a public subnet, a private subnet, route tables, a NAT gateway, and an internet gateway
- An EC2 Image Builder pipeline, recipe, and components
- A container image
- An AWS Key Management Service (AWS KMS) key for image encryption
- An SQS queue
- Three roles: one to run the EC2 Image Builder pipeline, one instance profile for EC2 Image Builder, and one for EventBridge rules
- Two EventBridge rules

Terraform module structure

For the source code, see the GitHub repository [Terraform EC2 Image Builder Container Hardening Pipeline](https://github.com/aws-samples/terraform-ec2-image-builder-container-hardening-pipeline).

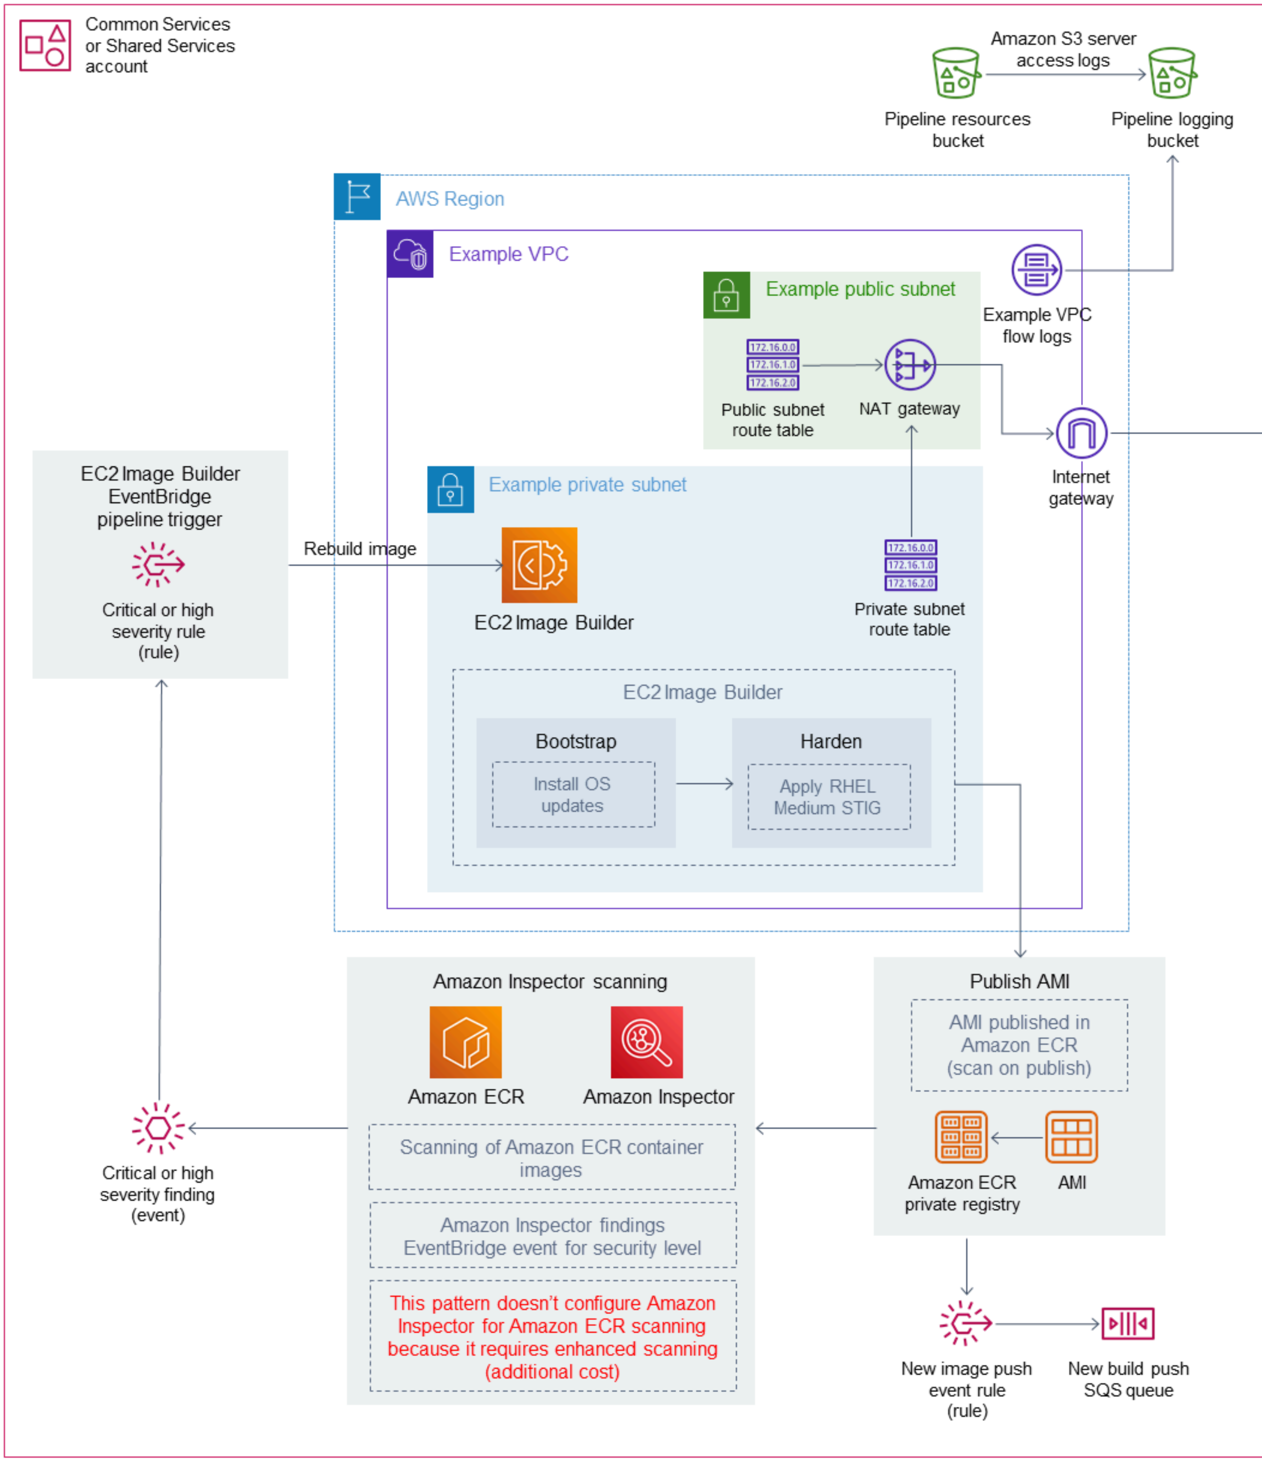
```
### components.tf
### config.tf
### dist-config.tf
### files
#   ###assumption-policy.json
### hardening-pipeline.tfvars
### image.tf
### infr-config.tf
### infra-network-config.tf
### kms-key.tf
### main.tf
### outputs.tf
### pipeline.tf
### recipes.tf
### roles.tf
### sec-groups.tf
### trigger-build.tf
### variables.tf
```

Module details

- `components.tf` contains an Amazon S3 upload resource to upload the contents of the `/files` directory. You can also modularly add custom component YAML files here as well.
- `/files` contains the `.yml` files that define the components used in `components.tf`.
- `image.tf` contains the definitions for the base image operating system. This is where you can modify the definitions for a different base image pipeline.
- `infr-config.tf` and `dist-config.tf` contain the resources for the minimum AWS infrastructure needed to spin up and distribute the image.
- `infra-network-config.tf` contains the minimum VPC infrastructure to deploy the container image into.
- `hardening-pipeline.tfvars` contains the Terraform variables to be used at apply time.
- `pipeline.tf` creates and manages an EC2 Image Builder pipeline in Terraform.
- `recipes.tf` is where you can specify different mixtures of components to create container recipes.

- `roles.tf` contains the AWS Identity and Access Management (IAM) policy definitions for the Amazon Elastic Compute Cloud (Amazon EC2) instance profile and pipeline deployment role.
- `trigger-build.tf` contains the EventBridge rules and SQS queue resources.

Target architecture



The diagram illustrates the following workflow:

1. EC2 Image Builder builds a container image by using the defined recipe, which installs operating system updates and applies the RHEL Medium STIG to the Amazon Linux 2 base image.

2. The hardened image is published to a private Amazon ECR registry, and an EventBridge rule sends a message to an SQS queue when the image has been published successfully.
3. If Amazon Inspector is configured for enhanced scanning, it scans the Amazon ECR registry.
4. If Amazon Inspector generates a **Critical** or **High** severity finding for the image, an EventBridge rule triggers the EC2 Image Builder pipeline to run again and publish a newly hardened image.

Automation and scale

- This pattern describes how to provision the infrastructure and build the pipeline on your computer. However, it is intended to be used at scale. Instead of deploying the Terraform modules locally, you can use them in a multi-account environment, such as an AWS Control Tower with Account Factory for Terraform environment. In that case, you should use a backend state S3 bucket to manage Terraform state files instead of managing the configuration state locally.
- For scaled use, deploy the solution to one central account, such as a Shared Services or Common Services account, from a Control Tower or landing zone account model, and grant consumer accounts permission to access the Amazon ECR repository and AWS KMS key. For more information about the setup, see the re:Post article How can I allow a secondary account to push or pull images in my Amazon ECR image repository? For example, in an account vending machine or Account Factory for Terraform, add permissions to each account baseline or account customization baseline to provide access to that Amazon ECR repository and encryption key.
- After the container image pipeline is deployed, you can modify it by using EC2 Image Builder features such as components, which help you package more components into the Docker build.
- The AWS KMS key that is used to encrypt the container image should be shared across the accounts that the image is intended to be used in.
- You can add support for other images by duplicating the entire Terraform module and modifying the following `recipes.tf` attributes:
  - Modify `parent_image = "amazonlinux:latest"` to another image type.
  - Modify `repository_name` to point to an existing Amazon ECR repository. This creates another pipeline that deploys a different parent image type to your existing Amazon ECR repository.

Tools

Tools

- Terraform (IaC provisioning)
- Git (if provisioning locally)
- AWS CLI version 1 or version 2 (if provisioning locally)

Code

The code for this pattern is in the GitHub repository Terraform EC2 Image Builder Container Hardening Pipeline. To use the sample code, follow the instructions in the next section.

Epics

Provision the infrastructure

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Set up local credentials.</td><td>Set up your AWS temporary credentials.

1. See if the AWS CLI is installed:
<pre>$ aws --version
aws-cli/1.16.249
 Python/3.6.8...</pre>• AWS CLI version should be 1.1 or later.
• If the command isn't found, install the AWS CLI.

2. Run <code>aws configure</code> and provide the following values:
<pre>$ aws configure
AWS Access Key ID
 [************xxxx</pre></td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	```]: <Your AWS access key ID> AWS Secret Access Key [**************xxxx]: <Your AWS secret access key> Default region name: [us-east-1]: <Your desired Region for deployment> Default output format [None]: <Your desired output format> ```	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Clone the repository.</td><td>
1. Clone the repository that's provided with this pattern. You can use HTTPS or Secure Shell (SSH).
HTTPS:
<pre><code>git clone https://github.com/aws-samples/terraform-ec2-image-builder-container-hardening-pipeline</code></pre>
SSH:
<pre><code>git clone git@github.com:aws-samples/terraform-ec2-image-builder-container-hardening-pipeline.git</code></pre>
2. Navigate to your local directory that contains this solution:
<pre><code>cd terraform-ec2-image-builder-container-hardening-pipeline</code></pre>
</td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required

Update variables.	Update the variables in the `hardening-pipeline .tfvars` file to match your environment and your desired configuration. You must provide your own `account_id` . However, you should also modify the rest of the variables to fit your desired deployment. All variables are required.
	
	`account_id = "<DEPLOYMENT-ACCOUNT-ID>"`
	`aws_region = "us-east-1"`
	`vpc_name = "example-hardening-pipeline-vpc"`
	`kms_key_alias = "image-builder-container-key"`
	`ec2_iam_role_name = "example-hardening-instance-role"`
	`hardening_pipeline_role_name = "example-hardening-pipeline-role"`
	`aws_s3_ami_resources_bucket = "example-hardening-ami-resources-bucket-0123"`
	`image_name = "example-hardening-al2-container-image"`
		AWS DevOps

Task	Description	Skills required

	`ecr_name = "example-hardening-container-repo"`
	`recipe_version = "1.0.0"`
	`ebs_root_vol_size = 10`
	
	Here's a description of each variable:
	
	• `account_id` – The AWS account number that you want to deploy the solution into.
	• `aws_region` – The AWS Region that you want to deploy the solution into.
	• `vpc_name` – The name for your VPC infrastructure.
	• `kms_key_alias` – The AWS KMS key name to be used by the EC2 Image Builder infrastructure configuration.
	• `ec2_iam_role_name` – The name for the role that will be used as the EC2 instance profile.
	• `hardening_pipeline_role_name` – The name for the role that will be used to deploy the hardening pipeline.
	• `aws_s3_ami_resources_bucket` – The name	

Task	Description	Skills required
	for an S3 bucket that will host all files necessary to build the pipeline and container images. • `image_name` – The container image name. This value must be between 3 and 50 characters and should contain alphanumeric characters and hyphens only. • `ecr_name` – The name of the Amazon ECR registry to store the container images in. • `recipe_version` – The version of the image recipe. The default value is 1.0.0. • `ebs_root_vol_size` – The size (in gigabytes) of the Amazon Elastic Block Store (Amazon EBS) root volume. The default value is 10 gigabytes.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Initialize Terraform.</td><td>After you update your variable values, you can initialize the Terraform configuration directory. Initializing a configuration directory downloads and installs the AWS provider, which is defined in the configuration.<pre><code>terraform init</code></pre>You should see a message that says Terraform has been successfully initialized and identifies the version of the provider that was installed.</td><td>AWS DevOps</td></tr>
<tr><td>Deploy the infrastructure and create a container image.</td><td>Use the following command to initialize, validate, and apply the Terraform modules to the environment by using the variables defined in your <code>.tfvars</code> file:<pre><code>terraform init &&
 terraform validate &&
 terraform apply -var-
file *.tfvars -auto-app
rove</code></pre></td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required
Customize the container.	You can create a new version of a container recipe after EC2 Image Builder deploys the pipeline and initial recipe. You can add any of the 31+ components available within EC2 Image Builder to customize the container build. For more information, see the *Components* section of [Create a new version of a container recipe](#) in the EC2 Image Builder documenta tion.	AWS administrator

Validate resources

Task	Description	Skills required

Validate AWS infrastructure provisioning.	After you have successfu lly completed your first Terraform `apply` command, if you're provisioning locally, you should see this snippet in your local machine's terminal:
	
	`Apply complete!`
	`Resources: 43 added, 0 changed, 0 destroyed.`
		AWS DevOps

Validate individual AWS infrastructure resources.	To validate the individual resources that were deployed, if you're provisioning locally,	AWS DevOps

Task	Description	Skills required
	you can run the following command: `terraform state list` This command returns a list of 43 resources.	

Remove resources

Task	Description	Skills required
Remove the infrastructure and container image.	When you’ve finished working with your Terraform configuration, you can run the following command to remove resources: `terraform init && terraform validate && terraform destroy -var-file *.tfvars -auto-approve`	AWS DevOps

Troubleshooting

Issue	Solution
Error validating provider credentials	When you run the Terraform `apply` or `destroy` command from your local machine, you might encounter an error similar to the following:

Issue	Solution
	`Error: configuring Terraform AWS Provider: error validating provider credentials: error calling sts:GetCallerIdentity: operation error STS: GetCallerIdentity, https response error StatusCode: 403, RequestID: 123456a9-fbc1-40ed-b8d8-513d0133ba7f, api error InvalidClientTokenId: The security token included in the request is invalid.` This error is caused by the expiration of the security token for the credentials used in your local machine's configuration. To resolve the error, see Set and view configuration settings in the AWS CLI documentation.

Centralize IAM access key management in AWS Organizations by using Terraform

Aarti Rajput, Chintamani Aphale, T.V.R.L.Phani Kumar Dadi, Pratap Kumar Nanda, Pradip kumar Pandey, and Mayuri Shinde, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

Enforcing security rules for keys and passwords is an essential task for every organization. One important rule is to rotate AWS Identity and Access Management (IAM) keys at regular intervals to enforce security. AWS access keys are generally created and configured locally whenever teams want to access AWS from the AWS Command Line Interface (AWS CLI) or from applications outside AWS. To maintain strong security across the organization, old security keys must be changed or deleted after the requirement has been met or at regular intervals. The process of managing key rotations across multiple accounts in an organization is time-consuming and tedious. This pattern helps you automate the rotation process by using Account Factory for Terraform (AFT) and AWS services.

The pattern provides these benefits:

- Manages your access key IDs and secret access keys across all the accounts in your organization from a central location.
- Automatically rotates the `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY` environment variables.
- Enforces renewal if user credentials are compromised.

The pattern uses Terraform to deploy AWS Lambda functions, Amazon EventBridge rules, and IAM roles. An EventBridge rule runs at regular intervals and calls a Lambda function that lists all user access keys based on when they were created. Additional Lambda functions create a new access key ID and secret access key, if the previous key is older than the rotation period you define (for example, 45 days), and notify a security administrator by using Amazon Simple Notification Service (Amazon SNS) and Amazon Simple Email Service (Amazon SES). Secrets are created in AWS Secrets Manager for that user, the old secret access key is stored in Secrets Manager, and permissions for accessing the old key are configured. To ensure that the old access key is no longer used, it is disabled after an inactive period (for example, 60 days, which would be 15 days after the keys were rotated in our example). After an inactive buffer period (for example, 90 days, or 45 days after the keys were rotated in our example), the old access keys are deleted from AWS Secrets Manager. For a detailed architecture and workflow, see the Architecture section.

Prerequisites and limitations

- A landing zone for your organization that's built by using AWS Control Tower (version 3.1 or later)
- Account Factory for Terraform (AFT) configured with three accounts:
  - Organization management account manages the entire organization from a central location.
  - AFT management account hosts the Terraform pipeline and deploys the infrastructure into the deployment account.
  - Deployment account deploys this complete solution and manages IAM keys from a central location.
- Terraform version 0.15.0 or later for provisioning the infrastructure in the deployment account.
- An email address that's configured in Amazon Simple Email Service (Amazon SES).
- (Recommended) To enhance security, deploy this solution inside a private subnet (deployment account) within a virtual private cloud (VPC). You can provide the details of the VPC and subnet when you customize the variables (see *Customize parameters for the code pipeline* in the Epics section).

Architecture

AFT repositories

This pattern uses Account Factory for Terraform (AFT) to create all required AWS resources and the code pipeline to deploy the resources in a deployment account. The code pipeline runs in two repositories:

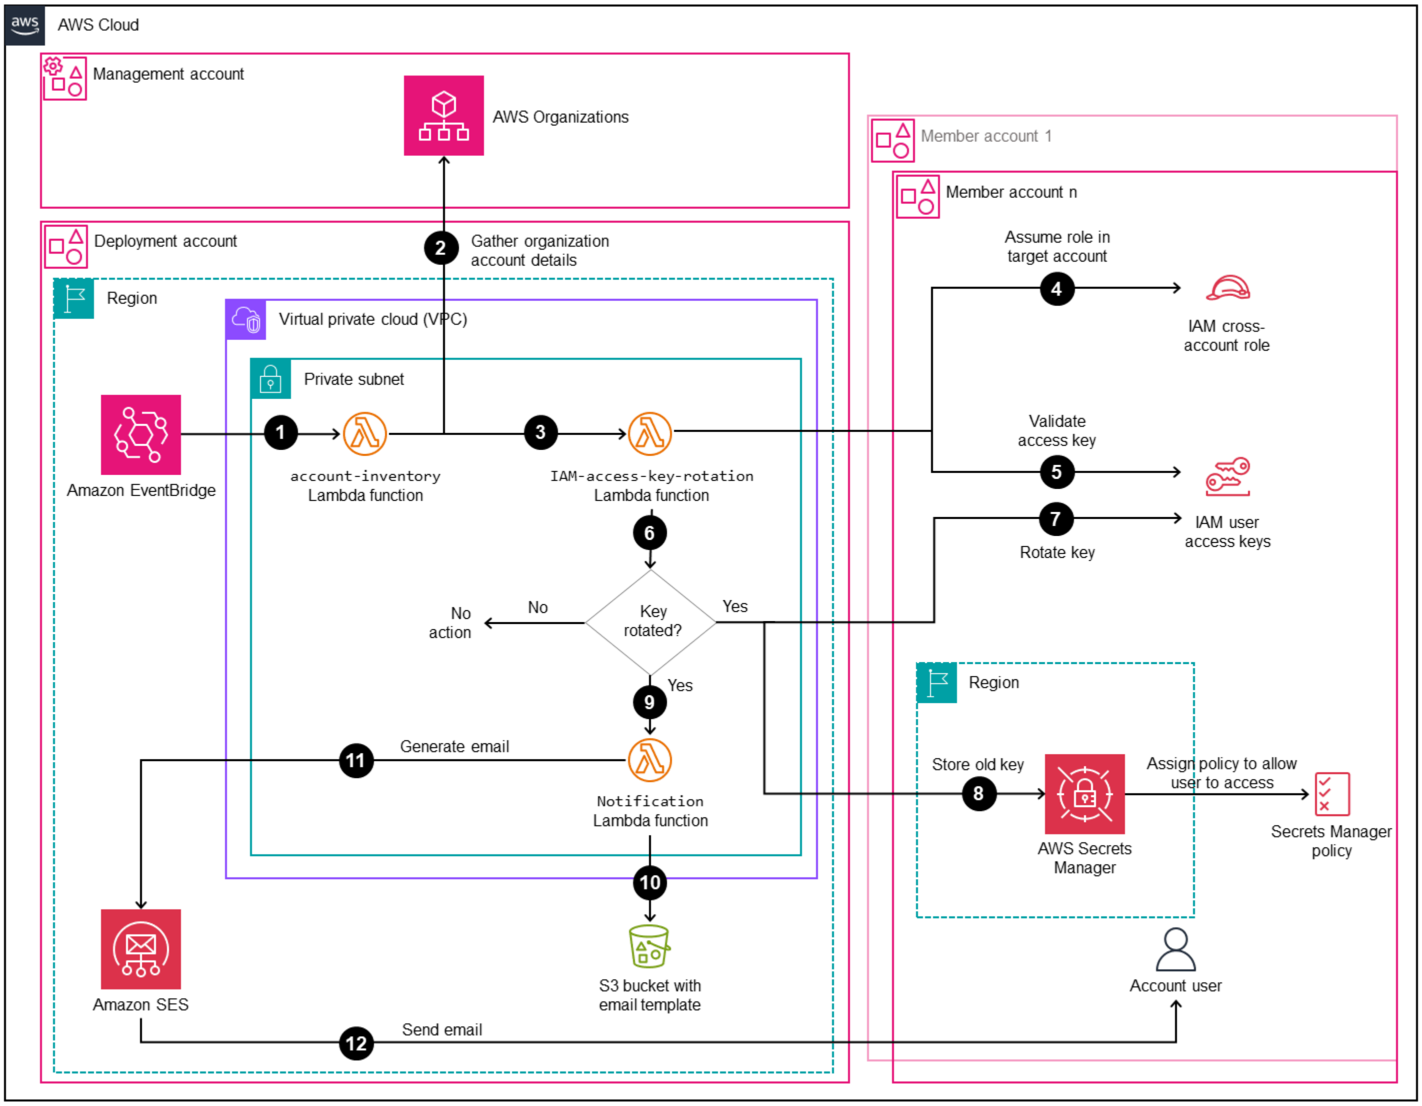
- **Global customization** contains Terraform code that will run across all accounts registered with AFT.
- **Account customizations** contains Terraform code that will run in the deployment account.

Resource details

AWS CodePipeline jobs create the following resources in the deployment account:

- AWS EventBridge rule and configured rule
- `account-inventory` Lambda function
- `IAM-access-key-rotation` Lambda function
- `Notification` Lambda function
- Amazon Simple Storage Service (Amazon S3) bucket that contains an email template
- Required IAM policy

Architecture



The diagram illustrates the following:

1. An EventBridge rule calls the `account-inventory` Lambda function every 24 hours.
2. The `account-inventory` Lambda function queries AWS Organizations for a list of all AWS account IDs, account names, and account emails.
3. The `account-inventory` Lambda function initiates an `IAM-access-key-auto-rotation` Lambda function for each AWS account and passes the metadata to it for additional processing.
4. The `IAM-access-key-auto-rotation` Lambda function uses an assumed IAM role to access the AWS account. The Lambda script runs an audit against all users and their IAM access keys in the account.
5. The IAM key rotation threshold (rotation period) is configured as an environment variable when the `IAM-access-key-auto-rotation` Lambda function is deployed. If the rotation period is modified, the `IAM-access-key-auto-rotation` Lambda function is redeployed with an updated environment variable. You can configure parameters to set the rotation period, the inactive period for old keys, and the inactive buffer after which old keys will be deleted (see *Customize parameters for the code pipeline* in the Epics section).
6. The `IAM-access-key-auto-rotation` Lambda function validates the age of the access key based on its configuration. If the IAM access key's age hasn't exceeded the rotation period you defined, the Lambda function takes no further action.
7. If the IAM access key's age has exceeded the rotation period you defined, the `IAM-access-key-auto-rotation` Lambda function creates a new key and rotates the existing key.
8. The Lambda function saves the old key in Secrets Manager and limits permissions to the user whose access keys deviated from security standards. The Lambda function also creates a resource-based policy that allows only the specified IAM principal to access and retrieve the secret.
9. The `IAM-access-key-rotation` Lambda function calls the `Notification` Lambda function.
10. The `Notification` Lambda function queries the S3 bucket for an email template and dynamically generates email messages with the relevant activity metadata.
11. The `Notification` Lambda function calls Amazon SES for further action.
12. Amazon SES sends email to the account owner's email address with the relevant information.

Tools

AWS services

- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them. This patern requires IAM roles and permissions.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon Simple Email Service (Amazon SES) helps you send and receive emails by using your own email addresses and domains.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The instructions and code for this pattern are available in the GitHub IAM access key rotation repository. You can deploy the code in the AWS Control Tower central deployment account to manage key rotation from a central location.

Best practices

- For IAM, see security best practices in the IAM documentation.
- For key rotation, see guidelines for updating access keys in the IAM documentation.

Epics

Set up source files

Task	Description	Skills required
Clone the repository.	1. Clone the IAM access key rotation GitHub repository:	DevOps engineer

Task	Description	Skills required

	`$ git clone https://github.com/aws-samples/centralized-iam-key-management-aws-organizations-terraform.git`
	
	2. Confirm that your local copy of the repository contains three folders:
	
	`$ cd Iam-Access-keys-Rotation`
	`$ ls`
	`org-account-customization`
	`global-account-customization`
	`account-customization`	

Configure accounts

Task	Description	Skills required
Configure the bootstrapping account.	As part of the AFT bootstrapping process, you should have a folder called `aft-bootstrap` on your local machine. 1. Copy all Terraform files manually from your local GitHub org-account-customization folder to your `aft-bootstrap` folder.	DevOps engineer

Task	Description	Skills required

	2. Run Terraform commands to configure the global cross-account role in the AWS Control Tower management account:
	```$ cd aft-bootstrap```
	```$ terraform init```
	```$ terraform apply –auto-approve```	

Configure global customizations.	As part of the [AFT folder](#) setup, you should have a folder called `aft-global-customizations` on your local machine.
	1. Manually copy all Terraform files from your local GitHub [global-account-customization](#) folder to your `aft-global-customizations/terraform` folder.
	2. Push the code to AWS CodeCommit:
	```$ git add *```
	```$ git commit -m "message"```
	```$ git push```
		DevOps engineer

Task	Description	Skills required

Configure account customizations.	As part of the [AFT folder setup](#), you have be a folder called `aft-account-customizations` on your local machine.
	
	1. Create a folder with your vended account number.
	2. Manually copy manual all Terraform files from your local GitHub [account-customization](#) folder to your `aft-account-customizations/<vended account>/terraform` folder.
	3. Push the code to AWS CodeCommit:
	
	`$ git add *`
	`$ git commit -m "message"`
	`$ git push`
		DevOps engineer

Customize parameters for the code pipeline

Task	Description	Skills required
Customize non-Terraform code pipeline parameters for all accounts.	Create a file called `input.auto.tfvars` in the `aft-global-customizations/terraform/` folder and provide the required input data. See the	DevOps engineer

Task	Description	Skills required
	file in the GitHub repository for default values.	

Task	Description	Skills required
Customize code pipeline parameters for the deployment account.	Create a file called `input.auto.tfvars` in the `aft-account-customizations/<AccountName>/terraform/` folder and push the code to AWS CodeCommit. Pushing code to AWS CodeCommit automatically initiates the code pipeline. Specify values for parameters based on your organization's requirements, including the following (see [the file in the Github repository](#) for default values): • `s3_bucket_name` – A unique bucket name for the email template. • `s3_bucket_prefix` – A folder name inside the S3 bucket. • `admin_email_address` – The email address for the administrator who should receive the notification. • `org_list_account` – The account number of the management account. • `rotation_period` – The number of days after which	DevOps engineer

Task	Description	Skills required
	a key should be rotated from active to inactive. • `inactive_period` – The number of days after which rotated keys should be deactivated. This value must be greater than the value of `rotation_period`. • `inactive_buffer` – The grace period between the rotation and the deactivation of a key. • `recovery_grace_period` – The grace period between the deactivation and the deletion of a key. • `dry_run_flag` – Set to **true** if you want to send a notification to the administrator for testing purposes, without rotating keys. • `store_secrets_in_central_account` – Set to **true** if you want to store the secret in the deployment account. If the variable is set to **false** (default), the secret will be stored in the member account. • `credential_replication_region` – The	

Task	Description	Skills required
	AWS Region where you want to deploy the Lambda function and the S3 buckets for the email template. • `run_lambda_in_vpc` – Set to **true** to run the Lambda function inside the VPC. • `vpc_id` – The VPC ID of the deployment account, if you want to run the Lambda function inside the VPC. • `vpc_cidr` – The CIDR range for the deployment account. • `subnet_id` – The subnet IDs for the deployment account. • `create_smtp_endpoint` – Set to **true** if you want to enable the email endpoint.	

Validate key rotation

Task	Description	Skills required
Validate the solution.	1. From the AWS Management Console, sign in to the deployment account. 2. Open the [IAM console](https://console.aws.amazon.com/iam/) and check whether user credentials (access key IDs	DevOps engineer

Task	Description	Skills required
	and secret keys) are being rotated as specified. 3. After an IAM key has been rotated, confirm the following: • The old value is stored in AWS Secrets Manager. • The secret name is in the format `Account_<account ID>_User_<username>_AccessKey` . • The user you specified in the `admin_email_address` parameter receives an email notification about the key rotation.	

Extend the solution

Task	Description	Skills required
Customize the email notification date.	If you want to send email notifications on a specific day before you disable the access key, you can update the `IAM-access-key-auto-rotation` Lambda function with those changes: 1. Define a variable called `notify-period` .	DevOps engineer

Task	Description	Skills required
	2. Add an `if` condition in `main.py` before you deactivate the key: `If (keyage>rotation-period-notify-period){ send_to_notifier(context, aws_account_id, account_name, resource_owner, resource_actions[resource_owner], dryrun, config.emailTemplateAudit) }`	

Troubleshooting

Issue	Solution
The `account-inventory` Lambda job fails with `AccessDenied` while listing accounts.	If you encounter this issue, you must validate permissions: 1. Log in to the newly vended account, open the [Amazon CloudWatch console](https://console.aws.amazon.com/cloudwatch/), and and then view the CloudWatch log group `/aws/lambda/account-inventory-lambda`. 2. In the latest CloudWatch logs, identify the account number that is causing the access denied issue. 3. Log in to the AWS Control Tower management account and confirm that the role `allow-list-account` was created.

Issue	Solution
	4. If the role doesn't exist, rerun the Terraform code by using the `terraform apply` command. 5. Choose the **Trusted Account** tab and validate that the same account is trusted.

Check an Amazon CloudFront distribution for access logging, HTTPS, and TLS version

SaiJeevan Devireddy and Bijesh Bal, Amazon Web Services

Summary

This pattern checks an Amazon CloudFront distribution to make sure that it uses HTTPS, uses Transport Layer Security (TLS) version 1.2 or later, and has access logging enabled. CloudFront is a service provided by Amazon Web Services (AWS) that speeds up the distribution of your static and dynamic web content, such as .html, .css, .js, and image files, to your users. CloudFront delivers your content through a worldwide network of data centers called *edge locations*. When a user requests content that you're serving with CloudFront, the request is routed to the edge location that provides the lowest latency (time delay), so that content is delivered with the best possible performance.

This pattern provides an AWS Lambda function that is initiated when Amazon CloudWatch Events detects the CloudFront API call CreateDistribution, CreateDistributionWithTags, or UpdateDistribution. The custom logic in the Lambda function evaluates all CloudFront distributions that were created or updated in the AWS account. It sends a violation notification by using Amazon Simple Notification Service (Amazon SNS) if it detects the following violations:

- Global checks:
  - Custom certificate doesn't use TLS version 1.2
  - Logging is disabled for distribution
- Origin checks:
  - Origin isn't configured with TLS version 1.2
  - Communication with origin is allowed on a protocol other than HTTPS
- Behavior checks:
  - Default behavior communication is allowed on a protocol other than HTTPS
  - Custom behavior communication is allowed on a protocol other than HTTPS

Prerequisites and limitations

Prerequisites

- An active AWS account
- An email address where you want to receive the violation notifications

Limitations

- This security control doesn't check for existing Cloudfront distributions unless an update has been made to the distribution.
- CloudFront is considered a global service and isn't tied to a specific AWS Region. However, Amazon CloudWatch Logs and AWS Cloudtrail API logging for global services occur in the US East (N. Virginia) Region (`us-east-1`). Therefore, this security control for CloudFront must be deployed and maintained in `us-east-1`. This single deployment monitors all distributions for CloudFront. Do not deploy the security control in any other AWS Regions. (Deployment in other Regions will result in a failure to initiate CloudWatch Events and the Lambda function, and no SNS notifications.)
- This solution has gone through extensive testing with CloudFront web content distributions. It does not cover real-time messaging protocol (RTMP) streaming distributions.

Architecture

Target technology stack

- Lambda function
- SNS topic
- Amazon EventBridge rule

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy the attached template across multiple accounts that you want to monitor.

Tools

AWS services

- AWS CloudFormation – CloudFormation is a service that helps you model and set up AWS resources by using infrastructure as code.
- Amazon EventBridge – EventBridge delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services, routing that data to targets such as Lambda functions.
- AWS Lambda – Lambda supports running code without provisioning or managing servers.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS – Amazon SNS coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

The attached code includes:

- A .zip file that contains the Lambda code (index.py)
- A CloudFormation template (.yml file) that you run to deploy the Lambda code

Epics

Upload the security control

Task	Description	Skills required
Create the S3 bucket for the Lambda code.	On the Amazon S3 console, create a S3 bucket with an	Cloud architect

Task	Description	Skills required
	unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. Your S3 bucket must be in the Region where you are planning to deploy the Lambda code.	
Upload the Lambda code to the S3 bucket.	Upload the Lambda code (cloudfront_ssl_log_lambda.zip file) that's provided in the *Attachments* section to the S3 bucket you created in the previous step.	Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	On the AWS CloudFormation console, in the same AWS Region as the S3 bucket, deploy the CloudFormation template (cloudfront-ssl-logging.yml) that's provided in the *Attachments* section.	Cloud architect
Specify the S3 bucket name.	For the **S3 Bucket** parameter, specify the name of the S3 bucket that you created in the first epic.	Cloud architect

Task	Description	Skills required
Specify the Amazon S3 key name for the Lambda file.	For the **S3 Key** parameter , specify the Amazon S3 location of the Lambda code .zip file in your S3 bucket. Do not include leading slashes (for example, you can enter lambda.zip or controls/lambda.zip).	Cloud architect
Provide a notification email address.	For the **Notification email** parameter, provide an email address where you would like to receive the violation notifications.	Cloud architect
Define the logging level.	For the **Lambda Logging level** parameter, define the logging level for your Lambda function. Choose one of the following values: • **INFO** to get detailed informational messages on the application's progress. • **ERROR** to get informati on about error events that could still allow the application to continue running. • **WARNING** to get informati on about potentially harmful situations.	Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the CloudFormation template has been deployed successfully, a new SNS topic is created and a subscript ion message is sent to the email address you provided. You must confirm this email subscription to receive violation notifications.	Cloud architect

Check for single-host network entries in security group ingress rules for IPv4 and IPv6

SaiJeevan Devireddy, Ganesh Kumar, and John Reynolds, Amazon Web Services

Summary

This pattern provides a security control that notifies you when Amazon Web Services (AWS) resources do not meet your specifications. It provides an AWS Lambda function that looks for single-host network entries in both Internet Protocol version 4 (IPv4) and IPv6 security group source address fields. The Lambda function is initiated when Amazon CloudWatch Events detects the Amazon Elastic Compute Cloud (Amazon EC2) AuthorizeSecurityGroupIngress API call. The custom logic in the Lambda function evaluates the subnet mask of the CIDR block of the security group ingress rule. If the subnet mask is determined to be anything other than /32 (IPv4) or /128 (IPv6), the Lambda function sends a violation notification by using Amazon Simple Notification Service (Amazon SNS).

Prerequisites and limitations

Prerequisites

- An active AWS account
- An email address where you want to receive the violation notifications

Limitations

- This security monitoring solution is regional and must be deployed in each AWS Region that you want to monitor.

Architecture

Target technology stack

- Lambda function
- SNS topic
- Amazon EventBridge rule

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use [AWS Cloudformation StackSets](#) to deploy this template across multiple accounts that you want to monitor.

Tools

AWS services

- [AWS CloudFormation](#) is a service that helps you model and set up AWS resources by using infrastructure as code.
- [Amazon EventBridge](#) delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services, and routes that data to targets such as Lambda functions.
- [AWS Lambda](#) supports running code without provisioning or managing servers.
- [Amazon Simple Storage Service (Amazon S3)](#) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [Amazon SNS](#) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

The attached code includes:

- A .zip file that contains the Lambda security control code (`index.py`)

- A CloudFormation template (`security-control.yml` file) that you run to deploy the Lambda code

Epics

Upload the security control

Task	Description	Skills required
Create the S3 bucket for the Lambda code.	On the [Amazon S3 console](https://console.aws.amazon.com/s3/), create a S3 bucket with an unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. Your S3 bucket must be in the AWS Region where you want to deploy the security group ingress check.	Cloud architect
Upload the Lambda code to the S3 bucket.	Upload the Lambda code (`security-control-lambda.zip` file) that's provided in the *Attachments* section to the S3 bucket that you created in the previous step.	Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Change the Python version.	Download the CloudFormation template (`security-control.yml`) that's	Cloud architect

Task	Description	Skills required
	provided in the *Attachments* section. Open the file and modify the Python version to reflect the latest version supported by Lambda (currently Python 3.9). For example, you can search for `python` in the code and change the value for `Runtime` from `python3.6` to `python3.9`. For the latest information about Python runtime version support, see the [AWS Lambda documentation]().	
Deploy the AWS CloudFormation template.	On the AWS CloudFormation console, in the same AWS Region as the S3 bucket, deploy the CloudFormation template (`security-control.yml`).	Cloud architect
Specify the S3 bucket name.	For the **S3 Bucket** parameter, specify the name of the S3 bucket that you created in the first epic.	Cloud architect

Task	Description	Skills required
Specify the Amazon S3 key name for the Lambda file.	For the **S3 Key** parameter , specify the Amazon S3 location of the Lambda code .zip file in your S3 bucket. Do not include leading slashes (for example, you can enter `lambda.zip` or `controls/lambda.zip`).	Cloud architect
Provide a notification email address.	For the **Notification email** parameter, provide an email address where you would like to receive the violation notifications.	Cloud architect
Define the logging level.	For the **Lambda Logging level** parameter, define the logging level for your Lambda function. Choose an Amazon Cognito authentication flow for enterprise applications

Michael Daehnert and Fabian Jahnke, Amazon Web Services

Summary

[Amazon Cognito](https://aws.amazon.com/cognito/) provides authentication, authorization, and user management for web and mobile applications. It offers beneficial features for authentication of federated identities. To get it up and running, technical architects need to decide how they want to use those features.

Amazon Cognito supports multiple flows for authentication requests. These flows define how your users can verify their identity. The decision about which authentication flow to use depends on specific requirements of your application and can become complex. This pattern helps you decide which authentication flow is the best fit for your enterprise application. It assumes that you already have a basic knowledge of Amazon Cognito, OpenID Connect (OIDC), and federation, and it guides you through details about different federated authentication flows.

This solution is intended for technical decision makers. It helps you understand the different authentication flows and map them to your application requirements. Technical leads should gather the required insights to start the Amazon Cognito integrations. Because enterprise organizations mainly focus on SAML federation, this pattern includes descriptions for Amazon Cognito user pools with SAML federation.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) roles and permissions with full access to Amazon Cognito
- (Optional) Access to your identity provider (IdP), such as Microsoft Entra ID, Active Directory Federation Service (AD FS), or Okta
- A high level of expertise for your application
- Basic knowledge of Amazon Cognito, OpenID Connect (OIDC), and federation

Limitations

- This pattern focuses on Amazon Cognito user pools and identity providers. For information about Amazon Cognito identity pools, see the [Additional information] section.

Architecture

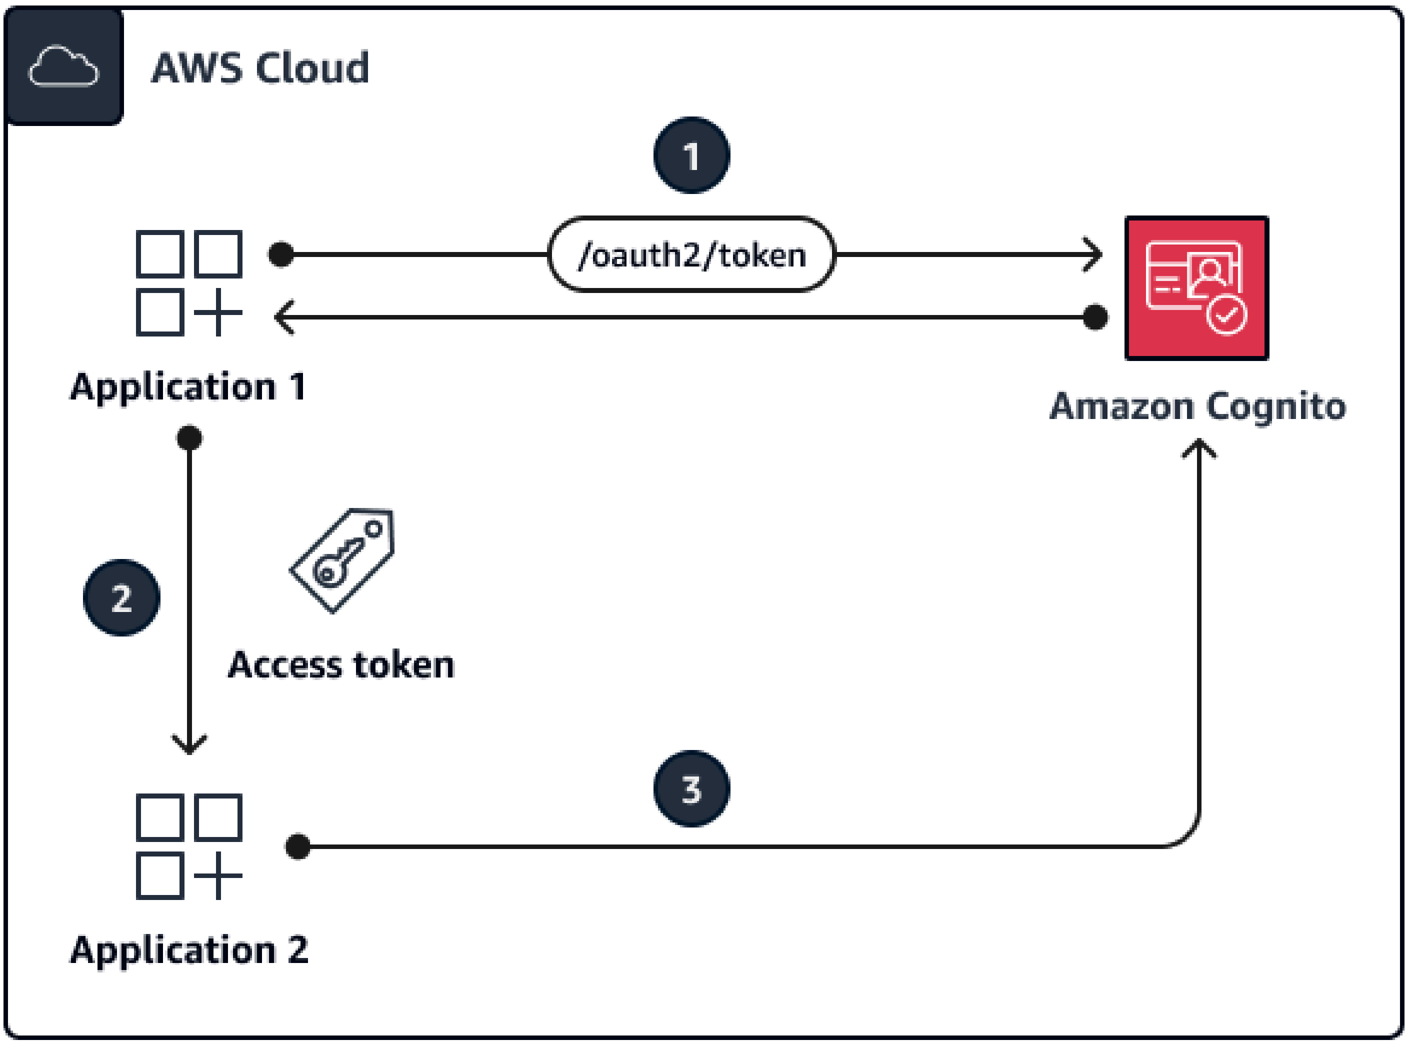
Use the following table to help you choose an authentication flow. More information about each flow is provided in this section.

Do you need machine-to-machine authentication?	Is your app a web-based application where the frontend is rendered on the server?	Is your app a single-page application (SPA) or mobile-based frontend application?	Does your application require refresh tokens for a "keep me signed in" feature?	Does the frontend offer a browser-based redirect mechanism?	Recommended Amazon Cognito flow
Yes	No	No	No	No	Client Credentials flow
No	Yes	No	Yes	Yes	Authorization Code flow
No	No	Yes	Yes	Yes	Authorization Code flow with Proof Key for Code Exchange (PKCE)
No	No	No	No	No	Resource Owner Password flow*

* Resource Owner Password flow should be used only if absolutely necessary. For more information, see the *Resource Owner Password flow* section in this pattern.

Client Credentials flow

The Client Credentials flow is the shortest of the Amazon Cognito flows. It should be used if systems or services communicate with each other without any user interaction. The requesting system uses the client ID and the client secret to retrieve an access token. Because both systems work without user interaction, no additional consent step is required.



The diagram illustrates the following:

1. Application 1 sends an authentication request with the client ID and client secret to the Amazon Cognito endpoint, and it retrieves an access token.
2. Application 1 uses this access token for every subsequent call to Application 2.

3. Application 2 validates the access token with Amazon Cognito.

This flow should be used:

- For communications between applications with no user interaction

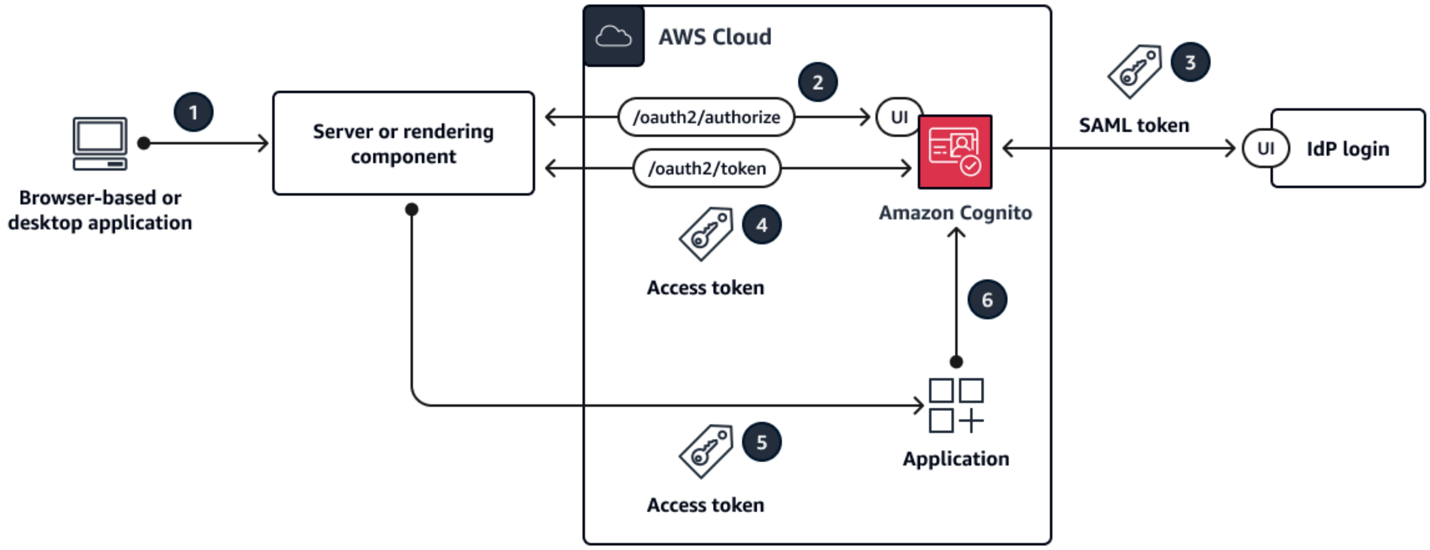
This flow should not be used:

- For any communication in which user interactions are possible

Authorization Code flow

The Authorization Code flow is for classic web-based authentication. In this flow, the backend handles all of the token exchange and storage. The browser-based client does not see the actual tokens. This solution is used for applications written in frameworks such as .NET Core, Jakarta Faces, or Jakarta Server Pages (JSP).

The Authorization Code flow is a redirection-based flow. The client must be able to interact with the web browser or a similar client. The client is redirected to an authentication server and authenticates against this server. If the client authenticates successfully, it is redirected back to the server.



The diagram illustrates the following:

1. The client sends a request to the web server.

2. The web server redirects the client to Amazon Cognito by using an HTTP 302 status code. The client automatically follows this redirect to the configured IdP login.
3. The IdP checks for an existing browser session on the IdP side. If none exists, the user receives a prompt to authenticate by providing their username and password. The IdP responds with a SAML token to Amazon Cognito.
4. Amazon Cognito returns success with a JSON web token (JWT), specifically a code token. The web server calls /oauth2/token to exchange the code token for an access token. The web server sends the client ID and client secret to Amazon Cognito for validation.
5. The access token is used for every subsequent call to other applications.
6. Other applications validate the access token with Amazon Cognito.

This flow should be used:

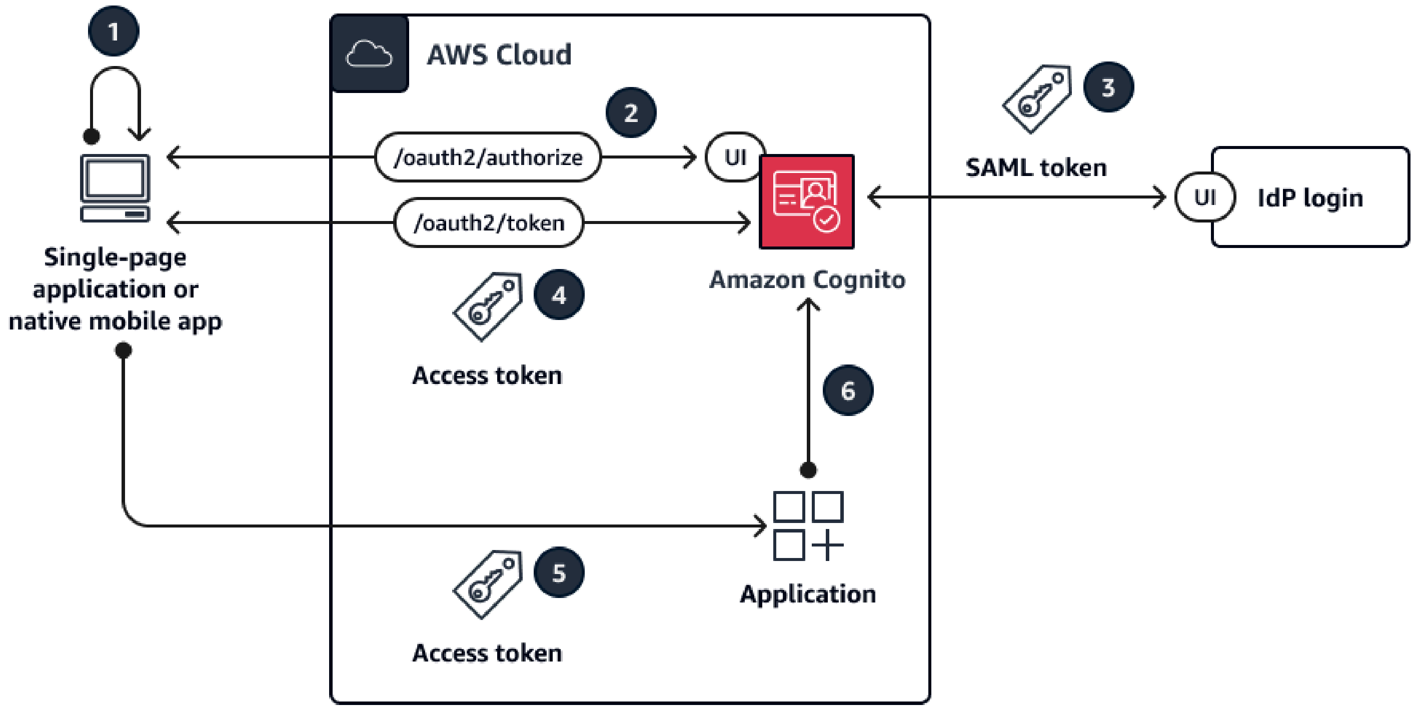
- If the user is able to interact with the web browser or client. The application code is run and rendered on the server to make sure that no secrets are exposed to the browser.

This flow should not be used:

- For single-page applications (SPAs) or mobile apps because they're rendered on the client and shouldn't use client secrets.

Authorization Code flow with PKCE

Authorization Code flow with Proof Key for Code Exchange (PKCE) should be used for single-page applications and mobile applications. It is the successor of the Implicit flow and is more secure because it uses PKCE. PKCE is an extension to the OAuth 2.0 authorization code grant for public clients. PKCE guards against the redemption of intercepted authorization codes.



The diagram illustrates the following:

1. The application creates a code verifier and code challenge. These are well defined, unique values that are sent to Amazon Cognito for future reference.
2. The application calls the /oauth2/authorization endpoint of Amazon Cognito. It automatically redirects the user to the configured IdP login.
3. The IdP checks for an existing session. If none exists, the user receives a prompt to authenticate by providing their username and password. The IdP responds with a SAML token to Amazon Cognito.
4. After Amazon Cognito returns success with a code token, the web server calls /oauth2/token to exchange the code token for an access token.
5. The access token is used for every subsequent call to other applications.
6. The other applications validate the access token with Amazon Cognito.

This flow should be used:

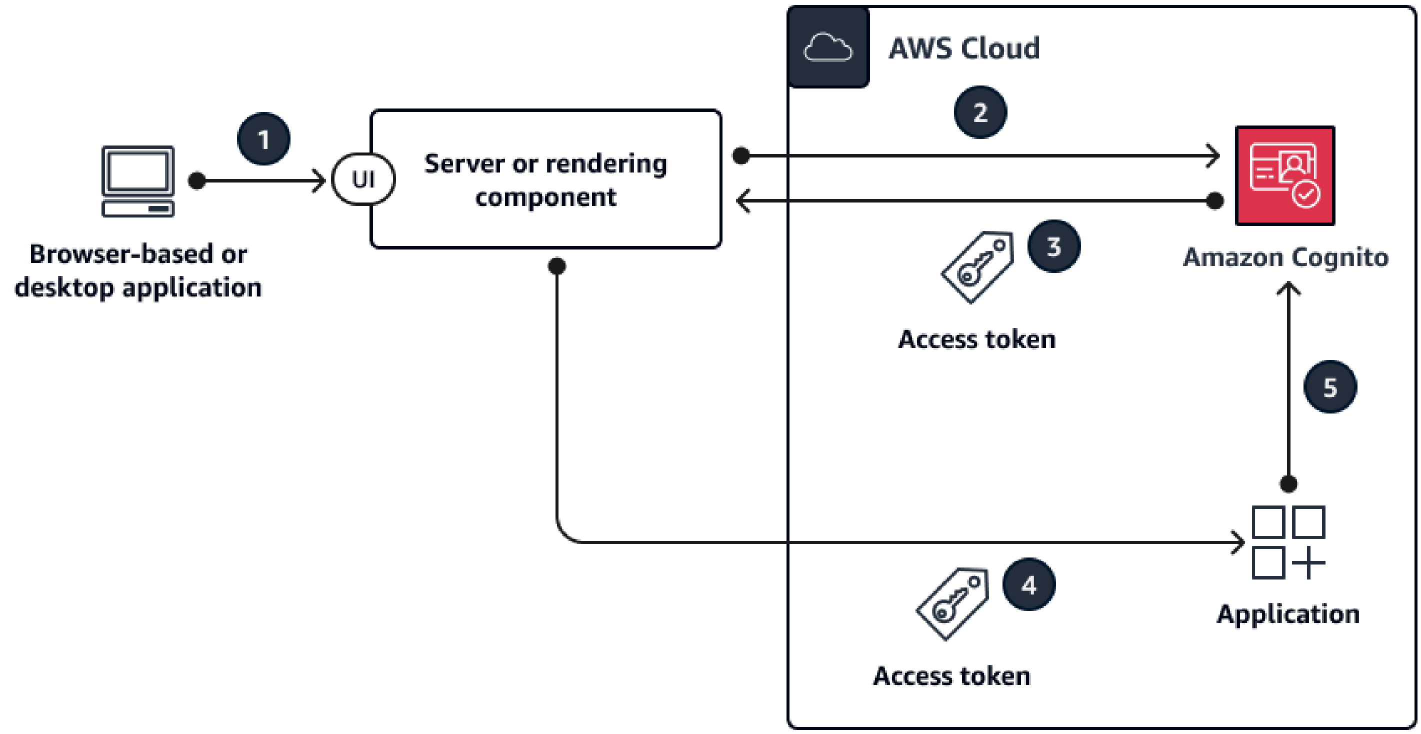
- For SPAs or mobile applications

This flow should not be used:

- If the application backend handles authentication

Resource Owner Password flow

The Resource Owner Password flow is intended for applications with no redirect capabilities. It is built by creating a login form in your own application. The login is checked on Amazon Cognito through a CLI or SDK call instead of relying on redirect flows. Federation is not possible in this authentication flow because federation requires browser-based redirects.



The diagram illustrates the following:

1. The user enters their credentials on a login form provided by the application.
2. The AWS Command Line Interface (AWS CLI) makes an admin-initiated-auth call to Amazon Cognito.

> **Note**
> Alternatively, you can use AWS SDKs instead of the AWS CLI.

3. Amazon Cognito returns an access token.
4. The access token is used for every subsequent call to other applications.

5. The other applications validate the access token with Amazon Cognito.

This flow should be used:

- When migrating existing clients that use direct authentication logic (such as basic access authentication or digest access authentication) to OAuth by converting the stored credentials to an access token

This flow should not be used:

- If you want to use federated identities
- If your application supports redirects

Tools

AWS services

- Amazon Cognito provides authentication, authorization, and user management for web and mobile apps.

Other tools

- JSON web token (JWT) debugger is a web-based JWT validation tool.

Epics

Assess your application

Task	Description	Skills required
Define authentication requirements.	Assess your application according to your specific authentication requirements.	App developer, App architect

Task	Description	Skills required
	choose your Amazon Cognito authentication flow.	

Set up the Amazon Cognito user pool

Task	Description	Skills required
Create a user pool.	1. Sign in to the AWS Management Console, and then open the [Amazon Cognito console](https://console.aws.amazon.com/cognito/). 2. Create a new Cognito user pool. For instructions, see [Amazon Cognito user pools](https://docs.aws.amazon.com/cognito/latest/developerguide/cognito-user-identity-pools.html). 3. Update the user pool settings and attributes as needed. For example, set a [password policy](https://docs.aws.amazon.com/cognito/latest/developerguide/user-pool-settings-policies.html) for the user pool. Do not create app clients yet.	General AWS
(Optional) Configure an identity provider.	1. Create a SAML identity provider in the Amazon Cognito user pool. For instructions, see [Adding and managing SAML identity providers in a user pool](https://docs.aws.amazon.com/cognito/latest/developerguide/cognito-user-pools-managing-saml-idp.html). 2. Configure your third-party SAML identity provider to work with federation for Amazon Cognito user pools. For more informati	General AWS, Federation administrator

Task	Description	Skills required
	on, see [Configuring your third-party SAML identity provider](). If you're using AD FS, see [Building AD FS Federation for your Web App using Amazon Cognito User Pools]() (AWS blog post).	
Create an app client.	1. Create an app client for the user pool. For instructions, see [Creating an app client](). Note the following: • Change settings as needed, such as token expirations. • If your authentication flow doesn't require a client secret, then clear the **Generate client secret** checkbox. 2. Choose **App client settings** to change its integrati on to a user pool login (username and password) or federated login through a SAML-based IdP. 3. Enable your IdP by defining URLs and defining OAuth flows or scopes as needed.	General AWS

Integrate the application with Amazon Cognito

Task	Description	Skills required
Exchange Amazon Cognito integration details.	Depending on your authentication flow, share Amazon Cognito information with the application, such as the user pool ID and app client ID.	App developer, General AWS
Implement Amazon Cognito authentication.	This depends on your chosen authentication flow, your programming language, and the frameworks you're using. For some links to get started, see the Related resources section.	App developer

Additional information

FAQ

Why is the Implicit flow deprecated?

Since the release of the OAuth 2.1 framework, the Implicit flow is marked as deprecated for security reasons. As an alternative, please use the Authorization Code flow with PKCE described in the Architecture section.

What if Amazon Cognito doesn't offer some functionality I require?

AWS Partners offer different integrations for authentication and authorization solutions. For more information, see AWS Partners for authentication solutions.

What about Amazon Cognito identity pool flows?

Amazon Cognito user pools and federated identities are for authentication. Amazon Cognito identity pools are used for authorization of AWS resources access by requesting temporary AWS credentials. The ID token and access token exchange for identity pools isn't discussed in this pattern. For more information, see What's the difference between Amazon Cognito user pools and identity pools and Common Amazon Cognito scenarios.

Next steps

This pattern provides an overview of Amazon Cognito authentication flows. As a next step, the detailed implementation for the application's programming language needs to be chosen. Multiple languages offer SDKs and frameworks, which you can use with Amazon Cognito. For helpful references, see the Related resources section.

Create AWS Config custom rules by using AWS CloudFormation Guard policies

Andrew Lok, Nicole Brown, Kailash Havildar, and Tanya Howell, Amazon Web Services

Summary

AWS Config rules help you evaluate your AWS resources and their target configuration state. There are two types of AWS Config rules: managed and custom. Your can create custom rules with AWS Lambda functions or with AWS CloudFormation Guard (GitHub), a policy-as-code language.

Rules created with Guard provide more granular control than managed rules, and they are typically easier to configure than fully custom Lambda rules. This approach provides engineers and architects the ability to build rules without needing to know Python, NodeJS, or Java, which are required to deploy custom rules through Lambda.

This pattern provides workable templates, code samples, and deployment approaches to help you adopt custom rules with Guard. By using this pattern, an administrator can use AWS Config to build custom compliance rules that have configuration item attributes. For example, developers can use Guard policies against AWS Config configuration items to continuously monitor the state of deployed AWS and non-AWS resources, detect rule violations, and automatically initiate remediation.

Objectives

After reading this pattern, you should be able to:

- Understand how Guard policy code interacts with the AWS Config service.
- Deploy *Scenario 1*, which is an AWS Config custom rule that uses Guard syntax to validate compliance for encrypted volumes. This rule verifies that the drive is in use and verifies that the drive type is gp3.
- Deploy *Scenario 2*, which is an AWS Config custom rule that uses Guard syntax to validate Amazon GuardDuty compliance. This rule verifies that GuardDuty recorders have Amazon Simple Storage Service (Amazon S3) Protection and Amazon Elastic Kubernetes Service (Amazon EKS) Protection enabled.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Config, set up in your AWS account

Limitations

- Guard custom rules are only able to query key-value pairs in a target configuration item JSON record

Architecture

You apply the Guard syntax to an AWS Config rule as a custom policy. AWS Config captures the hierarchical JSON of each of the resources specified. The JSON of the AWS Config configuration item contains key-value pairs. These attributes are used in the Guard syntax as variables that are assigned to their corresponding value.

The following is an explanation of the Guard syntax. The variables from the configuration item JSON are used and prepended with a % character.

```
# declare variable
let <variable name> = <'value'>

# create rule and assign condition and policy
    rule <rule name> when
        <CI json key> == <"CI json value"> {
            <top level CI json key>.<next level CI json key> == %<variable name>
        }
```

Scenario 1: Amazon EBS volumes

Scenario 1 deploys an AWS Config custom rule that uses Guard syntax to validate compliance for encrypted volumes. This rule verifies that the drive is in use and verifies that the drive type is gp3.

The following is an example of an AWS Config configuration item for scenario 1. There are three key-value pairs in this configuration item that used as variables in the Guard policy:

`volumestatus`, `volumeencryptionstatus`, and `volumetype`. Also, the `resourceType` key is used as a filter in the Guard policy.

```
{
  "version": "1.3",
  "accountId": "111111111111",
  "configurationItemCaptureTime": "2023-01-15T19:04:45.402Z",
  "configurationItemStatus": "ResourceDiscovered",

  "resourceId": "vol-222222222222",
  "awsRegion": "us-west-2",
  "availabilityZone": "us-west-2b",
  "resourceCreationTime": "2023-01-15T19:03:22.247Z",
  "tags": {},
  "relatedEvents": [],
  "relationships": [
    {
      "resourceType": "AWS::EC2::Instance",
      "resourceId": "i-33333333333333333",
      "relationshipName": "Is attached to Instance"
    }
  ],
  "configuration": {
    "attachments": [
      {
        "attachTime": "2023-01-15T19:03:22.000Z",
        "device": "/dev/xvda",
        "instanceId": "i-33333333333333333",
        "state": "attached",
        "volumeId": "vol-222222222222",
        "deleteOnTermination": true,
        "associatedResource": null,
        "instanceOwningService": null
      }
    ],
    "availabilityZone": "us-west-2b",
    "createTime": "2023-01-15T19:03:22.247Z",
    "encrypted": false,
    "kmsKeyId": null,
    "outpostArn": null,
```

```
    "size": 8,
    "snapshotId": "snap-55555555555555555",
    "state": "in-use",
    "volumeId": "vol-222222222222",
    "iops": 100,
    "tags": [],
    "volumeType": "gp2",
    "fastRestored": null,
    "multiAttachEnabled": false,
    "throughput": null,
    "sseType": null
  },
  "supplementaryConfiguration": {}
}
```

The following is an example of using Guard syntax to define the variables and rules in scenario 1. In the following example:

- The first three lines define the variables by using the `let` command. They are assigned a name and value that is derived from the attributes of the configuration item.
- The `compliancecheck` rule block adds a when conditional dependency that looks for a `resourceType` key-value pair that matches `AWS::EC2::Volume`. If a match is found, the rule proceeds through the rest of the JSON attributes and looks for matches on the following three conditions: `state`, `encrypted`, and `volumeType`.

```
let volumestatus = 'available'
let volumetype = 'gp3'
let volumeencryptionstatus = true

    rule compliancecheck when
        resourceType == "AWS::EC2::Volume" {
            configuration.state == %volumestatus
            configuration.encrypted == %volumeencryptionstatus
            configuration.volumeType == %volumetype
        }
```

For the complete Guard custom policy that implements this custom rule, see [awsconfig-guard-cft.yaml] or [awsconfig-guard-tf-ec2vol.json] in the GitHub code repository. For HashiCorp Terraform code that deploys this custom policy in Guard, see [awsconfig-guard-tf-example.json] in the code repository.

Scenario 2: GuardDuty compliance

Scenario 2 deploys an AWS Config custom rule that uses Guard syntax to validate Amazon GuardDuty compliance. This rule verifies that GuardDuty recorders have Amazon S3 Protection and Amazon EKS Protection enabled. It also verifies that GuardDuty findings are published every 15 minutes. This scenario could be deployed across all AWS accounts and AWS Regions in an organization (in AWS Organizations).

The following is an example of an AWS Config configuration item for scenario 2. There are three key-value pairs in this configuration item that used as variables in the Guard policy: `FindingPublishingFrequency`, `S3Logs`, and `Kubernetes`. Also, the `resourceType` key is used as a filter in the policy.

```
{
  "version": "1.3",
  "accountId": "111111111111",
  "configurationItemCaptureTime": "2023-11-27T13:34:28.888Z",
  "configurationItemStatus": "OK",
  "configurationStateId": "7777777777777",
  "configurationItemMD5Hash": "",
  "arn": "arn:aws:guardduty:us-
west-2:111111111111:detector/66666666666666666666666666666666",
  "resourceType": "AWS::GuardDuty::Detector",
  "resourceId": "66666666666666666666666666666666",
  "resourceName": "66666666666666666666666666666666",
  "awsRegion": "us-west-2",
  "availabilityZone": "Regional",
  "resourceCreationTime": "2020-02-17T02:48:04.511Z",
  "tags": {},
  "relatedEvents": [],
  "relationships": [],
  "configuration": {
    "Enable": true,
    "FindingPublishingFrequency": "FIFTEEN_MINUTES",
    "DataSources": {
      "S3Logs": {
        "Enable": true
      },
      "Kubernetes": {
        "AuditLogs": {
          "Enable": true
        }
```

```
      }
    },

    "Id": "66666666666666666666666666666666",
    "Tags": []
  },
  "supplementaryConfiguration": {
    "CreatedAt": "2020-02-17T02:48:04.511Z"
  }
}
```

The following is an example of using Guard syntax to define the variables and rules in scenario 2. In the following example:

- The first three lines define the variables by using the `let` command. They are assigned a name and value that is derived from the attributes of the configuration item.
- The `compliancecheck` rule block adds a when conditional dependency that looks for a `resourceType` key-value pair that matches `AWS::GuardDuty::Detector`. If a match is found, the rule proceeds through the rest of the JSON attributes and looks for matches on the following three conditions: `S3Logs.Enable`, `Kubernetes.AuditLogs.Enable`, and `FindingPublishingFrequency`.

```
let s3protection = true
let kubernetesprotection = true
let publishfrequency = 'FIFTEEN_MINUTES'

    rule compliancecheck when
        resourceType == "AWS::GuardDuty::Detector" {
            configuration.DataSources.S3Logs.Enable == %s3protection
            configuration.DataSources.Kubernetes.AuditLogs.Enable ==
 %kubernetesprotection
            configuration.FindingPublishingFrequency == %publishfrequency
        }
```

For the complete Guard custom policy that implements this custom rule, see [awsconfig-guard-cft-gd.yaml] in the GitHub code repository. For HashiCorp Terraform code that deploys this custom policy in Guard, see [awsconfig-guard-tf-gd.json] in the code repository.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time.

Other tools

- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.

Code repository

The code for this pattern is available in the GitHub AWS Config with AWS CloudFormation Guard repository. This code repository contains samples for both of the scenarios described in this pattern.

Epics

Creating AWS Config custom rules

Task	Description	Skills required
(Optional) Select key-value pairs for the rule.	Complete these steps if you are defining a custom Guard policy. If you are using one of the sample policies for scenario 1 or 2, skip these steps. 1. Sign in to the AWS Management Console and open the AWS Config console.	AWS administrator, Security engineer

Task	Description	Skills required
	2. In the left navigation, choose **Resources**. 3. In the resource inventory , choose the type of resource that you want to create an AWS Config custom rule for. 4. Choose **View details**. 5. Choose **View Configura tion Item (JSON)**. This section expands to show the configuration item in JSON format. 6. Identify the key-value pairs that you would like to build an AWS Config custom rule for.	
Create the custom rule.	Using the key-value pairs that you identified previously or using one of the provided sample Guard policies, follow the instructions in [Creating AWS Config Custom Policy Rules](https://docs.aws.amazon.com/config/latest/developerguide/evaluate-config_develop-rules_cfn-guard.html) to create a custom rule.	AWS administrator, Security engineer

Task	Description	Skills required
Validate the custom rule.	Do one of the following to validate the custom Guard rule: • Enter the following command in the AWS Command Line Interface (AWS CLI). `cfn-guard validate -r guard-s3.guard -d s3bucket-prod-pass.json` • Follow the instructions in *Detective mode* in Evaluating Your Resources with AWS Config Rules to deploy the rule in AWS Config. Confirm that the Guard syntax matches correctly to corresponding resources in the target account or file.	AWS administrator, Security engineer

Troubleshooting

Issue	Solution
Test the Guard policy outside of AWS Config	Unit testing can be done on your local device or in an integrated development environment (IDE), such as an AWS Cloud9 IDE. To perform unit testing, do the following: 1. Install the AWS CloudFormation Guard CLI and its dependencies.

Issue	Solution

	2. Save a JSON-formatted CI sample to your workstation as a .json file.
	3. Save the GuardDuty policy to your workstation as a .guard file.
	4. In the Guard CLI, enter the following command to validate the sample JSON file by using the Guard policy.
	`cfn-guard validate \`
	`-r guard-s3.guard \`
	`-d s3bucket-prod-pass.json`

Debug an AWS Config custom rule	In your Guard policy, change the `EnableDebugLogDelivery` value to `true`. The default value is `false`. The log messages are stored in Amazon CloudWatch.

Create a consolidated report of Prowler security findings from multiple AWS accounts

Mike Virgilio, Jay Durga, and Andrea Di Fabio, Amazon Web Services

Summary

[Prowler](https://github.com/prowler-cloud/prowler) (GitHub) is an open-source command line tool that can help you assess, audit, and monitor your Amazon Web Services (AWS) accounts for adherence to security best practices. In this pattern, you deploy Prowler in a centralized AWS account in your organization, managed by AWS Organizations, and then use Prowler to perform a security assessment of all of the accounts in the organization.

While there are many methods to deploy and utilize Prowler for an assessment, this solution has been designed for rapid deployment, full analysis of all accounts in the organization or defined target accounts, and accessible reporting of the security findings. In this solution, when Prowler completes the security assessment of all accounts in the organization, it consolidates the results. It also filters out any expected error messages, such as errors related to restrictions that prevent Prowler from scanning Amazon Simple Storage Service (Amazon S3) buckets in accounts provisioned through AWS Control Tower. The filtered, consolidated results are reported in a Microsoft Excel template that is included with this pattern. You can use this report to identify potential improvements for the security controls in your organization.

This solution was designed with the following in mind:

- The AWS CloudFormation templates reduce the effort required to deploy the AWS resources in this pattern.
- You can adjust the parameters in the CloudFormation templates and **prowler_scan.sh** script at the time of deployment to customize the templates for your environment.
- Prowler assessment and reporting speeds are optimized through parallel processing of AWS accounts, aggregated results, consolidated reporting with recommended remediations, and automatically generated visualizations.
- The user doesn't need to monitor the scan progress. When the assessment is complete, the user is notified through an Amazon Simple Notification Service (Amazon SNS) topic so that they can retrieve the report.
- The report template helps you read and assess only the relevant results for your entire organization.

Prerequisites and limitations

Prerequisites

- An AWS account for hosting security services and tools, managed as a member account of an organization in AWS Organizations. In this pattern, this account is referred to as the *security account*.
- In the security account, you must have a private subnet with outbound internet access. For instructions, see VPC with servers in private subnets and NAT in the Amazon Virtual Private Cloud (Amazon VPC) documentation. You can establish internet access by using an NAT gateway that is provisioned in a public subnet.
- Access to the AWS Organizations management account or an account that has delegated administrator permissions for CloudFormation. For instructions, see Register a delegated administrator in the CloudFormation documentation.
- Enable trusted access between AWS Organizations and CloudFormation. For instructions, see Enable trusted access with AWS Organizations in the CloudFormation documentation.

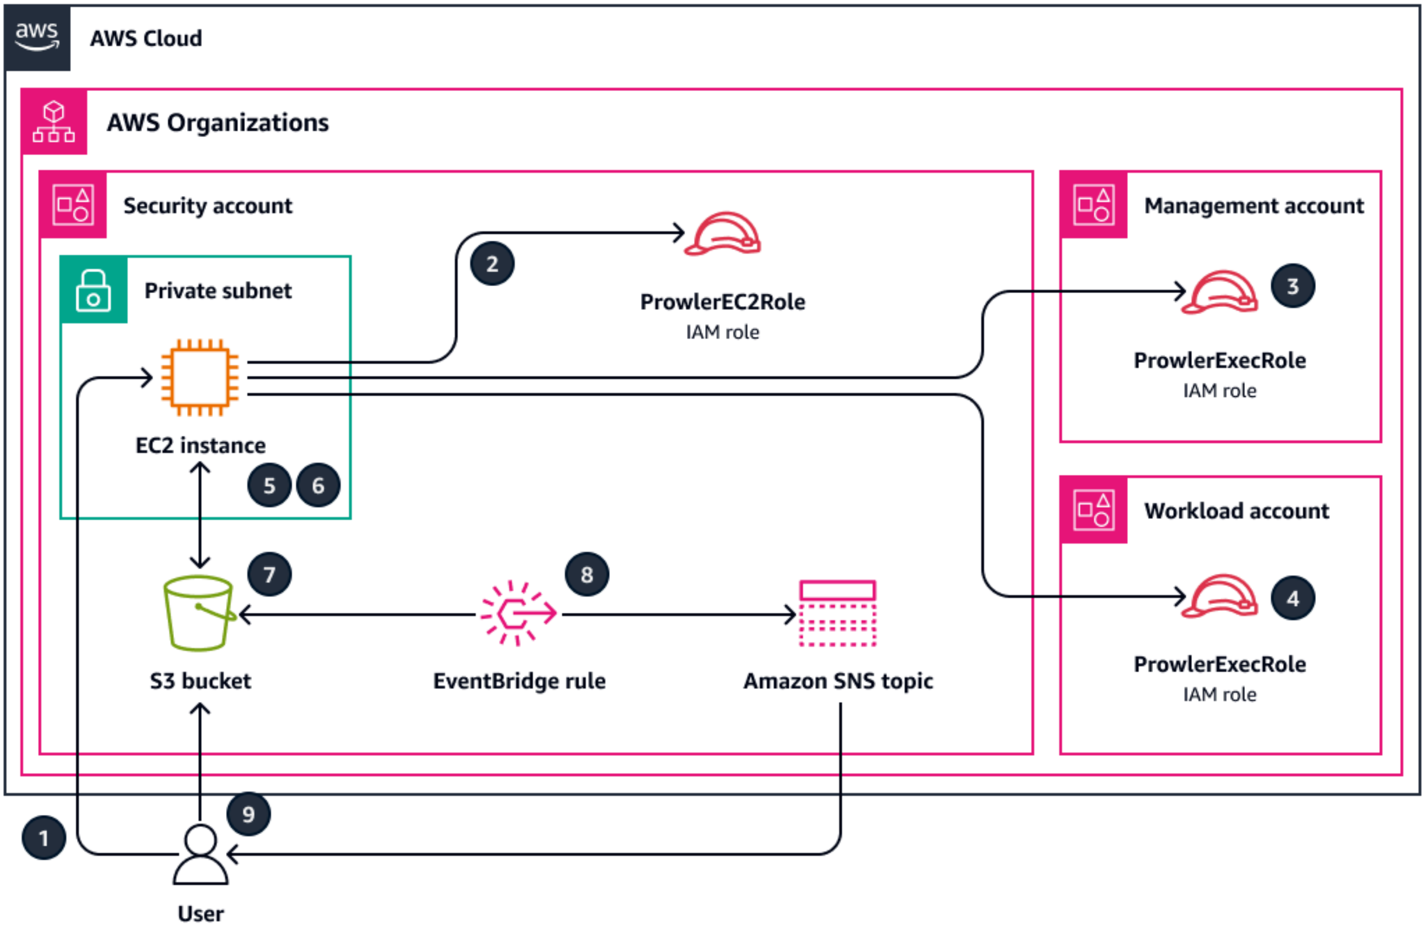
Limitations

- The target AWS accounts must be managed as an organization in AWS Organizations. If you are not using AWS Organizations, you can update the **IAM-ProwlerExecRole.yaml** CloudFormation template and the **prowler_scan.sh** script for your environment. Instead, you provide a list of AWS account IDs and Regions where you want to run the script.
- The CloudFormation template is designed to deploy the Amazon Elastic Compute Cloud (Amazon EC2) instance in a private subnet that has outbound internet access. The AWS Systems Manager Agent (SSM Agent) requires outbound access to reach the AWS Systems Manager service endpoint, and you need outbound access to clone the code repository and install dependencies. If you want to use a public subnet, you must modify the **prowler-resources.yaml** template to associate an Elastic IP address with the EC2 instance.

Product versions

- Prowler version 4.0 or later

Architecture



The diagram shows the following process:

1. Using Session Manager, a capability of AWS Systems Manager, the user authenticates to the EC2 instance and runs the **prowler_scan.sh** script. This shell script performs steps 2–8.
2. The EC2 instance assumes the `ProwlerEC2Role` IAM role, which grants permissions to access the S3 bucket and to assume the `ProwlerExecRole` IAM roles in the other accounts in the organization.
3. The EC2 instance assumes the `ProwlerExecRole` IAM role in the organization's management account and generates a list of the accounts in the organization.
4. The EC2 instance assumes the `ProwlerExecRole` IAM role in the organization's member accounts (called *workload accounts* in the architecture diagram) and performs a security assessment in each account. The findings are stored as CSV and HTML files on the EC2 instance.

> **Note**
>
> HTML files are an output of the Prowler assessment. Due to the nature of HTML, they aren't concatenated, processed, or used directly in this pattern. However, these might be useful for individual account report review.

5. The EC2 instance processes all of the CSV files to remove known, expected errors and consolidates the remaining findings into a single CSV file.
6. The EC2 instance packages the individual account results and aggregated results into a zip file.
7. The EC2 instance uploads the zip file to the S3 bucket.
8. An EventBridge rule detects the file upload and uses an Amazon SNS topic to send an email to the user notifying them that the assessment is complete.
9. The user downloads the zip file from the S3 bucket. The user imports the results into the Excel template and reviews the results.

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses Session Manger, a capability of Systems Manager.

Other tools

- [Prowler](#) is an open-source command-line tool that helps you assess, audit, and monitor your accounts for adherence to AWS security best practices and other security frameworks and standards.

Code repository

The code for this pattern is available in the GitHub [Multi-Account Security Assessment via Prowler](#) repository. The code repository contains the following files:

- **prowler_scan.sh** – This bash script is used to start a Prowler security assessment of multiple AWS accounts, in parallel. As defined in the **Prowler-resources.yaml** CloudFormationtemplate, this script is automatically deployed to the `usr/local/prowler` folder on the EC2 instance.
- **Prowler-Resources.yaml** – You use this CloudFormation template to create a stack in the security account in the organization. This template deploys all of the required resources for this account in order to support the solution. This stack must be deployed before the **IAM-ProwlerExecRole.yaml** template. We do not recommend that you deploy these resources in an account that hosts critical production workloads.

> **Note**
>
> If this stack is deleted and redeployed, you must rebuild the `ProwlerExecRole` stack set in order to rebuild the cross-account dependencies between the IAM roles.

- **IAM-ProwlerExecRole.yaml** – You use this CloudFormation template to create a stack set that deploys the `ProwlerExecRole` IAM role in all accounts in the organization, including the management account.
- **prowler-report-template.xlsm** – You use this Excel template to process the Prowler findings. The pivot tables in the report provide search capabilities, charts, and consolidated findings.

Epics

Prepare for deployment

Task	Description	Skills required
Clone the code repository.	1. In a command-line interface, change your working directory to the location where you want to store the sample files. 2. Enter the following command: `git clone https://github.com/aws-samples/multi-account-security-assessment-via-prowler.git`	AWS DevOps
Review the templates.	1. In the cloned repository, open the **Prowler-Resources.yaml** and **IAM-ProwlerExecRole.yaml** files. 2. Review the resources created by these templates and adjust the templates as needed for your environment. For more information, see [Working with templates](#) in the CloudFormation documentation. 3. Save and close the **Prowler-Resources.yaml**	AWS DevOps

Task	Description	Skills required
	and **IAM-ProwlerExecRole.yaml** files.	

Create the CloudFormation stacks

Task	Description	Skills required
Provision resources in the security account.	Using the **prowler-resources.yaml** template, you create a CloudFormation stack that deploys all of the required resources in the security account. For instructions, see [Creating a stack](#) in the CloudFormation documentation. Note the following when deploying this template: 1. On the **Specify template** page, choose **Template is ready**, and then upload the **prowler-resources.yaml** file. 2. On the **Specify stack details** page, in the **Stack name** box, enter `Prowler-Resources` . 3. In the **Parameters** section, enter the following: • `VPCId` – Select a VPC in the account. • `SubnetId` –– Select a private subnet that has internet access.	AWS DevOps

Task	Description	Skills required

	Note: If you select a public subnet, the EC2 instance won't be assigned a public IP address because the CloudFormation template, by default, doesn't provision and attach an Elastic IP address.
	• `InstanceType` – Select an instance size based on the number of parallel assessments:
	  • For 10, choose `r6i.large` .
	  • For 12, choose `r6i.xlarge` .
	  • For 14–18, choose `r6i.2xlarge` .
	• `InstanceImageId` – Leave the default for Amazon Linux.
	• `KeyPairName` – If you're using SSH for access, specify the name of an existing key pair.
	• `PermittedSSHInbound` – If you're using SSH for access, specify a permitted CIDR block. If you're not using SSH,	

Task	Description	Skills required
	keep the default value of `127.0.0.1` . • `BucketName` – The default value is `prowler-output-<accountID>-<region>` . You can modify this as needed. If you specify a custom value, the account ID and Region are automatically appended to the specified value. • `EmailAddress` – Specify an email address for an Amazon SNS notification when Prowler completes the assessment and uploads the .zip file to the S3 bucket. *Note:* The SNS subscription configuration must be confirmed prior to Prowler completing the assessment or a notification will not be sent. • `IAMProwlerEC2Role` – Keep the default unless your naming conventions require a different name for this IAM role.	

Task	Description	Skills required
	• `IAMProwlerExecRole` – Keep the default unless another name will be used when deploying the **IAM-ProwlerExecRole.yaml** file. • `Parallelism` – Specify the number of parallel assessments to perform. Make sure that the value in the `InstanceType` parameter supports this number of parallel assessments. • `FindingOutput` – If you want to exclude pass results, select `FailOnly`. This significantly reduces the output size and focuses on the checks that might need to be resolved. If you want to include pass results, select `FailAndPass`. 4. On the **Review** page, select **The following resource(s) require capabilities: [AWS::IAM::Role]**, and then choose **Create Stack**. 5. After the stack has been successfully created, in the CloudFormation console, on the **Outputs** tab, copy	

Task	Description	Skills required
	the `ProwlerEC2Role` Amazon Resource Name (ARN). You use this ARN later when deploying the **IAM-ProwlerExecRole.yaml** file.	

Task	Description	Skills required
Provision the IAM role in the member accounts.	In the AWS Organizations management account or an account with delegated administrator permissions for CloudFormation, use the **IAM-ProwlerExecRole.yaml** template to create a CloudFormation stack set. The stack set deploys the `ProwlerExecRole` IAM role in all member accounts in the organization. For instructions, see [Create a stack set with service-managed permissions](#) in the CloudFormation documentation. Note the following when deploying this template: 1. Under **Prepare template**, choose **Template is ready**, and then upload the **IAM-ProwlerExecRole.yaml** file. 2. On the **Specify StackSet details** page, name the stack set `IAM-ProwlerExecRole`. 3. In the **Parameters** section, enter the following: • `AuthorizedARN` – Enter the `ProwlerEC2Role` ARN, which you copied when you	AWS DevOps

Task	Description	Skills required
	created the `Prowler-Resources` stack. • `ProwlerExecRoleName` – Keep the default value of `ProwlerExecRole` unless another name was used when deploying the **Prowler-Resources.yaml** file. 4. Under **Permissions**, choose **Service-managed permissions**. 5. On the **Set deployment options** page, under **Deployment targets**, choose **Deploy to organization** and accept all defaults. *Note:* If you want the stacks deployed to all member accounts simultaneously, set **Maximum concurrent accounts** and **Failure tolerance** to a high value, such as `100`. 6. Under **Deployment regions**, choose the AWS Region where the EC2 instance for Prowler is deployed. Because IAM resources are global and not Regional, this deploys	

Task	Description	Skills required
	the IAM role in all active Regions. 7. On the **Review** page, select **I acknowledge that AWS CloudFormation might create IAM resources with custom names**, and then choose **Create StackSet**. 8. Monitor the **Stack instances** tab (for individua l account status) and the **Operations** tab (for overall status) to determine when the deployment is complete.	

Task	Description	Skills required
Provision the IAM role in the management account.	Using the **IAM-ProwlerExecRole.yaml** template, you create a CloudFormation stack that deploys the `ProwlerExecRole` IAM role in the management account of the organization. The stack set you created previously doesn't deploy the IAM role in the management account. For instructions, see Creating a stack in the CloudFormation documentation. Note the following when deploying this template: 1. On the **Specify template** page, choose **Template is ready**, and then upload the **IAM-ProwlerExecRole.yaml** file. 2. On the **Specify stack details** page, in the **Stack name** box, enter `IAM-ProwlerExecRole` . 3. In the **Parameters** section, enter the following: • `AuthorizedARN` – Enter the `ProwlerEC2Role` ARN, which you copied when you created the `Prowler-Resources` stack.	AWS DevOps

Task	Description	Skills required
	• `ProwlerExecRoleName` – Keep the default value of `ProwlerExecRole` unless another name was used when deploying the **Prowler-Resources.yaml** file. 4. On the **Review** page, select **The following resource(s) require capabilities: [AWS::IAM::Role]**, and then choose **Create Stack**.	

Perform the Prowler security assessment

Task	Description	Skills required
Run the scan.	1. Sign in to the security account in the organization. 2. Using Session Manager, connect to the EC2 instance for Prowler that you previously provisioned. For instructions, see [Connect to your Linux instance using Session Manager](). If you're unable to connect, see the [Troubleshooting]() section of this pattern.	AWS administrator

Task	Description	Skills required

	3. Navigate to `usr/local/prowler`, and then open the **prowler_scan.sh** file.
	4. Review and modify the adjustable parameters and variables in this script as needed for your environme nt. For more informati on about customization options, see the comments at the beginning of the script.
	
	For example, instead of getting a list of all member accounts in the organization from the management account, you can modify the script to specify the AWS account IDs or AWS Regions that you want to scan, or you can reference an external file that contains these parameters.
	5. Save and close the **prowler_scan.sh** file.
	6. Enter the following commands. This runs the **prowler_scan.sh** script.
	
	`sudo -i`
	`screen`
	`cd /usr/local/`
	`prowler`	

Task	Description	Skills required
	`./prowler_scan.sh` Note the following: • The screen command permits the script to continue running in the event that the connectio n times out or you lose console access. • After the scan starts, you can force a screen detach by pressing **Ctrl+A D**. The screen detaches, and you can close the instance connection and allow the assessment to proceed. • To resume a detached session, connect to the instance, enter `sudo -i` then enter `screen -r`. • To monitor progress of the individual account assessments, you can navigate to the `usr/local/prowler` directory and enter the command `tail -f output/stdout-<account-id>` . 7. Wait for Prowler to complete scans in all accounts. The script assesses multiple accounts	

Task	Description	Skills required
	at the same time. When the assessment is complete in all accounts, you receive a notification if you specified an email address when you deployed the **Prowler-Resources.yaml** file.	
Retrieve the Prowler findings.	1. Download the `prowler-output-<assessDate>.zip` file from the `prowler-output-<accountID>-<region>` bucket. For instructions, see [Downloading an object](#) in the Amazon S3 documentation. 2. Delete all objects in the bucket, including the file you downloaded. This is a best practice for cost optimization and to make sure that you can delete the `Prowler-Resources` CloudFormation stack at any time. For instructions, see [Deleting objects](#) in the Amazon S3 documentation.	General AWS

Task	Description	Skills required
Stop the EC2 instance.	To prevent billing while the instance is idle, stop the EC2 instance that runs Prowler. For instructions, see [Stop and start your instances]() in the Amazon EC2 documentation.	AWS DevOps

Create a report of the findings

Task	Description	Skills required
Import the findings.	1. In Excel, open the **prowler-report-template.xlsx** file, and then choose the **Prowler CSV** worksheet. 2. Delete all of the sample data, including the header row. If you are asked whether to delete the query associated with the data being removed, choose **No**. Deleting the query can affect the functionality of the pivot tables in the Excel template. 3. Extract the contents of the zip file you download from the S3 bucket. 4. In Excel, open the **prowler-fullorgresults-accessdeniedfiltered.txt**. We recommended that you	General AWS

Task	Description	Skills required
	use this file because the most common, non-actionable errors have already been removed, such as `Access Denied` errors related to attempted scans of AWS Control Tower resources. If you want the unfiltered findings, open the **prowler-fullorgresults.txt** file instead. 5. Select column A. 6. If you're using Windows, enter **Ctrl+C**, or if you're using MacOS, enter **Cmd+C**. This copies all of the data to the clipboard. 7. In the Excel report template, on the **Prowler CSV** worksheet, select cell A1. 8. If you're using Windows, enter **Ctrl+V**, or if you're using MacOS, enter **Cmd+V**. This pastes the findings into the report. 9. Confirm all of the cells containing pasted data are selected. If not, select column A. 10. On the **Data** tab, choose **Text to Columns**.	

Task	Description	Skills required
	11. In the wizard, do the following: • For step 1, choose **Delimited**. • For step 2, for **Delimiters**, choose **Semicolon**. In the **Data preview** pane, confirm that the data is being separated into columns. • For step 3, choose **Finish**. 12. Confirm that the text data is delimited across multiple columns. 13. Save the Excel report with a new name. 14. Search and delete any `Access Denied` errors in the findings. For instructions about how to remove these programmatically, see *Programmatically removing errors* in the [Additional information](#) section.	

Task	Description	Skills required
Finalize the report.	1. Choose the **Findings** worksheet, and then select cell A17. This cell is the header of the pivot table. 2. In the ribbon, under **PivotTable Tools**, choose **Analyze**, and then under **Refresh**, choose **Refresh All**. This updates the pivot tables with the new data set. 3. By default, Excel does not properly display AWS account numbers. To fix the number formatting, do the following: • On the **Findings** worksheet, open the context (right-click) menu for column A, and then choose **Format Cells**. • Choose **Number**, and in **Decimal places**, enter `0`. • Choose **OK**. *Note:* If an AWS account number starts with one or more zeros, Excel automatically removes the zeros. If you see an account number that is less than 12 digits in the report, the missing digits are zeros	General AWS

Task	Description	Skills required
	at the beginning of the number. 4. (Optional) You can collapse fields to make the findings easier to read. Do the following: • On the **Findings** worksheet, if you move the cursor to the line between rows 18 and 19 (the space between the critical header and the first finding), the cursor icon changes to a small arrow pointing down. • Click to select all finding fields. • Open the context (right-click) menu, find **Expand/Collapse**, and then choose **Collapse**. 5. For details about the assessment, review the **Findings**, **Severity**, and **Pass Fail** worksheets.	

(Optional) Update Prowler or the resources in the code repository

Task	Description	Skills required
Update Prowler.	If you want to update Prowler to the latest version, do the following:	General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

Connect to the EC2 instance for Prowler by using Session Manager. For instructions, see Connect to your Linux instance using Session Manager.
Enter the following command.
<pre><code>sudo -i
pip3 install --upgrade
 prowler</code></pre>

</td><td></td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Update the prowler_scan.sh script.</td><td>If you want to update the prowler_scan.sh script to the latest version in the repo, do the following:

1. Connect to the EC2 instance for Prowler by using Session Manager. For instructions, see Connect to your Linux instance using Session Manager.
2. Enter the following command.
<pre>sudo -i</pre>3. Navigate to the Prowler script directory.
<pre>cd /usr/local/prowler</pre>4. Enter the following command to stash the local script so that you can merge custom changes into the newest version.
<pre>git stash</pre>5. Enter the following command to get the latest version of the script.
<pre>git pull</pre></td><td>General AWS</td></tr>
</table>

Task	Description	Skills required
	6. Enter the following command to merge the custom script with the latest version of the script. `git stash pop` **Note** You might receive warnings related to any locally generated files that are not in the GitHub repo, such as finding reports. You can ignore these as long as the **prowler_scan.sh** shows that the locally stashed changes are merged back in.	

(Optional) Clean up

Task	Description	Skills required
Delete all deployed resources.	You can leave the resources deployed in the accounts. If you shut down the EC2 instance when it is not in use and keep the S3 bucket empty, this reduces the costs	AWS DevOps

Task	Description	Skills required
	of maintaining the resources for future scans. If you want to deprovision all resources, do the following: 1. Delete the `IAM-ProwlerExecRole` stack provisioned in the management account. For instructions, see [Deleting a stack](#) in the CloudFormation documentation. 2. Delete the `IAM-ProwlerExecRole` stack set provisioned in the organization's management account or in the delegated administrator account. For instructions, see [Delete a stack set](#) in the CloudFormation documentation. 3. Delete all objects in the `prowler-output` S3 bucket. For instructions, see [Deleting objects](#) in the Amazon S3 documentation. 4. Delete the `Prowler-Resources` stack provisioned in the security account. For instructions, see [Deleting a stack](#)	

Task	Description	Skills required
	in the CloudFormation documentation.	

Troubleshooting

Issue	Solution
Unable to connect to the EC2 instance by using Session Manager.	The SSM Agent must be able to communicate with the Systems Manager endpoint. Do the following: 1. Validate the subnet where the EC2 instance is deployed has internet access. 2. Reboot the EC2 instance.
When deploying the stack set, the CloudFormation console prompts you to `Enable trusted access with AWS Organizations to use service-managed permissions` .	This indicates that trusted access has not been enabled between AWS Organizations and CloudFormation. Trusted access is required to deploy the service-managed stack set. Choose the button to enable trusted access. For more information, see Enable trusted access in the CloudFormation documentation.

Other resources

- Prowler (GitHub)

Additional information

Programmatically removing errors

If the results contain `Access Denied` errors, you should remove them from the findings. These errors are typically due to external influencing permissions that prevent Prowler from assessing a particular resource. For example, some checks fail when reviewing S3 buckets provisioned through AWS Control Tower. You can programmatically extract these results and save the filtered results as a new file.

The following commands remove rows that contain a single text string (a pattern) and then output the results to a new file.

- For Linux or MacOS (Grep)

```
grep -v -i "Access Denied getting bucket" myoutput.csv > myoutput_modified.csv
```

- For Windows (PowerShell)

```
Select-String -Path myoutput.csv -Pattern 'Access Denied getting bucket' -NotMatch >
 myoutput_modified.csv
```

The following commands removes rows that match more than one text string and then output the results to a new file.

- For Linux or MacOS (Uses an escaped pipe between strings)

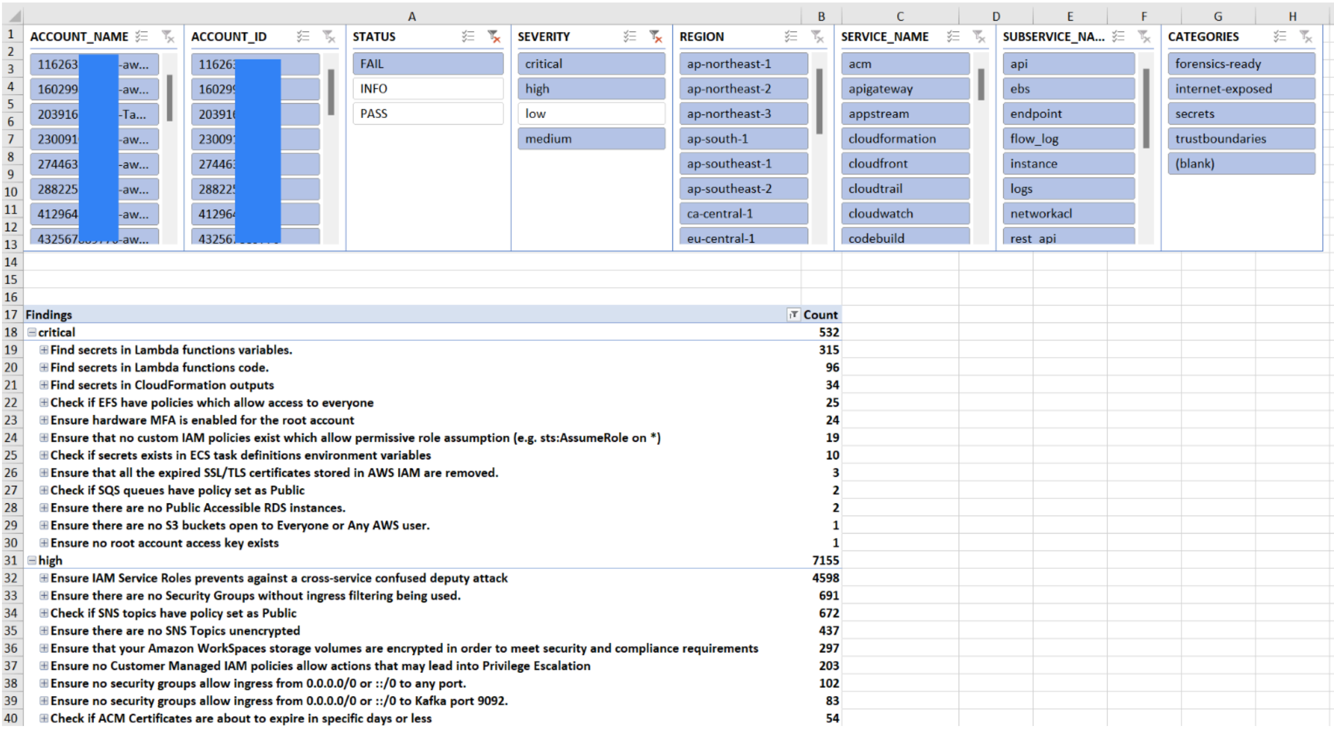
```
grep -v -i 'Access Denied getting bucket\|Access Denied Trying to Get' myoutput.csv >
 myoutput_modified.csv
```

- For Windows (Uses a comma between strings)

```
Select-String -Path myoutput.csv -Pattern 'Access Denied getting bucket', 'Access
 Denied Trying to Get' -NotMatch > myoutput_modified.csv
```

Report examples

The following image is an example of the **Findings** worksheet in the report of consolidated Prowler findings.



The following image is an example of the **Pass Fail** worksheet in the report of consolidated Prowler findings. (By default, pass results are excluded from the output.)

Delete unused Amazon EBS volumes by using AWS Config and AWS Systems Manager

Sankar Sangubotla, Amazon Web Services

Summary

The lifecycle of an Amazon Elastic Block Store (Amazon EBS) volume is typically independent from the lifecycle of the Amazon Elastic Compute Cloud (Amazon EC2) instance to which it is attached. Unless you select **Delete on Termination** option at the time of launch, terminating the Amazon EC2 instance detaches the Amazon EBS volume but doesn't delete it. Especially in development and testing environments where it's common to launch and terminate Amazon EC2 instances, this can result in a large number of unutilized Amazon EBS volumes. Amazon EBS volumes accrue charges in your AWS account, regardless of whether they're being used. Deleting these volumes can help you optimize costs for your AWS accounts. In addition, deleting unused Amazon EBS volumes is a security best practice to prevent access to any unused, potentially sensitive, data in those volumes.

AWS Config can help you manually or automatically remediate noncompliant resources. This pattern describes how to configure an AWS Config rule and automatic remediation action that deletes unused Amazon EBS volumes in the account. The remediation action is a predefined runbook for Automation, a capability of AWS Systems Manager. You can configure the runbook to create a snapshot of the volume before deleting it.

Prerequisites and limitations

Prerequisites

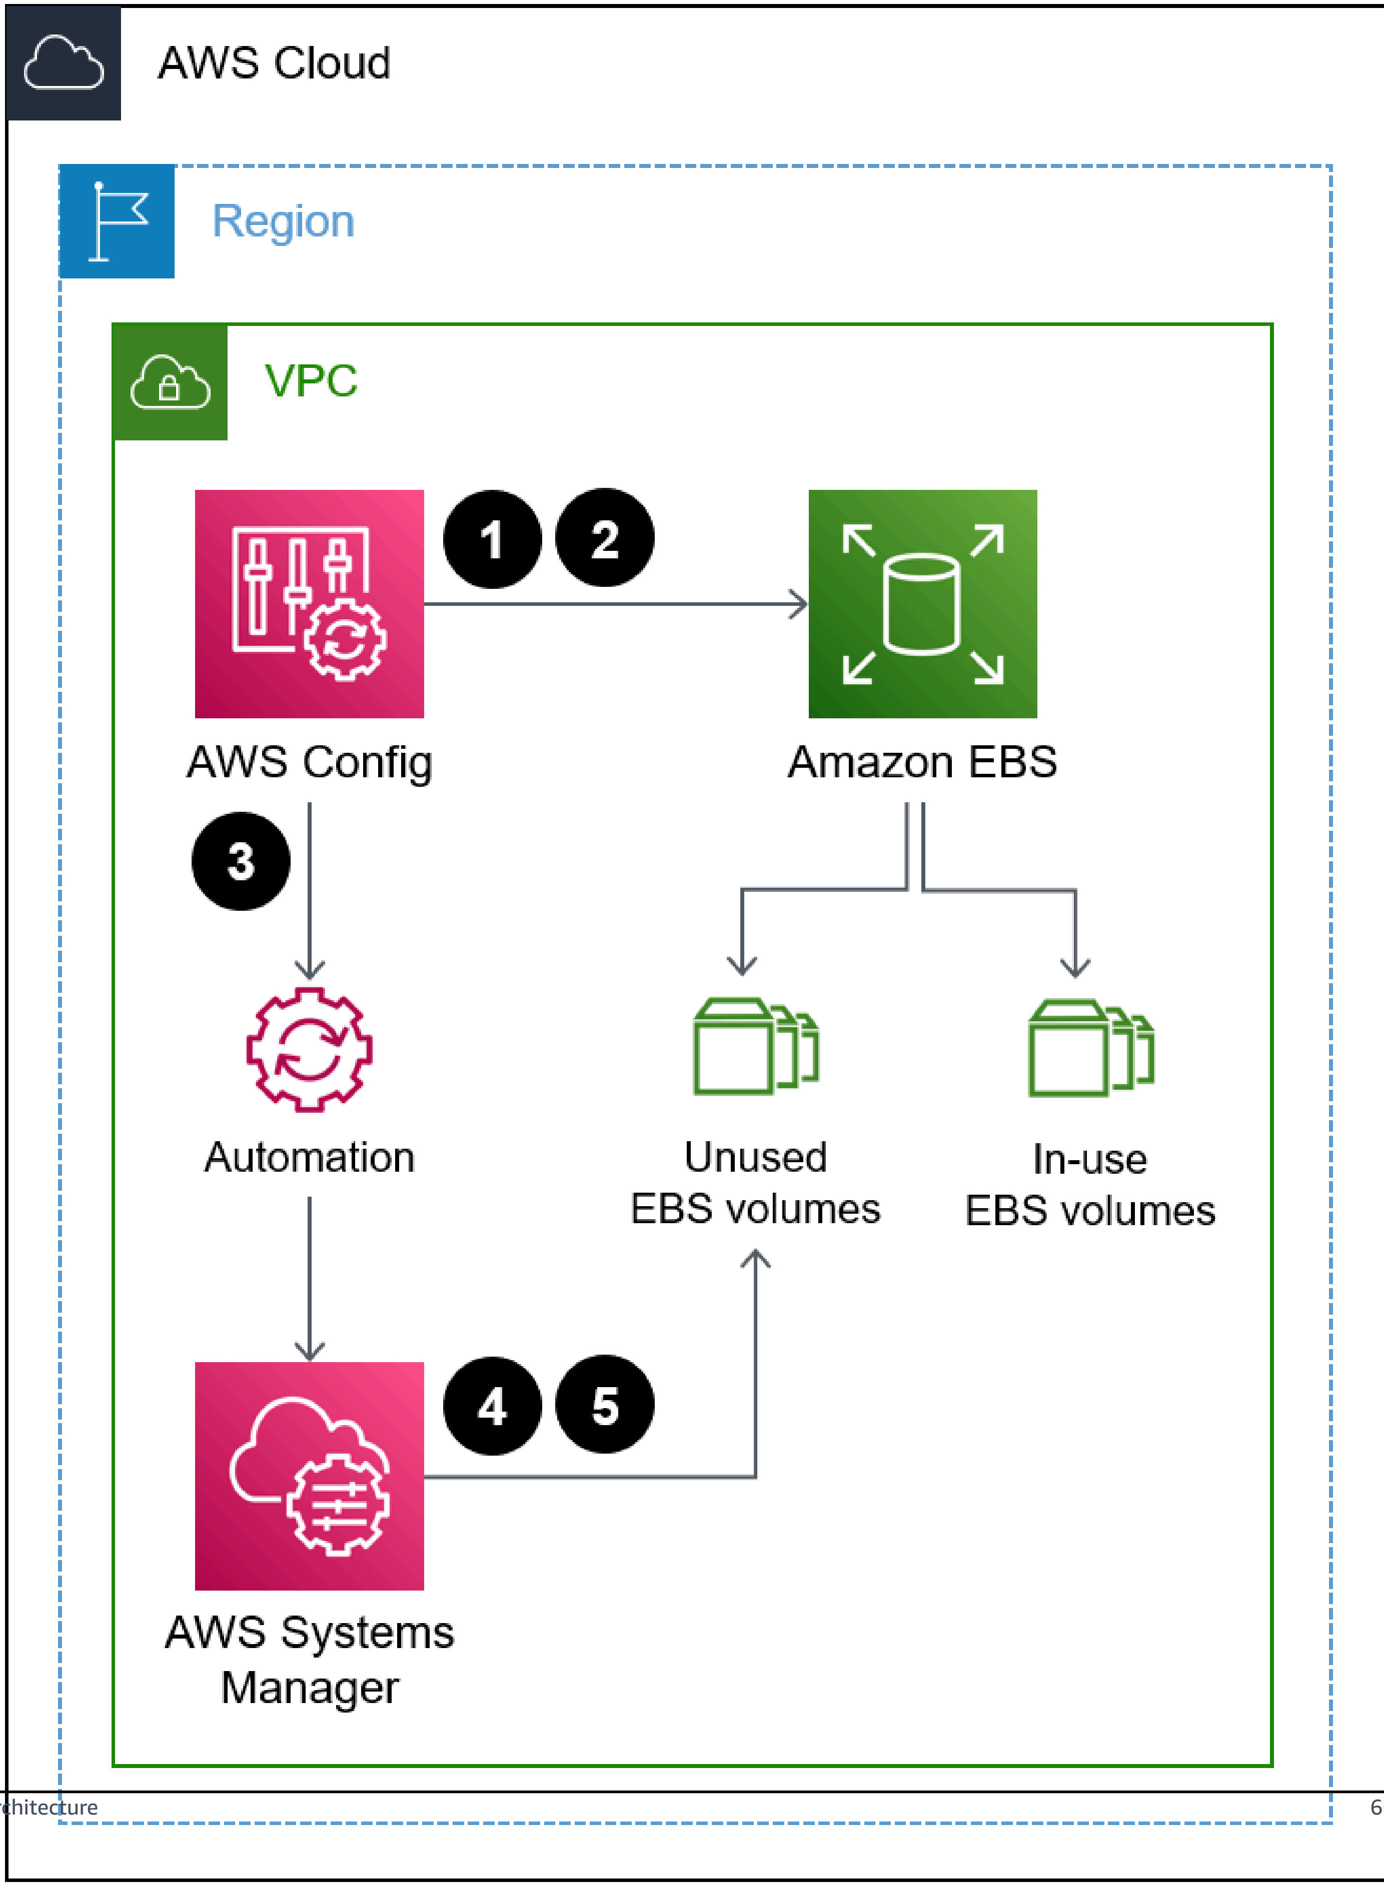
- An active AWS account.
- AWS Identity and Access Management (IAM) permissions to run the `AWSConfigRemediation-DeleteUnusedEBSVolume` runbook for Automation, a capability of Systems Manager. For more information, see *Required IAM permissions* in AWSConfigRemediation-DeleteUnusedEBSVolume.
- One or more unused Amazon EBS volumes.

Limitations

- The unused Amazon EBS volumes must be in the `available` state.

Architecture

Target architecture



AWS Cloud
Region
VPC
1
2
AWS Config
Amazon EBS
3
Automation
Unused
EBS volumes
In-use
EBS volumes
4
5
AWS Systems
Manager

1. The AWS Config rule evaluates the Amazon EBS volumes.
2. The rule returns a list of compliant and noncompliant resources. Amazon EBS volumes that are in the `available` state, which are unused volumes, are determined to be noncompliant.
3. AWS Config automatically starts the Automation runbook.
4. If configured, Systems Manager creates snapshots of the unused volumes before deleting them.
5. Systems Manager deletes the unused Amazon EBS volumes.

Automation and scale

You can apply this solution across all accounts in your organization. For more information, see Managing rules across all accounts in your organization in the AWS Config documentation.

Tools

- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.
- AWS Systems Manager Automation simplifies common maintenance, deployment, and remediation tasks for many AWS services.

Epics

Configure the AWS Config rule

Task	Description	Skills required
Create a role for the Automation runbook.	Create a role called `AssumeRole` . Systems Manager Automation uses this role to run the runbook. For instructions, see Configuring a service role (assume role) access for automations in the	AWS systems administrator

Task	Description	Skills required
	Systems Manager documentation.	
Turn on the AWS Config recorder.	Follow the instructions in Setting Up AWS Config with the Console in the AWS Config documentation to make sure that AWS Config is running and it is configured to record Amazon EBS volumes.	AWS systems administrator
Run the rule.	1. Follow the instructions in Evaluating your resources in the AWS Config documentation to run the `ec2-volume-inuse-check` rule. Wait for the evaluation to complete. 2. On the **Rules** page, select the `ec2-volume-inuse-check` rule, and then for **Resources in scope**, choose **Noncompliant**. 3. Confirm that there are one or more unused Amazon EBS volumes in the evaluation results.	AWS systems administrator

Configure automatic remediation of unused Amazon EBS volumes

Task	Description	Skills required
Add the automatic remediation action.	1. On the **Rules** page, select the `ec2-volume-inuse-check` rule. 2. Follow the instructions in [Setting up automatic remediation](#) in the AWS Config documentation. Note the following: 3. In the **Remediation action details** section, choose `AWSConfigRemediation-DeleteUnusedEBSVolume` . • Select **Resource ID parameter**, and then in the list, choose **VolumeId**. At runtime, this parameter is substituted with the ID of the noncompliant Amazon EBS volume. • In the **Parameters** section, provide values for the following parameters: • `CreateSnapshot` – (Optional) If set to `true`, the automation creates a snapshot of the Amazon EBS volume before it's deleted.	AWS systems administrator

Task	Description	Skills required
	• `AutomationAssumeRole` – Enter the Amazon Resource Name (ARN) of the `AssumeRole` service role that you created previously.	
Test the automatic remediation for the AWS Config rule.	1. In the AWS Config console, on the **Rules** page, select the `ec2-volume-inuse-check` rule. 2. In the **Action**s menu, choose **Re-evaluate**. 3. Allow the rule to evaluate the non-compliant resources, and then confirm that the unused Amazon EBS volumes are deleted.	AWS systems administrator

Troubleshooting

Issue	Solution
AWS Config doesn't accurately reflect the resource state.	Sometimes, AWS Config doesn't update the state of the resources. Turn the recorder off and then turn it back on again on the AWS Config **Settings** page. The recorder captures the state of the resources. For newly created or deleted resources, it might take some time for the recorder to reflect the current state. For more information about Amazon

Issue	Solution
	EBS volume states, see Volume states in the Amazon EBS documentation.

- Remediating noncompliant AWS resources with AWS Config rules

Deploy and manage AWS Control Tower controls by using AWS CDK and CloudFormation

Iker Reina Fuente and Ivan Girardi, Amazon Web Services

Summary

This pattern describes how to use AWS CloudFormation and AWS Cloud Development Kit (AWS CDK) to implement and administer preventive, detective, and proactive AWS Control Tower controls as infrastructure as code (IaC). A control (also known as a *guardrail*) is a high-level rule that provides ongoing governance for your overall AWS Control Tower environment. For example, you can use controls to require logging for your AWS accounts and then configure automatic notifications if specific security-related events occur.

AWS Control Tower helps you implement preventive, detective, and proactive controls that govern your AWS resources and monitor compliance across multiple AWS accounts. Each control enforces a single rule. In this pattern, you use a provided IaC template to specify which controls you want to deploy in your environment.

AWS Control Tower controls apply to an entire organizational unit (OU), and the control affects every AWS account within the OU. Therefore, when users perform any action in any account in your landing zone, the action is subject to the controls that govern the OU.

Implementing AWS Control Tower controls helps establish a strong security foundation for your AWS landing zone. By using this pattern to deploy the controls as IaC through CloudFormation and AWS CDK, you can standardize the controls in your landing zone and more efficiently deploy and manage them. This solution uses cdk_nag to scan the AWS CDK application during deployment. This tool checks the application for adherence to AWS best practices.

To deploy AWS Control Tower controls as IaC, you can also use HashiCorp Terraform instead of AWS CDK. For more information, see Deploy and manage AWS Control Tower controls by using Terraform.

Intended audience

This pattern is recommended for users who have experience with AWS Control Tower, CloudFormation, AWS CDK, and AWS Organizations.

Prerequisites and limitations

Prerequisites

- Active AWS accounts managed as an organization in AWS Organizations and an AWS Control Tower landing zone. For instructions, see Getting started in the AWS Control Tower documentation.
- AWS Command Line Interface (AWS CLI), installed and configured.
- Node package manager (npm), installed and configured for the AWS CDK.
- Prerequisites for AWS CDK.
- Permissions to assume an existing AWS Identity and Access Management (IAM) role in a deployment account.
- Permissions to assume an IAM role in the organization's management account that that can be used to bootstrap AWS CDK. The role must have permissions to modify and deploy CloudFormation resources. For more information, see Bootstrapping in the AWS CDK documentation.
- Permissions to create IAM roles and policies in the organization's management account. For more information, see Permissions required to access IAM resources in the IAM documentation.

Limitations

- This pattern provides instructions for deploying this solution across AWS accounts, from a deployment account to the organization's management account. For testing purposes, you can deploy this solution directly in the management account, but instructions for this configuration are not explicitly provided.
- For AWS Control Tower controls, this pattern requires the use of global identifiers that are in the following format:

  ```
  arn:<PARTITION>:controlcatalog:::control/<CONTROL_CATALOG_OPAQUE_ID>
  ```

  Previous versions of this pattern used regional identifiers that are no longer supported. We recommend that you migrate from Regional identifiers to global identifiers. Global identifiers help you manage controls and expand the number of controls you can use.

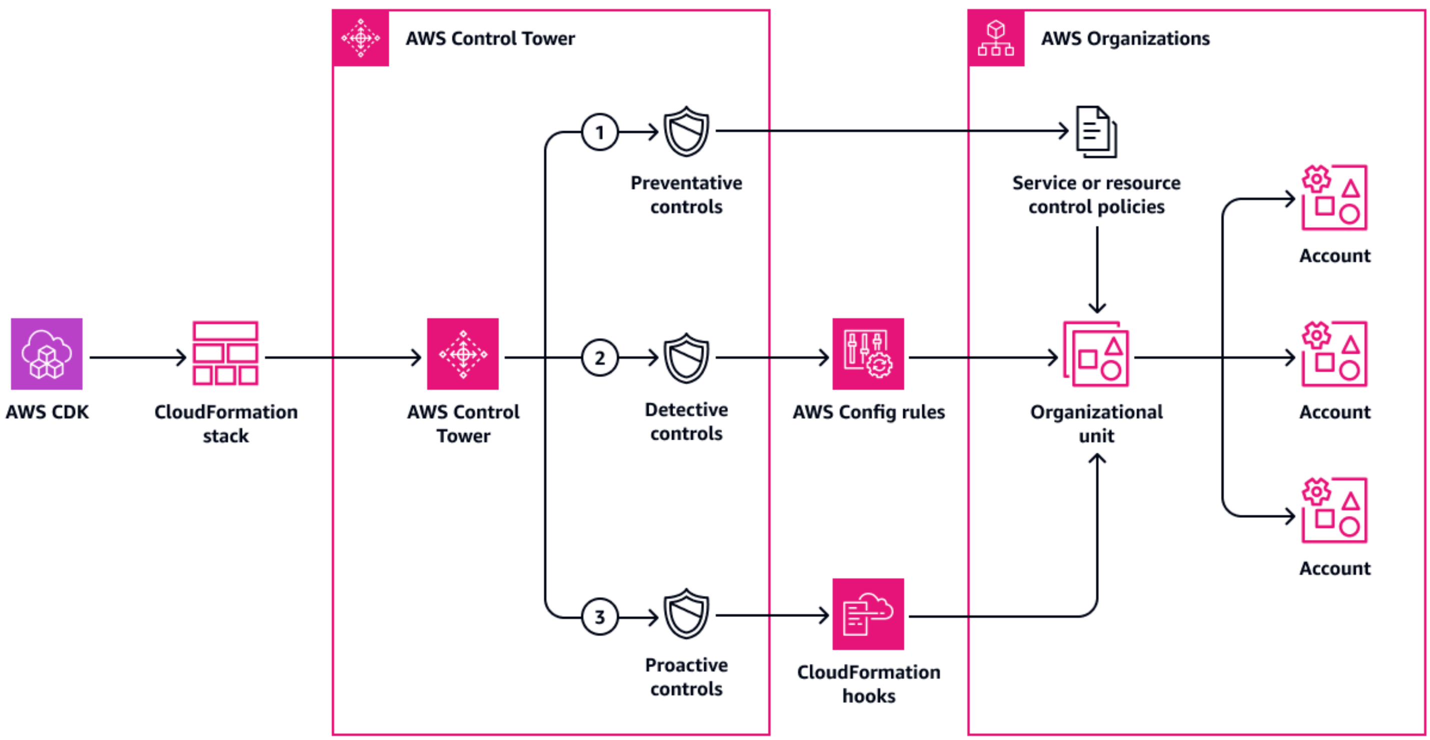
> **Note**
>
> In most cases, the value for `<PARTITION>` is `aws`.

Product versions

- AWS Control Tower version 3.2 or later
- Python version 3.9 or later
- npm version 8.9.0 or later

Architecture

This section provides a high-level overview of this solution and the architecture established by the sample code. The following diagram shows controls deployed across the various accounts in the OU.



AWS Control Tower controls are categorized according to their *behavior* and their *guidance*.

There are three primary types of control behaviors:

1. *Preventive controls* are designed to prevent actions from occurring. These are implemented with service control policies (SCPs) or resource control policies (RCPs) in AWS Organizations. The status of a preventive control is either **enforced** or **not enabled**. Preventive controls are supported in all AWS Regions.
2. *Detective controls* are designed to detect specific events when they occur and log the action in AWS CloudTrail. These are implemented with AWS Config rules. The status of a detective control is either **clear**, **in violation**, or **not enabled**. Detective controls apply only in those AWS Regions supported by AWS Control Tower.
3. *Proactive controls* scan resources that would be provisioned by AWS CloudFormation and check whether they are compliant with your company policies and objectives. Resources that are not compliant will not be provisioned. These are implemented with AWS CloudFormation hooks. The status of a proactive control is **PASS**, **FAIL**, or **SKIP**.

Control *guidance* refers to the recommended practice for how to apply each control to your OUs. AWS Control Tower provides three categories of guidance: *mandatory*, *strongly recommended*, and *elective*. The guidance of a control is independent of its behavior. For more information, see Control behavior and guidance.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code. The AWS CDK Toolkit is the primary tool for interacting with your AWS CDK app.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

Other tools

- cdk_nag is an open-source tool that uses a combination of rule packs to check AWS CDK applications for adherence to best practices.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub Deploy AWS Control Tower controls using AWS CDK repository. You use the **cdk.json** file to interact with the AWS CDK app, and you use the **package.json** file to install the npm packages.

Best practices

- Follow the principle of least-privilege (IAM documentation). The sample IAM policy and trust policy provided in this pattern include the minimum permissions required, and the AWS CDK stacks created in the management account are restricted by these permissions.
- Follow the Best practices for AWS Control Tower administrators (AWS Control Tower documentation).
- Follow the Best practices for developing and deploying cloud infrastructure with the AWS CDK (AWS CDK documentation).
- When bootstrapping the AWS CDK, customize the bootstrap template to define policies and the trusted accounts that should have the ability to read and write to any resource in the management account. For more information, see Customizing bootstrapping.
- Use code analysis tools, such as cfn_nag, to scan the generated CloudFormation templates. The cfn-nag tool looks for patterns in CloudFormation templates that might indicate the infrastructure is not secure. You can also use cdk-nag to check your CloudFormation templates by using the cloudformation-include module.

Epics

Prepare to enable the controls

Task	Description	Skills required
Create the IAM role in the management account.	1. Create an IAM policy in the management account with the permissions defined in *IAM policy* in the Additional information section. For instructions, see Creating IAM policies in the IAM documentation. Make note of the Amazon Resource Name (ARN) of the policy. The following is an example ARN. `arn:aws:iam::<MANAGEMENT-ACCOUNT-ID>:policy/<POLICY-NAME>` 2. Create an IAM role in the management account, attach the IAM permission policy that you created in the previous step, and attach the custom trust policy in *Trust policy* in the Additional information section. For instructions, see Creating a role using custom trust policies in the IAM documentation. The following is an example ARN for the new role.	DevOps engineer, General AWS

Task	Description	Skills required
	`arn:aws:iam:: <MANAGEMENT-ACCOUNT-ID>:role/<ROLE-NAME>`	

Task	Description	Skills required
Bootstrap AWS CDK.	1. In the management account, assume a role that has permissions to bootstrap AWS CDK. 2. Enter the following command, replacing the following: • `<MANAGEMENT-ACCOUNT-ID>` is the ID of the organization's management account. • `<AWS-CONTROL-TOWER-REGION>` is the AWS Region where AWS Control Tower is deployed. For a complete list of Region codes, see Regional endpoints in *AWS General Reference*. • `<DEPLOYMENT-ACCOUNT-ID>` is the ID of the deployment account. • `<DEPLOYMENT-ROLE-NAME>` is the name of the IAM role you are using the deployment account. • `<POLICY-NAME>` is the name of the policy you created in the management account. `$ npx cdk bootstrap aws://<MANAGEMENT-ACCOUNT-ID>/<AWS-C`	DevOps engineer, General AWS, Python

Task	Description	Skills required
	``` ONTROL-TOWER-REGIO N> \ --trust arn:aws:i am::<DEPLOYMENT-AC COUNT-ID>:role/<DE PLOYMENT-ROLE-NAME> \ --cloudformation- execution-policies arn:aws:iam::<MANA GEMENT-ACCOUNT-ID> :policy/<POLICY-NA ME> ```	
Clone the repository.	In a bash shell, enter the following command. This clones the Deploy AWS Control Tower controls using AWS CDK repository from GitHub. ``` git clone https://g ithub.com/aws-samp les/aws-control-to wer-controls-cdk.git ```	DevOps engineer, General AWS

Task	Description	Skills required
Edit the AWS CDK configura tion file.	1. In the cloned repository, open the **constants.py** file. 2. In the `ACCOUNT_ID` parameter, enter the ID of your management account. 3. In the `<AWS-CONTROL-TOWER-REGION>` parameter, enter the AWS Region where AWS Control Tower is deployed. 4. In the `ROLE_ARN` parameter, enter the ARN of the role you created in the management account. 5. Open [All global identifiers](#) in the AWS Control Tower documentation. 6. In the JSON-formatted list, locate the control that you want to implement, and then copy its global identifier (also known as the {CONTROL_ CATALOG_OPAQUE_ID} value). For example, the global identifier for the **AWS-GR_AUDIT_BUCKE T_ENCRYPTION_ENABL ED** control is `k4izcjxhu kijhajp6ks5mjxk` . 7. In the `GUARDRAIL S_CONFIGURATION` section, in the `Enable-`	DevOps engineer, General AWS

Task	Description	Skills required
	`Control` parameter, enter the global identifier that you copied. Enter the identifier in double quotation marks, and separate multiple identifiers with commas. 8. In the `GUARDRAILS_CONFIGURATION` section, in the `OrganizationalUnitIds` parameter, enter the ID of the organizational unit where you want to enable the control, such as `ou-1111-11111111` . Enter the ID in double quotation marks, and separate multiple IDs with commas. For more information about how to retrieve OU IDs, see [Viewing the details of an OU](#). 9. Save and close the **constants.py** file. For an example of an updated **constants.py** file, see the [Additional information](#) section of this pattern.	

Enable controls in the management account

Task	Description	Skills required
Assume the IAM role in the deployment account.	In the deployment account, assume the IAM role that has permissions to deploy the AWS CDK stacks in the management account. For more information about assuming an IAM role in the AWS CLI, see [Use an IAM role in the AWS CLI]().	DevOps engineer, General AWS

Activate the environment.	If you are using Linux or MacOS:
	
	1. Enter the following command to create a virtual environment.
	`$ python3 -m venv .venv`
	2. After the virtual environment is created, enter the following command to activate it.
	`$ source .venv/bin/activate`
	
	If you are using Windows:
	
	1. Enter the following command to activate a virtual environment.
		DevOps engineer, General AWS

Task	Description	Skills required
	`% .venv\Scripts\activate.bat`	
Install the dependencies.	After the virtual environment is activated, enter the following command to run the **install_deps.sh** script. This script installs the required dependencies. `$ ./scripts/install_deps.sh`	DevOps engineer, General AWS, Python
Deploy the stack.	Enter the following commands to synthesize and deploy the CloudFormation stack. `$ npx cdk synth` `$ npx cdk deploy`	DevOps engineer, General AWS, Python

Additional information

Example constants.py file

The following is an example of an updated **constants.py** file. This sample enables the **AWS-GR_DISALLOW_CROSS_REGION_NETWORKING** control (global ID: `dvuaav61i5cnfazfelmvn9m6k`) and the **AWS-GR_SUBNET_AUTO_ASSIGN_PUBLIC_IP_DISABLED** control (global ID: `50z1ot237wl8u1lv5ufau6qqo`). For a list of global IDs, see [All global identifiers](#) in the AWS Control Tower documentation.

```
ACCOUNT_ID = 111122223333
AWS_CONTROL_TOWER_REGION = us-east-2
ROLE_ARN = "arn:aws:iam::111122223333:role/CT-Controls-Role"
GUARDRAILS_CONFIGURATION = [
    {
        "Enable-Control": {
            "dvuaav61i5cnfazfelmvn9m6k": {  # AWS-GR_DISALLOW_CROSS_REGION_NETWORKING
                "Parameters": {
                    "ExemptedPrincipalArns": ["arn:aws:iam::111122223333:role/
RoleName"]
                },
                "Tags": [{"key": "Environment", "value": "Production"}]
            },
            ...
        },
        "OrganizationalUnitIds": ["ou-1111-11111111", "ou-2222-22222222"...],
    },
    {
        "Enable-Control": {
            "50z1ot237wl8u1lv5ufau6qqo",  # AWS-
GR_SUBNET_AUTO_ASSIGN_PUBLIC_IP_DISABLED
            ...
        },
        "OrganizationalUnitIds": ["ou-2222-22222222"...],
    },
]
```

IAM policy

The following sample policy allows the minimum actions required to enable or disable AWS Control Tower controls when deploying AWS CDK stacks from a deployment account to the management account.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "controltower:EnableControl",
                "controltower:DisableControl",
                "controltower:GetControlOperation",
                "controltower:ListEnabledControls",
                "organizations:AttachPolicy",
                "organizations:CreatePolicy",
                "organizations:DeletePolicy",
                "organizations:DescribeOrganization",
                "organizations:DescribeOrganizationalUnit",
                "organizations:DetachPolicy",
                "organizations:ListAccounts",
                "organizations:ListAWSServiceAccessForOrganization",
                "organizations:ListChildren",
                "organizations:ListOrganizationalUnitsForParent",
                "organizations:ListParents",
                "organizations:ListPoliciesForTarget",
                "organizations:ListRoots",
                "organizations:UpdatePolicy",
                "ssm:GetParameters"
            ],
            "Resource": "*"
        }
    ]
}
```

Trust policy

The following custom trust policy allows a specific IAM role in the deployment account to assume the IAM role in the management account. Replace the following:

- `<DEPLOYMENT-ACCOUNT-ID>` is the ID of the deployment account

- <DEPLOYMENT-ROLE-NAME> is the name of the role in the deployment account that is allowed to assume the role in the management account

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "AWS": "arn:aws:iam::<DEPLOYMENT-ACCOUNT-ID>:role/<DEPLOYMENT-ROLE-
NAME>"
            },
            "Action": "sts:AssumeRole",
            "Condition": {}
        }
    ]
}
```

Deploy and manage AWS Control Tower controls by using Terraform

Iker Reina Fuente and Ivan Girardi, Amazon Web Services

Summary

This pattern describes how to use AWS Control Tower controls, HashiCorp Terraform, and infrastructure as code (IaC) to implement and administer preventive, detective, and proactive security controls. A control (also known as a *guardrail*) is a high-level rule that provides ongoing governance for your overall AWS Control Tower environment. For example, you can use controls to require logging for your AWS accounts and then configure automatic notifications if specific security-related events occur.

AWS Control Tower helps you implement preventive, detective, and proactive controls that govern your AWS resources and monitor compliance across multiple AWS accounts. Each control enforces a single rule. In this pattern, you use a provided IaC template to specify which controls you want to deploy in your environment.

AWS Control Tower controls apply to an entire organizational unit (OU), and the control affects every AWS account within the OU. Therefore, when users perform any action in any account in your landing zone, the action is subject to the controls that govern the OU.

Implementing AWS Control Tower controls helps establish a strong security foundation for your AWS landing zone. By using this pattern to deploy the controls as IaC through Terraform, you can standardize the controls in your landing zone and more efficiently deploy and manage them.

To deploy AWS Control Tower controls as IaC, you can also use AWS Cloud Development Kit (AWS CDK) instead of Terraform. For more information, see Deploy and manage AWS Control Tower controls by using AWS CDK and AWS CloudFormation.

Intended audience

This pattern is recommended for users who have experience with AWS Control Tower, Terraform, and AWS Organizations.

Prerequisites and limitations

Prerequisites

- Active AWS accounts managed as an organization in AWS Organizations and an AWS Control Tower landing zone. For instructions, see Getting started in the AWS Control Tower documentation.
- AWS Command Line Interface (AWS CLI), installed and configured.
- An AWS Identity and Access Management (IAM) role in the management account that has permissions to deploy this pattern. For more information about the required permissions and a sample policy, see *Least privilege permissions for the IAM role* in the Additional information section of this pattern.
- Permissions to assume the IAM role in the management account.
- Terraform CLI, installed (Terraform documentation).
- Terraform AWS Provider, configured (Terraform documentation).
- Terraform backend, configured (Terraform documentation).

Limitations

- For AWS Control Tower controls, this pattern requires the use of global identifiers that are in the following format:

```
arn:<PARTITION>:controlcatalog:::control/<CONTROL_CATALOG_OPAQUE_ID>
```

  Previous versions of this pattern used regional identifiers that are no longer supported. We recommend that you migrate from Regional identifiers to global identifiers. Global identifiers help you manage controls and expand the number of controls that you can use.

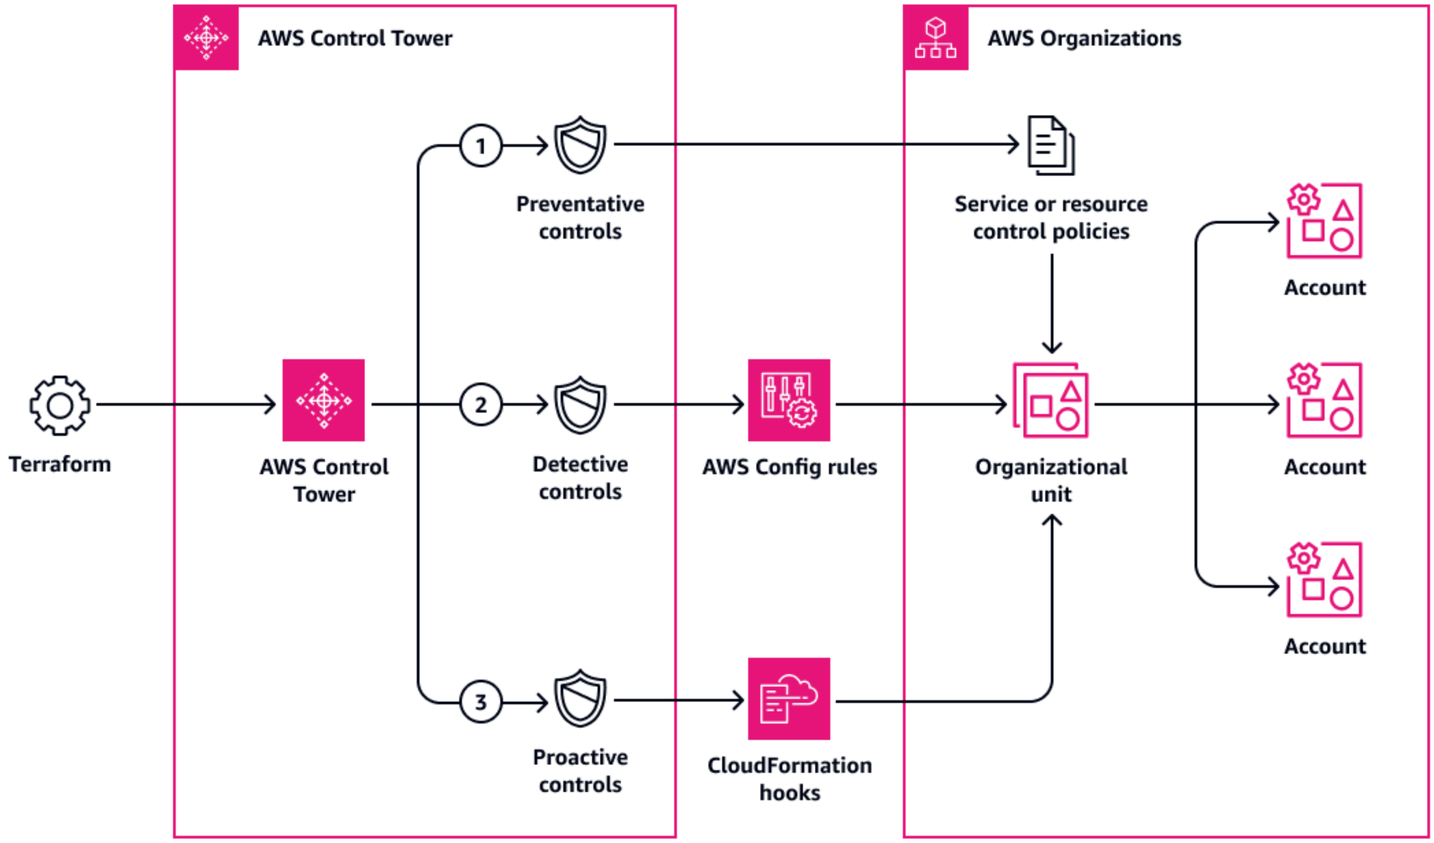
> **Note**
>
> In most cases, the value for `<PARTITION>` is `aws`.

Product versions

- AWS Control Tower version 3.2 or later
- Terraform version 1.5 or later
- Terraform AWS Provider version 4.67 or later

Architecture

This section provides a high-level overview of this solution and the architecture established by the sample code. The following diagram shows controls deployed across the various accounts in the OU.



AWS Control Tower controls are categorized according to their *behavior* and their *guidance*.

There are three primary types of control behaviors:

1. *Preventive controls* are designed to prevent actions from occurring. These are implemented with service control policies (SCPs) or resource control policies (RCPs) in AWS Organizations. The status of a preventive control is either **enforced** or **not enabled**. Preventive controls are supported in all AWS Regions.
2. *Detective controls* are designed to detect specific events when they occur and log the action in AWS CloudTrail. These are implemented with AWS Config rules. The status of a detective control is either **clear**, **in violation**, or **not enabled**. Detective controls apply only in those AWS Regions supported by AWS Control Tower.

3. *Proactive controls* scan resources that would be provisioned by AWS CloudFormation and check whether they are compliant with your company policies and objectives. Resources that are not compliant will not be provisioned. These are implemented with AWS CloudFormation hooks. The status of a proactive control is **PASS**, **FAIL**, or **SKIP**.

Control *guidance* is the recommended practice for how to apply each control to your OUs. AWS Control Tower provides three categories of guidance: *mandatory*, *strongly recommended*, and *elective*. The guidance of a control is independent of its behavior. For more information, see Control behavior and guidance.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

Other tools

- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.

Code repository

The code for this pattern is available in the GitHub Deploy and manage AWS Control Tower controls by using Terraform repository.

Best practices

- The IAM role used to deploy this solution should adhere to the principle of least-privilege (IAM documentation).
- Follow the Best practices for AWS Control Tower administrators (AWS Control Tower documentation).

Epics

Enable controls in the management account

Task	Description	Skills required
Clone the repository.	In a bash shell, enter the following command. This clones the Deploy and manage AWS Control Tower controls by using Terraform repository from GitHub. `git clone https://github.com/aws-samples/aws-control-tower-controls-terraform.git`	DevOps engineer
Edit the Terraform backend configuration file.	1. In the cloned repository, open the **backend.tf** file. 2. Edit the file to set the Terraform backend configuration. The configuration you define in this file depends on your environment. For more information, see Backend configuration (Terraform documentation).	DevOps engineer, Terraform

Task	Description	Skills required
	3. Save and close the **backend.tf** file.	
Edit the Terraform provider configuration file.	1. In the cloned repository, open the **provider.tf** file. 2. Edit the file to set the Terraform provider configuration. For more information, see [Provider configuration](#) (Terraform documentation). Set the AWS Region as the Region where the AWS Control Tower API is available. 3. Save and close the **provider.tf** file.	DevOps engineer, Terraform

Task	Description	Skills required
Edit the configuration file.	1. In the cloned repository, open the **variables.tfvars** file. 2. Open [All global identifiers](#) in the AWS Control Tower documentation. 3. In the JSON-formatted list, locate the control that you want to implement, and then copy its global identifier (also known as the {CONTROL_CATALOG_OPAQUE_ID} value). For example, the global identifier for the **AWS-GR_AUDIT_BUCKET_ENCRYPTION_ENABLED** control is `k4izcjxhukijhajp6ks5mjxk` . 4. In the `controls` section, in the `control_names` parameter, enter the global identifier that you copied. 5. In the `controls` section, in the `organizational_unit_ids` parameter, enter the ID of the organizational unit where you want to enable the control, such as `ou-1111-11111111` . Enter the ID in double quotation marks, and	DevOps engineer, General AWS, Terraform

Task	Description	Skills required
	separate multiple IDs with commas. For more information about how to retrieve OU IDs, see [Viewing the details of an OU](). 6. Save and close the **variables.tfvars** file. For an example of an updated **variables.tfvars** file, see the [Additional information]() section of this pattern.	
Assume the IAM role in the management account.	In the management account, assume the IAM role that has permissions to deploy the Terraform configuration file. For more information about the permissions required and a sample policy, see *Least privilege permissions for the IAM role* in the [Additional information]() section. For more information about assuming an IAM role in the AWS CLI, see [Use an IAM role in the AWS CLI]().	DevOps engineer, General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Deploy the configuration file.</td><td>
1. Enter the following command to initialize Terraform.

```
$ terraform init -
upgrade
```

2. Enter the following command to preview the changes compared the current state.

```
$ terraform plan -
var-file="variabl
es.tfvars"
```

3. Review the configuration changes in the Terraform plan and confirm that you want to implement these changes in the organizat ion.
4. Enter the following command to deploy the resources.

```
$ terraform apply -
var-file="variabl
es.tfvars"
```
</td><td>DevOps engineer, General AWS, Terraform</td></tr>
</table>

(Optional) Disable controls in the AWS Control Tower management account

Task	Description	Skills required
Run the `destroy` command.	Enter the following command to remove the resources deployed by this pattern. `$ terraform destroy -var-file="variables.tfvars"`	DevOps engineer, General AWS, Terraform

Troubleshooting

Issue	Solution
`Error: creating ControlTower Control ValidationException: Guardrail <control ID> is already enabled on organizational unit <OU ID>` error	The control you are trying to enable is already enabled in the target OU. This error can occur if a user manually enabled the control through the AWS Management Console, through AWS Control Tower or through AWS Organizations. To deploy the Terraform configuration file, you can use either of the following options. **Option 1: Update the Terraform current state file** You can import the resource to the Terraform current state file. When you rerun the `apply` command, Terraform will skip this resource. Do the following to import the resource to the current Terraform state: 1. In the AWS Control Tower managemen t account, enter the following command to retrieve a list of the Amazon Resource Names (ARNs) for the OUs, where `<root-`

Issue	Solution

	ID> is the organization root. For more information about retrieving this ID, see Viewing the details of the root.
	`aws organizations list-organizational-units-for-parent --parent-id <root-ID>`
	2. For each OU returned in the previous step, enter the following command, where <OU-ARN> is the ARN of the OU.
	`aws controltower list-enabled-controls --target-identifier <OU-ARN>`
	3. Copy the ARNs and perform the Terraform import in the required module so that it is included in the Terraform state. For instructions, see Import (Terraform documentation).
	4. Repeat the steps in *Deploy the configuration* in the Epics section.
	
	Option 2: Disable the control
	
	If you are working in a non-production environment, you can disable the control in the console. Re-enable it by repeating the steps in *Deploy the configuration* in the Epics section. This approach is not recommended for production environments because there is a period of time when the control will be disabled. If you want to use this option in a production environment, you can implement temporary controls, such as temporarily applying a SCP in AWS Organizations.

Additional information

Example variables.tfvars file

The following is an example of an updated **variables.tfvars** file. This sample enables the **AWS-GR_ENCRYPTED_VOLUMES** control (global ID: `503uicglhjkokaajywfpt6ros`) and the **AWS-GR_SUBNET_AUTO_ASSIGN_PUBLIC_IP_DISABLED** control (global ID: `50z1ot237wl8u1lv5ufau6qqo`). For a list of global IDs, see All global identifiers in the AWS Control Tower documentation.

The following example also enables controls that have parameters such as **CT.S3.PV.5** (global ID: `7mo7a2h2ebsq71l8k6uzr96ou`) and **CT.SECRETSMANAGER.PV.1** (global ID: `dvhe47fxg5o6lryqrq9g6sxg4`). For a list of controls with parameters, see Controls with parameters in the AWS Control Tower documentation.

```
controls = [
    {
        control_names = [
            "503uicglhjkokaajywfpt6ros", # AWS-GR_ENCRYPTED_VOLUMES
            ...
        ],
        organizational_unit_ids = ["ou-1111-11111111", "ou-2222-22222222"...],
    },
    {
        control_names = [
```

```
            "50z1ot237wl8u1lv5ufau6qqo", # AWS-GR_SUBNET_AUTO_ASSIGN_PUBLIC_IP_DISABLED
            ...
        ],
        organizational_unit_ids = ["ou-1111-11111111"...],
    },
]

controls_with_params = [
  {
    control_names = [
      { "7mo7a2h2ebsq71l8k6uzr96ou" = { # CT.S3.PV.5
        parameters = {
          "ExemptedPrincipalArns" : ["arn:aws:iam::*:role/RoleName"],
          "ExemptedResourceArns" : [],
        }
      } },
      { "dvhe47fxg5o6lryqrq9g6sxg4" = { # CT.SECRETSMANAGER.PV.1
        parameters = {
          "ExemptedPrincipalArns" : ["arn:aws:iam::*:role/RoleName"],
        }
      } },
      ...
    ],
    organizational_unit_ids = ["ou-1111-11111111"...]
  },
  {
    control_names = [
      { "dvuaav61i5cnfazfelmvn9m6k" = { # AWS-GR_DISALLOW_CROSS_REGION_NETWORKING
        parameters = {
          "ExemptedPrincipalArns" : ["arn:aws:iam::*:role/RoleName"],
        }
      } },
      { "41ngl8m5c4eb1myoz0t707n7h" = { # AWS-GR_DISALLOW_VPC_INTERNET_ACCESS
        parameters = {
          "ExemptedPrincipalArns" : ["arn:aws:iam::*:role/RoleName"],
        }
      } },
      ...
    ],
    organizational_unit_ids = ["ou-2222-22222222"...]
  }
]
```

Least privilege permissions for the IAM role

This pattern requires that you assume an IAM role in the management account. Best practice is to assume a role with temporary permissions and limit the permissions according to the principle of least privilege. The following sample policy allows the minimum actions required to enable or disable AWS Control Tower controls.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
                "controltower:EnableControl",
                "controltower:DisableControl",
                "controltower:GetControlOperation",
                "controltower:ListEnabledControls",
                "organizations:AttachPolicy",
                "organizations:CreatePolicy",
                "organizations:DeletePolicy",
                "organizations:DescribeOrganization",
                "organizations:DetachPolicy",
                "organizations:ListAccounts",
                "organizations:ListAWSServiceAccessForOrganization",
                "organizations:ListChildren",
                "organizations:ListOrganizationalUnitsForParent",
                "organizations:ListParents",
                "organizations:ListPoliciesForTarget",
                "organizations:ListRoots",
                "organizations:UpdatePolicy"
            ],
            "Resource": "*"
        }
    ]
}
```

Deploy the Security Automations for AWS WAF solution by using Terraform

Dr. Rahul Sharad Gaikwad and Tamilselvan P, Amazon Web Services

Summary

AWS WAF is a web application firewall that helps protect applications from common exploits by using customizable rules, which you define and deploy in *web access control lists* (ACLs). Configuring AWS WAF rules can be challenging, especially for organizations that do not have dedicated security teams. To simplify this process, Amazon Web Services (AWS) offers the Security Automations for AWS WAF solution, which automatically deploys a single web ACL with a set of AWS WAF rules that filters web-based attacks. During Terraform deployment, you can specify which protective features to include. After you deploy this solution, AWS WAF inspects web requests to existing Amazon CloudFront distributions or Application Load Balancers, and blocks any requests that don't match the rules.

The Security Automations for AWS WAF solution can be deployed by using AWS CloudFormation according to the instructions in the Security Automations for AWS WAF Implementation Guide. This pattern provides an alternative deployment option for organizations that use HashiCorp Terraform as their preferred infrastructure as code (IaC) tool to provision and manage their cloud infrastructure. When you deploy this solution, Terraform automatically applies the changes in the cloud and deploys and configures the AWS WAF settings and protective features.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2.4.25 or later, installed and configured with necessary permissions. For more information, see Getting started (AWS CLI documentation).
- Terraform version 1.1.9 or later, installed and configured. For more information, see Install Terraform (Terraform documentation).

Architecture

Target architecture

This pattern deploys the Security Automations for AWS WAF solution. For more information about the target architecture, see Architecture overview in the *Security Automations for AWS WAF Implementation Guide*. For more information about the AWS Lambda automations in this deployment, the Application log parser, the AWS WAF log parser, the IP lists parser, and the Access handler, see Component details in the *Security Automations for AWS WAF Implementation Guide*.

Terraform deployment

When you run `terraform apply`, Terraform does the following:

1. Terraform creates AWS Identity and Access Management (IAM) roles and Lambda functions based on the inputs from the **testing.tfvars** file.
2. Terraform creates AWS WAF ACL rules and IP sets based on the inputs from the **testing.tfvars** file.
3. Terraform creates the Amazon Simple Storage Service (Amazon S3) buckets, Amazon EventBridge rules, AWS Glue database tables, and Amazon Athena work groups based on the inputs from the **testing.tfvars** file.
4. Terraform deploys the AWS CloudFormation stack to provision the custom resources.
5. Terraform creates the Amazon API Gateway resources based on the given inputs from **testing.tfvars** file.

Automation and scale

You can use this pattern to create AWS WAF rules for multiple AWS accounts and AWS Regions to deploy the Security Automations for AWS WAF solution throughout your AWS Cloud environment.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS WAF is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources.

Other services

- Git is an open-source, distributed version control system.
- HashiCorp Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.

Code repository

The code for this pattern is available in the GitHub AWS WAF Automation Using Terraform repository.

Best practices

- Put static files in separate Amazon S3 buckets.
- Avoid hardcoding variables.
- Limit the use of custom scripts.
- Adopt a naming convention.

Epics

Set up your local workstation

Task	Description	Skills required
Install Git.	Follow the instructions in Getting started (Git website) to install Git on your local workstation.	DevOps engineer
Clone the repository.	On your local workstation, enter the following command to clone the code repository: `git clone https://github.com/aws-samples/aws-waf-automation-terraform-samples.git`	DevOps engineer

Task	Description	Skills required
Update the variables.	1. Navigate into the cloned directory by entering the following command: `cd terraform-aws-waf-automation` 2. In any text editor, open the **testing.tfvars** file. 3. Update the values of the variables in the **testing.t fvars** file. 4. Save and close the file.	DevOps engineer

Provision the target architecture using Terraform

Task	Description	Skills required
Initialize the Terraform configuration.	Enter the following command to initialize your working directory that contains the Terraform configuration files: `terraform init`	DevOps engineer
Preview the Terraform plan.	Enter the following command. Terraform evaluates the configura tion files to determine the target state for the declared resources. It then compares the target state against the current state and creates a plan:	DevOps engineer

Task	Description	Skills required
	`terraform plan -var-file ="testing.tfvars"`	
Verify the plan.	Review the plan and confirm that it configures the required architecture in your target AWS account.	DevOps engineer
Deploy the solution.	1. Enter the following command to apply the plan: `terraform apply -var-file="testing .tfvars"` 2. Enter `yes` to confirm. Terraform creates, updates, or destroys infrastru cture to achieve the target state declared in the configuration files. For more information about the sequence, see *Terraform deployment* in the [Architecture] section of this pattern.	DevOps engineer

Validate and clean up

Task	Description	Skills required
Verify the changes.	1. In the Terraform console, verify that the outputs match the expected results.	DevOps engineer

Task	Description	Skills required
	2. Sign in to the AWS Management Console. 3. Verify the outputs in the Terraform console have been successfully deployed in your AWS account.	
(Optional) Clean up the infrastructure.	If you want to remove all resources and configuration changes made by this solution, do the following: 1. In the Terraform console, enter the following command: `terraform destroy -var-file="testing.tfvars"` 2. Enter `yes` to confirm.	DevOps engineer

Troubleshooting

Issue	Solution
`WAFV2 IPSet: WAFOptimisticLockException` error	If you receive this error when you run the `terraform destroy` command, you must manually delete the IP sets. For instructions, see Deleting an IP set (AWS WAF documentation).

Deploy a pipeline that simultaneously detects security issues in multiple code deliverables

Benjamin Morris, Tim Hahn, Sapeksh Madan, Dina Odum, and Isaiah Schisler, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more.

The Simple Code Scanning Pipeline (SCSP) provides two-click creation of a code analysis pipeline that runs industry-standard open-source security tools in parallel. This enables developers to check the quality and security of their code without having to install tools or even understand how to run them. This helps you reduce vulnerabilities and misconfigurations in code deliverables. It also reduces the amount of time your organization spends installing, researching, and configuring security tools.

Before SCSP, scanning code using this particular suite of tools required developers to locate, manually install, and configure the software analysis tools. Even locally installed, all-in-one tools, such as Automated Security Helper (ASH), require configuring a Docker container in order to run. However, with SCSP, a suite of industry-standard code analysis tools runs automatically in the AWS Cloud. With this solution, you use Git to push your code deliverables, and then you receive a visual output with at-a-glance insights into which security checks failed.

Prerequisites and limitations

- An active AWS account
- One or more code deliverables that you want to scan for security issues
- AWS Command Line Interface (AWS CLI), installed and configured
- Python version 3.0 or later and pip version 9.0.3 or later, installed
- Git, installed
- Install git-remote-codecommit on your local workstation

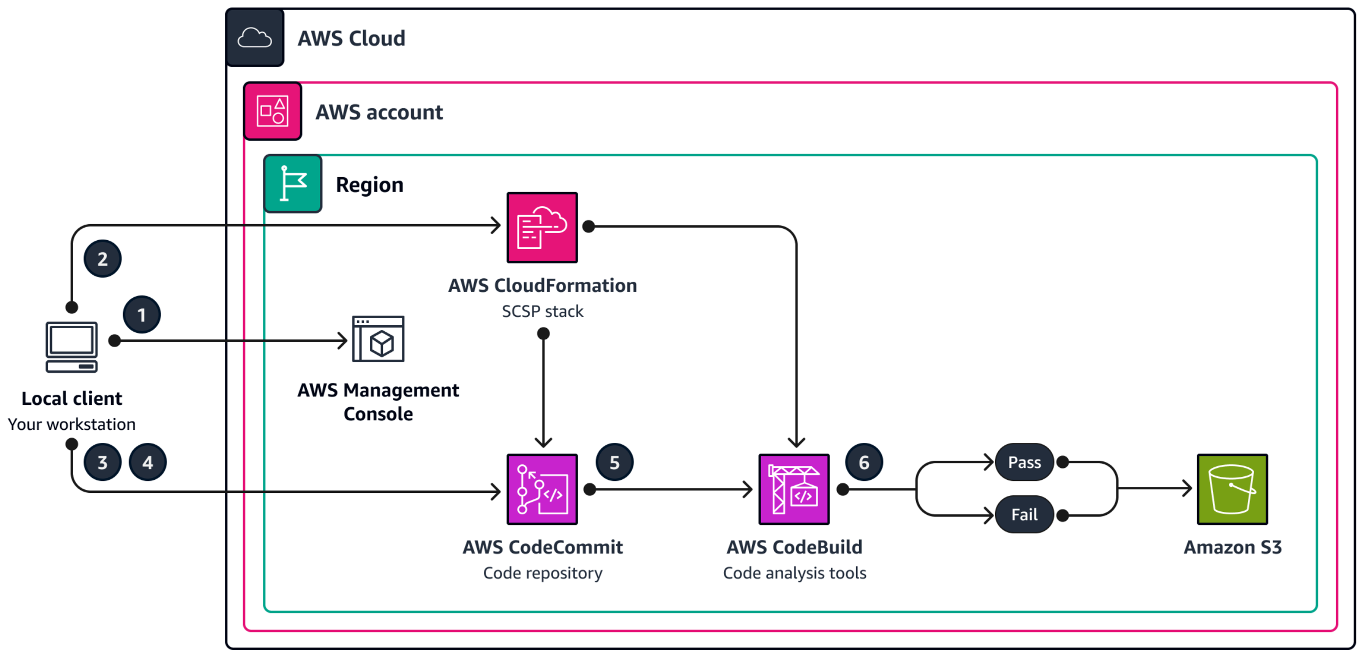
Architecture

Target technology stack

- AWS CodeCommit repository
- AWS CodeBuild project
- AWS CodePipeline pipeline
- Amazon Simple Storage Service (Amazon S3) bucket
- AWS CloudFormation template

Target architecture

The SCSP for static code analysis is a DevOps project designed to give security feedback on deliverable code.



1. In the AWS Management Console, log into the target AWS account. Confirm that you are in the AWS Region where you want to deploy the pipeline.
2. Use the CloudFormation template in the code repository to deploy the SCSP stack. This creates a new CodeCommit repository and CodeBuild project.

> **Note**
>
> As an alternative deployment option, you can use an existing CodeCommit repo by providing the Amazon Resource Name (ARN) of the repository as a parameter during stack deployment.

3. Clone the repository to your local workstation, and then add any files to their respective folders in the cloned repository.
4. Use Git to add, commit, and push the files to the CodeCommit repository.
5. Pushing to the CodeCommit repository initiates a CodeBuild job. The CodeBuild project uses the security tools to scan the code deliverables.
6. Review the output of the pipeline. Security tools that found error-level issues will result in failed actions in the pipeline. Fix these errors or suppress them as false positives. Review details of the tool output in the **Action details** in CodePipeline or in the pipeline's S3 bucket.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

Other tools

For a complete list of tools that SCSP uses to scan code deliverables, see the SCSP readme in GitHub.

Code repository

The code for this pattern is available in the Simple Code Scanning Pipeline (SCSP) repository in GitHub.

Epics

Deploy the SCSP

Task	Description	Skills required
Create the CloudFormation stack.	1. Sign in to the [AWS Management Console](https://console.aws.amazon.com/). 2. In the console, confirm that you're in the target Region where you want to deploy the solution. For more information, see [Choosing a Region](#). 3. Choose the following link. This opens the Quick create stack wizard in CloudFormation. https://console.aws.amazon.com/cloudformation/home?#/stacks/create/review?templateURL=https://proservetools.s3.amazonaws.com/cft/scsp-pipeline-stack.template.json&stackName=SimpleCodeScanPipeline 4. On the **Quick create stack** wizard, review the parameter settings for your stack and make any modifications as needed for your use case.	AWS DevOps, AWS administrator

Task	Description	Skills required
	5. Select **I acknowledge that AWS CloudFormation might create IAM resources**, and then choose **Create stack**. This creates a CodeCommit repository, a CodePipeline pipeline, several CodeBuild job definitions, and an S3 bucket. Build runs and scanning results are copied into this bucket. After the CloudFormation stack has been completely deployed, SCSP is ready to use.	

Use the pipeline

Task	Description	Skills required
Examine the results of the scan.	1. In the [Amazon S3 console](https://console.aws.amazon.com/s3/), in **Buckets**, choose the **simplecodescanpipeline-deleteresourcespipelinereso** bucket. 2. Choose the **scan_results** directory, and then choose the folder with the most recent scan date stamp. 3. Review the log files in this folder to review any issues detected by the security tools used in the pipeline.	App developer, AWS DevOps

Task	Description	Skills required
	Security tools that found error-level issues will result in `failed` actions in the pipeline. These need to be fixed or suppressed if they are false positives. **Note** You can also view details of the tool output (for both passing and failing scans) in the CodePipeline console, in the **Action details** section.	

Troubleshooting

Issue	Solution
HashiCorp Terraform or AWS CloudFormation files aren't being scanned.	Make sure that Terraform (.tf) and CloudFormation (.yml, .yaml, or .json) files are placed in the appropriate folders in the cloned CodeCommit repository.
The `git clone` command is failing.	Make sure that you have installed `git-remote-codecommit` and that your CLI has access to AWS credentials that have permissions to read the CodeCommit repository.

Issue	Solution
A concurrency error, such as `Project-level concurrent build limit cannot exceed the account-level concurrent build limit of 1 .`	Rerun the pipeline by choosing the **Release Change** button in the CodePipeline console. This is a known issue that seems to be most common during the first few times that the pipeline runs.

Additional information

FAQ

Is the SCSP project the same as Automated Security Helper (ASH)?

No. Use ASH when you want a CLI tool that runs code-scanning tools by using containers. Automated Security Helper (ASH) is a tool that is designed to reduce the probability of a security violation in new code, infrastructure, or IAM resource configuration. ASH is a command-line utility that can be run locally. Local use requires a container environment be installed and operational on the system.

Use SCSP when you want an easier setup pipeline than ASH. SCSP requires no local installations. SCSP is designed to run checks individually in a pipeline and display results by tool. SCSP also avoids a lot of the overhead with setting up Docker, and it is operating system (OS) agnostic.

Is SCSP just for security teams?

No, anyone can deploy the pipeline to determine which parts of their code are failing security checks. For example, non-security users can use SCSP to check their code before reviewing with their security teams.

Can I use SCSP if I'm working with another type of repository, such as GitLab, GitHub, or Bitbucket?

You can configure a local git repository to point to two different remote repositories. For example, you could clone an existing GitLab repository, create a SCSP instance (specifying CloudFormation, Terraform, and AWS Config Rules Development Kit (AWS RDK) folders, if needed), and then use `git remote add upstream <SCSPGitLink>` to point the local repository at the SCSP CodeCommit repository as well. This allows for code changes to be sent to SCSP first, validated, then, after any additional updates are made to address findings, pushed to the GitLab, GitHub, or Bitbucket repository. For more information about multiple remotes, see Push commits to an additional Git repository (AWS blog post).

> **Note**
>
> Be careful of drift, such as avoid making changes through web interfaces.

Contributing and adding your own actions

SCSP setup is maintained as a GitHub project, which contains the source code for the SCSP AWS Cloud Development Kit (AWS CDK) application. To add additional checks to the pipeline, the AWS CDK application needs to be updated and then synthesized or deployed into the target AWS account where the pipeline will run. To do this, start by cloning the SCSP GitHub project, and then find the stack definition file in the `lib` folder.

If there's an additional check you would like to add, the `StandardizedCodeBuildProject` class in the AWS CDK code makes it very straightforward to add actions. Provide the name, description, and `install` or `build` commands. AWS CDK creates the CodeBuild project by using sensible default values. In addition to creating the build project, you need to add it to the CodePipeline actions in the build stage. When designing a new check, the action should `FAIL` if the scanning tool detects problems or fails to run. The action should `PASS` if the scanning tool doesn't detect any problems. For an example of configuring a tool, review the code for the `Bandit` action.

For more information about expected input and outputs, see the repository documentation.

If you add custom actions, you need to deploy SCSP by using `cdk deploy` or `cdk synth + CloudFormation deploy`. This is because the **Quick create stack** CloudFormation template is maintained by the repo owners.

Deploy detective attribute-based access controls for public subnets by using AWS Config

Alberto Menendez, Amazon Web Services

Summary

Distributed edge network architectures rely on network edge security that runs alongside the workloads in their virtual private clouds (VPCs). This provides unprecedented scalability in comparison to the more common, centralized approach. Although deploying public subnets in workload accounts can provide benefits, it also introduces new security risks because it increases the attack surface. We recommend that you deploy only Elastic Load Balancing resources, such as Application Load Balancers, or NAT gateways in the public subnets of these VPCs. Using load balancers and NAT gateways in dedicated public subnets helps you implement fine-grained control for inbound and outbound traffic.

We recommend that you implement both preventative and detective controls to limit the types of resources that can be deployed in public subnets. For more information about using attribute-based access control (ABAC) to deploy preventative controls for public subnets, see [Deploy preventative attribute-based access controls for public subnets](). Although effective for most situations, these preventative controls might not address all possible use cases. Therefore, this pattern builds on the ABAC approach and helps you configure alerts about noncompliant resources that are deployed in public subnets. The solution checks whether elastic network interfaces belong to a resource that is not allowed in public subnets.

To achieve this, this pattern uses [AWS Config custom rules]() and [ABAC](). The custom rule processes the configuration of an elastic network interface whenever it is created or modified. At a high level, this rule performs two actions to determine whether the network interface is compliant:

1. To determine whether the network interface is in scope of the rule, the rule checks whether the subnet has specific [AWS tags]() that indicate it is a public subnet. For example, this tag might be `IsPublicFacing=True`.
2. If the network interface is deployed in a public subnet, the rule checks which AWS service created this resource. If the resource is not an Elastic Load Balancing resource or NAT gateway, it marks the resource as noncompliant.

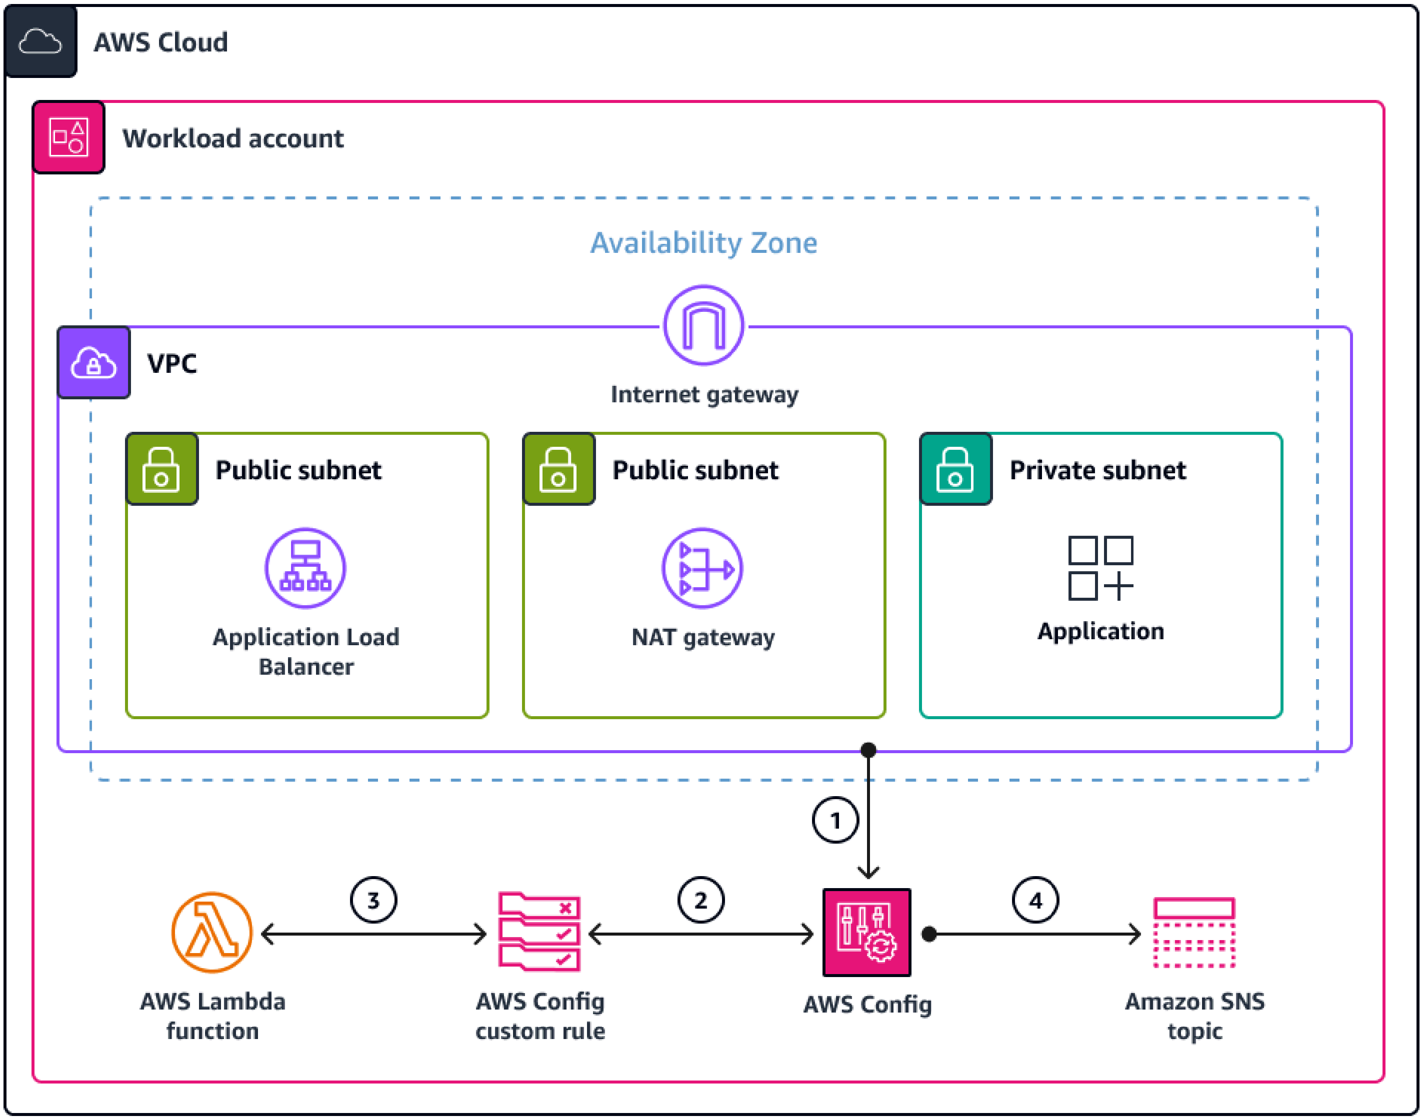
Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Config, set up in the workload account
- Permissions to deploy the required resources in the workload account
- A VPC with public subnets
- Tags properly applied to identify the target public subnets
- (Optional) An organization in AWS Organizations
- (Optional) A central security account that is the delegated administrator for AWS Config and AWS Security Hub

Architecture

Target architecture



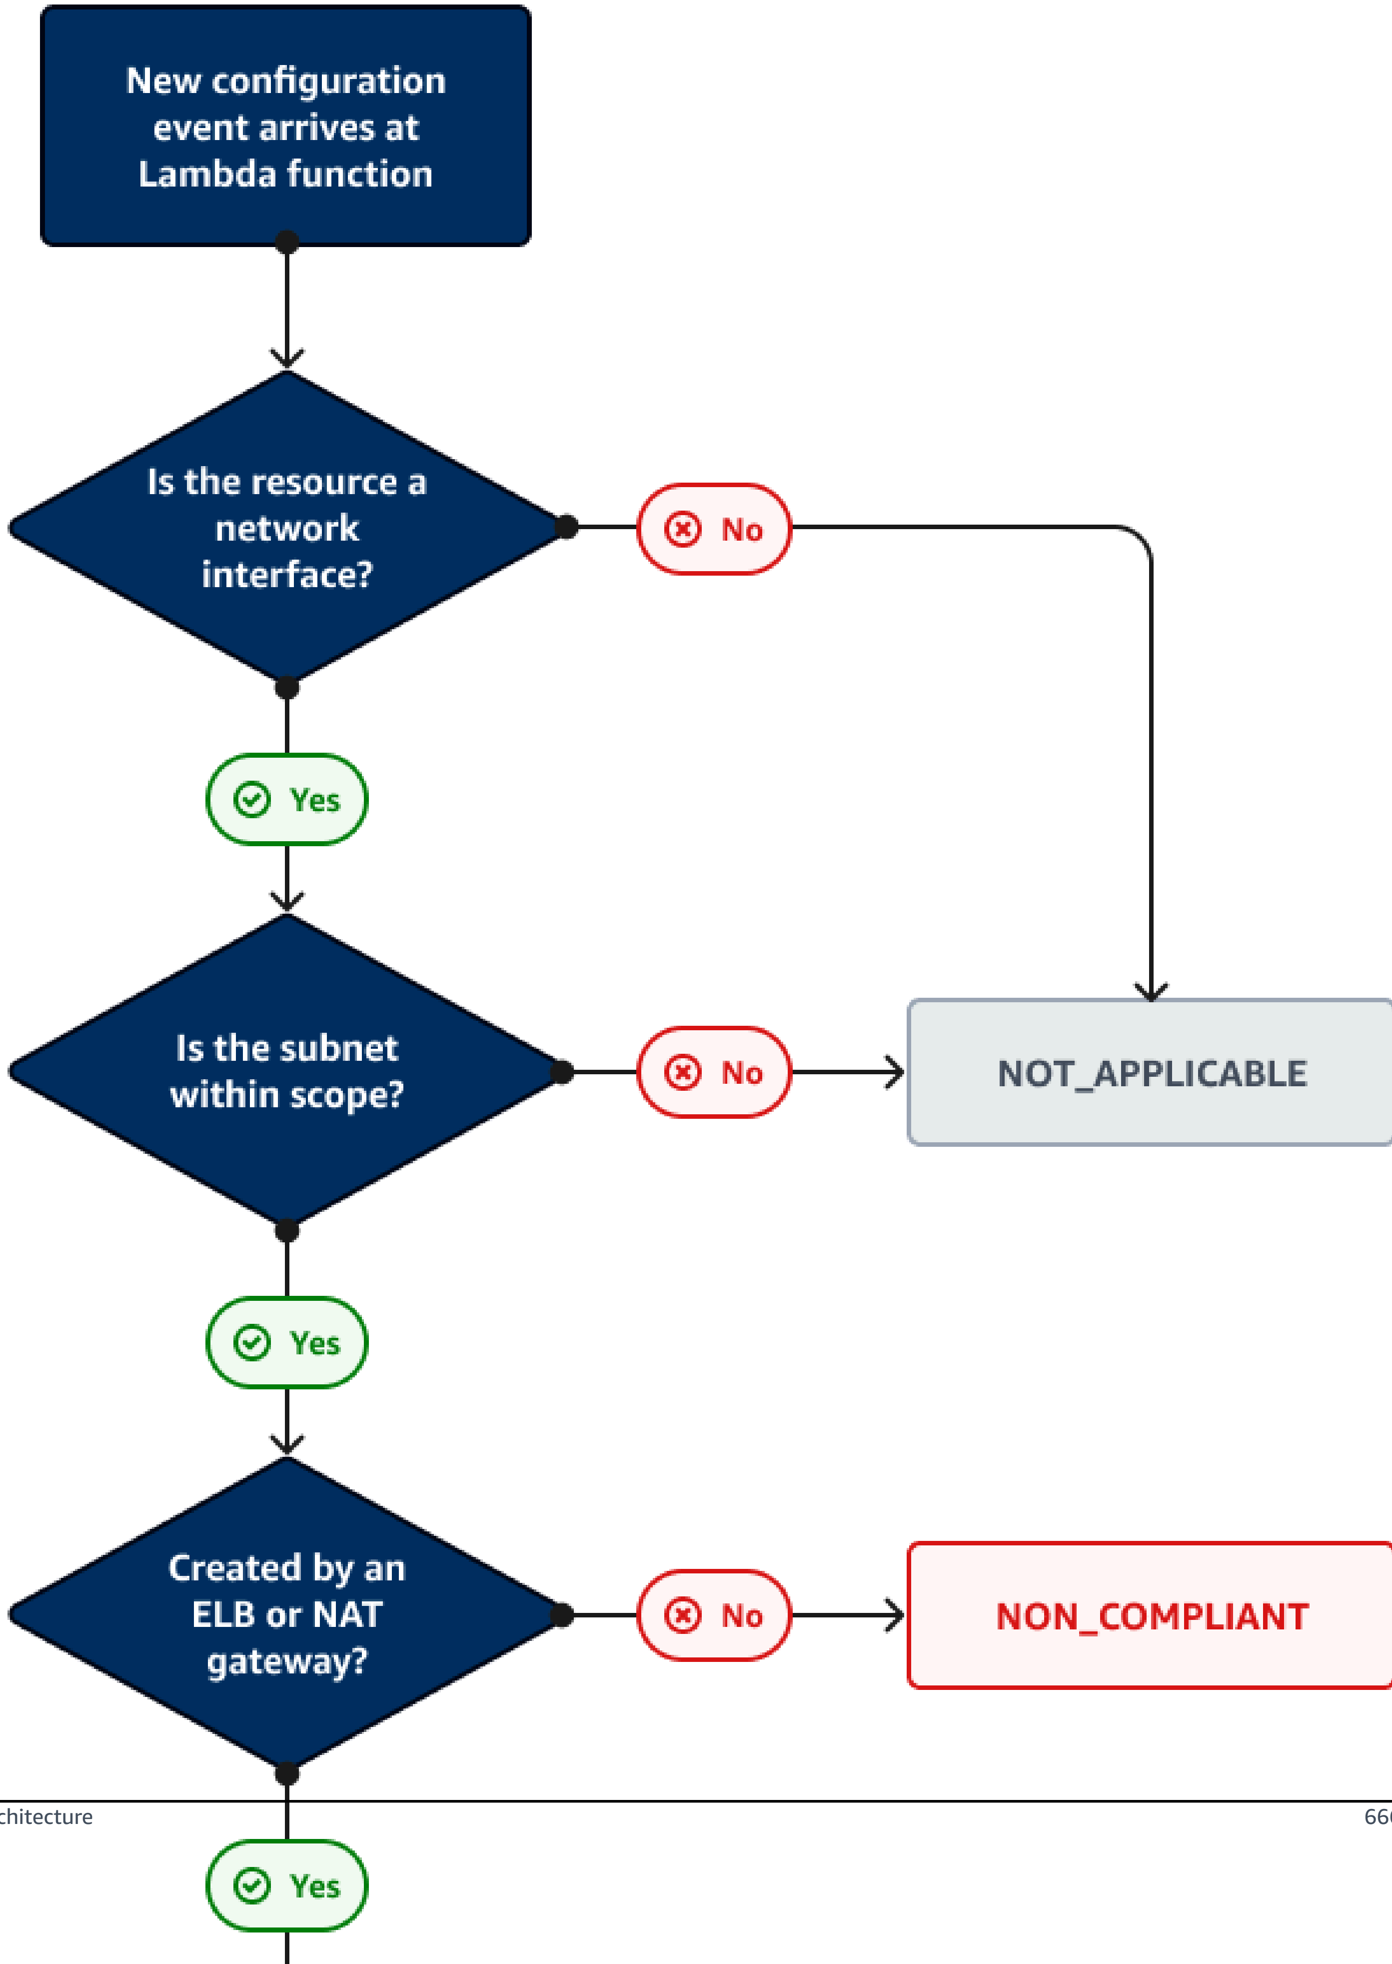
The diagram illustrates the following:

1. When an elastic network interface resource (`AWS::EC2::NetworkInterface`) is deployed or modified, AWS Config captures the event and the configuration.
2. AWS Config matches this event against the custom rule used to evaluate the configuration.
3. The AWS Lambda function associated with this custom rule is invoked. The function evaluates the resource and applies the specified logic to determine if the resource configuration is `COMPLIANT`, `NON_COMPLIANT` or `NOT_APPLICABLE`.
4. If a resource is determined to be `NON_COMPLIANT`, AWS Config sends an alert through Amazon Simple Notification Service (Amazon SNS).

Note: If this account is a member account in AWS Organizations, you can send compliance data to a central security account through AWS Config or AWS Security Hub.

Lambda function evaluation logic

The following diagram shows the logic applied by the Lambda function to evaluate the compliance of the elastic network interface.



New configuration event arrives at Lambda function
Is the resource a network interface?
No
Yes
Is the subnet within scope?
No
NOT_APPLICABLE
Yes
Created by an ELB or NAT gateway?
No
NON_COMPLIANT
Yes

Automation and scale

This pattern is a detective solution. You can also complement it with a remediation rule to automatically resolve any noncompliant resources. For more information, see Remediating Noncompliant Resources with AWS Config Rules.

You can scale this solution by:

- Enforcing application of the corresponding AWS tags that you establish to identify public-facing subnets. For more information, see Tag policies in the AWS Organizations documentation.
- Configuring a central security account that applies the AWS Config custom rule to every workload account in the organization. For more information, see Automate configuration compliance at scale in AWS (AWS blog post).
- Integrating AWS Config with AWS Security Hub in order to capture, centralize, and notify at scale. For more information, see Configuring AWS Config in the AWS Security Hub documentation.

Tools

- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- Elastic Load Balancing distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Best practices

For more examples and best practices for developing custom AWS Config rules, see the official [AWS Config Rules Repository] on GitHub.

Epics

Deploy the solution

Task	Description	Skills required
Create the Lambda function.	1. Sign in to the AWS Management Console, and then open the AWS Lambda console. 2. On the **Functions** page, choose **Create function**. 3. Select **Author from scratch**. 4. In the **Basic information** pane, for **Function name**, enter a name. 5. For **Runtime**, choose **Python 3.12**. 6. Leave **architecture** set to **x86_64**. 7. Choose **Create function**. 8. Choose the **Code** tab. 9. In the file explorer, choose **lambda_function.py**. 10. Paste the sample code provided in the Additional information section of this pattern into the **lambda_function.py** tab. Customize the sample code	General AWS

Task	Description	Skills required
	to identify any custom evaluation logic in the `evaluate_change_notification_compliance` function. 11. Choose **Deploy**.	

Task	Description	Skills required

Add permissions to the Lambda function's execution role.	1. In the navigation pane, choose **Functions**.
	2. Choose the function you just created.
	3. Choose **Configuration**, and then choose **Permissions**.
	4. Choose the role name to open the role in the AWS Identity and Access Management (IAM) console.
	5. Under **Permissions policies**, choose **Add permissions**, and then choose **Create inline policy**.
	6. Choose **JSON**.
	7. Paste the following policy into the policy editor. This allows the Lambda function to:
	• Get the details of the subnet tags.
	• Send the compliance outcome back to AWS Config.
	
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
		General AWS

Task	Description	Skills required
	``` "Action": ["config:PutEvaluations", "ec2:DescribeSubnets"], "Resource": "*", "Effect": "Allow" }] } ``` 8. Choose **Next**. 9. Enter a name for the policy, and then choose **Create policy**.	
Retrieve the Lambda function Amazon Resource Name (ARN).	1. Open the Lambda console. 2. In the navigation pane, choose **Functions**. 3. Choose the function you just created. 4. In the **Function overview** section, under **Function ARN**, copy the value.	General AWS

Task	Description	Skills required
Create the AWS Config custom rule.	1. Open the [AWS Config console](https://console.aws.amazon.com/config/). 2. On the **Rules** page, choose **Add rule**. 3. On the **Specify rule type** page, choose **Create custom Lambda rule**, and then choose **Next**. 4. On the **Configure rule** page, do the following: a. Enter a name and description. b. For **AWS Lambda function ARN**, paste the ARN that you previously copied. c. For **Trigger type**, choose **When configuration changes**. d. For **Scope of changes**, select **Resources**. e. For **Resource type**, choose **AWS EC2 NetworkInterface**. f. Choose **Next**. 5. On the **Review and create** page, verify your rule, and then choose **Save**.	General AWS

Task	Description	Skills required
Configure notifications.	1. Follow the instructions in Creating an Amazon SNS topic in order to create an Amazon SNS topic. 2. Follow the instructions in Subscribing to an Amazon SNS topic to configure an endpoint that receives notifications for the Amazon SNS topic. 3. Follow the instructions in How can I be notified when an AWS resource is non-compliant using AWS Config to configure a custom Amazon EventBridge rule for your noncompliant resources.	General AWS

Test the solution

Task	Description	Skills required
Create a compliant resource.	1. Use the following instructions to create one of the supported resources in a public subnet: • Create a NAT gateway • Getting started with Network Load Balancers • Create an Application Load Balancer	General AWS

Task	Description	Skills required
	2. After the resource is created, the AWS Config custom rule evaluates the elastic network interfaces associated with resource. It marks these network interfaces as `COMPLIANT` . You can view the resources in AWS Config by following these steps: a. Open the [AWS Config console](https://console.aws.amazon.com/config/). b. On the **Rules** page, choose your rule. c. On the **Rule detail** page, go to the bottom of the page. d. Under **Resources in scope**, select **Compliant** . Confirm that you see the IDs of the network interfaces that were created. e. For more detail about the network interface configuration, choose the resource ID.	

Task	Description	Skills required
Create a noncompliant resource.	1. Use the following instructions to create a noncompliant resource in a public subnet: • [Launch an Amazon EC2 instance](#) • [Creating an Amazon Relational Database Service (Amazon RDS) database instance](#) • [Create a VPC endpoint](#) 2. After the resource is created, the AWS Config custom rule evaluates the elastic network interfaces associated with resource. It marks these network interfaces as `NON_COMPLIANT` . You can view the resources in AWS Config by following these steps: a. Open the [AWS Config console](#). b. On the **Rules** page, choose your rule. c. On the **Rule detail** page, go to the bottom of the page. d. Under **Resources in scope**, select **NonCompliant**. Confirm that you see the IDs of	General AWS

Task	Description	Skills required
	the network interfaces that were created. e. For more detail about the network interface configuration, choose the resource ID. 3. Confirm that you receive the notification at the endpoint that you configured in Amazon SNS.	
Create a resource that is not applicable.	1. In a private subnet, create any resource that requires an elastic network interface. 2. After the resource is created, the AWS Config custom rule evaluates the elastic network interfaces associated with resource. It marks these network interfaces as `NOT_APPLICABLE` . These resources are not shown in the AWS Config console.	General AWS

Additional information

The following is a sample Lambda function that is provided for demonstration purposes.

```
import boto3
import json
import os

# Init clients
config_client = boto3.client('config')
ec2_client = boto3.client('ec2')

def lambda_handler(event, context):

    # Init values
    compliance_value = 'NOT_APPLICABLE'
    invoking_event = json.loads(event['invokingEvent'])
    configuration_item = invoking_event['configurationItem']

    status = configuration_item['configurationItemStatus']
    eventLeftScope = event['eventLeftScope']

    # First check if the event configuration applies. Ex. resource event is not delete
    if (status == 'OK' or status == 'ResourceDiscovered') and not eventLeftScope:
        compliance_value = evaluate_change_notification_compliance(configuration_item)

    config_client.put_evaluations(
       Evaluations=[
           {
               'ComplianceResourceType': invoking_event['configurationItem']
['resourceType'],
               'ComplianceResourceId': invoking_event['configurationItem']
['resourceId'],
               'ComplianceType': compliance_value,
               'OrderingTimestamp': invoking_event['configurationItem']
['configurationItemCaptureTime']
```

```
            },
        ],
        ResultToken=event['resultToken'])

# Function with the logs to evaluate the resource
def evaluate_change_notification_compliance(configuration_item):
    is_in_scope = is_in_scope_subnet(configuration_item['configuration']['subnetId'])

    if (configuration_item['resourceType'] != 'AWS::EC2::NetworkInterface') or not
 is_in_scope:
        return 'NOT_APPLICABLE'

    else:
        alb_condition = configuration_item['configuration']['requesterId'] in ['amazon-
elb']
        nlb_condition = configuration_item['configuration']['interfaceType'] in
 ['network_load_balancer']
        nat_gateway_condition = configuration_item['configuration']['interfaceType'] in
 ['nat_gateway']

        if alb_condition or nlb_condition or nat_gateway_condition:
            return 'COMPLIANT'
    return 'NON_COMPLIANT'

# Function to check if elastic network interface is in public subnet
def is_in_scope_subnet(eni_subnet):

    subnet_description = ec2_client.describe_subnets(
        SubnetIds=[eni_subnet]
    )

    for subnet in subnet_description['Subnets']:
        for tag in subnet['Tags']:
            if tag['Key'] == os.environ.get('TAG_KEY') and tag['Value'] ==
 os.environ.get('TAG_VALUE'):
                return True

    return False
```

Deploy preventative attribute-based access controls for public subnets

Joel Alfredo Nunez Gonzalez and Samuel Ortega Sancho, Amazon Web Services

Summary

In centralized network architectures, inspection and edge virtual private clouds (VPCs) concentrate all inbound and outbound traffic, such as traffic to and from the internet. However, this can create bottlenecks or result in reaching the limits of AWS service quotas. Deploying network edge security alongside the workloads in their VPCs provides unprecedented scalability in comparison to the more common, centralized approach. This is called a *distributed edge* architecture.

Although deploying public subnets in workload accounts can provide benefits, it also introduces new security risks because it increases the attack surface. We recommend that you deploy only Elastic Load Balancing (ELB) resources, such as Application Load Balancers, or NAT gateways in the public subnets of these VPCs. Using load balancers and NAT gateways in dedicated public subnets helps you implement fine-grained control for inbound and outbound traffic.

Attribute-based access control (ABAC) is the practice of creating fine-grained permissions based on user attributes, such as department, job role, and team name. For more information, see ABAC for AWS. ABAC can provide guardrails for public subnets in workload accounts. This helps application teams be agile, without compromising the security of the infrastructure.

This pattern describes how to help secure public subnets by implementing ABAC through a service control policy (SCP) in AWS Organizations and policies in AWS Identity and Access Management (IAM). You apply the SCP to either a member account of an organization or to an organizational unit (OU). These ABAC policies permit users to deploy NAT gateways in the target subnets and prevent them from deploying other Amazon Elastic Compute Cloud (Amazon EC2) resources, such as EC2 instances and elastic network interfaces.

Prerequisites and limitations

Prerequisites

- An organization in AWS Organizations
- Administrative access to the AWS Organizations root account

- In the organization, an active member account or OU for testing the SCP

Limitations

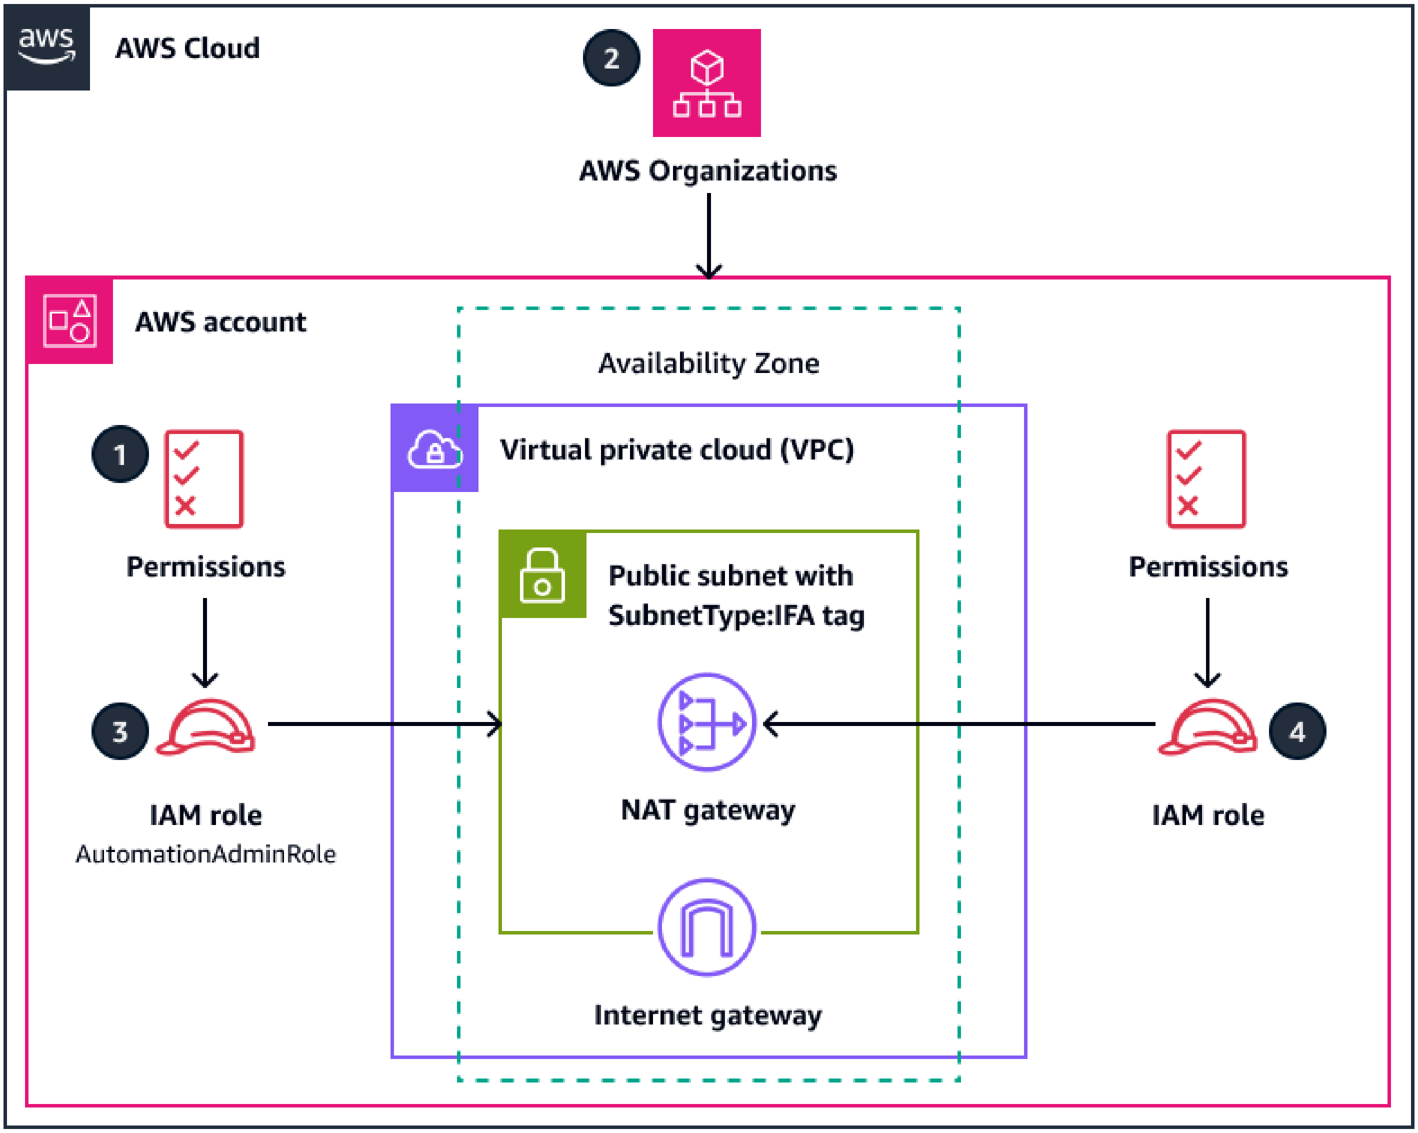
- The SCP in this solution doesn't prevent AWS services that use a service-linked role from deploying resources in the target subnets. Examples of these services are Elastic Load Balancing (ELB), Amazon Elastic Container Service (Amazon ECS), and Amazon Relational Database Service (Amazon RDS). For more information, see [SCP effects on permissions](#) in the AWS Organizations documentation. Implement security controls to detect these exceptions.

Architecture

Target technology stack

- SCP applied to an AWS account or OU in AWS Organizations
- The following IAM roles:
  - `AutomationAdminRole` – Used to modify subnet tags and create VPC resources after implementing the SCP
  - `TestAdminRole` – Used to test whether the SCP is preventing other IAM principals, including those with administrative access, from performing the actions reserved for the `AutomationAdminRole`

Target architecture



1. You create the `AutomationAdminRole` IAM role in the target account. This role has permissions to manage networking resources. Note the following permissions that are exclusive to this role:
   - This role can create VPCs and public subnets.
   - This role can modify the tag assignments for the target subnets.
   - This role can manage its own permissions.
2. In AWS Organizations, you apply the SCP to the target AWS account or OU. For a sample policy, see [Additional information](#) in this pattern.
3. A user or a tool in the CI/CD pipeline can assume the `AutomationAdminRole` role to apply the `SubnetType` tag to the target subnets.

4. By assuming other IAM roles, authorized IAM principals in your organization can manage NAT gateways in the target subnets and other permitted networking resources in the AWS account, such as route tables. Use IAM policies to grant these permissions. For more information, see Identity and access management for Amazon VPC.

Automation and scale

To help protect public subnets, the corresponding AWS tags must be applied. After applying the SCP, NAT gateways are the only kind of Amazon EC2 resource that authorized users can create in subnets that have the `SubnetType:IFA` tag. (`IFA` means *internet-facing assets*.) The SCP prevents the creation of other Amazon EC2 resources, such as instances and elastic network interfaces. We recommend that you use a CI/CD pipeline that assumes the `AutomationAdminRole` role to create VPC resources so that these tags are properly applied to public subnets.

Tools

AWS services

- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage. In AWS Organizations, you can implement service control policies (SCPs), which are a type of policy that you can use to manage permissions in your organization.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Apply the SCP

Task	Description	Skills required
Create a test admin role.	Create an IAM role named `TestAdminRole` in the target AWS account. Attach	AWS administrator

Task	Description	Skills required
	the **AdministratorAccess** AWS managed IAM policy to the new role. For instructions, see [Creating a role to delegate permissions to an IAM user](#) in the IAM documentation.	

Task	Description	Skills required
Create the automation admin role.	1. Create an IAM role named `AutomationAdminRole` in the target AWS account. 2. Attach the **AdministratorAccess** AWS managed IAM policy to the new role. The following is an example of a trust policy that you could use to test the role from the 111122223333 account. `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Principal": { "AWS": [ "arn:aws:iam::111122223333:root" ] }, "Action": "sts:AssumeRole", "Condition": {} } ] }`	AWS administrator

Task	Description	Skills required
Create and attach the SCP.	1. Using the sample code provided in the Additional information section, create a security control policy. For instructions, see Creating an SCP in the AWS Organizations documentation. 2. Attach the SCP to the target AWS account or OU. For instructions, see Attaching and detaching service control policies in the AWS Organizations documentation.	AWS administrator

Test the SCP

Task	Description	Skills required
Create a VPC or subnet.	1. Assume the `TestAdminRole` role in the target AWS account. 2. Try to create a VPC or a new public subnet in an existing VPC. For instructions, see Create a VPC, subnets, and other VPC resources in the Amazon VPC documentation. You shouldn't be able to create these resources.	AWS administrator

Task	Description	Skills required
	3. Assume the `AutomationAdminRole` role, and retry the previous step. Now, you should be able to create the networking resources.	
Manage tags.	1. Assume the `TestAdminRole` role in the target AWS account. 2. Add a `SubnetType:IFA` tag to an available public subnet. You should be able to add this tag. For instructions about how to add tags through the AWS Command Line Interface (AWS CLI), see create-tags in the *AWS CLI Command Reference*. 3. Without changing your credentials, attempt to modify the `SubnetType:IFA` tag assigned to this subnet. You shouldn't be able to modify this tag. 4. Assume the `AutomationAdminRole` role, and retry the previous steps. This role should be able to add and modify this tag.	AWS administrator

Task	Description	Skills required
Deploy resources in the target subnets.	1. Assume the `TestAdminRole` role. 2. For a public subnet that has the `SubnetType:IFA` tag, try to create an EC2 instance. For instructions, see [Launch an instance](#) in the Amazon EC2 documentation. In this subnet, you shouldn't be able to create, modify, or delete any Amazon EC2 resources except NAT gateways. 3. In the same subnet, create a NAT gateway. For instructions, see [Create a NAT gateway](#) in the Amazon VPC documentation. You should be able to create, modify, or delete NAT gateways in this subnet.	AWS administrator

Task	Description	Skills required
Manage the AutomationAdminRole role.	1. Assume the `TestAdminRole` role. 2. Try to modify the `AutomationAdminRole` role. For instructions, see [Modifying a role](#) in the IAM documentation. You shouldn't be able to modify this role. 3. Assume the `AutomationAdminRole` role, and retry the previous step. Now, you should be able to modify the role.	AWS administrator

Clean up

Task	Description	Skills required
Clean up deployed resources.	1. Detach the SCP from the AWS account or OU. For instructions, see [Detaching an SCP](#) in the AWS Organizations documentation. 2. Delete the SCP. For instructions, see [Deleting an SCP](#) (AWS Organizations documentation). 3. Delete the `AutomationAdminRole` role and the `TestAdminRole` role. For instructions, see	AWS administrator

Task	Description	Skills required
	Deleting roles in the IAM documentation. 4. Delete all networking resources, such as VPCs and subnets, that you created for this solution.

Detect Amazon RDS and Aurora database instances that have expiring CA certificates

Stephen DiCato and Eugene Shifer, Amazon Web Services

Summary

As a security best practice, it is recommended that you encrypt data in transit between application servers and relational databases. You can use SSL or TLS to encrypt a connection to a database (DB) instance or cluster. These protocols help provide confidentiality, integrity, and authenticity between an application and database. The database uses a server certificate, which is issued by a certificate authority (CA) and is used to perform server identity verification. SSL or TLS verifies the authenticity of the certificate by validating its digital signature and ensuring it is not expired.

In the AWS Management Console, Amazon Relational Database Service (Amazon RDS) and Amazon Aurora provide notifications about DB instances that require certificate updates. However, to check for these notifications, you must log into each AWS account and navigate to the service console in each AWS Region. This task becomes more complex if you need to assess certificate validity across many AWS accounts that are managed as an organization in AWS Organizations.

By provisioning the infrastructure as code (IaC) provided in this pattern, you can detect expiring CA certificates for all Amazon RDS and Aurora DB instances in your AWS account or AWS organization. The AWS CloudFormation template provisions an AWS Config rule, an AWS Lambda function, and the necessary permissions. You can deploy it into a single account as a stack, or you can deploy it across the entire AWS organization as a stack set.

Prerequisites and limitations

Prerequisites

- An active AWS account
- If you're deploying into a single AWS account:
  - Ensure that you have permissions to create CloudFormation stacks.
  - Enable AWS Config in the target account.
  - (Optional) Enable AWS Security Hub in the target account.
- If you're deploying into an AWS organization:

- Ensure that you have permissions to create CloudFormation stack sets.
- Enable Security Hub with AWS Organizations integration.
- Enable AWS Config in the accounts where you are deploying this solution.
- Designate an AWS account to be the delegated administrator for AWS Config and Security Hub.

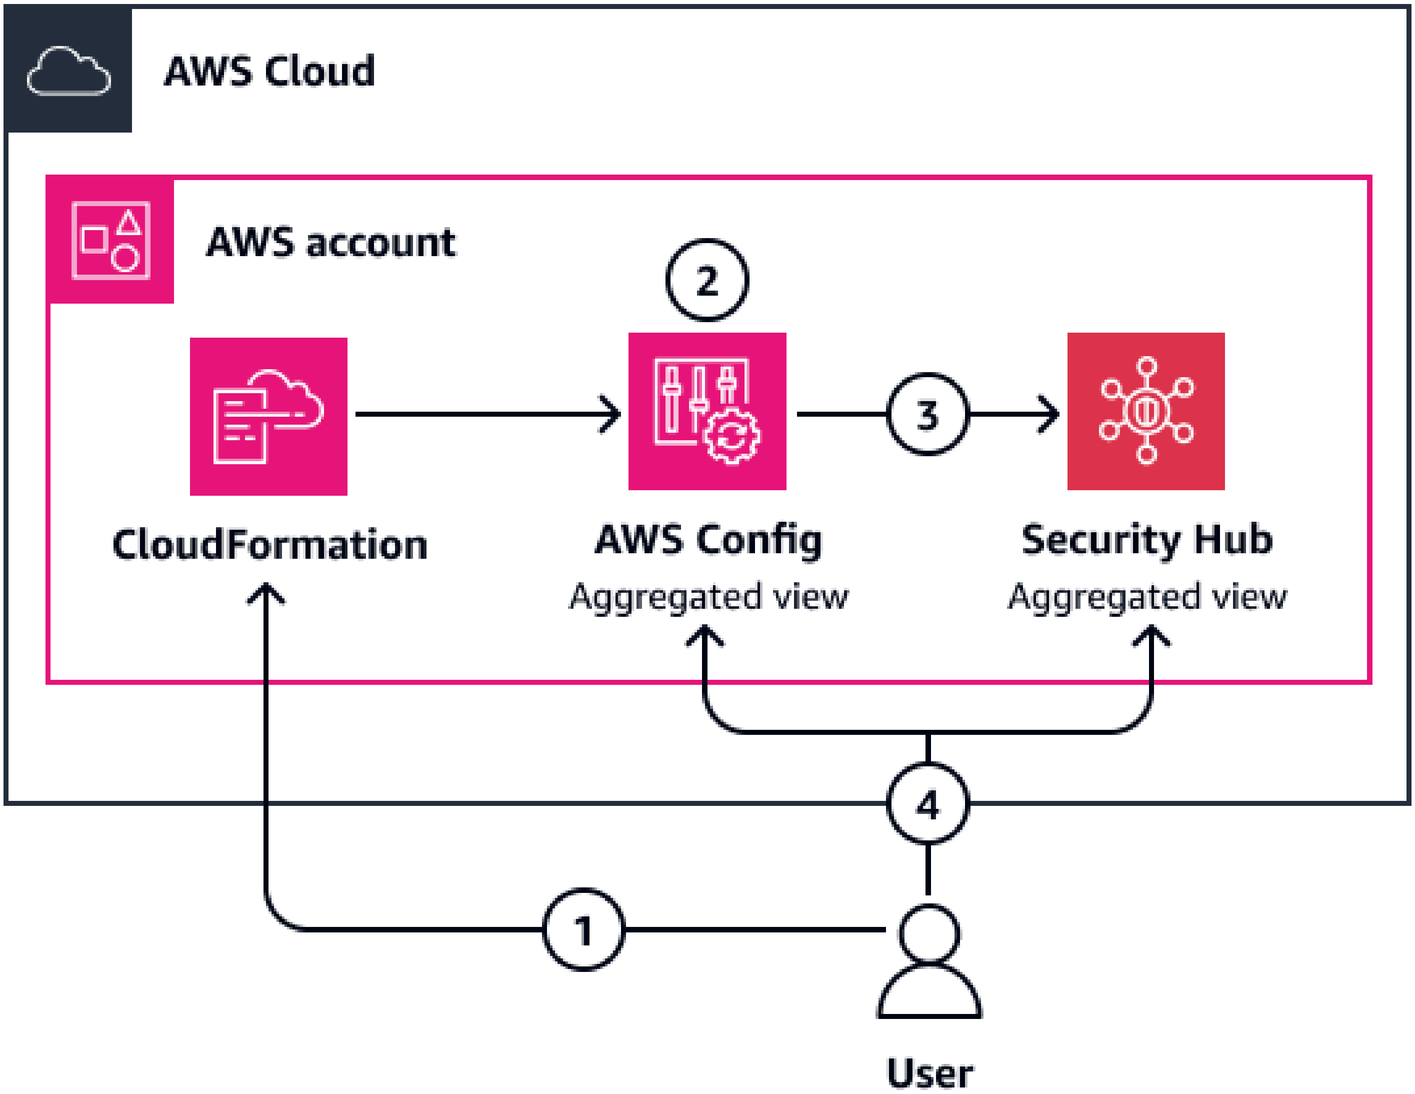
Limitations

- If you're deploying to an individual account that doesn't have Security Hub enabled, you can use AWS Config to evaluate the findings.
- If you're deploying to an organization that doesn't have a delegated administrator for AWS Config and Security Hub, you must log into the individual member accounts to view the findings.
- If you use AWS Control Tower to manage and govern the accounts in your organization, deploy the IaC in this pattern by using Customizations for AWS Control Tower (CfCT). Using the CloudFormation console will create configuration drift from AWS Control Tower guardrails and require that you re-enroll the organizational units (OUs) or managed accounts.
- Some AWS services aren't available in all AWS Regions. For Region availability, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

Deploying into an individual AWS account

The following architecture diagram shows the deployment of the AWS resources within a single AWS account. It's implemented by using a CloudFormation template directly through the CloudFormation console. If Security Hub is enabled, you can view the results in either AWS Config or Security Hub. If Security Hub is not enabled, you can view the results only in the AWS Config console.

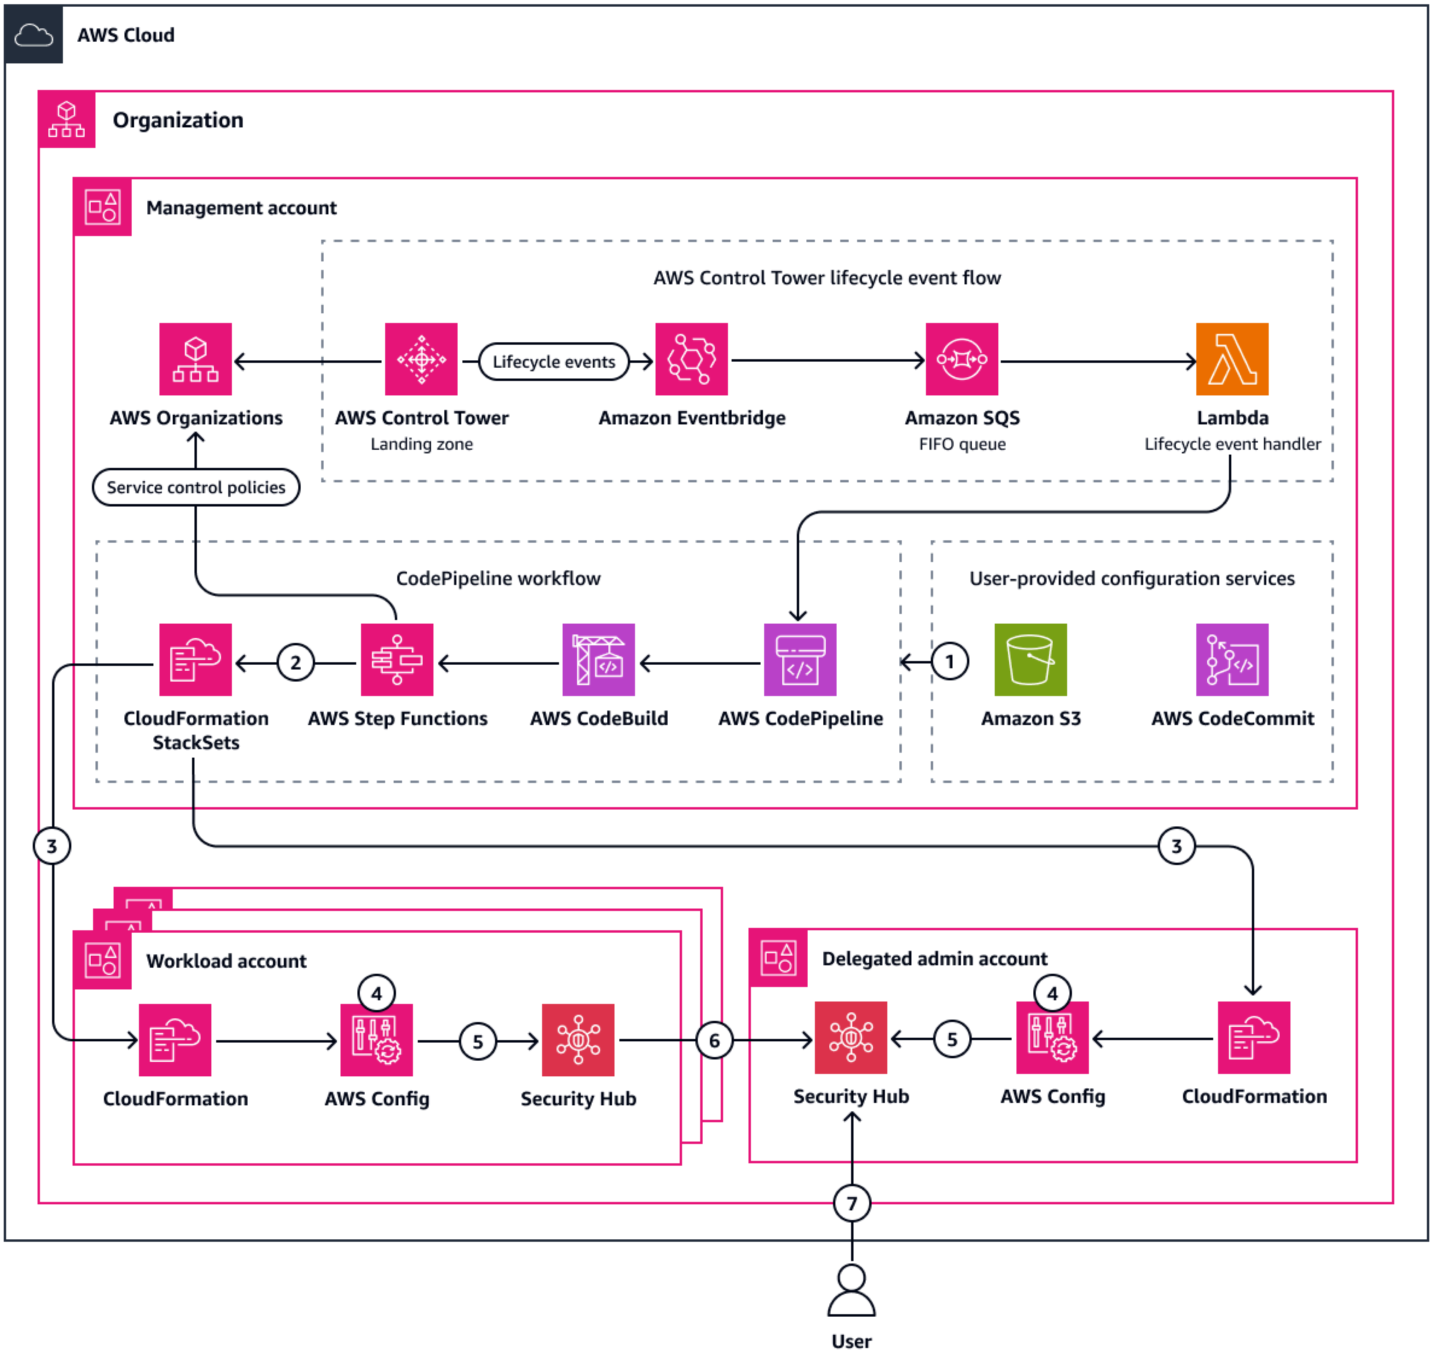


The diagram shows the following steps:

1. You create a CloudFormation stack. This deploys a Lambda function and an AWS Config rule. Both the rule and function are set up with the AWS Identity and Access Management (IAM) permissions required to publish resource evaluations in AWS Config and logs.
2. The AWS Config rule operates in [detective evaluation mode](#) and runs every 24 hours.
3. Security Hub receives all AWS Config findings.
4. You can view the findings in Security Hub or in AWS Config, depending on the account's configuration.

Deploying into an AWS organization

The following diagram shows the assessment of certificate expiration across multiple accounts that are managed through AWS Organizations and AWS Control Tower. You deploy the CloudFormation template through CfCT. The assessment outcomes are centralized in Security Hub in the delegated administrator account. The AWS CodePipeline workflow depicted in the diagram shows the background steps that occur during CfCT deployment.



The diagram shows the following steps:

1. Depending on the configuration for CfCT, in the management account, you push the IaC to an AWS CodeCommit repository or you upload a compressed (ZIP) file of the IaC to an Amazon Simple Storage Service (Amazon S3) bucket.
2. The CfCT pipeline unzips the file, runs cfn-nag (GitHub) checks, and deploys it as a CloudFormation stack set.
3. Depending on the configuration specified in the CfCT manifest file, CloudFormation StackSets deploys stacks into individual accounts or specified OUs. This deploys a Lambda function and an AWS Config rule in the target accounts. Both the rule and function are set up with the IAM permissions required to publish resource evaluations in AWS Config and logs.
4. The AWS Config rule operates in detective evaluation mode and runs every 24 hours.
5. AWS Config forwards all findings to Security Hub.
6. Security Hub findings are aggregated in the delegated administrator account.
7. You can view the findings in Security Hub in the delegated administrator account.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time. An AWS Config rule defines your ideal configuration settings for a resource, and AWS Config can evaluate whether your AWS resources comply with the conditions in your rules.
- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices. Customizations for AWS Control Tower (CfCT) helps you customize your AWS Control Tower landing zone and stay aligned with AWS best practices. Customizations are implemented with CloudFormation templates and service control policies (SCPs).
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

- AWS Security Hub provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.

Other tools

- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub Detect Amazon RDS instances with expiring CA certificates repository.

Best practices

We recommend that you adhere to the best practices in the following resources:

- Best Practices for Organizational Units with AWS Organizations (AWS Cloud Operations & Migrations Blog)
- Guidance for Establishing an Initial Foundation using AWS Control Tower on AWS (AWS Solutions Library)
- Guidance for creating and modifying AWS Control Tower resources (AWS Control Tower documentation)
- CfCT deployment considerations (AWS Control Tower documentation)

Epics

Review the solution and code

Task	Description	Skills required
Determine your deployment strategy.	Review the solution and code to determine how you will deploy it into your AWS environment. Determine if you will be deploying into a single account or an AWS organization.	App owner, General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Clone the repository.</td><td>Enter the following command to clone the Detect Amazon RDS instances with expiring CA certificates repository.<pre>git clone https://github.com/aws-samples/config-rds-ca-expiry.git</pre></td><td>App developer, App owner</td></tr>
<tr><td>Validate the Python version.</td><td>1. Navigate into the top-level directory in the cloned repository.<pre>cd config-rds-ca-expiry</pre>2. Open config-rds-ca-expiry.yaml.
3. In the <code>CertExpirationCheckLambdaFunction</code> resource, confirm that the Python version is compatible with your target AWS Regions. By default, this function uses Python 3.12. For more information, see AWS Lambda adds support for Python 3.12. If necessary, update the Python version.
4. Save and close config-rds-ca-expiry.yaml.</td><td>App developer, App owner</td></tr>
</table>

Deploy the solution

Task	Description	Skills required
Deploy the CloudFormation template.	Deploy the CloudFormation template to your AWS environment. Do one of the following: • If you're deploying to a single AWS account, follow the instructions in Creating a stack. • If you're deploying to an organization that isn't managed by AWS Control Tower, follow the instructions in Create a stack set. • If you're deploying to an organization that is managed by AWS Control Tower, see the instructions in the Build your own customizations.	App developer, AWS administrator, General AWS
Verify the deployment.	In the CloudFormation console, verify that the stack or stack set has deployed successfully.	AWS administrator, App owner

Review the findings

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>View the AWS Config rule findings.</td><td>In Security Hub, do the following to view a list of individual findings:

1. Open the Security Hub console.
2. In the navigation pane, choose Findings.
3. In the Add filters box, add the following filters:
• Compliance Status is <code>FAILED</code>
• Title is <code>rds-has-expiring-ca</code>
4. Choose Apply.

In Security Hub, do the following to view a list of total findings grouped by AWS account:

1. Open the Security Hub console.
2. In the navigation pane, choose Insights.
3. Choose Create insight.
4. To select the grouping attribute for the insight:
a. Choose the search box to display the filter options.</td><td>AWS administrator, AWS systems administrator, Cloud administrator</td></tr>
</table>

Task	Description	Skills required
	b. Choose **Group by**. c. Select **AwsAccountId**. d. Choose **Apply**. 5. In the **Add filters** box, add the following filters: • **Title** is `rds-has-expiring-ca` • **Compliance Status** is `FAILED` 6. Choose **Create insight**. 7. Enter an **Insight name**, and then choose **Create insight**. In AWS Config, to view a list of findings, follow the instructions in [Viewing Compliance Information and Evaluation Results](#) in the AWS Config documentation.	

Troubleshooting

Issue	Solution
CloudFormation stack set creation or deletion fails	When AWS Control Tower is deployed, it enforces necessary guardrails and assumes control over AWS Config aggregators and rules. This includes preventing any direct alterations through CloudFormation. To properly deploy or remove this CloudForm

Issue	Solution
	ation template, including all associated resources, you must use CfCT.
CfCT fails to delete the CloudFormation template	If the CloudFormation template persists even after making necessary changes in the manifest file and removing the template files, confirm that the manifest file contains the `enable_stack_set_deletion` parameter and that the value is set to `false`. For more information, see Delete a stack set in the CfCT documentation.

Dynamically generate an IAM policy with IAM Access Analyzer by using Step Functions

Thomas Scott, Koen van Blijderveen, Adil El Kanabi, and Rafal Pawlaszek, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more.

Least-privilege is the security best practice of granting the minimum permissions required to perform a task. Implementing least-privilege access in an already active Amazon Web Services (AWS) account can be challenging because you don't want to unintentionally block users from performing their job duties by changing their permissions. Before you can implement AWS Identity and Access Management (IAM) policy changes, you need to understand the actions and resources the account users are performing.

This pattern is designed to help you apply the principle of least-privilege access, without blocking or slowing down team productivity. It describes how to use IAM Access Analyzer and AWS Step Functions to dynamically generate an up-to-date IAM policy for your role, based on the actions that are currently being performed in the account. The new policy is designed to permit the current activity but remove any unnecessary, elevated privileges. You can customize the generated policy by defining allow and deny rules, and the solution integrates your custom rules.

This pattern includes options for implementing the solution with AWS Cloud Development Kit (AWS CDK) or HashiCorp CDK for Terraform (CDKTF). You can then associate the new policy to the role by using a continuous integration and continuous delivery (CI/CD) pipeline. If you have a multi-account architecture, you can deploy this solution in any account where you want to generate updated IAM policies for the roles, increasing the security of your entire AWS Cloud environment.

Prerequisites and limitations

Prerequisites

- An active AWS account with a AWS CloudTrail trail enabled.
- IAM permissions for the following:
  - Create and deploy Step Functions workflows. For more information, see Actions, resources, and condition keys for AWS Step Functions (Step Functions documentation).

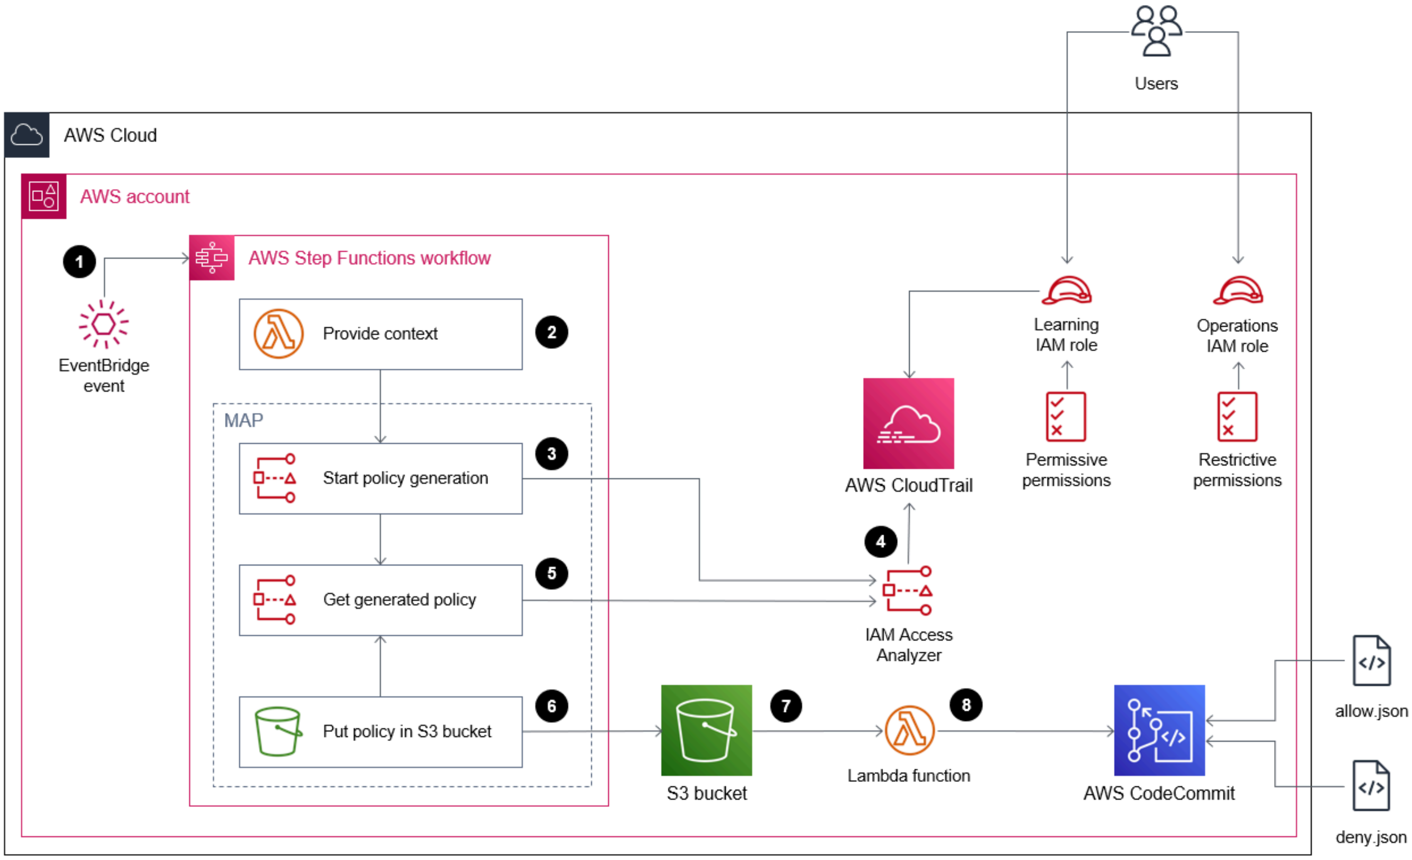
  - Create AWS Lambda functions. For more information, see Execution role and user permissions (Lambda documentation).
  - Create IAM roles. For more information, see Creating a role to delegate permissions to an IAM user (IAM documentation).
- npm installed. For more information, see Downloading and installing Node.js and npm (npm documentation).
- If you are deploying this solution with AWS CDK (Option 1):
  - AWS CDK Toolkit, installed and configured. For more information, see Install the AWS CDK (AWS CDK documentation).
- If you are deploying this solution with CDKTF (Option 2):
  - CDKTF, installed and configured. For more information, see Install CDK for Terraform (CDKTF documentation).
  - Terraform, installed and configured. For more information, see Get Started (Terraform documentation).
- AWS Command Line Interface (AWS CLI) locally installed and configured for your AWS account. For more information, see Installing or updating the latest version of the AWS CLI (AWS CLI documentation).

Limitations

- This pattern does not apply the new IAM policy to the role. At the end of this solution, the new IAM policy is stored in an AWS CodeCommit repository. You can use a CI/CD pipeline to apply policies to the roles in your account.

Architecture

Target architecture



1. A regularly scheduled Amazon EventBridge event rule starts a Step Functions workflow. You define this regeneration schedule as part of setting up this solution.
2. In the Step Functions workflow, a Lambda function generates the date ranges to use when analyzing account activity in the CloudTrail logs.
3. The next workflow step calls the IAM Access Analyzer API to start generating the policy.
4. Using the Amazon Resource Name (ARN) of the role you specify during set up, IAM Access Analyzer analyzes the CloudTrail logs for activity within the specified date rate. Based on the activity, IAM Access Analyzer generates an IAM policy that permits only the actions and services used by the role during the specified date range. When this step is complete, this step generates a job ID.
5. The next workflow step checks for the job ID every 30 seconds. When the job ID is detected, this step uses the job ID to call the IAM Access Analyzer API and retrieve the new IAM policy. IAM Access Analyzer returns the policy as a JSON file.
6. The next workflow step puts the **<IAM role name>/policy.json** file in an Amazon Simple Storage Service (Amazon S3) bucket. You define this S3 bucket as part of setting up this solution.

7. An Amazon S3 event notification starts a Lambda function.
8. The Lambda function retrieves the policy from the S3 bucket, integrates the custom rules you define in the **allow.json** and **deny.json** files, and then pushes the updated policy to CodeCommit. You define the CodeCommit repository, branch, and folder path as part of setting up this solution.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CDK Toolkit is a command line cloud development kit that helps you interact with your AWS Cloud Development Kit (AWS CDK) app.
- AWS CloudTrail helps you audit the governance, compliance, and operational risk of your AWS account.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them. This pattern uses IAM Access Analyzer, a feature of IAM, to analyze your CloudTrail logs to identify actions and services that have been used by an IAM entity (user or role) and then generate an IAM policy that is based on that activity.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications. In this pattern, you use AWS SDK service integrations in Step Functions to call service API actions from your workflow.

Other tools

- CDK for Terraform (CDKTF) helps you define infrastructure as code (IaC) by using common programming languages, such as Python and Typescript.
- Lerna is a build system for managing and publishing multiple JavaScript or TypeScript packages from the same repository.
- Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.

Code repository

The code for this pattern is available in the GitHub Automated IAM Access Analyzer Role Policy Generator repository.

Epics

Prepare for deployment

Task	Description	Skills required
Clone the repo.	The following command clones the Automated IAM Access Analyzer Role Policy Generator (GitHub) repository. `git clone https://github.com/aws-samples/automated-iam-access-analyzer.git`	App developer
Install Lerna.	The following command installs Lerna. `npm i -g lerna`	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Set up the dependencies.</td><td>The following command installs the dependencies for the repository.
<pre>cd automated-iam-access-analyzer/
npm install && npm run bootstrap</pre></td><td>App developer</td></tr>
<tr><td>Build the code.</td><td>The following command tests, builds, and prepares the zip packages of the Lambda functions.
<pre>npm run test:code
npm run build:code
npm run pack:code</pre></td><td>App developer</td></tr>
<tr><td>Build the constructs.</td><td>The following command builds the infrastructure synthesizing applications, for both AWS CDK and CDKTF.
<pre>npm run build:infra</pre></td><td></td></tr>
<tr><td>Configure any custom permissions.</td><td>In the repo folder of the cloned repository, edit the allow.json and deny.json files to define any custom permissions for the role. If the allow.json and deny.json files contain the same permission, the deny permission is applied.</td><td>AWS administrator, App developer</td></tr>
</table>

Option 1 – Deploy the solution using AWS CDK

Task	Description	Skills required

Deploy the AWS CDK stack.	The following command deploys the infrastructure through AWS CloudFormation. Define the following parameters:
	• `<NAME_OF_ROLE>` – The ARN of the IAM role for which you are creating a new policy.
	• `<TRAIL_ARN>` – The ARN of the CloudTrail trail in which the role activity is stored.
	• `<CRON_EXPRESSION_TO_RUN_SOLUTION>` – The Cron expression that defines the regeneration schedule for the policy. The Step Functions workflow runs on this schedule.
	• `<TRAIL_LOOKBACK>` – The period, in days, to look back in the trail when evaluating the role permissions.
	`cd infra/cdk`
	`cdk deploy —-parameters roleArn=<NAME_OF_ROLE> \`
	`—-parameters trailArn=<TRAIL_ARN> \`
		App developer

Task	Description	Skills required
	`--parameters schedule=<CRON_EXPRESSION_TO_RUN_SOLUTION> \ [ --parameters trailLookBack=<TRAIL_LOOKBACK> ]` **Note** The square brackets denote optional parameters.	
(Optional) Wait for the new policy.	If the trail does not contain a reasonable amount of historical activity for the role, wait until you are confident that there is enough logged activity for IAM Access Analyzer to generate an accurate policy. If the role has been active in the account for a sufficient period of time, this waiting period might not be necessary.	AWS administrator
Manually review the generated policy.	In your CodeCommit repository, review the generated **<ROLE_ARN>.json** file to confirm that the allow and deny permissions are appropriate for the role.	AWS administrator

Option 2 – Deploy the solution using CDKTF

Task	Description	Skills required
Synthesize the Terraform template.	The following command synthesizes the Terraform template. `lerna exec cdktf synth --scope @aiaa/tfm`	App developer
Deploy the Terraform template.	The following command navigates to the directory that contains the CDKTF-defined infrastructure. `cd infra/cdktf` The following command deploys the infrastructure in the target AWS account. Define the following parameters: • `<account_ID>` – The ID of the target account. • `<region>` - The target AWS Region. • `<selected_role_ARN>` – The ARN of the IAM role for which you are creating a new policy. • `<trail_ARN>` – The ARN of the CloudTrail trail in which the role activity is stored.	App developer

Task	Description	Skills required
	• `<schedule_expression>` – The Cron expression that defines the regeneration schedule for the policy. The Step Functions workflow runs on this schedule. • `<trail_look_back>` – The period, in days, to look back in the trail when evaluating the role permissions. `TF_VAR_accountId=<account_ID> \ TF_VAR_region=<region> \ TF_VAR_roleArns=<selected_role_ARN> \ TF_VAR_trailArn=<trail_ARN> \ TF_VAR_schedule=<schedule_expression> \ [ TF_VAR_trailLookBack=<trail_look_back> ] \ cdktf deploy` **Note** The square brackets denote optional parameters.	

Task	Description	Skills required
(Optional) Wait for the new policy.	If the trail does not contain a reasonable amount of historical activity for the role, wait until you are confident that there is enough logged activity for IAM Access Analyzer to generate an accurate policy. If the role has been active in the account for a sufficient period of time, this waiting period might not be necessary.	AWS administrator
Manually review the generated policy.	In your CodeCommit repository, review the generated **<ROLE_ARN>.json** file to confirm that the allow and deny permissions are appropriate for the role.	AWS administrator

Enable Amazon GuardDuty conditionally by using AWS CloudFormation templates

Ram Kandaswamy, Amazon Web Services

Summary

You can enable Amazon GuardDuty on an Amazon Web Services (AWS) account by using an AWS CloudFormation template. By default, if GuardDuty is already enabled when you try to use CloudFormation to turn it on, the stack deployment fails. However, you can use conditions in your CloudFormation template to check whether GuardDuty is already enabled. CloudFormation supports the use of conditions that compare static values; it does not support using the output of another resource property within the same template. For more information, see Conditions in the CloudFormation documentation.

In this pattern, you use a CloudFormation custom resource backed by an AWS Lambda function to conditionally enable GuardDuty if it is not already enabled. If GuardDuty is enabled, the stack captures the status and records it in the output section of the stack. If GuardDuty is not enabled, the stack enables it.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS Identity and Access Management (IAM) role that has permissions to create, update, and delete CloudFormation stacks
- AWS Command Line Interface (AWS CLI), installed and configured

Limitations

If GuardDuty has been manually disabled for an AWS account or AWS Region, this pattern does not enable GuardDuty for that target account or Region.

Architecture

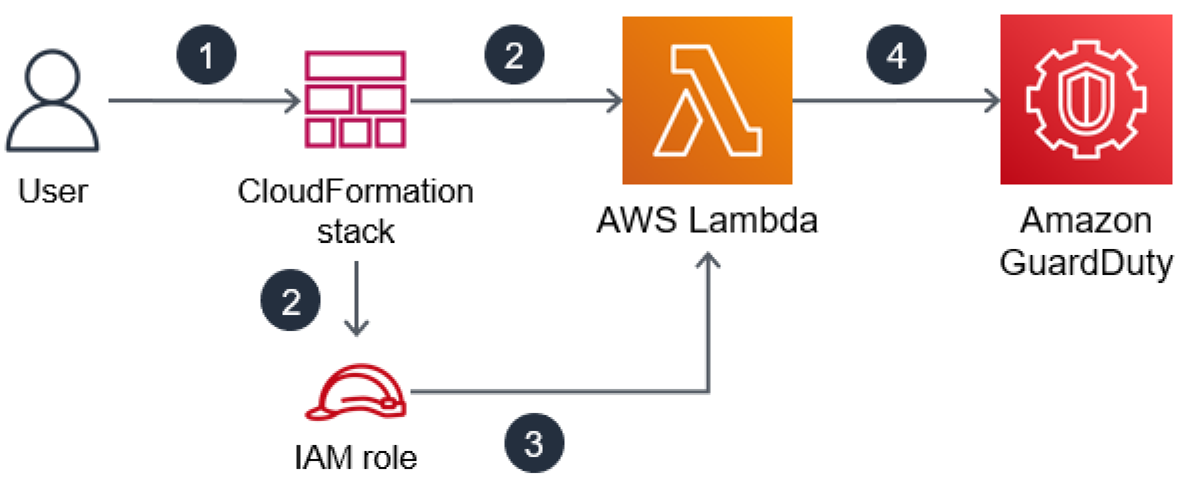
Target technology stack

The pattern uses CloudFormation for infrastructure as code (IaC). You use a CloudFormation custom resource backed by a Lambda function to achieve the dynamic service-enablement capability.

Target architecture

The following high-level architecture diagram shows the process of enabling GuardDuty by deploying a CloudFormation template:

1. You deploy a CloudFormation template to create a CloudFormation stack.
2. The stack creates an IAM role and a Lambda function.
3. The Lambda function assumes the IAM role.
4. If GuardDuty is not already enabled on the target AWS account, the Lambda function enables it.



Automation and scale

You can use the AWS CloudFormation StackSet feature to extend this solution to multiple AWS accounts and AWS Regions. For more information, see Working with AWS CloudFormation StackSets in the CloudFormation documentation.

Tools

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- [Amazon GuardDuty](#) is a continuous security monitoring service that analyzes and processes logs to identify unexpected and potentially unauthorized activity in your AWS environment.
- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Epics

Create the CloudFormation template and deploy the stack

Task	Description	Skills required
Create the CloudFormation template.	1. Copy the code in *CloudFormation template* in the Additional information section. 2. Paste the code in a text editor. 3. Save the file as `sample.yaml` on your workstation.	AWS DevOps
Create the CloudFormation stack.	1. In the AWS CLI, enter the following command. This creates a new CloudFormation stack using the `sample.yaml` file. For more information, see Creating a stack in the CloudFormation documentation.	AWS DevOps

Task	Description	Skills required

	`aws cloudformation create-stack \ --stack-name guardduty-cf-stack \ --template-body file://sample.yaml`
	2. Confirm the following value appears in the AWS CLI, indicating that the stack has been successfully created. The amount of time required to create the stack can vary.
	`"StackStatus": "CREATE_COMPLETE",`	

Validate that GuardDuty is enabled for the AWS account.	1. Sign in to the AWS Management Console and open the [GuardDuty console](#). 2. Verify that the GuardDuty service is enabled.	Cloud administrator, AWS administrator
Configure additional accounts or Regions.	As needed for your use case, use the CloudFormation StackSet feature to extend this solution to multiple AWS accounts and AWS Regions. For more information, see [Working with AWS CloudFormation StackSets](#) in the CloudFormation documentation.	Cloud administrator, AWS administrator

Alternative code option for the Lambda resource

The provided CloudFormation template uses inline code to reference the Lambda resource, for easier reference and guidance. Alternatively, you can place the Lambda code in an Amazon Simple Storage Service (Amazon S3) bucket and reference it in the CloudFormation template. Inline code doesn't support package dependencies or libraries. You can support these by placing the Lambda code in an Amazon S3 bucket and referencing it in the CloudFormation template.

Replace the following lines of code:

```
Code:
         ZipFile: |
```

with the following lines of code:

```
Code:
      S3Bucket: <bucket name>
      S3Key: <python file name>
      S3ObjectVersion: <version>
```

The `S3ObjectVersion` property can be omitted if you are not using versioning in your Amazon S3 bucket. For more information, see [Using versioning in Amazon S3 buckets] in the Amazon S3 documentation.

Enable transparent data encryption in Amazon RDS for SQL Server

Ranga Cherukuri, Amazon Web Services

Summary

This pattern describes how to implement transparent data encryption (TDE) in Amazon Relational Database Service (Amazon RDS) for SQL Server to encrypt data at rest.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS for SQL Server DB instance

Product versions

Amazon RDS currently supports TDE for the following SQL Server versions and editions:

- SQL Server 2016 Enterprise Edition
- SQL Server 2017 Enterprise Edition
- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2022 Standard and Enterprise Editions

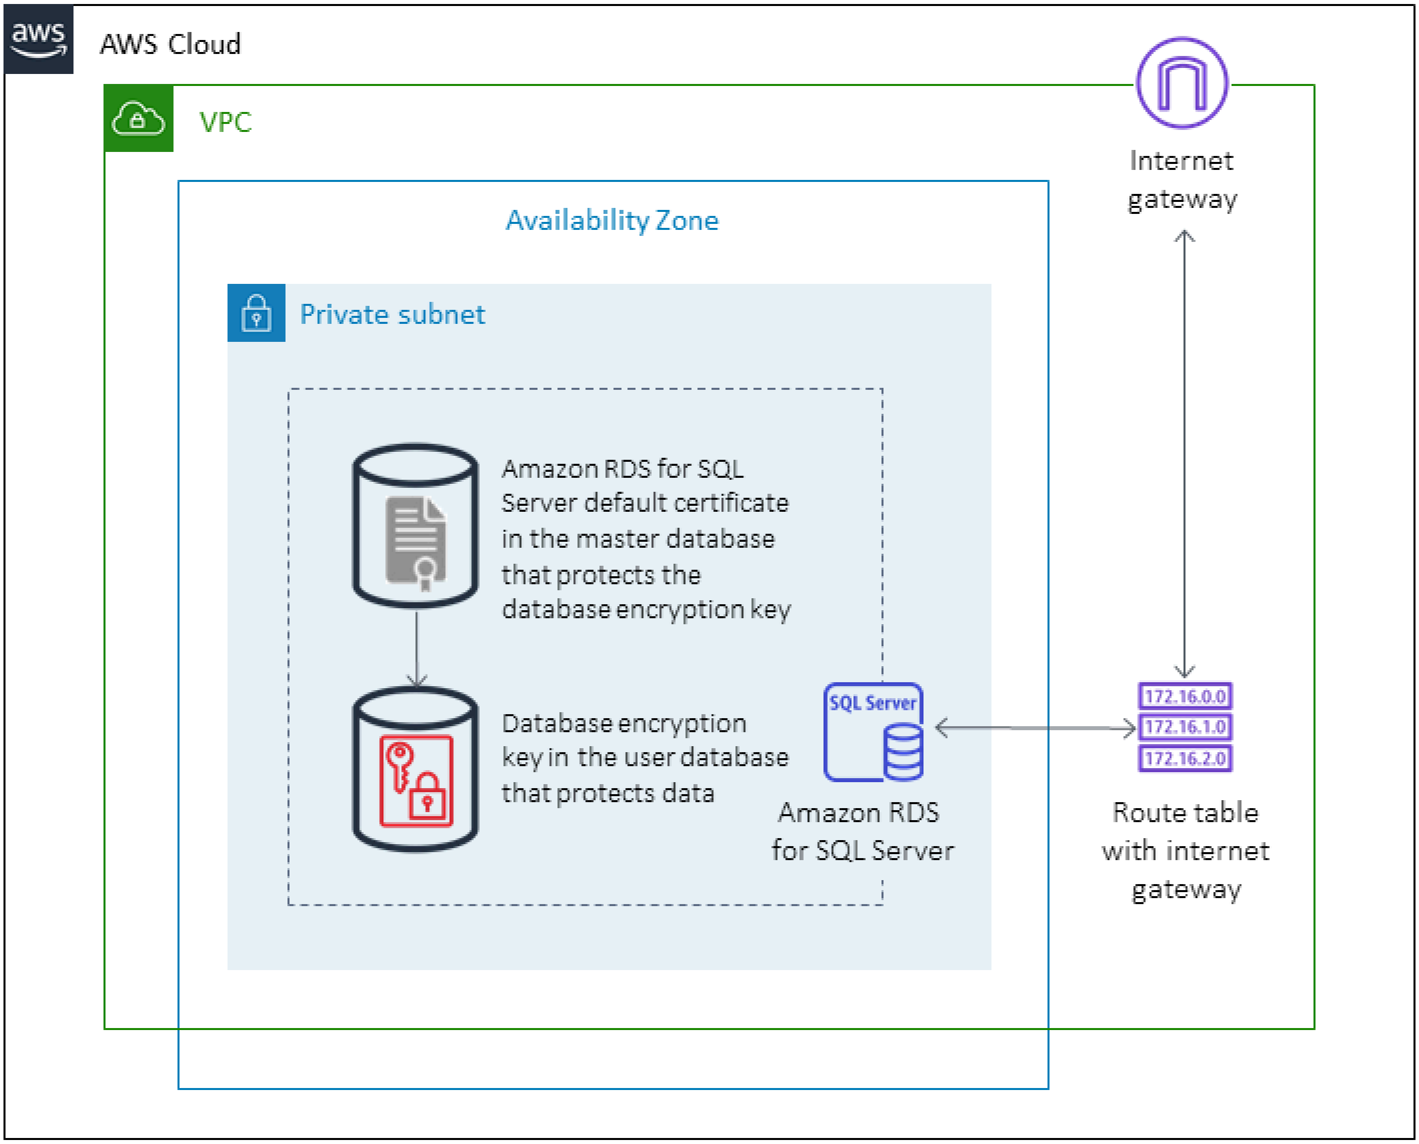
For the latest information about supported versions and editions, see Support for Transparent Data Encryption in SQL Server in the Amazon RDS documentation.

Architecture

Technology stack

- Amazon RDS for SQL Server

Architecture



Tools

- Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing a SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

Epics

Create an option group in the Amazon RDS console

Task	Description	Skills required
Open the Amazon RDS console.	Sign in to the AWS Management Console and open the [Amazon RDS console](https://console.aws.amazon.com/rds/).	Developer, DBA
Create an option group.	In the navigation pane, choose **Option groups**, **Create group**. Choose **sqlserver-ee** as the DB engine, and then select the engine version.	Developer, DBA
Add the TRANSPARENT_DATA_ENCRYPTION option.	Edit the option group you created and add the option called `TRANSPARENT_DATA_ENCRYPTION` .	Developer, DBA

Associate the option group with the DB instance

Task	Description	Skills required
Choose the DB instance.	In the Amazon RDS console, in the navigation pane, choose **Databases**, and then choose the DB instance you want to associate with the option group.	Developer, DBA
Associate the DB instance with the option group.	Choose **Modify**, and then use the **Option group** setting to associate the SQL Server	Developer, DBA

Task	Description	Skills required
	DB instance with the option group you created earlier.	
Apply the changes.	Apply the changes immediately or during the next maintenance window, as desired.	Developer, DBA

Get the certificate name.	Get the default certificate name by using the following query.
	`USE [master]`
	`GO`
	`SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'`
	`GO`
		Developer, DBA

Create the database encryption key

Task	Description	Skills required
Connect to the Amazon RDS for SQL Server DB instance using SSMS.	For instructions, see Using SSMS in the Microsoft documentation.	Developer, DBA
Create the database encryption key by using the default certificate.	Create a database encryption key by using the default certificate name you got earlier. Use the following T-SQL query to create a database encryption key. You can specify the	Developer, DBA

Task	Description	Skills required

	AES_256 algorithm instead of AES_128.
	`USE [Databasename]`
	`GO`
	`CREATE DATABASE ENCRYPTION KEY`
	`WITH ALGORITHM = AES_128`
	`ENCRYPTION BY SERVER CERTIFICATE [certificatename]`
	`GO`	

Enable the encryption on the database.	Use the following T-SQL query to enable database encryption.
	`ALTER DATABASE [Database Name]`
	`SET ENCRYPTION ON`
	`GO`
		Developer, DBA

Check the status of encryption.	Use the following T-SQL query to check the status of encryption. `SELECT DB_NAME(database_id) AS DatabaseName, encryption_state, percent_complete FROM sys.dm_database_encryption_keys`	Developer, DBA

Ensure AWS load balancers use secure listener protocols (HTTPS, SSL/TLS)

Chandini Penmetsa and Purushotham G K, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, Elastic Load Balancing automatically distributes incoming application traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, IP addresses, and AWS Lambda functions. The load balancers use listeners to define the ports and protocols that the load balancer uses to accept traffic from users. Application Load Balancers make routing decisions at the application layer and use the HTTP/HTTPS protocols. Network Load Balancers make routing decisions at the transport layer and use the Transmission Control Protocol (TCP), Transport Layer Security (TLS), User Datagram Protcol (UDP), or TCP_UDP protocols. Classic Load Balancers make routing decisions at either the transport layer, using TCP or Secure Sockets Layer (SSL) protocols, or at the application layer, using HTTP/HTTPS.

Your organization might have a security or compliance requirement that load balancers accept traffic from users only on secure protocols, such as HTTPS or SSL/TLS.

This pattern provides a security control that uses an Amazon EventBridge rule to monitor the `CreateListener` and `ModifyListener` API calls for Application Load Balancers and Network Load Balancers, and the `CreateLoadBalancerListeners` and `CreateLoadBalancer` API calls for Classic Load Balancers. If HTTP, TCP/UDP, or TCP_UDP is used for the load balancer's listener protocol, the control invokes a Lambda function. The Lambda function publishes a message to an Amazon Simple Notification Service (Amazon SNS) topic to send a notification that contains the load balancer details.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An email address where you want to receive the violation notification
- An Amazon Simple Storage Service (Amazon S3) bucket to store the Lambda code .zip file

Limitations

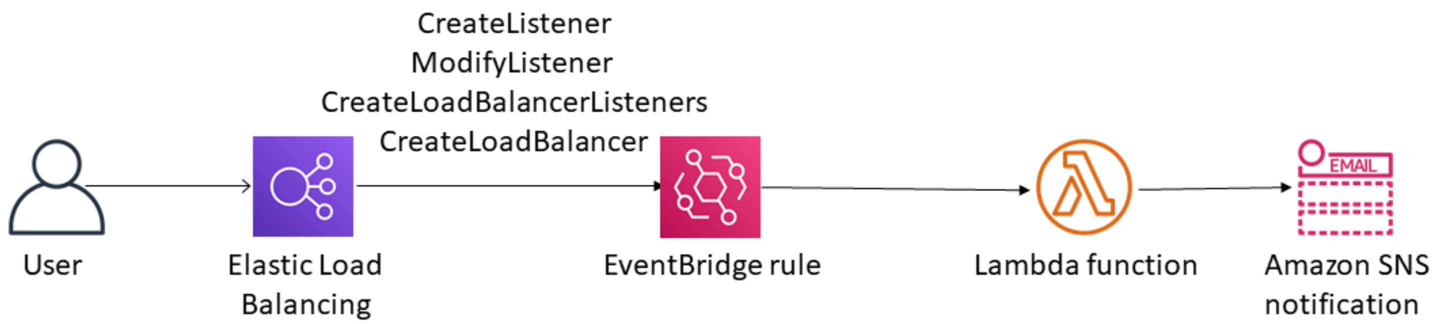
- This security control does not check for existing load balancers unless an update is made to the load balancer listeners.
- This security control is regional and must be deployed in the AWS Regions that you intend to monitor.

Architecture

Target technology stack

- Lambda function
- Amazon SNS topic
- EventBridge rule

Target architecture



Automation and scale

- If you are using AWS Organizations, you can use [AWS Cloudformation StackSets](#) to deploy this template in multiple accounts that you want this to monitor.

Tools

- [AWS CloudFormation](#) – AWS CloudFormation is a service that helps you model and set up AWS resources by using infrastructure as code.
- [Amazon EventBridge](#) – Amazon EventBridge delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services, routing that data to targets such as Lambda functions.
- [AWS Lambda](#) – Lambda supports running code without provisioning or managing servers.

- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Best practices

Ensure that the SNS topic used isn't publicly accessible. For more information, see the AWS documentation.

Epics

Upload the Lambda code

Task	Description	Skills required
Define the S3 bucket.	On the Amazon S3 console, choose or create an S3 bucket with a unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. Your S3 bucket needs to be in the same Region as the load balancer that is being evaluated.	Cloud Architect
Upload the Lambda code to the S3 bucket.	Upload the Lambda code .zip file that's provided in the "Attachments" section to the defined S3 bucket.	Cloud Architect

Task	Description	Skills required
Deploy the AWS CloudFormation template.	On the AWS CloudFormation console, in the same AWS Region as the S3 bucket, deploy the template that is provided in the "Attachments" section. In the next epic, provide the values for the parameters.	Cloud Architect

CloudFormation parameters

Task	Description	Skills required
Name the S3 bucket.	Enter the name of the S3 bucket that you created in the first epic.	Cloud Architect
Provide the Amazon S3 prefix.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, `<directory>/<file-name>.zip`).	Cloud Architect
Provide the SNS topic ARN.	Provide the SNS topic Amazon Resource Name (ARN) if you want to use an existing SNS topic for violation notifications. To create a new SNS topic, keep the value as None (the default value).	Cloud Architect

Task	Description	Skills required
Provide an email address.	Provide an active email address to receive Amazon SNS notifications.	Cloud Architect
Define the logging level.	Define the logging level and frequency for your Lambda function. `Info` designates detailed informational messages on the application's progress. `Error` designates error events that could still allow the application to continue running. `Warning` designates potentially harmful situations.	Cloud Architect

Deploy the CloudFormation template

Task	Description	Skills required
Download the template.	Download the CloudFormation template that's provided in the *Attachments* section.	Cloud architect
Create the stack.	In the same Region as the S3 bucket, navigate to the CloudFormation service console, and deploy the downloaded template. Refer to the previous epic for parameter details.	Cloud architect
Verify the resources.	After the stack is created completely, navigate to the	Cloud architect

Task	Description	Skills required
	Resources tab, and verify the resources. The template will create the following resources : • EventBridge rule • Lambda function • Lambda execution role • Lambda invoke permission	

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the template successfu lly deploys, if a new SNS topic was created, a subscription email message is sent to the email address provided in the parameters. You must confirm this email subscription to receive violation notifications.	Cloud architect

Troubleshooting

Issue	Solution
Stack creation failed. Error occurred while GetObject. S3 Error Code: PermanentRedirect. S3 Error Message: The bucket is in this region: xx-xxxx-1. Please use this region to retry the request.	Make sure that the S3 bucket Region and the Region where the stack is being deployed are the same.

Issue	Solution
Stack creation failed. The runtime parameter of python3.6 is no longer supported for creating or updating AWS Lambda functions.	Update the downloaded template at line 186 from Python version 3.6 to 3.9.

Ensure encryption for Amazon EMR data at rest is enabled at launch

Priyanka Chaudhary, Amazon Web Services

Summary

This pattern provides a security control for monitoring the encryption of Amazon EMR clusters on Amazon Web Services (AWS).

Data encryption helps prevent unauthorized users from reading data on a cluster and associated data storage systems. This includes data that may be intercepted as it travels the network, known as data in transit, and data that is saved to persistent media, known as data at-rest. Data at rest in Amazon Simple Storage Service (Amazon S3) can be encrypted in two ways.

- Server-side encryption with Amazon S3–managed keys (SSE-S3)
- Server-side encryption with AWS Key Management Service (AWS KMS) keys (SSE-KMS), set up with policies that are suitable for Amazon EMR.

This security control monitors for API calls and initiates an Amazon CloudWatch Events event on RunJobFlow. The trigger invokes AWS Lambda, which runs a Python script. The function retrieves the EMR cluster ID from the event JSON input and determines whether there is a security violation by performing the following checks.

1. Check if an EMR cluster is associated with an Amazon EMR specific security configuration.
2. If an Amazon EMR specific security configuration is associated with the EMR cluster, check if Encryption-at-Rest is turned on.
3. If Encryption-at-Rest is not turned on, send an Amazon Simple Notification Service (Amazon SNS) notification that includes the EMR cluster name, violation details, AWS Region, AWS account, and the Lambda Amazon Resource Name (ARN) that this notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account

- An S3 bucket for the Lambda code .zip file
- An email address where you want to receive the violation notification
- Amazon EMR logging turned off so that all the API logs can be retrieved

Limitations

- This detective control is regional and must be deployed in the AWS Regions you intend to monitor.

Product versions

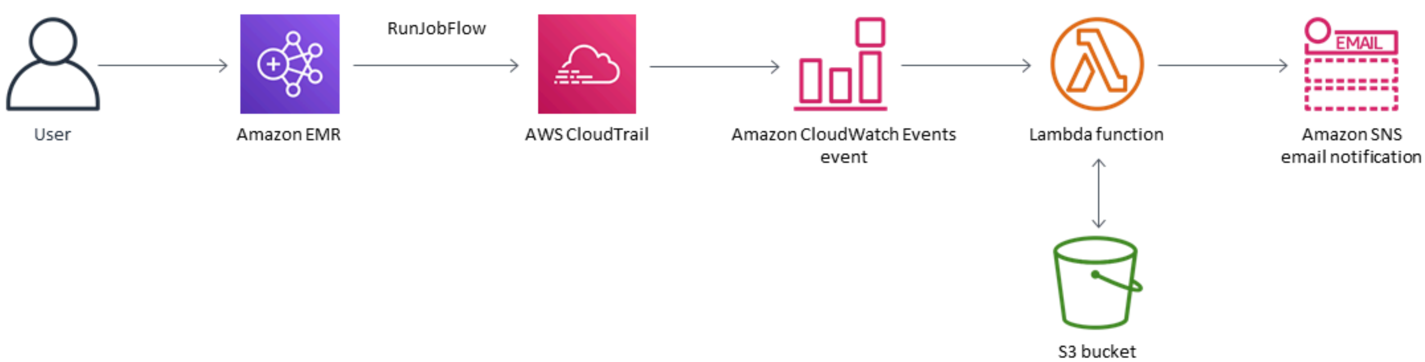
- Amazon EMR release 4.8.0 and above

Architecture

Target technology stack

- Amazon EMR
- Amazon CloudWatch Events event
- Lambda function
- Amazon SNS

Target architecture



Automation and scale

If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

Tools

- AWS CloudFormation is a service that helps you model and set up AWS resources using infrastructure as code.
- Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- Amazon EMR is a managed cluster platform that simplifies running big data frameworks.
- AWS Lambda supports running code without provisioning or managing servers.
- Amazon S3 is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

- The EMREncryptionAtRest.zip and EMREncryptionAtRest.yml files for this project available as an attachment.

Epics

Define the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the Amazon S3 console, choose or create an S3 bucket with a unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts.	Cloud Architect

Task	Description	Skills required
	Your S3 bucket needs to be in the same Region as the Amazon EMR cluster that is being evaluated.	

Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code to the S3 bucket.	Upload the Lambda code .zip file that's provided in the "Attachments" section to the defined S3 bucket.	Cloud Architect

Deploy the AWS CloudFormation template

Task	Description	Skills required
Deploy the AWS CloudForm ation template.	On the AWS CloudFormation console, in the same Region as your S3 bucket, deploy the AWS CloudFormation template that's provided as an attachment to this pattern. In the next epic, provide the values for the parameters. For more information about deploying AWS CloudForm ation templates, see the "Related resources" section.	Cloud Architect

Complete the parameters in the AWS CloudFormation template

Task	Description	Skills required
Name the S3 bucket.	Enter the name of the S3 bucket that you created in the first epic.	Cloud Architect
Provide the Amazon S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, <directory>/<file-name>.zip).	Cloud Architect
Provide an email address.	Provide an active email address to receive Amazon SNS notifications.	Cloud Architect
Define the logging level.	Define the logging level and frequency for your Lambda function. "Info" designate s detailed informational messages on the application's progress. "Error" designate s error events that could still allow the application to continue running. "Warning" designates potentially harmful situations.	Cloud Architect

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the template successfu lly deploys, it sends a subscription email message to	Cloud Architect

Task	Description	Skills required
	the email address provided. You must confirm this email subscription to receive violation notifications.

Ensure that an IAM profile is associated with an EC2 instance

Mansi Suratwala, Amazon Web Services

Summary

This pattern provides an AWS CloudFormation security control template that sets up automatic notification when an AWS Identity and Access Management (IAM) profile violation occurs for an Amazon Elastic Compute Cloud (Amazon EC2) instance.

An instance profile is a container for an IAM role that you can use to pass role information to an EC2 instance when the instance starts.

Amazon CloudWatch Events initiates this check when AWS CloudTrail logs Amazon EC2 API calls based on the `RunInstances`, `AssociateIamInstanceProfile`, and `ReplaceIamInstanceProfileAssociation` actions. The trigger calls an AWS Lambda function, which uses an Amazon CloudWatch Events event to check for an IAM profile.

If an IAM profile does not exist, the Lambda function initiates an Amazon Simple Notification Service (Amazon SNS) email notification that includes the Amazon Web Services (AWS) account ID and the AWS Region.

If an IAM profile does exist, the Lambda function checks for any wildcard entries in the policy documents. If the wildcards entries exist, initiates an Amazon SNS violation notification, which helps you to implement enhanced security. The notification contains the name of the IAM profile, the event, the EC2 instance ID, the name of the managed policy, the violation, the account ID, and the Region.

Prerequisites and limitations

Prerequisites

- An active account
- An Amazon Simple Storage Service (Amazon S3) bucket for the Lambda code .zip file

Limitations

- The AWS CloudFormation template must be deployed for the `RunInstances`, `AssociateIamInstanceProfile`, and `ReplaceIamInstanceProfileAssociation` actions only.

- The security control does not monitor the detachment of IAM profiles.
- The security control does not check for modification of IAM policies that are attached to the EC2 instance IAM profile.
- The security control does not account for unsupported resource-level permissions that require the use of `"Resource":*`.

Architecture

Target technology stack

- Amazon EC2
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon S3
- Amazon SNS

Target architecture

Automation and scale

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to launch the template only one time for each account or Region.

Tools

Tools

- Amazon EC2 – Amazon EC2 provides scalable computing capacity (virtual servers) in the AWS Cloud.
- AWS CloudTrail – AWS CloudTrail helps you enable governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are recorded as events in CloudTrail.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS Lambda – AWS Lambda is a compute service that you can use to run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon S3 provides highly scalable object storage that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS – Amazon SNS enables applications and devices to send and receive notifications from the cloud.

Code

- A .zip file of the project is available as an attachment.

Ensure an Amazon Redshift cluster is encrypted upon creation

Mansi Suratwala, Amazon Web Services

Summary

This pattern provides an AWS CloudFormation template that provides you with automatic notification when a new Amazon Redshift cluster is created without encryption.

The AWS CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any Amazon Redshift cluster being created or being restored from a snapshot through AWS CloudTrail. If the cluster is created without AWS Key Management Service (AWS KMS) or cloud hardware security model (HSM) encryption in the AWS account, CloudWatch initiates a Lambda function that sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A virtual private cloud (VPC) with a cluster subnet group, and an associated security group.

Limitations

- The AWS CloudFormation template can be deployed for the `CreateCluster` and `RestoreFromClusterSnapshot` actions only.

Architecture

Target technology stack

- Amazon Redshift
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda

- Amazon Simple Storage Service (Amazon S3)
- Amazon SNS

Target architecture

Automation and scale

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run it only one time in each Region or account.

Tools

Tools

- Amazon Redshift – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. Amazon Redshift is integrated with your data lake, which enables you to use your data to acquire new insights for your business and customers.
- AWS CloudTrail – AWS CloudTrail is an AWS service that helps you implement governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS Lambda – AWS Lambda supports running code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon S3 is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

- Amazon SNS – Amazon SNS is a web service that coordinates and manages the delivery or sending of messages to between publishers and clients, including web servers and email addresses.

Code

- A .zip file of the project is available as an attachment.

Epics

Define the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the Amazon S3 console, choose or create an S3 bucket. This S3 bucket will host the Lambda code .zip file. Your S3 bucket needs to be in the same Region as the Amazon Redshift cluster being evaluated. The S3 bucket's name cannot contain leading slashes.	Cloud Architect

Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code to the S3 bucket.	Upload the Lambda code provided in the *Attachments* section to the S3 bucket. The S3 bucket must be in the same Region as the Amazon Redshift cluster being evaluated.	Cloud Architect

Monitor and remediate scheduled deletion of AWS KMS keys

Mikesh Khanal and Ramya Pulipaka, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, deleting an AWS Key Management Services (AWS KMS) key can result in data loss. Deletion removes the key material and all metadata associated with the AWS KMS key, and it is irreversible. After an AWS KMS key is deleted, you can no longer decrypt the data that were encrypted under that AWS KMS key, so that data cannot be recovered.

This pattern sets up monitoring, with notifications when an application or a user schedules an AWS KMS key for deletion. If you receive a notification, you might want to cancel deletion of the AWS KMS key and reconsider your decision to delete it. The pattern uses the AWS Systems Manager automation runbook [AWSConfigRemediation-CancelKeyDeletion] to facilitate canceling the deletion of an AWS KMS key.

Note

The pattern's CloudFormation template must be deployed in all AWS Regions where you want to monitor deletion of AWS KMS keys.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Understanding of the following AWS services:
  - Amazon EventBridge
  - AWS KMS
  - Amazon Simple Notification Service (Amazon SNS)
  - AWS Systems Manager

Limitations

- Any customization of the solution requires knowledge of AWS CloudFormation templates and the AWS services used in this pattern.

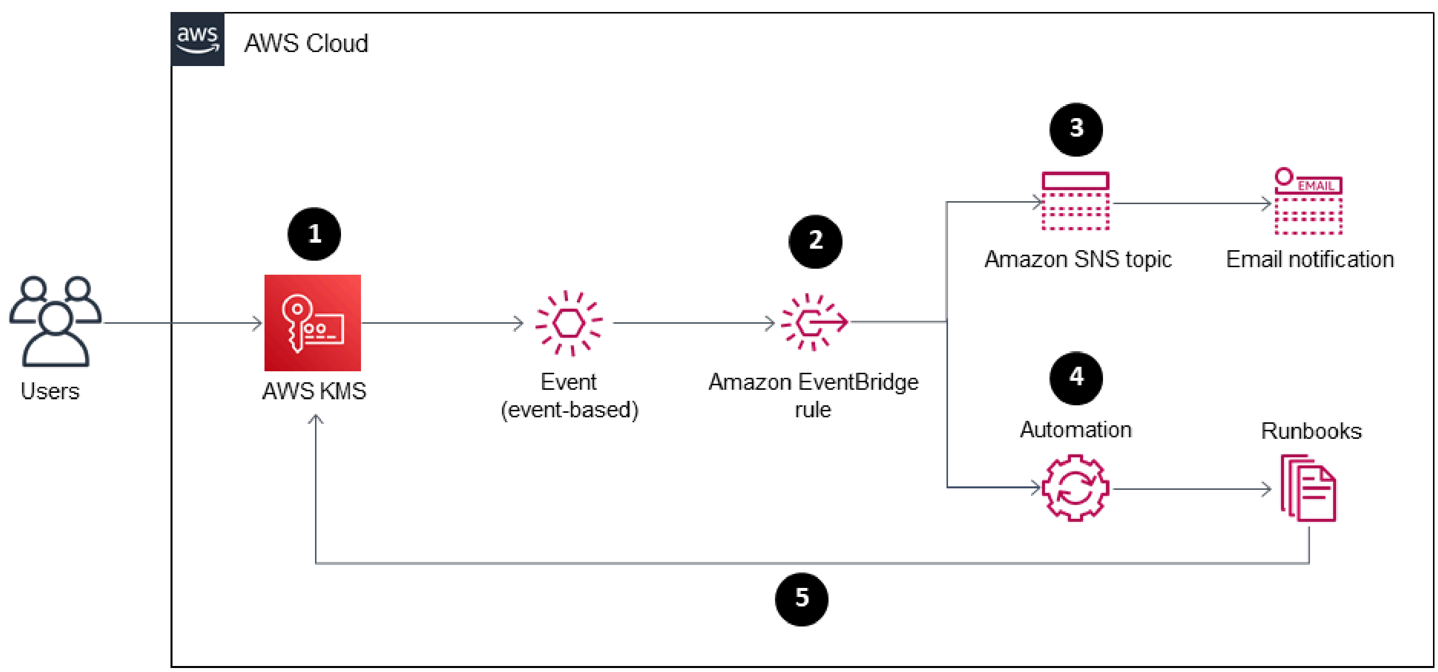
- Currently, this solution uses the default event bus, and it can be customized according to the requirements. For more information about the custom event bus, see the AWS documentation.

Architecture

Target technology stack

- Amazon EventBridge
- AWS KMS
- Amazon SNS
- AWS Systems Manager
- Automation using the following:
  - AWS Command Line Interface (AWS CLI) or AWS SDK
  - AWS CloudFormation stack

Target architecture



1. Deletion of an AWS KMS key is scheduled.
2. The scheduled-deletion event is evaluated by an EventBridge rule.
3. The EventBridge rule engages the Amazon SNS topic.

4. The EventBridge rule initiates the Systems Manager automation and runbooks.
5. The runbooks cancel the deletion.

Automation and scale

The CloudFormation stack deploys all the necessary resources and services for this solution to work. The pattern can be run independently in a single account or run using AWS CloudFormation StackSets for multiple independent accounts or an organization.

```
aws cloudformation create-stack --stack-name  <stack-name>\
    --template-body file://<Full-Path-of-file> \
    --parameters ParameterKey=,ParameterValue= \
    --capabilities CAPABILITY_NAMED_IAM
```

Tools

Tools

- AWS CloudFormation – AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run on AWS. You can use a CloudFormation template to create stacks in an AWS account in an AWS Region. The template describes all the AWS resources that you want, and CloudFormation provisions and configures those resources for you.
- AWS CLI – The AWS Command Line Interface (AWS CLI) is an open source tool that you can use to interact with AWS services using commands in your command line shell.
- Amazon EventBridge – Amazon EventBridge is a serverless event bus service connecting your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications and AWS services, and it routes that data to targets such as AWS Lambda. EventBridge simplifies the process of building event-driven architectures.
- AWS KMS – AWS Key Management Service (AWS KMS) is a managed service for creating and controlling AWS KMS keys, the encryption keys used to encrypt your data.
- AWS SDKs – AWS tools include SDKs so that you can develop and manage applications on AWS in the programming language of your choice.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and

consumers). Publishers communicate asynchronously with subscribers by sending messages to a topic, which is a logical access point and communication channel.

- [AWS Systems Manager](#) – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can automate operational tasks across your AWS resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting on (or taking corrective action on) any policy violations it detects.

Code

- The `alerting_ct_logs.yaml` CloudFormation template for the project is attached.

Epics

Prepare the AWS account

Task	Description	Skills required
Install and configure AWS CLI.	Install AWS CLI version 2. Then configure the security credentials settings for an identity, the default output format, and the default AWS Region that AWS CLI uses to interact with AWS. The identity must have the required permissions to perform the tasks.	Developer, Security engineer

Deploy the AWS CloudFormation template

Task	Description	Skills required
Download the CloudForm ation template.	Download the attachment to a local path on your computer	Developer, Security engineer

Task	Description	Skills required
	and extract the `alerting_ct_logs.yaml` template file.	
Deploy the template.	In the terminal window where the AWS account profile has been configured, run the following command. ```aws cloudformation create-stack --stack-name <stack_name> \ --capabilities <Value> \ --template-body file://<Full_Path> \ --parameters ParameterKey=DestinationEmailAddress,ParameterValue=<Value> \ ParameterKey=SNSTopicName,ParameterValue=<Value> \ ParameterKey=EnableRemediation ,ParameterValue=<Value> \ ParameterKey=AutomationAssumeRole,ParameterValue=<Value>``` In the next step, enter values for the template parameters.	Developer, Security engineer

Task	Description	Skills required
Complete the template parameters.	Enter the required values for the parameters. • `DestinationEmailAddress` – The email address to receive an alert when an AWS KMS key is scheduled for deletion. • `SNSTopicName` – The name of the Amazon SNS topic. • `EnableRemediation` – Cancellation of the scheduled key deletion using a Systems Manager runbook. Allowed values are `true` and `false`. • `AutomationAssumeRole` – The Amazon Resource Name (ARN) of the role that allows Systems Manager automation to perform the actions on your behalf. For more information, see the *Required IAM Permissions* section in the AWSConfigRemediation-CancelKeyDeletion documentation. • `Capabilities` – For AWS CloudFormation to create the stack, you must explicitly acknowledge that your	Developer, Security engineer

Task	Description	Skills required
	stack template contains certain capabilities.	

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	Check your email inbox and choose **Confirm subscription** in the email message that you receive from Amazon SNS. A web browser window will open and display a subscript ion confirmation and your subscription ID.	Developer, Security engineer

Identify public Amazon S3 buckets in AWS Organizations by using Security Hub

Mourad Cherfaoui, Arun Chandapillai, and Parag Nagwekar, Amazon Web Services

Summary

This pattern shows you how to build a mechanism for identifying public Amazon Simple Storage Service (Amazon S3) buckets in your AWS Organizations accounts. The mechanism works by using controls from the AWS Foundational Security Best Practices (FSBP) standard in AWS Security Hub to monitor Amazon S3 buckets. You can use Amazon EventBridge to process Security Hub findings, and then post these findings to an Amazon Simple Notification Service (Amazon SNS) topic. Stakeholders in your organization can subscribe to the topic and get immediate email notifications about the findings.

New Amazon S3 buckets and their objects don't allow public access by default. You can use this pattern in scenarios where you must modify default Amazon S3 configurations based on your organization's requirements. For example, this could be a scenario where you have an Amazon S3 bucket that hosts a public-facing website or files that everyone on the internet must be able to read from your Amazon S3 bucket.

Security Hub is often deployed as a central service to consolidate all security findings, including those related to security standards and compliance requirements. There are other AWS services that you can use to detect public Amazon S3 buckets, but this pattern uses an existing Security Hub deployment with minimal configuration.

Prerequisites and limitations

Prerequisites

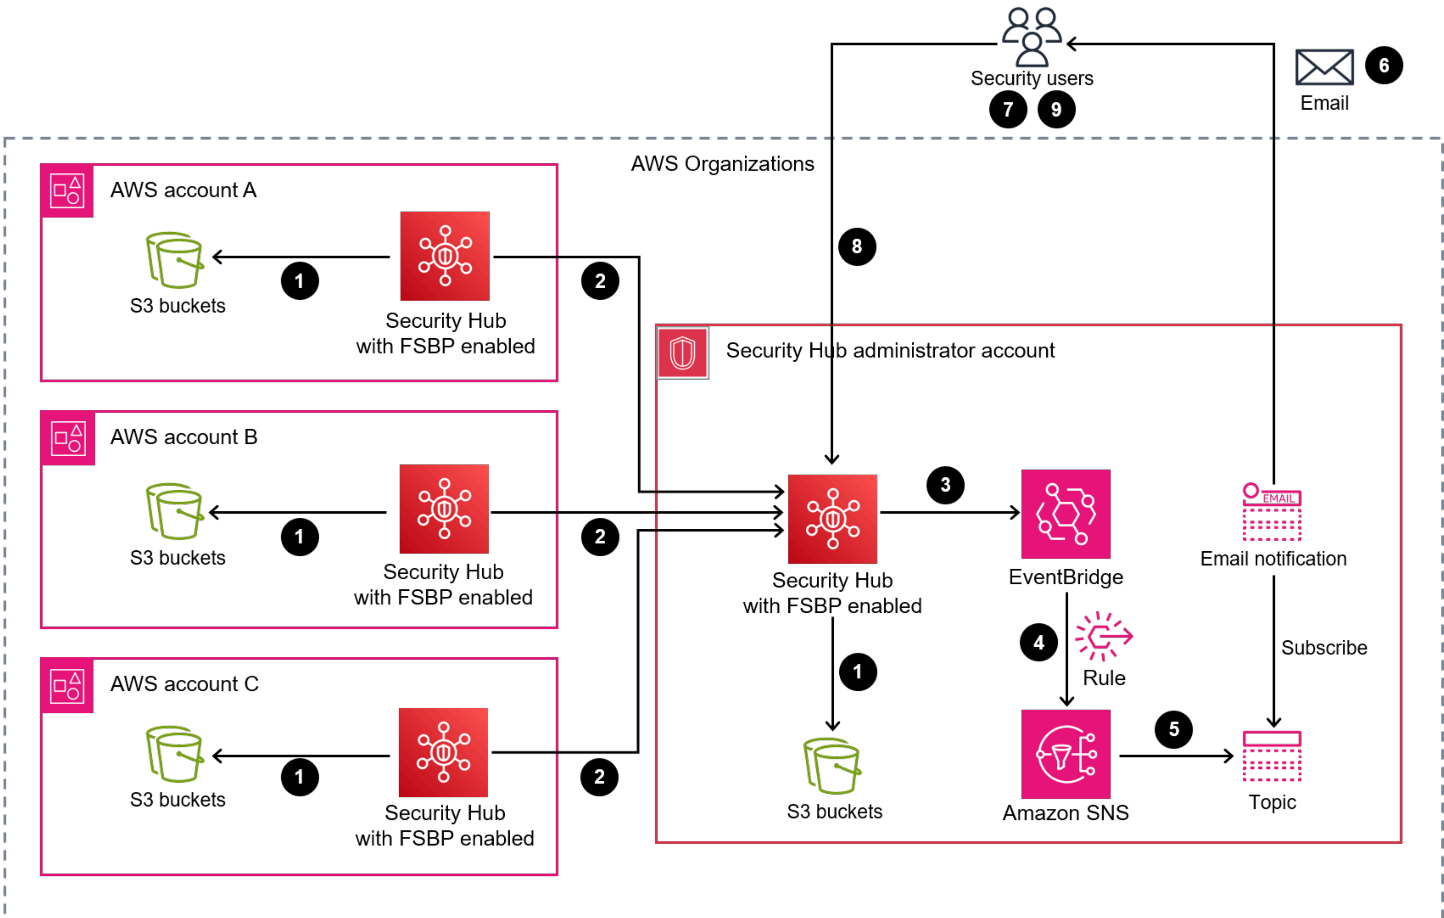
- An AWS multi-account setup with a dedicated Security Hub administrator account
- Security Hub and AWS Config, enabled in the AWS Region that you want to monitor

> **Note**
>
> You must enable cross-Region aggregation in Security Hub if you want to monitor multiple Regions from a single aggregation Region.

- User permissions for accessing and updating the Security Hub administrator account, read access to all the Amazon S3 buckets in the organization, and permissions for turning off public access (if required)

Architecture

The following diagram shows an architecture for using Security Hub to identify public Amazon S3 buckets.



The diagram show the following workflow:

1. Security Hub monitors the configuration of Amazon S3 buckets in all AWS Organizations accounts (including the administrator account) by using the S3.2 and S3.3 controls from the FSBP security standard, and detects a finding if a bucket is configured as public.
2. The Security Hub administrator account accesses the findings (including those for S3.2 and S3.3) from all member accounts.

3. Security Hub automatically sends all new findings and all updates to existing findings to EventBridge as **Security Hub Findings - Imported** events. This includes events for findings from both the administrator and member accounts.
4. An EventBridge rule filters on findings from S3.2 and S3.3 that have a `ComplianceStatus` of `FAILED`, a workflow status of `NEW`, and a `RecordState` of `ACTIVE`.
5. Rules use the event patterns to identify events and send them to an Amazon SNS topic once matched.
6. An Amazon SNS topic sends the events to its subscribers (through email, for example).
7. Security analysts designated to receive the email notifications review the Amazon S3 bucket in question.
8. If the bucket is approved for public access, the security analyst sets the workflow status of the corresponding finding in Security Hub to `SUPPRESSED`. Otherwise, the analyst sets the status to `NOTIFIED`. This eliminates future notifications for the Amazon S3 bucket and reduces notification noise.
9. If the workflow status is set to `NOTIFIED`, the security analyst reviews the finding with the bucket owner to determine if public access is justified and complies with privacy and data protection requirements. The investigation results in either removing public access to the bucket or approving public access. In the latter case, the security analyst sets the workflow status to `SUPPRESSED`.

Note

The architecture diagram applies to both single Region and cross-Region aggregation deployments. In accounts A, B, and C in the diagram, Security Hub can belong to the same Region as the administrator account or belong to different Regions if cross-Region aggregation is enabled.

Tools

- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, software as a service (SaaS) applications, and AWS services. EventBridge routes that data to targets such as Amazon SNS topics and AWS Lambda functions if the data matches user-defined rules.

- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Security Hub provides a comprehensive view of your security state in AWS. Security Hub also helps you check your AWS environment against security industry standards and best practices. Security Hub collects security data from across AWS accounts, services, and supported third-party partner products, and then helps to analyze security trends and identify the highest priority security issues.

Epics

Configure Security Hub accounts

Task	Description	Skills required
Enable Security Hub in AWS Organizations accounts.	To enable Security Hub in the organization accounts where you want to monitor Amazon S3 buckets, see the guideline s from Designating a Security Hub administrator account (console) and Managing member accounts that belong to an organization in the Security Hub documentation.	AWS administrator
(Optional) Enable cross-Reg ion aggregation.	If you want to monitor Amazon S3 buckets in multiple Regions from a single Region, set up cross-Region aggregation.	AWS administrator

Task	Description	Skills required
Enable the S3.2 and S3.3 controls for the FSBP security standard.	You must enable S3.2 and S3.3 controls for the FSBP security standard. 1. To enable S3.2 controls, follow the instructions from [S3.2] S3 buckets should prohibit public read access in the Security Hub documentation. 2. To enable S3.3 controls, follow the instructions from [3] S3 buckets should prohibit public write access in the Security Hub documentation.	AWS administrator

Set up the environment

Task	Description	Skills required
Configure the Amazon SNS topic and email subscription.	1. Sign in to the AWS Management Console and open the Amazon SNS console. 2. In the navigation pane, choose **Topics**, and then choose **Create topic**. 3. For **Type**, choose **Standard**. 4. For **Name**, enter a name for your topic (for example, **public-s3-buckets**). 5. Choose **Create topic**.	AWS administrator

Task	Description	Skills required
	6. On the **Subscriptions** tab for your topic, choose **Create subscription**. 7. For **Protocol**, select **Email**. 8. For **Endpoint**, enter the email address that will receive the notificat ions. You can use the email address of an AWS administrator, IT professio nal, or Infosec professional. 9. Choose **Create subscript ion**. To create additional email subscriptions, repeat steps 6–8 as needed.	

Task	Description	Skills required
Configure the EventBridge rule.	1. Open the [EventBridge console](). 2. In the **Get started** section, select **EventBridge Rule**, and then choose **Create rule**. 3. On the **Define rule detail** page, for **Name**, enter a name for your rule (for example, **public-s3-buckets**). Choose **Next**. 4. In the **Event pattern** section, choose **Edit pattern**. 5. Copy the following code, paste it into the **Event pattern** code editor, and then choose **Next**. `{ "source": ["aws.securityhub"], "detail-type": ["Security Hub Findings - Imported"], "detail": { "findings": { "Compliance": { "Status": ["FAILED"] }, "RecordState": ["ACTIVE"], "Workflow": { "Status": ["NEW"]`	AWS administrator

Task	Description	Skills required

	``
	      },
	      "ProductF
	ields": {
	        "ControlId":
	 ["S3.2", "S3.3"]
	      }
	    }
	  }
	}
	``
	6. On the **Select target(s)** page, for **Select a target**, select **SNS topic** as the target, and then select the topic that you created earlier.
	7. Choose **Next**, choose **Next** again, and then choose **Create rule**.	

Troubleshooting

Issue	Solution
I have an Amazon S3 bucket with public access enabled, but I'm not getting email notifications for it.	This could be because the bucket was created in another Region and cross-Region aggregation is not enabled in the Security Hub administrator account. To resolve this issue, enable cross-Region aggregation or implement this pattern's solution in the Region where your Amazon S3 bucket currently resides.

Additional information

Workflow for monitoring public Amazon S3 buckets

The following workflow illustrates how you can monitor the public Amazon S3 buckets in your organization. The workflow assumes that you completed the steps in the *Configure the Amazon SNS topic and email subscription* story of this pattern.

1. You receive an email notification when an Amazon S3 bucket is configured with public access.
   - If the bucket is approved for public access, set the workflow status of the corresponding finding to `SUPPRESSED` in the Security Hub administrator account. This prevents Security Hub from issuing further notifications for this bucket and can eliminate duplicate alerts.
   - If the bucket isn't approved for public access, set the workflow status of the corresponding finding in the Security Hub administrator account to `NOTIFIED`. This prevents Security Hub from issuing further notifications for this bucket from Security Hub and can eliminate noise.
2. If the bucket might contain sensitive data, turn off public access immediately until the review is completed. If you turn off public access, then Security Hub changes the workflow status to `RESOLVED`. Then, email notifications for the bucket stop.
3. Find the user who configured the bucket as public (for example, by using AWS CloudTrail) and start a review. The review results in either removing public access to the bucket or approving public access. If public access is approved, then set the workflow status of the corresponding finding to `SUPPRESSED`.

Ingest and analyze AWS security logs in Microsoft Sentinel

Ivan Girardi and Sebastian Wenzel, Amazon Web Services

Summary

This pattern describes how to automate the ingestion of AWS security logs, such as AWS CloudTrail logs, Amazon CloudWatch Logs data, Amazon VPC Flow Logs data, and Amazon GuardDuty findings, into Microsoft Sentinel. If your organization uses Microsoft Sentinel as a security information and event management (SIEM) system, this helps you centrally monitor and analyze logs in order to detect security-related events. As soon as the logs are available, they are automatically delivered to an Amazon Simple Storage Service (Amazon S3) bucket in less than 5 minutes. This can help you quickly detect security events in your AWS environment.

Microsoft Sentinel ingests CloudTrail logs in a tabular format that includes the original timestamp for when the event was recorded. The structure of the ingested logs enables query capabilities by using Kusto Query Language in Microsoft Sentinel.

The pattern deploys a monitoring and alerting solution that detects ingestion failures in less than 1 minute. It also includes a notification system that the external SIEM can monitor. You use AWS CloudFormation to deploy the required resources in the logging account.

Target audience

This pattern is recommended for users who have experience with AWS Control Tower, AWS Organizations, CloudFormation, AWS Identity and Access Management (IAM), and AWS Key Management Service (AWS KMS).

Prerequisites and limitations

Prerequisites

The following are the prerequisites for deploying this solution:

- Active AWS accounts that are managed as an organization in AWS Organizations and are part of an AWS Control Tower landing zone. The organization should include a dedicated account for logging. For instructions, see Creating and configuring an organization in the AWS Organizations documentation.
- A CloudTrail trail that logs events for the entire organization and stores logs in an Amazon S3 bucket in the logging account. For instructions, see Creating a trail for an organization.

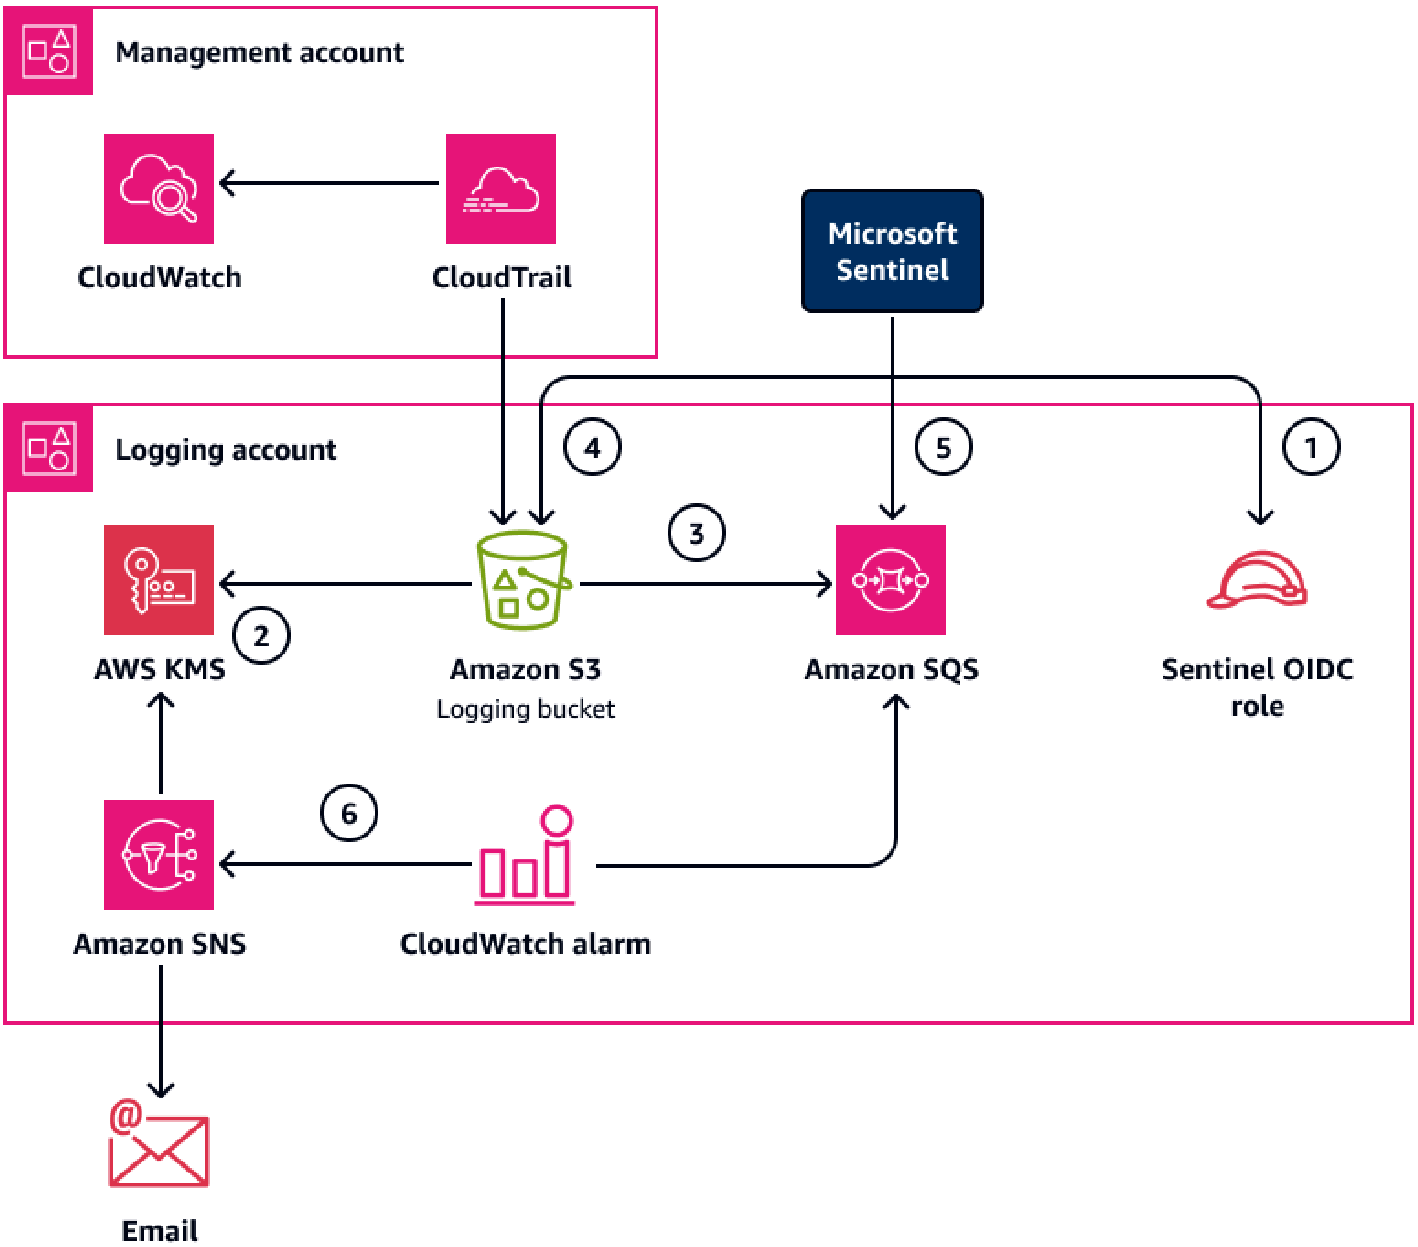
- In the logging account, permissions to assume an existing IAM role that has the following permissions:
  - Deploy the resources defined in the provided CloudFormation template.
  - Deploy the provided CloudFormation template.
  - Modify the AWS KMS key policy if the logs are encrypted with a customer managed key.
- AWS Command Line Interface (AWS CLI), installed and configured.
- A Microsoft Azure account with a subscription to use Microsoft Sentinel.
- Enable and set up Microsoft Sentinel. For instructions, see Enable Microsoft Sentinel and initial features and content in the Microsoft Sentinel documentation.
- Meet the prerequisites for setting up the Microsoft Sentinel S3 connector.

Limitations

- This solution forwards the security logs from an Amazon S3 bucket in the logging account to Microsoft Sentinel. Instructions for how to send the logs to Amazon S3 are not explicitly provided.
- This pattern provides instructions for deployment in an AWS Control Tower landing zone. However, use of AWS Control Tower is not required.
- This solution is compatible with an environment where the Amazon S3 logging bucket is restricted with service control policies (SCPs), such as Disallow Changes to Bucket Policy for AWS Control Tower Created Amazon S3 Buckets in Log Archive.
- This pattern provides instructions for forwarding CloudTrail logs, but you can adapt this solution to send other logs that Microsoft Sentinel supports, such as logs from CloudWatch Logs, Amazon VPC Flow Logs, and GuardDuty.
- The instructions use the AWS CLI to deploy the CloudFormation template, but you could also use the AWS Management Console. For instructions, see Using the AWS CloudFormation console. If you use the console to deploy the stack, deploy the stack in the same AWS Region as the logging bucket.
- This solution deploys an Amazon Simple Queue Service (Amazon SQS) queue to deliver Amazon S3 notifications. The queue contains messages with the paths of objects uploaded in the Amazon S3 bucket, not actual data. The queue uses SSE-SQS encryption to help protect the content of the messages. If you want to encrypt the SQS queue with SSE-KMS, you can use a customer managed KMS key. For more information, see Encryption at rest in Amazon SQS.

Architecture

This section provides a high-level overview of the architecture that the sample code establishes. The following diagram shows the resources deployed in the logging account in order to ingest logs from an existing Amazon S3 bucket into Microsoft Sentinel.



The architecture diagram shows the following resource interactions:

1. In the logging account, Microsoft Sentinel assumes an IAM role through OpenID Connect (OIDC) to access logs in a specific Amazon S3 bucket and Amazon SQS queue.

2. Amazon Simple Notification Service (Amazon SNS) and Amazon S3 use AWS KMS for encryption.
3. Amazon S3 sends notification messages to the Amazon SQS queue whenever it receives new logs.
4. Microsoft Sentinel checks Amazon SQS for new messages. The Amazon SQS queue uses SSE-SQS encryption. The message retention period is set to 14 days.
5. Microsoft Sentinel pulls messages from the Amazon SQS queue. The messages contain the path of the uploaded Amazon S3 objects. Microsoft Sentinel ingests those objects from the Amazon S3 bucket into the Microsoft Azure account.
6. A CloudWatch alarm monitors the Amazon SQS queue. If messages are not received and deleted from the Amazon SQS queue within 5 minutes, then it initiates an Amazon SNS notification that sends an email.

AWS Control Tower helps you set up the foundational organization unit (OU) structure and centralizes CloudTrail logs in the logging account. It also implements mandatory SCPs to protect the logging bucket.

We have provided the target architecture in an AWS Control Tower landing zone, but this is not strictly required. In this diagram, the resources in the management account reflect an AWS Control Tower deployment and a CloudTrail trail that logs events for the entire organization.

This pattern focuses on the deployment of resources in the logging account. If the logs stored in Amazon S3 in your AWS Control Tower landing zone are encrypted with a customer managed KMS key, then you must update the key policy to allow Microsoft Sentinel to decrypt the logs. In an AWS Control Tower landing zone, you manage the key policy from the management account, which is where the key was created.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- AWS Control Tower helps you set up and govern an AWS multi-account environment, following best practices.

- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- Microsoft Sentinel is a cloud-native SIEM system that provides security orchestration, automation, and response (SOAR).

Code repository

The code for this pattern is available in the GitHub Ingest and analyze AWS security logs in Microsoft Sentinel repository.

Best practices

- Follow the principle of least-privilege (IAM documentation).
- Follow the Best practices for AWS Control Tower administrators (AWS Control Tower documentation).
- Follow the AWS CloudFormation best practices (CloudFormation documentation).
- Use code analysis tools, such as cfn_nag, to scan the generated CloudFormation templates. The cfn_nag tool identifies potential security issues in CloudFormation templates by searching for patterns.

Epics

Connect Microsoft Sentinel to Amazon S3

Task	Description	Skills required
Prepare the Microsoft Sentinel S3 connector.	1. In Microsoft Sentinel, choose **Data connectors**. 2. From the data connector s gallery, choose **Amazon Web Services S3**. **Note** If you don't see the connector, install the [Amazon Web Services solution](#) from the Content Hub in Microsoft Sentinel. 3. In the details pane for the connector, choose **Open connector page**. 4. In the **Configuration** section, copy the **External ID**. You need this ID later.	DevOps engineer, General AWS

Deploy the CloudFormation stack

Task	Description	Skills required
Clone the repository.	In a bash shell, enter the following command. This clones the [Ingest and](#)	DevOps engineer, General AWS

Task	Description	Skills required
	analyze AWS Security Logs in Microsoft Sentinel repository. `git clone https://github.com/aws-samples/ingest-and-analyze-aws-security-logs-in-microsoft-sentinel.git`	
Assume the IAM role in the logging account.	In the logging account, assume the IAM role that has permissions to deploy the CloudFormation stack. For more information about assuming an IAM role in the AWS CLI, see Use an IAM role in the AWS CLI.	DevOps engineer, General AWS

Task	Description	Skills required
Deploy the stack.	To deploy the CloudFormation stack enter the following command, where: • `<Bucket name>` is the name of the logging Amazon S3 bucket. • `<Sentinel external ID>` is the external ID of the Amazon S3 connector in Microsoft Sentinel. • `<Email address>` is a valid email address where you want to receive notifications. • `<Customer managed key ARN>` is the Amazon Resource Name (ARN) of the customer managed KMS key. Provide this parameter only if the logs are encrypted with a customer managed KMS key. • `<Suffix>` is an optional parameter to avoid resource name conflicts. • `<ARN for the OIDC provider>` is the ARN of the OIDC provider if it already exists. If you do not provide this parameter, CloudFormation creates the OIDC provider.	DevOps engineer, General AWS

Task	Description	Skills required
	Important If the AWS organization is monitored with [Microsoft Code Defender](), the OIDC provider for Microsoft has been already deployed. You must provide this parameter and the ARN of the existing provider. `aws cloudformation deploy --stack-name cloudtrail-sentinel-integration \ --no-fail-on-empty-changeset \ --template-file template.yml \ --capabilities CAPABILITY_IAM CAPABILITY_NAMED_IAM CAPABILITY_AUTO_EXPAND \ --parameter-overrides \ ControlTowerS3BucketName="<Bucket name>" \ AzureWorkspaceID="<Sentinel external ID>" \`	

Task	Description	Skills required

	``
	    EmailAddress="<Ema
	il address>" \
	    KMSKeyArn="<Custom
	er managed key ARN>" \
	    Suffix="<Suffix to
	 avoid name conflicts>"
	 \
	    OIDCProviderArn="<
	ARN for the OIDC
	 provider>"
	``	

Copy outputs.	From the output of the CloudFormation stack, copy the values for `SentinelRoleArn` and `SentinelSQS` . You use these values later to complete the configuration in Microsoft Sentinel.	DevOps engineer, General AWS

Task	Description	Skills required

Modify the key policy.	If you aren't using a customer managed KMS key to encrypt the logs in the Amazon S3 bucket, you can skip this step.
	
	If the logs are encrypted with a customer managed KMS key, modify the key policy to grant Microsoft Sentinel permission to decrypt the logs. The following is an example key policy. This example policy allows cross-account access if the KMS key is in another AWS account.
	
	`{`
	`    "Version": "2012-10-17",`
	`    "Id": "key-policy",`
	`    "Statement": [`
	`        ...`
	`        {`
	`            "Sid": "Grant access to decrypt",`
	`            "Effect": "Allow",`
	`            "Principal": {`
	`                "AWS": "<SentinelRoleArn>"`
	`            },`
	`            "Action": "kms:Decrypt",`
	`            "Resource": "<KeyArn>"`
	`        }`
	`    ]`
		DevOps engineer, General AWS

Task	Description	Skills required
	`}`	

Configure the connector in Microsoft Sentinel

Task	Description	Skills required
Complete the configuration in Microsoft Sentinel.	1. In Microsoft Sentinel, choose **Data connectors**. 2. From the data connectors gallery, choose **Amazon Web Services S3**. 3. In the details pane for the connector, choose **Open connector page**. 4. In the **Configuration** section, do the following: a. In **Role to add**, enter the `SentinelRoleArn` value that you copied. b. In **SQS URL**, enter the `SentinelSQS` value that you copied. c. In the **Destination table** list, choose `AWSCloudTrail` . 5. Choose **Add connection**.	DevOps engineer
Send Amazon S3 event notifications to Amazon SQS.	Follow the instructions in [Enabling and configuring event notifications using the Amazon S3 console](#) to configure the Amazon S3 logging bucket to send event	DevOps engineer, General AWS

Task	Description	Skills required
	notifications to the Amazon SQS queue. If CloudTrail has been configured for the whole organization, logs in the this bucket have the prefix `<OrgID>/AWSLogs/<OrgID>/` , where `<OrgID>` is the organization ID. For more information, see [Viewing details about your organization]().	
Confirm that the logs are ingested.	1. Wait until the logs are ingested in Microsoft Sentinel. This can take several minutes. 2. In Microsoft Sentinel, open the Amazon S3 Data Connector page, and then do the following: • Confirm that the Amazon S3 Data Connector status is `Connected` . • Check the data volume in the **Data received** graph. For more information about inspecting the data connector activity, see [Data connector]() in the Microsoft documentation.	DevOps engineer

Validate the solution

Task	Description	Skills required
Compare CloudWatch and Sentinel logs.	In the default configura tion of AWS Control Tower, CloudTrail logs are sent to Amazon CloudWatch and stored in the AWS Control Tower management account. For more information, see [Logging and monitoring in AWS Control Tower](). Use the following steps to confirm that that logs are automatic ally ingested into Microsoft Sentinel: 1. Open the [CloudWatch console](). 2. In the navigation pane, choose **Logs**, and then choose **Logs Insights**. 3. For **Select log group(s)**, select the log group where the CloudTrail logs are stored, such as `aws-controltower/CloudTrail Logs` . 4. In the query editor box, enter `fields eventID`. 5. Choose **Run query**. 6. Choose **Export results**, and then choose **Copy table to clipboard (CSV)**.	DevOps engineer, General AWS

Task	Description	Skills required

	7. Paste the results to a text editor.
	8. Change the format of the output so that it can be used in a Microsoft Sentinel query. The following is an example that uses the Kusto Query Language:
	`AWSCloudTrail`
	`| where AwsEventId in`
	`(`
	`'aa08b5fe-3bfb-391a-a14e-5fcebe14dab2',`
	`'9decd805-269c-451c-b75b-762f5dce59f9'`
	`)`
	9. In Microsoft Sentinel, open the Amazon S3 Data Connector page. Next to the **Data received** graph, choose **Go to log analytics**.
	10. In the query editor box, enter the query, and then choose **Run**.
	11. In Microsoft Sentinel and CloudWatch, verify that the number of entries is the same. Adapt the time range if needed.

Manage AWS Organizations policies as code by using AWS CodePipeline and Amazon Bedrock

Andre Cavalcante and Mariana Pessoa de Queiroz, Amazon Web Services

Summary

You can use *authorization policies* in AWS Organizations to centrally configure and manage access for principals and resources in your member accounts. Service control policies (SCPs) define the maximum available permissions for the AWS Identity and Access Management (IAM) roles and users in your organization. Resource control policies (RCPs) define the maximum available permissions available for resources in your organization.

This pattern helps you to manage SCPs and RCPs as infrastructure as code (IaC) that you deploy through a continuous integration and continuous deployment (CI/CD) pipeline. By using AWS CloudFormation or Hashicorp Terraform to manage these policies, you can reduce the burden associated with building and maintaining multiple authorization policies.

This pattern includes the following features:

- You create, delete, and update the authorization policies by using *manifest files* (`scp-management.json` and `rcp-management.json`).
- You work with guardrails instead of policies. You define your guardrails and their targets in the manifest files.
- The pipeline, which uses AWS CodeBuild and AWS CodePipeline, merges and optimizes the guardrails in the manifest files. For each statement in the manifest file, the pipeline combines the guardrails into a single SCP or RCP and then applies it to the defined targets.
- AWS Organizations applies the policies to your targets. A *target* can be an AWS account, an organizational unit (OU), an environment (which is a group of accounts or OUs that you define in the `environments.json` file), or a group of accounts that share an AWS tag.
- Amazon Bedrock reads the pipeline logs and summarizes all policy changes.
- The pipeline requires a manual approval. The approver can review the executive summary that Amazon Bedrock prepared, which helps them understand the changes.

Prerequisites and limitations

Prerequisites

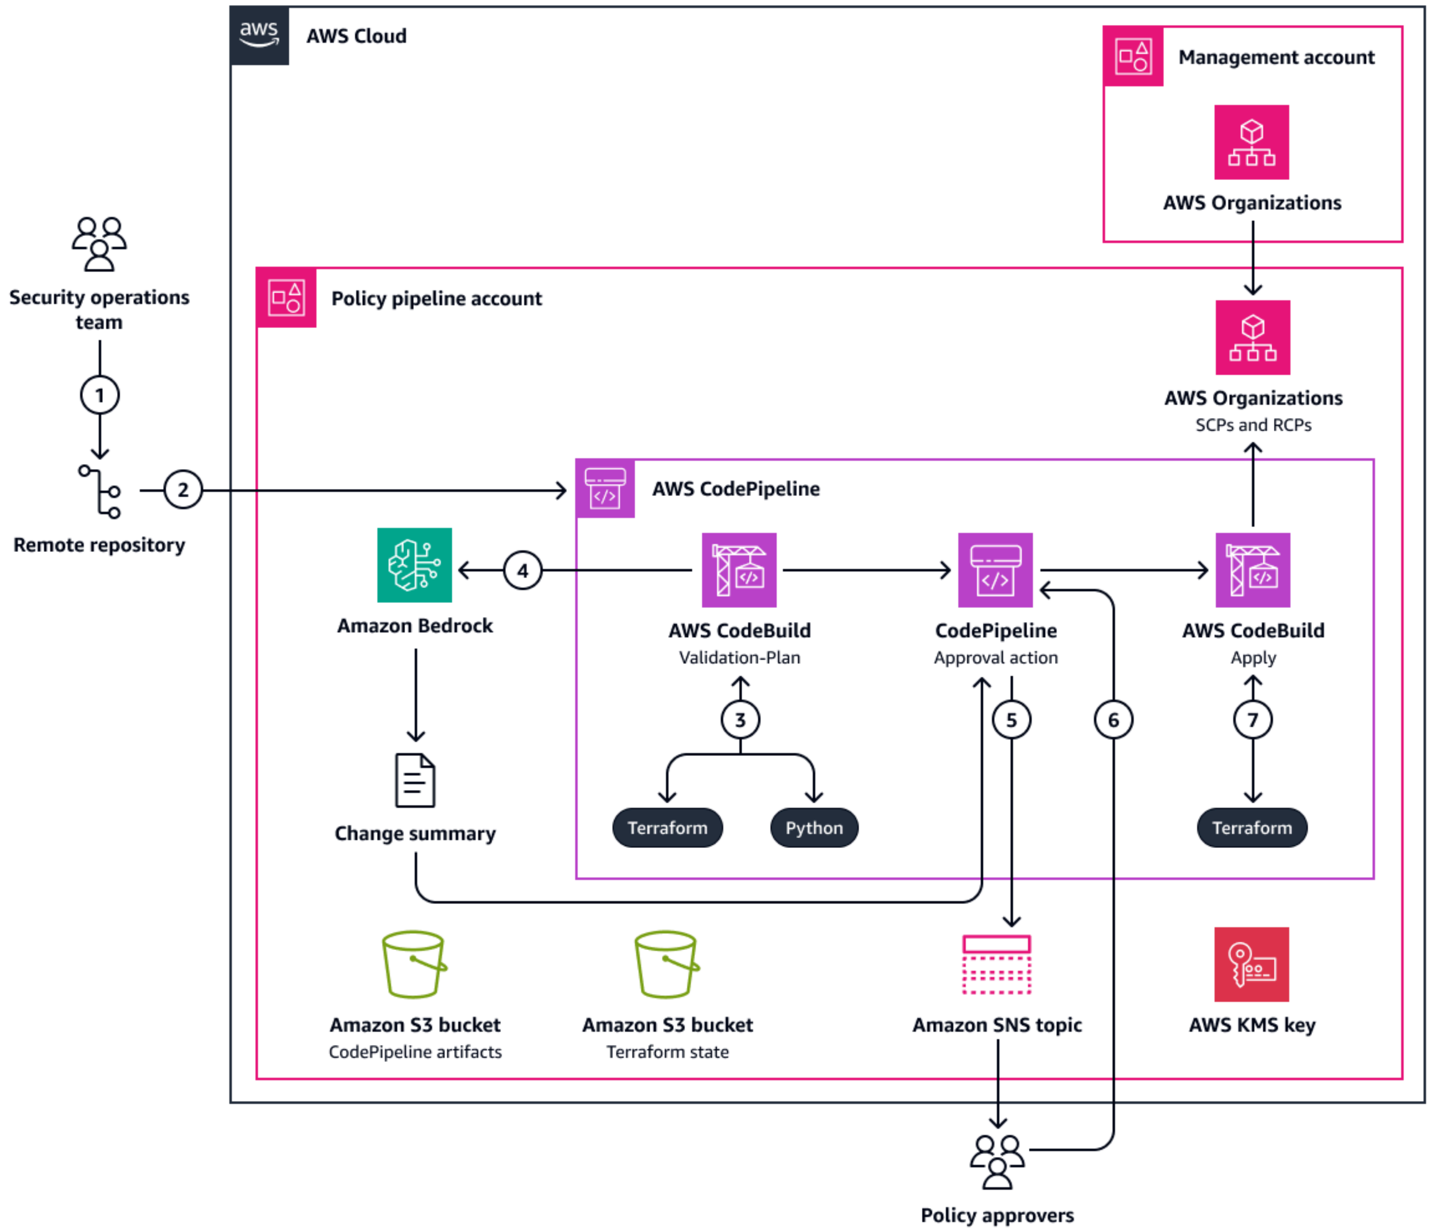
- Multiple AWS accounts that are managed as an organization in AWS Organizations. For more information, see Creating an organization.
- The SCP and RCP features are enabled in AWS Organizations. For more information, see Enabling a policy type.
- Terraform version 1.9.8 or later is installed.
- If you are not deploying this solution through a Terraform pipeline, then the Terraform state file must be stored in an Amazon Simple Storage Service (Amazon S3) bucket in the AWS account where you are deploying the policy management pipeline.
- Python version 3.13.3 or later is installed.

Limitations

- You cannot use this pattern to manage SCPs or RCPs that were created outside of this CI/CD pipeline. However, you can recreate existing policies through the pipeline. For more information, see *Migrating existing policies to the pipeline* in the Additional information section of this pattern.
- The number of accounts, OUs, and policies in each account are subject to the quotas and service limits for AWS Organizations.
- This pattern cannot be used to configure management policies in AWS Organizations, such as backup policies, tag policies, chat applications policies, or declarative policies.

Architecture

The following diagram shows the workflow of the policy management pipeline and its associated resources.



The diagram shows the following workflow:

1. A user commits changes to the `scp-management.json` or `rcp-management.json` manifest files in the main branch of the remote repository.
2. The change to the `main` branch initiates the pipeline in AWS CodePipeline.
3. CodePipeline starts the `Validate-Plan` CodeBuild project. This project uses a Python script in the remote repository to validate policies and the policy manifest files. This CodeBuild project does the following:
   a. Checks that the SCP and RCP manifest files contain unique statement IDs (`Sid`).

b. Uses the `scp-policy-processor/main.py` and `rcp-policy-processor/main.py` Python scripts to concatenate guardrails in the guardrails folder into a single RCP or SCP policy. It combines guardrails that have the same `Resource`, `Action`, and `Condition`.

c. Uses AWS Identity and Access Management Access Analyzer to validate the final, optimized policy. If any there are any findings, the pipeline stops.

d. Creates `scps.json` and `rcps.json` files, which Terraform uses to create resources.

e. Runs the `terraform plan` command, which creates a Terraform execution plan.

4. (Optional) The `Validate-Plan` CodeBuild project uses the `bedrock-prompt/prompt.py` script to send a prompt to Amazon Bedrock. You define the prompt in the `bedrock-prompt/prompt.txt` file. Amazon Bedrock uses Anthropic Claude Sonnet 3.5 to generate a summary of the proposed changes by analyzing the Terraform and Python logs.
5. CodePipeline uses an Amazon Simple Notification Service (Amazon SNS) topic in order to notify approvers that changes must be reviewed. If Amazon Bedrock generated a change summary, the notification includes this summary.
6. A policy approver approves the action in CodePipeline. If Amazon Bedrock generated a change summary, the approver can review the summary in CodePipeline prior to approving.
7. CodePipeline starts the `Apply` CodeBuild project. This project uses Terraform to apply the RCP and SCP changes in AWS Organizations.

The IaC template associated with this architecture also deploys the following resources that support the policy management pipeline:

- An Amazon S3 bucket for storing the CodePipeline artifacts and scripts, such as `scp-policy-processor/main.py` and `bedrock-prompt/prompt.py`
- An AWS Key Management Service (AWS KMS) key that encrypts the resources created by this solution

Tools

AWS services

- Amazon Bedrock is a fully managed AI service that makes many high-performing foundation models available for use through a unified API.

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- HashiCorp Terraform is an IaC tool that helps you use code to provision and manage cloud infrastructure and resources.

Code repository

The code for this pattern is available in the organizations-policy-pipeline GitHub repository. The following are the key files that are contained in the `sample-repository` folder:

- In the `environments` folder, `environments.json` contains a list of environments. *Environments* are a group of targets, and they can contain AWS account IDs or organizational units (OUs).
- In the `rcp-management` folder:
  - The `guardrails` folder contains the individual guardrails for your RCPs
  - The `policies` folder contains the individual RCPs
  - The `rcp-management.json` manifest file helps you manage RCP guardrails, full RCPs, and their associated targets.
- In the `scp-management` folder:
  - The `guardrails` folder contains the individual guardrails for your SCPs
  - The `policies` folder contains the individual SCPs
  - The `scp-management.json` manifest file helps you manage SCP guardrails, full SCPs, and their associated targets.

- The `utils` folder contains scripts that can help you migrate your current SCPs and RCPs so that you can manage them through the pipeline. For more information, see the Additional information section of this pattern.

Best practices

- Before you set up the pipeline, we recommend that you verify that you have not reached the limits of your AWS Organizations quotas.
- We recommend that you use the AWS Organizations management account only for tasks that must be performed in that account. For more information, see Best practices for the management account.

Epics

Set up the target account

Task	Description	Skills required
Create a repository.	Create a repository from which your security operation s team will manage the policies. Use one of the third-party repository providers that AWS CodeConnections supports.	DevOps engineer
Delegate policy administr ation.	Delegate administration of AWS Organizations policies to the member account where you are deploying the pipeline. For instructions, see Create a resource-based delegation policy with AWS Organizations. For a sample policy, see *Sample resource-based delegation policy* in	AWS administrator

Task	Description	Skills required
	the Additional information section of this pattern.	
(Optional) Enable the foundation model.	If you want to generate summaries of the policy changes, enable access to the Anthropic Claude 3.5 Sonnet foundation model in Amazon Bedrock in the AWS account where you are deploying the pipeline. For instructions, see Add or remove access to Amazon Bedrock foundation models.	General AWS

Deploy the resources for the pipeline

Task	Description	Skills required
Clone the repository.	Enter the following command to clone the organizations-policy-pipeline repository from GitHub: `git clone https://github.com/aws-samples/organizations-policy-pipeline.git`	DevOps engineer
Define your deployment method.	1. In the cloned repository, open the `variables.tf` file. 2. For `project_name`, enter the prefix that you want	DevOps engineer

Task	Description	Skills required
	to apply to names of the deployed resources. 3. For `provider_type` , enter the provider of the remote repository. Valid values are provided in the file. 4. For `full_repository_name` , enter the name of the remote repository. 5. For `branch_name` , enter the name of the Git branch that you will use to deploy policies. A push or merge in this branch starts the pipeline. Typically, this is the main branch. 6. For `terraform_version` , enter the version of Terraform that you are using. 7. For `enable_bedrock` , enter `true` if you want Amazon Bedrock to summarize the changes. Enter `false` if you do not want to generate a summary of the changes. 8. For `tags`, enter the key-value pairs that you want to assign as tags to the deployed resources.	

Task	Description	Skills required
	9. Save and close the `variables.tf` file.	

Deploy the pipeline.	1. Enter the following command to create a plan and review the changes:
	`terraform plan`
	2. Enter the following command to apply the plan and create the pipeline infrastructure:
	`terraform apply`
		DevOps engineer, Terraform

Connect the remote repository.	In the previous step, Terraform created an CodeConnections connection to the third-party repository. In the [AWS Developer Tools console](), change the status of the connection from `PENDING` to `AVAILABLE`. For instructions, see [Update a pending connection]().	AWS DevOps

Task	Description	Skills required
Subscribe to the Amazon SNS topic.	Terraform created an Amazon SNS topic. Subscribe an endpoint to the topic and confirm the subscription so that the approvers receive notifications about pending approval actions in the pipeline. For instructions, see [Creating a subscription to an Amazon SNS topic]().	General AWS

Define your guardrails and policies

Task	Description	Skills required
Populate the remote repository.	From the cloned repository, copy the contents of the `sample-repository` folder to your remote repository. This includes the `environments` , `rcp-management` , `scp-management` , and `utils` folders.	DevOps engineer
Define your environments.	1. In the `environments` folder, open the `environments.json` file. This is the file where you define the target AWS accounts and OUs for your RCPs and SCPs. 2. Delete the example environments.	DevOps engineer

Task	Description	Skills required
	3. Add your target environments in the following format: `[ { "ID": "<environment-name>", "Target": [ "<ou-name>:<ou-id>", "<account-name>:<account-id>" ] } ]` Where: • `<environment-name>` is the name you assign to the group of OUs and AWS accounts. You can use this name in the manifest file to define where you want to apply your policies. • `<ou-name>` is the name of the target OU. • `<ou-id>` is the ID of the target OU. • `<account-name>` is the name of the target AWS account.	

Task	Description	Skills required
	• `<account-id>` is the ID of the target AWS account. For examples, see the source code repository. 4. Save and close the `environments.json` file.	

Task	Description	Skills required
Define your guardrails.	1. Navigate to the `rcp-management/guardrails` folder in your remote repository. This is the folder where you define the guardrails for your RCP manifest file. Each guardrail must in an individual file. Guardrail files can contain one or more statements. **Note** You can use the same guardrail in multiple statements in the manifest files for SCPs and RCPs. If you modify the guardrail, any policies that include this guardrail are affected. 2. Delete any example guardrails that were copied from the source code repository. 3. Create a new .json file and give it a descriptive name. 4. Open the .json file you created.	DevOps engineer

Task	Description	Skills required
	5. Define the guardrail in the following format: ```[{ "Sid": "<guardrail-name>", "Effect": "<effect-value>", "Action": ["<action-name>"], "Resource": "<resource-arn>", "Condition": { "<condition-operator>": { "<condition-key>": ["<condition-value>"] } } }]``` Where: • `<guardrail-name>` is a unique name for the guardrail. This name cannot be used for any other guardrails. • `<effect-value>` must be `Allow` or `Deny`.	

Task	Description	Skills required
	For more information, see Effect. • `<action-name>` must be a valid name of an action that the service supports. For more information, see Action. • `<resource-arn>` is the Amazon Resource Name (ARN) of the resource that the guardrail applies to. You can also use wildcard characters, such as `*` or `?`. For more information, see Resource. • `<condition-operator>` is a valid condition operator. For more information, see Condition operators. • `<condition-key>` is a valid global condition context key or a service-specific context key. For more information, see Condition. • `<condition-value>` is the specific value used in a condition to evaluate whether a guardrail applies. For more information, see Condition.	

Task	Description	Skills required
	For example RCP guardrails, see the [source code repository](). 6. Save and close the .json file. 7. Repeat these steps to create as many RCP guardrails as needed. 8. Repeat these steps in the `scp-management/guardrails` folder to create as many guardrails as you need for your SCPs. For example SCP guardrails, see the [source code repository]().	

Task	Description	Skills required
Define your policies.	1. Navigate to the `rcp-management/policies` folder in your remote repository. This is the folder where you define full policies for your RCP manifest file. Each policy must be an individual file. **Note** If you modify a policy in this folder, the policy changes affect any accounts or OUs that this policy is applied to, as defined in the manifest file. 2. Delete any example policies that were copied from the source code repository. 3. Create a new .json file and give it a descriptive name. 4. Open the .json file you created. 5. Define the RCP. For example RCPs, see the source code repository or see Resource control policy examples in the AWS	DevOps engineer

Task	Description	Skills required
	Organizations documentation. 6. Save and close the .json file. 7. Repeat these steps to create as many RCPs as needed. 8. Repeat these steps in the `scp-management/policies` folder to create as many SCPs as needed. For example SCPs, see the [source code repository](#) or see [Service control policy examples](#) in the AWS Organizations documentation.	

Use the manifest file to manage the policies

Task	Description	Skills required
Configure the manifest files.	1. In the `rcp-management` folder, open the `rcp-management.json` file. This is the file where you define which RCP guardrails and full RCPs apply to your target environments. For an example of this file, see the [source code repository](#).	DevOps engineer

Task	Description	Skills required
	2. Delete the example statement. 3. Add a new statement in the following format: `[ { "SID": "<statement-name>", "Target": { "Type": "<target-type>", "ID": "<target-name>" }, "Guardrails": [ "<guardrail-name>" ], "Policy": "<policy-name>", "Comments": "<comment-text>" } ]` Where: • `<statement-name>` is a unique name for the statement. • `<target-type>` is the type of target where you want to apply the policy. Valid values are `Account`, `OU`, `Environment` , or `Tag`.	

Task	Description	Skills required
	• `<target-name>` is the identifier of the target where you want to apply the policy. Enter one of the following: ◦ For an AWS account, enter the identifier as `<account-name>:<account-id>` . ◦ For an OU, enter the identifier as `<OU-name>:<ou-id>` . ◦ For an environment, enter the unique name that you defined in the `environments.json` file. ◦ For a tag, enter the key-value pair as `<tag-key>:<tag-value>` . • `<guardrail-name>` is the unique name of the RCP guardrail that you defined in the `rcp-management/guardrails` folder. You can add multiple guardrails in this element. You can leave this field empty if you	

Task	Description	Skills required
	do not want to apply a guardrail. • `<policy-name>` is the unique name of the RCP that you defined in the `rcp-management/policies` folder. You can add only one policy in this element. You can leave this field empty if you do not want to apply a policy. • `<comment-text>` is a description that you can enter for documentation purposes. This field is not used during pipeline processing. You can leave this field empty if you do not want to add a comment. 4. Repeat these steps to add as many statements as necessary to configure RCPs for your organization. 5. Save and close the `rcp-management.json` file. 6. In the `scp-management` folder, repeat these steps in the `scp-management.json` file. This is the file where you define which SCP guardrails and full SCPs apply to your	

Task	Description	Skills required
	target environments. For an example of this file, see the source code repository.	
Start the pipeline.	Commit and push the changes to the branch of the remote repository that you defined in the `variables.tf` file. Typically, this is the `main` branch. The CI/CD pipeline automatically starts. If there are any pipeline errors, see the Troubleshooting section of this pattern.	DevOps engineer
Approve the changes.	When the `Validate-Plan` CodeBuild project is complete, the policy approvers receive a notification through the Amazon SNS topic that you previously configured. Do the following: 1. Open the notification message. 2. If available, review the summary of policy changes. 3. Follow the instructions in Approve or reject an approval action in CodePipeline.	General AWS, Policy approver

Task	Description	Skills required
Validate the deployment.	1. Sign in to the [AWS Organizations console](https://console.aws.amazon.com/organizations/) in the account that is the delegated administrator for AWS Organizations. 2. On the **Service control policies** page, confirm that the SCPs that you created are listed. 3. Choose an SCP that is managed through the pipeline and confirm that it applies to the intended targets. 4. On the **Resource control policies** page, confirm that the RCPs that you created are listed. 5. Choose an RCP that is managed through the pipeline and confirm that it applies to the intended targets.	General AWS

Troubleshooting

Issue	Solution
Manifest file errors in the `Validate-Plan` phase of the pipeline	A "Pipeline errors in the Validation & Plan phase for manifest files" message appears in the pipeline output if there are any errors in the `scp-management.json` or `rcp-management.json` files. Possible errors

Issue	Solution
	include an incorrect environment name, duplicated SIDs, or invalid fields or values. Do the following: 1. Follow the instructions in [View build details in AWS CodeBuild](). 2. In the build log, find the validation error. The error provides more information about what caused the build to fail. 3. Update the corresponding .json file. 4. Commit and push the updated file to the remote repository. The pipeline restarts. 5. Monitor the status to confirm that the validation error is resolved.

Issue	Solution
IAM Access Analyzer findings in the `Validate-Plan` phase of the pipeline	A "Findings in IAM Access Analyzer during Validation & Plan phase" message appears in the pipeline output if there are any errors in the guardrail or policy definitions. This pattern uses IAM Access Analyzer to validate the final policy. Do the following: 1. Follow the instructions in View build details in AWS CodeBuild. 2. In the build log, find the IAM Access Analyzer validation error. The error provides more information about what caused the build to fail. For more information about the finding types, see IAM policy validation check reference. 3. Update the corresponding .json file for the guardrail or policy. 4. Commit and push the updated file to the remote repository. The pipeline restarts. 5. Monitor the status to confirm that the validation error is resolved.

Related resources

- JSON policy element reference (IAM documentation)
- Resource control policies (AWS Organizations documentation)
- Service control policies (AWS Organizations documentation)
- Add or remove access to Amazon Bedrock foundation models (Amazon Bedrock documentation)
- Approve or reject an approval action in CodePipeline (CodePipeline documentation)

Additional information

Sample resource-based delegation policy

The following is a sample resource-based delegation policy for AWS Organizations. It allows the delegated administer account to manage SCPs and RCPs for the organization. In the following sample policy, replace <MEMBER_ACCOUNT_ID> with the ID of the account where you are deploying the policy management pipeline.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "DelegationToAudit",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<MEMBER_ACCOUNT_ID>:root"
      },
      "Action": [
        "organizations:ListTargetsForPolicy",
        "organizations:CreatePolicy",
        "organizations:DeletePolicy",
        "organizations:AttachPolicy",
        "organizations:DetachPolicy",
        "organizations:DisablePolicyType",
        "organizations:EnablePolicyType",
        "organizations:UpdatePolicy",
        "organizations:DescribeEffectivePolicy",
        "organizations:DescribePolicy",
        "organizations:DescribeResourcePolicy"
      ],
      "Resource": "*"
    }
  ]
}
```

Migrating existing policies to the pipeline

If you have existing SCPs or RCPs that you want to migrate and manage through this pipeline, you can use the Python scripts in the `sample-repository/utils` folder of the code repository. These scripts include:

- `check-if-scp-exists-in-env.py` – This script checks whether a specified policy applies to any targets in a specific environment, which you define in the `environments.json` file. Enter the following command to run this script:

```
python3 check-if-scp-exists-in-env.py \
   --policy-type <POLICY_TYPE> \
   --policy-name <POLICY_NAME> \
   --env-id <ENV_ID>
```

  Replace the following in this command:

  - `<POLICY_TYPE>` is `scp` or `rcp`
  - `<POLICY_NAME>` is the name of the SCP or RCP
  - `<ENV_ID>` is the ID of the environment that you defined in the `environments.json` file

- `create-environments.py` – This script creates an environments.json file based on the current SCPs and RCPs in your environment. It excludes policies deployed through AWS Control Tower. Enter the following command to run this script, where `<POLICY_TYPE>` is `scp` or `rcp`:

```
python create-environments.py --policy-type <POLICY_TYPE>
```

- `verify-policies-capacity.py` – This script checks each environment that you define to determine how much capacity remains for each AWS Organizations policy-related quota. You define the environments to check in the in `environments.json` file. Enter the following command to run this script, where `<POLICY_TYPE>` is `scp` or `rcp`:

```
python verify-policies-capacity.py --policy-type <POLICY_TYPE>
```

Manage AWS IAM Identity Center permission sets as code by using AWS CodePipeline

Andre Cavalcante and Claison Amorim, Amazon Web Services

Summary

AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and applications. You can create and manage user identities in IAM Identity Center, or you can connect an existing identity source, such as a Microsoft Active Directory domain or an external identity provider (IdP). IAM Identity Center provides a unified administration experience to define, customize, and assign fine-grained access to your AWS environment by using permission sets. Permission sets apply to the federated users and groups from your IAM Identity Center identity store or your external IdP.

This pattern helps you to manage IAM Identity Center permission sets as code in your multi-account environment that is managed as an organization in AWS Organizations. With this pattern, you can achieve the following:

- Create, delete, and update permission sets
- Create, update, or delete permission set assignments to target AWS accounts, organizational units (OUs), or your organization root.

To manage IAM Identity Center permissions and assignments as code, this solution deploys a continuous integration and continuous delivery (CI/CD) pipeline that uses AWS CodeBuild and AWS CodePipeline. You manage the permission sets and assignments in JSON templates that you store in a remote repository. When Amazon EventBridge rules detect a change to the repository or detect modifications to the accounts in the target OU, it starts an AWS Lambda function. The Lambda function initiates the CI/CD pipeline that updates the permission sets and assignments in IAM Identity Center.

Prerequisites and limitations

Prerequisites

- A multi-account environment managed as an organization in AWS Organizations. For more information, see Creating an organization.

- IAM Identity Center, enabled and configured with an identity source. For more information, see Getting Started in the IAM Identity Center documentation.
- A member account that is registered as the delegated administrator for the following AWS services:
  - IAM Identity Center – For instructions, see Register a member account in the IAM Identity Center documentation.
  - AWS Organizations – For instructions, see Delegated administrator for AWS Organizations. This account must have permissions to list and describe accounts and OUs.

> **Note**
>
> You must use the same account as the delegated administrator for both services.

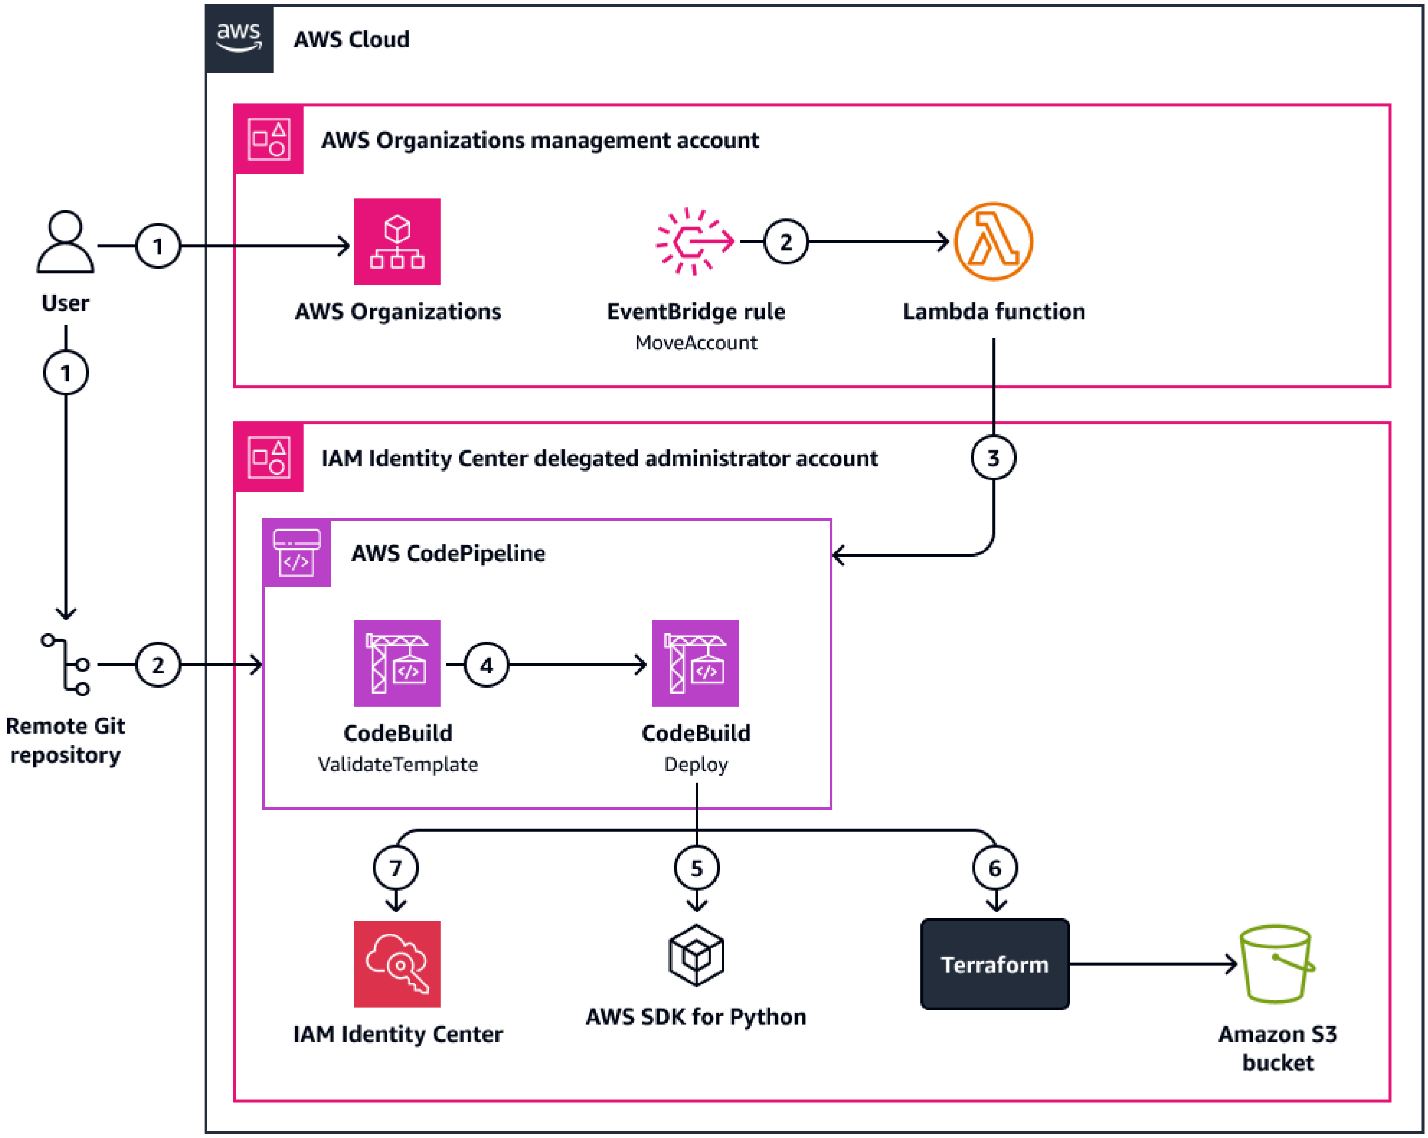
- Permissions to deploy AWS CloudFormation stacks in the IAM Identity Center delegated administrator account and in the organization's management account. For more information, see Controlling access in the CloudFormation documentation.
- An Amazon Simple Storage Service (Amazon S3) bucket in the IAM Identity Center delegated administrator account. You upload the artifact code into this bucket. For instructions, see Creating a bucket in the Amazon S3 documentation.
- The account ID of the organization's management account. For instructions, see Finding your AWS account ID.
- A repository in your source code host, such as GitHub.

Limitations

- This pattern cannot be used to manage or assign permission sets for single-account environments or for accounts that are not managed as an organization in AWS Organizations.
- Permission set names, assignment IDs, and IAM Identity Center principal types and IDs cannot be modified after deployment.
- This pattern helps you create and manage custom permissions. You cannot use this pattern to manage or assign predefined permissions.
- This pattern cannot be used to manage a permission set for the organization's management account.

Architecture

Target architecture



The diagram shows the following workflow:

1. A user makes one of the following changes:
   - Commits one or more changes to the remote repository, such as GitHub
   - Modifies the accounts in the OU in AWS Organizations
2. If the user committed a change to the remote repository to the main branch, the pipeline starts.

   If the user modified the accounts in the OU, then the `MoveAccount` EventBridge rule detects the change and starts a Lambda function in the organization's management account.

3. The initiated Lambda function starts the CI/CD pipeline in CodePipeline.
4. CodePipeline starts the `TemplateValidation` CodeBuild project. The `TemplateValidation` CodeBuild project uses a Python script in the remote repository to validate the permission set templates. CodeBuild validates the following:
   - The permission set names are unique.
   - The assignment statement IDs (`Sid`) are unique.
   - Policy definitions in the `CustomPolicy` parameter and valid. (This validation uses AWS Identity and Access Management Access Analyzer.)
   - The Amazon Resource Names (ARNs) of the managed policies are valid.
5. The `PermissionSet` action group in the `Deploy` CodeBuild project uses AWS SDK for Python (Boto3) to delete, create, or update the permission sets in IAM Identity Center. Only permission sets with the `SSOPipeline:true` tag are affected. All permission sets that are managed through this pipeline have this tag.
6. The `Assignments` action group in the `Deploy` CodeBuild project uses Terraform to delete, create, or update the assignments in IAM Identity Center. The Terraform backend state files are stored in an Amazon S3 bucket in the same account.
7. CodeBuild updates the permissions sets and assignments in IAM Identity Center.

Automation and scale

Because all new accounts in a multi-account environment are moved to a specific organizational unit in AWS Organizations, this solution automatically runs and grants the required permission sets to all accounts that you specify in the assignment templates. No additional automations or scaling actions are necessary.

In large environments, the number of API requests to IAM Identity Center might cause this solution to run more slowly. Terraform and Boto3 automatically manage throttling to minimize any performance degradation.

Tools

AWS services

- [AWS CloudFormation](#) helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and cloud applications.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code repository

The code for this pattern is available in the aws-iam-identity-center-pipeline repository. The templates folder in the repository includes sample templates for both permission sets and assignments. It also includes AWS CloudFormation templates for deploying the CI/CD pipeline and AWS resources in the target accounts.

Best practices

- Before you start modifying the permission set and assignment templates, we recommend that you plan permission sets for your organization. Consider what the permissions should be, which accounts or OUs the permission set should apply to, and which IAM Identity Center principals (users or groups) should be affected by the permission set. Permission set names, association IDs, and IAM Identity Center principal types and IDs cannot be modified after deployment.
- Adhere to the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the AWS Identity and Access Management (IAM) documentation.

Epics

Plan permission sets and assignments

Task	Description	Skills required
Clone the repository.	In a bash shell, enter the following command. This clones the [aws-iam-identity-center-pipeline](https://github.com/aws-samples/aws-iam-identity-center-pipeline) repository from GitHub. `git clone https://github.com/aws-samples/aws-iam-identity-center-pipeline.git`	DevOps engineer
Define the permission sets.	1. In the cloned repository, navigate to the `templates/permissionsets` folder, and then open one of the available templates. 2. In the `Name` parameter, enter a name for the permission set. This value must be unique, and it cannot be changed after deployment. 3. In the `Description` parameter, briefly describe the permission set, such as its use case. 4. In the `SessionDuration` parameter, specify the length of time that a user can be signed in	DevOps engineer

Task	Description	Skills required
	to an AWS account. Use ISO-8601 duration format (Wikipedia), such as PT4H for 4 hours. If no value is defined, the default in IAM Identity Center is 1 hour. 5. In the RelayState parameter, specify the URL that provides quick access to the console that is most appropriate for the user's role. 6. Customize the policies in the permission set. All of the following parameter s are optional and can be modified after deploymen t. You must use at least one of the parameters in order to define the policies in the permission set: • In the ManagedPo licies parameter, enter the ARNs of any AWS managed policies that you want to assign. • In the CustomerM anagedPolicies parameter, enter the names of any customer managed policies that you want to assign. Do not use the ARN.	

Task	Description	Skills required

	• In the `PermissionBoundary` parameter, do the following to assign a [permissions boundary](#):
	  • If you're using an AWS managed policy as a permissions boundary, in `PolicyType`, enter `AWS`, and in `Policy`, enter the ARN of the policy.
	  • If you're using a customer managed policy as a permissions boundary, in `PolicyType`, enter `Customer`, and in `Policy`, enter the name of the policy. Do not use the ARN.
	• In the `CustomPolicy` parameter, define any custom, JSON-formatted policies that you want to assign. For more information about the JSON policy structure, see [Overview of JSON policies](#).
	7. Save and close the permission set template. We recommend that you save the file with a name	

Task	Description	Skills required
	that matches the name of the permission set. 8. Repeat this process to create as many permissions sets as needed for your organization, and delete any sample templates that aren't required.	

Task	Description	Skills required
Define the assignments.	1. In the cloned repository, navigate to the `templates/assignments` folder, and then open `iam-identitycenter-assigments.json` . This file describes how you want to assign the permission sets to AWS accounts or OUs. 2. In the `SID` parameter, enter an identifier for the assignment. This value must be unique, and it cannot be modified after deployment. 3. In the `Target` parameter, define the accounts or organizations where you want to apply the permission set. Valid values are account IDs, OUs, or `root`. `root` assigns the permission set to all member accounts in the organization, excluding the management account. Enter the values in double quotation marks, and separate multiple values with commas. Account IDs and OUs should follow the pattern: `{{account_name}}:{{account_`	DevOps engineer

Task	Description	Skills required
	`id}}` or `{{ou_name}}:{{ou_id}}`. If you want to assign permissions recursively to nested OUs, use the OU pattern with a wildcard at the end. Example: `{{ou_name}}:{{ou_id}}:*` 4. In the `PrincipalType` parameter, enter the type of IAM Identity Center principal that will be affected by the permission set. Valid values are `USER` or `GROUP`. This value cannot be modified after deployment. 5. In the `PrincipalID` parameter, enter the name of the user or group in the IAM Identity Center identity store that will be affected by the permission set. This value cannot be modified after deployment. 6. In the `PermissionSetName` parameter, enter the name of the permission set that you want to assign. 7. Repeat steps 2–6 to create as many assignments as needed in this file. Typically, there is one	

Task	Description	Skills required
	assignment for each permission set. Delete any sample assignments that aren't required. 8. Save and close the `iam-identitycenter-assigments.json` file.	

Deploy the permission sets and assignments

Task	Description	Skills required
Deploy resources in the IAM Identity Center delegated administrator account.	1. In the IAM Identity Center delegated administrator account, open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/). 2. Deploy the `iam-identitycenter-pipeline.yaml` template. Give the stack a clear and descriptive name, and update the parameters as instructed. For instructions, see [Creating a stack](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/cfn-console-create-stack.html) in the CloudFormation documentation.	DevOps engineer
Deploy resources in the AWS Organizations management account.	1. Sign in to the organization's management account. 2. Open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/). 3. In the navigation bar, choose the name of the currently displayed AWS	DevOps engineer

Task	Description	Skills required
	Region. Then choose the `us-east-1` Region. This Region is required so that the `MoveAccount` EventBridge rule can detect AWS CloudTrail events associated with organization changes. 4. Deploy the `iam-identitycenter-organization` template. Give the stack a clear and descriptive name, and update the parameters as instructed. For instructions, see [Creating a stack](#) in the CloudFormation documentation.	
Finish the remote repository setup.	Change the status of the AWS CodeConnections connection from `PENDING` to `AVAILABLE`. This connection was created when you deployed the CloudFormation stack. For instructions, see [Update a pending connection](#) in the CodeConnections documentation.	DevOps engineer

Task	Description	Skills required
Upload files to the remote repository.	Upload all of files you have downloaded from the `aws-samples` repository and edited in previous steps to the remote repository. Changes to the `main` branch start the pipeline, which creates or updates the permission sets and assignments.	DevOps engineer

Updating the permission sets and assignments

Task	Description	Skills required
Update the permission sets and assignments.	When the `MoveAccount` Amazon EventBridge rule detects modifications to the accounts in the organization, the CI/CD pipeline automatically starts and updates the permission sets. For example, if you add an account to an OU specified in the assignments JSON file, then the CI/CD pipeline will apply the permission set to the new account. If you want to modify the deployed permission sets and assignments, update the JSON files and then commit them to the remote repository.	DevOps engineer

Task	Description	Skills required
	Note the following when using the CI/CD pipeline to manage previously deployed permission sets and associati ons: • If you change the name of a permission set, the CI/CD pipeline deletes the original permission set and creates a new one. • This pipeline manages only permission sets that have the `SSOPipeline:true` tag. • You can have multiple permission set and assignment templates in the same folder in the repository. • If you delete a template, the pipeline deletes the assignment or permission set. • If you delete an entire assignment JSON block, the pipeline deletes the assignment from IAM Identity Center. • You can't delete a permissio n set that is assigned to an AWS account. First, you must unassign the permission set.	

Troubleshooting

Issue	Solution
Access denied errors	Confirm that you have the permissions required to deploy the CloudFormation templates and the resources defined within them. For more information, see Controlling access in the CloudFormation documentation.
Pipeline errors in the validation phase	This error appears if there are any errors in the permission set or assignment templates. 1. In CodeBuild, view the build details. 2. In the build log, find the validation error that provides more information about what caused the build to fail. 3. Update the permission set or assignment templates, and then commit them to the repository. 4. The CI/CD pipeline restarts the CodeBuild project. Monitor the status to confirm that the validation error is resolved.

Manage credentials using AWS Secrets Manager

Durga Prasad Cheepuri, Amazon Web Services

Summary

This pattern walks you through using AWS Secrets Manager to dynamically fetch database credentials for a Java Spring application.

In the past, when you created a custom application that retrieves information from a database, you typically had to embed the credentials (the secret) for accessing the database directly in the application. When it was time to rotate the credentials, you had to invest time to update the application to use the new credentials, and then distribute the updated application. If you had multiple applications that shared credentials and you missed updating one of them, the application would fail. Because of this risk, many users chose not to regularly rotate their credentials, which effectively substituted one risk for another.

Secrets Manager enables you to replace hard-coded credentials in your code (including passwords) with an API call to retrieve the secret programmatically. This helps ensure that the secret can't be compromised by someone who is examining your code, because the secret simply isn't there. You can also configure Secrets Manager to automatically rotate the secret according to a schedule that you specify. This enables you to replace long-term secrets with short-term ones, which helps significantly reduce the risk of compromise. For more information, see the AWS Secrets Manager documentation.

Prerequisites and limitations

Prerequisites

- An AWS account with access to Secrets Manager
- A Java Spring application

Architecture

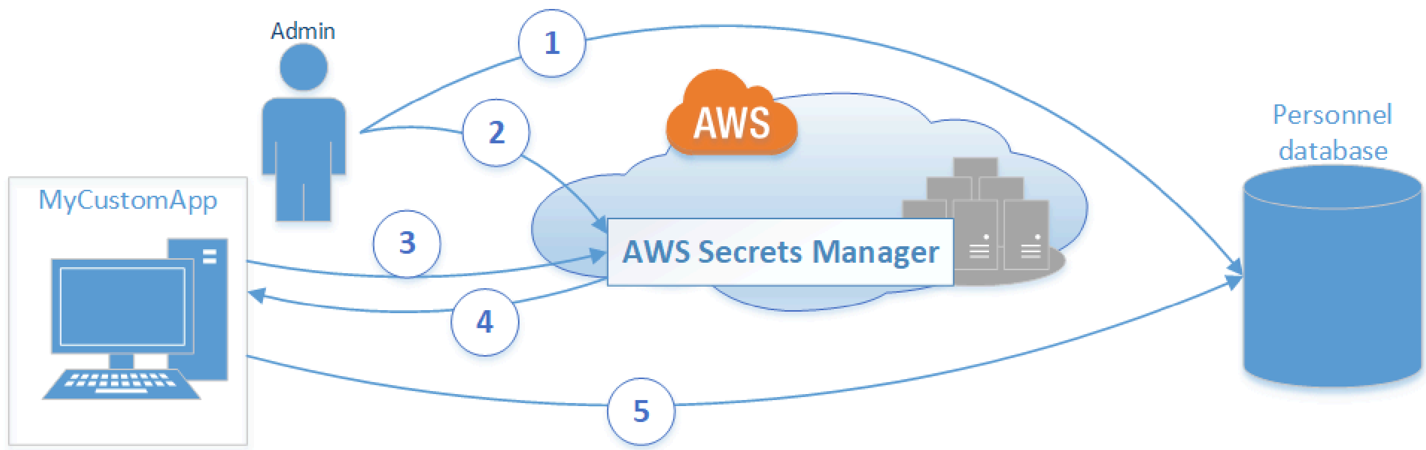
Source technology stack

- A Java Spring application with code that accesses a database, with DB credentials managed from the application.properties file.

Target technology stack

- A Java Spring application with code that accesses a database, with DB credentials managed in Secrets Manager. The application.properties file holds the secrets to Secrets Manager.

Secrets Manager integration with an application



Tools

- **Secrets Manager** – AWS Secrets Manager is an AWS service that makes it easier for you to manage secrets. Secrets can be database credentials, passwords, third-party API keys, and even arbitrary text. You can store and control access to these secrets centrally by using the Secrets Manager console, the Secrets Manager command-line interface (CLI), or the Secrets Manager API and SDKs.

Epics

Store secret in Secrets Manager

Task	Description	Skills required
Store the DB credentials as a secret in Secrets Manager.	Store Amazon Relational Database Service (Amazon RDS) or other DB credentials as a secret in Secrets Manager by following the steps in	Sys Admin

Task	Description	Skills required
	Creating a secret in the Secrets Manager documenta tion.	
Set permissions for the Spring application to access Secrets Manager.	Set the appropriate permissio ns based on how the Java Spring application uses Secrets Manager. To control access to the secret, create a policy based on the information provided in the Secrets Manager documenta tion, in the sections Using identity-based policies (IAM Policies) and ABAC for Secrets Manager and Using resource-based policies for Secrets Manager. Follow the steps in the section Retrieving the secret value in the Secrets Manager documentation.	Sys Admin

Update the Spring application

Task	Description	Skills required
Add JAR dependencies to use Secrets Manager.	See the *Additional informati on* section for details.	Java developer
Add the details of the secret to the Spring application.	Update the application.proper ties file with the secret name, endpoints, and AWS Region. For an example, see the *Additional information* section.	Java developer

Task	Description	Skills required
Update the DB credentials retrieval code in Java.	In the application, update the Java code that fetches the DB credentials to fetch those details from Secrets Manager. For example code, see the *Additional information* section.	Java developer

    String  dbname  =  secretsJson.get("dbname").textValue();
    String  username  =  secretsJson.get("username").textValue();
    String  password  =  secretsJson.get("password").textValue();
}
```

Monitor ElastiCache clusters for security groups

Susanne Kangnoh and Archit Mathur, Amazon Web Services

Summary

Amazon ElastiCache is an Amazon Web Services (AWS) service that provides a high-performance, scalable, and cost-effective caching solution for distributing an in-memory data store or cache environment in the cloud. It retrieves data from high-throughput and low-latency, in-memory data stores. This functionality makes it a popular choice for real-time use cases such as caching, session stores, gaming, geo-spatial services, real-time analytics, and queuing. ElastiCache offers Redis and Memcached data stores, both of which provide sub-millisecond response times.

A *security group* acts as a virtual firewall for your ElastiCache instances by controlling inbound and outbound traffic. Security groups act at the instance level, not at the subnet level. For each security group, you add one set of rules that control the inbound traffic to instances, and a separate set of rules that control the outbound traffic. You can specify allow rules but not deny rules.

This pattern provides a security control that monitors for API calls and generates an event in Amazon CloudWatch Events on the **CreateReplicationGroup**, **CreateCacheCluster**, **ModifyCacheCluster**, and **ModifyReplicationGroup** operations. This event calls an AWS Lambda function, which runs a Python script. The function gets the replication group ID from the event JSON input, and performs the following checks to determine whether there's a security violation:

- Checks if the security group of the cluster matches the security group that's configured in the Lambda function.
- If the security group of the cluster doesn't match, the function sends a violation message to an email address you provide, by using an Amazon Simple Notification Service (Amazon SNS) notification.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code.
- An email address where you would like to receive violation notifications.

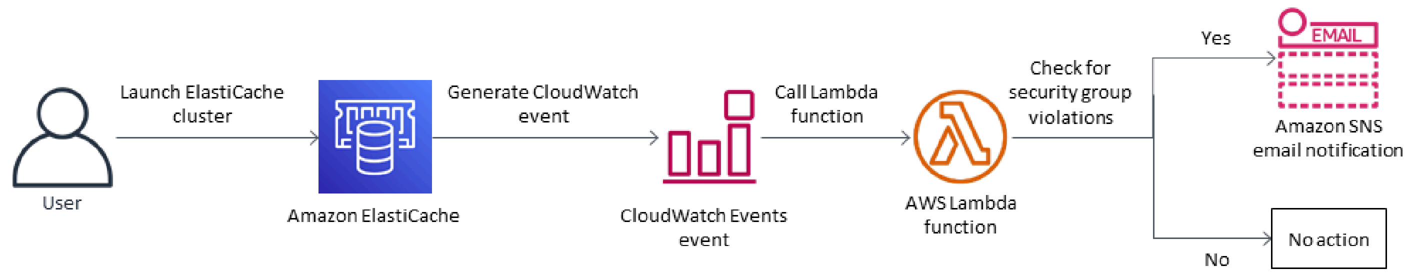
- ElastiCache logging enabled, for access to all the API logs.

Limitations

- This detective control is regional and must be deployed in each AWS Region that you want to monitor.
- The control supports replication groups that are running in a virtual private cloud (VPC).

Architecture

Workflow architecture



Automation and scale

- If you are using AWS Organizations, you can use [AWS CloudFormation StackSets] to deploy this template into multiple accounts that you want to monitor.

Tools

AWS services

- [Amazon ElastiCache] makes it easy to set up, manage, and scale distributed in-memory cache environments in the AWS Cloud. It provides a high performance, resizable, and cost-effective in-memory cache, while removing complexity associated with deploying and managing a distributed cache environment. ElastiCache works with both the Redis and Memcached engines.
- [AWS CloudFormation] helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- [Amazon CloudWatch Events] delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
- [AWS Lambda] is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- [Amazon Simple Notification Service (Amazon SNS)] coordinates and manages the sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

This pattern includes an attachment with two files:

- `ElastiCacheAllowedSecurityGroup.zip` is a compressed file that includes the security control (Lambda code).
- `ElastiCacheAllowedSecurityGroup.yml` is a CloudFormation template that deploys the security control.

See the *Epics* section for information about how to use these files.

Epics

Deploy the security control

Task	Description	Skills required
Upload the code to an S3 bucket.	Create a new S3 bucket or use an existing S3 bucket to upload the attached `ElastiCacheAllowedSecurityGroup.zip` file (Lambda code). This bucket must be in the same AWS	Cloud architect

Task	Description	Skills required
	Region as the resources that you want to evaluate.	
Deploy the CloudFormation template.	Open the CloudFormation console in the same AWS Region as the S3 bucket, and deploy the `ElasticCacheAllowedSecurityControl.yml` file that's provided in the attachment. In the next epic, provide values for the template parameters.	Cloud architect

Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or selected in the first epic. This S3 bucket contains the .zip file for the Lambda code and must be in the same AWS Region as the CloudFormation template and the resource that will be evaluated.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, `ElasticCacheAllowedSecurityGroup.zip` or `controls/ElasticCa`	Cloud architect

Task	Description	Skills required
	cheAllowedSecurity Group.zip).	
Provide an email address.	Provide an active email address where you want to receive violation notifications.	Cloud architect
Specify a logging level.	Specify the logging level and verbosity. `Info` designates detailed informational messages on the application's progress and should be used only for debugging. `Error` designates error events that could still allow the application to continue running. `Warning` designates potentially harmful situations.	Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the email subscription.	When the CloudFormation template deploys successfully, it sends a subscription email message to the email address you provided. To receive notifications, you must confirm this email subscription.	Cloud architect

Monitor Amazon EMR clusters for in-transit encryption at launch

Susanne Kangnoh, Amazon Web Services

Summary

This pattern provides a security control that monitors Amazon EMR clusters at launch and sends an alert if in-transit encryption hasn't been enabled.

Amazon EMR is a web service that makes it easy for you to run big data frameworks, such as Apache Hadoop, to process and analyze data. Amazon EMR enables you to process vast amounts of data in a cost-effective way by running mapping and reducing steps in parallel.

Data encryption prevents unauthorized users from accessing or reading data at rest or data in transit. *Data at rest* refers to data that is stored in media such as a local file system on each node, Hadoop Distributed File System (HDFS), or the EMR File System (EMRFS) through Amazon Simple Storage Service (Amazon S3). *Data in transit* refers to data that travels the network and is in flight between jobs. In-transit encryption supports open-source encryption features for Apache Spark, Apache TEZ, Apache Hadoop, Apache HBase, and Presto. You enable encryption by creating a security configuration from the AWS Command Line Interface (AWS CLI), the console, or AWS SDKs, and specifying the data encryption settings. You can provide the encryption artifacts for in-transit encryption in these two ways:

- By uploading a compressed file of certificates to Amazon S3.
- By referencing a custom Java class that provides encryption artifacts.

The security control that's included with this pattern monitors API calls and generates an Amazon CloudWatch Events event on the **RunJobFlow** action. The event calls an AWS Lambda function, which runs a Python script. The function gets the EMR cluster ID from the event JSON input, and performs the following checks to determine whether there's a security violation:

- Checks if the EMR cluster has an Amazon EMR-specific security configuration.
- If the cluster does have a security configuration, checks to see if encryption in transit is enabled.
- If the cluster doesn't have a security configuration, sends an alert to an email address that you provide, by using Amazon Simple Notification Service (Amazon SNS). The notification specifies

the EMR cluster name, violation details, AWS Region and account information, and the AWS Lambda ARN (Amazon Resource Name) that the notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An S3 bucket to upload the Lambda code that's provided with this pattern.
- An email address where you would like to receive violation notifications.
- Amazon EMR logging enabled, for access to all the API logs.

Limitations

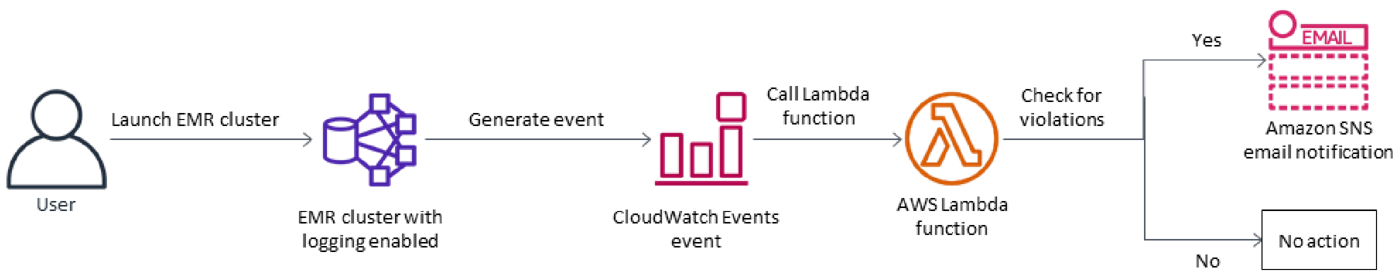
- This detective control is regional and must be deployed in each AWS Region that you want to monitor.

Product versions

- Amazon EMR release 4.8.0 or later.

Architecture

Workflow architecture



Automation and scale

- If you are using AWS Organizations, you can use AWS Cloudformation StackSets to deploy the template in multiple accounts that you want to monitor.

Tools

AWS services

- Amazon EMR – Amazon EMR is a managed cluster platform that simplifies running big data frameworks, such as Apache Hadoop and Apache Spark, on AWS to process and analyze vast amounts of data. By using these frameworks and related open-source projects, you can process data for analytics purposes and business intelligence workloads. Additionally, you can use Amazon EMR to transform and move large amounts of data into and out of other AWS data stores and databases, such as Amazon S3 and Amazon DynamoDB.
- AWS Cloudformation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- AWS Cloudwatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- AWS SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

This pattern includes an attachment with two files:

Monitor Amazon ElastiCache clusters for at-rest encryption

Susanne Kangnoh, Amazon Web Services

Summary

Amazon ElastiCache is an Amazon Web Services (AWS) service that provides a high-performance, scalable, and cost-effective caching solution for distributing an in-memory data store or cache environment in the cloud. It retrieves data from high-throughput and low-latency, in-memory data stores. This functionality makes it a popular choice for real-time use cases such as caching, session stores, gaming, geo-spatial services, real-time analytics, and queuing. ElastiCache offers Redis and Memcached data stores, both of which provide sub-millisecond response times.

Data encryption helps prevent unauthorized users from reading sensitive data available on your Redis clusters and their associated cache storage systems. This includes data saved to persistent media, known as *data at rest*, and data that can be intercepted as it travels through the network between clients and cache servers, known as *data in transit*.

You can enable at-rest encryption for ElastiCache for Redis when you create a replication group, by setting the **AtRestEncryptionEnabled** parameter to **true**. When this parameter is enabled, it encrypts the disk during sync, backup, and swap operations, and encrypts backups stored in Amazon Simple Storage Service (Amazon S3). You cannot enable at-rest encryption on an existing replication group. When you create a replication group, you can enable encryption at rest in these two ways:

- By choosing the **Default** option, which uses service-managed encryption at rest.
- By using a customer managed key and providing the key ID or Amazon Resource Name (ARN) from AWS Key Management Service (AWS KMS).

This pattern provides a security control that monitors for API calls and generates an Amazon CloudWatch Events event on the **CreateReplicationGroup** operation. This event calls an AWS Lambda function, which runs a Python script. The function gets the replication group ID from the event JSON input, and performs the following checks to determine whether there's a security violation:

- Checks if the **AtRestEncryptionEnabled** key exists.
- If **AtRestEncryptionEnabled** exists, checks the value to see if it is **true**.

- If the **AtRestEncryptionEnabled** value is set to **false**, sets a variable that tracks violations and sends a violation message to an email address you provide, by using an Amazon Simple Notification Service (Amazon SNS) notification.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An S3 bucket to upload the provided Lambda code.
- An email address where you would like to receive violation notifications.
- ElastiCache logging enabled, for access to all the API logs.

Limitations

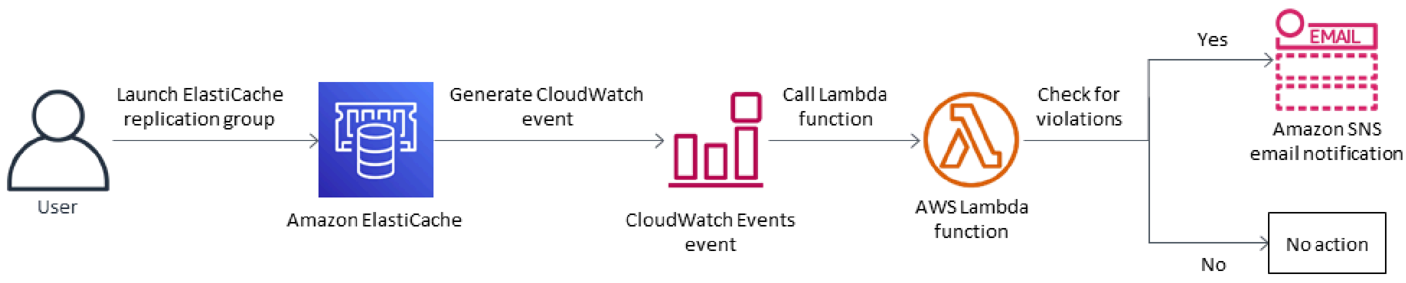
- This detective control is regional and must be deployed in each AWS Region that you want to monitor.
- The control supports replication groups that are running in a virtual private cloud (VPC).
- The control supports replication groups that are running the following node types:
  - R5, R4, R3
  - M5, M4, M3
  - T3, T2

Product versions

- ElastiCache for Redis version 3.2.6 or later

Architecture

Workflow architecture



Automation and scale

Task	Description	Skills required
	`est.yml` file that's provided in the attachment. In the next epic, provide values for the template parameters.	

Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or selected in the first epic. This S3 bucket contains the .zip file for the Lambda code and must be in the same AWS Region as the CloudFormation template and the resource that will be evaluated.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, `ElasticCache-EncryptionAtRest.zip` or `controls/ElasticCache-EncryptionAtRest.zip`).	Cloud architect
Provide an email address.	Provide an active email address where you want to receive violation notifications.	Cloud architect

Task	Description	Skills required
Specify a logging level.	Specify the logging level and verbosity. `Info` designates detailed informational messages on the application's progress and should be used only for debugging. `Error` designates error events that could still allow the application to continue running. `Warning` designates potentially harmful situations.	Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the email subscription.	When the CloudFormation template deploys successfully, it sends a subscription email message to the email address you provided. To receive notifications, you must confirm this email subscription.	Cloud architect

Monitor EC2 instance key pairs using AWS Config

Wassim Benhallam, Sergio Bilbao Lopez, and Vikrant Telkar, Amazon Web Services

Summary

When launching an Amazon Elastic Compute Cloud (Amazon EC2) instance on the Amazon Web Services (AWS) Cloud, a best practice is to create or use an existing key pair to connect to the instance. The key pair, which consists of a public key stored in the instance and a private key provided to the user, allows secure access through Secure Shell (SSH) to the instance and avoids the use of passwords. However, users can sometimes inadvertently launch instances without attaching a key pair. Because key pairs can be assigned only during the launch of an instance, it's important to quickly identify and flag as noncompliant any instances launched without key pairs. This is particularly useful when working in accounts or environments that mandate the use of key pairs for instance access.

This pattern describes how to create a custom rule in AWS Config to monitor EC2 instance key pairs. When instances are identified as noncompliant, an alert is sent using Amazon Simple Notification Service (Amazon SNS) notifications initiated through an Amazon EventBridge event.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Config enabled for the AWS Region you want to monitor and configured to record all AWS resources

Limitations

- This solution is Region-specific. All resources should be created in the same AWS Region.

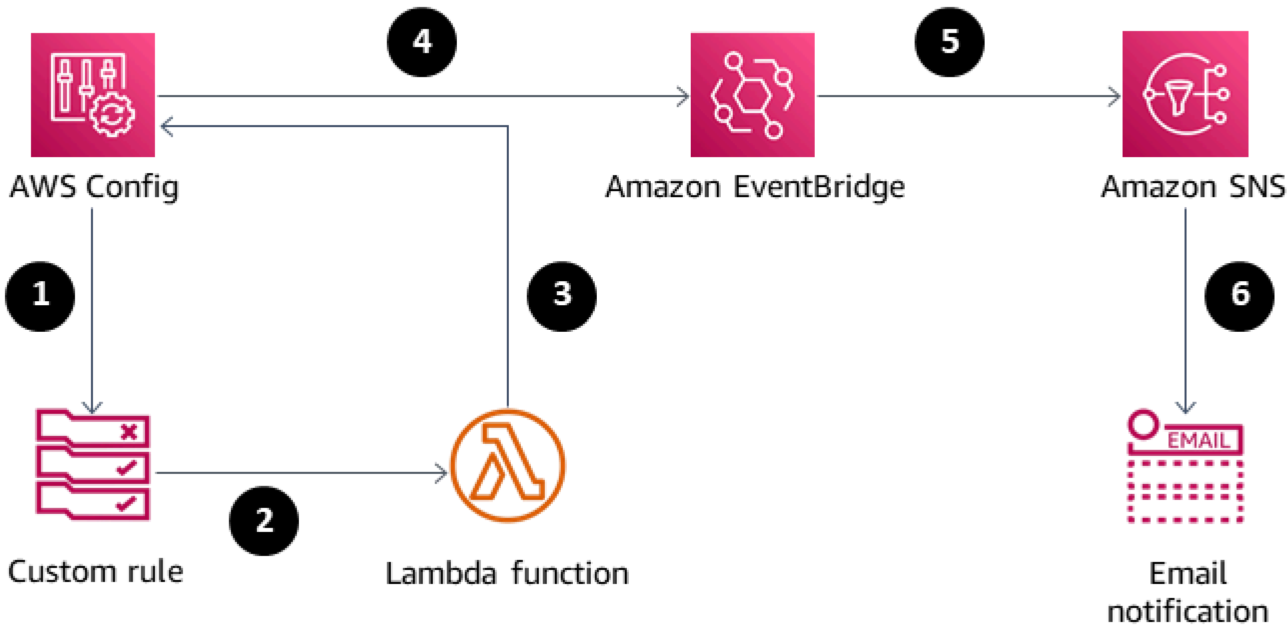
Architecture

Target technology stack

- AWS Config

- Amazon EventBridge
- AWS Lambda
- Amazon SNS

Target architecture



1. AWS Config initiates the rule.
2. The rule invokes the Lambda function to evaluate compliance of EC2 instances.
3. The Lambda function sends the updated compliance state to AWS Config.
4. AWS Config sends an event to EventBridge.
5. EventBridge publishes compliance change notifications to an SNS topic.
6. Amazon SNS sends an alert in email.

Automation and scale

The solution can monitor any number of EC2 instances within a Region.

Tools

Tools

- [AWS Config](#) – AWS Config is a service that enables you to assess, audit, and evaluate the configurations of your AWS resources. AWS Config continuously monitors and records your AWS resource configurations and allows you to automate the evaluation of recorded configurations against desired configurations.
- [Amazon EventBridge](#) – Amazon EventBridge is a serverless event bus service for connecting your applications with data from a variety of sources.
- [AWS Lambda](#) – AWS Lambda is a serverless compute service that supports running code without provisioning or managing servers, creating workload-aware cluster scaling logic, maintaining event integrations, or managing runtimes.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a fully managed messaging service for both application-to-application (A2A) and application-to-person (A2P) communication.

Code

The code for the Lambda function is attached.

Epics

Create a Lambda function to evaluate Amazon EC2 compliance

Task	Description	Skills required
Create an AWS Identity and Access Management (IAM) role for Lambda.	On the AWS Management Console, choose **IAM**, and then create the role, using Lambda as the trusted entity and adding the `AmazonEventBridgeFullAccess` and `AWSConfigRulesExecutionRole` permissions. For more information, see the [AWS documentation](#).	DevOps
Create and deploy the Lambda function.	1. On the Lambda console, create a function, using	DevOps

Task	Description	Skills required
	Author from scratch, with **Python 3.6** as the runtime and the previously created IAM role. Note the Amazon Resource Name (ARN). 2. On the **Code** tab, choose `lambda_function.py` , and paste the code that is attached to this pattern. 3. To save your changes, choose **Deploy**.	

Create a custom AWS Config rule

Task	Description	Skills required
Add a custom AWS Config rule.	On the AWS Config console, add a custom rule, using the following settings: • ARN – The ARN of the previously created Lambda function • Trigger type – Configura tion changes • Scope of changes – Resources • Resource type – Amazon EC2 instance For more information, see the [AWS documentation]().	DevOps

Configure email notifications when a compliance change event is detected

Task	Description	Skills required
Create the SNS topic and subscription.	On the Amazon SNS console, create a topic using **Standard** as the type, and then create a subscription using **Email** as the protocol. When you receive the confirmation email message, choose the link to confirm the subscription. For more information, see the [AWS documentation].	DevOps
Create an EventBridge rule to initiate Amazon SNS notificat ions.	On the EventBridge console, create a rule, using the following settings: • Service name – AWS Config • Event type – Config Rules Compliance Change • Message type – Specific message types, Complianc eChangeNotification • Specific rule name – The name of your previously created AWS Config rule • Target – SNS topic, your previously created topic For more information, see the [AWS documentation].	DevOps

Verify the rule and notifications

Task	Description	Skills required
Create EC2 instances.	Create two EC2 instances of any type and attach a key pair, and create one EC2 instance without a key pair.	DevOps
Verify the rule.	1. On the AWS Config console, on the **Rules** page, select your rule. 2. To see compliant and noncompliant EC2 instances, change **Resources in scope** to **All**. Verify that two instances are listed as compliant and that one instance is listed as noncompliant. 3. Wait to receive Amazon SNS email notification regarding the compliance state of the EC2 instances.	DevOps

Monitor IAM root user activity

Mostefa Brougui, Amazon Web Services

Summary

Every Amazon Web Services (AWS) account has a root user. As a security best practice for AWS Identity and Access Management (IAM), we recommend that you use the root user to complete the tasks that only the root user can perform. For the complete list, see Tasks that require root user credentials in the *AWS Account Management Reference Guide*. Because the root user has full access to all of your AWS resources and billing information, we recommend that you don't use this account and monitor it for any activity, which might indicate that the root user credentials have been compromised.

Using this pattern, you set up an event-driven architecture that monitors the IAM root user. This pattern sets up a hub-and-spoke solution that monitors multiple AWS accounts, the *spoke* accounts, and centralizes management and reporting in a single account, the *hub* account.

When the IAM root user credentials are used, Amazon CloudWatch and AWS CloudTrail record the activity in the log and trail, respectively. In the spoke account, an Amazon EventBridge rule sends the event to the central event bus in the hub account. In the hub account, an EventBridge rule sends the event to an AWS Lambda function. The function uses an Amazon Simple Notification Service (Amazon SNS) topic that notifies you of the root user activity.

In this pattern, you use an AWS CloudFormation template to deploy the monitoring and event-handling services in the spoke accounts. You use a HashiCorp Terraform template to deploy the event-management and notification services in the hub account.

Prerequisites and limitations

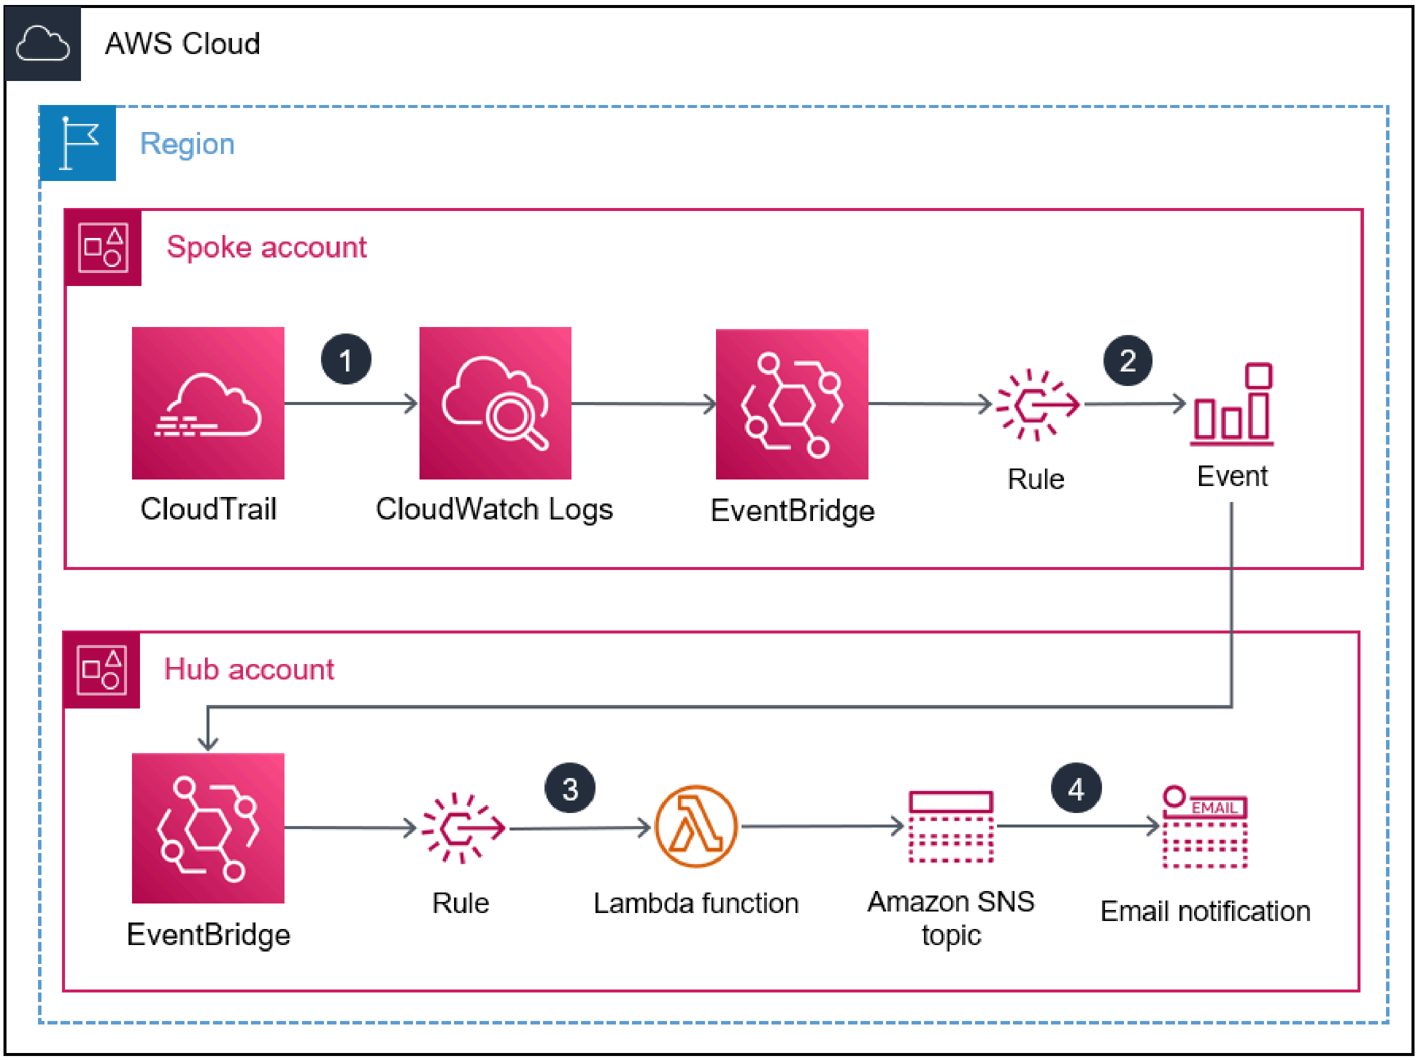
Prerequisites

1. Permissions to deploy AWS resources in your AWS environment.
2. Permissions to deploy CloudFormation stack sets. For more information, see Prerequisites for stack set operations (CloudFormation documentation).
3. Terraform installed and ready to use. For more information, see Get Started – AWS (Terraform documentation).
4. An existing trail in each spoke account. For more information, see Getting started with AWS CloudTrail (CloudTrail documentation).

5. The trail is configured to send events to CloudWatch Logs. For more information, see [Sending events to CloudWatch Logs](#) (CloudTrail documentation).
6. Your hub and spoke accounts must be managed by AWS Organizations.

Architecture

The following diagram illustrates the building blocks of the implementation.



1. When the IAM root user credentials are used, CloudWatch and CloudTrail record the activity in the log and trail, respectively.
2. In the spoke account, an EventBridge rule sends the event to the central [event bus](#) in the hub account.
3. In the hub account, an EventBridge rule sends the event to a Lambda function.

4. The Lambda function uses an Amazon SNS topic that notifies you of the root user activity.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CloudTrail helps you audit the governance, compliance, and operational risk of your AWS account.
- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

Other tools and services

- Terraform is a CLI application for provisioning and managing cloud infrastructure and resources by using code, in the form of configuration files.

Code repository

The source code and templates for this pattern are available in a GitHub repository. This pattern provides two templates:

- A Terraform template containing the resources you deploy in the hub account
- A CloudFormation template you deploy as a stack set instance in the spoke accounts

The repository has the following overall structure.

```
.
 |__README.md
 |__spoke-stackset.yaml
 |__hub.tf
 |__root-activity-monitor-module
     |__main.tf  # contains Terraform code to deploy resources in the Hub account
     |__iam      # contains IAM policies JSON files
         |__ lambda-assume-policy.json          # contains trust policy of the IAM role
 used by the Lambda function
         |__ lambda-policy.json                 # contains the IAM policy attached to
 the IAM role used by the Lambda function
     |__outputs  # contains Lambda function zip code
```

The *Epics* section provides step-by-step instructions for deploying the templates.

Epics

Deploy resources to the hub account

Task	Description	Skills required
Clone the sample code repository.	1. Open the [AWS IAM Root User Activity Monitor](#) repository. 2. On the Code tab, above the file list, choose **Code**, and then copy the HTTPS URL. 3. In a command-line interface, change your working directory to the location where you want to store the sample files. 4. Enter the following command: `git clone <repoURL>`	General AWS

Task	Description	Skills required
Update the Terraform template.	1. Retrieve your organization ID. For instructions, see [Viewing the details of an organization from the management account](#) (AWS Organizations documentation). 2. In the cloned repository, open `hub.tf`. 3. Update the following with the appropriate values for your environment: • `OrganizationId` – Add your organization ID. • `SNSTopicName` – Add a name for the Amazon SNS topic. • `SNSSubscriptions` – Add the email to which Amazon SNS notifications should be sent. • `Region` – Add the AWS Region code where you are deploying the resources. For example, `eu-west-1`. • `Tags` – Add your tags. For more information, see [Tagging AWS resources](#) (AWS General Reference).	General AWS

Task	Description	Skills required
	4. Save and close the `hub.tf` file.	

Deploy the resources to the AWS hub account.	1. In the Terraform command-line interface, navigate to the root folder of the cloned repositor y, and then enter the following command.
	`terraform init && terraform plan`
	2. Review the output and confirm you want to create the resources described.
	3. Enter the following command.
	`terraform apply`
	4. When prompted, confirm the deployment by entering `yes`.
		General AWS

Deploy resources to your spoke accounts

Task	Description	Skills required
Deploy the CloudFormation template.	1. Sign in to the AWS Management Console, and open the [CloudFormation console](https://console.aws.amazon.com/cloudformation/). 2. From the navigation pane, choose **StackSets**.	General AWS

Task	Description	Skills required
	3. At the top of the **StackSets** page, choose **Create StackSet**. 4. Under **Permissions**, choose **Service-managed permissions**. CloudFormation automatically configures the permissions required to deploy to the target accounts managed by AWS Organizations. 5. Under **Prerequisite - Prepare template**, choose **Template is ready**. 6. Under **Specify Template**, choose **Upload a template file**. 7. Choose **Choose file**, and then in the cloned repository, select `spoke-stackset.yaml` . 8. Choose **Next**. 9. On the **Specify StackSet details** page, enter a name for the stack set. 10. Under **Parameters**, enter the account ID of the hub account, and then choose **Next.** 11. On the **Configure StackSet options** page, under **Tags**, add your tags.	

Task	Description	Skills required
	12. Under **Execution configuration**, choose **Inactive**, and then choose **Next.** 13. On the **Set deployment options** page, specify the organizational units and Regions where you want to deploy the stack set, then choose **Next**. 14. On the Review page, select **I acknowledge that AWS CloudFormation might create IAM resources**, and then choose **Submit**. CloudFormation starts deploying your stack set. For more information and instructions, see Create a stack set (CloudFormation documentation).	

(Optional) Test the notifications

Task	Description	Skills required
Use the root user credentials.	1. Sign into a spoke account or the hub account by using the root user credentials. 2. Confirm that the email account you specified	General AWS

Task	Description	Skills required
	receives the Amazon SNS notification.	

Related resources

- Security best practices (IAM documentation)
- Working with StackSets (CloudFormation documentation)

Additional information

Amazon GuardDuty is a continuous security monitoring service that analyzes and processes logs to identify unexpected and potentially unauthorized activity in your AWS environment. As an alternative to this solution, if you have enabled GuardDuty, it can alert you when the root user credentials have been used. The GuardDuty finding is `Policy:IAMUser/RootCredentialUsage`, and the default severity is **Low**. For more information, see Managing Amazon GuardDuty findings.

Send a notification when an IAM user is created

Mansi Suratwala and Sergiy Shevchenko, Amazon Web Services

Summary

On Amazon Web Services (AWS), you can use this pattern to deploy an AWS CloudFormation template to receive notifications automatically when AWS Identity and Access Management (IAM) users are created.

Using IAM, you can manage access to AWS services and resources securely. You can create and manage AWS users and groups, and use permissions to allow and deny those users and groups access to AWS resources.

The CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event uses AWS CloudTrail to monitor for any IAM user being created in the AWS account. If a user is created, the CloudWatch Events event initiates a Lambda function, which sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the new user creation event.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An AWS CloudTrail trail created and deployed

Limitations

- The AWS CloudFormation template must be deployed for `CreateUser` only.

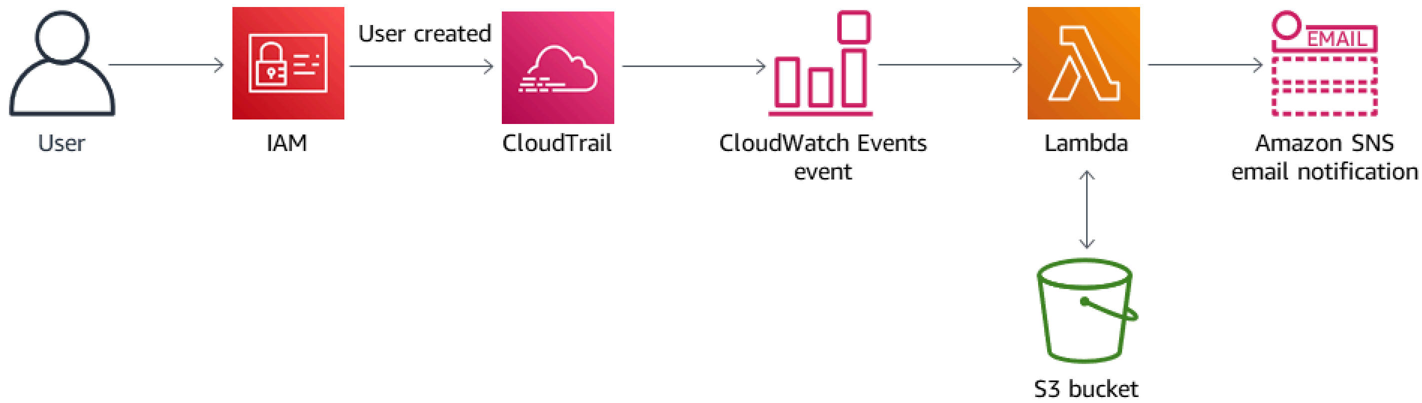
Architecture

Target technology stack

- IAM
- AWS CloudTrail
- Amazon CloudWatch Events

- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)
- Amazon SNS

Target architecture



Automation and scale

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run it only once in each Region or account. To automate deployment to multiple accounts, use AWS CloudFormation StackSets. The CloudFormation template will be able to deploy all the required resources in each account.

Tools

Tools

- IAM – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- AWS CloudFormation – AWS CloudFormation helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS. You create a template that describes all the AWS resources that you want, and CloudFormation takes care of provisioning and configuring those resources for you.
- AWS CloudTrail – AWS CloudTrail helps you manage governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are

recorded as events in CloudTrail. Events include actions taken in the AWS Management Console, AWS Command Line Interface, and AWS SDKs and APIs.

- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery using Lambda, HTTP, email, mobile push notifications, and mobile text messages (SMS).

Code

A .zip file of the project is available as an attachment.

Epics

Create the S3 bucket for the Lambda script

Task	Description	Skills required
Define the S3 bucket.	Open the Amazon S3 console, and choose or create an S3 bucket. This S3 bucket will host the Lambda code .zip file. The S3 bucket name cannot contain leading slashes.	Cloud architect

Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code.	Upload the Lambda code .zip file provided in the *Attachments* section to the S3 bucket that you defined.	Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	On the CloudFormation console, deploy the CloudFormation `createIAM user.yaml` template that's provided as an attachment to this pattern. In the next epic, provide values for the template parameters.	Cloud architect

Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or chose in the first epic.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example,	Cloud architect

Task	Description	Skills required
	`<directory>/<file-name>.zip`).	
Provide an email address.	Provide an active email address to receive Amazon SNS notifications.	Cloud architect
Define the logging level.	Define the logging level and frequency for your Lambda function. `Info` designates detailed informational messages on the application's progress. `Error` designates error events that could still allow the application to continue running. `Warning` designates potentially harmful situations.	Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the template successfully deploys, it sends a subscription email message to the email address provided. To receive notifications, you must confirm this email subscription.	Cloud architect

Prevent internet access at the account level by using a service control policy

Sergiy Shevchenko, Sean O'Sullivan, and Victor Mazeo Whitaker, Amazon Web Services

Summary

Organizations frequently want to limit internet access for account resources that should remain private. In these accounts, the resources in virtual private clouds (VPCs) should not access the internet by any means. Many organizations choose a centralized inspection architecture. For the east-west (VPC-to-VPC) traffic in a centralized inspection architecture, you need to make sure that the spoke accounts and their resources do not have access to the internet. For north-south (internet egress and on-premises) traffic, you want to allow internet access only through the inspection VPC.

This pattern uses a service control policy (SCP) to help prevent internet access. You can apply this SCP at the account or organizational unit (OU) level. The SCP limits internet connectivity by preventing the following:

- Creating or attaching an IPv4 or IPv6 internet gateway that allows direct internet access to the VPC
- Creating or accepting a VPC peering connection that might allow indirect internet access through another VPC
- Creating or updating an AWS Global Accelerator configuration that might allow direct internet access to VPC resources

Prerequisites and limitations

Prerequisites

- One or multiple AWS accounts managed as an organization in AWS Organizations.
- All features are enabled in AWS Organizations.
- SCPs are enabled in the organization.
- Permissions to:
  - Access the organization's management account.
  - Create SCPs. For more information about the minimum permissions, see Creating an SCP.

- Attach the SCP to the target accounts or organizational units (OUs). For more information about the minimum permissions, see Attaching and detaching service control policies.

Limitations

- SCPs don't affect users or roles in the management account. They affect only the member accounts in your organization.
- SCPs affect only AWS Identity and Access Management (IAM) users and roles that are managed by accounts that are part of the organization. For more information, see SCP effects on permissions.

Tools

AWS services

- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage. In this pattern, you use service control policies (SCPs) in AWS Organizations.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Best practices

After establishing this SCP in your organization, make sure to update it frequently to address any new AWS services or features that might affect internet access.

Epics

Create and attach the SCP

Task	Description	Skills required
Create the SCP.	1. Sign in to the AWS Organizations console. You must sign in to the	AWS administrator

Task	Description	Skills required

	organization's managemen t account.
	2. In the left pane, choose **Policies**.
	3. On the policies page, choose **Service control policies**.
	4. On the **Service control policies** page, choose **Create policy**.
	5. On the **Create new service control policy** page, enter a **Policy name** and an optional **Policy descripti on**.
	6. (Optional) Add [AWS tags](#) to your policy.
	7. In the JSON editor, delete the placeholder policy.
	8. Paste the following policy into the JSON editor.
	<pre>{
	  "Version":
	 "2012-10-17",
	  "Statement": [
	    {
	      "Action": [
	        "ec2:Atta
	chInternetGateway",
	        "ec2:Crea
	teInternetGateway",
	
	        "ec2:Crea
	teVpcPeeringConnec
	tion",</pre>	

Task	Description	Skills required

	<pre> "ec2:Acce
	ptVpcPeeringConnec
	tion",
	        "ec2:Crea
	teEgressOnlyIntern
	etGateway"
	      ],
	      "Resource":
	 "*",
	      "Effect": "Deny"
	    },
	    {
	      "Action": [
	        "globalac
	celerator:Create*",
	        "globalac
	celerator:Update*"
	      ],
	      "Resource":
	 "*",
	      "Effect": "Deny"
	    }
	  ]
	}</pre>9. Choose **Create policy**.	

Task	Description	Skills required
Attach the SCP.	1. On the **Service control policies** page, choose the policy you created. 2. On the **Targets** tab, choose **Attach**. 3. Select the OU or account that you want to attach the policy to. You might have to expand the OUs to find the OU or account that you want. 4. Choose **Attach policy**.	AWS administrator

Export a report of AWS IAM Identity Center identities and their assignments by using PowerShell

Jorge Pava, Frank Allotta, Manideep Reddy Gillela, and Chad Miles, Amazon Web Services

Summary

When you use AWS IAM Identity Center (successor to AWS Single Sign-On) to centrally manage single sign-on (SSO) access to all of your Amazon Web Services (AWS) accounts and cloud applications, reporting and auditing those assignments through the AWS Management Console can be tedious and time consuming. This is especially true if you're reporting on permissions for a user or group across dozens or hundreds of AWS accounts.

For many, the ideal tool to view this information would be in a spreadsheet application, such as Microsoft Excel. This can help you filter, search, and visualize the data for your entire organization, managed by AWS Organizations.

This pattern describes how to use AWS Tools for PowerShell to generate a report of SSO identity configurations in IAM Identity Center. The report is formatted as a CSV file, and it includes the identity name (principal), identity type (user or group), accounts the identity can access, and permission sets. After generating this report, you can open it in your preferred application to search, filter, and audit the data as needed. The following image shows sample data in a spreadsheet application.

AccountName	PermissionSet	Principal	Type
Audit	SecurityAudit	AWSAuditAccountAdmins	GROUP
Log Archive	AWSPowerUserAccess	AWSSecurityAuditPowerUsers	GROUP
Dev-Test	AWSAdministratorAccess	dev-Users	GROUP
Prod	AWSReadOnlyAccess	Prod@example.com	USER

Important: Because this report contains sensitive information, we highly recommend you store it securely and share it only on a need-to-know basis.

Prerequisites and limitations

Prerequisites

- IAM Identity Center and AWS Organizations, configured and enabled.

- PowerShell, installed and configured. For more information, see Installing PowerShell (Microsoft documentation).
- AWS Tools for PowerShell, installed and configured. For performance reasons, we highly recommend that you install the modularized version of AWS Tools for PowerShell, called `AWS.Tools`. Each AWS service is supported by its own individual, small module. In the PowerShell shell, enter the following commands to install the modules needed for this pattern: `AWS.Tools.Installer`, `Organizations`, `SSOAdmin`, and `IdentityStore`.

```
Install-Module AWS.Tools.Installer
Install-AWSToolsModule -Name Organizations, SSOAdmin, IdentityStore
```

  For more information, see Install AWS.Tools on Windows or Install AWS.Tools on Linux or macOS (AWS Tools for PowerShell documentation). If you receive an error when installing the modules, see the Troubleshooting section of this pattern.
- AWS Command Line Interface (AWS CLI) or the AWS SDK must be previously configured with working credentials by doing one of the following:
  - Use the AWS CLI `aws configure` For more information, see Quick configuration (AWS CLI documentation).
  - Configure AWS CLI or AWS Cloud Development Kit (AWS CDK) to get temporary access through an AWS Identity and Access Management (IAM) role. For more information, see Getting IAM role credentials for CLI access (IAM Identity Center documentation).
- A named profile for the AWS CLI that has saved credentials for an IAM principal that:
  - Has access to the AWS Organizations management account or the delegated administrator account for IAM Identity Center
  - Has the `AWSSSOReadOnly` and `AWSSSODirectoryReadOnly` AWS managed policies applied to it

  For more information, see Using named profiles (AWS CLI documentation) and AWS managed policies (IAM documentation).

Limitations

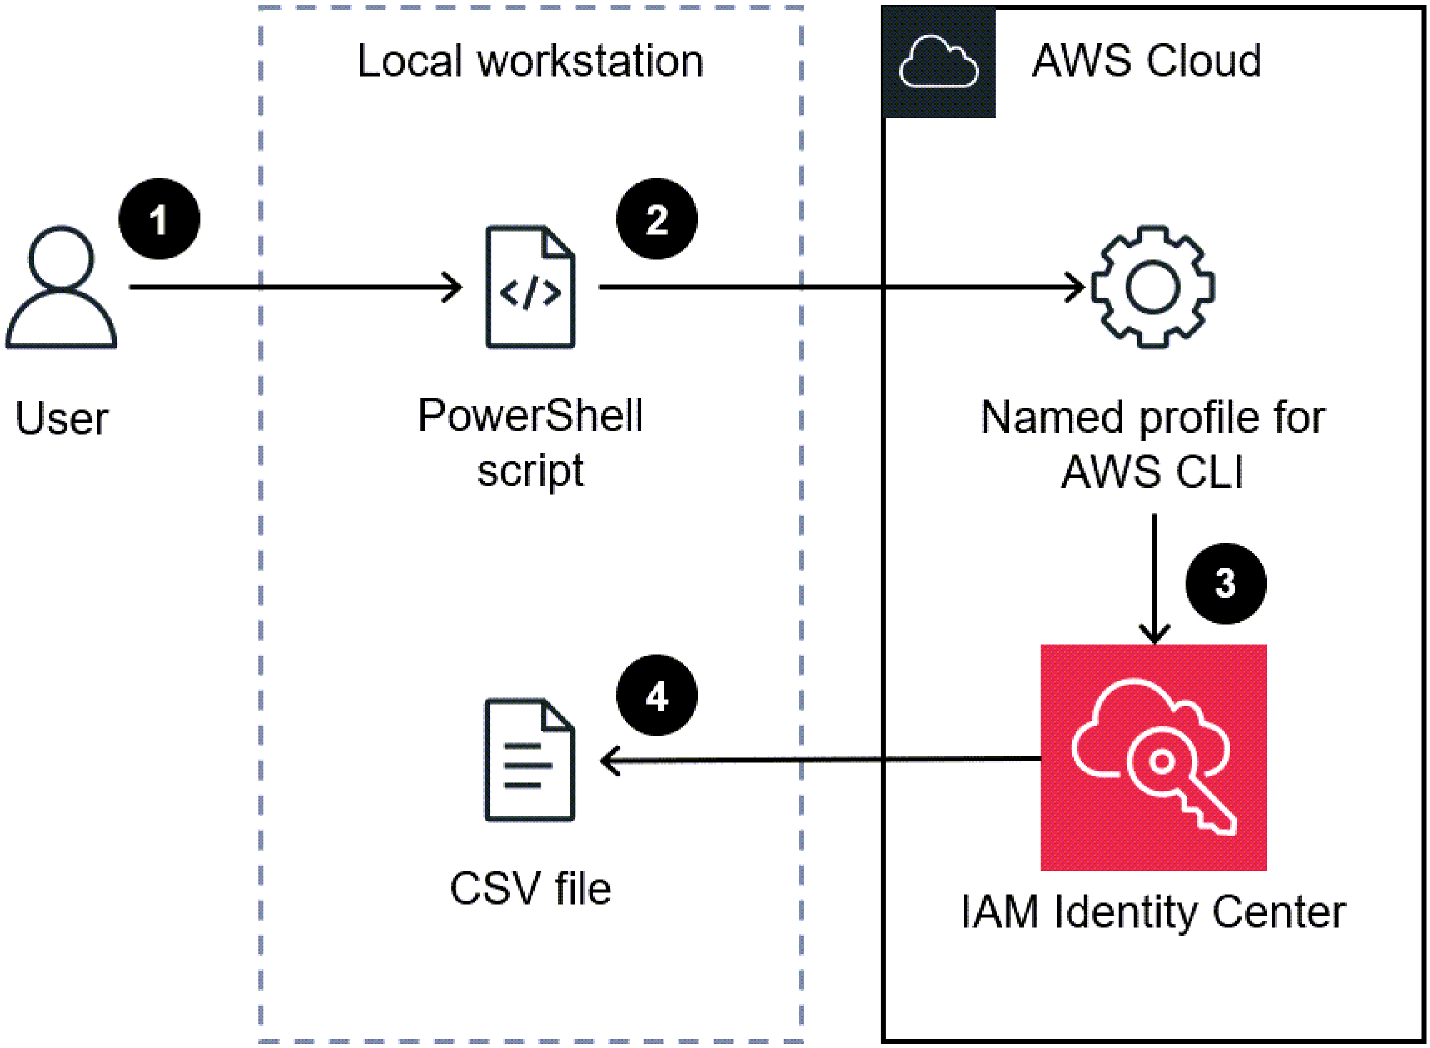
- The target AWS accounts must be managed as an organization in AWS Organizations.

Product versions

- For all operating systems, it is recommended that you use [PowerShell version 7.0]() or later.

Architecture

Target architecture



1. The user runs the script in a PowerShell command line.
2. The script assumes the named profile for AWS CLI. This grants access to IAM Identity Center.
3. The script retrieves the SSO identity configurations from IAM Identity Center.
4. The script generates a CSV file in the same directory on the local workstation where the script is saved.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and cloud applications.
- AWS Tools for PowerShell are a set of PowerShell modules that help you script operations on your AWS resources from the PowerShell command line.

Other tools

- PowerShell is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.

Epics

Generate the report

Task	Description	Skills required
Prepare the script.	1. Copy the PowerShell script in the Additional information section of this pattern. 2. In the `Param` section, for your AWS environment, define the values for the following variables: • `OutputFile` – The file name of the report. • `ProfileName` – The AWS CLI named profile that you want to use to generate the report.	Cloud administrator

Task	Description	Skills required
	• `Region` – The AWS Region in which IAM Identity Center is deployed. For a complete list of Regions and their codes, see [Regional endpoints](). 3. Save the script with the file name `SSO-Report.ps1` .	

Run the script.	It is recommended that you run your custom script in the PowerShell shell with the following command.
	`.\SSO-Report.ps1`
	Alternatively, you can run the script from another shell by entering the following command.
	`pwsh .\SSO-Report.ps1`
	The script generates a CSV file in the same directory as the script file.
		Cloud administrator

Task	Description	Skills required
Analyze report data.	The output CSV file has the headers **AccountName**, **PermissionSet**, **Principal**, and **Type**. Open this file in your preferred spreadsheet application. You can create a data table to filter and sort the output.	Cloud administrator

Troubleshooting

Issue	Solution

`The term ‘Get-<parameter>’ is not recognized as the name of a cmdlet, function, script file, or operable program.` error	AWS Tools for PowerShell or its modules are not installed. In the PowerShell shell, enter the following commands to install AWS Tools for PowerShell and the modules needed for this pattern: `AWS.Tools.Installer`, `Organizations`, `SSOAdmin`, and `IdentityStore`.
	`Install-Module AWS.Tools.Installer`
	`Install-AWSToolsModule -Name Organizations, SSOAdmin, IdentityStore`

`No credentials specified or obtained from persisted/shell defaults` error	In *Prepare the script* in the [Epics](#) section, confirm that you have correctly entered the `ProfileName` and `Region` variables. Make sure that the settings and credentials in the named profile have sufficient permissions to administer IAM Identity Center.

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td><code>Authenticode Issuer …</code> error when installing the AWS.Tools modules</td><td>Add the <code>-SkipPublisherCheck</code> parameter to the end of the <code>Install-AWSToolsModule</code> command.</td></tr>
<tr><td><code>Get-ORGAccountList : Assembly AWSSDK.SSO could not be found or loaded.</code> error</td><td>This error can occur when named AWS CLI profiles are specified, AWS CLI is configured to authenticate users with IAM Identity Center, and AWS CLI is configured to automatically retrieve refreshed authentication tokens. To resolve this error, do the following:

1. Enter the following command to confirm that the SSO and SSOOIDC modules are installed.
<pre><code>Install-AWSToolsModule SSO, SSOOIDC</code></pre>2. Insert the following lines into the script below the <code>param()</code> block.
<pre><code>Import-Module AWS.Tools.SSO</code></pre><pre><code>Import-Module AWS.Tools.SSOOIDC</code></pre></td></tr>
</table>

Related resources

- Where are configuration settings stored? (AWS CLI documentation)
- Configuring the AWS CLI to use AWS IAM Identity Center (AWS CLI documentation)
- Using named profiles (AWS CLI documentation)

Additional information

In the following script, determine whether you need to update the values for the following parameters:

- If you're using a named profile in AWS CLI to access the account in which IAM Identity Center is configured, update the `$ProfileName` value.
- If IAM Identity Center is deployed in a different AWS Region than the default Region for your AWS CLI or AWS SDK configuration, update the `$Region` value to use the Region where IAM Identity Center is deployed.
- If neither of these situations apply, then no script update is required.

```

Restrict access based on IP address or geolocation by using AWS WAF

Louis Hourcade, Amazon Web Services

Summary

AWS WAF is a web application firewall that helps protect web applications and APIs against common web exploits and bots that can affect availability, compromise security, or consume excessive resources. Web access control lists (web ACLs) in AWS WAF give you control over how traffic reaches your applications. In a web ACL, you add rules or rule groups that are designed to permit legitimate traffic, control bot traffic, and block common attack patterns. For more information, see How AWS WAF works.

You can associate the following types of rules to your AWS WAF web ACLs:

- Managed rule groups – AWS Managed Rules teams and AWS Marketplace sellers offer preconfigured sets of rules. Some managed rule groups are designed to help protect specific types of web applications. Others offer broad protection against known threats or common vulnerabilities.
- Custom rules and custom rule groups – You can also create rules and rule groups that customize access to your web applications and APIs. For example, you can restrict traffic based on a specific list of IP addresses or on a list of countries.

By using this pattern and the associated code repository, you can use the AWS Cloud Development Kit (AWS CDK) to deploy AWS WAF web ACLs with custom rules. These rules restrict access to web application resources based on the end user's IP address or geolocation. You can also optionally attach several managed rule groups.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Permissions to deploy AWS WAF resources
- AWS CDK, installed and configured in your account
- Git, installed

Limitations

- You can use this pattern only in AWS Regions where AWS WAF is available. For Region availability, see AWS services by Region.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS WAF is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources.

Code repository

The code for this pattern is available in the GitHub IP and geolocation restriction with AWS WAF repository. The code deploys two AWS WAF web ACLs. The first is a regional web ACL that is intended for Amazon API Gateway resources. The second is global web ACL for Amazon CloudFront resources. Both web ACLs contain the following custom rules:

- `IPMatch` blocks requests from non-allowed IP addresses.
- `GeoMatch` blocks requests from non-allowed countries.

During deployment, you can optionally attach all of the following managed rule groups to your web ACLs:

- Core rule set (CRS) – This rule group contains rules that are generally applicable to web applications. It helps protect against exploitation of a wide range of vulnerabilities, including some of the high risk and commonly occurring vulnerabilities described in OWASP publications, such as OWASP Top 10.
- Admin protection – This rule group contains rules that help you block external access to exposed administrative pages.
- Known bad inputs – This rule group helps block request patterns that are known to be invalid and are associated with the exploitation or discovery of vulnerabilities.

- Amazon IP reputation list – This rule group contains rules that are based on Amazon internal threat intelligence. It helps you block IP addresses that are typically associated with bots or other threats.
- Linux operating system managed rule group – This rule group helps block request patterns that are associated with the exploitation of Linux vulnerabilities, including Linux-specific Local File Inclusion (LFI) attacks.
- SQL database managed rule group – This rule group helps block request patterns that are associated with the exploitation of SQL databases, such as SQL injection attacks.

Epics

Configure the AWS WAF web ACLs

Task	Description	Skills required
Clone the repository.	Enter the following command to clone the IP and geolocation restriction with AWS WAF repository to your local workstation: `git clone https://github.com/aws-samples/ip-and-geolocation-restriction-with-waf-cdk.git`	Git

Configure the rules.	1. In the cloned repository, open the **app.py** file.
	2. Modify the values of the following variables to customize the rules:
	`aws_acccount = "AWS_ACCOUNT"`
	`region = "AWS_REGION"`
		General AWS, Python

Task	Description	Skills required

	<pre>ip_list = ["CIDR_RANGE_1", "CIDR_RANGE_2"]
	geo_list = ["COUNTRY_CODE_1", "COUNTRY_CODE_2"]
	aws_managed_rules = True</pre> Where: `aws_account` is the ID of the target AWS account. `region` is the target AWS Region for the web ACL for API Gateway resources. **Note** The web ACL for CloudFront resources is global and will be deployed in the `us-east-1` Region. `ip_list` is the list of CIDR ranges that are allowed access. `geo_list` is the list of countries that are allowed access. For valid values, see the AWS WAF documentation.	

Task	Description	Skills required
	• `aws_managed_rules` controls whether the managed rule groups are added to the web ACL. If this value is `True`, they are added. If this value is `False`, they are excluded. 3. Save and close the **app.py** file.	

Bootstrap and deploy the code

Task	Description	Skills required
Bootstrap your AWS environment.	If not already done, you need to [bootstrap](#) your AWS environment before you can deploy the AWS CDK applicati on. 1. In the AWS CDK CLI, enter the following command to bootstrap the `us-east-1` Region: `cdk bootstrap aws://<account-id>/us-east-1` 2. If you're deploying the web ACL for API Gateway in a Region other than `us-east-1` , enter the following command to	General AWS

Task	Description	Skills required
	bootstrap the target Region: ```cdk bootstrap aws://<account-id>/<region>```	
Deploy the AWS CDK application.	1. Enter the following command to deploy the AWS CDK application: ```cdk deploy --all``` 2. Wait until the AWS CloudFormation stack deployment is complete.	General AWS

Validate the deployment

Task	Description	Skills required
Confirm that the web ACLs successfully deployed.	1. Sign in to the AWS Management Console, and then open the [AWS WAF console](https://console.aws.amazon.com/wafv2/). 2. In the navigation pane, choose **Web ACLs**. 3. In the list of AWS Regions, choose **Global (CloudFront)**. 4. Verify that the new CloudFront web ACL was deployed, and confirm that it has the IP address	General AWS

Task	Description	Skills required
	and geolocation rules that you defined. The default name of this web ACL is `WebACLCloudfront-<ID>` . 5. In the list of AWS Regions, choose the Region in which you deployed the stack. 6. Verify that a new web ACL for API Gateway resources was deployed. Confirm that it has the IP address and geolocation rules that you defined. The default name of this web ACL is `WebACLApiGW-<ID>` .	
(Optional) Associate the web ACLs to your resources.	Associate the AWS WAF web ACLs with your AWS resources , such as an Application Load Balancer, API Gateway, or CloudFront distribution. For instructions, see Associating or disassociating a web ACL with an AWS resource. For an example, see class CfnWebACLAssociation (construct) in the AWS CDK documentation.	General AWS

Clean up resources

Task	Description	Skills required
Delete the stacks.	1. Disassociate the web ACL from any AWS resources . For instructions, see the AWS WAF documentation. 2. In the AWS CDK CLI, enter the following command to delete the AWS CDK application. `cdk destroy --all`	General AWS

Related resources

Scan Git repositories for sensitive information and security issues by using git-secrets

Saurabh Singh, Amazon Web Services

Summary

This pattern describes how to use the open-source git-secrets tool from AWS Labs to scan Git source repositories and find code that might potentially include sensitive information, such as user passwords or AWS access keys, or that has any other security issues.

`git-secrets` scans commits, commit messages, and merges to prevent sensitive information such as secrets from being added to your Git repositories. For example, if a commit, commit message, or any commit in a merge history matches one of your configured, prohibited regular expression patterns, the commit is rejected.

Prerequisites and limitations

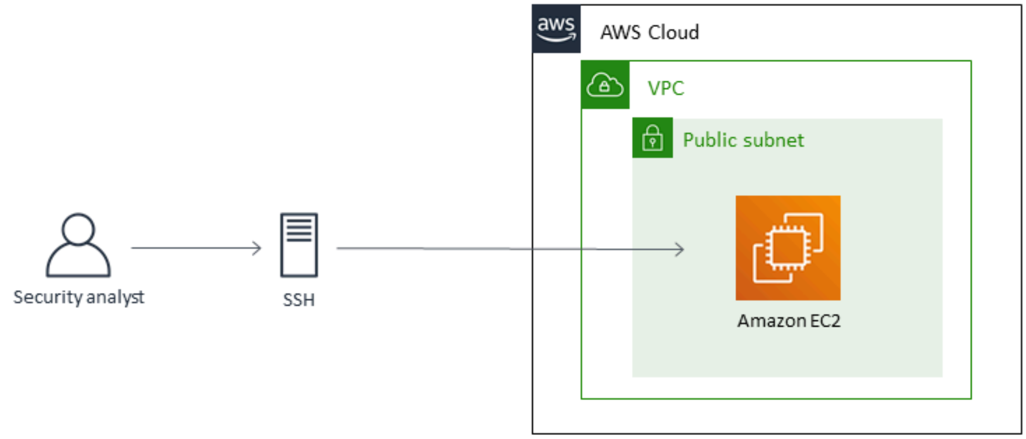
Prerequisites

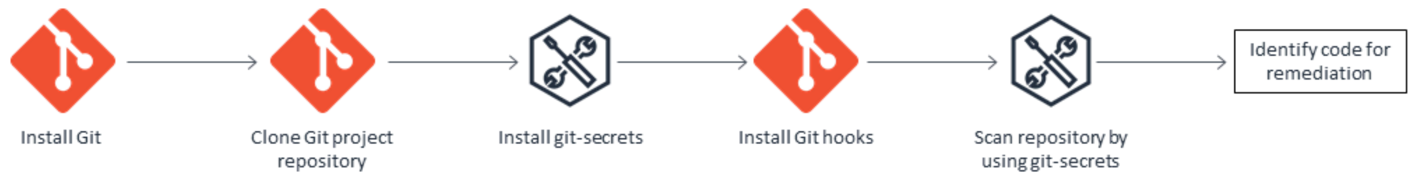
- An active AWS account
- A Git repository that requires a security scan
- A Git client (version 2.37.1 and later) installed

Architecture

Target architecture

- Git
- `git-secrets`





Tools

- git-secrets is a tool that prevents you from committing sensitive information into Git repositories.
- Git is an open-source distributed version control system.

Best practices

- Always scan a Git repository by including all revisions:

```
git secrets --scan-history
```

Epics

Connect to an EC2 instance

Task	Description	Skills required
Connect to an EC2 instance by using SSH.	Connect to an Amazon Elastic Compute Cloud (Amazon EC2) instance by using SSH and a key pair file. You can skip this step if you are scanning a repository on your local machine.	General AWS

Install Git

Task	Description	Skills required
Install Git.	Install Git by using the command: `yum install git -y` If you are using your local machine, you can install a Git client for a specific OS version. For more informati on, see the [Git website]().	General AWS

Clone the source repository and install git-secrets

Task	Description	Skills required
Clone the Git source repositor y.	To clone the Git repository that you want to scan, choose	General AWS

Task	Description	Skills required
	the **Git clone** command from your home directory.	
Clone git-secrets.	Clone the `git-secrets` Git repository. `git clone https://github.com/awslabs/git-secrets.git` Place `git-secrets` somewhere in your `PATH` so that Git picks it up when you run `git-secrets` .	General AWS

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install git-secrets.</td><td>

For Unix and variants (Linux/macOS):

You can use the <code>install</code> target of the <code>Makefile</code> (provided in the <code>git-secrets</code> repository) to install the tool. You can customize the installation path by using the <code>PREFIX</code> and <code>MANPREFIX</code> variables.

<pre><code>make install</code></pre>

For Windows:

Run the PowerShell <code>install.ps1</code> script provided in the <code>git-secrets</code> repository. This script copies the installation files to an installation directory (<code>%USERPROFILE%/.git-secrets</code> by default) and adds the directory to the current user PATH.

<pre><code>PS > ./install.ps1</code></pre>

For Homebrew (macOS users):

Run:

</td><td>General AWS</td></tr>
</table>

Task	Description	Skills required
	`brew install git-secrets`	

Scan git code repository

Task	Description	Skills required
Go to the source repository.	Switch to the directory for the Git repository that you want to scan: `cd my-git-repository`	General AWS
Register the AWS rule set (Git hooks).	To configure `git-secrets` to scan your Git repository on each commit, run the command: `git secrets --register-aws`	General AWS
Scan the repository.	Run the following command to start scanning your repository: `git secrets --scan`	General AWS
Review the output file.	The tool generates an output file if it finds a vulnerability in your Git repository. For example:	General AWS

Task	Description	Skills required
	``` example.sh:4:AWS_S ECRET_ACCESS_KEY = ********* [ERROR] Matched one or more prohibited patterns Possible mitigations: - Mark false positives as allowed using: git config --add secrets.a llowed ... - Mark false positives as allowed by adding regular expressions to .gitallowed at repository's root directory - List your configure d patterns: git config --get-all secrets.p atterns - List your configure d allowed patterns: git config --get-all secrets.allowed - List your configure d allowed patterns in .gitallowed at repository's root directory - Use --no-verify if this is a one-time false positive ```

Secure file transfers by using Transfer Family, Amazon Cognito, and GuardDuty

Manoj Kumar, Amazon Web Services

Summary

This solution helps you securely transfer files through an SFTP server by using AWS Transfer Family. It includes automated malware scanning capabilities through [Malware Protection for S3](), a feature of Amazon GuardDuty. It is designed for organizations that need to securely exchange files with external parties and validate that all incoming files are scanned for malware before being processed.

The infrastructure as code (IaC) templates provided with this pattern help you deploy the following:

- A secure SFTP server with Amazon Cognito authentication through AWS Lambda
- Amazon Simple Storage Service (Amazon S3) buckets for uploads and incoming files that have been scanned for malware
- A virtual private cloud (VPC)-based architecture with public and private subnets across multiple Availability Zones
- IP-based access control for both ingress and egress traffic, with configurable allow and deny lists
- Automated malware scanning through GuardDuty
- Intelligent file routing based on scan results through Amazon EventBridge and Lambda
- Real-time notifications for security incidents through Amazon Simple Notification Service (Amazon SNS)
- Encryption for Amazon S3 buckets and Lambda environment variables through AWS Key Management Service (AWS KMS)
- Amazon Virtual Private Cloud (Amazon VPC) endpoints for access without internet exposure
- Comprehensive logging through Amazon CloudWatch integration

Prerequisites and limitations

Prerequisites

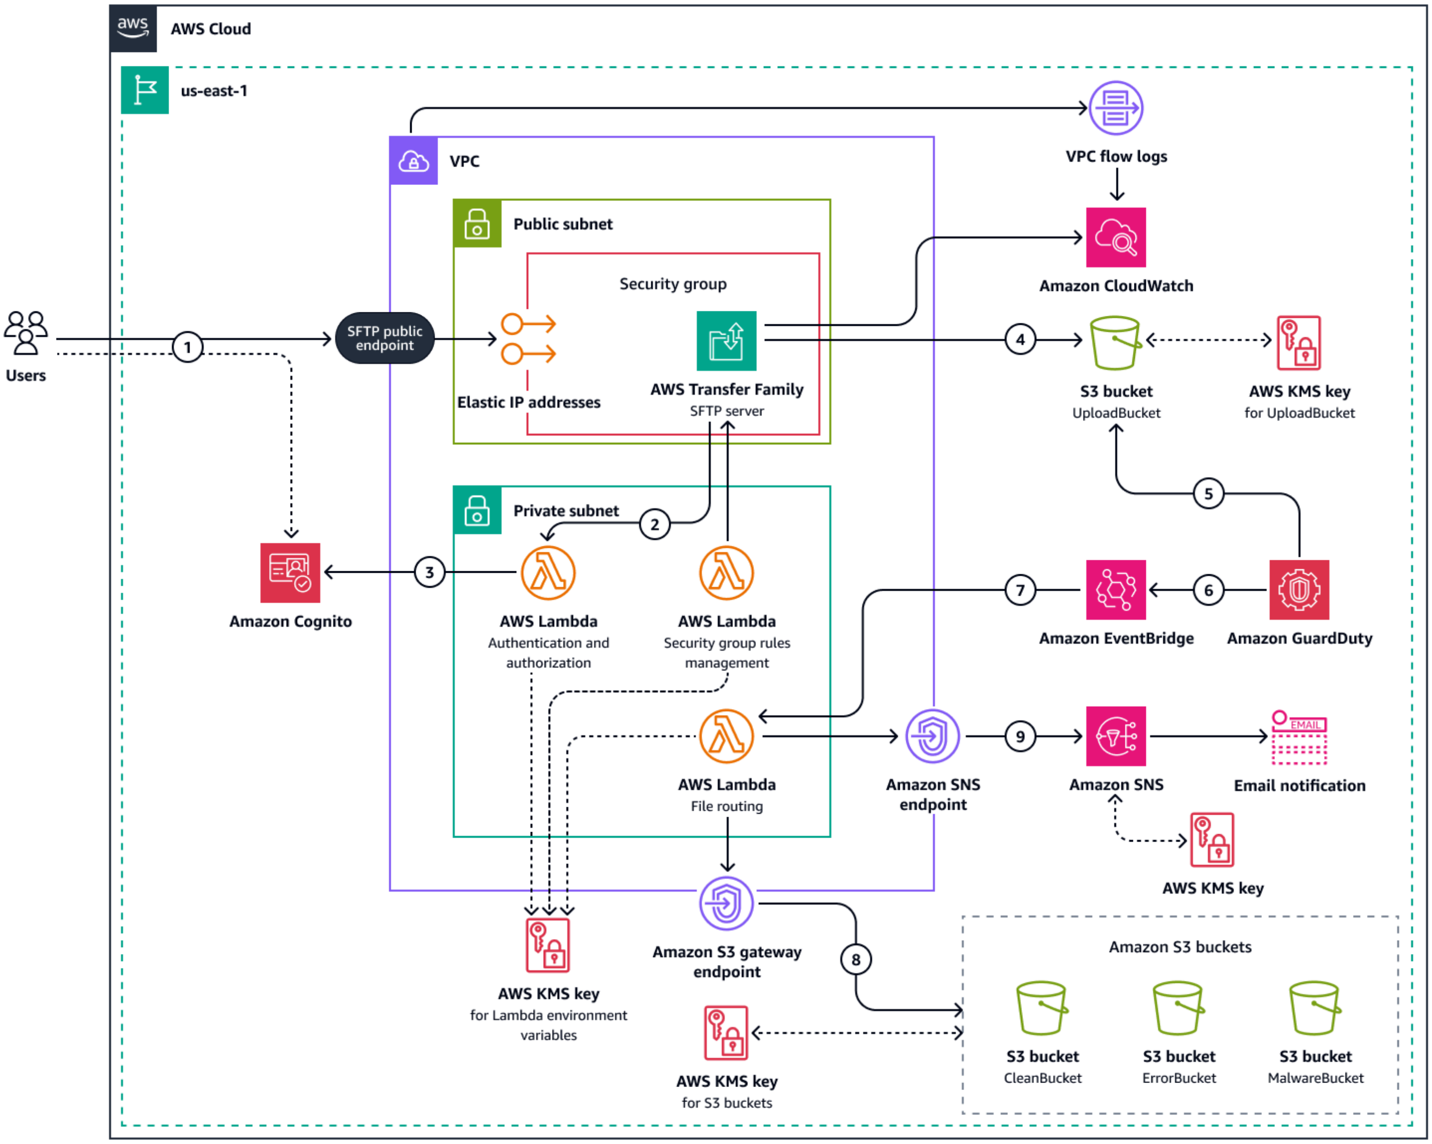
- An active AWS account
- Permissions in AWS Identity and Access Management (IAM) to perform the actions described in this pattern, including deploying AWS CloudFormation templates that provision IAM roles
- GuardDuty, enabled in the target account
- Malware Protection for S3, enabled in the target account
- Service quotas allow you to create the following in the target account:
  - One VPC
  - One private subnet
  - One public subnet
  - Three elastic IP addresses
  - Sufficient Lambda concurrency limits
- A valid email address for security-related notifications
- (Optional) A list of IP addresses or CIDR ranges that you want to allow or deny
- (Optional) AWS Command Line Interface (AWS CLI), installed and configured

Limitations

- Malware Protection for S3 is subject to quotas, such as maximum file sizes. For more information, see Quotas in Malware Protection for S3 and Supportability of Amazon S3 features in the GuardDuty documentation.
- This solution uses Amazon Cognito username and password authentication only. Certificate-based or other authentication methods are not supported in this template. By default, this solution does not configure multi-factor authentication (MFA).
- The solution implements IP-based access control through security groups only.

Architecture

The following architecture diagram shows the resources that are deployed in this pattern. This solution uses Amazon Cognito for user authentication and authorization. An AWS Transfer Family SFTP server is used for file uploads. Files are stored in Amazon S3 buckets, and Amazon GuardDuty scans the files for malware. Amazon SNS sends an email notification if malware is detected.



The diagram shows the following workflow:

1. A user connects to the SFTP server endpoint in AWS Transfer Family. This initiates the authentication process with the Amazon Cognito user pool.
2. A Lambda function initiates the authentication and authorization process and validates the user's credentials with Amazon Cognito.
3. The Lambda function returns the `UploadBucket` Amazon S3 bucket as the home directory. The user assumes the IAM role for the Transfer Family server, and the Lambda function notifies the user that they have been successfully authenticated.
4. The user uploads a file to the Transfer Family SFTP server. The file is stored in the `UploadBucket` Amazon S3 bucket.

5. GuardDuty scans the file for malware. The potential scan results are `NO_THREATS_FOUND`, `THREATS_FOUND`, `UNSUPPORTED`, `ACCESS_DENIED`, and `FAILED`. For sample results, see [S3 object scan result](#) in the GuardDuty documentation.
6. An EventBridge rule detects the scan result event.
7. EventBridge initiates the file-routing Lambda function.
8. The Lambda function processes the event and filters the files based on the scan results as follows:
   - Files that have a `NO_THREATS_FOUND` scan result are sent to the `CleanBucket` Amazon S3 bucket.
   - Files that have a `THREATS_FOUND` scan result are sent to the `MalwareBucket` Amazon S3 bucket.
   - Files that have an `UNSUPPORTED` scan result are sent to the `ErrorBucket` Amazon S3 bucket.
   - Files that have an `ACCESS_DENIED` scan result are sent to the `ErrorBucket` Amazon S3 bucket.
   - Files that have a `FAILED` scan result are sent to the `ErrorBucket` Amazon S3 bucket.

   All files are encrypted with an AWS KMS key.
9. If a file was sent to the `MalwareBucket` Amazon S3 bucket, the Lambda function initiates an Amazon SNS topic. The Amazon SNS topic sends an email notification to an email address that you configure.

Tools

AWS services

- [Amazon CloudWatch](#) helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- [Amazon Cognito](#) provides authentication, authorization, and user management for web and mobile apps.
- [Amazon EventBridge](#) is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- [Amazon GuardDuty](#) is a continuous security monitoring service that analyzes and processes logs to identify unexpected and potentially unauthorized activity in your AWS environment.

- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Transfer Family helps you transfer files into and out of AWS storage services over the SFTP, FTPS, or FTP protocols.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Code repository

The code for this pattern is available in the GitHub AWS Transfer Family and GuardDuty Malware Scanning Solution repository.

Best practices

The CloudFormation template provided is designed to incorporate many AWS best practices, such as least-privilege permissions for IAM roles and policies, encryption at rest and in transit, and automatic key rotation. For production environments, consider implementing the following additional recommendations:

- Enable MFA for Amazon Cognito users
- Implement AWS Shield for distributed denial of service (DDoS) protection
- Configure AWS Config for continuous compliance monitoring
- Implement AWS CloudTrail for comprehensive API logging
- Set up Amazon GuardDuty for threat detection beyond malware scanning
- Implement AWS Security Hub for centralized security management

- Use AWS Secrets Manager for credential management
- Implement network traffic monitoring with Traffic Mirroring
- Configure Amazon Macie for sensitive data discovery and protection in Amazon S3
- Implement regular security assessments and penetration testing
- Establish a formal incident response plan
- Implement automated patching for all components
- Conduct regular security training for administrators
- Set up AWS Organizations for multi-account security management

Epics

Deploy the resources

Task	Description	Skills required
Clone the repository.	Enter the following command to clone the AWS Transfer Family and GuardDuty malware scanning solution repository to your local workstation: `git clone https://github.com/aws-samples/sample-secure-transfer-family-code.git`	App developer, DevOps engineer
Create the CloudFormation stack.	1. Follow the instructions in the CloudFormation documentation to create a stack through the CloudFormation console or through the AWS CLI. Configure the following parameters:	Cloud administrator, DevOps engineer

Task	Description	Skills required
	• `UploadBucketName` - Upload bucket name • `CleanBucketName` - Clean files bucket name • `MalwareBucketName` - Malware files bucket name • `ErrorBucketName` - Error files bucket name • `SecurityTeamEmail` - Email address for alerts • `VpcCIDR` - CIDR range for VPC • `PublicSubnet1CIDR` - CIDR range for public subnet 1 • `PublicSubnet2CIDR` - CIDR range for public subnet 2 • `PrivateSubnet1CIDR` - CIDR range for private subnet 1 • `PrivateSubnet2CIDR` - CIDR range for private subnet 2 • `AllowedIPAddresses` - Allowed IP addresses or CIDR ranges • `EnableEgressRules` – If you want to enable egress rules for security groups, enter `true`.	

Task	Description	Skills required
	If you want disable the egress rules, enter `false`. 2. Wait for the stack deployment to complete. 3. In the stack creation outputs, make note of the SFTP server endpoint. You need this value later.	

Configure the resources

Task	Description	Skills required
Turn on malware protection.	1. Sign in to the AWS Management Console and open the [GuardDuty console](https://console.aws.amazon.com/guardduty/). 2. In the navigation pane, choose **Malware Protection for S3**. 3. In the **Protected buckets** section, choose **Enable**. 4. Under **Enter S3 bucket details**, enter the **Amazon S3 bucket** name. Alternatively, choose **Browse S3** to select a bucket. Choose the `UploadBucket` Amazon S3 bucket. 5. Under **Prefix**, select **All the objects in the S3 bucket**.	Cloud administrator, AWS administrator

Task	Description	Skills required
	6. Under **Tag scanned objects**, select **Tag objects**. 7. In the **Service access** section, choose **Create and use a new service role**. 8. Choose **Enable**.	
Add users to the user pool.	Add one or more users to the Amazon Cognito user pool. For instructions, see [Managing users in your user pool](#) in the Amazon Cognito documentation.	Cloud administrator, AWS administrator

Test the SFTP server

Task	Description	Skills required
Connect to the SFTP server endpoint.	1. Enter the following command to get the SFTP server endpoint, where `<stack-name>` is the name of your CloudFormation stack: `TRANSFER_ENDPOINT=$(aws cloudformation describe-stacks \ --stack-name <stack-name> \ --query 'Stacks[0].Outputs[?OutputKey==`TransferServerEndpoint`].OutputValue' \`	App developer, Cloud administrator, Cloud architect, DevOps engineer

Task	Description	Skills required

	`--output text)`
	2. Enter the following command to connect to the SFTP server:
	`sftp user@company.com@$TRANSFER_ENDPOINT`
	3. Validate that you receive the following prompt:
	`sftp>`
	This indicates that you can now enter commands to perform file transfers.	

Troubleshooting

Issue	Solution
User authentication fails	1. Verify that the user exists in the Amazon Cognito user pool. 2. Validate that the user is confirmed and enabled. 3. Make sure the user is providing the correct password. 4. Check for errors in CloudWatch Logs. For a list of AWS CLI commands that can help you perform these troubleshooting steps, see

Issue	Solution
	Useful commands for troubleshooting in the Additional information section.
SFTP authentication fails	1. Verify that the user exists in the Amazon Cognito user pool. 2. Validate that the user is confirmed and enabled. 3. Make sure the user is providing the correct password. 4. Verify that the IP address is allowed in the security group for the AWS Transfer Family server. 5. Check for errors in the logs for the authentication Lambda function. 6. Verify that the IAM role for AWS Transfer Family has correct permissions. For a list of AWS CLI commands that can help you perform these troubleshooting steps, see *Useful commands for troubleshooting* in the Additional information section.

Issue	Solution
File upload access denied	1. Verify that the AWS KMS key permissions are properly configured. 2. Check the Amazon S3 bucket policies. 3. Confirm that the IAM role permissions are properly configured. 4. Verify that the VPC endpoints are properly configured 5. Verify that the IAM role for AWS Transfer Family has correct permissions. For a list of AWS CLI commands that can help you perform these troubleshooting steps, see *Useful commands for troubleshooting* in the [Additional information] section.
No malware scanning	1. Enable GuardDuty in your account. 2. Enable Malware Protection for S3. 3. Verify that the Amazon EventBridge rule is active. 4. Check for errors in the logs for the file-rout ing Lambda function. 5. Verify that notifications are configured correctly in Amazon SNS. For a list of AWS CLI commands that can help you perform these troubleshooting steps, see *Useful commands for troubleshooting* in the [Additional information] section.

Issue	Solution
Lambda function errors	1. Check the VPC configuration. 2. Verify that the VPC endpoints are properly configured. 3. Verify that the IAM role for AWS Transfer Family has correct permissions. 4. Check for errors in CloudWatch Logs. 5. Verify that the AWS KMS key permissions are properly configured. For a list of AWS CLI commands that can help you perform these troubleshooting steps, see *Useful commands for troubleshooting* in the [Additional information](#) section.

Additional information

Useful commands for troubleshooting

Check the status of a CloudFormation stack:

```
aws cloudformation describe-stacks \
  --stack-name <STACK_NAME>
```

List all users in an Amazon Cognito user pool:

```
aws cognito-idp list-users \
  --user-pool-id <USER_POOL_ID>
```

View logs for Lambda functions:

```
aws logs describe-log-groups \
  --log-group-name-prefix /aws/lambda/
```

Check the status of GuardDuty:

```
aws guardduty list-detectors
```

Check security group rules:

```
aws ec2 describe-security-groups \
  --group-ids <SECURITY_GROUP_ID> \
  --output table
```

Check the status of the AWS Transfer Family server:

```
aws transfer describe-server \
  --server-id <SERVER_ID>
```

List all files in an Amazon S3 bucket:

```
aws s3 ls s3://<BUCKET_NAME>/ \
  --recursive
```

Check the status of an EventBridge rule:

```
aws events describe-rule \
  --name <RULE_NAME>
```

Send alerts from AWS Network Firewall to a Slack channel

Venki Srivatsav and Aromal Raj Jayarajan, Amazon Web Services

Summary

This pattern describes how to deploy a firewall by using Amazon Web Services (AWS) Network Firewall with the distributed deployment model and how to propagate the alerts generated by AWS Network Firewall to a configurable Slack channel.

Compliance standards such as Payment Card Industry Data Security Standard (PCI DSS) require that you install and maintain a firewall to protect customer data. In the AWS Cloud, a virtual private cloud (VPC) is considered the same as a physical network in the context of these compliance requirements. You can use Network Firewall to monitor network traffic between VPCs and to protect your workloads that run in VPCs governed by a compliance standard. Network Firewall blocks access or generates alerts when it detects unauthorized access from other VPCs in the same account. However, Network Firewall supports a limited number of destinations for delivering the alerts. These destinations include Amazon Simple Storage Service (Amazon S3) buckets, Amazon CloudWatch log groups, and Amazon Data Firehose delivery streams. Any further action on these notifications requires offline analysis by using either Amazon Athena or Amazon Kinesis.

This pattern provides a method for propagating alerts that are generated by Network Firewall to a configurable Slack channel for further action in near real time. You can also extend the functionality to other alerting mechanisms such as PagerDuty, Jira, and email. (Those customizations are outside the scope of this pattern.)

Prerequisites and limitations

Prerequisites

- Slack channel (see Getting started in the Slack help center)
- Required privileges to send a message to the channel
- The Slack endpoint URL with an API token (select your app and choose an incoming webhook to see its URL; for more information, see Creating an Incoming Webhook in the Slack API documentation)
- An Amazon Elastic Compute Cloud (Amazon EC2) test instance in the workload subnets
- Test rules in Network Firewall

- Actual or simulated traffic to trigger the test rules
- An S3 bucket to hold the source files to be deployed

Limitations

- Currently this solution supports only a single Classless Inter-Domain Routing (CIDR) range as a filter for source and destination IPs.

Architecture

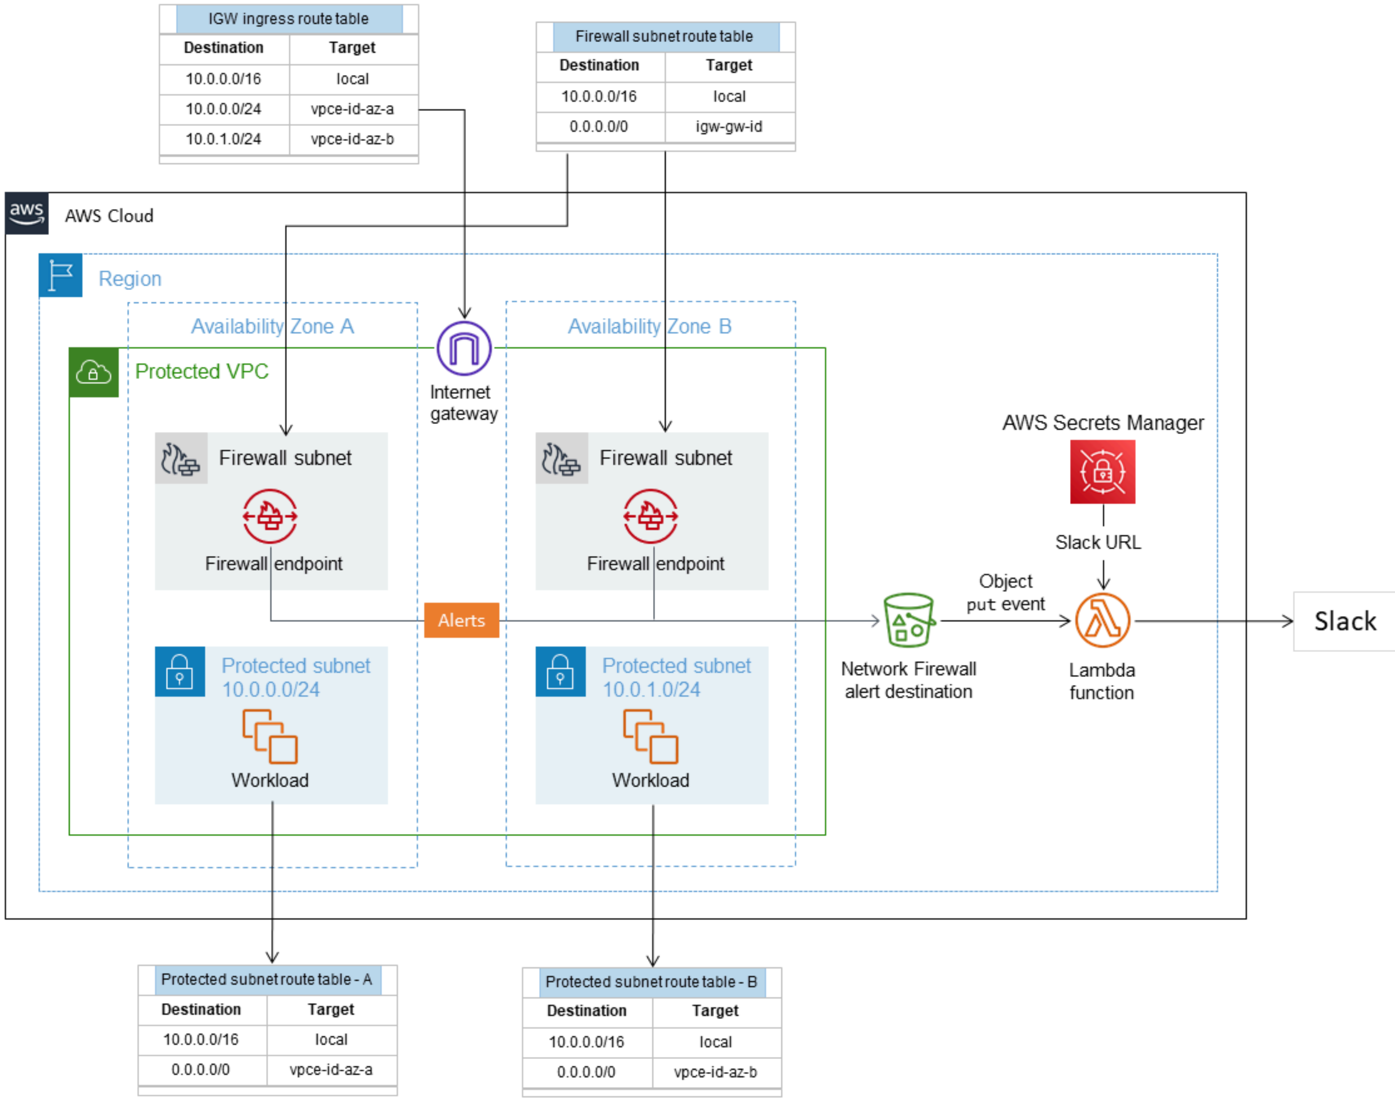
Target technology stack

- One VPC
- Four subnets (two for the firewall and two for workloads)
- Internet gateway
- Four route tables with rules
- S3 bucket used as an alert destination, configured with a bucket policy and event settings to run a Lambda function
- Lambda function with an execution role, to send Slack notifications
- AWS Secrets Manager secret for storing the Slack URL
- Network firewall with alert configuration
- Slack channel

All components except for the Slack channel are provisioned by the CloudFormation templates and the Lambda function that are provided with this pattern (see the [Code](#)section).

Target architecture

This pattern sets up a decentralized network firewall with Slack integration. This architecture consists of a VPC with two Availability Zones. The VPC includes two protected subnets and two firewall subnets with network firewall endpoints. All traffic going into and out of the protected subnets can be monitored by [creating firewall policies](#) and rules. The network firewall is configured to place all alerts in an S3 bucket. This S3 bucket is configured to call a Lambda function when it receives a `put` event. The Lambda function fetches the configured Slack URL from Secrets Manager and sends the notification message to the Slack workspace.



For more information about this architecture, see the AWS blog post [Deployment models for AWS Network Firewall](#).

Tools

AWS services

- [AWS Network Firewall](#) is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud. You can use Network Firewall to filter traffic at the perimeter of your VPC and protect your workloads on AWS.
- [AWS Secrets Manager](#) is a service for credential storage and retrieval. Using Secrets Manager, you can replace hardcoded credentials in your code, including passwords, with an API call to Secrets

Manager to retrieve the secret programmatically. This pattern uses Secrets Manager to store the Slack URL.

- [Amazon Simple Storage Service (Amazon S3)](https://docs.aws.amazon.com/AmazonS3/latest/userguide/Welcome.html) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses Amazon S3 to store the CloudFormation templates and Python script for the Lambda function. It also uses an S3 bucket as the network firewall alert destination.
- [AWS CloudFormation](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/Welcome.html) helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. This pattern uses AWS CloudFormation to automatically deploy a distributed architecture for Firewall Manager.

Code

The code for this pattern is available on GitHub, in the [Network Firewall Slack Integration](https://github.com/aws-samples/aws-network-firewall-automation-examples) repository. In the `src` folder of the repository, you'll find:

- A set of CloudFormation files in YAML format. You use these templates to provision the components for this pattern.
- A Python source file (`slack-lambda.py`) to create the Lambda function.
- A .zip archive deployment package (`slack-lambda.py.zip`) to upload your Lambda function code.

To use these files, follow the instructions in the next section.

Epics

Set up the S3 bucket

Task	Description	Skills required
Create an S3 bucket.	1. Sign in to the AWS Management Console and open the Amazon S3 console at https://console.aws.amazon.com/s3/.	App developer, App owner, Cloud administrator

Task	Description	Skills required
	2. Choose or create an S3 bucket to host the code. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes. We recommend that you use a prefix to organize the code for this pattern. For more information, see Creating a bucket in the Amazon S3 documentation.	
Upload the CloudFormation templates and Lambda code.	1. Download the following files from the GitHub repository for this pattern: • `base.yml` • `igw-ingress-route.yml` • `slack-lambda.py` • `slackLambda.yml` • `decentralized-deployment.yml` • `protected-subnet-route.yml` • `slack-lambda.py.zip` 2. Upload the files to the S3 bucket you created.	App developer, App owner, Cloud administrator

Deploy the CloudFormation template

Task	Description	Skills required
Launch the CloudFormation template.	Open the [AWS CloudFormation console]() in the same AWS Region as your S3 bucket and deploy the template `base.yml`. This template creates the required AWS resources and Lambda functions for the alerts to be transmitted to the Slack channel. For more information about deploying CloudFormation templates, see [Creating a stack on the AWS CloudFormation console]() in the CloudFormation documentation.	App developer, App owner, Cloud administrator
Complete the parameters in the template.	Specify the stack name and configure the parameter values. For a list of parameters, their descriptions, and default values, see *CloudFormation parameters* in the [Additional information]() section.	App developer, App owner, Cloud administrator
Create the stack.	1. Review stack details and update values based on your environment requirements.	App developer, App owner, Cloud administrator

Task	Description	Skills required
	2. Choose **Create stack** to deploy the template.	

Verify the solution

Task	Description	Skills required
Test the deployment.	Use the AWS CloudFormation console or the AWS Command Line Interface (AWS CLI) to verify that the resources listed in the [Target technology stack](#) section have been created. If the CloudFormation template fails to deploy successfully, check the values you provided for the `pAvailabilityZone1` and `pAvailabilityZone2` parameters. These should be appropriate for the AWS Region you're deploying the solution in. For a list of Availability Zones for each Region, see [Regions and Zones](#) in the Amazon EC2 documentation.	App developer, App owner, Cloud administrator
Test functionality.	1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/.	App developer, App owner, Cloud administrator

Task	Description	Skills required

	2. Create an EC2 instance in one of the protected subnets. Choose an Amazon Linux 2 AMI (HVM) to use as an HTTPS server. For instructions, see [Launch an instance](#) in the Amazon EC2 documentation.
	
	Note
	Amazon Linux 2 is nearing end of support. For more information, see the [Amazon Linux 2 FAQs](#).
	
	3. Use the following user data to install a web server on the EC2 instance:
	
	`#!/bin/bash`
	`yum install httpd -y`
	`systemctl start httpd`
	`systemctl stop firewalld`
	`cd /var/www/html`
	`echo "Hello!! this is a NFW alert test page, 200 OK" > index.html`
	
	4. Create the following network firewall rules:
	
	Stateless rule:	

Task	Description	Skills required
	``` Source: 0.0.0.0/0 Destination 10.0.3.65 /32 (private IP of the EC2 instance) Action: Forward ``` *Stateful rule:* ``` Protocol: HTTP Source ip/port: Any / Any Destination ip/port: Any /Any ``` 5. Get the public IP of the web server you created in step 3. 6. Access the public IP in a browser. You should see the following message in the browser: ``` Hello!! this is a NFW alert test page, 200 OK ``` You will also get a notificat ion in the Slack channel. The notification might be delayed, depending on the size of the message. For testing purposes, consider providing a CIDR filter that is not too narrow (for example, a CIDR value with /32 would	

Task	Description	Skills required
	be considered too narrow, and /8 would be too broad). For more information, see the *Filter behavior* section in [Additional information](#).	

Related resources

- [Create a Slack workspace](#) (Slack help center)

Additional information

CloudFormation parameters

Parameter	Description	Default or sample value
`pVpcName`	The name of the VPC to create.	Inspection
`pVpcCidr`	The CIDR range for the VPC to create.	10.0.0.0/16
`pVpcInstanceTenancy`	How EC2 instances are distributed across physical hardware. Options are `default` (shared tenancy) or `dedicated` (single tenancy).	default
`pAvailabilityZone1`	The first Availability Zone for the infrastructure.	us-east-2a

`pAvailabilityZone2`	The second Availability Zone for the infrastructure.	us-east-2b
`pNetworkFirewallSubnet1Cidr`	The CIDR range for the first firewall subnet (minimum /28).	10.0.1.0/24
`pNetworkFirewallSubnet2Cidr`	The CIDR range for the second firewall subnet (minimum /28).	10.0.2.0/24
`pProtectedSubnet1Cidr`	The CIDR range for the first protected (workload) subnet.	10.0.3.0/24
`pProtectedSubnet2Cidr`	The CIDR range for the second protected (workload) subnet.	10.0.4.0/24
`pS3BucketName`	The name of the existing S3 bucket where you uploaded the Lambda source code.	us-w2-yourname-lambda-functions
`pS3KeyPrefix`	The prefix of the S3 bucket where you uploaded the Lambda source code.	aod-test
`pAWSSecretName4Slack`	The name of the secret that holds the Slack URL.	SlackEnpoint-Cfn
`pSlackChannelName`	The name of the Slack channel you created.	somename-notifications
`pSlackUserName`	Slack user name.	Slack User
`pSecretKey`	This can be any key. We recommend that you use the default.	webhookUrl

`pWebHookUrl`	The value of the Slack URL.	https://hooks.slack.com/services/T???9T??/A031885JRM7/9D4Y??????
`pAlertS3Bucket`	The name of the S3 bucket to be used as the network firewall alert destination. This bucket will be created for you.	us-w2-yourname-security-aod-alerts
`pSecretTagName`	The tag name for the secret.	AppName
`pSecretTagValue`	The tag value for the specified tag name.	LambdaSlackIntegration
`pdestCidr`	The filter for the destination CIDR range. For more information, see the next section, *Filter behavior*.	10.0.0.0/16
`pdestCondition`	A flag to indicate whether to exclude or include the destination match. For more information, see the next section. Valid values are `include` and `exclude`.	include
`psrcCidr`	The filter for the source CIDR range to alert. For more information, see the next section.	118.2.0.0/16
`psrcCondition`	The flag to exclude or include the source match. For more information, see the next section.	include

Filter behavior

If you haven't configured any filters in AWS Lambda, all generated alerts are sent to your Slack channel. The source and destination IPs of the generated alerts are matched against the CIDR ranges you configured when you deployed the CloudFormation template. If a match is found, the condition is applied. If either the source or the destination falls within the configured CIDR range and at least one of them is configured with the condition `include`, an alert is generated. The following tables provide examples of CIDR values, conditions, and results.

	Configured CIDR	Alert IP	Configured	Alert
Source	10.0.0.0/16	10.0.0.25	include	Yes
Destination	100.0.0.0/16	202.0.0.13	include	

	Configured CIDR	Alert IP	Configured	Alert
Source	10.0.0.0/16	10.0.0.25	exclude	No
Destination	100.0.0.0/16	202.0.0.13	include	

	Configured CIDR	Alert IP	Configured	Alert
Source	10.0.0.0/16	10.0.0.25	include	Yes
Destination	100.0.0.0/16	100.0.0.13	include	

	Configured CIDR	Alert IP	Configured	Alert
Source	10.0.0.0/16	90.0.0.25	include	Yes
Destination	Null	202.0.0.13	include	

	Configured CIDR	Alert IP	Configured	Alert
Source	10.0.0.0/16	90.0.0.25	include	No

Destination	100.0.0.0/16	202.0.0.13	include

Send custom attributes to Amazon Cognito and inject them into tokens

Carlos Alessandro Ribeiro and Mauricio Mendoza, Amazon Web Services

Summary

Sending custom attributes to an Amazon Cognito authentication process can provide additional context to an application, enable more granular access controls, and make it easier to manage user profiles and authentication requirements. These features are useful in a wide range of applications and scenarios, and they can help you improve the overall security and functionality of an application.

This pattern shows how to send custom attributes to an Amazon Cognito authentication process when an application needs to provide additional context to the access token or identity (ID) token. You use the Node.js as the backend application. The application authenticates a user from an Amazon Cognito user pool and passes custom attributes that are needed for token generation. You can use AWS Lambda triggers for Amazon Cognito to customize your authentication process without major code customization or significant effort.

Important

The code and samples in this pattern are not recommended for production workloads because they are intended for demonstration purposes only. For production workloads, additional configuration is required on the client side. Use this pattern as a reference for pilot or proof-of-concept purposes only.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Permissions to create and manage Amazon Cognito user pools and AWS Lambda functions
- AWS Command Line Interface (AWS CLI), installed and configured
- An integrated development environment (IDE) that supports Node.js

- Node.js version 18 or later, installed
- npm version 8 or later, installed
- TypeScript, installed

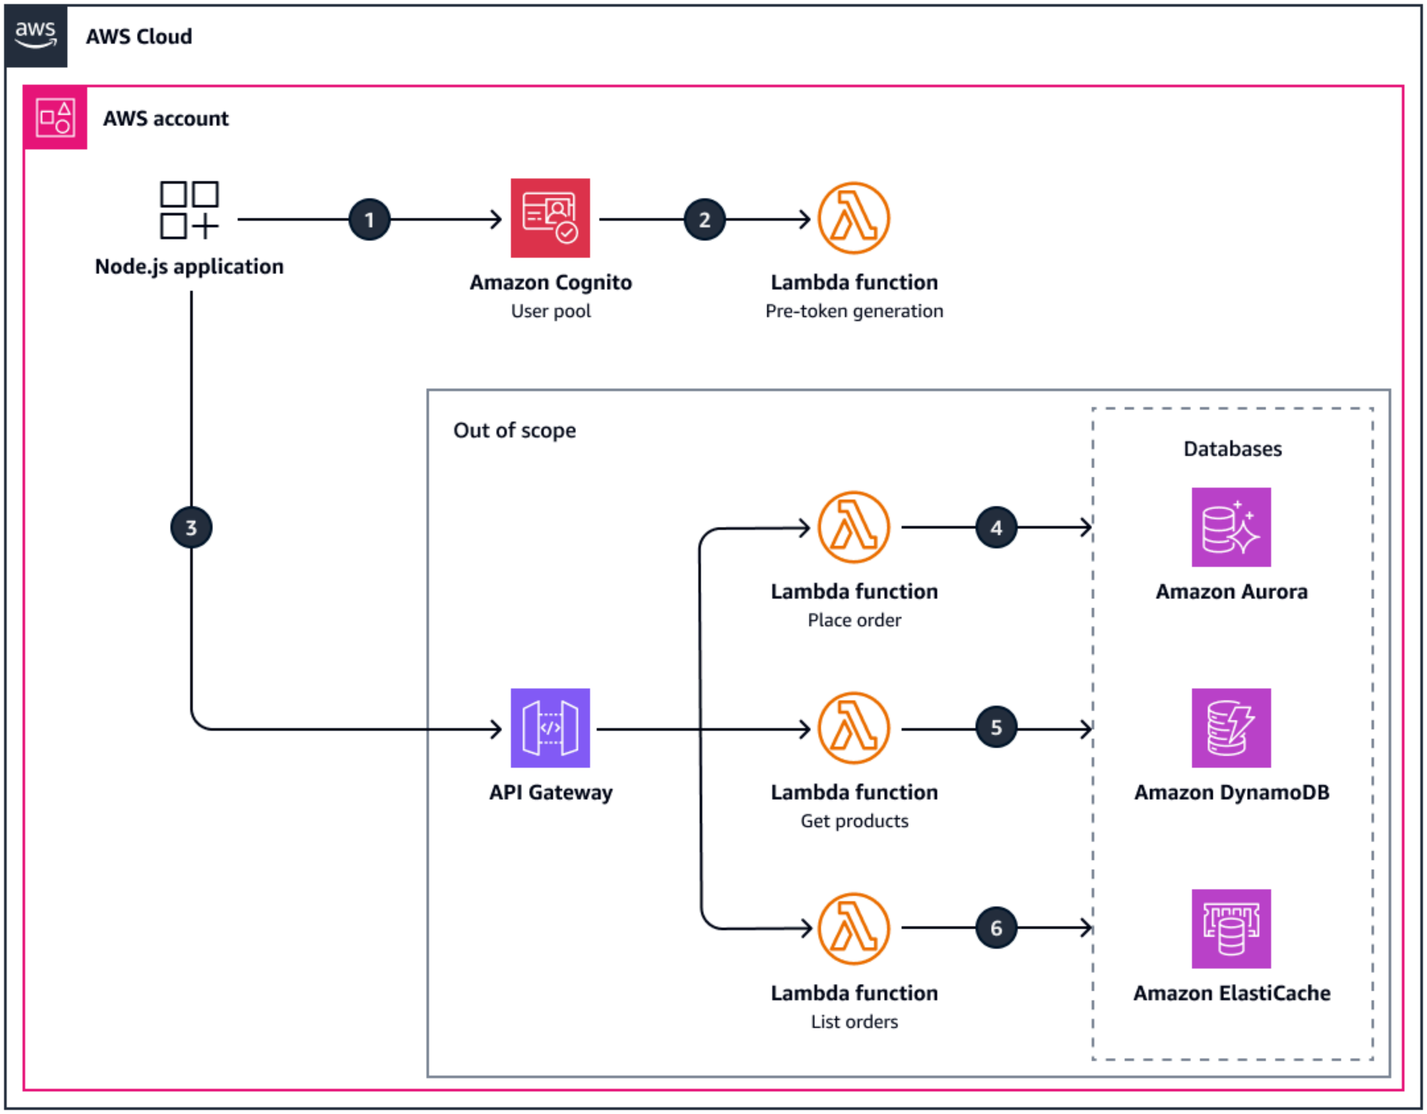
Limitations

- This pattern is not applicable for application integration through the Client Credentials authentication flow.
- The pre-token generation trigger can add or change only some attributes of the access token and identity token. For more information, see Pre token generation Lambda trigger in the Amazon Cognito documentation.

Architecture

Target architecture

The following diagram shows the target architecture for this pattern. It also shows how the Node.js application might work with a backend to update databases. However, the backend database updates are outside the scope of this pattern.



The diagram shows the following workflow:

1. The Node.js application issues an access token with custom attributes to the Amazon Cognito user pool.
2. The Amazon Cognito user pool initiates the pre-token generation Lambda function, which customizes the access and ID tokens.
3. The Node.js application makes an API call through Amazon API Gateway.

> **Note**
>
> The other architectural components shown in this architecture are for example only and are out of scope for this pattern.

Automation and scale

You can automate the provisioning of Amazon Cognito user pools, AWS Lambda functions, database instances, and other resources by using AWS CloudFormation, the AWS Cloud Development Kit (AWS CDK), HashiCorp Terraform, or any supported infrastructure as code (IaC) tool. If you want to scale your deployments, use continuous integration and continuous delivery (CI/CD) pipelines, which help prevent errors associated with manual deployments.

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- Amazon Cognito provides authentication, authorization, and user management for web and mobile apps.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS SDK for JavaScript provides a JavaScript API for AWS services. You can use it to build libraries or applications for Node.js or the browser.

Other tools

- Node.js is an event-driven JavaScript runtime environment that is designed for building scalable network applications.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.

Best practices

We recommend that you implement the following best practices:

- **Secrets and sensitive data** – Do not store secrets or sensitive data within the application. Use an external system that the application can pull the data from, such as AWS AppConfig, AWS Secrets Manager, or AWS Systems Manager Parameter Store.
- **Standardized deployment** – Use CI/CD pipelines to deploy your applications. You can use services such as AWS CodeBuild and AWS CodePipeline.
- **Token expiration** – Set a short expiration date for the access token.
- **Use a secure connection** – All communication between the client application and the backend should be encrypted by using SSL/TLS. Use AWS Certificate Manager (ACM) to generate and manage SSL/TLS certificates, and use Amazon CloudFront or Elastic Load Balancing to handle SSL/TLS termination.
- **Validate user input** – Make sure that all user input is validated to prevent injection attacks and other security vulnerabilities. Use input validation libraries and services such as Amazon API Gateway and AWS WAF to prevent common attack vectors.
- **Use IAM roles** – Use AWS Identity and Access Management (IAM) roles to control access to AWS resources and make sure that only authorized users have access. Follow the principle of least privilege and make sure that each user has only the necessary permissions to perform their role.
- **Use a password policy** – Configure a password policy that meets your security requirements, such as minimum length, complexity, and expiration. Use Secrets Manager or AWS Systems Manager Parameter Store to store and manage passwords securely.
- **Enable multi-factor authentication (MFA)** – Enable MFA for all users to provide an additional layer of security and reduce the risk of unauthorized access. Use AWS IAM Identity Center or Amazon Cognito to enable MFA and other authentication methods.
- **Store sensitive information securely** – Store sensitive information, such as passwords and access tokens, securely by using AWS Key Management Service (AWS KMS) or other encryption services.
- **Use strong authentication methods** – To increase the security of the authentication process, use strong authentication methods, such as biometric authentication or multi-factor authentication.
- **Monitor for suspicious activity** – Use AWS CloudTrail and other monitoring tools to monitor for suspicious activity and potential security threats. Set up automated alerts for unusual activity, and use Amazon GuardDuty or AWS Security Hub to detect potential threats.
- **Regularly review and update security policies** – Regularly review and update your security policies and procedures to make sure that they meet your changing security requirements

and best practices. Use AWS Config to track and audit changes to your security policies and procedures.

- **Automated sign-up** – Do not enable automated sign-up to an Amazon Cognito user pool. For more information, see Reduce risks of user sign-up fraud and SMS pumping with Amazon Cognito user pools (AWS blog post).

For additional best practices, see Security best practices for Amazon Cognito user pools in the Amazon Cognito documentation.

Epics

Set up the AWS resources

Task	Description	Skills required

Create a user pool.	1. In a CLI terminal, enter the following command to create an Amazon Cognito user pool:
	`aws cognito-idp create-user-pool \ --pool-name <MyUserPool>`
	2. Enter the following command to create a client ID and secret that will be used with the SDK for JavaScript:
	`aws cognito-idp create-user-pool-client \ --user-pool-id <UserPoolID> \ --client-name <MyNewClient> \`
		App developer, AWS DevOps

Task	Description	Skills required
	` --no-generate-secret \ --explicit-auth-flows "USER_PASSWORD_AUTH" "ADMIN_NO_SRP_AUTH"` For more information and instructions for how to set up a user pool in the AWS Management Console, see Getting started with user pools and Add more features and security options to your user pool. **Tip** To reduce costs, use the Essentials plan or Lite plan to test this pattern. For more information, see Amazon Cognito pricing.	

Task	Description	Skills required
Add a user to the user pool.	Enter the following command to create one user in the Amazon Cognito user pool: `aws cognito-idp sign-up \ --client-id <ClientID> \ --username <jane@example.com> \ --password <PASSWORD> \ --user-attributes Name="email",Value="<jane@example.com>" Name="name",Value="<Jane>"`	App developer, AWS DevOps

Task	Description	Skills required
Add the app client to the user pool.	1. Navigate to the [Amazon Cognito console](). 2. Choose **User pools**. 3. Choose the user pool that you created previously. 4. Under **Define your application**, choose the **Application type** that best fits the application scenario that you want to create authentication and authorization services for. 5. In **Name your application**, enter a descriptive name or proceed with the default name. 6. Under **Add a return URL**, enter a redirect path to your application for after users complete authentic ation. 7. Choose **Create your application**. You can set up the advanced options after you create your app client.	AWS systems administrator, AWS administrator, AWS DevOps, App developer

Task	Description	Skills required
Create a Lambda trigger for pre-token generation.	1. Open the [Functions page](#) of the Lambda console. 2. Choose **Create function**. 3. Select **Author from scratch**. 4. In the **Basic informati on** pane, for **Function name**, enter `myPreTokenGenerationLambdaFunction` . 5. For **Runtime**, choose **Node.js 22**. 6. Leave **architecture** set to **x86_64**. 7. Choose **Create function**. 8. On the **Code** tab, under **Code Source**, enter the sample Lambda function from the [Additional resources](#) section of this pattern. This Lambda function injects the custom attributes into the ID token and access token.	AWS DevOps, App developer

Task	Description	Skills required
Customize the user pool workflow.	1. Navigate to the [Amazon Cognito console](#). 2. Choose **User pools**. 3. Choose the user pool that you created previously. 4. In the left navigation pane, under **Authentication**, choose **Extensions**. 5. Choose **Add Lambda trigger**. 6. Add or edit a **Pre token generation trigger**. 7. For **Trigger type**, choose **Authentication**. 8. Under **Authentication**, choose **Pre token generation trigger**. 9. For **Assign Lambda function**, choose `myPreTokenGenerationLambdaFunction` . 10. Choose **Add Lambda trigger**. 11. Choose a **Trigger event version** of **Basic features + access token customization for user identities** or **Basic features + access token customization for user and machine identities**. This setting updates the request	AWS DevOps, App developer

Task	Description	Skills required
	parameters that Amazon Cognito sends to your function to include fields for access token customization. For more information, see [Customizing user pool workflows with Lambda triggers](#) in the Amazon Cognito documentation.	

Create the Node.js application

Task	Description	Skills required

Create the Node.js application.	1. In a terminal, enter the following commands:
	
	`mkdir my-app`
	`cd my-app`
	`npm init -y`
	`npm install --save-dev typescript`
	`npm i --save-dev @types/node`
	`npm i amazon-cognito-identity-js`
	`npx tsc --init`
	`mkdir src`
	`touch src/index.ts`
	
	2. Modify the `package.json` file to include the TypeScript compilation scripts:
		App developer

Task	Description	Skills required

	``
	"scripts": {
	  "start": "node src/index.js",
	  "build": "tsc"
	},
	``	

Implement the authentication logic.	1. Open the `index.ts` file. 2. Paste the sample Typescript provided in the [Additional resources](#) section of this pattern. 3. Save and close the `index.ts` file. **Note** You can create your own TypeScript file or modify the sample provided as needed for your use case.	App developer

Task	Description	Skills required

Configure the environment variables and configuration file.	In a terminal, enter the following commands to create the environment variables:
	`export USERNAME="<COGNITO_USER_NAME>"`
	`export PASSWORD="<COGNITO_USER_PASSWORD>"`
	`export USER_POOL_ID="<COGNITO_USER_ID>"`
	`export CLIENT_ID="<COGNITO_CLIENT_ID>"`
	Important
	Do not hardcode secrets or expose your credentials.
		App developer

Run the application.	Enter the following commands to run the application and confirm that it is working:
	`npm run build`
	`npm start`
		App developer

Task	Description	Skills required
Confirm that the custom attributes are injected into the tokens.	Use the debugging features for your IDE to view the access and ID tokens. Confirm that the custom attribute s were added. For sample tokens, see the Additional information section of this pattern.	App developer

Troubleshooting

Issue	Solution
Invalid client ID when trying to authenticate the user	This error typically occurs when you are using a client ID with a generated client secret. You must create a client ID without a secret attached to it. For more information, see Application-specific settings with app clients.

Related resources

- Customizing user pool workflows with Lambda triggers (Amazon Cognito documentation)
- Pre token generation Lambda trigger (Amazon Cognito documentation)
- CognitoIdentityProviderClient (AWS SDK for JavaScript documentation)
- cognito-idp (AWS CLI documentation)

Additional information

Sample TypeScript file

The following code sample is a TypeScript file that invokes the authentication process by using an AWS SDK to send custom attributes to Amazon Cognito:

```
import * as AmazonCognitoIdentity from "amazon-cognito-identity-js";

const userPoolId: string = process.env.USER_POOL_ID ?? '';
const clientId: string = process.env.CLIENT_ID ?? '';

const poolData = {
  UserPoolId: userPoolId,
  ClientId: clientId
};
const userPool = new AmazonCognitoIdentity.CognitoUserPool(poolData);

export const loginWithCognitoSDK = function (userName: string, password: string) {
  const authenticationDetails = new AmazonCognitoIdentity.AuthenticationDetails({
    Username: userName,
    Password: password,
    ClientMetadata: {
        customGroup: "MyCustomGroup",
        customApplicationData: "Custom data from a custom application"
    }
  });
  const userData = {
    Username: userName,
    Pool: userPool
  };

  const cognitoUser = new AmazonCognitoIdentity.CognitoUser(userData);

  // Authenticate the user using the authenticationDetails object
  cognitoUser.authenticateUser(authenticationDetails, {
    onSuccess: function (result: any) {},
    onFailure: function (err: any) {},
  });
}
loginWithCognitoSDK(process.env.USERNAME ?? '', process.env.PASSWORD ?? '');
```

The sample uses the `AuthenticationDetails` model from the SDK for JavaScript to provide the username, password, and the `ClientMetadada`. After the authentication in Amazon Cognito, the client metadata can be retrieved from the access and ID tokens.

Sample Lambda function

The following code sample is a Lambda function that is linked to the Pre-Generation Token from Amazon Cognito. It helps you customize the access token and ID token that Amazon Cognito uses.

The tokens are passed through the integrations between your architecture. This sample includes a custom claim attribute called `customApplicationData` and a custom group name called `MyCustomGroup`:

```
export const handler = async(event, context, callback) => {
    event.response = {
        claimsOverrideDetails: {
            claimsToAddOrOverride: { customApplicationData:
 event.request.clientMetadata.customApplicationData },
            groupOverrideDetails: { groupsToOverride:
 [event.request.clientMetadata.customGroup] }
        }
    };
    callback(null, event);
};
```

Sample access token

You can decode the access token to visualize the custom attributes that were added. The following is a sample access token:

```
{
  "sub": "6daf331f-4451-48b4-abde-774579299204",
  "cognito:groups": [
    "MyCustomGroup"
  ],
  "iss": "https://cognito-idp.<REGION>.amazonaws.com/<USERPOOL_ID>",
  "client_id": "<YOUR_CLIENT_ID>",
  "origin_jti": "acff7e91-09f9-4fde-8eec-38b0f8c47cdc",
  "event_id": "c5113a9c-1f01-435b-9b73-a5cd3e88514e",
  "token_use": "access",
  "scope": "aws.cognito.signin.user.admin",
  "auth_time": 1677979246,
  "exp": 1677982846,
  "iat": 1677979246,
  "jti": "5c9c2708-a871-4428-bd9b-18ad261bea90",
  "username": "<USER_NAME>"
}
```

Sample ID token

You can decode the access token to visualize the custom attributes that were added. The following is a sample access token:

```
{
  "sub": "6daf331f-4451-48b4-abde-774579299204",
  "cognito:groups": [
    "MyCustomGroup"
  ],
  "iss": "https://cognito-idp.<REGION>.amazonaws.com/<USERPOOL_ID>",
  "cognito:username": "<USER_NAME>",
  "origin_jti": "acff7e91-09f9-4fde-8eec-38b0f8c47cdc",
  "customApplicationData": "Custom data from a custom application",
  "aud": "<YOUR_CLIENT_ID>",
  "event_id": "c5113a9c-1f01-435b-9b73-a5cd3e88514e",

```

Simplify private certificate management by using AWS Private CA and AWS RAM

Everett Hinckley and Vivek Goyal, Amazon Web Services

Summary

You can use AWS Private Certificate Authority (AWS Private CA) to issue private certificates for authenticating internal resources and signing computer code. This pattern provides an AWS CloudFormation template for the rapid deployment of a multi-level CA hierarchy and consistent provisioning experience. Optionally, you can use AWS Resource Access Manager (AWS RAM) to securely share the CA within your organizations or organizational units (OUs) in AWS Organizations, and centralize the CA while using AWS RAM to manage permissions. There is no need for a private CA in every account, so this approach saves you money. Additionally, you can use Amazon Simple Storage Service (Amazon S3) to store the certificate revocation list (CRL) and access logs.

This implementation provides the following features and benefits:

- Centralizes and simplifies the management of the private CA hierarchy by using AWS Private CA.
- Exports certificates and keys to customer-managed devices on AWS and on premises.
- Uses an AWS CloudFormation template for a rapid deployment and consistent provisioning experience.
- Creates a private root CA along with 1, 2, 3, or 4 subordinate CA hierarchy.
- Optionally, uses AWS RAM to share the end-entity subordinate CA with other accounts at the organization or OU level.
- Saves money by removing the need for a private CA in every account by using AWS RAM.
- Creates an optional S3 bucket for the CRL.
- Creates an optional S3 bucket for CRL access logs.

Prerequisites and limitations

Prerequisites

If you want to share the CA within an AWS Organizations structure, identify or set up the following:

- A security account for creating the CA hierarchy and share.
- A separate OU or account for testing.
- Sharing enabled within the AWS Organizations management account. For more information, see [Enable resource sharing within AWS Organizations] in the AWS RAM documentation.

Limitations

- CAs are regional resources. All CAs reside in a single AWS account and in a single AWS Region.
- User-generated certificates and keys are not supported. For this use case, we recommend that you customize this solution to use an external root CA.
- A public CRL bucket is not supported. We recommend that you keep the CRL private. If internet access to the CRL is required, see the section on using Amazon CloudFront to serve CRLs in [Enabling the S3 Block Public Access (BPA) feature] in the AWS Private CA documentation.
- This pattern implements a single-Region approach. If you require a multi-Region certificate authority, you can implement subordinates in a second AWS Region or on premises. That complexity is outside the scope of this pattern, because the implementation depends on your specific use case, workload volume, dependencies, and requirements.

Architecture

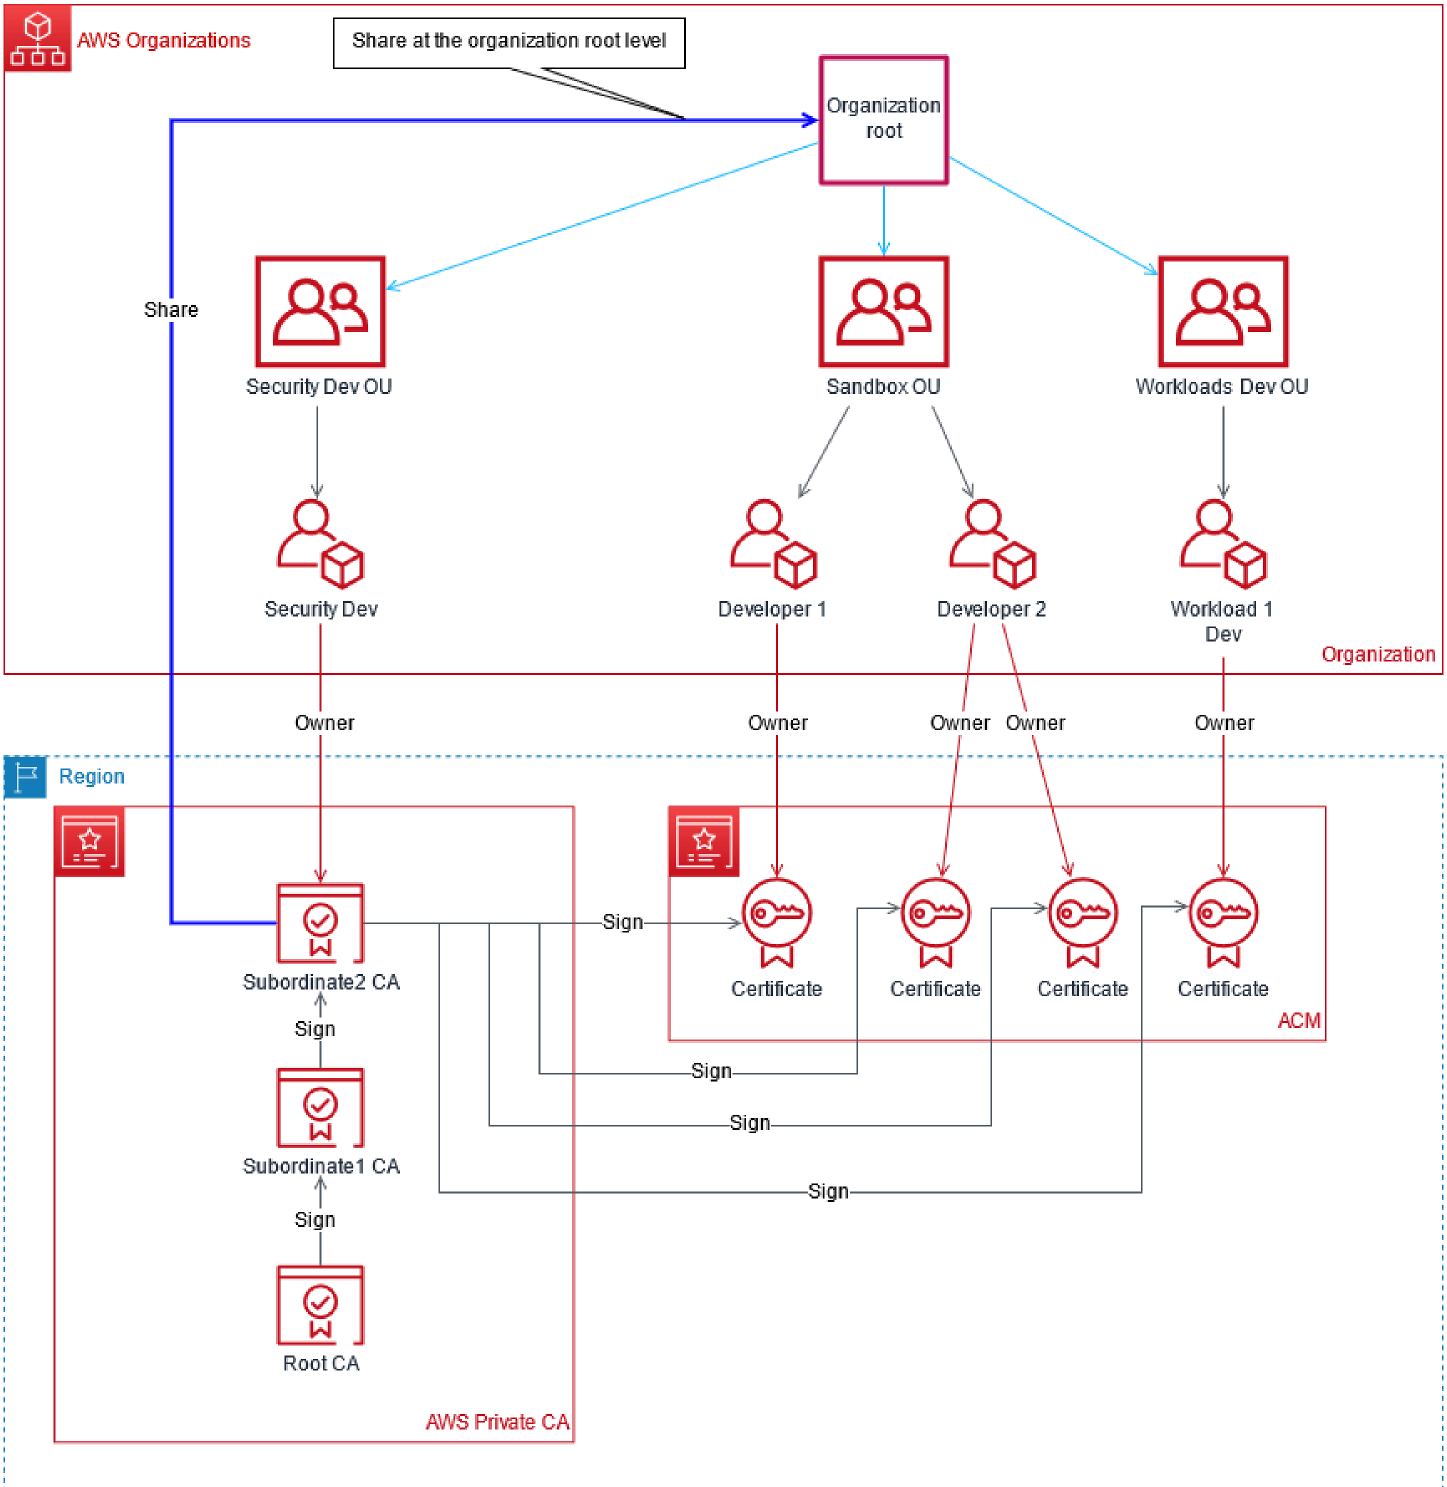
Target technology stack

- AWS Private CA
- AWS RAM
- Amazon S3
- AWS Organizations
- AWS CloudFormation

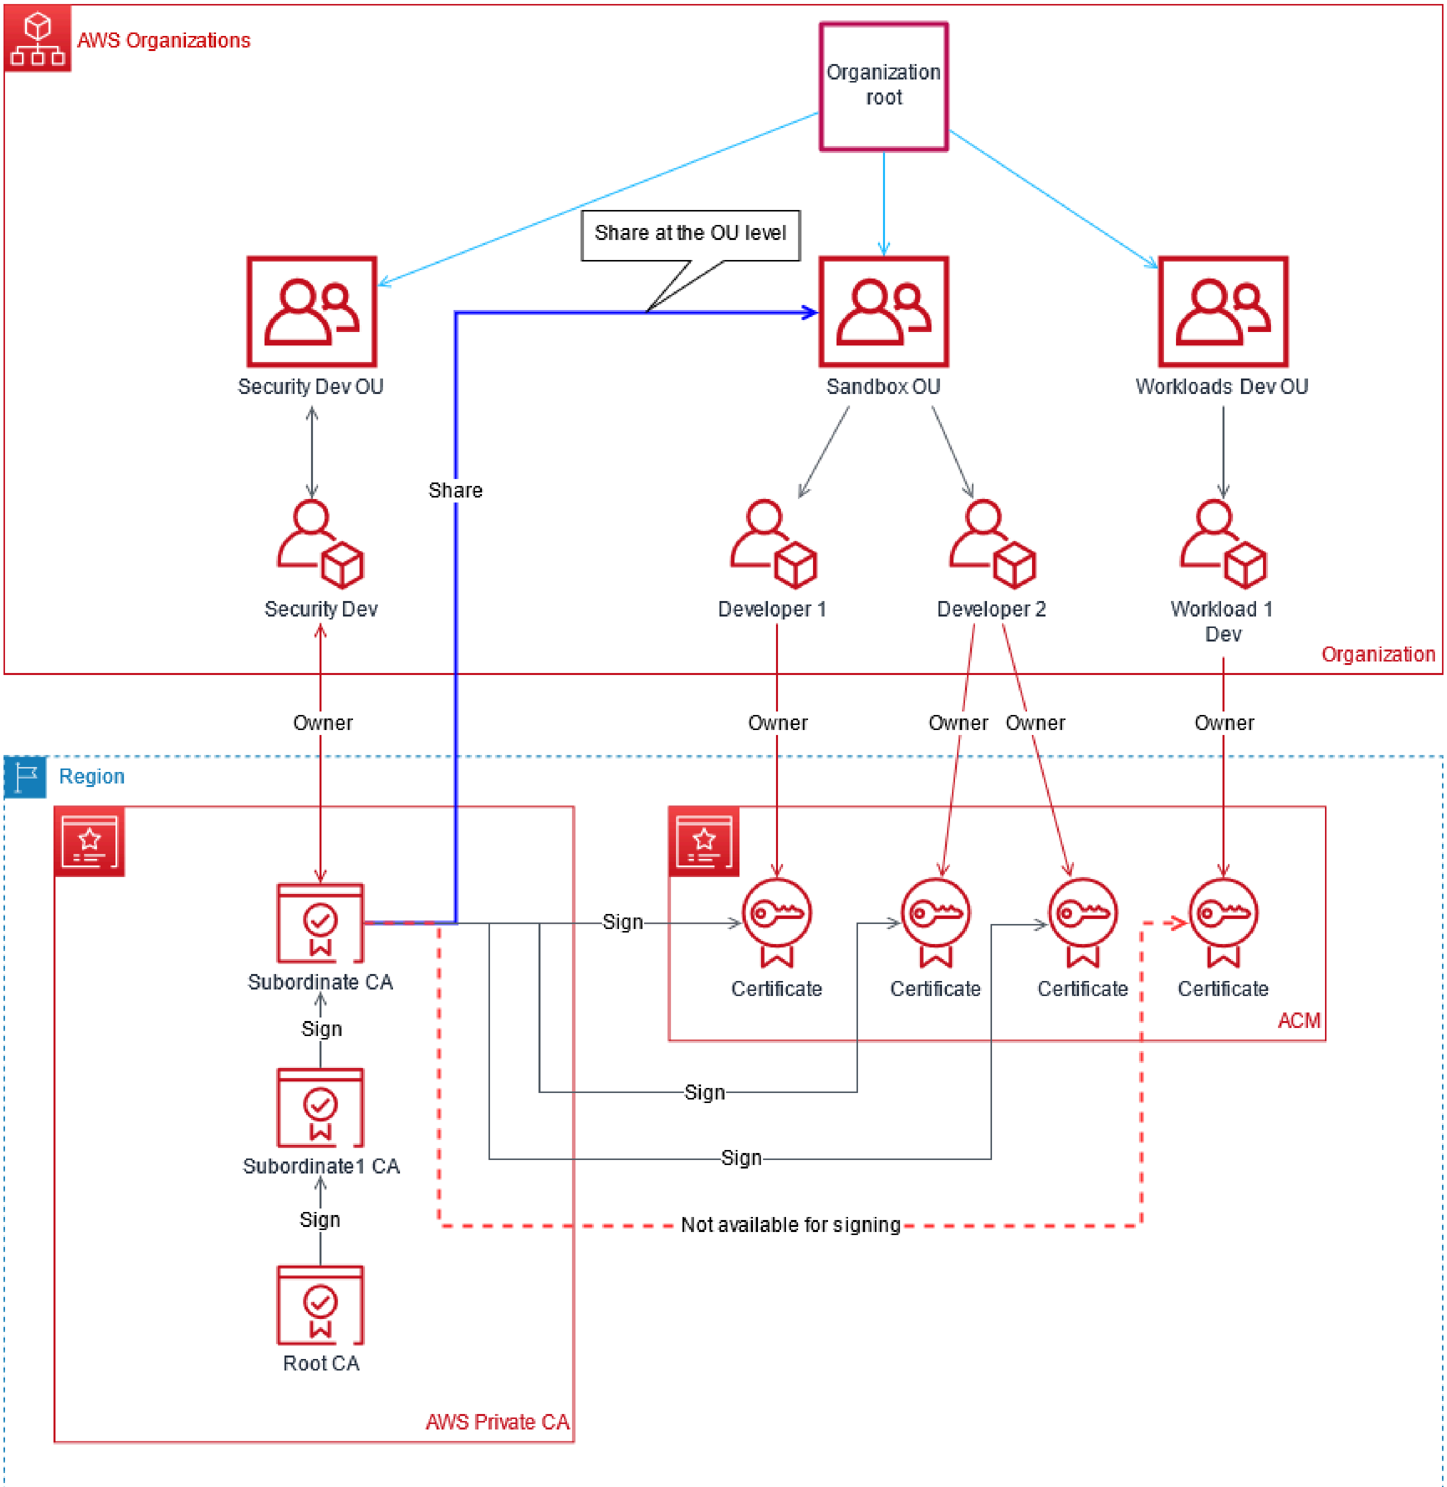
Target architecture

This pattern provides two options for sharing to AWS Organizations:

Option 1 – Create the share at the organization level. All accounts in the organization can issue the private certificates by using the shared CA, as shown in the following diagram.



Option 2 – Create the share at the organizational unit (OU) level. Only the accounts in the specified OU can issue the private certificates by using the shared CA. For example, in the following diagram, if the share is created at the Sandbox OU level, both Developer 1 and Developer 2 can issue private certificates by using the shared CA.



Tools

AWS services

- AWS Private CA – AWS Private Certificate Authority (AWS Private CA) is a hosted private CA service for issuing and revoking private digital certificates. It helps you create private CA hierarchies, including root and subordinate CAs, without the investment and maintenance costs of operating an on-premises CA.
- AWS RAM – AWS Resource Access Manager (AWS RAM) helps you securely share your resources across AWS accounts and within your organization or OUs in AWS Organizations. To reduce operational overhead in a multi-account environment, you can create a resource and use AWS RAM to share that resource across accounts.
- AWS Organizations – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses Amazon S3 to store the certificate revocation list (CRL) and access logs.
- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. This pattern uses AWS CloudFormation to automatically deploy a multi-level CA hierarchy.

Code

The source code for this pattern is available on GitHub, in the AWS Private CA hierarchy repository. The repository includes:

- The AWS CloudFormation template `ACMPCA-RootCASubCA.yaml`. You can use this template to deploy the CA hierarchy for this implementation.
- Test files for use cases such as requesting, exporting, describing, and deleting a certificate.

To use these files, follow the instructions in the *Epics* section.

Epics

Architect the CA hierarchy

Task	Description	Skills required
Collect certificate subject information.	Gather certificate subject information about the certificate owner: organizat ion name, organization unit, country, state, locality, and common name.	Cloud architect, Security architect, PKI engineer
Collect optional information about AWS Organizations.	If the CA will be part of an AWS Organizations structure and you want to share the CA hierarchy inside that structure , collect the managemen t account number, the organization ID, and optionall y the OU ID (if you want to share the CA hierarchy only with a specific OU). Also, determine the AWS Organizat ions accounts or OUs, if any, that you want to share the CA with.	Cloud architect, Security architect, PKI engineer
Design the CA hierarchy.	Determine which account will house the root and subordina te CAs. Determine how many subordinate levels the hierarchy requires between the root and the end-entit y certificates. For more information, see Designing	Cloud architect, Security architect, PKI engineer

Task	Description	Skills required
	a CA hierarchy in the AWS Private CA documentation.	
Determine naming and tagging conventions for the CA hierarchy.	Determine the names for the AWS resources: the root CA and each subordinate CA. Determine which tags should be assigned to each CA.	Cloud architect, Security architect, PKI engineer
Determine required encryption and signing algorithms.	Determine the following: • Your organization's encryption algorithm requirements for the public keys that your CA uses when it issues a certificate. The default is RSA_2048. • The key algorithm that your CA uses for certificate signing. The default is SHA256WITHRSA.	Cloud architect, Security architect, PKI engineer
Determine certificate revocation requirements for the CA hierarchy.	If certificate revocation capabilities are required, establish a naming convention for the S3 bucket that contains the certificate revocation list (CRL).	Cloud architect, Security architect, PKI engineer
Determine the logging requirements for the CA hierarchy.	If access logging capabilities are required, establish a naming convention for the S3 bucket that contains the access logs.	Cloud architect, Security architect, PKI engineer

Task	Description	Skills required
Determine certificate expiration periods.	Determine the expiration date for the root certificate (the default is 10 years), end-entity certificates (the default is 13 months), and subordinate CA certificates (the default is 3 years). Subordinate CA certificates should expire earlier than the CA certificates at higher levels in the hierarchy. For more information, see Managing the private CA lifecycle in the AWS Private CA documentation.	Cloud architect, Security architect, PKI engineer

Deploy the CA hierarchy

Task	Description	Skills required
Complete prerequisites.	Complete the steps in the Prerequisites section of this pattern.	Cloud administrator, Security engineers, PKI engineers
Create CA roles for various personas.	1. Determine the types of AWS Identity and Access Management (IAM) roles or users in AWS IAM Identity Center (successor to AWS Single Sign-On) required to administer the various levels of the CA hierarchy , such as RootCAAdmin,	Cloud administrator, Security engineers, PKI engineers

Task	Description	Skills required
	SubordinateCAAdmin, and CertificateConsumer. 2. Determine the granularity of policies needed to separate duties. 3. Create the required IAM roles or users in IAM Identity Center in the account that the CA hierarchy resides in.	
Deploy the CloudFormation stack.	1. From the GitHub repository for this pattern, download the AWSPCA-RootCASubCA .yaml template. 2. Deploy the template from the AWS CloudFormation console or from the AWS Command Line Interface (AWS CLI). For more information, see Working with stacks in the CloudFormation documentation. 3. Complete the parameters in the template, including the organization name, the OU name, the key algorithm, the signing algorithm, and other options.	Cloud administrator, Security engineers, PKI engineers

Task	Description	Skills required
Architect a solution for updating certificates used by user-managed resources.	Resources of integrated AWS services, such as Elastic Load Balancing, update certifica tes automatically before expiration. However, user-managed resources, such as web servers that are running on Amazon Elastic Compute Cloud (Amazon EC2) instances , require another mechanism. 1. Determine which user-managed resources require end-entity certificates from the private CA. 2. Plan a process to be notified about the expiratio n of user-managed resources and certifica tes. For examples, see the following: • Using an AWS Config managed rule • Using Amazon CloudWatch and Amazon EventBridge 3. Write custom scripts to update certificates on user-managed resources and integrate them with AWS services to automate the updates. For more information about integrated AWS Services,	Cloud administrator, Security engineers, PKI engineers

Task	Description	Skills required
	see [Services integrated with AWS Certificate Manager](#) in the ACM documentation.	

Validate and document the CA hierarchy

Task	Description	Skills required
Validate optional AWS RAM sharing.	If the CA hierarchy is shared with other accounts in AWS Organizations, log in to one of those accounts from the AWS Management Console, navigate to the [AWS Private CA console](#), and confirm that the newly created CA is shared to this account. Only the lowest-level CA in the hierarchy will be visible, because that is the CA that generates the end-entity certificates. Repeat for a sampling of the accounts that the CA is shared with.	Cloud administrator, Security engineers, PKI engineers
Validate the CA hierarchy with certificate lifecycle tests.	In the [GitHub repository](#) for this pattern, locate the lifecycle tests. Run the tests from the AWS CLI to request a certificate, export a certificate, describe a certificate, and delete a certificate.	Cloud administrator, Security engineers, PKI engineers

Task	Description	Skills required
Import the certificate chain into trust stores.	For browsers and other applications to trust a certificate, the certificate's issuer must be included in the browser's trust store, which is a list of trusted CAs. Add the certificate chain for the new CA hierarchy to your browser's and application's trust store. Confirm that the end-entity certificates are trusted.	Cloud administrator, Security engineers, PKI engineers
Create a runbook to document the CA hierarchy.	Create a runbook document to describe the architect ure of the CA hierarchy, the account structure that can request end-entity certifica tes, the build process, and basic management tasks such as issuing end-entity certifica tes (unless you want to allow self-service by child accounts), usage, and tracking.	Cloud administrator, Security engineers, PKI engineers

Additional information

When you export certificates, use a passphrase that is cryptographically strong and aligns with your organization's data loss prevention strategy.

Streamline Amazon EC2 compliance management with Amazon Bedrock agents and AWS Config

Anand Bukkapatnam Tirumala, Amazon Web Services

Summary

This pattern describes how to integrate Amazon Bedrock with AWS Config rules to facilitate compliance management for Amazon Elastic Compute Cloud (Amazon EC2) instances. The approach uses advanced generative AI capabilities to provide tailored recommendations that are aligned with the AWS Well-Architected Framework, to ensure optimal instance type selection and system efficiency. Key features of this pattern include:

- Automated compliance monitoring: AWS Config rules continuously assess EC2 instances against predefined criteria for desired instance types.
- AI-driven recommendations: The generative AI models in Amazon Bedrock analyze infrastructure patterns. These models provide intelligent suggestions for improvements based on best practices that are outlined in the AWS Well-Architected Framework.
- Remediation: Amazon Bedrock action groups enable automated remediation steps to swiftly address non-compliant instances and minimize potential performance or cost inefficiencies.
- Scalability and adaptability: The solution is designed to scale with your infrastructure and adapt to your evolving cloud architecture needs.
- Enhanced security recommendations: Compliance with AWS Well-Architected principles contributes to improved security posture and system performance.

You can use this pattern as a blueprint to deploy your own generative AI-based infrastructure into multiple environments with minimal changes, using DevOps practices as necessary.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS Identity and Access Management (IAM) role with permissions to create and manage resources in Amazon Simple Storage Service (Amazon S3) buckets, AWS Config, AWS Lambda functions, Amazon Bedrock, IAM, Amazon CloudWatch Logs, and Amazon EC2.

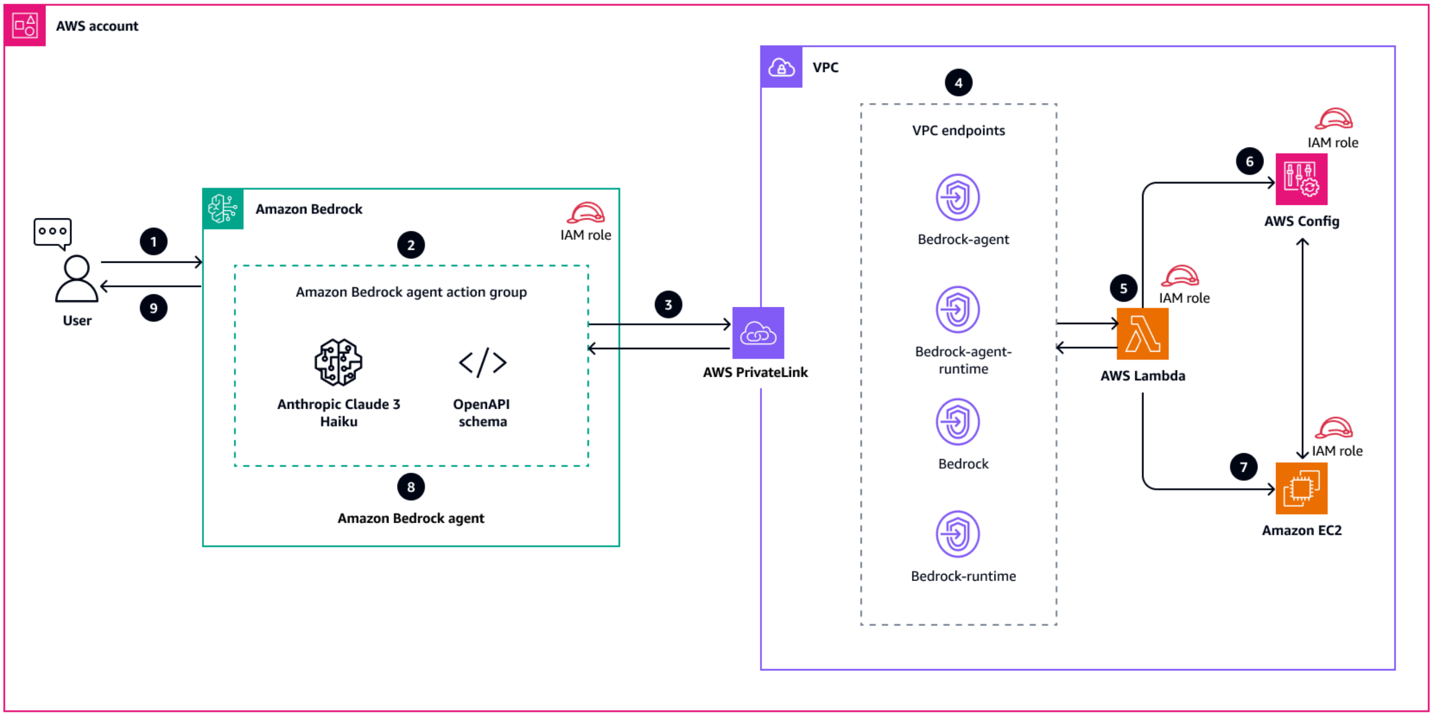
- An EC2 instance to flag as non-compliant. Do not use the `t2.small` type for this instance.
- Amazon Titan Text Embeddings V2 and Anthropic Claude 3 Haiku models enabled in your AWS account. To enable model access for the AWS Region where you are deploying the solution, see Add or remove access to Amazon Bedrock foundation models in the Amazon Bedrock documentation.
- Terraform, installed and configured.
- The AWS Command Line Interface (AWS CLI) v2 installed and configured in the deployment environment.
- Completed review of the Amazon Responsible AI policy.

Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.
- This solution has been tested by using the Amazon Titan Text Embeddings V2 and Claude 3 Haiku models. If you prefer to use other models, you can customize the Terraform code, which is parameterized for easy changes.
- This solution does not include a chat history feature, and the chat isn't stored.

Architecture

The following diagram shows the workflow and architecture components for this pattern.



The workflow consists of these steps:

1. The user interacts with the model through the Amazon Bedrock chat console. The user asks questions such as:
   - `What can you help me with?`
   - `List non-complaint resources`
   - `Suggest security best practices`
2. If the model is pre-trained, it responds to the prompts directly from its existing knowledge. Otherwise, the prompt goes to the Amazon Bedrock action group.
3. The action group reaches the VPC endpoints by using AWS PrivateLink for secure service communication.
4. The request reaches the Lambda function through the VPC endpoints for Amazon Bedrock services.
5. The Lambda function is the primary execution engine. Based on the request, the function calls the API to perform actions on the AWS services. It also handles operation routing and execution.
6. The Lambda function calls AWS Config to determine non-complaint resources (the non-compliant EC2 instance that you created as a prerequisite).
7. AWS Config flags the non-complaint resource. This pattern deploys the AWS Config desired-instance-type rule to find the ideal EC2 instance size.

8. AWS Config prompts the user to pause or remediate the instance, and takes action accordingly on the EC2 instance. Amazon Bedrock understands this return payload.
9. The user receives a response on the Amazon Bedrock chat console.

Automation and scale

This solution uses Terraform as an infrastructure as code (IaC) tool to enable easy deployment to AWS accounts and to function as a standalone utility across multiple accounts. This approach simplifies management and improves consistency in deployments.

Tools

AWS services

- AWS Config enables you to assess, audit, and evaluate the configurations of your AWS resources for compliance and desired settings.
- Amazon Bedrock is a fully managed AI service that provides access to many high-performing foundation models through a unified API.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

Other tools

- Git is an open source, distributed version control system.
- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub sample-awsconfig-bedrock-compliance-manager repository.

Best practices

- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices and use cases in the IAM documentation.
- Monitor Lambda execution logs regularly. For more information, see Monitoring, debugging, and troubleshooting Lambda functions and Best practices for working with AWS Lambda functions in the Lambda documentation.

Epics

Deploy the solution

Task	Description	Skills required
Clone the repository.	To clone the repository for this pattern, use the following command: `git clone "git@github.com:aws-samples/sample-awsconfig-bedrock-compliance-manager.git"`	AWS DevOps, Build lead, DevOps engineer, Cloud administrator
Edit the environment variables.	In the root directory of the cloned repository on your local machine, edit the `terraform.tfvars` file. Review the placeholders that are marked with `[XXXXX]`, and edit them based on your environment.	AWS systems administrator, AWS DevOps, DevOps engineer, AWS administrator
Create the infrastructure.	1. To create the infrastructure for this solution, run the following commands:	AWS DevOps, DevOps engineer, AWS systems

Task	Description	Skills required
	``` terraform init terraform plan ``` 2. Review the execution plan, and then run the command: ``` terraform apply -- auto-approve ```	administrator, Cloud administrator

Use the agent

Task	Description	Skills required
Chat with the agent.	Deploying the solution in the previous step deploys `security-bot-agent` , which is an Amazon Bedrock agent with a chat console. To use the agent: 1. Sign in to the AWS Management Console with an IAM identity that has permissions to use the Amazon Bedrock console. Then, open the [Amazon Bedrock console](https://console.aws.amazon.com/bedrock/). 2. In the navigation pane, choose **Build**, **Agents**. Select **security-bot-agent**. 3. Start conversing with the agent. For example:	AWS DevOps, DevOps engineer, AWS systems administrator, Cloud administrator

Task	Description	Skills required
	`List non-complaint EC2 instances` and: `Replace these non-complaint EC2 instances with compliant instances`	

Clean up resources

Task	Description	Skills required
Delete the infrastructure and resources.	When you've completed your work with this solution, you can delete the infrastructure created by this pattern by running the command: `terraform destroy --auto-approve`	AWS DevOps, DevOps engineer, AWS systems administrator, Cloud administrator

Troubleshooting

Issue	Solution
Agent behavior issues	For troubleshooting information, see Test and troubleshoot agent behavior in the Amazon Bedrock documentation.

Issue	Solution
AWS Lambda network issues	For more information, see Troubleshoot networking issues in Lambda in the Lambda documentation.
IAM permissions	For more information, see Troubleshoot IAM in the IAM documentation.

Turn off security standard controls across all Security Hub member accounts in a multi-account environment

Michael Fuellbier and Ahmed Bakry, Amazon Web Services

Summary

> **Important**
>
> AWS Security Hub now supports central configuration for security standards and controls, across accounts. This new feature addresses many of the scenarios that are covered by the solution in this AWS Prescriptive Guidance pattern. Before you deploy the solution in this pattern, see Central configuration in Security Hub.

In the Amazon Web Services (AWS) Cloud, AWS Security Hub standard controls, such as CIS AWS Foundations Benchmark or AWS Foundational Security Best Practices, can only be turned off (disabled) manually from within a single AWS account. In a multi-account environment, you can't turn off the controls across multiple Security Hub member accounts with "one click" (that is, one API call). This pattern demonstrates how to use one click to turn off the Security Hub standard controls across all the Security Hub member accounts managed by your Security Hub administrator account.

Prerequisites and limitations

Prerequisites

- A multi-account environment consisting of a Security Hub administrator account that manages multiple member accounts
- AWS Command Line Interface (AWS CLI) version 2, installed
- AWS Serverless Application Model Command Line Interface (AWS SAM CLI), installed

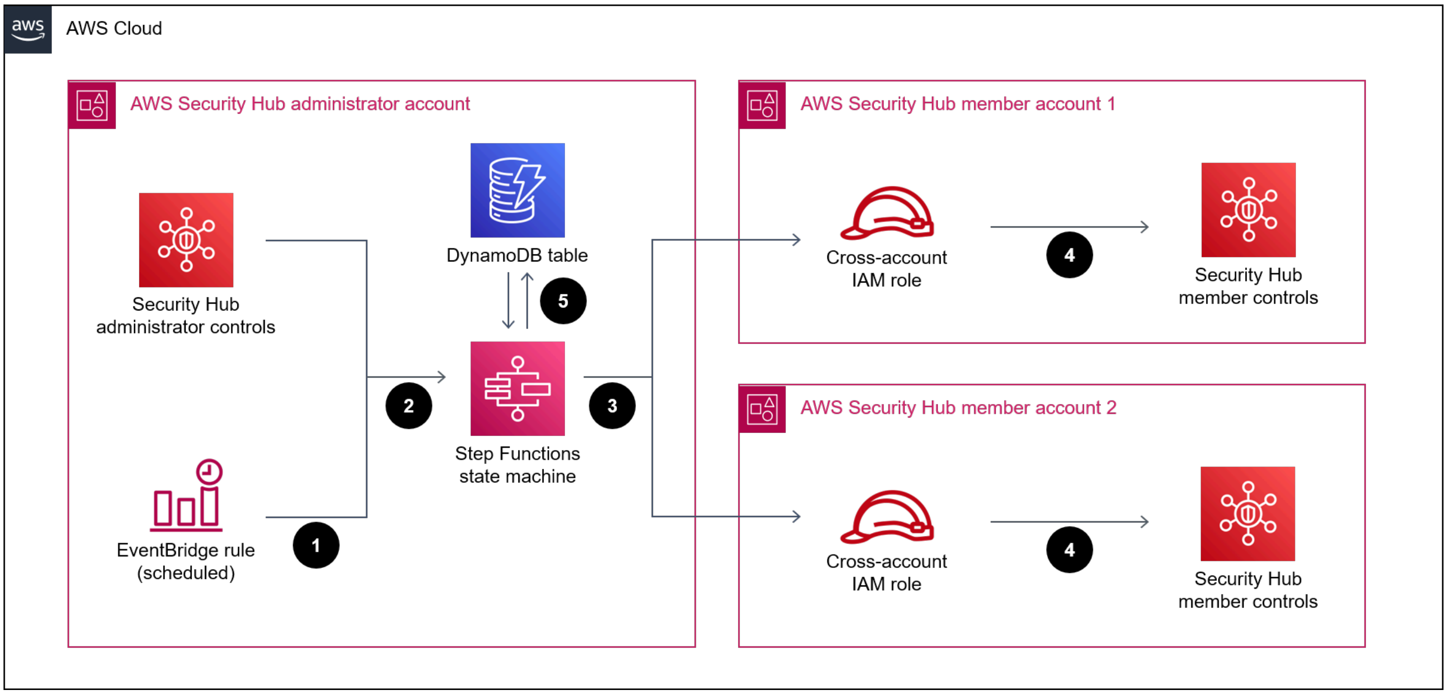
Limitations

- This pattern works only in a multi-account environment where a single Security Hub administrator account manages multiple member accounts.

- The event initiation causes multiple parallel invocations if you change a lot of controls in a very short time frame. This can lead to API throttling and cause the invocations to fail. For example, this scenario can happen if you programmatically change a lot of controls by using the Security Hub Controls CLI.

Architecture

The following diagram shows an example of a AWS Step Functions workflow that turns off Security Hub standard controls across multiple Security Hub member accounts (as viewed from the Security Hub administrator account).



The diagram includes the following workflow:

1. An Amazon EventBridge rule is initiated on a daily schedule and invokes the state machine. You can modify the timing of the rule by updating the `Schedule` parameter in your AWS CloudFormation template.
2. An EventBridge rule is initiated whenever a control is turned on or off in the Security Hub administrator account.
3. A Step Functions state machine propagates the status of the security standard controls (that is, controls that are turned on or off) from the Security Hub administrator account to the member accounts.

4. A cross-account AWS Identity and Access Management (IAM) role is deployed in each member account and assumed by the state machine. The state machine turns the controls on or off in each member account.
5. A Amazon DynamoDB table contains exceptions and information about which controls to turn on or off in a particular account. This information overrides the configurations fetched from the Security Hub administrator account for the specified member account.

Note

The purpose of the scheduled EventBridge rule is to ensure that newly added Security Hub member accounts have the same control status as existing accounts.

Tools

AWS services

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Serverless Application Model (AWS SAM) is an open-source framework that helps you build serverless applications in the AWS Cloud.
- AWS Security Hub provides a comprehensive view of your security state in AWS. It also helps you check your AWS environment against security industry standards and best practices.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

Code repository

The code for this pattern is available on the GitHub AWS Security Hub Cross-Account Controls Disabler repository. The code repository contains the following files and folders:

- **UpdateMembers/template.yaml** – This file contains components deployed in the Security Hub administrator account, including the Step Functions state machine and the EventBridge rules.
- **member-iam-role/template.yaml** – This file contains the code to deploy the cross-account IAM role in a member account.
- **stateMachine.json** – This file defines the state machine's workflow.
- **GetMembers/index.py** – This file contains the code for the **GetMembers** state machine. A script retrieves the status of the security standard controls in all existing Security Hub member accounts.
- **UpdateMember/index.py** – This file contains a script that updates the control status in each member account.
- **CheckResult/index.py** – This file contains a script that checks the status of the workflow invocation (accepted or failed).

Epics

Deploy a cross-account IAM role in the Security Hub member accounts

Task	Description	Skills required
Identify the account ID of the Security Hub administrator account.	Set up a Security Hub administrator account and then note the account ID of the administrator account.	Cloud architect
Deploy the CloudFormation template that includes the cross-account IAM role in the member accounts.	To deploy the **member-iam-role/template.yaml** template in all the member accounts managed by the Security Hub administrator account, run the following command: `aws cloudformation deploy \`	AWS DevOps

Task	Description	Skills required
	`--template-file member-iam-role/template.yaml \ --capabilities CAPABILITY_NAMED_IAM \ --stack-name <your-stack-name> \ --parameter-overrides SecurityHubAdminAccountId=<account-ID>` The `SecurityHubAdminAccountId` parameter must match the Security Hub administrator account ID that you noted earlier.	

Deploy a state machine in the Security Hub administrator account

Task	Description	Skills required
Package the CloudFormation template that includes the state machine with AWS SAM.	To package the **UpdateMembers/template.yaml** template in the Security Hub administrator account, run the following command: `sam package \ --template-file UpdateMembers/template.yaml \ --output-template-file UpdateMembers/template-out.yaml \ --s3-bucket <amzn-s3-demo-bucket>`	AWS DevOps

Task	Description	Skills required
	Note Your Amazon Simple Storage Service (Amazon S3) bucket must be in the same AWS Region where you deploy the CloudFormation template.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Deploy the packaged CloudFormation template in the Security Hub administr ator account.</td><td>To deploy the CloudForm ation template in the Security Hub administrator account, run the following command:

<pre><code>aws cloudformation
 deploy \
   --template-file
 UpdateMembers/temp
late-out.yaml \
   --capabilities
 CAPABILITY_IAM \
   --stack-name <stack-
name></code></pre>

In the member-iam-role/ template.yaml template, the <code>MemberIAMRolePath</code> parameter must match the <code>IAMRolePath</code> parameter and <code>MemberIAMRoleName</code> must match <code>IAMRoleName</code> .

Note

Because Security Hub is a regional service, you must deploy the template individually in each AWS Region. Be sure to first package the solution into an Amazon S3 bucket in each Region.</td><td>AWS DevOps</td></tr>
</table>

Update AWS CLI credentials from AWS IAM Identity Center by using PowerShell

Chad Miles and Andy Bowen, Amazon Web Services

Summary

If you want to use AWS IAM Identity Center (successor to AWS Single Sign-On) credentials with AWS Command Line Interface (AWS CLI), AWS SDKs, or AWS Cloud Development Kit (AWS CDK), you typically have to copy and paste the credentials from the IAM Identity Center console into the command line interface. This process can take a considerable amount of time and has to be repeated for each account that requires access.

One common solution is to use the AWS CLI `aws sso configure` command. This command adds an IAM Identity Center enabled profile to your AWS CLI or AWS SDK. However, the disadvantage of this solution is that you must run the command `aws sso login` for each AWS CLI profile or account that you have configured this way.

As an alternative solution, this pattern describes how to use AWS CLI named profiles and AWS Tools for PowerShell to store and refresh credentials for multiple accounts from a single IAM Identity Center instance simultaneously. The script also stores IAM Identity Center session data in memory for refreshing credentials without logging into IAM Identity Center again.

Prerequisites and limitations

Prerequisites

- PowerShell, installed and configured. For more information, see Installing PowerShell (Microsoft documentation).
- AWS Tools for PowerShell, installed and configured. For performance reasons, we highly recommend that you install the modularized version of AWS Tools for PowerShell, called `AWS.Tools`. Each AWS service is supported by its own individual, small module. In the PowerShell prompt, enter the following commands to install the modules needed for this pattern: `AWS.Tools.Installer`, `SSO`, and `SSOIDC`.

```
Install-Module AWS.Tools.Installer
Install-AWSToolsModule SSO, SSOIDC
```

For more information, see Install AWS.Tools on Windows or Install AWS.Tools on Linux or macOS.

- AWS CLI or the AWS SDK must be previously configured with working credentials by doing one of the following:
  - Use the AWS CLI `aws configure` command. For more information, see Quick configuration (AWS CLI documentation).
  - Configure AWS CLI or AWS CDK to get temporary access through an IAM role. For more information, see Getting IAM role credentials for CLI access (IAM Identity Center documentation).

Limitations

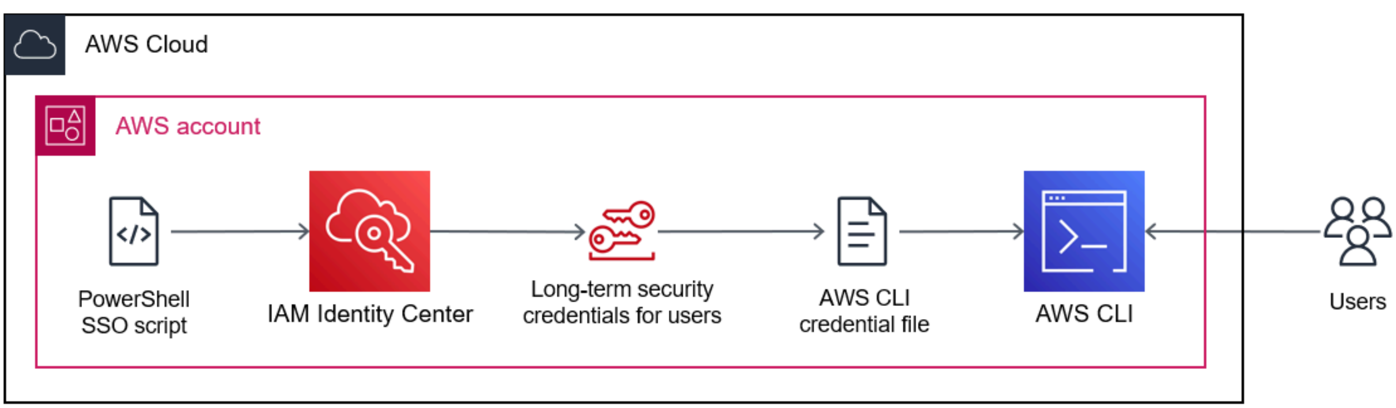
- This script can't be used in a pipeline or fully automated solution. When you deploy this script, you must manually authorize access from IAM Identity Center. The script then continues automatically.

Product versions

- For all operating systems, it is recommended that you use PowerShell version 7.0 or later.

Architecture

You can use the script in this pattern to simultaneously refresh multiple IAM Identity Center credentials, and you can create a credential file for use with AWS CLI, AWS SDKs, or AWS CDK.



Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and cloud applications.
- AWS Tools for PowerShell are a set of PowerShell modules that help you script operations on your AWS resources from the PowerShell command line.

Other tools

- PowerShell is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.

Best practices

Keep one copy of this script for each IAM Identity Center instance. Using one script for multiple instances is not supported.

Epics

Run the SSO script

Task	Description	Skills required
Customize the SSO script.	1. Copy the SSO script in the Additional information section. 2. In the `Param` section, for your AWS environment, define the values for the following variables: • `DefaultRoleName` – The IAM role or	Cloud administrator

Task	Description	Skills required
	permission set to use by default. • `Region` – The AWS Region in which IAM Identity Center is deployed. For a complete list of Regions and their codes, see [Regional endpoints](#). • `StartUrl` – The URL used to access your IAM Identity Center login page. Use the same format as the example value in the script. • `EnvironmentName` – A short name to reference this copy of the script, to be used when you're running multiple script copies in the same session. 3. Under line 10, which reads `# Add your Account Information`, edit the following values in the hash tables to reflect your environment: • `Profile` – The AWS CLI profile name in which to store the temporary credentials.	

Task	Description	Skills required
	`AccountId` – The ID of the AWS account for which you are retrieving credentials. `RoleName` – The name of the IAM Identity Center role or permission set you want to use. You can leave this as `$DefaultRoleName` if you want to use the same role you defined in the `Param` section. Each line in the hash table must end with a comma except the last one.	

Run the SSO script.	It is recommended that you run your custom script in the PowerShell shell with the following command.
	`./Set-AwsCliSsoCredentials.ps1`
	Alternatively, you can run the script from another shell by entering the following command.
	`pwsh Set-AwsCliSsoCredentials.ps1`
		Cloud administrator

Troubleshooting

Issue	Solution
`No Access` error	The IAM role that you are using doesn't have permissions to access the role or permission set that you defined in a `RoleName` parameter . Update the permissions for the role you are using, or define a different role or permission set in the script.

Related resources

- Where are configuration settings stored? (AWS CLI documentation)
- Configuring the AWS CLI to use AWS IAM Identity Center (AWS CLI documentation)
- Using named profiles (AWS CLI documentation)

Additional information

SSO script

In the following script, replace placeholders in angle brackets (<>) with your own information and remove the angle brackets.

```
Set-AwsCliSsoCredentials.ps1
Param(
    $DefaultRoleName = '<AWSAdministratorAccess>',
    $Region          = '<us-west-2>',
    $StartUrl        = "<https://d-12345abcde.awsapps.com/start/>",
    $EnvironmentName = "<CompanyName>"
)
Try {$SsoAwsAccounts = (Get-Variable -name "$($EnvironmentName)SsoAwsAccounts" -Scope
 Global -ErrorAction 'SilentlyContinue').Value.Clone()}
Catch {$SsoAwsAccounts = $False}
if (-not $SsoAwsAccounts) { $SsoAwsAccounts = @(
# Add your account information in the list of hash tables below, expand as necessary,
 and do not forget the commas
```

Use AWS Config to monitor Amazon Redshift security configurations

Lucas Kauffman and abhishek sengar, Amazon Web Services

Summary

Using AWS Config, you can evaluate the security configurations for your AWS resources. AWS Config can monitor the resources, and if configuration settings violate your defined rules, AWS Config flags the resource as *noncompliant*.

You can use AWS Config to evaluate and monitor your Amazon Redshift clusters and databases. For more information about security recommendations and features, see Security in Amazon Redshift. This pattern includes custom AWS Lambda rules for AWS Config. You can deploy these rules in your account to monitor the security configurations of your Amazon Redshift clusters and databases. The rules in this pattern help you use AWS Config to confirm that:

- Audit logging is enabled for the databases in the Amazon Redshift cluster
- SSL is required to connect to the Amazon Redshift cluster
- Federal Information Processing Standards (FIPS) ciphers are in use
- Databases in the Amazon Redshift cluster are encrypted
- User activity monitoring is enabled

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Config must be enabled in your AWS account. For more information, see Setting Up AWS Config with the Console or Setting Up AWS Config with the AWS CLI.
- Python version 3.9 or later must be used for the AWS Lambda handler. For more information, see Working with Python (AWS Lambda documentation).

Product versions

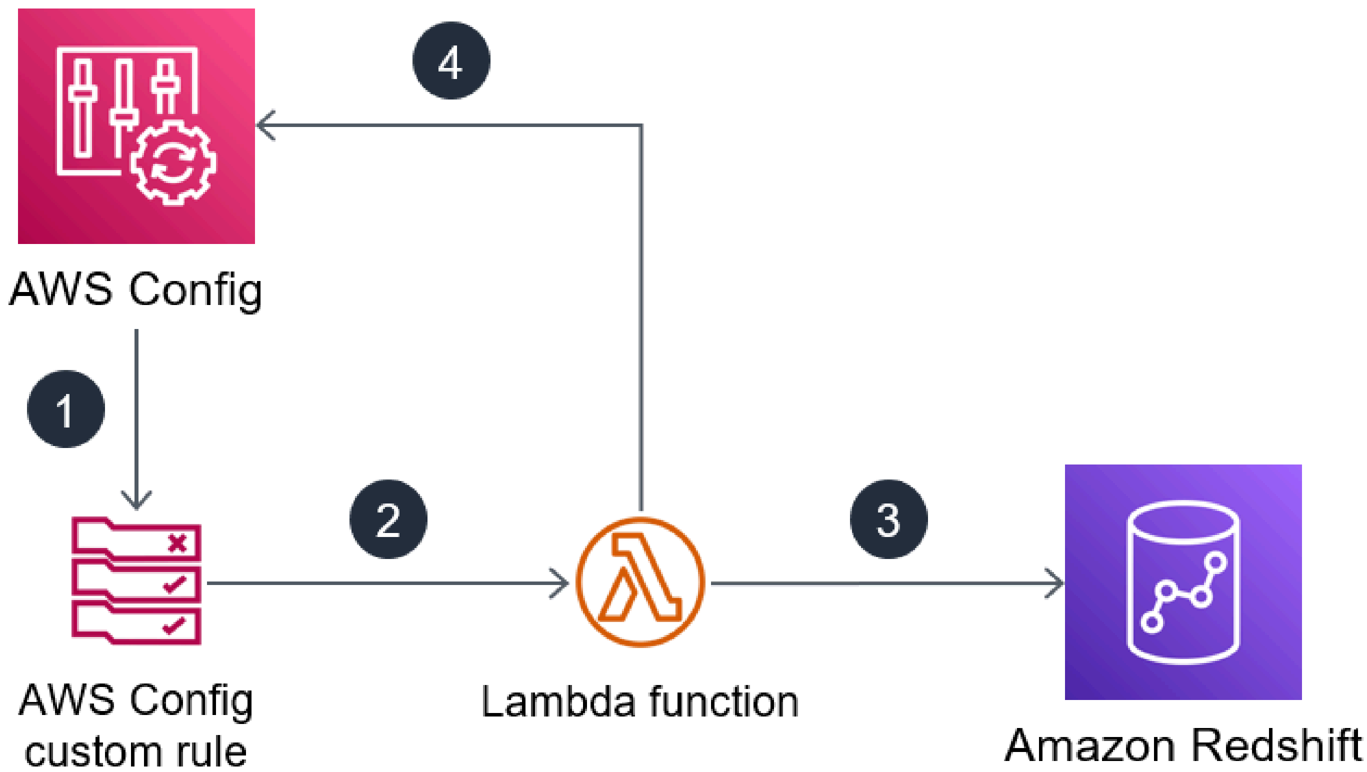
- Python version 3.9 or later

Architecture

Target technology stack

- AWS Config

Target architecture



1. AWS Config periodically runs the custom rule.
2. The custom rule invokes the Lambda function.
3. The Lambda function checks the Amazon Redshift clusters for non-compliant configurations.
4. The Lambda function reports the compliance state of each Amazon Redshift cluster to AWS Config.

Automation and scale

The AWS Config custom rules scale to assess all Amazon Redshift clusters in your account. No additional action is required to scale this solution.

Tools

AWS services

- [AWS Config](#) provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Redshift](#) is a managed petabyte-scale data warehouse service in the AWS Cloud.

Code repository

The code for this pattern is available in the GitHub [aws-config-rules](#) repository. The custom rules in this repository are Lambda rules in the Python programming language. This repository contains many custom rules for AWS Config. Only the following rules are used in this pattern:

- `REDSHIFT_AUDIT_ENABLED` – Confirm that audit logging is enabled on the Amazon Redshift cluster. If you also want to confirm that user activity monitoring is enabled, deploy the `REDSHIFT_USER_ACTIVITY_MONITORING_ENABLED` rule instead.
- `REDSHIFT_SSL_REQUIRED` – Confirm that SSL is required to connect to the Amazon Redshift cluster. If you also want to confirm that Federal Information Processing Standards (FIPS) ciphers are in use, deploy the `REDSHIFT_FIPS_REQUIRED` rule instead.
- `REDSHIFT_FIPS_REQUIRED` – Confirm that SSL is required and FIPS ciphers are in use.
- `REDSHIFT_DB_ENCRYPTED` – Confirm that the databases in the Amazon Redshift cluster are encrypted.
- `REDSHIFT_USER_ACTIVITY_MONITORING_ENABLED` – Confirm that audit logging and user activity monitoring is enabled.

Epics

Prepare to deploy the rules

Task	Description	Skills required

Configure IAM policies.	1. Create a custom IAM identity-based policy that allows the Lambda execution role to read the Amazon Redshift cluster configurations. For more information, see [Managing access to resources](#) (Amazon Redshift documentation) and [Creating IAM policies](#) (IAM documentation).

	2. Assign the AWSLambda Execute and AWSConfig RulesExecutionRole managed policies as a permissions policy for the Lambda execution role. For instructions, see Adding IAM identity permissions (IAM documentation).	

Clone the repository.	In a Bash shell, run the following command. This clones the aws-config-rules repository from GitHub. ``` git clone https://g ithub.com/awslabs/ aws-config-rules.git ```	General AWS

Deploy the rules in AWS Config

Task	Description	Skills required
Deploy the rules in AWS Config.	Following the instructions in Creating custom Lambda rules (AWS Config documentation), deploy one or more of the following rules in your account: • `REDSHIFT_AUDIT_ENABLED` • `REDSHIFT_SSL_REQUIRED` • `REDSHIFT_FIPS_REQUIRED` • `REDSHIFT_DB_ENCRYPTED` • `REDSHIFT_USER_ACTIVITY_MONITORING_ENABLED`	AWS administrator
Verify the rules are functional.	After deploying the rules, follow the instructions in Evaluating your resources (AWS Config documentation) to confirm that AWS Config is correctly evaluating your Amazon Redshift resources.	General AWS

Related resources

AWS service documentation

- Security in Amazon Redshift (Amazon Redshift documentation)

- Managing database security (Amazon Redshift documentation)
- AWS Config custom rules (AWS Config documentation)

AWS Prescriptive Guidance

- Verify that new Amazon Redshift clusters have required SSL endpoints
- Ensure an Amazon Redshift cluster is encrypted upon creation

Additional information

You can use the following AWS Managed Rules in AWS Config to confirm the following security configurations for Amazon Redshift:

- redshift-cluster-configuration-check – Use this rule to confirm that audit logging is enabled for the databases in the Amazon Redshift cluster and confirm that the databases are encrypted.
- redshift-require-tls-ssl – Use this rule to confirm that SSL is required to connect to the Amazon Redshift cluster.

Use Network Firewall to capture the DNS domain names from the Server Name Indication for outbound traffic

Kirankumar Chandrashekar, Amazon Web Services

Summary

This pattern shows you how to use AWS Network Firewall to collect the DNS domain names that are provided by the Server Name Indication (SNI) in the HTTPS header of your outbound network traffic. Network Firewall is a managed service that makes it easy to deploy critical network protections for Amazon Virtual Private Cloud (Amazon VPC), including the ability to secure outbound traffic with a firewall that blocks packets that fail to meet certain security requirements. Securing outbound traffic to specific DNS domain names is called egress filtering, which is the practice of monitoring and potentially restricting the flow of outbound information from one network to another.

After you capture the SNI data that passes through Network Firewall, you can use Amazon CloudWatch Logs and AWS Lambda to publish the data to an Amazon Simple Notification Service (Amazon SNS) topic that generates email notifications. The email notifications include the server name and other relevant SNI information. Additionally, you can use the output of this pattern to allow or restrict outbound traffic by domain name in the SNI by using firewall rules. For more information, see Working with stateful rule groups in AWS Network Firewall in the Network Firewall documentation.

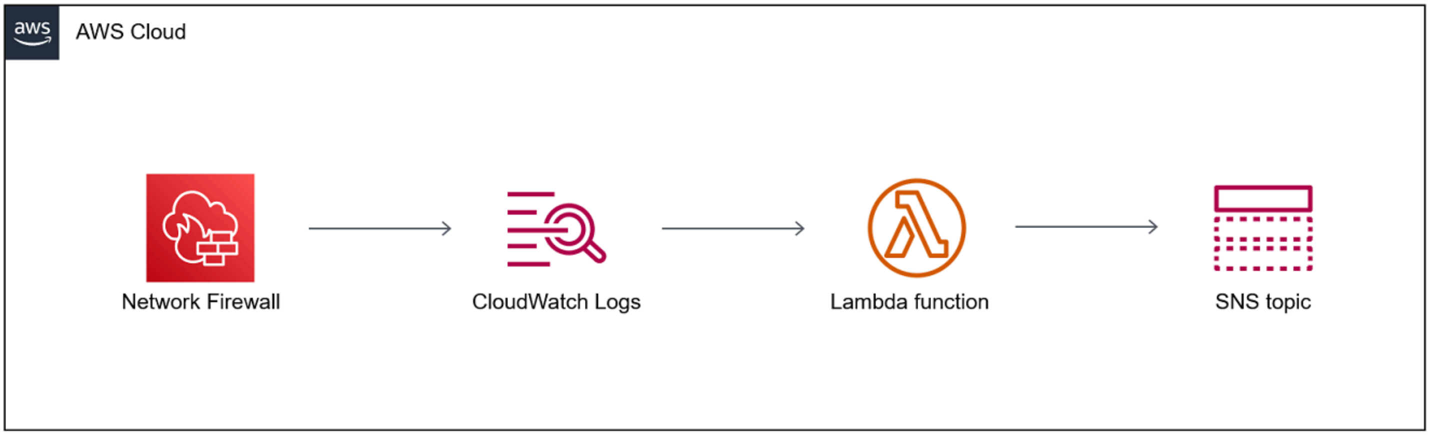
Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows.
- Network Firewall, set up and configured in Amazon VPC and in use for inspecting outbound traffic. You can configure Network Firewall to use any of the following VPC configurations:
  - Simple single zone architecture with an internet gateway
  - Multi zone architecture with an internet gateway
  - Architecture with an internet gateway and a NAT gateway

Architecture

The following diagram shows how to use Network Firewall to collect SNI data from outbound network traffic, and then publish that data to an SNS topic by using CloudWatch Logs and Lambda.



The diagram shows the following workflow:

1. Network Firewall collects domain names from the SNI data in the HTTPS header of your outbound network traffic.
2. CloudWatch Logs monitors the SNI data and invokes a Lambda function whenever the outbound network traffic passes through Network Firewall.
3. The Lambda function reads the SNI data captured by CloudWatch Logs and then publishes that data to an SNS topic.
4. The SNS topic sends you an email notification that includes the SNI data.

Automation and scale

- You can use AWS CloudFormation to create this pattern by using infrastructure as code.

Technology stack

- Amazon CloudWatch Logs
- Amazon SNS
- Amazon VPC
- AWS Lambda
- AWS Network Firewall

Tools

AWS services

- Amazon CloudWatch Logs – You can use Amazon CloudWatch Logs to monitor, store, and access your log files from Amazon Elastic Compute Cloud (Amazon EC2) instances, AWS CloudTrail, Amazon Route 53, and other sources.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).
- Amazon VPC – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- AWS Lambda – AWS Lambda is a compute service that lets you run code without provisioning or managing servers.
- AWS Network Firewall – AWS Network Firewall is a managed service that makes it easy to deploy essential network protections for all of your Amazon VPCs.

Epics

Create a CloudWatch log group for Network Firewall

Task	Description	Skills required
Create a CloudWatch log group.	1. Sign in to the AWS Management Console and open the CloudWatch console. 2. In the navigation pane, choose **Log groups**. 3. Choose **Actions**, and then choose **Create log group**.	Cloud administrator

Task	Description	Skills required
	4. Enter a name for the log group, and then choose **Create log group**. For more information, see Working with log groups and log streams in the CloudWatc h documentation.	

Create an SNS topic and subscription

Task	Description	Skills required
Create an SNS topic.	To create an SNS topic, follow the instructions in the Amazon SNS documentation.	Cloud administrator
Subscribe an endpoint to the SNS topic.	To subscribe an email address as an endpoint to the SNS topic that you created, follow the instructions in the Amazon SNS documentation. For **Protocol**, choose Email/ Email-JSON. **Note** You can also choose a different endpoint based on your requirements.	Cloud administrator

Set up logging in Network Firewall

Task	Description	Skills required
Enable firewall logging.	1. Sign in to the AWS Management Console and open the [Amazon VPC console](). 2. In the navigation pane, under **NETWORK FIREWALL**, choose **Firewalls**. 3. In the **Firewalls** section, choose the firewall where you want to capture the server name from the SNI for outbound traffic. 4. Choose the **Firewall details** tab, and then choose **Edit** in the **Logging** section. 5. For **Log type**, select **Alert**. For **Log destinati on for alerts**, select **CloudWatch log group**. 6. For **CloudWatch log group**, search for and choose the log group that you created earlier, and then choose **Save**. For more information about using CloudWatch Logs as a log destination for Network Firewall, see [Amazon]()	Cloud administrator

Task	Description	Skills required
	CloudWatch Logs in the Network Firewall documentation.	

Set up a stateful rule in Network Firewall

Task	Description	Skills required
Create a stateful rule.	1. Sign in to the AWS Management Console and open the Amazon VPC console. 2. In the navigation pane, under **NETWORK FIREWALL**, choose **Network Firewall Rule Groups**. 3. Choose **Create Network Firewall rule group**. 4. On the **Create Network Firewall rule group** page, for the **Rule group type**, choose **Stateful rule group**. **Note**: For more information, see Working with stateful rule groups in AWS Network Firewall. 5. In the **Stateful rule group** section, enter a name and description for the rule group. 6. For **Capacity**, set the maximum capacity that	Cloud administrator

Task	Description	Skills required
	you want to allow for the stateful rule group (up to the maximum of 30,000). **Note**: You can't change this setting after you create the rule group. For information about how to calculate capacity, see [Setting rule group capacity in AWS Network Firewall](). For information about the maximum setting, see [AWS Network Firewall quotas](). 7. For **Stateful rule group options**, select **5-tuple**. 8. In the **Stateful rule order** section, choose **Default**. 9. In the **Rule variables** section, keep the default values. 10. In the **Add rule** section, choose **TLS** for **Protocol**. For **Source**, choose **Any**. For **Source port**, choose **Any port**. For **Destination**, choose **Any**. For **Destination port**, choose **Any port**. For **Traffic direction**, choose **Forward**. For **Action**, choose **Alert**. Choose **Add rule**.	

Task	Description	Skills required
	11. Choose **Create stateful rule group**.	
Associate the stateful rule to Network Firewall.	1. Sign in to the AWS Management Console and open the [Amazon VPC console](https://console.aws.amazon.com/vpc/). 2. In the navigation pane, under **NETWORK FIREWALL**, choose **Firewalls**. 3. Choose the firewall where you want to capture the server name from the SNI for outbound traffic. 4. In the **Stateful rule groups** section, choose **Actions**, and then choose **Add unmanaged stateful rule groups**. 5. On the **Add unmanaged stateful rule groups** page, select the stateful rule group that you created earlier, and then choose **Add stateful rule group**.	Cloud administrator

Create a Lambda function to read the logs

Task	Description	Skills required
Create the code for the Lambda function.	In an integrated developme nt environment (IDE) that can read the CloudWatch Logs	App developer

Task	Description	Skills required
	event from Network Firewall for outbound traffic, paste in the following Python 3 code and replace `<SNS-topic-ARN>` with your value:	

```
import json
import gzip
import base64
import boto3
sns_client = boto3.cli
ent('sns')
def lambda_handler(eve
nt, context):
    decoded_event =
 json.loads(gzip.de
compress(base64.b6
4decode(event['aws
logs']['data'])))
    body = '''
    {filtermatch}
    '''.format(
        loggroup=
decoded_event['log
Group'],
        logstream
=decoded_event['lo
gStream'],
        filtermat
ch=decoded_event['
logEvents'][0]['me
ssage'],
    )
    print(body)
    filterMatch =
 json.loads(body)
    data = []
    if 'http' in
 filterMatch['event']:
        data.appe
nd(filterMatch['ev
```

Task	Description	Skills required

	``
	ent']['http']['hos
	tname'])
	    elif 'tls' in
	 filterMatch['event']:
	        data.appe
	nd(filterMatch['ev
	ent']['tls']['sni'])
	    result = 'Domain
	 accessed ' + 1*' ' +
	 (data[0]) + 1*' ' 'via
	 AWS Network Firewall
	 ' + 1*' ' + (filterMa
	tch['firewall_name'])
	    print(result)
	    message = {'ServerN
	ame': result}
	    send_to_sns =
	 sns_client.publish(
	        TargetArn=<SNS-
	topic-ARN>,
	 #Replace with the SNS
	 topic ARN
	        Message=j
	son.dumps({'default':
	 json.dumps(message),
	
	    'sms': json.dump
	s(message),
	
	   'email': json.dump
	s(message)}),
	        Subject='Server
	 Name passed through the
	 Network Firewall',
	        MessageSt
	ructure='json'
	    )
	``
	
	This code sample parses the CloudWatch Logs content and captures the server name	

Task	Description	Skills required
	provided by the SNI in the HTTPS header.	
Create the Lambda function.	To create the Lambda function, follow the instructions in the Lambda documentation and choose **Python 3.9** for **Runtime**.	Cloud administrator
Add the code to the Lambda function.	To add your Python code to the Lambda function that you created earlier, follow the instructions in the Lambda documentation.	Cloud administrator

Task	Description	Skills required
Add CloudWatch Logs as a trigger to the Lambda function.	1. Sign in to the AWS Management Console and open the Lambda console. 2. In the navigation pane, choose **Functions**, and then choose the function that you created earlier. 3. In the **Function overview** section, choose **Add trigger**. 4. On the **Add trigger** page, in the **Trigger configura tion** section, choose **CloudWatch Logs**, and then choose **Add**. 5. For **Log group**, choose the CloudWatch log group that you created earlier. 6. For **Filter name**, enter a name for your filter. 7. Choose **Add**. 8. On the **Configuration** tab of your function's page, in the **Triggers** section, select the trigger that you just added, and then choose **Enable**. For more information, see Using Lambda with CloudWatch Logs in the Lambda documentation.	Cloud administrator

Task	Description	Skills required
Add SNS publish permissions.	Add the **sns:Publish** permission to the Lambda execution role, so that Lambda can make API calls to publish messages to SNS. 1. Find the execution role of the Lambda function that you created earlier. 2. Add the following policy to your AWS Identity and Access Management (IAM) role: `{ "Version": "2012-10-17", "Statement": [ { "Sid": "AllowSNSPublish", "Effect": "Allow", "Action": [ "sns:GetTopicAttributes", "sns:Subscribe", "sns:Unsubscribe", "sns:Publish" ], "Resource": "*" } ]`	Cloud administrator

Task	Description	Skills required
	`}`	

Test the functionality of your SNS notification

Task	Description	Skills required

Send traffic through Network Firewall.	1. Send or wait for HTTPS traffic to pass through Network Firewall.
	2. Check the SNS notification email that you receive from AWS when traffic passes through Network Firewall. The email includes the SNI details for outbound traffic. For example, the email generated from the Lambda code above will have the following content if the accessed domain name is **https://aws.amazon.com** and the subscription protocol is **EMAIL-JSON**:
	
	`{`
	`    "Type": "Notifica`
	`tion",`
	`    "MessageId":`
	` "<messageID>",`
	`    "TopicArn":`
	` "arn:aws:sns:us-we`
	`st-2:123456789:tes`
	`tSNSTopic",`
		Test engineer

Task	Description	Skills required
	"Subject": "Server Name passed through the Network Firewall", "Message": "{\"ServerName\": \"Domain 'aws.amazon.com' accessed via AWS Network Firewall 'AWS-Network-Firewall-Multi-AZ-firewall\"}", "Timestamp": "2022-03-22T04:10:04.217Z", "SignatureVersion": "1", "Signature": "<Signature>", "SigningCertURL": "<SigningCertUrl>", "UnsubscribeURL": "<UnsubscribeURL>" } Then, check the Network Firewall alert log in Amazon CloudWatch by following the instructions in the [Amazon CloudWatch documentation](). The alert log shows the following output: { "firewall_name": "AWS-Network-Firewall-Multi-AZ-firewall", "availability_zone": "us-east-2b",	

Task	Description	Skills required
	"event_timestamp": "<event timestamp>", "event": { "timestamp": "2021-03-22T04:10:04.214222+0000", "flow_id": <flow ID>, "event_type": "alert", "src_ip": "10.1.3.76", "src_port": 22761, "dest_ip": "99.86.59.73", "dest_port": 443, "proto": "TCP", "alert": { "action": "allowed", "signature_id": 2, "rev": 0, "signature": "", "category": "", "severity": 3 }, "tls": { "subject": "CN=aws.amazon.com", "issuerdn": "C=US, O=Amazon, OU=Server CA 1B, CN=Amazon", "serial": "<serial number>",	

Task	Description	Skills required
	`"fingerprint": "<fingerprint ID>", "sni": "aws.amazon.com", "version": "TLS 1.2", "notbefore": "2020-09-30T00:00:00", "notafter": "2021-09-23T12:00:00", "ja3": {}, "ja3s": {} }, "app_proto": "tls" } }`	

Use Terraform to automatically enable Amazon GuardDuty for an organization

Aarthi Kannan, Amazon Web Services

Summary

Amazon GuardDuty continuously monitors your Amazon Web Services (AWS) accounts and uses threat intelligence to identify unexpected and potentially malicious activity within your AWS environment. Manually enabling GuardDuty for multiple accounts or organizations, across multiple AWS Regions, or through the AWS Management Console can be cumbersome. You can automate the process by using an infrastructure as code (IaC) tool, such as Terraform, which can provision and manage multi-account, multi-Region services and resources in the cloud.

AWS recommends using AWS Organizations to set up and manage multiple accounts in GuardDuty. This pattern adheres to that recommendation. One benefit of this approach is that, when new accounts are created or added to the organization, GuardDuty will be auto-enabled in these accounts for all supported Regions, without the need for manual intervention.

This pattern demonstrates how to use HashiCorp Terraform to enable Amazon GuardDuty for three or more Amazon Web Services (AWS) accounts in an organization. The sample code provided with this pattern does the following:

- Enables GuardDuty for all AWS accounts that are current members of the target organization in AWS Organizations
- Turns on the *Auto-Enable* feature in GuardDuty, which automatically enables GuardDuty for any accounts that are added to the target organization in the future
- Allows you select the Regions where you want to enable GuardDuty
- Uses the organization's security account as the GuardDuty delegated administrator
- Creates an Amazon Simple Storage Service (Amazon S3) bucket in the logging account and configures GuardDuty to publish the aggregated findings from all accounts in this bucket
- Assigns a life-cycle policy that transitions findings from the S3 bucket to Amazon S3 Glacier Flexible Retrieval storage after 365 days, by default

You can manually run this sample code, or you can integrate it into your continuous integration and continuous delivery (CI/CD) pipeline.

Target audience

This pattern is recommended for users who have experience with Terraform, Python, GuardDuty, and AWS Organizations.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An organization is set up in AWS Organizations, and it contains at least the following three accounts:
  - **A management account –** This is the account from which you deploy the Terraform code, either standalone or as part of the CI/CD pipeline. The Terraform state is also stored in this account.
  - **A security account –** This account is used as the GuardDuty delegated administrator. For more information, see Important considerations for GuardDuty delegated administrators (GuardDuty documentation).
  - **A logging account –** This account contains the S3 bucket where GuardDuty publishes the aggregated findings from all member accounts.

  For more information about how to set up the organization with the required configuration, see Create an account structure (AWS Well-Architected Labs).
- An Amazon S3 bucket and an Amazon DynamoDB table that serve as a remote backend to store Terraform's state in the management account. For more information on using remote backends for the Terraform state, see S3 Backends (Terraform documentation). For a code sample that sets up remote state management with an S3 backend, see remote-state-s3-backend (Terraform Registry). Note the following requirements:
  - The S3 bucket and DynamoDB table must be in the same Region.
  - When creating the DynamoDB table, the partition key must be `LockID` (case-sensitive), and the partition key type must be **String**. All other table settings must be at their default values. For more information, see About primary keys and Create a table (DynamoDB documentation).
- An S3 bucket that will be used to store access logs for the S3 bucket in which GuardDuty will publish findings. For more information, see Enabling Amazon S3 server access logging (Amazon S3 documentation). If you're deploying to an AWS Control Tower landing zone, you can reuse the S3 bucket in the **log archive** account for this purpose.

- Terraform version 0.14.6 or later is installed and configured. For more information, see Get Started – AWS (Terraform documentation).
- Python version 3.9.6 or later is installed and configured. For more information, see Source releases (Python website).
- AWS SDK for Python (Boto3) is installed. For more information, see Installation (Boto3 documentation).
- jq is installed and configured. For more information, see Download jq (jq documentation).

Limitations

- This pattern supports macOS and Amazon Linux 2 operating systems. This pattern has not been tested for use in Windows operating systems.

> **Note**
>
> Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs.

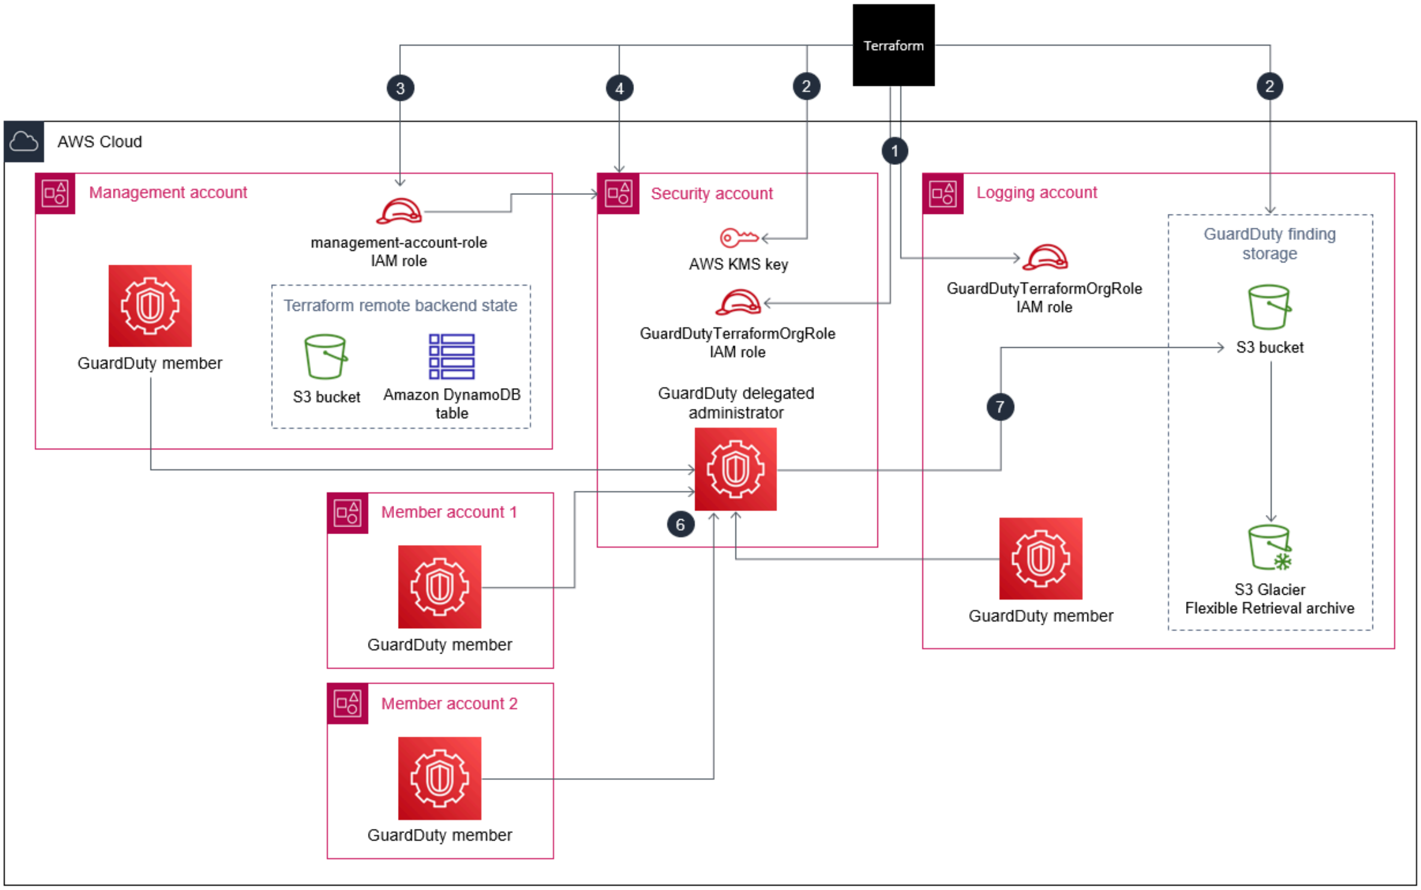
- GuardDuty must not already be enabled in any of the accounts, in any of the target Regions.
- The IaC solution in this pattern does not deploy the prerequisites.
- This pattern is designed for an AWS landing zone that adheres to the following best practices:
  - The landing zone was created by using AWS Control Tower.
  - Separate AWS accounts are used for security and logging.

Product versions

- Terraform version 0.14.6 or later. The sample code has been tested for version 1.2.8.
- Python version 3.9.6 or later.

Architecture

This section gives a high-level overview of this solution and the architecture established by the sample code. The following diagram shows the resources deployed across the various accounts in the organization, within a single AWS Region.



1. Terraform creates the **GuardDutyTerraformOrgRole** AWS Identity and Access Management (IAM) role in the security account and the logging account.
2. Terraform creates an S3 bucket in the default AWS Region in the logging account. This bucket is used as the publishing destination to aggregate all GuardDuty findings across all Regions and from all accounts in the organization. Terraform also creates an AWS Key Management Service (AWS KMS) key in the security account that is used to encrypt the findings in the S3 bucket and configures automatic archiving of findings from the S3 bucket into S3 Glacier Flexible Retrieval storage.
3. From the management account, Terraform designates the security account as the delegated administrator for GuardDuty. This means that the security account now manages the GuardDuty service for all member accounts, including the management account. Individual member accounts cannot suspend or disable GuardDuty by themselves.
4. Terraform creates the GuardDuty detector in the security account, for the GuardDuty delegated administrator.
5. If it is not already enabled, Terraform enables S3 protection in GuardDuty. For more information, see [Amazon S3 protection in Amazon GuardDuty](#) (GuardDuty documentation).

6. Terraform enrolls all current, active member accounts in the organization as GuardDuty members.
7. Terraform configures the GuardDuty delegated administrator to publish the aggregated findings from all member accounts to the S3 bucket in the logging account.
8. Terraform repeats steps 3 through 7 for each AWS Region you choose.

Automation and scale

The sample code provided is modularized so that you can integrate it into your CI/CD pipeline for automated deployment.

Tools

AWS services

- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- Amazon GuardDuty is a continuous security monitoring service that analyzes and processes logs to identify unexpected and potentially unauthorized activity in your AWS environment.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to protect your data.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

Other tools and services

- HashiCorp Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.
- Python is a general-purpose programming language.
- jq is a command-line processor that helps you work with JSON files.

Code repository

The code for this pattern is available on GitHub, in the amazon-guardduty-for-aws-organizations-with-terraform repository.

Epics

Enable GuardDuty in the organization

Task	Description	Skills required
Clone the repository.	In a Bash shell, run the following command. In *Clone the repository* in the Additional information section, you can copy the full command containing the URL of the GitHub repository. This clones the amazon-guardduty-for-aws-organizations-with-terraform repository from GitHub. `git clone <github-repository-url>`	DevOps engineer
Edit the Terraform configuration file.	1. In the `root` folder of the cloned repository, replicate the **configuration.json.sample** file by running the following command. `cp configuration.json.sample configuration.json` 2. Edit the new **configuration.json** file, and define	DevOps engineer, General AWS, Terraform, Python

Task	Description	Skills required
	the values for each of the following variables: • `management_acc_id` – Account ID of the management account. • `delegated_admin_acc_id` – Account ID of the security account. • `logging_acc_id` – Account ID of the logging account. • `target_regions` – Comma-separated list of AWS Regions where you want to enable GuardDuty. • `organization_id` – AWS Organizations ID of the organization in which you are enabling GuardDuty. • `default_region` – The Region where your Terraform state is stored in the management account. This is the same Region where you deployed the S3 bucket and DynamoDB table for the Terraform backend. • `role_to_assume_for_role_creation` – Name that you want	

Task	Description	Skills required
	to assign to a new IAM role in the security and logging accounts. You create this new role in the next story. Terraform assumes this role to create the `GuardDuty TerraformOrgRole` IAM role in the security and logging accounts. • `finding_publishing_frequency` – Frequency at which GuardDuty publishes findings to the S3 bucket. • `guardduty_findings_bucket_region` – Preferred Region where you want to create the S3 bucket for published findings. • `logging_acc_s3_bucket_name` – Preferred name for the S3 bucket for published findings. • `security_acc_kms_key_alias` – AWS KMS alias for the key used to encrypt GuardDuty findings. • `s3_access_log_bucket_name` – Name of a preexisting S3 bucket	

Task	Description	Skills required
	where you want to collect access logs for the S3 bucket used for GuardDuty findings. This bucket should be in the same AWS Region as the GuardDuty findings bucket. • `tfm_state_backend_s3_bucket` – Name of the preexisting S3 bucket to store the Terraform remote backend state. • `tfm_state_backend_dynamodb_table` – Name of the preexisting DynamoDB table for locking the Terraform state. 3. Save and close the configuration file.	

Task	Description	Skills required
Generate CloudFormation templates for new IAM roles.	This pattern includes an IaC solution to create two CloudFormation templates. These templates create two IAM roles that Terraform uses during the setup process. These templates adhere to the security best practice of [least-privilege permissions](). 1. In a Bash shell, in the repository `root` folder, navigate to `cfn-templates/` . This folder contains CloudFormation templates files with stubs. 2. Run the following command. This replaces the stubs with the values you provided in the **configuration.json** file. `bash scripts/replace_config_stubs.sh` 3. Confirm that the following CloudFormation templates were created in the `cfn-templates/` folder: • **management-account-role.yaml** – This file contains the role definition and the associated permissions	DevOps engineer, General AWS

Task	Description	Skills required
	for the IAM role in the management account, which has the minimum permissions required to complete this pattern. • **role-to-assume-for-role-creation.yaml** – This file contains the role definition and the associated permissions for the IAM role in the security and logging accounts. Terraform assumes this role in order to create the **GuardDutyTerraformOrgRole** role in these accounts.	

Task	Description	Skills required
Create the IAM roles.	Following the instructions in [Creating a stack](#) (CloudFormation documentation), do the following: 1. Deploy the **role-to-assume-for-role-creation.yaml** stack in both the security and logging accounts. 2. Deploy the **management-account-role.yaml** stack in the management account. When you successfully create the stack and see the `CREATE_COMPLETE` stack status, in the output, make note of the Amazon Resource Name (ARN) of this new role.	DevOps engineer, General AWS
Assume the IAM role in the management account.	As a security best practice, we recommend that you assume the new **management-account-role** IAM role before proceeding. In the AWS Command Line Interface (AWS CLI), enter the command in *Assume the management account IAM role* in the [Additional Information](#) section.	DevOps engineer, General AWS

Task	Description	Skills required
Run the setup script.	In the repository `root` folder, run the following command to start the setup script. `bash scripts/full-setup.sh` The **full-setup.sh** script performs the following actions: • Exports all configuration values as environment variables • Generates the **backend.tf** and **terraform.tfvars** code files for each Terraform module • Enables trusted access for GuardDuty in the organization through the AWS CLI. • Imports the organization state into the Terraform state • Creates the S3 bucket for publishing findings in the logging account • Creates the AWS KMS key for encrypting findings in the security account • Enables GuardDuty across the organization, in all selected Regions, as	DevOps engineer, Python

Task	Description	Skills required
	described in the Architecture section	

(Optional) Disable GuardDuty in the organization

Task	Description	Skills required
Run the clean-up script.	If you used this pattern to enable GuardDuty for the organization and want to disable GuardDuty, in the repository `root` folder, run the following command to start the **cleanup-gd.sh** script. `bash scripts/cleanup-gd.sh` This script disables GuardDuty in the target organization, removes any deployed resources, and restores the organization to its previous state before using Terraform to enable GuardDuty. **Note** This script does not remove the Terraform state files or lock files from the local and remote backends. If you need	DevOps engineer, General AWS, Terraform, Python

Task	Description	Skills required
	to do so, you must perform these actions manually. Also, this script does not delete the imported organization or the accounts managed by it. Trusted access for GuardDuty isn't disabled as part of the clean-up script.	
Remove IAM roles.	Delete the stacks that were created with the **role-to-assume-for-role-creation.yaml** and **management-account-role.yaml** CloudFormation templates. For more information, see [Deleting a stack](#) (CloudFormation documentation).	DevOps engineer, General AWS

Additional information

Clone the repository

Run the following command to clone the GitHub repository.

```
git clone https://github.com/aws-samples/amazon-guardduty-for-aws-organizations-with-terraform
```

Assume the management account IAM role

To assume the IAM role in the management account, run the following command. Replace `<IAM role ARN>` with the ARN of the IAM role.

```
export ROLE_CREDENTIALS=$(aws sts assume-role --role-arn <IAM role ARN> --role-session-name AWSCLI-Session --output json)
export AWS_ACCESS_KEY_ID=$(echo $ROLE_CREDENTIALS | jq .Credentials.AccessKeyId | sed 's/"//g')
export AWS_SECRET_ACCESS_KEY=$(echo $ROLE_CREDENTIALS | jq .Credentials.SecretAccessKey | sed 's/"//g')
export AWS_SESSION_TOKEN=$(echo $ROLE_CREDENTIALS | jq .Credentials.SessionToken | sed 's/"//g')
```

Verify operational best practices for PCI DSS 4.0 by using AWS Config

Tala Qraitem and Alex Goff, Amazon Web Services

Summary

The Payment Card Industry Data Security Standard (PCI DSS) outlines essential technical and operational protocols to help safeguard payment data. PCI DSS was developed to encourage and enhance data security for payment card accounts. It also facilitates the global adoption of consistent security measures. Although it's specifically designed for environments with payment card account data, you can use PCI DSS to help protect against threats and secure other elements in the payment ecosystem.

PCI DSS version 4.0 was released to address evolving requirements, provide clarification or additional guidance, and improve the structure and format of the standard. For more information about the changes, see Summary of changes from PCI DSS version 3.2.1 to 4.0.

An AWS Config conformance pack is a collection of AWS Config rules and remediation actions that help you create security, operational, or cost-optimization governance checks. You can deploy a conformance pack as a single entity in an AWS account and AWS Region, or you can deploy across an organization in AWS Organizations.

The conformance packs for PCI DSS version 4.0 augment and build upon the conformance pack for version 3.2.1. The rules in the conformance pack map to the rules in the standard. For more information, see the mapping provided in the *Attachments* section. You can choose between two versions of this conformance pack: one that includes global resource types and one that excludes them.

Important

Conformance packs are not designed to fully ensure compliance with a specific governance or compliance standard. You are responsible for making your own assessment of whether usage meets applicable legal and regulatory requirements.

Prerequisites and limitations

Prerequisites

- Have an active AWS account.
- Set up AWS Config.
- Meet the prerequisites for conformance packs.
- Deploy the PCI DSS version 3.2.1 conformance pack.
- Have permissions to access AWS Config and manage conformance packs. For an example policy, see the Additional information section of this pattern.

Limitations

- Your AWS account has default quotas, formerly referred to as *limits*, for each AWS service. Unless otherwise noted, each quota is Region-specific. You can request increases for some quotas, but not all quotas can be increased. Make sure that you are familiar with the AWS Config service limits, including the limits for single account conformance packs and organization conformance packs.
- The version of this conformance pack that includes global resource types is intended for deployment only in the `us-east-1` Region.
- The version of this conformance pack that excludes global resources types is intended for deployment only in the following Regions:
  - `ap-east-1`
  - `ap-south-1`
  - `ap-northeast-2`
  - `ap-southeast-1`
  - `ap-southeast-2`
  - `ap-northeast-1`
  - `ca-central-1`
  - `eu-central-1`
  - `eu-west-1`
  - `eu-west-2`
  - `eu-west-3`
  - `eu-north-1`
  - `sa-east-1`
  - `us-east-2`

- `us-west-1`
- `us-west-2`

Tools

AWS services

- AWS Config provides a detailed view of the resources in your AWS account and how they're configured. It helps you identify how resources are related to one another and how their configurations have changed over time.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

Code repository

The conformance packs are located in the AWS Config conformance packs GitHub repository. This repository contains the following templates related to PCI DSS version 4.0:

- Operational-Best-Practices-for-PCI-DSS-v4.0-including-global-resourcetypes.yaml
- Operational-Best-Practices-for-PCI-DSS-v4.0-excluding-global-resourcetypes.yaml

Epics

Deploy and manage the conformance pack

Task	Description	Skills required
Download the conformance pack.	If you're deploying the conformance pack in the `us-east-1` Region, download the Operational-Best-Practices-for-PCI-DSS-v4.0-including-global-resourcetypes.yaml template.	DevOps engineer

Task	Description	Skills required
	If you're deploying the conformance pack in a different Region, download the Operational-Best-Practices-for-PCI-DSS-v4.0-excluding-global-resourcetypes.yaml template.	
(Optional) Modify the conformance pack.	You can modify the conformance pack template for the unique needs of your organization. For example, you can create custom remediation actions. For more information about how to create and modify templates, see Creating templates for custom conformance packs in the AWS Config documentation.	General AWS

Task	Description	Skills required
Deploy the conformance pack.	If you're deploying in a target AWS account or AWS Region, follow the instructions in [Deploying conformance packs](#) in the AWS Config documenta tion. You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI). If you're deploying the conformance pack across an organization in AWS Organizations, follow the instructions in [Deploy AWS Config conformance pack using Quick Setup](#) in the AWS Systems Manager documenta tion.	General AWS
(Optional) Edit the conforman ce pack.	If you want to edit the conformance pack, follow the instructions in [Editing conformance packs](#) in the AWS Config documenta tion. You can use the AWS Management Console or the AWS CLI.	General AWS

Task	Description	Skills required
(Optional) Delete the conformance pack.	If you want to delete the conformance pack, follow the instructions in Deleting conformance packs in the AWS Config documenta tion. You can use the AWS Management Console or the AWS CLI.	General AWS

Verify that new Amazon Redshift clusters have required SSL endpoints

Priyanka Chaudhary, Amazon Web Services

Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that automatically notifies you when a new Amazon Redshift cluster is launched without Secure Sockets Layer (SSL) endpoints.

Amazon Redshift is a fully managed, petabyte-scale, cloud-based data warehouse service. It is designed for large-scale dataset storage and analysis. It is also used to perform large-scale database migrations. For security, Amazon Redshift supports SSL to encrypt the connection between the user's SQL Server client application and the Amazon Redshift cluster. To configure your cluster to require an SSL connection, you set the `require_SSL` parameter to `true` in the parameter group that is associated with the cluster during launch.

The security control provided with this pattern monitors Amazon Redshift API calls in AWS CloudTrail logs and initiates an Amazon CloudWatch Events event for the CreateCluster, ModifyCluster, RestoreFromClusterSnapshot, CreateClusterParameterGroup, and ModifyClusterParameterGroup APIs. When the event detects one of these APIs, it calls AWS Lambda, which runs a Python script. The Python function analyzes the CloudWatch event for the listed CloudTrail events. When an Amazon Redshift cluster is created, modified, or restored from an existing snapshot, a new parameter group is created for the cluster, or an existed parameter group is modified, the function checks the `require_SSL` parameter for the cluster. If the parameter value is `false`, the function sends an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon Redshift cluster name, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

Prerequisites and limitations

Prerequisites

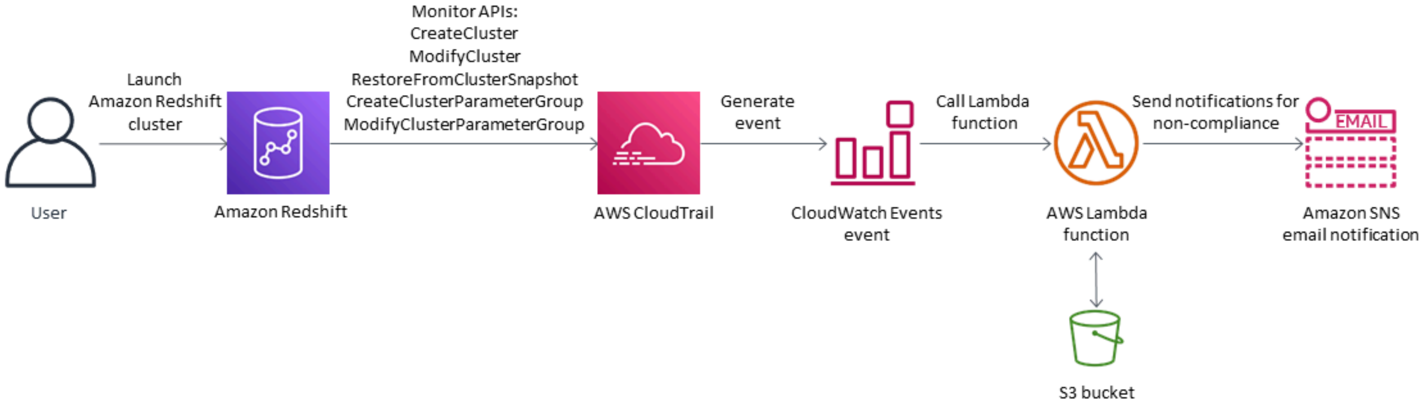
- An active AWS account.
- A virtual private cloud (VPC) with a cluster subnet group, and an associated security group.

Limitations

- This security control is regional. You must deploy it in each AWS Region you want to monitor.

Architecture

Target architecture



Automation and scale

- If you are using [AWS Organizations](), you can use [AWS Cloudformation StackSets]() to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- [AWS CloudFormation]() – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually.
- [Amazon CloudWatch Events]() – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [AWS Lambda]() – AWS Lambda is a compute service that supports running code without provisioning or managing servers.

- Amazon Redshift – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

This pattern includes the following attachments:

- `RedshiftSSLEndpointsRequired.zip` – The Lambda code for the security control.
- `RedshiftSSLEndpointsRequired.yml` – The CloudFormation template that sets up the event and Lambda function.

Epics

Set up the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the Amazon S3 console, choose or create an S3 bucket to host the Lambda code .zip file. This S3 bucket must be in the same AWS Region as the Amazon Redshift cluster you want to monitor. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes.	Cloud architect

Task	Description	Skills required
Upload the Lambda code.	Upload the Lambda code .zip file provided in the *Attachments* section to the S3 bucket.	Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Launch the AWS CloudFormation template.	Open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/) in the same AWS Region as your S3 bucket and deploy the attached template `RedshiftSSLEndpointsRequired.yml` . For more information about deploying AWS CloudFormation templates, see [Creating a stack on the AWS CloudFormation console](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/cfn-console-create-stack.html) in the CloudFormation documentation.	Cloud architect
Complete the parameters in the template.	When you launch the template, you'll be prompted for the following information: • **S3 bucket**: Specify the bucket that you created or selected in the first epic. This is where you uploaded the attached Lambda code (.zip file).	Cloud architect

Task	Description	Skills required
	• **S3 key**: Specify the location of the Lambda .zip file in your S3 bucket (for example, *filename*.zip or controls/*filename*.zip). Do not include leading slashes. • **Notification email**: Provide an active email address where you want to receive Amazon SNS notifications. • **Lamba logging level**: Specify the logging level and frequency for the Lambda function. Use **Info** to log detailed informati onal messages on progress, **Error** for error events that would still allow the deployment to continue, and **Warning** for potential ly harmful situations.	

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the CloudFormation template deploys successfu lly, it sends a subscription email to the email address you provided. You must confirm this email subscript	Cloud architect

Task	Description	Skills required
	ion to start receiving violation notifications.

Verify that new Amazon Redshift clusters launch in a VPC

Priyanka Chaudhary, Amazon Web Services

Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that automatically notifies you when an Amazon Redshift cluster is launched outside a virtual private cloud (VPC).

Amazon Redshift is a fully managed, petabyte-scale, cloud-based data warehouse product. It is designed for large-scale dataset storage and analysis. It is also used to perform large-scale database migrations. Amazon Virtual Private Cloud (Amazon VPC) lets you provision a logically isolated section of the AWS Cloud where you can launch AWS resources such as Amazon Redshift clusters in a virtual network that you define.

The security control provided with this pattern monitors Amazon Redshift API calls in AWS CloudTrail logs, and initiates an Amazon CloudWatch Events event for the CreateCluster and RestoreFromClusterSnapshot APIs. When the event detects one of these APIs, it calls AWS Lambda, which runs a Python script. The Python function analyzes the CloudWatch event. If an Amazon Redshift cluster is created or restored from a snapshot and appears outside the Amazon VPC network, the function sends an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon Redshift cluster name, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

Prerequisites and limitations

Prerequisites

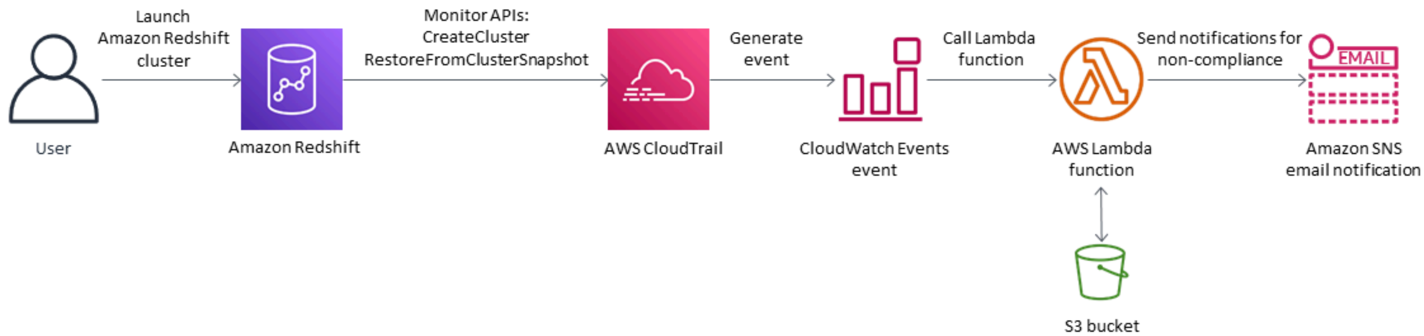
- An active AWS account.
- A VPC with a cluster subnet group, and an associated security group.

Limitations

- The AWS CloudFormation template supports the CreateCluster and RestoreFromClusterSnapshot actions (new clusters) only. It does not detect existing Amazon Redshift clusters that were created outside a VPC.
- This security control is regional. You must deploy it in each AWS Region you want to monitor.

Architecture

Target architecture



Automation and scale

If you are using [AWS Organizations](), you can use [AWS Cloudformation StackSets]() to deploy this template in multiple accounts that you want to monitor.

Tools

AWS services

- [AWS CloudFormation]() – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually.
- [AWS CloudTrail]() – AWS CloudTrail helps you implement governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- [Amazon CloudWatch Events]() – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- [AWS Lambda]() – AWS Lambda is a compute service that supports running code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- [Amazon Redshift]() – Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. Amazon Redshift is integrated with your data lake, which enables you to use your data to acquire new insights for your business and customers.

- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3)is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses.

Code

This pattern includes the following attachments:

- `RedshiftMustBeInVPC.zip` – The Lambda code for the security control.
- `RedshiftMustBeInVPC.yml` – The CloudFormation template that sets up the event and Lambda function.

To use these files, follow the instructions in the next section.

Epics

Set up the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the Amazon S3 console, choose or create an S3 bucket to host the Lambda code .zip file. This S3 bucket must be in the same AWS Region as the Amazon Redshift cluster that you want to monitor. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts. The S3 bucket name cannot include leading slashes.	Cloud architect

Task	Description	Skills required
Upload the Lambda code.	Upload the Lambda code (`RedshiftMustBeInVPC.zip` file) provided in the *Attachments* section to the S3 bucket.	Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Launch the CloudFormation template.	Open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/) in the same AWS Region as your S3 bucket and deploy the attached template (`RedshiftMustBeInVPC.yml`). For more information about deploying AWS CloudFormation templates, see [Creating a stack on the AWS CloudFormation console](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/cfn-console-create-stack.html) in the CloudFormation documentation.	Cloud architect
Complete the parameters in the template.	When you launch the template, you'll be prompted for the following information: • **S3 bucket**: Specify the bucket that you created or selected in the first epic. This is where you uploaded the attached Lambda code (.zip file).	Cloud architect

Task	Description	Skills required
	• **S3 key**: Specify the location of the Lambda .zip file in your S3 bucket (for example, *filename*.zip or controls/*filename*.zip). Do not include leading slashes. • **Notification email**: Provide an active email address where you want to receive Amazon SNS notifications. • **Lamba logging level**: Specify the logging level and frequency for the Lambda function. Use **Info** to log detailed informati onal messages on progress, **Error** for error events that would still allow the deployment to continue, and **Warning** for potential ly harmful situations.	

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the CloudFormation template deploys successfu lly, it sends a subscription email to the email address you provided. You must confirm this email subscript	Cloud architect

Task	Description	Skills required
	ion to start receiving violation notifications.

- Enable encrypted connections for PostgreSQL DB instances in Amazon RDS
- Encrypt an existing Amazon RDS for PostgreSQL DB instance
- Enforce automatic tagging of Amazon RDS databases at launch
- Enforce tagging of Amazon EMR clusters at launch
- Ensure Amazon EMR logging to Amazon S3 is enabled at launch
- Generate an AWS CloudFormation template containing AWS Config managed rules using Troposphere
- Get Amazon SNS notifications when the key state of an AWS KMS key changes
- Help enforce DynamoDB tagging
- Identify and alert when Amazon Data Firehose resources are not encrypted with an AWS KMS key
- Implement Microsoft Entra ID-based authentication in an AWS Blu Age modernized mainframe application
- Implement SAML 2.0 authentication for Amazon WorkSpaces by using Auth0 and AWS Managed Microsoft AD
- Implement SHA1 hashing for PII data when migrating from SQL Server to PostgreSQL
- Improve operational performance by enabling Amazon DevOps Guru across multiple AWS Regions, accounts, and OUs with the AWS CDK
- Ingest and migrate EC2 Windows instances into an AWS Managed Services account
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL in SSL mode by using AWS DMS
- Migrate an ELK Stack to Elastic Cloud on AWS
- Migrate an F5 BIG-IP workload to F5 BIG-IP VE on the AWS Cloud
- Monitor Amazon Aurora for instances without encryption
- Provision least-privilege IAM roles by deploying a role vending machine solution
- Rotate database credentials without restarting containers

- Secure and streamline user access in a Db2 federation database on AWS by using trusted contexts
- Send AWS WAF logs to Splunk by using AWS Firewall Manager and Amazon Data Firehose
- Serve static content in an Amazon S3 bucket through a VPC by using Amazon CloudFront
- Set up end-to-end encryption for applications on Amazon EKS using cert-manager and Let's Encrypt
- Use user IDs in IAM policies for access control and automation
- Verify that ELB load balancers require TLS termination
- View AWS Network Firewall logs and metrics by using Splunk
- Visualize IAM credential reports for all AWS accounts using Amazon QuickSight
