To estimate the DynamoDB cost for a project, it's important to calculate how much RRU, WRU, and storage will be consumed at different stages of your product lifecycle. For a rough cost estimation, you can use [AWS Pricing Calculator](#), but you must provide an approximate number of RRUs, WRUs, and storage requirements for your table. These can be difficult to estimate at the beginning of the project. AWS Pricing Calculator doesn't consider data growth rate or item size, and it doesn't consider the number of reads and writes for the base table and global secondary indexes (GSIs) separately. To use AWS Pricing Calculator, you must estimate all those aspects to assume ballpark figures for WRU, RRU, and storage size to obtain your cost estimation.

This pattern provides a mechanism and a re-usable Microsoft Excel template to estimate basic DynamoDB cost factors, such as write, read, storage, backup and recovery cost, for on-demand capacity mode. It is more granular than AWS Pricing Calculator, and it considers base table and GSIs requirements independently. It also considers the monthly item data growth rate and forecasts costs for three years.

Prerequisites and limitations

Prerequisites

- Basic knowledge of DynamoDB and DynamoDB data model design
- Basic knowledge of DynamoDB pricing, WRU, RRU, storage, and backup and recovery (for more information, see [Pricing for On-Demand Capacity](#))

- Knowledge of your data, data model, and item size in DynamoDB
- Knowledge of DynamoDB GSIs

Limitations

- The template provides you with an approximate calculation, but it isn't appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
- For a more accurate estimate, you must consider the expected number of writes (insert, update, and delete) and reads for each item in an average month.
- This pattern supports estimating only write, read, storage, and backup and recovery costs for next few years based on fixed data growth assumptions.

Tools

AWS services

- [Amazon DynamoDB](#) is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

Other tools

- [AWS Pricing Calculator](#) is a web-based planning tool that you can use to create estimates for your AWS use cases.

Best practices

To help keep costs low, consider the following DynamoDB design best practices.

- Partition key design – Use a high-cardinality partition key to distribute load evenly.
- Adjacency list design pattern – Use this design pattern for managing one-to-many and many-to-many relationships.
- Sparse index – Use sparse index for your GSIs. When you create a GSI, you specify a partition key and optionally a sort key. Only items in the base table that contain a corresponding GSI partition key appear in the sparse index. This helps to keep GSIs smaller.
- Index overloading – Use the same GSI for indexing various types of items.

- GSI write sharding – Shard wisely to distribute data across the partitions for efficient and faster queries.
- Large items – Store only metadata inside the table, save the blob in Amazon S3, and keep the reference in DynamoDB. Break large items into multiple items, and efficiently index by using sort keys.

For more design best practices, see the Amazon DynamoDB Developer Guide.

Epics

Extract item information from your DynamoDB data model

Task	Description	Skills required
Get item size.	1. Check how many different types of item you are going to store in your table. 2. To calculate the size of each item in kilobytes, add the Key and Value size of each attribute. 3. Calculate item size for a base table and for each GSI.	Data engineer
Estimate the write cost.	To estimate write cost in on-demand capacity mode, first you have to measure how many WRUs will be consumed in a month. For that, you need to consider the following factors: • Number of create, update, and delete operations for each item in a month.	Data engineer

Task	Description	Skills required

	• Number of available GSIs. Consider each index independently.
	  ◦ Average size of an index item
	  ◦ Number of synchroni zation times on an index
	• How many new things (for example, components or products) will be added in the table each month? The number of added things could be different every month, but you can assume an average growth rate based on your business cases.
	
	For more information, see the *Additional information* section.	

Task	Description	Skills required
Estimate the read cost.	To estimate read cost in on-demand mode, first you have to measure how many RRUs will be consumed in a month. For that, you need to consider the following factors: • Number of available GSIs. Consider each index independently. ◦ Average size of an index item • Average number of reads per product per month. • Number of total available things (components or products) in the DynamoDB table.	Data engineer, App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Estimate the storage size and cost.</td><td> First, estimate the average monthly storage requirement based on your item size in the table. Then calculate storage cost by multiplying storage size by the per GB storage price for your AWS Region. If you already entered data for estimating the write cost, you don't need to enter it again for calculating storage size. Otherwise, to estimate storage size, you need to consider the following factors: Number of data items in a module (product) based on your table design.
Average item size in kilobytes.
Number of available GSIs. Consider each index independently.
Average size of an index item
How many new products will be added in the table each month? The number of new products could be different every month, but you can assume an average growth rate based</td><td>Data engineer</td></tr>
</table>

Task	Description	Skills required
	on your business cases. This example uses an average of 10 million new products each month.	

Enter the item and object information in the Excel template

Task	Description	Skills required
Download the Excel template from the Attachments section, and adjust it for your use case table.	1. Download the Excel template. 2. Adjust the business module and GSIs, based on your table design.	Data engineer
Enter information in the Excel template.	1. Update item information in the sheet. Update data only in orange cells. 2. Adjust the object numbers: How much could be added into the table each month? 3. Update the WRU and RRU prices per million for your AWS Region. 4. Update the storage and backup prices per GB-month for your AWS Region. 5. Update the recovery price per GB for your AWS Region.	Data engineer

Task	Description	Skills required
	In the template, there are three items, or entities: information, metadata, and relationship. There are two GSIs. For your use case, if you need more items, create new rows. If you need more GSIs, copy an existing GSI block, and paste to create as many GSI blocks as you need. Then adjust the SUM and TOTAL column calculations.

Guides and patterns

- Modeling data with Amazon DynamoDB
- Estimate storage costs for an Amazon DynamoDB table

Additional information

Write cost calculation example

The DynamoDB data model design shows three items for a product, and an average item size of 4 KB. When you add a new product into the DynamoDB base table, it consumes the number of items

* (item size/1 KB write unit) = 3 * (4/1) = 12 WRU. In this example, for writing 1 KB, the product consumes 1 WRU.

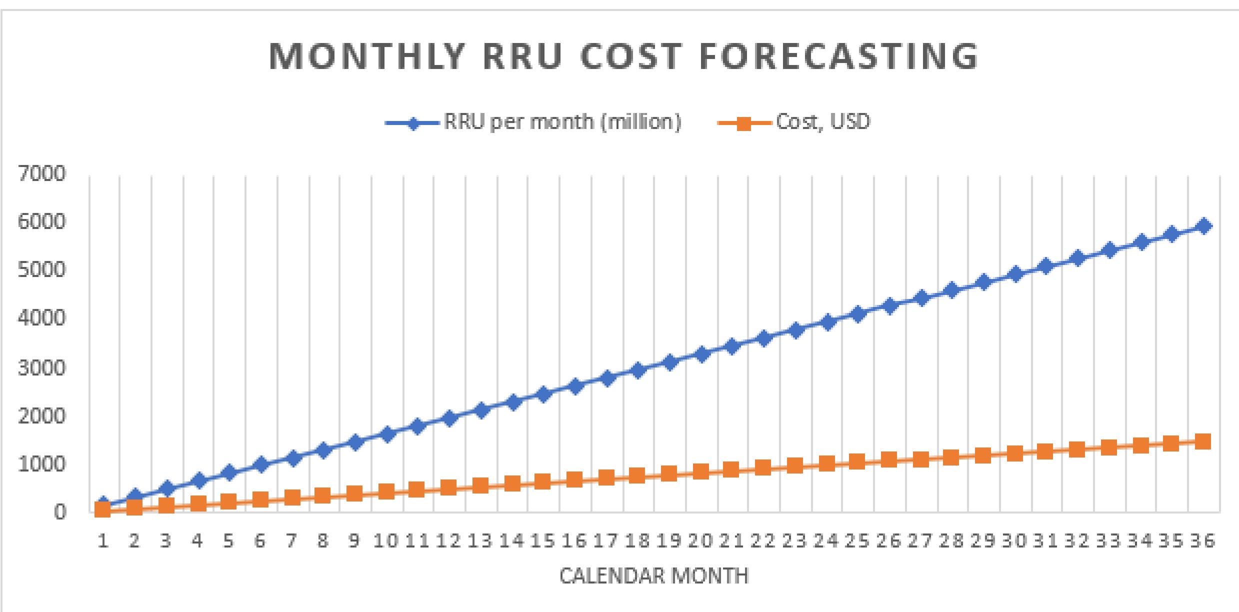
Read cost calculation example

To get the RRU estimation, consider the average of how many times each item will be read in a month. For example, the Information item will be read, on average, 10 times in a month, and the metadata item will be read two times, and the relationship item will be read five times. In the example template, total RRU for all components = number of new components created each month * RRU per component per month = 10 million * 17 RRU = 170 million RRU each month.

Every month, new things (components or products will be added, and the total number of products will grow over time. So, RRU requirements will also grow over time.

- For the first month RRU, consumption will be 170 million.
- For the second month, RRU consumption will be 2 * 170 million = 340 million.
- For the third month RRU consumption will be 3 * 170 million = 510 million.

The following graph shows monthly RRU consumption and cost forecasting.



Note that prices within the graph are for illustration only. To create accurate forecasts for your use case, check the AWS pricing page, and use those prices in the Excel sheet.

Storage, backup, and recovery cost calculation examples

DynamoDB storage, backup and restore all are connected with each other. Backup is directly connected with storage, and recovery is directly connected with backup size. As the table size increases, corresponding storage, backup, and restore costs will increase proportionally.

Storage size and cost

Storage cost will increase over time based on your data growth rate. For example, assume that the average size of a component or product in the base table and GSIs is 11 KB, and 10 million new products will be added every month into your database table. In that case, your DynamoDB table size will grow (11 KB * 10 million)/1024/1024 = 105 GB per month. At the first month, your table storage size will be 105 GB, at second month it will be 105 + 105 = 210 GBs, and so on.

- For the first month, storage cost will be 105 GB * storage price per GB for your AWS Region.
- For the second month, storage cost will be 210 GB * storage price per GB for your Region.
- For the third month, storage cost will be 315 GB * storage price per GB for your Region.

For storage size and cost for next three years, see the *Storage size and forecasting* section.

Backup cost

Backup cost will increase over time based on your data growth rate. When you turn on continuous backup with point-in-time-recovery (PITR), continuous backup charges are based on average storage GB-Month. In a calendar month, the average backup size would be the same as your table storage size, although the actual size could be a bit different. As new products will be added every month, the total storage size and the backup size will grow over time. For example, for the first month, the average backup size of 105 GB could grow to 210 GB for the second month.

- For the first month, backup cost will be 105 GB-month * continuous backup price per GB for your AWS Region.
- For the second month, backup cost will be 210 GB-month * continuous backup price per GB for your Region.
- For the third month, backup cost will be 315 GB-month * continuous backup price per GB for your Region.
- and, so on

Backup cost is included in the graph in the *Storage size and cost forecasting* section.

Recovery cost

When you are taking continuous backup with PITR enabled, recovery operation charges are based on the size of the restore. Each time that you restore, you pay based on gigabytes of restored data. If your table size is large and you perform restore multiple times in a month, it will be costly.

To estimate restore cost, this example assumes that you perform a PITR recovery one time each month at the end of the month. The example uses the monthly average backup size as the restore data size for that month. For the first month, the average backup size is 105 GB, and for the recovery at end of the month, the restore data size would be 105 GB. For the second month, it would be 210 GBs, and so on.

Recovery cost will increase over time based on your data growth rate.

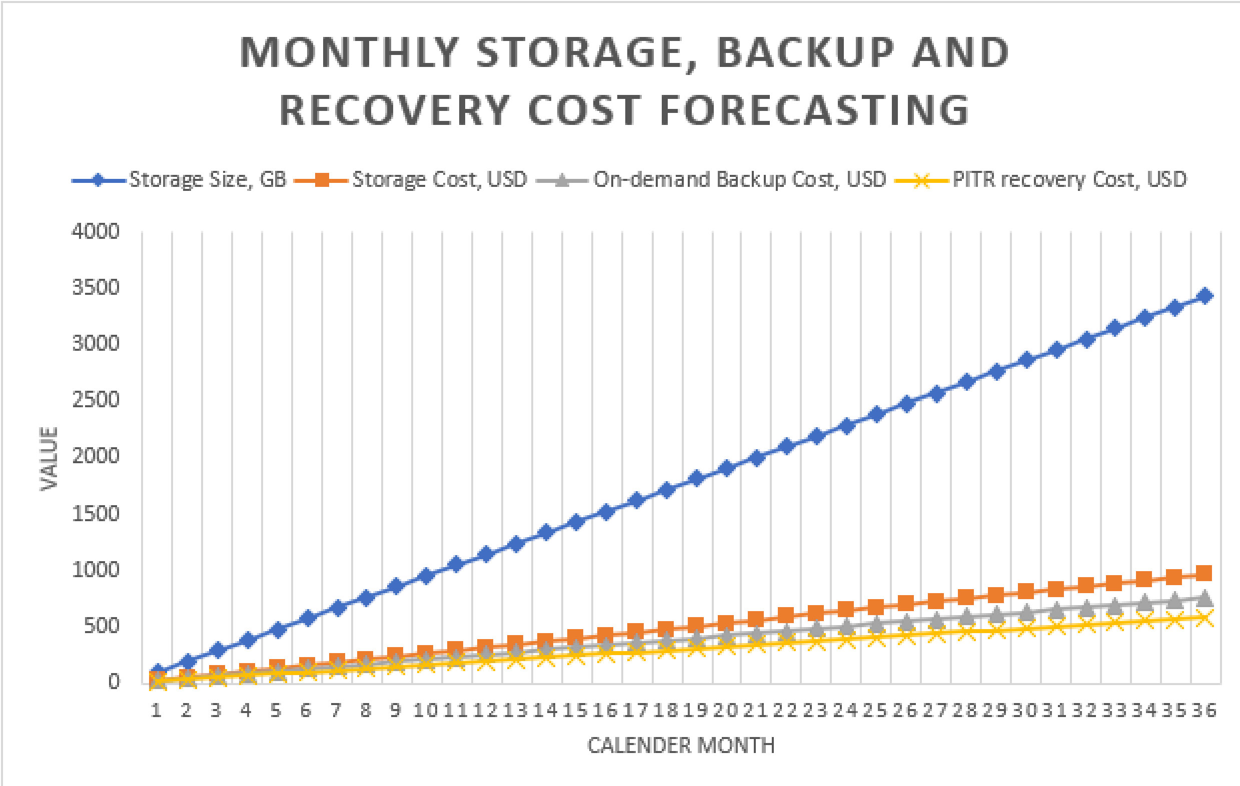
- For the first month, recovery cost will be 105 GB * restore price per GB for your AWS Region.
- For the second month, recovery cost will be 210 GB * restore price per GB for your Region.
- For the third month, recovery cost will be 315 GB * restore price per GB for your Region.

For more information, see the Storage, backup and recovery tab in the Excel template and the graph in the following section.

Storage size and cost forecasting

In the template, actual billable storage size is calculated by subtracting the free tier 25 GB per month for the Standard table class. In the sheet, you will get a forecasting graph broken out into monthly values.

The following example chart forecasts monthly storage size in GB, billable storage cost, on-demand backup cost, and recovery cost for next 36 calendar months. All costs are in USD. From the graph, it's clear that storage, backup, and recovery costs increase proportionally to increases in storage size.



Note that prices used in the graph are for illustration purposes only. To create accurate prices for your use case, check the AWS pricing page, and use those prices in the Excel template.

Estimate storage costs for an Amazon DynamoDB table

Moinul Al-Mamun, Amazon Web Services

Summary

Amazon DynamoDB is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This popular serverless offering from AWS provides consistent performance and scalability. You do not need to provision storage, and your single table can grow up to petabytes.

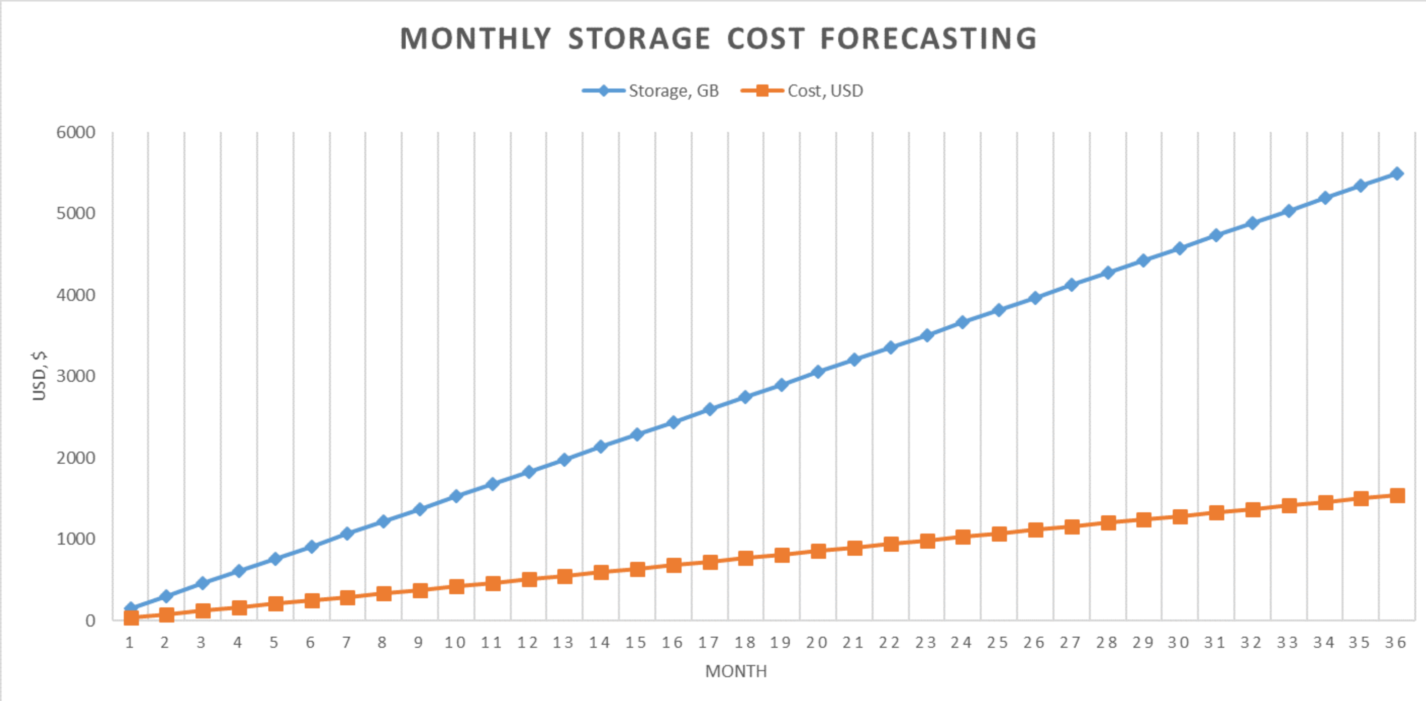
DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. AWS then charges you for the average size of storage in gigabytes. The more that your table grows over time, the more that your storage cost will grow. To calculate storage cost, you can use AWS Pricing Calculator, but you need to provide the approximate size of your table, including global secondary indexes (GSIs), which is really difficult to estimate at the beginning of the project. Also, AWS Pricing Calculator does not consider the data growth rate.

This pattern provides a mechanism and a reusable Microsoft Excel template to calculate DynamoDB storage size and cost. It considers the storage requirements for the base table and the GSIs independently. It calculates storage size by considering the size of your individual items and data growth rate over time.

To get an estimate, insert two pieces of information into the template:

- The individual item size in kilobytes for the base table and GSIs
- How many new objects or products could be added to the table, on average, in a month, (for example, 10 million)

The template generates a storage and cost forecasting graph for the next three years, which is shown in the following example.



Prerequisites and limitations

Prerequisites

- Basic knowledge of DynamoDB, including DynamoDB storage and pricing
- Knowledge of your data, data model, and item size in DynamoDB
- Knowledge of DynamoDB global secondary indexes (GSIs)

Limitations

- The template provides you with an approximate calculation, but it isn't appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
- This pattern supports estimating only storage size and cost for the next few years based on fixed data growth assumptions.

Tools

AWS services

- [Amazon DynamoDB] is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

Other tools

- [AWS Pricing Calculator] is a web-based planning tool that you can use to create estimates for your AWS use cases.

Epics

Extract item information from your DynamoDB data model

Task	Description	Skills required
Get item size.	1. Determine how many different item types you are going to store in your table. 2. To calculate the size of each item in kilobytes, add the `Key` and `Value` size of each attribute. 3. Calculate item size for a base table and for each GSI.	Data engineer
Get the number of objects added in a month.	Estimate how many components, or objects, will be added into the DynamoDB table, on average, in one month.	Data engineer

Enter the item and object information in the Excel template

Task	Description	Skills required
Download and adjust the Excel spreadsheet.	1. Download the Excel template from the attached document. 2. Adjust the business module and GSIs, based on your table design.	Data engineer
Enter information in the Excel template.	1. Update the item informati on in the sheet. 2. Adjust the object numbers: How much could be added into the table each month? 3. Update the storage price per GB-month for your AWS Region.	Data engineer

Related resources

- Pricing for On-Demand Capacity for Amazon DynamoDB
- AWS Pricing Calculator for DynamoDB

Additional information

Note that the attached template forecasts only storage size and cost for Standard storage table class. Based on the forecast for storage costs, and considering individual item size and product or object growth rate, you can estimate the following:

- Data export cost
- Backup and recovery cost
- Data storage requirements.

Amazon DynamoDB data storage cost

DynamoDB monitors the size of your tables continuously to determine your storage charges. DynamoDB measures the size of your billable data by adding the raw byte size of your data plus a per-item storage overhead that depends on the features you have enabled. For more information, see the DynamoDB Developer Guide.

The price for data storage depends on your table class. The first 25 GB stored each month is free if you're using the DynamoDB Standard table class. For more information about storage costs for the Standard and Standard-Infrequent Access table classes in different AWS Regions, see Pricing for On-Demand Capacity.

Estimate the Amazon RDS engine size for an Oracle database by using AWR reports

Abhishek Verma and Eduardo Valentim, Amazon Web Services

Summary

When you migrate an Oracle database to Amazon Relational Database Service (Amazon RDS) or Amazon Aurora, computing the CPU, memory, and disk I/O for the target database is a key requirement. You can estimate the required capacity of the target database by analyzing the Oracle Automatic Workload Repository (AWR) reports. This pattern explains how to use AWR reports to estimate these values.

The source Oracle database could be on premises or hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance, or it could be an Amazon RDS for Oracle DB instance. The target database could be any Amazon RDS or Aurora database.

> **Note**
>
> Capacity estimates will be more precise if your target database engine is Oracle. For other Amazon RDS databases, the engine size can vary due to differences in database architecture.

We recommend that you run the performance test before you migrate your Oracle database.

Prerequisites and limitations

Prerequisites

- An Oracle Database Enterprise Edition license and Oracle Diagnostics Pack license in order to download AWR reports.

Product versions

- All Oracle Database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c,19c.
- This pattern doesn't cover Oracle Engineered Systems or Oracle Cloud Infrastructure (OCI).

Architecture

Source technology stack

One of the following:

- An on-premises Oracle database
- An Oracle database on an EC2 instance
- An Amazon RDS for Oracle DB instance

Target technology stack

- Any Amazon RDS or Amazon Aurora database

Target architecture

For information about the full migration process, see the pattern Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT.

Automation and scale

If you have multiple Oracle databases to migrate and you want to use additional performance metrics, you can automate the process by following the steps described in the blog post Right-size Amazon RDS instances at scale based on Oracle performance metrics.

Tools

- Oracle Automatic Workload Repository (AWR) is a repository that's built into Oracle databases. It periodically gathers and stores system activity and workload data, which is then analyzed by Automatic Database Diagnostic Monitor (ADDM). AWR takes snapshots of system performance data periodically (by default, every 60 minutes) and stores the information (by default, up to 8 days). You can use AWR views and reports to analyze this data.

Best practices

- To calculate resource requirements for your target database, you can use a single AWR report, multiple AWR reports, or dynamic AWR views. We recommend that you use multiple AWR reports during the peak load period to estimate the resources required to handle those peak loads. In addition, dynamic views provide more data points that help you calculate resource requirements more precisely.

- You should estimate IOPS only for the database that you plan to migrate, not for other databases and processes that use the disk.
- To calculate how much I/O is being used by the database, don't use the information in the Load Profile section of the AWR report. Use the I/O Profile section instead, if it's available, or skip to the Instance Activity Stats section and look at the total values for physical read and write operations.
- When you estimate CPU utilization, we recommend that you use the database metrics method instead of operating system (OS) statistics, because it's based on the CPU used only by databases. (OS statistics also include CPU usage by other processes.) You should also check CPU-related recommendations in the ADDM report to improve performance after migration.
- Consider I/O throughput limits—Amazon Elastic Block Store (Amazon EBS) throughput and network throughput—for the specific instance size when you're determining the right instance type.
- Run the performance test before migration to validate the engine size.

Epics

Create an AWR report

Task	Description	Skills required
Enable the AWR report.	To enable the report, follow the instructions in the Oracle documentation.	DBA
Check the retention period.	To check the retention period of the AWR report, use the following query. `SQL> SELECT snap_interval,retention FROM dba_hist_wr_control;`	DBA

Task	Description	Skills required
Generate the snapshot.	If the AWR snapshot interval isn't granular enough to capture the spike of the peak workload, you can generate the AWR report manually. To generate the manual AWR snapshot, use the following query. `SQL> EXEC dbms_workload_repository.create_snapshot;`	DBA
Check recent snapshots.	To check recent AWR snapshots, use the following query. `SQL> SELECT snap_id, to_char(begin_interval_time,'dd/MON/yy hh24:mi') Begin_Interval, to_char(end_interval_time,'dd/MON/yy hh24:mi') End_Interval FROM dba_hist_snapshot ORDER BY 1;`	DBA

Estimate disk I/O requirements

Task	Description	Skills required
Choose a method.	IOPS is the standard measure of input and output operations per second on a storage	DBA

Task	Description	Skills required
	device, and includes both read and write operations. If you are migrating an on-premises database to AWS, you need to determine the peak disk I/O used by the database. You can use the following methods to estimate disk I/O for your target database: • Load Profile section of the AWR report • Instance Activity Stats section of the AWR report (use this section for Oracle Database 12c or later) • I/O Profile section of the AWR report (use this section for Oracle Database versions before 12c) • AWR views The following steps describe these four methods.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Option 1: Use the load profile.</td><td>The following table shows an example of the Load Profile section of the AWR report.

Important
For more accurate information, we recommend that you use option 2 (I/O profiles) or option 3 (instance activity statistics) instead of the load profile.

<table>
<tr><th></th><th>Per Seco</th><th>Per Trans on</th><th>Per Exec</th><th>Per Call</th></tr>
<tr><td>DB Time</td><td>26.6</td><td>0.2</td><td>0.00</td><td>0.02</td></tr>
<tr><td>DB CPU(</td><td>18.0</td><td>0.1</td><td>0.00</td><td>0.01</td></tr>
<tr><td>Backd CPU(</td><td>0.2</td><td>0.0</td><td>0.00</td><td>0.00</td></tr>
<tr><td>Redo size (byte</td><td>2,45 .9</td><td>17,0</td><td></td><td></td></tr>
<tr><td>Logi read</td><td>3,37 .5</td><td>23,4</td><td></td><td></td></tr>
</table>
</td><td>DBA</td></tr>
</table>

Task	Description	Skills required
	(bloc Bloc 21,6 150. chan Phys 13,5 94.4 read (bloc Phys 3,46 24.1 write (bloc Reac 3,58 24.9 IO requ Writ 574. 4.0 IO requ Reac 106. 0.7 IO (MB) Writ 27.1 0.2 IO (MB) IM 0.0 0.0 scan rows Sessi Logi Reac IM:	

Task	Description	Skills required
	<table><tr><td>**User calls**</td><td>1,24</td><td>8.7</td></tr><tr><td>**Pars (SQL**</td><td>4,62</td><td>32.2</td></tr><tr><td>**Hard pars (SQL**</td><td>8.9</td><td>0.1</td></tr><tr><td>**SQL Worl Area (MB)**</td><td>824.</td><td>5.7</td></tr><tr><td>**Logo**</td><td>1.7</td><td>0.0</td></tr><tr><td>**Exec (SQL**</td><td>136,</td><td>950.</td></tr><tr><td>**Rolll :**</td><td>22.9</td><td>0.2</td></tr><tr><td>**Tran ons:**</td><td>143.</td><td></td></tr></table> Based on this information, you can calculate IOPs and throughput as follows: *IOPS = Read I/O requests: + Write I/O requests = 3,586.8 + 574.7 = 4134.5* *Throughput = Physical read (blocks) + Physical write*	

Task	Description	Skills required
	(blocks) = 13,575.1 + 3,467.3 = 17,042.4 Because the block size in Oracle is 8 KB, you can calculate total throughput as follows: *Total throughput in MB is 17042.4 * 8 * 1024 / 1024 / 1024 = 133.2 MB* **Warning** Don't use the load profile to estimate the instance size. It isn't as precise as instance activity statistics or I/O profiles.	

Task	Description	Skills required
Option 2: Use instance activity statistics.	If you're using an Oracle Database version before 12c, you can use the Instance Activity Stats section of the AWR report to estimate IOPS and throughput. The following table shows an example of this section. <table><tr><td>Statisti</td><td>Total</td><td>per Secon</td><td>per Trans</td></tr><tr><td>**physic read total IO reque**</td><td>2,547, ,217</td><td>3,610.</td><td>25.11</td></tr><tr><td>**physic read total bytes**</td><td>80,77(6,124,</td><td>114,48 26.26</td><td>796,149 8</td></tr><tr><td>**physic write total IO reque**</td><td>534,19 08</td><td>757.1'</td><td>5.27</td></tr><tr><td>**physic write total bytes**</td><td>25,51: 8,849,</td><td>36,16! 1.84</td><td>251,508 8</td></tr></table>	DBA

Task	Description	Skills required
	Based on this information, you can calculate total IOPS and throughput as follows: *Total IOPS = 3,610.28 + 757.11 = 4367* *Total Mbps = 114,482,426.26 + 36,165,631.84 = 150648058.1 / 1024 / 1024 = 143 Mbps*	

Task	Description	Skills required
Option 3: Use I/O profiles.	In Oracle Database 12c, the AWR report includes an I/O Profiles section that presents all the information in a single table and provides more accurate data about database performance. The following table shows an example of this section.	DBA

	Read +Write Per Secon	Read per Secon	Write Per Second
Total Reque	4,367.	3,610.	757.1
Datab Reque	4,161.	3,586.	574.7
Optin Reque	0.0	0.0	0.0
Redo Reque	179.3	2.8	176.6
Total (MB):	143.7	109.2	34.5
Datab (MB):	133.1	106.1	27.1

Task	Description	Skills required
	(continued, see below)	

Optim Total (MB):	0.0	0.0	0.0
Redo (MB):	7.6	2.7	4.9
Datab (block	17,04	13,57	3,467.3
Via Buffer Cache (block	5,898.	5,360.	537.6
Direct (block	11,14	8,214.	2,929.7

This table provides the following values for throughput and total IOPS:

Throughput = 143 MBPS (from the fifth row, labeled Total, second column)

IOPS = 4,367.4 (from the first row, labeled Total Requests, second column)

Task	Description	Skills required
Option 4: Use AWR views.	You can see the same IOPS and throughput informati on by using AWR views. To get this information, use the following query: `break on report compute sum of Value on report select METRIC_NAME,avg(AVERAGE) as "Value" from dba_hist_sysmetric_summary where METRIC_NAME in ('Physical Read Total IO Requests Per Sec','Physical Write Total IO Requests Per Sec') group by metric_name;`	DBA

Estimate CPU requirements

Task	Description	Skills required
Choose a method.	You can estimate the CPU required for the target database in three ways: • By using the actual available cores of the processor • By using the utilized cores based on OS statistics	DBA

Task	Description	Skills required
	• By using the utilized cores based on database statistics If you're looking at utilized cores, we recommend that you use the database metrics method instead of OS statistics, because it's based on the CPU used only by the databases that you're planning to migrate. (OS statistics also include CPU usage by other processes.) You should also check CPU-related recommendations in the ADDM report to improve performance after migration. You can also estimate requirements based on CPU generation. If you are using different CPU generations, you can estimate the required CPU of the target database by following the instructions in the whitepaper [Demystifying the Number of vCPUs for Optimal Workload Performance]().	

Task	Description	Skills required

Option 1: Estimate requirements based on available cores.	In AWR reports:
	
	• CPUs refer to logical and virtual CPUs.
	• Cores are the number of processors in a physical CPU chipset.
	• A socket is a physical device that connects a chip to a board. Multi-core processors have sockets with several CPU cores.
	
	You can estimate available cores in two ways:
	
	• By using OS commands
	• By using the AWR report
	
	To estimate available cores by using OS commands
	
	Use the following command to count the cores in the processor.
	
	`$ cat /proc/cpuinfo | grep "cpu cores"|uniq`
	`cpu cores    : 4`
	`cat /proc/cpuinfo | egrep "core id|physical id" | tr -d "\n" | sed s/physical/\\nphysical/g | grep -v ^$ | sort | uniq | wc -l`
		DBA

Task	Description	Skills required

	Use the following command to count the sockets in the processor.
	`grep "physical id" /proc/cpuinfo | sort -u`
	`  physical id     : 0`
	`  physical id     : 1`
	Note
	We don't recommend using OS commands such as **nmon** and **sar** to extract CPU utilization. This is because those calculations include CPU utilization by other processes and might not reflect the actual CPU that is used by the database.
	To estimate available cores by using the AWR report
	You can also derive CPU utilization from the first section of the AWR report. Here's an excerpt from the report.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>
<table>
<tr><th>D N</th><th>DB Id</th><th>Inst</th><th>Inst nun</th><th>Star Tim</th><th>Rele</th><th>RA</th></tr>
<tr><td>X</td><td><DE</td><td>XXX</td><td>1</td><td>05-Sep 23:(</td><td>12.1 0</td><td>NC</td></tr>
</table>
<table>
<tr><th>Hos Nar</th><th>Plat</th><th>CPU</th><th>Cor</th><th>Soc</th><th>Mem (GB)</th></tr>
<tr><td><ho e></td><td>Linu x86 64-bit</td><td>80</td><td>80</td><td>2</td><td>441.7</td></tr>
</table>
In this example, the CPUs count is 80, which indicates that these are logical (virtual) CPUs. You can also see that this configuration has two sockets, one physical processor on each socket (for a total of two physical processors), and 40 cores for each physical processor or socket.</td><td></td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Option 2: Estimate CPU utilization by using OS statistics.</td><td>You can check the OS CPU usage statistics either directly in the OS (using sar or another host OS utility) or by reviewing the IDLE/(IDLE+BUSY) values from the Operating System Statistics section of the AWR report. You can see the seconds of CPU consumed directly from v$osstat. The AWR and Statspack reports also show this data in the Operating System Statistics section.

If there are multiple databases on the same box, they all have the same v$osstat values for BUSY_TIME.

<table>
<tr><th>Statistic</th><th>Value</th><th>End Value</th></tr>
<tr><td>FREE_MIRY_BYTE</td><td>6,810,67,248</td><td>12,280,799,232</td></tr>
<tr><td>INACTIVMEMORTES</td><td>175,627,33,632</td><td>160,380,653,568</td></tr>
<tr><td>SWAP_F_BYTES</td><td>17,145,64,336</td><td>17,145,872,384</td></tr>
</table>
</td><td>DBA</td></tr>

Task	Description	Skills required

GLOBAL_ CEIVE_S E_MAX	4,194,30
GLOBAL_ ND_SIZE AX	2,097,15
TCP_REC VE_SIZE_ EFAULT	87,380
TCP_REC VE_SIZE_ AX	6,291,45
TCP_REC VE_SIZE_ IN	4,096
TCP_SEN SIZE_DE ULT	16,384
TCP_SEN SIZE_MA	4,194,30
TCP_SEN SIZE_MI	4,096

If there are no other major CPU consumers in the system, use the following formula to calculate the percentage of CPU utilization:

Task	Description	Skills required
	Utilization = Busy time / Total time *Busy time = requirements = v $osstat.BUSY_TIME* *C = Total time (Busy + Idle)* *C = capacity = v$ostat.B USY_TIME + v$ostat.I DLE_TIME* *Utilization = BUSY_TIME / (BUSY_TIME + IDLE_TIME)* *= -1,305,569,937 / (1,305,569,937 + 4,312,718 ,839)* *= 23% utilized*	

Task	Description	Skills required
Option 3: Estimate CPU utilization by using database metrics.	If multiple databases are running in the system, you can use the database metrics that appears at the beginning of the report. <table><tr><td></td><td>Snap Id</td><td>Snap Time</td><td>Sessi</td><td>Cursor S ession</td></tr><tr><td>**Begi Snap**</td><td>1846</td><td>28-Sep-09:00</td><td>1226</td><td>35.8</td></tr><tr><td>**End Snap**</td><td>1854</td><td>06-Oct-13:00</td><td>1876</td><td>41.1</td></tr><tr><td>**Elap**</td><td></td><td>11,7. (min</td><td></td><td></td></tr><tr><td>**DB Time**</td><td></td><td>312,0 (min</td><td></td><td></td></tr></table> To get CPU utilization metrics, use this formula: *Database CPU usage (% of CPU power available) = CPU time / NUM_CPUS / elapsed time* where CPU usage is described by *CPU time* and represents	DBA

Task	Description	Skills required
	the time spent on CPU, not the time waiting for CPU. This calculation results in: *= 312,625.40 / 11,759.64 /80 = 33% of CPU is being used* *Number of cores (33%) * 80 = 26.4 cores* *Total cores = 26.4 * (120%) = 31.68 cores* You can use the greater of these two values to calculate the CPU utilization of the Amazon RDS or Aurora DB instance. **Note** On IBM AIX, the calculated utilization doesn't match the values from the operating system or the database. These values do match on other operating systems.	

Estimate memory requirements

Task	Description	Skills required
Estimate memory requirements by using memory statistics.	You can use the AWR report to calculate the memory of the source database and match it in the target database. You should also check the performance of the existing database and reduce your memory requirements to save costs, or increase your requirements to improve performance. That requires a detailed analysis of the AWR response time and the service-level agreement (SLA) of the application. Use the sum of Oracle system global area (SGA) and program global area (PGA) usage as the estimated memory utilization for Oracle. Add an extra 20 percent for the OS to determine a target memory size requirement. For Oracle RAC, use the sum of the estimated memory utilization on all RAC nodes and reduce the total memory, because it's stored on common blocks. 1. Check for the metrics in the Instance Efficiency Percentage table. The table uses the following terms:	DBA

Task	Description	Skills required
	• *Buffer Hit %* is the percentage of times a particular block was found in the buffer cache instead of performing a physical I/O. For better performance, target 100 percent . • *Buffer Nowait %* should be close to 100 percent. • *Latch Hit %* should be close to 100 percent. • *% Non-Parse CPU* is the percentage of CPU time spent in non-parsing activities. This value should be close to 100 percent.. **Instance Efficiency Percentages (target 100%)** Buffe Nowa %: 99.99 Redo NoWa %: 100.00 **Buffe Hit %:** 99.84 **In-mem Sort %:** 100.00 **Libra Hit %:** 748.7 **Soft Parse %:** 99.81	

Task	Description	Skills required
	<table><tr><td>**Execu to Parse %:**</td><td>96.61</td><td>**Latch Hit %:**</td><td>100.00</td></tr><tr><td>**Parse CPU to Parse Elaps %:**</td><td>72.73</td><td>**% Non-Parse CPU:**</td><td>99.21</td></tr><tr><td>**Flash Cache Hit %:**</td><td>0.00</td><td></td><td></td></tr></table> In this example, all the metrics look fine, so you can use the SGA and PGA for the existing database as the capacity planning requirement. 2. Check the memory statistic s section and calculate the SGA/PGA. <table><tr><td></td><td>Begin</td><td>End</td></tr><tr><td>**Host Mem (MB):**</td><td>452,387</td><td>452,387.</td></tr></table>	

Task	Description	Skills required
	<table><tr><td>**SGA use (MB):**</td><td>220,544</td><td>220,544.0</td></tr><tr><td>**PGA use (MB):**</td><td>36,874.9</td><td>45,270.0</td></tr></table> *Total instance memory in use = SGA + PGA = 220 GB + 45 GB = 265 GB* Add 20 percent of buffer: *Total instance memory = 1.2 * 265 GB = 318 GB* Because SGA and PGA account for 70 percent of host memory, the total memory requirement is: *Total host memory = 318/0.7 = 464 GB* **Note** When you migrate to Amazon RDS for Oracle, the PGA and SGA are pre-calculated based on a predefined formula. Make sure that the pre-calculated values	

Task	Description	Skills required
	are close to your estimates.	

Determine the DB instance type of the target database

Task	Description	Skills required
Determine the DB instance type based on disk I/O, CPU, and memory estimates.	Based on the estimates in the previous steps, the capacity of the target Amazon RDS or Aurora database should be: • 68 cores of CPU • 143 MBPS of throughput • 4367 IOPS for disk I/O • 464 GB of memory In the target Amazon RDS or Aurora database, you can map these values to the db.r5.16x large instance type, which has a capacity of 32 cores, 512 GB of RAM, and 13,600 Mbps of throughput. For more information, see the AWS blog post Right-size Amazon RDS instances at scale based on Oracle performance metrics.	DBA

Export Amazon RDS for SQL Server tables to an S3 bucket by using AWS DMS

Subhani Shaik, Amazon Web Services

Summary

Amazon Relational Database Service (Amazon RDS) for SQL Server doesn’t support loading data onto other DB engine linked servers on the Amazon Web Services (AWS) Cloud. Instead, you can use AWS Database Migration Service (AWS DMS) to export Amazon RDS for SQL Server tables to an Amazon Simple Storage Service (Amazon S3) bucket, where the data is available to other DB engines.

AWS DMS helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.

This pattern uses AWS Secrets Manager while configuring the AWS DMS endpoints. Secrets Manager helps you protect secrets needed to access your applications, services, and IT resources. You can use the service to rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets with a call to Secrets Manager, reducing the need to hardcode sensitive information. Secrets Manager offers secret rotation with built-in integration for Amazon RDS, Amazon Redshift, and Amazon DocumentDB. Also, the service is extensible to other types of secrets, including API keys and OAuth tokens. With Secrets Manager, you can control access to secrets by using fine-grained permissions and audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on premises.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An S3 bucket
- A virtual private cloud (VPC)
- A DB subnet
- Amazon RDS for SQL Server

- An AWS Identity and Access Management (IAM) role with access (list, get, and put objects) to the S3 bucket on behalf of the Amazon RDS instance.
- Secrets Manager to store the RDS instance credentials.

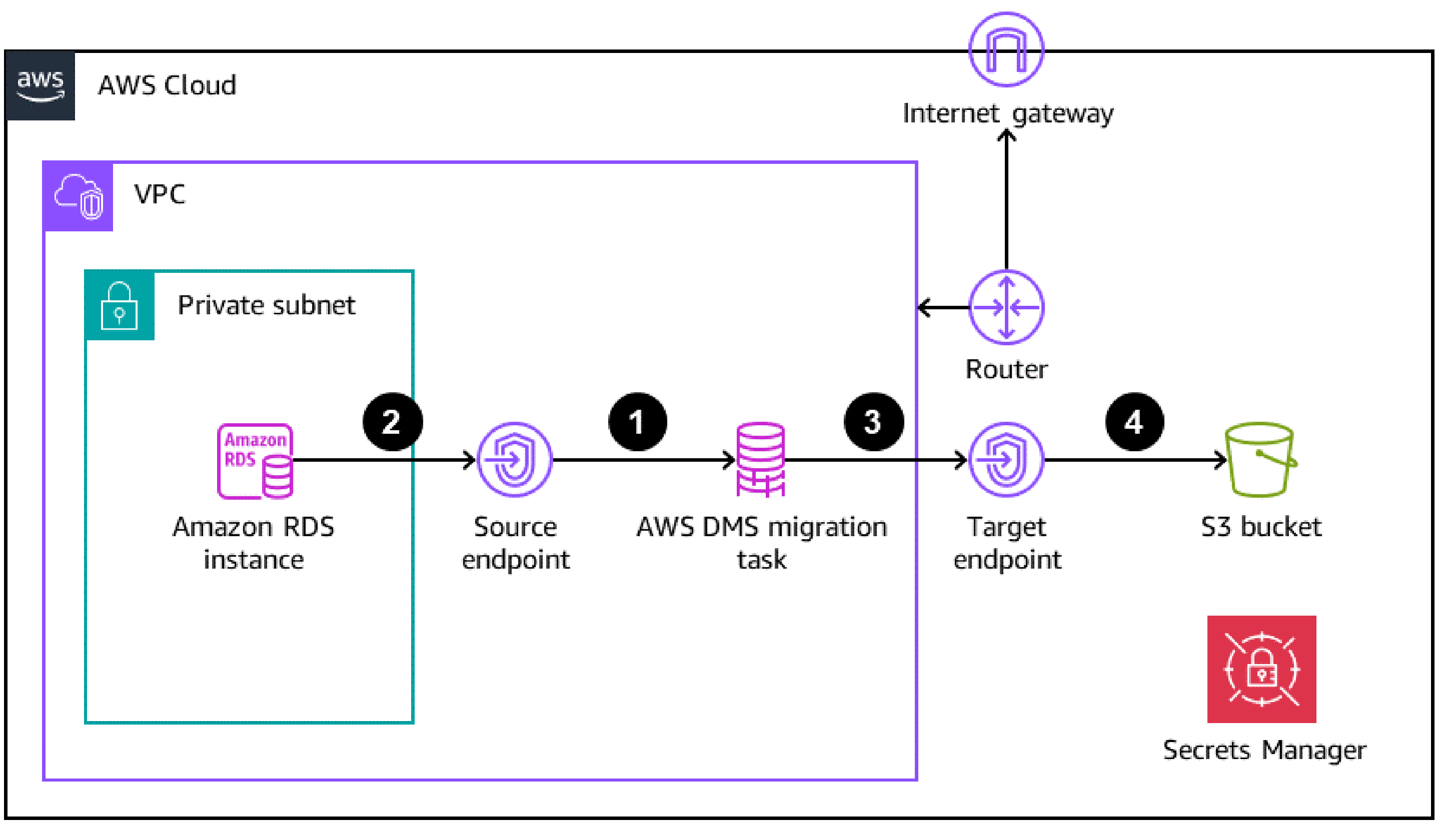
Architecture

Technology stack

- Amazon RDS for SQL Server
- AWS DMS
- Amazon S3
- AWS Secrets Manager

Target architecture

The following diagram shows the architecture for importing data from the Amazon RDS instance to the S3 bucket with the help of AWS DMS.



1. The AWS DMS migration task connecting to the source Amazon RDS instance through the source endpoint
2. Copying data from the source Amazon RDS instance
3. The AWS DMS migration task connecting to the target S3 bucket through the target endpoint
4. Exporting copied data to the S3 bucket in comma-separated values (CSV) format

Tools

AWS services

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.

Other services

- Microsoft SQL Server Management Studio (SSMS) is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.

Epics

Configure the Amazon RDS for SQL Server instance

Task	Description	Skills required
Create the Amazon RDS for SQL Server instance.	1. Open the AWS Managemen t Console, choose **RDS**, and use the **Standard**	DBA, DevOps engineer

Task	Description	Skills required
	create option to create an **Amazon RDS** instance with the required edition, such as SQL Server Express Edition, SQL Server Standard Edition, or SQL Server Enterprise Edition. For the version, choose 2016 or later. 2. Under **Templates**, choose **Dev/Test**.	
Set up credentials for the instance.	1. Enter a name for the instance. 2. Provide a **username** and password for the Amazon RDS instance.	DBA, DevOps engineer

Task	Description	Skills required
Configure the instance class, storage, auto scaling, and availability.	1. Select the **DB instance class** from the list: **Standard**, **Memory Optimized**, and **Burstable** classes. Choose the DB instance type that allocates the computational, network, and memory capacity required by the workloads planned for this DB instance. For more information, see the [AWS documentation](). 2. Select the Storage Type from the list: **General Purpose SSD**, **Provisioned IOPS SSD**, or **Magnetic**. Allocate the default storage size as required. 3. Choose **Enable storage autoscaling** to increase the Amazon RDS storage based on your capacity planning. 4. A Multi-AZ deployment with a replication instance is supported by AWS DMS. In the event of an outage in the Availability Zone, internal hardware, or network, AWS DMS will create a standby instance and provide high availability (HA) through automatic failover to the standby	DBA, DevOps engineer

Task	Description	Skills required
	replicas. Depending on the size of your import, select the appropriate option.	
Specify the VPC, subnet group, public access, and security group.	Select the **VPC**, **DB subnet groups**, and **VPC security group** as required to create the Amazon RDS instance. Follow the best practices, for example: • Do not enable public access to the RDS DB instance. • Do not use the CIDR 0.0.0.0/0 in the security groups. • Use only the required IP address and port details to access the RDS instance.	DBA, DevOps engineer
Configure monitoring, backup, and maintenance.	1. Specify the backup options that you want. By default, automated backups are enabled with a retention period of 7 days. 2. Choose the appropria te **auto minor version upgrade** and **Maintenance window** settings to apply the pending modificat ions or maintenance to the database by Amazon RDS. 3. Choose **Create database**.	DBA, DevOps engineer

Set up the database and example data

Task	Description	Skills required
Create a table and load the example data.	In the new database, create a table. Use the example code in the *Additional information* section to load data into the table.	DBA, DevOps engineer

Set up credentials

Task	Description	Skills required
Create the secret.	1. On the console, choose **Secrets Manager**, and choose **Store a new secret**. 2. Enter a username and password for the Amazon RDS for SQL Server database. This secret will be used for the AWS DMS source endpoint.	DBA, DevOps engineer

Set up access between the database and the S3 bucket

Task	Description	Skills required
Create an IAM role for access to Amazon RDS.	1. On the console, choose **IAM**, and create an IAM role that gives an S3 bucket read/write access to Amazon RDS.	DBA, DevOps engineer

Task	Description	Skills required
	2. Under **Feature**, select **S3 Integration**.	

Create the S3 bucket

Task	Description	Skills required
Create the S3 bucket.	To save the data from Amazon RDS for SQL Server, on the console, choose **S3**, and then choose **Create bucket**. Make sure that the S3 bucket is not publicly available.	DBA, DevOps engineer

Set up access between AWS DMS and the S3 bucket

Task	Description	Skills required
Create an IAM role for AWS DMS to access Amazon S3.	Create an IAM role that allows AWS DMS to list, get, and put objects from the S3 bucket.	DBA, DevOps engineer

Configure AWS DMS

Task	Description	Skills required
Create the AWS DMS source endpoint.	1. On the console, choose **Database Migration Service**, and choose **Endpoints**. Create the **Source endpoint**, selecting	DBA, DevOps engineer

Task	Description	Skills required
	the **Select RDS DB instance** check box. 2. For the Source engine, select **Microsoft SQL Server**. 3. Under **Access to endpoint database**, choose **AWS Secrets Manager**, and enter the secret and IAM role that you created earlier, and the database name. 4. Test the source endpoint.	
Create the AWS DMS target endpoint.	Create the **Target endpoint,** selecting Amazon S3 as the **Target engine**. Provide the S3 bucket name and folder name for the IAM role that you created previously.	DBA, DevOps engineer
Create the AWS DMS replicati on instance.	In the same VPC, subnet, and security group, create the AWS DMS replication instance. For more informati on about choosing an instance class, see the [AWS documentation]().	DBA, DevOps engineer

Task	Description	Skills required
Create the AWS DMS migration task.	To export the data from Amazon RDS for SQL Server to the S3 bucket, create a database migration task. For the migration type, choose **Migrate existing data**. Select the AWS DMS endpoints and replication instance that you created.	DBA, DevOps engineer

Export the data to the S3 bucket

Task	Description	Skills required
Run the database migration task.	To export the SQL Server table data, start the database migration task. The task will export the data from Amazon RDS for SQL Server to the S3 bucket in CSV format.	DBA, DevOps engineer

Clean up resources

Task	Description	Skills required
Delete the resources.	To avoid incurring extra costs, use the console to delete the resources in the following order: 1. Migration task 2. Replication instance 3. Endpoints	DBA, DevOps engineer

Task	Description	Skills required
	4. S3 bucket 5. Database instance

Additional information

To create the database and table, and to load the example data, use the following code.

```
--Step1: Database creation in RDS SQL Server
CREATE DATABASE [Test_DB]
 ON  PRIMARY
( NAME = N'Test_DB', FILENAME = N'D:\rdsdbdata\DATA\Test_DB.mdf' , SIZE = 5120KB ,
 FILEGROWTH = 10%)
 LOG ON
( NAME = N'Test_DB_log', FILENAME = N'D:\rdsdbdata\DATA\Test_DB_log.ldf' , SIZE =
 1024KB , FILEGROWTH = 10%)
GO

--Step2: Create Table
USE Test_DB
GO
Create Table Test_Table(ID int, Company Varchar(30), Location Varchar(20))

--Step3: Load sample data.
USE Test_DB
GO
Insert into Test_Table values(1,'AnyCompany','India')
Insert into Test_Table values(2,'AnyCompany','USA')
Insert into Test_Table values(3,'AnyCompany','UK')
Insert into Test_Table values(4,'AnyCompany','Hyderabad')
Insert into Test_Table values(5,'AnyCompany','Banglore')
```

Handle anonymous blocks in Dynamic SQL statements in Aurora PostgreSQL

anuradha chintha, Amazon Web Services

Summary

This pattern shows you how to avoid the error that you get when handling anonymous blocks in Dynamic SQL statements. You receive an error message when you use the AWS Schema Conversion Tool to convert an Oracle database to an Aurora PostgreSQL-Compatible Edition database. To avoid the error, you must know the value of an `OUT` bind variable, but you can't know the value of an `OUT` bind variable until after you run the SQL statement. The error results from the AWS Schema Conversion Tool (AWS SCT) not understanding the logic inside the Dynamic SQL statement. AWS SCT can't convert the dynamic SQL statement in PL/SQL code (that is, functions, procedures, and packages).

Prerequisites and limitations

Prerequisites

- Active AWS account
- Aurora PostgreSQL database (DB) instance
- Amazon Relational Database Service (Amazon RDS) for Oracle DB instance
- PostgreSQL interactive terminal (psql)
- SQL *Plus
- `AWS_ORACLE_EXT` schema (part of the AWS SCT extension pack) in your target database
- Latest version of AWS Schema Conversion Tool (AWS SCT) and its required drivers

Architecture

Source technology stack

- On-premises Oracle Database 10g and later version

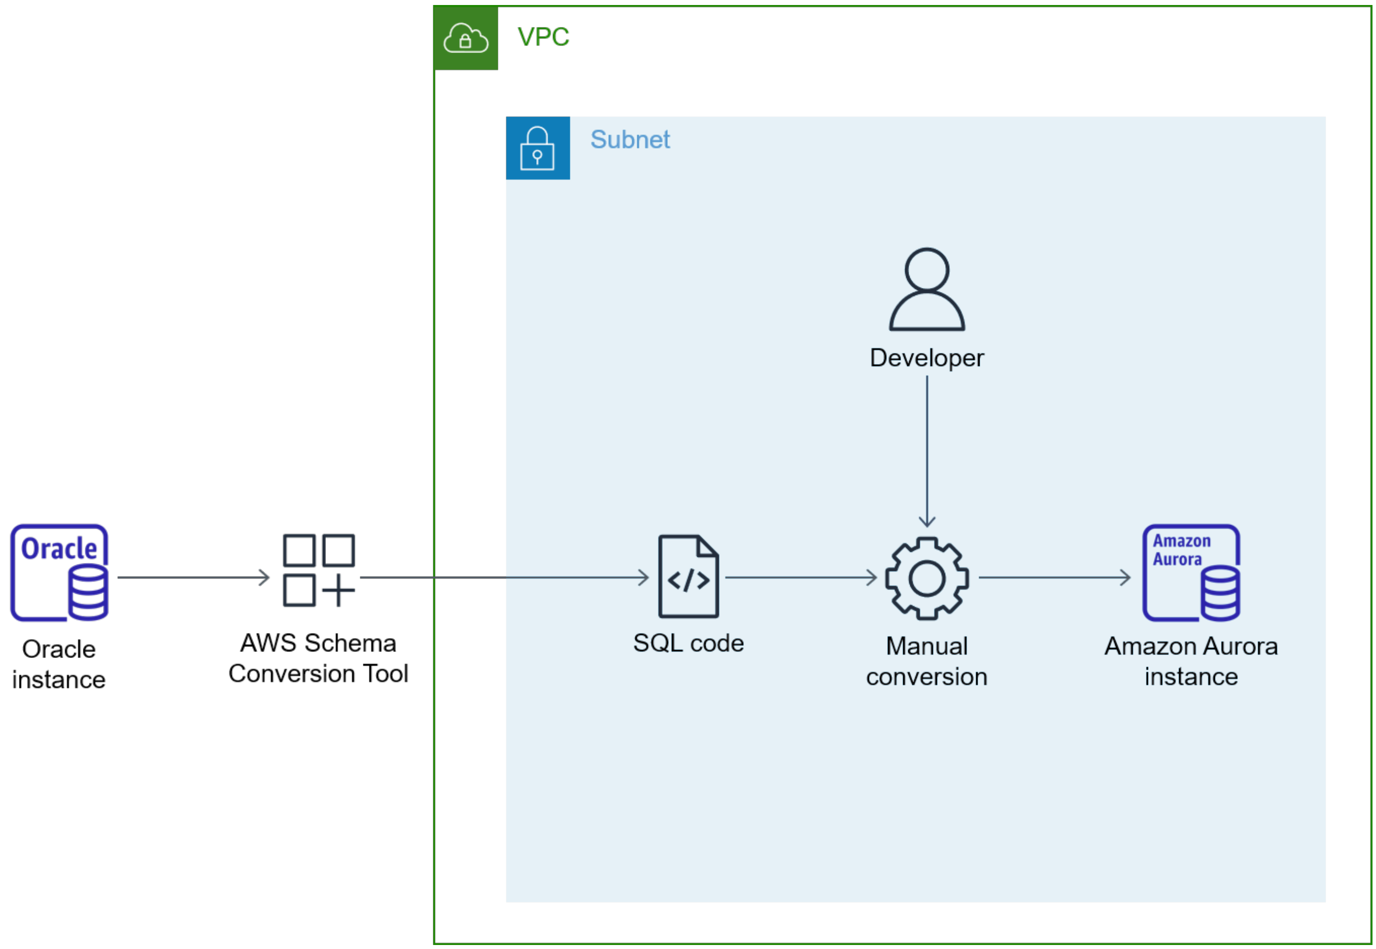
Target technology stack

- Amazon Aurora PostgreSQL

- Amazon RDS for PostgreSQL
- AWS Schema Conversion Tool (AWS SCT)

Migration architecture

The following diagram shows how to use AWS SCT and Oracle OUT bind variables to scan your application code for embedded SQL statements and convert the code to a compatible format that an Aurora database can use.



The diagram shows the following workflow:

1. Generate an AWS SCT report for the source database by using Aurora PostgreSQL as the target database.
2. Identify the anonymous block in the Dynamic SQL code block (for which AWS SCT raised the error).
3. Convert the code block manually and deploy the code on a target database.

Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- Amazon Relational Database Service (Amazon RDS) for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- AWS Schema Conversion Tool (AWS SCT) helps you make heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects to a format compatible with the target database.

Other tools

- pgAdmin enables you to connect to and interact with your database server.
- Oracle SQL Developer is an integrated development environment that you can use to develop and manage databases in Oracle Database. You can use either SQL *Plus or Oracle SQL Developer for this pattern.

Epics

Configure the Oracle source database

Task	Description	Skills required
Create an Oracle instance on Amazon RDS or Amazon EC2.	To create an Oracle DB instance on Amazon RDS, see Creating an Oracle DB instance and connecting to a database on an Oracle DB instance in the Amazon RDS documentation. To create an Oracle DB instance on Amazon Elastic Compute Cloud (Amazon EC2), see Amazon EC2 for	DBA

Task	Description	Skills required
	Oracle in the AWS Prescriptive Guidance documentation.	
Create a database schema and objects for migration.	You can use Amazon Cloud Directory to create a database schema. For more information, see Create a Schema in the Cloud Directory documentation.	DBA
Configure inbound and outbound security groups.	To create and configure security groups, see Controlling access with security groups in the Amazon RDS documentation.	DBA
Confirm that the database is running.	To check the status of your database, see Viewing Amazon RDS events in the Amazon RDS documentation.	DBA

Configure the target Aurora PostgreSQL database

Task	Description	Skills required
Create an Aurora PostgreSQL instance in Amazon RDS.	To create an Aurora PostgreSQL instance, see Creating a DB cluster and connecting to a database on an Aurora PostgreSQL DB cluster in the Amazon RDS documentation.	DBA
Configure an inbound and outbound security group.	To create and configure security groups, see Provide	DBA

Task	Description	Skills required
	access to the DB cluster in the VPC by creating a security group in the Aurora documentation.	
Confirm that the Aurora PostgreSQL database is running.	To check the status of your database, see Viewing Amazon RDS events in the Aurora documentation.	DBA

Set up AWS SCT

Task	Description	Skills required
Connect AWS SCT to the source database.	To connect AWS SCT to your source database, see Connecting to PostgreSQL as a source in the AWS SCT documentation.	DBA
Connect AWS SCT to the target database.	To connect AWS SCT to your target database, see the What is the AWS Schema Conversio n Tool? in the AWS Schema Conversion Tool User Guide.	DBA
Convert the database schema in AWS SCT and save the automated converted code as a SQL file.	To save AWS SCT converted files, see Saving and applying your converted schema in AWS SCT in the AWS Schema Conversion Tool User Guide.	DBA

Migrate the code

Task	Description	Skills required
Get the SQL file for manual conversion.	In the AWS SCT converted file, pull the SQL file that requires manual conversion.	DBA
Update the script.	Manually update the SQL file.	DBA

Additional information

The following example code shows how to configure the Oracle source database:

```
CREATE or replace PROCEDURE calc_stats_new1 (
  a NUMBER,
  b NUMBER,
  result out NUMBER)
IS
BEGIN
result:=a+b;
END;
/
```

```
set serveroutput on ;

DECLARE
  a NUMBER := 4;
  b NUMBER := 7;
  plsql_block VARCHAR2(100);
  output number;
BEGIN
  plsql_block := 'BEGIN calc_stats_new1(:a, :b,:output); END;';
  EXECUTE IMMEDIATE plsql_block USING a, b,out output;
```

```
  DBMS_OUTPUT.PUT_LINE('output:'||output);

END;
```

The following example code shows how to configure the target Aurora PostgreSQL database:

```
 w integer,
 x integer)
RETURNS integer
AS
$BODY$
DECLARE
begin
return w + x ;
end;
$BODY$
LANGUAGE  plpgsql;

CREATE OR REPLACE FUNCTION test_pg.init()
RETURNS void
AS
$BODY$
BEGIN
if aws_oracle_ext.is_package_initialized
      ('test_pg' ) then
      return;
    end if;
    perform aws_oracle_ext.set_package_initialized
      ('test_pg' );

PERFORM aws_oracle_ext.set_package_variable('test_pg', 'v_output', NULL::INTEGER);
PERFORM aws_oracle_ext.set_package_variable('test_pg', 'v_status', NULL::text);
END;
$BODY$
LANGUAGE  plpgsql;

DO $$
declare
v_sql text;
v_output_loc int;
a integer :=1;
```

```
b integer :=2;
BEGIN
perform  test_pg.init();
--raise notice 'v_sql %',v_sql;
execute 'do $a$ declare v_output_l int; begin select * from test_pg.calc_stats_new1('||
a||','||b||') into v_output_l;
PERFORM aws_oracle_ext.set_package_variable(''test_pg'', ''v_output'', v_output_l) ;
 end; $a$'  ;
v_output_loc := aws_oracle_ext.get_package_variable('test_pg', 'v_output');
raise notice 'v_output_loc %',v_output_loc;
END ;
$$
```

Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible

Sumana Yanamandra, Amazon Web Services

Summary

The code you migrate from an on-premises Oracle database to Amazon Aurora PostgreSQL-Compatible Edition might include overloaded functions. These functions have the same definition —that is, the same function name and the same number and data type of input (`IN`) parameters— but the data type or the number of output (`OUT`) parameters might differ.

These parameter mismatches can cause problems in PostgreSQL, because it's difficult to determine which function to run. This pattern illustrates how to handle overloaded functions when you migrate your database code to Aurora PostgreSQL-Compatible.

Prerequisites and limitations

Prerequisites

- An Oracle database instance as your source database
- An Aurora PostgreSQL-Compatible DB instance as your target database (see instructions in the Aurora documentation)

Product versions

- Oracle Database 9i or later
- Oracle SQL Developer version 18.4.0.376
- pgAdmin 4 client
- Aurora PostgreSQL-Compatible version 11 or later (see Identifying versions of Amazon Aurora PostgreSQL in the Aurora documentation)

Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

Other tools

- [Oracle SQL Developer](#) is a free, integrated development environment for working with SQL in Oracle databases in both traditional and cloud deployments.
- [pgAdmin](#) is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Epics

Create a simple function

Task	Description	Skills required
Create a function in PostgreSQL that has one input parameter and one output parameter.	The following example illustrates a function named `test_overloading` in Aurora PostgreSQL-Compatible. This function has two parameters: one input text parameter and one output text parameter. ```CREATE OR REPLACE FUNCTION public.test_overloading(str1 text, OUT str2 text) LANGUAGE 'plpgsql' COST 100 VOLATILE AS $BODY$ DECLARE BEGIN str2 := 'Success'; RETURN ; EXCEPTION WHEN others THEN RETURN ; END;```	Data engineer, Aurora PostgreSQL-Compatible

Task	Description	Skills required
	`$BODY$;`	

Run the function in PostgreSQL.	Run the function that you created in the previous step.
	`select public.test_overloading('Test');`
	It should display the following output.
	`Success`
		Data engineer, Aurora PostgreSQL-Compatible

Overload the function

Task	Description	Skills required

Use the same function name to create an overloaded function in PostgreSQL.	Create an overloaded function in Aurora PostgreSQL-Compatible that uses the same function name as your previous function. The following example is also named `test_overloading` , but it has three parameters: one input text parameter, one output text parameter, and one output integer parameter.
	`CREATE OR REPLACE FUNCTION public.test_overloading(`
	`str1 text,`
		Data engineer, Aurora PostgreSQL-Compatible

Task	Description	Skills required

	<pre> OUT str2 text,
	        OUT num1
	 integer)
	    LANGUAGE 'plpgsql'
	
	    COST 100
	    VOLATILE
	AS $BODY$
	DECLARE
	str3 text;
	
	BEGIN
	
	        str2 :=
	 'Success';
	        num1 := 100;
	
	    RETURN ;
	    EXCEPTION
	        WHEN others THEN
	            RETURN ;
	END;
	$BODY$;</pre>	

Task	Description	Skills required

Run the function in PostgreSQL.	When you run this function, it fails with the following error message.
	`ERROR: cannot change return type of existing function`
	`HINT: Use DROP FUNCTION test_overloading(text) first.`
	This happens because Aurora PostgreSQL-Compatible doesn't support function overloading directly. It can't identify which function to run, because the number of output parameters is different in the second version of the function, although the input parameters are the same.
		Data engineer, Aurora PostgreSQL-Compatible

Apply the workaround

Task	Description	Skills required

Add INOUT to the first output parameter.	As a workaround, modify the function code by representing the first output parameter as `INOUT`.
	`CREATE OR REPLACE FUNCTION public.test_overloading(`
	`str1 text,`
		Data engineer, Aurora PostgreSQL-Compatible

Task	Description	Skills required

	<pre> INOUT str2
	 text,
	        OUT num1
	 integer)
	    LANGUAGE 'plpgsql'
	
	    COST 100
	    VOLATILE
	AS $BODY$
	DECLARE
	str3 text;
	BEGIN
	
	        str2 :=
	 'Success';
	        num1 := 100;
	
	    RETURN ;
	    EXCEPTION
	        WHEN others THEN
	            RETURN ;
	END;
	$BODY$;</pre>	

Task	Description	Skills required

Run the revised function.	Run the function that you updated by using the following query. You pass a null value as the second argument of this function, because you declared this parameter as `INOUT` to avoid the error.
	`select public.test_overloading('Test', null);`
	The function is now created successfully.
	`Success, 100`

Help enforce DynamoDB tagging

Mansi Suratwala, Amazon Web Services

Summary

This pattern sets up automatic notifications when a predefined Amazon DynamoDB tag is missing or removed from a DynamoDB resource on the Amazon Web Services (AWS) Cloud.

DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability. DynamoDB lets you offload the administrative burdens of operating and scaling a distributed database. When you use DynamoDB, you don't have to worry about hardware provisioning, setup and configuration, replication, software patching, or cluster scaling.

The pattern uses an AWS CloudFormation template, which creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any new or existing DynamoDB tagging information by using AWS CloudTrail. If a predefined tag is missing or removed, CloudWatch triggers a Lambda function, which sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket for the Lambda .zip file that contains the Python script for running the Lambda function

Limitations

- The solution works only when the `TagResource` or `UntagResource` CloudTrail events occur. It does not create notifications for any other events.

Architecture

Target technology stack

- Amazon DynamoDB
- AWS CloudTrail

- Amazon CloudWatch
- AWS Lambda
- Amazon S3
- Amazon SNS

Target architecture

Automation and scale

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

Tools

Tools

- Amazon DynamoDB – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.
- AWS CloudTrail – CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near-real time stream of system events that describe changes in AWS resources.
- AWS Lambda – Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

Code

- A .zip file of the project is available as an attachment.

Epics

Define the S3 bucket

Task	Description	Skills required
Define the S3 bucket.	On the Amazon S3 console, choose or create an S3 bucket with a unique name that does not contain leading slashes. This S3 bucket will host the Lambda code .zip file. Your S3 bucket must be in the same AWS Region as the DynamoDB resource that is being monitored.	Cloud Architect

Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code to the S3 bucket.	Upload the Lambda code .zip file provided in the *Attachments* section to the S3 bucket. The S3 bucket must be in the same Region as the DynamoDB resource that is being monitored.	Cloud Architect

Deploy the AWS CloudFormation template

Task	Description	Skills required
Deploy the AWS CloudFormation template.	On the AWS CloudFormation console, deploy the AWS CloudFormation template that's provided in the *Attachments* section. In the next epic, provide values for the parameters.	Cloud Architect

Complete the parameters in the AWS CloudFormation template

Task	Description	Skills required
Name the S3 bucket.	Enter the name of the S3 bucket that you created or chose in the first epic.	Cloud Architect
Provide the Amazon S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, `<folder>/<file-name>.zip`).	Cloud Architect
Provide an email address	Provide an active email address to receive Amazon SNS notifications.	Cloud Architect
Define the logging level.	Define the logging level and frequency for your Lambda function. `Info` designates detailed informational messages on the application's progress. `Error` designate	Cloud Architect

Task	Description	Skills required
	s error events that could still allow the application to continue running. `Warning` designates potentially harmful situations.	
Enter the required DynamoDB tag keys.	Be sure that the tags are separated by commas, with no spaces between them (for example, `ApplicationId,CreatedBy,Environment,Organization`). The CloudWatch Events event searches for these tags and sends a notification if they are not found.	Cloud Architect

Confirm the subscription.

Task	Description	Skills required
Confirm the subscription.	When the template successfully deploys, it sends a subscription email to the email address that you provided. To receive violation notifications, you must confirm this email subscription.	Cloud Architect

Implement cross-Region disaster recovery with AWS DMS and Amazon Aurora

Mark Hudson, Amazon Web Services

Summary

Natural or human-induced disasters can occur at any time and can impact the availability of services and workloads running in a given AWS Region. To mitigate the risks, you must develop a disaster recovery (DR) plan that incorporates the built-in cross-Region capabilities of AWS services. For AWS services that do not inherently provide cross-Region functionality, the DR plan must also provide a solution to handle their failover across AWS Regions.

This pattern guides you through a disaster recovery setup involving two Amazon Aurora MySQL-Compatible Edition database clusters in a single Region. To meet DR requirements, the database clusters are configured to use the Amazon Aurora global database feature, with a single database spanning multiple AWS Regions. An AWS Database Migration Service (AWS DMS) task replicates data between the clusters in the local Region. AWS DMS, however, currently doesn't support task failover between Regions. This pattern includes the steps required to work around that limitation and independently configure AWS DMS in both Regions.

Prerequisites and limitations

Prerequisites

- Selected primary and secondary AWS Regions that support Amazon Aurora global databases.
- Two independent Amazon Aurora MySQL-Compatible Edition database clusters in a single account in the primary Region.
- Database instance class db.r5 or higher (recommended).
- An AWS DMS task in the primary Region performing ongoing replication between the existing database clusters.
- DR Region resources in place to meet requirements for creating database instances. For more information, see Working with a DB instance in a VPC.

Limitations

- For the full list of Amazon Aurora global database limitations, see Limitations of Amazon Aurora global databases.

Product versions

- Amazon Aurora MySQL-Compatible Edition 5.7 or 8.0. For more information, see Amazon Aurora versions.

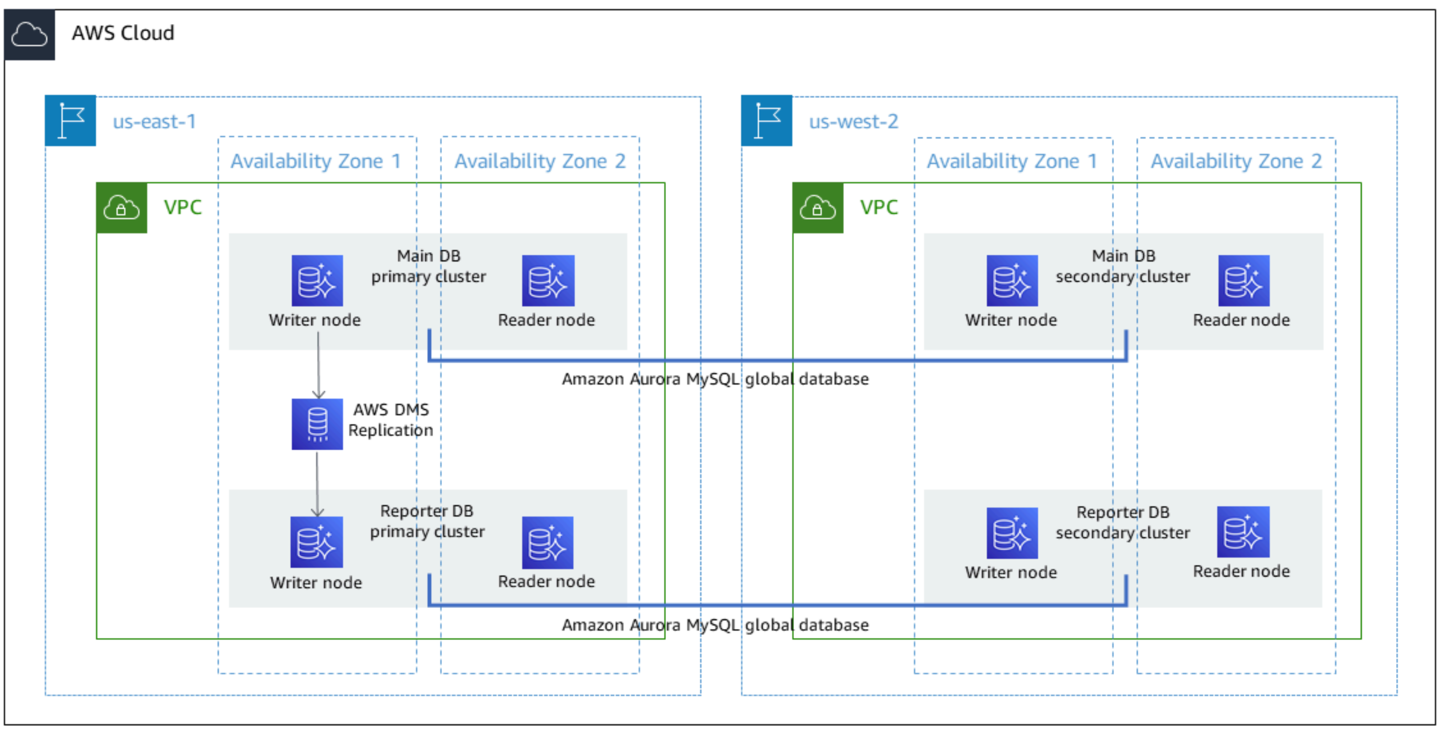
Architecture

Target technology stack

- Amazon Aurora MySQL-Compatible Edition global database cluster
- AWS DMS

Target architecture

The following diagram shows a global database for two AWS Regions, one with the primary main and reporter databases and AWS DMS replication, and one with the secondary main and reporter databases.



Automation and scale

You can use AWS CloudFormation to create the prerequisite infrastructure in the secondary Region, such as the virtual private cloud (VPC), subnets, and parameter groups. You can also use

AWS CloudFormation to create the secondary clusters in the DR Region and add them to the global database. If you used CloudFormation templates to create the database clusters in the primary Region, you can update or augment them with an additional template to create the global database resource. For more information, see Creating an Amazon Aurora DB cluster with two DB instances and Creating a global database cluster for Aurora MySQL.

Finally, you can create the AWS DMS tasks in the primary and secondary Regions using CloudFormation after failover and failback events occur. For more information, see AWS::DMS::ReplicationTask.

Tools

- Amazon Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. This pattern uses Amazon Aurora MySQL-Compatible Edition.
- Amazon Aurora global databases are designed for globally distributed applications. A single Amazon Aurora global database can span multiple AWS Regions. It replicates your data with no impact on database performance. It also enables fast local reads with low latency in each Region, and it provides disaster recovery from Region-wide outages.
- AWS DMS provides one-time migration or on-going replication. An on-going replication task keeps your source and target databases in sync. After it is set up, the on-going replication task continuously applies source changes to the target with minimal latency. All AWS DMS features, such as data validation and transformations, are available for any replication task.

Epics

Prepare the existing database clusters in the primary Region

Task	Description	Skills required
Modify the database cluster parameter group.	In the existing database cluster parameter group, activate row-level binary logging by setting the `binlog_format` parameter to a value of **row**. AWS DMS requires row-level binary logging for MYSQL-	AWS administrator

Task	Description	Skills required
	compatible databases when performing ongoing replication or change data capture (CDC). For more information, see Using an AWS managed MySQL-compatible database as a source for AWS DMS.	

Task	Description	Skills required

Update the database binary log retention period.	Using a MySQL client installed on your end-user device or an Amazon Elastic Compute Cloud (Amazon EC2) instance, run the following stored procedure provided by Amazon Relational Database Service (Amazon RDS) on the main database cluster's writer node, where XX is the number of hours to retain the logs.
	
	`call mysql.rds_set_configuration('binlog retention hours', XX)`
	
	Confirm the setting by running the following command.
	
	`call mysql.rds_show_configuration;`
	
	MySQL-compatible databases managed by AWS purge the binary logs as soon as possible. Therefore, the retention period must be long enough to ensure that the logs are not purged before the AWS DMS task runs. A value of 24 hours is usually sufficient, but the value should be based on the time
		DBA

Task	Description	Skills required
	required to set up the AWS DMS task in the DR Region.	

Update the existing AWS DMS task in the primary Region

Task	Description	Skills required

Record the AWS DMS task ARN.	Use the Amazon Resource Name (ARN) to obtain the AWS DMS task name for later use. To retrieve the AWS DMS task ARN, view the task in the console or run the following command.
	`aws dms describe-replication-tasks`
	An ARN looks like the following.
	`arn:aws:dms:us-east-1:<accountid>:task:AN6HFFMPM246XOZVEUHCNSOVF7MQCLTOZUIRAMY`
	The characters after the last colon correspond to the task name used in a later step.
		AWS administrator

Modify the existing AWS DMS task to record the checkpoint.	AWS DMS creates checkpoints that contain information so that the replication engine knows the recovery point	AWS administrator

Task	Description	Skills required
	for the change stream. To record checkpoint informati on, perform the following steps in the console: 1. Stop the AWS DMS task. 2. Use the JSON editor in the task to set the TaskRecoveryTableEnabled parameter to **true**. 3. Start the AWS DMS task.	
Validate checkpoint informati on.	Using a MySQL client connected to the writer endpoint for the cluster, query the new metadata table in the reporter database cluster to verify that it exists and contains the replication state information. Run the following command. `select * from awsdms_control.awsdms_txn_state;` The task name from the ARN should be found in this table in the `Task_Name` column.	DBA

Expand both Amazon Aurora clusters to a DR Region

Task	Description	Skills required
Create base infrastructure in the DR Region.	Create the base component s required for the creation of and access to the Amazon Aurora clusters: • Virtual private cloud (VPC) • Subnets • Security group • Network access control lists • Subnet group • DB parameter group • DB cluster parameter group Ensure that the configuration of both parameter groups matches the configuration in the primary Region.	AWS administrator
Add the DR Region to both Amazon Aurora clusters.	Add a secondary Region (the DR Region) to the main and reporter Amazon Aurora clusters. For more informati on, see Adding an AWS Region to an Amazon Aurora global database.	AWS administrator

Perform failover

Task	Description	Skills required
Stop the AWS DMS task.	The AWS DMS task in the primary Region will not function properly after failover occurs and should be stopped to avoid errors.	AWS administrator
Perform a managed failover.	Perform a managed failover of the main database cluster to the DR Region. For instructi ons, see Performing managed planned failovers for Amazon Aurora global databases. After failover on the main database cluster is complete, perform the same activity on the reporter database cluster.	AWS administrator, DBA
Load data into the main database.	Insert test data into writer node of the main database in the DR database cluster. This data will be used to validate that replication is functioning properly.	DBA
Create the AWS DMS replicati on instance.	To create the AWS DMS replication instance in the DR Region, see Creating a replication instance.	AWS administrator, DBA
Create the AWS DMS source and target endpoints.	To create the AWS DMS source and target endpoints in the DR Region, see Creating source and target endpoints . The source should point to	AWS administrator, DBA

Task	Description	Skills required
	the writer instance of the main database cluster. The target should point to the writer instance of the reporter database cluster.	
Obtain the replication checkpoint.	To obtain the replication checkpoint, use a MySQL client to query the metadata table by running the following against the writer node in the reporter database cluster in the DR Region. `select * from awsdms_control.awsdms_txn_state;` In the table, find the task_name value that corresponds to the AWS DMS task's ARN that exists in the primary Region that you obtained in the second epic.	DBA

Task	Description	Skills required
Create an AWS DMS task.	Using the console, create an AWS DMS task in the DR Region. In the task, specify a migration method of **Replicate data changes only**. For more information, see [Creating a task](). 1. In the task settings, use the wizard to specify the following: • **CDC start mode for source transactions** – Enable custom CDC start mode • **Custom CDC start point for source transactions** – Specify a recovery checkpoint 2. In the **Recovery checkpoint** box, enter the replication checkpoint value previously obtained through the database query on the `awsdms_txn_state` table. 3. In the task settings section, select the JSON editor, and set the **TaskRecoveryTableEnabled** parameter to **true**.	AWS administrator, DBA

Task	Description	Skills required
	Set the AWS DMS task **Start migration task** setting to **Automatically on create**.	
Record the AWS DMS task ARN.	Use the ARN to obtain the AWS DMS task name for later use. To retrieve the AWS DMS task ARN, run the following command. `aws dms describe-replication-tasks`	AWS administrator, DBA
Validate the replicated data.	Query the reporter database cluster in the DR Region to confirm that the test data that you loaded into the main database cluster has been replicated.	DBA

Perform failback

Task	Description	Skills required
Stop the AWS DMS task.	The AWS DMS task in the DR Region will not function properly after failback occurs and should be stopped to avoid errors.	AWS administrator
Perform a managed failback.	Fail back the main database cluster to the primary Region. For instructions, see Performing managed planned failovers for Amazon	AWS administrator, DBA

Task	Description	Skills required
	Aurora global databases. After the failback on the main database cluster is complete, perform the same activity on the reporter database cluster.	
Obtain the replication checkpoint.	To obtain the replication checkpoint, use a MySQL client to query the metadata table by running the following against the writer node in the reporter database cluster in the DR Region. `select * from awsdms_control.awsdms_txn_state;` In the table, find the `task_name` value that corresponds to the AWS DMS task's ARN that exists in the DR Region that you obtained in the fourth epic.	DBA

Task	Description	Skills required
Update the AWS DMS source and target endpoints.	After the database clusters have failed back, check the clusters in the primary Region to determine which nodes are the writer instances . Then verify the existing AWS DMS source and target endpoints in the primary Region are pointing to the writer instances. If not, update the endpoints with the writer instance Domain Name System (DNS) names.	AWS administrator

Task	Description	Skills required
Create an AWS DMS task.	Using the console, create an AWS DMS task in the primary Region. In the task, specify a migration method of **Replicate data changes only**. For more information, see [Creating a task](#). 1. In the task settings, use the wizard and specify the following: • **CDC start mode for source transactions** – Enable custom CDC start mode • **Custom CDC start point for source transacti ons** – Specify a recovery checkpoint 2. In the **Recovery checkpoin t** box, enter the replication checkpoint value previousl y obtained through the database query on the `awsdms_txn_state` table. 3. Also within the task settings section, select the JSON editor and set the **TaskRecoveryTableE nabled** parameter to **true**. 4. Finally, set the AWS DMS task **Start migration task**	AWS administrator, DBA

Task	Description	Skills required
	setting to **Automatically on create**.	
Record the AWS DMS task Amazon Resource Name (ARN).	Use the ARN to obtain the AWS DMS task name for later use. To retrieve the AWS DMS task ARN, run the following command: `aws dms describe-replication-tasks` The task name will be needed when performing another managed failover or during a DR scenario.	AWS administrator, DBA
Delete AWS DMS tasks.	Delete the original (currentl y stopped) AWS DMS task in the primary Region and the existing AWS DMS task (currently stopped) in the secondary Region.	AWS administrator

Additional information

Amazon Aurora global databases are used in this example for DR because they provide an effective recovery time objective (RTO) of 1 second and a recovery point objective (RPO) of less than 1 minute, both lower than traditional replicated solutions and ideal for DR scenarios.

Amazon Aurora global databases offer many other advantages, including the following:

- Global reads with local latency – Global consumers can access information in a local Region, with local latency.
- Scalable secondary Amazon Aurora DB clusters – Secondary clusters can be scaled independently, adding up to 16 read-only replicas.
- Fast replication from primary to secondary Amazon Aurora DB clusters – Replication has little performance impact on the primary cluster. It occurs at the storage layer, with typical cross-Region replication latencies of less than 1 second.

This pattern also uses AWS DMS for replication. Amazon Aurora databases provide the ability to create read replicas, which can simplify the replication process and the DR setup. However, AWS DMS is often used to replicate when data transformations are required or when the target database requires additional indexes that the source database does not have.

Migrate Oracle functions and procedures that have more than 100 arguments to PostgreSQL

Srinivas Potlachervoo, Amazon Web Services

Summary

This pattern shows how to migrate Oracle Database functions and procedures that have more than 100 arguments to PostgreSQL. For example, you can use this pattern to migrate Oracle functions and procedures to one of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

PostgreSQL doesn’t support functions or procedures that have more than 100 arguments. As a workaround, you can define a new data type that has type fields that match the source function’s arguments. Then, you can create and run a PL/pgSQL function that uses the custom data type as an argument.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS Oracle database (DB) instance
- An Amazon RDS for PostgreSQL DB instance or an Aurora PostgreSQL-Compatible DB instance

Product versions

- Amazon RDS Oracle DB instance versions 10.2 and later
- Amazon RDS PostgreSQL DB instance versions 9.4 and later, or Aurora PostgreSQL-Compatible DB instance versions 9.4 and later
- Oracle SQL Developer version 18 and later
- pgAdmin version 4 and later

Architecture

Source technology stack

- Amazon RDS Oracle DB instance versions 10.2 and later

Target technology stack

- Amazon RDS PostgreSQL DB instance versions 9.4 and later, or Aurora PostgreSQL-Compatible DB instance versions 9.4 and later

Tools

AWS services

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

Other services

- Oracle SQL Developer is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.
- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Best practices

Make sure that the data type that you create matches the type fields that are included in the source Oracle function or procedure.

Epics

Run an Oracle function or procedure that has more than 100 arguments

Task	Description	Skills required
Create or identify an existing Oracle/PLSQL function or procedure that has more than 100 arguments.	Create an Oracle/PLSQL function or procedure that has more than 100 arguments . -or- Identify an existing Oracle/ PLSQL function or procedure that has more than 100 arguments. For more information, see sections 14.7 CREATE FUNCTION Statement and 14.11 CREATE PROCEDURE Statement in the Oracle Database documentation.	Oracle/PLSQL knowledge
Compile the Oracle/PLSQL function or procedure.	Compile the Oracle/PLSQL function or procedure. For more information, see Compiling a function in the Oracle Database documenta tion.	Oracle/PLSQL knowledge
Run the Oracle/PLSQL function.	Run the Oracle/PLSQL function or procedure. Then, save the output.	Oracle/PLSQL knowledge

Define a new data type that matches the source function's or procedure's arguments

Task	Description	Skills required
Define a new data type in PostgreSQL.	Define a new data type in PostgreSQL that includes all of the same fields that appear in the source Oracle function's or procedure's arguments. For more information, see [CREATE TYPE] in the PostgreSQL documentation.	PostgreSQL PL/pgSQL knowledge

Create a PostgreSQL function that includes the new TYPE argument

Task	Description	Skills required
Create a PostgreSQL function that includes the new data type.	Create a PostgreSQL function that includes the new TYPE argument. To review an example function, see the **Additional information** section of this pattern.	PostgreSQL PL/pgSQL knowledge
Compile the PostgreSQL function.	Compile the function in PostgreSQL. If the new data type fields match the source function's or procedure's arguments, then the function successfully compiles.	PostgreSQL PL/pgSQL knowledge
Run the PostgreSQL function.	Run the PostgreSQL function.	PostgreSQL PL/pgSQL knowledge

Troubleshooting

Issue	Solution
The function returns the following error: **ERROR: syntax error near "<statement>"**	Make sure that all of the function's statements end with a semicolon (`;`).
The function returns the following error: **ERROR: "<variable>" is not a known variable**	Make sure that the variable that's used in the function body is listed within the function's `DECLARE` section.

Additional information

Example PostgreSQL function that includes a TYPE argument

```
CREATE OR REPLACE FUNCTION test_proc_new
(
    IN p_rec type_test_proc_args
)
RETURNS void
AS
$BODY$
BEGIN

    /*
    **************
    The body would contain code to process the input values.
    For our testing, we will display couple of values.
    ***************
    */
    RAISE NOTICE USING MESSAGE = CONCAT_WS('', 'p_acct_id: ', p_rec.p_acct_id);
    RAISE NOTICE USING MESSAGE = CONCAT_WS('', 'p_ord_id: ', p_rec.p_ord_id);
    RAISE NOTICE USING MESSAGE = CONCAT_WS('', 'p_ord_date: ', p_rec.p_ord_date);
```

```
END;
$BODY$
LANGUAGE plpgsql
COST 100;
```

Migrate SAP HANA to AWS using SAP HSR with the same hostname

Pradeep Puliyampatta, Amazon Web Services

Summary

SAP HANA migrations to Amazon Web Services (AWS) can be performed using multiple options, including backup and restore, export and import, and SAP HANA System Replication (HSR). The selection of a particular option depends on the network connectivity between source and target SAP HANA databases, the size of the source database, downtime considerations, and other factors.

The SAP HSR option for migrating SAP HANA workloads to AWS works well when there is a stable network between the source and target systems and the entire database (SAP HANA DB replication snapshot) can be completely replicated within 1 day, as stipulated by SAP for network throughput requirements for SAP HSR. The downtime requirements with this approach are limited to performing the takeover on the target AWS environment, SAP HANA DB backup, and post-migration tasks.

SAP HSR supports the use of different hostnames (hostnames mapped to different IP addresses) for replication traffic between the primary, or source, and secondary, or target, systems. You can do this by defining those specific sets of hostnames under the `[system_replication_hostname_resolution]` section in `global.ini`. In this section, all hosts of the primary and the secondary sites must be defined on each host. For detailed configuration steps, see the [SAP documentation](#).

One key takeaway from this setup is that the hostnames in the primary system must be different from the hostnames in the secondary system. Otherwise, the following errors can be observed.

- `"each site must have a unique set of logical hostnames"`
- `"remoteHost does not match with any host of the source site. All hosts of source and target site must be able to resolve all hostnames of both sites correctly"`

However, the number of post-migration steps can be reduced by using the same SAP HANA DB hostname on the target AWS environment.

This pattern provides a workaround for using the same hostname on source and target environments when using the SAP HSR option. With this pattern, you can use the SAP HANA Hostname Rename option. You assign a temporary hostname to the target SAP HANA DB to

facilitate hostname uniqueness for SAP HSR. After the migration completes the takeover milestone on the target SAP HANA environment, you can revert the target system hostname back to the hostname of the source system.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router.
- AWS Client VPN or AWS Direct Connect configured to transfer files from the source to the target.
- SAP HANA databases in both the source and the target environment. The target SAP HANA DB patch level should be equal to or higher than the source SAP HANA DB patch level, within the same SAP HANA Platform edition. For example, replication cannot be set up between HANA 1.0 and HANA 2.0 systems. For more information, see question 15 in SAP Note: 1999880 – FAQ: SAP HANA System Replication.
- SAP application servers in the target environment.
- Amazon Elastic Block Store (Amazon EBS) volumes in the target environment.

Limitations

The following list of SAP documents covers known issues that are related to this workaround, including constraints regarding SAP HANA dynamic tiering and scale-out migrations:

- 2956397 – Renaming of SAP HANA Database System failed
- 2222694 – When trying to rename the HANA system, the following error appears "Source files are not owned by the original sidadm user (uid = xxxx)"
- 2607227 – hdblcm: register_rename_system: Renaming SAP HANA instance failed
- 2630562 – HANA Hostname Rename failed and HANA does not start up
- 2935639 – sr_register is not using the hostname that is specified under system_replication_hostname_resolution in the global.ini section
- 2710211 – Error: source system and target system have overlapping logical hostnames
- 2693441 – Failed to rename an SAP HANA System due to error
- 2519672 – HANA Primary and Secondary has different system PKI SSFS data and key or unable to check

- 2457129 – SAP HANA System Host Rename is not Permitted when Dynamic Tiering is Part of Landscape
- 2473002 – Using HANA System Replication to migrate scale out system (There are no restrictions provided by SAP in using this hostname rename approach for scale-out SAP HANA systems. However, the procedure must be repeated on each individual host. Other scale-out migration limitations also apply to this approach.)

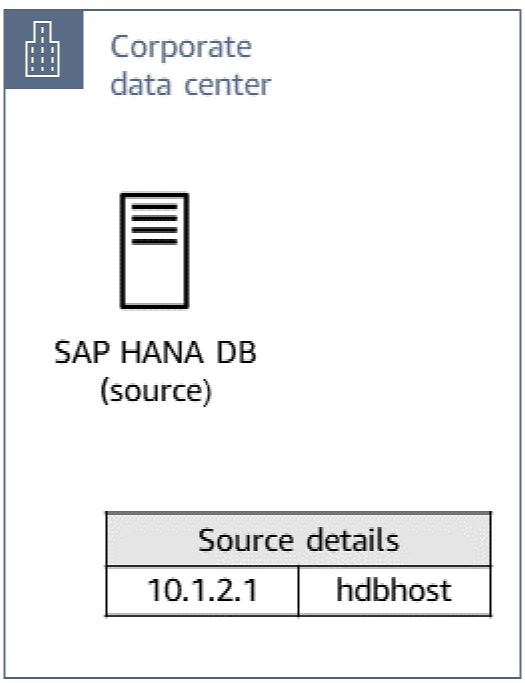
Product versions

- This solution applies to SAP HANA DB platform edition 1.0 and 2.0.

Architecture

Source setup

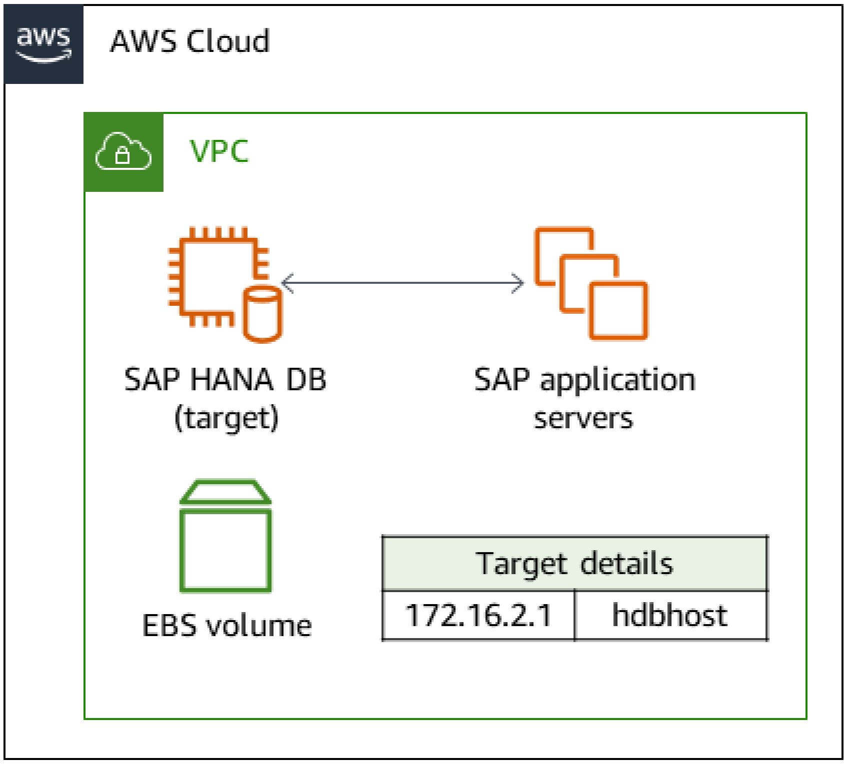
An SAP HANA database is installed on the source environment. All the SAP application server connections and DB interfaces use the same hostname for client connections. The following diagram shows the example source hostname `hdbhost` and its corresponding IP address.



Target setup

The AWS Cloud target environment uses the same hostname to run an SAP HANA database. The target environment on AWS includes the following:

- SAP HANA database
- SAP application servers
- EBS volumes

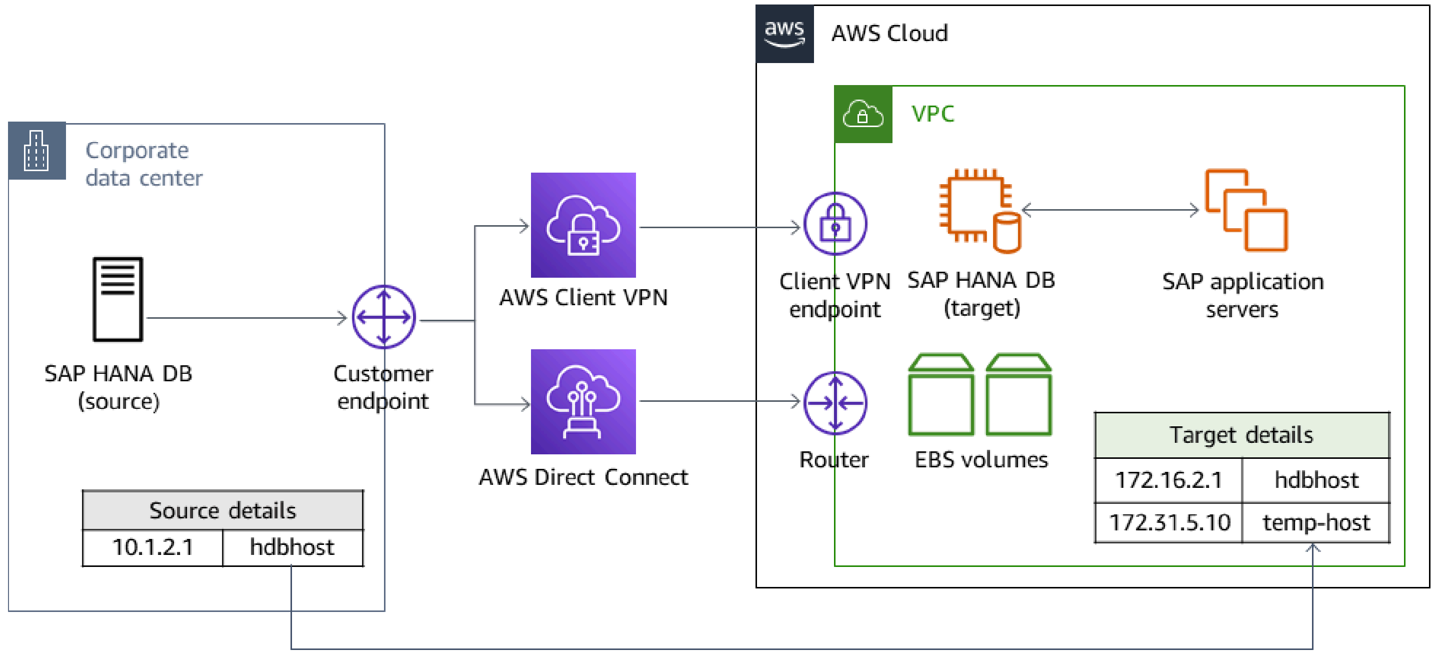


Intermediate configuration

In the following diagram, the hostname on the AWS target environment is temporarily renamed as `temp-host` so that the hostnames on the source and target are unique. After the migration completes the takeover milestone on the target environment, the target system virtual hostname is renamed using the original name, `hdbhost`.

The intermediate configuration includes one of the following options:

- AWS Client VPN with a Client VPN endpoint
- AWS Direct Connect connecting to a router



SAP application servers on the AWS target environment can be installed either before replication setup or after the takeover. However, installing the application servers before replication setup can help with reduction of downtime during installation, configuration of high availability, and backups.

Tools

AWS services

- AWS Client VPN is a managed client-based VPN service that enables you to securely access AWS resources and resources in your on-premises network.
- AWS Direct Connect links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services, bypassing internet service providers in your network path.
- Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

Other tools

- SAP application servers – SAP application servers provide programmers with a way to express business logic. The SAP application server performs the data processing based on the business logic. The actual data is stored in a database, which is a separate component.
- SAP HANA cockpit and SAP HANA Studio – Both SAP HANA cockpit and SAP HANA Studio provide an administrative interface to the SAP HANA database. In SAP HANA Studio, the SAP HANA Administration console is the system view that provides relevant content for SAP HANA database administration.
- SAP HANA System Replication – SAP HANA System Replication (SAP HSR) is the standard procedure provided by SAP for replicating SAP HANA databases. The required executables for SAP HSR are part of the SAP HANA server kernel itself.

Epics

Prepare the source and target environments

Task	Description	Skills required
Install and configure the SAP HANA databases.	In the source and target environments, ensure that the SAP HANA DB is installed and configured according to SAP HANA on best practices. For more information, see SAP HANA on AWS.	SAP Basis administration
Map the IP address.	In the target environment, ensure that the temporary hostname is assigned to an internal IP address. 1. Assign a secondary IPv4 address to the EC2 instance on the AWS Managemen t Console by navigating to **EC2**, **Instance**, **Actions**, **Networking**, **Manage IP**	AWS administration

Task	Description	Skills required
	address, **Assign new IP address**. 2. To assign the same address to the EC2 network adaptor (NIC), from the operating system, as root user, run the command `ip addr add <IP>/32 dev eth0`, replacing `<IP>` with the IP address from step 1.	
Resolve target hostnames.	On the secondary SAP HANA DB, confirm that both hostnames (`hdbhost` and `temp-host`) are resolved for the SAP HANA replicati on networks by updating the relevant hostnames in the `/etc/hosts` file.	Linux administration
Back up the source and target SAP HANA databases.	Use SAP HANA Studio or the SAP HANA cockpit to perform backups on the SAP HANA databases.	SAP Basis administration

Task	Description	Skills required
Exchange system PKI certifica tes.	(Applies only to SAP HANA 2.0 and later) Exchange certificates in the system public key infrastructure (PKI) secure store in the file system (SSFS) store between the primary and secondary databases. For more informati on, see SAP Note 2369981 – Required configuration steps for authentication with SAP HANA System Replication.	SAP Basis administration

Rename the target SAP HANA DB

Task	Description	Skills required
Stop target client connectio ns.	In the target environment, shut down the SAP applicati on servers and other client connections.	SAP Basis administration

Rename the target SAP HANA DB to the temporary hostname.	1. As root user, rename the target SAP HANA DB hostname to the temporary hostname by using resident `hdblcm`.
	`root $> cd /hana/shared/<SID/hdblcm`
	`root $> ./hdblcm`
	2. Choose option 9 | `rename_system` |
		SAP Basis administration

Task	Description	Skills required
	`Rename the SAP HANA Database System`. 3. Provide the new name: `temp-host` . 4. You can validate other options as needed. However, be sure that you don't mix up the host rename with a SID change (SAP Note 2598814 – hdblcm: SID rename fails). The SAP HANA DB stop and start will be controlled by `hdblcm`.	
Assign replication networks.	In the `global.ini` file of the source system, under the `[system_replication_hostname_resolution]` header, provide the source and target replication network details. Then copy the entries to the `global.ini` file on the target system.	SAP Basis administration
Enable replication on primary.	To enable replication on the source SAP HANA DB, run the following command. `hdbnsutil -sr_enable --name=siteA`	SAP Basis administration

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Register the target SAP HANA DB as a secondary system.</td><td>To register the target SAP HANA DB as a secondary system to source for SAP HSR, choose async replication.
<pre><code>(sid)adm $> HDB stop
(sid)adm $> hdbnsutil -
sr_register -name=sit
eB -remotehost=hdbhos
t /
--remoteInstance=00 -
replicationMode=async
 -operationMode=log
replay
(sid)adm $> HDB start</code></pre>Alternatively, you can choose the <code>–online</code> option to register. In that case, you don't need to stop and start the SAP HANA DB.</td><td>SAP Basis administration</td></tr>
<tr><td>Validate synchronization.</td><td>On the source SAP HANA DB, verify that all the logs are applied on the target system (because it is async replicati on).

To verify the replication, on the source, run the following commands.
<pre><code>(sid)adm $> cdpy
(sidadm $> python
 systemReplicationS
tatus.py</code></pre></td><td>SAP Basis administration</td></tr>
</table>

Task	Description	Skills required
Shut down the source SAP application and SAP HANA DB.	During the migration cutover, perform a shutdown of the source system (the SAP application and SAP HANA database.	SAP Basis administration
Perform a takeover at the target.	To perform a takeover at the target on AWS, run the command `hdbnsutil -sr_takeover` .	SAP Basis administration
On the target SAP HANA DB, turn off replication.	To clear the replication metadata, stop replication on the target system by running the command `hdbnsutil -sr_disable` . **Note** This is in accordanc e with SAP Note 2693441 – Failed to rename an SAP HANA System due to error.	SAP Basis administration
Back up the target SAP HANA DB.	After the takeover is successfu l, we recommend performing a full SAP HANA DB backup.	SAP Basis administration

Revert to the original hostname in the target system

Task	Description	Skills required

Revert the target SAP HANA DB hostname to the original.	1. To revert the target SAP HANA DB hostname to the original virtual hostname, use resident `hdblcm`.
	`root $> cd /hana/shared/<SID>/hdblcm`
	`root $> ./hdblcm`
	2. Choose option `9 | rename_system | Rename the SAP HANA Database System`.
	3. Provide the new name: `hdbhost`.
	
	You can validate other options as needed. However, be sure that you don't mix up the host rename with a SID change (SAP Note 2598814 – hdblcm: SID rename fails).
		SAP Basis administration

Adjust hdbuserstore.	Adapt the `hdbuserstore` details pointing to the source `schema/user` details. For detailed steps, see the SAP documentation. To validate this step, run the command `R3trans -d`. The result should reflect a	SAP Basis administration

Task	Description	Skills required
	successful connection to the SAP HANA database.	
Start up client connections.	In the target environment, start up the SAP applicati on servers and other client connections.	SAP Basis administration

Migrate Microsoft SQL Server Always On availability group using AWS Application Migration Service

Sreenivas Nettem, Bharath Kumar Pammi Ramesh, Anantharaman Seshadri, and Gireesh Sreekantan, Amazon Web Services

Summary

AWS Application Migration Service (AWS MGN) is a preferred tool for rehosting existing environments in the AWS Cloud, which allows customers to move away from on-premises data centers. This pattern outlines the process of using AWS MGN to migrate Windows clusters with Microsoft SQL Server Always On availability groups.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS Identity and Access Management (IAM) role for AWS MGN orchestration.
- Access to source database servers (SQL Server Always On availability group).
- Active Directory in an AWS landing zone to retain DNS names.
- A staging subnet with closed network communication to Active Directory.
- Target subnets that can communicate with Active Directory.
- Two reserved IP addresses for the Windows cluster in a target subnet (one in each Availability Zone).
- Two reserved IP addresses for the SQL Always On listener in a target subnet (one in each Availability Zone).

Product versions

- Windows Server 2012 or later
- SQL Server 2012 or later

Architecture

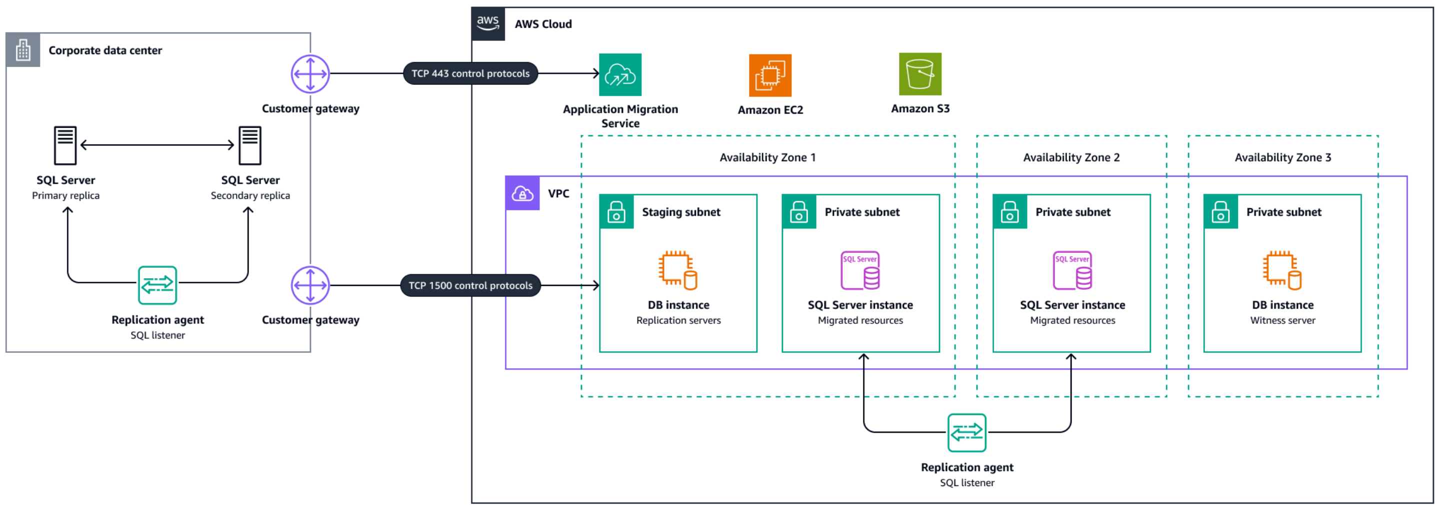
Source technology stack

Microsoft Windows cluster (on-premises physical or virtual machine) Microsoft SQL Server Always On availability group

Target technology stack

Amazon EC2 Windows instance

Target architecture



Tools

AWS services

- [Amazon Elastic Compute Cloud (Amazon EC2)] provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [AWS Application Migration Service] helps you rehost (lift and shift) applications to the AWS Cloud without change and with minimal downtime.
- [AWS Identity and Access Management (IAM)] helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Other tools

- [Microsoft SQL Server Management Studio (SSMS)] is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.

Best practices

For AWS MGN, see Best practices for AWS Application Migration Service.

Epics

Prepare the target account

Task	Description	Skills required
Initialize AWS MGN.	Initialize AWS MGN in the target AWS Region. This creates the required IAM roles and policies. For more information, see Initializing Application Migration Service with the console.	Cloud administrator
Create replication and launch templates.	Configure the replication and launch templates for use with AWS MGN. For more information, see Configuring the templates in the AWS documentation.	Cloud administrator
Allow communication ports.	To enable network communications for AWS MGN, allow traffic over TCP ports 443 and 1500. For more information, see Network requirements for Application Migration Service in the AWS documentation.	Cloud administrator, Network administrator

Prepare the source server

Task	Description	Skills required
Verify AWS MGN prerequis ites.	Verify that the source servers meet the prerequisites for the AWS MGN agent installat ion. For more information, see [Installation requirements](#) in the AWS documentation.	Migration engineer
Install AWS MGN agent.	Install the AWS MGN agent on the source servers. During the installation, choose the AWS Region where the servers will be migrated. After installat ion, the agent communica tes with the service and starts replication. For more information, see [Installing the AWS Replication Agent on Windows servers](#).	Migration engineer
Check source server status.	In the AWS MGN console, check the status of source servers. The servers display **Ready for testing** when replication begins. If you encounter any errors, see [Troubleshooting communication errors](#) in the AWS MGN documentation.	Cloud administrator, Migration engineer
Optimize replication settings.	SQL Always On clusters use high I/O synchronous replicati on from the primary server to the secondary server. To	Cloud administrator, Migration engineer

Task	Description	Skills required
	optimize replication and avoid lag, use a dedicated replication server for each SQL Always On server. If the database is greater than 5 TB, consider choosing a larger replication server instance size such as **m5.large** instead of the default **t3.small**.	
Update launch template.	Update the launch settings and choose subnets for the SQL Always On servers. The SQL Always On cluster servers are spread across different AWS Availability Zones for high availability.	Migration engineer, Migration lead
Update launch settings.	Based on your size and performance requirements, update the instance type and input/output operations per second (IOPS) in the launch settings. (Optional) Choose an existing elastic network interface in the launch settings.	Migration engineer, Migration lead

Test cutover

Task	Description	Skills required
Verify source servers.	In the AWS MGN console, verify that the source server status is **Ready for testing**.	Cloud administrator, Migration engineer
Launch the test instances.	1. Launch the test instances and verify in the Amazon EC2 console that the automated checks pass. 2. Select and launch test instances for the witness server. 3. Verify that you can sign in to the servers through the AWS MGN console. 4. Select the SQL Always On cluster servers and launch the test instances together.	Cloud administrator, Migration engineer
Test for connectivity and database integrity.	Test the connectivity and database integrity of the test instances. Then mark the source servers as **Ready for cutover** in the AWS MGN console.	Cloud administrator, Migration engineer

Pre-migration tasks

Task	Description	Skills required
Test the database integrity.	This helps to ensure there are no database integrity issues at the source prior	Data engineer, DBA

Task	Description	Skills required
	to migration. Run `DBCC CHECKDB` and specify `WITH_PHYSICAL_ONLY` . Running this check without `WITH_PHYSICAL_ONLY` can cause performance issues at the source. To maintain database integrity, run a weekly full check of the database. These commands check the database's logical and physical integrity by detecting potential corruption issues. The check verifies the database's structure, such as pages, rows, indexes, and system tables.	
Test the connections to linked servers.	Test the connections among all existing servers, and document their status. This helps to ensure that linked servers work as intended after the migration.	Data engineer, DBA
Verify the backups.	Confirm the integrity of source backups.	Data engineer, DBA

AWS MGN cutover

Task	Description	Skills required
Stop the SQL Server and cluster services.	Stop the SQL Server and Microsoft cluster services on all SQL cluster nodes.	DBA, Migration engineer
Verify the servers.	In the AWS MGN console, verify that the status of the source servers is **Ready for cutover** and that the data replication status is **Healthy**.	Migration engineer
Launch the cutover.	1. Launch the AWS MGN cutover for the witness server. 2. Launch the AWS MGN cutover for the SQL Always On cluster instances. 3. Verify that the status changes to **Cutover in progress**. For more information, see [Launching a cutover instance](#) in the AWS MGN documenta tion.	Migration engineer
Test the launched servers.	Log in to the launched Amazon EC2 instances and validate the cluster’s health. Verify that the servers are in the correct subnets, the instance size and IOPS	DBA, Migration engineer

Task	Description	Skills required
	settings are correct, and the witness server is accessible.	

Database post-cutover tasks

Task	Description	Skills required
Update the cluster IP address.	Update the cluster IP address for the Windows cluster using the two reserved IP addresses in the target subnets. For more information, see [Change the IP Address of a Failover Cluster Instance]().	DBA, Migration engineer
Update the Always On availability group listener IPs.	1. Open the failover cluster manager. 2. Choose the Always On availability group role. 3. Expand the availability group listener name. 4. In the context (right-click) menu, choose **IP address properties**. 5. Update the IP address using the address reserved for the listener in the target subnet. 6. Connect to the SQL Server primary instance using SSMS, and verify that the Always On listener is using both subnet IPs.	DBA, Migration engineer

Task	Description	Skills required
Verify the connection.	Using SSMS, connect to the Always On availability group listener, and confirm that the connection succeeds.	DBA, Migration engineer
Check the health of Always On availability group.	1. Navigate to the **Availability groups** folder, open the context (right-click) menu, and choose **Show dashboard**. 2. For all replicas, verify that the synchronization state is **Synchronized**.	DBA, Migration engineer
Check the error log.	Open the error log, and verify any errors reported for the SQL Server instance. Ensure that the recovery is complete for all databases.	DBA, Migration engineer
Test the linked servers.	Test the connectivity of any linked servers. In case of any connectivity issues, ensure that the target server and port are accessible.	DBA, Migration engineer

Finalize the cutover

Task	Description	Skills required
Finalize the cutover.	After you validate the target SQL Always On clusters, finalize the cutover through the AWS MGN console. This stops data replication	Cloud administrator, Migration engineer

Task	Description	Skills required
	from the source servers and discards the data from the replication server. It also removes the replication server and its associated resources.	

Troubleshooting

Issue	Solution

Migrate SQL Server to AWS using distributed availability groups

Praveen Marthala, Amazon Web Services

Summary

Microsoft SQL Server Always On availability groups provide a high availability (HA) and disaster recovery (DR) solution for SQL Server. An availability group consists of a primary replica that accepts read/write traffic, and up to eight secondary replicas that accept read traffic. An availability group is configured on a Windows Server Failover Cluster (WSFC) with two or more nodes.

Microsoft SQL Server Always On distributed availability groups provide a solution to configure two separate availability groups between two independent WFSCs. The availability groups that are part of the distributed availability group don't have to be in the same data center. One availability group can be on premises, and the other availability group can be on the Amazon Web Services (AWS) Cloud on Amazon Elastic Compute Cloud (Amazon EC2) instances in a different domain.

This pattern outlines steps for using a distributed availability group to migrate on-premises SQL Server databases that are part of an existing availability group to SQL Server with availability groups set up on Amazon EC2. By following this pattern, you can migrate the databases to the AWS Cloud with minimal downtime during cutover. The databases are highly available on AWS immediately after the cutover. You can also use this pattern to change the underlying operating system from on-premises to AWS while keeping the same version of SQL Server.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Direct Connect or AWS Site-to-Site VPN
- The same version of SQL Server installed on-premises and on the two nodes on AWS

Product versions

- SQL Server version 2016 and later
- SQL Server Enterprise Edition

Architecture

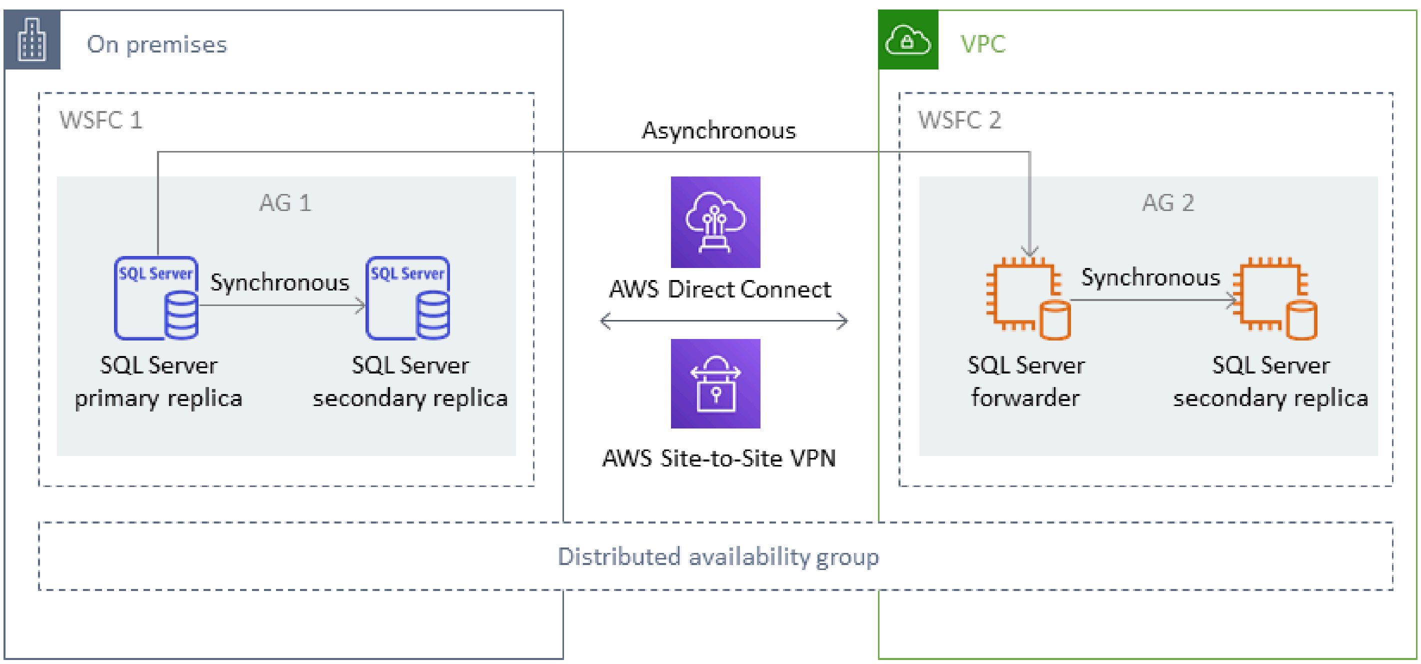
Source technology stack

- Microsoft SQL Server database with Always On availability groups on premises

Target technology stack

- Microsoft SQL Server database with Always On availability groups on Amazon EC2 on the AWS Cloud

Migration architecture



Terminology

- WSFC 1 – WSFC on premises
- WSFC 2 – WSFC on the AWS Cloud
- AG 1 – First availability group, which is in WSFC 1
- AG 2 – Second availability group, which is in WSFC 2
- SQL Server primary replica – Node in AG 1 that is considered the global primary for all writes
- SQL Server forwarder – Node in AG 2 that receives data asynchronously from the SQL Server primary replica

- SQL Server secondary replica – Nodes in AG 1 or AG 2 that receive data synchronously from the primary replica or the forwarder

Tools

- [AWS Direct Connect](#) – AWS Direct Connect links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create *virtual interfaces* directly to public AWS services, bypassing internet service providers in your network path.
- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- [AWS Site-to-Site VPN](#) – AWS Site-to-Site VPN supports creating a site-to-site virtual private network (VPN). You can configure the VPN to pass traffic between instances that you launch on AWS and your own remote network.
- [Microsoft SQL Server Management Studio](#) – Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

Epics

Set up a second availability group on AWS

Task	Description	Skills required
Create a WSFC on AWS.	Create WSFC 2 on Amazon EC2 instances with two nodes for HA. You will use this failover cluster to create the second availability group (AG 2) on AWS.	Systems administrator, SysOps administrator
Create the second availability group on WSFC 2.	Using SSMS, create AG 2 on two nodes in WSFC 2. The first node in WSFC 2 will act as the forwarder. The second	DBA, Developer

Task	Description	Skills required
	node in WSFC 2 will act as the secondary replica of AG 2. At this stage, no databases are available in AG 2. This is the starting point for setting up the distributed availability group.	
Create databases with no recovery option on AG 2.	Back up databases on the on-premises availability group (AG 1). Restore the databases to both the forwarder and the secondary replica of AG 2 with no recovery option. While restoring the databases , specify a location with enough disk space for the database data files and the log files. At this stage, the databases are in the restoring state. They are not part of AG 2 or the distributed availabil ity group, and they are not synchronizing.	DBA, Developer

Configure the distributed availability group

Task	Description	Skills required
Create the distributed availability group on AG 1.	To create the distributed availability group on AG 1,	DBA, Developer

Task	Description	Skills required
	use the `CREATE AVAILABILITY GROUP` with the `DISTRIBUTED` option. 1. Use `LISTENER_URL` endpoint addresses for AG 1 and AG 2. 2. For `AVAILABILITY-MODE`, use `ASYNCHRONOUS_COMMIT` to avoid network latency, if any. This will not impact the performance of the database. 3. For `FAILOVER_MODE`, use `MANUAL`. It is the only availability mode that works with distributed availability groups. 4. To restore the databases manually on AG 2 and have more control on larger databases, use `MANUAL` for `SEEDING_MODE`.	

Task	Description	Skills required
Create the distributed availability group on AG 2.	To create the distributed availability group on AG 2, use `ALTER AVAILABILITY GROUP` with the `DISTRIBUTED` option. 1. Use `LISTENER_URL` endpoint addresses for AG 1 and AG 2. 2. For `AVAILABILITY-MODE`, use `ASYNCHRONOUS_COMMIT` to avoid network latency, if any. This will not impact the performance of the database. 3. For `FAILOVER_MODE`, use `MANUAL`. It is the only availability mode that works with distributed availability groups. 4. To restore the databases manually on AG 2 and have more control on larger databases, use `MANUAL` for `SEEDING_MODE`. The distributed availability group is created between AG 1 and AG 2. The databases in AG 2 are not yet configured to take part in	DBA, Developer

Task	Description	Skills required
	the data flow from AG 1 to AG 2.	
Add databases to the forwarder and secondary replica on AG 2.	Add the databases to the distributed availability group by using `ALTER DATABASE` with the `SET HADR AVAILABILITY GROUP` option in both the forwarder and the secondary replica on AG 2. This starts asynchronous data flow between databases on AG 1 and AG 2. The global primary takes writes, sends data synchrono usly to the secondary replica on AG 1, and sends data asynchronously to the forwarder on AG 2. The forwarder on AG 2 sends data synchronously to the secondary replica on AG 2.	DBA, Developer

Monitor asynchronous data flow between AG 1 and AG 2

Task	Description	Skills required
Use DMVs and SQL Server logs.	Monitor the status of the data flow between two availabil ity groups by using dynamic management views (DMVs) and SQL Server logs.	DBA, Developer

Task	Description	Skills required
	DMVs that are of interest for monitoring include `sys.dm_hadr_availability_replica_states` and `sys.dm_hadr_automatic_seeding` . For the status of forwarder synchronization, monitor the *synchronized state* in the SQL Server log on the forwarder.	

Perform cutover activities for final migration

Task	Description	Skills required
Stop all traffic to the primary replica.	Stop incoming traffic to the primary replica in AG 1 so that no write activity occurs on the databases and the databases are ready for migration.	App owner, Developer
Change the availability mode of the distributed availability group on AG 1.	On the primary replica, set the availability mode of the distributed availability group to synchronous. After you change the availability mode to synchronous, the data are sent synchronously from the primary replica in AG 1 to the forwarder in AG 2.	DBA, Developer

Task	Description	Skills required
Check the LSNs in both availability groups.	Check the last Log Sequence Numbers (LSNs) in both AG 1 and AG 2. Because no writes are happening in the primary replica in AG 1, the data are synchronized, and last LSNs for both availability groups should match.	DBA, Developer
Update AG 1 to the secondary role.	When you update AG 1 to the secondary role, AG 1 loses the primary replica role and doesn't accept writes, and the data flow between two availability groups stops.	DBA, Developer

Fail over to the second availability group

Task	Description	Skills required
Manually fail over to AG 2.	On the forwarder in AG 2, alter the distributed availability group to allow data loss. Because you already checked and confirmed that the last LSNs on AG 1 and AG 2 match, data loss is not a concern. When you allow data loss on the forwarder in AG 2, the roles of AG 1 and AG 2 change:	DBA, Developer

Task	Description	Skills required
	• AG 2 becomes the availability group with the primary replica and secondary replica. • AG 1 becomes the availability group with the forwarder and secondary replica.	
Change the availability mode of the distributed availability group on AG 2.	On the primary replica in AG 2, change the availability mode to asynchronous. This changes the data movement from AG 2 to AG 1, from synchronous to asynchronous. This step is required to avoid network latency between AG 2 and AG 1, if any, and will not impact the performance of the database.	DBA, Developer
Start sending traffic to the new primary replica.	Update the connection string to use the listener URL endpoint on AG 2 for sending traffic to the databases. AG 2 now accepts writes and sends data to the forwarder in AG 1, along with sending data to its own secondary replica in AG 2. Data moves asynchronously from AG 2 to AG 1.	App owner, Developer

Perform post-cutover activities

Task	Description	Skills required
Drop the distributed availabil ity group on AG 2.	Monitor the migration for the planned amount of time. Then drop the distributed availability group on AG 2 to remove distributed availabil ity group setup between AG 2 and AG 1. This removes the distributed availability group configuration, and data flow from AG 2 to AG 1 stops. At this point, AG 2 is highly available on AWS, with a primary replica that takes writes and a secondary replica in the same availability group.	DBA, Developer
Decommission the on-premis es servers.	Decommission the on-premis es servers in WSFC 1 that are part of AG 1.	Systems administrator, SysOps administrator

Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS

Ramu Jagini, Amazon Web Services

Summary

This pattern describes how to migrate an on-premises Oracle 8i or 9i database to an Amazon Relational Database Service (Amazon RDS) for Oracle database. You can use this pattern to complete your migration with reduced downtime by using Quest SharePlex for synchronous replication.

You must use an intermediate Oracle database instance for your migration because AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source environment. You can use SharePlex 7.6.3 to replicate from previous Oracle database versions to later Oracle database versions. The intermediate Oracle database instance is compatible as a target for SharePlex 7.6.3 and supported as a source for AWS DMS or newer releases of SharePlex. This support enables onward replication of data to the Amazon RDS for Oracle target environment.

Consider that several deprecated data types and features can impact a migration from Oracle 8i or 9i to the latest version of Oracle Database. To mitigate this impact, this pattern uses Oracle 11.2.0.4 as an intermediate database version to help optimize the schema code prior to migrating to the Amazon RDS for Oracle target environment.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises environment
- Oracle Database 12c Release 2 (12CR2) for staging on Amazon Elastic Compute Cloud (Amazon EC2)
- Quest SharePlex 7.6.3 (commercial grade)

Limitations

- RDS for Oracle limitations

Product versions

- Oracle 8i or 9i for the source database
- Oracle 12CR2 for the staging database (must match the Amazon RDS for Oracle version)
- Oracle 12CR2 or later for the target database (Amazon RDS for Oracle)

Architecture

Source technology stack

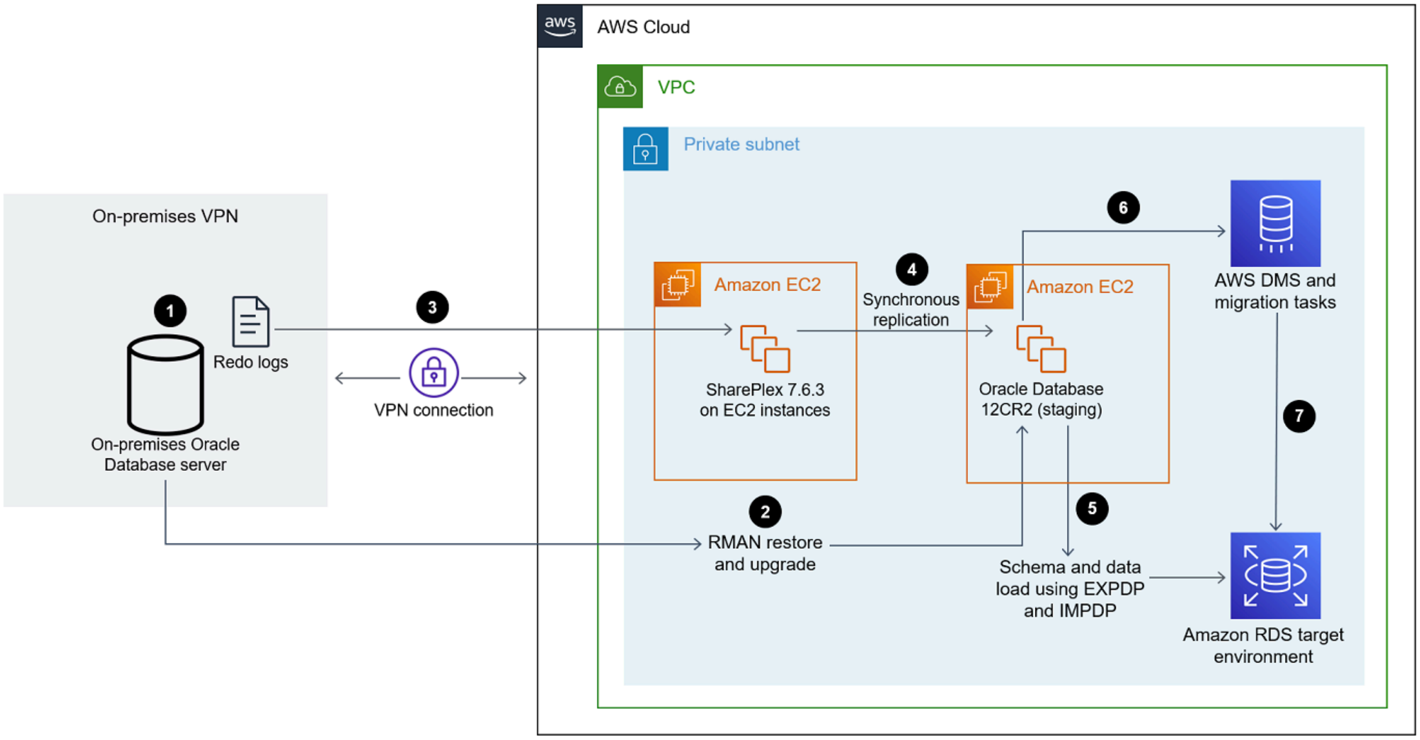
- Oracle 8i or 9i database
- SharePlex

Target technology stack

- Amazon RDS for Oracle

Migration architecture

The following diagram shows how to migrate an Oracle 8i or 9i database from an on-premises environment to an Amazon RDS for Oracle DB instance in the AWS Cloud.



The diagram shows the following workflow:

1. Enable the Oracle source database with archive log mode, force logging, and supplemental logging.
2. Restore the Oracle staging database from the Oracle source database by using Recovery Manager (RMAN) point-in-time recovery and FLASHBACK_SCN.
3. Configure SharePlex to read redo logs from the Oracle source database by using FLASHBACK_SCN (used in RMAN).
4. Start SharePlex replication to synchronize data from the Oracle source database to the Oracle staging database.
5. Restore the Amazon RDS for Oracle target database by using EXPDP and IMPDP with FLASHBACK_SCN.
6. Configure AWS DMS and its source tasks as the Oracle staging database and Amazon RDS for Oracle as the target database by using FLASHBACK_SCN (used in EXPDP).
7. Start AWS DMS tasks to synchronize data from the Oracle staging database to the Oracle target database.

Tools

- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Quest SharePlex is an Oracle-to-Oracle data replication tool for moving data with minimal downtime and no data loss.
- Recovery Manager (RMAN) is an Oracle Database client that performs backup and recovery tasks on your databases. It greatly simplifies backing up, restoring, and recovering database files.
- Data Pump Export helps you upload data and metadata into a set of operating system files called a dump file set. The dump file set can be imported only by the Data Pump Import utility or DBMS_DATAPUMP package.

Epics

Set up SharePlex and the Oracle staging database on Amazon EC2

Task	Description	Skills required
Create an EC2 instance.	1. Create an EC2 instance. 2. Install Oracle 12CR2 on the EC2 instance to serve as the Oracle staging database.	Oracle administration
Prepare the staging database.	Prepare the Oracle staging database for restore as an upgrade on Oracle 12CR2 by taking the RMAN backup from the Oracle 8i or 9i database source environment. For more information, see Oracle 9i Recovery Manager User's Guide and Database	Oracle administration

Task	Description	Skills required
	[Backup and Recovery User's Guide] in the Oracle documentation.	
Configure SharePlex.	Configure the SharePlex source as an on-premises Oracle 8i or 9i database, and configure the target as the Oracle 12CR2 staging database hosted on Amazon EC2.	SharePlex, Oracle administr ation

Set up Amazon RDS for Oracle as your target environment

Task	Description	Skills required
Create an Oracle DB instance.	Create an Amazon RDS for Oracle database, and then connect Oracle 12CR2 to the database. For more information, see [Creating an Oracle DB instance and connecting to a database on an Oracle DB instance] in the Amazon RDS documentation.	DBA
Restore Amazon RDS for Oracle from the staging database.	1. Take an EXPDP backup from the Oracle staging database server by using `FLASHBACK_SCN` . 2. Restore Amazon RDS for Oracle from the staging database.	DBA

Task	Description	Skills required
	For more information, see 54 DBMS_DATAPUMP in the Oracle documentation.	

Set up AWS DMS

Task	Description	Skills required
Create endpoints for the databases.	Create a source endpoint for the Oracle staging database and a target endpoint for the Amazon RDS for Oracle database. For more information, see How do I create source or target endpoints using AWS DMS? in the AWS Knowledge Center.	DBA
Create a replication instance.	Use AWS DMS to launch a replication instance for the Oracle staging database to the Amazon RDS for Oracle database. For more information, see How do I create an AWS DMS replication instance? in the AWS Knowledge Center.	DBA
Create and start replication tasks.	Create AWS DMS replication tasks for change data capture (CDC) by using `FLASHBACK_SCN` from EXPDP (since the	DBA

Task	Description	Skills required
	full load already happened through EXPDP). For more information, see Creating a task in the AWS DMS documentation.	

Cut over to Amazon RDS for Oracle

Task	Description	Skills required
Stop the application workload.	Stop the application servers and its applications during the planned cutover window.	App developer, DBA
Validate the synching of the on-premises Oracle staging database with the EC2 instance.	Confirm that all messages have been posted for replicati on tasks from the SharePlex replication instance to the Oracle staging database on Amazon EC2 by performing a few log switches on the on-premises source database. For more information, see 6.4.2 Switching a Log File in the Oracle documentation.	DBA
Validate the synching of the Oracle staging database with the Amazon RDS for Oracle database.	Confirm that all your AWS DMS tasks have no lag and no errors, and then check the validation state of the tasks.	DBA
Stop the replication of SharePlex and Amazon RDS.	If both the SharePlex and AWS DMS replications are not	DBA

Task	Description	Skills required
	showing any errors, then stop both replications.	
Remap the application to Amazon RDS.	Share the Amazon RDS for Oracle endpoint details with the application server and its applications, and then start the application to resume business operations.	App developer, DBA

Test the AWS target environment

Task	Description	Skills required
Test the Oracle staging database environment on AWS.	1. Test the SharePlex replicati on and verify that there are no sync gaps or replicati on errors on the Oracle staging database. 2. Verify that the applicati on behaves as expected through benchmarks defined in the on-premises environment.	SharePlex, Oracle administr ation
Test the Amazon RDS environment.	1. Verify that all data propagated to Amazon RDS after replication is error free. 2. Point another applicati on to the Amazon RDS DB instance, and then run performance tests to verify expected behavior.	Oracle administration

Task	Description	Skills required
	For more information, see Amazon RDS for Oracle in the Amazon RDS documentation.

Monitor Amazon Aurora for instances without encryption

Mansi Suratwala, Amazon Web Services

Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that you can deploy to set up automatic notifications when an Amazon Aurora instance is created without encryption turned on.

Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. With some workloads, Aurora can deliver up to five times the throughput of MySQL and up to three times the throughput of PostgreSQL without requiring changes to most of your existing applications.

The CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event uses AWS CloudTrail to monitor for any Aurora instance creation or a point in time restoration of an existing instance. The Cloudwatch Events event initiates the Lambda function, which checks whether encryption is enabled. If encryption is not turned on, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

Prerequisites and limitations

Prerequisites

- An active AWS account

Limitations

- This service control works with Amazon Aurora instances only. It does not support other Amazon Relational Database Service (Amazon RDS) instances.
- The CloudFormation template must be deployed for `CreateDBInstance` and `RestoreDBClusterToPointInTime` only.

Product versions

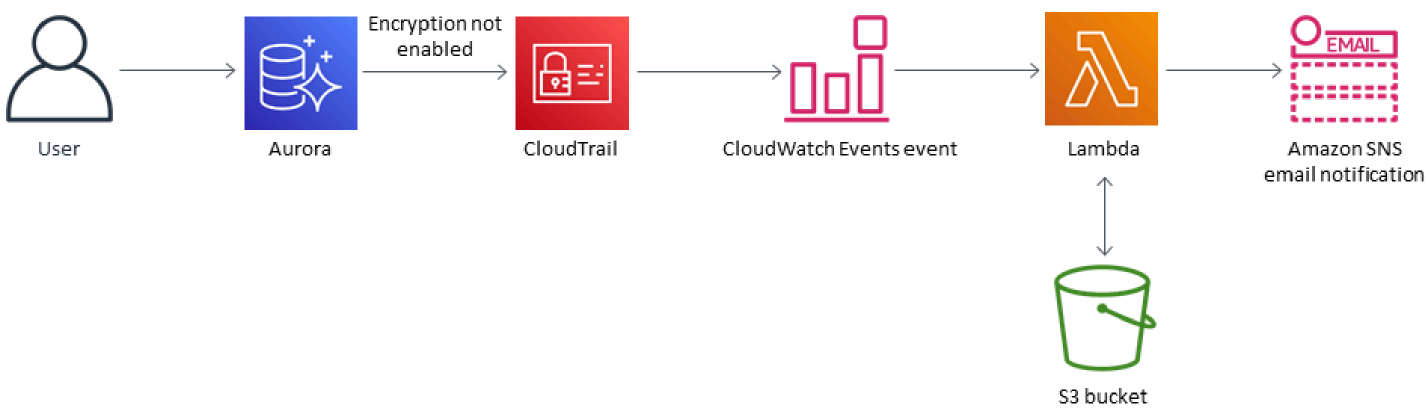
- PostgreSQL versions that are supported in Amazon Aurora
- MySQL versions that are supported in Amazon Aurora

Architecture

Target technology stack

- Amazon Aurora
- AWS CloudTrail
- Amazon CloudWatch
- AWS Lambda
- Amazon Simple Storage Service (Amazon S3)
- Amazon SNS

Target architecture



Automation and scale

You can use the CloudFormation template multiple times for different Regions and accounts. You need to run it only once in each Region or account.

Tools

Tools

- [Amazon Aurora](#) – Amazon Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL.
- [AWS CloudTrail](#) – AWS CloudTrail helps you manage governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are recorded as events in CloudTrail.

- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery using Lambda, HTTP, email, mobile push notifications, and mobile text messages (SMS).

Code

A .zip file of the project is available as an attachment.

Epics

Create the S3 bucket for the Lambda script

Task	Description	Skills required
Define the S3 bucket.	Open the Amazon S3 console, and choose or create an S3 bucket. This S3 bucket will host the Lambda code .zip file. Your S3 bucket needs to be in the same Region as Aurora. The S3 bucket name cannot contain leading slashes.	Cloud architect

Upload the Lambda code to the S3 bucket

Task	Description	Skills required
Upload the Lambda code.	Upload the Lambda code .zip file provided in the *Attachments* section to the S3 bucket that you defined.	Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	On the CloudFormation console, deploy the `RDS_Aurora_Encryption_At_Rest.yml` CloudFormation template that's provided as an attachment to this pattern. In the next epic, provide values for the template parameters.	Cloud architect

Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or chose in the first epic.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example,	Cloud architect

Task	Description	Skills required
	`<directory>/<file-name>.zip`).	
Provide an email address.	Provide an active email address to receive Amazon SNS notifications.	Cloud architect
Define the logging level.	Define the logging level and frequency for your Lambda function. `Info` designates detailed informational messages on the application's progress. `Error` designates error events that could still allow the application to continue running. `Warning` designates potentially harmful situations.	Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the subscription.	When the template successfully deploys, it sends a subscription email message to the email address provided. To receive notifications, you must confirm this email subscription.	Cloud architect

Monitor Oracle GoldenGate logs by using Amazon CloudWatch

Chithra Krishnamurthy, Amazon Web Services

Summary

Oracle GoldenGate provides real-time replication between Amazon Relational Database Service (Amazon RDS) for Oracle databases, or between Oracle databases hosted on Amazon Elastic Compute Cloud (Amazon EC2). It supports both unidirectional and bidirectional replication.

When you use GoldenGate for replication, monitoring is critical to verify that the GoldenGate process is up and running, to make sure that the source and target databases are in sync.

This pattern explains the steps to implement Amazon CloudWatch monitoring for a GoldenGate error log, and how to set alarms to send notifications for specific events such as `STOP` or `ABEND` so you can take appropriate actions to resume replication quickly.

Prerequisites and limitations

Prerequisites

- GoldenGate installed and configured on an EC2 instance, so you can set up CloudWatch monitoring on those EC2 instances. If you want to monitor GoldenGate across AWS Regions for bidirectional replication, you must install the CloudWatch agent in each EC2 instance where the GoldenGate process is running.

Limitations

- This pattern explains how to monitor the GoldenGate process by using CloudWatch. CloudWatch doesn't monitor replication lag or data synchronization issues during replication. You must run separate SQL queries to monitor replication lag or data-related errors, as explained in the [GoldenGate documentation](https://docs.oracle.com/en/middleware/goldengate/).

Product versions

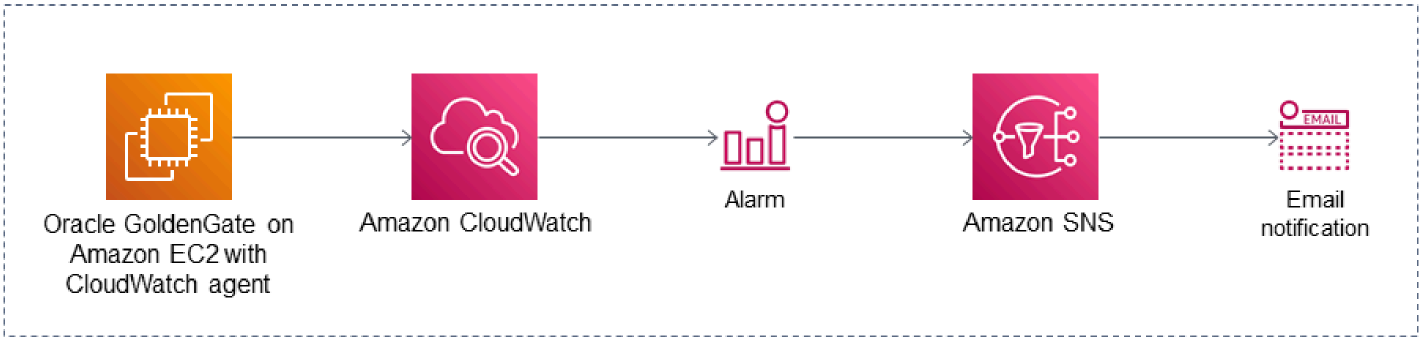
- This document is based on the implementation of Oracle GoldenGate 19.1.0.0.4 for Oracle on Linux x86-64. However, this solution is applicable to all major versions of GoldenGate.

Architecture

Target technology stack

- GoldenGate binaries for Oracle installed on an EC2 instance
- Amazon CloudWatch
- Amazon Simple Notification Service (Amazon SNS)

Target architecture



Tools

AWS services

- [Amazon CloudWatch](#) is a monitoring service that is used in this pattern to monitor GoldenGate error logs.
- [Amazon SNS](#) is a message notification service that is used in this pattern to send email notifications.

Other tools

- [Oracle GoldenGate](#) is a data replication tool that you can use for Amazon RDS for Oracle databases or Oracle databases that are hosted on Amazon EC2.

High-level implementation steps

1. Create an AWS Identity and Access Management (IAM) role for the CloudWatch agent.
2. Attach the IAM role to the EC2 instance where GoldenGate error logs are generated.
3. Install the CloudWatch agent on the EC2 instance.

4. Configure the CloudWatch agent configuration files: `awscli.conf` and `awslogs.conf`.
5. Start the CloudWatch agent.
6. Create metric filters in the log group.
7. Set up Amazon SNS.
8. Create an alarm for the metric filters. Amazon SNS sends email alerts when those filters capture events.

For detailed instructions, see the next section.

Epics

Step 1. Create an IAM role for the CloudWatch agent

Task	Description	Skills required
Create the IAM role.	Access to AWS resources requires permissions, so you create IAM roles to include the permissions necessary for each server to run the CloudWatch agent. To create the IAM role: 1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/. 2. In the navigation pane, choose **Roles**, and then choose **Create role**. 3. For **Trusted entity type**, choose **AWS service**.	AWS general

Task	Description	Skills required
	4. For **Common use cases**, choose **EC2**, and then choose **Next**. 5. In the list of policies, select the check box next to **CloudWatchAgentServerPolicy**. If necessary, use the search box to find the policy. 6. Choose **Next**. 7. For **Role name**, enter a name for your new role, such as `goldengate-cw-monitoring-role` or another name that you prefer. 8. (Optional) For **Role description**, enter a description. 9. Confirm that **CloudWatchAgentServerPolicy** appears under **Policy name**. 10. (Optional) Add one or more tags (key-value pairs) to organize, track, or control access for this role, and then choose **Create role**.	

Step 2. Attach the IAM role to the GoldenGate EC2 instance

Task	Description	Skills required
Attach the IAM role to the EC2 instance where GoldenGate error logs are generated.	The error logs generated by GoldenGate have to be populated to CloudWatch and monitored, so you need to attach the IAM role you created in step 1 to the EC2 instance where GoldenGate is running. To attach an IAM role to an instance: 1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. 2. In the navigation pane, choose **Instances**, and then find the instance where GoldenGate is running. 3. Select the instance, and then choose **Actions**, **Security**, **Modify IAM role**. 4. Select the IAM role created in the first step to attach to your instance, and then choose **Save**.	AWS general

Steps 3-5. Install and configure the CloudWatch agent on the Goldengate EC2 instance

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install the CloudWatch agent on the GoldenGate EC2 instance.</td><td>To install the agent, run the command:<pre><code>sudo yum install -y
 awslogs</code></pre></td><td>AWS general</td></tr>
<tr><td>Edit the agent configuration files.</td><td>1. Run the following command.<pre><code>sudo su -</code></pre>2. Edit this file to update the AWS Region as necessary.<pre><code>cat /etc/awslogs/conf
[plugins]
cwlogs = cwlogs
[default]
region = us-east-1</code></pre>3. Edit the <code>/etc/awslogs/awslogs.conf</code> file to update the file name, log group name, and the date/time format. You must specify the date/time to match the date format in <code>ggserror.log</code> ; otherwise, the log stream won't flow into CloudWatch. For example:<pre><code>datetime_format = %Y-
%m-%dT%H:%M:%S%z</code></pre></td><td>AWS general</td></tr>
</table>

Task	Description	Skills required
	`file = /u03/oracle/oragg/ggserr.log log_group_name = goldengate_monitor`	
Start the CloudWatch agent.	To start the agent, use the following command. `$ sudo service awslogsd start` After you start the agent, you can view the log group in the CloudWatch console. The log stream will have the contents of the file.	AWS general

Step 6. Create metric filters for the log group

Task	Description	Skills required
Create metric filters for the keywords ABEND and STOPPED.	When you create metric filters for the log group, whenever the filters are identified in the error log, it starts an alarm and sends an email notificat ion based on the Amazon SNS configuration. To create metric filters: 1. Open the CloudWatc h console at https://console.aws.amazon.com/cloudwatch/.	CloudWatch

Task	Description	Skills required
	2. Choose the name of the log group. 3. Choose **Actions**, and then choose **Create metric filter**. 4. For the **Filter pattern**, specify a pattern such as `ABEND`. 5. Choose **Next**, and then enter a name for your metric filter. 6. Under **Metric details**, for **Metric namespace**, enter a name for the CloudWatch namespace where the metric will be published. If the namespace doesn't already exist, make sure that **Create new** is selected. 7. For **Metric value**, enter 1, because your metric filter is counting occurrences of the keywords in the filter. 8. Set **Unit** to **None**. 9. Choose **Create metric filter**. You can find the metric filter that you created from the navigation pane. 10. Create another metric filter for the `STOPPED` pattern. Within one log group, you	

Task	Description	Skills required
	can create multiple metric filters and set alarms individually.	

Step 7. Set up Amazon SNS

Task	Description	Skills required
Create an SNS topic.	In this step, you configure Amazon SNS to create alarms for the metric filters. To create an SNS topic: 1. Sign in to the Amazon SNS console at https://console.aws.amazon.com/sns/home. 2. In the **Create topic** box, enter a topic name such as `goldengate-alert` , and then choose **Next step**. 3. For **Type**, choose **Standard**. 4. Scroll to the end of the form and choose **Create topic**. The console opens the new topic's **Details** page.	Amazon SNS
Create a subscription.	To create a subscription to the topic: 1. In the left navigation pane, choose **Subscriptions**.	Amazon SNS

Task	Description	Skills required
	2. On the **Subscriptions** page, choose **Create subscription**. 3. On the **Create subscription** page, choose the **Topic ARN** field to see a list of the topics in your AWS account. 4. Choose the topic that you created in the previous step. 5. For **Protocol**, choose **Email**. 6. For **Endpoint**, enter an email address that can receive notifications. 7. Choose **Create subscription**. The console opens the new subscription's **Details** page. 8. Check your email inbox for a message from AWS Notifications, and then choose **Confirm subscription** in the email. Amazon SNS opens your web browser and displays a subscription confirmation with your subscription ID.	

Step 8. Create an alarm to send notifications for the metric filters

Task	Description	Skills required
Create an alarm for the SNS topic.	To create an alarm based on a log group-metric filter: 1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/. 2. From the navigation pane, choose **Logs**, and then choose **Log groups**. 3. Choose the log group that includes your metric filter. 4. Choose **Metric filters**. 5. In the **Metric filters** tab, select the check box for the metric filter that you want to base your alarm on. 6. Choose **Create alarm**. 7. For **Conditions**, specify the following in each section: • For **Threshold type**, choose **Static** . • For **Whenever <metric-name> is . . .**, choose **Greater**. • For **than . . .**, specify **0**. 8. Choose **Next**. 9. Under **Notification**: • For **Alarm state trigger**, choose **In alarm**.	CloudWatch

Task	Description	Skills required
	• For **Send notification to following SNS topic**, choose **Select an existing topic**. • In the email box, select the Amazon SNS topic that you created in the previous step. 10.Choose **Next**. 11.For **Name and description**, enter a name and description for your alarm. **Note** For the description, you can specify the instance name so that the notification email is descriptive. 12.For **Preview and create**, check that your configuration is correct, and then choose **Create alarm**. After these steps, whenever these patterns are detected in the GoldenGate error log file (`ggserr.log`) that you are monitoring, you will get an email notification.	

Troubleshooting

Issue	Solution
The log stream from the GoldenGate error log doesn't flow into CloudWatch.	Check the `/etc/awslogs/awslogs.conf` file to verify the file name, log group name, and the date/time format. You must specify the date/time to match the date format in `ggserror.log` . Otherwise, the log stream won't flow into CloudWatch.

Replatform Oracle Database Enterprise Edition to Standard Edition 2 on Amazon RDS for Oracle

Lanre (Lan-Ray) showunmi and Tarun Chawla, Amazon Web Services

Summary

Oracle Database Enterprise Edition (EE) is a popular choice for running applications in many enterprises. In some cases, however, applications use few or no Oracle Database EE features, so there is a lack of justification for incurring huge licensing costs. You can achieve cost savings by downgrading such databases to Oracle Database Standard Edition 2 (SE2) when you migrate to Amazon RDS.

This pattern describes how to downgrade from Oracle Database EE to Oracle Database SE2 when migrating from on premises to Amazon RDS for Oracle. The steps presented in this pattern also apply if your EE Oracle database is already running on Amazon RDS or on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

For more information, see the AWS Prescriptive Guidance guide on how to Evaluate downgrading Oracle databases to Standard Edition 2 on AWS.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Oracle Database Enterprise Edition
- A client tool, such as Oracle SQL Developer or SQL*Plus, for connecting to and running SQL commands on Oracle database
- Database user for performing the assessment; for example, one of the following:
  - User with sufficient privileges for running AWS Schema Conversion Tool (AWS SCT) assessment
  - User with sufficient privileges to run SQL queries on Oracle database dictionary tables
- Database user for performing database migration; for example, one of the following:
  - User with sufficient privileges for running AWS Database Migration Service (AWS DMS)
  - User with sufficient privileges for performing Oracle Data Pump export and import
  - User with sufficient privileges for running Oracle GoldenGate

Limitations

- Amazon RDS for Oracle has a maximum database size. For more information, see Amazon RDS DB instance storage.

Product versions

The general logic described in this document applies to Oracle versions from 9i and later. For supported versions of self-managed and Amazon RDS for Oracle databases, see the AWS DMS documentation.

To identify feature usage in cases where AWS SCT is not supported, run SQL queries on the source database. To migrate from earlier versions of Oracle where AWS DMS and Oracle Data Pump are not supported, use Oracle Export and Import utilities.

For a current list of supported versions and editions, see Oracle on Amazon RDS in the AWS documentation. For details on pricing and supported instance classes, see Amazon RDS for Oracle pricing.

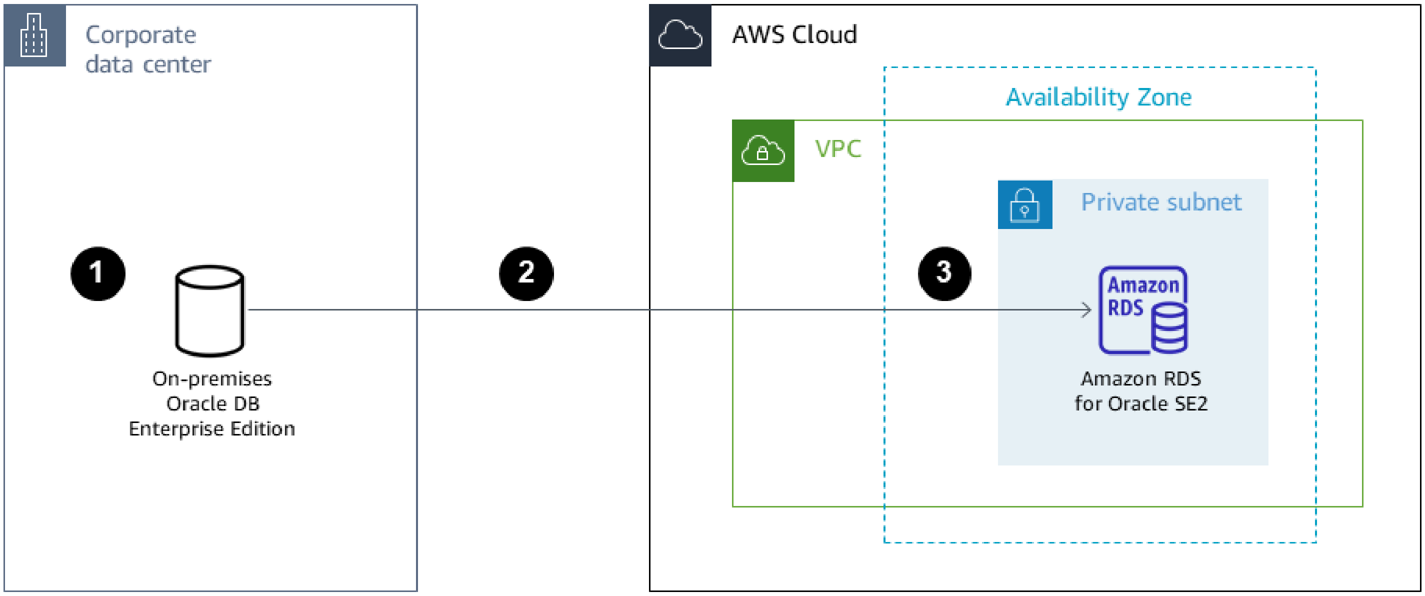
Architecture

Source technology stack

- Oracle Database Enterprise Edition running on premises or on Amazon EC2

Target technology stack using native Oracle tools

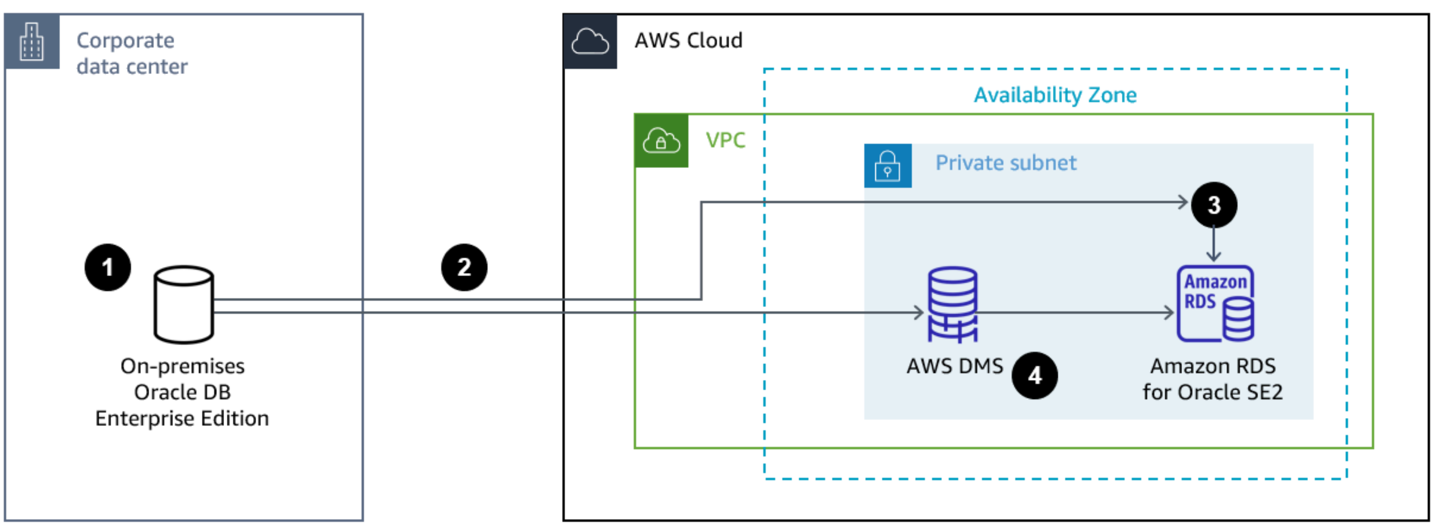
- Amazon RDS for Oracle running Oracle Database SE2



1. Export data by using Oracle Data Pump.
2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.

Target technology stack using AWS DMS

- Amazon RDS for Oracle running Oracle Database SE2
- AWS DMS



1. Export data by using Oracle Data Pump with FLASHBACK_SCN.
2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.
4. Use AWS DMS change data capture (CDC).

Tools

AWS services

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle.
- AWS SCT provides a project-based user interface to automatically assess, convert, and copy the database schema of your source Oracle database into a format compatible with Amazon RDS for Oracle. AWS SCT enables you to analyze potential cost savings that can be achieved by changing your license type from Enterprise to Standard Edition of Oracle. The **License Evaluation and Cloud Support** section of the AWS SCT report provides detailed information about Oracle features in use so you can make an informed decision while migrating to Amazon RDS for Oracle.

Other tools

- Native Oracle import and export utilities support moving Oracle data in and out of Oracle databases. Oracle offers two types of database import and export utilities: Original Export and Import (for earlier releases) and Oracle Data Pump Export and Import (available in Oracle Database 10g release 1 and later).
- Oracle GoldenGate offers real-time replication capabilities so that you can synchronize your target database after an initial load. This option can help reduce application downtime during go-live.

Epics

Make a pre-migration assessment

Task	Description	Skills required
Validate database requirements for your applications.	Ensure that your applications are certified to run on Oracle Database SE2. Check directly with the software vendor, developer, or application documentation.	App developer, DBA, App owner
Investigate use of EE features directly in the database.	To determine EE feature use, do one of the following: • Generate an AWS SCT assessment report for your Oracle EE database. The report tells you which features from your current EE database should be removed if you want to change license types. • If you have an Oracle Support account, obtain and run the script `options_packs_usage_statistics.sql` in Support document 1317265.1 to generate a report of options and features that are being used on your Oracle database. • Query DBA_FEATURE_USAGE_STATISTICS	App owner, DBA, App developer

Task	Description	Skills required
	to display details of all features that are in use.	
Identify use of EE features for operational activities.	Database or application administrators sometimes rely on EE-only features for operational activities. Common examples include online maintenance activities (index rebuild, table move) and use of parallelism by batch jobs. These dependencies can be mitigated by modifying your operations where possible. Identify the use of these features and make a decision based on cost compared with benefits. Use the [Comparing Oracle Database EE and SE2 features](#) table as a guide to identify features that are available in Oracle Database SE2.	App developer, DBA, App owner

Task	Description	Skills required
Review workload patterns of the EE Oracle database.	Oracle Database SE2 automatically restricts usage to a maximum of 16 CPU threads at any time. If your Oracle EE database is licensed to use the Oracle Diagnostic Pack, use the Automatic Workload Repository (AWR) tool, or DBA_HIST_* views, to analyze database workload patterns to determine whether the maximum limit of 16 CPU threads will negatively impact service levels when you downgrade to SE2. Ensure that your assessmen t covers periods of peak activity, such as end of day, month, or year processing.	App owner, DBA, App developer

Prepare the target infrastructure on AWS

Task	Description	Skills required
Deploy and configure networking infrastructure.	Create a [virtual private cloud (VPC) and subnets](), [security groups](), and [network access control lists]().	AWS administrator, Cloud architect, Network administr ator, DevOps engineer
Provision the Amazon RDS for Oracle SE2 database.	Provision the target [Amazon RDS for Oracle]() SE2 database to meet your applications'	Cloud administrator, Cloud architect, DBA, DevOps engineer, AWS administrator

Task	Description	Skills required
	performance, availability, and security requirements. We recommend Multi-AZ configuration for production workloads. However, to improve migration performance, you can defer enabling Multi-AZ until after data migration.	
Customize the Amazon RDS environment.	Configure custom parameters and options, and enable additional monitoring. For more information, see Best practices for migrating to Amazon RDS for Oracle.	AWS administrator, AWS systems administrator, Cloud administrator, DBA, Cloud architect

Perform the migration dry run and application testing

Task	Description	Skills required
Migrate the data (dry run).	Migrate data from the source Oracle EE database to the Amazon RDS for Oracle SE2 database instance using the approach best suited to your specific environment. Select a migration strategy based on factors such as size, complexity, and the available downtime window. Use one or a combination of the following:	DBA

Task	Description	Skills required
	• Native Oracle tools such as Oracle Data Pump (recommended), Oracle Import-Export utilities, and Oracle GoldenGate. • AWS DMS, using the full load with continuous replication through CDC.	
Validate the target database.	Perform post-migration validation of database storage and code objects. Review migration logs, and fix any identified issues. For more information, see the guide Migrating Oracle databases to the AWS Cloud.	DBA
Test the applications.	Application and database administrators should conduct functional, performance, and operation al tests as appropriate. For more information, see Best practices for migrating to Amazon RDS for Oracle. Lastly, obtain sign-offs on test-results from stakehold ers.	App developer, App owner, DBA, Migration engineer, Migration lead

Cut over

Task	Description	Skills required
Refresh data from Oracle Database EE.	Select a data refresh approach based on the application availability requirement. For more information, see the migration methods in [Strategies for Migrating Oracle Databases to AWS](). For example, you can achieve near-zero downtime by using tools such as Oracle GoldenGate or AWS DMS with ongoing replication. If the downtime window permits, you can perform the final data cutover using offline methods such as Oracle Data Pump or Original Export-Im port utilities.	App owner, Cutover lead, DBA, Migration engineer, Migration lead
Point applications to the target database instance.	Update connection parameter s in applications and other clients to point to the Amazon RDS for Oracle SE2 database.	App developer, App owner, Migration engineer, Migration lead, Cutover lead
Perform post-migration activities.	Perform post data migration tasks such as enabling Multi-AZ, data validation, and other checks.	DBA, Migration engineer

Task	Description	Skills required
Perform post-cutover monitoring.	Use tools such as Amazon CloudWatch and Amazon RDS Performance Insights to monitor the Amazon RDS for Oracle SE2 database.	App developer, App owner, AWS administrator, DBA, Migration engineer

Replicate mainframe databases to AWS by using Precisely Connect

Lucio Pereira, Sayantan Giri, and Balaji Mohan, Amazon Web Services

Summary

This pattern outlines steps for replicating data from mainframe databases to Amazon data stores in near real time by using Precisely Connect. It implements an event-based architecture with Amazon Managed Streaming for Apache Kafka (Amazon MSK) and custom database connectors in the cloud to improve scalability, resilience, and performance.

Precisely Connect is a replication tool that captures data from legacy mainframe systems and integrates it into cloud environments. Data is replicated from mainframes to AWS through change data capture (CDC) by using near real-time message flows with low-latency and high-throughput heterogeneous data pipelines.

This pattern also covers a disaster recovery strategy for resilient data pipelines with multi-Region data replication and failover routing.

Prerequisites and limitations

Prerequisites

- An existing mainframe database—for example, IBM DB2, IBM Information Management System (IMS), or Virtual Storage Access Method (VSAM)—that you want to replicate to the AWS Cloud
- An active [AWS account](https://aws.amazon.com/account/)
- [AWS Direct Connect](https://aws.amazon.com/directconnect/) or [AWS Virtual Private Network (AWS VPN](https://aws.amazon.com/vpn/)) from your corporate environment to AWS
- A [virtual private cloud](https://aws.amazon.com/vpc/) with a subnet that is reachable by your legacy platform

Architecture

Source technology stack

A mainframe environment that includes at least one of the following databases:

- IBM IMS database
- IBM DB2 database

- VSAM files

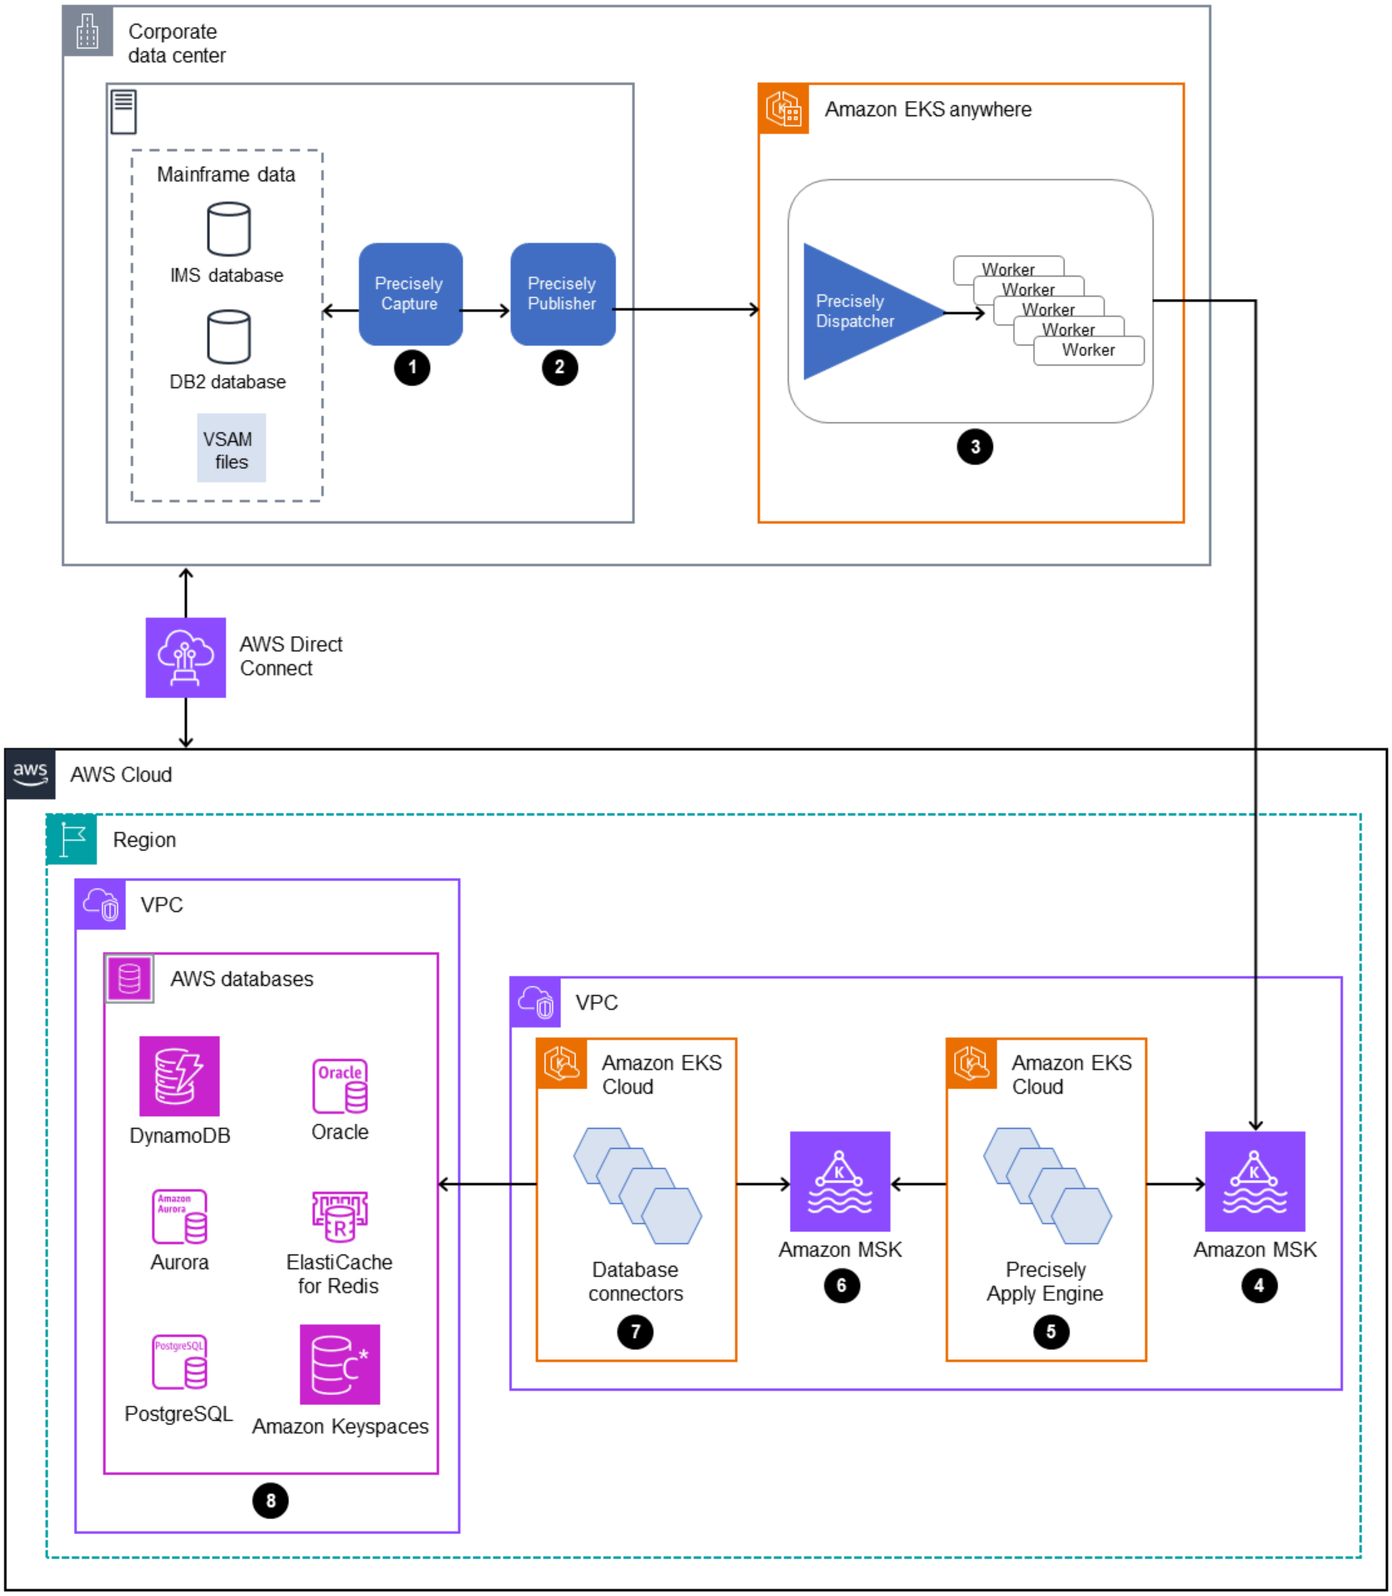
Target technology stack

- Amazon MSK
- Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon EKS Anywhere
- Docker
- An AWS relational or NoSQL database such as the following:
  - Amazon DynamoDB
  - Amazon Relational Database Service (Amazon RDS) for Oracle, Amazon RDS for PostgreSQL, or Amazon Aurora
  - Amazon ElastiCache for Redis
  - Amazon Keyspaces (for Apache Cassandra)

Target architecture

Replicating mainframe data to AWS databases

The following diagram illustrates the replication of mainframe data to an AWS database such as DynamoDB, Amazon RDS, Amazon ElastiCache, or Amazon Keyspaces. The replication occurs in near real time by using Precisely Capture and Publisher in your on-premises mainframe environment, Precisely Dispatcher on Amazon EKS Anywhere in your on-premises distributed environment, and Precisely Apply Engine and database connectors in the AWS Cloud.



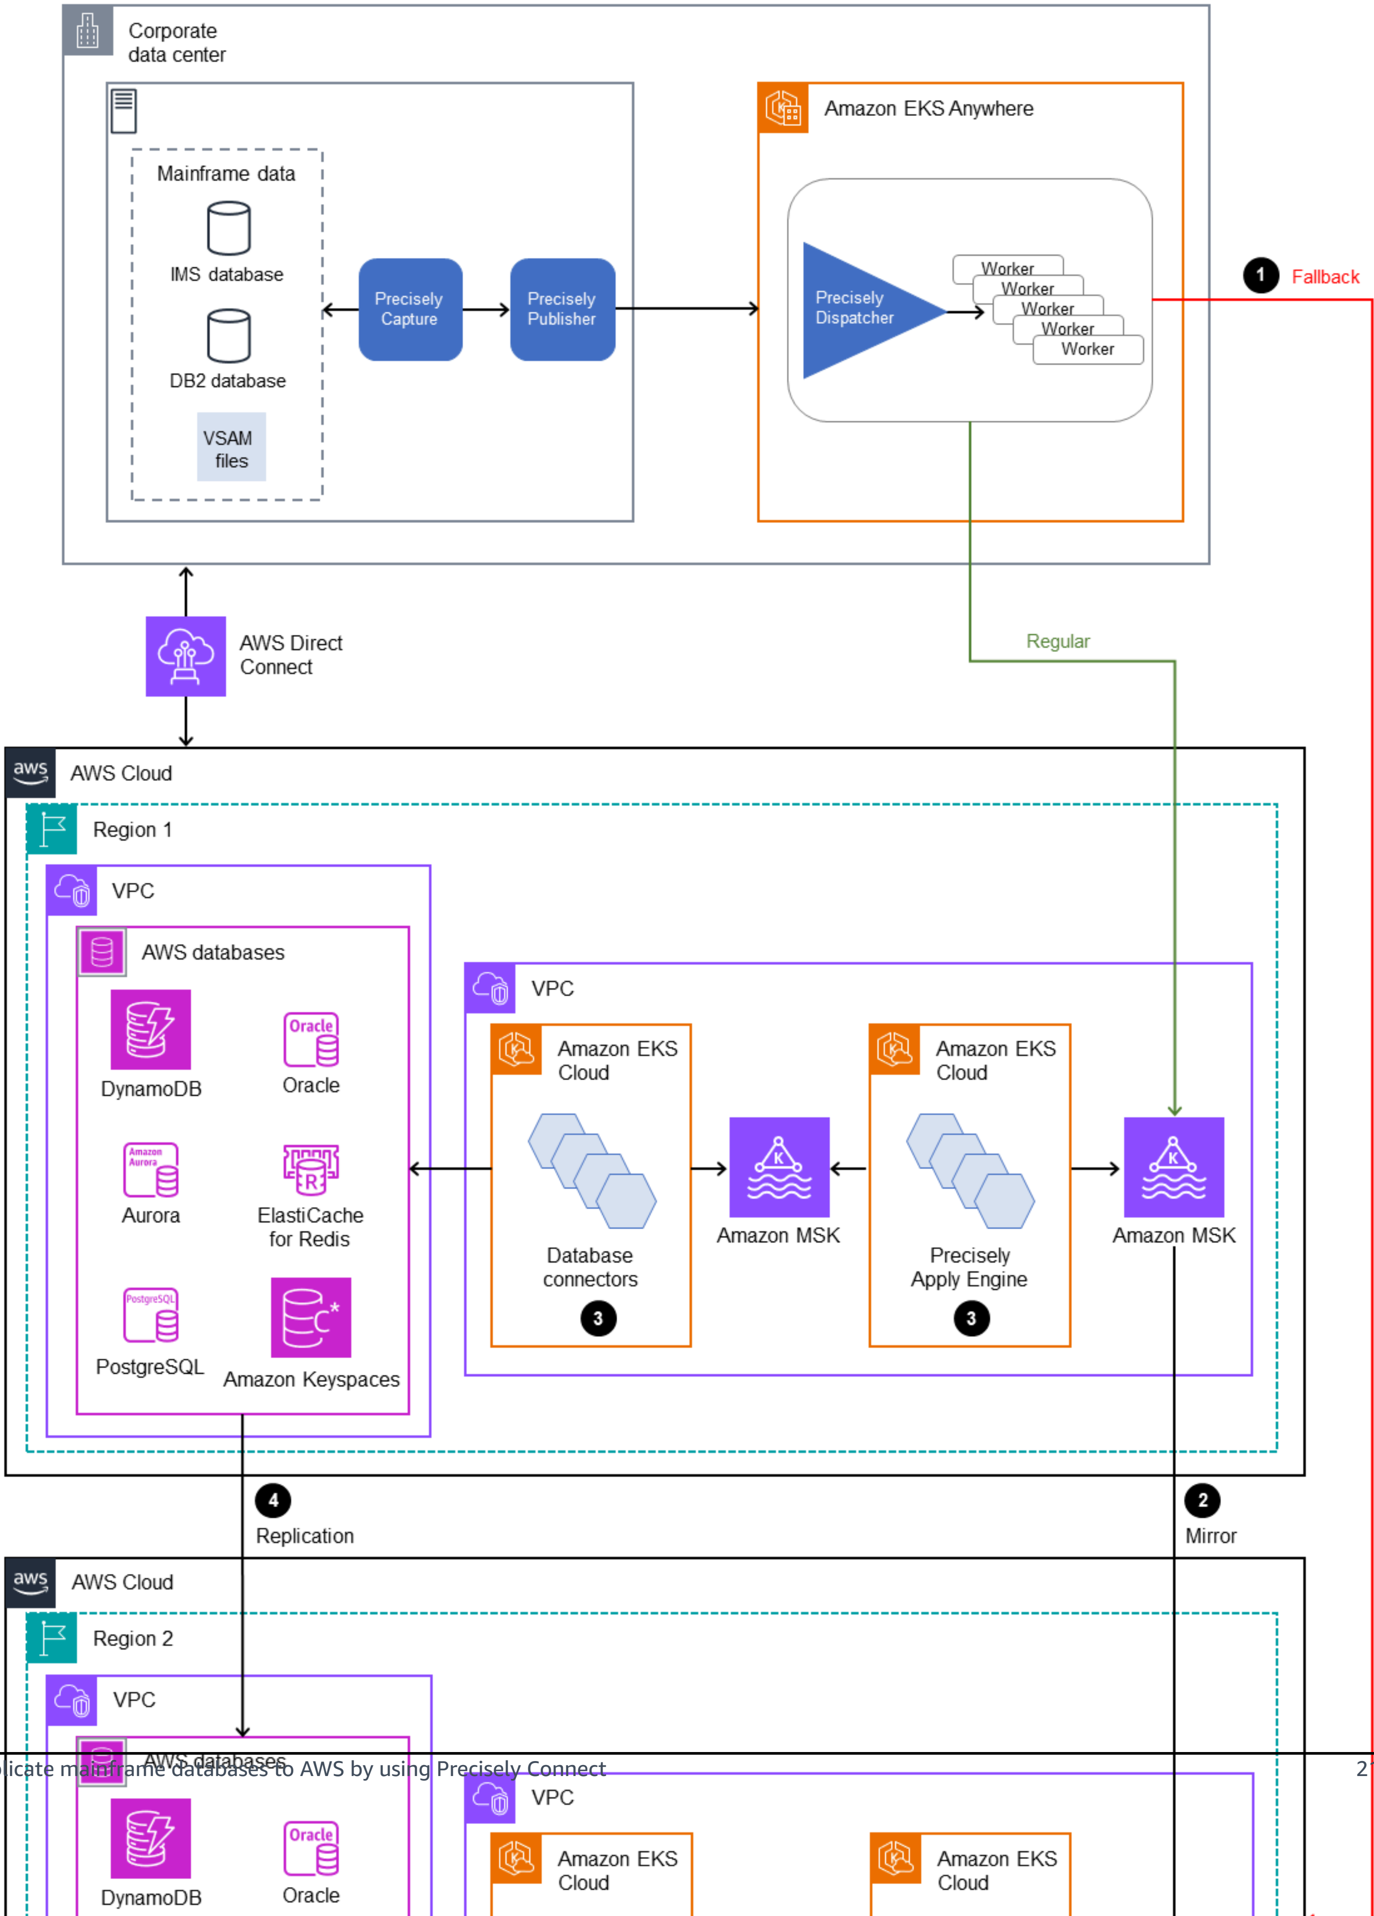
The diagram shows the following workflow:

1. Precisely Capture gets mainframe data from CDC logs and maintains the data in internal transient storage.
2. Precisely Publisher listens for changes in the internal data storage and sends CDC records to Precisely Dispatcher through a TCP/IP connection.
3. Precisely Dispatcher receives the CDC records from Publisher and sends them to Amazon MSK. Dispatcher creates Kafka keys based on the user configuration and multiple worker tasks to push data in parallel. Dispatcher sends an acknowledgment back to Publisher when records have been stored in Amazon MSK.
4. Amazon MSK holds the CDC records in the cloud environment. The partition size of topics depends on your transaction processing system (TPS) requirements for throughput. The Kafka key is mandatory for further transformation and transaction ordering.
5. The Precisely Apply Engine listens to the CDC records from Amazon MSK and transforms the data (for example, by filtering or mapping) based on target database requirements. You can add customized logic to the Precisely SQD scripts. (SQD is Precisely's proprietary language.) The Precisely Apply Engine transforms each CDC record to Apache Avro or JSON format and distributes it to different topics based on your requirements.
6. The target Kafka topics hold CDC records in multiple topics based on the target database, and Kafka facilitates transaction ordering based on the defined Kafka key. The partition keys align with the corresponding partitions to support a sequential process.
7. Database connectors (customized Java applications) listen to the CDC records from Amazon MSK and store them in the target database.
8. You can select a target database based on your requirements. This pattern supports both NoSQL and relational databases.

Disaster recovery

Business continuity is key to your organization's success. The AWS Cloud provides capabilities for high availability (HA) and disaster recovery (DR), and supports your organization's failover and fallback plans. This pattern follows an active/passive DR strategy and provides high-level guidance for implementing a DR strategy that meets your RTO and RPO requirements.

The following diagram illustrates the DR workflow.



Corporate data center
Mainframe data
IMS database
DB2 database
VSAM files
Precisely Capture
Precisely Publisher
Amazon EKS Anywhere
Precisely Dispatcher
Worker
Worker
Worker

3
Amazon MSK
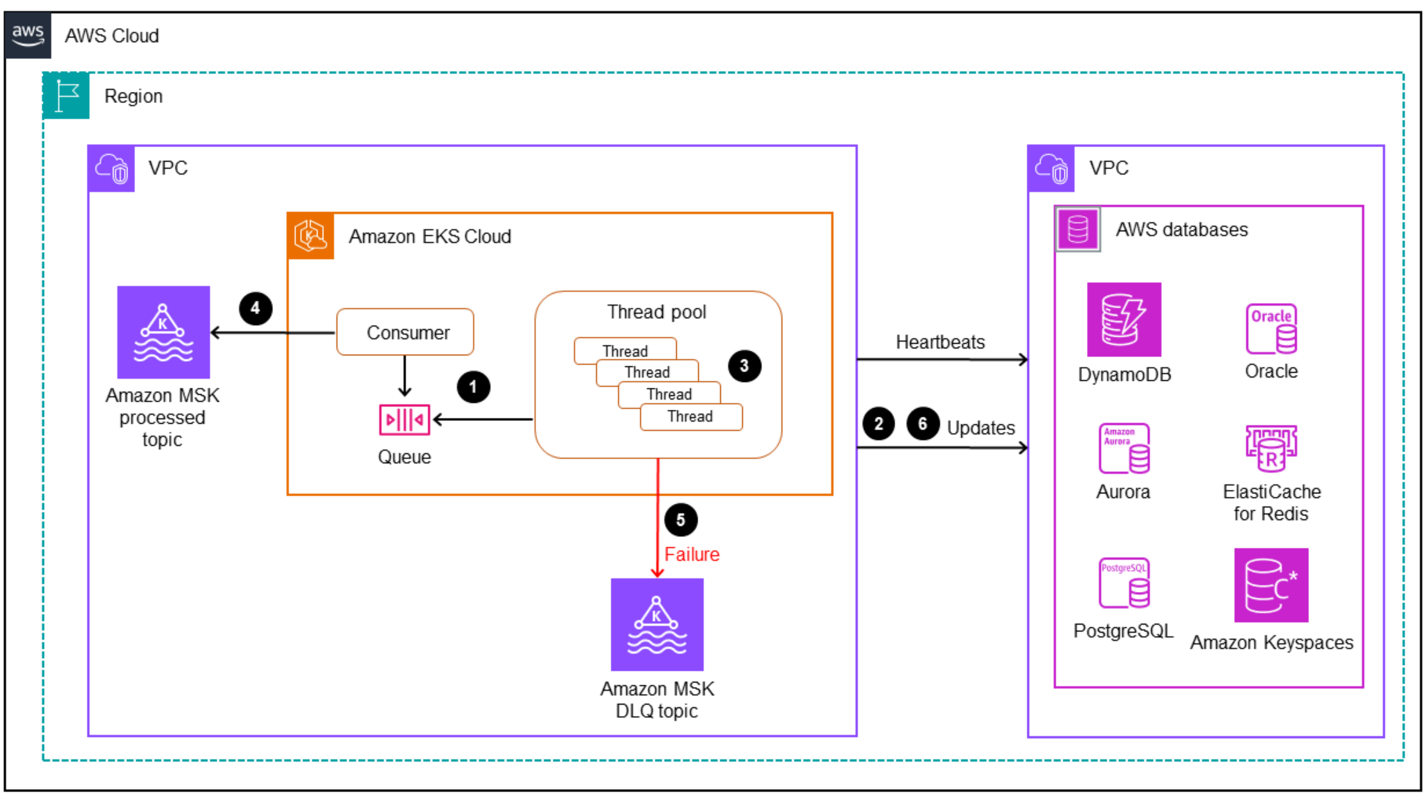
4
Replication
2
Mirror
AWS Cloud
Region 2
VPC
AWS databases
DynamoDB
Oracle
VPC
Amazon EKS Cloud
Amazon EKS Cloud

The diagram shows the following:

1. A semi-automated failover is required if any failure happens in AWS Region 1. In the case of failure in Region 1, the system must initiate routing changes to connect Precisely Dispatcher to Region 2.
2. Amazon MSK replicates data through mirroring between Regions, For this reason, during failover, the Amazon MSK cluster in Region 2 has to be promoted as the primary leader.
3. The Precisely Apply Engine and database connectors are stateless applications that can work in any Region.
4. Database synchronization depends on the target database. For example, DynamoDB can use global tables, and ElastiCache can use global datastores.

Low-latency and high-throughput processing through database connectors

Database connectors are critical components in this pattern. Connectors follow a listener-based approach to collect data from Amazon MSK and send transactions to the database through high-throughput and low-latency processing for mission-critical applications (tiers 0 and 1). The following diagram illustrates this process.



This pattern supports the development of a customized application with single-threaded consumption through a multithreaded processing engine.

1. The connector main thread consumes CDC records from Amazon MSK and sends them to the thread pool for processing.
2. Threads from the thread pool process CDC records and send them to the target database.
3. If all threads are busy, the CDC records are kept on hold by the thread queue.
4. The main thread waits to get all the records cleared from the thread queue and commits offsets into Amazon MSK.
5. The child threads handle failures. If failures happen during processing, the failed messages are sent to the DLQ (dead letter queue) topic.
6. The child threads initiate conditional updates (see Condition expressions in the DynamoDB documentation), based on the mainframe timestamp, to avoid any duplication or out-of-order updates in the database.

For information about how to implement a Kafka consumer application with multi-threading capabilities, see the blog post Multi-Threaded Message Consumption with the Apache Kafka Consumer on the Confluent website.

Tools

AWS services

- Amazon Managed Streaming for Apache Kafka (Amazon MSK) is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without having to install or maintain your own Kubernetes control plane or nodes.
- Amazon EKS Anywhere helps you deploy, use, and manage Kubernetes clusters that run in your own data centers.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon ElastiCache helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud.

- [Amazon Keyspaces (for Apache Cassandra)](#) is a managed database service that helps you migrate, run, and scale your Cassandra workloads in the AWS Cloud.

Other tools

- [Precisely Connect](#) integrates data from legacy mainframe systems such as VSAM datasets or IBM mainframe databases into next-generation cloud and data platforms.

Best practices

- Find the best combination of Kafka partitions and multi-threaded connectors to balance optimal performance and cost. Multiple Precisely Capture and Dispatcher instances can increase cost because of higher MIPS (million instructions per second) consumption.
- Avoid adding data manipulation and transformation logic to the database connectors. For this purpose, use the Precisely Apply Engine, which provides processing times in microseconds.
- Create periodic request or health check calls to the database (*heartbeats*) in database connectors to warm up the connection frequently and reduce latency.
- Implement thread pool validation logic to understand the pending tasks in the thread queue and wait for all threads to be completed before the next Kafka polling. This helps avoid data loss if a node, container, or process crashes.
- Expose latency metrics through health endpoints to enhance observability capabilities through dashboards and tracing mechanisms.

Epics

Prepare the source environment (on premises)

Task	Description	Skills required
Set up the mainframe process (batch or online utility) to start the CDC process from mainframe databases.	1. Identify the mainframe environment. 2. Identify the mainframe databases that will be involved in the CDC process.	Mainframe engineer

Task	Description	Skills required
	3. In the mainframe environment, develop a process that launches the CDC tool to capture changes in the source database. For instructions, see your mainframe documentation. 4. Document the CDC process, including the configuration. 5. Deploy the process in both test and production environments.	
Activate mainframe database log streams.	1. Configure log streams in the mainframe environment to capture CDC logs. For instructions, see your mainframe documentation. 2. Test the log streams to ensure that they capture the necessary data. 3. Deploy the log streams in test and production environments.	Mainframe DB specialist

Task	Description	Skills required
Use the Capture component to capture CDC records.	1. Install and configure the Precisely Capture component in the mainframe environment. For instructions, see the [Precisely documentation](). 2. Test the configuration to ensure that the Capture component works correctly . 3. Set up a replication process to replicate the captured CDC records through the Capture component. 4. Document the Capture configuration for each source database. 5. Develop a monitoring system to ensure that the Capture component collects logs properly over time. 6. Deploy the installation and configurations in the test and production environme nts.	Mainframe engineer, Precisely Connect SME

Task	Description	Skills required
Configure the Publisher component to listen to the Capture component.	1. Install and configure the Precisely Publisher component in the mainframe environment. For instructions, see the [Precisely documentation](). 2. Test the configuration to ensure that the Publisher component works correctly . 3. Set up a replication process to publish the CDC records to the Precisely Dispatcher component from Publisher. 4. Document the Publisher configuration. 5. Develop a monitoring system to ensure that the Publisher component works properly over time. 6. Deploy the installation and configurations in the test and production environme nts.	Mainframe engineer, Precisely Connect SME

Task	Description	Skills required
Provision Amazon EKS Anywhere in the on-premises distributed environment.	1. Install Amazon EKS Anywhere on the on-premises infrastructure and ensure that it is properly configured. For instructi ons, see the [Amazon EKS Anywhere](https://anywhere.eks.amazonaws.com/docs/) documentation. 2. Set up a secure network environment for the Kubernetes cluster, including firewalls. 3. Implement and test the sample application deployment to the Amazon EKS Anywhere cluster. 4. Implement automatic scaling capabilities for the cluster. 5. Develop and implement backup and disaster recovery procedures.	DevOps engineer

Task	Description	Skills required
Deploy and configure the Dispatcher component in the distributed environment to publish the topics in the AWS Cloud.	1. Configure and container ize the Precisely Dispatche r component. For instructi ons, see the [Precisely documentation](). 2. Deploy the Dispatcher Docker image into the on-premises Amazon EKS Anywhere environment. 3. Set up a secure connectio n between the AWS Cloud and Dispatcher. 4. Develop a monitoring system to ensure that the Dispatcher component works properly over time. 5. Deploy the installation and configurations in the test and production environme nts.	DevOps engineer, Precisely Connect SME

Prepare the target environment (AWS)

Task	Description	Skills required
Provision an Amazon EKS cluster in the designated AWS Region.	1. Sign in to your AWS account and configure it to ensure that the necessary permissions are in place to create and manage the Amazon EKS cluster. 2. Create a virtual private cloud (VPC) and subnets in	DevOps engineer, Network administrator

Task	Description	Skills required
	the selected AWS Region. For instructions, see the Amazon EKS documentation. 3. Create and configure the necessary network security groups to allow communications between the Amazon EKS cluster and other resources in the VPC. For more information, see the Amazon EKS documentation. 4. Create the Amazon EKS cluster and configure it with the correct node group size and instance types. 5. Validate the Amazon EKS cluster by deploying a sample application.	

Task	Description	Skills required
Provision an MSK cluster and configure applicable Kafka topics.	1. Configure your AWS account to ensure that the necessary permissions are in place to create and manage the MSK cluster. 2. Create and configure the necessary network security groups to allow communications between the MSK cluster and other resources in the VPC. For more information, see the [Amazon VPC documentation](#). 3. Create the MSK cluster and configure it to include the Kafka topics that will be used by the application. For more information, see the [Amazon MSK documentation](#).	DevOps engineer, Network administrator

Task	Description	Skills required
Configure the Apply Engine component to listen to the replicated Kafka topics.	1. Configure and containerize the Precisely Apply Engine component. 2. Deploy the Apply Engine Docker image into the Amazon EKS cluster in your AWS account. 3. Set up the Apply Engine to listen to MSK topics. 4. Develop and configure a SQD script in the Apply Engine to handle filtering and transformation. For more information, see the Precisely documentation. 5. Deploy the Apply Engine in test and production environments.	Precisely Connect SME

Task	Description	Skills required
Provision DB instances in the AWS Cloud.	1. Configure your AWS account to ensure that the necessary permissions are in place to create and manage DB clusters and tables. For instructions, see the AWS documentation for the AWS database service you want to use. (See the Resources section for links.) 2. Create a VPC and subnets in the selected AWS Region. 3. Create and configure the necessary network security groups to allow communications between the DB instances and other resources in the VPC. 4. Create the databases and configure them to include the tables that the application will use. 5. Design and validate the database schemas.	Data engineer, DevOps engineer

Task	Description	Skills required
Configure and deploy database connectors to listen to the topics published by the Apply Engine.	1. Design database connector s to connect the Kafka topics with the AWS databases that you created in the earlier steps. 2. Develop the connector s based on the target database. 3. Configure the connectors to listen to the Kafka topics that are published by the Apply Engine. 4. Deploy the connectors into the Amazon EKS cluster.	App developer, Cloud architect, Data engineer

Set up business continuity and disaster recovery

Task	Description	Skills required
Define disaster recovery goals for your business applications.	1. Define the RPO and RTO goals for CDC pipelines based on your business needs and impact analysis. 2. Define the communica tion and notification procedures to ensure that all stakeholders are aware of the disaster recovery plan. 3. Determine the budget and resources needed to implement the disaster recovery plan.	Cloud architect, Data engineer, App owner

Task	Description	Skills required
	4. Document the disaster recovery goals, including the RPO and RTO goals.	
Design disaster recovery strategies based on defined RTO/RPO.	1. Determine the most appropriate disaster recovery strategies for CDC pipelines based on your criticality and recovery requirements. 2. Define the disaster recovery architecture and topology. 3. Define the failover and failback procedures for CDC pipelines to ensure that they can be quickly and seamlessly switched to the backup Region. 4. Document the disaster recovery strategies and procedures and ensure that all stakeholders have a clear understanding of the design.	Cloud architect, Data engineer

Task	Description	Skills required
Provision disaster recovery clusters and configurations.	1. Provision a secondary AWS Region for disaster recovery. 2. In the secondary AWS Region, create an environment that's identical to the primary AWS Region. 3. Configure Apache Kafka MirrorMaker between the primary and secondary Regions. For more information, see the [Amazon MSK documentation](#). 4. Configure standby applications in the secondary Region. 5. Configure database replications between the primary and secondary Regions.	DevOps engineer, Network administrator, Cloud architect

Task	Description	Skills required
Test the CDC pipeline for disaster recovery.	1. Define the scope and objectives of the disaster recovery test for the CDC pipeline, including the test scenarios and RTO to be achieved. 2. Identify the test environment and infrastructure for conducting the disaster recovery test. 3. Prepare the test datasets and script to simulate failure scenarios. 4. Verify data integrity and consistency to ensure that there is no data loss.	App owner, Data engineer, Cloud architect

Schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL by using Lambda and Secrets Manager

Yaser Raja, Amazon Web Services

Summary

For on-premises databases and databases that are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances, database administrators often use the **cron** utility to schedule jobs.

For example, a job for data extraction or a job for data purging can easily be scheduled using **cron**. For these jobs, database credentials are typically either hard-coded or stored in a properties file. However, when you migrate to Amazon Relational Database Service (Amazon RDS) or Amazon Aurora PostgreSQL-Compatible Edition, you lose the ability to log in to the host instance to schedule **cron** jobs.

This pattern describes how to use AWS Lambda and AWS Secrets Manager to schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL-Compatible databases after migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database

Limitations

- A job must complete within 15 minutes, which is the Lambda function timeout limit. For other limits, see the AWS Lambda documentation.
- Job code must be written in a language supported by Lambda.

Architecture

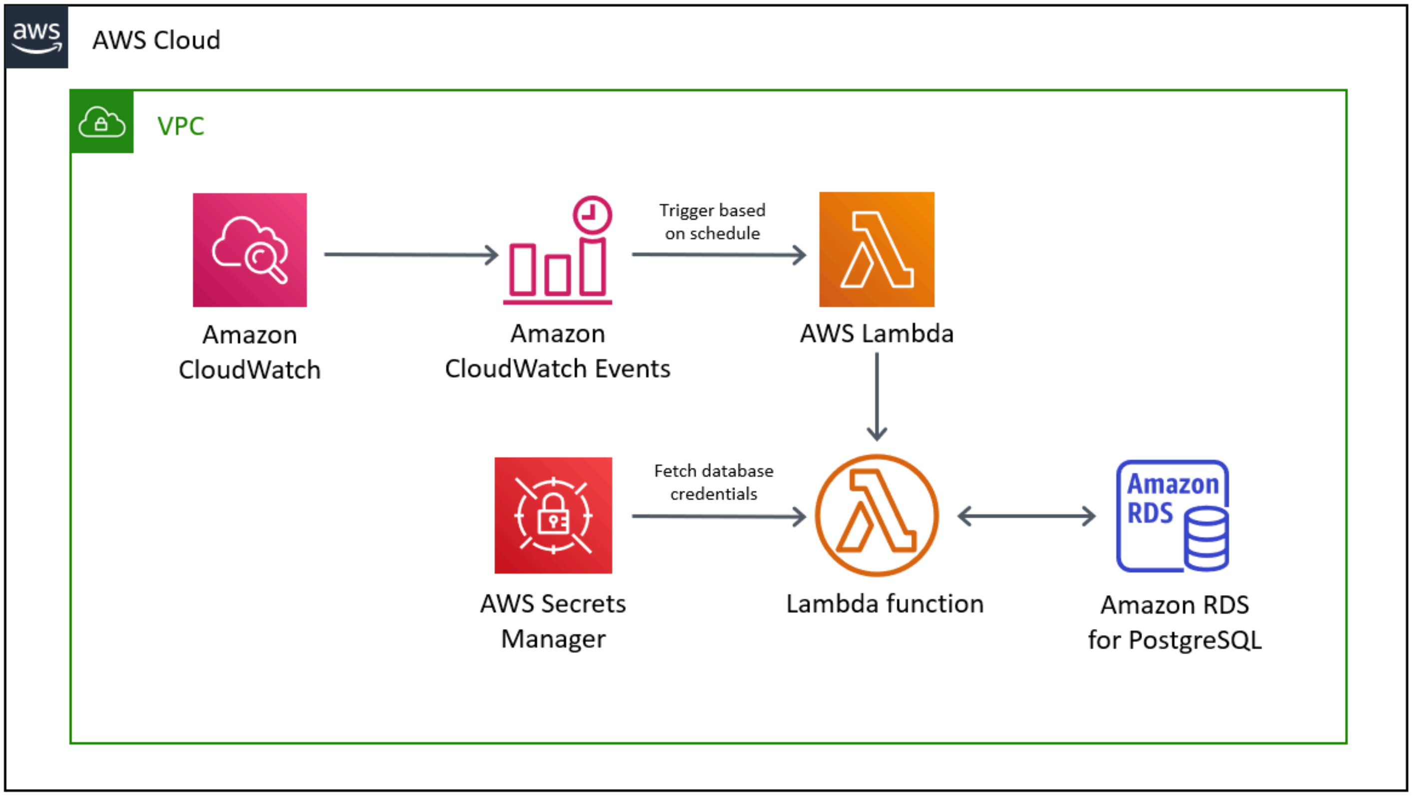
Source technology stack

This stack features jobs written in languages such as Bash, Python, and Java. Database credentials are stored in the properties file, and the job is scheduled using Linux **cron**.

Target technology stack

This stack has a Lambda function that uses the credentials stored in Secrets Manager to connect to the database and to perform the activity. The Lambda function is initiated at the scheduled interval by using Amazon CloudWatch Events.

Target architecture



Tools

- [Amazon CloudWatch Events](https://docs.aws.amazon.com/AmazonCloudWatch/latest/events/WhatIsCloudWatchEvents.html) delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using **cron** or **rate** expressions.
- [AWS Lambda](https://docs.aws.amazon.com/lambda/latest/dg/welcome.html) is a compute service that lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests

per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code is not running. With Lambda, you can run code for virtually any type of application or backend service with zero administration. Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging. All you need to do is provide your code in one of the languages that Lambda supports.

- AWS Secrets Manager helps you protect secrets for accessing your applications, services, and IT resources. You can easily rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, which eliminates the need to hard-code sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon RDS, Amazon Redshift, and Amazon DocumentDB. The service is extensible to other types of secrets, including API keys and OAuth tokens. Secrets Manager enables you to control access to secrets using fine-grained permissions and to audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on premises.

Epics

Store database credentials in Secrets Manager

Task	Description	Skills required
Create a database user for the Lambda function.	It is a good practice to use separate database users for different parts of your application. If a separate database user already exists for your cron jobs, use that. Otherwise, create a new database user. For more information, see Managing PostgreSQL users and roles (AWS blog post).	DBA
Store database credentials as a secret in Secrets Manager.	Follow the instructions in Create a database secret	DBA, DevOps

Task	Description	Skills required
	(Secrets Manager documentation).	

Author the code for the Lambda function

Task	Description	Skills required
Choose a programming language supported by Lambda.	For a list of supported languages, see [Lambda runtimes](#) (Lambda documentation).	Developer
Write the logic to fetch the database credentials from Secrets Manager.	For sample code, see [How to securely provide database credentials to Lambda functions by using AWS Secrets Manager](#) (AWS blog post).	Developer
Write the logic to perform the scheduled database activity.	Migrate your existing code for the scheduling job that you're using on premises to the Lambda function. For more information, see [Deploying Lambda functions](#) (Lambda documentation).	Developer

Deploy the code and create the Lambda function

Task	Description	Skills required
Create the Lambda function deployment package.	This package contains the code and its dependencies. For more information,	Developer

Task	Description	Skills required
	see Deployment packages (Lambda documentation).	
Create the Lambda function.	In the Lambda console, choose **Create function**, enter a function name, choose the runtime environment, and then choose **Create function**.	DevOps
Upload the deployment package.	Choose the Lambda function you created to open its configuration. You can write your code directly in the code section or upload your deployment package. To upload your package, go to the **Function code** section, choose the **Code entry type** to upload a .zip file, and then select the package.	DevOps
Configure the Lambda function per your requireme nts.	For example, you can set the **Timeout** parameter to the duration you expect your Lambda function to take. For more information, see Configuring function options (Lambda documentation).	DevOps
Set permissions for the Lambda function role to access Secrets Manager.	For instructions, see Use secrets in AWS Lambda functions (Secrets Manager documentation).	DevOps

Task	Description	Skills required
Test the Lambda function.	Initiate the Lambda function manually to make sure it works as expected.	DevOps

Schedule the Lambda function by using CloudWatch Events

Task	Description	Skills required
Create a rule to run your Lambda function on a schedule.	Schedule the Lambda function by using CloudWatc h Events. For instructions, see Schedule Lambda functions using CloudWatch Events (CloudWatch Events tutorial).	DevOps

Send notifications for an Amazon RDS for SQL Server database instance by using an on-premises SMTP server and Database Mail

Nishad Mankar, Amazon Web Services

Summary

Database Mail (Microsoft documentation) sends email messages, such as notifications or alerts, from a Microsoft SQL Server database by using a Simple Mail Transfer Protocol (SMTP) server. The Amazon Relational Database Service (Amazon RDS) for Microsoft SQL Server documentation provides instructions for using Amazon Simple Email Service (Amazon SES) as the SMTP server for Database Mail. For more information, see Using Database Mail on Amazon RDS for SQL Server. As an alternative configuration, this pattern explains how to configure Database Mail to send email from an Amazon RDS for SQL Server database (DB) instance by using an on-premises SMTP server as the mail server.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS DB instance running a Standard or Enterprise edition of SQL Server
- The IP address or hostname of the on-premises SMTP server
- An inbound security group rule that allows connections to the Amazon RDS for SQL Server DB instance from the IP address of the SMTP server
- A connection, such as an AWS Direct Connect connection, between your on-premises network and the virtual private cloud (VPC) that contains the Amazon RDS DB instance

Limitations

- Express editions of SQL Server aren't supported.
- For more information about limitations, see Limitations in *Using Database Mail on Amazon RDS for SQL Server* in the Amazon RDS documentation.

Product versions

- Standard and Enterprise editions of SQL Server versions supported in RDS

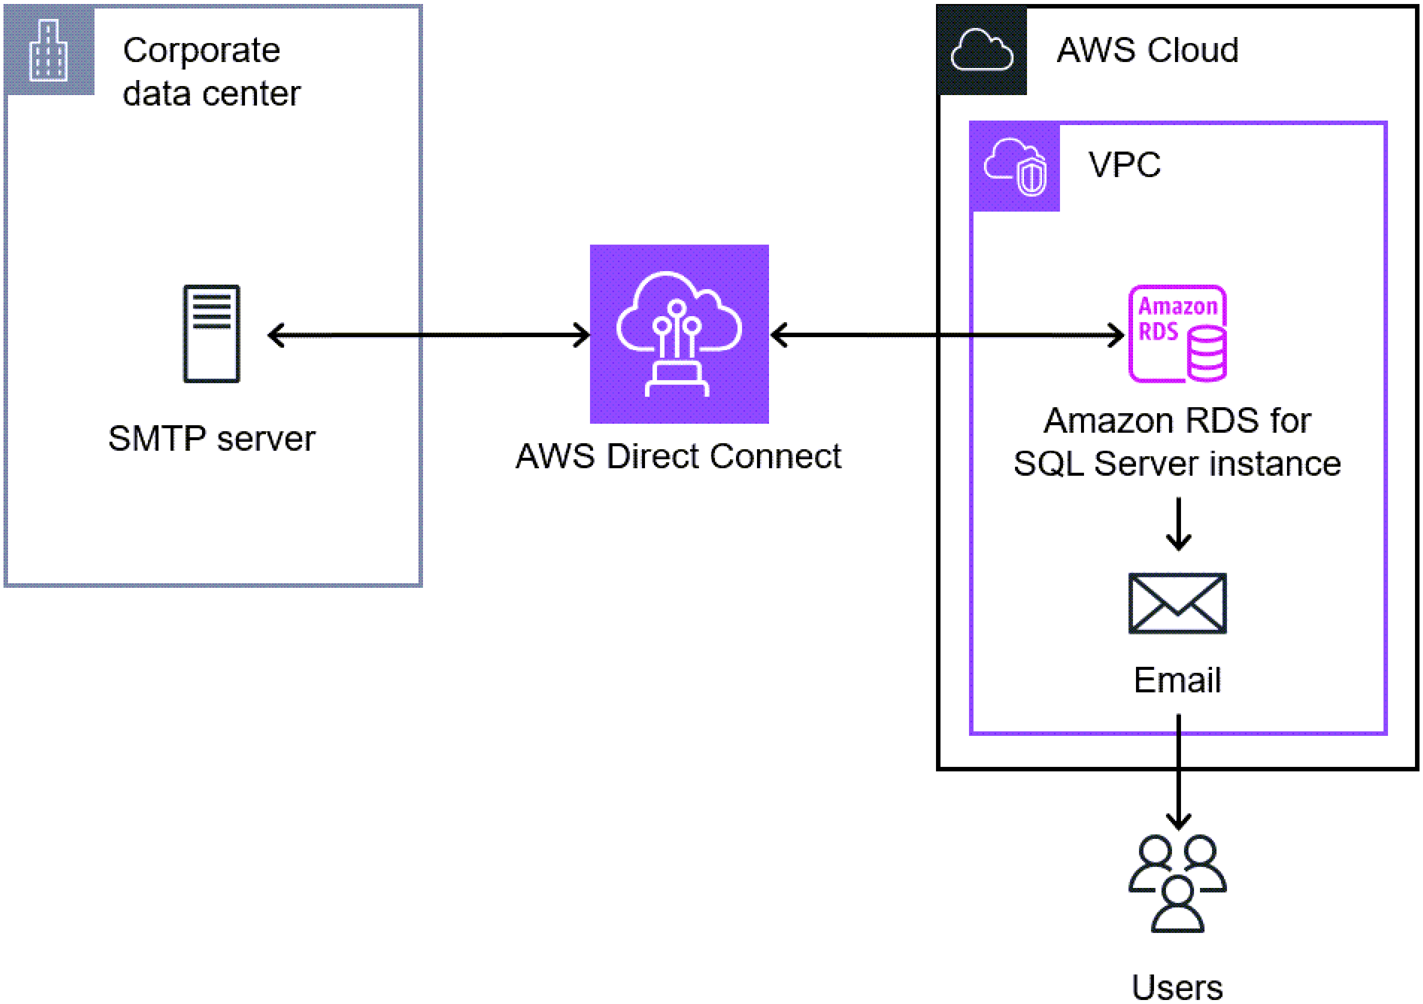
Architecture

Target technology stack

- Amazon RDS for SQL Server database instance
- Amazon Route 53 forwarding rule
- Database Mail
- On-premises SMTP server
- Microsoft SQL Server Management Studio (SSMS)

Target architecture

The following image shows the target architecture for this pattern. When an event or action occurs that initiates a notification or alert regarding the database instance, Amazon RDS for SQL Server uses Database Mail to send an email notification. Database Mail uses the on-premises SMTP server to send the email.



Tools

AWS services

- [Amazon Relational Database Service (Amazon RDS) for Microsoft SQL Server](#) helps you set up, operate, and scale a SQL Server relational database in the AWS Cloud.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

Other tools

- [Database Mail](#) is a tool that sends e-mail messages, such as notifications and alerts, from the SQL Server Database Engine to users.
- [Microsoft SQL Server Management Studio (SSMS)](#) is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components. In this pattern, you use

SSMS to run the SQL commands to set up Database Mail on an Amazon RDS for SQL Server DB instance.

Epics

Enable network connectivity with the on-premises SMTP server

Task	Description	Skills required
Remove Multi-AZ from the RDS DB instance.	If you're using a Multi-Zone RDS DB instance, convert the Multi-AZ instance to a Single-AZ instance. When you have finished configuring Database Mail, you will convert the DB instance back to a Multi-AZ deployment. The Database Mail configuration then works in both the primary and secondary nodes. For instructions, see Removing Multi-AZ from a Microsoft SQL Server DB instance.	DBA
Create an allow list for the Amazon RDS endpoint or IP address on the on-premises SMTP server.	The SMTP server is outside of the AWS network. On the on-premises SMTP server, create an allow list that permits the server to communicate with the outbound endpoint or IP address for the Amazon RDS instance or the Amazon Elastic Compute Cloud (Amazon EC2) instance hosted on Amazon RDS. This procedure varies from organization to organization.	DBA

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>For more information about the DB instance endpoint, see Finding the DB instance endpoint and port number.</td><td></td></tr>
<tr><td>Remove port 25 restrictions.</td><td>By default, AWS restricts port 25 on EC2 instances. To remove the port 25 restricti on, do the following:

1. Sign in with your AWS account, and then open the Request to remove email sending limitations form.
2. Enter your email address so that AWS Support can contact you with updates about your request.
3. Provide the required information in the Use case description field.
4. Choose Submit.

Note

• If you have instances in more than one AWS Region, then submit a separate request for each Region.
• It can take up to 48 hours to process your request.</td><td>General AWS</td></tr>
</table>

Task	Description	Skills required
Add a Route 53 rule to resolve DNS queries for the SMTP server.	Use Route 53 to resolve DNS queries between your AWS resources and the on-premises SMTP server. You must create a rule that forwards the DNS queries to the SMTP server domain, such as `example.com` . For instructions, see [Creating forwarding rules](#) in the Route 53 documentation.	Network administrator

Set up Database Mail on the Amazon RDS for SQL Server DB instance

Task	Description	Skills required
Enable Database Mail.	Create a parameter group for Database Mail, set the `database mail xps` parameter to 1, and then associate the Database Mail parameter group with the target RDS DB instance. For instructions, see [Enabling Database Mail](#) in the Amazon RDS documentation. Do not proceed to the *Configuring Database Mail* section in these instructions. The configuration for the on-premises SMTP server differs from Amazon SES.	DBA

Task	Description	Skills required
Connect to the DB instance.	From a bastion host, use Microsoft SQL Server Management Studio (SSMS) to connect to the Amazon RDS for SQL Server database instance. For instructions, see Connecting to a DB instance running the Microsoft SQL Server database engine. If you encounter any errors, see the connection troubleshooting references in the Related resources section.	DBA

Task	Description	Skills required
Create the profile.	In SSMS, enter the following SQL statement to create the Database Mail profile. Replace the following values: • For `profile_name` , enter a name for the new profile. • For `description` , enter a brief description of the new profile. For more information about this stored procedure and its arguments, see sysmail_add_profile_sp in the Microsoft documentation. `EXECUTE msdb.dbo. sysmail_add_profile_sp @profile_name = 'SQL Alerts profile', @description = 'Profile used for sending outgoing notifications using OM SMTP Server.';`	DBA

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add principals to the profile.</td><td>Enter the following SQL statement to add public or private principals to the Database Mail profile. A principal is an entity that can request SQL Server resources. Replace the following values:
For <code>profile_name</code> , enter the name of the profile you created previously.
For <code>principal_name</code> , enter the name of the database user or role. This value must map to an SQL Server authentication user, a Windows Authentic ation user, or a Windows Authentication group.
For more information about this stored procedure and its arguments, see sysmail_a dd_principalprofile_sp in the Microsoft documentation.<pre>EXECUTE msdb.dbo.
sysmail_add_princi
palprofile_sp
 @profile_name = 'SQL
 Alerts profile',
 @principal_name =
 'public',
 @is_default = 1 ;</pre></td><td>DBA</td></tr>
</table>

Task	Description	Skills required
Create the account.	Enter the following SQL statement to create the Database Mail account. Replace the following values: • For `account_name`, enter a name for the new account. • For `description`, enter a brief description of the new account. • For `email_address`, enter the e-mail address to send the Database Mail messages from. • For `display_address`, enter a display name to use for outgoing messages for this account, such as `SQL Server Automated Notification`. You can also use the value you entered for `email_address`. • For `mailserver_name`, enter the name or IP address of the SMTP mail server. • For `port`, leave the value of `25`. • For `enable_ssl`, leave the value at `1` or enter `0` if you don't want Database	DBA

Task	Description	Skills required
	Mail to encrypt communication by using SSL. • For `username`, enter the username for logging on to the SMTP mail server. If the server doesn't require authentication, enter `NULL`. • For `password`, enter the password for logging on to the SMTP mail server. If the server doesn't require authentication, enter `NULL`. For more information about this stored procedure and its arguments, see sysmail_add_account_sp in the Microsoft documentation. `EXECUTE msdb.dbo.sysmail_add_account_sp @account_name = 'SQL Alerts account', @description = 'Database Mail account for sending outgoing notifications.', @email_address = 'xyz@example.com', @display_name = 'xyz@example.com', @mailserver_name = 'test_smtp.example.com', @port = 25, @enable_ssl = 1,`	

Task	Description	Skills required
	` @username = 'SMTP-username',` ` @password = 'SMTP-password';`	

Add the account to the profile.	Enter the following SQL statement to add the Database Mail account to the Database Mail profile. Replace the following values:
	
	• For `profile_name` , enter the name of the profile you created previously.
	• For `account_name` , enter the name of the account you created previously.
	
	For more information about this stored procedure and its arguments, see [sysmail_add_profileaccount_sp](#) in the Microsoft documentation.
	
	`EXECUTE msdb.dbo.sysmail_add_profileaccount_sp`
	` @profile_name = 'SQL Alerts profile',`
	` @account_name = 'SQL Alerts account',`
	` @sequence_number = 1;`
		DBA

Task	Description	Skills required
(Optional) Add Multi-AZ to the RDS DB instance.	If you want to add Multi-AZ with Database Mirroring (DBM) or Always On Availability Groups (AGs), see the instructions in Adding Multi-AZ to a Microsoft SQL Server DB instance.	DBA

Set up disaster recovery for SAP on IBM Db2 on AWS

Ambarish Satarkar and Debasis Sahoo, Amazon Web Services

Summary

This pattern outlines the steps to set up a disaster recovery (DR) system for SAP workloads with IBM Db2 as the database platform, running on the Amazon Web Services (AWS) Cloud. The objective is to provide a low-cost solution for providing business continuity in the event of an outage.

The pattern uses the pilot light approach. By implementing pilot light DR on AWS, you can reduce downtime and maintain business continuity. The pilot light approach focuses on setting up a minimal DR environment in AWS, including an SAP system and a standby Db2 database, that is synchronized with the production environment.

This solution is scalable. You can extend it to a full-scale disaster recovery environment as needed.

Prerequisites and limitations

Prerequisites

- An SAP instance running on an Amazon Elastic Compute Cloud (Amazon EC2) instance
- An IBM Db2 database
- An operating system that is supported by the SAP Product Availability Matrix (PAM)
- Different physical database hostnames for production and standby database hosts
- An Amazon Simple Storage Service (Amazon S3) bucket in each AWS Region with Cross-Region Replication (CRR) enabled

Product versions

- IBM Db2 Database version 11.5.7 or later

Architecture

Target technology stack

- Amazon EC2

- Amazon Simple Storage Service (Amazon S3)
- Amazon Virtual Private Cloud (VPC peering)
- Amazon Route 53
- IBM Db2 High Availability Disaster Recovery (HADR)

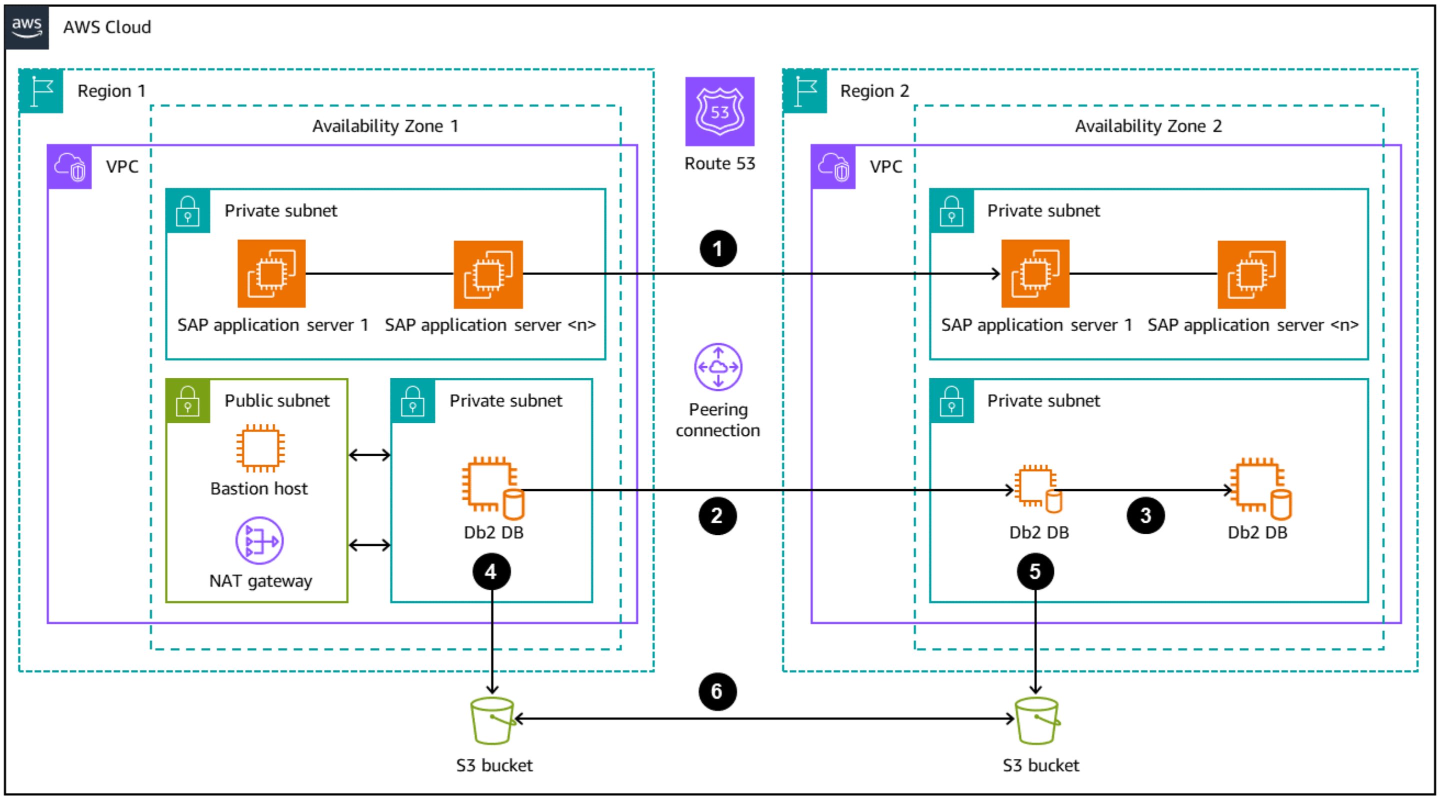
Target architecture

This architecture implements a DR solution for SAP workloads with Db2 as the database platform. The production database is deployed in AWS Region 1 and a standby database is deployed in a second Region. The standby database is referred to as the DR system. Db2 Database supports multiple standby databases (up to three). It uses Db2 HADR for setting up the DR database and automating log shipping between the production and standby databases.

In the event of a disaster that makes Region 1 unavailable, the standby database in the DR Region takes over the production database role. SAP application servers can be built in advance or by using AWS Elastic Disaster Recovery or an Amazon Machine Image (AMI) to meet the recovery time objective (RTO) requirements. This pattern uses an AMI.

Db2 HADR implements a production-standby setup, where production acts as the primary server, and all users are connected to it. All transactions are written to log files, which are transferred to the standby server by using TCP/IP. The standby server updates its local database by rolling forward the transferred log records, which helps to ensure that it is kept in sync with the production server.

VPC peering is used so that instances in the production Region and DR Region can communicate with each other. Amazon Route 53 routes end users to internet applications.



1. [Create an AMI](#) of the application server in Region 1 and [copy the AMI](#) to Region 2. Use the AMI to launch servers in Region 2 in the event of a disaster.
2. Set up Db2 HADR replication between the production database (in Region 1) and the standby database (in Region 2).
3. Change the EC2 instance type to match the production instance in the event of a disaster.
4. In Region 1, `LOGARCHMETH1` is set to `db2remote: S3 path`.
5. In Region 2, `LOGARCHMETH1` is set to `db2remote: S3 path`.
6. Cross-Region Replication is performed between the S3 buckets.

Tools

AWS services

- [Amazon Elastic Compute Cloud (Amazon EC2)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

- [Amazon Simple Storage Service (Amazon S3)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [Amazon Virtual Private Cloud (Amazon VPC)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses [VPC peering](#).

Best practices

- The network plays a key role in deciding the HADR replication mode. For DR across AWS Regions, we recommend that you use Db2 HADR ASYNC or SUPERASYNC mode.
- For more information about replication modes for Db2 HADR, see the [IBM documentation](#).
- You can use the AWS Management Console or the AWS Command Line Interface (AWS CLI) to [create a new AMI](#) of your existing SAP system. You can then use the AMI to recover your existing SAP system or to create a clone.
- [AWS Systems Manager Automation](#) can help with the common maintenance and deployment tasks of EC2 instances and other AWS resources.
- AWS provides multiple native services to monitor and manage your infrastructure and applications on AWS. Services such as Amazon CloudWatch and AWS CloudTrail can be used to monitor your underlying infrastructure and API operations, respectively. For more details, see [SAP on AWS – IBM Db2 HADR with Pacemaker](#).

Epics

Prepare the environment

Task	Description	Skills required
Check the system and logs.	1. Confirm that the productio n SAP on Db2 system is set up. 2. Confirm that log backup is turned on and configure d to save the logs in the S3 bucket. This can	AWS administrator, SAP Basis administrator

Task	Description	Skills required
	be checked by the Db2 parameter `LOGARCHMETH1` . 3. Create an AMI of the additional application server.	

Set up the servers and replication

Task	Description	Skills required
Create the SAP and database servers.	1. To deploy the infrastructure for the DR Region, use an AWS CloudFormation script or use an AMI of the production instance. As a part of the pilot light approach, you can use a smaller EC2 instance in the same family as the production instance. For example, if your production instance type is `r6i.12xlarge` , you can use the `r6i.xlarge` instance type for the DR build. However, make sure that you allocate the same storage capacity on the DR instance to restore the production database backup. 2. Create Amazon Elastic File System (Amazon	SAP Basis administrator

Task	Description	Skills required
	EFS) mount points for /`sapmnt/<SID>/`, and make sure that it is [set to be replicated](#) from the primary system. 3. Take a FULL database backup (online or offline) from the production system. You will use this backup to build the DR database. 4. In the DR system, use the SAP Software Provisioning Manager (SWPM) system copy method with **Using system copy with backup/restore for HA/DR purposes** to build the DR SAP system. 5. When asked by SWPM, restore the database in DR with the backup that you took from the production. The DR database will be in the rollforward pending state. The rollforward pending state is set by default after the full backup is restored. The rollforward pending state indicates that the database is in the process of being restored and that some	

Task	Description	Skills required
	changes might need to be applied. For more informati on, see the IBM documenta tion.	

Task	Description	Skills required

Check the configuration.	1. To set up log archiving for HADR, both the production and DR databases must be able to retrieve logs automatically from all log archive locations. Verify that the `LOGARCHMETH1` parameter in the DR database is set to the same location as in the production database. If the same location is not accessible because of Regional limitations, ensure that the DR system can automatically fetch logs from the primary system.
	2. To enable TCP/IP ports for database replication enablement, modify `/etc/services` in the production and DR hosts by adding the following two entries. In the code, `<SID>` refers to the System ID (SID) of the Db2 database (for example, PR1).
	`<SID>_HADR_1 55001/tcp # DB2 HADR Port1`
	`<SID>_HADR_2 55002/tcp # DB2 HADR Port2`
		AWS administrator, SAP Basis administrator

Task	Description	Skills required
	Confirm that both ports allow inbound and outbound traffic between both the primary and the standby. 3. Check `/etc/hosts` in the production and DR hosts to confirm that hostnames for both production and standby hosts are pointing to the correct IP addresses.	

Task	Description	Skills required

Set up replication from the production DB to the DR DB (using ASYNC mode).	1. In the production database, run the following commands to update the parameters.
	`db2 UPDATE DB CFG FOR <SID> USING HADR_LOCAL_HOST HOST1`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_LOCAL_SVC <SID>_HADR_1`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_REMOTE_HOST HOST2`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_REMOTE_SVC <SID>_HADR_2`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_REMOTE_INST db2<sid>`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_TIMEOUT 120`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_SYNCMODE ASYNC`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_SPOOL_LIMIT 1000`
	`db2 UPDATE DB CFG FOR <SID> USING HADR_PEER_WINDOW 240`
	`db2 UPDATE DB CFG FOR <SID> USING indexrec RESTART logindexbuild ON`
	2. In the DR database, run the following commands to update the parameters.
		SAP Basis administrator

Task	Description	Skills required

	<pre>db2 UPDATE DB CFG FOR <SID> USING HADR_LOCAL_HOST HOST2
	db2 UPDATE DB CFG FOR <SID> USING HADR_LOCAL_SVC <SID>_HADR_2
	db2 UPDATE DB CFG FOR <SID> USING HADR_REMOTE_HOST HOST1
	db2 UPDATE DB CFG FOR <SID> USING HADR_REMOTE_SVC <SID>_HADR_1
	db2 UPDATE DB CFG FOR <SID> USING HADR_REMOTE_INST db2<sid>
	db2 UPDATE DB CFG FOR <SID> USING HADR_TIMEOUT 120
	db2 UPDATE DB CFG FOR <SID> USING HADR_SYNCMODE ASYNC
	db2 UPDATE DB CFG FOR <SID> USING HADR_SPOOL_LIMIT 1000
	db2 UPDATE DB CFG FOR <SID> USING HADR_PEER_WINDOW 240
	db2 UPDATE DB CFG FOR <SID> USING indexrec RESTART logindexbuild ON</pre>
	These parameters are required to provide HADR-related information to both databases. In the Db2 database, HADR gets activated based on the values for each of the	

Task	Description	Skills required

	previously set parameters. For more information about these parameters, see the [IBM documentation]().
	3. Start HADR first on the newly created standby database by using the following command.
	`db2 deactivate db <SID>`
	`db2 start hadr on db <SID> as standby`
	4. Start HADR on the production database by using the following command.
	`db2 deactivate db <SID>`
	`db2 start hadr on db <SID> as primary`
	5. Check whether the production and standby Db2 databases are in sync and log shipping is ongoing.
	To monitor HADR replication status, use the following `db2pd` command.
	`db2pd -d <SID> -hadr`	

Task	Description	Skills required
	For more information about monitoring HADR, see the [IBM documentation]().	

Test DR failover tasks

Task	Description	Skills required
Plan the production business downtime for the DR test.	Make sure that you plan the required business downtime on production environment for testing the DR failover scenario.	SAP Basis administrator
Create a test user.	Create a test user (or any test changes) that can be validated in the DR host to confirm log replication after DR failover.	SAP Basis administrator
On the console, stop the production EC2 instances.	Ungraceful shutdown is initiated in this step to mimic a disaster scenario.	AWS systems administrator
Scale up the DR EC2 instance to match the requirements.	On the EC2 console, change the instance type in the DR Region. 1. Stop the instance: If the instance is running, you must stop it before you can change its instance type. On the EC2 console, select	SAP Basis Admin

Task	Description	Skills required

	the instance, and choose **Stop**.
	2. Modify the instance type: On the EC2 console, select the instance, and choose **Actions**, **Instance Settings**, **Change Instance Type**. Select the instance type that matches the primary instance, and choose **Apply**.
	3. Start the instance: After the instance type change is complete, start the instance from the EC2 console by selecting the instance and choosing **Start**.
	4. To start the Db2 database, use the following command.
	`db2start`
	`    db2 start HADR on db <SID> as standby`	

Task	Description	Skills required

Initiate takeover.	From the DR system (`host2`), initiate the take-over process and bring up the DR database as the primary.
	`db2 takeover hadr on database <SID> by force`
	Optionally, you can set the following parameters to adjust database memory allocation automatically based on the instance type. The `INSTANCE_MEMORY` value can be decided based on the dedicated portion of memory to be allocated to the Db2 database.
	`db2 update db cfg for <SID> using INSTANCE_MEMORY <FIXED VALUE> IMMEDIATE;`
	`db2 get db cfg for <SID> | grep -i DATABASE_MEMORY AUTOMATIC IMMEDIATE;`
	`db2 update db cfg for <SID> using self_tuning_mem ON IMMEDIATE;`
	Verify the change by using the following commands.
	`db2 get db cfg for <SID> | grep -i MEMORY`
		SAP Basis administrator

Task	Description	Skills required
	`db2 get db cfg for <SID> | grep -i self_tuning_mem`	
Launch the application server for SAP in the DR Region.	Using the AMI that you made of the production system, [launch a new additional application server](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/launching-instance.html) in the DR Region.	SAP Basis administrator
Perform validation before starting the SAP application.	1. Validate the `/etc/hosts` and `/etc/fstab` entries. 2. Mount `/sapmnt/<SID>/` on the DR system. 3. Validate that the DR file system `/sapmnt/<SID>/` is synced with the production `/sapmnt/<SID>/`. 4. Log in to `<sid>adm` user, run `R3trans -d`, and verify the output in the `trans.log` file. The `trans.log` file is generated in the same location where you ran the `R3trans -d` command.	AWS administrator, SAP Basis administrator

Task	Description	Skills required

Start the SAP application on the DR system.	Start the SAP application on the DR system by using `<sid>adm` user. Use the following code, in which XX represents the instance number of your SAP ABAP SAP Central Services (ASCS) server, and YY represents the instance number of your SAP application server.
	`sapconrol -nr XX -function StartService <SID>`
	`sapconrol -nr XX -function StartSystem`
	`sapconrol -nr YY -function StartService <SID>`
	`sapconrol -nr YY -function StartSystem`
		SAP Basis administrator

Perform SAP validation.	This is performed as a DR test to provide evidence or to check the data replication success to the DR Region.	Test engineer

Perform DR failback tasks

Task	Description	Skills required
Start the production SAP and database servers.	On the console, start the EC2 instances that host SAP and the database in the productio n system.	SAP Basis administrator

Task	Description	Skills required

Start the production database and set up HADR.	Log in to production system (`host1`) and verify that the DB is in recovery mode by using the following command.
	`db2start`
	`db2 start HADR on db P3V as standby`
	`db2 connect to <SID>`
	Verify that the HADR status is `connected` . Replication status should be `peer`.
	`db2pd -d <SID> -hadr`
	If the database is not inconsistent and is not at `connected` and `peer` status, a backup and restore might be required to bring the database (on `host1`) in sync with the currently active database (`host2` in the DR Region). In that case, restore the DB backup from the database in the `host2` DR Region to the database in the `host1` production Region.
		SAP Basis administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Fail back the database to the production Region.</td><td>In a normal business-as-usual scenario, this step is performed in a scheduled downtime. Applications running on the DR system are stopped, and the database is failed back to the production Region (Region 1) to resume operations from the production Region.

1. Log in to the SAP application server in the DR Region, and stop the SAP application.
2. Unmount <code>/sapmnt/<SID></code> from the DR system, making sure that the changes are reverse-replicated to <code>/sapmnt/<SID></code> of the production system.
3. Log in to the database server (<code>host1</code>) in the production Region, and perform the takeover.
<pre>db2 takeover hadr on
 database <SID></pre>4. Check the HADR status: <code>HADR_ROLE</code> should be <code>PRIMARY</code> on <code>host1</code> and <code>StandBy</code> on <code>host2</code>.</td><td>SAP Basis administrator</td></tr>
</table>

Task	Description	Skills required
	`db2pd -d <SID> -hadr`	
Perform validation before starting the SAP application.	1. Validate the `/etc/hosts` and `/etc/fstab` entries. 2. Mount `/sapmnt/<SID>/` on the production system. 3. Make sure it is in sync with the DR system `/sapmnt/<SID>/` . 4. Log in to `<sid>adm` user, run `R3trans -d`, and verify the output in the `trans.log` file. The `trans.log` file is generated in the same location where you ran the `R3trans -d` command.	AWS administrator, SAP Basis administrator

Task	Description	Skills required

Start the SAP application.	1. Start the SAP application on the production system using `<sid>adm` user. Use the following code, in which XX represents the instance number of your SAP ASCS server, and YY represents the instance number of your SAP application server.
	`sapconrol -nr XX -function StartService <SID>`
	`sapconrol -nr XX -function StartSystem`
	`sapconrol -nr YY -function StartService <SID>`
	`sapconrol -nr YY -function StartSystem`
	2. To confirm that applicati on servers are available, log in to SAP and perform checks by using the SICK and SM51 transactions.
		SAP Basis administrator

Troubleshooting

Issue	Solution
Key log files and commands to troubleshoot HADR-related issues	• `db2 get db cfg | grep -i hadr` • `db2pd -d sid -hadr`

Issue	Solution
	• `Db2diag.log` (This file is generally located inside the `db2dump` directory, and the `db2dump` path is defined by the parameter `DIAGPATH`.)
SAP note for troubleshooting HADR issues on Db2 UDB	Refer to SAP Note 1154013 - DB6: DB problems in HADR environment. (You need SAP portal credentials to access this note.)

Related resources

- Disaster recovery approaches for Db2 databases on AWS (blog post)
- SAP on AWS – IBM Db2 HADR with Pacemaker
- Step by Step Procedure to set up HADR replication between DB2 databases
- Db2 HADR Wiki

Additional information

Using this pattern, you can set up a disaster recovery system for an SAP system running on the Db2 database. In a disaster situation, business should be able to continue within your defined recovery time objective (RTO) and recovery point objective (RPO) requirements:

- **RTO** is the maximum acceptable delay between the interruption of service and restoration of service. This determines what is considered an acceptable time window when service is unavailable.
- **RPO** is the maximum acceptable amount of time since the last data recovery point. This determines what is considered an acceptable loss of data between the last recovery point and the interruption of service.

For FAQs related to HADR, see SAP note #1612105 - DB6: FAQ on Db2 High Availability Disaster Recovery (HADR). (You need SAP portal credentials to access this note.)

Set up a CI/CD pipeline for database migration by using Terraform

Dr. Rahul Sharad Gaikwad, Ashish Bhatt, Aniket Dekate, Ruchika Modi, Tamilselvan P, Nadeem Rahaman, Aarti Rajput, and Naveen Suthar, Amazon Web Services

Summary

This pattern is about establishing a continuous integration and continuous deployment (CI/CD) pipeline for managing database migrations in a reliable and automated manner. It covers the process of provisioning the necessary infrastructure, migrating data, and customizing schema changes by using Terraform, which is an infrastructure as code (IaC) tool.

Specifically, the pattern sets up a CI/CD pipeline to migrate an on-premises Microsoft SQL Server database to Amazon Relational Database Service (Amazon RDS) on AWS. You can also use this pattern to migrate a SQL Server database that's on a virtual machine (VM) or in another cloud environment to Amazon RDS.

This pattern addresses the following challenges associated with database management and deployment:

- Manual database deployments are time-consuming, error-prone, and lack consistency across environments.
- Coordinating infrastructure provisioning, data migrations, and schema changes can be complex and difficult to manage.
- Ensuring data integrity and minimizing downtime during database updates is crucial for production systems.

This pattern provides the following benefits:

- Streamlines the process of updating and deploying database changes by implementing a CI/CD pipeline for database migrations. This reduces the risk of errors, ensures consistency across environments, and minimizes downtime.
- Helps improve reliability, efficiency, and collaboration. Enables faster time to market and reduced downtime during database updates.
- Helps you adopt modern DevOps practices for database management, which leads to increased agility, reliability, and efficiency in your software delivery processes.

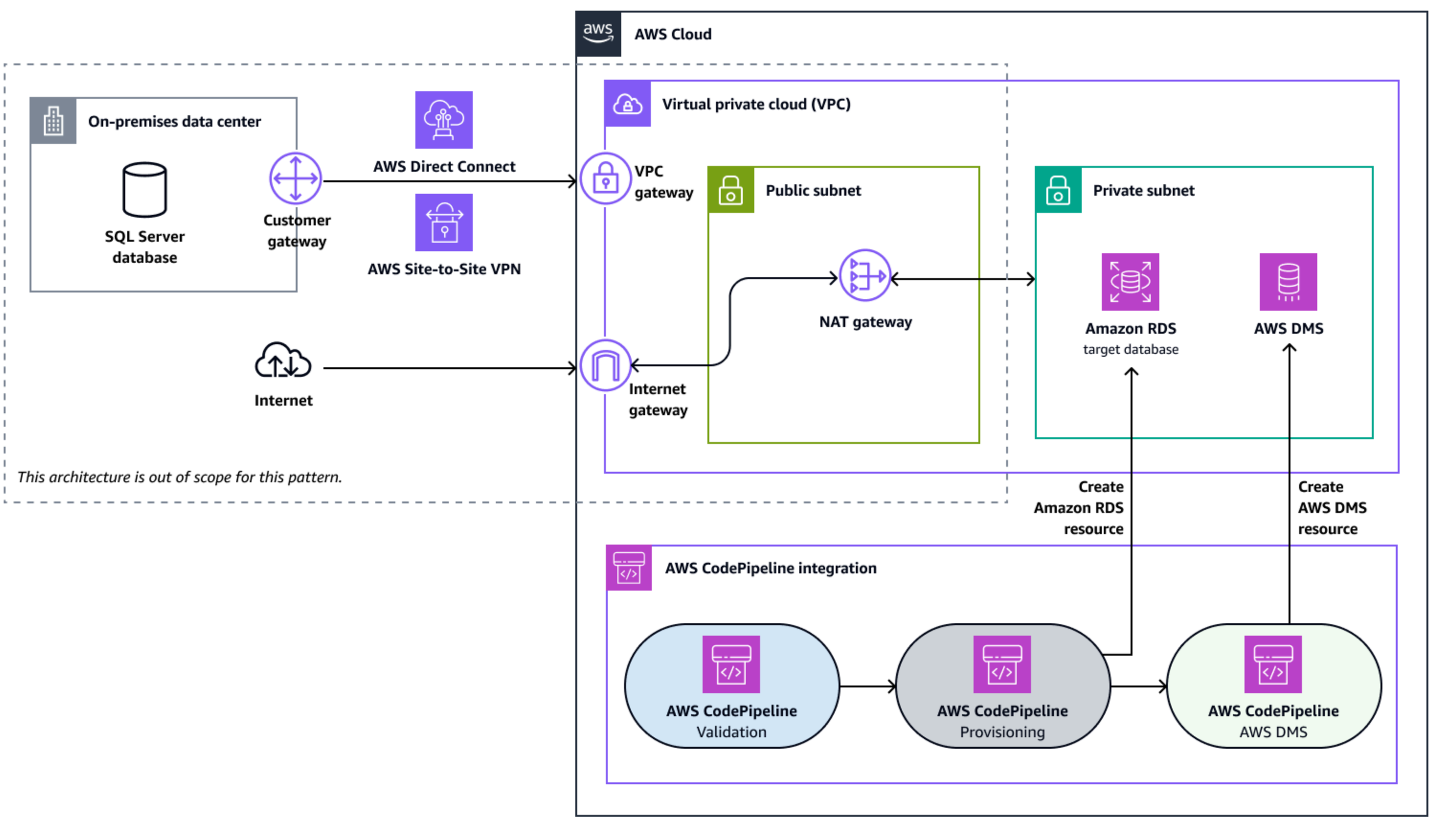
Prerequisites and limitations

Prerequisites

- An active AWS account
- Terraform 0.12 or later installed on your local machine (for instructions, see the Terraform documentation)
- Terraform AWS Provider version 3.0.0 or later from HashiCorp (see the GitHub repository for this provider)
- Least privilege AWS Identity and Access Management (IAM) policy (see the blog post Techniques for writing least privilege IAM policies)

Architecture

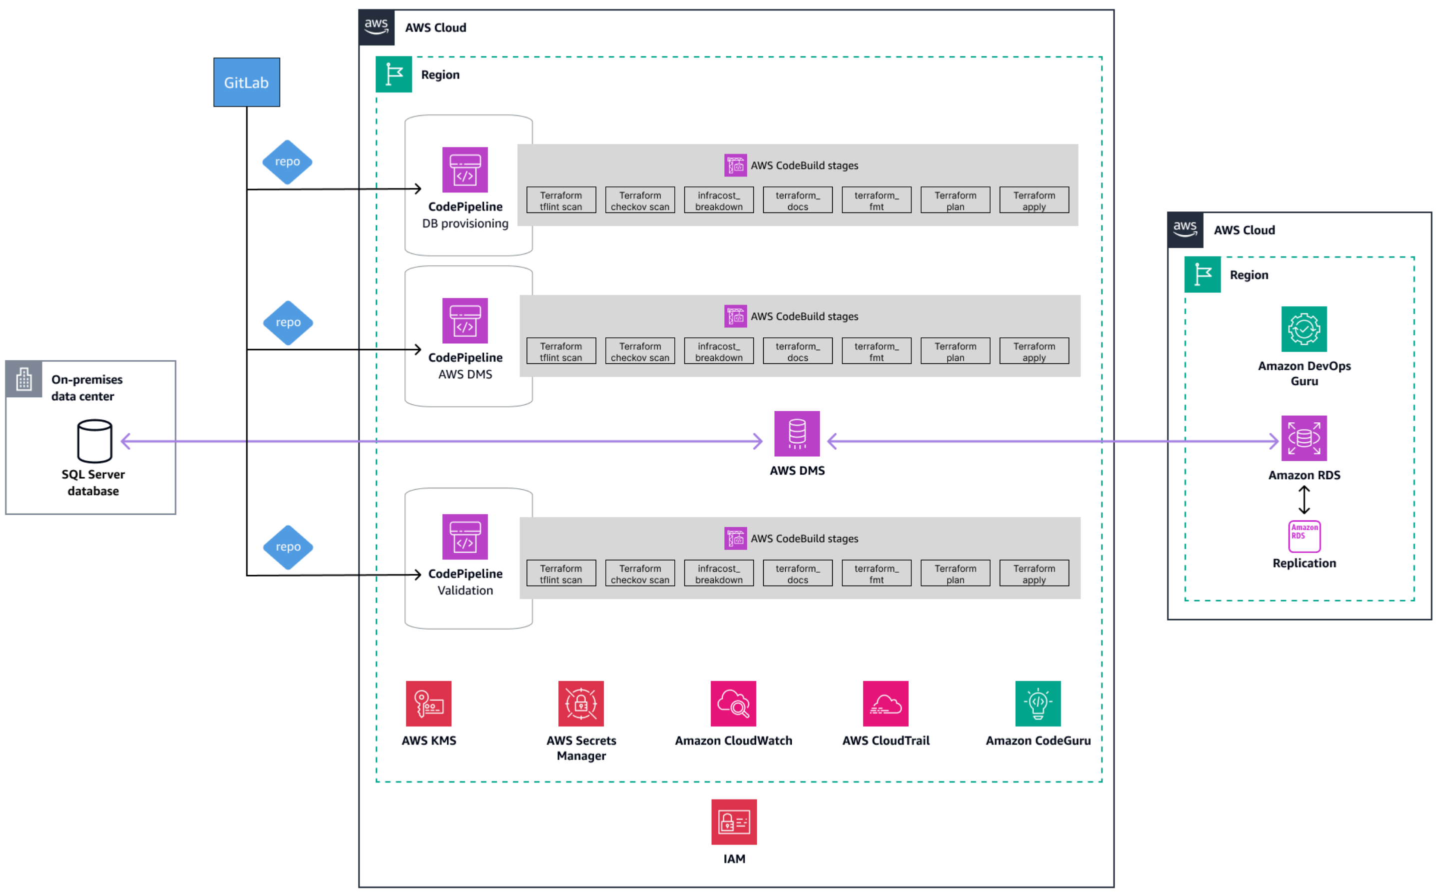
This pattern implements the following architecture, which provides the complete infrastructure for the database migration process.



In this architecture:

- The source database is a SQL Server database that is on premises, on a virtual machine (VM), or hosted by another cloud provider. The diagram assumes that the source database is in an on-premises data center.
- The on-premises data center and AWS are connected through a VPN or AWS Direct Connect connection. This provides secure communications between the source database and the AWS infrastructure.
- The target database is an Amazon RDS database that is hosted inside the virtual private cloud (VPC) on AWS with the help of a database provisioning pipeline.
- AWS Database Migration Service (AWS DMS) replicates your on-premises database to AWS. It is used to configure the replication of the source database to the target database.

The following diagram shows the infrastructure set up with different levels of the database migration process, which involves provisioning, AWS DMS setup, and validation.



In this process:

- The validation pipeline validates all checks. The integrated pipeline moves to the next step when all necessary validations are complete.
- The DB provisioning pipeline consists of various AWS CodeBuild stages that perform Terraform actions on the provided Terraform code for the database. When these steps are complete, it deploys resources in the target AWS account.
- The AWS DMS pipeline consists of various CodeBuild stages that perform tests and then provision the AWS DMS infrastructure for performing the migration by using IaC.

Tools

AWS services and tools

- AWS CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces ready-to-deploy software packages.
- AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Simple Storage Service (Amazon S3) is an object storage service that offers scalability, data availability, security, and performance.
- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

Other services

- Terraform is an IaC tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub Database Migration DevOps Framework using Terraform samples repository.

Best practices

- Implement automated tests for your database migration to verify the correctness of schema changes and data integrity. This includes unit tests, integration tests, and end-to-end tests.
- Implement a robust backup and restore strategy for your databases, especially before migration. This ensures data integrity and provides a fallback option in case of failures.
- Implement a robust rollback strategy to revert database changes in case of failures or issues during migration. This could involve rolling back to a previous database state or reverting individual migration scripts.
- Set up monitoring and logging mechanisms to track the progress and status of database migrations. This helps you identify and resolve issues quickly.

Epics

Set up your local workstation

Task	Description	Skills required
Set up and configure Git on your local workstation.	Install and configure Git on your local workstation by following the instructions in the [Git documentation]().	DevOps engineer
Create a project folder and add the files from the GitHub repository.	1. Open the [GitHub repository]() for this pattern. 2. Choose **Code** to see cloning options, and copy the URL provided in the HTTPS tab. 3. Create a folder for your project on your workstation. 4. Open a terminal and navigate to this folder. 5. Clone the GitHub repository:	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>
<pre><code>git clone <github-r
epository-url></code></pre>
where <code><github-r epository-url></code> is the URL you copied in step 2.
<ol start="6">
When cloning is complete, go to the cloned repository in your project folder:
<pre><code>cd <folder-name>/aws-
terraform-db-migra
tion-framework-sam
ples</code></pre>
Open this project in an integrated development environment (IDE) of your choice.

</td><td></td></tr>
</table>

Provision the target architecture

Task	Description	Skills required
Update required parameters.	The `ssm-parameters.sh` file stores all required AWS Systems Manager parameter s. You can configure these parameters with the custom values for your project. In the `setup/db-ssm-params` folder on your local workstation, open the `ssm-`	DevOps engineer

Task	Description	Skills required
	`parameters.sh` file and set these parameters before you run the CI/CD pipeline.	
Initialize the Terraform configuration.	In the `db-cicd-integration` folder, enter the following command to initialize your working directory that contains the Terraform configuration files: `terraform init`	DevOps engineer
Preview the Terraform plan.	To create a Terraform plan, enter the following command: `terraform plan -var-file="terraform.sample"` Terraform evaluates the configuration files to determine the target state for the declared resources. It then compares the target state against the current state and creates a plan.	DevOps engineer
Verify the plan.	Review the plan and confirm that it configures the required architecture in your target AWS account.	DevOps engineer

Task	Description	Skills required
Deploy the solution.	1. Enter the following command to apply the plan: `terraform apply -var-file="terraform.sample"` 2. Enter `yes` to confirm. Terraform creates, updates, or destroys infrastructure to achieve the target state declared in the configuration files. For more information about the sequence, see the [Architecture](#) section of this pattern.	DevOps engineer

Verify the deployment

Task	Description	Skills required
Validate the deployment.	Verify the status of the `db-cicd-integration` pipeline to confirm that the database migration is complete. 1. Sign in to the AWS Management Console, and then open the [AWS CodePipeline console](#).	DevOps engineer

Task	Description	Skills required
	2. In the navigation pane, choose **Pipelines**. 3. Choose the `db-cicd-integration` pipeline. 4. Validate that the pipeline execution has completed successfully.	

Clean up infrastructure after use

Task	Description	Skills required
Clean up the infrastructure.	1. After your project is complete, clean up the infrastructure you created by using the command: `terraform destroy --var-file=terraform.sample` 2. Enter `yes` to confirm.	DevOps engineer

Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database

Simon Cunningham, Amazon Web Services

Nitin Saxena, None

Summary

This pattern describes how you can architect your Oracle E-Business solution on Amazon Relational Database Service (Amazon RDS) Custom for high availability (HA) and disaster recovery (DR) by setting up an Amazon RDS Custom read replica database in another Amazon Web Services (AWS) Availability Zone and converting it to an active standby database. The creation of the Amazon RDS Custom read replica is fully automated through the AWS Management Console.

This pattern doesn't discuss the steps for adding additional application tiers and shared file systems, which can also be part of an HA/DR architecture. For more information about those topics, see the following Oracle Support Notes: 1375769.1, 1375670.1, and 1383621.1 (section 5, *Advanced Cloning Options*). (Access requires an Oracle Support account.)

To migrate E-Business Suite system to a single-tier, Single-AZ architecture on Amazon Web Services (AWS), see the pattern Migrate Oracle E-Business Suite to Amazon RDS Custom.

Oracle E-Business Suite is an Enterprise Resource Planning (ERP) solution for automating enterprise-wide processes such as financials, human resources, supply chains, and manufacturing. It has a three-tier architecture: client, application, and database. Previously, you had to run your E-Business Suite database on a self-managed Amazon Elastic Compute Cloud (Amazon EC2) instance, but you can now benefit from Amazon RDS Custom.

Prerequisites and limitations

Prerequisites

- An existing E-Business Suite installation on Amazon RDS Custom; see the pattern Migrate Oracle E-Business Suite to Amazon RDS Custom
- If you want to change the read replica to read-only and use it to offload reporting to the standby, an Oracle Active Data Guard database license (see the *Oracle Technology Commercial Price List*)

Limitations

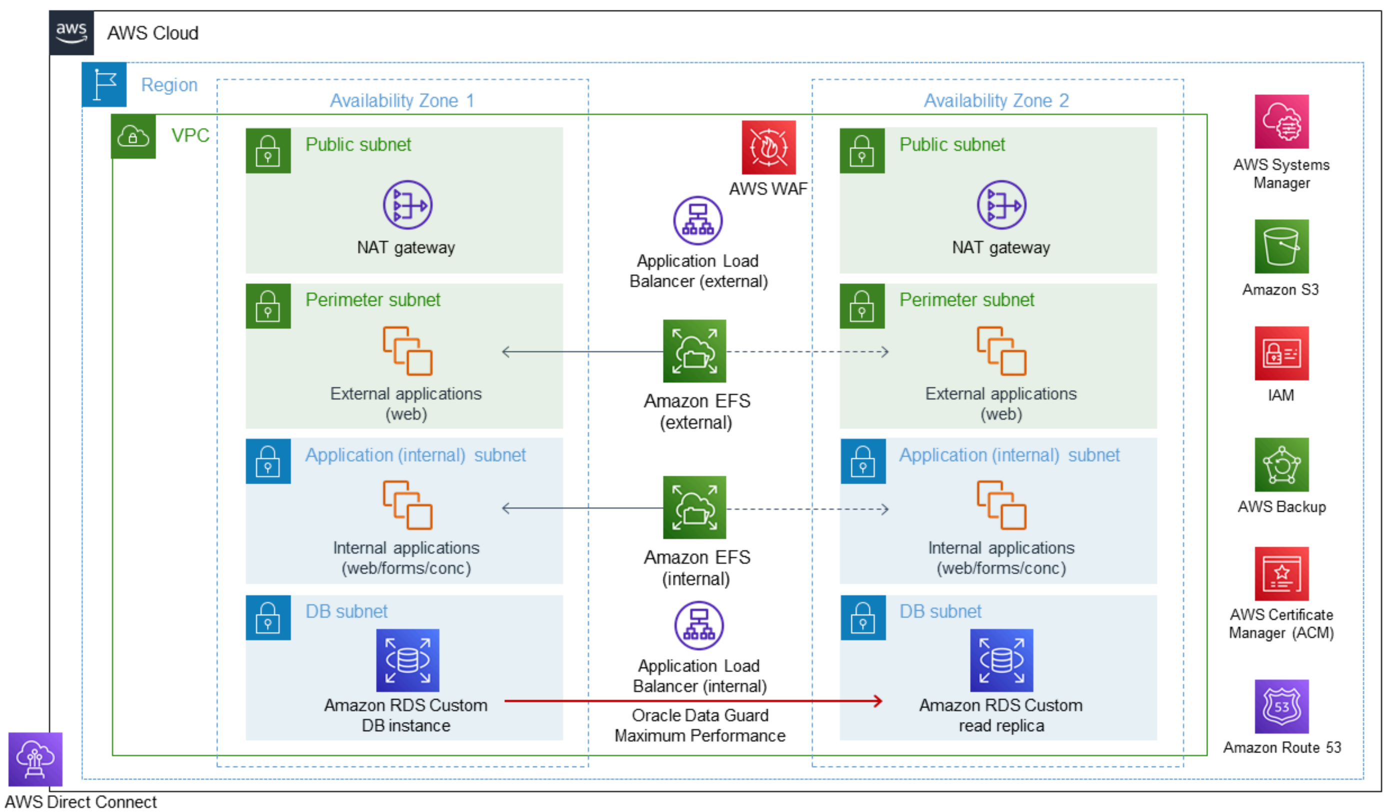
- Limitations and unsupported configurations for Oracle databases on Amazon RDS Custom
- Limitations associated with Amazon RDS Custom for Oracle read replicas

Product versions

For Oracle Database versions and instance classes supported by Amazon RDS Custom, see Requirements and limitations for Amazon RDS Custom for Oracle.

Architecture

The following diagram illustrates a representative architecture for E-Business Suite on AWS that includes multiple Availability Zones and application tiers in an active/passive setup. The database uses an Amazon RDS Custom DB instance and Amazon RDS Custom read replica. The read replica uses Active Data Guard to replicate to another Availability Zone. You can also use the read replica to offload read traffic on the primary database and for reporting purposes.



For more information, see Working with read replicas for Amazon RDS Custom for Oracle in the Amazon RDS documentation.

The Amazon RDS Custom read replica is created by default as mounted. However, if you want to offload some of your read-only workloads to the standby database to reduce the load on your primary database, you can manually change the mode of mounted replicas to read-only by following the steps in the Epics section. A typical use case for this would be to run your reports from the standby database. Changing to read-only requires an active standby database license.

When you create a read replica on AWS, the system uses Oracle Data Guard broker under the covers. This configuration is automatically generated and set up in Maximum Performance mode as follows:

```
DGMGRL> show configuration
Configuration - rds_dg
  Protection Mode: MaxPerformance
  Members:
  vis_a - Primary database
    vis_b - Physical standby database
Fast-Start Failover: DISABLED
Configuration Status:
SUCCESS   (status updated 58 seconds ago)
```

Tools

AWS services

- Amazon RDS Custom for Oracle is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks and operations while making it possible for you, as a database administrator, to access and customize your database environment and operating system.

Other tools

- Oracle Data Guard is a tool that helps you create and manage Oracle standby databases. This pattern uses Oracle Data Guard to set up an active standby database on Amazon RDS Custom.

Epics

Create a read replica

Task	Description	Skills required
Create a read replica of the Amazon RDS Custom DB instance.	To create a read replica, follow the instructions in the [Amazon RDS documentation](#) and use the Amazon RDS Custom DB instance you created (see the [Prerequisites](#) section) as the source database. By default, the Amazon RDS Custom read replica is created as a physical standby and is in the mounted state. This is intentional to ensure compliance with the Oracle Active Data Guard license. Follow the next steps to convert the read replica to read-only mode.	DBA

Change the read replica to a read-only active standby

Task	Description	Skills required
Connect to the Amazon RDS Custom read replica.	Use the following commands to convert your physical standby database to an active standby database.	DBA

Task	Description	Skills required

	Important These commands require an Oracle active standby license. To get a license, contact your Oracle representative.
	
	`$ sudo su - rdsdb`
	`-bash-4.2$ sql`
	`SQL> select process,status,sequence# from v$managed_standby;`
	
	`PROCESS   STATUS   SEQUENCE#`
	`--------- ------------ ----------`
	`ARCH      CLOSING      3956`
	`ARCH      CONNECTED    0`
	`ARCH      CLOSING      3955`
	`ARCH      CLOSING      3957`
	`RFS       IDLE         0`
	`RFS       IDLE         3958`
	`MRP0      APPLYING_LOG 3958`
	`SQL> select name, database_role, open_mode from v$database;`	

Task	Description	Skills required

	<pre>NAME DATABASE_
	ROLE OPEN_MODE
	--------- ---------
	------- ---------
	----------- 	
	VIS PHYSICAL
	 STANDBY MOUNTED
	SQL> alter database
	 recover managed standby
	 database cancel;
	Database altered.
	Open the standby
	 database
	SQL> alter database
	 open;
	Database altered.
	SQL> select name,
	 database_role,
	 open_mode from v
	$database;
	
	NAME DATABASE_
	ROLE OPEN_MODE
	--------- ---------
	------- ---------
	----------- 	
	VIS PHYSICAL
	 STANDBY READ ONLY</pre>	

Task	Description	Skills required
Start media recovery with real-time log apply.	To enable the real-time log apply feature, use the following commands. These convert and validate the standby (read replica) as an active standby database, so you can connect and run read-only queries. ``` SQL> alter database recover managed standby database using current logfile disconnect from session; Database altered ```	DBA
Check the database status.	To check the status of the database, use the following command. ``` SQL> select name, database_role, open_mode from v $database; NAME DATABASE_ROLE OPEN_MODE --------- --------- ------- --------- ----------- VIS PHYSICAL STANDBY READ ONLY WITH APPLY ```	DBA

Task	Description	Skills required

Check redo apply mode.	To check redo apply mode, use the following command.
	
	`SQL> select process,status,sequence# from v$managed_standby;`
	`PROCESS STATUS SEQUENCE#`
	`--------- ------------ ----------`
	`ARCH CLOSING 3956`
	`ARCH CONNECTED 0`
	`ARCH CLOSING 3955`
	`ARCH CLOSING 3957`
	`RFS IDLE 0`
	`RFS IDLE 3958`
	`MRP0 APPLYING_LOG 3958`
	
	`SQL> select open_mode from v$database;`
	`OPEN_MODE`
	`--------------------`
	`READ ONLY WITH APPLY`
		DBA

Set up data replication between Amazon RDS for MySQL and MySQL on Amazon EC2 using GTID

Rajesh Madiwale, Amazon Web Services

Summary

This pattern describes how to set up data replication on the Amazon Web Services (AWS) Cloud between an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance and a MySQL database on an Amazon Elastic Compute Cloud (Amazon EC2) instance by using MySQL native global transaction identifier (GTID) replication.

With GTIDs, transactions are identified and tracked when they are committed on the originating server and applied by replicas. You don't need to refer to log files when starting a new replica during failover.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Linux instance deployed

Restrictions

- This setup requires an internal team to run the read-only queries.
- The source and target MySQL versions must be the same.
- Replication is set up in the same AWS Region and virtual private cloud (VPC).

Product versions

- Amazon RDS versions 5.7.23 and later, which are the versions that support GTID

Architecture

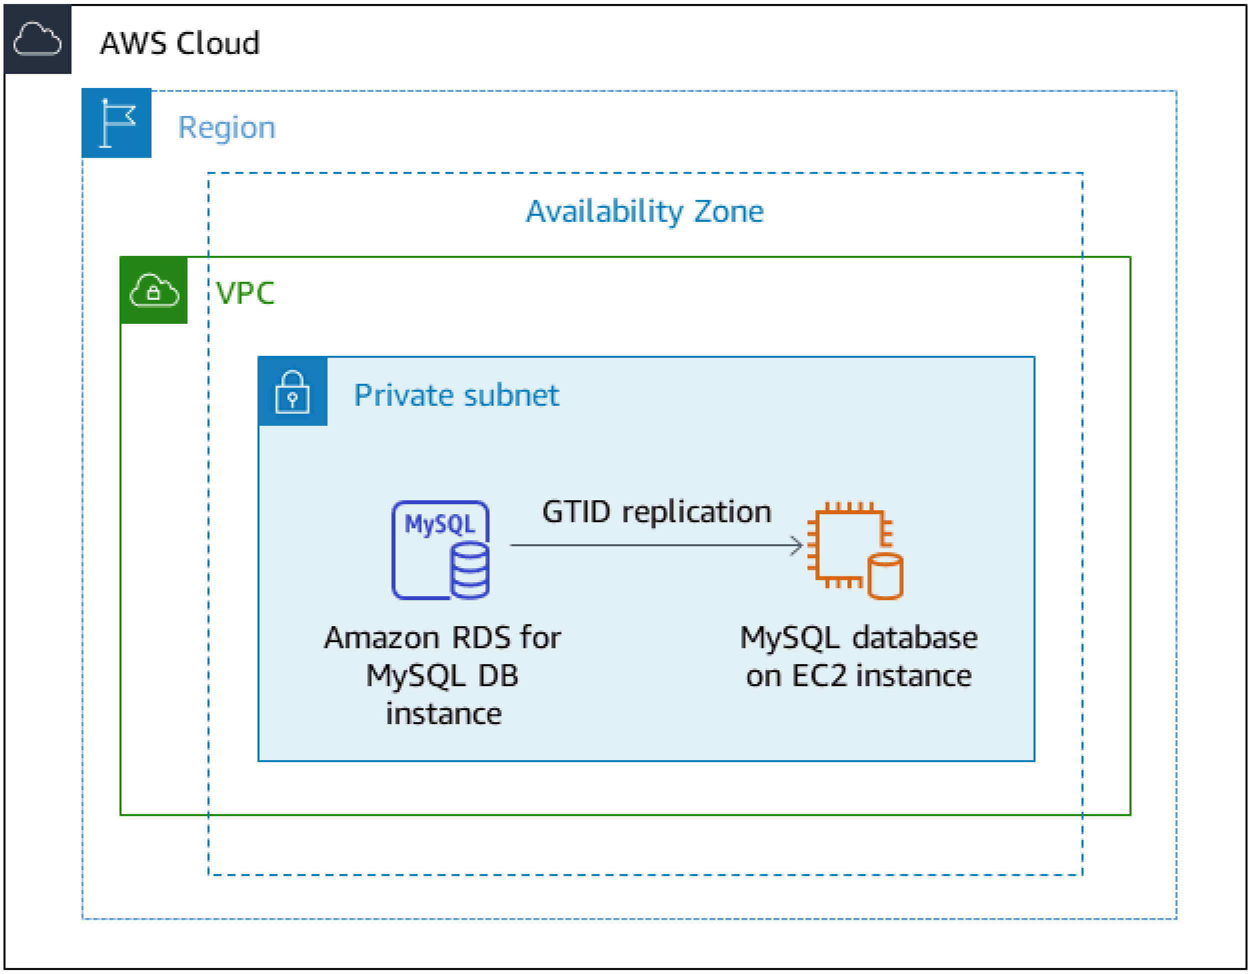
Source technology stack

- Amazon RDS for MySQL

Target technology stack

- MySQL on Amazon EC2

Target architecture



Tools

AWS services

- [Amazon Elastic Compute Cloud (Amazon EC2)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- [Amazon Relational Database Service (Amazon RDS) for MySQL](#) helps you set up, operate, and scale a MySQL relational database in the AWS Cloud.

Other services

- Global transaction identifiers (GTIDs) are unique identifiers generated for committed MySQL transactions.
- mysqldump is a client utility for performing logical backups by producing SQL statements that can be run to reproduce the source database object definitions and table data.
- mysql is the command-line client for MySQL.

Epics

Create and prepare the Amazon RDS for MySQL DB instance

Task	Description	Skills required
Create the RDS for MySQL instance.	To create the RDS for MySQL instance, follow the steps in the Amazon RDS documentation, using the parameter values that are covered in the next task.	DBA, DevOps engineer
Enable GTID-related settings in the DB parameter group.	Enable the following parameters in the Amazon RDS for MySQL DB parameter group. Set `enforce_gtid_consistency` to on, and set `gtid-mode` to on.	DBA
Reboot the Amazon RDS for MySQL instance.	A reboot is required for the parameter changes to take effect.	DBA
Create a user and grant it replication permissions.	To install MySQL, use the following commands.	DBA

Task	Description	Skills required
	``` CREATE USER 'repl'@'%' IDENTIFIED BY 'xxxx'; GRANT REPLICATI ON slave ON *.* TO 'repl'@'%' ; FLUSH PRIVILEGES; ```	

Install and prepare MySQL on the Amazon EC2 instance

Task	Description	Skills required
Install MySQL on Amazon Linux.	To install MySQL, use the following commands. ``` sudo yum update sudo wget https://d ev.mysql.com/get/m ysql57-community-r elease-el7-11.noar ch.rpm sudo yum localinstall mysql57-community- release-el7-11.noa rch.rpm sudo yum install mysql- community-server sudo systemctl start mysqld ```	DBA
Log in to MySQL on the EC2 instance and create the database.	The database name should be the same as the database name in Amazon RDS for MySQL. In the following example, the database name is `replication` .	DBA

Task	Description	Skills required
	`create database replication;`	

Edit the MySQL config file, and restart the database.	Edit the `my.conf` file that is located in `/etc/` by adding the following parameters.
	`server-id=3`
	`gtid_mode=ON`
	`enforce_gtid_consistency=ON`
	`replicate-ignore-db=mysql`
	`binlog-format=ROW`
	`log_bin=mysql-bin`
	Then restart the `mysqld` service.
	`systemctl mysqld restart`
		DBA

Set up replication

Task	Description	Skills required
Export the data dump from the Amazon RDS for MySQL database.	To export the dump from Amazon RDS for MySQL, use the following command. `mysqldump --single-transaction  -h mydb.xxxxxxx.amazonaws.com  -uadmin -p --databases replication > replication-db.sql`	DBA

Task	Description	Skills required
Restore the .sql dump file in the MySQL database on Amazon EC2.	To import the dump to the MySQL database on Amazon EC2, use the following command. `mysql -D replication -uroot -p < replication-db.sql`	DBA

Configure the MySQL database on Amazon EC2 as a replica.	To start the replication and to check the replication status, log in to the MySQL database on Amazon EC2, and use the following command.
	`CHANGE MASTER TO MASTER_HOST="mydb.xxxxxxx.amazonaws.com", MASTER_USER="repl", MASTER_PASSWORD="rep123", MASTER_PORT=3306, MASTER_AUTO_POSITION = 1;`
	`START SLAVE;`
	`SHOW SLAVE STATUS\G`
		DBA

Transition roles for an Oracle PeopleSoft application on Amazon RDS Custom for Oracle

sampath kathirvel, Amazon Web Services

Summary

To run the Oracle PeopleSoft enterprise resource planning (ERP) solution on Amazon Web Services (AWS), you can use Amazon Relational Database Service (Amazon RDS) or Amazon RDS Custom for Oracle, which supports legacy, custom, and packaged applications that require access to the underlying operating system (OS) and database environment. For key factors to consider when planning a migration, see Oracle database migration strategies in AWS Prescriptive Guidance.

This pattern focuses on the steps to perform an Oracle Data Guard switchover, or role transition, for a PeopleSoft application database running on Amazon RDS Custom as the primary database with a read replica database. The pattern includes steps to configure fast-start failover (FSFO). During this process, the databases in the Oracle Data Guard configuration continue to function in their new roles. Typical use cases for Oracle Data Guard switchover are disaster recovery (DR) drills, scheduled maintenance activities on databases, and Standby-First Patch Apply rolling patches. For more information, see the blog post Reduce database patching downtime in Amazon RDS Custom.

Prerequisites and limitations

Prerequisites

- Completion of the Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica pattern.

Limitations

- Limitations and unsupported configurations for RDS Custom for Oracle
- Limitations associated with Amazon RDS Custom for Oracle read replicas

Product versions

- For Oracle Database versions supported by Amazon RDS Custom, see RDS Custom for Oracle.
- For Oracle Database instance classes supported by Amazon RDS Custom, see DB instance class support for RDS Custom for Oracle.

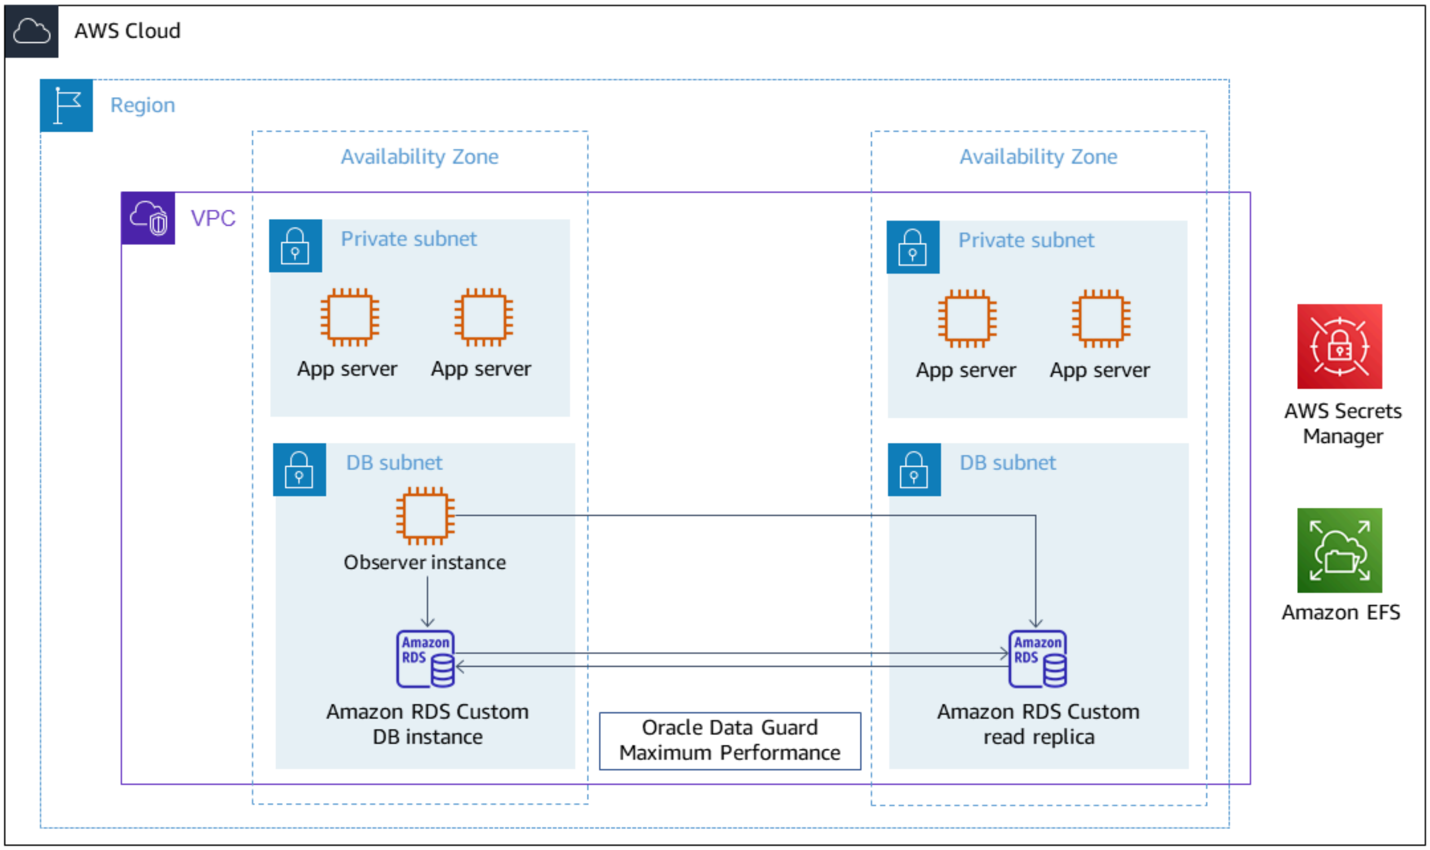
Architecture

Technology stack

- Amazon RDS Custom for Oracle

Target architecture

The following diagram shows an Amazon RDS Custom DB instance and an Amazon RDS Custom read replica. Oracle Data Guard provides role transition during failover for DR.



For a representative architecture using Oracle PeopleSoft on AWS, see [Set up a highly available PeopleSoft architecture on AWS](#).

Tools

AWS services

- [Amazon RDS Custom for Oracle](#) is a managed database service for legacy, custom, and packaged applications that require access to the underlying OS and database environment.

- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically. In this pattern, you retrieve the database user passwords from Secrets Manager for `RDS_DATAGUARD` with the secret name `do-not-delete-rds-custom-+<<RDS Resource ID>>+-dg`.

Other services

- [Oracle Data Guard](#) helps you create, maintain, manage, and monitor standby databases. This pattern uses Oracle Data Guard Maximum Performance for transitioning roles ([Oracle Data Guard switchover](#)).

Best practices

For your production deployment, we recommend launching the observer instance in a third Availability Zone, separate from the primary and read replica nodes.

Epics

Initiate role transition

Task	Description	Skills required
Pause database automation for both the primary and the replica.	Although the RDS Custom automation framework doesn't interfere with the role transition process, it's a good practice to pause automatio n during Oracle Data Guard switchover. To pause and resume RDS Custom database automatio n, follow the instructions at [Pausing and resuming RDS Custom automation](#).	Cloud administrator, DBA
Check the Oracle Data Guard status.	To check the Oracle Data Guard status, log in to the	DBA

Task	Description	Skills required

	primary database. This pattern includes code for using a multitenant container database (CDB) or a non-CDB instance.
	
	Non-CDB

Verify the instance role on the Amazon RDS console.	After you perform the role switch, the Amazon RDS console shows the new roles under the **Replication** section on the **Connectiv ity & Security** tab under **Databases**. It might take a few minutes for **Replication state** to update from empty to **Replicating**.	DBA

Configure FSFO

Task	Description	Skills required
Reset the switchover.	Set the switchover back to the primary node.	DBA
Install and start the observer.	An observer process is a DGMGRL client component , typically running in a different machine from the primary and standby	DBA

Task	Description	Skills required
	databases. The ORACLE HOME installation for the observer can be an Oracle Client Administrator installat ion, or you can install either Oracle Database Enterprise Edition or Personal Edition. For more information about observer installation for your database release, see Installin g and Starting the Observer. To configure high availabil ity for the observer process, you might want to do the following: • Enable EC2 instance automatic recovery for the EC2 instance running your observer. You need to automate the observer startup process as part of the OS startup. • Deploy an observer in the EC2 instance and configure an Amazon EC2 Auto Scaling group with size one (1). In the event of EC2 instance failure, the automatic scaling group automatically spins up another EC2 instance. For Oracle 12c Release 2 and later, you can deploy up to	

Task	Description	Skills required
	three observers. One observer is the primary observer, and the rest are backup observers . When the primary observer fails, one of the backup observers takes the primary role.	

Task	Description	Skills required

Connect to DGMGRL from the observer host.	The observer host is configured with `tnsnames.ora` entries for primary and standby database connectivity. You can enable FSFO with maximum performance protection mode as long as data loss is within the [FastStartFailoverLagLimit](#) configuration (value in seconds), However, you must use maximum availability protection mode to work to achieve zero data loss (RPO=0).

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Configure FastStartFailoverT hreshold for the connection to DGMGRL.</td><td>The default value is 30 seconds in Oracle 19c, and the minimum value is 6 seconds. A lower value can potentially shorten the recovery time objective (RTO) during the failover. A higher value helps reduce the chance of unnecessary failover transient errors on the primary database.

The RDS Custom for Oracle automation framework monitors database health and performs corrective actions every few seconds. Therefore, we recommend setting FastStartFailoverT hreshold to a value higher than 10 seconds. The following example configure s the threshold value at 35 seconds.

Non-CBD or CDB

<pre>DGMGRL> edit configura
tion set property
 FastStartFailoverT
hreshold=35;
Property "faststar
tfailoverthreshold"
 updated

Task	Description	Skills required
Verify the failover.	In this scenario, a failover test can be performed by manually stopping the primary EC2 instance. Before stopping the EC2 instance, use the `tail` command to monitor the observer log file based on your configura tion. Use `DGMGRL` to log in to standby database `orcl_d` with user `RDS_DATAGUARD` , and check the Oracle Data Guard status. It should show that `orcl_d` is the new primary database. **Note** In this failover testing scenario, `orcl_d` is the non-CDB database. Before failover, the flashback database has been enabled on `orcl_a`. After the former primary database returns online and starts in `MOUNT` state, the observer reinstate s it into a new standby database. The reinstated database acts as the FSFO target for the new primary	DBA

[W000 2023-01-1 8T07:55:57.701+00:00] Try to connect to the new standby orcl_a. ```	

Task	Description	Skills required
	`ORA-12170: TNS:Connect timeout occurred`	

Configure connectivity between the Oracle Peoplesoft application and the database

Task	Description	Skills required

Create and start the service in the primary database.	You can avoid application configuration changes during a role transition by using a TNS entry that contains both the primary and standby database endpoints in the configuration. You can define two role-based database services to support both read/write and read-only workloads. In the following example, `orcl_rw` is the read/write service that's active on the primary database. `orcl_ro` is the read-only service and is active on the standby database that has been opened in read-only mode.
	`SQL> select name,open_mode from v$database;`
	`NAME OPEN_MODE`
	`--------- --------- -----------`
	`ORCL READ WRITE`
	`SQL> exec dbms_service.create_service`
		DBA

Task	Description	Skills required

	<pre>('orcl_rw','orcl_r
	w');
	PL/SQL procedure
	 successfully completed
	.
	SQL> exec dbms_serv
	ice.create_service
	('orcl_ro','orcl_r
	o');
	PL/SQL procedure
	 successfully completed
	.
	
	SQL> exec dbms_serv
	ice.start_service(
	'orcl_rw');
	PL/SQL procedure
	 successfully completed
	.
	SQL></pre>	

Start the service in the standby database.	To start the service in the read-only standby database, use the following code.
	<pre>SQL> select name,open
	_mode from v$database;
	NAME OPEN_MODE
	--------- ---------
	----------- 	
	ORCL READ ONLY WITH
	 APPLY
	SQL> exec dbms_serv
	ice.start_service(
	'orcl_ro');
	PL/SQL procedure
	 successfully completed
	.
	SQL></pre>
		DBA

Task	Description	Skills required
Automate starting the service when the primary DB is restarted.	To automatically start the service in the primary database when it's restarted, use the following code. `SQL> CREATE OR REPLACE TRIGGER TrgDgServices after startup on database DECLARE db_role VARCHAR(30); db_open_mode VARCHAR(30); BEGIN SELECT DATABASE_ROLE, OPEN_MODE INTO db_role, db_open_mode FROM V$DATABASE; IF db_role = 'PRIMARY' THEN DBMS_SERV 2 ICE.START_SERVICE('orcl_rw'); END IF; IF db_role = 'PHYSICAL STANDBY' AND db_open_mode LIKE 'READ ONLY%' THEN DBMS_SERVICE.START_SERVICE('orcl_ro'); END IF; END; / Trigger created. SQL>`	DBA

Task	Description	Skills required

Configure a connection between the read/write and read-only databases.	You can use the following application-configuration example for the read/write and read-only connection.
	`ORCL_RW = (DESCRIPTION =`
	`(CONNECT_TIMEOUT= 120)(RETRY_COUNT=20)(RETRY_DELAY=3)(TRANSPORT_CONNECT_TIMEOUT=3)`
	`(ADDRESS_LIST =`
	`(ADDRESS = (PROTOCOL = TCP)(HOST=devpsftdb.******.us-west-2.rds.amazonaws.com)(PORT=1521))`
	`(ADDRESS = (PROTOCOL = TCP)(HOST=psftread.******.us-west-2.rds.amazonaws.com)(PORT=1521))`
	`)`
	`(CONNECT_DATA=(SERVICE_NAME = orcl_rw))`
	`)`
	`ORCL_RO = (DESCRIPTION =`
	`(CONNECT_TIMEOUT= 120)(RETRY_COUNT=20)(RETRY_DELAY=3)(TRANSPORT_CONNECT_TIMEOUT=3)`
	`(ADDRESS_LIST =`
	`(ADDRESS = (PROTOCOL = TCP)(HOST=devpsftdb.******.us-west-2.rds.amazonaws.com)(PORT=1521))`
		DBA

Task	Description	Skills required
	`(ADDRESS = (PROTOCOL = TCP)(HOST=psftread.******.us-west-2.rds.amazonaws.com)(PORT=1521)) ) (CONNECT_DATA=(SERVICE_NAME = orcl_ro)) )`

Unload data from an Amazon Redshift cluster across accounts to Amazon S3

Andrew Kamel, Amazon Web Services

Summary

When you test applications, it's helpful to have production data in your test environment. Using production data can give you a more accurate assessment of the application that you're developing.

This pattern extracts data from an Amazon Redshift cluster in a production environment to an Amazon Simple Storage Service (Amazon S3) bucket in a development environment on Amazon Web Services (AWS).

The pattern steps through the setup of both DEV and PROD accounts, including the following:

- Required resources
- AWS Identity and Access Management (IAM) roles
- Network adjustments to subnets, security groups, and the virtual private cloud (VPC) to support the Amazon Redshift connection
- An example AWS Lambda function with a Python runtime for testing the architecture

To grant access to the Amazon Redshift cluster, the pattern uses AWS Secrets Manager to store the relevant credentials. The benefit is having all the needed information to directly connect to the Amazon Redshift cluster without needing to know where the Amazon Redshift cluster resides. Additionally, you can monitor use of the secret.

The secret saved in Secrets Manager includes the Amazon Redshift cluster's host, database name, port, and relevant credentials.

For information about security considerations when using this pattern, see the Best practices section.

Prerequisites and limitations

Prerequisites

- An Amazon Redshift cluster running in the PROD account
- An S3 bucket created in the DEV account
- VPC peering between the DEV and PROD accounts, with route tables adjusted accordingly
- DNS hostnames and DNS resolution enabled for both peered VPCs

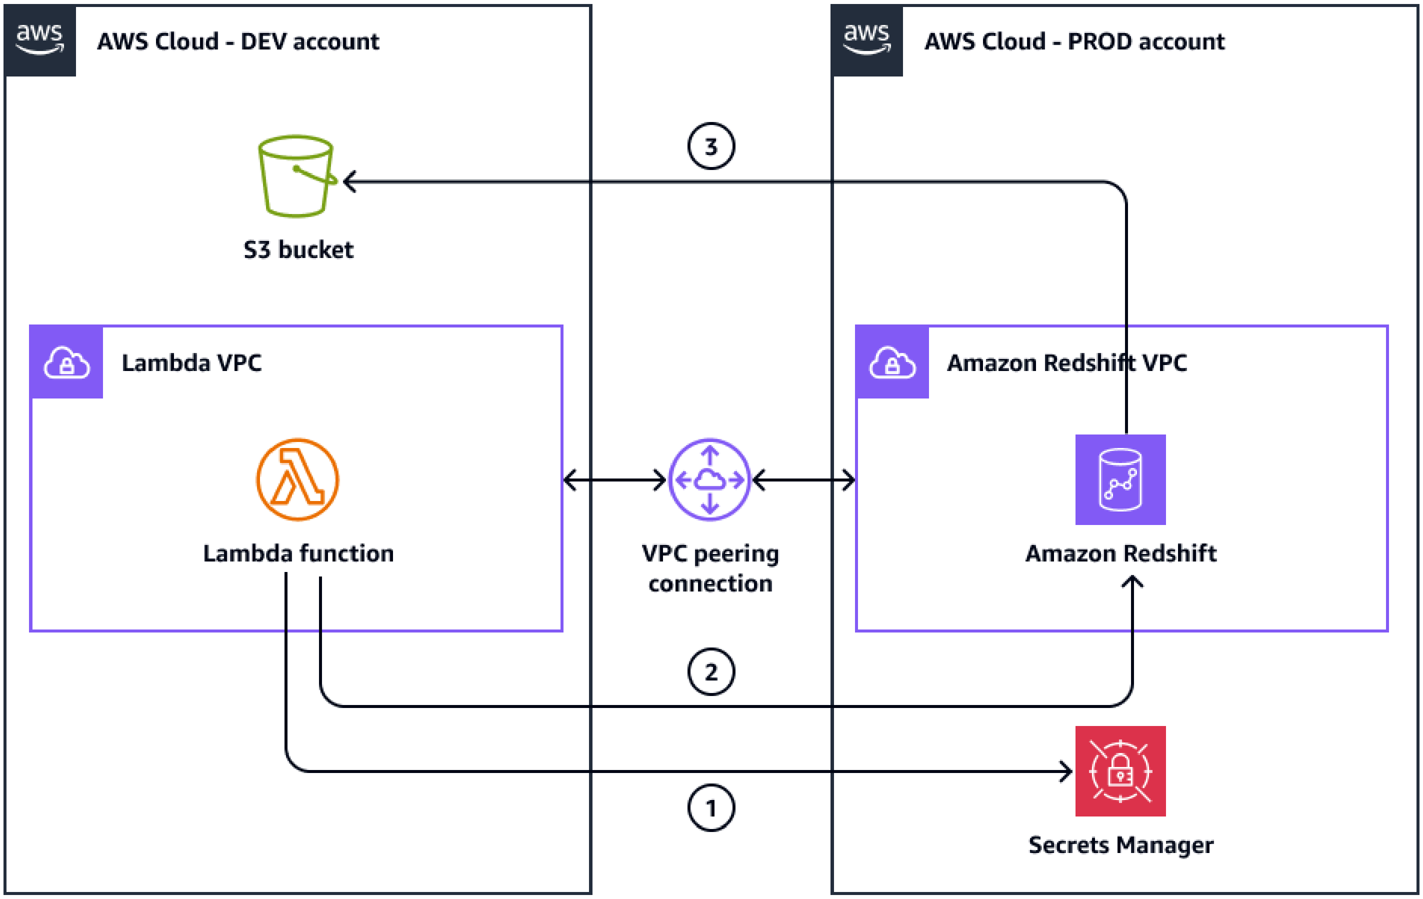
Limitations

- Depending on the amount of data that you want to query, the Lambda function might time out.

  If your run takes more time than the maximum Lambda timeout (15 minutes), use an asynchronous approach for your Lambda code. The code example for this pattern uses the psycopg2 library for Python, which doesn't currently support asynchronous processing.
- Some AWS services aren’t available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

The following diagram shows the target architecture, with DEV and PROD accounts.



The diagram shows the following workflow:

1. The Lambda function in the DEV account assumes the IAM role that's required to access the Amazon Redshift credentials in Secrets Manager in the PROD account.

   The Lambda function then retrieves the Amazon Redshift cluster secret.

2. The Lambda function in the DEV account uses the information to connect to the Amazon Redshift cluster in the PROD account through the peered VPCs.

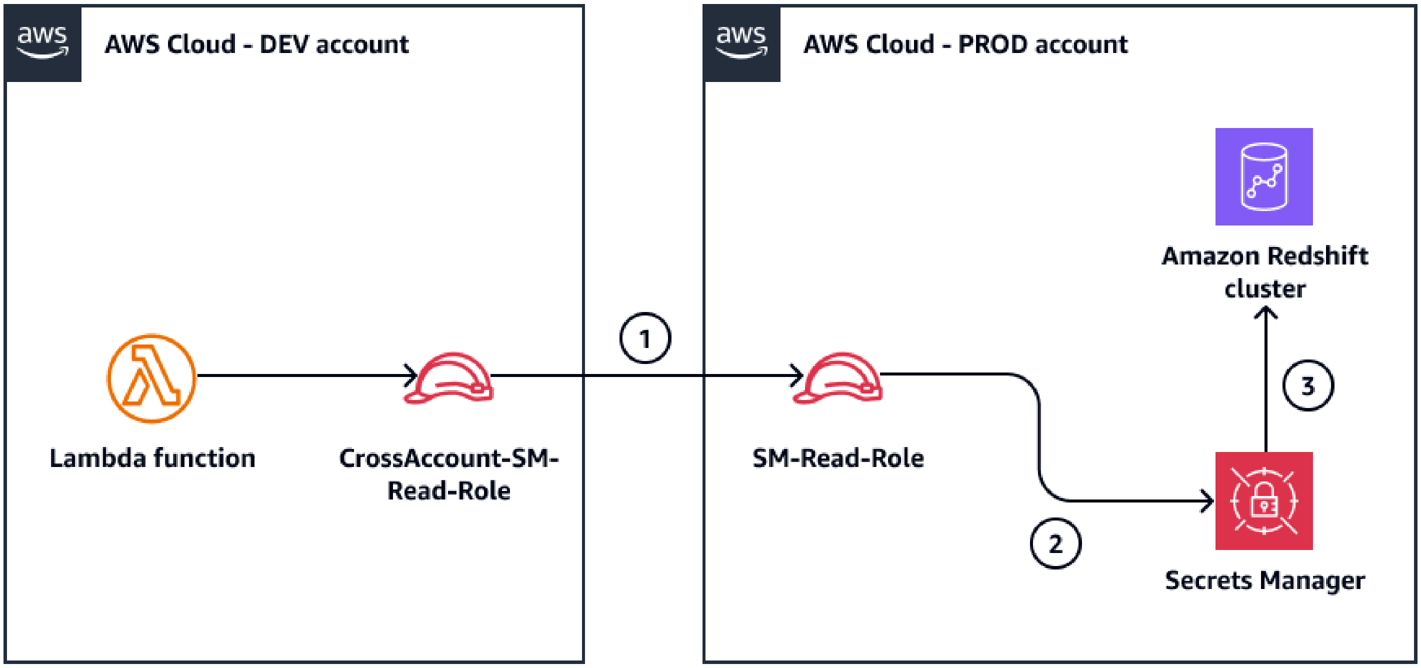
   The Lambda function then sends an unload command to query the Amazon Redshift cluster in the PROD account.

3. The Amazon Redshift cluster in the PROD account assumes the relevant IAM role to access the S3 bucket in the DEV account.

   The Amazon Redshift cluster unloads the queried data to the S3 bucket in the DEV account.

Querying data from Amazon Redshift

The following diagram shows the roles that are used to retrieve the Amazon Redshift credentials and connect to the Amazon Redshift cluster. The workflow is initiated by the Lambda function.

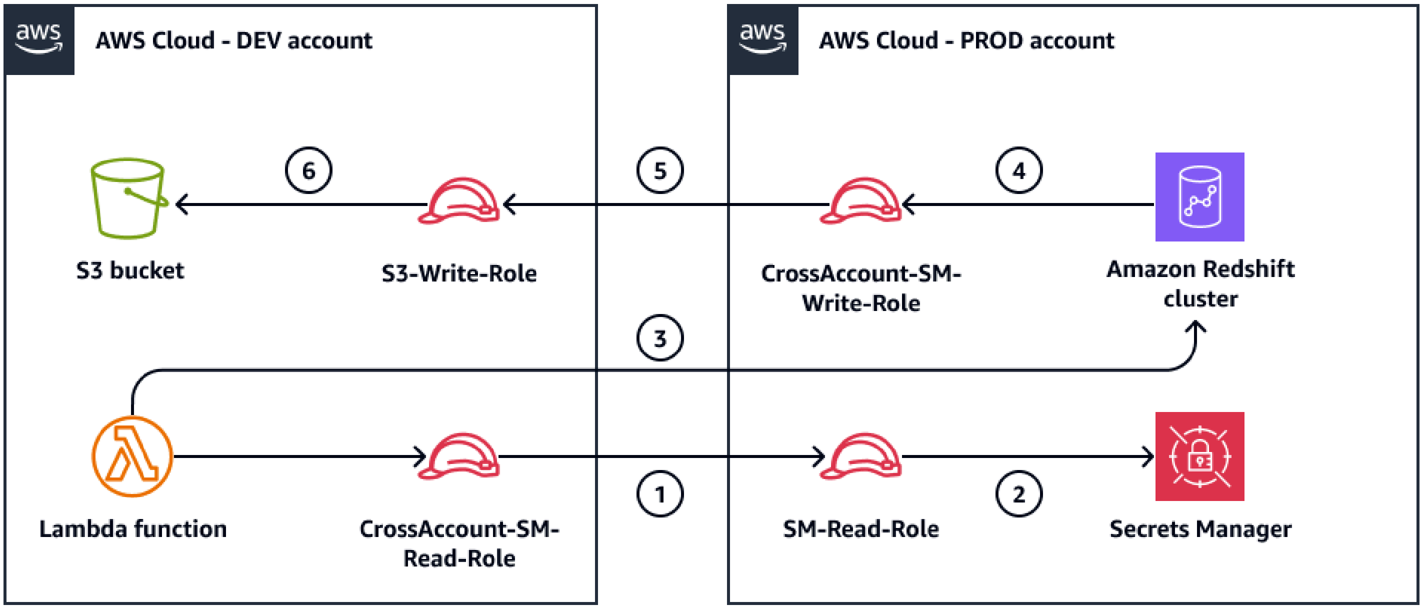


The diagram shows the following workflow:

1. The `CrossAccount-SM-Read-Role` in the DEV account assumes the `SM-Read-Role` in the PROD account.
2. The `SM-Read-Role` role uses the attached policy to retrieve the secret from Secrets Manager.
3. The credentials are used to access the Amazon Redshift cluster.

Uploading data to Amazon S3

The following diagram shows the cross-account read-write process for extracting data and uploading it to Amazon S3. The workflow is initiated by the Lambda function. The pattern chains IAM roles in Amazon Redshift. The unload command that comes from the Amazon Redshift cluster assumes the `CrossAccount-S3-Write-Role`, and then assumes the `S3-Write-Role`. This role chaining gives Amazon Redshift access to Amazon S3.



The workflow includes the following steps:

1. The `CrossAccount-SM-Read-Role` in the DEV account assumes the `SM-Read-Role` in the PROD account.
2. The `SM-Read-Role` retrieves the Amazon Redshift credentials from Secrets Manager.
3. The Lambda function connects to the Amazon Redshift cluster and sends a query.
4. The Amazon Redshift cluster assumes the `CrossAccount-S3-Write-Role`.
5. The `CrossAccount-S3-Write-Role` assumes the `S3-Write-Role` in the DEV account.
6. The query results are unloaded to the S3 bucket in the DEV account.

Tools

AWS services

- [AWS Key Management Service (AWS KMS)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Redshift](#) is a managed petabyte-scale data warehouse service in the AWS Cloud.

- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code repository

The code for this pattern is available in the GitHub unload-redshift-to-s3-python repository.

Best practices

Security disclaimer

Before you implement this solution, consider the following important security recommendations:

- Remember that connecting development and production accounts can increase the scope and lower overall security posture. We recommend deploying this solution only temporarily, extracting the required portion of data and then immediately destroying the deployed resources. To destroy the resources, you should delete the Lambda function, remove any IAM roles and policies created for this solution, and revoke any network access that was granted between the accounts.
- Consult your security and compliance teams before copying any data from production to development environments. Personally identifiable information (PII), Protected health information (PHI), and other confidential or regulated data should generally not be copied in this manner. Copy only publicly available, non-confidential information (for example, public stock data from a shop frontend). Consider tokenizing or anonymizing data, or generating synthetic test data, instead of using production data whenever possible. One of the AWS security principles is to keep people away from data. In other words, developers should not perform operations in the production account.
- Restrict access to the Lambda function in the development account because it can read data from the Amazon Redshift cluster in the production environment.
- To avoid disrupting the production environment, implement the following recommendations:
  - Use a separate, dedicated development account for testing and development activities.
  - Implement strict network access controls and limit traffic between accounts to only what is necessary.
  - Monitor and audit access to the production environment and data sources.
  - Implement least-privilege access controls for all resources and services involved.

  - Regularly review and rotate credentials, such as AWS Secrets Manager secrets and IAM role access keys.
- Refer to the following security documentation for the services used in this article:
  - AWS Lambda security
  - Amazon Redshift security
  - Amazon S3 security
  - AWS Secrets Manager security
  - IAM security best practices

Security is a top priority when accessing production data and resources. Always follow best practices, implement least-privilege access controls, and regularly review and update your security measures.

Epics

Query data from Amazon Redshift

Task	Description	Skills required
Create a secret for the Amazon Redshift cluster.	To create the secret for the Amazon Redshift cluster, do the following: 1. In the PROD account, sign in to the AWS Management Console, and open the Secrets Manager console at https://console.aws.amazon.com/secretsmanager/. 2. Choose **Store a new Secret**. 3. Select **Credentials for Amazon Redshift data warehouse**.	DevOps engineer

Task	Description	Skills required
	4. For **User name** and **Password**, enter values for your instance, and confirm or choose a value for **Encryption key**. 5. Choose the Amazon Redshift data warehouse that your secret will access. 6. Enter `Redshift-Creds-Secret` for the secret name. 7. Complete the remaining the creation steps with the default choices, and then choose **Store**. 8. View your secret, and note the **Secret ARN** value that was generated to identify the secret.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a role to access Secrets Manager.</td><td>To create the role, do the following:

1. In the PROD account, open the IAM console at https://console.aws.amazon.com/iam/.
2. Choose Policies.
3. Choose Create policy.
4. Choose the JSON tab, and then enter an IAM policy such as the following:
<pre>{
    "Version":
 "2012-10-17",
    "Statement": [
        {
            "Effect":
 "Allow",
            "Action":
 [

 "secretsmanager:Ge
tResourcePolicy",

 "secretsmanager:Ge
tSecretValue",

 "secretsmanager:De
scribeSecret",

 "secretsmanager:Li
stSecretVersionIds"
            ],
            "Resource
": [</pre></td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required

	``
	 "<Redshift-Creds-S
	ecret-ARN>"
	            ]
	        },
	        {
	            "Effect":
	 "Allow",
	            "Action":
	 "secretsmanager:Li
	stSecrets",
	            "Resource
	": "*"
	        }
	    ]
	}
	``
	Replace `Redshift-Creds-Secret-ARN` with the Amazon Resource Name (ARN) of the Secrets Manager secret that contains the information and credentials for the Amazon Redshift cluster.	

Upload data to Amazon S3

Task	Description	Skills required
Create a role to access the S3 bucket.	To create the role for accessing the S3 bucket, do the following: 1. In the DEV account, open the IAM console. 2. Choose **Policies**.	DevOps engineer

Task	Description	Skills required

	3. Choose **Create policy**.
	4. Choose the **JSON** tab, and then enter an IAM policy such as the following:
	<pre>{
	  "Version":
	 "2012-10-17",
	  "Statement": [
	    {
	      "Sid": "kmsstmt"
	,
	      "Effect":
	 "Allow",
	      "Action": [
	        "kms:Decr
	ypt",
	        "kms:Encr
	ypt",
	        "kms:Gene
	rateDataKey"
	      ],
	      "Resource": [
	        "<kms-key-
	arn>"
	      ]
	    },
	    {
	      "Sid":
	 "s3stmt",
	      "Effect":
	 "Allow",
	      "Action": [
	        "s3:PutOb
	ject",
	        "s3:Get*",
	        "s3:List*"
	      ],
	      "Resource": [
	        "arn:aws:
	s3:::mybucket",</pre>	

Task	Description	Skills required

	``
	        "arn:aws:
	s3:::mybucket/*"
	      ]
	    }
	  ]
	}
	``
	Replace `mybucket` with the name of the S3 bucket that you want to access. Also, if the S3 bucket is encrypted, replace `kms-key-arn` with the ARN of the AWS Key Management Service (AWS KMS) key used to encrypt the S3 bucket. Otherwise, you don't need the AWS KMS section in the policy.
	5. Choose **Review policy,** enter `S3-Write-Policy` as the policy name, and then choose **Create policy**.
	6. In the navigation pane, choose **Roles.**
	7. Choose **Create role**.
	8. For the trusted entity role, choose **Custom trust policy**.
	9. Choose **Next: Permissions**, and then select the **S3-Write-Policy** policy that you created.	

Task	Description	Skills required
	10. Enter `S3-Write-Role` as the role name, and then choose **Create role**.	

Task	Description	Skills required
Create the Amazon Redshift role.	To create the Amazon Redshift role, do the following: 1. In the PROD account, open the IAM console. 2. Choose **Policies**. 3. Choose **Create policy**. 4. Choose the **JSON** tab, and then enter an IAM policy such as the following: `{ "Version": "2012-10-17", "Statement": [ { "Sid": "CrossAccountPolicy", "Effect": "Allow", "Action": "sts:AssumeRole", "Resource": "S3-Write-Role-ARN" } ] }` Replace `S3-Write-Role-ARN` with the ARN for the `S3-Write-Role` in the DEV account. 5. Choose **Review policy,** enter `S3-Write-Role-`	DevOps engineer

Task	Description	Skills required
	`Assume-Policy` as the policy name, and then choose **Create policy**. 6. In the navigation pane, choose **Roles**, and then choose **Create role**. 7. Choose **AWS service** as your trusted entity type, and then choose **Redshift**, **Redshift - Customizable**. 8. Choose **Next: Permissions**, and then select the **S3-Write-Role-Assume-Policy** policy that you created. 9. Enter `CrossAccount-S3-Write-Role` as the role name, and then choose **Create role**. 10. Associate the IAM role with your Amazon Redshift cluster.	

Deploy the Lambda function

Task	Description	Skills required
Deploy the Lambda function.	To deploy a Lambda function in the peered VPC, do the following: 1. Open the Lambda console at https://console.aws.amazon.com/lambda/.	DevOps engineer

Task	Description	Skills required
	2. Choose **Functions**. 3. Choose **Create function**. 4. Under **Basic information**, for **Function name**, enter a name for your function. 5. For **Runtime**, choose **Python 3.8**. 6. Expand **Change default execution role**, and then do the following: a. Choose **Use an existing role**. b. For **Existing role**, select the **CrossAccount-RM-Read-Role** Lambda role that you created previously. 7. Expand **Advanced settings**, and do the following: a. Select the **Enable VPC** check box. b. For **VPC**, select the peered VPC in the DEV account. c. For **Subnets**, select the private subnet. d. For **Security groups**, select the default security group. 8. Choose **Create function.**	

Task	Description	Skills required
	9. Add the psycopg2 library as a layer to the Lambda function. **Note** You can use an already deployed layer from the psycopg2-lambda-layer repository. Make sure to use the URL based on your AWS Region and Python runtime.	

Test the architecture

Task	Description	Skills required

Import the required resources.	To import the required resources, run the following commands:
	
	`import ast`
	`import boto3`
	`import psycopg2`
	`import base64`
	`from botocore.exceptions import ClientError`
		App developer

Run the Lambda handler function.	The Lambda function uses AWS Security Token Service	App developer

Task	Description	Skills required

	(AWS STS) for cross-account access and temporary credential management. The function uses the AssumeRole API operation to temporarily assume the permissions of the `sm_read_role` IAM role.
	
	To run the Lambda function, use the following example code:
	
	`def lambda_handler(event, context):`
	`    sts_client = boto3.client('sts')`
	
	`    # Secrets Manager Configurations`
	`    secret_name = "redshift_creds"`
	`    sm_region = "eu-west-1"`
	`    sm_read_role = "arn:aws:iam::PROD_ACCOUNT_NUMBER:role/SM-Read-Role"`
	
	`    # S3 Bucket Configurations`
	`    s3_bucket_path = "s3://mybucket/"`
	`    s3_bucket_region = "eu-west-1"`
	`    s3_write_role = "arn:aws:iam::DEV_ACCOUNT_NUMBER:role/S3-Write-Role"`	

Task	Description	Skills required

	``
	    # Redshift Configura
	tions
	    sql_query = "select
	 * from category"
	    redshift_db = "dev"
	    redshift_s3_write_
	role = "arn:aws:
	iam::PROD_ACCOUNT_
	NUMBER:role/CrossA
	ccount-S3-Write-Role"
	
	    chained_s3_write_r
	ole = "%s,%s" %
	 (redshift_s3_write
	_role, s3_write_role)
	
	    assumed_role_objec
	t = sts_client.assume_
	role(
	        RoleArn=s
	m_read_role,
	        RoleSessi
	onName="CrossAccou
	ntRoleAssumption",
	        ExternalI
	d="YOUR_EXTERNAL_ID",
	    )
	    credentials =
	 assumed_role_objec
	t['Credentials']
	
	    secret_dict =
	 ast.literal_eval(g
	et_secret(credenti
	als, secret_name,
	 sm_region))
	    execute_query(secr
	et_dict, sql_query
	, s3_bucket_path,
	 chained_s3_write_r
	ole, s3_bucket_region,
	 redshift_db)
	``	

Task	Description	Skills required

	``
	    return {
	        'statusCode':
	200
	    }
	``	

Task	Description	Skills required

Get the secret.	To get the Amazon Redshift secret, use the following example code:
	
	`def get_secret(credentials, secret_name, sm_region):`
	`    # Create a Secrets Manager client`
	`    session = boto3.session.Session()`
	`    sm_client = session.client(`
	`        service_name='secretsmanager',`
	`        aws_access_key_id=credentials['AccessKeyId'],`
	`        aws_secret_access_key=credentials['SecretAccessKey'],`
	`        aws_session_token=credentials['SessionToken'],`
	`        region_name=sm_region`
	`    )`
	
	`    try:`
	`        get_secret_value_response = sm_client.get_secret_value(`
	`            SecretId=secret_name`
	`        )`
	`    except ClientError as e:`
	`        print(e)`
	`        raise e`
		App developer

Task	Description	Skills required

	<pre> else:
	        if 'SecretSt
	ring' in get_secre
	t_value_response:
	            return
	 get_secret_value_r
	esponse['SecretStr
	ing']
	        else:
	            return
	 base64.b64decode(g
	et_secret_value_re
	sponse['SecretBina
	ry'])</pre>	

Task	Description	Skills required

Run the unload command.	To unload the data to the S3 bucket, use the following example code.
	<pre>def execute_query(secr
	et_dict, sql_query
	, s3_bucket_path,
	 chained_s3_write_r
	ole, s3_bucket_region,
	 redshift_db):
	    conn_string =
	 "dbname='%s' port='%s'
	 user='%s' password=
	'%s' host='%s'" \
	                  %
	 (redshift_db,
	
	 secret_dict["port"],
	
	 secret_dict["usern
	ame"],
	
	 secret_dict["passw
	ord"],
	
	 secret_dict["host"])
	
	    con = psycopg2.
	connect(conn_string)
	
	    unload_command =
	 "UNLOAD ('{}') TO '{}'
	 IAM_ROLE '{}' DELIMITER
	 '|' REGION '{}';" \
	        .format(s
	ql_query,
	
	 s3_bucket_path +
	 str(datetime.datet
	ime.now()) + ".csv",</pre>
		App developer

Task	Description	Skills required

	<pre> chained_s3_write_r
	ole,
	
	 s3_bucket_region)
	
	    # Opening a cursor
	 and run query
	    cur = con.cursor()
	    cur.execute(unload
	_command)
	
	    print(cur.fetchone
	())
	    cur.close()
	    con.close()</pre>	

Clean up

Task	Description	Skills required
Delete the Lambda function.	To avoid incurring unplanned costs, remove the resources and the connection between the DEV and PROD accounts. To remove the Lambda function, do the following: 1. Open the AWS Lambda console at https://console.aws.amazon.com/lambda/. 2. Locate and select the Lambda function you created.	DevOps engineer

Task	Description	Skills required
	3. Choose **Actions**, and then choose **Delete**. 4. Confirm the deletion.	

Task	Description	Skills required

Remove the IAM roles and policies.	Remove the IAM roles and policies from the DEV and PROD accounts.
	
	In the DEV account, do the following:
	
	1. Open the IAM console.
	2. Delete the following roles:
	  • `S3-Write-Role`
	  • `CrossAccount-RM-Read-Role` (Lambda role)
	3. Delete the associated policies:
	  • `S3-Write-Policy`
	  • The CrossAccount policy for assuming PROD account roles
	
	In the PROD account, do the following:
	
	1. Open the IAM console.
	2. Delete the following roles:
	  • `SM-Read-Role`
	  • `CrossAccount-S3-Write-Role`
	3. Delete the associated policies:
	  • The CrossAccount policy for accessing Secrets Manager
		DevOps engineer

Task	Description	Skills required
	• `S3-Write-Role-Assume-Policy`	
Delete the secret in Secrets Manager.	To delete the secret, do the following: 1. In the PROD account, open the Secrets Manager console. 2. Locate and select the secret named `Redshift-Creds-Secret` . 3. Choose **Actions**, and then choose **Delete secret**. 4. Confirm the deletion.	DevOps engineer

Task	Description	Skills required
Remove VPC peering and security group rules.	To remove VPC peering and security group rules, do the following: 1. In the PROD account, open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. 2. Navigate to **Security Groups**. 3. Find the security group used by the Amazon Redshift cluster. 4. Edit the inbound rules, and remove the rule that allows connections from the DEV account's Lambda VPC. 5. Navigate to **VPC Peering Connections**, and delete the peering connection.	DevOps engineer
Remove data from the S3 bucket.	To remove the data from Amazon S3, do the following: 1. In the DEV account, open the Amazon S3 console at https://console.aws.amazon.com/s3/. 2. Locate the bucket you used for data storage. 3. Delete the objects within the bucket, or delete the entire bucket if it's no longer needed.	DevOps engineer

Task	Description	Skills required
Clean up AWS KMS keys.	If you created any custom AWS KMS keys for encryption, do the following: 1. Open the AWS KMS console at https://console.aws.amazon.com/kms/. 2. Locate any keys created for this pattern. 3. Schedule the keys for deletion. (There is a mandatory waiting period for key deletion).	DevOps engineer
Review and delete Amazon CloudWatch logs.	To delete the CloudWatch logs, do the following: 1. Open the CloudWatch console at https://console.aws.amazon.com/cloudwatch/. 2. Check for any log groups created by your Lambda function or Amazon Redshift cluster. 3. Delete these log groups if they are no longer needed.	DevOps engineer

Additional information

After you unload the data from Amazon Redshift to Amazon S3, you can analyze it by using Amazon Athena.

Amazon Athena is a big data query service that's beneficial when you need to access large volumes of data. You can use Athena without having to provision servers or databases. Athena supports complex queries, and you can run it on different objects.

As with most AWS services, the main benefit to using Athena is that it provides great flexibility in how you run queries without the added complexity. When you use Athena, you can query different data types, such as CSV and JSON, in Amazon S3 without changing the data type. You can query data from various sources, including outside AWS. Athena reduces complexity because you don't have to manage servers. Athena reads data directly from Amazon S3 without loading or changing the data before you run the query.

Database migration patterns by workload

Topics

- IBM
- Microsoft
- N/A
- Open source
- Oracle
- SAP

IBM

- Migrate a Db2 database from Amazon EC2 to Aurora MySQL-Compatible by using AWS DMS
- Migrate Db2 for LUW to Amazon EC2 by using log shipping to reduce outage time
- Migrate Db2 for LUW to Amazon EC2 with high availability disaster recovery
- Migrate from IBM Db2 on Amazon EC2 to Aurora PostgreSQL-Compatible using AWS DMS and AWS SCT
- Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2
- Stream data from IBM Db2, SAP, Sybase, and other databases to MongoDB Atlas on AWS

Microsoft

- Accelerate the discovery and migration of Microsoft workloads to AWS
- Access on-premises Microsoft SQL Server tables from Microsoft SQL Server on Amazon EC2 using linked servers
- Assess query performance for migrating SQL Server databases to MongoDB Atlas on AWS
- Automate database tasks in SQL Server Express edition running on Amazon EC2 by using AWS Lambda and Task Scheduler
- Change Python and Perl applications to support database migration from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition
- Configure read-only routing in an Always On availability group in SQL Server on AWS
- Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel and Python
- Deploy SQL Server failover cluster instances on Amazon EC2 and Amazon FSx by using Terraform
- Export a Microsoft SQL Server database to Amazon S3 by using AWS DMS
- Export Amazon RDS for SQL Server tables to an S3 bucket by using AWS DMS
- Implement SHA1 hashing for PII data when migrating from SQL Server to PostgreSQL
- Ingest and migrate EC2 Windows instances into an AWS Managed Services account
- Migrate a messaging queue from Microsoft Azure Service Bus to Amazon SQS
- Migrate a Microsoft SQL Server database from Amazon EC2 to Amazon DocumentDB by using AWS DMS
- Migrate a Microsoft SQL Server database to Aurora MySQL by using AWS DMS and AWS SCT
- Migrate a .NET application from Microsoft Azure App Service to AWS Elastic Beanstalk
- Migrate an on-premises Microsoft SQL Server database to Amazon EC2
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using linked servers
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using native backup and restore methods
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents

- Migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on Amazon EC2 running Linux
- Migrate data from Microsoft Azure Blob to Amazon S3 by using Rclone
- Migrate Microsoft SQL Server Always On availability group using AWS Application Migration Service
- Migrate an on-premises Microsoft SQL Server database to Amazon EC2 using Application Migration Service
- Migrate a relational database to MongoDB Atlas on AWS
- Migrate SQL Server to AWS using distributed availability groups
- Migrate Windows SSL certificates to an Application Load Balancer using ACM
- Rehost on-premises workloads in the AWS Cloud: migration checklist
- Resolve connection errors after migrating Microsoft SQL Server to the AWS Cloud
- Send notifications for an Amazon RDS for SQL Server database instance by using an on-premises SMTP server and Database Mail
- Set up a CI/CD pipeline for database migration by using Terraform
- Set up Multi-AZ infrastructure for a SQL Server Always On FCI by using Amazon FSx

N/A

- Create an approval process for firewall requests during a rehost migration to AWS
- Encrypt an existing Amazon RDS for PostgreSQL DB instance
- Estimate storage costs for an Amazon DynamoDB table
- Implement cross-Region disaster recovery with AWS DMS and Amazon Aurora

Open source

- Automatically generate a PynamoDB model and CRUD functions for Amazon DynamoDB by using a Python application
- Connect by using an SSH tunnel in pgAdmin
- Create application users and roles in Aurora PostgreSQL-Compatible
- Enable encrypted connections for PostgreSQL DB instances in Amazon RDS
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation
- Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools
- Migrate an on-premises MySQL database to Amazon EC2
- Migrate an on-premises MySQL database to Amazon RDS for MySQL
- Migrate an on-premises MySQL database to Aurora MySQL
- Migrate an on-premises PostgreSQL database to Aurora PostgreSQL
- Migrate a Couchbase Server database to Amazon EC2
- Migrate from IBM WebSphere Application Server to Apache Tomcat on Amazon EC2 with Auto Scaling
- Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS
- Migrate from Oracle GlassFish to AWS Elastic Beanstalk
- Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical
- Migrate on-premises Java applications to AWS using AWS App2Container
- Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3
- Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible
- Migrate Oracle functions and procedures that have more than 100 arguments to PostgreSQL
- Migrate Redis workloads to Redis Enterprise Cloud on AWS
- Monitor Amazon Aurora for instances without encryption
- Restart the AWS Replication Agent automatically without disabling SELinux after rebooting a RHEL source server
- Schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL by using Lambda and Secrets Manager
- Set up data replication between Amazon RDS for MySQL and MySQL on Amazon EC2 using GTID

- Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport
- Unload data from an Amazon Redshift cluster across accounts to Amazon S3

Oracle

- Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica
- Convert JSON Oracle queries into PostgreSQL database SQL
- Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL
- Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database
- Emulate Oracle PL/SQL associative arrays in Amazon Aurora PostgreSQL and Amazon RDS for PostgreSQL
- Estimate the Amazon RDS engine size for an Oracle database by using AWR reports
- Handle anonymous blocks in Dynamic SQL statements in Aurora PostgreSQL
- Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible
- Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT
- Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL in SSL mode by using AWS DMS
- Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication
- Migrate an Amazon RDS for Oracle DB instance to another VPC
- Migrate an on-premises Oracle database to Amazon EC2 by using Oracle Data Pump
- Migrate an on-premises Oracle database to Amazon OpenSearch Service using Logstash
- Migrate an on-premises Oracle database to Amazon RDS for MySQL using AWS DMS and AWS SCT
- Migrate an on-premises Oracle database to Amazon RDS for Oracle
- Migrate an on-premises Oracle database to Amazon RDS for Oracle by using direct Oracle Data Pump Import over a database link
- Migrate an on-premises Oracle database to Amazon RDS for Oracle using Oracle Data Pump
- Migrate an on-premises Oracle database to Amazon RDS for PostgreSQL by using an Oracle bystander and AWS DMS
- Migrate an on-premises Oracle database to Oracle on Amazon EC2
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for Oracle using AWS DMS

- Migrate an Oracle database to Amazon DynamoDB using AWS DMS
- Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters
- Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT
- Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT
- Migrate an Oracle JD Edwards EnterpriseOne database to AWS by using Oracle Data Pump and AWS DMS
- Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS
- Migrate an Oracle PeopleSoft database to AWS by using AWS DMS
- Migrate data from an on-premises Oracle database to Aurora PostgreSQL
- Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS
- Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate
- Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT
- Migrate from Oracle to Amazon DocumentDB using AWS DMS
- Migrate from Oracle WebLogic to Apache Tomcat (TomEE) on Amazon ECS
- Migrate function-based indexes from Oracle to PostgreSQL
- Migrate legacy applications from Oracle Pro*C to ECPG
- Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS
- Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database
- Migrate Oracle native functions to PostgreSQL using extensions
- Migrate Oracle PeopleSoft to Amazon RDS Custom
- Migrate Oracle ROWID functionality to PostgreSQL on AWS
- Migrate Oracle SERIALLY_REUSABLE pragma packages into PostgreSQL
- Migrate virtual generated columns from Oracle to PostgreSQL
- Monitor Oracle GoldenGate logs by using Amazon CloudWatch
- Replatform Oracle Database Enterprise Edition to Standard Edition 2 on Amazon RDS for Oracle
- Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database

- Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible
- Transition roles for an Oracle PeopleSoft application on Amazon RDS Custom for Oracle
- Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL

SAP

- Automatically back up SAP HANA databases using Systems Manager and EventBridge
- Migrate an on-premises SAP ASE database to Amazon EC2
- Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS
- Migrate SAP ASE on Amazon EC2 to Amazon Aurora PostgreSQL-Compatible using AWS SCT and AWS DMS
- Migrate SAP HANA to AWS using SAP HSR with the same hostname
- Reduce homogeneous SAP migration cutover time by using Application Migration Service
- Set up disaster recovery for SAP on IBM Db2 on AWS

More patterns

- Access an Amazon Neptune database from an Amazon EKS container
- Access, query, and join Amazon DynamoDB tables using Athena
- Aggregate data in Amazon DynamoDB for ML forecasting in Athena
- Allow EC2 instances write access to S3 buckets in AMS accounts
- Analyze and visualize nested JSON data with Amazon Athena and Amazon QuickSight
- Authenticate Microsoft SQL Server on Amazon EC2 using AWS Directory Service
- Automate backups for Amazon RDS for PostgreSQL DB instances by using AWS Batch
- Automatically archive items to Amazon S3 using DynamoDB TTL
- Automatically remediate unencrypted Amazon RDS DB instances and clusters
- Automatically stop and start an Amazon RDS DB instance using AWS Systems Manager Maintenance Windows
- Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9
- Build COBOL Db2 programs by using AWS Mainframe Modernization and AWS CodeBuild
- Build an enterprise data mesh with Amazon DataZone, AWS CDK, and AWS CloudFormation
- Change Python and Perl applications to support database migration from Microsoft SQL Server to Amazon Aurora PostgreSQL-Compatible Edition
- Convert and unpack EBCDIC data to ASCII on AWS by using Python
- Convert the Teradata NORMALIZE temporal feature to Amazon Redshift SQL
- Convert the Teradata RESET WHEN feature to Amazon Redshift SQL
- Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL
- Create application users and roles in Aurora PostgreSQL-Compatible
- Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel and Python
- Deliver DynamoDB records to Amazon S3 using Kinesis Data Streams and Firehose with AWS CDK
- Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing
- Develop advanced generative AI chat-based assistants by using RAG and ReAct prompting
- Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database
- Enable transparent data encryption in Amazon RDS for SQL Server
- Export a Microsoft SQL Server database to Amazon S3 by using AWS DMS
- Implement SHA1 hashing for PII data when migrating from SQL Server to PostgreSQL

- Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT
- Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible
- Manage credentials using AWS Secrets Manager
- Migrate a Db2 database from Amazon EC2 to Aurora MySQL-Compatible by using AWS DMS
- Migrate a Microsoft SQL Server database from Amazon EC2 to Amazon DocumentDB by using AWS DMS
- Migrate a Microsoft SQL Server database to Aurora MySQL by using AWS DMS and AWS SCT
- Migrate a self-hosted MongoDB environment to MongoDB Atlas on AWS
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL in SSL mode by using AWS DMS
- Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation
- Migrate an Amazon RDS DB instance to another VPC or account
- Migrate an Amazon RDS for Oracle database to another AWS account and AWS Region using AWS DMS for ongoing replication
- Migrate an Amazon RDS for Oracle DB instance to another VPC
- Migrate an Amazon Redshift cluster to an AWS Region in China
- Migrate an on-premises MariaDB database to Amazon RDS for MariaDB using native tools
- Migrate an on-premises Microsoft SQL Server database to Amazon EC2
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using linked servers
- Migrate an on-premises Microsoft SQL Server database to Amazon RDS for SQL Server using native backup and restore methods
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS DMS
- Migrate an on-premises Microsoft SQL Server database to Amazon Redshift using AWS SCT data extraction agents
- Migrate an on-premises Microsoft SQL Server database to Microsoft SQL Server on Amazon EC2 running Linux
- Migrate an on-premises MySQL database to Amazon EC2
- Migrate an on-premises MySQL database to Amazon RDS for MySQL
- Migrate an on-premises MySQL database to Aurora MySQL

- Migrate an on-premises Oracle database to Oracle on Amazon EC2
- Migrate an on-premises PostgreSQL database to Aurora PostgreSQL
- Migrate an on-premises SAP ASE database to Amazon EC2
- Migrate an on-premises ThoughtSpot Falcon database to Amazon Redshift
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for MariaDB using AWS DMS and AWS SCT
- Migrate an Oracle database from Amazon EC2 to Amazon RDS for Oracle using AWS DMS
- Migrate an Oracle database to Amazon DynamoDB using AWS DMS
- Migrate an Oracle database to Amazon RDS for Oracle by using Oracle GoldenGate flat file adapters
- Migrate an Oracle Database to Amazon Redshift using AWS DMS and AWS SCT
- Migrate an Oracle database to Aurora PostgreSQL using AWS DMS and AWS SCT
- Migrate an Oracle JD Edwards EnterpriseOne database to AWS by using Oracle Data Pump and AWS DMS
- Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS
- Migrate an Oracle PeopleSoft database to AWS by using AWS DMS
- Migrate a Couchbase Server database to Amazon EC2
- Migrate data from an on-premises Oracle database to Aurora PostgreSQL
- Migrate data to the AWS Cloud by using Starburst
- Migrate Db2 for LUW to Amazon EC2 by using log shipping to reduce outage time
- Migrate Db2 for LUW to Amazon EC2 with high availability disaster recovery

- Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL
- Migrate from Couchbase Server to Couchbase Capella on AWS
- Migrate from IBM Db2 on Amazon EC2 to Aurora PostgreSQL-Compatible using AWS DMS and AWS SCT
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS
- Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS
- Migrate from Oracle Database to Amazon RDS for PostgreSQL by using Oracle GoldenGate
- Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT
- Migrate from Oracle to Amazon DocumentDB using AWS DMS
- Migrate from PostgreSQL on Amazon EC2 to Amazon RDS for PostgreSQL using pglogical
- Migrate from SAP ASE to Amazon RDS for SQL Server using AWS DMS
- Migrate function-based indexes from Oracle to PostgreSQL
- Migrate legacy applications from Oracle Pro*C to ECPG
- Migrate an on-premises Microsoft SQL Server database to Amazon EC2 using Application Migration Service
- Migrate on-premises Cloudera workloads to Cloudera Data Platform on AWS
- Migrate on-premises MySQL databases to Aurora MySQL using Percona XtraBackup, Amazon EFS, and Amazon S3
- Migrate Oracle Business Intelligence 12c to the AWS Cloud from on-premises servers
- Migrate Oracle CLOB values to individual rows in PostgreSQL on AWS
- Migrate Oracle Database error codes to an Amazon Aurora PostgreSQL-Compatible database
- Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible
- Migrate Oracle native functions to PostgreSQL using extensions
- Migrate Oracle PeopleSoft to Amazon RDS Custom
- Migrate Oracle ROWID functionality to PostgreSQL on AWS
- Migrate Oracle SERIALLY_REUSABLE pragma packages into PostgreSQL
- Migrate Redis workloads to Redis Enterprise Cloud on AWS
- Migrate a relational database to MongoDB Atlas on AWS
- Migrate SAP ASE on Amazon EC2 to Amazon Aurora PostgreSQL-Compatible using AWS SCT and AWS DMS

- Migrate virtual generated columns from Oracle to PostgreSQL
- Set up a minimum viable data space to share data between organizations
- Monitor Amazon ElastiCache clusters for at-rest encryption
- Monitor ElastiCache clusters for security groups
- Query Amazon DynamoDB tables with SQL by using Amazon Athena
- Reduce homogeneous SAP migration cutover time by using Application Migration Service
- Rotate database credentials without restarting containers
- Run message-driven workloads at scale by using AWS Fargate
- Secure and streamline user access in a Db2 federation database on AWS by using trusted contexts
- Set up a highly available PeopleSoft architecture on AWS
- Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible
- Stream data from IBM Db2, SAP, Sybase, and other databases to MongoDB Atlas on AWS
- Streamline PostgreSQL deployments on Amazon EKS by using PGO
- Transfer large-scale Db2 z/OS data to Amazon S3 in CSV files
- Transport PostgreSQL databases between two Amazon RDS DB instances using pg_transport
- Validate database objects after migrating from Oracle to Amazon Aurora PostgreSQL
- Verify that new Amazon Redshift clusters launch in a VPC

Storage & backup

Topics

- Allow EC2 instances write access to S3 buckets in AMS accounts
- Automate data stream ingestion into a Snowflake database by using Snowflake Snowpipe, Amazon S3, Amazon SNS, and Amazon Data Firehose
- Automatically encrypt existing and new Amazon EBS volumes
- Back up Sun SPARC servers in the Stromasys Charon-SSP emulator on the AWS Cloud
- Back up and archive data to Amazon S3 with Veeam Backup & Replication
- Configure Veritas NetBackup for VMware Cloud on AWS
- Copy data from an S3 bucket to another account and Region by using the AWS CLI
- Copy data from an S3 bucket to another account and Region by using S3 Batch Replication
- Migrate data from an on-premises Hadoop environment to Amazon S3 using DistCp with AWS PrivateLink for Amazon S3
- More patterns

Allow EC2 instances write access to S3 buckets in AMS accounts

Mansi Suratwala, Amazon Web Services

Summary

AWS Managed Services (AMS) helps you operate your AWS infrastructure more efficiently and securely. AMS accounts have security guardrails for standardized administration of your AWS resources. One guardrail is that default Amazon Elastic Compute Cloud (Amazon EC2) instance profiles don't allow write access to Amazon Simple Storage Service (Amazon S3) buckets. However, your organization might have multiple S3 buckets and require more control over access by EC2 instances. For example, you might want to store database backups from EC2 instances in an S3 bucket.

This pattern explains how to use requests for change (RFCs) to allow your EC2 instances write access to S3 buckets in your AMS account. An RFC is a request created by you or AMS to make a change in your managed environment and that includes a change type (CT) ID for a particular operation.

Prerequisites and limitations

Prerequisites

- An AMS Advanced account. For more information about this, see AMS operations plans in the AMS documentation.
- Access to the AWS Identity and Access Management (IAM) `customer-mc-user-role` role to submit RFCs.
- AWS Command Line Interface (AWS CLI), installed and configured with the EC2 instances in your AMS account.
- An understanding of how to create and submit RFCs in AMS. For more information about this, see What are AMS change types? in the AMS documentation.
- An understanding of manual and automated change types (CTs). For more information about this, see Automated and manual CTs in the AMS documentation.

Architecture

Technology stack

- AMS
- AWS CLI
- Amazon EC2
- Amazon S3
- IAM

Tools

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Managed Services (AMS) helps you operate your AWS infrastructure more efficiently and securely.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

Epics

Create an S3 bucket with an RFC

Task	Description	Skills required
Create an S3 bucket by using an automated RFC.	1. Sign in to your AMS account, choose the **Choose change type** page, choose **RFCs**, and then choose **Create RFC**. 2. Submit the **Create S3 Bucket** automated RFC.	AWS systems administrator, AWS developer

Task	Description	Skills required
	Note Make sure that you record the S3 bucket's name.	

Create an IAM instance profile and associate it with the EC2 instances

Task	Description	Skills required
Submit a manual RFC to create an IAM role.	When an AMS account is onboarded, a default IAM instance profile named `customer-mc-ec2-instance-profile` is created and associated with each EC2 instance in your AMS account. However, the instance profile doesn't have write permissions to your S3 buckets. To add the write permissions, submit the **Create IAM Resource** manual RFC to create an IAM role that has the following three policies: `customer_ec2_instance_`, `customer_deny_policy`, and `customer_ec2_s3_integration_policy`.	AWS systems administrator, AWS developer

Task	Description	Skills required
	Important The `customer_ec2_instance_` and `customer_deny_policy` policies already exist in your AMS account. However, you need to create `customer_ec2_s3_integration_policy` by using the following sample policy:	

```
{
  "Version": "2012-10-
17",
   "Statement": [
    {
      "Sid": "",
       "Effect":
 "Allow",
       "Principal": {
         "Service":
 "ec2.amazonaws.com"
      },
       "Action":
 "sts:AssumeRole"
    }
  ]
}

Role Permissions:
{
```

Task	Description	Skills required

	``
	    "Version":
	 "2012-10-17",
	    "Statement": [
	        {
	            "Action": [
	
	 "s3:ListBucket",
	
	 "s3:GetBucketLocat
	ion"
	            ],
	            "Resource
	": "arn:aws:s3:::",
	            "Effect":
	 "Allow"
	        },
	        {
	            "Action": [
	
	 "s3:GetObject",
	
	 "s3:PutObject",
	
	 "s3:ListMultipartU
	ploadParts",
	
	 "s3:AbortMultipart
	Upload"
	            ],
	            "Resource
	": "arn:aws:s3:::/*",
	            "Effect":
	 "Allow"
	        }
	    ]
	}
	``	

Task	Description	Skills required
Submit a manual RFC to replace the IAM instance profile.	Submit a manual RFC to associate the target EC2 instances with the new IAM instance profile.	AWS systems administrator, AWS developer
Test a copy operation to the S3 bucket.	Test a copy operation to the S3 bucket by running the following command in the AWS CLI: `aws s3 cp test.txt s3://<S3 bucket>/test2.txt`	AWS systems administrator, AWS developer

Related resources

- Create an IAM instance profile for your Amazon EC2 instances
- Creating an S3 bucket (using the Amazon S3 console, AWS SDKs, or AWS CLI)

Automate data stream ingestion into a Snowflake database by using Snowflake Snowpipe, Amazon S3, Amazon SNS, and Amazon Data Firehose

Bikash Chandra Rout, Amazon Web Services

Summary

This pattern describes how you can use services on the Amazon Web Services (AWS) Cloud to process a continuous stream of data and load it into a Snowflake database. The pattern uses Amazon Data Firehose to deliver the data to Amazon Simple Storage Service (Amazon S3), Amazon Simple Notification Service (Amazon SNS) to send notifications when new data is received, and Snowflake Snowpipe to load the data into a Snowflake database.

By following this pattern, you can have continuously generated data available for analysis in seconds, avoid multiple manual `COPY` commands, and have full support for semi-structured data on load.

Prerequisites and limitations

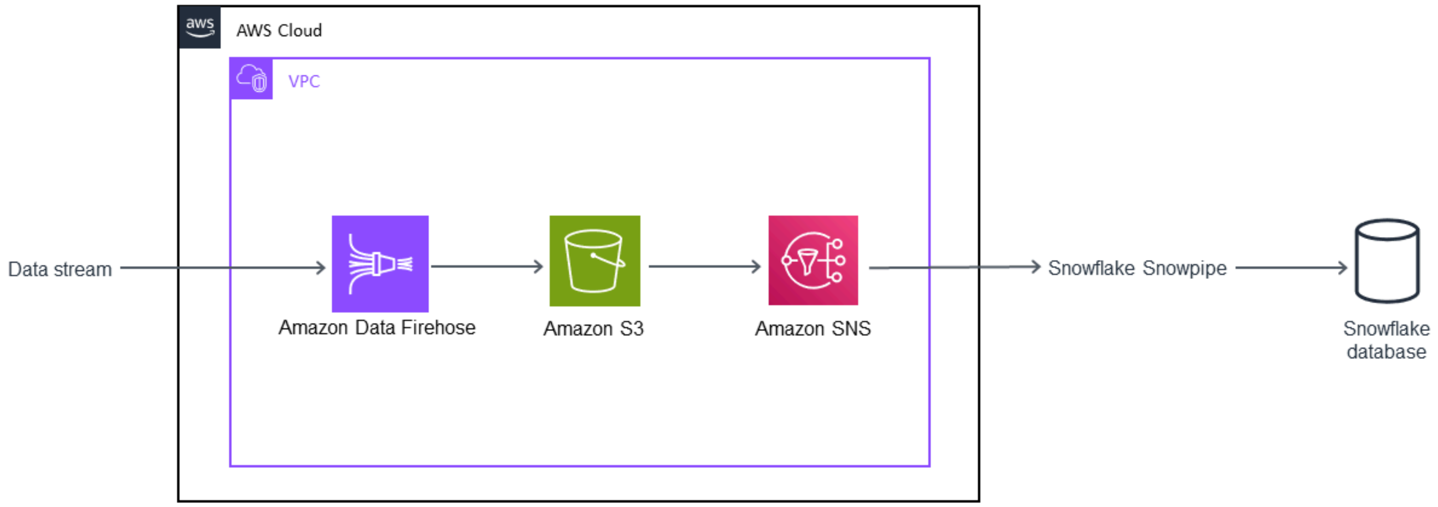
Prerequisites

- An active AWS account.
- A data source that is continuously sending data to a Firehose delivery stream.
- An existing S3 bucket that is receiving the data from the Firehose delivery stream.
- An active Snowflake account.

Limitations

- Snowflake Snowpipe doesn't connect directly to Firehose.

Architecture



Technology stack

- Amazon Data Firehose
- Amazon SNS
- Amazon S3
- Snowflake Snowpipe
- Snowflake database

Tools

- Amazon Data Firehose is a fully managed service for delivering real-time streaming data to destinations such as Amazon S3, Amazon Redshift, Amazon OpenSearch Service, Splunk, and any custom HTTP endpoint or HTTP endpoints owned by supported third-party service providers.
- Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages to subscribing endpoints or clients.
- Snowflake – Snowflake is an analytic data warehouse provided as Software-as-a-Service (SaaS).
- Snowflake Snowpipe – Snowpipe loads data from files as soon as they're available in a Snowflake stage.

Epics

Set up a Snowflake Snowpipe

Task	Description	Skills required
Create a CSV file in Snowflake .	Sign in to Snowflake and run the `CREATE FILE FORMAT` command to create a CSV file with a specified field delimiter . For more information about this and other Snowflake commands, see the [Additional information](#) section.	Developer
Create an external Snowflake stage.	Run the `CREATE STAGE` command to create an external Snowflake stage that references the CSV file you created earlier. Important: You will need the URL for the S3 bucket, your AWS access key, and your AWS secret access key. Run the `SHOW STAGES` command to verify that the Snowflake stage is created.	Developer
Create the Snowflake target table.	Run the `CREATE TABLE` command to create the Snowflake table.	Developer
Create a pipe.	Run the `CREATE PIPE` command; make sure that `auto_ingest=true` is in the command. Run the `SHOW PIPES` command to verify that the pipe is created. Copy	Developer

Task	Description	Skills required
	and save the `notification_channel` column value. This value will be used to configure Amazon S3 event notifications.	

Configure the S3 bucket

Task	Description	Skills required
Create a 30-day lifecycle policy for the S3 bucket.	Sign in to the AWS Management Console and open the Amazon S3 console. Choose the S3 bucket that contains the data from Firehose. Then choose the **Management** tab in the S3 bucket and choose **Add lifecycle rule**. Enter a name for your rule in the **Lifecycle rule** dialog box, and configure a 30-day lifecycle rule for your bucket. For help with this and other stories, see the Related resources section.	System Administrator, Developer
Create an IAM policy for the S3 bucket.	Open the AWS Identity and Access Management (IAM) console and choose **Policies**. Choose **Create policy**, and choose the **JSON** tab. Copy and paste the policy from the Additional information section into the JSON field. This policy will grant	System Administrator, Developer

Task	Description	Skills required
	`PutObject` and `DeleteObject` permissions, as well as `GetObject`, `GetObjectVersion`, and `ListBucket` permissions. Choose **Review policy**, enter a policy name, and then choose **Create policy**.	
Assign the policy to an IAM role.	Open the IAM console, choose **Roles**, and then choose **Create role**. Choose **Another AWS account** as the trusted entity. Enter your AWS account ID, and choose **Require external ID**. Enter a placeholder ID that you will change it later. Choose **Next**, and assign the IAM policy you created earlier. Then create the IAM role.	System Administrator, Developer
Copy the Amazon Resource Name (ARN) for the IAM role.	Open the IAM console, and choose **Roles**. Choose the IAM role you created earlier, and then copy and store the **Role ARN**.	System Administrator, Developer

Set up a storage integration in Snowflake

Task	Description	Skills required
Create a storage integration in Snowflake.	Sign in to Snowflake and run the `CREATE STORAGE INTEGRATION` command.	System Administrator, Developer

Task	Description	Skills required
	This will modify the trusted relationship, grant access to Snowflake, and provide the external ID for your Snowflake stage.	
Retrieve the IAM role for your Snowflake account.	Run the `DESC INTEGRATION` command to retrieve the ARN for the IAM role. **Important** `<integration_name>` is the name of the Snowflake storage integration you created earlier.	System Administrator, Developer
Record two column values.	Copy and save the values for the `storage_aws_iam_user_arn` and `storage_aws_external_id` columns.	System Administrator, Developer

Allow Snowflake Snowpipe to access the S3 bucket

Task	Description	Skills required
Modify the IAM role policy.	Open the IAM console and choose **Roles**. Choose the IAM role you created earlier and choose the **Trust relationships** tab. Choose **Edit trust relationship**. Replace	System Administrator, Developer

Task	Description	Skills required
	`snowflake_external_id` with the `storage_aws_external_id` value you copied earlier. Replace `snowflake_user_arn` with the `storage_aws_iam_user_arn` value you copied earlier. Then choose **Update trust policy**.	

Turn on and configure SNS notifications for the S3 bucket

Task	Description	Skills required
Turn on event notifications for the S3 bucket.	Open the Amazon S3 console and choose your bucket. Choose **Properties**, and under **Advanced setting**s, choose **Events**. Choose **Add notification**, and enter a name for this event. If you don't enter a name, a globally unique identifier (GUID) will be used.	System Administrator, Developer
Configure Amazon SNS notifications for the S3 bucket.	Under **Events**, choose **ObjectCreate (All)**, and then choose **SQS Queue** in the **Send to** dropdown list. In the **SNS** list, choose **Add SQS queue ARN**, and paste the `notification_channel` value you copied earlier. Then choose **Save**.	System Administrator, Developer

Task	Description	Skills required
Subscribe the Snowflake SQS queue to the SNS topic.	Subscribe the Snowflake SQS queue to the SNS topic you created. For help with this step, see the Related resources section.	System Administrator, Developer

Check the Snowflake stage integration

Task	Description	Skills required
Check and test Snowpipe.	Sign in to Snowflake and open the Snowflake stage. Drop files into your S3 bucket and check if the Snowflake table loads them. Amazon S3 will send SNS notifications to Snowpipe when new objects appear in the S3 bucket.	System Administrator, Developer

Related resources

- Managing your storage lifecycle
- Subscribe the Snowflake SQS Queue to the Amazon SNS Topic

Additional information

Create a file format:

```
CREATE FILE FORMAT <name>
TYPE = 'CSV'
FIELD_DELIMITER = '|'
SKIP_HEADER = 1;
```

Create an external stage:

```
externalStageParams (for Amazon S3) ::=
  URL = 's3://[//]'

  [ { STORAGE_INTEGRATION =  } | { CREDENTIALS = ( {  { AWS_KEY_ID = `` AWS_SECRET_KEY
 = `` [ AWS_TOKEN = `` ] } | AWS_ROLE = ``  } ) ) }` ]
  [ ENCRYPTION = ( [ TYPE = 'AWS_CSE' ] [ MASTER_KEY = '' ] |
                   [ TYPE = 'AWS_SSE_S3' ] |
                   [ TYPE = 'AWS_SSE_KMS' [ KMS_KEY_ID = '' ] |
                   [ TYPE = NONE ] )
```

Create a table:

```
CREATE [ OR REPLACE ] [ { [ LOCAL | GLOBAL ] TEMP[ORARY] | VOLATILE } | TRANSIENT ]
 TABLE [ IF NOT EXISTS ]
  <table_name>
    ( <col_name> <col_type> [ { DEFAULT <expr>
                               | { AUTOINCREMENT | IDENTITY } [ ( <start_num> ,
 <step_num> ) | START <num> INCREMENT <num> ] } ]
                                /* AUTOINCREMENT / IDENTITY supported only for numeric
 data types (NUMBER, INT, etc.) */
                            [ inlineConstraint ]
      [ , <col_name> <col_type> ... ]
      [ , outoflineConstraint ]
      [ , ... ] )
  [ CLUSTER BY ( <expr> [ , <expr> , ... ] ) ]
  [ STAGE_FILE_FORMAT = ( { FORMAT_NAME = '<file_format_name>'
                           | TYPE = { CSV | JSON | AVRO | ORC | PARQUET | XML }
 [ formatTypeOptions ] } ) ]
  [ STAGE_COPY_OPTIONS = ( copyOptions ) ]
  [ DATA_RETENTION_TIME_IN_DAYS = <num> ]
  [ COPY GRANTS ]
  [ COMMENT = '<string_literal>' ]
```

Show stages:

```
SHOW STAGES;
```

Create a pipe:

```
CREATE [ OR REPLACE ] PIPE [ IF NOT EXISTS ]
  [ AUTO_INGEST = [ TRUE | FALSE ] ]
  [ AWS_SNS_TOPIC =  ]
```

```
  [ INTEGRATION = '' ]
  [ COMMENT = '' ]
  AS
```

Show pipes:

```
SHOW PIPES [ LIKE '<pattern>' ]
           [ IN { ACCOUNT | [ DATABASE ] <db_name> | [ SCHEMA ] <schema_name> } ]
```

Create a storage integration:

```
CREATE STORAGE INTEGRATION <integration_name>
  TYPE = EXTERNAL_STAGE
  STORAGE_PROVIDER = S3
  ENABLED = TRUE
  STORAGE_AWS_ROLE_ARN = '<iam_role>'
  STORAGE_ALLOWED_LOCATIONS = ('s3://<bucket>/<path>/', 's3://<bucket>/<path>/')
  [ STORAGE_BLOCKED_LOCATIONS = ('s3://<bucket>/<path>/', 's3://<bucket>/<path>/') ]
```

Example:

```
create storage integration s3_int
  type = external_stage
  storage_provider = s3
  enabled = true
  storage_aws_role_arn = 'arn:aws:iam::001234567890:role/myrole'
  storage_allowed_locations = ('s3://amzn-s3-demo-bucket1/mypath1/', 's3://amzn-s3-
demo-bucket2/mypath2/')
  storage_blocked_locations = ('s3://amzn-s3-demo-bucket1/mypath1/sensitivedata/',
 's3://amzn-s3-demo-bucket2/mypath2/sensitivedata/');
```

For more information about this step, see Configuring a Snowflake storage integration to access Amazon S3 from the Snowflake documentation.

Describe an integration:

```
DESC INTEGRATION <integration_name>;
```

S3 bucket policy:

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": [
              "s3:PutObject",
              "s3:GetObject",
              "s3:GetObjectVersion",
              "s3:DeleteObject",
              "s3:DeleteObjectVersion"
            ],
            "Resource": "arn:aws:s3:::/*"
        },
        {
            "Effect": "Allow",
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::",
            "Condition": {
                "StringLike": {
                    "s3:prefix": [
                        "/*"
                    ]
                }
            }
        }
    ]
}
```

Automatically encrypt existing and new Amazon EBS volumes

Tony DeMarco and Josh Joy, Amazon Web Services

Summary

Encryption of Amazon Elastic Block Store (Amazon EBS) volumes is important to an organization's data protection strategy. It is an important step in establishing a well-architected environment. Although there is no direct way to encrypt existing unencrypted EBS volumes or snapshots, you can encrypt them by creating a new volume or snapshot. For more information, see Encrypt EBS resources in the Amazon EC2 documentation. This pattern provides preventative and detective controls for encrypting your EBS volumes, both new and existing. In this pattern, you configure account settings, create automated remediation processes, and implement access controls.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- AWS Command Line Interface (AWS CLI), installed and configured on macOS, Linux, or Windows
- jq, installed and configured on macOS, Linux, or Windows
- AWS Identity and Access Management (IAM) permissions are provisioned to have read and write access to AWS CloudFormation, Amazon Elastic Compute Cloud (Amazon EC2), AWS Systems Manager, AWS Config, and AWS Key Management Service (AWS KMS)
- AWS Organizations is configured with all features enabled, a requirement for service control policies
- AWS Config is enabled in the target accounts

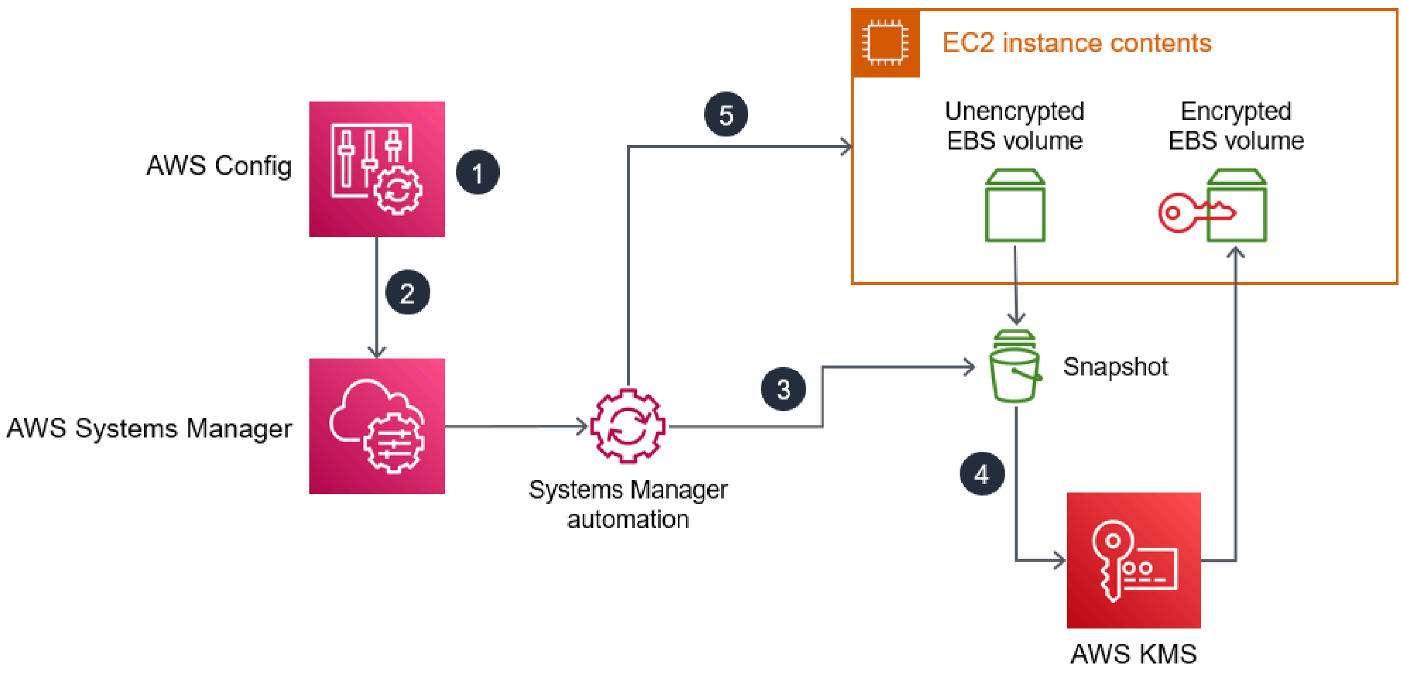
Limitations

- In your target AWS account, there must be no AWS Config rules named **encrypted-volumes**. This solution deploys a rule with this name. Preexisting rules with this name can cause the deployment to fail and result in unnecessary charges related to processing the same rule more than once.
- This solution encrypts all EBS volumes with the same AWS KMS key.

- If you enable encryption of EBS volumes for the account, this setting is Region-specific. If you enable it for an AWS Region, you cannot disable it for individual volumes or snapshots in that Region. For more information, see Encryption by default in the Amazon EC2 documentation.
- When you remediate existing, unencrypted EBS volumes, ensure that the EC2 instance is not in use. This automation shuts down the instance in order to detach the unencrypted volume and attach the encrypted one. There is downtime while the remediation is in progress. If this is a critical piece of infrastructure for your organization, make sure that manual or automatic high-availability configurations are in place so as to not impact the availability of any applications running on the instance. We recommend that you remediate critical resources only during standard maintenance windows.

Architecture

Automation workflow



1. AWS Config detects an unencrypted EBS volume.
2. An administrator uses AWS Config to send a remediation command to Systems Manager.
3. The Systems Manager automation takes a snapshot of the unencrypted EBS volume.
4. The Systems Manager automation uses AWS KMS to create an encrypted copy of the snapshot.
5. The Systems Manager automation does the following:

a. Stops the affected EC2 instance if it is running

b. Attaches the new, encrypted copy of the volume to the EC2 instance

c. Returns the EC2 instance to its original state

Tools

AWS services

- AWS CLI – The AWS Command Line Interface (AWS CLI) provides direct access to the public application programming interfaces (APIs) of AWS services. You can explore a service's capabilities with the AWS CLI and develop shell scripts to manage your resources. In addition to the low-level API-equivalent commands, several AWS services provide customizations for the AWS CLI. Customizations can include higher-level commands that simplify using a service with a complex API.
- AWS CloudFormation – AWS CloudFormation is a service that helps you model and set up your AWS resources. You create a template that describes all the AWS resources that you want (such as Amazon EC2 instances), and CloudFormation provisions and configures those resources for you.
- AWS Config – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.
- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.
- AWS KMS – AWS Key Management Service (AWS KMS) is an encryption and key management service scaled for the cloud. AWS KMS keys and functionality are used by other AWS services, and you can use them to protect data in your AWS environment.
- AWS Organizations – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Systems Manager Automation – Systems Manager Automation simplifies common maintenance and deployment tasks for Amazon EC2 instances and other AWS resources.

Other services

- jq – jq is a lightweight and flexible command-line JSON processor. You use this tool to extract key information from the AWS CLI output.

Code

- The code for this pattern is available in the GitHub Automatically remediate unencrypted EBS Volumes using customer KMS keys repository.

Epics

Automate remediation of unencrypted volumes

Task	Description	Skills required
Download scripts and CloudFormation templates.	Download the shell script, JSON file, and CloudFormation templates from the GitHub Automatically remediate unencrypted EBS Volumes using customer KMS keys repository.	AWS administrator, General AWS
Identify the administrator for the AWS KMS key.	1. Sign in to the AWS Management Console and open the IAM console at https://console.aws.amazon.com/iam/. 2. Identify a user or role who will be the AWS KMS key administrator. If a new user or role needs to be created for this purpose, create it now. For more information, see IAM Identities in the IAM documentation. This automation creates a new AWS KMS key.	AWS administrator, General AWS

Task	Description	Skills required
	3. Once identified, copy the user's or role's Amazon Resource Name (ARN). For more information, see IAM ARNs in the IAM documentation. You use this ARN in the next step.	

Task	Description	Skills required
Deploy the Stack1 CloudFormation template.	1. Open the AWS CloudFormation console at https://console.aws.amazon.com/cloudformation/. 2. In CloudFormation, deploy the `Stack1.yaml` template. Note the following deployment details: • Give the stack a clear and descriptive name. Note the stack name because you need this value in the next step. • Paste the ARN of the key administrator into the only parameter field in Stack1. This user or role becomes the administrator for the AWS KMS key created by the stack. For more information about deploying a CloudFormation template, see [Working with AWS CloudFormation templates](#) in the CloudFormation documentation.	AWS administrator, General AWS

Task	Description	Skills required
Deploy the Stack2 CloudFormation template.	In CloudFormation, deploy the `Stack2.yaml` template. Note the following deployment details: • Give the stack a clear and descriptive name. • For the only parameter of Stack2, enter the name of the stack you created in the previous step. This allows Stack2 to reference the new AWS KMS key and role deployed by the stack in the previous step.	AWS administrator, General AWS
Create an unencrypted volume for testing.	Create an EC2 instance with an unencrypted EBS volume. For instructions, see [Create an Amazon EBS volume](#) in the Amazon EC2 documentation. The instance type does not matter, and access to the instance is not needed. You can create a t2.micro instance to stay in the free tier, and you don't need to create a key pair.	AWS administrator, General AWS

Task	Description	Skills required
Test the AWS Config rule.	1. Open the AWS Config console at https://console.aws.amazon.com/config/. On the **Rules** page, choose the **encrypted-volumes** rule. 2. Confirm that your new, unencrypted test instance appears in the list of non-compliant resources. If the volume does not appear immediately, wait a few minutes and refresh the results. The AWS Config rule detects the resource changes shortly after the instance and volume are created. 3. Select the resource, and then then choose **Remediate**. You can view the remediati on progress and status in Systems Manager as follows: 1. Open the AWS Systems Manager console at https://console.aws.amazon.com/systems-manager/. 2. In the navigation pane, choose **Automation**.	AWS administrator, General AWS

Task	Description	Skills required
	3. Choose the **Execution ID** link to view the steps and the status.	
Configure additional accounts or AWS Regions.	As needed for your use case, repeat this epic for any additional accounts or AWS Regions.	AWS administrator, General AWS

Enable account-level encryption of EBS volumes

Task	Description	Skills required
Run the enable script.	1. In a bash shell, use the `cd` command to navigate into the cloned repository. 2. Enter the following command to run the `enable-ebs-encryption-for-account` script. `./Bash/enable-ebs-encryption-for-account.sh`	AWS administrator, General AWS, bash
Confirm the settings are updated.	1. Open the Amazon EC2 console at https://console.aws.amazon.com/ec2/. 2. On the right side of the screen, under **Settings**,	AWS administrator, General AWS

Task	Description	Skills required
	choose **Data protection and security**. 3. Under the **EBS encryption** section, confirm that **Always encrypt new EBS volumes** is turned on and that the **Default encryption key** is set to the ARN that you specified previously. **Note** If the **Always encrypt new EBS volumes** setting is turned off or the key is still set to **alias/aws/ebs**, confirm that you are logged into the same account and AWS Region where you ran the shell script, and check your shell for error messages.	
Configure additional accounts or AWS Regions.	As needed for your use case, repeat this epic for any additional accounts or AWS Regions.	AWS administrator, General AWS

Prevent creation of unencrypted instances

Task	Description	Skills required
Create a service control policy.	1. Open the AWS Organizations console at https://console.aws.amazon.com/organizations/v2/. 2. Create a new service control policy. For more information, see [Creating a service control policy](#) in the AWS Organizations documentation. 3. Add the contents of `DenyUnencryptedEC2.json` to the policy and save it. You downloaded this JSON file from the GitHub repository in the first epic. 4. Attach this policy to the organization root or any necessary organizational units (OUs). For more information, see [Attaching and detaching service control policies](#) in the AWS Organizations documentation.	AWS administrator, General AWS

Back up Sun SPARC servers in the Stromasys Charon-SSP emulator on the AWS Cloud

Kevin Yung and Rohit Darji, Amazon Web Services

Luis Ramos, Stromasys

Summary

This pattern provides four options for backing up your Sun Microsystems SPARC servers after a migration from an on-premises environment to the Amazon Web Services (AWS) Cloud. These backup options help you to implement a backup plan that meets your organization's recovery point objective (RPO) and recovery time objective (RTO), uses automated approaches, and lowers your overall operational costs. The pattern provides an overview of the four backup options and steps to implement them.

If you use a Sun SPARC server hosted as a guest on a Stromasys Charon-SSP emulator, you can use one of the following three backup options:

- **Backup option 1: Stromasys virtual tape –** Use the Charon-SSP virtual tape feature to set up a backup facility in the Sun SPARC server and archive your backup files to Amazon Simple Storage Service (Amazon S3) and Amazon Simple Storage Service Glacier using AWS Systems Manager Automation.
- **Backup option 2: Stromasys snapshot –** Use the Charon-SSP snapshot feature to set up a backup facility for the Sun SPARC guest servers in Charon-SSP.
- **Backup option 3**: **Amazon Elastic Block Store (Amazon EBS) volume snapshot –** If you host the Charon-SSP emulator on Amazon Elastic Compute Cloud (Amazon EC2), you can use an Amazon EBS volume snapshot to create backups for a Sun SPARC file system.

If you use a Sun SPARC server hosted as a guest on hardware and Charon-SSP on Amazon EC2, you can use the following backup option:

- **Backup option 4: AWS Storage Gateway virtual tape library (VTL) –** Use a backup application with a Storage Gateway VTL Tape Gateway to back up the Sun SPARC servers.

If you use a Sun SPARC server hosted as a branded zone in a Sun SPARC server, you can use backup options 1, 2, and 4.

Stromasys provides software and services to emulate legacy SPARC, Alpha, VAX, and PA-RISC critical systems. For more information about migrating to the AWS Cloud using Stromasys emulation, see Rehosting SPARC, Alpha, or other legacy systems to AWS with Stromasys on the AWS Blog.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Existing Sun SPARC servers.
- Existing licenses for Charon-SSP. Licenses for Charon-SSP are available from AWS Marketplace and licenses for Stromasys Virtual Environment (VE) are available from Stromasys. For more information, contact Stromasys sales.
- Familiarity with Sun SPARC servers and Linux backups.
- Familiarity with Charon-SSP emulation technology. For more information about this, see Stromasys legacy server emulation in the Stromasys documentation.
- If you want to use the virtual tape facility or backup applications for your Sun SPARC servers file systems, you must create and configure the backup facilities for the Sun SPARC server file system.
- An understanding of RPO and RTO. For more information about this, see Disaster recovery objectives from the Reliability Pillar whitepaper in the AWS Well-Architected Framework documentation.
- To use **Backup option 4**, you must have the following:
  - A software-based backup application that supports a Storage Gateway VTL Tape Gateway. For more information about this, see Working with VTL devices in the AWS Storage Gateway documentation.
  - Bacula Director or a similar backup application, installed and configured. For more information about this, see the Bacula Director documentation.

The following table provides information about the four backup options in this pattern.

Backup options	Achieves crash consistency?	Achieves application consistency?	Virtual backup appliance solution?	Typical use cases

Option 1 – Stromasys virtual tape	**Yes** You can automate Sun SPARC file system snapshots to back up data in a virtual tape. For example, you can use UFS or ZFS snapshots.	**Yes** This backup option requires an automated script to flush in-flight transactions, configure a read-only or temporary offline mode during the file system snapshot, or take an application data dump. You might also require application downtime or read-only mode.	**Yes**	Sun SPARC server file systems backup with .tar or .zip files Application data backup

Option 2 – Stromasys snapshot	**Yes** You must configure [Charon-SSP Manager]() or use a command-line startup argument to enable this feature. You must also run a Linux command to ask the Charon-SSP emulator to save the Sun SPARC guest server state into a snapshot file. **Important** You must shut down the Sun SPARC guest server.	**Yes** This backup option creates a snapshot of the emulated guest server, including its virtual disks and memory dump. **Important** You must shut down the Sun SPARC guest server during the snapshot.	**No**	Sun SPARC server snapshot Application data backup

Option 3 – Amazon EBS volume snapshot	**Yes** You can use AWS Backup to automate the Amazon EBS snapshot.	**Yes** This backup option requires an automated script to flush in-flight transactions and configure a read-only or temporary stop of the EC2 instance during the Amazon EBS volume snapshot. **Important** This backup option might require application downtime or read-only mode to achieve application consistency.	**No**	Sun SPARC server file systems snapshot Application data backup

Option 4 – AWS Storage Gateway VTL	**Yes** You can automatically back up Sun SPARC file system backup data to the VTL by using a backup agent.	**Yes** This backup option requires an automated script to flush in-flight transactions and configure a read-only or temporary offline mode during the file system snapshot or application data dump. **Important** This backup option might require application downtime or read-only mode.	**Yes**	A large fleet of Sun SPARC server file system backups Application data backup

Limitations

- You can use this pattern's approaches to back up individual Sun SPARC servers, but you can also use these backup options for shared data if you have applications that run in a cluster.

Tools

Backup option 1: Stromasys virtual tape

- [Stromasys Charon-SSP emulator]() – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including operating systems (OSs) such as SunOS or Solaris, their layered products, and applications.
- [Amazon EC2]() – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.
- [Amazon EFS]() – Amazon Elastic File System (Amazon EFS) provides a simple, serverless, set-and-forget elastic file system for use with AWS Cloud services and on-premises resources.
- [Amazon S3]() – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- [Amazon S3 Glacier]() – Amazon Simple Storage Service Glacier is a secure, durable, and extremely low-cost Amazon S3 storage class for data archiving and long-term backup.
- [AWS Systems Manager Automation]() – Automation, a capability of AWS Systems Manager, simplifies common maintenance and deployment tasks of EC2 instances and other AWS resources.

Backup option 2: Stromasys snapshot

- [Stromasys Charon-SSP emulator]() – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including OSs such as SunOS or Solaris, their layered products, and applications.
- [Amazon EC2]() – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.
- [Amazon EFS]() – Amazon Elastic File System (Amazon EFS) provides a simple, serverless, set-and-forget elastic file system for use with AWS Cloud services and on-premises resources.
- [Amazon S3]() – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

- Amazon S3 Glacier – Amazon Simple Storage Service Glacier is a secure, durable, and extremely low-cost Amazon S3 storage class for data archiving and long-term backup.
- AWS Systems Manager Automation – Automation, a capability of AWS Systems Manager, simplifies common maintenance and deployment tasks of EC2 instances and other AWS resources.

Backup option 3: Amazon EBS volume snapshot

- Stromasys Charon-SSP emulator – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including OSs such as SunOS or Solaris, their layered products, and applications.
- AWS Backup – AWS Backup is a fully-managed data protection service that makes it easy to centralize and automate across AWS services, in the cloud, and on premises.
- Amazon EBS – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances.
- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.

Backup option 4: AWS Storage Gateway VTL

- Stromasys Charon-SSP emulator – Charon-SSP emulator creates the virtual replica of the original SPARC hardware inside a standard 64-bit x86 compatible computer system. It runs the original SPARC binary code, including OSs such as SunOS or Solaris, their layered products, and applications.
- Bacula – Bacula is an open-source, enterprise-level computer backup system. For more information about whether your existing backup application supports Tape Gateway, see Supported third-party backup applications for a Tape Gateway in the AWS Storage Gateway documentation.
- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides resizable computing capacity that you use to build and host your software systems.

- Amazon RDS for MySQL – Amazon Relational Database Service (Amazon RDS) supports DB instances running several versions of MySQL.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- Amazon S3 Glacier – Amazon Simple Storage Service Glacier is a secure, durable, and extremely low-cost Amazon S3 storage class for data archiving and long-term backup.
- AWS Storage Gateway – Storage Gateway connects an on-premises software appliance with cloud-based storage to provide seamless integration with data security features between your on-premises IT environment and the AWS storage infrastructure.

Epics

Backup option 1 – Create a Stromasys virtual tape backup

Task	Description	Skills required
Create an Amazon EFS shared file system for virtual tape file storage.	Sign in to the AWS Management Console or use AWS CLI to create an Amazon EFS file system. For more information about this, see Create an Amazon EFS file system in the Amazon EFS documentation.	Cloud architect
Configure the Linux host to mount the shared file system.	Install the Amazon EFS driver on the Amazon EC2 Linux instance and configure the Linux OS to mount the Amazon EFS shared file system during startup. For more information about this, see Mounting file systems using the EFS mount helper in the Amazon EFS documentation.	DevOps engineer

Task	Description	Skills required
Install the Charon-SSP emulator.	Install the Charon-SSP emulator on the Amazon EC2 Linux instance. For more information about this, see [Setting up an AWS Cloud instance for Charon-SSP]() in the Stromasys documentation.	DevOps engineer
Create a virtual tape file container in the shared file system for each Sun SPARC guest server.	Run the `touch <vtape-container-name>` command to create a virtual tape file container in the shared file system for each Sun SPARC guest server deployed in the Charon-SSP emulator.	DevOps engineer
Configure Charon-SSP Manager to create virtual tape devices for the Sun SPARC guest servers.	Log in to Charon-SSP Manager, create virtual tape devices, and configure them to use the virtual tape container files for each Sun SPARC guest server. For more information about this, see the [Charon-SSP 5.2 for Linux user guide]() in the Stromasys documentation.	DevOps engineer

Task	Description	Skills required
Validate that the virtual tape device is available in the Sun SPARC guest servers.	Log in to each Sun SPARC guest server and run the `mt -f /dev/rmt/1` command to validate that the virtual tape device is configured in the OS.	DevOps engineer
Develop the Systems Manager Automation runbook and automation.	Develop the Systems Manager Automation runbook and set up maintenance windows and associations in Systems Manager for scheduling the backup process. For more information about this, see [Automation walkthroughs]() and [Setting up maintenance windows]() in the AWS Systems Manager documentation.	Cloud architect
Configure Systems Manager Automation to archive rotated virtual tape container files.	Use the code sample from **Back option 1** in the *Additional information* section to develop a Systems Manager Automation runbook to archive rotated virtual tape container files to Amazon S3 and Amazon S3 Glacier.	Cloud architect

Task	Description	Skills required
Deploy the Systems Manager Automation runbook for archiving and scheduling.	Deploy the Systems Manager Automation runbook and schedule it to automatically run in Systems Manager. For more information about this, see Automation walkthroughs in the Systems Manager documentation.	Cloud architect

Backup option 2 – Create a Stromasys snapshot

Task	Description	Skills required
Create an Amazon EFS shared file system for virtual tape file storage.	Sign in to the AWS Management Console or use AWS CLI to create an Amazon EFS file system. For more information about this, see Create your Amazon EFS file system in the Amazon EFS documentation.	Cloud architect
Configure the Linux host to mount the shared file system.	Install the Amazon EFS driver in the Amazon EC2 Linux instance and configure the Linux OS to mount the Amazon EFS shared file system during startup. For more information about this, see Mounting file systems using the EFS mount	DevOps engineer

Task	Description	Skills required
	helper in the Amazon EFS documentation.	
Install the Charon-SSP emulator.	Install the Charon-SSP emulator on the Amazon EC2 Linux instance. For more information about this, see Setting up an AWS Cloud instance for Charon-SSP in the Stromasys documentation.	DevOps engineer
Configure the Sun SPARC guest servers to start up with the snapshot option.	Use Charon-SSP Manager to set up the snapshot option for each Sun SPARC guest servers. For more information about this, see the Charon-SSP 5.2 for Linux user guide in the Stromasys documentation.	DevOps engineer
Develop the Systems Manager Automation runbook.	Use the code sample from **Backup option 2** in the *Additional information* section to develop a Systems Manager Automation runbook to remotely run the snapshot command on a Sun SPARC guest server during a maintenance window.	Cloud architect

Task	Description	Skills required
Deploy the Systems Manager Automation runbook and set up the association to the Amazon EC2 Linux hosts.	Deploy the Systems Manager Automation runbook and set up maintenance windows and associations in Systems Manager for scheduling the backup process. For more information about this, see [Automation walkthroughs]() and [Setting up Maintenance Windows]() in the AWS Systems Manager documentation.	Cloud architect
Archive snapshots into long-term storage.	Use the runbook sample code from the *Additional informati on* section to develop a Systems Manager Automation runbook to archive snapshot files to Amazon S3 and Amazon S3 Glacier.	Cloud architect

Backup option 3 – Create an Amazon EBS volume snapshot

Task	Description	Skills required
Install the Charon-SSP emulator.	Install the Charon-SSP emulator on the Amazon EC2 Linux instance. For more information about this, see [Setting up an AWS Cloud instance for Charon-SSP]() in the Stromasys documentation.	DevOps engineer

Task	Description	Skills required
Create EBS volumes for the Sun SPRAC guest servers.	Sign in to the AWS Management Console, open the Amazon EBS console, and then create EBS volumes for the Sun SPRAC guest servers. For more information about this, see [Setting up an AWS Cloud instance for Charon-SSP]() in the Stromasys documentation.	Cloud architect
Attach the EBS volumes to the Amazon EC2 Linux instance.	On the Amazon EC2 console, attach the EBS volumes to the Amazon EC2 Linux instance. For more information about this, see [Attach an Amazon EBS volume to an instance]() in the Amazon EC2 documenta tion.	AWS DevOps
Map EBS volumes as SCSI drives in the Charon-SSP emulator.	Configure Charon-SSP Manager to map the EBS volumes as SCSI drives in the Sun SPARC guest servers. For more information about this, see the *SCSI storage configuration* section of the [Charon-SSP V5.2 for Linux]() guide in the Stromasys documentation.	AWS DevOps

Task	Description	Skills required
Configure the AWS Backup schedule for snapshotting the EBS volumes.	Set up AWS Backup policy and schedules to snapshot the EBS volumes. For more information about this, see the Amazon EBS backup and restore using AWS Backup tutorial in the AWS Developer Center documentation.	AWS DevOps

Backup option 4 – Create an AWS Storage Gateway VTL

Task	Description	Skills required
Create a Tape Gateway device.	Sign in to the AWS Management Console, open the AWS Storage Gateway console, and then create a Tape Gateway device in a VPC. For more information about this, see Creating a gateway in the AWS Storage Gateway documentation.	Cloud architect
Create an Amazon RDS DB instance for the Bacula Catalog.	Open the Amazon RDS console and create an Amazon RDS for MySQL DB instance. For more information about this, see Creating a MySQL DB instance and connecting to	Cloud architect

Task	Description	Skills required
	a database on a MySQL DB instance in the Amazon RDS documentation.	
Deploy the backup application controller in the VPC.	Install Bacula on the EC2 instance, deploy the backup application controller, and then configure the backup storage to connect with the Tape Gateway device. You can use the sample Bacula Director storage daemon configuration in the `Bacula-storage-daemon-config.txt` file (attached). For more information about this, see the Bacula documentation.	AWS DevOps
Set up backup application on the Sun SPARC guest servers.	Set up a second client to install and set up the backup application on the Sun SPARC guest servers by using the sample Bacula configuration in the `SUN-SPARC-Guest-Bacula-Config.txt` file (attached).	DevOps engineer

Task	Description	Skills required
Set up the backup configuration and schedule.	Set up backup configuration and schedules in the backup application controller by using the sample Bacula Director configuration in the `Bacula-Directory-Config.txt` file (attached). For more information about this, see the [Bacula documentation]().	DevOps engineer
Validate that the backup configuration and schedules are correct.	Follow the instruction from the [Bacula documentation]() to perform the validation and backup testing for your setup in the Sun SPARC guest servers. For example, you can use the following commands to validate the configuration files: • `bacula-dir -t -c bacula-dir.conf` • `bacula-fd -t -c bacula-fd.conf` • `bacula-sd -t -c bacula-sd.conf`	DevOps engineer

Additional information

Backup option 1 – Create a Stromasys virtual tape

You can use the following sample Systems Manager Automation runbook code to automatically start the backup and then swap the tapes:

```
...
# example backup script saved in SUN SPARC Server
 #!/usr/bin/bash
 mt -f  rewind
 tar -cvf
 mt -f  offline
...
         mainSteps:
         - action: aws:runShellScript
           name:
           inputs:
             onFailure: Abort
             timeoutSeconds: "1200"
             runCommand:
             - |
               # Validate tape backup container file exists
               if [ ! -f {{TapeBackupContainerFile}} ]; then
                 logger -s -p local3.warning "Tape backup container file is not exists
 - {{TapeBackupContainerFile}}, create a new one"
                 touch {{TapeBackupContainerFile}}
               fi
         - action: aws:runShellScript
           name: startBackup
           inputs:
             onFailure: Abort
             timeoutSeconds: "1200"
             runCommand:
             - |
               user={{BACKUP_USER}}
               keypair={{KEYPAIR_PATH}}
               server={{SUN_SPARC_IP}}
```

```
                backup_script={{BACKUP_SCRIPT}}
                ssh -i $keypair $user@$server -c "/usr/bin/bash $backup_script"
          - action: aws:runShellScript
            name: swapVirtualDiskContainer
            inputs:
              onFailure: Abort
              timeoutSeconds: "1200"
              runCommand:
              - |
                mv {{TapeBackupContainerFile}} {{TapeBackupContainerFile}}.$(date +%s)
                touch {{TapeBackupContainerFile}}
          - action: aws:runShellScript
            name: uploadBackupArchiveToS3
            inputs:
              onFailure: Abort
              timeoutSeconds: "1200"
              runCommand:
              - |
                aws s3 cp {{TapeBackupContainerFile}} s3://{{BACKUP_BUCKET}}/
{{SUN_SPARC_IP}}/$(date '+%Y-%m-%d')/
 ...
```

Backup option 2 – Stromasys snapshot

You can use the following sample Systems Manager Automation runbook code to automate the backup process:

```
      ...

         mainSteps:
         - action: aws:runShellScript
           name: startSnapshot
           inputs:
             onFailure: Abort
             timeoutSeconds: "1200"
             runCommand:
             - |
               # You may consider some graceful stop of the application before taking a
 snapshot
               # Query SSP PID by configuration file
               # Example: ps ax | grep ssp-4 | grep Solaris10.cfg | awk '{print $1"
 "$5}' | grep ssp4 | cut -f1 -d" "
```

```
              pid=`ps ax | grep ssp-4 | grep {{SSP_GUEST_CONFIG_FILE}} | awk '{print
 $1" "$5}' | grep ssp4 | cut -f1 -d" "`
              if [ -n "${pid}" ]; then
                kill -SIGTSTP ${pid}
              else
                echo "No PID found for SPARC guest with config
 {{SSP_GUEST_CONFIG_FILE}}"
                exit 1
              fi
        - action: aws:runShellScript
          name: startBackup
          inputs:
            onFailure: Abort
            timeoutSeconds: "1200"
            runCommand:
            - |
              # upload snapshot and virtual disk files into S3
              aws s3 sync {{SNAPSHOT_FOLDER}} s3://{{BACKUP_BUCKET}}/$(date '+%Y-%m-
%d')/
              aws s3 cp {{VIRTUAL_DISK_FILE}} s3://{{BACKUP_BUCKET}}/$(date '+%Y-%m-
%d')/
        - action: aws:runShellScript
          name: restratSPARCGuest
          inputs:
            onFailure: Abort
            timeoutSeconds: "1200"
            runCommand:
            - |
              /opt/charon-ssp/ssp-4u/ssp4u -f {{SSP_GUEST_CONFIG_FILE}} -d -a
 {{SPARC_GUEST_NAME}} --snapshot {{SNAPSHOT_FOLDER}}
 ...
```

Backup option 4 – AWS Storage Gateway VTL

If you use Solaris non-global zones to run virtualized legacy Sun SPARC servers, the backup application approach can be applied to non-global zones running in the Sun SPARC servers (for example, the backup client can run inside the non-global zones). However, the backup client can also run in the Solaris host and take snapshots of the non-global zones. The snapshots can then be backed up on a tape.

The following sample configuration adds the file system that hosts the Solaris non-global zones into the backup configuration for the Solaris host:

```
FileSet {
   Name = "Branded Zones"
   Include {
     Options {
       signature = MD5
     }
     File = /zones
   }
 }
```

Back up and archive data to Amazon S3 with Veeam Backup & Replication

Jeanna James, Anthony Fiore (AWS), and William Quigley, Amazon Web Services

Summary

This pattern details the process for sending backups created by Veeam Backup & Replication to supported Amazon Simple Storage Service (Amazon S3) object storage classes by using the Veeam scale-out backup repository capability.

Veeam supports multiple Amazon S3 storage classes to best fit your specific needs. You can choose the type of storage based on the data access, resiliency, and cost requirements of your backup or archive data. For example, you can store data that you don't plan to use for 30 days or longer in Amazon S3 infrequent access (IA) for lower cost. If you're planning to archive data for 90 days or longer, you can use Amazon Simple Storage Service Glacier (Amazon S3 Glacier) Flexible Retrieval or S3 Glacier Deep Archive with Veeam's archive tier. You can also use S3 Object Lock to make backups that are immutable within Amazon S3.

This pattern doesn't cover how to set up Veeam Backup & Replication with a tape gateway in AWS Storage Gateway. For information about that topic, see Veeam Backup & Replication using AWS VTL Gateway - Deployment Guide on the Veeam website.

Warning: This scenario requires AWS Identity and Access Management (IAM) users with programmatic access and long-term credentials, which present a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed. Access keys can be updated if necessary. For more information, see Updating access keys in the *IAM User Guide*.

Prerequisites and limitations

Prerequisites

- Veeam Backup & Replication, including Veeam Availability Suite or Veeam Backup Essentials, installed (you can register for a free trial)
- Veeam Backup & Replication license with Enterprise or Enterprise Plus functionality, which includes Veeam Universal License (VUL)

- An active IAM user with access to an Amazon S3 bucket
- An active IAM user with access to Amazon Elastic Compute Cloud (Amazon EC2) and Amazon Virtual Private Cloud (Amazon VPC), if using archive tier
- Network connectivity from on premises to AWS services with available bandwidth for backup and restore traffic through a public internet connection or an AWS Direct Connect public virtual interface (VIF)
- The following network ports and endpoints opened to ensure proper communication with object storage repositories:
  - Amazon S3 storage – TCP – port 443: Used to communicate with Amazon S3 storage.
  - Amazon S3 storage – cloud endpoints – `*.amazonaws.com` for AWS Regions and the AWS GovCloud (US) Regions, or `*.amazonaws.com.cn` for China Regions: Used to communicate with Amazon S3 storage. For a complete list of connection endpoints, see [Amazon S3 endpoints]() in the AWS documentation.
  - Amazon S3 storage – TCP HTTP – port 80: Used to verify certificate status. Consider that certificate verification endpoints—certificate revocation list (CRL) URLs and Online Certificate Status Protocol (OCSP) servers—are subject to change. The actual list of addresses can be found in the certificate itself.
  - Amazon S3 storage – certificate verification endpoints – `*.amazontrust.com`: Used to verify certificate status. Consider that certificate verification endpoints (CRL URLs and OCSP servers) are subject to change. The actual list of addresses can be found in the certificate itself.

Limitations

- Veeam doesn't support S3 Lifecycle policies on any S3 buckets that are used as Veeam object storage repositories. These include polices with Amazon S3 storage class transitions and S3 Lifecycle expiration rules. Veeam **must** be the sole entity that manages these objects. Enabling S3 Lifecycle policies might have unexpected results, including data loss.

Product versions

- Veeam Backup & Replication v9.5 Update 4 or later (backup only or capacity tier)
- Veeam Backup & Replication v10 or later (backup or capacity tier and S3 Object Lock)
- Veeam Backup & Replication v11 or later (backup or capacity tier, archive or archive tier, and S3 Object Lock)

- Veeam Backup & Replication v12 or later (performance tier, backup or capacity tier, archive or archive tier, and S3 Object Lock)
- S3 Standard
- S3 Standard-IA
- S3 One Zone-IA
- S3 Glacier Flexible Retrieval (v11 and later only)
- S3 Glacier Deep Archive (v11 and later only)
- S3 Glacier Instant Retrieval (v12 and later only)

Architecture

Source technology stack

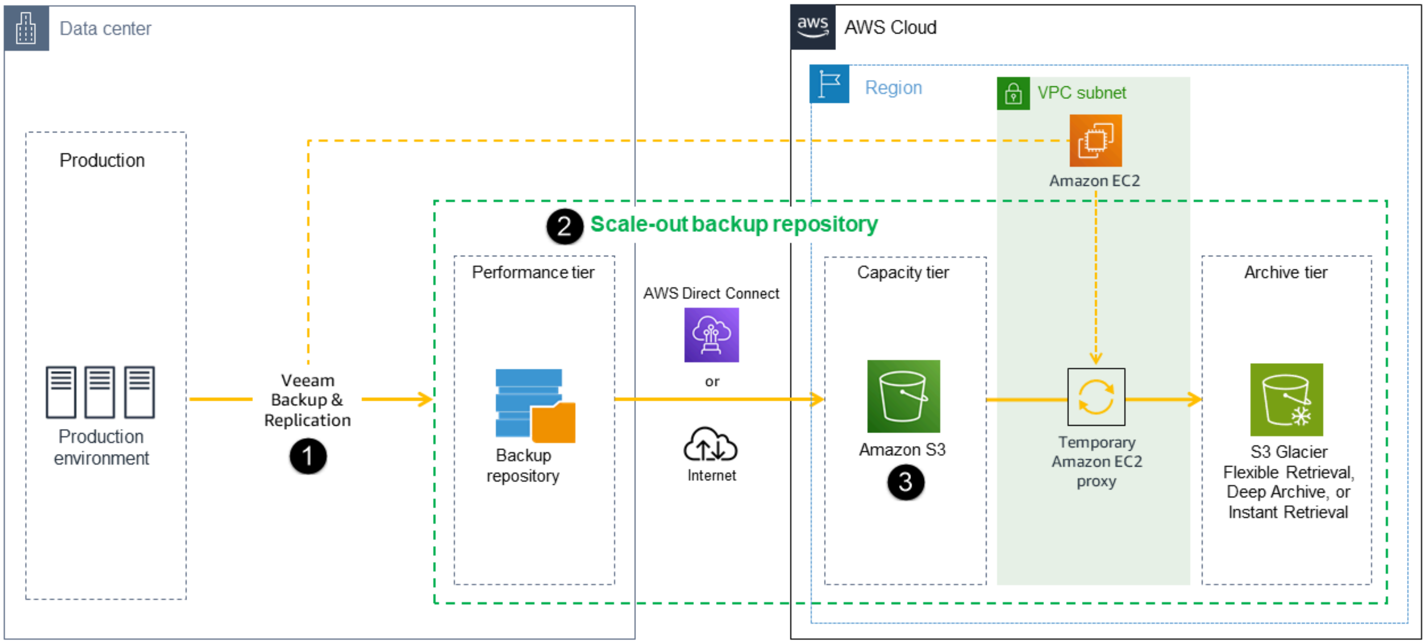
- On-premises Veeam Backup & Replication installation with connectivity from a Veeam backup server or a Veeam gateway server to Amazon S3

Target technology stack

- Amazon S3
- Amazon VPC and Amazon EC2 (if using archive tier)

Target architecture: SOBR

The following diagram shows the scale-out backup repository (SOBR) architecture.



Veeam Backup and Replication software protects data from logical errors such as system failures, application errors, or accidental deletion. In this diagram, backups are run on premises first, and a secondary copy is sent directly to Amazon S3. A backup represents a point-in-time copy of the data.

The workflow consists of three primary components that are required for tiering or copying backups to Amazon S3, and one optional component:

- Veeam Backup & Replication (1) – The backup server that is responsible for coordinating, controlling, and managing backup infrastructure, settings, jobs, recovery tasks, and other processes.
- Veeam gateway server (not shown in the diagram) – An optional on-premises gateway server that is required if the Veeam backup server doesn't have outbound connectivity to Amazon S3.
- Scale-out backup repository (2) – Repository system with horizontal scaling support for multi-tier storage of data. The scale-out backup repository consists of one or more backup repositories that provide fast access to data and can be expanded with Amazon S3 object storage repositories for long-term storage (capacity tier) and archiving (archive tier). Veeam uses the scale-out backup repository to tier data automatically between local (performance tier) and Amazon S3 object storage (capacity and archive tiers).

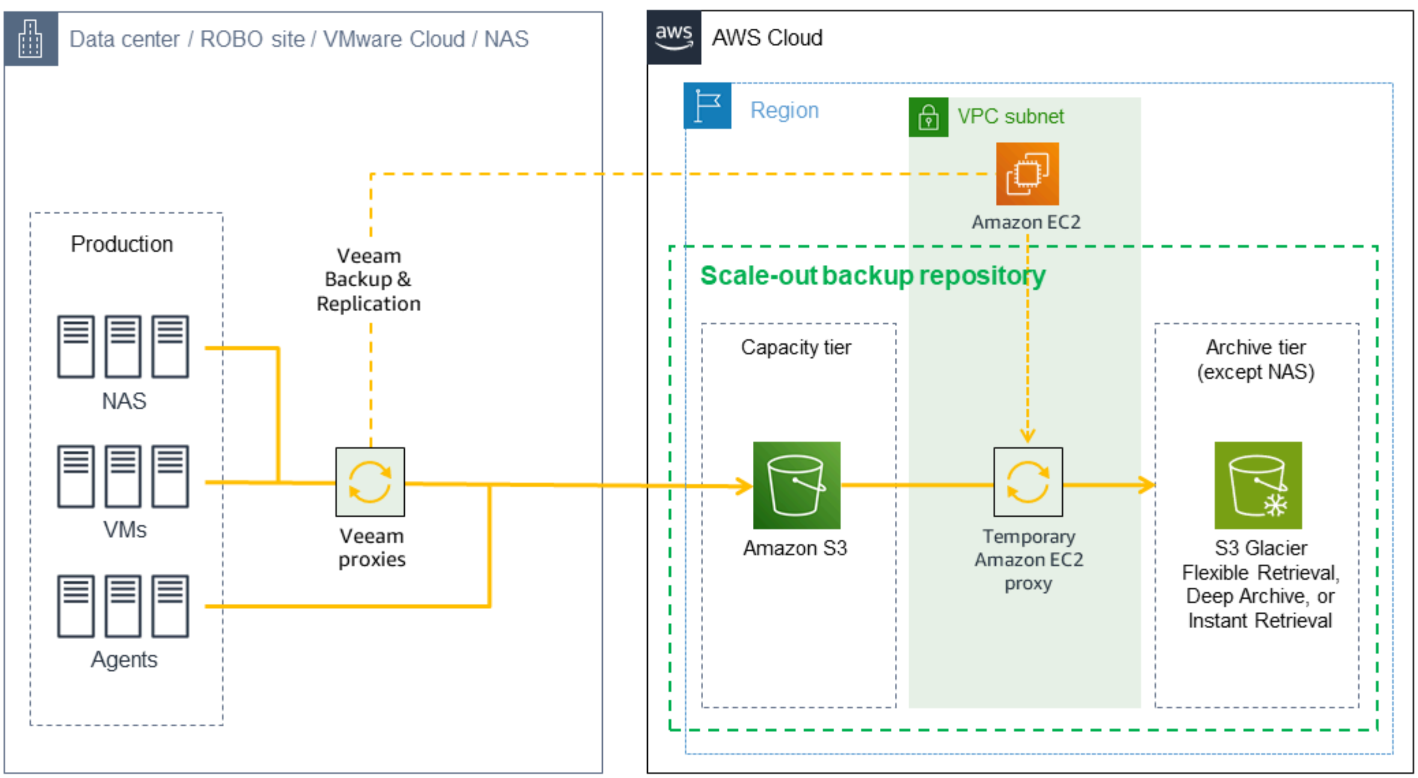
Note

Starting with Veeam Backup & Replication v12.2, the Direct to S3 Glacier feature makes the S3 capacity tier optional. A SOBR can be configured with a performance tier and a S3 Glacier archive tier. This configuration is useful for users who have significant investments in local (on-premises) storage for the capacity tier and who require only long-term archive retention in the cloud. For more information, see the [Veeam Backup & Replication documentation](https://helpcenter.veeam.com/docs/backup/vsphere/archive_tier.html).

- Amazon S3 (3) – AWS object storage service that offers scalability, data availability, security, and performance.

Target architecture: DTO

The following diagram shows the direct-to-object (DTO) architecture.



In this diagram, backup data goes directly to Amazon S3 without being stored on premises first. Secondary copies can be stored in S3 Glacier.

Automation and scale

You can automate the creation of IAM resources and S3 buckets by using the AWS CloudFormation templates provided in the VeeamHub GitHub repository. The templates include both standard and immutable options.

Tools

Tools and AWS services

- Veeam Backup & Replication is a solution from Veeam for protecting, backing up, replicating, and restoring your virtual and physical workloads.
- AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
- Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- Amazon S3 Glacier (S3 Glacier) is a secure and durable service for low-cost data archiving and long-term backup.
- Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Code

Use the CloudFormation templates provided in the VeeamHub GitHub repository to automatically create the IAM resources and S3 buckets for this pattern. If you prefer to create these resources manually, follow the steps in the *Epics* section.

Best practices

- In accordance with IAM best practices, we strongly recommend that you regularly rotate long-term IAM user credentials, such as the IAM user that you use for writing Veeam Backup & Replication backups to Amazon S3. For more information, see Security best practices in the IAM documentation.

Epics

Configure Amazon S3 storage in your account

Task	Description	Skills required
Create an IAM user.	Follow the instructions in the IAM documentation to create an IAM user. This user should not have AWS console access, and you will need to create an access key for this user. Veeam uses this entity to authenticate with AWS to read and write to your S3 buckets. You must grant least privilege (that is, grant only the permissions required to perform a task) so the user doesn't have more authority than it needs. For example IAM policies to attach to your Veeam IAM user, see the Additional information section. **Note** Alternatively, you can use the	AWS administrator

Task	Description	Skills required
	CloudFormation templates provided in the VeeamHub GitHub repository to create an IAM user and S3 bucket for this pattern.	

Task	Description	Skills required
Create an S3 bucket.	1. Sign in to the AWS Management Console and open the Amazon S3 console. 2. If you don't already have an existing S3 bucket to use as the target storage, choose **Create bucket**, and specify a bucket name, AWS Region, and bucket settings. • We recommend that you enable the Block Public Access option for the S3 bucket and set up the access and user permission policies to meet your organizat ion's requirements. For an example, see the Amazon S3documen tation. • We recommend that you enable S3 Object Lock, even if you don't intend to use it right away. This setting can be enabled only at the time of S3 bucket creation. For more information, see Creating a bucket in the Amazon S3 documentation.	AWS administrator

Add Amazon S3 and S3 Glacier Flexible Retrieval (or S3 Glacier Deep Archive) to Veeam Backup & Replication

Task	Description	Skills required
Launch the New Object Repository wizard.	Before you set up the object storage and scale-out backup repositories in Veeam, you must add the Amazon S3 and S3 Glacier storage repositories that you want to use for the capacity and archive tiers. In the next epic, you’ll connect these storage repositories to your scale-out backup repository. 1. On the Veeam console, open the **Backup Infrastru cture** view. 2. In the inventory pane, choose the **Backup Repositories** node, and then choose **Add Repositor y**. 3. In the **Add Backup Repository** dialog box, choose **Object Storage**, **Amazon S3**.	AWS administrator, App owner
Add Amazon S3 storage for the capacity tier.	1. In the **Amazon Cloud Storage Services** dialog box, choose **Amazon S3**. 2. At the **Name** step of the wizard, specify the object storage name and a brief	AWS administrator, App owner

Task	Description	Skills required
	description, such as the creator and creation date. 3. At the **Account** step of the wizard, specify the object storage account. • For **Credentials**, choose the IAM user that you created in the first epic to access your Amazon S3 object storage. • For **AWS region**, choose the AWS Region where the S3 bucket is located. 4. At the **Bucket** step of the wizard, specify object storage settings. • For **Data center region**, choose the AWS Region where the S3 bucket is located. • For **Bucket**, choose the S3 bucket that you created in the first epic. • For **Folder**, create or select a cloud folder to map your object storage repository to. • If you want to enable immutability, choose **Make recent backups immutable for X days** and set the period of time during which	

Task	Description	Skills required
	your backups should be locked. Note that enabling immutability results in increased costs because of the increased number of API calls to Amazon S3 from Veeam. 5. At the **Summary** step of the wizard, review the configuration information, and then choose **Finish**.	

Task	Description	Skills required

Add S3 Glacier storage for the archive tier.	If you want to create an archive tier, use the IAM permissions detailed in the [Additional information](#) section.
	
	1. Launch the New Object Repository wizard as described previously.
	2. In the **Amazon Cloud Storage Services** dialog box, choose **Amazon S3 Glacier**.
	3. At the **Name** step of the wizard, specify the object storage name and a brief description, such as the creator and creation date.
	4. At the **Account** step of the wizard, specify the object storage account.
	  • For **Credentials**, choose the IAM user that you created in the first epic to access your S3 Glacier object storage.
	  • For **AWS region**, choose the AWS Region where the S3 bucket is located.
	5. At the **Bucket** step of the wizard, specify object storage settings.
		AWS administrator, App owner

Task	Description	Skills required
	• For **Data center region**, choose the AWS Region. • For **Bucket**, choose an S3 bucket to store your backup data. This can be the same bucket you used for the capacity tier. • For **Folder**, create or select a cloud folder to map your object storage repository to. • If you want to enable immutability, choose **Make recent backups immutable for the entire duration of their retention policy**. Note that enabling immutabil ity results in increased costs because of the increased number of API calls to Amazon S3 from Veeam. • If you want to use S3 Glacier Deep Archive as your archival storage class, choose **Use the Deep Archive Storage Class**. 6. At the **Proxy Appliance** step of the wizard, configure the auxiliary instance that is used to transfer the	

Task	Description	Skills required
	data from Amazon S3 to S3 Glacier. You can use the default settings or configure each setting manually. To configure the settings manually: • Choose **Customize**. • For **EC2 instance type**, choose the instance type for the proxy appliance, based on your speed and cost requirements for transferring the backup files to the archive tier of your scale-out backup repository. • For **Amazon VPC**, choose the VPC for the target instance. • For **Subnet**, choose the subnet for the proxy appliance. • For **Security group**, choose the security group to associate with the proxy appliance. • For **Redirector port**, specify the TCP port for routing requests between the proxy appliance and backup infrastructure components.	

Task	Description	Skills required
	• Choose **OK** to confirm your settings. 7. At the **Summary** step of the wizard, review the configuration information, and then choose **Finish**.	

Add scale-out backup repositories

Task	Description	Skills required
Launch the New Scale-Out Backup Repository wizard.	1. On the Veeam console, open the **Backup Infrastru cture** view. 2. In the inventory pane, choose **Scale-out Repositories,** and then choose **Add Scale-out Repository**.	App owner, AWS systems administrator
Add a scale-out backup repository and configure capacity and archive tiers.	1. At the **Name** step of the wizard, specify the name and a brief description of the scale-out backup repository. 2. If needed, add performan ce extents. You can also use your existing Veeam local backup repository as your performance tier. Starting with Veeam version 12, you can add an S3 bucket as a performance extent for direct-to-object (DTO)	App owner, AWS systems administrator

Task	Description	Skills required
	backups, bypassing a local performance tier. 3. Choose **Advanced**, and specify additional options for the scale-out backup repository. • Choose **Use per-machine backup files** to create a separate backup file for each machine and write these files to the backup repository in multiple streams simultaneously. This option is recommended for better storage and compute resource utilization. • Choose **Perform full backup when required extent is offline** to create a full backup file in case an extent that contains restore points for an incremental backup goes offline. This option requires free space in the scale-out backup repository to host a full backup file. 4. At the **Policy** step of the wizard, specify the backup placement policy for the repository.	

Task	Description	Skills required
	• Choose **Data locality** to store full and incremental backup files that belong to the same chain together, to the same performance extent. You can store files that belong to a new backup chain to the same performance extent or to another one (unless you use a deduplicating storage appliance as a performance extent). • Choose **Performance** to store full and incremental backup files to different performance extents. This option requires a fast and reliable network connection. If you choose **Performance**, you can restrict the types of backup files to store on each performance extent. For example, you can store full backup files on one extent and incremental backup files on other extents. To choose file types: • Choose **Customize**.	

Task	Description	Skills required
	- In the **Backup Placement Settings** dialog box, choose a performance extent, and then choose **Edit**. - Choose the type of backup files you want to store on the extent. 5. At the **Capacity Tier** step of the wizard, configure the long-term storage tier that you want to attach to the scale-out backup repository. - Choose **Extend scale-out backup repository capacity with object storage**. For the object storage repository, choose the Amazon S3 storage for the capacity tier that you added in the previous epic. - Choose **Window** to select a time window for moving or copying data. - Choose **Copy backups to object storage as soon as they are created** to copy all or only recently created backup files to the capacity extent.	

Task	Description	Skills required
	• Choose **Move backups to object storage as they age out of the operational restores window** to transfer inactive backup chains to the capacity extent. In the **Move backup files older than X days** field, specify a duration after which backup files should be offloaded . (To offload inactive backup chains on the day they were created, specify 0 days.) You can also choose **Override** to move backup files sooner if the scale-out backup repository has reached a threshold that you specify. • Choose **Encrypt data uploaded to object storage** and specify a password to encrypt all data and their metadata for offloading. Choose **Add** or **Manage passwords** to specify a new password. 6. At the **Archive Tier** step of the wizard, configure the archive storage tier	

Task	Description	Skills required
	that you want to attach to the scale-out backup repository. (This step doesn't appear if you skipped adding Amazon S3 Glacier storage.) • Choose **Archive GFS full backups to object storage**. For the object storage repository, choose the Amazon S3 Glacier storage you added in the previous epic. • For **Archive GFS backups older than N days**, choose a time window for moving files to the archive extent. (To archive inactive backup chains on the day they were created, specify 0 days.) 7. At the **Summary** step of the wizard, review the configuration of the scale-out backup repository, and then choose **Finish**.

- Veeam technical documentation
- How to Create Secure IAM Policy for Connection to S3 Object Storage (Veeam documentation)

Additional information

The following sections provide sample IAM policies you can use when you create an IAM user in the Epics section of this pattern.

IAM policy for capacity tier

> **Note**
>
> Change the name of the S3 buckets in the example policy from `<yourbucketname>` to the name of the S3 bucket that you want to use for Veeam capacity tier backups. Also note that the policy should be restricted to the specific resources used for Veeam (indicated by the `Resource` specification in the following policy), and that the first part of the policy disables client-side encryption, as discussed in the AWS blog post Preventing unintended encryption of Amazon S3 objects.

```

IAM policy for archive tier

Note

Change the name of the S3 buckets in the example policy from `<yourbucketname>` to the name of the S3 bucket that you want to use for Veeam archive tier backups.

To use your existing VPC, subnet, and security groups:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3Permissions",
            "Effect": "Allow",
            "Action": [
                "s3:DeleteObject",
                "s3:PutObject",
                "s3:GetObject",
                "s3:RestoreObject",
                "s3:ListBucket",
                "s3:AbortMultipartUpload",
                "s3:GetBucketVersioning",
                "s3:ListAllMyBuckets",
                "s3:GetBucketLocation",
                "s3:GetBucketObjectLockConfiguration",
                "s3:PutObjectRetention",
                "s3:GetObjectVersion",
                "s3:PutObjectLegalHold",
                "s3:GetObjectRetention",
                "s3:DeleteObjectVersion",
                "s3:ListBucketVersions"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket-name>",
                "arn:aws:s3:::<bucket-name>/*"
            ]
        }
    ]
}

{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "EC2Permissions",
            "Effect": "Allow",
            "Action": [
                "ec2:DescribeInstances",
                "ec2:CreateKeyPair",
                "ec2:DescribeKeyPairs",
```

```
                "ec2:RunInstances",
                "ec2:DeleteKeyPair",
                "ec2:DescribeVpcAttribute",
                "ec2:CreateTags",
                "ec2:DescribeSubnets",
                "ec2:TerminateInstances",
                "ec2:DescribeSecurityGroups",
                "ec2:DescribeImages",
                "ec2:DescribeVpcs"
            ],
            "Resource": "arn:aws:ec2:<region>:<account-id>:*"
        }
    ]
}
```

To create new VPC, subnet, and security groups:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "S3Permissions",
            "Effect": "Allow",
            "Action": [
                "s3:DeleteObject",
                "s3:PutObject",
                "s3:GetObject",
                "s3:RestoreObject",
                "s3:ListBucket",
                "s3:AbortMultipartUpload",
                "s3:GetBucketVersioning",
                "s3:ListAllMyBuckets",
                "s3:GetBucketLocation",
                "s3:GetBucketObjectLockConfiguration",
                "s3:PutObjectRetention",
                "s3:GetObjectVersion",
                "s3:PutObjectLegalHold",
                "s3:GetObjectRetention",
                "s3:DeleteObjectVersion",
                "s3:ListBucketVersions"
            ],
            "Resource": [
                "arn:aws:s3:::<bucket-name>",
```

```
                "arn:aws:s3:::<bucket-name>/*"
            ]
        }
    ]
}

{
    "Version": "2012-10-17",

Configure Veritas NetBackup for VMware Cloud on AWS

Shubham Salani, Amazon Web Services

Summary

Notice: As of April 30, 2024, VMware Cloud on AWS is no longer resold by AWS or its channel partners. The service will continue to be available through Broadcom. We encourage you to reach out to your AWS representative for details.

Many enterprises use Veritas NetBackup as a backup and recovery solution for their on-premises VMware vSphere-based workloads. Once enterprises migrate their workloads to software-defined data centers (SDDCs) in the VMware Cloud on Amazon Web Services (AWS) infrastructure, there is no clear lift-and-shift procedure to integrate NetBackup. This pattern describes how you can set up Veritas NetBackup in your AWS account and configure it to back up the workloads in your VMware SDDCs.

This pattern does not include instructions for migrating your workloads. For more information, see [Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX](). When setting up your workloads to VMware Cloud on AWS, use a [stretched cluster]() (VMware documentation). In this configuration, your cluster spans two AWS Availability Zones within a single Region. This provides high availability and resiliency in the event that one of the Availability Zones becomes unavailable. [Elastic DRS]() and a [vSAN witness host]() (VMware documentation) seamlessly copy the data to a third Availability Zone, known as a *fault domain*. This parity solution can help you recover the data in the event of a failure. Because this approach requires three Availability Zones, when selecting an AWS Region for your VMware Cloud environment, make sure that it has three or more Availability Zones. For more information, see [Regions and Availability Zones]().

In this pattern, each SDDC has a backup host, which is a proxy server. Using Amazon Elastic Compute Cloud (Amazon EC2) instances, you set up the NetBackup master and media servers in a separate virtual private cloud (VPC), one for each SDDC. Because elastic network interfaces provide high bandwidth and low latency, you use them to configure connectivity between the backup hosts and their corresponding NetBackup master and media servers. The EC2 instances direct the backups to Amazon Elastic Block Store (Amazon EBS) volumes, which is the first point of backup. You can use AWS DataSync to keep your EBS volumes for the SDDCs synchronized.

You can also use AWS Transit Gateway and an interface VPC endpoint to connect the EBS volumes to another storage service, such as Amazon Simple Storage Service (Amazon S3). According to your retention policy, you can use S3 Intelligent-Tiering S3 Glacier storage classes to optimize your storage costs. For more information, see Using Amazon S3 storage classes (Amazon S3 documentation).

Prerequisites and limitations

Prerequisites

- Your VMware Cloud on AWS environment uses a stretched cluster that spans two Availability Zones.
- The backup host must reside on the VMware Cloud on AWS SDDC that has access to the datastore where the VMware Virtual Machine Disk File (VMDK) files are deployed.
- HotAdd transport mode must be enabled on the NetBackup client to back up and restore virtual machines (VMs), and it must permit restores from user-directed files and folders.

Limitations

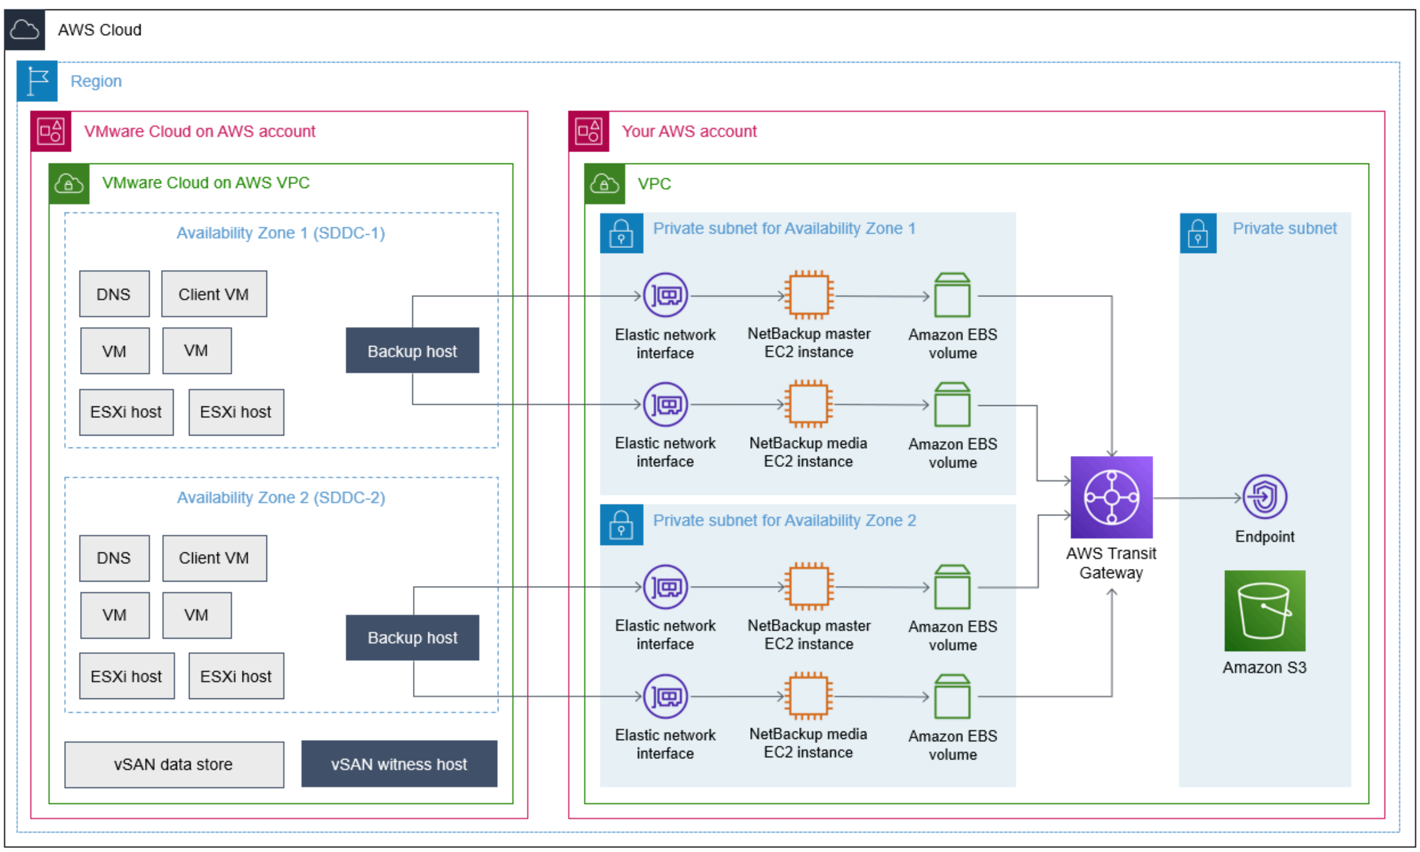
- The NetBackup master server must use DNS resolution to a private IP address for the vCenter backup host in the SDDC.
- The hosts files on the NetBackup master server and backup host should contain the following:
  - The private IP address and private DNS name of the master server
  - The private IP address and private DNS name of the backup host
- If you are configuring interface VPC endpoints to an S3 bucket, the SDDC Compute Gateway firewall must be configured to allow HTTPS from a Classless Inter-Domain Routing (CIDR) block source. For more information, see Access an S3 Bucket Using an S3 Endpoint (VMware documentation).
- VMware Cloud on AWS does not support the following features of NetBackup:
  - Backing up or restoring VM templates
  - Using NetBackup vSphere Client (HTML5 plug-in)
  - Locking and unlocking VMs for backups or restores
  - Backups cannot be stored in a vSAN datastore
  - Network block device (NBD), NBDSSL, and SAN transport modes

Product versions

- VMware Cloud on AWS SDDC version 1.0 or later
- Veritas NetBackup version 8.1.2 or later
- Linux version 6.8 or later
- VMware vSphere version 6.0 or later

Architecture

The following diagram shows the configuration of NetBackup for VMware Cloud on AWS. The NetBackup master and media servers are deployed in a separate VPC and are connected to the backup hosts in the SDDCs by elastic network interfaces. The NetBackup master and media servers store the backups in Amazon EBS volumes. You can optionally configure additional storage in Amazon S3 buckets by using AWS Transit Gateway and an AWS PrivateLink interface VPC endpoint.



Tools

AWS services and tools

- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- AWS PrivateLink helps you create unidirectional, private connections from your virtual private clouds (VPCs) to services outside of the VPC.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other services

- VMware Cloud on AWS is an integrated cloud offering jointly developed by Amazon Web Services (AWS) and VMware.
- NetBackup for VMware backs up and restores the VMware virtual machines that run on VMware ESXi hosts.

Epics

Configure the NetBackup servers

Task	Description	Skills required
Update the firewall rules.	Update the firewall rules to establish connectivity between the VMware Cloud on AWS SDDC and the NetBackup master and media servers. Do the following: 1. Log in to VMware Cloud on AWS at https://vmc.vmware.com/ 2. On the **Networking and Security** tab, choose **Gateway Firewall**.	Network administrator, Cloud administrator

Task	Description	Skills required
	3. On the **Gateway Firewall** page, choose **Compute Gateway**. 4. Choose **ADD Rule**, and then create a new rule with the necessary firewall port settings. For more information, see NetBackup firewall port requirements (Veritas documentation).	

Task	Description	Skills required
Launch the NetBackup master and media servers.	1. Sign in to the AWS Management Console, and open the Amazon EC2 console at https://console.aws.amazon.com/ec2/ 2. Launch an EC2 instance (Amazon EC2 documentation), and use the following configuration details: a. For the NetBackup master and media servers, select the `NBU-Linux-GA-8-1-2-Setup-f032d23e-881b-4dee-ba70-b9ca3e915910-ami-072509a7ffc156938.4` Amazon Machine Image (AMI). This preconfigured AMI is available through the AWS Marketplace. b. Select an instance type. NetBackup recommends `m5.2xlarge` for the master and media servers.	Cloud administrator, Backup administrator

Task	Description	Skills required
Configure the backup host for NetBackup.	1. Log in to VMware Cloud on AWS at https://vmc.vmware.com/ 2. Select the SDDC. 3. Choose the **Open VCENTER** tab. This opens the SDDC vCenter. 4. Note the fully qualified domain name (FQDN) of the backup host. 5. Log in to the NetBackup Administration Console. For more information, see [Logging in to the NetBackup Administration Console](#) (Veritas documentation). 6. Select the master and media servers, and then choose **VMware Access Hosts**. 7. Add the FQDN of the backup host. 8. Choose **Apply**, and then choose **OK**.	Cloud administrator, Backup administrator

(Optional) Set up Amazon S3 storage

Task	Description	Skills required
Configure storage in Amazon S3.	1. Review the [Amazon S3 cloud storage options](#) (Veritas documentation)	Cloud administrator, General AWS

Task	Description	Skills required
	and select the appropriate storage class for your requirements. 2. Configure NetBackup to use Amazon S3 for cloud storage according to the instructions in Configuring cloud storage in NetBackup (Veritas documentation).

Copy data from an S3 bucket to another account and Region by using the AWS CLI

Appasaheb Bagali and Purushotham G K, Amazon Web Services

Summary

This pattern describes how to migrate data from an Amazon Simple Storage Service (Amazon S3) bucket in an AWS source account to a destination S3 bucket in another AWS account, either in the same AWS Region or in a different Region.

The source S3 bucket allows AWS Identity and Access Management (IAM) access by using an attached resource policy. A user in the destination account has to assume a role that has `PutObject` and `GetObject` permissions for the source bucket. Finally, you run `copy` and `sync` commands to transfer data from the source S3 bucket to the destination S3 bucket.

Accounts own the objects that they upload to S3 buckets. If you copy objects across accounts and Regions, you grant the destination account ownership of the copied objects. You can change the ownership of an object by changing its [access control list (ACL)](#) to `bucket-owner-full-control`. However, we recommend that you grant programmatic cross-account permissions to the destination account because ACLs can be difficult to manage for multiple objects.

> Warning: This scenario requires IAM users with programmatic access and long-term credentia ls, which present a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed. Access keys can be updated if necessary. For more information, see [Updating access keys](#) in the *IAM User Guide*.

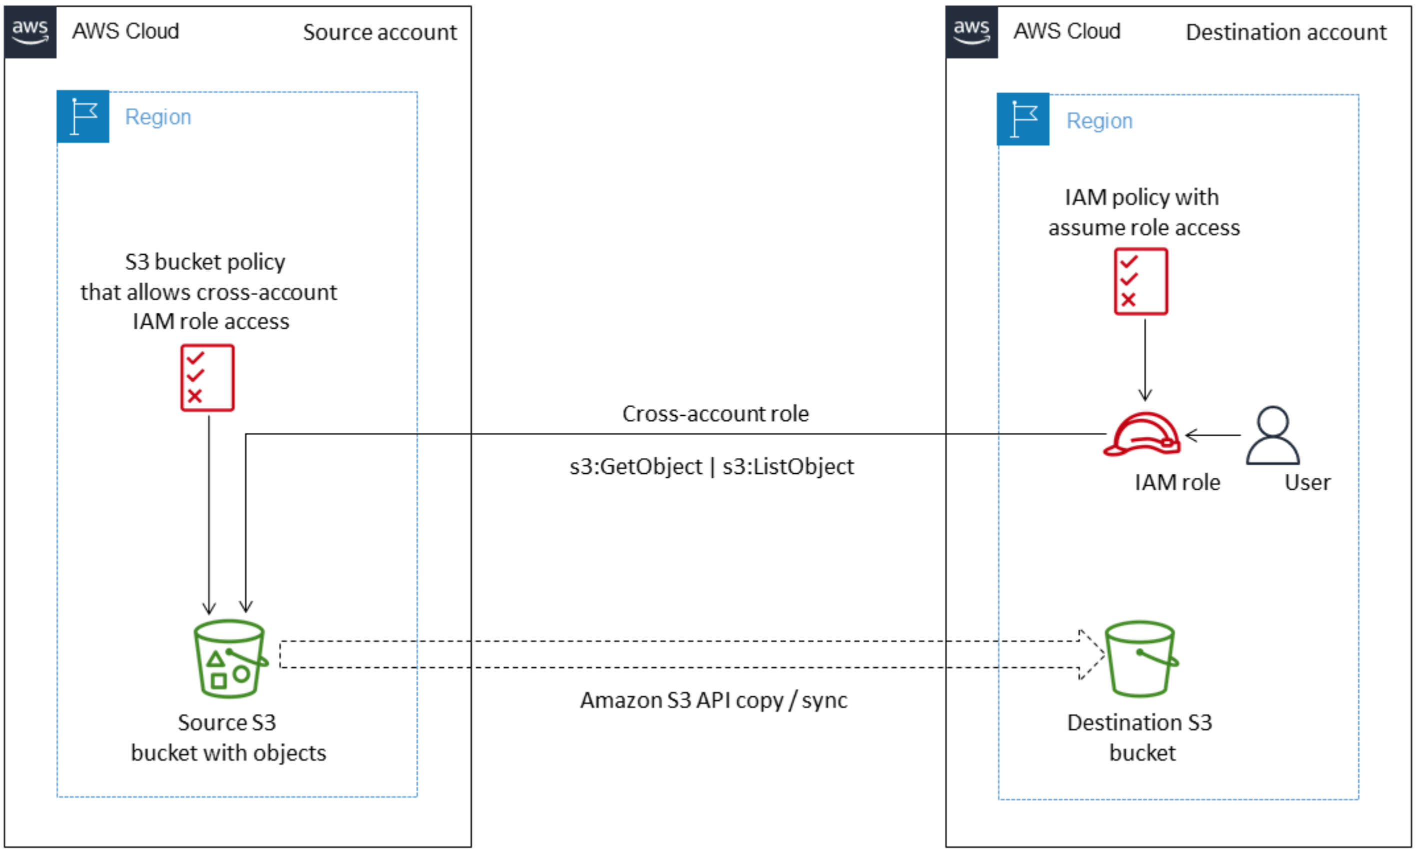
This pattern covers one-time migration. For scenarios that require continuous and automatic migration of new objects from a source bucket to a destination bucket, you can use S3 Batch Replication instead, as described in the pattern [Copy data from an S3 bucket to another account and Region by using S3 Batch Replication](#).

Prerequisites and limitations

- Two active AWS accounts in the same or different AWS Regions.
- An existing S3 bucket in the source account.

- If your source or destination Amazon S3 bucket has default encryption enabled, you must modify the AWS Key Management Service (AWS KMS) key permissions. For more information, see the AWS re:Post article on this topic.
- Familiarity with cross-account permissions.

Architecture



Tools

- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command line shell.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Best practices

- Security best practices in IAM (IAM documentation)
- Applying least-privilege permissions (IAM documentation)

Epics

Create an IAM user and role in the destination AWS account

Task	Description	Skills required
Create an IAM user and get the access key.	1. Sign in to the AWS Management Console and create an IAM user that has programmatic access. For detailed steps, see Creating IAM users in the IAM documentation. There is no need to attach any policies for this user. 2. Generate an access key and secret key for this user. For instructions, see AWS Account and Access Keys in the AWS documentation.	AWS DevOps

Create an IAM identity-based policy.	Create an IAM Identity-based policy named `S3MigrationPolicy` by using the following permissions. For detailed steps, see Creating IAM policies in the IAM documentation.
	`{`
	`"Version":`
	`"2012-10-17",`

	``
	
	Note
	
	Modify the source and destination bucket names according to your use case.
	
	This identity-based policy allows the user who is assuming this role to access	

Task	Description	Skills required
	the source bucket and destination bucket.	

Task	Description	Skills required
Create an IAM role.	Create an IAM role named `S3MigrationRole` by using the following trust policy, and then attach the previously created `S3MigrationPolicy`. For detailed steps, see [Creating a role to delegate permissions to an IAM user](#) in the IAM documentation. `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Principal": { "AWS": "arn:aws:iam::<destination_account>:user/<user_name>" }, "Action": "sts:AssumeRole", "Condition": {} } ] }` **Note** Modify the Amazon Resource Name (ARN) of the destination	AWS DevOps

Task	Description	Skills required
	IAM role or user name in the trust policy according to your use case. This trust policy allows the newly created IAM user to assume `S3MigrationRole` .	

Create and attach the S3 bucket policy in the source account

Task	Description	Skills required

Create and attach an S3 bucket policy.	Sign in to the AWS Management Console for your source account and open the Amazon S3 console. Choose your source S3 bucket and then choose **Permissions**. Under **Bucket policy**, choose **Edit** and then paste the following bucket policy. Choose **Save**.
	
	`{`
	`    "Version":`
	` "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Sid":`
	` "DelegateS3Access",`
	`            "Effect":`
	` "Allow",`
	`            "Principa`
	`l": {"AWS": "arn:aws:`
		Cloud administrator

Task	Description	Skills required

	``
	iam::<destination_
	account>:role/<Rol
	eName>"},
	            "Action":
	 ["s3:ListBucket",
	
	 "s3:GetObject",
	
	  "s3:GetObjectTaggi
	ng",
	
	  "s3:GetObjectVersi
	on",
	
	  "s3:GetObjectVersi
	onTagging"
	
	],
	            "Resource":
	 [
	
	 "arn:aws:s3:::amazon-
	s3-demo-source-bucket/
	*",
	
	 "arn:aws:s3:::amazon-
	s3-demo-source-bucket"
	            ]
	        }
	    ]
	}
	``
	
	Note
	
	Make sure that you include the AWS account ID for the destination account and configure the bucket policy	

Task	Description	Skills required
	template according to your requirements. This resource-based policy allows the destination role `S3MigrationRole` to access S3 objects in the source account.	

Configure the destination S3 bucket

Task	Description	Skills required
Create a destination S3 bucket.	Sign in to the AWS Management Console for your destination account, open the Amazon S3 console, and then choose **Create bucket**. Create an S3 bucket according to your requireme nts. For more information, see [Creating a bucket](#) in the Amazon S3 documentation.	Cloud administrator

Copy data to the destination S3 bucket

Task	Description	Skills required
Configure AWS CLI with the newly created user credentia ls.	1. Install the latest release of the AWS CLI. For instructi ons, see [Installing or updating the latest version](#)	AWS DevOps

Task	Description	Skills required
	of the AWS CLI in the AWS CLI documentation. 2. Run `$ aws configure` and update CLI with the AWS access key of the user you created. For more information, see Configuration and credential file settings in the AWS CLI documentation.	

Task	Description	Skills required
Assume the S3 migration role.	1. Use the AWS CLI to assume `S3MigrationRole` : `aws sts assume-role \ --role-arn "arn:aws:iam::<destination_account>:role/S3MigrationRole" \ --role-session-name AWSCLI-Session` This command outputs several pieces of information. Inside the credentials block you need the `AccessKeyId` , `SecretAccessKey` , and `SessionToken` . This example uses the environment variables `RoleAccessKeyID` , `RoleSecretKey` , and `RoleSessionToken` . Note that the timestamp of the expiration field is in the UTC time zone. The timestamp indicates when the temporary credentials of the IAM role expire. If the temporary credentials expire, you must call the `sts:AssumeRole` API again.	AWS administrator

Task	Description	Skills required

	2. Create three environment variables to assume the IAM role. These environment variables are filled out with the following output:
	
	`# Linux`
	`export AWS_ACCESS_KEY_ID=RoleAccessKeyID`
	`export AWS_SECRET_ACCESS_KEY=RoleSecretKey`
	`export AWS_SESSION_TOKEN=RoleSessionToken`
	`# Windows`
	`set AWS_ACCESS_KEY_ID=RoleAccessKeyID`
	`set AWS_SECRET_ACCESS_KEY=RoleSecretKey`
	`set AWS_SESSION_TOKEN=RoleSessionToken`
	
	3. Verify that you assumed the IAM role by running the following command:
	
	`aws sts get-caller-identity`
	
	For more information, see the AWS Knowledge Center.	

Task	Description	Skills required

Copy and synchronize data from the source S3 bucket to the destination S3 bucket.	When you have assumed the role `S3MigrationRole` you can copy the data using the copy (**cp**) or synchronize (**sync**) command.
	
	Copy (see the [AWS CLI Command Reference](#) for details):
	
	`aws s3 cp s3://amazon-s3-demo-source-bucket/ \ s3://amazon-s3-demo-destination-bucket/ \ --recursive --source-region SOURCE-REGION-NAME --region DESTINATION-REGION-NAME`
	
	Synchronize (see the [AWS CLI Command Reference](#) for details):
	
	`aws s3 sync s3://amazon-s3-demo-source-bucket/ \ s3://amazon-s3-demo-destination-bucket/ \ --source-region SOURCE-REGION-NAME --region DESTINATION-REGION-NAME`
		Cloud administrator

Troubleshooting

Issue	Solution
An error occurred (`AccessDenied`) when calling the `ListObjects` operation: Access Denied	• Make sure that you have assumed the role `S3MigrationRole` . • Run `aws sts get-caller-identity` to check the role used. If the output doesn't display the ARN for `S3MigrationRole` , assume the role again and retry.

Copy data from an S3 bucket to another account and Region by using S3 Batch Replication

Appasaheb Bagali, Lakshmikanth B D, Shubham Harsora, Purushotham G K, and Suman Rajotia, Amazon Web Services

Summary

This pattern explains how you can use Amazon Simple Storage Service (Amazon S3) Batch Replication to copy the contents of an S3 bucket to another S3 bucket automatically, without any manual intervention, after you set up the buckets. The source and destination buckets can be in the same or in different AWS accounts or Regions.

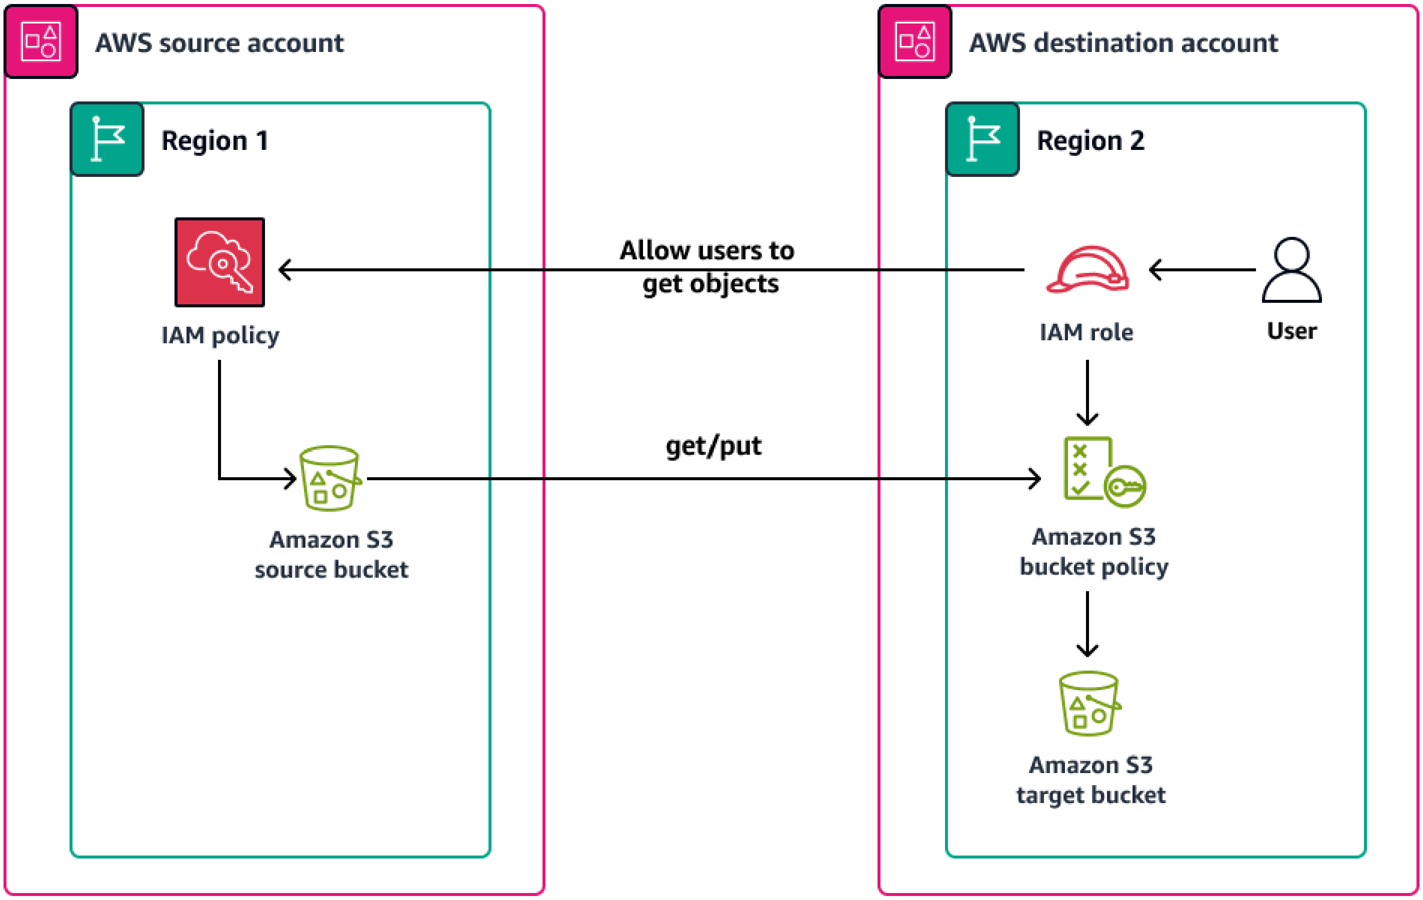
S3 Batch Replication gives you a way to replicate Amazon S3 objects that existed before a replication configuration was in place, objects that were previously replicated, and objects that failed replication. This method uses an S3 Batch Operations job. When the job finishes, you receive a completion report.

You can use S3 Batch Replication in scenarios that require continuous and automatic migration of new objects from a source bucket to a destination bucket. For one-time migration, you can use the AWS Command Line Interface (AWS CLI) instead, as described in the pattern Copy data from an S3 bucket to another account and Region by using the AWS CLI.

Prerequisites and limitations

- A source AWS account.
- A destination AWS account.
- An S3 bucket in the source account with a few objects (files or folders).
- One or more S3 buckets in the destination account.
- S3 Versioning enabled on the source and destination buckets.
- AWS Identity and Access Management (IAM) permissions to create an IAM policy, IAM role, and S3 bucket policy on the source and destination accounts.
- Amazon S3 Lifecycle rules disabled while the S3 Batch Replication job is active. This ensures parity between the source and destination buckets. Otherwise, the destination bucket might not be an exact replica of the source bucket.

Architecture



Tools

AWS services

- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [Amazon Simple Storage Service (Amazon S3)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Best practices

The following video from AWS re:Invent 2022 discusses best practices for using Amazon S3 replication for regulatory compliance, data protection, and increased application performance.

Epics

Create an IAM policy and role for cross-account replication in the source account

Task	Description	Skills required

Create an IAM policy for cross-account replication.	In the AWS source account:
	
	1. Open the [IAM console](https://console.aws.amazon.com/iam/).
	2. Create a new IAM policy.
	3. In the **Policy editor** section, choose **JSON**, and paste the following code.
	
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Sid": "GetSourceBucketConfiguration",`
	`            "Effect": "Allow",`
	`            "Action": [`
	`                "s3:ListBucket",`
	`                "s3:GetBucketLocation",`
	`                "s3:GetBucketAcl",`
	`                "s3:GetReplicationConfiguration",`
	`                "s3:GetObjectVersionForReplication",`
	`                "s3:GetObjectVersionAcl",`
		Cloud administrator, AWS administrator

Task	Description	Skills required

	``
	 "s3:GetObjectVersi
	onTagging"
	            ],
	            "Resource
	": [
	
	 "arn:aws:s3:::sour
	ce-bucket-name",
	
	 "arn:aws:s3:::sour
	ce-bucket-name/*"
	            ]
	        },
	        {
	            "Sid":
	 "ReplicateToDestin
	ationBuckets",
	            "Effect":
	 "Allow",
	            "Action":
	 [
	
	 "s3:List*",
	
	 "s3:*Object",
	
	 "s3:ReplicateObjec
	t",
	
	 "s3:ReplicateDelet
	e",
	
	 "s3:ReplicateTags"
	            ],
	            "Resource
	": [
	
	 "arn:aws:s3:::dest
	ination-bucket-nam
	e*",
	``	

Task	Description	Skills required

	<pre>"arn:aws:s3:::dest
	ination-bucket-nam
	e/*"
	            ]
	        },
	        {
	            "Sid":
	 "PermissionToOverr
	ideBucketOwner",
	            "Effect":
	 "Allow",
	            "Action":
	 [
	
	 "s3:ObjectOwnerOve
	rrideToBucketOwner"
	            ],
	            "Resource
	": [
	
	 "arn:aws:s3:::dest
	ination-bucket-nam
	e*",
	
	 "arn:aws:s3:::dest
	ination-bucket-nam
	e/*"
	            ]
	        }
	    ]
	}</pre>This policy includes three statements:
	
	• `GetSourceBucketConfiguration` provides access to the replication configuration and object	

Task	Description	Skills required
	version for replication on the source bucket. • `ReplicateToDestinationBuckets` provides access to replicate to the destination bucket. You can specify multiple destination buckets in the array. • `PermissionToOverrideBucketOwner` provides access to `ObjectOwnerOverrideToBucketOwner` so that the destination bucket can own the objects in the destination account that were replicated from the source account. 4. Choose **Next**, provide a policy name such as `cross-account-bucket-replication-policy` , and then choose **Create policy**. For more information, see [Creating IAM policies](#) in the IAM documentation.	

Task	Description	Skills required

Create an IAM role for cross-account replication.	In the AWS source account:
	
	1. On the [IAM console](https://console.aws.amazon.com/iam/), create an IAM role with the following information:
	  a. For **Trusted entity type**, choose **AWS service**.
	  b. For service, choose **S3**.
	  c. For use case, choose **S3 Batch Operations**.
	  d. Choose the policy you created in the previous step.
	2. Provide a role name such as cross-account-bucket-replication-role, and then choose **Create role**.
	
	For more information, see [Creating IAM roles](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create.html) in the IAM documentation.
		Cloud administrator, AWS administrator

Create a replication rule in the source account

Task	Description	Skills required
Create a replication rule against the source bucket in the source account.	In the AWS source account: 1. Open the [Amazon S3 console](https://console.aws.amazon.com/s3/). 2. Navigate to the source bucket, and choose the **Management** tab.	AWS administrator, Cloud administrator

Task	Description	Skills required
	3. Create a replication rule with the following configuration: a. Provide a rule name such as `s3-replication-rule`. b. For **Status**, choose **Enabled**. c. For rule scope, choose **Applies to all objects in the bucket**. d. For **Destination**, choose **Specify a bucket in another account**, and then enter the destination AWS account number and the bucket name. e. Choose the option to change object ownership to the destination bucket owner. f. For **IAM role**, choose the role you created earlier in the source account. g. For **Additional replication options**, select all available options. These provide the ability to replicate content quickly, monitor the progress of replication through Amazon CloudWatch metrics,	

Task	Description	Skills required
	replicate delete markers, and replicate metadata changes. h. Choose **Save**. 4. If you have multiple destination buckets, create additional replication rules. For more information, see [Configuring replication when source and destinati on buckets are owned by different accounts]() in the Amazon S3 documentation.	

Apply a bucket policy to the destination bucket

Task	Description	Skills required
Apply a bucket policy to the destination bucket.	This step has to be performed for each destination bucket individually in AWS destinati on accounts. In the AWS destination account: 1. Open the [Amazon S3 console](), navigate to the destination bucket, and choose the **Permissions** tab. 2. Edit the bucket policy by providing the following	AWS administrator, AWS systems administrator, Cloud administrator

Task	Description	Skills required

	JSON code, and save the policy:
	`{`
	`    "Version":`
	` "2012-10-17",`
	`    "Id": "PolicyFo`
	`rDestinationBucket",`
	`    "Statement": [`
	`        {`
	`            "Sid":`
	` "Permissions on`
	` objects and buckets",`
	`            "Effect":`
	` "Allow",`
	`            "Principa`
	`l": {`
	`                "AWS":`
	` "arn:aws:iam::Sour`
	`ceAWSAccountNumber`
	`:role/IAM-Role-cre`
	`ated-in-step1-in-s`
	`ource-account"`
	`            },`
	`            "Action": [`
	
	` "s3:List*",`
	
	` "s3:GetBucketVersi`
	`oning",`
	
	` "s3:PutBucketVersi`
	`oning",`
	
	` "s3:ReplicateDelete",`
	
	` "s3:ReplicateObject"`
	`            ],`
	`            "Resource":`
	` [`	

Task	Description	Skills required

	``
	 "arn:aws:s3:::dest
	ination-bucket",
	
	 "arn:aws:s3:::dest
	ination-bucket/*"
	            ]
	        },
	        {
	            "Sid":
	 "Permission to
	 override bucket owner",
	            "Effect":
	 "Allow",
	            "Principa
	l": {
	                "AWS":
	 "arn:aws:iam::Sour
	ceAWSAccountNumber
	:role/IAM-Role-cre
	ated-in-step1-in-s
	ource-account"
	            },
	            "Action":
	 "s3:ObjectOwnerOve
	rrideToBucketOwner",
	            "Resource
	": "arn:aws:s3:::dest
	ination-bucket/*"
	        }
	    ]
	}
	``
	
	This policy includes two statements:
	
	• `Permissions on objects and buckets` indicates that the destinati on bucket can replicate	

Task	Description	Skills required
	content based on the role defined in the source account. The role provides permissions to the source bucket. • `Permission to override bucket owner` indicates that the destinati on bucket has permissions to override the ownership from the source account.	

Test Amazon S3 cross-account replication

Task	Description	Skills required
Verify that replication works correctly.	1. Add an object to the source bucket. 2. Verify that the new object appears in the S3 buckets in the destination accounts. 3. View CloudWatch metrics: a. In the source bucket, choose the **Metrics** tab. b. In the **Replication metrics** section, select a replication rule. c. Choose **Display charts**. The charts reflect the state of replication by displaying the operation s that are pending replication, the replicati	AWS administrator, Cloud administrator

Task	Description	Skills required
	on latency, and the bytes pending replication. For more information, see [Monitoring metrics with Amazon CloudWatch] in the Amazon S3 documentation.

Migrate data from an on-premises Hadoop environment to Amazon S3 using DistCp with AWS PrivateLink for Amazon S3

Jason Owens, Andres Cantor, Jeff Klopfenstein, Bruno Rocha Oliveira, and Samuel Schmidt, Amazon Web Services

Summary

This pattern demonstrates how to migrate nearly any amount of data from an on-premises Apache Hadoop environment to the Amazon Web Services (AWS) Cloud by using the Apache open-source tool DistCp with AWS PrivateLink for Amazon Simple Storage Service (Amazon S3). Instead of using the public internet or a proxy solution to migrate data, you can use AWS PrivateLink for Amazon S3 to migrate data to Amazon S3 over a private network connection between your on-premises data center and an Amazon Virtual Private Cloud (Amazon VPC). If you use DNS entries in Amazon Route 53 or add entries in the **/etc/hosts** file in all nodes of your on-premises Hadoop cluster, then you are automatically directed to the correct interface endpoint.

This guide provides instructions for using DistCp for migrating data to the AWS Cloud. DistCp is the most commonly used tool, but other migration tools are available. For example, you can use offline AWS tools like AWS Snowball or AWS Snowmobile, or online AWS tools like AWS Storage Gateway or AWS DataSync. Additionally, you can use other open-source tools like Apache NiFi.

Prerequisites and limitations

Prerequisites

- An active AWS account with a private network connection between your on-premises data center and the AWS Cloud
- Hadoop, installed on premises with DistCp
- A Hadoop user with access to the migration data in the Hadoop Distributed File System (HDFS)
- AWS Command Line Interface (AWS CLI), installed and configured
- Permissions to put objects into an S3 bucket

Limitations

Virtual private cloud (VPC) limitations apply to AWS PrivateLink for Amazon S3. For more information, see Interface endpoint properties and limitations and AWS PrivateLink quotas (AWS PrivateLink documentation).

AWS PrivateLink for Amazon S3 doesn't support the following:

- Federal Information Processing Standard (FIPS) endpoints
- Website endpoints
- Legacy global endpoints

Architecture

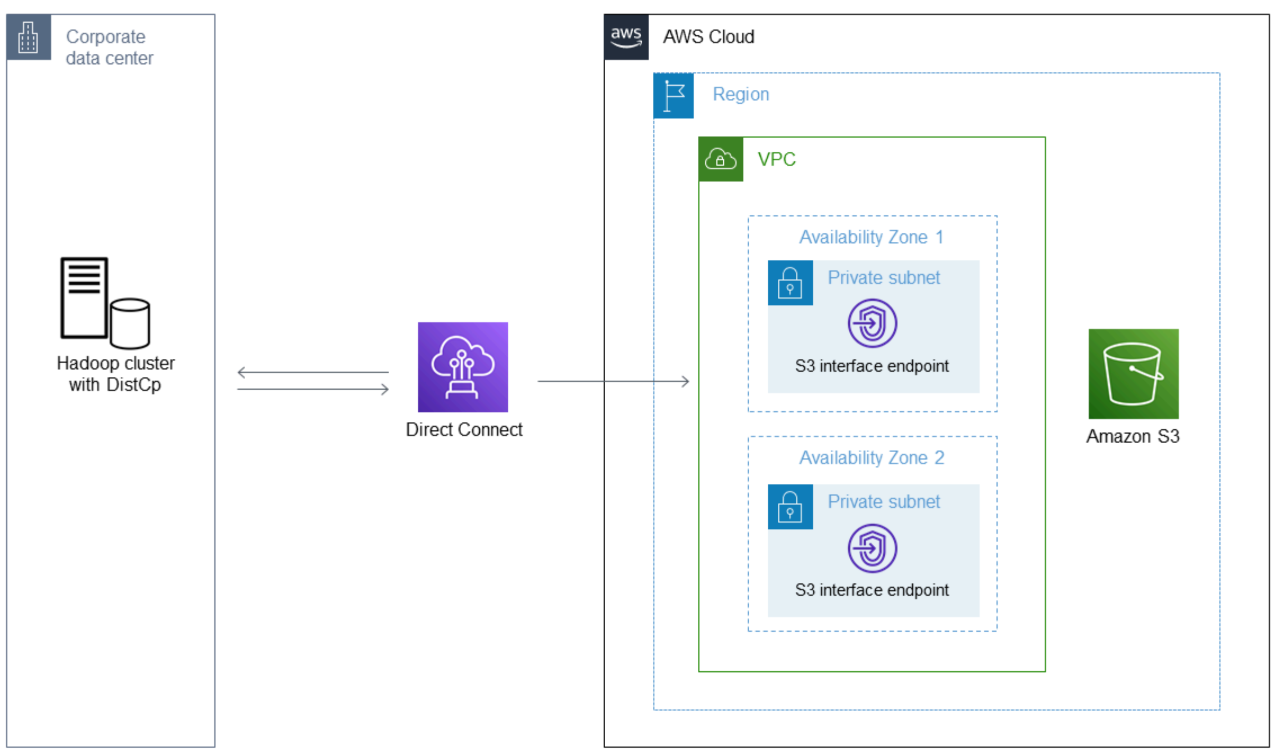
Source technology stack

- Hadoop cluster with DistCp installed

Target technology stack

- Amazon S3
- Amazon VPC

Target architecture



The diagram shows how the Hadoop administrator uses DistCp to copy data from an on-premises environment through a private network connection, such as AWS Direct Connect, to Amazon S3 through an Amazon S3 interface endpoint.

Tools

AWS services

- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- Apache Hadoop DistCp (distributed copy) is a tool used for copying large inter-clusters and intra-clusters. DistCp uses Apache MapReduce for distribution, error handling and recovery, and reporting.

Epics

Migrate data to the AWS Cloud

Task	Description	Skills required
Create an endpoint for AWS PrivateLink for Amazon S3.	1. Sign in to the AWS Management Console and open the Amazon VPC console. 2. On the navigation pane, choose **Endpoints**, and then choose **Create Endpoint**.	AWS administrator

Task	Description	Skills required
	3. For **Service category**, choose **AWS services**. 4. In the search box, enter **s3**, and then press **Enter**. 5. In the search results, choose the **com.amazonaws.<your-aws-region>.s3** service name where the value in the **Type** column is **Interface**. 6. For **VPC**, choose your VPC. For **Subnets**, choose your subnets. 7. For **Security group**, choose or create a security group that allows TCP 443. 8. Add tags based on your requirements and then choose **Create endpoint**.	

Task	Description	Skills required
Verify the endpoints and find the DNS entries.	1. Open the [Amazon VPC console](https://console.aws.amazon.com/vpc/), choose **Endpoints**, and then select the endpoint that you created earlier. 2. On the **Details** tab, find the first DNS entry for **DNS names**. This is the Regional DNS entry. When you use this DNS name, requests alternate between DNS entries specific to Availability Zones. 3. Choose the **Subnets** tab. You can find the address of the endpoint's elastic network interface in each Availability Zone.	AWS administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr>
<td>Check the firewall rules and routing configurations.</td>
<td>

To confirm that your firewall rules are open and that your networking configuration is correctly set up, use Telnet to test the endpoint on port 443. For example:

```
$ telnet vpce-<your-VPC-endpoint-ID>.s3.us-east-2.vpce.amazonaws.com 443

Trying 10.104.88.6...

Connected to vpce-<your-VPC-endpoint-ID>.s3.us-east-2.vpce.amazonaws.com.

...

$ telnet vpce-<your-VPC-endpoint-ID>.s3.us-east-2.vpce.amazonaws.com 443

Trying 10.104.71.141...

Connected to vpce-<your-VPC-endpoint-ID>.s3.us-east-2.vpce.amazonaws.com.
```

Note

If you use the Regional entry, a successful test shows

</td>
<td>Network administrator, AWS administrator</td>
</tr>
</table>

Task	Description	Skills required
	that the DNS is alternating between the two IP addresses that you can see on the **Subnets** tab for your selected endpoint in the Amazon VPC console.	

Task	Description	Skills required
Configure the name resolutio n.	You must configure the name resolution to allow Hadoop to access the Amazon S3 interface endpoint. You can't use the endpoint name itself. Instead, you must resolve `<your-bucket-name> .s3.<your-aws-regi on>.amazonaws.com` or `*.s3.<your-aws-reg ion>.amazonaws.com` . For more information on this naming limitation, see [Introducing the Hadoop S3A client](#) (Hadoop website). Choose one of the following configuration options: • Use on-premises DNS to resolve the private IP address of the endpoint. You can override behavior for all buckets or selected buckets. For more informati on, see "Option 2: Access Amazon S3 using Domain Name System Response Policy Zones (DNS RPZ)" in [Secure hybrid access to Amazon S3 using AWS PrivateLink](#) (AWS blog post). • Configure on-premises DNS to conditionally forward	AWS administrator

Task	Description	Skills required
	traffic to the resolver inbound endpoints in the VPC. Traffic is forwarded to Route 53. For more information, see "Option 3: Forwarding DNS requests from on premises using Amazon Route 53 Resolver Inbound Endpoints" in [Secure hybrid access to Amazon S3 using AWS PrivateLink](#) (AWS blog post). • Edit the **/etc/hosts** file on all the nodes in your Hadoop cluster. This is a temporary solution for testing and isn't recommended for production. To edit the **/etc/hosts** file, add an entry for either `<your-bucket-name>.s3.<your-aws-region>.amazonaws.com` or `s3.<your-aws-region>.amazonaws.com`. The **/etc/hosts** file can't have multiple IP addresses for an entry. You must choose a single IP address from one of the Availability Zones, which then becomes a single point of failure.	

Task	Description	Skills required
Configure authentication for Amazon S3.	To authenticate to Amazon S3 through Hadoop, we recommend that you export temporary role credentials to the Hadoop environme nt. For more information, see [Authenticating with S3](#) (Hadoop website). For long-running jobs, you can create a user and assign a policy that has permissio ns to put data into an S3 bucket only. The access key and secret key can be stored on Hadoop, accessible only to the DistCp job itself and to the Hadoop administr ator. For more informati on on storing secrets, see [Storing secrets with Hadoop Credential Providers](#) (Hadoop website). For more informati on on other authentication methods, see [How to get credentials of an IAM role for use with CLI access to an AWS account](#) in the documentation for AWS IAM Identity Center (successor to AWS Single Sign-On). To use temporary credentials, add the temporary credentia ls to your credentials file, or run the following commands	AWS administrator

Task	Description	Skills required

	to export the credentials to your environment:
	`export AWS_SESSION_TOKEN=SECRET-SESSION-TOKEN`
	`export AWS_ACCESS_KEY_ID=SESSION-ACCESS-KEY`
	`export AWS_SECRET_ACCESS_KEY=SESSION-SECRET-KEY`
	
	If you have a traditional access key and secret key combination, run the following commands:
	`export AWS_ACCESS_KEY_ID=my.aws.key`
	`export AWS_SECRET_ACCESS_KEY=my.secret.key`
	
	Note
	If you use an access key and secret key combination, then change the credentials provider in the DistCp commands from `"org.apache.hadoop.fs.s3a.TemporaryAWSCredent`	

Task	Description	Skills required
	`ialsProvider"` to `"org.apache.hadoop.fs.s3a.SimpleAWSCredentialsProvider"` .	

Task	Description	Skills required
Transfer data by using DistCp.	To use DistCp to transfer data, run the following commands: `hadoop distcp -Dfs.s3a.aws.credentials.provider=\ "org.apache.hadoop.fs.s3a.TemporaryAWSCredentialsProvider" \ -Dfs.s3a.access.key="${AWS_ACCESS_KEY_ID}" \ -Dfs.s3a.secret.key="${AWS_SECRET_ACCESS_KEY}" \ -Dfs.s3a.session.token="${AWS_SESSION_TOKEN}" \ -Dfs.s3a.path.style.access=true \ -Dfs.s3a.connection.ssl.enabled=true \ -Dfs.s3a.endpoint=s3.<your-aws-region>.amazonaws.com \ hdfs:///user/root/ s3a://<your-bucket-name>` **Note** The AWS Region of the endpoint isn't automatically discovered when you use the DistCp	Migration engineer, AWS administrator

Task	Description	Skills required
	command with AWS PrivateLink for Amazon S3. Hadoop 3.3.2 and later versions resolve this issue by enabling the option to explicitly set the AWS Region of the S3 bucket. For more information, see [S3A to add option fs.s3a.endpoint.region to set AWS region](#) (Hadoop website). For more information on additional S3A providers, see [General S3A Client configuration](#) (Hadoop website). For example, if you use encryption, you can add the following option to the series of commands above depending on your type of encryption: `-Dfs.s3a.server-side-encryption-algorithm=AES-256 [or SSE-C or SSE-KMS]` **Note** To use the interface endpoint with S3A,	

Task	Description	Skills required
	you must create a DNS alias entry for the S3 Regional name (for example, `s3.<your-aws-region>.amazonaws.com`) to the interface endpoint. See the *Configure authentication for Amazon S3* section for instructions. This workaround is required for Hadoop 3.3.2 and earlier versions. Future versions of S3A won't require this workaround. If you have signature issues with Amazon S3, add an option to use Signature Version 4 (SigV4) signing: `-Dmapreduce.map.java.opts="-Dcom.amazonaws.services.s3.enableV4=true"`	

More patterns

- Access AWS services from IBM z/OS by installing the AWS CLI

- Automatically build CI/CD pipelines and Amazon ECS clusters for microservices using AWS CDK
- Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9
- Build and push Docker images to Amazon ECR using GitHub Actions and Terraform
- Build and test iOS apps with AWS CodeCommit, AWS CodePipeline, and AWS Device Farm
- Check AWS CDK applications or CloudFormation templates for best practices by using cdk-nag rule packs
- Configure mutual TLS authentication for applications running on Amazon EKS
- Automate the creation of AppStream 2.0 resources using AWS CloudFormation
- Create a custom log parser for Amazon ECS using a Firelens log router
- Create a pipeline and AMI using CodePipeline and HashiCorp Packer
- Create dynamic CI pipelines for Java and Python projects automatically
- Deploy CloudWatch Synthetics canaries by using Terraform
- Deploy a CI/CD pipeline for Java microservices on Amazon ECS

- Deploy a ChatOps solution to manage SAST scan results by using Amazon Q Developer in chat applications custom actions and AWS CloudFormation
- Deploy agentic systems on Amazon Bedrock with the CrewAI framework by using Terraform
- Deploy an AWS Glue job with an AWS CodePipeline CI/CD pipeline
- Deploy an Amazon EKS cluster from AWS Cloud9 using an EC2 instance profile
- Deploy code in multiple AWS Regions using AWS CodePipeline, AWS CodeCommit, and AWS CodeBuild
- Deploy artifact updates to on-premises Amazon EC2 instances using AWS CodePipeline
- Deploy workloads from Azure DevOps pipelines to private Amazon EKS clusters
- Execute Amazon Redshift SQL queries by using Terraform
- Export AWS Backup reports from across an organization in AWS Organizations as a CSV file
- Export tags for a list of Amazon EC2 instances to a CSV file
- Generate an AWS CloudFormation template containing AWS Config managed rules using Troposphere
- Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account
- Implement a GitHub Flow branching strategy for multi-account DevOps environments
- Implement a Gitflow branching strategy for multi-account DevOps environments
- Implement a Trunk branching strategy for multi-account DevOps environments
- Implement centralized custom Checkov scanning to enforce policy before deploying AWS infrastructure
- Implement AI-powered Kubernetes diagnostics and troubleshooting with K8sGPT and Amazon Bedrock integration
- Automatically detect changes and initiate different CodePipeline pipelines for a monorepo in CodeCommit
- Integrate a Bitbucket repository with AWS Amplify using AWS CloudFormation
- Launch a CodeBuild project across AWS accounts using Step Functions and a Lambda proxy function
- Manage Multi-AZ failover for EMR clusters by using Application Recovery Controller
- Manage blue/green deployments of microservices to multiple accounts and Regions by using AWS code services and AWS KMS multi-Region keys

- Monitor Amazon ECR repositories for wildcard permissions using AWS CloudFormation and AWS Config
- Optimize multi-account serverless deployments by using the AWS CDK and GitHub Actions workflows
- Provision AWS Service Catalog products based on AWS CloudFormation templates by using GitHub Actions
- Provision least-privilege IAM roles by deploying a role vending machine solution
- Publish Amazon CloudWatch metrics to a CSV file
- Remove Amazon EC2 entries across AWS accounts from AWS Managed Microsoft AD by using AWS Lambda automation
- Remove Amazon EC2 entries in the same AWS account from AWS Managed Microsoft AD by using AWS Lambda automation
- Run unit tests for Python ETL jobs in AWS Glue using the pytest framework
- Set up a Helm v3 chart repository in Amazon S3
- Set up a CI/CD pipeline by using AWS CodePipeline and AWS CDK
- Set up centralized logging at enterprise scale by using Terraform
- Set up end-to-end encryption for applications on Amazon EKS using cert-manager and Let's Encrypt
- Simplify Amazon EKS multi-tenant application deployment by using Flux
- Subscribe multiple email endpoints to an SNS topic by using a custom resource
- Coordinate resource dependency and task execution by using the AWS Fargate WaitCondition hook construct
- Use third-party Git source repositories in AWS CodePipeline
- Create a CI/CD pipeline to validate Terraform configurations by using AWS CodePipeline
- More patterns

Automate AWS infrastructure operations by using Amazon Bedrock

Ishwar Chauthaiwale and Anand Bukkapatnam Tirumala, Amazon Web Services

Summary

In cloud native solutions, automating common infrastructure operations play a vital role in maintaining efficient, secure, and cost-effective environments. Manually handling operations is time-consuming and prone to human error. Additionally, team members with varying levels of AWS expertise need to perform these tasks while ensuring compliance with security protocols. This pattern demonstrates how to use Amazon Bedrock to automate common AWS infrastructure operations through natural language processing (NLP).

This pattern can help organizations to develop reusable, modular, and secure code for deploying generative AI-based infrastructure across multiple environments. Through its focus on infrastructure as code (IaC) and automation, it delivers key DevOps benefits including version control, consistent deployments, reduced errors, faster provisioning, and improved collaboration.

The pattern implements a secure architecture that enables teams to manage operations related to key AWS services including:

- Amazon Simple Storage Service (Amazon S3) bucket versioning management
- Amazon Relational Database Service (Amazon RDS) snapshot creation
- Amazon Elastic Compute Cloud (Amazon EC2) instance management

The architecture employs Amazon Virtual Private Cloud (Amazon VPC) endpoints and private networking for secure communication, with AWS Lambda functions operating as task executors within private subnets. Amazon S3 provides data management and implements comprehensive AWS Identity and Access Management (IAM) roles and permissions to ensure proper access controls. This solution doesn’t include a chat history feature, and the chat isn’t stored.

Prerequisites and limitations

- An active AWS account.
- Proper access control measures should be in place to help secure and control access. Examples of access control include using AWS Systems Manager, foundation models access, an IAM role for deployment, and service-based roles, disabling public access to Amazon S3 buckets, and setting up a dead-letter queue.

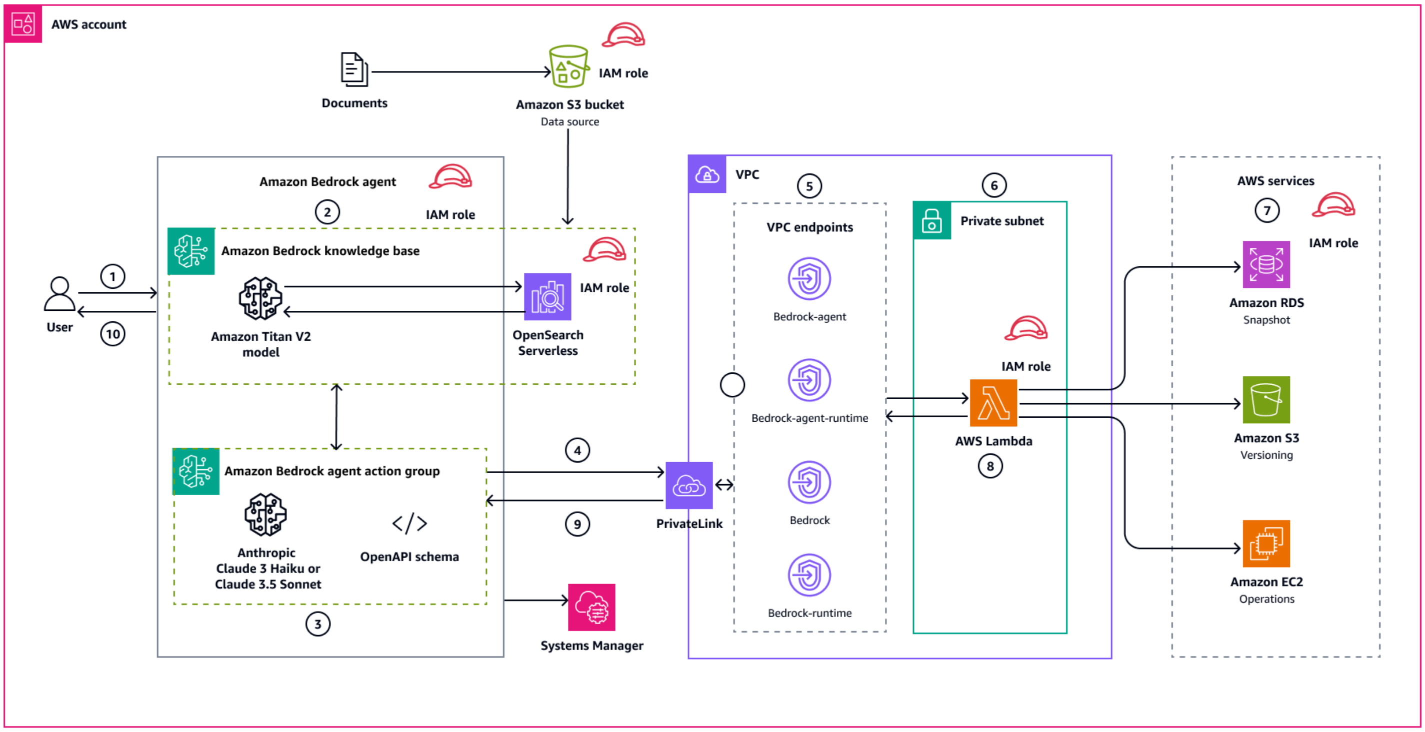
- An AWS Key Management Service (AWS KMS) customer managed key.
- AWS Command Line Interface (AWS CLI) version 2 or later, installed and configured on the deployment environment.
- Terraform AWS Provider version 4 or later installed and configured.
- Terraform version 1.5.7 or later installed and configured.
- Review and Define OpenAPI schemas for your agent's action groups in Amazon Bedrock to help protect against unauthorized access and maintain data integrity.
- Access enabled in your AWS account for the required Amazon Titan Text Embeddings v2 and either the Claude 3.5 Sonnet or Claude 3 Haiku foundation models. To avoid deployment failure, confirm that your target deployment AWS Region supports the required models.
- A configured virtual private cloud (VPC) that follows the AWS Well Architected Framework best practices.
- Completed review of the Amazon Responsible AI policy.

Product versions

- Amazon Titan Text Embeddings v2
- Anthropic Claude 3.5 Sonnet or Claude 3 Haiku
- Terraform AWS Provider version 4 or later
- Terraform version 1.5.7 or later

Architecture

The following diagram shows the workflow and architecture components for this pattern.



The solution architecture consists of multiple layers that work together to process natural language requests and execute corresponding AWS operations:

1. The user makes operations requests through the Amazon Bedrock chat console.
2. The chatbot uses Amazon Bedrock Knowledge Bases for request processing. It implements the Amazon Titan Text Embeddings v2 model for natural language processing.
3. If the user prompt includes an action request, the Amazon Bedrock action group uses either the Anthropic Claude 3 Haiku or the Claude 3.5 Sonnet model (depending on your choice) for execution logic and defines operations through an OpenAPI schema.
4. The action group reaches the Amazon VPC endpoints using AWS PrivateLink for secure service communication.
5. The AWS Lambda function is reached through Amazon VPC endpoints for Amazon Bedrock services.
6. The Lambda functions are the primary execution engine. Based on the request, the Lambda function calls the API to perform actions on the AWS services. The Lambda function also handles operation routing and execution.
7. The AWS services get the API request from the Lambda function and corresponding operations are performed.
8. The Lambda function computes an output payload that is understood by Amazon Bedrock.

9. This payload is sent to Amazon Bedrock by using PrivateLink for secure service communication. The large language model (LLM) used by Amazon Bedrock understands this payload and converts it into human understandable format.
10. The output is then shown to the user on the Amazon Bedrock chat console.

The solution enables the following primary operations:

- Amazon S3 – Enable bucket versioning for version control.
- Amazon RDS – Create database snapshots for backup.
- Amazon EC2 – List instances and control the start and stop of instances.

Tools

AWS services

- Amazon Bedrock is a fully managed service that makes high-performing foundation models (FMs) from leading AI startups and Amazon available for your use through a unified API.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon OpenSearch Serverless is an on-demand serverless configuration for Amazon OpenSearch Service.
- AWS PrivateLink helps you create unidirectional, private connections from your virtual private clouds (VPCs) to services outside of the VPC.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

- [AWS Systems Manager](#) helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.
- [Amazon Virtual Private Cloud (Amazon VPC)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- [Git](#) is an open source, distributed version control system.
- [Terraform](#) is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub [aws-samples/infra-ops-orchestrator](#) repository.

Best practices

- Monitor Lambda execution logs regularly. For more information, see [Monitoring and troubleshooting Lambda functions](#). For more information about best practices, see [Best practices for working with AWS Lambda functions](#).
- Review security configurations periodically to ensure compliance with your organization's requirements. For more information, see [Security best practices](#).
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see [Grant least privilege](#) and [Security best practices](#) in the IAM documentation.

Epics

Deploy the solution

Task	Description	Skills required
Clone the repository.	To clone the repository on your local machine, run the following command:	AWS DevOps, DevOps engineer

Task	Description	Skills required
	`git clone "git@github.com:aws-samples/infra-ops-orchestrator.git"` `cd infra-ops-orchestrator`	
Edit the environment variables.	Edit the `terraform.tfvars` file. in the root directory of the cloned repository. Review the placeholders that are indicated by `[XXXXX]`, and update them according to your environment.	AWS DevOps, DevOps engineer

Create the infrastructure.	To create the infrastructure, run the following commands:
	`terraform init`
	`terraform plan`
	Review the execution plan carefully. If the planned changes are acceptable, then run the following command:
	`terraform apply --auto-approve`
		AWS DevOps, DevOps engineer

Access the solution

Task	Description	Skills required

Access the solution.	After successful deployment, follow these steps to use the chat-based interface:
	
	1. To access the Infrastructure Orchestrator Assistant, sign in to the AWS Managemen t Console using an [IAM role with Amazon Bedrock permissions](), and open the Amazon Bedrock console at [https://console.a ws.amazon.com/bedrock/](https://console.aws.amazon.com/bedrock/). Select **Agents** from the left navigation pane. Then, choose the Infrastructure Orchestrator Assistant in the **Agents** section.
	2. Make sure that target resources exist in your AWS environment for the following suggestions, and then try these example operations:
	  • Create a snapshot backup of an Amazon RDS instance by asking: 'Create a snapshot of RDS instance [instance-name]'
	  • Enable versioning on an Amazon S3 bucket by
		AWS DevOps, DevOps engineer

Task	Description	Skills required
	asking: 'Enable versioning for bucket [bucket-name]' • List Amazon EC2 instances by asking: 'List all EC2 instances' • Start or stop an Amazon EC2 instance by asking: 'Start EC2 instance [instance-id]' or 'Stop EC2 instance [instance-id]' Note: Replace the values in brackets with the actual resource names or IDs from your AWS environment.	

Clean up resources

Task	Description	Skills required

Delete the created resources.	To delete all infrastructure created by this pattern, run the following command:
	
	`terraform plan -destroy`
	
	Review the destruction plan carefully. If the planned deletions are acceptable, then run the following command:
	
	`terraform destroy`
		AWS DevOps, DevOps engineer

Task	Description	Skills required
	Note: This command will permanently delete all resources created by this pattern. The command will prompt for confirmat ion before removing any resources.	

Troubleshooting

Issue	Solution
Agent behavior	For information about this issue, see Test and troubleshoot agent behavior in the Amazon Bedrock documentation.
Lambda network issues	For information about these issues, see Troubleshoot networking issues in Lambda in the Lambda documentation.
IAM permissions	For information about these issues, see Troubleshoot IAM in the IAM documentation.

Automate CloudFront updates when load balancer endpoints change by using Terraform

Tamilselvan P, Mohan Annam, and Naveen Suthar, Amazon Web Services

Summary

When users of Amazon Elastic Kubernetes Service (Amazon EKS) delete and re-install their ingress configuration through Helm charts, a new Application Load Balancer (ALB) is created. This creates a problem because Amazon CloudFront continues to reference the old ALB's DNS record. As a result, services destined to this endpoint will not be reachable. (For more details about this problematic workflow, see [Additional information](#).)

To solve this issue, this pattern describes using a custom AWS Lambda function that was developed with Python. This Lambda function automatically detects when a new ALB is created through Amazon EventBridge rules. Using the AWS SDK for Python (Boto3), the function then updates the CloudFront configuration with the new ALB's DNS address, ensuring that traffic is routed to the correct endpoint.

This automated solution maintains service continuity without additional routing or latency. The process helps to ensure that CloudFront always references the correct ALB DNS endpoint, even when the underlying infrastructure changes.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A sample web application for testing and validation that is deployed on Amazon EKS by using Helm. For more information, see Deploy applications with Helm on Amazon EKS in the Amazon EKS documentation.
- Configure CloudFront to route calls to an ALB that is created by a Helm ingress controller. For more information, see Install AWS Load Balancer Controller with Helm in the Amazon EKS documentation and Restrict access to Application Load Balancers in the CloudFront documentation.
- Terraform installed and configured in a local workspace.

Limitations

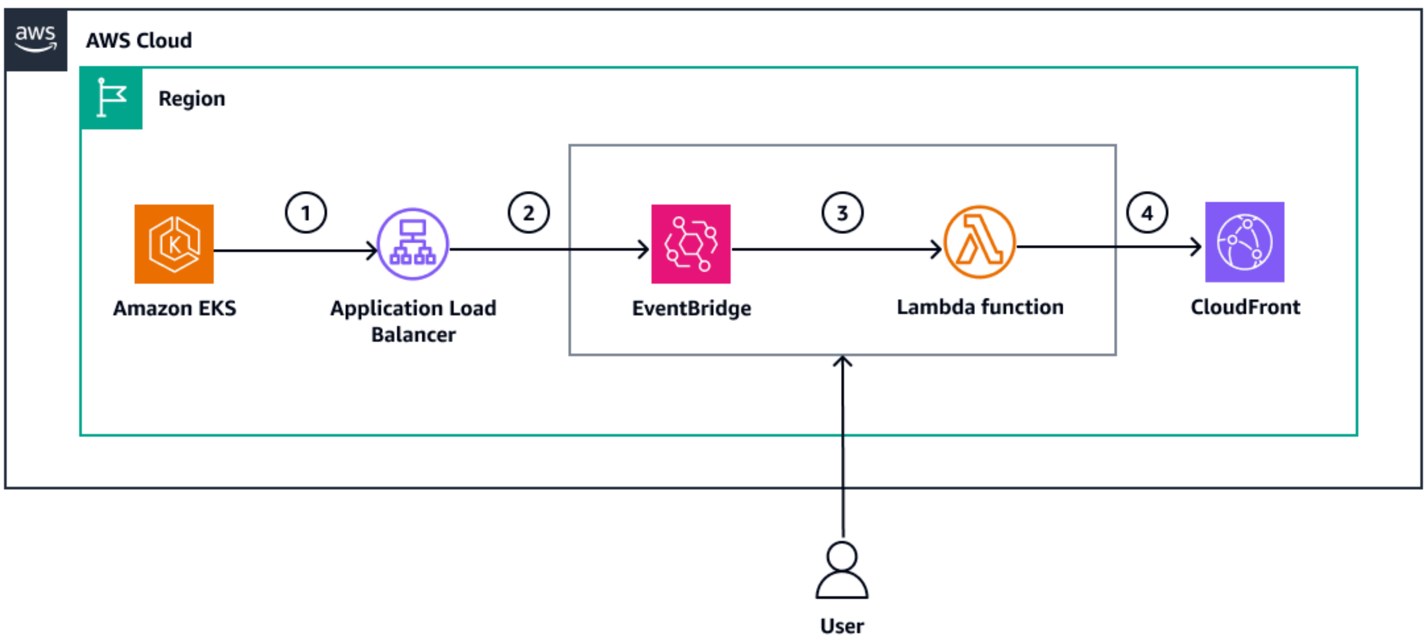
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- Terraform version 1.0.0 or later
- Terraform AWS Provider version 4.20 or later

Architecture

The following diagram shows the workflow and architecture components for this pattern.



This solution performs the following steps:

1. The Amazon EKS ingress controller creates a new Application Load Balancer (ALB) whenever there is a Helm restart or deployment.
2. EventBridge looks for ALB creation events.
3. The ALB creation event triggers the Lambda function.
4. The Lambda function has been deployed based on python 3.9 and uses boto3 API to call AWS services. The Lambda function updates the CloudFront entry with the latest load balancer DNS name, which is received from create load balancer events.

Tools

AWS services

- Amazon CloudFront speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

Other tools

- Python is a general-purpose computer programming language.
- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub aws-cloudfront-automation-terraform-samples repository.

Epics

Set up local workstation

Task	Description	Skills required
Set up and configure the Git CLI.	To install and configure the Git command line interface (CLI) in your local workstati	DevOps engineer

Task	Description	Skills required
	on, follow the Getting Started – Installing Git instructions in the Git documentation.	

Task	Description	Skills required
Create the project folder and add the files.	1. Go to the pattern's [GitHub repository](), and choose the **Code** button. 2. On the **Clone** dialog, choose the **HTTPS** tab. In **Clone using the web URL**, copy the URL that's shown. 3. Create a folder on your local machine. Name it with your project name. 4. Open a terminal on your local machine, and navigate to this folder. 5. To clone this pattern's git repository, run the following command: `git clone https://github.com/aws-samples/aws-cloudfront-automation-terraform-samples` 6. After the repository has been cloned, use the following command to go to the cloned directory: `cd <directory name>/cloudfront-update` Open this project in an Integrated Development Environment (IDE) of your choice.	DevOps engineer

Provision the target architecture using the Terraform configuration

Task	Description	Skills required

Deploy the solution.	To deploy resources in the target AWS account, use the following steps:
	1. Go to the `cloudfront-update` folder.
	2. Update the `terraform .tfvars` file with the `cloudfront_distribution_id` .
	3. To set the AWS Region for your AWS profile, run the following command:
	`export AWS_REGION={{ REGION }}`
	4. To initialize Terraform, run the following command:
	`terraform init`
	5. To validate Terraform, run the following command:
	`terraform validate`
	6. To create a Terraform execution plan, run the following command:
	`terraform plan`
		DevOps engineer

Task	Description	Skills required
	7. To apply the actions from `terraform plan`, run the following command: `terraform apply`	

Verify the deployment

Task	Description	Skills required
Validate the deployment.	1. Sign in to the AWS Management Console and open the Amazon CloudFront console at https://console.aws.amazon.com/cloudfront/v4/home. 2. In the left navigation pane, choose **Distributions** and then open the CloudFront distribution. 3. On the **Origins** tab, verify that the origin name and origin mapping have the updated ALB DNS record.	DevOps engineer

Clean up infrastructure

Task	Description	Skills required
Clean up the infrastructure.	To clean up the infrastructure that you created earlier, use the following steps:	DevOps engineer

Task	Description	Skills required
	1. Run the following command: `terraform destroy` 2. To confirm the destroy command, enter `yes`.	

Troubleshooting

Issue	Solution
Error validating provider credentials	When you run the Terraform `apply` or `destroy` commands from your local machine, you might encounter an error similar to the following: `Error: configuring Terraform AWS Provider: error validating provider credentials: error calling sts:GetCallerIdentity: operation error STS: GetCallerIdentity, https response error StatusCode: 403, RequestID: 123456a9-fbc1-40ed-b8d8-513d0133ba7f, api error InvalidClientTokenId: The security token included in the request is invalid.` This error is caused by the expiration of the security token for the credentials used in your local machine's configuration. To resolve the error, see [Set and view configuration settings](#) in the AWS Command Line Interface (AWS CLI) documentation.

Related resources

AWS resources

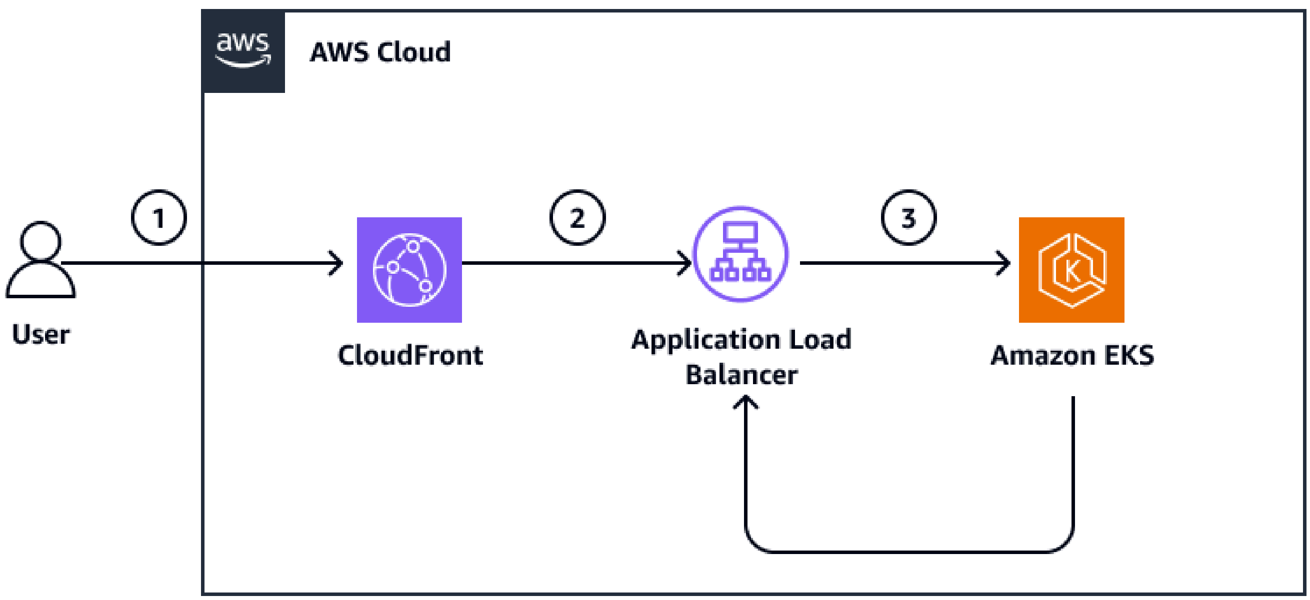
- Restrict access to Application Load Balancers
- Route internet traffic with AWS Load Balancer Controller

Terraform documentation

- AWS Provider
- Install Terraform
- Remote State

Additional information

Problematic workflow



The diagram shows the following workflow:

1. When the user accesses the application, the call goes to CloudFront.
2. CloudFront routes the calls to the respective Application Load Balancer (ALB).
3. The ALB includes the target IP addresses which are the application pod's IP addresses. From there, the ALB provides the expected results to the user.

However, this workflow demonstrates a problem. The application deployments are happening through Helm charts. Whenever there is a deployment or if someone restarts Helm, the respective ingress is also re-created. As a result, the external load balancer controller re-creates the ALB. Also, during each re-creation, the ALB is re-created with a different DNS name. Because of this, CloudFront will have a stale entry in the origin settings. Because of this stale entry, the application will not be reachable for the user. This issue results in downtime for users.

Alternative solution

Another possible solution is to create an external DNS for the ALB and then point it to the Amazon Route 53 private hosted zone endpoint in CloudFront. However, this approach adds another hop in the application flow, which might cause application latency. This pattern's Lambda function solution doesn't disrupt current flow.

Automate Amazon CodeGuru reviews for AWS CDK Python applications by using GitHub Actions

Vanitha Dontireddy and Sarat Chandra Pothula, Amazon Web Services

Summary

This pattern showcases the integration of Amazon CodeGuru automated code reviews for AWS Cloud Development Kit (AWS CDK) Python applications, orchestrated through GitHub Actions. The solution deploys a serverless architecture defined in AWS CDK Python. By automating expert code analysis within the development pipeline, this approach can do the following for AWS CDK Python projects:

- Enhance code quality.
- Streamline workflows.
- Maximize the benefits of serverless computing.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2.9.11 or later, installed and configured.
- An active GitHub account and a GitHub repository with read and write workflow permissions and creation of pull requests (PR) by GitHub Actions to ensure the PR workflow operates correctly.
- An OpenID Connect (OIDC) role in GitHub Actions to deploy the solution in the AWS account. To create the role, use the AWS CDK construct.

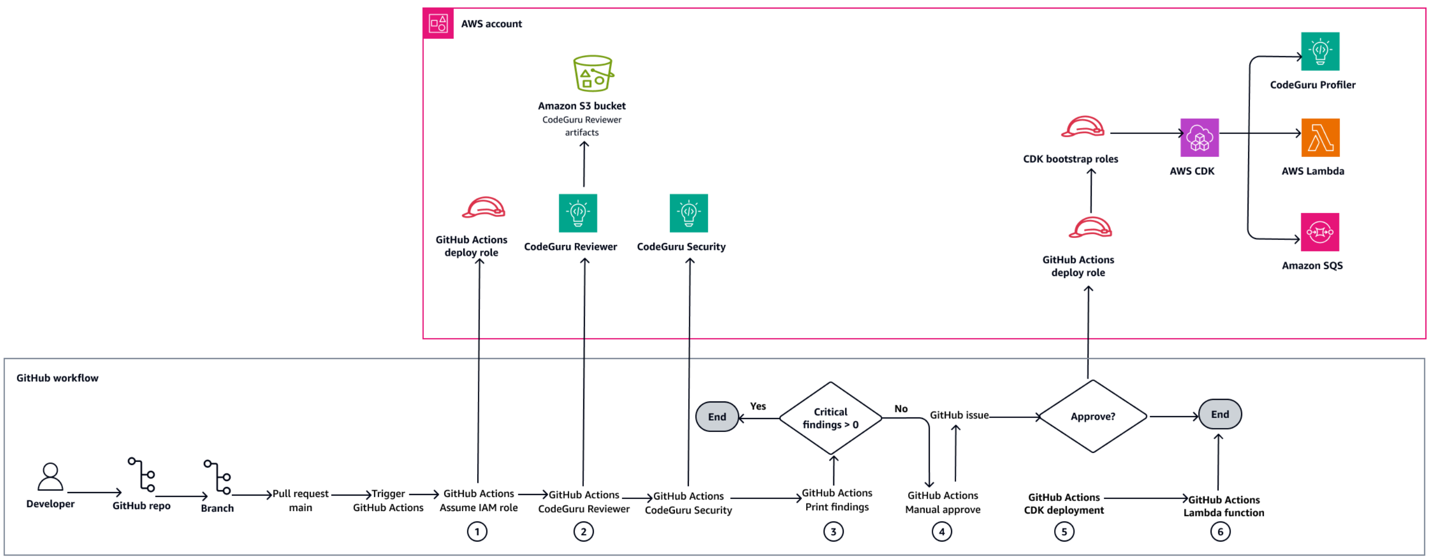
Limitations

- Amazon CodeGuru Profiler supports applications written in all Java virtual machine (JVM) languages (such as Scala and Kotlin) and runtimes and Python 3.6 or later.
- Amazon CodeGuru Reviewer supports associations with Java and Python code repositories only from the following source providers: AWS CodeCommit, Bitbucket, GitHub, GitHub Enterprise Cloud, and GitHub Enterprise Server. In addition, Amazon Simple Storage Service (Amazon S3) repositories are only supported through GitHub Actions.

- There isn’t an automated way to print the findings during the continuous integration and continuous deployment (CI/CD) pipeline. Instead, this pattern uses GitHub Actions as an alternative method to handle and display the findings.
- Some AWS services aren’t available in all AWS Regions. For Region availability, see [AWS services by Region](). For specific endpoints, see [Service endpoints and quotas](), and choose the link for the service.

Architecture

The following diagram shows the architecture for this solution.



As shown in the diagram, when a developer creates a pull request (PR) for review, GitHub Actions triggers the following steps:

1. IAM role assumption – The pipeline uses the IAM role that’s specified in GitHub Secrets to perform deployment tasks.
2. Code analysis
   - CodeGuru Reviewer analyzes the code stored in the Amazon S3 bucket. It identifies defects and provides recommendations for fixes and optimizations.
   - CodeGuru Security scans for policy violations and vulnerabilities.
3. Findings review
   - The pipeline prints a link to the findings dashboard in the console output.
   - If critical findings are detected, the pipeline fails immediately.

- For high, normal, or low severity findings, the pipeline continues to the next step.

4. PR approval
   - A reviewer must manually approve the PR.
   - If the PR is denied, the pipeline fails and halts further deployment steps.
5. CDK deployment – Upon PR approval, the CDK deployment process begins. It sets up the following AWS services and resources:
   - CodeGuru Profiler
   - AWS Lambda function
   - Amazon Simple Queue Service (Amazon SQS) queue
6. Profiling data generation – To generate sufficient profiling data for CodeGuru Profiler:
   - The pipeline invokes the Lambda function multiple times by sending messages to the Amazon SQS queue periodically.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- CDK Toolkit is a command line cloud development kit that helps you interact with your AWS CDK app.
- Amazon CodeGuru Profiler collects runtime performance data from your live applications, and provides recommendations that can help you fine-tune your application performance.
- Amazon CodeGuru Reviewer uses program analysis and machine learning to detect potential defects that are difficult for developers to find. Then, CodeGuru Profiler offers suggestions for improving your Java and Python code.
- Amazon CodeGuru Security is a static application security tool that uses machine learning to detect security policy violations and vulnerabilities. It provides suggestions for addressing security risks and generates metrics so you can track the security posture of your applications.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- GitHub Actions is a continuous integration and continuous delivery (CI/CD) platform that's tightly integrated with GitHub repositories. You can use GitHub Actions to automate your build, test, and deployment pipeline.

Code repository

The code for this pattern is available in the GitHub amazon-codeguru-suite-cdk-python repository.

Best practices

- Adhere to the Best practices for developing and deploying cloud infrastructure with the AWS CDK.
- Follow Security best practices in IAM when using AWS services in GitHub Actions workflows, including:
  - Do not store credentials in your repository code.
  - Assume an IAM role to receive temporary credentials, and use temporary credentials when possible.
  - Grant least privilege to the IAM role used in GitHub Actions workflows. Grant only the permissions that are required to perform the actions in your GitHub Actions workflows.
  - Monitor the activity of the IAM role that's used in GitHub Actions workflows.
  - Periodically rotate any long-term credentials that you use.

Epics

Set up your environment

Task	Description	Skills required

Set up AWS credentials.	To export the variables that define the AWS account and AWS Region where you're deploying the stack, run the following commands:
	`export CDK_DEFAULT_ACCOUNT=<12-digit AWS account number>`
	`export CDK_DEFAULT_REGION=<AWS Region>`
	The AWS credentials for the AWS CDK are provided through environment variables.
		AWS DevOps, DevOps engineer

Clone the repository.	To clone the repository on your local machine, run the following command: `git clone https://github.com/aws-samples/amazon-codeguru-suite-cdk-python.git`	AWS DevOps, DevOps engineer
Install the CDK Toolkit.	To confirm that the CDK Toolkit is installed and to check the version, run the following command:	AWS DevOps, DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>cdk --version</code></pre>If the CDK Toolkit version is earlier than 2.27.0, enter the following command to update it to version 2.27.0:<pre><code>npm install -g aws-cdk@2
.27.0</code></pre>If the CDK Toolkit is not installed, run the following command to install it:<pre><code>npm install -g aws-cdk@2
.27.0 --force</code></pre></td><td></td></tr>
<tr><td>Install the required dependencies.</td><td>To install the required project dependencies, run the following command:<pre><code>python -m pip install --
upgrade pip
pip install -r requireme
nts.txt</code></pre></td><td>AWS DevOps, DevOps engineer</td></tr>
</table>

Task	Description	Skills required

Bootstrap the CDK environme nt.	To [bootstrap](#) an AWS CDK environment, run the following commands:
	`npm install`
	`npm run cdk bootstrap "aws://${ACCOUNT_NUMBER}/${AWS_REGION}"`
	After you successfully bootstrap the environment, the following output should be displayed:
	`#  Bootstrapping environment aws://{account}/{region}...`
	`#  Environment aws://{account}/{region} bootstrapped`
		AWS DevOps, DevOps engineer

Deploy the CDK app

Task	Description	Skills required
Synthesize the AWS CDK app.	To synthesize an AWS CDK app, run the following command: `cdk synth` For more information about this command, see [cdk synthesize](#) in the AWS CDK documentation.	AWS DevOps, DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Deploy the resources.</td><td>To deploy the resources, run the following command:<pre><code>cdk deploy --require-approval never</code></pre>Note
The <code>--require-approval never</code> flag means that the CDK will approve and execute all changes automatically. This includes changes that the CDK would normally flag as needing manual review (such as IAM policy changes or removal of resources). Make sure that your CDK code and CI/CD pipeline are well-tested and secure before you use the <code>--require-approval never</code> flag in production environments.</td><td>AWS DevOps, DevOps engineer</td></tr>
</table>

Create GitHub secrets and personal access token

Task	Description	Skills required
Create the required secrets in GitHub.	To allow GitHub Actions workflows to access AWS resources securely without exposing sensitive information in your repository's code, create secrets. To create the secrets in GitHub for `ROLE_TO_ASSUME`, `CodeGuruReviewArtifactBucketName`, and `AWS_ACCOUNT_ID`, follow the instructions in [Creating secrets for a repository](#) in the GitHub Actions documentation. Following is more information about the variables: • `AWS_ACCOUNT_ID` – The AWS account ID where the pipeline is executed. • `CodeGuruReviewArtifactBucketName` – The name of the S3 bucket where CodeGuru Reviewer artifacts are stored. This pattern uses the bucket name `codeguru-reviewer-build-artifacts-<ACCOUNT_ID>-<REGION>`.	AWS DevOps, DevOps engineer

Task	Description	Skills required
	• `AWS_REGION` – The AWS Region where the resources are located. • `ROLE_TO_ASSUME` – The name of the IAM role that the pipeline assumes. This pattern uses the role name `githubActionsDeployRole`.	
Create a GitHub personal access token.	To set up a secure way for your GitHub Actions workflows to authenticate and interact with GitHub, do the following: 1. To create a GitHub personal access token that has read and write access to your repository, follow the instructions in [Managing your personal access tokens](#) in the GitHub documentation. 2. To save this token as a repository secret for GitHub Actions, follow the instructions in [Creating secrets for a repository](#) in the GitHub Actions documentation.	AWS DevOps, DevOps engineer

Clean up

Task	Description	Skills required
Clean up resources.	To clean up your AWS CDK Python app, run the following command: `cdk destroy --all`	DevOps engineer

Troubleshooting

Issue	Solution
Display link to the dashboard findings.	There is no way to print the findings during the CI/CD pipeline. Instead, this pattern uses GitHub Actions as an alternative method to handle and display the findings.

- Triggering a workflow

Automate AWS resource assessment

Naveen Suthar, Arun Bagal, Manish Garg, and Sandeep Gawande, Amazon Web Services

Summary

This pattern describes an automated approach for setting up resource assessment capabilities by using the AWS Cloud Development Kit (AWS CDK). By using this pattern, operations teams gather resource auditing details in an automated manner and view the details of all resources deployed in an AWS account on a single dashboard. This is helpful in the following use cases:

- Identifying infrastructure as code (IaC) tools and isolating resources created by different IaC solutions such as HashiCorp Terraform, AWS CloudFormation, AWS CDK, and AWS Command Line Interface (AWS CLI)
- Fetching resource-auditing information

This solution will also help the leadership team obtain insights about the resources and activities in an AWS account from a single dashboard.

Note: Amazon QuickSight is a paid service. Before running it to analyze data and create a dashboard, review the Amazon QuickSight pricing.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Identity and Access Management (IAM) roles and permissions with access to provision resources
- An Amazon QuickSight account created with access to Amazon Simple Storage Service (Amazon S3) and Amazon Athena
- AWS CDK version 2.55.1 or later installed
- Python version 3.9 or later installed

Limitations

- This solution is deployed to a single AWS account.
- The solution will not track the events that happened before its deployment unless AWS CloudTrail was already set up and storing data in an S3 bucket.

Product versions

- AWS CDK version 2.55.1 or later
- Python version 3.9 or later

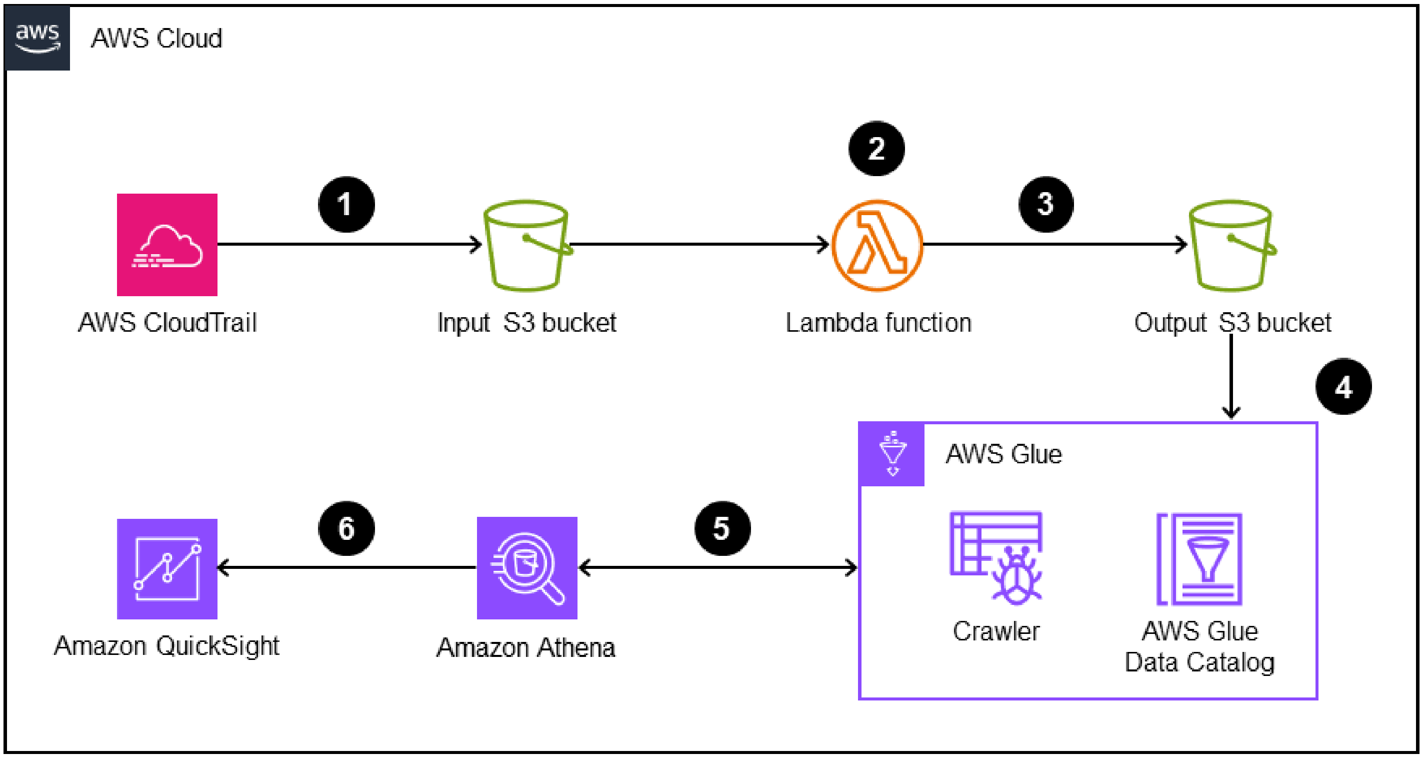
Architecture

Target technology stack

- Amazon Athena
- AWS CloudTrail
- AWS Glue
- AWS Lambda
- Amazon QuickSight
- Amazon S3

Target architecture

The AWS CDK code will deploy all the resources that are required to set up resource-assessment capabilities in an AWS account. The following diagram shows the process of sending CloudTrail logs to AWS Glue, Amazon Athena, and QuickSight.



1. CloudTrail sends logs to an S3 bucket for storage.
2. An event notification invokes a Lambda function that processes the logs and generates filtered data.
3. The filtered data is stored in another S3 bucket.
4. An AWS Glue crawler is set up on the filtered data that is in the S3 bucket to create a schema in the AWS Glue Data Catalog table.
5. The filtered data is ready to be queried by Amazon Athena.
6. The queried data is accessed by QuickSight for visualization.

Automation and scale

- This solution can be scaled from one AWS account to multiple AWS accounts if there is an organization-wide CloudTrail trail in AWS Organizations. By deploying CloudTrail at the organizational level, you can also use this solution to fetch resource-auditing details for all the required resources.
- This pattern uses AWS serverless resources to deploy the solution.

Tools

AWS services

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- AWS CloudTrail helps you audit the governance, compliance, and operational risk of your AWS account.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams. This pattern uses an AWS Glue crawler and an AWS Glue Data Catalog table.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon QuickSight is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code repository

The code for this pattern is available in the GitHub infrastructure-assessment-iac-automation repository.

The code repository contains the following files and folders:

- `lib` folder – The AWS CDK construct Python files used to create AWS resources
- `src/lambda_code` – The Python code that is run in the Lambda function
- `requirements.txt` – The list of all Python dependencies that must be installed
- `cdk.json` – The input file to provide values required to spin up resources

Best practices

Set up monitoring and alerting for the Lambda function. For more information, see Monitoring and troubleshooting Lambda functions. For general best practices when working with Lambda functions, see the AWS documentation.

Epics

Set up your environment

Task	Description	Skills required
Clone the repo on your local machine.	To clone the repository, run the command `git clone https://github.com/aws-samples/infrastructure-assessment-iac-automation.git .`	AWS DevOps, DevOps engineer

Set up the Python virtual environment and install required dependencies.	To set up the Python virtual environment, run the following commands.
	`cd infrastructure-assessment-iac-automation`
	`python3 -m venv .venv`
	`source .venv/bin/activate`
	To set up the required dependencies, run the command `pip install -r requirements.txt .`
		AWS DevOps, DevOps engineer

Set up the AWS CDK environment and synthesize the AWS CDK code.	1. To set up the AWS CDK environment in your AWS account, run the command	AWS DevOps, DevOps engineer

Task	Description	Skills required
	`cdk bootstrap aws://ACCOUNT-NUMBER/REGION .` 2. To convert the code to an AWS CloudFormation stack configuration, run the command `cdk synth`.	

Set up AWS credentials on your local machine

Task	Description	Skills required

Export variables for the account and Region where the stack will be deployed.	To provide AWS credentials for AWS CDK by using environment variables, run the following commands.
	`export CDK_DEFAULT_ACCOUNT=<12 Digit AWS Account Number>`
	`export CDK_DEFAULT_REGION=<region>`
		AWS DevOps, DevOps engineer

Set up the AWS CLI profile.	To set up the AWS CLI profile for the account, follow the instructions in the [AWS documentation].	AWS DevOps, DevOps engineer

Configure and deploy the resource-assessment tool

Task	Description	Skills required
Deploy resources in the account.	To deploy resources in the AWS account by using AWS CDK, do the following: 1. In the root of the cloned repository, in the `cdk.json` file, provide inputs for the following parameters: • `s3_context` • `ct_context` • `kms_context` • `lambda_context` • `glue_context` • `qs_context` These values define resource configurations and nomenclature. Default values are set and can be changed if required. **Note** To avoid an error saying that the S3 bucket already exists, make sure to provide unique names for `s3_contex`	AWS DevOps

Task	Description	Skills required
	`t` in the `ct` and `output` sections. 2. To deploy resources, run the command `cdk deploy`. The `cdk deploy` command creates a CloudTrail resource to log events and save the log file in the input S3 bucket. The trail's log files will be processed by the Lambda function. The filtered results are stored in the output S3 bucket and are ready to be consumed by Amazon Athena and Amazon QuickSight.	

Task	Description	Skills required
Run the AWS Glue crawler and create the Data Catalog table.	An [AWS Glue crawler](#) is used to keep the data schema dynamic. The solution creates and updates partitions in the [AWS Glue Data Catalog table](#) by running the crawler periodically as defined by the AWS Glue crawler scheduler . After the data is available in the output S3 bucket, use the following steps to run the AWS Glue crawler and create the Data Catalog table schema for testing: 1. Sign in to the AWS Management Console and navigate to the AWS Glue console. 2. In the navigation pane, under **Data Catalog**, choose **Crawlers**. 3. Select the `iac-tool-qa-resource-iac-json-crawler` crawler. 4. Run the crawler. 5. After the crawler runs successfully, it creates an AWS Glue Data Catalog table. AWS QuickSight will use the table to visualize the data.	AWS DevOps, DevOps engineer

Task	Description	Skills required
	Note The AWS CDK code configures the AWS Glue crawler to run at a particular time, but you can also run it on demand.	
Deploy the QuickSight construct.	1. To deploy the QuickSight construct, uncomment the code between `#QuickSight setup - start` and `#QuickSight setup – ends` in `resource_iac_tool_stack.py` . 2. After you uncomment , run the `cdk deploy` command to create `QuickSight DataSource` and `QuickSight DataSet` in the QuickSight account.	AWS DevOps, DevOps engineer

Task	Description	Skills required
Create the QuickSight dashboard.	To create the example QuickSight dashboard and analysis, do the following: 1. Navigate to the QuickSight console and select the AWS Region where resources are deployed. 2. In the navigation pane, choose **Datasets**, and validate that a dataset named `ct-operations-iac-ds` has been created in the Amazon QuickSight dataset. If you don't see the dataset, redeploy the QuickSight construct. 3. Select the `ct-operations-iac-ds` dataset, and choose **USE IN ANALYSIS**. 4. Select the default sheet. 5. Select the respective columns from the field list on the left side. 6. After selecting the required columns, select the appropriate visual type to view the data. For more information, see [Starting an analysis in](#)	AWS DevOps, DevOps engineer

Task	Description	Skills required
	Amazon QuickSight and Visual types in Amazon QuickSight.	

Clean up all AWS resources in the solution

Task	Description	Skills required
Remove the AWS resources.	1. To remove AWS resources deployed by the solution, run the command `cdk destroy`. 2. Delete all objects from the two S3 buckets, and then remove the buckets. For more information, see Deleting a bucket.	AWS DevOps, DevOps engineer

Set up additional features on top of the AWS resource-assessment tool automation

Task	Description	Skills required
Monitor and clean up manually created resources.	(Optional) If your organizat ion has compliance requireme nts to create resources using IaC tools, you can achieve compliance by using AWS resource-assessment tool automation to fetch manually provisioned resources. You can also use the tool to import the resources to an IaC tool or to re-create them. To	AWS DevOps, DevOps engineer

Task	Description	Skills required
	monitor manually provision ed resources, perform the following high-level tasks: 1. Deploy AWS resource-assessment tool automatio n. 2. Set up a Lambda function to query the Athena tables on a daily basis, find the relevant data about manually provisioned resources, and export it to a comma-separated values (CSV) file. 3. After the Lambda function runs, a notification with the required data can be sent to respective stakeholders. 4. For longer retention, the .csv file can be stored in the S3 bucket. 5. Based on the information in the .csv file, delete the manually created resources or import them to an existing IaC solution.	

Troubleshooting

Issue	Solution
AWS CDK returns errors.	For help with AWS CDK issues, see Troublesh ooting common AWS CDK issues.

Additional information

Multiple accounts

To set up the AWS CLI credential for multiple accounts, use AWS profiles. For more information, see the *Configure multiple profiles* section in Set up the AWS CLI.

AWS CDK commands

When working with AWS CDK, keep in mind the following useful commands:

- Lists all stacks in the app

```
cdk ls
```

- Emits the synthesized AWS CloudFormation template

```
cdk synth
```

- Deploys the stack to your default AWS account and Region

```
cdk deploy
```

- Compares the deployed stack with the current state

```
cdk diff
```

- Opens the AWS CDK documentation

```
cdk docs
```

Install SAP systems automatically by using open-source tools

Guilherme Sesterheim, Amazon Web Services

Summary

This pattern shows how to automate SAP systems installation by using open-source tools to create the following resources:

- An SAP S/4HANA 1909 database
- An SAP ABAP Central Services (ASCS) instance
- An SAP Primary Application Server (PAS) instance

HashiCorp Terraform creates the SAP system's infrastructure and Ansible configures the operating system (OS) and installs SAP applications. Jenkins runs the installation.

This setup turns SAP systems installation into a repeatable process, which can help increase deployment efficiency and quality.

Note

The example code provided in this pattern works for both high-availability (HA) systems and non-HA systems.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket that contains all of your SAP media files
- An AWS Identity and Access Management (IAM) principal with an access key and secret key, and that has the following permissions:
  - **Read only permissions:** Amazon Route 53, AWS Key Management Service (AWS KMS)
  - **Read and write permissions:** Amazon S3, Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic File System (Amazon EFS), IAM, Amazon CloudWatch, Amazon DynamoDB
- A Route 53 private hosted zone

- A subscription to the Red Hat Enterprise Linux for SAP with HA and Update Services 8.2 Amazon Machine Image (AMI) in Amazon Marketplace
- An AWS KMS customer managed key
- A Secure Shell (SSH) key pair
- An Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you install Jenkins (the hostname is most likely **localhost**)
- Vagrant by HashiCorp installed and configured
- VirtualBox by Oracle installed and configured
- Familiarity with Git, Terraform, Ansible, and Jenkins

Limitations

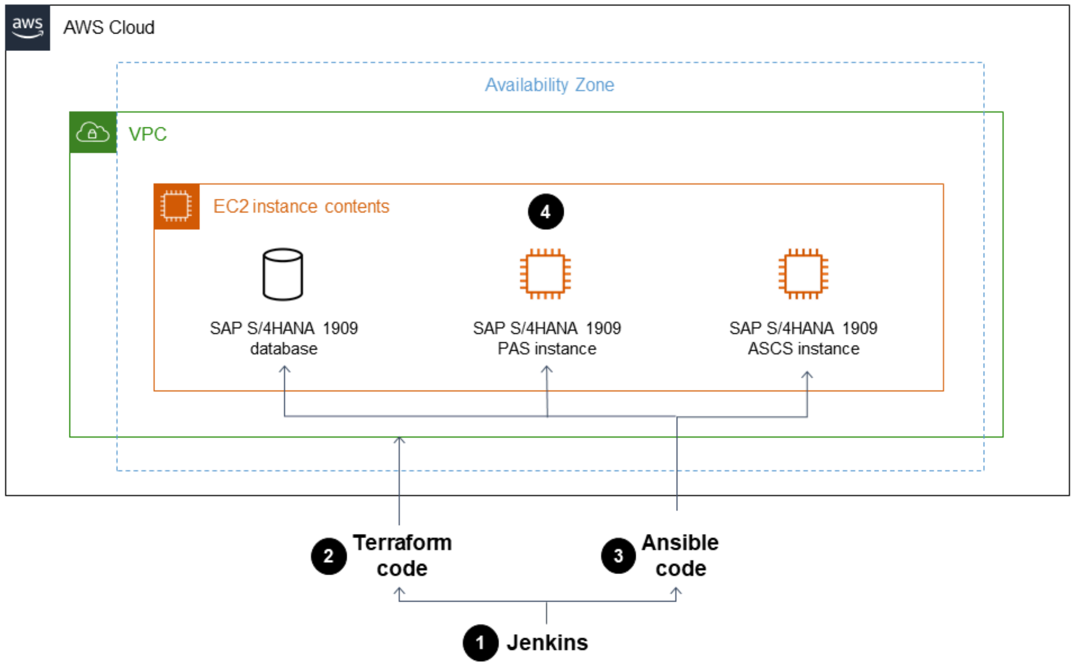
- Only SAP S/4HANA 1909 is fully tested for this specific scenario. The example Ansible code in this pattern requires modification if you use another version of SAP HANA.
- The example procedure in this pattern works for Mac OS and Linux operating systems. Some of the commands can be run only in Unix-based terminals. However, you can achieve a similar result by using different commands and a Windows OS.

Product versions

- SAP S/4HANA 1909
- Red Hat Enterprise Linux (RHEL) 8.2 or higher versions

Architecture

The following diagram shows an example workflow that uses open-source tools to automate SAP systems installation in an AWS account:



The diagram shows the following workflow:

1. Jenkins orchestrates running the SAP system installation by running Terraform and Ansible code.
2. Terraform code builds the SAP system's infrastructure.
3. Ansible code configures the OS and installs SAP applications.
4. An SAP S/4HANA 1909 database, an ASCS instance, and PAS instance that include all defined prerequisites are installed on an Amazon EC2 instance.

> **Note**
>
> The example setup in this pattern automatically creates an Amazon S3 bucket in your AWS account to store the Terraform state file.

Technology stack

- Terraform

- Ansible
- Jenkins
- An SAP S/4HANA 1909 database
- An SAP ASCS instance
- An SAP PAS instance
- Amazon EC2

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to protect your data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- HashiCorp Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.
- Ansible is an open-source configuration as code (CaC) tool that helps automate applications, configurations, and IT infrastructure.
- Jenkins is an open-source automation server that enables developers to build, test, and deploy their software.

Code

The code for this pattern is available in the GitHub aws-install-sap-with-jenkins-ansible repository.

Epics

Configure the prerequisites

Task	Description	Skills required
Add your SAP media files to an Amazon S3 bucket.	Create an Amazon S3 bucket that contains all of your SAP media files. **Important** Make sure that you follow the AWS Launch Wizard's folder hierarchy for **S/4HANA** in the Launch Wizard documentation.	Cloud administrator
Install VirtualBox.	Install and configure VirtualBox by Oracle.	DevOps engineer
Install Vagrant.	Install and configure Vagrant by HashiCorp.	DevOps engineer
Configure your AWS account.	1. Verify that you have an IAM principal with an access key and secret key, and that has the following permissions: • **Read only permissions:** Amazon Route 53, AWS Key Management Service (AWS KMS) • **Read and write permissions:** Amazon	General AWS

Task	Description	Skills required
	S3, Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic File System (Amazon EFS), IAM, Amazon CloudWatch, Amazon DynamoDB 2. Save the IAM principal's access key and secret key for reference later. 3. Create a Route 53 private hosted zone, if you don't have one already. Save the zone name (for example, **sapteam.net**) for reference later. 4. Subscribe to the Red Hat Enterprise Linux for SAP with HA and Update Services 8.2 AMI in Amazon Marketplace. Save the **AMI ID** (for example, **ami-0000000**) for reference later. 5. Create an AWS KMS customer managed key. Save the KMS key's Amazon Resource Name (ARN) for reference later. **Note** The following is an example AWS KMS customer	

Task	Description	Skills required
	managed key ARN: **arn:aws:kms:us-east-1:123412341234:key/uuid** 6. Create an SSH key pair. Save the key pair's name and .pem file for reference later. 7. Create an Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you install Jenkins. Save the **security group ID** for reference later. **Note** The hostname is most likely **localhost**.	

Build and run your SAP installation

Task	Description	Skills required
Clone the code repository from GitHub.	Clone the aws-install-sap-with-jenkins-ansible repository on GitHub.	DevOps engineer
Start the Jenkins service.	Open the Linux terminal. Then, navigate to the local folder that contains the	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>cloned code repository folder and run the following command:
<pre>sudo vagrant up</pre>
Note
The Jenkins startup takes about 20 minutes. The command returns a Service is up and running message when successful.</td><td></td></tr>
<tr><td>Open Jenkins in a web browser and log in.</td><td>1. In a web browser, enter http://localhost:5555. Jenkins opens.
2. Log in to Jenkins by using admin for the username and my_secret_pass_from_vault for the password.</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
Configure your SAP system installation parameters.	1. In Jenkins, choose **Manage Jenkins**. Then, choose **Manage Credentials**. A list of credential variables that you can configure appears. 2. Configure all of the following credential variables: • For **AWS_ACCOUNT_CREDENTIALS**, enter your IAM principal's access key ID and secret access key ID. • For **AMI_ID**, enter the Red Hat Enterprise Linux for SAP with HA and Update Services 8.2 AMI's AMI ID. • For **KMS_KEY_ARN**, enter your AWS KMS customer managed key's ARN. • For **SSH_KEYPAIR_NAME**, enter the name of your SSH key pair, without entering the **.pem** file type. • For **SSH_KEYPAIR_FILE**, enter the full name of your key pair's .pem file (for example, **mykeypair.pem**). Make sure that you also upload the key pairs' .pem file to Jenkins.	AWS systems administrator, DevOps engineer

Task	Description	Skills required
	• For **S3_ROOT_FOLDER_INSTALL_FILES**, enter the name of the Amazon S3 bucket—and folder, if applicable—(for example, **s3://my-media-bucket/S4H1909**) that contains your SAP media files. • For **PRIVATE_DNS_ZONE_NAME**, enter the name of your Route 53 private hosted zone (for example, **myprivatecompanyurl.net**). • For **VPC_ID**, enter the VPC ID (for example, **vpc-12345**) of the Amazon VPC that you're creating the SAP resources in. • For **SUBNET_IDS**, enter two public subnet IDs if you're working in a test environment (for future HA capabilities). If you're working in a production environment, it's a best practice to use two private subnets with a bastion host. • For **SECURITY_GROUP_ID**, enter the ID of the Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you installed Jenkins.	

Task	Description	Skills required
	Note You can configure the other nonrequired parameters as needed, based on your use case. For example, you can change the SAP system ID (SID) of the instances, default password, names, and tags for your SAP system. All of the required variables have **(Required)** at the beginning of their names.	

Task	Description	Skills required
Run you SAP system installat ion.	1. In Jenkins, choose **Jenkins Home**. Then, choose **SAP Hana+ASCS+PAS 3 Instances**. 2. Choose **Spin up and install**. Then, choose **Main**. 3. Choose **Build now**. For information on the pipeline steps, see the **Understanding the pipeline steps** section of Automating SAP installation with open-source tools on the AWS Blog. **Note** If an error occurs, move your cursor over the red error box that appears and choose **Logs**. The logs for the pipeline step that errored out appear. Most errors occur because of incorrect parameter settings.	DevOps engineer, AWS systems administrator

Automate AWS Service Catalog portfolio and product deployment by using AWS CDK

Sandeep Gawande, Viyoma Sachdeva, and RAJNEESH TYAGI, Amazon Web Services

Summary

AWS Service Catalog helps you centrally manage catalogs of IT services, or *products*, that are approved for use in your organization's AWS environment. A collection of products is called a *portfolio*, and a portfolio also contains configuration information. With AWS Service Catalog, you can create a customized portfolio for each type of user in your organization and then grant access to the appropriate portfolio. Those users can then quickly deploy any product they need from within the portfolio.

If you have a complex networking infrastructure, such as multi-Region and multi-account architectures, it is recommended that you create and manage Service Catalog portfolios in a single, central account. This pattern describes how to use AWS Cloud Development Kit (AWS CDK) to automate creation of Service Catalog portfolios in a central account, grant end users access to them, and then, optionally, provision products in one or more target AWS accounts. This ready-to-use solution creates the Service Catalog portfolios in the source account. It also, optionally, provisions products in target accounts by using AWS CloudFormation stacks and helps you configure TagOptions for the products:

- **AWS CloudFormation StackSets –** You can use StackSets to launch Service Catalog products across multiple AWS Regions and accounts. In this solution, you have the option to automatically provision products when you deploy this solution. For more information, see Using AWS CloudFormation StackSets (Service Catalog documentation) and StackSets concepts (CloudFormation documentation).
- **TagOption library –** You can manage tags on provisioned products by using TagOption library. A *TagOption* is a key-value pair managed in AWS Service Catalog. It is not an AWS tag, but it serves as a template for creating an AWS tag based on the TagOption. For more information, see TagOption library (Service Catalog documentation).

Prerequisites and limitations

Prerequisites

- An active AWS account that you want to use as the source account for administering Service Catalog portfolios.
- If you are using this solution to provision products in one or more target accounts, the target account must already exist and be active.
- AWS Identity and Access Management (IAM) permissions to access AWS Service Catalog, AWS CloudFormation, and AWS IAM.

Product versions

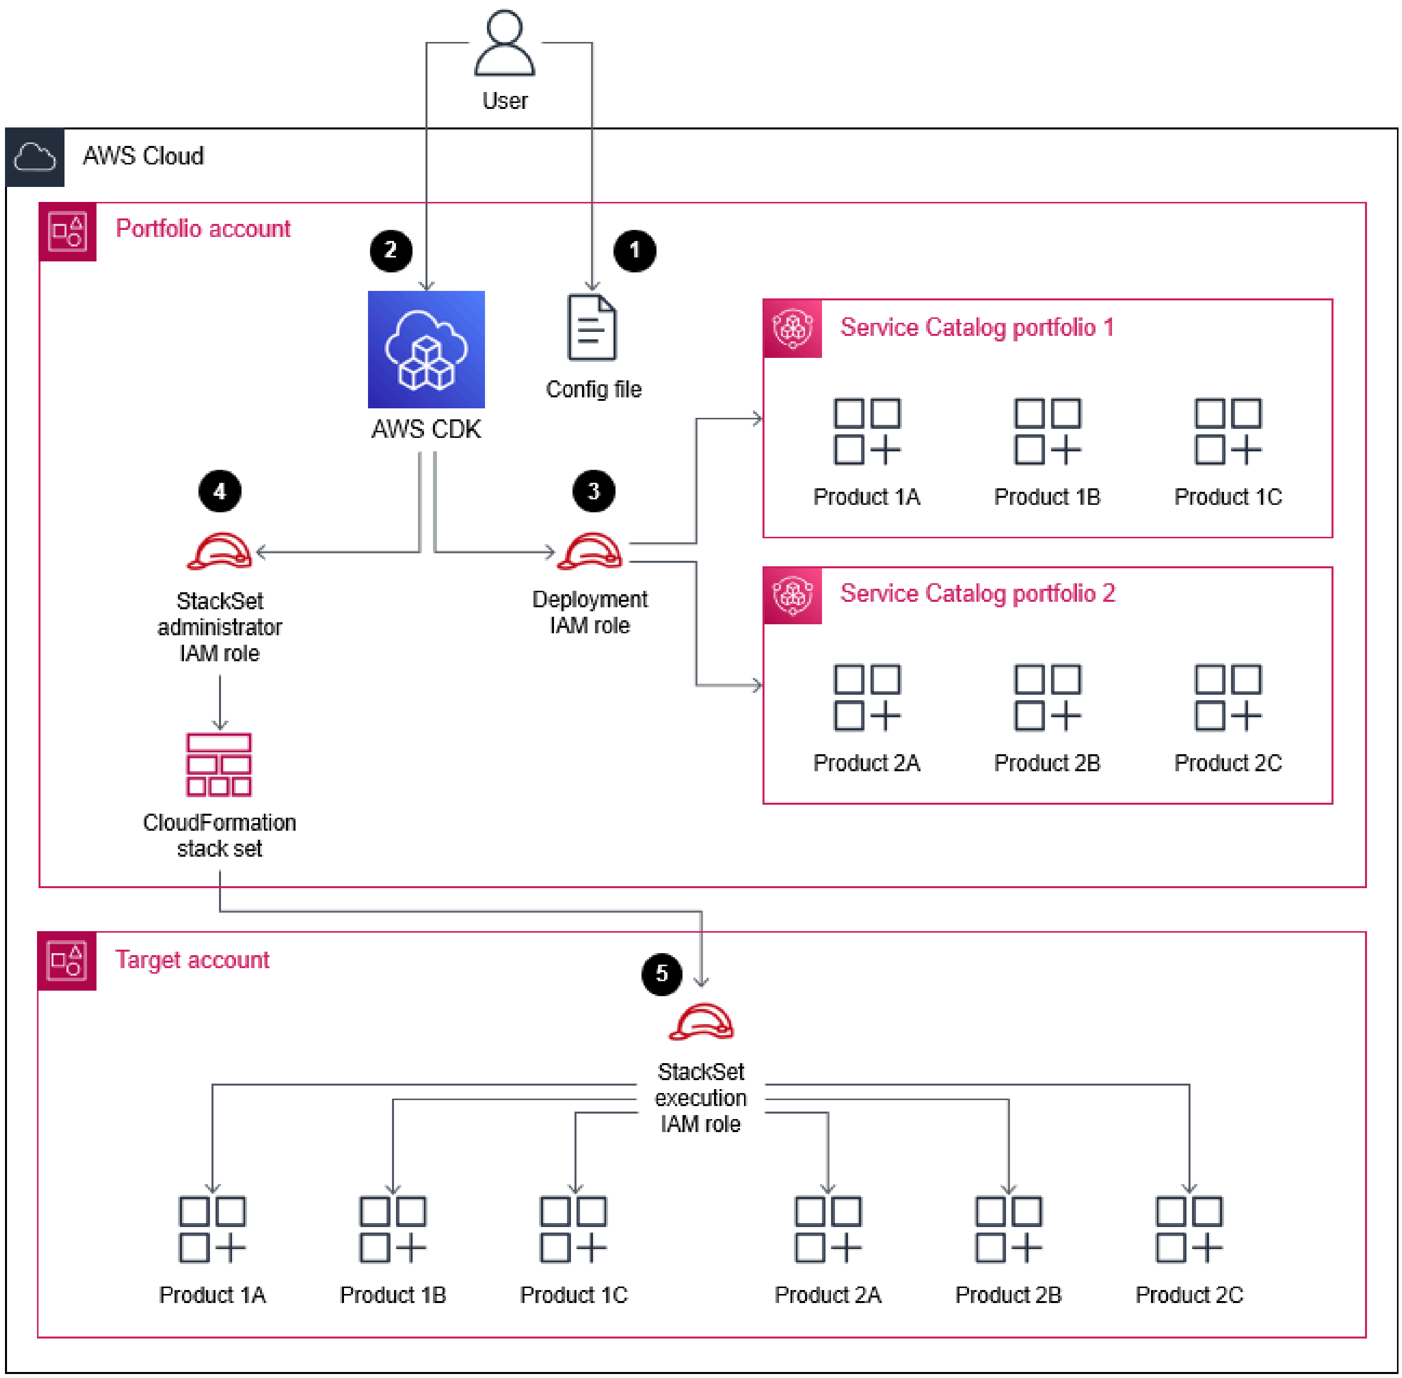
- AWS CDK version 2.27.0

Architecture

Target technology stack

- Service Catalog portfolios in a centralized AWS account
- Service Catalog products deployed in target account

Target architecture



1. In the portfolio (or *source*) account, you update the **config.json** file with the AWS account, AWS Region, IAM role, portfolio, and product information for your use case.
2. You deploy the AWS CDK application.
3. The AWS CDK application assumes the deployment IAM role and creates the Service Catalog portfolios and products defined in the **config.json** file.

If you configured StackSets to deploy products in a target account, the process continues. If you didn't configure StackSets to provision any products, then the process is complete.

4. The AWS CDK application assumes the **StackSet administrator** role and deploys the AWS CloudFormation stack set you defined in the **config.json** file.
5. In the target account, StackSets assumes the **StackSet execution** role and provisions the products.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CDK Toolkit is a command line cloud development kit that helps you interact with your AWS CDK app.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Service Catalog helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

Code repository

The code for this pattern is available on GitHub, in the aws-cdk-servicecatalog-automation repository. The code repository contains the following files and folders:

- **cdk-sevicecatalog-app** – This folder contains the AWS CDK application for this solution.
- **config** – This folder contains the **config.json** file and the CloudFormation template for deploying the products in the Service Catalog portfolio.
- **config/config.json** – This file contains all of the configuration information. You update this file to customize this solution for your use case.
- **config/templates** – This folder contains the CloudFormation templates for the Service Center products.

- **setup.sh** – This script deploys the solution.
- **uninstall.sh** – This script deletes the stack and all of the AWS resources created when deploying this solution.

To use the sample code, follow the instructions in the Epics section.

Best practices

- IAM roles used to deploy this solution should adhere to the principle of least-privilege (IAM documentation).
- Adhere to the Best practices for developing cloud applications with AWS CDK (AWS blog post).
- Adhere to the AWS CloudFormation best practices (CloudFormation documentation).

Epics

Set up your environment

Task	Description	Skills required

Install the AWS CDK Toolkit.	Make sure you have AWS CDK Toolkit installed. Enter the following command to confirm whether it is installed and check the version.
	`cdk --version`
	If AWS CDK Toolkit is not installed, then enter the following command to install it.
	`npm install -g aws-cdk@2.27.0`
	If AWS CDK Toolkit version is earlier than 2.27.0, then enter
		AWS DevOps, DevOps engineer

Task	Description	Skills required
	the following command to update it to version 2.27.0. `npm install -g aws-cdk@2.27.0 --force`	

Clone the repository.	Enter the following command. In *Clone the repository* in the [Additional information](#) section, you can copy the full command containing the URL for the repository. This clones the [aws-cdk-servicecatalog-automation](#) repository from GitHub.
	`git clone <repository-URL>.git`
	This creates a `cd aws-cdk-servicecatalog-automation` folder in the target directory. Enter the following command to navigate into this folder.
	`cd aws-cdk-servicecatalog-automation`
		AWS DevOps, DevOps engineer

Task	Description	Skills required

Set up AWS credentials.	Enter the following commands. These export the following variables, which define the AWS account and Region where you are deploying the stack.
	
	`export CDK_DEFAULT_ACCOUNT=<12-digit AWS account number>`
	
	`export CDK_DEFAULT_REGION=<AWS Region>`
	
	AWS credentials for AWS CDK are provided through environment variables.
		AWS DevOps, DevOps engineer

Configure permissions for end user IAM roles.	If you are going to use IAM roles to grant access to the portfolio and the products in it, the roles must have permissions to be assumed by the **servicecatalog.amazonaws.com** service principal. For instructions about how to grant these permissions, see [Enabling trusted access with Service Catalog](#) (AWS Organizations documentation).	AWS DevOps, DevOps engineer

Task	Description	Skills required
Configure IAM roles required by StackSets.	If you are using StackSets to automatically provision products in target accounts, you need to configure the IAM roles that administer and run the stack set. 1. In the source account, confirm whether the `AWSCloudFormationStackSetAdministrationRole` already exists. In the target accounts, confirm whether `AWSCloudFormationStackSetExecutionRole` already exists. If these roles already exist, you can skip to the next epic. 2. Follow the instructions in [Grant self-managed permissions](#) (IAM documentation) to create the stack set administration role in the portfolio account and create the execution role in each target account.	AWS DevOps, DevOps engineer

Customize and deploy the solution

Task	Description	Skills required
Create the CloudFormation templates.	In the `config/templates` folder, create CloudFormation templates for any products that you want to include in your portfolios. For more information, see [Working with AWS CloudFormation templates](#) (CloudFormation documentation).	App developer, AWS DevOps, DevOps engineer
Customize the config file.	In the `config` folder, open the **config.json** file and define the parameters as appropriate for your use case. The following parameters are required unless otherwise noted: In the `portfolios` section, define the following parameters to create one or more Service Catalog portfolios: • `portfolioName` – The name of the portfolio. • `providerName` – The name of the person, team, or organization that manages the portfolio. • `description` – A brief description of the portfolio.	App developer, DevOps engineer, AWS DevOps

Task	Description	Skills required
	`roles` – (Optional) Names of any IAM roles that should have access to this portfolio. Users who have this role can access the products in this portfolio. `users` – (Optional) Names of any IAM users who should have access to this portfolio and its products. `groups` – (Optional) Names of any IAM user groups that should have access to this portfolio and its products. **Warning** IAM users have long-term credentials, which presents a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed.	

Task	Description	Skills required
	Important `roles`, `users`, and `groups` are all optional parameters, but if you do not define one of these parameters, then no one can view the portfolio products in the Service Catalog console. Define at least one of these parameters. For more information, see [Grant permissions to Service Catalog end users](#) (Service Catalog documentation). • (Optional) In the `tagOption` section, define TagOptions for the products: 　• `key` – Name of the TagOption key 　• `value` – Allowed string values for the TagOption For more information, see [TagOption library](#) (Service Catalog documentation).	

Task	Description	Skills required
	• In the `products` section, define the following parameters for the products: • `portfolioName` – The name of the portfolio where you want to add the product. You can specify only one portfolio. • `productName` – The name of the product. • `owner` – The owner of the product. • `productVersionName` – The name of the product version in string value, such as `v1`. • `templatePath` – The file path for the CloudFormation template for the product. • `deployWithStackSets` – (Optional) Specify one or more accounts and Regions where you want to use StackSets to automatically provision products in the portfolios. If you use this deployment option, all of the following parameter	

Task	Description	Skills required
	s in this section are required: • `accounts` – The target accounts. • `regions` – The target Regions. • `stackSetAdministrationRoleName` – The name of the IAM role used to administer the StackSets configuration. Do not change this value. This role must have this exact name. • `stackSetExecutionRoleName` – The name of the IAM role in the target account that deploys the stack instances. Do not change this value. This role must have this exact name. For an example of a completed config file, see *Sample config file* in the [Additional information](#) section.	

Task	Description	Skills required
Deploy the solution.	Enter the following command. This deploys the AWS CDK app and provisions the Service Catalog portfolios and products as specified in the **config.json** file. `sh +x setup.sh`	App developer, DevOps engineer, AWS DevOps

Task	Description	Skills required
Verify the deployment.	Verify successful deployment by doing the following: 1. Sign in to the AWS Management Console with credentials that can access one or more of the portfolios you defined in the config file. 2. Open the Service Catalog console at https://console.aws.amazon.com/servicecatalog/. 3. In the navigation pane, under **Provisioning**, choose **Products**. Verify that you see a list of products that you specified for the portfolio. 4. Follow the instructi ons in Launching a product (Service Catalog documentation) to launch one of the available products. Confirm that the available product versions and tags match the values you provided in the config file. 5. If you chose to automatic ally provision products in one or more target accounts by using	General AWS

Task	Description	Skills required
	StackSets, do the following : a. Sign in with credentials that give you permissions to view the provisioned products in one of the target accounts. b. In the Service Catalog console, in the navigation pane, under **Provisioning**, choose **Provisioned products**. c. Confirm that the expected products appear in the list.	

Task	Description	Skills required
(Optional) Update the portfolios and products.	If you want to use this solution to update the portfolios or products or to provision new products: 1. Make the required changes in the **config.json** file. 2. Add or modify any CloudFormation templates as needed in the `config/template` folder. 3. Redeploy the solution. For example, you can add additional portfolios or provision more resources. The AWS CDK app implement s only the changes. If there are no changes to previousl y deployed portfolios or products, the redeployment doesn't affect them.	App developer, DevOps engineer, General AWS

Clean up the solution

Task	Description	Skills required
(Optional) Remove AWS resources deployed by this solution.	If you want to delete a provisioned product, follow the instructions in [Deleting provisioned products](#) (Service Catalog documentation).	AWS DevOps, DevOps engineer, App developer

Task	Description	Skills required
	If you want to delete all the resources created by this solution, enter the following command. `sh uninstall.sh`

Automate deletion of AWS CloudFormation stacks and associated resources

SANDEEP SINGH and James Jacob, Amazon Web Services

Summary

AWS CloudFormation is a widely-used service for managing cloud infrastructure as code (IaC). When you use CloudFormation, you manage related resources as a single unit called a *stack*. You create, update, and delete a collection of resources by creating, updating, and deleting stacks.

Sometimes, you no longer need the resources in a CloudFormation stack. Depending on the resources and their configurations, it can be complicated to delete a stack and its associated resources. In real-world production systems, deletions sometimes fail or take a long time due to conflicting conditions or restrictions that CloudFormation cannot override. It can require careful planning and execution to make sure that all resources are properly deleted in an efficient and consistent manner. This pattern describes how to set up a framework that helps you manage the deletion of CloudFormation stacks that involve the following complexities:

- **Resources with delete protection –** Some resources might have delete protection enabled. Common examples are Amazon DynamoDB tables and Amazon Simple Storage Service (Amazon S3) buckets. Delete protection prevents automated deletion, such as deletion through CloudFormation. If you want to delete these resources, you must manually or programmatically override or temporarily disable the delete protection. You should carefully consider the implication of deleting these resources before proceeding.
- **Resources with retention policies –** Certain resources, such as AWS Key Management Service (AWS KMS) keys and Amazon S3 buckets, might have retention policies that specify how long they should be retained after deletion is requested. You should account for these policies in the cleanup strategy to maintain compliance with organizational policies and regulatory requirements.
- **Delayed deletion of Lambda functions that are attached to a VPC –** Deleting an AWS Lambda function that is attached to a virtual private cloud (VPC) can take 5–40 minutes, depending the multiple interconnected dependencies involved in the process. If you detach the function from the VPC before deleting the stack, you can reduce this delay to under 1 minute.
- **Resources not directly created by CloudFormation –** In certain application designs, resources might be created outside of the original CloudFormation stack, either by the application itself or by resources provisioned through the stack. The following are two examples:

  - CloudFormation might provision an Amazon Elastic Compute Cloud (Amazon EC2) instance that runs a user data script. Then, this script might create an AWS Systems Manager parameter to store application-related data. This parameter is not managed through CloudFormation.
  - CloudFormation might provision a Lambda function that automatically generates an Amazon CloudWatch Logs group for storing logs. This log group is not managed through CloudFormation.

  Even though these resources aren't directly managed by CloudFormation, they often need to be cleaned up when the stack is deleted. If left unmanaged, they can become orphaned and lead to unnecessary resource consumption.

Although these guardrails can cause complexity, they are intentional and critical. Allowing CloudFormation to override all constraints and indiscriminately delete resources could lead to detrimental and unforeseen consequences in many scenarios. However, as a DevOps or cloud engineer who is responsible for managing the environment, there are times when overriding these constraints might be necessary, particularly in development, testing, or staging environments.

Targeted business outcomes

By implementing this framework, you can achieve the following benefits:

- **Cost management** – Regular and efficient cleanup of temporary environments, such as end-to-end or user-acceptance testing environments, helps prevent resources from running longer than necessary. This can significantly reduce costs.
- **Security** – Automated cleanup of outdated or unused resources reduces the attack surface and helps maintain a secure AWS environment.
- **Operational efficiency** – Regular and automated cleanup can provide the following operational benefits:
  - Automated scripts that remove old log groups or empty Amazon S3 buckets can improve operational efficiency by keeping the environment clean and manageable.
  - Quickly deleting and recreating stacks supports rapid iteration for design and implementation, which can lead to a more robust and resilient architecture.
  - Regularly deleting and rebuilding environments can help you identify and fix potential issues. This can help you make sure that the infrastructure can withstand real-world scenarios.

Prerequisites and limitations

Prerequisites

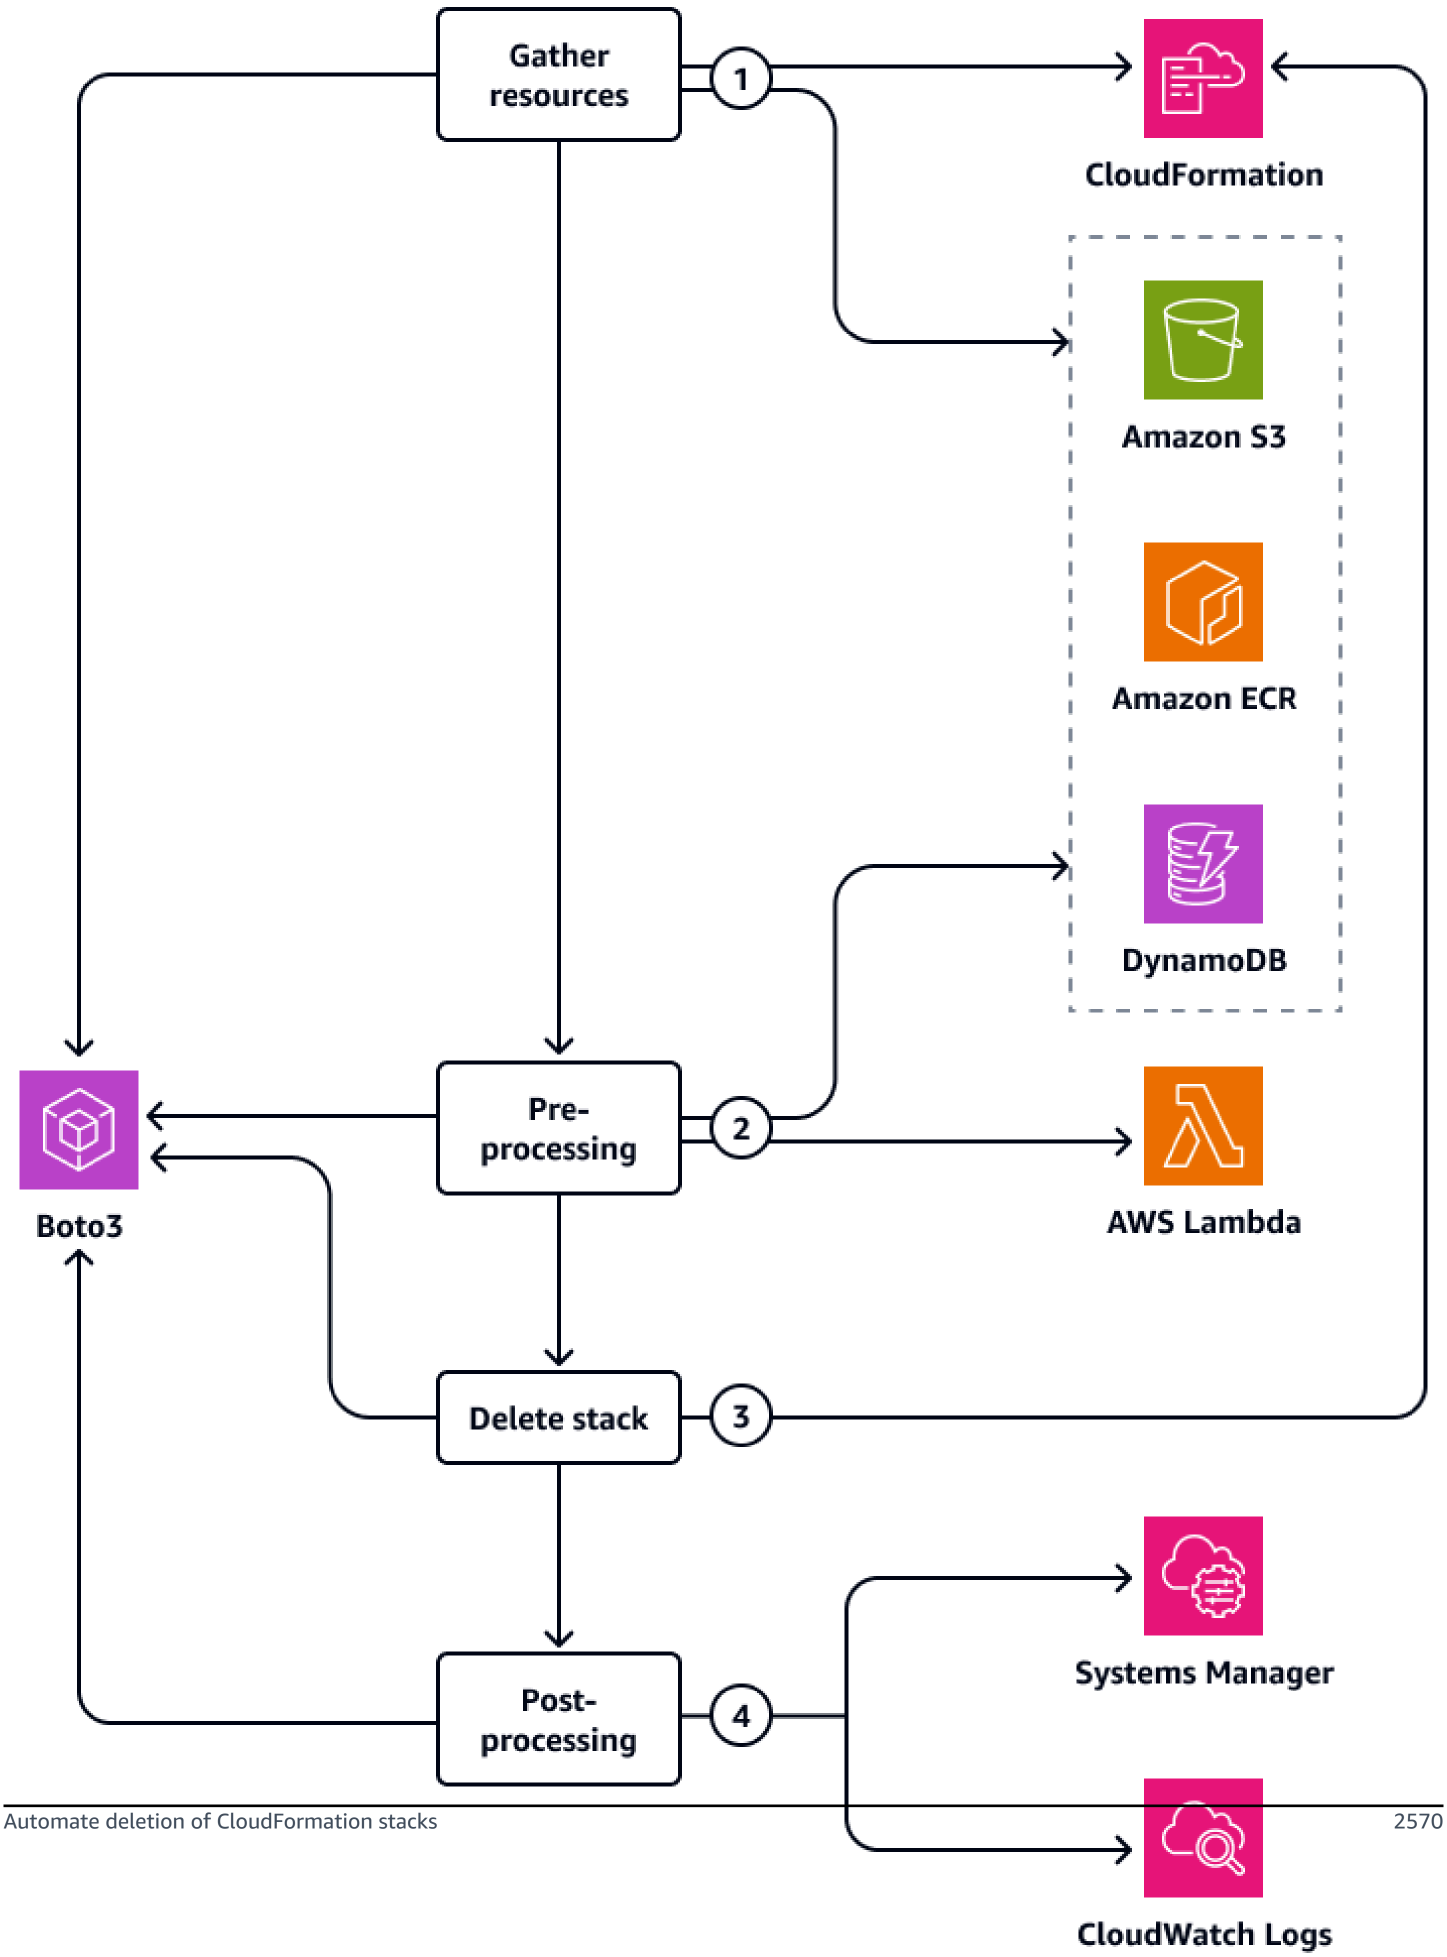
- An active AWS account
- Python version 3.6 or later, installed
- AWS Command Line Interface (AWS CLI), installed and configured

Limitations

- A naming convention is used to identify the resources that should be deleted. The sample code in this pattern uses a prefix for the resource name, but you can define your own naming convention. Resources that do not use this naming convention will not be identified or subsequently deleted.

Architecture

The following diagram shows how this framework identifies the target CloudFormation stack and the additional resources associated with it.



Gather resources
1
CloudFormation
Amazon S3
Amazon ECR
DynamoDB
Boto3
Pre-processing
2
AWS Lambda
Delete stack
3
Systems Manager
Post-processing
4
CloudWatch Logs

The diagram shows the following workflow:

1. **Gather resources** – The automation framework uses a naming convention to return all relevant CloudFormation stacks, Amazon Elastic Container Registry (Amazon ECR) repositories, DynamoDB tables, and Amazon S3 buckets.

   > **Note**
   >
   > The functions for this stage use paginators, a feature in Boto3 that abstracts the process of iterating over a truncated API result set. This makes sure that all resources are processed. To further optimize performance, consider applying server-side filtering or consider using JMESPath to perform client-side filtering.

2. **Pre-processing** – The automation framework identifies and addresses the service constraints that must be overridden in order to allow CloudFormation to delete the resources. For example, it changes the `DeletionProtectionEnabled` setting for DynamoDB tables to `False`. In the command-line interface, for each resource, you receive a prompt asking if you want to override the constraint.
3. **Delete stack** – The automation framework deletes the CloudFormation stack. In the command-line interface, you receive a prompt asking if you want to delete the stack.
4. **Post-processing** – The automation framework deletes any related resources that were not directly provisioned through CloudFormation as part of the stack. Examples of these resource types include Systems Manager parameters and CloudWatch log groups. Separate functions gather these resources, pre-process them, and then delete them. In the command-line interface, for each resource, you receive a prompt asking if you want to delete the resource.

   > **Note**
   >
   > The functions for this stage use paginators, a feature in Boto3 that abstracts the process of iterating over a truncated API result set. This makes sure that all resources are processed. To further optimize performance, consider applying server-side filtering or consider using JMESPath to perform client-side filtering.

Automation and scale

If your CloudFormation stack includes other resources that are not included in the sample code, or if the stack has a constraint that has not been addressed in this pattern, then you can adapt the automation framework for your use case. Follow the same methodology of gathering resources, pre-processing, deleting the stack, and then post-processing.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- CloudFormation Command Line Interface (CFN-CLI) is an open source tool that helps you develop and test AWS and third-party extensions and then register them for use in CloudFormation.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

Other tools

- Click is a Python tool that helps you create command line interfaces.
- Poetry is a tool for dependency management and packaging in Python.
- Pyenv is a tool that helps you manage and switch between versions of Python.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub cloudformation-stack-cleanup repository.

Best practices

- **Tag resources for easy identification –** Implement a tagging strategy to identify resources that are created for different environments and purposes. Tags can simplify the cleanup process by helping you filter resources based on their tags.
- **Set up resource life cycles –** Define resource life cycles in order to automatically delete resources after a certain period. This practice helps you make sure that temporary environments do not become permanent cost liabilities.

Epics

Install tools

Task	Description	Skills required
Clone the repository.	1. Create a folder in your virtual environment. Name it with your project name. 2. Open a terminal on your local machine, and navigate to this folder. 3. Enter the following command to clone the [cloudformation-stack-cleanup](https://github.com/aws-samples/cloudformation-stack-cleanup) repository to your project directory: `git clone https://github.com/aws-samples/cloudformation-stack-cleanup.git`	DevOps engineer
Install Poetry.	Follow the [instructions](https://python-poetry.org/docs/) (Poetry documentation) to install Poetry in the target virtual environment.	DevOps engineer
Install dependencies.	1. Enter the following command to navigate to the project directory: `cd cloudformation-stack-cleanup` 2. Enter the following command:	DevOps engineer

Task	Description	Skills required
	`poetry install` This installs all of the required dependencies, such as Boto3, click, and the source code for the CloudFormation CLI.	
(Optional) Install Pyenv.	Follow the instructions (GitHub) to install Pyenv.	DevOps engineer

(Optional) Customize the framework

Task	Description	Skills required
Create functions that gather, pre-process, and delete the target resources.	1. In the cloned repository, enter the following command to navigate to the `cli` directory: `cd cfncli/cli` 2. Open the **cleanup_enviornment.py** file. 3. Create a new Python function that gathers the type of resource that you want to modify. For an example, see the `gather_ddb_tables` function in this file. 4. Create a new Python function that overrides the service constraints	DevOps engineer, Python

Task	Description	Skills required
	for the target resource. For an example, see the `remove_ddb_deletion_protection` function in this file. 5. Create a new Python function that collects unmanaged target resources. For an example, see the `gather_log_groups` function in this file. 6. Create a new Python function that deletes unmanaged target resources. For an example, see the `delete_log_group` function in this file. 7. Save and close the **cleanup_enviornment.py** file.	

Create sample resources

Task	Description	Skills required
Create a CloudFormation stack.	1. Navigate to the project directory. 2. Enter the following command to create a CloudFormation stack that provisions a DynamoDB	AWS DevOps

Task	Description	Skills required
	table and a security group. Update the value for <VPCID>: `aws cloudformation create-stack \ --stack-name sampleforcleanup-Stack \ --template-body file://samples/sample-cfn-stack.yaml \ --parameters ParameterKey=VpcId,ParameterValue=<VPCID> \ --region us-east-1`	
Create a Systems Manager parameter.	Enter the following command to create a Systems Manager parameter that isn't provisioned through CloudFormation: `aws ssm put-parameter \ --name "/sampleforcleanup/database/password" \ --value "your_db_password" \ --type "SecureString" \ --description "Database password for my app" \ --tier "Standard" \ --region "us-east-1"`	AWS DevOps

Task	Description	Skills required
Create an Amazon S3 bucket.	Enter the following command to create an Amazon S3 bucket that isn't provisioned through CloudFormation: `aws s3api create-bucket \ --bucket samplesorcleanup-unmanagedbucket-<UniqueIdentifier> \ --region us-east-1 \ --create-bucket-configuration LocationConstraint=us-east-1`	AWS DevOps

Delete the sample resources

Task	Description	Skills required
Delete the CloudFormation stack.	1. Enter the following command to delete the sample CloudFormation stack, Systems Manager parameter, and Amazon S3 bucket that you created: `cfncli --region us-east-1 \ dev cleanup-env \ --prefix-list sampleforcleanup` 2. When prompted, enter Y to continue.	AWS DevOps

Task	Description	Skills required
Validate resource deletion.	In the output, confirm that all of the sample resources have been deleted. For a sample output, see the Additiona l resources section of this pattern.	AWS DevOps

Related resources

- Delete a stack (CloudFormation documentation)
- Troubleshooting CloudFormation (CloudFormation documentation)
- Giving Lambda functions access to resources in an Amazon VPC (Lambda documentation)
- How do I delete an AWS CloudFormation stack that's stuck in DELETE_FAILED status? (AWS Knowledge Center)

Additional information

The following is a sample output from the `cfncli` command:

```
cfncli --region aus-east-1  dev cleanup-env --prefix-list sampleforcleanup

https://sts.us-east-1.amazonaws.com
Cleaning up: ['sampleforcleanup'] in xxxxxxxxxx:us-east-1
Do you want to proceed? [Y/n]: Y
No S3 buckets
No ECR repositories
No Lambda functions in VPC
The following DynamoDB tables will have their deletion protection removed:
sampleforcleanup-MyDynamoDBTable
Do you want to proceed with removing deletion protection from these tables? [Y/n]: Y
Deletion protection disabled for DynamoDB table 'sampleforcleanup-MyDynamoDBTable'.
The following CloudFormation stacks will be deleted:
sampleforcleanup-Stack
Do you want to proceed with deleting these CloudFormation stacks? [Y/n]: Y
Initiated deletion of CloudFormation stack: `sampleforcleanup-Stack`
```

```
Waiting for stack `sampleforcleanup-Stack` to be deleted...
CloudFormation stack `sampleforcleanup-Stack` deleted successfully.
The following ssm_params will be deleted:
/sampleforcleanup/database/password
Do you want to proceed with deleting these ssm_params? [Y/n]: Y
Deleted SSM Parameter: /sampleforcleanup/database/password
Cleaned up: ['sampleforcleanup']
```

Automate dynamic pipeline management for deploying hotfix solutions in Gitflow environments by using AWS Service Catalog and AWS CodePipeline

Balaji Vedagiri, Faisal Shahdad, Shanmugam Shanker, and Vivek Thangamuthu, Amazon Web Services

Summary

> **Note**
>
> AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern addresses a scenario of managing a dynamic hotfix pipeline that's dedicated solely to deploying hotfix solutions to a production environment securely. The solution is implemented and managed by using an AWS Service Catalog portfolio and product. An Amazon EventBridge rule is used for event automation. Restrictions are enforced by using Service Catalog portfolio constraints and AWS Identity and Access Management (IAM) roles for developers. Only an AWS Lambda function is allowed to launch the Service Catalog product, triggered by the EventBridge rule. This pattern is designed for environments with a specific Gitflow setup, which is described in Additional information.

Typically, a hotfix is deployed to address critical or security issues reported in a live environment, such as Production. Hotfixes should be deployed directly to Staging and Production environments only. The Staging and Production pipelines are used extensively for regular development requests. These pipelines can't be used to deploy hotfixes because there are ongoing features in quality assurance that can't be promoted to Production. To release hotfixes, this pattern describes a dynamic, short-lived pipeline with the following security features:

- **Automatic creation** – A hotfix pipeline is automatically created whenever a hotfix branch is created in an AWS CodeCommit repository.
- **Access restrictions** – Developers don't have access to create this pipeline outside of the hotfix process.
- **Controlled stage** – The pipeline has a controlled stage with a special access token, ensuring that a pull request (PR) can only be created once.

- **Approval stages –** Approval stages are included in the pipeline to get necessary approvals from relevant stakeholders.
- **Automatic deletion –** The hotfix pipeline is automatically deleted whenever a `hotfix` branch is deleted in the CodeCommit repository after it's merged with a PR.

Prerequisites and limitations

Prerequisites

- Three active AWS accounts are required as follows:
  - Tools account - For continuous integration and continuous delivery (CI/CD) setup.
  - Stage account - For user acceptance testing.
  - Production account - For a business end user.
  - (Optional) Add an AWS account to act as a QA account. This account is required if you want both a main pipeline setup, including QA, and a hotfix pipeline solution for testing.
- An AWS CloudFormation stack with an optional condition to deploy in the QA account using the main pipeline, if needed. The pattern can still be tested without the main pipeline setup by creating and deleting a `hotfix` branch.
- An Amazon Simple Storage Service (Amazon S3) bucket to store the CloudFormation templates that are used to create Service Catalog products.
- Create PR approval rules for the CodeCommit repository in accordance with the compliance requirements (after creating the repository).
- Restrict the IAM permissions of developers and team leads to deny the execution of the prcreation-lambda Lambda function because it should be invoked only from the pipeline.

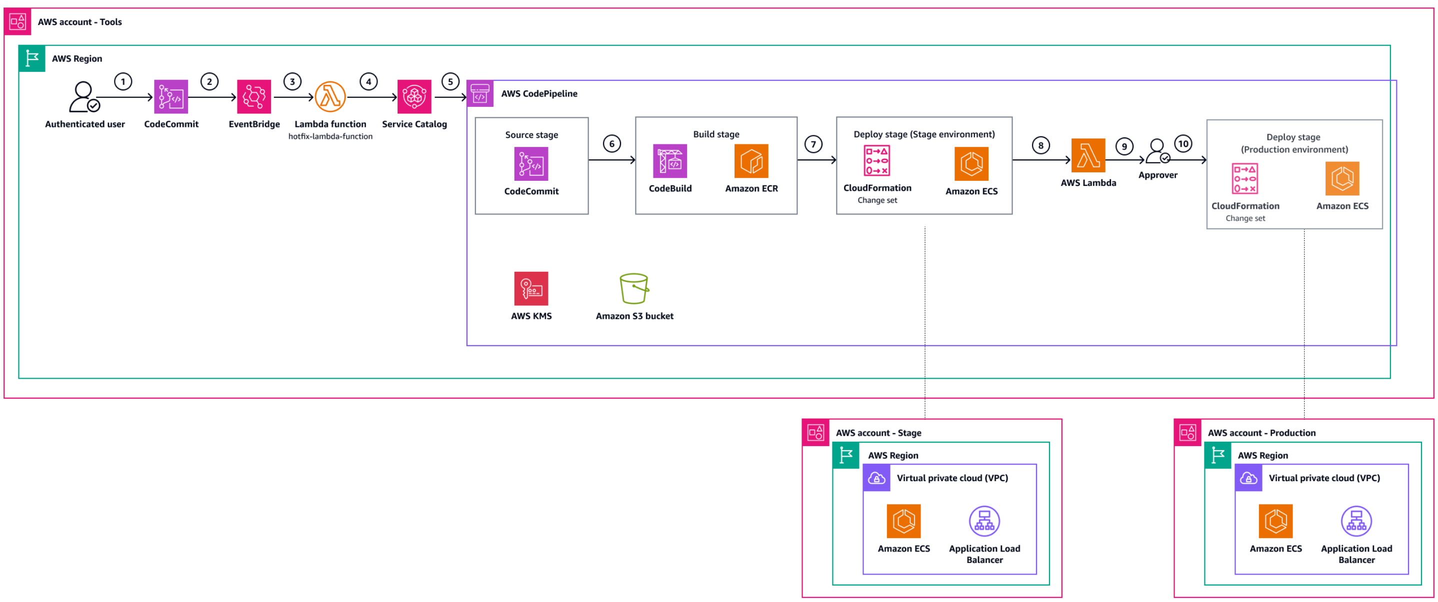
Limitations

- The CloudFormation provider is used in the deploy stage, and the application is deployed using a CloudFormation change set. If you want to use a different deployment option, modify the CodePipeline stack as required.
- This pattern uses AWS CodeBuild and other configuration files to deploy a sample microservice. If you have a different workload type (for example, serverless workloads), you must update all relevant configurations.

- This pattern deploys the application in a single AWS Region (for example, US East (N. Virginia) us-east-1) across AWS accounts. To deploy across multiple Regions, change the Region reference in commands and stacks.
- Some AWS services aren't available in all AWS Regions. For Region availability, see [AWS services by Region](). For specific endpoints, see [Service endpoints and quotas](), and choose the link for the service.

Architecture

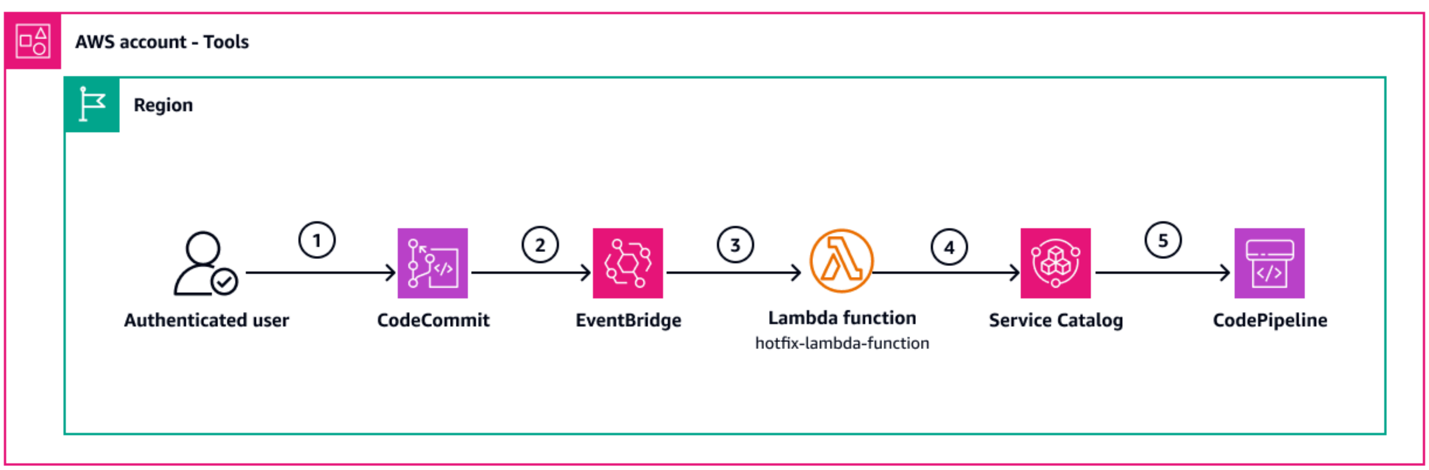
The diagrams in this section provide workflows for a create lifecycle event and for a delete lifecycle event.



The preceding diagram for creating a lifecycle event shows the following:

1. The developer creates a `hotfix-*` branch in the CodeCommit repository to develop a hotfix-related solution.
2. The `hotfix-*` branch creation event is captured through the EventBridge rule. The event details include the repository name and branch name.
3. The EventBridge rule invokes the AWS Lambda function `hotfix-lambda-function`. The EventBridge rule passes the event information to the Lambda function as input.
4. The Lambda function processes the input to retrieve the repository name and branch name. It launches the Service Catalog product with values retrieved from the processed input.

5. The Service Catalog product includes a pipeline setup that will deploy the solution to the Stage and Production environments. The pipeline block includes source, build, and deploy stages. Also, there is a manual approval stage to promote the deployment for the Production environment.
6. The source stage retrieves the code from the repository and `hotfix-*` branch that was created in the first step. The code is passed to the build stage through an Amazon S3 bucket for artifacts. In the build stage, a container image is created that includes the hotfix that is developed in the `hotfix-*` branch and pushed into Amazon Elastic Container Registry (Amazon ECR).
7. The deploy stage to the stage environment updates Amazon Elastic Container Service (Amazon ECS) with the latest container image that includes the hotfix. The hotfix is deployed by creating and executing a CloudFormation change set.
8. The `prcreation-lambda` Lambda function is invoked after successful deployment in the Stage environment. This Lambda function creates a PR from the `hotfix-*` branch to the `develop` and `main` branches of the repository. The Lambda function ensures that the fix developed in the `hotfix-*` branch is backmerged and included in subsequent deployments.
9. A manual approval stage helps to ensure that the necessary stakeholders review the fix and give approval to deploy in Production.
10. The deploy stage to the production environment updates Amazon ECS with the latest container image that includes the hotfix. The hotfix is deployed by creating and executing a CloudFormation change set.



The preceding diagram for deleting a lifecycle event shows the following:

1. The developer deletes the `hotfix-*` branch after successful deployment of the hotfix to the production environment.
2. The `hotfix-*` branch deletion event is captured through an EventBridge rule. The event details include the repository name and branch name.
3. The EventBridge rule invokes the Lambda function. The EventBridge rule passes the event information to the Lambda function as input.
4. The Lambda function processes the input to retrieve the repository name and branch name. The Lambda function determines the respective Service Catalog product from the passed input and then terminates the product.
5. The Service Catalog provisioned product termination deletes the pipeline and relevant resources that were created earlier in that product.

Automation and scale

- The pattern includes an EventBridge rule and a Lambda function, which can handle multiple hotfix branch creation requests in parallel. The Lambda function provisions the Service Catalog product for the matching event rule.
- The pipeline setup is handled by using the Service Catalog product, which provides version control capabilities. The solution also scales automatically to handle multiple hotfix developments for the same application in parallel.
- The prcreation-lambda function ensures that these hotfix changes are also merged back into the `main` and the `develop` branches through an automatic pull request creation. This approach is essential to keep the `main` and the `develop` branches up to date with all fixes and avoid potential code regressions. This process helps to maintain consistency across branches and prevent code regressions by ensuring that all long-lived branches have the latest fixes.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.

- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system. AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. For more information, see How to migrate your AWS CodeCommit repository to another Git provider.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Service Catalog helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other tools

- AWS CloudFormation Linter (cfn-lint) is a linter that checks CloudFormation YAML or JSON templates against the CloudFormation resource specification. It also performs other checks, such as checking for valid values for resource properties and adherence to best practices.
- cfn-nag is an open source tool that that identifies potential security issues in CloudFormation templates by searching for patterns.
- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers. This pattern uses Docker to build and test container images locally.
- Git is an open-source, distributed version control system.

Code repository

The code for this pattern is available in the GitHub dynamic_hotfix_codepipeline repository.

Best practices

Review and adjust IAM roles and service control policies (SCP) in your environment to ensure that they restrict access appropriately. This is crucial to prevent any actions that could override the security measures included in this pattern. Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see [Grant least privilege](#) and [Security best practices](#) in the IAM documentation.

Epics

Set up the work environment

Task	Description	Skills required
Clone the repository.	To clone the sample [repository](#) into a new directory in your work location, run the following command: `git clone git@github.com:aws-samples/dynamic_hotfix_codepipeline.git`	AWS DevOps
Export environment variables for CloudFormation stack deployment.	Define the following environment variables that will be used as input to the CloudFormation stacks later in this pattern. • `ApplicationName` – This variable is used to name resources created for an application, making it easier to track them. Use the following command, replacing `Applicati`	AWS DevOps

Task	Description	Skills required

	onname with your actual application name:
	`export ApplicationName=<Applicationname>`
	• `BucketStartName` – This variable is for naming an Amazon S3 bucket. S3 bucket names must be globally unique across all AWS accounts. Use the following command, replacing `BucketName` with a unique name for your S3 bucket:
	`export BucketStartName=<BucketName>`
	• **Account numbers and Regions** – These variables store AWS account numbers for different environments and the deployment Region. Use the following commands, replacing the placeholders (such as `prodaccountnumber` and `region`) with your actual AWS account numbers and the AWS Region that you're using.	

Task	Description	Skills required

	Note
	`QAAccount` is optional. If you want to use `QAAccount` , set it up by using the parameters for the main pipeline stack.
	
	`export ProdAccount=<prodaccountnumber>`
	`export StageAccount=<stage/preprodaccountnumber>`
	`export QAAccount=<qaccountnumber>`
	`export ToolsAccount=<toolsaccountnumber>`
	`export DepRegion=<region>`	

Set up prerequisites required in AWS accounts

Task	Description	Skills required
Create resources required for CI/CD in the tools account.	To deploy the CloudFormation stack in the tools account, use the following commands. (Remove the `QAAccount` parameter	AWS DevOps

Task	Description	Skills required
	if you're not using the QA account for setup.) `#InToolsAccount aws cloudformation deploy \ --template-file pre-requisites/pre-reqs.yaml \ --stack-name prereqs \ --parameter-overrides BucketStartName=${BucketStartName} \ ApplicationName=${ApplicationName} ProdAccount=${ProdAccount} \ StageAccount=${StageAccount} ToolsAccount=${ToolsAccount} \ QAAccount=${QAAccount} \ --capabilities CAPABILITY_IAM CAPABILITY_NAMED_IAM --region ${DepRegion}` Make a note of the resources that the CodeCommit repository and Amazon ECR created from the preceding stack. These parameters are necessary to set up the `main` branch of the pipeline in upcoming steps.	

Task	Description	Skills required

Create resources required for CI/CD in the workload accounts.	1. To package the CloudFormation template in each workload account (stage, production, and optional QA), use the following commands. In the following command, replace `S3bucketpackage` with the Amazon S3 bucket name that you want to use for packaging.
	
	`#InStageAccount aws cloudformation package \ --template-file pre-requisites/infrastack.yaml \ --s3-bucket <S3bucketpackage> \ --s3-prefix infraStack \ --region ${DepRegion} \ --output-template-file pre-requisites/infrastructure_stage.template`
	
	`#InProdAccount aws cloudformation package \ --template-file pre-requisites/infrastack.yaml \ --s3-bucket <S3bucketpackage> \`
		AWS DevOps

Task	Description	Skills required

	``
	    --s3-prefix
	 infraStack \
	    --region ${DepRegi
	on} \
	    --output-
	template-file
	 pre-requisites/inf
	rastructure_prod.t
	emplate
	``
	2. To deploy the CloudFormation template in each workload account, use the following commands:
	``
	#InStageAccount
	aws cloudformation
	 deploy --stack-name
	 inframainstack \
	--parameter-over
	rides Applicati
	onName=${Applicati
	onName} ToolsAcco
	unt=${ToolsAccount
	} DepRegion=${DepReg
	ion} \
	--template-file
	 pre-requisites/inf
	rastructure_stage.
	template --region
	 ${DepRegion}
	 --capabilities
	 CAPABILITY_NAMED_I
	AM
	
	#InProdAccount
	aws cloudformation
	 deploy --stack-name
	 inframainstack \
	--parameter-over
	rides Applicati
	``	

Task	Description	Skills required
	```onName=${ApplicationName} ToolsAccount=${ToolsAccount} DepRegion=${DepRegion} \ --template-file pre-requisites/infrastructure_prod.template --region ${DepRegion} --capabilities CAPABILITY_NAMED_IAM```	

Task	Description	Skills required

Update the S3 artifact bucket policy to allow access for workload accounts.	To update the CloudFormation stack prerequisites in the tools account, use the following commands to add all required permissions for the Stage and Production workload accounts. (Remove the `QAAccount` parameter if you're not using it for setup.)
	
	`#InToolsAccount`
	`aws cloudformation deploy \`
	`    --template-file pre-requisites/pre-reqs.yaml \`
	`    --stack-name prereqs \`
	`    --parameter-overrides BucketStartName=${BucketStartName} \`
	`    ApplicationName=${ApplicationName} ProdAccount=${ProdAccount} \`
	`    StageAccount=${StageAccount} ToolsAccount=${ToolsAccount} \`
	`    QAAccount=${QAAccount} PutPolicy=true \`
	`    --capabilities CAPABILITY_IAM CAPABILITY_NAMED_IAM --region ${DepRegion}`
		AWS DevOps

Set up Lambda function and Service Catalog resources in tools account

Task	Description	Skills required

Set up the Service Catalog portfolio and products.	To set up the Service Catalog portfolio and products, do the following:
	
	1. Upload the templates [pipeline-main.yaml]() and [pipeline-hotfix.yaml]() from the repository in the CodePipeline directory to an existing Amazon S3 bucket (`Bucketname`) in the Region that you want to deploy to (`DepRegion`).
	
	`#InToolsAccount`
	`aws s3 cp ./codepipeline/pipeline-main.yaml s3://<Bucketname>/pipeline-main.yaml`
	`aws s3 cp ./codepipeline/pipeline-hotfix.yaml s3://<Bucketname>/pipeline-hotfix.yaml`
	
	2. Set up the Service Catalog portfolio and product that will manage the pipeline for the `main` and `hotfix` branches. Make a note of the details from the `Outputs` section for `MainProductId` and
		AWS DevOps

Task	Description	Skills required
	`MainProductArtifactId` from the following stack. The information is required in later steps during the pipeline setup for the `main` branch. `#InToolsAccount aws cloudformation deploy \ --template-file pre-requisites/servicecatalogsetup.yaml \ --stack-name servicecatalogsetup \ --parameter-overrides TemplateBucket=<Bucketname> \ --capabilities CAPABILITY_IAM CAPABILITY_NAMED_IAM --region ${DepRegion}` 3. Provide access for an IAM role that will deploy resources in the tools account to the Service Catalog portfolio main pipeline portfolio. Use this portfolio to deploy the application by using the `main` branch. For more information about how to provide access, see [Granting Access to Users](#)	

Task	Description	Skills required
	in the Service Catalog documentation.	

Task	Description	Skills required
Set up Lambda functions.	This solution uses the following Lambda functions to manage hotfix workflows: • `hotfix-lambda-function` handles Service Catalog product provisioning when a `hotfix` branch is created. • `hotfix-cleanup-lambda-function` manages product termination when a `hotfix` branch is deleted. • `prcreation-lambda` creates pull requests from the `hotfix` branch to the `develop` and `main` branches. To enable the Lambda functions to provision and terminate Service Catalog products when `hotfix` branches are created or deleted through the associated EventBridge rule, use the following steps: 1. To create the IAM roles and permissions for the Lambda functions, use the following command to	AWS DevOps

Task	Description	Skills required
	deploy a CloudFormation stack: `#InToolsAccount aws cloudformation deploy \ --template-file pre-requisites/lambdasetup.yaml \ --stack-name prsclambdasetup \ --capabilities CAPABILITY_IAM CAPABILITY_NAMED_IAM --region ${DepRegion}` 2. After the stack deployment, grant the `hotfix-lambda-execution-role` access to the Service Catalog portfolio hotfix pipeline portfolio by using the [AWS Management Console](https://docs.aws.amazon.com/servicecatalog/latest/adminguide/catalogs_portfolios_users.html). This access allows the Lambda function to launch or terminate the Service Catalog product for hotfix branches.	

Create pipeline for main branch and deploy application in workload accounts

Task	Description	Skills required
Set up pipeline for `main` branch.	To set up the pipeline for the main branch, run the following command in the tools account. Replace the	AWS DevOps

Task	Description	Skills required

	parameters for `MainProductId` and `MainProductArtifactId` with values from `servicecatalogsetup` stack outputs.
	`#InToolsAccount`
	`aws servicecatalog provision-product \`
	`    --product-id <MainProductId> \`
	`    --provisioning-artifact-id <MainProductArtifactId> \`
	`    --provisioned-product-name "${ApplicationName}-main-pipeline" \`
	`    --provisioning-parameters Key=CodeCommitRepoName,Value="${ApplicationName}-repository" Key=ECRRepository,Value="${ApplicationName}-app" \`
	`    --region=${DepRegion}`	

Task	Description	Skills required
Deploy application using the `main` branch.	1. To clone the CodeCommit repository that was created in the *prereqs*, use the `git clone` command. For more information, see [Connect to the CodeCommit repository by cloning the repository](#) as described in the CodeCommit documentation. 2. Copy all the application files from the `repotemplates` [directory](#) available in the repository into your local repository clone (`${ApplicationName}-repository`). Modify the following files to update the `ToolsAccount` ID. In each file, locate the `RegistryAccountid` parameter and set its value to your `ToolsAccount` ID. Commit the changes to the CodeCommit repository, and push the files to both the `main` and `develop` branches. • [ecs-configuration-prod.yaml](#) • [ecs-configuration-qa.yaml](#)	AWS DevOps

Task	Description	Skills required
	• [ecs-configuration-stage.yaml] 3. To verify the application deployment, monitor the CodePipeline execution by using the AWS Managemen t Console. After deploymen t is complete, access the application by using the Application Load Balancer FQDN in the stage environment. Confirm that the application works as expected. 4. To approve the deploymen t to production, use the CodePipeline console to locate the pipeline for your application. Find the `ApprovalToStart` stage. Review the changes and, if satisfactory, provide manual approval to proceed with the productio n deployment.	

Create the pipeline for a hotfix-* branch and deploy the hotfix

Task	Description	Skills required
Create a `hotfix-*` branch and commit changes.	To create a pipeline for the `hotfix-*` branch and deploy the hotfix to the workload accounts, do the following:	AWS DevOps

Task	Description	Skills required
	1. Create a branch using a name that starts with the keyword `hotfix`. For example, this pattern uses the `hotfix-check1` branch in the CodeCommit application repository (`${ApplicationName}-repository`). For more detailed steps, see [Connect to an AWS CodeCommit repository](#) and [Basic Git commands](#) in the CodeCommit documentation. 2. Verify that the Service Catalog product `Hotfix CICD Pipeline` is successfully provisioned dynamically for the `hotfix-check1` branch. The provisioned product name is named after this hotfix branch name and the application's CodeCommit repository name. 3. Commit some minor changes in the [index.html](#) file, and push them to the CodeCommit repository. 4. Verify that the CodePipeline execution is successful in the stage environme	

Task	Description	Skills required
	nt. To deploy in the production environment, provide manual approval in CodePipeline. 5. Confirm the changes are visible in the application home page by using the Application Load Balancer fully qualified domain name (FQDN). The FQDN is available in the `Outputs` section of `inframainstack-ALBStack-*` .	
Delete the `hotfix-check1` branch.	To delete the `hotfix-check1` branch created earlier, do the following: 1. Delete the `hotfix-check1` branch that's in the CodeCommit application repository. 2. Verify that the Service Catalog product that was provisioned for the `hotfix-check1` branch terminated successfully.	AWS DevOps

Clean up resources

Task	Description	Skills required

Clean up the deployed resources.	To clean up the resources that were deployed earlier, do the following:
	1. To scale down the Amazon ECS service to zero replicas in the workload accounts, use the following command:
	`aws ecs update-service --cluster ${ApplicationName}-Cluster --service ${ApplicationName}-Service-stage --desired-count 0 --region ${DepRegion}`
	`aws ecs update-service --cluster ${ApplicationName}-Cluster --service ${ApplicationName}-Service-prod --desired-count 0 --region ${DepRegion}`
	2. Terminate the Service Catalog product that was provisioned for the `main` branch.
	3. Clean up objects created in the Amazon S3 buckets in the tools account. Delete all Docker images
		AWS DevOps

Task	Description	Skills required

	in Amazon ECR before deleting the registry itself.
	4. Remove IAM roles in the access granted section of the Service Catalog portfolios before you delete the Service Catalog portfolio.
	5. Delete the CloudFormation stacks deployed in the tools account and the workload accounts.
	
	`##In Tools Account## aws cloudformation delete-stack --stack-name servicecatalogsetup --region ${DepRegion} aws cloudformation delete-stack --stack-name prlambdasetup --region ${DepRegion} aws cloudformation delete-stack --stack-name prereqs --region ${DepRegion}`
	
	`##In Workload Accounts## aws cloudformation delete-stack --stack-name inframainstack --region ${DepRegion}`	

Task	Description	Skills required
	For more information, see Deleting provisioned products in the Service Catalog documentation.	

Troubleshooting

Issue	Solution
Changes that you committed to the CodeCommit repository aren't getting deployed.	Check the CodeBuild logs for errors in the Docker build action. For more information, see the CodeBuild documentation.
The Service Catalog product isn't being provisioned.	Review the related CloudFormation stacks for failed events. For more information, see the CloudFormation documentation.

- Basic Git commands
- Configure an IAM policy to limit pushes and merges to a branch
- Connect to an AWS CodeCommit repository
- Granting access to users
- Pushing a Docker image to an Amazon ECR private repository
- Troubleshooting AWS CodeBuild
- What is AWS CodePipeline?

Additional information

This pattern is designed for environments with a Gitflow setup that is adopted for the development workflow in the CI/CD process. The pipelines follow the deployment cycle that starts from development and moves through quality assurance (QA), stage, and production environments. The CI/CD setup includes two git branches with promotional deployments to environments as follows:

- The `develop` branch deploys to the development environment.
- The `main` branch deploys to the QA, stage, and production environments.

In this setup, it's a challenge to apply a hotfix or a security patch faster than the usual deployment cycle while the active development of new features is ongoing. A dedicated process is necessary to address hotfix or security requests, ensuring that live environments remain properly functioning and secure.

However, you can use other available options without requiring a dedicated deployment process if:

- The CI/CD process is well-equipped with automated testing, such as functional and end-to-end tests, which eliminate the need for manual testing and prevent delays in deployments to production. However, if automated testing isn't well integrated into the CI/CD process, pushing a small fix to the production environment can become complex and cumbersome for developers. This is because there might be new features waiting in the QA environment for approval and sign-off. A hotfix or security fix can't be pushed into production in a straightforward manner simultaneously.
- Development teams continuously deploy new features into the production environment, integrating hotfixes or security patches into the scheduled deployment of each new feature. In other words, the next feature update to the production environment comprises two components: The addition of a new feature and the inclusion of the hotfix or security patch. However, if the deployment cycle isn't continuous, there can be multiple new features already awaiting approval in the QA environment. Managing different versions and ensuring the correct changes are reapplied can then become complex and error-prone.

> **Note**
>
> If you're using [version 2](#) of AWS CodePipeline with proper triggers set up on the `hotfix` branch, you still require a dedicated process to address unscheduled requests. In version 2, you can set up triggers for either push or pull requests. The execution will either be queued or executed immediately, depending on the previous state of the pipeline. However, with a dedicated pipeline, the fixes are applied immediately to the production environment, ensuring that urgent issues are resolved without delay.

Automate ingestion and visualization of Amazon MWAA custom metrics on Amazon Managed Grafana by using Terraform

Faisal Abdullah and Satya Vajrapu, Amazon Web Services

Summary

This pattern discusses how to use Amazon Managed Grafana to create and monitor custom metrics that are ingested by Amazon Managed Workflows for Apache Airflow (Amazon MWAA). Amazon MWAA serves as the orchestrator for workflows, employing Directed Acyclic Graphs (DAGs) that are scripted in Python. This pattern centers on the monitoring of custom metrics, including the total number of DAGs running within the last hour, the count of passed and failed DAGs each hour, and the average duration of these processes. This analysis shows how Amazon Managed Grafana integrates with Amazon MWAA to enable comprehensive monitoring and insights into the orchestration of workflows within this environment.

Prerequisites and limitations

Prerequisites

- An active AWS account with the necessary user permissions to create and manage the following AWS services:
  - AWS Identity and Access Management (IAM) roles and policies
  - AWS Lambda
  - Amazon Managed Grafana
  - Amazon Managed Workflows for Apache Airflow (Amazon MWAA)
  - Amazon Simple Storage Service (Amazon S3)
  - Amazon Timestream
- Access to a shell environment which can be a terminal on your local machine or AWS CloudShell.
- A shell environment with Git installed and the latest version of the AWS Command Line Interface (AWS CLI) installed and configured. For more information, see Installing or updating to the latest version of the AWS CLI in the AWS CLI documentation.
- The following Terraform version installed: `required_version = ">= 1.6.1, < 2.0.0"` You can use tfswitch to switch between different versions of Terraform.
- Configured identity source in AWS IAM Identity Center for your AWS account. For more information, see Confirm your identity sources in IAM Identity Center in the IAM Identity Center

documentation. You can choose from the default IAM Identity Center directory, Active Directory, or an external Identity provider (IdP) such as Okta. For more information, see Related resources.

Limitations

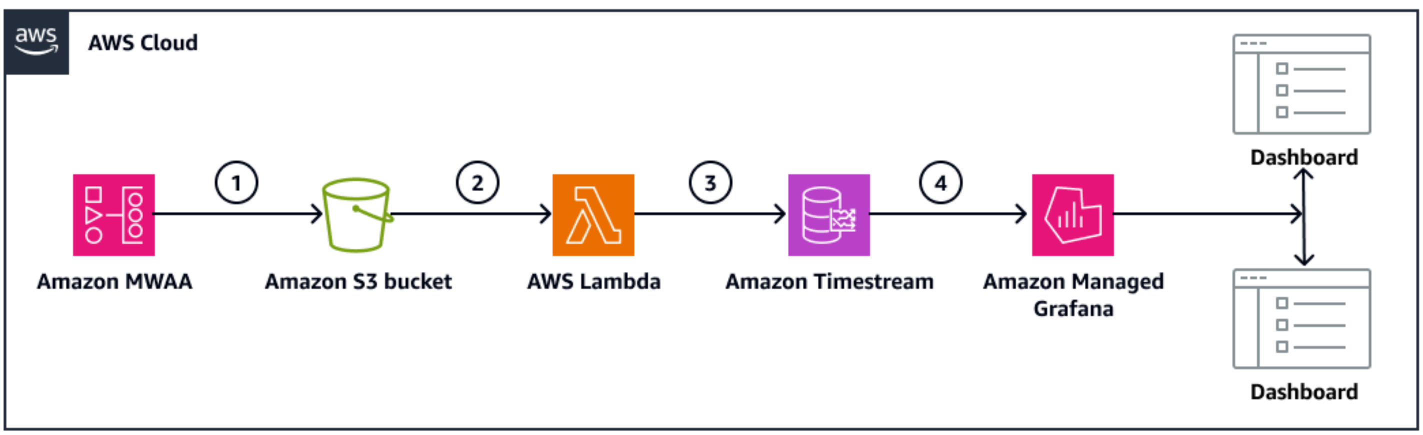
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- Terraform `required_version = ">= 1.6.1, < 2.0.0"`
- Amazon Managed Grafana version 9.4 or later. This pattern was tested on version 9.4.

Architecture

The following architecture diagram highlights the AWS services used in the solution.



The preceding diagram steps through the following workflow:

1. Custom metrics within Amazon MWAA originate from DAGs that are executing within the environment. The metrics upload to the Amazon S3 bucket in a CSV file format. The following DAGs use the database querying capabilities of Amazon MWAA:
   - `run-example-dag` – This DAG contains sample Python code that defines one or more tasks. It runs every 7 minutes and prints the date. After printing the date, the DAG includes a task to sleep, or pause, execution for a specific duration.

- `other-sample-dag` – This DAG runs every 10 mins and prints the date. After printing the date, the DAG includes a task to sleep, or pause, execution for a specific duration.
- `data-extract` – This DAG runs every hour and queries the Amazon MWAA database and collects metrics. After the metrics are collected, this DAG writes them to an Amazon S3 bucket for further processing and analysis.

2. To streamline data processing, Lambda functions run when they're triggered by Amazon S3 events, which facilitates the loading of metrics into Timestream.
3. Timestream is integrated as a data source within Amazon Managed Grafana where all the custom metrics from Amazon MWAA are stored.
4. Users can query the data and construct custom dashboards to visualize key performance indicators and gain insights into the orchestration of workflows within Amazon MWAA.

Tools

AWS services

- AWS IAM Identity Center helps you centrally manage single sign-on (SSO) access to all of your AWS accounts and cloud applications.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use. In this pattern, AWS Lambda runs the Python code in response to Amazon S3 events and manages the compute resources automatically.
- Amazon Managed Grafana is a fully managed data visualization service that you can use to query, correlate, and visualize, and alert on your metrics, logs, and traces. This pattern uses Amazon Managed Grafana to create a dashboard for metrics visualization and alerts.
- Amazon Managed Workflows for Apache Airflow (Amazon MWAA) is a managed orchestration service for Apache Airflow that you can use to set up and operate data pipelines in the cloud at scale. Apache Airflow is an open source tool used to programmatically author, schedule, and monitor sequences of processes and tasks referred to as workflows. In this pattern, sample DAGs and a metrics extractor DAG are deployed in Amazon MWAA.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. In this pattern, Amazon S3 is used to store DAGs, scripts, and custom metrics in CSV format.
- Amazon Timestream for LiveAnalytics is is a fast, scalable, fully managed, purpose-built time series database that makes it easy to store and analyze trillions of time series data points

per day. Timestream for LiveAnalytics also integrates with commonly used services for data collection, visualization, and machine learning. In this pattern, it's used to ingest the generated Amazon MWAA custom metrics.

Other tools

- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses a Terraform module to automate the provisioning of infrastructure in AWS.

Code repository

The code for this pattern is available on GitHub in the visualize-amazon-mwaa-custom-metrics-grafana repository. The `stacks/Infra` folder contains the following:

- Terraform configuration files for all AWS resources
- Grafana dashboard .json file in the `grafana` folder
- Amazon Managed Workflows for Apache Airflow DAGs in the `mwaa/dags` folder
- Lambda code to parse the .csv file and store metrics in the Timestream database in the `src` folder
- IAM policy .json files in the `templates` folder

Best practices

Terraform must store state about your managed infrastructure and configuration so that it can map real-world resources to your configuration. By default, Terraform stores state locally in a file named `terraform.tfstate`. It's crucial to ensure the safety and integrity of your Terraform state file because it maintains the current state of your infrastructure. For more information, see Remote State in the Terraform documentation.

Epics

Deploy the infrastructure using Terraform

Task	Description	Skills required

Deploy the infrastructure.	To deploy the solution infrastructure, do the following:
	1. Open a terminal or command prompt on your local computer or by using AWS CloudShell.
	2. Navigate to the directory where you want to clone the repository.
	3. To clone the repository, run the following command:
	`git clone https://github.com/aws-samples/visualize-amazon-mwaa-custom-metrics-grafana`
	4. After the cloning process is finished, run the following command to navigate into the cloned repository directory:
	`cd visualize-amazon-mwaa-custom-metrics-grafana/stacks/infra`
	5. To download and initialize the required providers, run the following command:
		AWS DevOps

Task	Description	Skills required

	`terraform init`
	
	6. To get a comprehensive view of all the resources that Terraform will create, run the following command:
	
	`terraform plan`
	
	Terraform provisions the following resources:
	• Amazon Virtual Private Cloud (Amazon VPC) and associated networking components
	• Amazon S3 resources
	• AWS Lambda functions
	• Amazon Managed Grafana resources (workspace, dashboards, data source)
	• Supporting IAM resources (roles and policies)
	
	7. To create the AWS resources from the plan output, run the following command:
	
	`terraform apply -auto-approve`	

Task	Description	Skills required
	The infrastructure provisioning completes in approximately 20 minutes. 8. To create the specified AWS resources according to the configuration defined in your Terraform files, run the following command: `terraform apply`	

Validate the deployed infrastructure resources

Task	Description	Skills required
Validate the Amazon MWAA environment.	To validate the Amazon MWAA environment, do the following: 1. Sign in to the AWS Management Console, navigate to the [Amazon MWAA dashboard console](#) and select **Open Airflow UI**. 2. You should see the following three DAGs in **Active** status: • data-extract • run-example-dag • other-sample-dag	AWS DevOps, Data engineer

Task	Description	Skills required
	3. If a DAG isn't active, you can activate it by enabling the toggle switch next to the DAG name.	
Verify the DAG schedules.	To view each DAG schedule, go to the **Schedule** tab in the **Airflow UI**. Each of the following DAGs has a pre-configured schedule, which runs in the Amazon MWAA environment and generates custom metrics: • **run-example-dag** - Runs every 7 minutes • **other-sample-dag** - Runs every 10 minutes • **data-extract** - Runs every hour You can also see the successful runs of each DAG under the **Runs** column.	Data engineer, AWS DevOps

Configure the Amazon Managed Grafana environment

Task	Description	Skills required
Configure access to the Amazon Managed Grafana workspace.	The Terraform scripts created the required Amazon Managed Grafana workspace	AWS DevOps

Task	Description	Skills required
	, dashboards, and metrics page. To configure access so that you can view them, do the following: 1. Open the [Amazon Managed Grafana](#) console. 2. In **Workspaces**, select the workspace `grafana-ws-dev`, and navigate to the **Authentication** tab in the lower pane. 3. Choose the **Assign new user or group** button. 4. Add either your group in the **Groups** tab or a user in the **Users** tab, and then choose the **Assign user and groups** button. 5. After the user (or group) is added, make this user (or group) an admin. Select the user in **Assigned users or group** in the **Assigned user group** tab and choose **Make admin** from the dropdown menu. For more information, see [Use AWS IAM Identity Center with your Amazon Managed Grafana workspace](#) in the Amazon Managed Grafana documentation.	

Task	Description	Skills required
	6. Navigate to **Workspaces**, and then choose the **Grafana workspace URL**. To sign in to Amazon Managed Grafana as an admin, choose **Sign in with AWS IAM Identity Center**.	

Task	Description	Skills required
Install the Amazon Timestream plugin.	Amazon MWAA custom metrics are loaded into the Timestream database. You use the Timestream plugin to visualize the metrics with Amazon Managed Grafana dashboards. To install the Timestream plugin, do the following: 1. In the Amazon Managed Grafana console, expand the menu in the left navigation pane and go to **Administration, Plugins**. 2. Search for and then install latest version of the Amazon Timestream plugin. 3. After the plugin is installed, go to **Administration**, **Data sources** to see the Timestream data source. If the data source isn't listed, refresh the page. For more information, see Extend your workspace with plugins in the Amazon Managed Grafana documentation.	AWS DevOps, DevOps engineer

Visualize the custom metrics in the Amazon Managed Grafana dashboard

Task	Description	Skills required
View the Amazon Managed Grafana dashboard.	To view the metrics that were ingested into the Amazon Managed Grafana workspace, do the following: 1. In the Amazon Managed Grafana console, choose **Dashboards** in the left navigation pane. 2. To view the metrics, choose **MWAA events dashboards** and then select **mwaa_metrics**. The dashboard metrics page shows the following informati on: • Total DAG runs in the last one hour • Total successful, failed, and running DAG runs in the last one hour • Average duration for all, successful, and failed DAG runs	AWS DevOps
Customize the Amazon Managed Grafana dashboard.	To customize the dashboards for further future enhanceme nts, do the following: 1. On the Amazon Managed Grafana dashboard	AWS DevOps

Task	Description	Skills required
	`mwaa_metrics` page, choose the **Dashboard settings** icon. 2. To view the data structure that defines the dashboard , choose **JSON model**. You can customize the dashboard by making edits to this JSON model directly in the console. Alternatively, the source code for this dashboard is available in the `dashboard .json` file in the `stacks/ infra/grafana` folder in the [GitHub repository]().	

Clean up AWS resources

Task	Description	Skills required
Pause the Amazon MWAA DAG runs.	To pause the DAG runs, do the following: 1. In the Amazon MWAA console, navigate to [Airflow environments]() and choose **Open Airflow UI**. 2. To pause the DAG, use the toggle switch next to each DAG. 3. Refresh the **Airflow UI** page, which should list	AWS DevOps, Data engineer

Task	Description	Skills required
	three DAGs in the **Paused** section.	
Delete the objects in the Amazon S3 buckets.	To delete the Amazon S3 buckets **mwaa-events-bucket-*** and **mwaa-metrics-bucket-***, follow the instructions for using the Amazon S3 console in [Deleting a bucket](#) in the Amazon S3 documentation.	AWS DevOps

Task	Description	Skills required
Destroy the resources created by Terraform.	To destroy the resources created by Terraform and the associated local Terraform state file, do the following: 1. (Optional) Before deleting the resources, you can preview the changes that Terraform will make. To generate a plan, run the following command: `terraform plan -destroy` The command output shows that the `destroy` command will delete all the AWS resources that were created earlier. 2. `terraform destroy -auto-approve` This command takes approximately 20 minutes to destroy the infrastru cture. **Note** To destroy all resources managed by Terraform, run the following command. : The -	AWS DevOps

Task	Description	Skills required

	`auto-approve` tag doesn't wait for user confirmation to start destroying the resources.
	3. To delete the local Terraform state file, run the following commands:
	`rm .terraform.lock.hcl`
	`rm -rf .terraform`
	`rm terraform.tfstate*`	

Troubleshooting

Issue	Solution
`null_resource.plugin_mgmt (local-exec): aws: error: argument operation: Invalid choice, valid choices are:`	Upgrade your AWS CLI to the latest version.
Loading data sources error - `Fetch error: 404 Not Found Instantiating…`	The error is intermittent. Wait a few minutes, and then refresh your data sources to view the listed Timestream data source.

- Amazon Managed Grafana for dashboarding and visualization

- Configure Amazon Managed Grafana to use Okta
- Use AWS IAM Identity Center with your Amazon Managed Grafana workspace
- Working with DAGs on Amazon MWAA

AWS videos

- Configure IAM Identity Center with Amazon Managed Grafana for authentication, as shown in the following video.

https://www.youtube-nocookie.com/embed/XX2Xcz-Ps9U?controls=0

- If IAM Identity Center isn't available, you can also integrate the Amazon Managed Grafana authentication by using an external Identity provider (IdP) such as Okta, as shown in the following video.

https://www.youtube-nocookie.com/embed/Z4JHxl2xpOg?controls=0

Additional information

You can create a comprehensive monitoring and alerting solution for your Amazon MWAA environment, enabling proactive management and rapid response to potential issues or anomalies. Amazon Managed Grafana includes the following capabilities:

Alerting – You can configure alerts in Amazon Managed Grafana based on predefined thresholds or conditions. Set up email notifications to alert relevant stakeholders when certain metrics exceed or fall below specified thresholds. For more information, see Grafana alerting in the Amazon Managed Grafana documentation.

Integration – You can integrate Amazon Managed Grafana with various third-party tools such as OpsGenie, PagerDuty, or Slack for enhanced notification capabilities. For example, you can set up webhooks or integrate with APIs to trigger incidents and notifications in these platforms based on alerts generated in Amazon Managed Grafana. In addition, this pattern provides a GitHub repository to create AWS resources. You can further integrate this code with your infrastructure deployment workflows.

Streamline Amazon Lex bot development and deployment by using an automated workflow

Balaji Panneerselvam, Attila Dancso, Pavan Dusanapudi, Anand Jumnani, and James O'Hara, Amazon Web Services

Summary

Developing and deploying Amazon Lex conversational bots can be challenging when you're trying to manage multiple features, developers, and environments. An automated workflow using infrastructure as code (IaC) principles can help streamline the process. This pattern can help improve the productivity of Amazon Lex developers and enable efficient bot lifecycle management in the following ways:

- **Enable concurrent development of multiple features** - With an automated workflow, developers can work on different features in parallel in separate branches. Changes can then be merged and deployed without blocking other work.
- **Use the Amazon Lex console UI** - Developers can use the user-friendly Amazon Lex console to build and test bots. The bots are then described in infrastructure code for deployment.
- **Promote bots across environments** - The workflow automates promoting bot versions from lower environments like development and test up to production. This approach reduces the risk and overhead of manual promotions.
- **Maintain version control** - Managing bot definitions in Git rather than solely through the Amazon Lex service provides you with version control and an audit trail. Changes are tracked to individual developers, unlike when only using the AWS Management Console or APIs to modify bots stored in AWS.

By automating the Amazon Lex bot release process, teams can deliver features faster with reduced risk and effort. Bots remain under version control rather than isolated in the Amazon Lex console.

Prerequisites and limitations

Prerequisites

- The workflow involves multiple AWS accounts for different environments (development, production, and DevOps), which requires account management and cross-account access configurations.

- Python 3.9 available in your deployment environment or pipeline.
- Git installed and configured on a local workstation for source control.
- AWS Command Line Interface (AWS CLI) installed and configured to authenticate by using the command line or Python.

Limitations

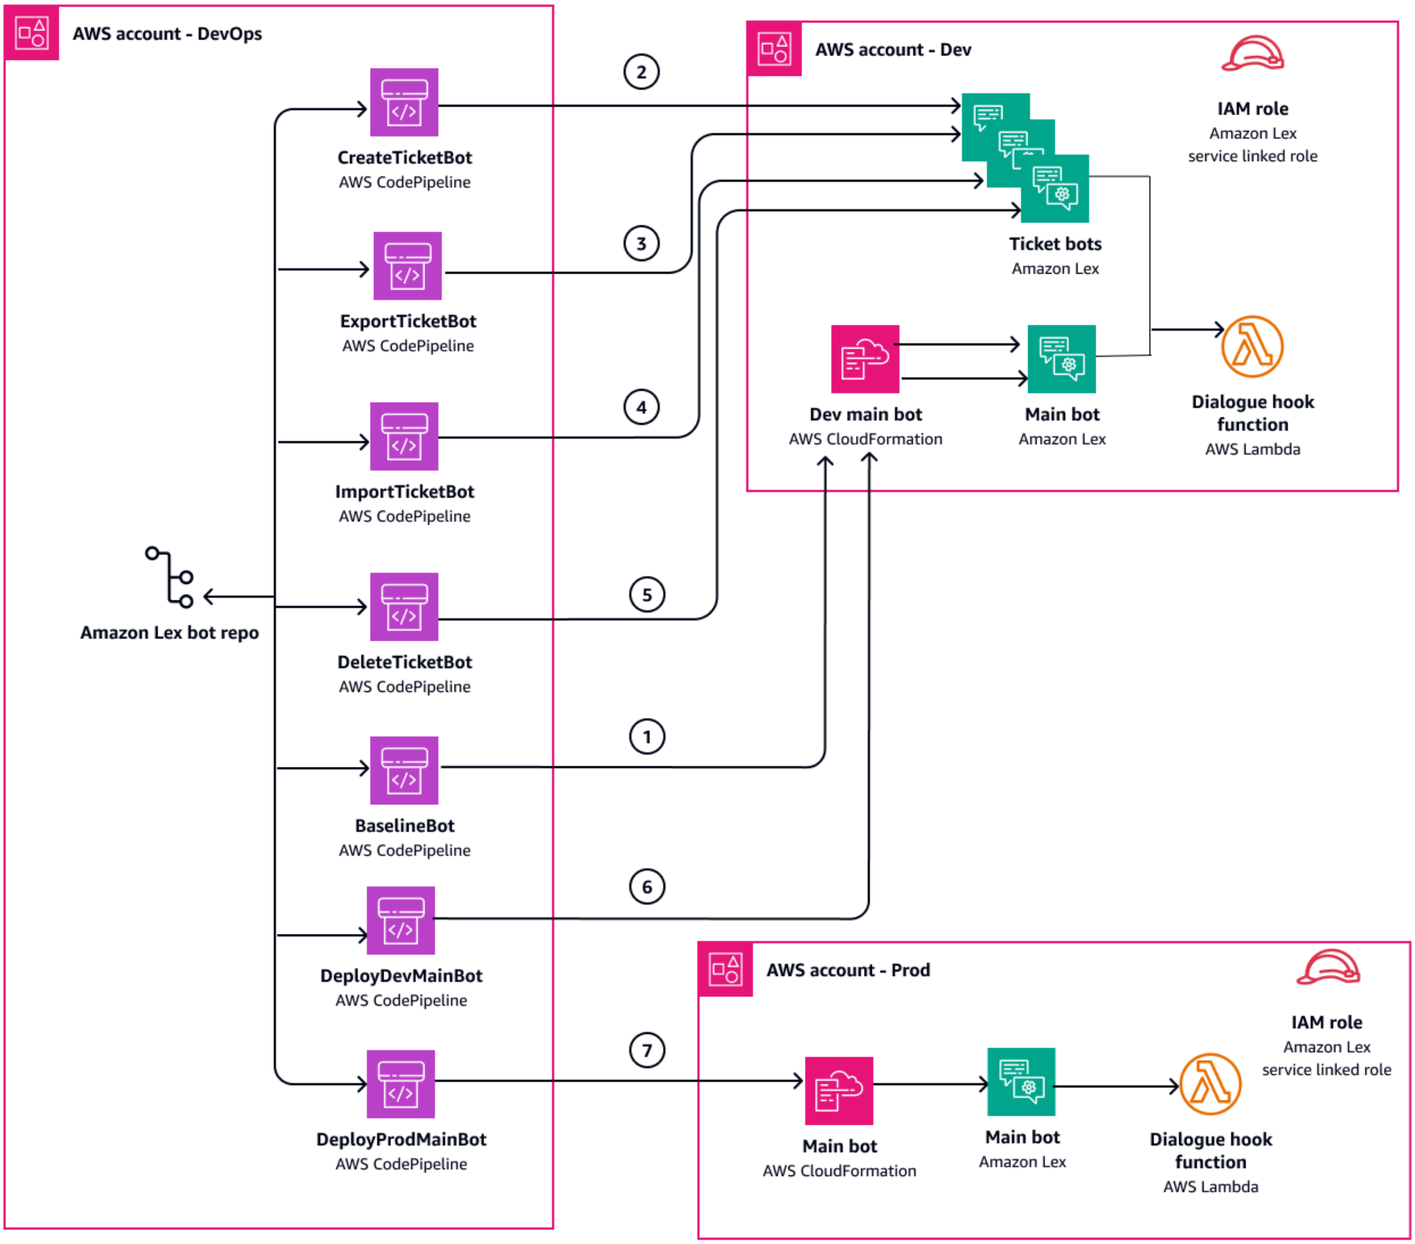
- **Repository access –** The workflow assumes that the continuous integration and continuous delivery (CI/CD) pipeline has the necessary permissions to commit changes to the source code repository.
- **Initial bot version –** The tooling requires that an initial version of the bot is deployed by using AWS CloudFormation templates. You must create the first iteration of the bot and commit it to the repo before the automated workflow can take over.
- **Merge conflicts –** Although the workflow aims to enable concurrent development, there is still a possibility of merge conflicts when integrating changes from different branches. Resolving conflicts in bot configurations might require manual intervention.

Product versions

- Python 3.9 or above
- AWS CDK v2 2.124.0 or above
- AWS SDK for Python (Boto3)1.28 or above

Architecture

The following diagram displays the high-level architecture and key components of the solution.



Key components include the following:

- **Lex bot repo –** A Git repository that stores the IaC definitions for the Amazon Lex bots.
- **DevOps –** An AWS account dedicated to housing the CI/CD pipelines and related resources for the development and deployment process.
- **Pipelines –** The AWS CodePipeline instances that automate various stages of the bot development and deployment lifecycle, such as creating a new bot, exporting a bot's definition, importing a bot definition, and deleting a bot.

- **Ticket bots and main bot –** The Amazon Lex bot resources, where the ticket bots are feature-specific bots developed by individual teams or developers and the main bot is the baseline bot that integrates all the features.

The architecture diagram illustrates the following workflow:

1. **Baseline main bot –** The starting point of the workflow is to baseline the main bot in the development (Dev) environment. The main bot serves as the foundation for future development and feature additions.
2. **Create ticket bot –** When a new feature or change is required, a ticket bot is created. The ticket bot is essentially a copy or branch of the main bot that developers can work on without affecting the main version.
3. **Export ticket bot** - After work on the ticket bot is complete, it's exported from the Amazon Lex service. Then, the branch that contains the ticket bot is rebased from the main branch. This step ensures that any changes made to the main bot while the ticket bot was in development are incorporated, reducing potential conflicts.
4. **Import rebased ticket bot and validate –** The rebased ticket bot is imported back into the development environment and validated to ensure it functions correctly with the latest changes from the main branch. If validation is successful, a pull request (PR) is created to merge the ticket bot changes into the main branch.
5. **Delete ticket bot –** After the changes have been successfully merged into the main branch, the ticket bot is no longer needed. The ticket bot can be deleted to keep the environment clean and manageable.
6. **Deploy main bot into development environment and test –** The updated main bot, now including the new features or changes, is deployed to the development environment. Here, it undergoes thorough testing to ensure all functionalities work as expected.
7. **Deploy main bot into production environment –** After testing in the development environment is complete and successful, the main bot is deployed to the production environment. This step is the final stage of the workflow, where the new features become available to end users.

Automation and scale

The automated workflow allows developers to work on different features in parallel, each in separate branches. This facilitates concurrent development, enabling teams to collaborate effectively and deliver features faster. With branches isolated from each other, changes can be merged and deployed without blocking or interfering with other ongoing work.

The workflow automates the deployment and promotion of bot versions across different environments, such as development, testing, and production.

Storing bot definitions in a version control system such as Git provides a comprehensive audit trail and enables efficient collaboration. Changes are tracked to individual developers, ensuring transparency and accountability throughout the development lifecycle. This approach also facilitates code reviews, enabling teams to identify and address issues before deploying to production.

By using AWS CodePipeline and other AWS services, the automated workflow can scale to accommodate increasing workloads and team sizes.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is an open-source software development framework for defining AWS Cloud infrastructure in code by using familiar programming languages and provisioning it through AWS CloudFormation. The sample implementation in this pattern uses Python.
- AWS CDK Command Line Interface (AWS CDK CLI) - The AWS CDK Toolkit is the primary tool for interacting with your AWS CDK app. It executes your app, interrogates the application model you defined, and produces and deploys the AWS CloudFormation templates generated by the CDK.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions. This pattern uses CloudFormation for deploying the Amazon Lex bot configurations and related resources using infrastructure as code.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy. This pattern uses CodeBuild for building and packaging the deployment artifacts.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously. This pattern uses CodePipeline to orchestrate the continuous delivery pipeline.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact withAWS services through commands in your command line shell.

- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [Amazon Lex V2](#) is an AWS service for building conversational interfaces (bots) for applications using voice and text.
- [AWS SDK for Python (Boto3)](#) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

Other tools

- [Git](#) is an open source distributed version control system.

Code repository

The code for this pattern is available in the GitHub [management-framework-sample-for-amazon-lex](#) repository. The code repo contains the following folders and files:

- `prerequisite` folder – Contains CloudFormation stack definitions (using the AWS CDK) for setting up the required resources and environments.
- `prerequisite/lexmgmtworkflow` folder – Main directory for the Lex Management Workflow project, including stack definitions and Python code.
- `prerequisite/tests` – Contains unit tests.
- `src` folder – Source code directory, including Amazon Lex bot management wrapper and utilities.
- `src/dialogue_lambda` – Source code directory of the dialogue hook Lambda function that intercepts and processes user inputs during a conversation with an Amazon Lex bot.

Best practices

- **Separation of concerns**
  - Maintain a clear separation of responsibilities between the DevOps, development, and production environments.
  - Use separate AWS accounts for each environment to enforce proper isolation and security boundaries.

  - Use cross-account roles and least-privilege access principles to ensure controlled access between environments.
- **Infrastructure as code**
  - Regularly review and update the infrastructure code to align with best practices and evolving requirements.
  - Establish a clear branching and merging strategy for the source code repository
- **Testing and validation**
  - Implement automated testing at various stages of the pipeline to catch issues early in the development cycle.
  - Use the Amazon Lex console or automated testing frameworks to validate bot configurations and functionality before promoting to higher environments.
  - Consider implementing manual approval gates for deployments to production or critical environments.
- **Monitoring and logging**
  - Set up monitoring and logging mechanisms for the pipelines, deployments, and bot interactions.
  - Monitor pipeline events, deployment statuses, and bot performance metrics to identify and address issues promptly.
  - Use AWS services such as Amazon CloudWatch, AWS CloudTrail, and AWS X-Ray for centralized logging and monitoring.
  - Regularly review and analyze the performance, efficiency, and effectiveness of the automated workflow.
- **Security and compliance**
  - Implement secure coding practices and follow AWS security best practices for Amazon Lex bot development and deployment.
  - Regularly review and update IAM roles, policies, and permissions to align with the principle of least privilege.
  - Consider integrating security scanning and compliance checks into the pipelines.

Epics

Set up IaC for Amazon Lex bot management

Task	Description	Skills required

Set up the local CDK environment.	1. To clone this pattern's repo and navigate to the `prerequisite` directory, run the following command:
	`git clone https://github.com/aws-samples/management-framework-sample-for-amazon-lex.git`
	
	`cd management-framework-sample-for-amazon-lex`
	2. To install and activate the Python virtual environment, run the following command that installs the CDK's dependencies locally in the project folder, instead of globally:
	`pip install virtualenv`
	`python<version> -m venv .venv`
	`source .venv/bin/activate`
	`python -m pip install -r requirements.txt`
		AWS DevOps

Task	Description	Skills required

Create a cross-account role in the `devops` environment.	The `devops` account is responsible for hosting and managing the CI/CD pipelines. To enable the CI/CD pipelines to interact with the `dev` and `prod` environments, run the following commands to create a cross-account role in the `devops` account.
	
	`cdk bootstrap --profile =devops`
	
	`cdk deploy LexMgmtDevopsRoleStack -c dev-account-id=2222222222222 -c prod-account-id=333333333333 --profile=devops`
		AWS DevOps

Task	Description	Skills required

Create a cross-account role in the `dev` environment.	Create an IAM role in the `dev` account with the necessary permissions to allow the `devops` account to assume this role. The CI/CD pipeline uses this role to perform actions in the `dev` account, such as deploying and managing Amazon Lex bot resources.
	
	To create the IAM role, run the following commands:
	
	`cdk bootstrap --profile=dev`
	
	`cdk deploy LexMgmtCrossaccountRoleStack -c devops-account-id=1111111111111 --profile=dev`
		AWS DevOps

Task	Description	Skills required

Create a cross-account role in the `prod` environment.	Create an IAM role in the `prod` account with the necessary permissions to allow the `devops` account to assume this role. The CI/CD pipeline uses this role to perform actions in the `prod` account, such as deploying and managing Amazon Lex bot resources.
	
	`cdk bootstrap --profile=prod`
	
	`cdk deploy LexMgmtCrossaccountRoleStack -c devops-account-id=1111111111111 --profile=prod`
		AWS DevOps

Create pipelines in the `devops` environment.	To manage the development workflow for Amazon Lex bots, run the following command to set up pipelines in the `devops` environment . `cdk deploy LexMgmtWorkflowStack -c devops-account-id=1111111111111 -c dev-account-id=2222222222222 -c prod-account-id=333333333333 --profile=devops`	AWS DevOps

Establish the baseline for the main bot

Task	Description	Skills required
Define the initial version of the main bot.	To define the initial version of the main bot, [trigger](#) the `BaselineBotPipeline` pipeline. The pipeline deploys the basic bot definition that's defined in the CloudFormation template, exports the main bot definition as .json files. and stores the main bot code in a version control system.	AWS DevOps

Implement the feature development workflow

Task	Description	Skills required
Create the ticket bot to develop and test a feature.	`TicketBot` is a new bot instance that's imported from the existing main bot definition in the feature branch. This approach ensures that the new bot has all the current functionality and configurations from the main bot. To define the initial version of the ticket bot, trigger the `CreateTicketBotPipeline` pipeline.	Lex Bot Developer

Task	Description	Skills required
	The pipeline creates a new feature branch in the version control system and creates a new ticket bot instance based on the main bot.	
Develop and test the ticket bot feature.	To develop and test the feature, sign in to the AWS Management Console and open the Amazon Lex console at https://console.aws.amazon.com/lex/. For more information, see [Testing a bot using the console](#) in the Amazon Lex documentation. With the `TicketBot` instance, you can now add, modify, or extend the bot's functionality to implement the new feature. For example, you can create or modify intents, utterances, slots, and dialog flows. For more information, see [Adding intents](#) in the Amazon Lex documentation.	Lex Bot Developer

Task	Description	Skills required
Export the ticket bot definitio n.	The exported bot definition is essentially a representation of the bot's configuration and functionality in a JSON format. To export the ticket bot definition, trigger the `ExportTicketBotPipeline` pipeline. The pipeline exports the ticket bot definition as .json files and stores the ticket bot code in a feature branch in the version control system.	Lex Bot Developer
Rebase the feature branch from the latest main branch.	During the development of a new feature, the main branch might have received other changes from different developers or teams. To incorporate these changes into the feature branch, perform a Git `rebase` operation. This operation essentially replays the commits from the feature branch on top of the latest commits from the main branch, ensuring that the feature branch includes all the latest changes	Lex Bot Developer

Task	Description	Skills required
Import and validate the rebased ticket bot.	After you rebase the feature branch, you must import it into the ticket bot instance. This import updates the existing ticket bot with the latest changes from the rebased branch. To import the rebased ticket bot, trigger the `ImportTicketBotPipeline` pipeline. The pipeline imports the ticket bot definition .json files in the feature branch in the version control system into the `TicketBot` instance.	Lex Bot Developer

Task	Description	Skills required
Validate the rebased bot definition.	After you import the rebased bot definition, it's crucial to validate its functionality. You want to make sure that the new feature works as expected and doesn't conflict with existing functionality. This validation typically involves testing the bot with various input scenarios, checking the responses, and verifying that the bot behaves as intended. You can perform validation in either of the following ways: • Test the bot manually by using the Amazon Lex console. • Use an automated approach by using testing frameworks and tools that can simulate user interacti ons and assert expected responses.	Lex Bot Developer

Task	Description	Skills required
Merge the feature branch into the main branch.	After you develop and test the new feature in the isolated `TicketBot` instance, do the following: 1. Commit the changes to the corresponding feature branch in the version control system. 2. To merge the feature branch into the main branch, create a pull request (PR). This PR serves as a request to review and incorporate the changes into the main codebase.	Lex Bot Developer, Repository Adminstrator

Task	Description	Skills required
Delete the feature branch and the ticket bot.	After a feature branch is merged successfully into the main branch, delete the feature branch and the ticket bot from the source code repo. To delete the feature branch and the ticket bot, trigger the `DeleteTicketBotPipeline` pipeline. The pipeline removes temporary bot resources that were created during the development process (for example, the ticket bot). This action helps to maintain a clean repo and prevent confusion or conflicts with future feature branches.	Lex Bot Developer

Maintain the main bot

Task	Description	Skills required
Import the latest main bot definition into the `dev` environment.	To import the latest main bot definition in the main branch into the `dev` environment, trigger the `DeployBotDevPipeline` pipeline. The pipeline also creates a git tag on approval.	AWS DevOps

Task	Description	Skills required
Import the latest main bot definition into the `prod` environment.	To import the latest bot definition in the main branch into the `prod` environment, provide the tag reference from the previous task as a parameter and trigger the `DeployBotProdPipeline` pipeline. The pipeline imports the latest bot definition from a specific tag into the `prod` environment.	AWS DevOps

Troubleshooting

Issue	Solution
When you deploy Amazon Lex bots to different AWS accounts, the tooling services must have the necessary permissions to access resources in those accounts.	To grant cross-account access, use IAM roles and policies. Create IAM roles in the target accounts and attach policies to the roles that grant the required permissions. Then, assume these roles from the account where the Amazon Lex bot is deployed. For more information, see IAM permissions required to import and IAM permissions required to export bots in Lex V2 in the Amazon Lex documentation.

Automate stack set deployment by using AWS CodePipeline and AWS CodeBuild

Thiyagarajan Mani, Mihir Borkar, and Raghu Gowda, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

In your continuous integration and continuous delivery (CI/CD) processes, you might want to deploy applications automatically into all your existing AWS accounts and into new accounts that you add to your organization in AWS Organizations. When you architect a CI/CD solution for this requirement, the delegated stack set administrator capability of AWS CloudFormation is useful because it enables a layer of security by restricting access to the management account. However, AWS CodePipeline uses the service-managed permissions model to deploy applications into multiple acounts and Regions. You must use the AWS Organizations management account to deploy with stack sets, because AWS CodePipeline doesn't support the delegated stack set administrator feature.

This pattern describes how you can work around this limitation. The pattern uses AWS CodeBuild and a custom script to automate stack set deployment with AWS CodePipeline. It automates these application deployment activities:

- Deploy an application as stack sets into existing organizational units (OUs)
- Extend the deployment of an application into additional OUs and Regions
- Remove a deployed application from all or specific OUs or Regions

Prerequisites and limitations

Prerequisites

Before you follow the steps in this pattern:

- Create organizations in your AWS Organizations management account. For instructions, see the AWS Organizations documentation.

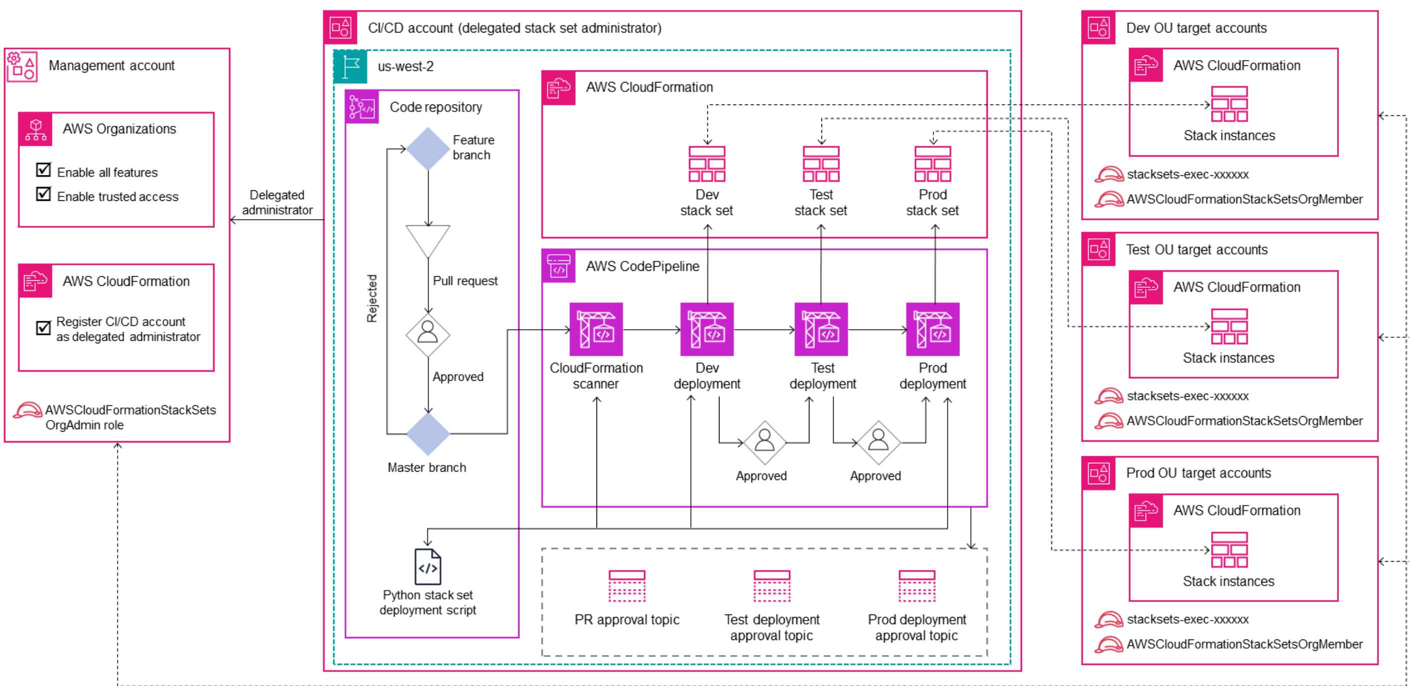
- Enable trusted access between AWS Organizations and CloudFormation to use service-managed permissions. For instructions, see [Enable trusted access with AWS Organizations](#) in the CloudFormation documentation.

Limitations

The code that's supplied with this pattern has the following limitations:

- You can deploy only a single CloudFormation template for an application; multiple template deployment isn't currently supported.
- Customizing the current implementation requires DevOps expertise.
- This pattern doesn't use AWS Key Management System (AWS KMS) keys. However, you can enable this functionality by reconfiguring the CloudFormation template included with this pattern.

Architecture



This architecture for the CI/CD deployment pipeline handles the following:

- Restricts direct access to the management account by delegating stack set deployment responsibility to a dedicated CI/CD account as the stack set administrator for application deployments.
- Uses the service-managed permission model to deploy the application automatically whenever a new account is created and mapped under an OU.
- Ensures application version consistency across all accounts at the environment level.
- Uses multiple approval stages at the repository and pipeline levels to provide additional layers of security and governance for the deployed application.
- Overcomes the current limitation of CodePipeline by using a custom-built deployment script in CodeBuild to automatically deploy or remove stack sets and stack instances. For an illustration of the flow control and hierarchy of API calls implemented by the custom script, see the Additional information section.
- Creates individual stack sets for the development, testing, and production environments. In addition, you can create stack sets that combine multiple OUs and Regions at every stage. For example, you can combine sandbox and development OUs within a development deployment stage.
- Supports application deployment into, or exclusion from, a subset of accounts or list of OUs.

Automation and scale

You can use the code provided with this pattern to create a AWS CodeCommit repository and a code pipeline for your application. You can then deploy these as stack sets into multiple accounts at the OU level. The code also automates components such as Amazon Simple Notification Service (Amazon SNS) topics to notify approvers, the required AWS Identity and Access Management (IAM) roles, and the service control policy (SCP) to apply in the management account.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

- AWS CodeDeploy automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

Code repository

The code for this pattern is available in the GitHub automated-code-pipeline-stackset-deployment repository. For the folder structure and other details, see the readme file for the repository.

Best practices

This pattern restricts direct access to the management account while deploying the application at the OU level. Adding multiple approval stages to the pipeline and repository process helps provide additional security and governance for the applications and components that you deploy by using this approach.

Epics

Configure accounts in AWS Organizations

Task	Description	Skills required
Enable all features in the management account.	Enable all features in the management account for your organization by following the instructions in the AWS Organizations documentation.	AWS administrator, Platform administrator
Create a CI/CD account.	In AWS Organizations, in your organization, create a	AWS administrator

Task	Description	Skills required
	dedicated CI/CD account, and assign a team to own and control access to the account.	
Add a delegated administrator.	In the management account, register the CI/CD account that you created in the previous step as a delegated stack set administrator. For instructions, see the [AWS CloudFormation documentation]().	AWS administrator, Platform administrator

Create an application repository and CI/CD pipeline

Task	Description	Skills required
Clone the code repository.	1. Clone the code repository that's provided with this pattern to your computer: `git clone https://github.com/aws-samples/automated-code-pipeline-stackset-deployment.git` 2. Review the [readme file]() to understand the directory structure and other details.	AWS DevOps
Create SNS topics.	You can use the `sns-template.yaml` template that's provided in the GitHub repository to create SNS	AWS DevOps

	tion files and script .zip file will be stored. • **DeploymentConfigKey** – The path and .zip filename (Amazon S3 key). • **PRApprovalSNSARN** – The ARN for the SNS topic for pull request notifications. • **ProdApprovalSNSARN** – The ARN for the SNS topic for production approvals. • **TESTApprovalSNSARN** – The ARN for the SNS topic for test approvals. • **TemplateBucket** – The name of the S3 bucket in the CI/CD account where the CI/CD pipeline creation template will be stored. 7. Choose **Next**, **Next**, and **Submit**. 8. When the stack completes successfully, it creates a CodeCommit repository that has the specified name and a default directory structure, deployment configuration	

Task	Description	Skills required
	files, scripts, and a code pipeline for the repository.	

Deploy a stack set

Task	Description	Skills required

Clone the application repository.	The CI/CD pipeline template you used previously creates a sample application repositor y and code pipeline. To clone and verify the repository:
	
	1. Sign in to the CI/CD account.
	2. Find the application repository and CI/CD pipeline that you created in the previous epic.
	3. Copy the URL for the repository and use the git clone command to clone the repository on your local machine.
	4. Verify that the directory structure and files match the following:
	
	`root`
	` |- deploy_configs`
	` |        |- deploymen t_config.json`
	` |- parameters`
	` |      |- template- parameter-dev.json`
		App developer, Data engineer

Task	Description	Skills required
	``` | |- template- parameter-test.json | |- template- parameter-prod.json |- templates | |- template. yml |- buildspec.yml ``` where the `deploy_configs` folder contains the deployment configuration file, and the `templates` and `parameters` folders include default files that you'll replace with your own CloudFormation template and parameter files. **Important** Do not customize the folder structure. 5. Create a feature branch.	

Task	Description	Skills required
Add application artifacts.	Update the application repository by using a CloudFormation template. **Note** This solution supports the deploymen t of only a single CloudFormation template. 1. Build your CloudFormation template for deploying your application code changes, and name it `<application-name>.yaml`. 2. Replace the `template.yml` file in the `templates` folder of the application repository with the CloudFormation template you created in step 1. 3. Prepare parameter files for each environment (development, testing, and production). 4. Name the parameter files by using the format `<cloudformation-template-name>-param`	App developer, Data engineer

Task	Description	Skills required
	`eter-<environment-name>.json` . 5. Replace the default parameter files in the `parameters` folder with your files from step 4.	

Task	Description	Skills required
Update the deployment configuration file.	Update the `deployment_config.json` file: 1. In the application repository, navigate to the `deploy_configs` folder. 2. Open the file `deployment_config.json` :	App developer, Data engineer

	``
	3. Update the values for deployment action, stack set name, stack set description, and deployment targets.
	
	For example, you can set `deployment_action` to `delete` to delete the entire stack set and its associated stack instances . Use `deploy` to create a new stack set, to update	

Task	Description	Skills required
	an existing stack set, or to add or remove stack instances for additional OUs or Regions. For more examples, see the [Additional information](#) section. This pattern creates individual stack sets for each environment by adding the environment name to the stack set name you provide in the deployment configuration file.	

Task	Description	Skills required
Commit changes and deploy the stack set.	Commit the changes you specified in your applicati on template, and merge and deploy the stack set into multiple environments stage by stage: 1. Save all your files and commit changes to the feature branch of your local application repository. 2. Push the feature branch to the remote repository. 3. Create a pull request to merge the changes to the main branch. When the pull request has been approved and changes have been merged to the main branch, the CI/ CD pipeline will be initiated . 4. When the Dev-deployment stage has completed successfully, check the CloudFormation console, **StackSets**, **Service-M anaged** tab. You'll see a new stack set with the suffix `dev`. 5. Check the CodeBuild logs for the Dev-deployment stage for any issues.	App developer, Data engineer

Task	Description	Skills required
	6. Deploy the stack set into the testing and productio n environments by asking your approvers to approve the deployments for those stages and repeating steps 5 and 6. The stack sets for the testing and productio n environments have the suffixes `test` and `prod`.	

Troubleshooting

Issue	Solution
Deployment fails with the exception: *Change the Name of Template Parameter file as <application name>-parameter-<evn>.json with, default names are not allowed*	The CloudFormation template parameter files must follow the naming convention specified . Update the parameter file names and try again.
Deployment fails with the exception: *Change the Name of CloudFormation Template as <application name>.yml, default template. yml or template.yaml are not allowed*	The CloudFormation template name must follow the naming convention specified. Update the file name and try again.
Deployment fails with the exception: *No valid CloudFormation Template and its Parameter File found for {environment name} environment*	Check the file naming conventions for the CloudFormation template and its parameter file for the specified environment.
Deployment fails with the exception:	You specified an invalid value for the `deployment_action` parameter in the deployment configuration file. The parameter

Issue	Solution
Invalid deployment action provided in deployment config file. Valid options are 'deploy' and 'delete'.	has two valid values: `deploy` and `delete`. Use `deploy` to create and update the stack sets and their associated stack instances. Use `delete` only when you want to remove the entire stack set and associated stack instances.

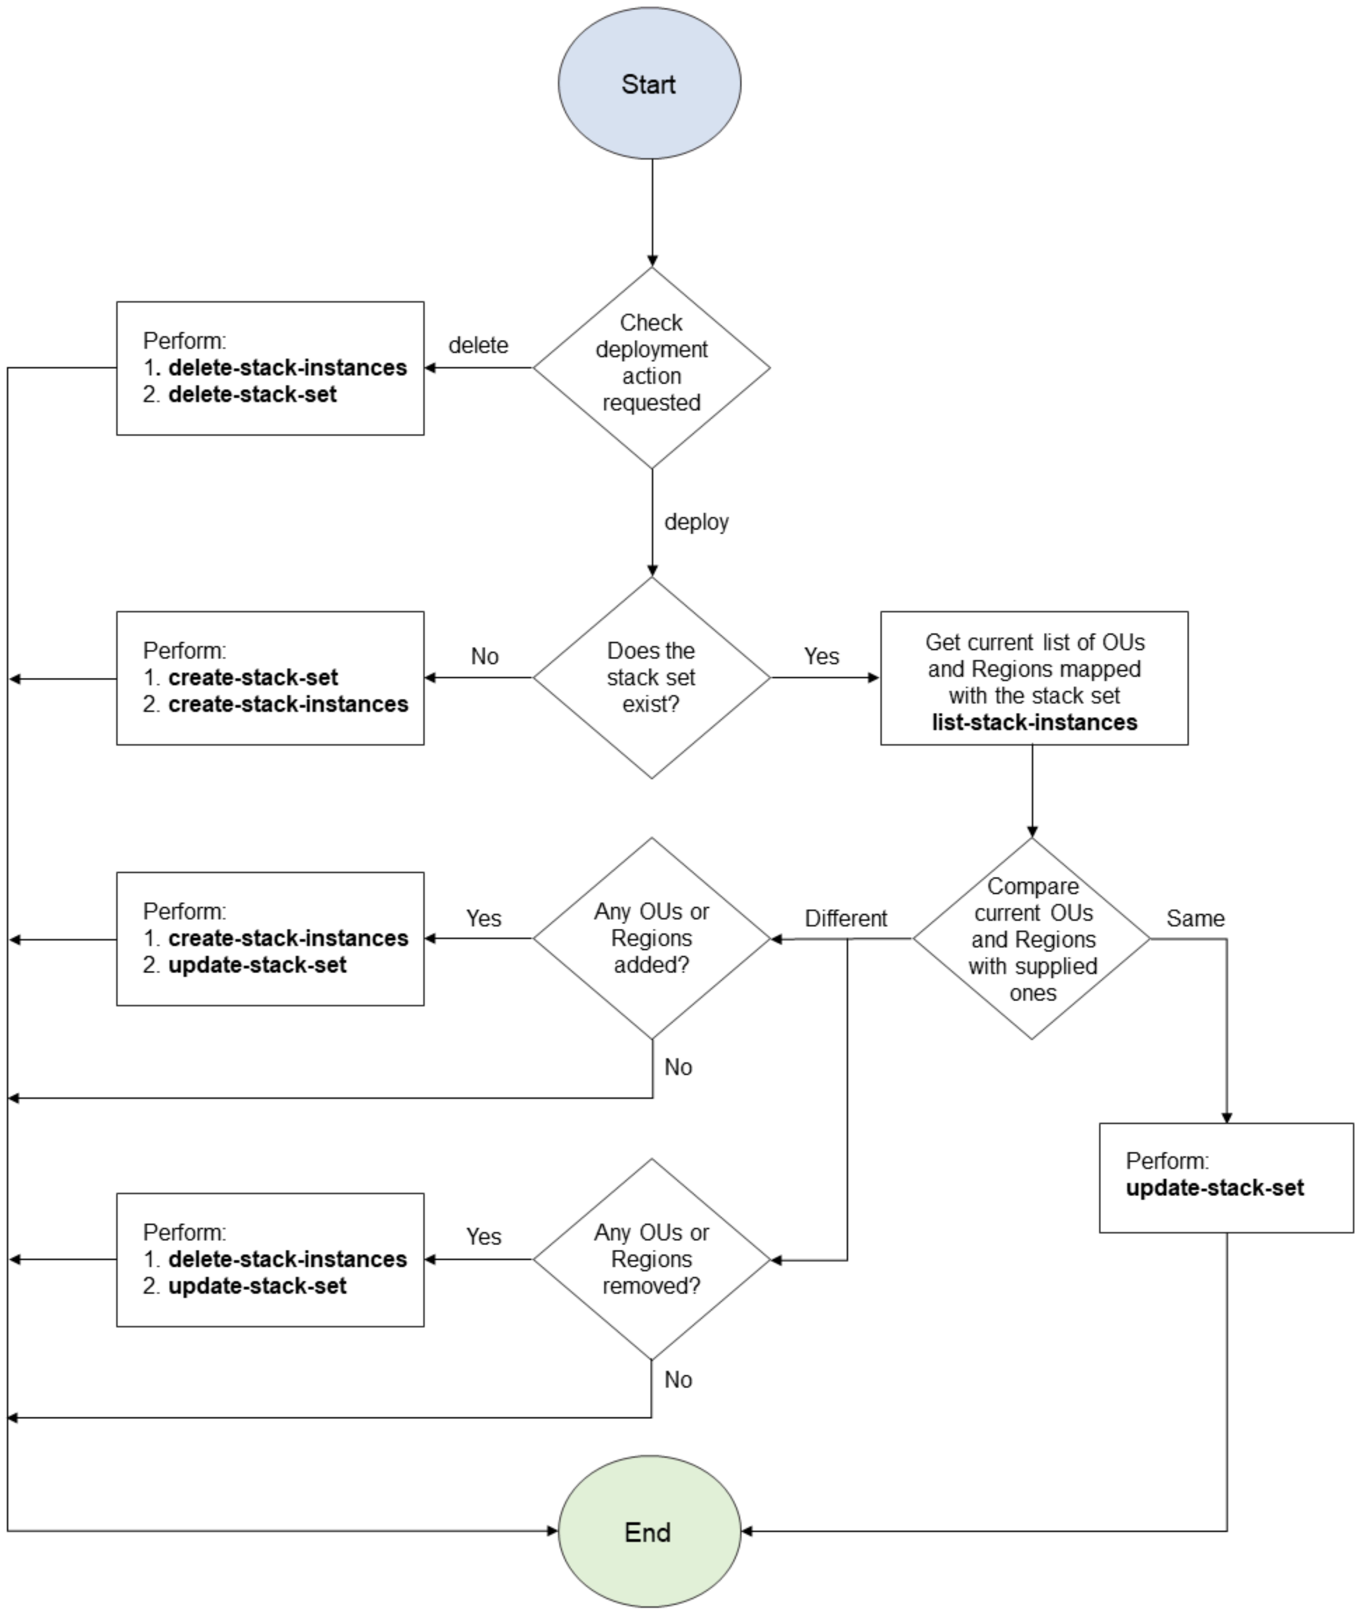
Additional information

Flow chart

The following flow chart depicts the flow control and hierarchy of API calls implemented by the custom script to automate stack set deployment.



Sample deployment configuration files

Creating a new stack set

The following deployment configuration file creates a new stack set called `sample-stack-set` in the AWS Region `us-east-1` in three OUs.

```
{
     "deployment_action": "deploy",
     "stack_set_name": "sample-stack-set",
     "stack_set_desciption": "this is a sample stack set",
    "deployment_targets": {
                           "dev": {
                                       "org_units": ["dev-org-unit-1"],
                                       "regions": ["us-east-1"],
                                       "filter_accounts": [],
                                       "filter_type": ""
                                   },
                           "test": {
                                       "org_units": ["test-org-unit-1"],
                                       "regions": ["us-east-1"],
                                       "filter_accounts": [],
                                       "filter_type": ""
                                   },
                           "prod": {
                                       "org_units": ["prod-org-unit-1"],
                                       "regions": ["us-east-1"],
                                       "filter_accounts": [],
                                       "filter_type": ""
                                   }
                         },
     "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
     "auto_deployement": "True",
     "retain_stacks_on_account_removal": "True",
     "region_deployment_concurrency": "PARALLEL"
 }
```

Deploying an existing stack set to another OU

If you deploy the configuration shown in the previous example and you want to deploy the stack set to an additional OU called `dev-org-unit-2` in the development environment, the deployment configuration file might look like the following.

```
{
     "deployment_action": "deploy",
```

```
     "stack_set_name": "sample-stack-set",
     "stack_set_desciption": "this is a sample stack set",
    "deployment_targets": {
                            "dev": {
                                        "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    },
                            "test": {
                                        "org_units": ["test-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    },
                            "prod": {
                                        "org_units": ["prod-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    }
                          },
     "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
     "auto_deployement": "True",
     "retain_stacks_on_account_removal": "True",
     "region_deployment_concurrency": "PARALLEL"
 }
```

Deploying an existing stack set to another AWS Region

If you deploy the configuration shown in the previous example and you want to deploy the stack set to an additional AWS Region (`us-east-2`) in the development environment for two OUs (`dev-org-unit-1` and `dev-org-unit-2`), the deployment configuration file might look like the following.

> **Note**
>
> The resources in the CloudFormation template must be valid and Region-specific.

```
{
```

```
     "deployment_action": "deploy",
     "stack_set_name": "sample-stack-set",
     "stack_set_desciption": "this is a sample stack set",
    "deployment_targets": {
                        "dev": {
                                    "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
                                    "regions": ["us-east-1", "us-east-2"],
                                    "filter_accounts": [],
                                    "filter_type": ""
                                },
                        "test": {
                                    "org_units": ["test-org-unit-1"],
                                    "regions": ["us-east-1"],
                                    "filter_accounts": [],
                                    "filter_type": ""
                                },
                        "prod": {
                                    "org_units": ["prod-org-unit-1"],
                                    "regions": ["us-east-1"],
                                    "filter_accounts": [],
                                    "filter_type": ""
                                }
                      },
     "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
     "auto_deployement": "True",
     "retain_stacks_on_account_removal": "True",
     "region_deployment_concurrency": "PARALLEL"
 }
```

Removing a stack instance from an OU or AWS Region

Let's say that the deployment configuration shown in the previous example has been deployed. The following configuration file removes the stack instances from both Regions of the OU `dev-org-unit-2`.

```
{
     "deployment_action": "deploy",
     "stack_set_name": "sample-stack-set",
     "stack_set_desciption": "this is a sample stack set",
    "deployment_targets": {
                        "dev": {
                                    "org_units": ["dev-org-unit-1"],
```

```
                                        "regions": ["us-east-1", "us-east-2"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    },
                            "test": {
                                        "org_units": ["test-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    },
                            "prod": {
                                        "org_units": ["prod-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    }
                          },
     "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
     "auto_deployement": "True",
     "retain_stacks_on_account_removal": "True",
     "region_deployment_concurrency": "PARALLEL"
 }
```

The following configuration file removes the stack instance from the AWS Region `us-east-1` for both OUs in the development environment.

```
{
     "deployment_action": "deploy",
     "stack_set_name": "sample-stack-set",
     "stack_set_desciption": "this is a sample stack set",
    "deployment_targets": {
                            "dev": {
                                        "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
                                        "regions": ["us-east-2"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    },
                            "test": {
                                        "org_units": ["test-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
```

```
                                        "filter_type": ""
                                    },
                            "prod": {
                                        "org_units": ["prod-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    }
                          },
     "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
     "auto_deployement": "True",
     "retain_stacks_on_account_removal": "True",
     "region_deployment_concurrency": "PARALLEL"
 }
```

Deleting the entire stack set

The following deployment configuration file deletes the entire stack set and all its associated stack instances.

```
{
     "deployment_action": "delete",
     "stack_set_name": "sample-stack-set",
     "stack_set_desciption": "this is a sample stack set",
    "deployment_targets": {
                            "dev": {
                                        "org_units": ["dev-org-unit-1", "dev-org-
unit-2"],
                                        "regions": ["us-east-2"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    },
                            "test": {
                                        "org_units": ["test-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
                                    },
                            "prod": {
                                        "org_units": ["prod-org-unit-1"],
                                        "regions": ["us-east-1"],
                                        "filter_accounts": [],
                                        "filter_type": ""
```

```
                                    }
                            },
    "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
    "auto_deployement": "True",
    "retain_stacks_on_account_removal": "True",
    "region_deployment_concurrency": "PARALLEL"
}
```

Excluding an account from deployment

The following deployment configuration file excludes the account 111122223333, which is part of the OU `dev-org-unit-1`, from deployment.

```
{
    "deployment_action": "deploy",
    "stack_set_name": "sample-stack-set",
    "stack_set_desciption": "this is a sample stack set",
   "deployment_targets": {
                              "dev": {
                                          "org_units": ["dev-org-unit-1"],
                                          "regions": ["us-east-1"],
                                          "filter_accounts": ["111122223333"],
                                          "filter_type": "DIFFERENCE"
                                      },
                              "test": {
                                          "org_units": ["test-org-unit-1"],
                                          "regions": ["us-east-1"],
                                          "filter_accounts": [],
                                          "filter_type": ""
                                      },
                              "prod": {
                                          "org_units": ["prod-org-unit-1"],
                                          "regions": ["us-east-1"],
                                          "filter_accounts": [],
                                          "filter_type": ""
                                      }
                            },
    "cft_capabilities": ["CAPABILITY_IAM", "CAPABILITY_NAMED_IAM"],
    "auto_deployement": "True",
    "retain_stacks_on_account_removal": "True",
    "region_deployment_concurrency": "PARALLEL"
}
```

Deploying the application to a subset of accounts in an OU

The following deployment configuration file deploys the application to only three accounts (111122223333, 444455556666, and 777788889999) in the OU `dev-org-unit-1`.

```

```

Automatically attach an AWS managed policy for Systems Manager to EC2 instance profiles using Cloud Custodian and AWS CDK

Ali Asfour and Aaron Lennon, Amazon Web Services

Summary

You can integrate Amazon Elastic Compute Cloud (Amazon EC2) instances with AWS Systems Manager to automate operational tasks and provide more visibility and control. To integrate with Systems Manager, EC2 instances must have an installed [AWS Systems Manager Agent (SSM Agent)](#) and an `AmazonSSMManagedInstanceCore` AWS Identity and Access Management (IAM) policy attached to their instance profiles.

However, if you want to ensure that all EC2 instance profiles have the `AmazonSSMManagedInstanceCore` policy attached, you can face challenges updating new EC2 instances that don't have instance profiles or EC2 instances that have an instance profile but don't have the `AmazonSSMManagedInstanceCore` policy. It can also be difficult to add this policy across multiple Amazon Web Services (AWS) accounts and AWS Regions.

This pattern helps solve these challenges by deploying three [Cloud Custodian](#) policies in your AWS accounts:

- The first Cloud Custodian policy checks for existing EC2 instances that have an instance profile but don't have the `AmazonSSMManagedInstanceCore` policy. The `AmazonSSMManagedInstanceCore` policy is then attached.
- The second Cloud Custodian policy checks for existing EC2 instances without an instance profile and adds a default instance profile that has the `AmazonSSMManagedInstanceCore` policy attached.
- The third Cloud Custodian policy creates [AWS Lambda functions](#) in your accounts to monitor the creation of EC2 instances and instance profiles. This ensures that the `AmazonSSMManagedInstanceCore` policy is automatically attached when an EC2 instance is created.

This pattern uses [AWS DevOps](#) tools to achieve a continuous, at-scale deployment of the Cloud Custodian policies to a multi-account environment, without provisioning a separate compute environment.

Prerequisites and limitations

Prerequisites

- Two or more active AWS accounts. One account is the *security account* and the others are *member accounts*.
- Permissions to provision AWS resources in the security account. This pattern uses administrator permissions, but you should grant permissions according to your organization's requirements and policies.
- Ability to assume an IAM role from the security account to member accounts and create the required IAM roles. For more information about this, see Delegate access across AWS accounts using IAM roles in the IAM documentation.
- > **Important**
  >
  > AWS Command Line Interface (AWS CLI), installed and configured. For testing purposes, you can configure AWS CLI by using the `aws configure` command or setting environment variables. : This isn't recommended for production environments and we recommend that this account is only granted least privilege access. For more information about this, see Grant least privilege in the IAM documentation.
- The `devops-cdk-cloudcustodian.zip` file (attached), downloaded to your local computer.
- Familiarity with Python.
- The required tools (Node.js, AWS Cloud Development Kit (AWS CDK), and Git), installed and configured. You can use the `install-prerequisites.sh` file in the `devops-cdk-cloudcustodian.zip` file to install these tools. Make sure you run this file with root privileges.

Limitations

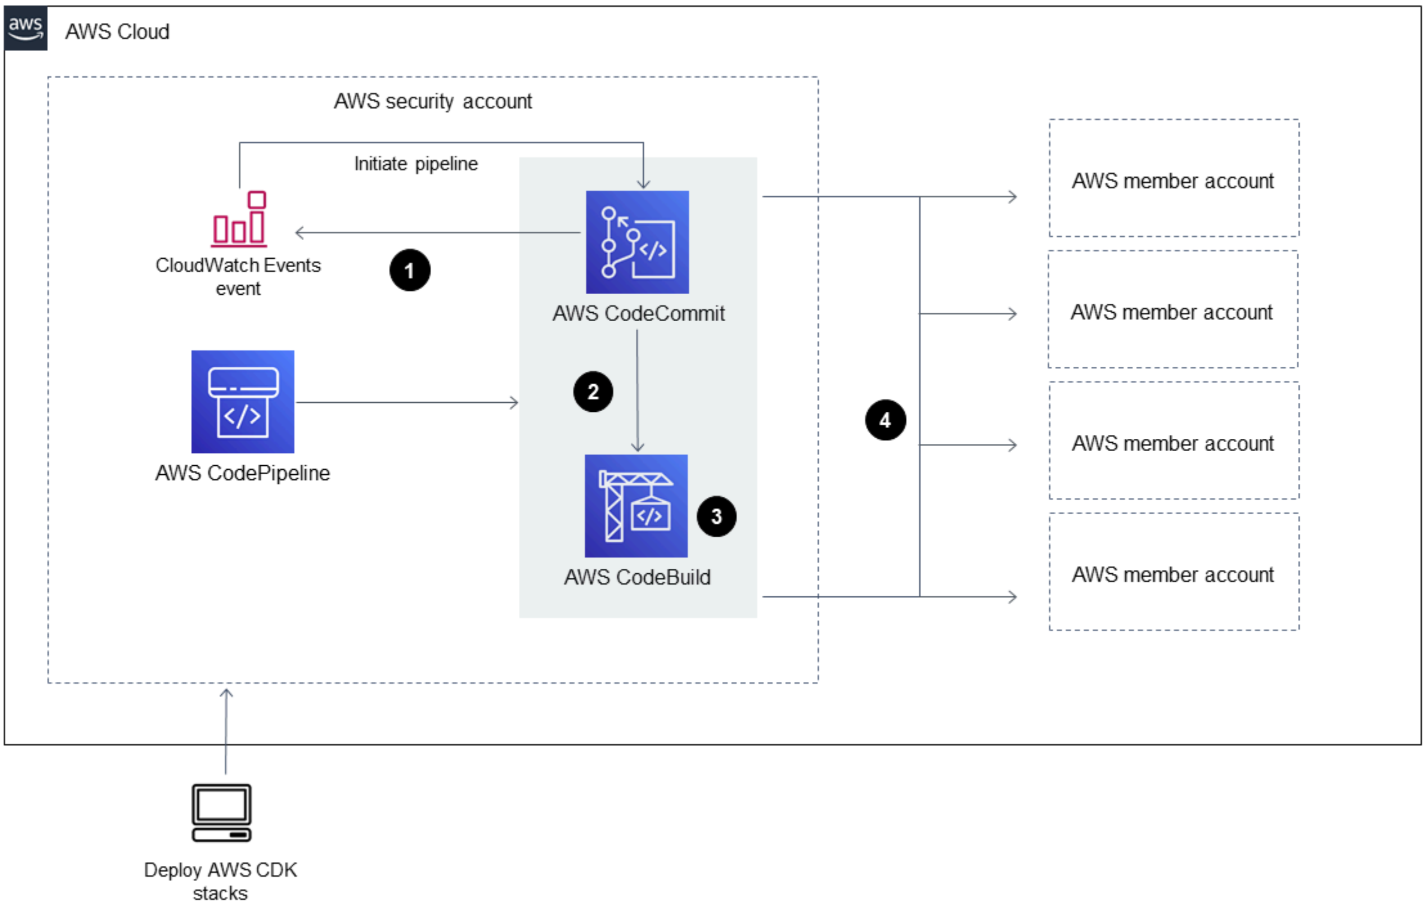
- Although this pattern can be used in a production environment, make sure that all IAM roles and policies meet your organization's requirements and policies.

Package versions

- Cloud Custodian version 0.9 or later
- TypeScript version 3.9.7 or later
- Node.js version 14.15.4 or later

- npm version 7.6.1 or later
- AWS CDK version 1.96.0 or later

Architecture



The diagram shows the following workflow:

1. Cloud Custodian policies are pushed to an AWS CodeCommit repository in the security account. An Amazon CloudWatch Events rule automatically initiates the AWS CodePipeline pipeline.
2. The pipeline fetches the most recent code from CodeCommit and sends it to the continuous integration part of the continuous integration and continuous delivery (CI/CD) pipeline handled by AWS CodeBuild.
3. CodeBuild performs the complete DevSecOps actions, including policy syntax validation on the Cloud Custodian policies, and runs these policies in `--dryrun` mode to check which resources are identified.

4. If there are no errors, the next task alerts an administrator to review the changes and approve the deployment into the member accounts.

Technology stack

- AWS CDK
- CodeBuild
- CodeCommit
- CodePipeline
- IAM
- Cloud Custodian

Automation and scale

The AWS CDK pipelines module provisions a CI/CD pipeline that uses CodePipeline to orchestrate the building and testing of source code with CodeBuild, in addition to the deployment of AWS resources with AWS CloudFormation stacks. You can use this pattern for all member accounts and Regions in your organization. You can also extend the `Roles creation` stack to deploy other IAM roles in your member accounts.

Tools

- AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- AWS CodeBuild is a fully managed build service in the cloud.
- AWS CodeCommit is a version control service that you can use to privately store and manage assets.
- AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.
- AWS Identity and Access Management is a web service that helps you securely control access to AWS resources.
- Cloud Custodian is a tool that unifies the dozens of tools and scripts most organizations use for managing their public cloud accounts into one open-source tool.

- Node.js is a JavaScript runtime built on Google Chrome's V8 JavaScript engine.

Code

For a detailed list of modules, account functions, files, and deployment commands used in this pattern, see the `README` file in the `devops-cdk-cloudcustodian.zip` file (attached).

Epics

Set up the pipeline with AWS CDK

Task	Description	Skills required
Set up the CodeCommit repository.	1. Unzip the `devops-cdk-cloudcustodian.zip` file (attached) in the working directory on your local computer. 2. Sign in to the AWS Management Console for your security account, open the CodeCommit console, and then create a new `devops-cdk-cloudcustodian` repository. 3. Change into the project directory and set up the CodeCommit repository as the origin, commit the changes, and then push them to the origin branch by running the following commands: • `cd devops-cdk-cloudcustodian`	Developer

Task	Description	Skills required
	• `git init --initial-branch=main` • `git add . git commit -m 'initial commit'` • `git remote add origin https://git-codecommit.us-east-1.amazonaws.com/v1/devops-cdk-cloudcustodian` • `git push origin main` For more information about this, see Creating a CodeCommit repository in the AWS CodeCommit documentation.	
Install the required tools.	Use the `install-prerequisites.sh` file to install all the required tools on Amazon Linux. This doesn't include AWS CLI because it comes pre-installed. For more information about this, see the Prerequisites section of Getting started with the AWS CDK in the AWS CDK documentation.	Developer

Task	Description	Skills required
Install the required AWS CDK packages.	1. Set up your virtual environment by running the following command in AWS CLI: `$ python3 -m venv .env` 2. Activate your virtual environment by running the following command: `$ source .env/bin/activate` 3. After the virtual environment is activated, install the required dependencies by running the following command: `$ pip install -r requirements.txt` 4. To add additional dependencies (for example, other AWS CDK libraries), add them to the `requirements.txt` file, and then run the following command: `pip install -r requirements.txt` The following packages are required by AWS CDK and are included in the `requirements.txt` file: • `aws-cdk.aws-cloudwatch`	Developer

Task	Description	Skills required
	• `aws-cdk.aws-codebuild` • `aws-cdk.aws-codecommit` • `aws-cdk.aws-codedeploy` • `aws-cdk.aws-codepipeline` • `aws-cdk.aws-codepipeline-actions` • `aws-cdk.aws-events` • `aws-cdk.aws-events-targets` • `aws-cdk.aws-iam` • `aws-cdk.aws-logs` • `aws-cdk.aws-s3` • `aws-cdk.aws-sns` • `aws-cdk.aws-sns-subscriptions` • `aws-cdk.aws-sqs` • `aws-cdk.core`	

Configure your environment

Task	Description	Skills required
Update the required variables.	Open the `vars.py` file in the root folder of your CodeCommit repository and update the following variables:	Developer

Task	Description	Skills required
	• Update `var_deploy_region = 'us-east-1'` with the AWS Region where you want the pipeline to be deployed. • Update `var_codecommit_repo_name = "cdk-cloudcustodian"` with the name of your CodeCommit repository. • Update `var_codecommit_branch_name = "main"` with name of the CodeCommit branch. • Update `var_adminEmail=notifyadmin@email.com'` with the email address for the administrator that approves changes. • Update `var_slackWebHookUrl = https://hooks.slack.com/services/T00000000/B00000000/XXXXXXXXXXXXXXXXXXXXXXX '` with the Slack webhook used to send Cloud Custodian notifications when changes are made.	

Task	Description	Skills required
	• Update `var_orgId = 'o-yyyyyyyyyy'` with your organization ID. • Update `security_account = '123456789011'` with the AWS account ID for the account where the pipeline is deployed. • Update `member_accounts = ['111111111111','111111111112','111111111113']` with the member accounts where you want to bootstrap the AWS CDK stack and deploy the required IAM roles. • Set `cdk_bootstrap_member_accounts = True` to `True` if you want the pipeline to automatically bootstrap the AWS CDK to your member accounts. If set to `True` this also requires the name of an existing IAM role in the member accounts that can be assumed from the security account. This IAM role must also have the required permissions to bootstrap the AWS CDK.	

Task	Description	Skills required
	• **Note** Update `cdk_bootstrap_role = 'AWSControlTowerExecution'` with the existing IAM role in the member accounts that can be assumed from the security account. This role must also permission to bootstrap the AWS CDK. : This only applies if `cdk_bootstrap_member_accounts` is set to `True`.	

Task	Description	Skills required

Update the account.yml file with the member account information.	To run the [c7n-org Cloud Custodian](https://cloudcustodian.io/docs/tools/c7n-org.html) tool against multiple accounts, you must place the `accounts.yml` config file in the root of the repository. The following is a sample Cloud Custodian config file for AWS:
	`accounts:`
	`- account_id: '123123123123'`
	`  name: account-1`
	`  regions:`
	`  - us-east-1`
	`  - us-west-2`
	`  role: arn:aws:iam::123123123123:role/CloudCustodian`
	`  vars:`
	`    charge_code: xyz`
	`  tags:`
	`  - type:prod`
	`  - division:some division`
	`  - partition:us`
	`  - scope:pci`
		Developer

Bootstrap the AWS accounts

Task	Description	Skills required
Boostrap the security account.	Bootstrap the `deploy_account` with the `cloudcustodian_stack` applicati	Developer

Task	Description	Skills required
	on by running the following command: `cdk bootstrap -a 'python3 cloudcustodian/cloudcustodian_stack.py`	
Option 1 - Automatically bootstrap the member accounts.	If the `cdk_bootstrap_member_accounts` variable is set to `True` in the `vars.py` file, the accounts specified in the `member_accounts` variable are automatically bootstrapped by the pipeline. If required, you can update `*cdk_bootstrap_role*` with an IAM role that you can assume from the security account and that has the required permissions to bootstrap the AWS CDK. New accounts added to the `member_accounts` variable are automatically bootstrapped by the pipeline so that the required roles can be deployed.	Developer

Task	Description	Skills required

Option 2 - Manually bootstrap the member accounts.	Although we don't recommend using this approach, you can set the value of `cdk_bootstrap_member_accounts` to `False` and perform this step manually by running the following command:
	
	`$ cdk bootstrap -a 'python3 cloudcustodian/member_account_roles_stack.py' \`
	
	`--trust {security_account_id} \`
	
	`--context assume-role-credentials:writeIamRoleName={role_name} \`
	
	`--context assume-role-credentials:readIamRoleName={role_name} \`
	
	`--mode=ForWriting \`
	
	`--context bootstrap=true \`
	
	`--cloudformation-execution-policies arn:aws:iam::aws:policy/AdministratorAccess`
		Developer

Task	Description	Skills required
	Important Make sure that you update the `{security_account_id}` and `{role_name}` values with the name of an IAM role that you can assume from the security account and that has the required permissions to bootstrap the AWS CDK. You can also use other approaches to bootstrap the member accounts, for example, with AWS CloudFormation. For more information about this, see [Bootstrapping]() in the AWS CDK documentation.	

Deploy the AWS CDK stacks

Task	Description	Skills required
Create the IAM roles in the member accounts.	Run the following command to deploy the `member_account_roles_stack`	Developer

Task	Description	Skills required
	stack and create the IAM roles in the member accounts: `cdk deploy --all -a 'python3 cloudcustodian/member_account_roles_stack.py' --require-approval never`	
Deploy the Cloud Custodian pipeline stack.	Run the following command to create the Cloud Custodian `cloudcustodian_stack.py` pipeline that is deployed into the security account: `cdk deploy -a 'python3 cloudcustodian/cloudcustodian_stack.py'`	Developer

Automatically build CI/CD pipelines and Amazon ECS clusters for microservices using AWS CDK

Varsha Raju, Amazon Web Services

Summary

This pattern describes how to automatically create the continuous integration and continuous delivery (CI/CD) pipelines and underlying infrastructure for building and deploying microservices on Amazon Elastic Container Service (Amazon ECS). You can use this approach if you want to set up proof-of-concept CI/CD pipelines to show your organization the benefits of CI/CD, microservices, and DevOps. You can also use this approach to create initial CI/CD pipelines that you can then customize or change according to your organization's requirements.

The pattern's approach creates a production environment and non-production environment that each have a virtual private cloud (VPC) and an Amazon ECS cluster configured to run in two Availability Zones. These environments are shared by all your microservices and you then create a CI/CD pipeline for each microservice. These CI/CD pipelines pull changes from a source repository in AWS CodeCommit, automatically build the changes, and then deploy them into your production and non-production environments. When a pipeline successfully completes all of its stages, you can use URLs to access the microservice in the production and non-production environments.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
- An existing Amazon Simple Storage Service (Amazon S3) bucket that contains the `starter-code.zip` file (attached).
- AWS Cloud Development Kit (AWS CDK), installed and configured in your account. For more information about this, see [Getting started with the AWS CDK] in the AWS CDK documentation.
- Python 3 and `pip`, installed and configured. For more information about this, see the [Python documentation].
- Familiarity with AWS CDK, AWS CodePipeline, AWS CodeBuild, CodeCommit, Amazon Elastic Container Registry (Amazon ECR), Amazon ECS, and AWS Fargate.
- Familiarity with Docker.
- An understanding of CI/CD and DevOps.

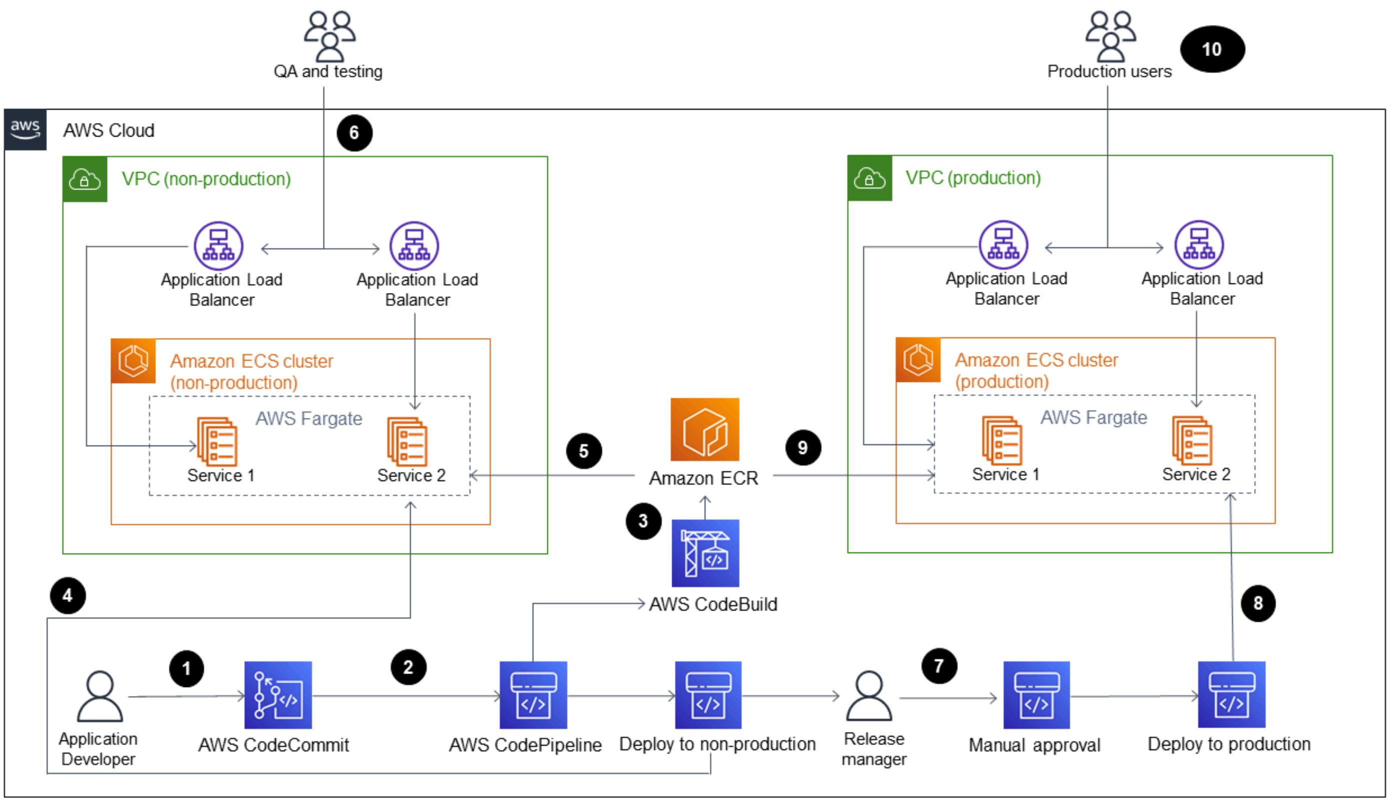
Limitations

- General AWS account limits apply. For more information about this, see [AWS service quotas](#) in the AWS General Reference documentation.

Product versions

- The code was tested using Node.js version 16.13.0 and AWS CDK version 1.132.0.

Architecture



The diagram shows the following workflow:

1. An application developer commits code to a CodeCommit repository.
2. A pipeline is initiated.
3. CodeBuild builds and pushes the Docker image to an Amazon ECR repository
4. CodePipeline deploys a new image to an existing Fargate service in a non-production Amazon ECS cluster.

5. Amazon ECS pulls the image from the Amazon ECR repository into a non-production Fargate service.
6. Testing is performed using a non-production URL.
7. The release manager approves the production deployment.
8. CodePipeline deploys the new image to an existing Fargate service in a production Amazon ECS cluster
9. Amazon ECS pulls the image from the Amazon ECR repository into the production Fargate service.

10Production users access your feature by using a production URL.

Technology stack

- AWS CDK
- CodeBuild
- CodeCommit
- CodePipeline
- Amazon ECR
- Amazon ECS
- Amazon VPC

Automation and scale

You can use this pattern's approach to create pipelines for microservices deployed in a shared AWS CloudFormation stack. The automation can create more than one Amazon ECS cluster in each VPC and also create pipelines for microservices deployed in a shared Amazon ECS cluster. However, this requires that you provide new resource information as inputs to the pipeline stack.

Tools

- AWS CDK – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- AWS CodeBuild – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.

- AWS CodeCommit – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.
- AWS CodePipeline – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process. CodePipeline automates the steps required to release your software changes continuously.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that is used for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.
- Docker – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Code

The code for this pattern is available in the `cicdstarter.zip` and `starter-code.zip` files (attached).

Epics

Set up your environment

Task	Description	Skills required
Set up the working directory for AWS CDK.	1. Create a directory named `cicdproject` on your local machine. 2. Download the `cicdstarter.zip` file (attached) into the `cicdproject` directory and unzip it. This creates a folder named `cicdstarter`.	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
	3. Run the `cd <user-home>/cicdproject/cicdstarter` command. 4. Set up the Python virtual environment by running the `python3 -m venv .venv` command. 5. Run the `source ./.venv/bin/activate` command. 6. Configure your AWS environment by running the `aws configure` command or by using the following environment variables: • `AWS_ACCESS_KEY_ID` • `AWS_SECRET_ACCESS_KEY` • `AWS_DEFAULT_REGION`	

Create the shared infrastructure

Task	Description	Skills required
Create the shared infrastructure.	1. In your working directory, run the `cd cicdvpcecs` command. 2. Run the `pip3 install -r requirements.txt` command to install	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
	all required Python dependencies 3. Run the `cdk bootstrap` command to set the AWS environment for the AWS CDK. 4. Run the `cdk synth --context aws_account=<aws_account_ID> --context aws_region=<aws-region>` command. 5. Run the `cdk deploy --context aws_account=<aws_account_ID> --context aws_region=<aws-region>` command. 6. The AWS CloudFormation stack creates the following infrastructure: • A non-production VPC named `cicd-vpc-ecs/cicd-vpc-nonprod` • A production VPC named `cicd-vpc-ecs/cicd-vpc-prod` • A non-production Amazon ECS cluster named `cicd-ecs-nonprod`	

Task	Description	Skills required
	• A production Amazon ECS cluster named `cicd-ecs-prod`	
Monitor the AWS CloudFormation stack.	1. Sign in to the AWS Management Console, open the AWS CloudFormation console, and then choose the `cicd-vpc-ecs` stack from the list. 2. In the stack details pane, choose the **Events** tab and monitor the progress of your stack creation.	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
Test the AWS CloudFormation stack.	1. After the `cicd-vpc-ecs` AWS CloudFormation stack is created, ensure that the `cicd-vpc-ecs/cicd-vpc-nonprod` and `cicd-vpc-ecs/cicd-vpc-prod` VPCs are created. 2. Ensure that the `cicd-ecs-nonprod` and `cicd-ecs-prod` Amazon ECS clusters are created. **Important** Make sure that you record the IDs for the two VPCs and the security group IDs for the default security groups in both VPCs.	AWS DevOps, Cloud infrastructure

Create a CI/CD pipeline for a microservice

Task	Description	Skills required
Create the infrastructure for the microservice.	1. Name your microservice. For example, this pattern uses `myservice1` as the microservice's name. 2. In your working directory run the `cd <working-`	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
	directory>/cdkpipeline command. 3. Run the `pip3 install -r requirements.txt` command. 4. Run the full `cdk synth` command that is available in the *Additional information* section of this pattern. 5. Run the full `cdk deploy` command that is available in the *Additional information* section of this pattern. **Note** You can also provide the values for both commands by using the `cdk.json` file in the directory.	
Monitor the AWS CloudFormation stack.	Open the AWS CloudFormation console and monitor the progress of the `myservice1-cicd-stack` stack. Eventually, the status changes to `CREATE_COMPLETE`.	AWS DevOps, Cloud infrastructure

Task	Description	Skills required
Test the AWS CloudFormation stack.	1. On the AWS CodeCommit console, verify that a repository named `myservice1` exists and contains the starter code. 2. On the AWS CodeBuild console, verify that a build project named `myservice1` exists. 3. On the Amazon ECR console, verify that an Amazon ECR repository named `myservice1` exists. 4. On the Amazon ECS console, verify that a Fargate service named `myservice1` exists in both a non-production and production Amazon ECS cluster. 5. On the Amazon Elastic Compute Cloud (Amazon EC2) console, verify that the non-production and production Application Load Balancers are created. Record the DNS names of the ALBs. 6. On the AWS CodePipeline console, verify that a pipeline named `myservice1` exists. It	

Task	Description	Skills required
	must have `Source`, `Build`, `Deploy-NonProd`, and `Deploy-Prod` stages. The pipeline should also have an `in progress` status. 7. Monitor the pipeline until all stages are complete. 8. Manually approve it for production. 9. In a browser window, enter the DNS names of the ALBs. 10. The application should display `Hello World` in the non-production and production URLs.	

Task	Description	Skills required
Use the pipeline.	1. Open the CodeCommit repository that you created earlier and open the `index.js` file. 2. Replace `Hello World` with `Hello CI/CD`. 3. Save and commit the changes to the main branch. 4. Verify that the pipeline initiates and that the change goes through the `Build`, `Deploy-NonProd` , and `Deploy-Prod` stages. 5. Manually approve the production. 6. Both production and non-production URLs should now display `Hello CICD`.	AWS DevOps, Cloud infrastructure
Repeat this epic for each microservice.	Repeat the tasks in this epic to create a CI/CD pipeline for each of your microservices.	AWS DevOps, Cloud infrastructure

Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9

Alexandre Nardi, Amazon Web Services

Summary

Notice: AWS Cloud9 is no longer available to new customers. Existing customers of AWS Cloud9 can continue to use the service as normal. Learn more

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern demonstrates how to develop a typical web application in a serverless architecture, for developers and development leads who are beginning to test DevOps practices on Amazon Web Services (AWS). It builds a sample application that creates a storefront and backend for browsing and purchasing books, and provides a microservice that can be developed independently. The pattern uses AWS Cloud9 as a development environment, an Amazon DynamoDB database as a data store, and AWS services such as AWS CodePipeline and AWS CodeBuild for continuous integration and continuous deployment (CI/CD) functionality.

The pattern guides you through the following development activities:

- Creating a standard AWS Cloud9 development environment
- Using AWS CloudFormation templates to create a web application and a microservice for books
- Using AWS Cloud9 to modify the front-end, commit changes, and test changes
- Creating and testing a CI/CD pipeline to the microservice
- Automating unit tests

The code for this pattern is provided in GitHub, in the AWS DevOps End-to-End Workshop repository.

Prerequisites and limitations

Prerequisites

- An active AWS account

- Files from the AWS DevOps End-to-End Workshop downloaded to your computer

> **Important**
>
> Building this demo application in your AWS account creates and consumes AWS resources. You are responsible for the cost of the AWS services and resources used to create and run the application. After you finish your work, be sure to remove all resources to avoid ongoing charges. For cleanup instructions, see the *Epics* section.

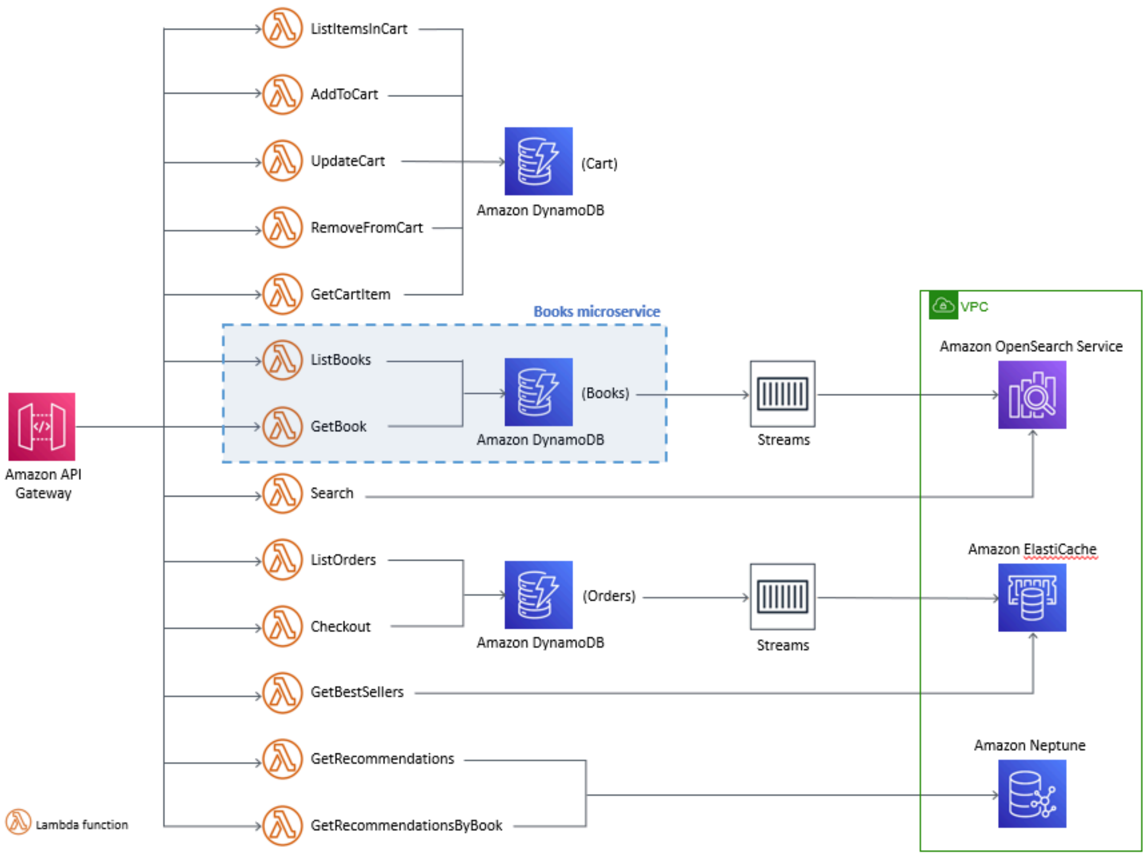
Limitations

This walkthrough is intended for demonstration and development purposes only. To use it in a production environment, see Security best practices in the AWS Identity and Access Management (IAM) documentation, and make the necessary changes to IAM roles, Amazon DynamoDB, and other services used. The web application is derived from the AWS Bookstore Demo App; for additional considerations, see the Known limitations section of the README file.

Architecture

The architecture of the bookstore application is illustrated in the Architecture section of the README file for the AWS Bookstore Demo App.

From a deployment perspective, the Bookstore Demo App uses a single CloudFormation template to deploy all services and objects in one stack. This pattern makes a few changes to demonstrate how a particular developer or team could work in a specific product (Books), and update it independently from the rest of the application. For this reason, the code for this pattern separates the AWS Lambda functions and related objects for the Books microservice into a second CloudFormation template, which creates a Books stack. That makes it possible to see the microservice being updated by using CI/CD practices. In the following diagram, the dashed border identifies the Books microservice.



Tools

Tools

- Jest framework for JavaScript testing
- Python 3.9

Code

The source code and templates for this pattern are available on GitHub, in the AWS DevOps End-to-End Workshop repository. Before you follow the steps in the *Epics* section, download all the files from the repository to your computer.

> **Note**
>
> The *Epics* section provides the high-level steps for this walkthrough, to give you general information about the process. To complete each step, see the README file in the AWS DevOps End-to-End Workshop repository for detailed instructions.

The AWS DevOps End-to-End Workshop repository extends the AWS Bookstore Demo App repository and uses a modified version of the AWS Cloud9 Bootstrapping code to create the AWS Cloud9 IDE.

Best practices

Using the Bookstore application is straightforward. Here are some recommended best practices:

- When you install the application, you can use a project name of your choice or use the default name (`demobookstore`) for convenience.
- After you have the application up and running, it's a good practice to shut down the Amazon Neptune database if you want to keep testing for another day, because the database instance could result in additional charges. However, be aware that the database will automatically be started after seven days.
- For code details, see the documentation for the AWS Bookstore Demo App repository. It describes each microservice and table.
- For additional best practices, see the *Some challenges if you have time...* section of the README file in the AWS DevOps End-to-End Workshop repository. We recommend that you review the information to dive deep into additional features for security and to practice decoupling services.

Epics

Download the source code

Task	Description	Skills required
Download the source code from GitHub.	The source code and templates for this pattern are available in GitHub, in the AWS DevOps End-to-End Workshop repository. Before you follow the next steps in the *Epics* section, download all the files from the repository to your computer.	App developer

Task	Description	Skills required
	Note The *Epics* section provides the high-level steps for this walkthrough, to give you general information about the process. To complete each step, see the README file in the AWS DevOps End-to-End Workshop repository for detailed instructions. The AWS DevOps End-to-End Workshop repository extends the AWS Bookstore Demo App repository and uses a modified version of the AWS Cloud9 Bootstrapping code to create the AWS Cloud9 IDE.	

Build the Bookstore web application and the Books microservice

Task	Description	Skills required
Create the front-end and Lambda functions for the Bookstore app.	1. Log in to the CloudFormation console, and deploy the `DemoBookstoreMainTemplate.yml` template to create	Developer

Task	Description	Skills required
	the DemoBookStoreStack stack. This creates the front-end and Lambda functions that are outside the Books microservice. 2. In the **Outputs** tab of the stack, note the website URL under the **WebApplication** label.	
Create the Books microservice.	On the [CloudFormation console](https://console.aws.amazon.com/cloudformation/), deploy the `DemoBookstoreBooksServiceTemplate.yml` template to create the DemoBooksServiceStack stack.	Developer
Test your application.	Use the website URL from the DemoBookStoreStack stack to access the Bookstore application.	Developer

Use the Cloud9 environment to maintain your application

Task	Description	Skills required
Create an AWS Cloud9 IDE.	On the [CloudFormation console](https://console.aws.amazon.com/cloudformation/), deploy the `C9EnvironmentTemplate.yml` template to create an AWS Cloud9 environment.	Developer, Developer lead
Create CodeCommit repositories.	1. Log in to the [AWS CodeCommit console](https://console.aws.amazon.com/codecommit/),	Developer

Task	Description	Skills required
	and verify that you have a `demobookstore-WebAssets` repository, which contains the code for the front-end application. 2. Create a repository for the Books microservice called `demobookstore-BooksService` . 3. Clone the two repositories in AWS Cloud9 (`demobookstore-WebAssets` and `demobookstore-BooksService`) by using the `git clone` command.	
Change the code in the frontend and check the pipeline.	1. Use AWS Cloud9 to make some code changes on a webpage. This will update the `demobookstore-WebAssets` repository. 2. On the [AWS CodePipeline console](https://console.aws.amazon.com/codepipeline/), verify that **demobookstore-Assets-Pipeline** is running. 3. Test your web application by refreshing it from the browser (**Ctrl+F5** on Firefox).	Developer

Implement a CI/CD pipeline for the Books microservice

Task	Description	Skills required
Add the YAML files for the build and service update.	1. In AWS Cloud9, upload the `buildspec.yml` and `DemoBookstoreBooksServiceUpdateTemplate.yml` files. • `buildspec.yml` has building instructions, and also includes testing instructions for automated tests. They are commented at this point, and will be used later. • `DemoBookstoreBooksServiceUpdateTemplate.yml` is an updated version of `DemoBookstoreBooksServiceTemplate.yml` , to be used in the deployment stage of the pipeline. 2. Commit and push the files.	Developer
Create an S3 bucket for the build pipeline.	To create an S3 bucket, follow the instructions in the [Amazon S3 documentation](). • The bucket name must be globally unique; for example, `demobookstore-books-service`	Developer

Task	Description	Skills required
	`-pipeline-bucket-<YYYYMMDDHHMM>` . • Clear the **Block all public access** check box, and select the **I acknowledge...** check box.	
Use IAM to create a role for CloudFormation deployment.	Create a `demobookstore-CloudFormation-role` role and attach the `AdministratorAccess` policy. In the next epic, you can reconfigure this role for minimum permissions.	Developer
Create a new pipeline to automate building and deploying the Books microservice.	Create a pipeline (for example, **demobookstore-BooksService-Pipeline**) with Commit, Build, and Deploy stages, as described in the README file.	Developer
Test your microservice in AWS Cloud9.	Make a change in the **ListBooks** function and see the pipeline working.	Developer
Automate the unit test for the ListBooks Lambda function.	In the AWS Cloud9 IDE, enable the build to run unit tests, and check the test results. For instructions, see the README file.	Developer

(Optional) Implement additional functionality

Task	Description	Skills required
Make your solution secure.	Configure `demobookstore-CloudFormation-role` to have minimum permissions, and check other used roles as well.	Developer
Eliminate dependencies in the CloudFormation templates.	The method for exchanging information between the `DemoBookstoreMainTemplate.yml` template and the `DemoBookstoreBooksServiceTemplate.yml` template is based on outputs and imports. Passing values between these two templates adds dependencies. To eliminate the dependencies, consider using [AWS Systems Manager Parameter Store]().	Developer
Create a Cart microservice.	Use the Books microservice as an example for taking shopping cart-related functions out of the `DemoBookstoreMainTemplate.yml` template and creating a Cart microservice.	Developer

Clean up

Task	Description	Skills required
Delete the S3 buckets.	On the Amazon S3 console, delete the following buckets that are associated with the sample web application: • Two buckets created for the AWS Bookstore Demo App. The buckets names start with the stack name you provided for AWS CloudFormation when you created the frontend; for example, **DemoBookStoreStack**. • One bucket for the build pipeline; for example, **demobookstore-books-service-pipeline-bucket-<YYYYMMDDHHMM>**.	Developer
Delete the stacks.	On the CloudFormation console, delete the stacks associated with the sample web applicaton: • DemoBooksServiceStack • DemoBookStoreStack The removal could take more than 90 minutes. If the removal fails, delete them again, and also delete any manual resources (for	Developer

Task	Description	Skills required
	example, the VPC or network interfaces) based on notificat ions.	
Delete the IAM roles.	On the IAM console, delete the following roles: • `demobookstore-Clou dformation-role` • `demobookstore-Book sService-BuildProj ect-service-role` For step-by-step instructions, see the IAM documentation.	Developer

- Creating a bucket (Amazon S3 documentation)

Additional information

For detailed, step-by-step instructions, see the README file in the AWS DevOps End-to-End Workshop GitHub repository.

About the May 2023 update: This pattern was updated to use newer versions of Node and Python. We updated many of the packages in the source code and removed Glyphicon because it's no longer free. We also removed all dependencies on the AWS Bookstore Demo App repository, so the two repositories can now evolve independently.

Build and push Docker images to Amazon ECR using GitHub Actions and Terraform

Ruchika Modi, Amazon Web Services

Summary

This pattern explains how you can create reusable GitHub workflows to build your Dockerfile and push the resulting image to Amazon Elastic Container Registry (Amazon ECR). The pattern automates the build process of your Dockerfiles by using Terraform and GitHub Actions. This minimizes the possibility of human error and substantially reduces deployment time.

A GitHub push action to the main branch of your GitHub repository initiates the deployment of resources. The workflow creates a unique Amazon ECR repository based on the combination of the GitHub organization and repository name. It then pushes the Dockerfile image to the Amazon ECR repository.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An active GitHub account.
- A [GitHub repository](https://docs.github.com/en/repositories/creating-and-managing-repositories/creating-a-new-repository).
- Terraform version 1 or later [installed and configured](https://developer.hashicorp.com/terraform/tutorials/aws-get-started/install-cli).
- An Amazon Simple Storage Service (Amazon S3) bucket for the [Terraform backend](https://developer.hashicorp.com/terraform/language/settings/backends/configuration).
- An [Amazon DynamoDB](https://aws.amazon.com/dynamodb/) table for Terraform state locking and consistency. The table must have a partition key named `LockID` with a type of `String`. If this isn't configured, state locking will be disabled.
- An AWS Identity and Access Management (IAM) role that has permissions to set up the Amazon S3 backend for Terraform. For configuration instructions, see the [Terraform documentation](https://developer.hashicorp.com/terraform/language/settings/backends/s3#assume-role-configuration).

Limitations

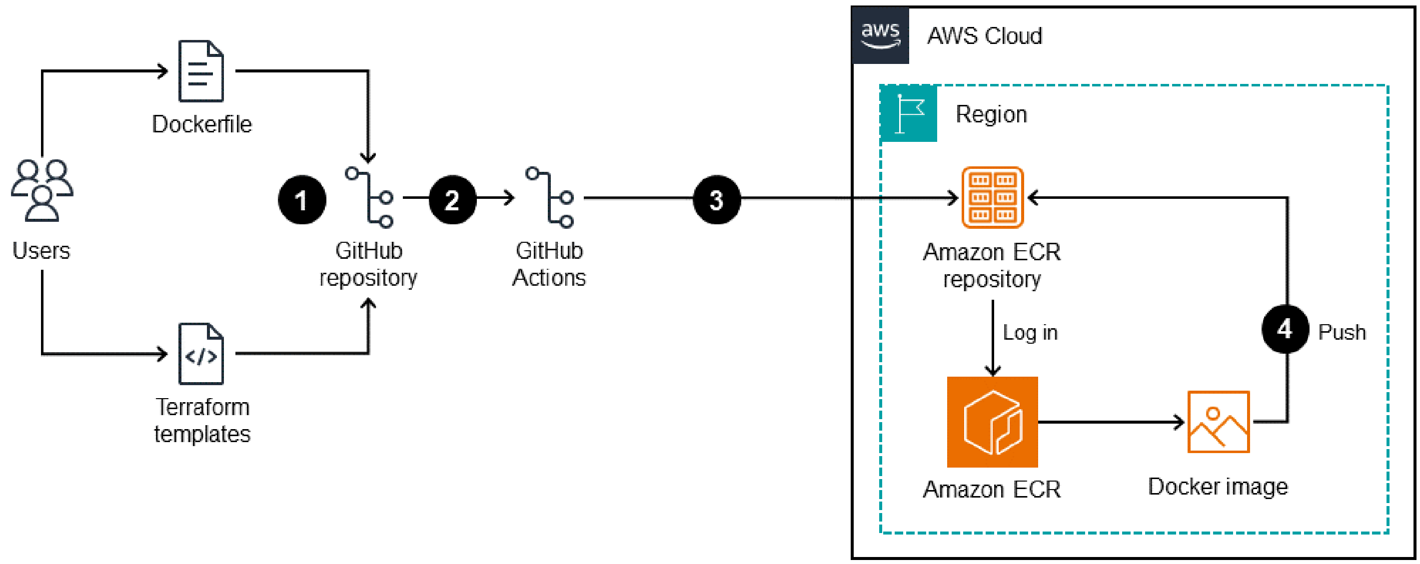
This reusable code has been tested only with GitHub Actions.

Architecture

Target technology stack

- Amazon ECR repository
- GitHub Actions
- Terraform

Target architecture



The diagram illustrates the following:

1. A user adds a Dockerfile and Terraform templates to the GitHub repository.

2. These additions initiate a GitHub Actions workflow.

3. The workflow checks whether an Amazon ECR repository exists. If not, it creates the repository based on the GitHub organization and repository name.

4. The workflow builds the Dockerfile and pushes the image to the Amazon ECR repository.

Tools

Amazon services

- Amazon Elastic Container Registry (Amazon ECR) is a managed container registry service that's secure, scalable, and reliable.

Other tools

- GitHub Actions is integrated into the GitHub platform to help you create, share, and run workflows within your GitHub repositories. You can use GitHub Actions to automate tasks such as building, testing, and deploying your code.
- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises infrastructure.

Code repository

The code for this pattern is available in the GitHub Docker ECR Actions Workflow repository.

- When you create GitHub Actions, Docker workflow files are saved in the `/.github/workflows/` folder of this repository. The workflow for this solution is in the workflow.yaml file.
- The `e2e-test` folder provides a sample Dockerfile for reference and testing.

Best practices

- For best practices for writing Dockerfiles, see the Docker documentation.
- Use a VPC endpoint for Amazon ECR. VPC endpoints are powered by AWS PrivateLink, a technology that enables you to privately access Amazon ECR APIs through private IP addresses. For Amazon ECS tasks that use the Fargate launch type, the VPC endpoint enables the task to pull private images from Amazon ECR without assigning a public IP address to the task.

Epics

Set up the OIDC provider and GitHub repository

Task	Description	Skills required
Configure OpenID Connect.	Create an OpenID Connect (OIDC) provider. You will use the provider in the trust policy for the IAM role used in this action. For instructi ons, see Configuring OpenID	AWS administrator, AWS DevOps, General AWS

Task	Description	Skills required
	Connect in Amazon Web Services in the GitHub documentation.	
Clone the GitHub repository.	Clone the GitHub Docker ECR Actions Workflow repository into your local folder: `$git clone https://github.com/aws-samples/docker-ecr-actions-workflow`	DevOps engineer

Customize the GitHub reusable workflow and deploy the Docker image

Task	Description	Skills required
Customize the event that initiates the Docker workflow.	The workflow for this solution is in workflow.yaml. This script is currently configured to deploy resources when it receives the `workflow_dispatch` event. You can customize this configuration by changing the event to `workflow_call` and calling the workflow from another parent workflow.	DevOps engineer
Customize the workflow.	The workflow.yaml file is configured to create a dynamic, reusable GitHub workflow. You can edit this file to customize the default configuration, or you can	DevOps engineer

Task	Description	Skills required

	pass the input values from the GitHub Actions console if you're using the `workflow_dispatch` event to initiate deployment manually.
	
	• Make sure to specify the correct AWS account ID and target Region.
	• Create an Amazon ECR lifecycle policy (see [sample policy](#)) and update the default path (`e2e-test/policy.json`) accordingly.
	• The workflow file requires two IAM roles as input:
	  • An IAM role that has permissions to set up the Amazon S3 backend for Terraform (see the [Prerequisites](#) section). You can update the default role name `workload-assumable-role` in the `.yaml` file accordingly.
	  • An IAM role that has permissions to access GitHub. This role is also used in the Amazon ECR policy to restrict Amazon ECR operations. For more	

Task	Description	Skills required
	information, see the data.tf file.	
Deploy the Terraform templates.	The workflow automatically deploys the Terraform templates that create the Amazon ECR repository, based on the GitHub event you configured. These templates are available as `.tf` files at the root of the Github repository.	AWS DevOps, DevOps engineer

Troubleshooting

Issue	Solution
Issues or errors when you configure Amazon S3 and DynamoDB as the Terraform remote backend.	Follow the instructions in the Terraform documentation to set up the required permissions on the Amazon S3 and DynamoDB resources for the remote backend configuration.
Unable to run or start the workflow with the `workflow_dispatch` event.	The workflow that's configured to deploy from the `workflow_dispatch` event will work only if the workflow is configured on the main branch as well.

Build and test iOS apps with AWS CodeCommit, AWS CodePipeline, and AWS Device Farm

Abdullahi Olaoye, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern outlines the steps for creating a continuous integration and continuous delivery (CI/CD) pipeline that uses AWS CodePipeline to build and test iOS applications on real devices on AWS. The pattern uses AWS CodeCommit to store the application code, the Jenkins open-source tool to build the iOS application, and AWS Device Farm to test the built application on real devices. These three phases are orchestrated together in a pipeline by using AWS CodePipeline.

This pattern is based on the post Building and testing iOS and iPadOS apps with AWS DevOps and mobile services on the AWS DevOps blog. For detailed instructions, see the blog post.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Apple developer account
- Build server (macOS)
- Xcode version 11.3 (installed and set up on the build server)
- AWS Command Line Interface (AWS CLI) installed and configured on the workstation
- Basic knowledge of Git

Limitations

- The application build server must be running macOS.
- The build server must have a public IP address, so CodePipeline can connect to it remotely to initiate builds.

Architecture

Source technology stack

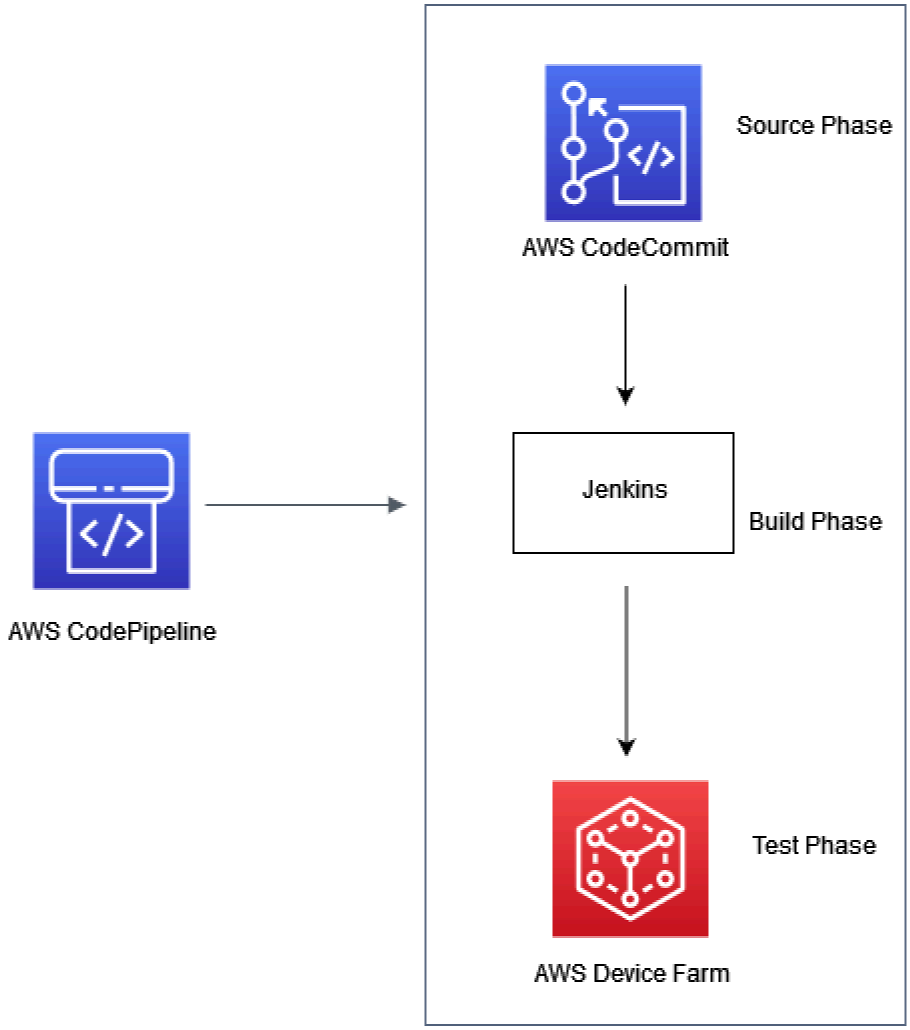
- An on-premises iOS application build process that involves using a simulator or manual test on physical devices

Target technology stack

- An AWS CodeCommit repository for storing application source code
- A Jenkins server for application builds using Xcode
- An AWS Device Farm device pool for testing applications on real devices

Target architecture

When a user commits changes to the source repository, the pipeline (AWS CodePipeline) fetches the code from the source repository, initiates a Jenkins build, and passes the application code to Jenkins. After the build, the pipeline retrieves the build artifact and starts an AWS Device Farm job to test the application against a device pool.



Tools

- [AWS CodePipeline] is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deploy phases of your release process every time there is a code change, based on the release model you define.
- [AWS CodeCommit] is a fully managed source control service that hosts secure Git-based repositories. It makes it easy for teams to collaborate on code in a secure and highly scalable ecosystem. CodeCommit eliminates the need to operate your own source control system or worry about scaling its infrastructure.
- [AWS Device Farm] is an application testing service that lets you improve the quality of your web and mobile apps by testing them across an extensive range of desktop browsers and real mobile devices, without having to provision and manage any testing infrastructure.

- Jenkins is an open-source automation server that enables developers to build, test, and deploy their software.

Epics

Set up the build environment

Task	Description	Skills required
Install Jenkins on the build server that's running macOS.	Jenkins will be used for building the application, so you must first install it on the build server. To get detailed instructions for this and subsequent tasks, see the AWS blog post Building and testing iOS and iPadOS apps with AWS DevOps and mobile services and other resources in the Related resources section at the end of this pattern.	DevOps
Configure Jenkins.	Follow the on-screen instructions to configure Jenkins.	DevOps
Install the AWS CodePipeline plugin for Jenkins.	This plugin must be installed on the Jenkins server in order for Jenkins to interact with the AWS CodePipeline service.	DevOps
Create a Jenkins freestyle project.	In Jenkins, create a freestyle project. Configure the project to specify triggers and other build configuration options.	DevOps

Configure AWS Device Farm

Task	Description	Skills required
Create a Device Farm project.	Open the AWS Device Farm console. Create a project and a device pool for testing. For instructions, see the blog post.	Developer

Configure the source repository

Task	Description	Skills required
Create a CodeCommit repository.	Create a repository where the source code will be stored.	DevOps
Commit your application code to the repository.	Connect to the CodeCommit repository you created. Push the code from your local machine to the repository.	DevOps

Configure the pipeline

Task	Description	Skills required
Create a pipeline in AWS CodePipeline.	Open the AWS CodePipeline console, and create a pipeline. The pipeline orchestrates all the phases of the CI/CD process. For instructions, see the AWS blog post [Building and testing iOS and iPadOS apps with AWS DevOps and mobile services]().	DevOps

Task	Description	Skills required
Add a test stage to the pipeline.	To add a test stage and integrate it with AWS Device Farm, edit the pipeline.	DevOps
Initiate the pipeline.	To start the pipeline and the CI/CD process, choose **Release change**.	DevOps

View application test results

Task	Description	Skills required
Review test results.	In the AWS Device Farm console, select the project you created, and review the results of the tests. The console will show the details of each test.	Developer

Check AWS CDK applications or CloudFormation templates for best practices by using cdk-nag rule packs

Arun Donti, Amazon Web Services

Summary

This pattern explains how you can use the cdk-nag utility to check AWS Cloud Development Kit (AWS CDK) applications for best practices by using a combination of rule packs. **cdk-nag** is an open-source project that was inspired by cfn_nag. It implements rules in evaluation packs such as AWS Solutions Library, Health Insurance Portability and Accountability Act (HIPAA), and National Institute of Standards and Technology (NIST) 800-53 by using AWS CDK Aspects. You can check your AWS CDK applications for best practices by using the rules in these packs, detect and remediate code based on best practices, and suppress the rules that you don't want to use in your evaluations.

You can also use **cdk-nag** to check your AWS CloudFormation templates by using the cloudformation-include module.

For information about all available packs, see the Rules section of the cdk-nag repository. Evaluation packs are available for:

- AWS Solutions Library
- HIPAA security
- NIST 800-53 rev 4
- NIST 800-53 rev 5
- Payment Card Industry Data Security Standard (PCI DSS) 3.2.1

Prerequisites and limitations

Prerequisites

- An application that uses the AWS CDK

Tools

- AWS CDK – Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and you can launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

Epics

Integrate cdk-nag with your AWS CDK application

Task	Description	Skills required
Learn about cdk-nag.	Navigate to the cdk-nag GitHub repository and read through the documentation.	App developer
Install the cdk-nag package in your AWS CDK application.	To use **cdk-nag** in your AWS CDK application, you must install it first. **cdk-nag** is available to download from PyPI, npm, NuGet, and Apache Maven. For the latest information about available versions and download locations, see the Readme file in the repository.	App developer
Choose your NagPacks.	**cdk-nag** has different packs of rules called *NagPacks*. Each NagPack contains rules that conform to a specific standard. For example, the AWS Solutions NagPack	App developer

Task	Description	Skills required
	contains general best practices, and the NIST 800-53 rev 5 NagPack can help with compliance. You can apply multiple NagPacks to your application, and you can add and remove packs as necessary. For a list of available packs, see the Readme file in the GitHub repository. For informati on about the individual rules in each pack, see the Rules section of the GitHub repository.	

Task	Description	Skills required

Integrate cdk-nag into your AWS CDK application.	You can integrate **cdk-nag** into your application on an applicationwide level, or integrate it into individual stages or stacks in your application. For example, to integrate the AWS Solutions and HIPAA security NagPacks into an AWS CDK v2 TypeScript application on an applicationwide level, you can use the following code:
	`import { App, Aspects } from 'aws-cdk-lib';`
	`import { CdkTestStack } from '../lib/cdk-test-stack';`
	`import { AwsSolutionsChecks, HIPAASecurityChecks } from 'cdk-nag';`
	
	`const app = new App();`
	`new CdkTestStack(app, 'CdkNagDemo');`
	`// Simple rule informational messages`
	`Aspects.of(app).add(new AwsSolutionsChecks());`
	`// Additional explanations on the purpose of triggered rules`
	`Aspects.of(app).add(new HIPAASecurityChecks({ verbose: true }));`
		App developer

Configure mutual TLS authentication for applications running on Amazon EKS

Mahendra Siddappa, Amazon Web Services

Summary

Certificate-based mutual Transport Layer Security (TLS) is an optional TLS component that provides two-way peer authentication between servers and clients. With mutual TLS, clients must provide an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client.

Mutual TLS is a common requirement for Internet of Things (IoT) applications and can be used for business-to-business applications or standards such as Open Banking.

This pattern describes how to configure mutual TLS for applications running on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster by using an NGINX ingress controller. You can enable built-in mutual TLS features for the NGINX ingress controller by annotating the ingress resource. For more information about mutual TLS annotations on NGINX controllers, see Client certificate authentication in the Kubernetes documentation.

Important

This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments. If you want to use this pattern in a production environment, you can use AWS Private Certificate Authority (AWS Private CA) or your existing public key infrastructure (PKI) standard to issue private certificates.

Prerequisites and limitations

Prerequisites

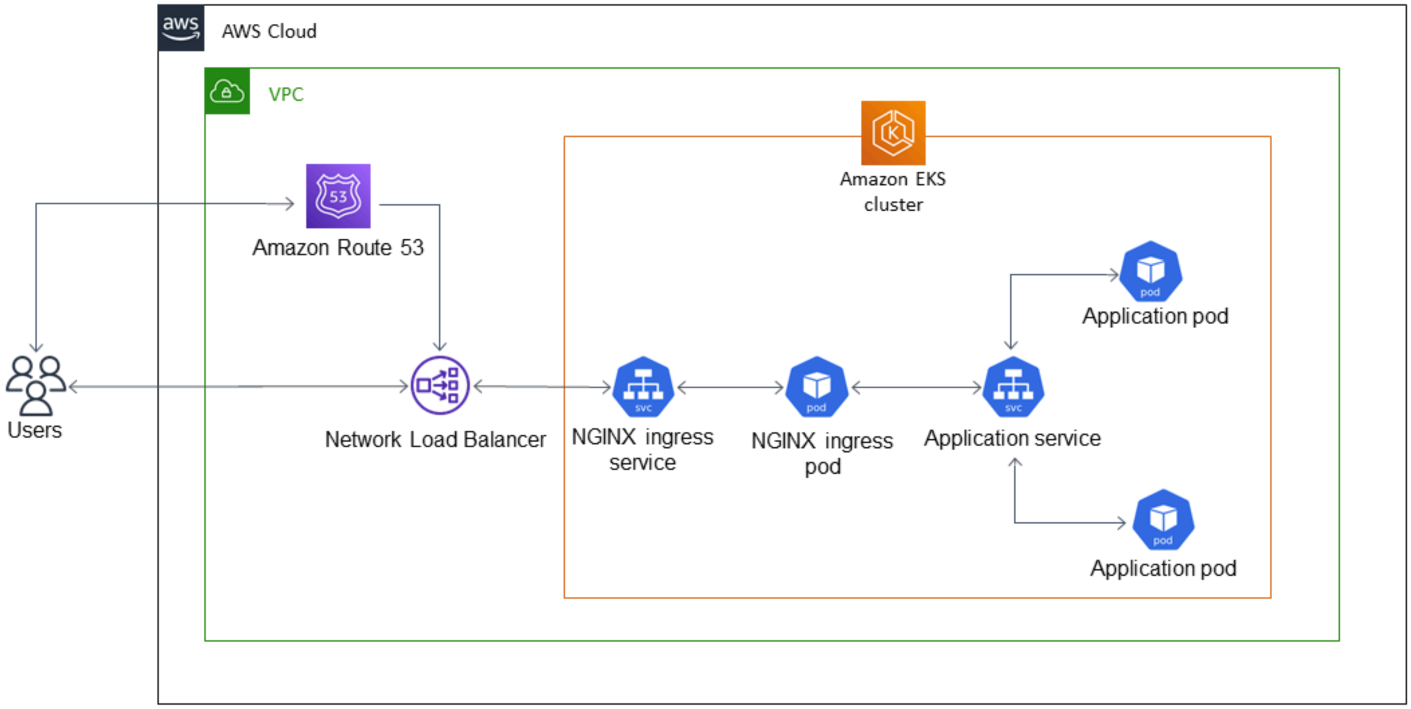
- An active Amazon Web Services (AWS) account.
- An existing Amazon EKS cluster.
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
- The kubectl command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see Installing kubectl in the Amazon EKS documentation.

- An existing Domain Name System (DNS) name to test the application.

Limitations

- This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments.

Architecture



Technology stack

- Amazon EKS
- Amazon Route 53
- Kubectl

Tools

- [Amazon Elastic Kubernetes Service (Amazon EKS)](#) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- [Amazon Route 53](#) is a highly available and scalable DNS web service.

- Kubectl is a command line utility that you use to interact with an Amazon EKS cluster.

Epics

Generate the self-signed certificates

Task	Description	Skills required
Generate the CA key and certificate.	Generate the certificate authority (CA) key and certificate by running the following command. `openssl req -x509 -sha256 -newkey rsa:4096 -keyout ca.key -out ca.crt -days 356 -nodes -subj '/CN=Test Cert Authority'`	DevOps engineer
Generate the server key and certificate, and sign with the CA certificate.	Generate the server key and certificate, and sign with the CA certificate by running the following command. `openssl req -new -newkey rsa:4096 -keyout server.key -out server.csr -nodes -subj '/CN= <your_domain_name> ' && openssl x509 -req -sha256 -days 365 -in server.csr -CA ca.crt -CAkey ca.key -set_serial 01 -out server.crt`	DevOps engineer

Task	Description	Skills required
	Important Make sure sure that you replace `<your_domain_name>` with your existing domain name.	
Generate the client key and certificate, and sign with the CA certificate.	Generate the client key and certificate, and sign with the CA certificate by running the following command. `openssl req -new -newkey rsa:4096 -keyout client.key -out client.csr -nodes -subj '/CN=Test' && openssl x509 -req -sha256 -days 365 -in client.csr -CA ca.crt -CAkey ca.key -set_serial 02 -out client.crt`	DevOps engineer

Deploy the NGINX ingress controller

Task	Description	Skills required
Deploy the NGINX ingress controller in your Amazon EKS cluster.	Deploy the NGINX ingress controller by using the following command. `kubectl apply -f https://raw.githubusercontent.com/ku`	DevOps engineer

Task	Description	Skills required
	`bernetes/ingress-nginx/controller-v1.7.0/deploy/static/provider/aws/deploy.yaml`	
Verify that the NGINX ingress controller service is running.	Verify that the NGINX ingress controller service is running by using the following command. `kubectl get svc -n ingress-nginx` **Important** Make sure that the field of service address contains the Network Load Balancer's domain name.	DevOps engineer

Create a namespace in the Amazon EKS cluster to test mutual TLS

Task	Description	Skills required
Create a namespace in the Amazon EKS cluster.	Create a namespace called `mtls` in your Amazon EKS cluster by running the following command. `kubectl create ns mtls`	DevOps engineer

Task	Description	Skills required
	This deploys the sample application to test mutual TLS.	

Create the deployment and service for the sample application

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create the Kubernetes deployment and service in the mtls namespace.</td><td>Create a file named <code>mtls.yaml</code> . Paste the following code into the file.
<pre><code>kind: Deployment
apiVersion: apps/v1
metadata:
  name: mtls-app
  labels:
    app: mtls
spec:
  replicas: 1
  selector:
    matchLabels:
      app: mtls
  template:
    metadata:
      labels:
        app: mtls
    spec:
      containers:
      - name: mtls-app
        image: hashicorp
/http-echo
        args:
          - "-text=mTLS
 is working"

</code></pre></td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required

	<pre>kind: Service
	apiVersion: v1
	metadata:
	  name: mtls-service
	spec:
	  selector:
	    app: mtls
	  ports:
	    - port: 5678 #
	 Default port for image</pre> Create the Kubernetes deployment and service in the `mtls` namespace by running the following command. <pre>kubectl create -f
	 mtls.yaml -n mtls</pre>	

Verify that the Kubernetes deployment is created.	Run the following command to verify that the deployment is created and has one pod in available status. <pre>kubectl get deploy -n
	 mtls</pre>
		DevOps engineer

Verify that the Kubernetes service is created.	Verify that the Kubernetes service is created by running the following command. <pre>kubectl get service -n
	 mtls</pre>
		DevOps engineer

Create a secret in the mtls namespace

Task	Description	Skills required
Create a secret for the ingress resource.	Run the folllowing command to create a secret for the NGINX ingress controller by using the certificates that you created earlier. `kubectl create secret generic mtls-certs --from-file=tls.crt=server.crt --from-file=tls.key=server.key --from-file=ca.crt=ca.crt -n mtls` Your secret has a server certificate for the client to identify the server and a CA certificate for the server to verify the client certificates.	DevOps engineer

Create the ingress resource in the mtls namespace

Task	Description	Skills required

Create the ingress resource in the mtls namespace.	Create a file named `ingress.yaml` . Paste the following code into the file (replace `<your_domain_name>` with your existing domain name).
	`apiVersion: networking.k8s.io/v1`
	`kind: Ingress`
		DevOps engineer

Task	Description	Skills required

	``
	metadata:
	  annotations:
	    nginx.ingress.kubernetes.io/auth-tls-verify-client: "on"
	    nginx.ingress.kubernetes.io/auth-tls-secret: mtls/mtls-certs
	  name: mtls-ingress
	spec:
	  ingressClassName: nginx
	  rules:
	  - host: "*.<your_domain_name>"
	    http:
	      paths:
	      - path: /
	        pathType: Prefix
	        backend:
	          service:
	            name: mtls-service
	            port:
	              number: 5678
	  tls:
	  - hosts:
	    - "*.<your_domain_name>"
	    secretName: mtls-certs
	``
	Create the ingress resource in the `mtls` namespace by running the following command.
	``
	kubectl create -f ingress.yaml -n mtls
	``	

Task	Description	Skills required
	This means that the NGINX ingress controller can route traffic to your sample application.	
Verify that the ingress resource is created.	Verify that the ingress resource is created by running the following command. `kubectl get ing -n mtls` **Important** Make sure that the address of the ingress resource shows the load balancer created for the NGINX ingress controller.	DevOps engineer

Configure DNS to point the hostname to the load balancer

Task	Description	Skills required
Create CNAME record that points to the load balancer for the NGINX ingress controller.	Sign in to the AWS Management Console, open the Amazon Route 53 console, and create a Canonical Name (CNAME) record that points `mtls.<your_domain_name>` to the load balancer for the NGINX ingress controller.	DevOps engineer

Task	Description	Skills required
	For more information, see [Creating records by using the Route 53 console] in the Route 53 documentation.	

Test the application

Task	Description	Skills required
Test mutual TLS setup without certificates.	Run the following command. `curl -k https://mtls.<your_domain_name>` You should receive the "400 No required SSL certificate was sent" error response.	DevOps engineer
Test mutual TLS setup with certificates.	Run the following command. `curl -k https://mtls.<your_domain_name> --cert client.crt --key client.key` You should receive the "mTLS is working" response.	DevOps engineer

Automate the creation of AppStream 2.0 resources using AWS CloudFormation

Ram Kandaswamy, Amazon Web Services

Summary

This pattern provides code samples and steps to automate the creation of Amazon AppStream 2.0 resources in the Amazon Web Services (AWS) Cloud by using an AWS CloudFormation template. The pattern shows you how to use an AWS CloudFormation stack to automate the creation of your AppStream 2.0 application resources, including an image builder, image, fleet instance, and stack. You can stream your AppStream 2.0 application to end users on an HTML5-compliant browser by using either the desktop or application delivery mode.

Prerequisites and limitations

Prerequisites

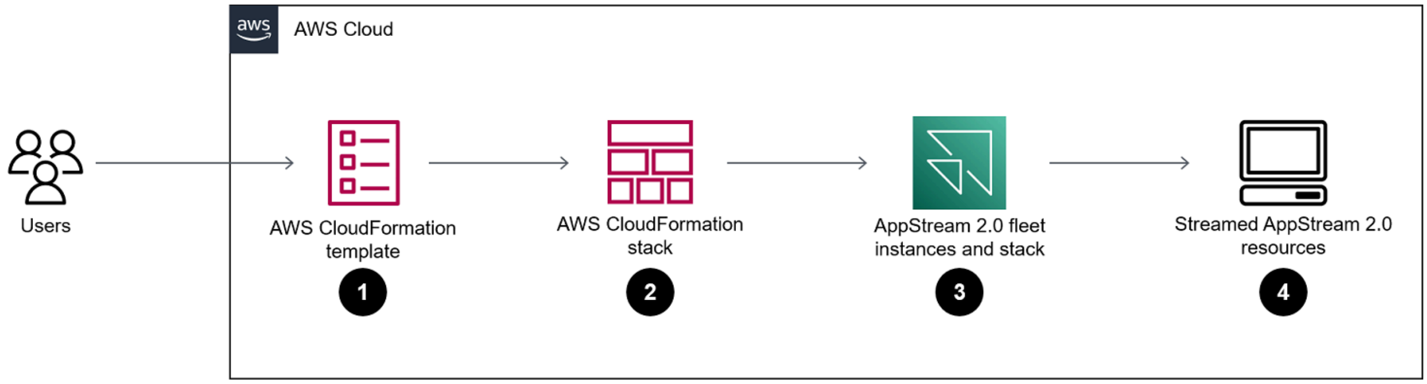
- An active AWS account
- An acceptance of AppStream 2.0 terms and conditions
- Basic knowledge of AppStream resources, such as stacks, fleets, and image builders

Limitations

- You can't modify the AWS Identity and Access Management (IAM) role associated with an AppStream 2.0 instance after that instance is created.
- You can't modify properties (such as the subnet or security group) on the AppStream 2.0 image builder instance after that image builder is created.

Architecture

The following diagram shows you how to automate the creation of AppStream 2.0 resources by using an AWS CloudFormation template.



The diagram shows the following workflow:

1. You create an AWS CloudFormation template based on the YAML code in the *Additional information* section of this pattern.
2. The AWS CloudFormation template creates an AWS CloudFormation test stack.
   a. (Optional) You create an image builder instance by using AppStream 2.0.
   b. (Optional) You create a Windows image by using your custom software.
3. The AWS CloudFormation stack creates an AppStream 2.0 fleet instance and stack.
4. You deploy your AppStream 2.0 resources to end users on an HTML5-compliant browser.

Technology stack

- Amazon AppStream 2.0
- AWS CloudFormation

Tools

- Amazon AppStream 2.0 is a fully managed application streaming service that provides you with instant access to your desktop applications from anywhere. AppStream 2.0 manages the AWS resources required to host and run your applications, scales automatically, and provides access to your users on demand.
- AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

Epics

(Optional) Create an AppStream 2.0 image

Task	Description	Skills required
Install custom software and create an image.	1. Install the AppStream 2.0 application that you plan to deploy to your users. 2. Use the Photon create image agent or a PowerShell script to create a new Windows image for your custom software. **Note** Consider using the Windows AppLocker feature to further lock down the image.	AWS DevOps, Cloud architect

Deploy the AWS CloudFormation template

Task	Description	Skills required
Update the AWS CloudFormation template.	1. Save the code in the *Additional information* section of this pattern as a YAML file. 2. Update the YAML file with the required values for the parameters in your environment.	AWS systems administrator, Cloud administrator, Cloud architect, General AWS, AWS administrator

Task	Description	Skills required
Create an AWS CloudFormation stack using the template.	1. Sign in to the AWS Management Console and open the [AWS CloudFormation console](). 2. On the navigation pane, choose **Stacks**. 3. Choose **Create stack** and then choose **With new resources (standard)**. 4. In the **Prerequisite – Prepare template** section, choose **Template is ready**. 5. In the **Specify template** section, choose **Upload a template file**. 6. Choose **Choose file** and then choose your updated AWS CloudFormation template. 7. Complete the rest of the steps in the wizard to create your stack.	App owner, AWS systems administrator, Windows Engineer

Additional information

The following code is an example of an AWS CloudFormation template that allows you to automatically create AppStream 2.0 resources.

```
AWSTemplateFormatVersion: 2010-09-09
Parameters:
  SubnetIds:
    Type: 'List<AWS::EC2::Subnet::Id>'
  testSecurityGroup:
    Type: 'AWS::EC2::SecurityGroup::Id'
  ImageName:
    Type: String
Resources:

  AppStreamFleet:
    Type: 'AWS::AppStream::Fleet'
    Properties:
      ComputeCapacity:
        DesiredInstances: 5
      InstanceType: stream.standard.medium
      Name: appstream-test-fleet
      DisconnectTimeoutInSeconds: 1200
      FleetType: ON_DEMAND
      IdleDisconnectTimeoutInSeconds: 1200
      ImageName: !Ref ImageName
      MaxUserDurationInSeconds: 345600
      VpcConfig:
        SecurityGroupIds:
          - !Ref testSecurityGroup
        SubnetIds: !Ref SubnetIds
  AppStreamStack:
    Type: 'AWS::AppStream::Stack'
    Properties:
      Description: AppStream stack for test
      DisplayName: AppStream test Stack
      Name: appstream-test-stack
      StorageConnectors:
```

```
        - ConnectorType: HOMEFOLDERS
      UserSettings:
        - Action: CLIPBOARD_COPY_FROM_LOCAL_DEVICE
          Permission: ENABLED
        - Action: CLIPBOARD_COPY_TO_LOCAL_DEVICE
          Permission: ENABLED
        - Action: FILE_DOWNLOAD
          Permission: ENABLED
        - Action: PRINTING_TO_LOCAL_DEVICE
          Permission: ENABLED
  AppStreamFleetAssociation:
    Type: 'AWS::AppStream::StackFleetAssociation'
    Properties:
      FleetName: appstream-test-fleet
      StackName: appstream-test-stack
    DependsOn:
      - AppStreamFleet
      - AppStreamStack
```

Create a custom log parser for Amazon ECS using a Firelens log router

Varun Sharma, Amazon Web Services

Summary

Firelens is a log router for Amazon Elastic Container Service (Amazon ECS) and AWS Fargate. You can use Firelens to route container logs from Amazon ECS to Amazon CloudWatch and other destinations (for example, Splunk or Sumo Logic). Firelens works with Fluentd or Fluent Bit as the logging agent, which means that you can use Amazon ECS task definition parameters to route logs.

By choosing to parse logs at the source level, you can analyze your logging data and perform queries to more efficiently and effectively respond to operational issues. Because different applications have different logging patterns, you need to use a custom parser that structures the logs and makes searching easier at your end destination.

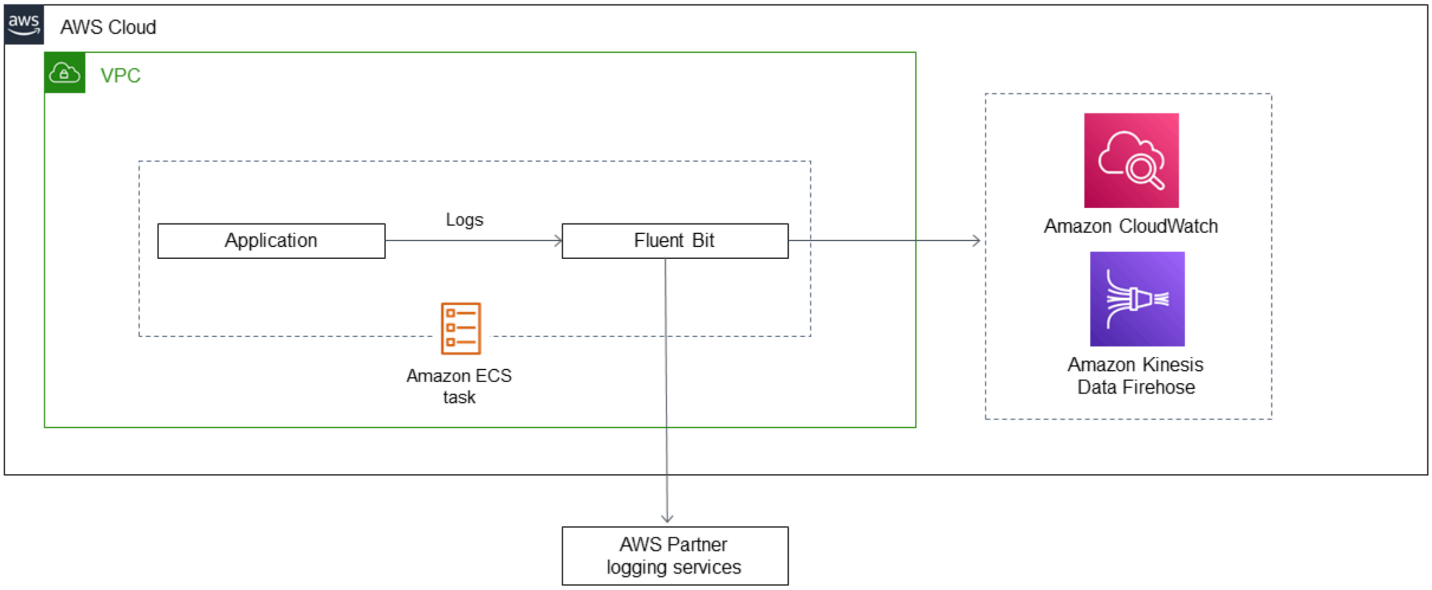
This pattern uses a Firelens log router with a custom parser to push logs to CloudWatch from a sample Spring Boot application running on Amazon ECS. You can then use Amazon CloudWatch Logs Insights to filter the logs based on custom fields that are generated by the custom parser.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
- AWS Command Line Interface (AWS CLI), installed and configured on your local machine.
- Docker, installed and configured on your local machine.
- An existing Spring Boot-based containerized application on Amazon Elastic Container Registry (Amazon ECR).

Architecture



Technology stack

- CloudWatch
- Amazon ECR
- Amazon ECS
- Fargate
- Docker
- Fluent Bit

Tools

- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster.
- AWS Identity and Access Management (IAM) – IAM is a web service for securely controlling access to AWS services.
- AWS CLI – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- Docker – Docker is an open platform for developing, shipping, and running applications.

Code

The following files are attached to this pattern:

- `customFluentBit.zip` – Contains the files to add the custom parsing and configurations.
- `firelens_policy.json` – Contains the policy document to create an IAM policy.
- `Task.json` – Contains a sample task definition for Amazon ECS.

Epics

Create a custom Fluent Bit image

Task	Description	Skills required
Create an Amazon ECR repository.	Sign in to the AWS Management Console, open the Amazon ECR console, and create a repository called `fluentbit_custom` . For more information about this, see [Creating a repository](#) in the Amazon ECR documentation.	Systems administrator, Developer
Unzip the customFluentBit.zip package.	1. Download the `customFluentBit.zip` package (attached) to your local machine. 2. Unzip to the `customFluentBit` directory by running the following command: `unzip -d customFluentBit.zip`	

Task	Description	Skills required
	3. The directory contains the following files that are required for adding the custom parsing and configurations: • `parsers/springboot_parser.conf` – Contains the parser directive and defines the regular expression (regex) pattern for the custom parser. You can add the regex pattern for your specific parser. • `conf/parse_springboot.conf` – Contains the filter and the service directive. • The Dockerfile	

Task	Description	Skills required
Create the custom Docker image.	1. Change the directory to `customFluentBit .` 2. Open the Amazon ECR console, choose the `fluentbit_custom` repository, and then choose **View push commands**. 3. Upload your project. 4. After the upload is complete, copy the build's URL. This URL is required when you create a container in Amazon ECS For more information about this, see Pushing a Docker image in the Amazon ECR documentation.	Systems administrator, Developer

Set up the Amazon ECS cluster

Task	Description	Skills required
Create an Amazon ECS cluster.	Create an Amazon ECS cluster by following the instructions from the *Networking only template* section of Creating a cluster in the Amazon ECS documentation.	Systems administrator, Developer

Task	Description	Skills required
	Note Make sure that you choose **Create VPC** to create a new virtual private cloud (VPC) for your Amazon ECS cluster.	

Set up the Amazon ECS task

Task	Description	Skills required
Set up the Amazon ECS task execution IAM role.	Create an Amazon ECS task execution IAM role by using the `AmazonECSTaskExecutionRolePolicy` managed policy. For more information about this, see [Amazon ECS task execution IAM role] in the Amazon ECS documentation. **Note** Make sure that you record the IAM role's Amazon Resource Name (ARN).	Systems administrator, Developer
Attach the IAM policy to the Amazon ECS task execution IAM role.	1. Create an IAM policy by using the `firelens_policy.json` (attached	Systems administrator, Developer

Task	Description	Skills required
	) policy document. For more information about this, see Creating policies on the JSON tab in the IAM documentation. 2. Attach this policy to the Amazon ECS task execution IAM role that you created earlier. For more informati on about this, see Adding IAM policies (AWS CLI) in the IAM documentation.	

Task	Description	Skills required
Set up the Amazon ECS task definition.	1. Update the following sections in the `Task.json` sample task definition (attached): • Update the `executionRoleArn` and `taskRoleArn` with the ARN of the task execution IAM role • Update the image in `containerDefinitions` with the custom Fluent Bit Docker image that you created earlier • Update the image in `containerDefinitions` with your application image's name 2. Open the Amazon ECS console, choose **Task Definitions**, choose **Create new task definition**, and then choose **Fargate** on the **Select compatibilities** page. 3. Choose **Configure via Json**, paste the updated `Task.json` file into the text area, and then choose **Save**. 4. Create the task definition.	Systems administrator, Developer

Task	Description	Skills required
	For more information about this, see Creating a task definition in the Amazon ECS documentation.	

Run the Amazon ECS task

Task	Description	Skills required
Run the Amazon ECS task.	On the Amazon ECS console, choose **Clusters**, choose the cluster that you created earlier, and then run the standalone task. For more information about this, see Run a standalone task in the Amazon ECS documentation.	Systems administrator, Developer

Verify the CloudWatch logs

Task	Description	Skills required
Verify the logs.	1. Open the CloudWatch console, choose **Log groups**, and then choose `/aws/ecs/containerinsights/{{cluster_ARN}}/firelens/application` . 2. Verify the logs, particularly the custom fields added by the custom parser.	Systems administrator, Developer

Task	Description	Skills required
	3. Use CloudWatch to filter logs based on the custom fields.

Create a pipeline and AMI using CodePipeline and HashiCorp Packer

Akash Kumar, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern provides code samples and steps to create both a pipeline in the Amazon Web Services (AWS) Cloud by using AWS CodePipeline and an Amazon Machine Image (AMI) by using HashiCorp Packer. The pattern is based on the continuous integration practice, which automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, create a project and configure your source code by using AWS CodeBuild. Finally, create an AMI that gets committed to your repository.

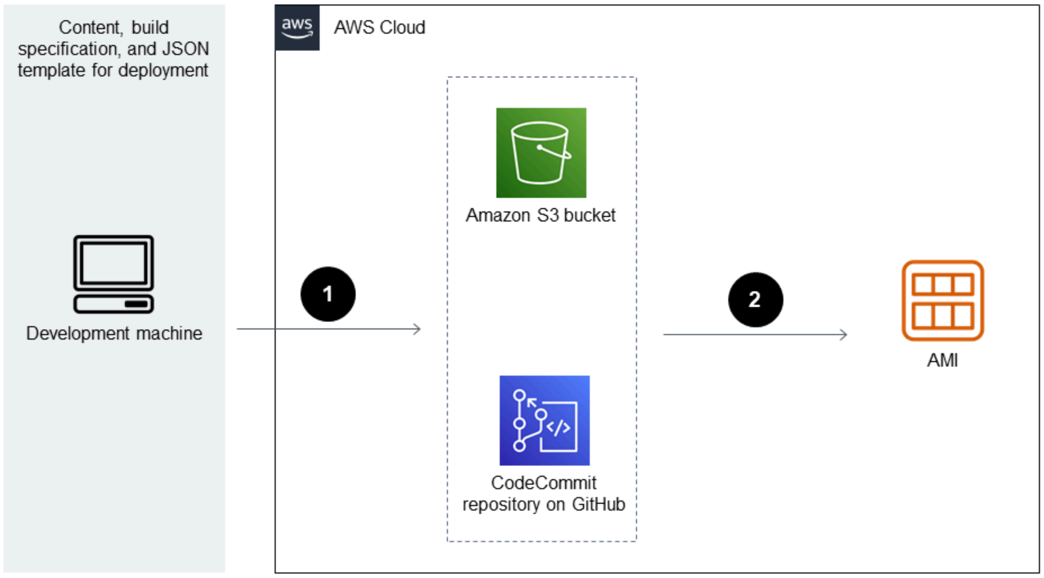
Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Linux AMI for launching Amazon Elastic Compute Cloud (Amazon EC2) instances
- HashiCorp Packer 0.12.3 or later
- Amazon CloudWatch Events (optional)
- Amazon CloudWatch Logs (optional)

Architecture

The following diagram shows an example of application code that automates the creation of an AMI by using this pattern's architecture.



The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository. Then, CodePipeline uses CodeBuild to initiate the build and add new [artifacts](https://docs.aws.amazon.com/codepipeline/latest/userguide/welcome-introducing-artifacts.html) that are ready for deployment to the Amazon Simple Storage Service (Amazon S3) bucket.
2. CodeBuild uses Packer to bundle and package the AMI based on a JSON template. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.

Technology stack

- CodeBuild
- CodeCommit
- CodePipeline
- CloudWatch Events (optional)

Tools

- AWS CodeBuild – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- AWS CodeCommit – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.
- AWS CodePipeline – AWS CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software.
- HashiCorp Packer – HashiCorp Packer is an open-source tool for automating the creation of identical machine images from a single source configuration. Packer is lightweight, runs on every major operating system, and creates machine images for multiple platforms in parallel.

Code

This pattern includes the following attachments:

- `buildspec.yml` – This file uses CodeBuild to build and create an artifact for deployment.
- `amazon-linux_packer-template.json` – This file uses Packer to create an Amazon Linux AMI.

Epics

Set up the code repository

Task	Description	Skills required
Create the repository.	Create a CodeCommit repository.	AWS systems administrator
Clone the repository.	Connect to the CodeCommit repository by cloning the repository.	App developer
Push the source code to the remote repository.	1. Create a commit to add the `buildspec.yml` and `amazon-linux_packe`	App developer

Task	Description	Skills required
	`r-template.json` files to your local repository. 2. [Push the commit](#) from your local repository to the remote CodeCommit repository.	

Create a CodeBuild project for the application

Task	Description	Skills required
Create a build project.	1. Sign in to the AWS Management console, open the [AWS CodeBuild console](#), and then choose **Create build project**. 2. For **Project name**, enter the name of your project. 3. For **Source provider**, choose **AWS CodeCommit**. 4. For **Repository**, choose the repository where you want to build the code pipeline. 5. For **Environment image**, choose **Managed image** or **Custom image**. 6. For **Operating system**, choose **Ubuntu**. 7. For **RunTime(s)**, choose **Standard**. 8. For **Image**, choose **aws/codebuild/standard:4.0**.	App developer, AWS systems administrator

Task	Description	Skills required
	9. For **Image version**, choose **Always use the latest image for this runtime version**. 10. For **Environment**, choose **Linux**. 11. Choose the **Privileged** check box. 12. For **Service role**, choose **New service role** or **Existing service role**. 13. For **Build specifications**, choose **Use a buildspec file** or **Insert build commands**. 14. (Optional) For **Type** in the **Artifacts** section, choose **No artifacts**. 15. (Recommended) To upload build output logs to CloudWatch Logs, choose **CloudWatch logs**. 16. (Optional) To upload build output logs to Amazon S3, choose the **S3 logs** check box. 17. Choose **Create build project**.	

Set up the pipeline

Task	Description	Skills required
Pipeline name	1. Sign in to the AWS Management console, open the [AWS CodePipeline console](), and then choose **Create pipeline**. 2. For **Pipeline name**, enter a name for the pipeline. 3. For **Service role**, choose **New service role** or **Existing service role**. 4. For **Role name**, enter a name for your role. 5. In the **Advanced settings** section, for **Artifact store**, choose **Default location** if you want Amazon S3 to create a bucket and store the artifacts in the bucket. To use an existing S3 bucket, choose **Custom location**. Choose **Next**. 6. For **Source provider**, choose **AWS CodeCommit**. 7. For **Repository name**, choose the repository that you cloned earlier. For **Branch name**, choose your source code branch. 8. For **Change detection options**, choose **Amazon CloudWatch Events**	App developer, AWS systems administrator

Task	Description	Skills required
	(recommended) to start the pipeline or **AWS CodePipeline** to periodically check for changes. Choose **Next**. 9. For **Build provider**, choose **AWS CodeBuild**. 10. For **Project Name**, choose the build project that you created in the *Create a CodeBuild project for the application* epic. 11. Choose your build options and then choose **Next**. 12. Choose **Skip deploy stage**. 13. Choose **Create pipeline**.

Create dynamic CI pipelines for Java and Python projects automatically

Aromal Raj Jayarajan, Vijesh Vijayakumaran Nair, MAHESH RAGHUNANDANAN, and Amarnath Reddy, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. [Learn more]

This pattern shows how to create dynamic continuous integration (CI) pipelines for Java and Python projects automatically by using AWS developer tools.

As technology stacks diversify and development activities increase, it can become difficult to create and maintain CI pipelines that are consistent across an organization. By automating the process in AWS Step Functions, you can make sure that your CI pipelines are consistent in their usage and approach.

To automate the creation of dynamic CI pipelines, this pattern uses the following variable inputs:

- Programming language (Java or Python only)
- Pipeline name
- Required pipeline stages

> **Note**
> Step Functions orchestrates pipeline creation by using multiple AWS services. For more information about the AWS services used in this solution, see the **Tools** section of this pattern.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon S3 bucket in the same AWS Region that this solution is being deployed

- An AWS Identity and Access Management (IAM) principal that has the AWS CloudFormation permissions required to create the resources needed for this solution

Limitations

- This pattern supports Java and Python projects only.
- The IAM roles provisioned in this pattern follow the principle of least privilege. The IAM roles' permissions must be updated based on the specific resources that your CI pipeline needs to create.

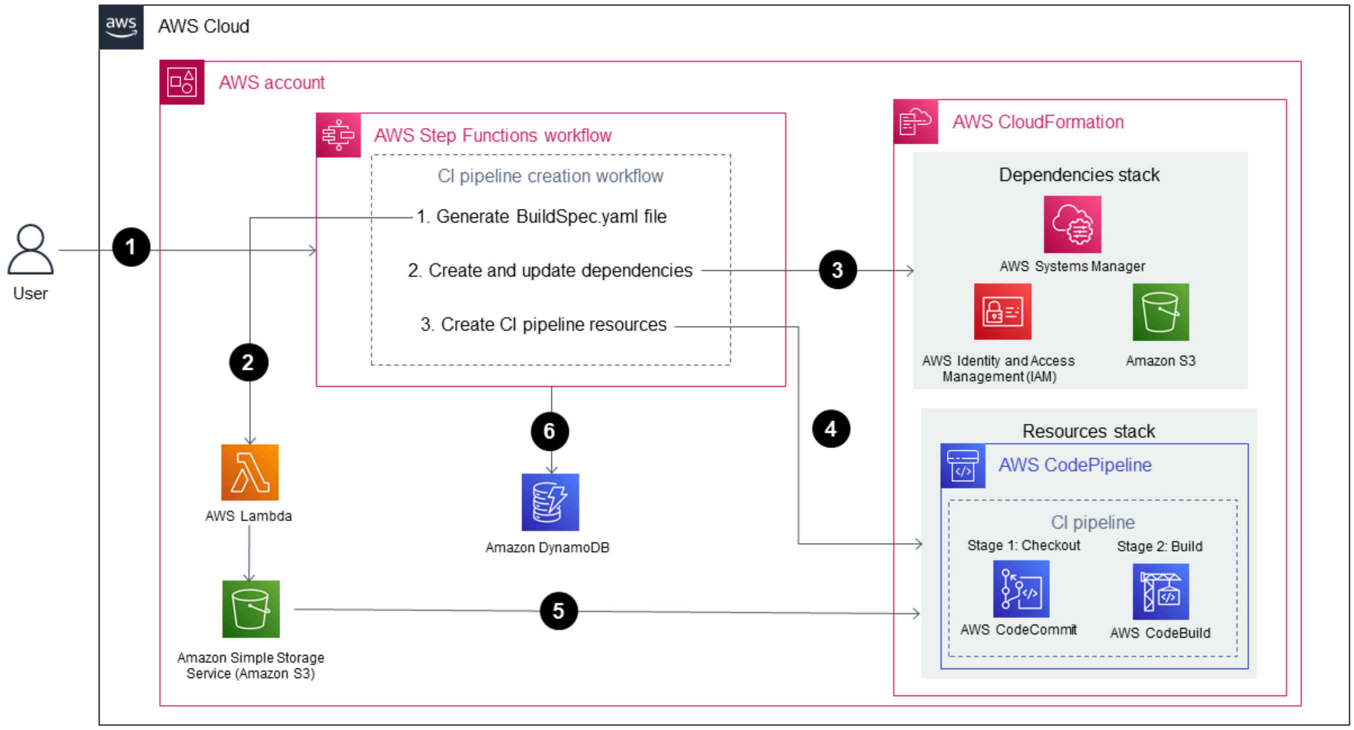
Architecture

Target technology stack

- AWS CloudFormation
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- IAM
- Amazon Simple Storage Service (Amazon S3)
- AWS Systems Manager
- AWS Step Functions
- AWS Lambda
- Amazon DynamoDB

Target architecture

The following diagram shows an example workflow for creating dynamic CI pipelines for Java and Python projects automatically by using AWS developer tools.



The diagram shows the following workflow:

1. An AWS user provides the input parameters for CI pipeline creation in JSON format. This input starts a Step Functions workflow (*state machine*) that creates a CI pipeline by using AWS developer tools.
2. A Lambda function reads a folder named **input-reference**, which is stored in an Amazon S3 bucket, and then generates a **buildspec.yml** file. This generated file defines the CI pipeline stages and is stored back in the same Amazon S3 bucket that stores the parameter references.
3. Step Functions checks the CI pipeline creation workflow's dependencies for any changes, and updates the dependencies stack as needed.
4. Step Functions creates the CI pipeline resources in a CloudFormation stack, including a CodeCommit repository, CodeBuild project, and a CodePipeline pipeline.
5. The CloudFormation stack copies the sample source code for the selected technology stack (Java or Python) and the **buildspec.yml** file to the CodeCommit repository.
6. CI pipeline runtime details are stored in a DynamoDB table.

Automation and scale

- This pattern is for use in a single development environment only. Configuration changes are required for use across multiple development environments.
- To add support for more than one CloudFormation stack, you can create additional CloudFormation templates. For more information, see Getting started with AWS CloudFormation in the CloudFormation documentation.

Tools

Tools

- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Systems Manager Parameter Store provides secure, hierarchical storage for configuration data management and secrets management.

Code

The code for this pattern is available in the GitHub automated-ci-pipeline-creation repository. The repository contains the CloudFormation templates required to create the target architecture outlined in this pattern.

Best practices

- Don't enter credentials (*secrets*) such as tokens or passwords directly into CloudFormation templates or Step Functions action configurations. If you do, the information will be displayed in the DynamoDB logs. Instead, use AWS Secrets Manager to set up and store secrets. Then, reference the secrets stored in Secrets Manager within the CloudFormation templates and Step Functions action configurations as needed. For more information, see What is AWS Secrets Manager in the Secrets Manager documentation.
- Configure server-side encryption for CodePipeline artifacts stored in Amazon S3. For more information, see Configure server-side encryption for artifacts stored in Amazon S3 for CodePipeline in the CodePipeline documentation.
- Apply least-privilege permissions when configuring IAM roles. For more information, see Apply least-privilege permissions in the IAM documentation.
- Make sure that your Amazon S3 bucket is not publicly accessible. For more information, see Configuring block public access setting for your S3 buckets in the Amazon S3 documentation.
- Make sure that you activate versioning for your Amazon S3 bucket. For more information, see Using versioning in S3 buckets in the Amazon S3 documentation.
- Use IAM Access Analyzer when configuring IAM policies. The tool provides actionable recommendations to help you author secure and functional IAM policies. For more information, see Using AWS Identity and Access Management Access Analyzer in the IAM documentation.
- When possible, define specific access conditions when configuring IAM policies.
- Activate Amazon CloudWatch logging for monitoring and auditing purposes. For more information, see What is Amazon CloudWatch Logs? in the CloudWatch documentation.

Epics

Configure the prerequisites

Task	Description	Skills required
Create an Amazon S3 bucket.	Create an Amazon S3 bucket (or use an existing bucket) to store the required CloudFormation templates, source code, and input files for the solution. For more information, see [Step 1: Create your first S3 bucket](#) in the Amazon S3 documentation. **Note** The Amazon S3 bucket must be in the same AWS Region that you're deploying the solution to.	AWS DevOps
Clone the GitHub repository.	Clone the GitHub [automated-ci-pipeline-creation](#) repository by running the following command in a terminal window: `git clone https://github.com/aws-samples/automated-ci-pipeline-creation.git`	AWS DevOps

Task	Description	Skills required
	For more information, see [Cloning a repository] in the GitHub documentation.	
Upload the Solution Templates folder from the cloned GitHub repository to your Amazon S3 bucket.	Copy the contents from the cloned **Solution-Templates** folder and upload them into the Amazon S3 bucket that you created. For more information, see Uploading objects in the Amazon S3 documentation. **Note** Make sure that you upload the contents of the **Solution-Templates** folder only. You can upload the files at the Amazon S3 bucket's root level only.	AWS DevOps

Deploy the solution

Task	Description	Skills required
Create a CloudFormation stack to deploy the solution by using the template.yml file in the cloned GitHub repository.	1. Sign into the AWS Management Console and then open the AWS CloudFormation console.	AWS administrator, AWS DevOps

Task	Description	Skills required
	2. Choose **Create stack**. A dropdown list appears. 3. In the dropdown list, select **With new resources (standard)**. The **Create stack** page opens. 4. In the **Specify template** section, select the checkbox next to **Upload a template file**. 5. Select **Choose file**. Then, navigate to the cloned GitHub repository's root folder and select the **template.yml** file. Then, choose **Open**. 6. Choose **Next**. The **Specify stack details** page opens. 7. In the **Parameters** section, specify the following parameters: • For **S3TemplateBucketName**, enter the name of the Amazon S3 bucket that you created earlier, which contains the source code and references for this solution. Make sure that the bucket name parameter is in lowercase.	

Task	Description	Skills required
	• For **DynamoDBTable**, enter a name for the DynamoDB table that the CloudFormation stack creates. • For **StateMachineName**, enter a name for the Step Functions state machine that the CloudFormation stack creates. 8. Choose **Next**. The **Configure stack options** page opens. 9. On the **Configure stack options** page, choose **Next**. Don't change any of the default values. The **Review** page opens. 10Review the stack creation settings. Then, choose **Create stack** to launch your stack. **Note** While your stack is being created, it's listed on the **Stacks** page with a status of **CREATE_IN_PROGRESS**. Make sure that you wait	

Task	Description	Skills required
	for the stack's status to change to **CREATE_COMPLETE** before completing the remaining steps in this pattern.	

Test the setup

Task	Description	Skills required

Run the step function that you created.	1. Sign in to the AWS Management Console and then open the [Step Functions console](#).
	2. Open the step function that you created.
	3. Choose **Start execution**. Then, enter your input values for the workflow in JSON format (see the following example inputs).
	4. Choose **Start execution**.
	
	JSON formatting
	
	`{`
	`  "details": {`
	`    "tech_stack": "Name of the Tech Stack (python/java)",`
	`    "project_name": "Name of the Project`
		AWS administrator, AWS DevOps

Task	Description	Skills required

	``
	that you want to create
	with",
	    "pre_build":
	"Choose the step if
	it required in the
	buildspec.yml file
	i.e., yes/no",
	    "build": "Choose the
	step if it required in
	the buildspec.yml file
	i.e., yes/no",
	    "post_build":
	"Choose the step if
	it required in the
	buildspec.yml file
	i.e., yes/no",
	    "reports": "Choose
	the step if it required
	in the buildspec.yml
	file i.e., yes/no",
	  }
	}

	    "pre_build": "yes",
	    "build": "yes",
	    "post_build": "yes",
	    "reports": "yes"
	  }
	}
	``	

Confirm that the CodeCommit repository for the CI pipeline was created.	1. Sign in to the AWS Management Console and then open the [CodeCommit console](). 2. On the **Repositories** page, verify that the name of the CodeCommit repository that you created appears in the list of repositories. The name of the repository is appended with the following: **pipeline-java-pjt-Repo** 3. Open the CodeCommit repository and validate that the sample source code along with **buildspec.yml** files are pushed to the main branch.	AWS DevOps

Task	Description	Skills required
Check the CodeBuild project resources.	1. Sign in to the AWS Management Console and then open the [CodeBuild console](https://console.aws.amazon.com/codesuite/codebuild/home). 2. On the **Build projects** page, verify that the name of the CodeBuild project that you created appears in the list of projects. The name of the project is appended with the following: **pipeline-java-pjt-Build** 3. Select the name of your CodeBuild project to open the project. Then, review and validate the following configurations: • **Project Configuration** • **Source** • **Environment** • **Buildspec** • **Batch Configuration** • **Artifacts**	AWS DevOps

Task	Description	Skills required
Validate the CodePipeline stages.	1. Sign in to the AWS Management Console and then open the [CodePipeline console](). 2. On the **Pipelines** page, verify that the name of the pipeline that you created appears in the list of pipelines. The name of the pipeline is appended with the following: **pipeline-java-pjt-Pipeline** 3. Select the name of your pipeline to open the pipeline. Then, review and validate each stage of the pipeline, including **Commit** and **Deploy**.	AWS DevOps
Confirm that the CI pipeline ran successfully.	1. In the [CodePipeline console](), on the **Pipelines** page, select the name of your pipeline to view the pipeline's status. 2. Verify that each stage of the pipeline has a **Succeeded** status.	AWS DevOps

Clean up your resources

Task	Description	Skills required
Delete the resources stack in CloudFormation.	Delete the CI pipeline's resources stack in CloudFormation. For more information, see [Deleting a stack on the AWS CloudFormation console](#) in the CloudFormation documentation. **Note** Make sure that you delete the stack named **<project_name>-stack**.	AWS DevOps
Delete the CI pipeline's dependencies in Amazon S3 and CloudFormation.	1. Empty the Amazon S3 bucket named **DeploymentArtifactBucket**. For more information, see [Emptying a bucket](#) in the Amazon S3 documentation. 2. Delete the CI pipeline's dependency stack in CloudFormation. For more information, see [Deleting a stack on the AWS CloudFormation console](#) in the CloudFormation documentation.	AWS DevOps

Task	Description	Skills required
	Note Make sure that you delete the stack named **pipeline-creation-dependencies-stack**.	
Delete the Amazon S3 template bucket.	Delete the Amazon s3 bucket that you created in the **Configure the prerequisites** section of this pattern, which stores the templates for this solution. For more information, see Deleting a bucket in the Amazon S3 documentation.	AWS DevOps

Deploy CloudWatch Synthetics canaries by using Terraform

Dhrubajyoti Mukherjee and Jean-Francois Landreau, Amazon Web Services

Summary

It's important to validate the health of a system from a customer perspective and confirm that customers are able to connect. This is more difficult when the customers don't constantly call the endpoint. [Amazon CloudWatch Synthetics](#) supports the creation of canaries, which can test both public and private endpoints. By using canaries, you can know the status of a system even if it isn't in use. These canaries are either Node.js Puppeteer scripts or Python Selenium scripts.

This pattern describes how to use HashiCorp Terraform to deploy canaries that test private endpoints. It embeds a Puppeteer script that tests whether a URL returns `200-OK`. The Terraform script can then be integrated with the script that deploys the private endpoint. You can also modify the solution to monitor public endpoints.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account with a virtual private cloud (VPC) and private subnets
- The URL of the endpoint that can be reached from the private subnets
- Terraform installed in the deployment environment

Limitations

The current solution works for the following CloudWatch Synthetics runtime versions:

- syn-nodejs-puppeteer-3.4
- syn-nodejs-puppeteer-3.5
- syn-nodejs-puppeteer-3.6
- syn-nodejs-puppeteer-3.7

As new runtime versions are released, you might need to update the current solution. You will also need to modify the solution to keep up with security updates.

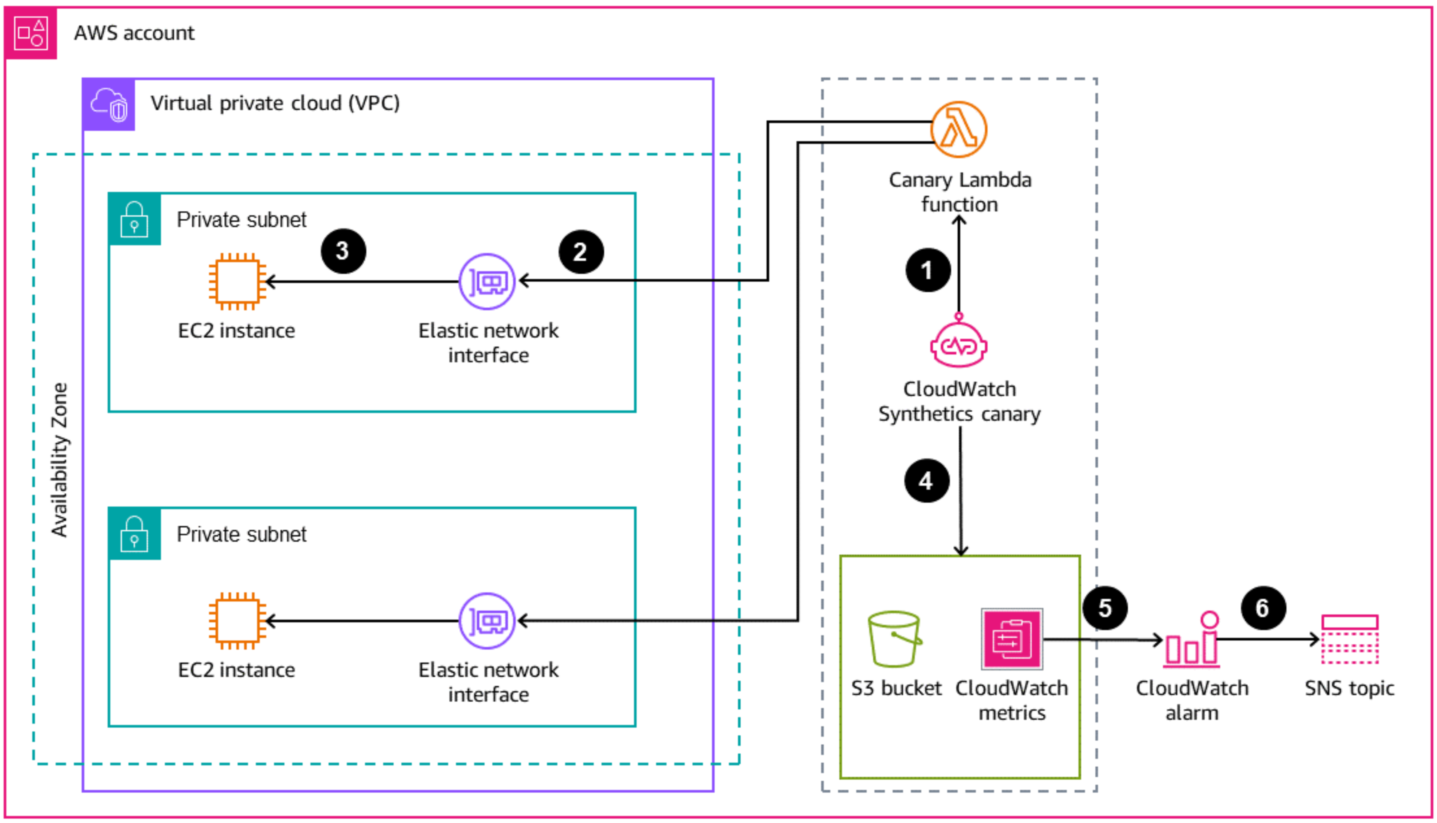
Product versions

- Terraform 1.3.0

Architecture

Amazon CloudWatch Synthetics is based on CloudWatch, Lambda, and Amazon Simple Storage Service (Amazon S3). Amazon CloudWatch offers a wizard to create the canaries and a dashboard that displays the status of the canary runs. The Lambda function runs the script. Amazon S3 stores the logs and screenshots from the canary runs.

This pattern simulates a private endpoint through an Amazon Elastic Compute Cloud (Amazon EC2) instance deployed in the targeted subnets. The Lambda function requires elastic network interfaces in the VPC where the private endpoint is deployed.



The diagram shows the following:

1. The Synthetics canary initiates the canary Lambda function.
2. The canary Lambda function connects to the elastic network interface.
3. The canary Lambda function monitors the status of the endpoint.

4. The Synthetics canary pushes run data to the S3 bucket and CloudWatch metrics.
5. A CloudWatch alarm is initiated based on the metrics.
6. The CloudWatch alarm initiates the Amazon Simple Notification Service (Amazon SNS) topic.

Tools

AWS services

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. This pattern uses VPC endpoints and elastic network interfaces.

Other services

- HashiCorp Terraform is an open-source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses Terraform to deploy the infrastructure.
- Puppeteer is a Node.js library. The CloudWatch Synthetics runtime uses the Puppeteer framework.

Code

The solution is available in the GitHub cloud watch-synthetics-canary-terraform repository. For more information, see the *Additional information* section.

Epics

Implement the solution for monitoring a private URL

Task	Description	Skills required
Gather requirements for monitoring the private URL.	Gather the full URL definition: domain, parameters, and headers. To communicate privately to Amazon S3 and Amazon CloudWatch, use VPC endpoints. Note how the VPC and subnets are accessible to the endpoint. Consider the frequency of canary runs.	Cloud architect, Network administrator
Modify the existing solution to monitor the private URL.	Modify the `terraform.tfvars` file: • `name` – The name of your canary. • `runtime_version` – The runtime version of the canary. We recommend using syn-nodejs-puppeteer-3.7. • `take_screenshot` – Whether a screenshot should be taken. • `api_hostname` – The hostname of the endpoint that is monitored. • `api_path` – The path of the endpoint that is monitored.	Cloud architect

Task	Description	Skills required
	`vpc_id` – The VPC ID that is used by the canary Lambda function. `subnet_ids` – The subnet IDs that are used by the canary Lambda function. `frequency` – The run frequency of the canary in minutes. `alert_sns_topic` – The SNS topic to which the CloudWatch alarm notification is sent.	

Deploy and operate the solution.	To deploy the solution, do the following:
	
	1. From the `cloudwatch-synthetics-canary-terraform` directory in your development environment, initialize Terraform.
	`terraform init`
	2. Plan and review the changes.
	`terraform plan`
	3. Deploy the solution.
	`terraform apply`
		Cloud architect, DevOps engineer

Troubleshooting

Issue	Solution
Deletion of the provisioned resources gets stuck.	Manually delete the canary Lambda function, corresponding elastic network interface, and security group, in that order.

- Using synthetic monitoring
- Monitor API Gateway endpoints with Amazon CloudWatch Synthetics (blog post)

Additional information

Repository artifacts

The repository artifacts are in the following structure.

```
.
### README.md
### main.tf
### modules
#   ### canary
#   ### canary-infra
### terraform.tfvars
### tf.plan
### variable.tf
```

The `main.tf` file contains the core module, and it deploys two submodules:

- `canary-infra` deploys the infrastructure required for the canaries.
- `canary` deploys the canaries.

The input parameters for the solution are located in the `terraform.tfvars` file. You can use the following code example to create one canary.

```
module "canary" {
```

```
    source = "./modules/canary"
    name   = var.name
    runtime_version = var.runtime_version
    take_screenshot = var.take_screenshot
    api_hostname = var.api_hostname
    api_path = var.api_path
    reports-bucket = module.canary_infra.reports-bucket
    role = module.canary_infra.role
    security_group_id = module.canary_infra.security_group_id
    subnet_ids = var.subnet_ids
    frequency = var.frequency
    alert_sns_topic = var.alert_sns_topic
}
```

The corresponding .var file follows.

```
name   = "my-canary"
runtime_version = "syn-nodejs-puppeteer-3.7"
take_screenshot = false
api_hostname = "mydomain.internal"
api_path = "/path?param=value"
vpc_id = "vpc_id"
subnet_ids = ["subnet_id1"]
frequency = 5
alert_sns_topic = "arn:aws:sns:eu-central-1:111111111111:yyyyy"
```

Cleaning up the solution

If you are testing this in a development environment, you can clean up the solution to avoid accruing costs.

1. On the AWS Management Console, navigate to the Amazon S3 console. Empty the Amazon S3 bucket that the solution created. Make sure to take a backup of the data, if required.
2. In your development environment, from the `cloudwatch-synthetics-canary-terraform` directory, run the `destroy` command.

   ```
   terraform destroy
   ```

Deploy a CI/CD pipeline for Java microservices on Amazon ECS

Vijay Thompson and Sankar Sangubotla, Amazon Web Services

Summary

This pattern guides you through the steps for deploying a continuous integration and continuous delivery (CI/CD) pipeline for Java microservices on an existing Amazon Elastic Container Service (Amazon ECS) cluster by using AWS CodeBuild. When the developer commits the changes, the CI/CD pipeline is initiated and the build process starts in CodeBuild. When the build is complete, the artifact is pushed to Amazon Elastic Container Registry (Amazon ECR) and the latest build from Amazon ECR is picked up and pushed to the Amazon ECS service.

Prerequisites and limitations

Prerequisites

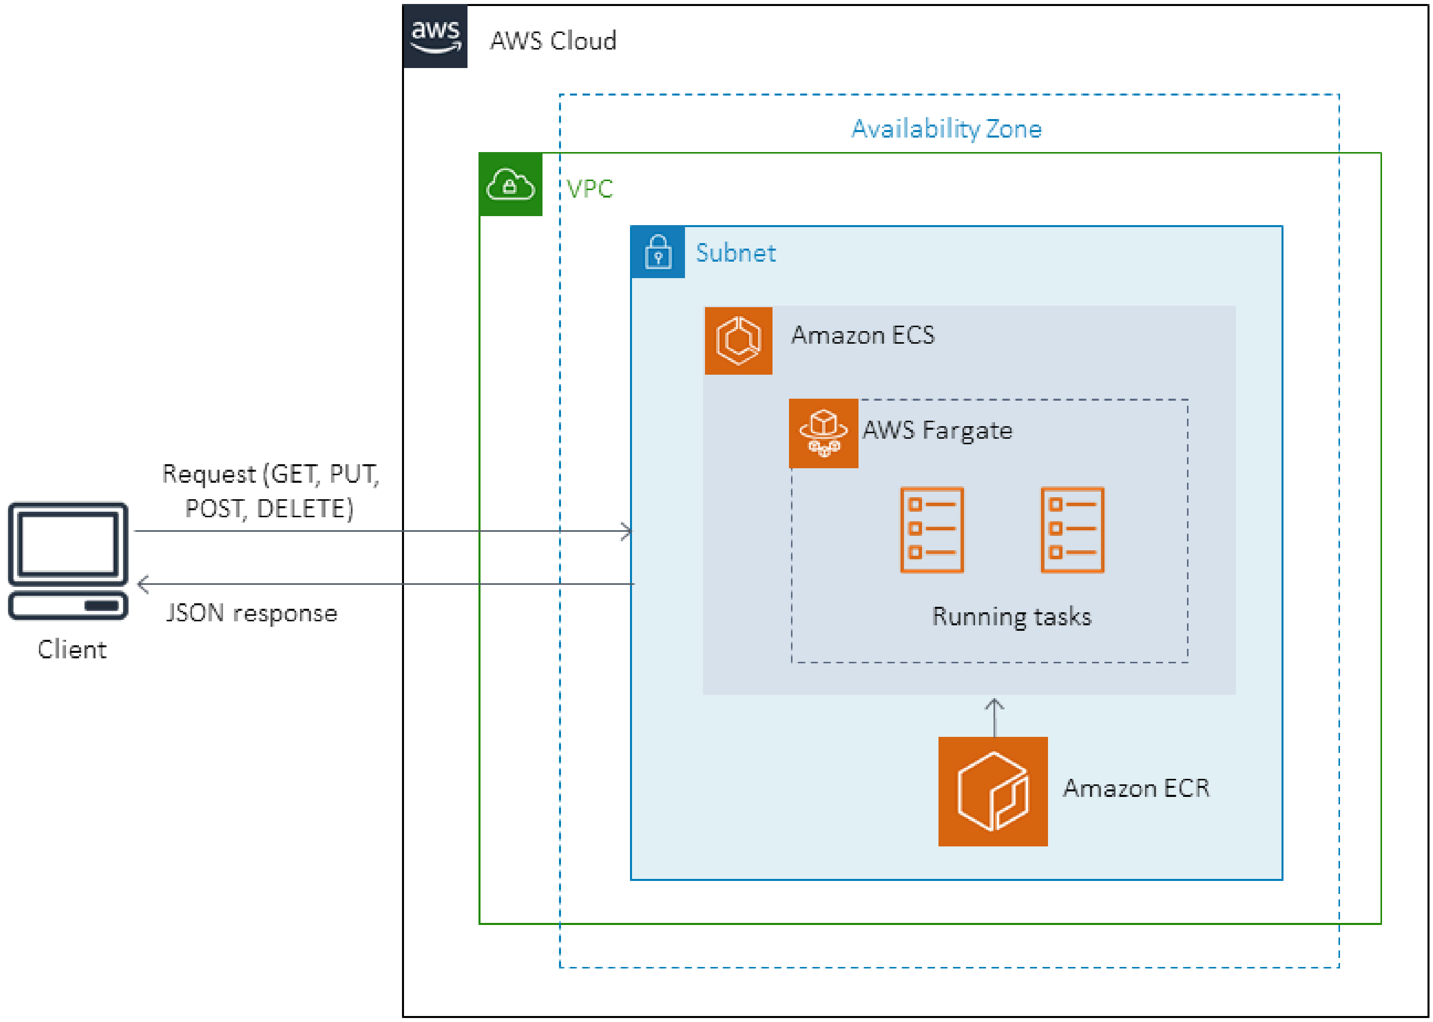
- An existing Java microservices application running on Amazon ECS
- Familiarity with AWS CodeBuild and AWS CodePipeline

Architecture

Source technology stack

- Java microservices running on Amazon ECS
- Code repository in Amazon ECR
- AWS Fargate

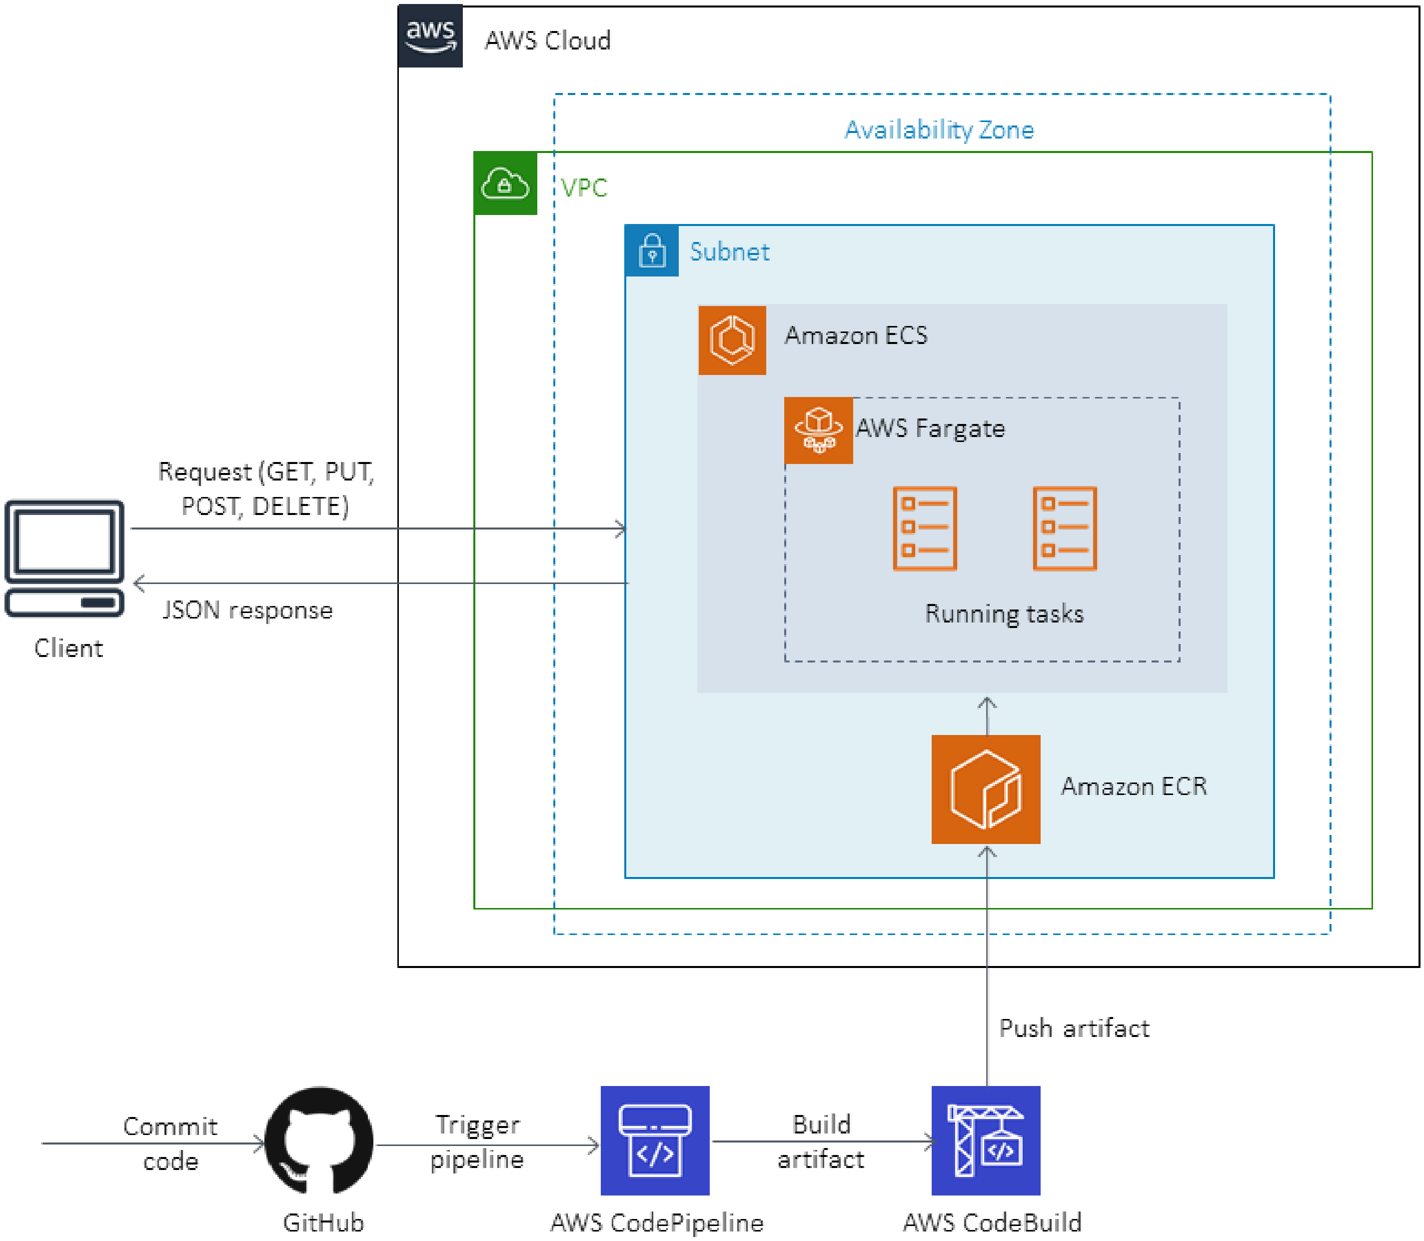
Source architecture



Target technology stack

- Amazon ECR
- Amazon ECS
- AWS Fargate
- AWS CodePipeline
- AWS CodeBuild

Target architecture



Automation and scale

CodeBuild `buildspec.yml` file:

```
version: 0.2

phases:
  pre_build:
    commands:
      - echo Logging in to Amazon ECR...
      - aws --version
```

```
      - $(aws ecr get-login --region $AWS_DEFAULT_REGION --no-include-email)
      - REPOSITORY_URI=$AWS_ACCOUNT_ID.dkr.ecr.$AWS_DEFAULT_REGION.amazonaws.com/
$IMAGE_REPO
      - COMMIT_HASH=$(echo $CODEBUILD_RESOLVED_SOURCE_VERSION | cut -c 1-7)
      - IMAGE_TAG=build-$(echo $CODEBUILD_BUILD_ID | awk -F":" '{print $2}')
  build:
    commands:
      - echo Build started on `date`
      - echo building the Jar file
      - mvn clean install
      - echo Building the Docker image...
      - docker build -t $REPOSITORY_URI:$BUILD_TAG .
      - docker tag $REPOSITORY_URI:$BUILD_TAG $REPOSITORY_URI:$IMAGE_TAG
  post_build:
    commands:
      - echo Build completed on `date`
      - echo Pushing the Docker images...
      - docker push $REPOSITORY_URI:$BUILD_TAG
      - docker push $REPOSITORY_URI:$IMAGE_TAG
      - echo Writing image definitions file...
      - printf '[{"name":"%s","imageUri":"%s"}]' $DOCKER_CONTAINER_NAME
 $REPOSITORY_URI:$IMAGE_TAG > imagedefinitions.json
      - cat imagedefinitions.json
artifacts:
    files:
     - imagedefinitions.json
     - target/DockerDemo.jar
```

Tools

AWS services

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy. AWS CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left in the queue.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously. You can integrate AWS CodePipeline with third-party services like GitHub, or use an AWS service such as Amazon ECR.
- Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated

with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can deploy containers for your applications reliably. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

- Amazon Elastic Container Service (Amazon ECS) highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS. Amazon ECS eliminates the need for you to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.
- AWS Fargate is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters. With AWS Fargate, you no longer have to provision, configure, and scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

Other tools

- Docker is a platform that lets you build, test, and deliver applications in packages called *containers*.
- Git is a distributed version-control system for tracking changes in source code during software development. It is designed for coordinating work among programmers, but it can be used to track changes in any set of files. Its goals include speed, data integrity, and support for distributed, non-linear workflows.

Epics

Set up the build project in AWS CodeBuild

Task	Description	Skills required
Create a CodeBuild build project.	In the AWS CodeBuild console, create a build project, and specify its name.	App developer, AWS systems administrator
Select the source.	This pattern uses Git for the code repository, so choose **GitHub** from the list of	App developer, AWS systems administrator

Task	Description	Skills required
	available options. Choose a public repository or from your GitHub account.	
Select a repository.	Select the repository from which you want to build the code.	App developer, AWS systems administrator
Select the environment.	You can select from a list of managed images or opt for a custom image using Docker. This pattern uses the following managed image: • **Note** Amazon Linux 2 (: Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs.) • Runtime: Standard • Image version 1.0	App developer, AWS systems administrator
Choose a service role.	You can create a service role or select from a list of existing roles.	App developer, AWS systems administrator

Task	Description	Skills required
Add environment variables.	In the **Additional configuration** section, configure the following environment variables: • **AWS_DEFAULT_REGION** for the default AWS Region • **AWS_ACCOUNT_ID** for the user account number • **IMAGE_REPO** for the Amazon ECR private repository • **BUILD_TAG** for the version of the build (**latest** build is the value for this variable) • **DOCKER_CONTAINER_NAME** for the name of the container in the task These variables are placeholders in the `buildspec.yml` file and will be replaced with their respective values.	App developer, AWS systems administrator

Task	Description	Skills required
Create a buildspec file.	You can create a `buildspec.yml` file at the same location as `pom.xml` and add the configuration that is provided in this pattern, or use the online buildspec editor and add the configuration. Configure the environmental variables with the appropriate values by following the steps provided.	App developer, AWS systems administrator
Configure the project for artifacts.	(Optional) Configure the build project for artifacts, if required.	App developer, AWS systems administrator
Configure Amazon CloudWatch Logs.	(Optional) Configure Amazon CloudWatch Logs for the build project, if required. This step is optional but recommended.	App developer, AWS systems administrator
Configure Amazon S3 logs.	(Optional) Configure Amazon Simple Storage Service (Amazon S3) logs for the build project, if you want to store the logs.	App developer, AWS systems administrator

Configure the pipeline in AWS CodePipeline

Task	Description	Skills required
Create a pipeline.	On the [AWS CodePipeline console](), create a pipeline and specify its name. For	App developer, AWS systems administrator

Task	Description	Skills required
	more information about creating a pipeline, see the [AWS CodePipeline documentation]().	
Select a service role.	Create a service role or select from the list of existing service roles. If you are creating a service role, provide a name for the role and select the option for CodePipeline to create the role.	App developer, AWS systems administrator
Choose an artifact store.	In **Advanced settings**, if you want Amazon S3 to create a bucket and store the artifacts in it, use the default location for the artifact store. Or, select a custom location and specify an existing bucket. You can also choose to encrypt the artifact by using an encryption key.	App developer, AWS systems administrator
Specify the source provider.	For **Source provider**, choose **GitHub (Version 2)**.	App developer, AWS systems administrator
Select the repository and branch of the code.	If you are not logged in, provide the connection details to connect to GitHub, and then select the repository name and branch name.	App developer, AWS systems administrator

Task	Description	Skills required
Change detection options.	Choose **Start the pipeline on source code change** and move to the next page.	App developer, AWS systems administrator
Select a build provider.	For **Build provider**, choose **AWS CodeBuild**, and then provide the AWS Region and project name details for the build project. For **Build type**, choose **Single build**.	App developer, AWS systems administrator
Choose a deploy provider.	For **Deploy provider**, choose Amazon ECS. Choose the cluster name, the service name, the image definitions file, if any, and a deploymen t timeout value, if required. Choose **Create pipeline**.	App developer, AWS systems administrator

Deploy a ChatOps solution to manage SAST scan results by using Amazon Q Developer in chat applications custom actions and AWS CloudFormation

Anand Bukkapatnam Tirumala, Amazon Web Services

Summary

This pattern presents a comprehensive solution that uses Amazon Q Developer in chat applications to streamline the management of static application security testing (SAST) scan failures reported through SonarQube. This innovative approach integrates custom actions and notifications into a conversational interface, enabling efficient collaboration and decision-making processes within development teams.

In today's fast-paced software development environment, managing SAST scan results efficiently is crucial for maintaining code quality and security. However, many organizations face the following significant challenges:

- Delayed awareness of critical vulnerabilities because of inefficient notification systems
- Slow decision-making processes caused by disconnected approval workflows
- Lack of immediate, actionable responses to SAST scan failures
- Fragmented communication and collaboration around security findings
- Time-consuming and error-prone manual infrastructure setup for security tooling

These issues often lead to increased security risks, delayed releases, and reduced team productivity. To address these challenges effectively requires a solution that can streamline SAST result management, enhance team collaboration, and automate infrastructure provisioning.

Key features of the solution include:

- **Customized notifications –** Real-time alerts and notifications are delivered directly to team chat channels, ensuring prompt awareness and action on SAST scan vulnerabilities or failures.
- **Conversational approvals –** Stakeholders can initiate and complete approval workflows for SAST scan results seamlessly within the chat interface, accelerating decision-making processes.
- **Custom actions –** Teams can define and execute custom actions based on SAST scan outcomes, such as automatically triggering email messages for quality gate failures, enhancing responsiveness to security issues.

- **Centralized collaboration –** All SAST scan-related discussions, decisions, and actions are kept within a unified chat environment, fostering improved collaboration and knowledge-sharing among team members.
- **Infrastructure as code (IaC) –** The entire solution is wrapped with AWS CloudFormation templates, enabling faster and more reliable infrastructure provisioning while reducing manual setup errors.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS Identity and Access Management (IAM) role with permissions to create and manage resources associated with the AWS services listed in Tools.
- A Slack workspace.
- Amazon Q Developer in chat applications added to the required Slack workspace as a plugin. For more information, see Add apps to your Slack workspace in the Slack documentation. Keep a note of the Slack workspace ID as shown on the AWS Management Console after successful registration.
- A configured Amazon Q Developer in chat applications client, with the workspace ID readily available for input in the AWS CloudFormation console. For instructions, see Configure a Slack client in the *Amazon Q Developer in chat applications Administrator Guide*.
- A source email account that is created and verified in Amazon Simple Email Service (Amazon SES) to send out approval email messages. For setup instructions, see Creating and verifying email identities in the *Amazon Simple Email Service Developer Guide*.
- A destination email address for receiving approval notifications. This address can be a shared inbox or a specific team distribution list.
- An operational SonarQube instance that's accessible from your AWS account. For more information, see the SonarQube installation instructions.
- A SonarQube user token with permissions to trigger and create projects through the pipeline.

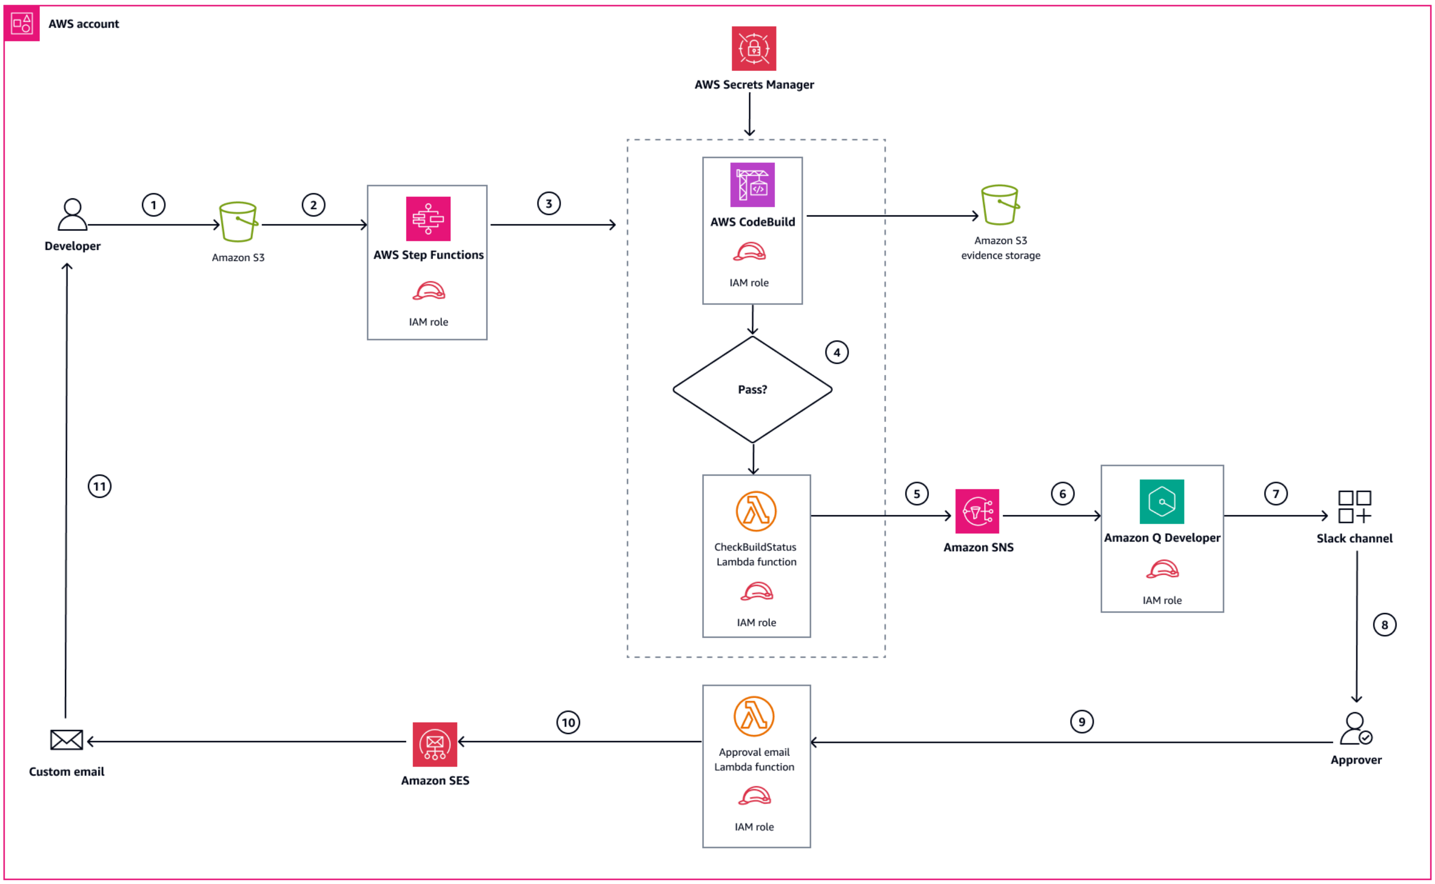
Limitations

- The creation of custom action buttons is a manual process in this solution.

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

The following diagram shows the workflow and architecture components for this pattern.



The diagram shows the automated code quality assurance workflow:

1. Code preparation and upload:
   - The developer compresses the codebase into a .zip file.
   - The developer manually uploads the .zip file to a designated Amazon Simple Storage Service (Amazon S3) bucket.
2. Amazon S3 event trigger and AWS Step Functions orchestration:
   - The Amazon S3 upload event triggers a Step Functions workflow.
   - Step Functions orchestrates a SAST scan using SonarQube.

- The workflow monitors the AWS CodeBuild job status to determine next actions. If CodeBuild succeeds (quality gate pass), the workflow terminates. If CodeBuild fails, an AWS Lambda function is invoked for diagnostics. For more details, see **AWS Step Functions logic** later in this section.

3. AWS CodeBuild execution:
   - The CodeBuild job executes a SonarQube scan on the uploaded codebase.
   - Scan artifacts are stored in a separate Amazon S3 bucket for auditing and analysis.
4. Failure analysis (Lambda function):
   - On CodeBuild failure, the `CheckBuildStatus` Lambda function is triggered.
   - On CodeBuild success, the process is terminated and no further action is needed.
5. Lambda function analyzes failure cause (quality gate failure or other issues)
   - The `CheckBuildStatus` function creates a custom payload with detailed failure information.
   - The `CheckBuildStatus` function publishes the custom payload to an Amazon Simple Notification Service (Amazon SNS) topic.
6. Notification system:
   - Amazon SNS forwards the payload to Amazon Q Developer in chat applications for Slack integration.
7. Slack integration:
   - Amazon Q Developer in chat applications posts a notification in the designated Slack channel.
8. Approval process:
   - Approvers review the failure details in the Slack notification.
   - Approvers can initiate approval using the **Approve** button in Slack.
9. Approval handler:
   - An Approval Lambda function processes the approval action from Slack.
   - The Approval function publishes the custom message to Amazon SES.
10. Message generated:
    - The Approval function generates a custom message for developer notification.
11. Developer notification:
    - Amazon SES sends an email message to the developer with next steps or required actions.

This workflow combines manual code upload with automated quality checks, provides immediate feedback through Slack, and allows for human intervention when necessary, ensuring a robust and flexible code review process.

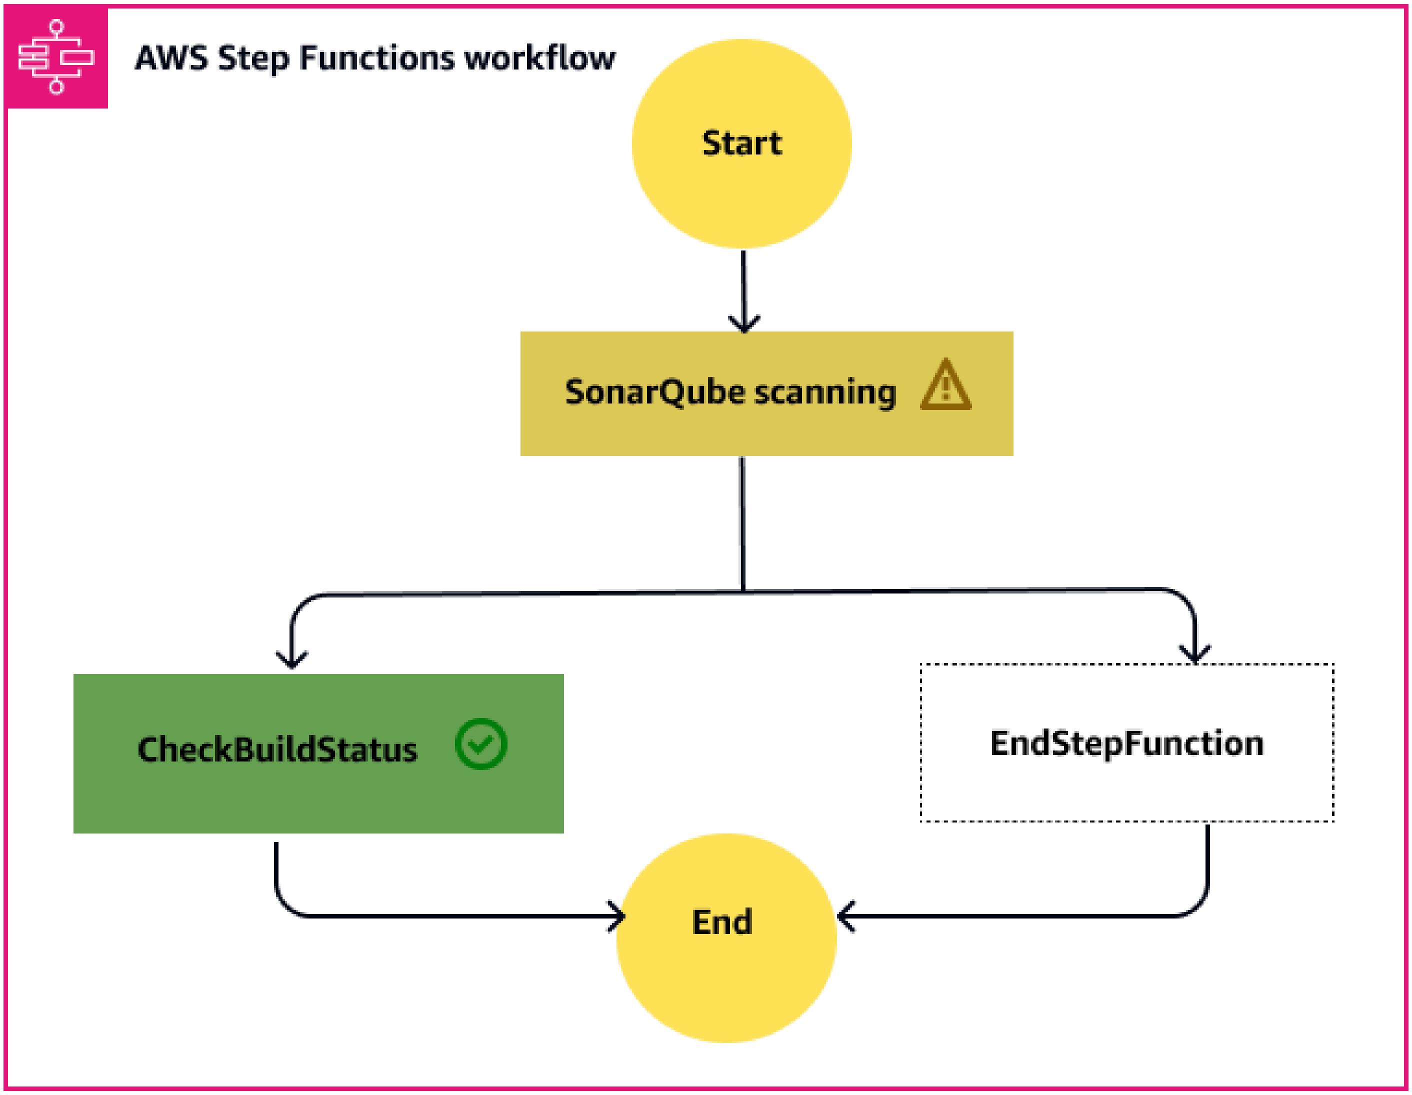
AWS Step Functions logic

As shown in the previous architecture diagram, if the quality gate pass on SonarQube fails, the workflow goes to the `CheckBuildStatus` Lambda function. The `CheckBuildStatus` function triggers a notification on the Slack channel. Each notification includes information with suggested next steps. Following are the types of notifications:

- **Application has failed in code security scan** – The user receives this notification when the uploaded code did not pass the SonarQube security scan. The user can choose **APPROVE** to accept the build. However, the notification advises the user to beware of potential poor code quality and security risks. The notification includes the following details:
  - Next steps: Error: Quality gate status: FAILED – View details at the provided URL.
  - Triage the vulnerabilities as mentioned in the document at the provided URL.
  - CodeBuild details are available at the location at the provided URL.
- **Application scan pipeline has failed because of some other reason** – The user receives this notification when the pipeline failed for some reason other than failing the code security scan. The notification includes the following details:
  - For next steps, go to the link provided for further troubleshooting.

To see screenshots of the notifications as they appear in a Slack channel, go to the assets folder in the GitHub chatops-slack repository.

The following diagram shows an example of Step Functions step status after the quality gate pass fails.



Tools

AWS services

- Amazon Q Developer in chat applications enables you to use Amazon Chime, Microsoft Teams, and Slack chat channels to monitor and respond to operational events in your AWS applications. *End of support notice:* On February 20, 2026, AWS will end support for the Amazon Chime service. After February 20, 2026, you will no longer be able to access the Amazon Chime console or Amazon Chime application resources. For more information, visit the blog post. This does not impact the availability of the Amazon Chime SDK service.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Key Management Service (AWS KMS)](#) helps you create and control cryptographic keys to help protect your data.
- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS Secrets Manager](#) helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- [Amazon Simple Email Service (Amazon SES)](#) helps you send and receive email messages by using your own email addresses and domains.
- [Amazon Simple Notification Service (Amazon SNS)](#) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- [Amazon Simple Storage Service (Amazon S3)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- [AWS Step Functions](#) is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

Other tools

- [Slack](#), a Salesforce offering, is an AI-powered conversational platform that provides chat and video collaboration, automates processes with no code, and supports information sharing.
- [SonarQube](#) is an on-premises analysis tool designed to detect coding issues in over 30 languages, frameworks, and IaC platforms.

Code repository

The code for this pattern is available in the GitHub [chatops-slack](#) repository.

Best practices

- **CloudFormation stack management** – If you encounter any failures during CloudFormation stack execution, we recommend that you delete the failed stack. Then, re-create it with the correct parameter values. This approach supports a clean deployment and helps avoid potential conflicts or partial implementations.
- **Shared inbox email configuration** – When you configure the `SharedInboxEmail` parameter, use a common distribution list that's accessible to all relevant developers. This approach promotes transparency and helps important notifications reach the relevant team members.
- **Production approval workflow** – For production environments, restrict access to the Slack channel that's used for build approvals. Only designated approvers should be members of this channel. This practice maintains a clear chain of responsibility and enhances security by limiting who can approve critical changes.
- **IAM permissions** – Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Perform initial setup

Task	Description	Skills required
Clone the repository.	To clone the chatops-slack repository for this pattern, use the following command. `git clone "git@github.com:aws-samples/chatops-slack.git"`	AWS DevOps, Build lead, DevOps engineer, Cloud administrator
Create the .zip files that contain Lambda code.	Create the .zip files for the AWS Lambda function code for the `CheckBuildStatus` and `ApprovalEmail` functionality. To create `notification.zip` and	AWS DevOps, Build lead, DevOps engineer, Cloud administrator

Task	Description	Skills required

	`approval.zip` , use the following commands.
	`cd chatops-slack/src`
	`chmod -R 775 *`
	`zip -r approval.zip approval`
	`zip -r notification.zip notification`	

Deploy the pre-requisite.yml stack file

Task	Description	Skills required
Execute the `pre-requisite.yml` stack file.	The `pre-requisite.yml` CloudFormation stack file deploys the initial resources that are required before you execute the `app-security.yml` stack file. To execute the `pre-requisite.yml` file, do the following: 1. Sign in to the AWS Management Console, and open the [AWS CloudFormation](https://console.aws.amazon.com/cloudformation/) console. Choose **Create stack**, and then choose **With new**	AWS administrator, AWS DevOps, Build lead, DevOps engineer

Task	Description	Skills required
	resources (standard) from the dropdown list. 2. On the **Create stack** page, choose **Choose an existing template** and **Upload a template file**. Then, choose **Choose file** and select **pre-requisite.yml**. Choose **Next**. 3. On the **Specify stack details** page, enter values for the parameters as described in [Additional information](). Then, choose **Next**. 4. On the **Configure stack options** page, choose the IAM role for creating the resources as described in [Prerequisites](). Then, choose **Next**. 5. On the **Review and create** page, choose **Submit.** 6. On the details page for the stack, choose the **Resources** and **Outputs** tabs. Make a note of the values for the `S3Lambda`, `CKMSKeyArn` , and `CKMSKeyId` parameters that are used in the following steps.	

Task	Description	Skills required
Upload the .zip files to the Amazon S3 bucket.	Upload the `notification.zip` and `approval.zip` files that you created earlier to the Amazon S3 bucket named `S3LambdaBucket`. The `app-security.yml` CloudFormation stack file uses `S3LambdaBucket` to provision the Lambda function.	AWS DevOps, Build lead, DevOps engineer, AWS systems administrator

Execute the app-security.yml stack file

Task	Description	Skills required
Execute the `app-security.yml` stack file.	The `app-security.yml` stack files deploys the remaining infrastructure for the notification and the approval system. To execute the `app-security.yml` file, do the following: 1. Sign in to the AWS Management Console, and open the [AWS CloudFormation](https://console.aws.amazon.com/cloudformation/) console. Choose **Create stack**, and then choose **With new resources (standard)** from the dropdown list. 2. On the **Create stack** page, choose **Choose an existing template** and **Upload**	AWS DevOps, AWS systems administrator, DevOps engineer, Build lead

Task	Description	Skills required
	a template file. Then, choose **Choose file** and select **app-security.yml**. Choose **Next**. 3. On the **Specify stack details** page, enter values for the parameters as described in [Additional information](). Then, choose **Next**. 4. On the **Configure stack options** page, choose the IAM role for creating the resources as described in [Prerequisites](). Then, choose **Next**. 5. On the **Review and create** page, choose **Submit.**	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Test the notification setup.</td><td>To test the notification setup, do the following:

1. Open the Amazon SNS console. In the left navigation pane, choose Topics.
2. Select the topic name that ends with LambdaToAWSSlackChatbot.
3. On the topic’s details page, choose Publish message.
4. On the Publish message to topic page, for Message body to send to the endpoint, enter the following:
<pre>{
    "version": "1.0",
    "source": "custom",
    "content": {
        "description": ":warning: This is a test notification"
    }
}</pre>5. Choose Publish message.

After the test message is delivered successfully, you should see a notification on the Slack channel. For more</td><td>AWS DevOps, AWS systems administrator, DevOps engineer, Build lead</td></tr>
</table>

Task	Description	Skills required
	information, see [Test notifications from AWS services to Slack](#) in the *Amazon Q Developer in chat applications Administrator Guide.*	

Set up approval flow

Task	Description	Skills required
Configure custom Lambda action.	To set up the custom AWS Lambda action, do the following: 1. Choose the vertical ellipsis button on the bottom of the delivery notification in your Slack channel. 2. In **Manage actions**, choose **Create**. 3. Enter a custom action name, for example, **Approve**. This name is a unique identifier for your custom action. 4. Enter a name for your custom action button, for example, **Approve**. This name is shown on a button on your notification. This name should be 20 characters or less and can incorporate emojis.	AWS administrator, AWS DevOps, Build lead, DevOps engineer, Slack Admin

Task	Description	Skills required
	5. For **Custom action type**, select **Lambda action**. 6. Choose **Next**. 7. Select the AWS account and AWS Region where you want to deploy this action. 8. Choose **Load Lambdas**. 9. In **Define Lambda Function**, select a Lambda function that ends with **ApprovalEmailLambda.** Then, choose **Next**. 10. To create the **Approve** button, choose **Save** on the **Display criteria** page.	
Validate approval flow.	To validate that the approval flow works as expected, choose the **Approve** button in Slack. Slackbot should send a notification on the message thread with the confirmation string **Approval Email sent successfully**.	AWS administrator, AWS DevOps, DevOps engineer, Slack Admin

Troubleshooting

Issue	Solution
Slack misconfigurations	For information about troubleshooting issues related to Slack misconfigurations, see Troubleshooting Amazon Q Developer in

Issue	Solution
	the *Amazon Q Developer in chat applications Administrator Guide*.
Scan failed because of some other reason	This error means that the code build task has failed. To troubleshoot the issue, go to the link that's in the message. The failure of the code build task might have the following possible causes: • The application is not packaged properly. The `sonar-scanner` command can't find the `sonar.project.env.properties` file. • The values for the `SonarFileName`, `SonarFileDirectory`, or `SonarToken` parameters are incorrect. Check the values, and then execute the stack files again. • The Sonar host is not reachable. • Other issues that you can use the logs to troubleshoot.

Additional information

This solution emphasizes Amazon Q Developer in chat applications custom actions for release management purposes. However, you can reuse the solution by modifying the Lambda code for your specific use case and build on top of it.

Parameters of CloudFormation stack files

The following table shows the parameters and their descriptions for the CloudFormation stack file `pre-requisite.yml`.

Key	Description
`StackName`	The name of the CloudFormation stack.
`S3LambdaBucket`	The name of the Amazon S3 bucket where you upload the Lambda code. The name must be globally unique.
`SonarToken`	The SonarQube user token as described in [Prerequisites](#).

The following table shows the parameters and their descriptions for the CloudFormation stack file `app-security.yml`.

Key	Description
`CKMSKeyArn`	The AWS KMS key Amazon Resource Name (ARN) that is used in IAM roles and Lambda functions created in this stack.
`CKMSKeyId`	The AWS KMS key ID that is used in the Amazon SNS topic created in this stack.

`EnvironmentType`	The name of the client environment for deployment of the application scan pipeline. Select the environment name from the dropdown list of allowed values.
`S3LambdaBucket`	The name of the Amazon S3 bucket that contains the `approval.zip` and `notification.zip` files.
`SESEmail`	The name of the registered email identity in Amazon SES as described in Prerequisites. This identity is the source email address.
`SharedInboxMail`	The destination email address to which the scan notifications are sent.
`SlackChannelId`	The channel ID of the Slack channel where you want the notifications sent. To find the channel ID, right-click the channel name in **Channel Details** on the Slack app. The channel ID is at the bottom.
`SlackWorkspaceId`	The Slack workspace ID as described in Prerequisites. To find the Slack workspace ID, sign in to the AWS Management Console, open the Amazon Q Developer in chat applications console, and choose **Configured clients**, **Slack**, **WorkspaceID**.
`StackName`	The name of the CloudFormation stack.
`SonarFileDirectory`	The directory that contains the `sonar.project.<env>.properties` file.
`SonarFileName`	The name of the `sonar.project.<env>properties` file.

`SourceCodeZip`	The name of the .zip file that contains the `sonar.project.<env>properties` file and the source code.

Deploy agentic systems on Amazon Bedrock with the CrewAI framework by using Terraform

Vanitha Dontireddy, Amazon Web Services

Summary

This pattern demonstrates how to implement scalable multi-agent AI systems by using the CrewAI framework integrated with Amazon Bedrock and Terraform. The solution enables organizations to create, deploy, and manage sophisticated AI agent workflows through infrastructure as code (IaC). In this pattern, CrewAI multi-agent orchestration capabilities combine with Amazon Bedrock foundation models and Terraform infrastructure automation. As a result, teams can build production-ready AI systems that tackle complex tasks with minimal human oversight. The pattern implements enterprise-grade security, scalability, and operational best practices.

Prerequisites and limitations

Prerequisites

- An active AWS account with appropriate permissions to access Amazon Bedrock foundation models
- Terraform version 1.5 or later installed
- Python version 3.9 or later installed
- CrewAI framework installed

Limitations

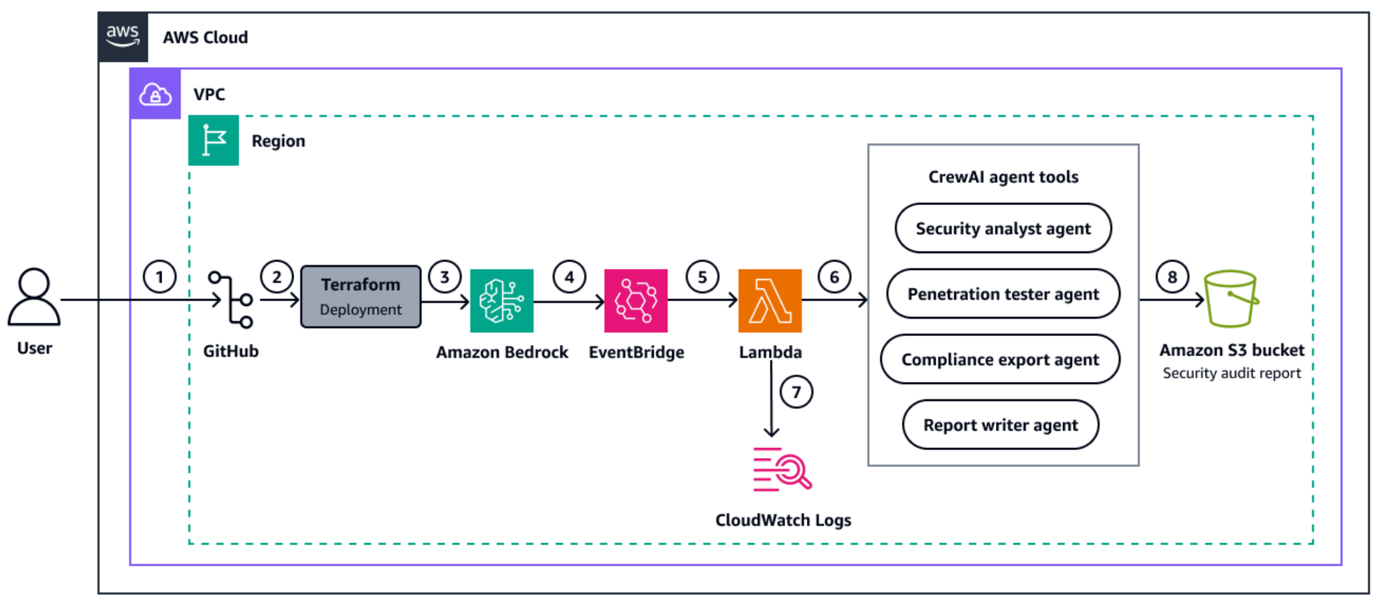
- Agent interactions are limited by model context windows.
- Terraform state management considerations for large-scale deployments apply to this pattern.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

In this pattern, the following interactions occur:

- Amazon Bedrock provides the foundation for agent intelligence through its suite of foundation models (FMs). It enables natural language processing (NLP), reasoning, and decision-making capabilities for the AI agents while maintaining high availability and scalability.
- The CrewAI framework serves as the core orchestration layer for creating and managing AI agents. It handles agent communication protocols, task delegation, and workflow management while integrating with Amazon Bedrock.
- Terraform manages the entire infrastructure stack through code, including compute resources, networking, security groups, and AWS Identity and Access Management (IAM) roles. It ensures consistent, version-controlled deployments across environments. The Terraform deployment creates the following:
  - AWS Lambda function to run the CrewAI application
  - Amazon Simple Storage Service (Amazon S3) buckets for code and reports
  - IAM roles with appropriate permissions
  - Amazon CloudWatch logging
  - Scheduled execution by Amazon EventBridge

The following diagram illustrates the architecture for deploying CrewAI multi-agent systems by using Amazon Bedrock and Terraform.



The diagram shows the following workflow:

1. The user clones the repository.

2. The user runs the command `terraform apply` to deploy the AWS resources.
3. Amazon Bedrock model configuration includes specifying the foundation model (FM) to use for configuring the CrewAI agents.
4. An EventBridge rule is established to trigger the Lambda function according to the defined schedule.
5. When triggered (either by schedule or manually), the Lambda function initializes and assumes the IAM role with permissions to access AWS services and Amazon Bedrock.
6. The CrewAI framework loads agent configurations from YAML files and creates specialized AI agents (the *AWS infrastructure security audit* crew). The Lambda function sequentially executes these agents to scan AWS resources, analyze security vulnerabilities, and generate comprehensive audit reports.
7. CloudWatch Logs captures detailed execution information from the Lambda function with a 365-day retention period and AWS Key Management Service (AWS KMS) encryption for compliance requirements. The logs provide visibility into agent activities, error tracking, and performance metrics, enabling effective monitoring and troubleshooting of the security audit process.
8. The security audit report is automatically generated and stored in the designated Amazon S3 bucket. The automated setup helps maintain consistent security monitoring with minimal operational overhead.

After the initial deployment, the workflow provides ongoing security auditing and reporting for your AWS infrastructure without manual intervention.

Overview of AI agents

This pattern creates multiple AI agents, each with unique roles, goals, and tools:

- The **security analyst agent** collects and analyzes AWS resource information.
- The **penetration tester agent** identifies vulnerabilities in AWS resources.
- The **compliance expert agent** checks configurations against compliance standards.
- The **report writer agent** compiles findings into comprehensive reports.

These agents collaborate on a series of tasks, leveraging their collective skills to perform security audits and generate comprehensive reports. (The `config/agents.yaml` file outlines the capabilities and configurations of each agent in this crew.)

Security analysis processing consists of the following actions:

1. The security analyst agent examines the collected data about AWS resources such as the following:
   - Amazon Elastic Compute Cloud (Amazon EC2) instances and security groups
   - Amazon S3 buckets and configurations
   - IAM roles, policies, and permissions
   - Virtual private cloud (VPC) configurations and network settings
   - Amazon RDS databases and security settings
   - Lambda functions and configurations
   - Other AWS services within audit scope
2. The penetration tester agent identifies potential vulnerabilities.
3. The agents collaborate through the CrewAI framework to share findings.

Report generation consists of the following actions:

1. The report writer agent compiles findings from all other agents.
2. Security issues are organized by service, severity, and compliance impact.
3. Remediation recommendations are generated for each identified issue.
4. A comprehensive security audit report is created in markdown format and uploaded to the designated Amazon S3 bucket. Historical reports are preserved for compliance tracking and security posture improvement.

Logging and monitoring activities include:

- CloudWatch logs capture execution details and any errors.
- Lambda execution metrics are recorded for monitoring.

> **Note**
>
> The code for `aws-security-auditor-crew` is sourced from the GitHub [3P-Agentic_frameworks](https://github.com/aws-samples/3P-Agentic_frameworks) repository, available in the AWS Samples collection.

Availability and scale

You can expand the available agents to more than the four core agents. To scale with additional specialized agents, consider the following new agent types:

- A *threat intelligence specialist* agent can do the following:
  - Monitors external threat feeds and correlates with internal findings
  - Provides context on emerging threats relevant to your infrastructure
  - Prioritizes vulnerabilities based on active exploitation in the wild
- *Compliance framework* agents can focus on specific regulatory areas such as the following:
  - Payment Card Industry Data Security Standard (PCI DSS) compliance agent
  - Health Insurance Portability and Accountability Act of 1996 (HIPAA) compliance agent
  - System and Organization Controls 2 (SOC 2) compliance agent
  - General Data Protection Regulation (GDPR) compliance agent

By thoughtfully expanding the available agents, this solution can provide deeper, more specialized security insights while maintaining scalability across large AWS environments. For more information about an implementation approach, tool development, and scaling considerations, see Additional information.

Tools

AWS services

- Amazon Bedrock is a fully managed AI service that makes high-performing foundation models (FMs) available for use through a unified API.
- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts. In this pattern, it's used for scheduling and orchestrating agent workflows.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- [AWS Lambda](#) is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- [AWS SDK for Python (Boto3)](#) is a software development kit that helps you integrate your Python application, library, or script with AWS services.
- [Amazon Simple Storage Service (Amazon S3)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data. In this pattern, it provides object storage for agent artifacts and state management.

Other tools

- CrewAI is an open source Python-based framework for building multi-agent AI systems.
- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub deploy-crewai-agents-terraform repository.

Best practices

- Implement proper state management for Terraform by using an Amazon S3 backend with Amazon DynamoDB locking. For more information, see Backend best practices in *Best practices for using the Terraform AWS Provider*.
- Use workspaces to separate development, staging, and production environments.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.
- Enable detailed logging and monitoring through CloudWatch Logs.
- Implement retry mechanisms and error handling for agent operations.

Epics

Deploy CrewAI framework

Task	Description	Skills required

Clone the repository.	To clone this pattern’s repository on your local machine, run the following command:
	`git clone "git@github.com:aws-samples/deploy-crewai-agents-terraform.git"`
	`cd deploy-crewai-agents-terraform`
		DevOps engineer

Edit the environment variables.	To edit the environment variables, do the following: 1. Create a `terraform.tfvars` file from the example `terraform.tfvars.example` in the terraform directory. 2. Edit the environment variables to use your own information.	DevOps engineer

Create the infrastructure.	To create the infrastructure, run the following commands:
	`cd terraform`
	`terraform init`
		DevOps engineer

Task	Description	Skills required

	`terraform plan`
	
	Review the execution plan carefully. If the planned changes are acceptable, then run the following command:
	
	`terraform apply --auto-approve`	

Access CrewAI agents

Task	Description	Skills required
Access the agents.	The agents in the AWS Infrastructure Security Audit and Reporting crew are deployed as a Lambda function. To access the agents, use the following steps: 1. Sign in to the AWS Management Console and open the AWS Lambda console at https://console.aws.amazon.com/lambda/. 2. On the **Functions** page, find and then select the function named `{project_name}` \function (as	DevOps engineer

Task	Description	Skills required
	defined in your Terraform variables). 3. From the function's page, you can take the following actions: • View configuration details. • Monitor execution metrics. • View CloudWatch logs. • Test the function manually.	

Task	Description	Skills required
(Optional) Configure manual execution of the agents.	The agents are configured to run automatically on a daily schedule (midnight UTC). However, you can trigger them manually by using the following steps: 1. In the Lambda console, select the function named `{project_name}` . 2. On the function's page, choose the **Test** tab. 3. Create a new test event with an empty JSON object `{}`. 4. To execute the event, choose **Test**. For more details, see [Testing Lambda functions in the console](#) in the Lambda documentation.	DevOps engineer

Task	Description	Skills required
Access agent logs for debugging.	The CrewAI agents are running in a Lambda environment with the necessary permissions to perform security audits and store reports in Amazon S3. The output is a markdown report that provides a comprehensive security analysis of your AWS infrastructure. To assist with detailed debugging of agent behavior, do the following: 1. In the AWS Management Console, navigate to CloudWatch Logs. 2. Find the log group for your Lambda function. 3. Look for log entries with agent names (for example, *Infrastructure mapping specialist* and *Exploratory security analyst*). 4. Review the logs for insights into the actions of each agent.	DevOps engineer

Task	Description	Skills required
View results of agent execution.	To view the results of an agent execution, do the following: 1. In the AWS Managemen t Console, navigate to Amazon S3. 2. Open the Amazon S3 bucket named `{project_name}-reports-{random_suffix}` (as defined in your Terraform variables). Reports are stored with timestamp-based filenames as follows: `security-audit-report-YYYY-MM-DD-HH-MM-SS.md`)	DevOps engineer

Task	Description	Skills required
Monitor agent execution.	To monitor the agents' execution through CloudWatch logs, do the following: 1. In the AWS Management Console, navigate to CloudWatch. 2. Go to **Log groups**. 3. Select the log group named `/aws/lambda/{project_name}-function` . 4. In **Log streams**, choose the most recent log stream to see detailed execution information.	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Customize agent behavior.</td><td>To modify the agents or their tasks, do the following:

1. Update the configuration files in your local repository:

• The following file defines each agent's role, capabilities, and settings: <code>src/aws_infrastructure_security_audit_and_reporting/config/agents.yaml</code>

• The following dile defines the tasks and workflows for the agents:

<code>src/aws_infrastructure_security_audit_and_reporting/config/tasks.yaml</code>

2. To repackage and update the Lambda function, use the following commands:

<code>cd terraform</code>

<code>terraform apply</code></td><td>DevOps engineer</td></tr>
</table>

Clean up resources

Task	Description	Skills required

Delete the created resources.	To delete all infrastructure created by this pattern, run the following command:
	`terraform plan -destroy`
	Warning
	The following command will permanently delete all resources created by this pattern. The command will prompt for confirmation before removing any resources.
	Review the destruction plan carefully. If the planned deletions are acceptable, then run the following command:
	`terraform destroy`
		DevOps engineer

Troubleshooting

Issue	Solution
Agent behavior	For information about this issue, see Test and troubleshoot agent behavior in the Amazon Bedrock documentation.
Lambda network issues	For information about these issues, see Troubleshoot networking issues in Lambda in the Lambda documentation.
IAM permissions	For information about these issues, see Troubleshoot IAM in the IAM documentation.

Additional information

This section contains information about an implementation approach, tool development, and scaling considerations related to the earlier discussion in Automation and scale.

Implementation approach

Consider the following approach to adding agents:

1. Agent configuration:
   - Add new agent definitions to the `config/agents.yaml` file.
   - Define specialized backstories, goals, and tools for each agent.
   - Configure memory and analysis capabilities based on agent specialty.
2. Task orchestration:
   - Update the `config/tasks.yaml` file to include new agent-specific tasks.
   - Create dependencies between tasks to help ensure proper information flow.
   - Implement parallel task execution where appropriate.

Technical implementation

Following is an addition to the `agents.yaml` file for a proposed Threat Intelligence Specialist agent:

```
Example new agent configuration in agents.yaml
threat_intelligence_agent:
 name: "Threat Intelligence Specialist"
 role: "Cybersecurity Threat Intelligence Analyst"
 goal: "Correlate AWS security findings with external threat intelligence"
 backstory: "Expert in threat intelligence with experience in identifying emerging
 threats and attack patterns relevant to cloud infrastructure."
verbose: true
allow_delegation: true
tools:
- "ThreatIntelligenceTool"
- "AWSResourceAnalyzer"
```

Tool development

With the CrewAI framework, you can take the following actions to enhance your security audit crew's effectiveness:

- Create custom tools for new agents.
- Integrate with external APIs for threat intelligence.
- Develop specialized analyzers for different AWS services.

Scaling considerations

When expanding your AWS Infrastructure Security Audit and Reporting system to handle larger environments or more comprehensive audits, address the following scaling factors:

- **Computational resources**
  - Increase Lambda memory allocation to handle additional agents.
  - Consider splitting agent workloads across multiple Lambda functions.
- **Cost management**
  - Monitor Amazon Bedrock API usage as agent count increases.
  - Implement selective agent activation based on audit scope.
- **Collaboration efficiency**
  - Optimize information sharing between agents.
  - Implement hierarchical agent structures for complex environments.
- **Knowledge base enhancement**
  - Provide agents with specialized knowledge bases for their domains.
  - Regularly update agent knowledge with new security best practices.

Deploy an AWS Glue job with an AWS CodePipeline CI/CD pipeline

Bruno Klein and Luis Henrique Massao Yamada, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern demonstrates how you can integrate AWS CodeCommit and AWS CodePipeline with AWS Glue, and use AWS Lambda to launch jobs as soon as a developer pushes their changes to a remote AWS CodeCommit repository.

When a developer submits a change to an extract, transform, and load (ETL) repository and pushes the changes to AWS CodeCommit, a new pipeline is invoked. The pipeline initiates a Lambda function that launches an AWS Glue job with these changes. The AWS Glue job performs the ETL task.

This solution is helpful in the situation where businesses, developers, and data engineers want to launch jobs as soon as changes are committed and pushed to the target repositories. It helps achieve a higher level of automation and reproducibility, therefore avoiding errors during the job launch and lifecycle.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Git installed on the local machine
- Amazon Cloud Development Kit (Amazon CDK) installed on the local machine
- Python installed on the local machine
- The code in the *Attachments* section

Limitations

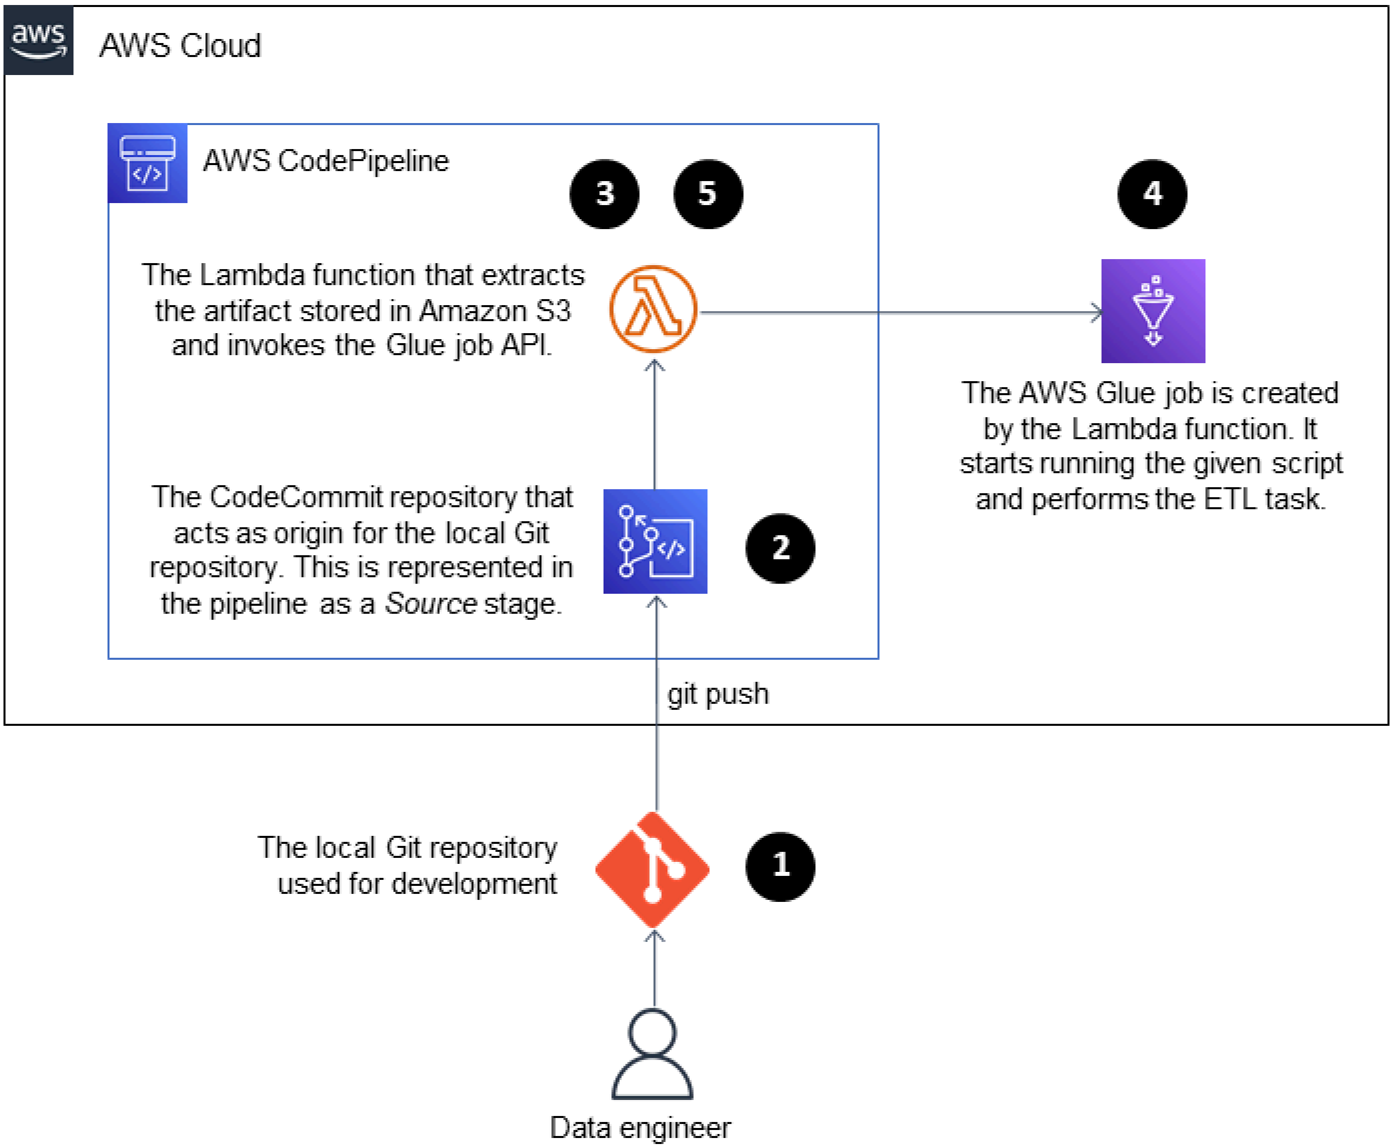
- The pipeline is finished as soon as the AWS Glue job is successfully launched. It does not wait for the conclusion of the job.
- The code provided in the attachment is intended for demo purposes only.

Architecture

Target technology stack

- AWS Glue
- AWS Lambda
- AWS CodePipeline
- AWS CodeCommit

Target architecture



The process consists of these steps:

1. The developer or data engineer makes a modification in the ETL code, commits, and pushes the change to AWS CodeCommit.
2. The push initiates the pipeline.
3. The pipeline initiates a Lambda function, which calls `codecommit:GetFile` on the repository and uploads the file to Amazon Simple Storage Service (Amazon S3).
4. The Lambda function launches a new AWS Glue job with the ETL code.
5. The Lambda function finishes the pipeline.

Automation and scale

The sample attachment demonstrates how you can integrate AWS Glue with AWS CodePipeline. It provides a baseline example that you can customize or extend for your own use. For details, see the *Epics* section.

Tools

- AWS CodePipeline – AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
- AWS CodeCommit – AWS CodeCommit is a fully managed source control service that hosts secure, Git-based repositories.
- AWS Lambda – AWS Lambda is a serverless compute service that lets you run code without provisioning or managing servers.
- AWS Glue – AWS Glue is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development.
- Git client – Git provides GUI tools, or you can use the command line or a desktop tool to check out the required artifacts from GitHub.
- AWS CDK – The AWS CDK is an open source software development framework that helps you define your cloud application resources by using familiar programming languages.

Epics

Deploy the sample code

Task	Description	Skills required
Configure the AWS CLI.	Configure the AWS Command Line Interface (AWS CLI) to target and authenticate with your current AWS account. For instructions, see the [AWS CLI documentation]().	Developer, DevOps engineer
Extract the sample project files.	Extract the files from the attachment to create a folder that contains the sample project files.	Developer, DevOps engineer

Deploy the sample code.	After you extract the files, run the following commands from the extract location to create a baseline example:
	`cdk bootstrap`
	`cdk deploy`
	`git init`
	`git remote add origin <code-commit-repository-url>`
	`git stage .`
	`git commit -m "adds sample code"`
	`git push --set-upstream origin main`
	After the last command, you can monitor the status of the pipeline and the AWS Glue job.
		Developer, DevOps engineer

Task	Description	Skills required
Customize the code.	Customize the code for the etl.py file in accordance with your business requirements. You can revise the ETL code, modify the pipeline stages, or extend the solution.	Data engineer

Deploy an Amazon EKS cluster from AWS Cloud9 using an EC2 instance profile

Sagar Panigrahi, Amazon Web Services

Summary

Notice: AWS Cloud9 is no longer available to new customers. Existing customers of AWS Cloud9 can continue to use the service as normal. Learn more

This pattern describes how to use AWS Cloud9 and AWS CloudFormation to create an Amazon Elastic Kubernetes Service (Amazon EKS) cluster that can be operated without enabling programmatic access for users in your Amazon Web Services (AWS) account.

AWS Cloud9 is a cloud-based integrated development environment (IDE) that helps you write, run, and debug your code by using a browser. AWS Cloud9 is used as a control center that provisions an Amazon EKS cluster by using Amazon Elastic Compute Cloud (Amazon EC2) instance profiles and AWS CloudFormation templates.

You can use this pattern if you don't want to create AWS Identity and Access Management (IAM) users and want to use IAM roles instead. Role-based access control (RBAC) regulates access to resources based on the roles of individual users. This pattern demonstrates how to update RBAC within an Amazon EKS cluster to allow access to a specific IAM role.

The pattern's setup also helps your DevOps team use AWS Cloud9 features to maintain and develop infrastructure as code (IaC) resources for creating Amazon EKS infrastructure.

Prerequisites and limitations

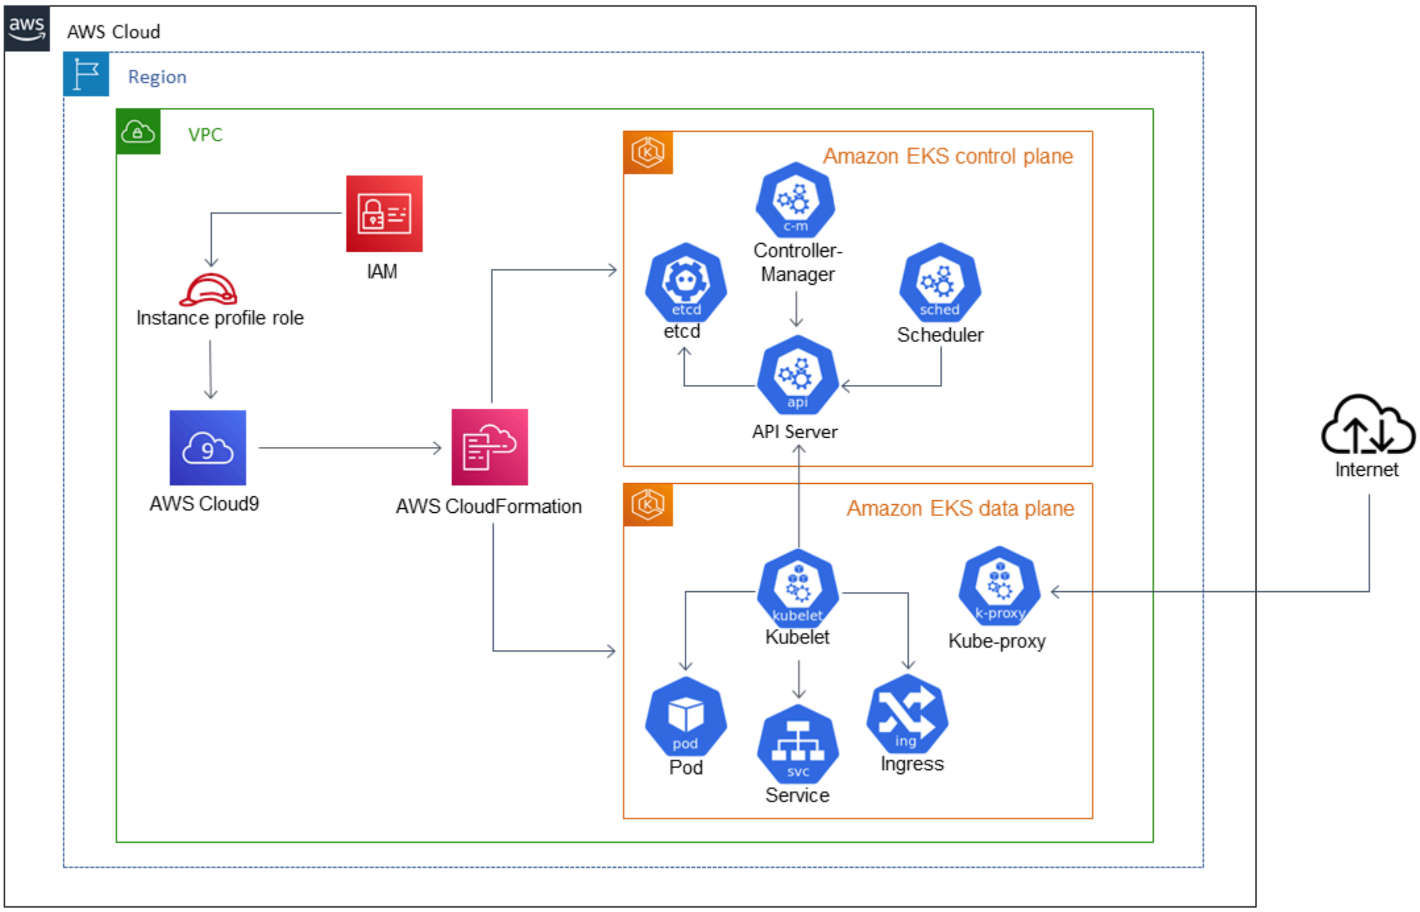
Prerequisites

- An active AWS account.
- Permissions to create IAM roles and policies for the account. The IAM role for the user must include the `AWSCloud9Administrator` policy. The `AWSServiceRoleForAmazonEKS` and `eksNodeRoles` roles must also be created because they are required to create an Amazon EKS cluster.
- Knowledge of Kubernetes concepts.

Limitations

- This pattern describes how to create a basic Amazon EKS cluster. For production clusters, you must update the AWS CloudFormation template.
- The pattern doesn't deploy additional Kubernetes components (for example, Fluentd, ingress controllers, or storage controllers).

Architecture



Technology stack

- AWS Cloud9
- AWS CloudFormation
- Amazon EKS
- IAM

Automation and scale

You can expand this pattern and incorporate it into continuous integration and continuous deployment (CI/CD) pipelines to automate the complete provisioning of Amazon EKS.

Tools

- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications.
- AWS Cloud9 – AWS Cloud9 offers a rich code-editing experience with support for several programming languages and runtime debuggers, and a built-in terminal.
- AWS CLI – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- Kubectl – `kubectl` is a command line utility that you can use to interact with an Amazon EKS cluster.

Epics

Create the IAM roles for the EC2 instance profile

Task	Description	Skills required
Create the IAM policy.	Sign in to the AWS Management Console, open the IAM console, choose **Policies**, and then choose **Create policy**. Choose the **JSON** tab and paste the contents from the policy-ro le-eks-instance-profile-for-cloud9.json file (attached). Resolve any security warnings, errors, or general warnings generated during the policy validation, and	Cloud administrator

Task	Description	Skills required
	then choose **Review policy**. Enter a **Name** for the policy. We recommend that you use `eks-instance-profile-for-cloud9` for the policy name. Review the policy **Summary** to see the permissions that are granted by your policy. Then choose **Create policy**.	
Create an IAM role using the policy.	On the IAM console, choose **Roles** and then choose **Create role**. Choose **AWS Service** and then choose **EC2** from the list. Choose **Next: Permissions** and search for the IAM policy that you created earlier. Choose the appropriate tags for your requirements. In the **Review** section, enter a name for the role. We recommend that you use `role-eks-instance-profile-for-cloud9` for the role name. Then choose **Create role**.	Cloud administrator

Create an IAM policy and role for the Amazon EKS RBAC

Task	Description	Skills required
Create the IAM policy.	On the IAM console, choose **Policies** and then choose **Create policy**. Choose the **JSON** tab and paste the contents from the policy-for-eks-rbac.json file (attached). Resolve any security warnings, errors, or general warnings generated during the policy validation, and then choose **Review policy**. Enter a **Name** for the policy. We recommend that you use `policy-for-eks-rbac` for the policy name. Review the policy **Summary** to see the permissions that are granted by your policy. Then choose **Create policy**.	Cloud administrator
Create an IAM role using the policy.	On the IAM console, choose **Roles** and then choose **Create role**. Choose **AWS Service** and then choose **EC2** from the list. Choose **Next: Permissions** and search for the IAM policy that you created earlier. Choose the appropriate tags for your requirements. In the **Review** section, enter a name for the role. We	Cloud administrator

Task	Description	Skills required
	recommend that you use `role-eks-admin-for-rbac` for the role name. Then choose **Create role**.	

Create the AWS Cloud9 environment

Task	Description	Skills required
Create the AWS Cloud9 environment.	Open the AWS Cloud9 console and choose **Create environment**. On the **Name environment** page, enter a name for your environment. We recommend that you use `eks-management-env` for the environment name. Configure the remaining settings according to your requirements and then choose **Next step**. On the **Review** page, choose **Create environment**. Wait while AWS Cloud9 creates your environment. This can take several minutes. For more information about the available configuration options, see [Creating an EC2 environment](#) in the AWS Cloud9 documentation.	Cloud administrator

Task	Description	Skills required
Remove the temporary IAM credentials for AWS Cloud9.	After your AWS Cloud9 environment is provisioned, choose **Settings** in the gear icon. Under **Preferences**, choose **AWS settings** and then choose **Credentials**. Turn off **AWS managed temporary credentials** and close the tab.	Cloud administrator
Attach the EC2 instance profile to the underlying EC2 instance.	Open the Amazon EC2 console and choose the EC2 instance that matches your environment in AWS Cloud9. If you used the name that we recommended, the EC2 instance is called `aws-cloud9-eks-management-env` . Choose the EC2 instance, choose **Actions**, and then choose **Instance settings**. Choose **Attach/replace IAM role**. Search for `role-eks-instance-profile-for-cloud9` or the name of the IAM role that you created earlier, and then choose **Apply**.	Cloud administrator

Create the Amazon EKS cluster

Task	Description	Skills required
Create the Amazon EKS cluster.	Download and open the eks-cfn.yaml (attached) template for AWS CloudFormation. Edit the template according to your requirements. Open the AWS Cloud9 environment and choose **New file**. Paste the AWS CloudFormation template that you created earlier into the field. We recommend that you use eks-cfn.yaml for the template name. In the AWS Cloud9 terminal, run the following command to create the Amazon EKS cluster: `aws cloudformation create-stack --stack-name eks-cluster --template-body file://eks-cfn.yaml --region <your_AWS_Region>` If the AWS CloudFormation call is successful, you receive the AWS CloudFormation stack's Amazon Resource Name (ARN) in your output.	Cloud administrator

Task	Description	Skills required
	The stack creation can take between 10 to 20 minutes.	
Verify the Amazon EKS cluster's status.	On the AWS CloudFormation console, open the **Stacks** page and then choose the stack name. The stack is created when the stack status code shows `CREATE_COMPLETE` . For more information, see Viewing AWS CloudFormation stack data and resources in the AWS CloudFormation documentation.	Cloud administrator

Access the Kubernetes resources in the Amazon EKS cluster

Task	Description	Skills required
Install kubectl in the AWS Cloud9 environment.	Install `kubectl` in your AWS Cloud9 environment by following the instructions from Installing kubectl in the Amazon EKS documentation.	Cloud administrator
Update the new Amazon EKS configuration in AWS Cloud9.	Run the following command in the AWS Cloud9 terminal to update the `kubeconfig` from the Amazon EKS cluster to the AWS Cloud9 environme nt:	Cloud administrator

Task	Description	Skills required
	`aws eks update-kubeconfig --name EKS-DEV2 --region <your_AWS_Region>` **Important** `EKS-DEV2` is the name of the Amazon EKS cluster in the AWS CloudFormation template that you used to create the cluster. Run the `kubectl get all -A` command to view all Kubernetes resources.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add the administrator IAM role to the Kubernetes RBAC.</td><td>Run the following command in your AWS Cloud9 terminal to open the RBAC configura tion map for Amazon EKS in edit mode:

<code>kubectl edit cm/aws-auth -n kube-system</code>

Append the following lines under the <code>mapRoles</code> section:

<pre>- groups:
- system:masters
rolearn: <ARN_of_IAM_role _from_second_epic>
username: eksadmin</pre>
Lint the YAML-formatted file to avoid syntax errors. Save the file using <code>vi</code> commands and then exit the file.

Note
By adding this section, you inform the Kubernetes RBAC that <code><ARN_of_IAM_role _from_second_epic></code> is to receive full administr ator access on the Amazon EKS cluster. This means that</td><td>Cloud administrator</td></tr>
</table>

Task	Description	Skills required
	the identified IAM role can carry out administrative actions on the Kubernetes cluster. AWS adds the existing section under `mapRoles` while the Amazon EKS cluster is provisioned.

Deploy code in multiple AWS Regions using AWS CodePipeline, AWS CodeCommit, and AWS CodeBuild

Anand Krishna Varanasi, Amazon Web Services

Summary

This pattern demonstrates how to build infrastructure or architecture across multiple Amazon Web Services (AWS) Regions by using AWS CloudFormation. It includes continuous integration (CI)/ continuous deployment (CD) across multiple AWS Regions for faster deployments. The steps in this pattern have been tested for the creation of an AWS CodePipeline job to deploy to three AWS Regions as an example. You can change the number of Regions based on your use case.

Prerequisites and limitations

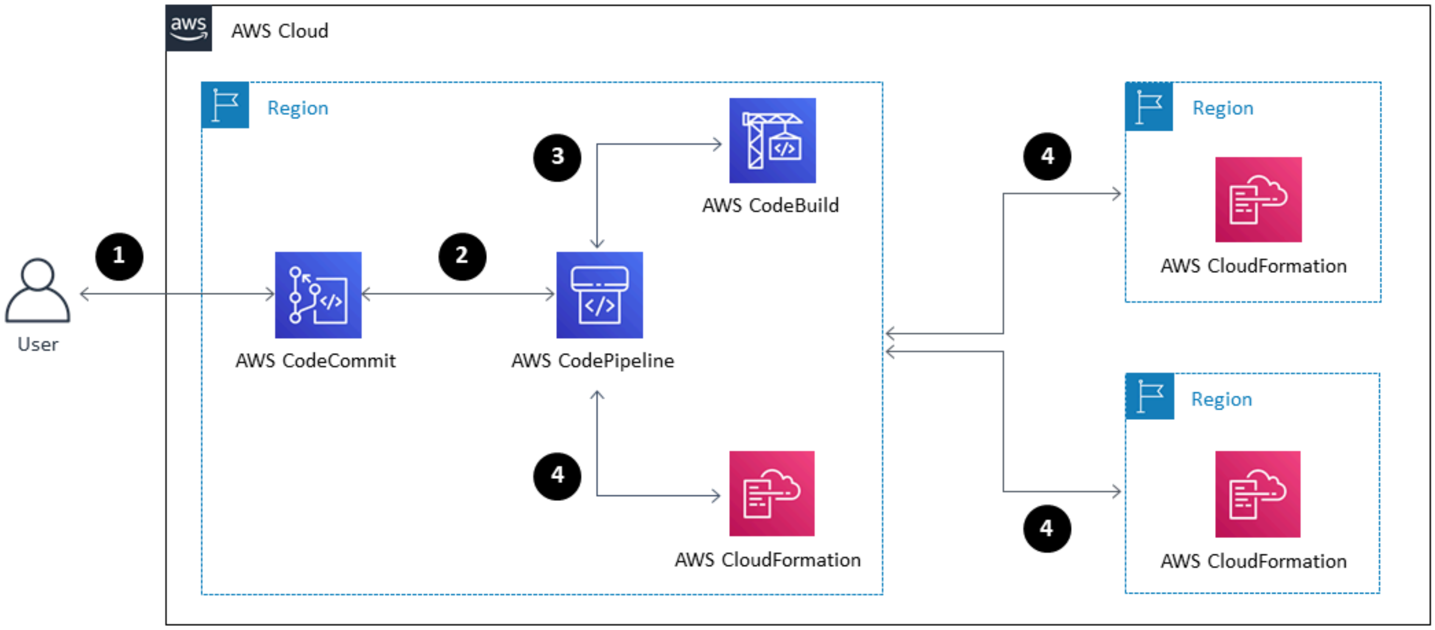
Prerequisites

- An active AWS account.
- - A CodeBuild role with the *AmazonS3FullAccess* and *CloudWatchFullAccess* policies. These policies give CodeBuild access to watch events of AWS CodeCommit through Amazon CloudWatch and to use Amazon Simple Storage Service (Amazon S3) as an artifact store.
  - An AWS CloudFormation role with the following policies, which give AWS CloudFormation, in the final Build stage, the ability to create or update AWS Lambda functions, push or watch Amazon CloudWatch logs, and to create and update change sets.
    - *AWSLambdaFullAccess*
    - *AWSCodeDeployFullAccess*
    - *CloudWatchFullAccess*
    - *AWSCloudFormationFullAccess*
    - *AWSCodePipelineFullAccess*

> **Note**
>
> Two AWS Identity and Access Management (IAM) roles for AWS CodeBuild and AWS CloudFormation with proper policies for CodeBuild to perform the CI tasks of testing, bundling, packaging the artifacts, and deploying to multiple AWS Regions in parallel.

Cross-check the policies created by CodePipeline to verify that CodeBuild and AWS CloudFormation have proper permissions in the CI and CD phases.

Architecture



This pattern's multiple-Region architecture and workflow comprise the following steps.

1. You send your code to a CodeCommit repository.
2. Upon receiving any code update or commit, CodeCommit invokes a CloudWatch event, which in turn starts a CodePipeline job.
3. CodePipeline engages the CI that is handled by CodeBuild. The following tasks are performed.
   - Testing of the AWS CloudFormation templates (optional)
   - Packaging of the AWS CloudFormation templates for each Region included in the deployment. For example, this pattern deploys in parallel to three AWS Regions, so CodeBuild packages the AWS CloudFormation templates into three S3 buckets, one in each specified Region. The S3 buckets are used by CodeBuild as artifact repositories only.
4. CodeBuild packages the artifacts as input for next Deploy phase, which runs in parallel in the three AWS Regions. If you specify a different number of Regions, CodePipeline will deploy to those Regions.

Tools

Tools

- [AWS CodePipeline](#) – CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software changes continuously.
- AWS CodeBuild – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- AWS CodeCommit – CodeCommit is a version control service hosted by Amazon Web Services that you can use to privately store and manage assets (such as source code and binary files) in the cloud.
- AWS CloudFormation – AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
- AWS Identity and Access Management – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.

Code

The following sample code is for the `BuildSpec.yaml` file (Build phase).

Epics

Prepare the code and the CodeCommit repository

Task	Description	Skills required
Select the primary AWS Region for the deployment.	Sign in to your AWS account and choose the primary Region for the deployment. The CodeCommit repository will be in the primary Region.	DevOps
Create the CodeCommit repository.	Create the CodeCommit repository, and push the required code into it. The code generally includes the AWS CloudFormation or AWS SAM templates, Lambda code if any, and the CodeBuild `buildspec.yaml` files as	DevOps

Task	Description	Skills required
	input to the AWS CodePipel ine.	
Push the code into the CodeCommit repository.	In the *Attachments* section, download the code for this example, and then push the required code into it. Generally, the code can include AWS CloudForm ation or AWS SAM templates , Lambda code and the CodeBuild `buildspec .yaml` files as input to the pipeline.	DevOps

Source phase: Create the pipeline

Task	Description	Skills required
Create the CodePipeline job.	On the CodePipeline console, choose **Create pipeline**.	DevOps
Name the CodePipeline job and choose the service role setting.	Enter a name for the job, and keep the default service role setting so that CodePipel ine creates the role with the necessary policies attached.	DevOps
Specify the location for the artifact store.	Under **Advanced settings**, keep the default option so that CodePipeline creates an S3 bucket to use for code artifact storage. If you use an existing S3 bucket instead, the bucket must be in the	DevOps

Task	Description	Skills required
	primary Region that you specified in the first epic.	
Specify the encryption key.	Keep the default option, **Default AWS Managed Key**, or choose to use your own AWS Key Management Service (AWS KMS) customer managed key.	DevOps
Specify the source provider.	Under **Source provider**, choose **AWS CodeCommit**.	DevOps
Specify the repository.	Choose the CodeCommit repository that you created in the first epic. If you placed the code in a branch, choose the branch.	DevOps
Specify how code changes are detected.	Keep the default, **Amazon CloudWatch Events**, as the change trigger for CodeCommit to start the CodePipeline job.	DevOps

Build phase: Configure the pipeline

Task	Description	Skills required
Specify the build provider.	For the build provider, choose **AWS CodeBuild**.	DevOps
Specify the AWS Region.	Choose the primary Region, which you specified in the first epic.	DevOps

Build phase: Create and configure the project

Task	Description	Skills required
Create the project	Choose **Create project**, and enter a name for the project.	DevOps
Specify the environment image.	For this pattern demonstration, use the default CodeBuild managed image. You also have the option to use a custom Docker image if you have one.	DevOps
Specify the operating system.	Choose either Amazon Linux 2 or Ubuntu. **Note** Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs.	DevOps
Specify the service role.	Choose the role you created for CodeBuild before you started to create the CodePipeline job. (See the *Prerequisites* section.)	DevOps
Set additional options.	For **Timeout** and **Queued timeout**, keep the default values. For certificate, keep the default setting unless you have a custom certificate that you want to use.	DevOps

Task	Description	Skills required
Create the environment variables.	For each AWS Region that you want to deploy to, create environment variables by providing the S3 bucket name and the Region name (for example, us-east-1).	DevOps
Provide the buildspec file name, if it is not buildspec .yml.	Keep this field blank if the file name is the default, `buildspec.yaml` . If you renamed the buildspec file, enter the name here. Make sure it matches the name of the file that is in the CodeCommit repository.	DevOps
Specify logging.	To see logs for Amazon CloudWatch Events, keep the default setting. Or you can define any specific group or logger names.	DevOps

Skip the Deploy phase

Task	Description	Skills required
Skip the deploy phase and complete the creation of the pipeline.	When you set up the pipeline, CodePipeline allows you to create only one stage in the Deploy phase. To deploy to multiple AWS Regions, skip this phase. After the pipeline is created, you can	DevOps

Task	Description	Skills required
	add multiple Deploy phase stages.	

Deploy phase: Configure the pipeline for deployment to the first Region

Task	Description	Skills required
Add a stage to the Deploy phase.	Edit the pipeline and choose **Add stage** in the Deploy phase. This first stage is for the primary Region.	DevOps
Provide an action name for the stage.	Enter a unique name that reflects the first (primary) stage and Region. For example, enter **primary_<region>_deploy**.	DevOps
Specify the action provider.	For **Action provider**, choose AWS CloudFormation.	DevOps
Configure the Region for the first stage.	Choose the first (primary) Region, the same Region where CodePipeline and CodeBuild are set up. This is the primary Region where you want to deploy the stack.	DevOps
Specify the input artifact.	Choose **BuildArtifact**. This is the output of the build phase.	DevOps
Specify the action to take.	For **Action mode**, choose **Create or update a stack**.	DevOps
Enter a name for the CloudFormation stack.		DevOps

Task	Description	Skills required
Specify the template for the first Region.	Select the Region-specific package name that was packaged by CodeBuild and dumped into the S3 bucket for the first (primary) Region.	DevOps
Specify the capabilities.	Capabilities are required if the stack template includes IAM resources or if you create a stack directly from a template that contains macros. For this pattern, use CAPABILITY_IAM, CAPABILITY_NAMED_IAM, CAPABILITY_AUTO_EXPAND.	DevOps

Deploy phase: Configure the pipeline for deployment to the second Region

Task	Description	Skills required
Add the second stage to the Deploy phase.	To add a stage for the second Region, edit the pipeline and choose **Add stage** in the Deploy phase. Important: The process of creating the second Region is the same as that of the first Region, except for the following values.	DevOps
Provide an action name for the second stage.	Enter a unique name that reflects the second stage and the second Region.	DevOps

Task	Description	Skills required
Configure the Region for the second stage.	Choose the second Region where you want to deploy the stack.	DevOps
Specify the template for the second Region.	Select the Region-specific package name that was packaged by CodeBuild and dumped into the S3 bucket for the second Region.	DevOps

Deploy phase: Configure the pipeline for deployment to the third Region

Task	Description	Skills required
Add the third stage to the Deploy phase.	To add a stage for the third Region, edit the pipeline and choose **Add stage** in the Deploy phase. Important : The process of creating the second Region is the same as that of the previous two Regions, except for the following values.	DevOps
Provide an action name for the third stage.	Enter a unique name that reflects the third stage and the third Region.	DevOps
Configure the Region for the third stage.	Choose the third Region where you want to deploy the stack.	DevOps
Specify the template for the third Region.	Select the Region-specific package name that was packaged by CodeBuild and	DevOps

Task	Description	Skills required
	dumped into the S3 bucket for the third Region.	

Clean up the deployment

Task	Description	Skills required
Delete the AWS resources.	To clean up the deploymen t, delete the CloudFormation stacks in each Region. Then delete the CodeCommit, CodeBuild, and CodePipeline resources from the primary Region.	DevOps

Deploy artifact updates to on-premises Amazon EC2 instances using AWS CodePipeline

Akash Kumar and Sandeep Reddy Jogammagari, Amazon Web Services

Summary

This pattern provides code samples and steps to create a pipeline in the Amazon Web Services (AWS) Cloud and deploy updated artifacts to on-premises Amazon Elastic Compute Cloud (Amazon EC2) instances in AWS CodePipeline. The pattern is based on the continuous integration practice. This practice automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, you create a project and configure your source code by using AWS CodeBuild. Finally, you create your application and configure its target environment for on-premises EC2 instances by using AWS CodeDeploy.

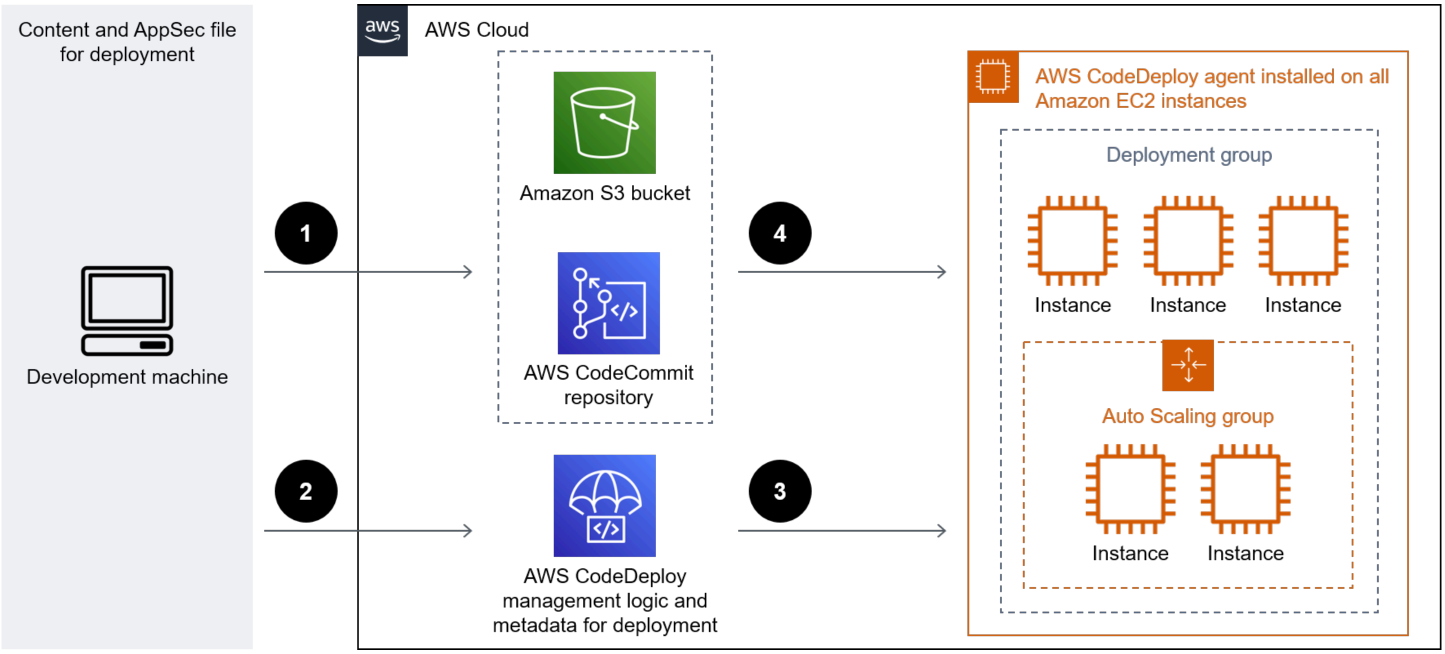
Prerequisites and limitations

Prerequisites

- An active AWS account
- User-defined tags to identify EC2 instances during deployment
- CodeDeploy agent, installed on EC2 instances
- Your required runtime software, installed on EC2 instances
- Amazon Corretto 8 for the Java Development Kit
- Apache Tomcat web server, installed
- Amazon CloudWatch Events (optional)
- A key pair to log in to the web server (optional)
- An Apache Maven application project for a web application

Architecture

The following diagram shows an example Java web application that's deployed to on-premises EC2 instances by using this pattern's architecture.



The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository.
2. CodePipeline uses CodeBuild to initiate the build and add new artifacts that are ready for deployment in the Amazon Simple Storage Service (Amazon S3) bucket.
3. CodePipeline uses the CodeDeploy agent to pre-install any dependencies required for the deployment artifact changes.
4. CodePipeline uses the CodeDeploy agent to deploy the artifacts from the S3 bucket to target EC2 instances. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.

Technology stack

- CodeBuild
- CodeCommit
- CodeDeploy
- CodePipeline
- CloudWatch Events (optional)

Tools

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodeDeploy automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

Code

This pattern includes the following attachments:

- `buildspec.yml` – This file specifies the actions that CodeBuild requires to build and create an artifact for deployment.
- `appspec.yml` – This file specifies the actions that CodeDeploy requires to create an application and configure a target environment for on-premises EC2 instances.
- `install_dependencies.sh` – This file installs dependencies for the Apache Tomcat web server.
- `start_server.sh` – This file starts the Apache Tomcat web server.
- `stop_server.sh` – This file stops the Apache Tomcat web server.

Epics

Set up the code repository

Task	Description	Skills required
Create the repository.	Create a CodeCommit repository.	AWS systems administrator

Task	Description	Skills required
Clone the repository.	Connect to the CodeCommit repository by cloning the repository.	App developer
Push the source code to the remote repository.	1. Create a commit to add the `buildspec.yml` and `appspec.yml` files to your local repository. 2. Push the commit from your local repository to the remote CodeCommit repository.	App developer

Create a CodeBuild project for the application

Task	Description	Skills required
Create a build project.	1. Sign in to the AWS Management Console, open the AWS CodeBuild console, and then choose **Create build project**. 2. For **Project name**, enter the name of your project. 3. For **Source provider**, choose **AWS CodeCommit**. 4. For **Repository**, choose the repository where you want to build the code pipeline. 5. For **Environment image**, choose **Managed image** or **Custom image**.	AWS administrator, App developer

Task	Description	Skills required
	6. For **Operating system**, choose **Amazon Linux 2**. **Note** Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs. 7. For **RunTime(s)**, choose **Standard**. 8. For **Image**, choose **aws/codebuild/amazonlinux2-aarch64-standard:2.0**. 9. For **Image version**, choose **Always use the latest image for this runtime version**. 10.For **Service role**, choose **New service role** or **Existing service role**. 11.For **Build specifications**, choose **Use a buildspec file** or **Insert build commands**. 12.(Optional) Choose **Add artifact to configure artifacts**. 13.(Optional) To upload build output logs to Amazon	

Task	Description	Skills required
	CloudWatch, choose **CloudWatch logs**. 14. Choose **Create build project**.	

Configure artifact deployment for on-premises EC2 instances

Task	Description	Skills required
Create the application.	1. Sign in to the AWS Management Console, open the [AWS CodeDeploy console](), and then choose **Create application**. 2. For **Application name**, enter a name for your application. 3. For **Compute platform**, choose **EC2/On-premises**. 4. Choose **Create application** and then choose **Create deployment group**. 5. For **Deployment group name**, enter a name. 6. **Note** Create a [service role]() for CodeDeploy. : The service role must have permissions to grant CodeDeploy access to your	AWS systems administrator, App developer

Task	Description	Skills required
	target environment. 7. For **Service role**, choose the service role that you created in step 6. 8. For **Deployment type**, choose either **In-place** or **Blue/green** based on your business requirements. 9. For **Environment configuration**, choose the options that meet your business requirements. 10. (Optional) [Create a target group]() for your load balancer separately in the Amazon EC2 console, and then go back to the **Create deployment group** page of the AWS CodeDeploy console to choose your load balancer and target group. 11. Choose **Create deployment group**.	

Set up the pipeline

Task	Description	Skills required
Create the pipeline.	1. Sign in to the AWS Management Console,	AWS systems administrator, App developer

Task	Description	Skills required
	open the [AWS CodePipeline console](), and then choose **Create pipeline**. 2. For **Pipeline name**, enter a name for the pipeline. 3. For **Service role**, choose **New service role** or **Existing service role**. 4. For **Role name**, enter a name for your role. 5. In the **Advanced settings** section, for **Artifact store**, choose **Default location** if you want Amazon S3 to create a bucket and store the artifacts in the bucket. To use an existing S3 bucket, choose **Custom location**. Choose **Next**. 6. For **Source provider**, choose **AWS CodeCommit**. 7. For **Repository name**, choose the repository that you cloned earlier. For **Branch name**, choose your source code branch. 8. For **Change detection options**, choose **Amazon CloudWatch Events (recommended)** or **AWS CodePipeline**. Choose **Next**.	

Task	Description	Skills required
	9. For **Build provider**, choose **AWS CodeBuild**. 10. For **Project Name**, choose the build project that you created in the *Create a CodeBuild project for the application* section of this pattern. 11. Choose your build options and then choose **Next**. 12. For **Deploy provider**, choose **AWS CodeDeploy**. 13. Choose an application name and deployment group, and then choose **Next**. 14. Choose **Create pipeline**.

Deploy workloads from Azure DevOps pipelines to private Amazon EKS clusters

Mahendra Revanasiddappa, Amazon Web Services

Summary

This pattern demonstrates how to implement continuous integration and continuous delivery (CI/CD) from Azure DevOps pipelines to private Amazon Elastic Kubernetes Service (Amazon EKS) clusters. It addresses a critical challenge faced by organizations that are enhancing their security posture by transitioning to private API server endpoints for their Amazon EKS clusters.

A public endpoint exposes the Kubernetes API server directly to the internet, creating a larger attack surface that malicious actors could potentially target. By switching to a private endpoint, access to the cluster's control plane is restricted to within the customer's virtual private cloud (VPC).

Although transitioning an Amazon EKS cluster to a private API endpoint significantly enhances security, it introduces connectivity challenges for external CI/CD platforms like Azure DevOps. The private endpoint is only accessible from within the cluster's VPC or peered networks. Therefore, standard Microsoft-hosted Azure DevOps agents, operating outside the AWS private network, can't reach the Kubernetes API server directly. This breaks typical deployment workflows that rely on tools like kubectl or Helm running on these agents because they fail to establish a connection to the cluster.

To overcome this problem, this pattern showcases an efficient approach by using self-hosted Azure DevOps agents within private Amazon EKS clusters. This solution offers superior cost optimization, operational efficiency, and scalability while preserving security requirements. This approach particularly benefits enterprises seeking to streamline their multi-cloud DevOps processes without compromising on performance or security.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2.13.17 or later, installed.
- kubectl version 1.25.1 or later, installed.

- A private Amazon EKS cluster version 1.24 or later created, with permissions to create namespaces, secrets, and deployments.
- Worker nodes in an Amazon EKS cluster with outbound connectivity to the internet so that the Azure DevOps agent running on them can connect to Azure DevOps agent pool.
- GitHub account created.
- An Azure DevOps project with access to configure service connections, which are authenticated connections between Azure Pipelines and external or remote services, created.
- The AWS Toolkit for Azure DevOps version 1.15 or later installed for the Azure DevOps project described in the previous point. For installation instructions, see AWS Toolkit for Azure DevOps in Visual Studio Marketplace.

Limitations

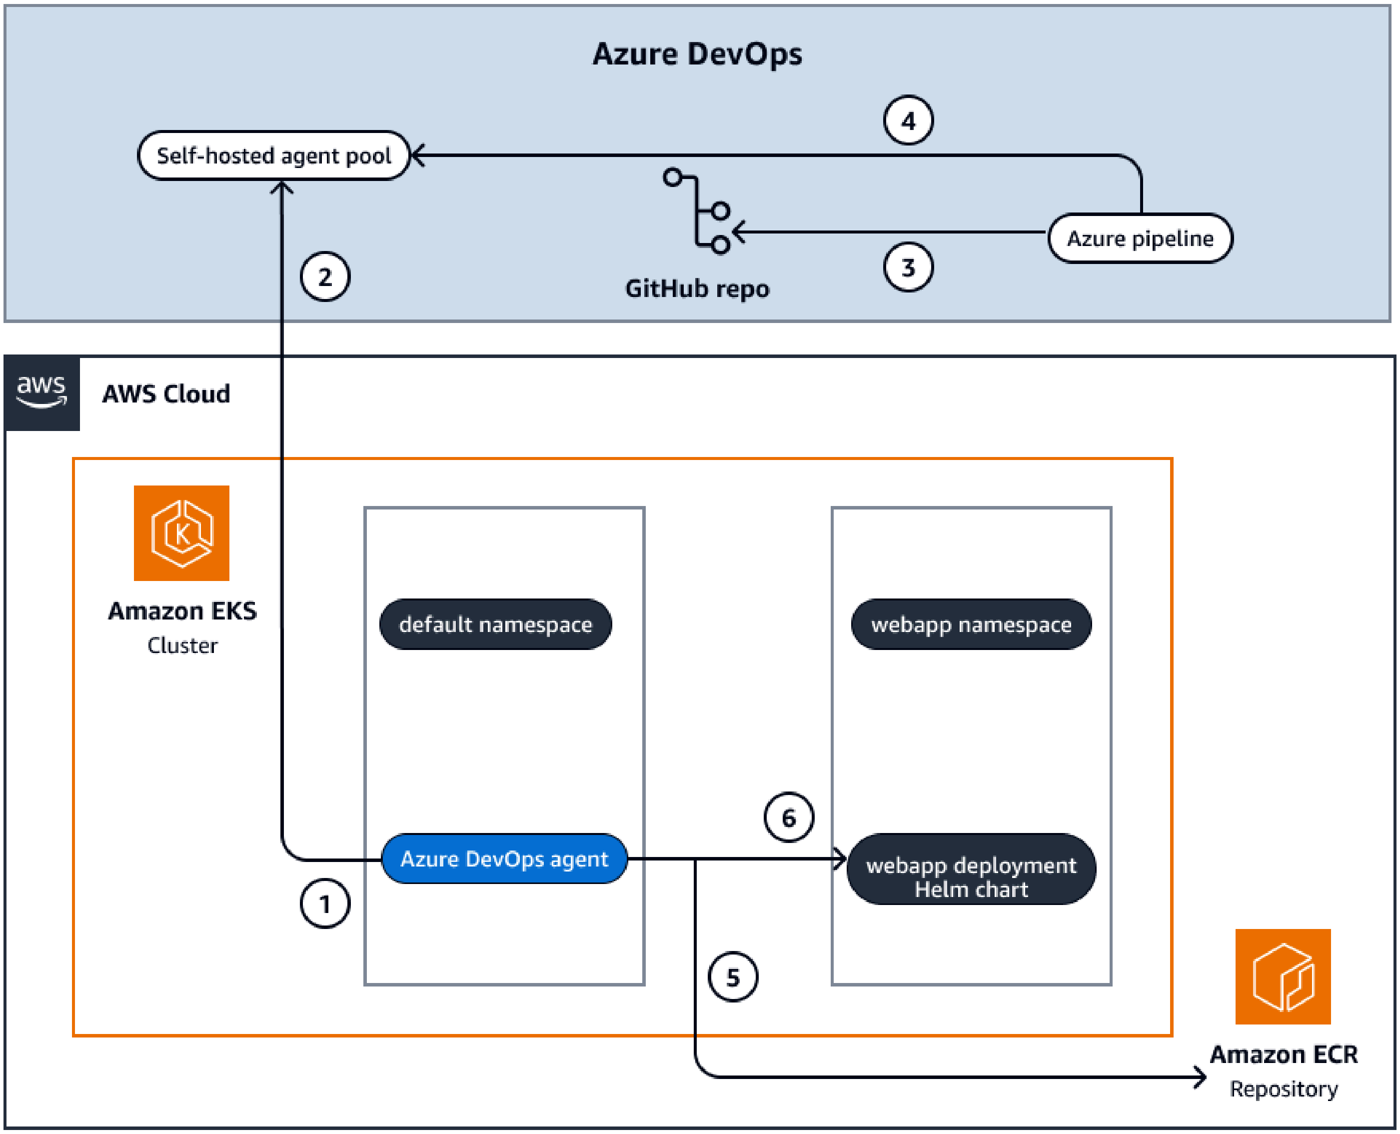
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

This pattern creates the following:

- **Amazon ECR repository** - The Amazon Elastic Container Registry (Amazon ECR) repository stores the Docker image with the Azure DevOps agent and the sample app that is deployed.
- **Azure DevOps agent pool** - An Azure DevOps self-hosted agent pool registers the agent running on the private Amazon EKS cluster.
- **IAM role** - An AWS Identity and Access Management (IAM) role for the Azure service connection to provide required access to the agent that's running on a private Amazon EKS cluster.
- **Azure DevOps service connection** - A service connection in an Azure DevOps account to use the IAM role that provides the required access for the pipeline jobs to access AWS services.

The following diagram shows the architecture of deploying a self-hosted Azure DevOps agent on a private Amazon EKS cluster and deploying a sample application on the same cluster.



The diagram shows the following workflow:

1. Deploy a self-hosted Azure DevOps agent as a deployment inside an Amazon EKS cluster.
2. An Azure DevOps agent connects to the agent pool on an Azure DevOps account using a personal access token (PAT) for authentication.
3. Azure Pipelines configures a pipeline to deploy by using code from a GitHub repository.
4. The pipeline runs on the agent from the agent pool that was configured in the pipeline configuration. The Azure DevOps agent gets the job information of the pipeline by constantly polling to the Azure DevOps account.
5. The Azure DevOps agent builds a Docker image as part of the pipeline job and pushes the image to the Amazon ECR repository.

6. The Azure DevOps agent deploys the sample application on a private Amazon EKS cluster in a namespace called `webapp`.

Tools

Tools

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- kubectl is a command-line interface that helps you run commands against Kubernetes clusters.

Code repository

- The code for this pattern is available in the GitHub deploy-kubernetes-resources-to-amazon-eks-using-azure-devops repository.

Best practices

- For Amazon EKS, see the Amazon EKS Best Practices Guide.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Epics

Create a service connection

Task	Description	Skills required
Find the Azure DevOps organization GUID.	Sign in to your Azure DevOps account, and then use the following URL to find the organization GUID: `https://dev.azure.com/{DevOps_Org_ID}/_apis/projectCollections?api-version=6.0` In the URL, replace `{DevOps_org_ID}` with your Azure DevOps organization ID.	AWS DevOps
Configure an IdP in the AWS account.	To configure an Identity provider (IdP) in the AWS account for an Azure service connection, use the following steps: 1. Sign in to the AWS Management Console, and open the IAM console at https://console.aws.amazon.com/iam/. 2. In the left pane, choose **Identity providers**. 3. Choose **Add Provider**. 4. Choose **OpenID Connect** as the **Provider type**. 5. For **Provider URL**, enter the Azure DevOps issuer URL. Each tenant of Azure	AWS DevOps

Task	Description	Skills required
	DevOps has a unique `OrganizationGUID` that typically uses the following format: `https://vstoken.dev.azure.com/{OrganizationGUID}` Replace `{OrganizationGUID}` with your Azure DevOps organization ID. 6. For **Audience**, enter **api://AzureADTokenExchange**. This is a fixed value for Azure DevOps. 7. Choose **Add Provider**. 8. Take note of the ARN of the newly created provider for your use in the next task. For more details, see [How to federate into AWS from Azure DevOps using OpenID Connect]().	

Task	Description	Skills required

Create an IAM policy in the AWS account.	To create an IAM policy to provide the required permissions to the IAM role used by the Azure DevOps pipeline, use the following steps:
	
	1. In the IAM console, in the left pane, choose **Policies**.
	2. Choose **Create Policy**.
	3. For **Specify Permissions**, in **Policy editor**, select **JSON**. Replace the default JSON policy with the following JSON:
	
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Sid": "Statement1",`
	`            "Effect": "Allow",`
	`            "Action": [`
	`                "ecr:*",`
	`                "eks:DescribeCluster",`
	`                "eks:ListClusters"`
	`            ],`
	`            "Resource": "*"`
		AWS DevOps

Task	Description	Skills required

	``
	        }
	    ]
	}
	``
	4. Choose **Next.**
	5. For **Policy name**, enter a name for the IAM policy. This pattern uses the name **ADO-policy**.
	6. Choose **Create policy**.	

Task	Description	Skills required
Create an IAM role in the AWS account.	To configure an IAM role in the AWS account for the Azure service connection, use the following steps: 1. In the IAM console, in the left pane, choose **Roles**. 2. Choose **Create role**. 3. For **Trusted entity type**, select **Web Identity**. 4. Select the correct IdP from the dropdown list. The IdP name starts with `vstoken.dev.azure.com/{OrganizationGUID}` . 5. In the **Audience** dropdown list, select **api://AzureADTokenExchange**. 6. To limit this role to only one service connection, add a condition. Under **Condition**, select **Add condition**, and for **Key**, select **vstoken.dev.azure.com/{OrganizationGUID}:sub**. In **Condition**, select **StringEquals**. For **Value**, use the following format: `sc://{OrganizationName}/{ProjectName}/{ServiceConnectionName}` . For `ServiceCo`	AWS DevOps

Task	Description	Skills required

	nnectionName , use **aws-sc.** You will create this service connection in the next task.
	7. Choose **Next**.
	8. For **Add permissions**, select **ADO-policy**, which is the policy that you created in a previous task.
	9. Choose **Next**, and for **Role name**, enter **ado-role**. For **Select Trusted Entities**, use the following trust policy:
	`{`
	`  "Version": "2012-10-17",`
	`  "Statement": [`
	`    {`
	`      "Effect": "Allow",`
	`      "Principal": {`
	`        "Federated": "arn:aws:iam::{account_id}:oidc-provider/vstoken.dev.azure.com/{OrganizationGUID}"`
	`      },`
	`      "Action": "sts:AssumeRoleWithWebIdentity",`
	`      "Condition": {`
	`        "StringEquals": {`
	`          "vstoken.dev.azure.com/{Org`	

Task	Description	Skills required

	``
	anizationGUID}:aud
	": "api://AzureADToke
	nExchange",
	          "vstoken.
	dev.azure.com/{Org
	anizationGUID}:sub
	": "sc://{Organizatio
	nName}/{ProjectNam
	e}/{ServiceConnect
	ionName}"
	        }
	      }
	    }
	  ]
	}
	``
	
	In the policy, provide your information for the following placeholders:
	
	• `{account_id}` - AWS account ID
	• `{OrganizationGUID}` - Azure DevOps Organization GUID
	• `{OrganizationName}` - Azure DevOps Organization name
	• `{ProjectName}` - Azure DevOps project name
	• `{ServiceConnectionName}` - Azure DevOps service connection name. Use **aws-sc.** You will create this service connection in the next task.	

Task	Description	Skills required
Create a service connection in the Azure DevOps account.	To configure an Azure service connection, use the following steps: 1. In your Azure DevOps project, select **Project settings**, **Service connections**. 2. Choose **New service connection**, select the type of service connection as `aws`, and then select **Next**. 3. For **Role to Assume**, enter the arn for the IAM role **ado-role.** You created **ado-role** in the previous task *Create an IAM role in the AWS account*. 4. Select the **Use OIDC** checkbox. 5. For **Service connection name**, enter **aws-sc** in task properties. 6. Choose **Save**. For more details, see [Create a service connection](#) in the Microsoft documentation.	AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add IAM role to Amazon EKS configuration file.</td><td>The IAM role must have the necessary permissions to perform the required operations on the Amazon EKS cluster. Because it's a pipeline role, the IAM role must be able to manage almost all types of resources on the cluster. Therefore, the <code>system:masters</code> group permission is appropriate for this role.

To add the required configuration to the <code>aws-auth ConfigMap</code> within Kubernetes, use the following code:

<pre>- groups:
  - system:masters
  rolearn: arn:aws:iam::{account_id}:role/ADO-role
  username: ADO-role</pre>
Replace <code>{account_id}</code> with your AWS account ID.

For more information, see How Amazon EKS works with IAM in the Amazon EKS documentation.</td><td>AWS DevOps</td></tr>
</table>

Create an agent pool

Task	Description	Skills required
Create a self-hosted agent pool.	To configure a self-hosted agent pool in the Azure DevOps account, use the following steps: 1. Sign in to your Azure DevOps account organization. 2. Choose **Azure DevOps Organization**. 3. Choose your Azure DevOps project. 4. Choose **Project settings**. 5. Choose **Agent pools**. 6. Choose **Add pool**. 7. Select **Self-hosted**. 8. For **Name**, enter **eks-agent**. 9. Select the **Grant access permission to all pipelines** checkbox. 10. Choose **Create**. For more details, see [Create and manage agent pools] in the Microsoft documentation.	

Build Azure DevOps agent image and push to Amazon ECR

Task	Description	Skills required
Create an Amazon ECR repository.	The Docker images that are used to deploy the Azure DevOps agent and sample application (`webapp`) on the private Amazon EKS cluster must be stored in an Amazon ECR repository. To create an Amazon ECR repository, use the following steps: 1. Open the Amazon ECR console at https://console.aws.amazon.com/ecr/repositories. 2. From the navigation bar, choose the **AWS Region** to create your repository in. 3. On the **Repositories** page, choose **Private repositories**, and then choose **Create repository**. 4. For **Repository name**, enter **webapp**. For the sample application in this pattern to work, the Amazon ECR repository name must use **webapp**. If you use a different name for the repository, see [Troubleshooting](#).	AWS DevOps

Task	Description	Skills required
	For more details, see Creating an Amazon ECR private repository to store images in the Amazon ECR documentation.	

Task	Description	Skills required

Create a Dockerfile to build the Azure DevOps agent.	Create a Dockerfile to build the Docker image that has the Azure DevOps agent installed. Store the following content in a file named `Dockerfile` :
	
	`FROM ubuntu:22.04`
	`ENV TARGETARCH="linux-x64"`
	`RUN apt update && apt upgrade -y && apt install -y curl git jq libicu70 unzip wget`
	
	`RUN curl "https://awscli.amazonaws.com/awscli-exe-linux-x86_64.zip" -o "awscliv2.zip"`
	`RUN unzip awscliv2.zip`
	`RUN ./aws/install`
	`RUN rm -rf aws awscliv2.zip`
	
	`RUN curl -sSL https://get.docker.com/ | sh`
	
	`RUN curl -sL https://aka.ms/InstallAzureCLIDeb | bash`
	`RUN mkdir -p azp`
	`WORKDIR /azp/`
	
	`COPY ./start.sh ./`
	`RUN chmod +x ./start.sh`
	
	`RUN useradd -m -d /home/agent agent`
		AWS DevOps

Task	Description	Skills required

	`RUN chown -R agent:agent /azp /home/agent`
	`RUN groupadd -f docker`
	`RUN usermod -aG docker agent`
	`USER agent`
	
	`ENTRYPOINT [ "./start.sh" ]`	

Create script for the Azure DevOps agent.	To create the `start.sh` script, use the following steps: 1. Go to the procedure [Create and build the Dockerfile](#) in the Microsoft documentation, and scroll to **step 5. Save the following content to** `~/azp-agent-in-docker/start.sh` **, making sure to use Unix-style (LF) line endings**. 2. Copy the script's content, and save it in a file named `start.sh` in the same directory as the Dockerfile.	AWS DevOps

Task	Description	Skills required

Build a Docker image with the Azure DevOps agent.	To create a Docker image to install the Azure DevOps agent, use the Dockerfile that you created earlier to build the image. In the same directory where the Dockerfile is stored, run the following commands:
	`aws ecr get-login-password --region region | docker login --username AWS --password-stdin aws_account_id.dkr.ecr.region.amazonaws.com`
	
	`docker build --platform linux/amd64 -t ado-agent:latest .`
	
	`docker tag ado-agent:latest aws_account_id.dkr.ecr.region.amazonaws.com/webapp:latest`
	
	`docker push aws_account_id.dkr.ecr.region.amazonaws.com/webapp:latest`
	
	Replace `aws_account_id` and `region` with your AWS account ID and AWS Region.
		AWS DevOps

Deploy the Azure DevOps agent to a private Amazon EKS cluster

Task	Description	Skills required
Generate an Azure personal access token.	The agent running on the private Amazon EKS cluster requires a personal access token (PAT) so that it can authenticate with the Azure DevOps account. To generate a PAT, use the following steps: 1. Sign in with the user account you plan to use in your Azure DevOps organization (`https://dev.azure.com/{Your_Organization}`). 1. From your home page, open your user settings, and then select **Personal access tokens**. 2. Choose **New Token.** 3. Enter the **Name** for the token. 4. Choose **Show all scopes.** 5. For **Agent Pools**, select the **Read & manage** checkbox. 6. Choose **Create.** 7. To create a secret on the private Amazon EKS cluster, use the following configuration:	AWS DevOps

Task	Description	Skills required

	<pre>apiVersion: v1
	kind: Secret
	metadata:
	  name: azdevops-pat
	  namespace: default
	type: Opaque
	stringData:
	  AZP_TOKEN: <PAT
	 Token></pre> 1. Store the configuration in a file named `ado-secret.yaml` . Replace `<PAT Token>` with the personal access token that you just created. To create the secret, run the following command: <pre>kubectl create -f ado-
	secret.yaml</pre> For more details, see Register an agent using a personal access token (PAT) in the Microsoft documentation.	

Task	Description	Skills required

Use the Kubernetes manifest file for agent deployment.	To deploy the Azure DevOps agent on the private Amazon EKS cluster, copy the following manifest file and store the file as `agent-deployment.yaml` :
	``apiVersion: apps/v1
	kind: Deployment
	metadata:
	  name: azure-pipelines-agent-eks
	  labels:
	    app: azure-pipelines-agent
	spec:
	  replicas: 1
	  selector:
	    matchLabels:
	      app: azure-pipelines-agent
	  template:
	    metadata:
	      labels:
	        app: azure-pipelines-agent
	    spec:
	      containers:
	      - name: docker
	        image: docker:dind
	        securityContext:
	          privileged: true
	        volumeMounts:
	        - name: shared-workspace
	          mountPath: /workspace```
		AWS DevOps

Task	Description	Skills required

	``
	        - name: dind-
	storage
	          mountPath: /
	var/lib/docker
	        env:
	        - name:
	 DOCKER_TLS_CERTDIR
	          value: ""
	      - name: azure-pip
	elines-agent
	        image: aws_accou
	nt_id.dkr.ecr.regi
	on.amazonaws.com/w
	ebapp:latest
	        env:
	        - name: AZP_URL
	          value: "<Azure
	 account URL>"
	        - name: AZP_POOL
	          value: "eks-
	agent"
	        - name:
	 AZP_TOKEN
	          valueFrom:
	            secretKey
	Ref:
	              name:
	 azdevops-pat
	              key:
	 AZP_TOKEN
	        - name:
	 AZP_AGENT_NAME
	          valueFrom:
	            fieldRef:
	              fieldPath
	: metadata.name
	        - name:
	 DOCKER_HOST
	          value: tcp://
	localhost:2375
	        volumeMounts:
	``	

Task	Description	Skills required

	``
	        - mountPath: /
	workspace
	          name: shared-
	workspace
	      volumes:
	      - name: dind-stor
	age
	        emptyDir: {}
	      - name: shared-wo
	rkspace
	        emptyDir: {}
	``
	Replace `aws_account_id` and `<Azure account URL>` with your AWS account ID and Azure DevOps account URL.	

Deploy the agent on the private Amazon EKS cluster.	To deploy the Azure Devops agent on the private Amazon EKS cluster, use the following command: ``` kubectl create -f agent- deployment.tf ```	AWS DevOps

Task	Description	Skills required

Verify the agent is running.	To verify that the Azure DevOps agent is running, use the following command:
	`kubectl get deploy azure-pipelines-agent-eks`
	The expected output should be similar to the following:
	`NAME READY UP-TO-DATE AVAILABLE AGE`
	`azure-pipelines-agent-eks 1/1 1 1 58s`
	Make sure that the READY column shows 1/1.
		AWS DevOps

Task	Description	Skills required
Verify the agent is registered with the Azure DevOps agent pool.	To verify that the agent is deployed on the private Amazon EKS cluster and is registered with the agent pool `eks-agent`, use the following steps: 1. Sign in to your Azure DevOps organization (`https://dev.azure.com/{Your_Organization}`). 2. Choose **Project settings**. 3. Choose **Agent pools**. 4. Select the **eks-agent** pool, and then check the **Agents** tab. You should see one agent listed with a **Status** of **Online**, and the name of the agent should start with **azure-pipelines-agent-eks-***.	AWS DevOps

Deploy sample application

Task	Description	Skills required
Fork the sample application repository to your GitHub account.	Fork the following AWS Samples repository to your GitHub account: https://github.com/aws-samples/deploy-kubernetes-re	AWS DevOps

Task	Description	Skills required
	sources-to-amazon-eks-using-azure-devops	

Task	Description	Skills required
Create a pipeline.	To create a pipeline in your Azure DevOps account, use the following steps: 1. Sign in with the user account you plan to use in your Azure DevOps organization (`https://dev.azure.com/{Your_Organization}`). 2. Navigate to your project and pipelines console. 3. Choose **New Pipeline.** 4. For **Where is your code**, choose **GitHub.** 5. Provide the credentials required for the pipeline to connect to your GitHub account 6. Select the repository **deploy-kubernetes-resources-to-amazon-eks-using-azure-devops**. 7. For **Configure your pipeline,** select **Existing Azure Pipelines YAML file**. 8. For **Select an existing YAML file,** select **main** for **Branch** and **azure_pipelines.yaml** for **path**. 9. Choose **Continue**. 10For **Review your pipeline YAML**, replace the	AWS DevOps

Task	Description	Skills required

	input parameter values for `awsRegion` and `awsEKSClusterName` with your information:
	
	`pool:`
	`  name: eks-agent`
	`#pool: self-hosted # If you are running self-hosted Azure DevOps Agents`
	
	`stages:`
	`# Refering the pipeline template, input parameter that are not specified will be added with defaults`
	`- template: ./pipeline_templates/main_template.yaml`
	`  parameters:`
	`    serviceConnectionName: aws-sc`
	`    awsRegion: <your region>`
	`    awsEKSClusterName: <name of your EKS cluster>`
	`    projectName: webapp`
	
	1. Choose **RUN**.	

Task	Description	Skills required
Verify that the sample application deployed.	After the pipeline completes , verify the successful deployment of the sample application by checking both the Amazon ECR repository and the Amazon EKS cluster. To verify artifacts in the Amazon ECR repository, use the following steps: 1. Navigate to the webapp Amazon ECR repository. 2. Confirm the presence of the following new artifacts: • Docker image – <date>.<build_number>-image • Helm chart – <date>.<build_number>-helm For example, 20250501.1-image and 20250501.1-helm. To verify deployment on the private Amazon EKS cluster in the namespace webapp, use the following command: kubectl get deploy -n webapp	AWS DevOps

Task	Description	Skills required

	The expected output is as follows:
	`NAME      READY   UP-TO-DATE   AVAILABLE`
	`webapp   1/1     1            1`
	Note: If this is your first pipeline run, you might need to authorize the service connection and agent pool. Look for permission requests in the Azure DevOps pipeline interface, and approve them to proceed.	

Troubleshooting

Issue	Solution
Pipeline fails when Amazon ECR repository name doesn't match `webapp`	The sample application expects the Amazon ECR repository name to match the `projectName: webapp` parameter in `azure_pipeline.yml` . To resolve this issue, rename your Amazon ECR repository to `webapp`, or update the following: • Rename the `webapp` directory in your forked GitHub repository to match your Amazon ECR repository name.

Issue	Solution
	• Update the `projectName` parameter in `azure_pipeline.yml` to match your Amazon ECR repository name.
Error: Kubernetes cluster unreachable: the server has asked for the client to provide credentials	If you encounter this error in the "Pull and Deploy Helm Chart" step in your Azure pipeline, the root cause typically stems from an incorrect IAM role configuration in your Amazon EKS cluster's `aws-auth ConfigMap` . To resolve this issue, check the following: • Verify your `aws-auth ConfigMap` configuration. • Check your Amazon EKS cluster's authentic ation settings: Open the Amazon EKS console, **Cluster details**, **Access configura tion**. Make sure that **Authentication mode** is set to **EKS API and ConfigMap** (not just **EKS API**).

Execute Amazon Redshift SQL queries by using Terraform

Sylvia Qi and Aditya Ambati, Amazon Web Services

Summary

Using infrastructure as code (IaC) for the deployment and management of Amazon Redshift is a prevalent practice within DevOps. IaC facilitates the deployment and configuration of various Amazon Redshift resources, such as clusters, snapshots, and parameter groups. However, IaC doesn't extend to the management of database resources like tables, schemas, views, and stored procedures. These database elements are managed through SQL queries and are not directly supported by IaC tools. Although solutions and tools exist for managing these resources, you might prefer not to introduce additional tools into your technology stack.

This pattern outlines a methodology that uses Terraform to deploy Amazon Redshift database resources, including tables, schemas, views, and stored procedures. The pattern distinguishes between two types of SQL queries:

- **Nonrepeatable queries –** These queries are executed once during the initial Amazon Redshift deployment to establish the essential database components.
- **Repeatable queries –** These queries are immutable and can be rerun without impacting the database. The solution uses Terraform to monitor changes in repeatable queries and apply them accordingly.

For more details, see *Solution walkthrough* in Additional information.

Prerequisites and limitations

Prerequisites

You must have an active AWS account and install the following on your deployment machine:

- AWS Command Line Interface (AWS CLI)
- An AWS CLI profile configured with Amazon Redshift read/write permissions
- Terraform version 1.6.2 or later
- Python3
- Boto3

Limitations

- This solution supports a single Amazon Redshift database because Terraform only allows for the creation of one database during cluster creation.
- This pattern doesn't include tests to validate changes to the repeatable queries before applying them. We recommend that you incorporate such tests for enhanced reliability.
- To illustrate the solution, this pattern provides a sample `redshift.tf` file that uses a local Terraform state file. However, for production environments, we strongly recommend that you employ a remote state file with a locking mechanism for enhanced stability and collaboration.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

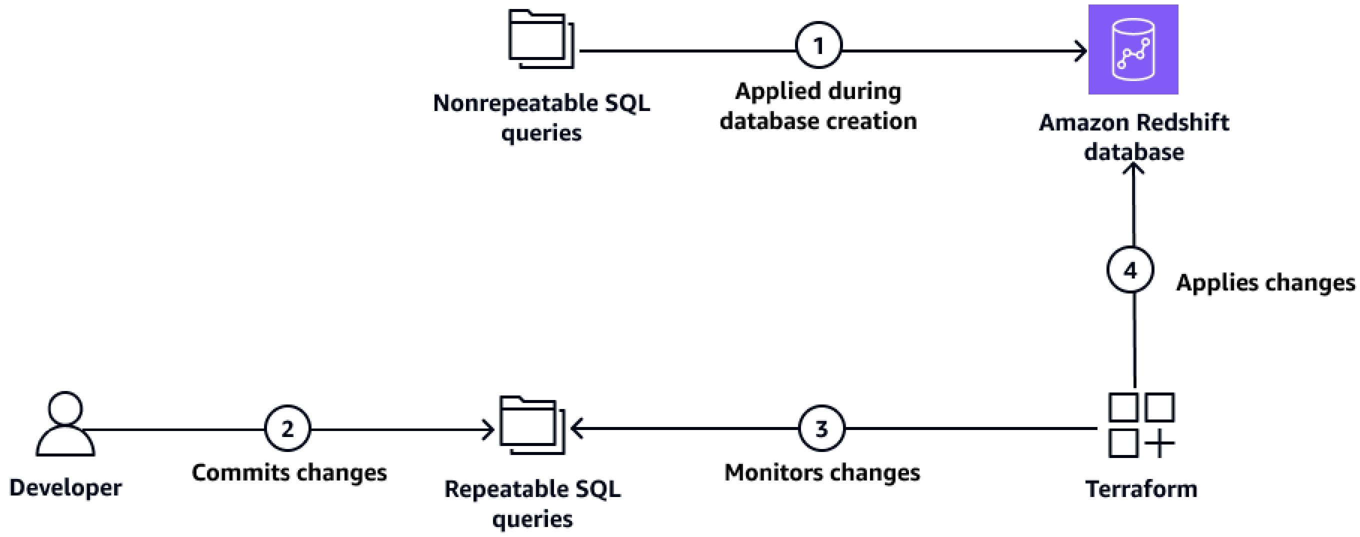
This solution is developed and tested on Amazon Redshift patch 179.

Code repository

The code for this pattern is available in the GitHub amazon-redshift-sql-deploy-terraform repository.

Architecture

The following diagram illustrates how Terraform manages the Amazon Redshift database resources by handling both nonrepeatable and repeatable SQL queries.



The diagram shows the following steps:

1. Terraform applies nonrepeatable SQL queries during the initial Amazon Redshift cluster deployment.
2. The developer commits changes to the repeatable SQL queries.
3. Terraform monitors changes in the repeatable SQL queries.
4. Terraform applies repeatable SQL queries to the Amazon Redshift database.

The solution provided by this pattern is built based on the Terraform module for Amazon Redshift. The Terraform module provisions an Amazon Redshift cluster and database. To enhance the module, we used `terraform_data` resources, which invokes a custom Python script to execute SQL queries using the Amazon Redshift ExecuteStatement API operation. As a result, the module can do the following:

- Deploy any number of database resources by using SQL queries after the database is provisioned.
- Monitor continuously for changes in the repeatable SQL queries and apply those changes using Terraform.

For more details, see *Solution walkthrough* in Additional information.

Tools

AWS services

- Amazon Redshift is a fully managed petabyte-scale data warehouse service in the AWS Cloud.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.
- Python is a general-purpose programming language that's used in this pattern to execute SQL queries.

Best practices

- Amazon Redshift best practices
- Using the Amazon Redshift Data API to interact with Amazon Redshift clusters

Epics

Deploy the solution using Terraform

Task	Description	Skills required
Clone the repository.	To clone the Git repository containing the Terraform code for provisioning an Amazon Redshift cluster, use the following command. `git clone https://github.com/aws-samples/amazon-redshift-sql-deploy-terraform.git`	DevOps engineer
Update the Terraform variables.	To customize the Amazon Redshift cluster deployment according to your specific requirements, update the	DevOps engineer

Task	Description	Skills required

	following parameters in the `terraform.tfvars` file.
	``
	region
	  = "<AWS_REGION>"
	cluster_identifier
	        = "<REDSHIF
	T_CLUSTER_IDENTIFI
	ER>"
	node_type
	   = "<REDSHIFT_NODE_TY
	PE>"
	number_of_nodes
	         = "<REDSHIF
	T_NODE_COUNT>"
	database_name
	         = "<REDSHIF
	T_DB_NAME>"
	subnet_ids
	   = "<REDSHIFT_SUBNET_
	IDS>"
	vpc_security_group_id
	s = "<REDSHIF
	T_SECURITY_GROUP_I
	DS>"
	run_nonrepeatable_quer
	ies = true
	run_repeatable_queries
	    = true
	sql_path_bootstrap
	        = "<BOOTSTR
	AP_SQLS_PATH>"
	sql_path_nonrepeatabl
	e = "<NON-REP
	EATABLE_SQLS_PATH>"
	sql_path_repeatable
	       = "<REPEATA
	BLE_SQLS_PATH>"
	sql_path_finalize
	         = "<FINALIZ
	E_SQLS_PATH>"
	``	

Task	Description	Skills required

	<pre>create_random_password
	    = false
	master_username
	         = "<REDSHIF
	T_MASTER_USERNAME>"</pre>	

Deploy the resources using Terraform.	1. To prepare for the deployment process, use the following command to initialize Terraform within the cloned repository.
	<pre>terraform init</pre>2. To preview the changes that Terraform will apply to the infrastructure, use the following command to create an execution plan.
	<pre>terraform plan -var-
	file terraform.tfvars</pre>3. To provision the Amazon Redshift cluster and associated resources, use the following command to apply the Terraform execution plan.
	<pre>terraform apply -var-
	file terraform.tfvars</pre>
		DevOps engineer

Task	Description	Skills required

(Optional) Execute additional SQL queries.	The sample repository provides several SQL queries for demo purposes. To execute your own SQL queries, add them to the following folders:
	
	`/bootstrap`
	
	`/nonrepeatable`
	
	`/repeatable`
	
	`/finalize`	

Monitor the execution of SQL statements

Task	Description	Skills required
Monitor the deployment of SQL statements.	You can monitor the results of the SQL executions to an Amazon Redshift cluster. For examples of output that show a failed and a successfu l SQL execution, see *Example SQL statements* in Additional information.	DBA, DevOps engineer
Clean up resources.	To delete all the resources deployed by Terraform, run the following command. `terraform destroy`	DevOps engineer

Validate the results

Task	Description	Skills required
Validate the data in the Amazon Redshift cluster.	1. Sign in to the AWS Management Console, and open the Amazon Redshift console. 2. On the navigation menu, choose **Clusters**. Choose the relevant cluster name in the list. 3. Follow the instructions in [Querying a database using the Amazon Redshift query editor v2](#) in the Amazon Redshift documentation.	DBA, AWS DevOps

Additional information

Solution walkthrough

To use the solution, you must organize your Amazon Redshift SQL queries in a specific way. All SQL queries must be stored in files with a `.sql` extension.

In the code example provided with this pattern, the SQL queries are organized in the following folder structure. You can modify the code (`sql-queries.tf` and `sql-queries.py`) to work with any structure that fits your unique use case.

```
/bootstrap
     |- Any # of files
     |- Any # of sub-folders
/nonrepeatable
     |- Any # of files
     |- Any # of sub-folders
/repeatable
     /udf
          |- Any # of files
          |- Any # of sub-folders
     /table
          |- Any # of files
          |- Any # of sub-folders
     /view
          |- Any # of files
          |- Any # of sub-folders
     /stored-procedure
          |- Any # of files
          |- Any # of sub-folders
/finalize
     |- Any # of files
     |- Any # of sub-folders
```

Given the preceding folder structure, during Amazon Redshift cluster deployment, Terraform executes the queries in the following order:

1. `/bootstrap`
2. `/nonrepeatable`
3. `/repeatable`
4. `/finalize`

The `/repeatable` folder contains four subfolders: `/udf`, `/table`, `/view`, and `/stored-procedure`. These subfolders indicate the order in which Terraform executes the SQL queries.

The Python script that executes the SQL queries is `sql-queries.py`. First, the script reads all the files and subfolders of a specific source directory, for example, the `sql_path_bootstrap` parameter. Then the script executes the queries by calling the Amazon Redshift ExecuteStatement API operation. You might have one or more SQL queries in a file. The following code snippet shows the Python function that executes SQL statements stored in a file against an Amazon Redshift cluster.

```
def execute_sql_statement(filename, cluster_id, db_name, secret_arn, aws_region):
    """Execute SQL statements in a file"""
    redshift_client = boto3.client(
        'redshift-data', region_name=aws_region)
    contents = get_contents_from_file(filename),
    response = redshift_client.execute_statement(
        Sql=contents[0],
        ClusterIdentifier=cluster_id,
        Database=db_name,
        WithEvent=True,
        StatementName=filename,
        SecretArn=secret_arn
    )
    ...
```

The Terraform script `sql-queries.tf` creates the terraform_data resources that invoke the `sql-queries.py` script. There is a `terraform_data` resource for each of the four folders: `/bootstrap`, `/nonrepeatable`, `/repeatable`, and `/finalize`. The following code snippet shows the `terraform_data` resource that execute the SQL queries in the `/bootstrap` folder.

```
locals {
  program               = "${path.module}/sql-queries.py"
  redshift_cluster_name = try(aws_redshift_cluster.this[0].id, null)
}

resource "terraform_data" "run_bootstrap_queries" {
  count      = var.create && var.run_nonrepeatable_queries && (var.sql_path_bootstrap !
= "") && (var.snapshot_identifier == null) ? 1 : 0
  depends_on = [aws_redshift_cluster.this[0]]

  provisioner "local-exec" {
    command = "python3 ${local.program} ${var.sql_path_bootstrap}
 ${local.redshift_cluster_name} ${var.database_name} ${var.redshift_secret_arn}
 ${local.aws_region}"
  }
}
```

You can control whether to run these queries by using the following variables. If you don't want to run queries in `sql_path_bootstrap`, `sql_path_nonrepeatable`, `sql_path_repeatable`, or `sql_path_finalize`, set their values to `""`.

```
run_nonrepeatable_queries = true
run_repeatable_queries    = true
sql_path_bootstrap        = "src/redshift/bootstrap"
sql_path_nonrepeatable    = "src/redshift/nonrepeatable"
sql_path_repeatable       = "src/redshift/repeatable"
sql_path_finalize         = "src/redshift/finalize"
```

When you run `terraform apply`, Terraform considers the `terraform_data` resource added after the script is completed, regardless of the results of the script. If some SQL queries failed, and you want to rerun them, you can manually remove the resource from the Terraform state, and run `terraform apply` again. For example, the following command removes the `run_bootstrap_queries` resource from the Terraform state.

```
terraform state rm module.redshift.terraform_data.run_bootstrap_queries[0]
```

The following code example shows how the `run_repeatable_queries` resource monitors changes in the `repeatable` folder by using the [sha256 hash](). If any file within the folder is updated, Terraform marks the entire directory for an update. Then, Terraform runs the queries in the directory again during the next `terraform apply`.

```
resource "terraform_data" "run_repeatable_queries" {
  count      = var.create_redshift && var.run_repeatable_queries &&
 (var.sql_path_repeatable != "") ? 1 : 0
  depends_on = [terraform_data.run_nonrepeatable_queries]

  # Continuously monitor and apply changes in the repeatable folder
  triggers_replace = {
    dir_sha256 = sha256(join("", [for f in fileset("${var.sql_path_repeatable}",
 "**") : filesha256("${var.sql_path_repeatable}/${f}")]))
  }

  provisioner "local-exec" {
    command = "python3 ${local.sql_queries} ${var.sql_path_repeatable}
 ${local.redshift_cluster_name} ${var.database_name} ${var.redshift_secret_arn}"
  }
}
```

To refine the code, you can implement a mechanism to detect and apply changes only to the files that have been updated within the `repeatable` folder, rather than applying changes to all files indiscriminately.

Example SQL statements

The following output shows a failed SQL execution, along with an error message.

```
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec): Executing:
 ["/bin/sh" "-c" "python3 modules/redshift/sql-queries.py src/redshift/nonrepeatable
 testcluster-1 db1 arn:aws:secretsmanager:us-east-1:XXXXXXXXXXXX:secret:/redshift/
master_user/password-8RapGH us-east-1"]
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec):
 -------------------------------------------------------------------
module.redshift.terraform_data.run_nonrepeatable_queries[0] (local-exec): src/redshift/

Export AWS Backup reports from across an organization in AWS Organizations as a CSV file

Aromal Raj Jayarajan and Purushotham G K, Amazon Web Services

Summary

This pattern shows how to export AWS Backup job reports from across an organization in AWS Organizations as a CSV file. The solution uses AWS Lambda and Amazon EventBridge to categorize AWS Backup job reports based on their status, which can help when configuring status-based automations.

AWS Backup helps organizations centrally manage and automate data protection across AWS services, in the cloud, and on premises. However, for AWS Backup jobs configured within AWS Organizations, consolidated reporting is available only in the AWS Management Console of each organization's management account. Bringing this reporting outside of the management account can reduce the effort required for auditing and increase the scope for automations, notifications, and alerting.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An active organization in AWS Organizations that includes at least a management account and a member account
- AWS Backup configured at the organization level in AWS Organizations (for more information, see Automate centralized backup at scale across AWS services using AWS Backup on the AWS Blog)
- Git, installed and configured on your local machine

Limitations

The solution provided in this pattern identifies AWS resources that are configured for AWS Backup jobs only. The report can't identify AWS resources that aren't configured for backup through AWS Backup.

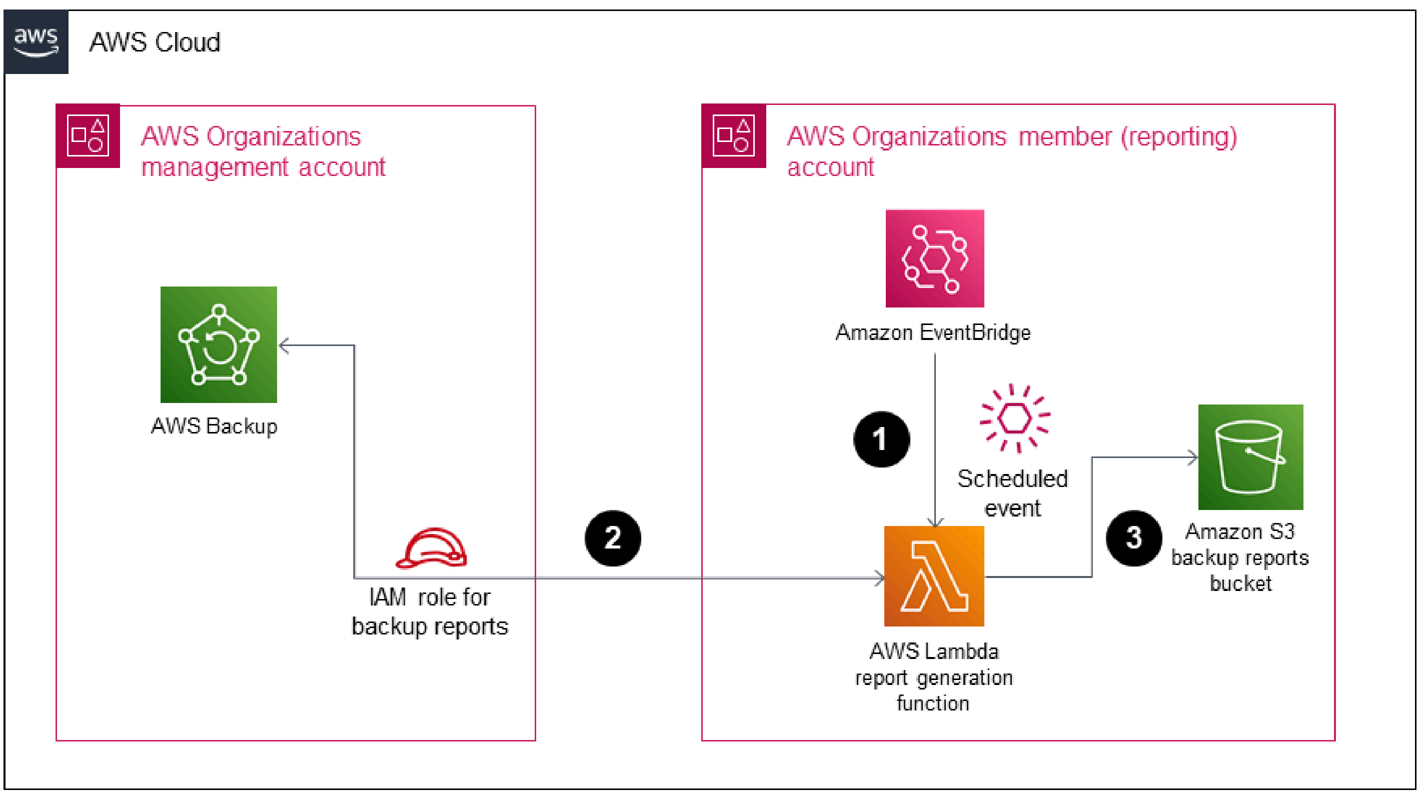
Architecture

Target technology stack

- AWS Backup
- AWS CloudFormation
- Amazon EventBridge
- AWS Lambda
- AWS Security Token Service (AWS STS)
- Amazon Simple Storage Service (Amazon S3)
- AWS Identity and Access Management (IAM)

Target architecture

The following diagram shows an example workflow for exporting AWS Backup job reports from across an organization in AWS Organizations as a CSV file.



The diagram shows the following workflow:

1. A scheduled EventBridge event rule invokes a Lambda function in the member (reporting) AWS account.
2. The Lambda function then uses AWS STS to assume an IAM role that has the permissions required to connect to the management account.
3. The Lambda function then does the following:
   - Requests the consolidated AWS Backup jobs report from the AWS Backup service
   - Categorizes the results based on AWS Backup job status
   - Converts the response to a CSV file
   - Uploads the results to an Amazon S3 bucket in the reporting account within folders that are labeled based on their creation date

Tools

Tools

- AWS Backup is a fully managed service that helps you centralize and automate data protection across AWS services, in the cloud, and on premises.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code

The code for this pattern is available in the GitHub aws-backup-report-generator repository.

Best practices

- Security best practices for Amazon S3 (*Amazon S3 User Guide*)
- Best practices for working with AWS Lambda functions (*AWS Lambda Developer Guide*)
- Best practices for the management account (*AWS Organizations User Guide*)

Epics

Deploy the solution components

Task	Description	Skills required
Clone the GitHub repository.	Clone the GitHub aws-backup-report-generator repository by running the following command in a terminal window: `git clone https://github.com/aws-samples/aws-backup-report-generator.git` For more information, see Cloning a repository in the GitHub Docs.	AWS DevOps, DevOps engineer
Deploy the solution components in the member (reporting) AWS account.	1. In the member (reporting) account, sign in to the AWS Management Console and then open the CloudFormation console. 2. Choose **Create stack**, and then choose **With new resources (standard)**. 3. On the **Create stack** page, in the **Specify template**	DevOps engineer, AWS DevOps

Task	Description	Skills required
	section, choose **Upload a template file**. 4. Select **Choose file**. Then, navigate to the root folder of the cloned GitHub repository on your local workstation and choose **template-reporting.yaml**. 5. Choose **Open**, and then choose **Next**. 6. On the **Specify stack details** page, for **Stack name**, enter a name for your CloudFormation stack. 7. For **ManagementAccountID**, enter the AWS account ID for your organization's management account in AWS Organizations. 8. Choose **Next**. 9. On the **Configure Stack Options** page, choose **Next**. 10. On the **Review** page, select the check box to acknowledge that you reviewed the configuration. 11. Choose **Create stack**. The stack shows **CREATE_COMPLETE** status when the solution components are deployed in the member (reporting) account.	

Test the solution

Task	Description	Skills required
Make sure that the EventBridge rule runs prior to testing.	Make sure that the EventBridge rule runs by waiting at least 24 hours, or by increasing the report frequency in the CloudFormation template's **template-reporting.yml** file. **To increase the report frequency** 1. Open the **template-reporting.yml** file in the cloned repository. 2. In the event rule with the logical ID **'LambdaSchedule'**, find the **'Schedule Expression'**. 3. Edit the **'Schedule Expression'** key so that it includes a valid cron expression. For example, the following cron expression schedules the event rule to run every five minutes: `"cron (* /5 * * * *)"`	AWS DevOps, DevOps engineer
Check the Amazon S3 bucket for the generated report.	1. In the member (reporting) account, sign in to the AWS Management Console and then open the [CloudFormation console]().	AWS DevOps, DevOps engineer

Task	Description	Skills required
	2. In the **Stacks** pane, select the name of the stack you created. Then, choose the **Resources** tab. 3. In the **Resources** pane, in the **Logical ID** column, find **BackupReportS3Bucket**. Then, open the associated Amazon S3 bucket in a new tab by selecting the link in the **Physical ID** column next to that logical ID. 4. Make sure that the bucket contains a report that's generated in the following format: **BackupReports/<yyyy>/<mm>/<dd>/BackupReport-<BACKUP JOB STATUS>-<dd>-<Mon>-<yyyy>.csv**	

Clean up your resources

Task	Description	Skills required
Delete the solution components from the member (reporting) account.	1. In the member (reporting) account, open the solution's Amazon S3 bucket. For instructions, see steps 2-4 in the **Check the S3 bucket for the generated report** story of the **Test the solution** section of this pattern.	AWS DevOps, DevOps engineer

Task	Description	Skills required
	2. Delete the contents of the bucket and empty the bucket. For instructions, see [Emptying a bucket](#) in the *Amazon S3 User Guide*. 3. In the member (reporting) account, sign in to the AWS Management Console and then open the [CloudFormation console](#). 4. In the **Stacks** pane, select the checkbox next to the name of the stack you created. Then, choose **Delete**.	
Delete the solution components from the management account.	1. In the management account, sign in to the AWS Management Console and then open the [CloudFormation console](#). 2. In the **Stacks** pane, select the checkbox next to the name of the stack you created. Then, choose **Delete**.	AWS DevOps, DevOps engineer

Export tags for a list of Amazon EC2 instances to a CSV file

Sida Ju and Pac Joonhyun, Amazon Web Services

Summary

This pattern shows how to programmatically export tags for a list of Amazon Elastic Compute Cloud (Amazon EC2) instances to a CSV file.

By using the example Python script provided, you can reduce how long it takes to review and categorize your Amazon EC2 instances by specific tags. For example, you could use the script to quickly identify and categorize a list of instances that your security team has flagged for software updates.

Prerequisites and limitations

Prerequisites

- Python 3 installed and configured
- AWS Command Line Interface (AWS CLI) installed and configured

Limitations

The example Python script provided in this pattern can search Amazon EC2 instances based on the following attributes only:

- Instance IDs
- Private IPv4 addresses
- Public IPv4 addresses

Tools

- Python is a general-purpose computer programming language.
- virtualenv helps you create isolated Python environments.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Code repository

The example Python script for this pattern is available in the GitHub search-ec2-instances-export-tags repository.

Epics

Install and configure the prerequisites

Task	Description	Skills required
Clone the GitHub repository.	**Note:** If you receive errors when running AWS CLI commands, make sure that you're using the most recent AWS CLI version. Clone the GitHub search-ec2-instances-export-tags repository by running the following Git command in a terminal window: `git clone https://github.com/aws-samples/search-ec2-instances-export-tags.git`	DevOps engineer
Install and activate virtualenv.	1. Install virtualenv by running the following command: `python3 -m pip install virtualenv`	DevOps engineer

Task	Description	Skills required

	2. Create a new virtual environment by running the following command:
	`python3 -m venv env`
	3. Activate the new virtual environment by running the following command:
	`source env/bin/activate`
	
	For more information, see the [virtualenv User Guide]().	

Install dependencies.	1. Open the code directory by running the following command in the terminal:
	`cd search-ec2-instances-export-tags`
	2. Install the `requirements.txt` file by running the following pip command:
	`pip3 install -r requirements.txt`
		DevOps engineer

Task	Description	Skills required
Configure an AWS named profile.	If you haven't already, configure an AWS named profile that includes the required credentials to run the script. To create a named profile, run the aws configure command. For more information, see Using named profiles in the AWS CLI documentation.	DevOps engineer

Configure and run the Python script

Task	Description	Skills required
Create the input file.	Create an input file that contains a list of the Amazon EC2 instances that you want the script to search and export tags for. You can list instance IDs, private IPv4 addresses, or public IPv4 addresses. **Important** Make sure that each Amazon EC2 instance is listed on its own line in the input file. **Input file example**	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

```
i-0547c351bdfe85b9f
54.157.194.156
172.31.85.33
54.165.198.144
i-0b6223b5914111a4b
172.31.85.44
54.165.198.145
172.31.80.219
172.31.94.199
```

</td><td></td></tr>
</table>

Task	Description	Skills required
Run the Python script.	Run the script by running the following command in the terminal: `python search_instances.py -i INPUTFILE -o OUTPUTFILE -r REGION [-p PROFILE]` **Note** Replace `INPUTFILE` with the name of your input file. Replace `OUTPUTFILE` with the name you want to give the CSV output file. Replace `REGION` with the AWS Region that your Amazon EC2 resources are in. If you're using an AWS named profile, replace `PROFILE` with the named profile that you're using. To get a list of supported parameters and their description, run the following command:	DevOps engineer

Task	Description	Skills required
	`python search_instances.py -h` For more information and to see an output file example, see the `README.md` file in the GitHub search-ec2-instances-export-tags repository.

- Configuring the AWS CLI (*AWS CLI User Guide*)

Generate an AWS CloudFormation template containing AWS Config managed rules using Troposphere

Lucas Nation and Freddie Wilson, Amazon Web Services

Summary

Many organizations use AWS Config managed rules to evaluate the compliance of their Amazon Web Services (AWS) resources against common best practices. However, these rules can be time consuming to maintain and this pattern helps you leverage Troposphere, a Python library, to generate and manage AWS Config managed rules.

The pattern helps you to manage your AWS Config managed rules by using a Python script to convert a Microsoft Excel spreadsheet containing AWS managed rules into an AWS CloudFormation template. Troposphere acts as the infrastructure as code (IaC) and this means that you can update the Excel spreadsheet with managed rules, instead of using a JSON or YAML-formatted file. You then use the template to launch an AWS CloudFormation stack that creates and updates the managed rules in your AWS account.

The AWS CloudFormation template defines each AWS Config managed rule by using the Excel spreadsheet and helps you to avoid manually creating individual rules in the AWS Management Console. The script defaults each managed rule's parameters to an empty dictionary and the scope's `ComplianceResourceTypes` defaults from `THE_RULE_IDENTIFIER.template file`. For more information about the rule identifier, see Creating AWS Config managed rules with AWS CloudFormation templates in the AWS Config documentation.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Familiarity with using AWS CloudFormation templates to create AWS Config managed rules. For more information about this, see Creating AWS Config managed rules with AWS CloudFormation templates in the AWS Config documentation.
- Python 3, installed and configured. For more information about this, see the Python documentation.
- An existing integrated development environment (IDE).

- Identify your organizational units (OUs) in a column in the sample `excel_config_rules.xlsx` Excel spreadsheet (attached).

Epics

Customize and configure the AWS Config managed rules

Task	Description	Skills required
Update the sample Excel spreadsheet.	Download the sample `excel_config_rules.xlsx` Excel spreadsheet (attached) and label as `Implemented` the AWS Config managed rules that you want to use. Rules marked as `Implemented` will be added to the AWS CloudFormation template.	Developer

(Optional) Update the config_rules_params.json file with AWS Config rule parameters.	Some AWS Config managed rules require parameters and should be passed to the Python script as a JSON file by using the `--param-file` option. For example, the `access-keys-rotated` managed rule uses the following `maxAccessKeyAge` parameter:
	
	`{`
	`"access-keys-rotated": {`
	`"InputParameters": {`
		Developer

Task	Description	Skills required

	``
	"maxAccessKeyAge": 90
	            }
	        }
	    }
	``
	In this sample parameter, the `maxAccessKeyAge` is set to 90 days. The script reads the parameter file and adds any `InputParameters` that it finds.	

Task	Description	Skills required
(Optional) Update the config_rules_params.json file with AWS Config ComplianceResourceTypes.	By default, the Python script retrieves the `ComplianceResourceTypes` from AWS defined templates. If you want to override the scope of a specific AWS Config managed rule, then you need to pass it to the Python script as a JSON file using the `--param-file` option. For example, the following sample code shows how the `ComplianceResourceTypes` for `ec2-volume-inuse-check` is set to the `["AWS::EC2::Volume"]` list: `{ "ec2-volume-inuse-check": { "Scope": { "ComplianceResourceTypes": [ "AWS::EC2::Volume" ] } } }`	Developer

Run the Python script

Task	Description	Skills required
Install the pip packages from the requirements.txt file.	Download the `requirements.txt` file (attached) and run the following command in your IDE to install the Python packages: `pip3 install -r requirements.txt`	Developer
Run the Python script.	1. Download the `aws_config_rules.py` file (attached) to your local machine. 2. **Note** Run the - `python3 aws_config_rules.py --ou <OU_NAME>` command. : --ou defines which OU column to choose in the Excel spreadsheet. You can also add the following optional parameters: • `--config-rule-option` – Defines the rules	Developer

Task	Description	Skills required
	to choose from the Excel spreadsheet. The default is the `Implemented` parameter. • `--excel-file` – The path for the Excel spreadsheet. The default is `aws_config_rules.xlsx`. • `--param-file` – The path of the parameter JSON file. The default is `config_rules_params.json`. • `--max-execution-frequency` – Defines how often the AWS Config managed rules are evaluated. The choices are `One_Hour`, `Three_Hours`, `Six_Hours`, `Twelve_Hours`, or `TwentyFour_Hours`. The default is `TwentyFour_Hours`.	

Deploy the AWS Config managed rules

Task	Description	Skills required
Launch the AWS CloudFormation stack.	1. Sign in to the AWS Management Console, open the AWS CloudForm	Developer

Task	Description	Skills required
	ation console, and then choose **Create stack.** 2. On the **Specify template** page, choose **Upload a template file** and then upload your AWS CloudFormation template. 3. Specify a stack name and then choose **Next**. 4. Specify tags and then choose **Next**. 5. Choose **Create stack**.

Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account

Helge Aufderheide, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. [Learn more]

This pattern shows how to grant Amazon SageMaker notebook instances and users temporary access to an AWS CodeCommit repository that's in another AWS account. This pattern also shows how you can grant granular permissions for specific actions each entity can perform on each repository.

Organizations often store CodeCommit repositories in a different AWS account than the account that hosts their development environment. This multi-account setup helps control access to the repositories and reduces the risk of their accidental deletion. To grant these cross-account permissions, it's a best practice to use AWS Identity and Access Management (IAM) roles. Then, predefined IAM identities in each AWS account can temporarily assume the roles to create a controlled chain of trust across the accounts.

> **Note**
>
> You can apply a similar procedure to grant other IAM identities cross-account access to a CodeCommit repository. For more information, see [Configure cross-account access to an AWS CodeCommit repository using roles] in the *AWS CodeCommit User Guide*.

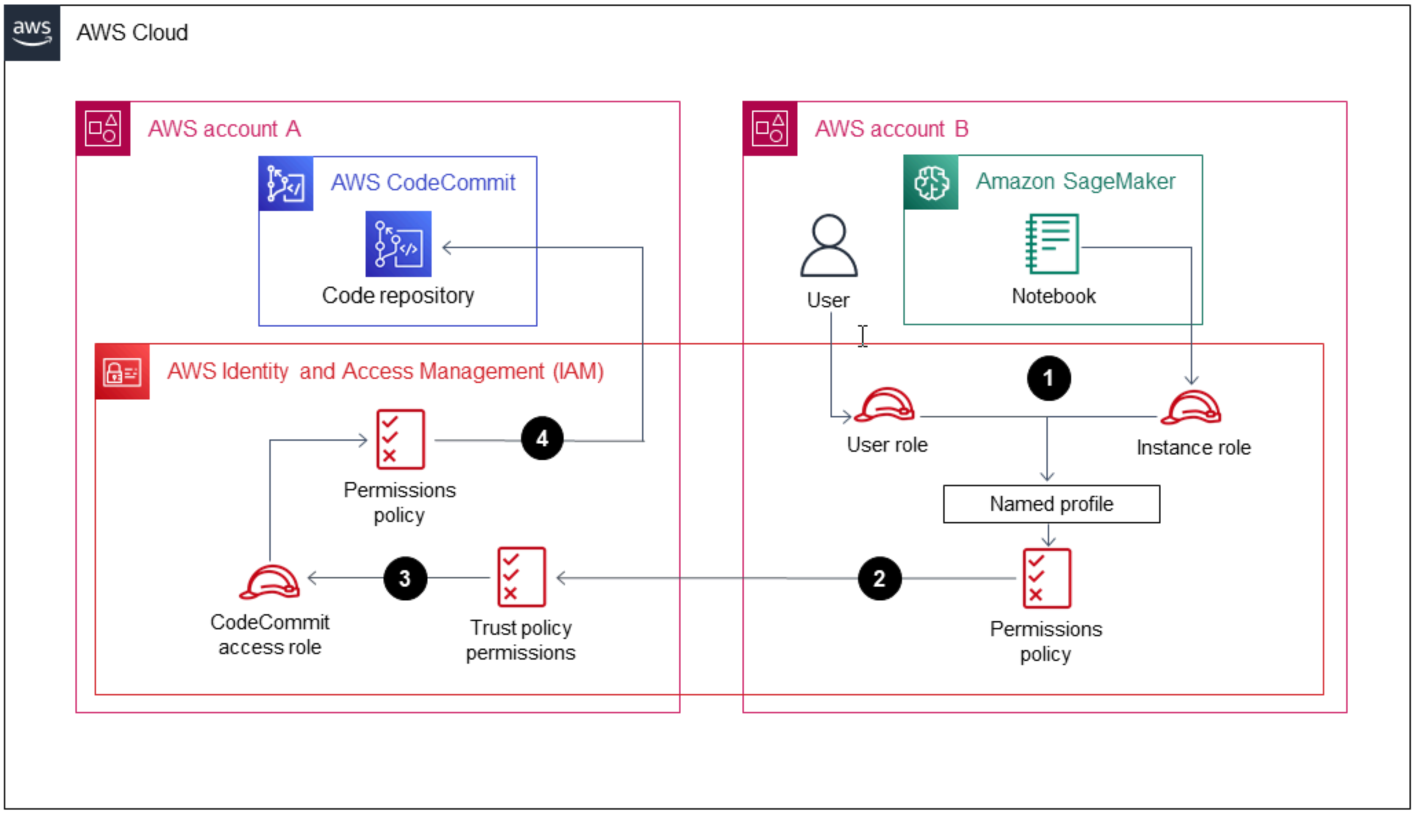
Prerequisites and limitations

Prerequisites

- An active AWS account with a CodeCommit repository (*account A*)
- A second active AWS account with a SageMaker notebook instance (*account B*)
- An AWS user with sufficient permissions to create and modify IAM roles in account A
- A second AWS user with sufficient permissions to create and modify IAM roles in account B

Architecture

The following diagram shows an example workflow for granting a SageMaker notebook instance and users in one AWS account cross-account access to a CodeCommit repository:



The diagram shows the following workflow:

1. The AWS user role and SageMaker notebook instance role in account B assume a [named profile](#).
2. The named profile's permissions policy specifies a CodeCommit access role in account A that the profile then assumes.
3. The CodeCommit access role's trust policy in account A allows the named profile in account B to assume the CodeCommit access role.
4. The CodeCommit repository's IAM permissions policy in account A allows the CodeCommit access role to access the CodeCommit repository.

Technology stack

- CodeCommit
- Git

- IAM
- pip
- SageMaker

Tools

- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Git is a distributed version-control system for tracking changes in source code during software development.
- git-remote-codecommit is a utility that helps you push and pull code from CodeCommit repositories by extending Git.
- pip is the package installer for Python. You can use pip to install packages from the Python Package Index and other indexes.

Best practices

When you set permissions with IAM policies, make sure that you grant only the permissions required to perform a task. For more information, see Apply least-privilege permissions in the IAM documentation.

When implementing this pattern, make sure that you do the following:

- Confirm that IAM principles have only the permissions required to perform specific, needed actions within each repository. For example, it's recommended to allow approved IAM principles to push and merge changes to specific repository branches, but only request merges to protected branches.
- Confirm that IAM principles are assigned different IAM roles based on their respective roles and responsibilities for each project. For example, a developer will have different access permissions than a release manager or AWS Administrator.

Epics

Configure the IAM roles

Task	Description	Skills required
Configure the CodeCommit access role and permissions policy.	**Note** To automate the manual setup process documented in this epic, you can use an AWS CloudFormation template. In the account that contains the CodeCommit repository (*account A*), do the following: 1. Create an IAM role that can be assumed by the SageMaker notebook instance role in account B. 2. Create an IAM policy that grants access to the repository and attach the policy to the role. For testing purposes only, choose the AWSCodeCommitPowerUser AWS managed policy. This policy grants all CodeCommit permissions except the ability to delete resources.	General AWS, AWS DevOps

Task	Description	Skills required
	3. Modify the role's trust policy so that account B is listed as a trusted entity. **Important** Before moving this setup into your production environment, it's a best practice to write your own IAM policy that applies least-privilege permissions. For more information, see the **Additional information** section of this pattern.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Grant the SageMaker notebook instance's role in account B permissions to assume the CodeCommit access role in account A.</td><td>In the account that contains the SageMaker notebook instance’s IAM role (account B), do the following:

Create an IAM policy that allows an IAM role or user to assume the CodeCommi t access role in account A.
Example IAM permissions policy that allows an IAM role or user to assume a cross-account role
<pre><code>{
  "Version":
 "2012-10-17",
  "Statement": [
      {
    "Sid": "VisualEd
itor0",
    "Effect": "Allow",
    "Action":
 "sts:AssumeRole",
    "Resource":
 "arn:aws:iam:::acc
ountA_ID:role/acco
untArole_ID"
  }
}</code></pre>
Attach the policy to your SageMaker notebook instance’s role in account B.
Have the SageMaker notebook instance’s role in account B assume the
</td><td>General AWS, AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	CodeCommit access role in account A. **Note** To view your repository's Amazon Resource Name (ARN), see [View CodeCommit repository details](#) in the *AWS CodeCommit User Guide*.	

Set up your SageMaker notebook instance in account B

Task	Description	Skills required
Set up a user profile on the AWS SageMaker notebook instance to assume the role in account A.	**Important** [Make sure that you have the latest version of the AWS Command Line Interface (AWS CLI) installed](#). In the account that contains the SageMaker notebook instance (*account B)*, do the following: 1. Sign in to the AWS Management Console	General AWS, AWS DevOps

Task	Description	Skills required

	and open the SageMaker console.
	2. Access your SageMaker notebook instance. The Jupyter interface opens.
	3. Choose **New**, and then choose **Terminal**. A new terminal window opens in your Jupyter environment.
	4. Navigate to the SageMaker notebook instance's **~/.aws/config** file. Then, add a user profile to the file by entering the following statement:
	`------.aws/config-`
	`-------------`
	`[profile remoterep`
	`ouser]`
	`role_arn = arn:aws:i`
	`am::<ID of Account`
	` A>:role/<rolename>`
	`role_session_name =`
	` remoteaccesssession`
	`region = eu-west-1`
	`credential_source  =`
	` Ec2InstanceMetadata`
	`----------------`
	`------------------`	

Install the git-remote-codecommit utility.	Follow the instructions in Step 2: Install git-remote-codecommit in the *AWS CodeCommit User Guide*.	Data scientist

Access the repository

Task	Description	Skills required
Access the CodeCommit repository by using Git commands or SageMaker.	**To use Git** IAM principals that assume the SageMaker notebook instance's role in account B can now run Git commands to access the CodeCommit repository in account A. For example, users can run commands such as `git clone`, `git pull`, and `git push`. For instructions, see [Connect to an AWS CodeCommit repository](#) in the *AWS CodeCommit User Guide*. For information about how to use Git with CodeCommit, see [Getting started with AWS CodeCommit](#) in the *AWS CodeCommit User Guide*. **To use SageMaker** To use Git from the SageMaker console, you must allow Git to retrieve credentials from your CodeCommit repository. For instructions, see [Associate a CodeCommit repository in a different AWS account with a notebook](#)	Git, bash console

Task	Description	Skills required
	instance in the SageMaker documentation.

- Configure cross-account access to an AWS CodeCommit repository using roles (AWS CodeCommit documentation)
- IAM tutorial: Delegate access across AWS accounts using IAM roles (IAM documentation)

Additional information

Restricting CodeCommit permissions to specific actions

To restrict the actions that an IAM principal can take in the CodeCommit repository, modify the actions that are allowed in the CodeCommit access policy.

For more information about CodeCommit API operations, see CodeCommit permissions reference in the *AWS CodeCommit User Guide*.

> **Note**
>
> You can also edit the AWSCodeCommitPowerUser AWS managed policy to fit your use case.

Restricting CodeCommit permissions to specific repositories

To create a multitenant environment where more than one code repository is accessible to only specific users, do the following:

1. Create multiple CodeCommit access roles in account A. Then, configure each access role's trust policy to allow specific users in account B to assume the role.
2. Restrict what code repositories that each role can assume by adding a **"Resource"** condition to each CodeCommit access role's policy.

Example "Resource" condition that restricts an IAM principal's access to a specific CodeCommit repository

```
"Resource" : [<REPOSITORY_ARN>,<REPOSITORY_ARN> ]
```

Note

To help identify and differentiate multiple code repositories in the same AWS account, you can assign different prefixes to the repositories' names. For example, you can name code repositories with prefixes that align to different developer groups, such as **myproject-subproject1-repo1** and **myproject-subproject2-repo1**. Then, you can create an IAM role for each developer group based on their assigned prefixes. For example, you could create a role named **myproject-subproject1-repoaccess** and grant it access to all of the code repositories that include the prefix **myproject-subproject1**.

Example "Resource" condition that refers to a code repository ARN that includes a specific prefix

```
"Resource" : arn:aws:codecommit:<region>:<account-id>:myproject-subproject1-*
```

Implement a GitHub Flow branching strategy for multi-account DevOps environments

Mike Stephens and Abhilash Vinod, Amazon Web Services

Summary

When managing a source code repository, different branching strategies affect the software development and release processes that development teams use. Examples of common branching strategies include Trunk, GitHub Flow, and Gitflow. These strategies use different branches, and the activities performed in each environment are different. Organizations that are implementing DevOps processes would benefit from a visual guide to help them understand the differences between these branching strategies. Using this visual in your organization helps development teams align their work and follow organizational standards. This pattern provides this visual and describes the process of implementing a GitHub Flow branching strategy in your organization.

This pattern is part of a documentation series about choosing and implementing DevOps branching strategies for organizations with multiple AWS accounts. This series is designed to help you apply the correct strategy and best practices from the outset, to streamline your experience in the cloud. GitHub Flow is just one possible branching strategy that your organization can use. This documentation series also covers Trunk and Gitflow branching models. If you haven't done so already, we recommend that you review Choosing a Git branching strategy for multi-account DevOps environments prior to implementing the guidance in this pattern. Please use due diligence to choose the right branching strategy for your organization.

This guide provides a diagram that shows how an organization might implement the GitHub Flow strategy. It is recommended that you review the AWS Well-Architected DevOps Guidance to review best practices. This pattern includes recommended tasks, steps, and restrictions for each step in the DevOps process.

Prerequisites and limitations

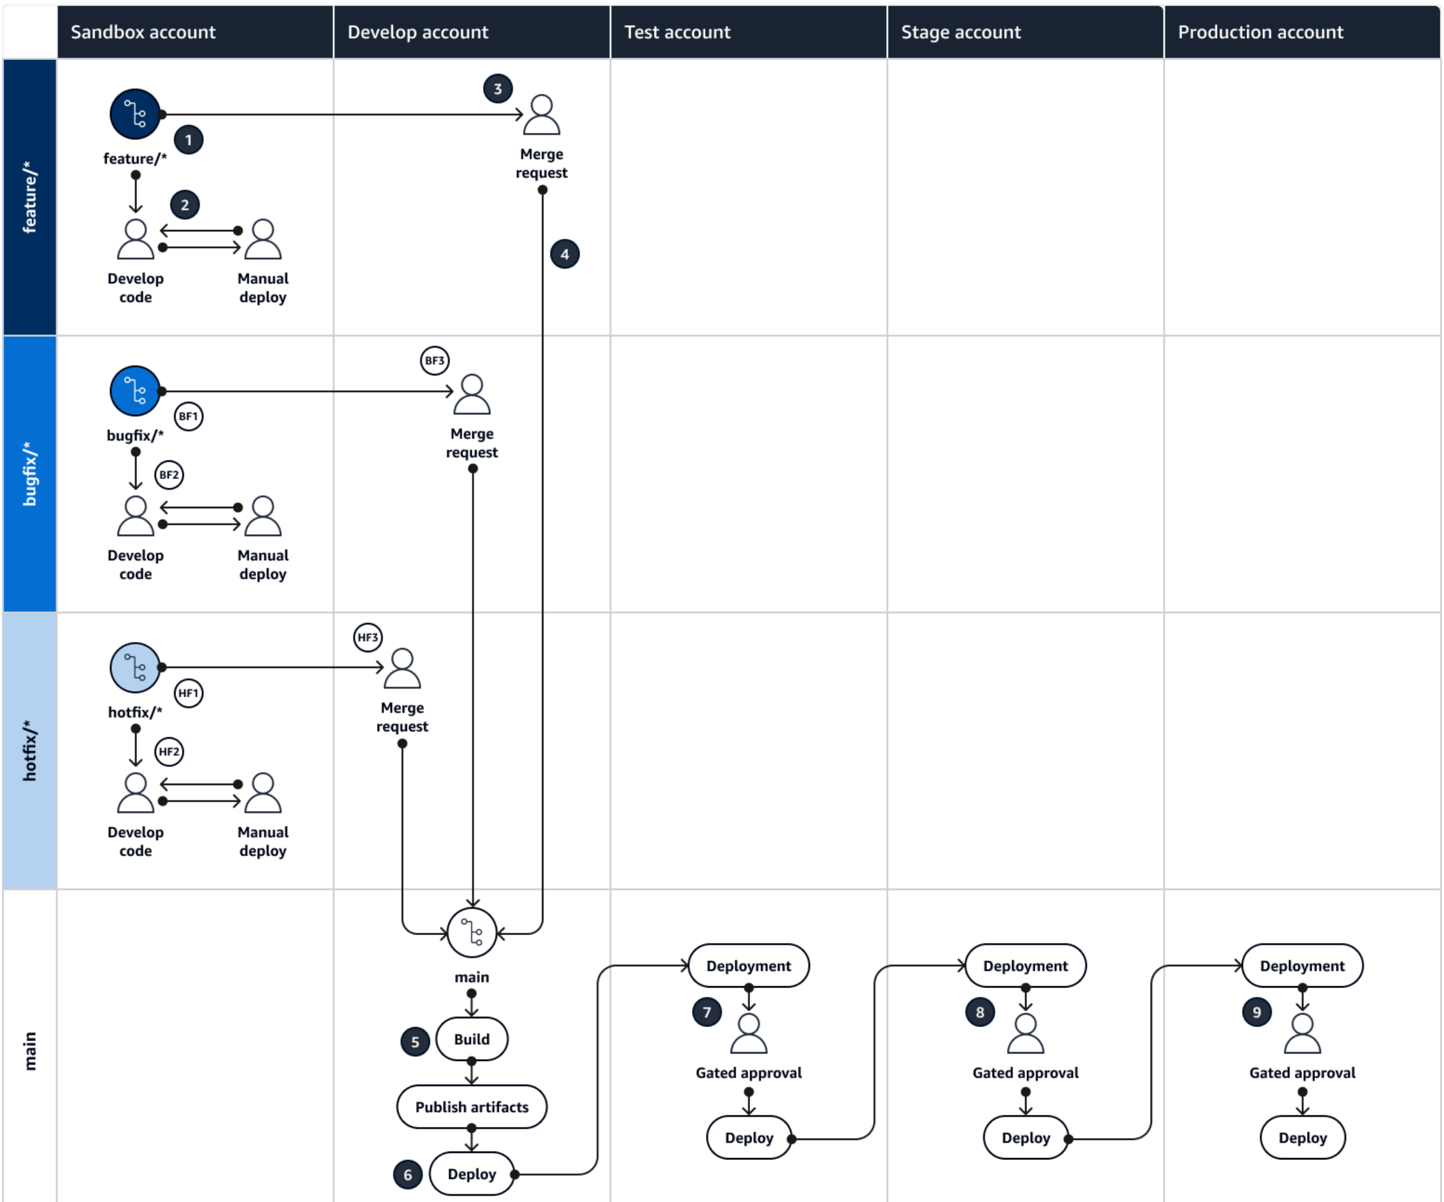
Prerequisites

- Git, installed. This is used as a source code repository tool.
- Draw.io, installed. This application is used to view and edit the diagram.

Architecture

Target architecture

The following diagram can be used like a [Punnett square](https://en.wikipedia.org/wiki/Punnett_square) (Wikipedia). You line up the branches on the vertical axis with the AWS environments on the horizontal axis to determine what actions to perform in each scenario. The numbers indicate the sequence of the actions in the workflow. This example takes you from a `feature` branch through deployment in production.



For more information about the AWS accounts, environments, and branches in a GitHub Flow approach, see [Choosing a Git branching strategy for multi-account DevOps environments](https://docs.aws.amazon.com/prescriptive-guidance/latest/choosing-git-branch-approach/).

Automation and scale

Continuous integration and continuous delivery (CI/CD) is the process of automating the software release lifecycle. It automates much or all of the manual processes traditionally required to get new code from an initial commit into production. A CI/CD pipeline encompasses the sandbox, development, testing, staging, and production environments. In each environment, the CI/CD pipeline provisions any infrastructure that is needed to deploy or test the code. By using CI/CD, development teams can make changes to code that are then automatically tested and deployed. CI/CD pipelines also provide governance and guardrails for development teams by enforcing consistency, standards, best practices, and minimal acceptance levels for feature acceptance and deployment. For more information, see Practicing Continuous Integration and Continuous Delivery on AWS.

AWS offers a suite of developer services that are designed to help you build CI/CD pipelines. For example, AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. AWS CodeBuild compiles source code, runs tests, and produces ready-to-deploy software packages. For more information, see Developer Tools on AWS.

Tools

AWS services and tools

AWS provides a suite of developer services that you can use to implement this pattern:

- AWS CodeArtifact is a highly scalable, managed artifact repository service that helps you store and share software packages for application development.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeDeploy automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

Other tools

- Draw.io Desktop is an application for making flowcharts and diagrams. The code repository contains templates in .drawio format for Draw.io.
- Figma is an online design tool designed for collaboration. The code repository contains templates in .fig format for Figma.

Code repository

This source file for the diagram in this pattern is available in the GitHub Git Branching Strategy for GitHub Flow repository. It includes files in PNG, draw.io, and Figma formats. You can modify these diagrams to support your organization's processes.

Best practices

Follow the best practices and recommendations in AWS Well-Architected DevOps Guidance and Choosing a Git branching strategy for multi-account DevOps environments. These help you effectively implement GitHub Flow-based development, foster collaboration, improve code quality, and streamline the development process.

Epics

Reviewing the GitHub Flow workflows

Task	Description	Skills required
Review the standard GitHub Flow process.	1. In the sandbox environme nt, the developer creates a `feature` branch from the `main` branch and uses the naming pattern `feature/<ticket>_<initials>_<short description>` . 2. The developer adds one or more commits to the `feature` branch, each representing a discrete change or improvement.	DevOps engineer

Task	Description	Skills required
	3. The developer opens a merge request (MR) to merge the changes into the `main` branch. This initiates a review process. 4. During the review process, developers discuss the code changes and provide feedback. The goal is to ensure that the changes are of high quality and meet the project's standards. 5. After the developer creates the merge request, an automated build process starts and deploys the changes in the `feature` branch to the development environment. 6. Automated tests verify the integrity and quality of the changes encapsulated in the merge request. A successful build, successful deployment, and successful testing are required to complete the merge request. 7. When the review process is complete, the changes are merged into the `main` branch.	

Task	Description	Skills required
	8. An approver manually approves the deployment of the release artifacts to the testing environment. 9. An approver manually approves the deployment of the release artifacts to the staging environment. 10. An approver manually approves the deployment of the release artifacts to the production environme nt.	

Task	Description	Skills required
Review the bugfix GitHub Flow process.	1. The developer creates a `bugfix` branch from the `main` branch and uses the naming pattern `bugfix/<ticket number>_<developer initials>_<descriptor>` . 2. The developer fixes the issue, commits the fix, and builds the `bugfix` branch. 3. The developer opens a merge request to merge the `bugfix` branch into the `main` branch. This initiates a review process. 4. During the review process, developers discuss the code changes and provide feedback. 5. Upon review completion and approval, the developer completes the merge request of the `bugfix` branch into the `main` branch. 6. An approver manually approves the deployment of the release artifacts to higher environments.	DevOps engineer

Task	Description	Skills required
Review the hotfix GitHub Flow process.	GitHub Flow is designed to enable continuous delivery, where code changes are frequently and reliably deployed to higher environme nts. The key is that every `feature` branch is deployabl e at any time. `Hotfix` branches, which are akin to `feature` or `bugfix` branches, can follow the same process as either of these other branches. However, given their urgency, hotfixes typically have a higher priority. Depending on the team's policies and the immediacy of the situation, certain steps in the process could be expedited. For instance, code reviews for hotfixes might be fast-trac ked. Therefore, while the hotfix process parallels the feature or bugfix process, the urgency surrounding hotfixes may warrant modifications in the procedural adherence . It's crucial to establish guidelines about managing hotfixes to make sure that they are handled efficiently and securely.	DevOps engineer

Troubleshooting

Issue	Solution
Branch conflicts	A common issue that can occur with the GitHub Flow model is where a hotfix needs to occur in production but a corresponding change needs to occur in a `feature`, `bugfix`, or `hotfix` branch where the same resources are being modified. We recommend that you frequently merge changes from `main` into lower branches to avoid significant conflicts when you merge to `main`.
Team maturity	GitHub Flow encourages daily deploymen ts to higher environments, embracing true continuous integration and continuous delivery (CI/CD). It is imperative that the team has the engineering maturity to build features and create automation tests for them. The team must perform an exhaustive merge request review before changes are approved. This fosters a robust engineering culture that promotes quality, accountability, and efficienc y in the development process.

Do not use a squash merge. 10.If a conflict is detected, developers receive an alert and resolve the conflict with a merge request.	

Troubleshooting

Issue	Solution
Branch conflicts	A common issue that can occur with the Gitflow model is where a hotfix needs to occur in production but a corresponding change needs to occur in a lower environme nt, where another branch is modifying the

Issue	Solution
	same resources. We recommend that you have only a single release branch active at a time. If you have more than one active at a time, the changes in the environments might collide, and you might be unable to move a branch forward to production.
Merging	Releases should be merged back into main and develop as soon as possible to consolidate work back into the primary branches.
Squash merging	Only use a squash merge when you are merging from a `feature` branch to a `develop` branch. Using squash merges in higher branches causes difficulty when merging changes back down to lower branches.

Implement a Trunk branching strategy for multi-account DevOps environments

Mike Stephens and Rayjan Wilson, Amazon Web Services

Summary

When managing a source code repository, different branching strategies affect the software development and release processes that development teams use. Examples of common branching strategies include Trunk, GitHub Flow, and Gitflow. These strategies use different branches, and the activities performed in each environment are different. Organizations that are implementing DevOps processes would benefit from a visual guide to help them understand the differences between these branching strategies. Using this visual in your organization helps development teams align their work and follow organizational standards. This pattern provides this visual and describes the process of implementing a Trunk branching strategy in your organization.

This pattern is part of a documentation series about choosing and implementing DevOps branching strategies for organizations with multiple AWS accounts. This series is designed to help you apply the correct strategy and best practices from the outset, to streamline your experience in the cloud. Trunk is just one possible branching strategy that your organization can use. This documentation series also covers GitHub Flow and Gitflow branching models. If you haven't done so already, we recommend that you review Choosing a Git branching strategy for multi-account DevOps environments prior to implementing the guidance in this pattern. Please use due diligence to choose the right branching strategy for your organization.

This guide provides a diagram that shows how an organization might implement the Trunk strategy. It is recommended that you review the official AWS Well-Architected DevOps Guidance to review best practices. This pattern includes recommended tasks, steps, and restrictions for each step in the DevOps process.

Prerequisites and limitations

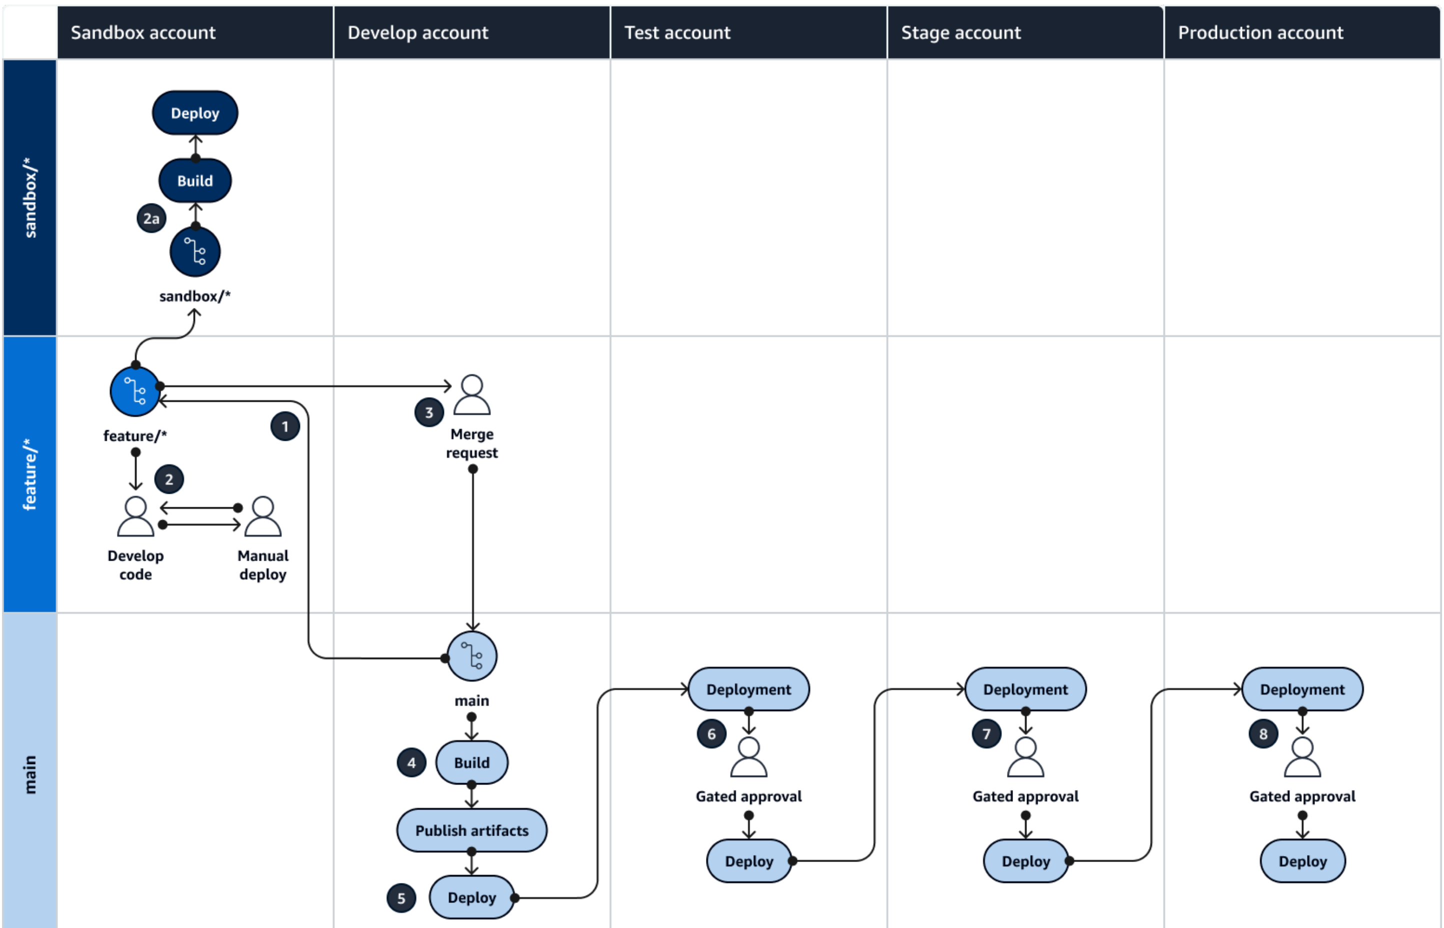
Prerequisites

- Git, installed. This is used as a source code repository tool.
- Draw.io, installed. This application is used to view and edit the diagram.

Architecture

Target architecture

The following diagram can be used like a [Punnett square](https://en.wikipedia.org/wiki/Punnett_square) (Wikipedia). You line up the branches on the vertical axis with the AWS environments on the horizontal axis to determine what actions to perform in each scenario. The numbers indicate the sequence of the actions in the workflow. This example takes you from a `feature` branch through deployment in production.



For more information about the AWS accounts, environments, and branches in a Trunk approach, see [Choosing a Git branching strategy for multi-account DevOps environments](#).

Automation and scale

Continuous integration and continuous delivery (CI/CD) is the process of automating the software release lifecycle. It automates much or all of the manual processes traditionally required to get new code from an initial commit into production. A CI/CD pipeline encompasses the sandbox, development, testing, staging, and production environments. In each environment, the CI/CD pipeline provisions any infrastructure that is needed to deploy or test the code. By using CI/CD, development teams can make changes to code that are then automatically tested and deployed. CI/CD pipelines also provide governance and guardrails for development teams by enforcing consistency, standards, best practices, and minimal acceptance levels for feature acceptance and deployment. For more information, see Practicing Continuous Integration and Continuous Delivery on AWS.

AWS offers a suite of developer services that are designed to help you build CI/CD pipelines. For example, AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. AWS CodeBuild compiles source code, runs tests, and produces ready-to-deploy software packages. For more information, see Developer Tools on AWS.

Tools

AWS services and tools

AWS provides a suite of developer services that you can use to implement this pattern:

- AWS CodeArtifact is a highly scalable, managed artifact repository service that helps you store and share software packages for application development.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeDeploy automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

Other tools

- Draw.io Desktop – An application for making flowcharts and diagrams.
- Figma is an online design tool designed for collaboration. The code repository contains templates in .fig format for Figma.

Code repository

This source file for the diagram in this pattern is available in the GitHub Git Branching Strategy for Trunk repository. It includes files in PNG, draw.io, and Figma formats. You can modify these diagrams to support your organization's processes.

Best practices

Follow the best practices and recommendations in AWS Well-Architected DevOps Guidance and Choosing a Git branching strategy for multi-account DevOps environments. These help you effectively implement Trunk-based development, foster collaboration, improve code quality, and streamline the development process.

Epics

Reviewing the Trunk workflow

Task	Description	Skills required
Review the standard Trunk process.	1. In the sandbox environment, the developer creates a `feature` branch from the `main` branch and uses the naming pattern `feature/<ticket>_<initials>_<short description>` . 2. The developer develops code and deploys the code to the sandbox environment iteratively in order to complete the ticket. **Note** The developer can optionally create a `sandbox` branch to run an automated build or deploy	DevOps engineer

	the production environme nt.	

Troubleshooting

Issue	Solution
Branch conflicts	A common issue that can occur with the Trunk model is where a hotfix needs to occur in production but a corresponding change needs to occur in a `feature` branch, where the same resources are being modified. We recommend that you frequently merge changes from `main` into lower branches to avoid significant conflicts on merge to `main`.

Related resources

This guide doesn't include training for Git; however, there are many high-quality resources available on the internet if you need this training. We recommend that you start with the Git documentation site.

The following resources can help you with your Trunk branching journey in the AWS Cloud.

Implement centralized custom Checkov scanning to enforce policy before deploying AWS infrastructure

Benjamin Morris, Amazon Web Services

Summary

This pattern provides a GitHub Actions framework for writing custom Checkov policies in one repository that can be reused across a GitHub organization. By following this pattern, an information security team can write, add, and maintain custom policies based on company requirements. The custom policies can be pulled into all pipelines in the GitHub organization automatically. This approach can be used to enforce company standards for resources before the resources are deployed.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A GitHub organization using GitHub Actions
- AWS infrastructure deployed with either HashiCorp Terraform or AWS CloudFormation

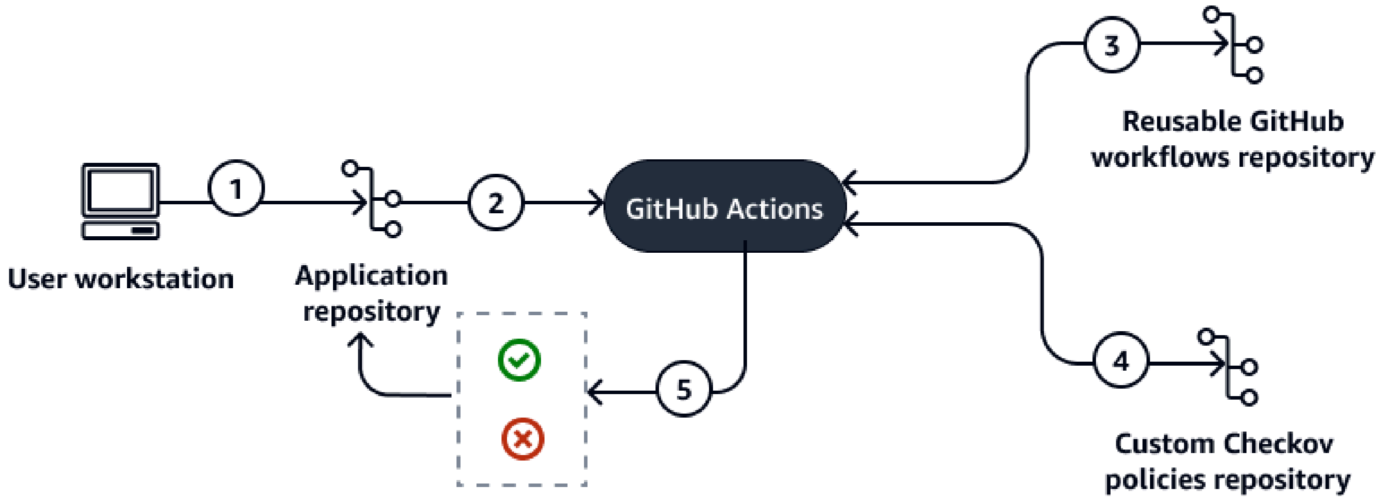
Limitations

- This pattern is written for GitHub Actions. However, it can be adapted to similar continuous integration and continuous delivery (CI/CD) frameworks such as GitLab. No specific paid version of GitHub is required.
- Some AWS services aren't available in all AWS Regions. For Region availability, see [Service endpoints and quotas] in the AWS documentation, and choose the link for the service.

Architecture

This pattern is designed to be deployed as a GitHub repository that contains a GitHub reusable workflow and custom Checkov policies. The reusable workflow can scan both Terraform and CloudFormation infrastructure as code (IaC) repositories.

The following diagram shows the **Reusable GitHub workflows repository** and **Custom Checkov policies repository** as separate icons. However, you can implement these repositories either as separate repositories or a single repository. The example code uses a single repository, with files for workflows (`.github/workflows`) and files for custom policies (`custom_policies` folder and the `.checkov.yml` config file) in the same repository.



The diagram shows the following workflow:

1. A user creates a pull request in a GitHub repository.
2. Pipeline workflows start in GitHub Actions, including a reference to a Checkov reusable workflow.
3. The pipeline workflow downloads the referenced Checkov reusable workflow from an external repository and runs that Checkov workflow by using GitHub Actions.
4. The Checkov reusable workflow downloads the custom policies from an external repository.
5. The Checkov reusable workflow evaluates the IaC in the GitHub repository against both built-in and custom Checkov policies. The Checkov reusable workflow passes or fails based on whether security issues are found.

Automation and scale

This pattern allows for central management of Checkov configuration, so that policy updates can be applied in one location. However, this pattern does require that each repository use a workflow that contains a reference to the central reusable workflow. You can add this reference manually or use scripts to push the file to the `.github/workflows` folder for each repository.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions. Checkov can scan CloudFormation.

Other tools

- Checkov is a static code analysis tool that checks IaC for security and compliance misconfigurations.
- GitHub Actions is integrated into the GitHub platform to help you create, share, and run workflows within your GitHub repositories. You can use GitHub Actions to automate tasks such as building, testing, and deploying your code.
- Terraform is an IaC tool from HashiCorp that helps you create and manage cloud and on-premises resources. Checkov can scan Terraform.

Code repository

The code for this pattern is available in the GitHub centralized-custom-checkov-sast repository.

Best practices

- To maintain a consistent security posture, align your company's security policies with the Checkov policies.
- In the early phases of implementing Checkov custom policies, you can use the soft-fail option in your Checkov scan to allow IaC with security issues to be merged. As the process matures, switch from the soft-fail option to the hard-fail option.

Epics

Create a central Checkov repository for custom policies

Task	Description	Skills required
Create a central Checkov repository.	Create a repository to store custom Checkov policies that will be used within the organization.	DevOps engineer

Task	Description	Skills required
	For a quick start, you can copy the contents of this pattern's GitHub centralized-custom-checkov-sast repository into your central Checkov repository.	
Create a repository for reusable workflows.	If a repository for reusable workflows already exists, or you plan to include reusable workflow files in the same repository as the custom Checkov policies, you can skip this step. Create a GitHub repository to hold reusable workflows. Other repositories' pipelines will reference this repository.	DevOps engineer

Create reusable and example Checkov workflows

Task	Description	Skills required
Add a reusable Checkov workflow.	Create a reusable Checkov GitHub Actions workflow (YAML file) in the reusable workflows repository. You can adapt this reusable workflow from the workflow file provided in this pattern. An example of a change that you might want to make is to change the reusable	DevOps engineer

Task	Description	Skills required
	workflow to use the soft-fail option. Setting `soft-fail` to `true` allows the job to complete successfully even if there is a failed Checkov scan. For instructions, see [Hard and soft fail](#) in the Checkov documentation.	
Add an example workflow.	Add an example Checkov workflow that references the `reusable` workflow. This will provide a template for how to reuse the `reusable` workflow. In the example repository, `checkov-source.yaml` is the reusable workflow and `checkov-scan.yaml` is the example that consumes `checkov-source`. For more details about writing an example Checkov workflow, see [Additional information](#).	DevOps engineer

Associate company policies to Checkov custom policies

Task	Description	Skills required
Determine policies that can be enforced with Checkov.	1. Review company policies that are related to infrastructure security and which	Security and Compliance

Task	Description	Skills required
	requirements should be in place. 2. Determine which requirements can be implemented by using Checkov custom policies. 3. Create a naming convention that maps the policy control to the Checkov custom policy. Typically, Checkov custom policies have an identifier with a Checkov name, the policy source (custom), and a policy number (for example, `CKV2_CUSTOM_123`). For more details about creating Checkov custom policies, see Custom Policies Overview in the Checkov documentation.	
Add Checkov custom policies.	Convert the identified company policies to custom Checkov policies in the central repository. You can write simple Checkov policies in either Python or YAML.	Security

Implement centralized Checkov custom policies

Task	Description	Skills required
Add the Checkov reusable workflow to all repositories.	At this point, you should have an example Checkov workflow that references the reusable workflow. Copy the sample Checkov workflow that references the reusable workflow to each repository that requires it.	DevOps engineer
Create a mechanism to ensure that Checkov runs before merges.	To ensure that the Checkov workflow gets run for every pull request, create a [status check](https://docs.github.com/en/pull-requests/collaborating-with-pull-requests/collaborating-on-repositories-with-code-quality-features/about-status-checks) that requires a successful Checkov workflow before pull requests can be merged. GitHub allows you to require that specific workflows run before pull requests can be merged.	DevOps engineer
Create an organization-wide PAT, and share it as a secret.	If your GitHub organization is publicly visible, you can skip this step. This pattern requires that the Checkov workflow be able to download custom policies from the custom policy repository in your GitHub organization. You must provide permissio ns such that the Checkov workflow can access those repositories.	DevOps engineer

Task	Description	Skills required
	To do this, create a personal access token (PAT) with permissions to read organizat ion repositories. Share this PAT with repositories, either as an organization-wide secret (if on a paid plan) or a secret in each repository (free version). In the sample code, the default name for the secret is `ORG_PAT`.	

Task	Description	Skills required
(Optional) Protect the Checkov workflow files from modification.	To protect the Checkov workflow files from unwanted changes, you can use a `CODEOWNERS` file. The `CODEOWNERS` file is typically deployed in the root of the directory. For example, to require approvals from your GitHub organization's `secEng` group when the `checkov-scan.yaml` file is modified, append the following to a repository's `CODEOWNERS` file: `[Checkov] .github/workflows/checkov-scan.yaml @myOrg/secEng` A `CODEOWNERS` file is specific to the repository it lives in. To protect the Checkov workflow used by the repository, you must add (or update) a `CODEOWNERS` file in each repository. For more information about protecting Checkov workflow files, see [Additional information](). For more information about `CODEOWNERS` files, see the official documentation for	DevOps engineer

Task	Description	Skills required
	your CI/CD provider (such as GitHub).

Additional information

Writing Checkov workflow files

When writing `checkov-scan.yaml`, consider when you want it to run. The top-level `on` key determines when the workflow runs. In the example repository, the workflow will run when there is a pull request targeting the `main` branch (and any time that pull request's source branch is modified). The workflow can also be run as required because of the `workflow_dispatch` key.

You can change the workflow trigger conditions based on how often you want the workflow to run. For example, you could change the workflow to run every time code is pushed to any branch by replacing `pull_request` with `push` and removing the `branches` key.

You can modify the example workflow file that you created within an individual repository. For example, you could adjust the target branch's name from `main` to `production` if a repository is structured around a `production` branch.

Protecting Checkov workflow files

Checkov scanning provides useful information about potential security misconfiguration. However, some developers might perceive it to be a barrier to their productivity and attempt to remove or disable the scanning workflow.

There are several ways to address this problem, including better messaging about the long-term value of security scanning and clearer documentation about how to deploy secure infrastructure. These are important "soft" approaches to DevSecOps collaboration that can be seen as the solution to this problem's root cause. However, you can also use technical controls such as a `CODEOWNERS` file as guardrails to help keep developers on the right path.

Testing pattern in a sandbox

To test this pattern in a sandbox environment, follow these steps:

1. Create a new GitHub organization. Create a token with read-only access to all repositories in the organization. Because this token is for a sandbox environment, not a paid environment, you will not be able to store this token in an organization-wide secret.
2. Create a `checkov` repository to hold the Checkov configuration and a `github-workflows` repository to hold the reusable workflow configuration. Populate the repositories with the contents of the example repository.
3. Create an application repository, and copy and paste the `checkov-scan.yaml` workflow to its `.github/workflows` folder. Add a secret to the repository that contains the PAT you created for organization read-only access. The default secret is `ORG_PAT`.
4. Create a pull request that adds some Terraform or CloudFormation code to the application repository. Checkov should scan and return a result.

Implement AI-powered Kubernetes diagnostics and troubleshooting with K8sGPT and Amazon Bedrock integration

Ishwar Chauthaiwale, Muskan ., and Prafful Gupta, Amazon Web Services

Summary

This pattern demonstrates how to implement AI-powered Kubernetes diagnostics and troubleshooting by integrating K8sGPT with the Anthropic Claude v2 model available on Amazon Bedrock. The solution provides natural language analysis and remediation steps for Kubernetes cluster issues through a secure bastion host architecture. By combining K8sGPT Kubernetes expertise with Amazon Bedrock advanced language capabilities, DevOps teams can quickly identify and resolve cluster problems. With these capabilities, it's possible to reduce mean time to resolution (MTTR) by up to 50 percent.

This cloud-native pattern leverages Amazon Elastic Kubernetes Service (Amazon EKS) for Kubernetes management. The pattern implements security best practices through proper AWS Identity and Access Management (IAM) roles and network isolation. This solution is particularly valuable for organizations who want to streamline their Kubernetes operations and enhance their troubleshooting capabilities with AI assistance.

Prerequisites and limitations

Prerequisites

- An active AWS account with appropriate permissions
- AWS Command Line Interface (AWS CLI) installed and configured
- An Amazon EKS cluster
- Access to Anthropic Claude 2 model on Amazon Bedrock
- A bastion host with required security group settings
- K8sGPT installed

Limitations

- K8sGPT analysis is limited by the context window size of the Claude v2 model.
- Amazon Bedrock API rate limits apply based on your account quotas.

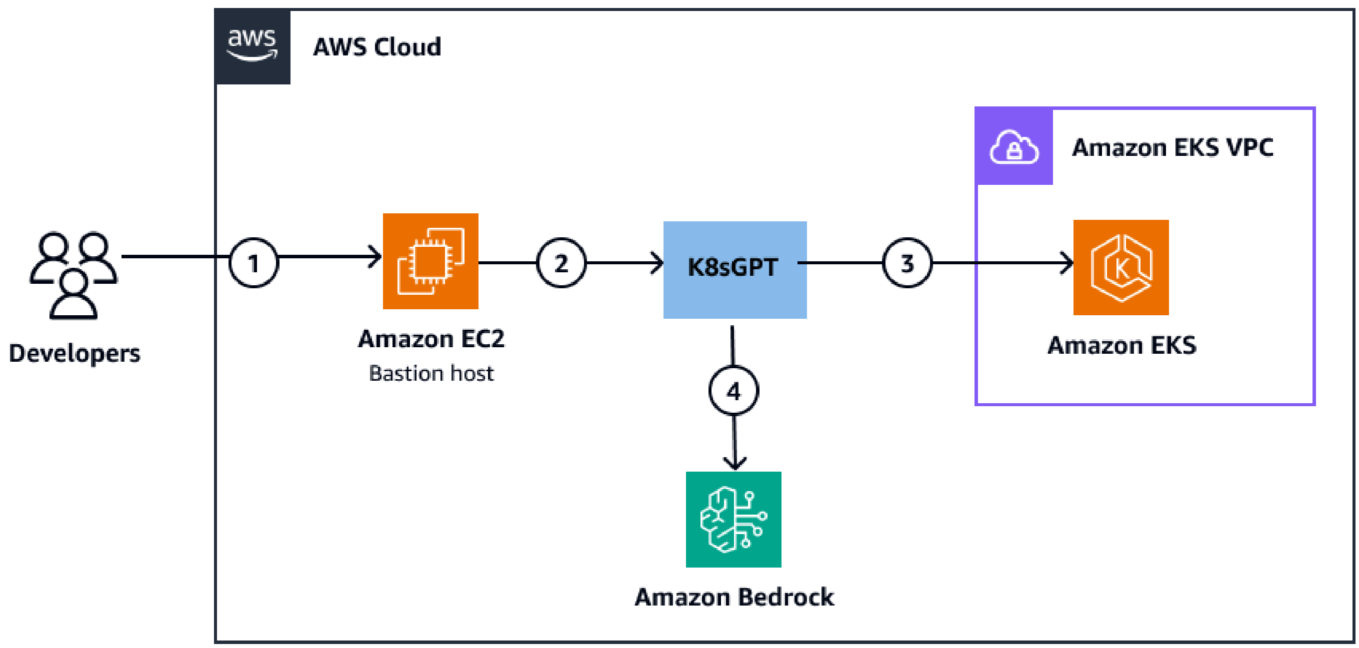
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- Amazon EKS version 1.31 or later
- Claude 2 model on Amazon Bedrock
- K8sGPT v0.4.2 or later

Architecture

The following diagram shows the architecture for AI-powered Kubernetes diagnostics using K8sGPT integrated with Amazon Bedrock in the AWS Cloud.



The architecture shows the following workflow:

1. Developers access the environment through a secure connection to the bastion host. This Amazon EC2 instance serves as the secure entry point and contains the K8sGPT command line interface (CLI) installation and required configurations.

2. The bastion host, configured with specific IAM roles, establishes secure connections to both the Amazon EKS cluster and the Amazon Bedrock endpoints. K8sGPT is installed and configured on the bastion host to perform Kubernetes cluster analysis.
3. Amazon EKS manages the Kubernetes control plane and worker nodes, providing the target environment for K8sGPT analysis. The service runs across multiple Availability Zones within a virtual private cloud (VPC), which helps to provide high availability and resilience. Amazon EKS supplies operational data through the Kubernetes API, enabling comprehensive cluster analysis.
4. K8sGPT sends analysis data to Amazon Bedrock, which provides the Claude v2 foundation model (FM) for natural language processing. The service processes K8sGPT analysis to generate human-readable explanations and offers detailed remediation suggestions based on identified issues. Amazon Bedrock operates as a serverless AI service with high availability and scalability.

Note

Throughout this workflow, IAM controls access between components through roles and policies, managing authentication for the bastion host, Amazon EKS, and Amazon Bedrock interactions. IAM implements the principle of least privilege and enables secure cross-service communication throughout the architecture.

Automation and scale

K8sGPT operations can be automated and scaled across multiple Amazon EKS clusters through various AWS services and tools. This solution supports continuous integration and continuous deployment (CI/CD) integration using Jenkins, GitHub Actions, or AWS CodeBuild for scheduled analysis. The K8sGPT operator enables continuous in-cluster monitoring with automated issue detection and reporting capabilities. For enterprise-scale deployments, you can use Amazon EventBridge to schedule scans and trigger automated responses with custom scripts. AWS SDK integration enables programmatic control across large fleet of clusters.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command line shell.

- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Other tools

- K8sGPT is an open source AI-powered tool that transforms Kubernetes management. It acts as a virtual site reliability engineering (SRE) expert, automatically scanning, diagnosing, and troubleshooting Kubernetes cluster issues. Administrators can interact with K8sGPT using natural language and get clear, actionable insights about cluster state, pod crashes, and service failures. The tool's built-in analyzers detect a wide range of issues, from misconfigured components to resource constraints, and provide easy-to-understand explanations and solutions.

Best practices

- Implement secure access controls by using AWS Systems Manager Session Manager for bastion host access.
- Make sure that K8sGPT authentication uses dedicated IAM roles with least privilege permissions for Amazon Bedrock and Amazon EKS interactions . For more information, see Grant least privilege and Security best practices in the IAM documentation.
- Configure resource tagging, enable Amazon CloudWatch logging for audit trails, and implement data anonymization for sensitive information.
- Maintain regular backups of K8sGPT configurations while setting up automated scanning schedules during off-peak hours to minimize operational impact.

Epics

Add Amazon Bedrock to AI backend provider list.

Task	Description	Skills required
Set Amazon Bedrock as the AI backend provider for K8sGPT.	To set Amazon Bedrock as the AI backend provider for K8sGPT, use the following AWS CLI command:	AWS DevOps

Task	Description	Skills required
	``` k8sgpt auth add -b amazonbedrock \ -r us-west-2 \ -m anthropic.claude-v 2 \ -n endpoint-name ``` The example command uses `us-west-2` for the AWS Region. However, you can select another Region, provided that both the Amazon EKS cluster and the corresponding Amazon Bedrock model are available and enabled in that selected Region. To check that `amazonbedrock` is added to the AI backend provider list and is in the `Active` state, run the following command: ``` k8sgpt auth list ``` Following is an example of the expected output of this command: ``` Default: > openai Active: > amazonbedrock Unused: > openai > localai ```	

Task	Description	Skills required

	<pre>> ollama
	> azureopenai
	> cohere
	> amazonsagemaker
	> google
	> noopai
	> huggingface
	> googlevertexai
	> oci
	> customrest
	> ibmwatsonxai</pre>	

Scan resources using a filter

Task	Description	Skills required

View a list of available filters.	To see the list of all available filters, use the following AWS CLI command:
	<pre>k8sgpt filters list</pre>Following is an example of the expected output of this command:
	<pre>Active:
	> Deployment
	> ReplicaSet
	> PersistentVolumeCl
	aim
	> Service
	> CronJob
	> Node
	> MutatingWebhookCon
	figuration
	> Pod
	> Ingress</pre>
		AWS DevOps

Task	Description	Skills required
	``` > StatefulSet > ValidatingWebhookC onfiguration ```	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Scan a pod in a specific namespace by using a filter.</td><td>
This command is useful for targeted debugging of specific pod issues within a Kubernetes cluster, using Amazon Bedrock AI capabilities to analyze and explain the problems it finds.
To scan a pod in a specific namespace by using a filter, use the following AWS CLI command:
<pre><code>k8sgpt analyze --backend
 amazonbedrock --
explain --filter Pod -n
 default</code></pre>
Following is an example of the expected output of this command:
<pre><code>100% |#################
##################
##################
###| (1/1, 645 it/s)

AI Provider: amazonbed
rock

0: Pod default/c
rashme()
- Error: the last
 termination reason
 is Error container
=crashme pod=crashme
Error: The pod named
 crashme terminated</code></pre>
</td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	``` because the container named crashme crashed. Solution: Check logs for crashme pod to identify reason for crash. Restart pod or redeploy application to resolve crash. ```	

Task	Description	Skills required

Scan a deployment in a specific namespace by using a filter.	This command is useful for identifying and troubleshooting deployment-specific issues, particularly when the actual state doesn't match the desired state.
	
	To scan a deployment in a specific namespace by using a filter, use the following AWS CLI command:
	
	`k8sgpt analyze --backend amazonbedrock --explain --filter Deployment -n default`
	
	Following is an example of the expected output of this command:
	
	`100% |#################################################################| (1/1, 10 it/min)`
	
	`AI Provider: amazonbedrock`
	
	`0: Deployment default/nginx()`
	`- Error: Deployment default/nginx has 1 replicas but 2 are available`
	`Error: The Deployment named nginx in the default namespace has`
		AWS DevOps

Task	Description	Skills required
	``` 1 replica specified but 2 pod replicas are running. Solution: Check if any other controlle rs like ReplicaSet or StatefulSet have created extra pods. Delete extra pods or adjust replica count to match available pods. ```	
Scan a node in a specific namespace by using a filter.	To scan a node in a specific namespace by using a filter, use the following AWS CLI command: ``` k8sgpt analyze --backend amazonbedrock -- explain --filter Node -n default ``` Following is an example of the expected output of this command: ``` AI Provider: amazonbed rock No problems detected ```	AWS DevOps

Analyze detailed outputs

Task	Description	Skills required

Get detailed outputs.	To get detailed outputs, use the following AWS CLI command:
	```k8sgpt analyze --backend amazonbedrock --explain --ouput json```
	Following is an example of the expected output of this command:
	```{ "provider": "amazonbedrock", "errors": null, "status": "ProblemDetected", "problems": 1, "results": [{ "kind": "Pod", "name": "default/crashme", "error": [{ "Text": "the last termination reason is Error container=crashme pod=crashme", "KubernetesDoc": "", "Sensitive": [] }],```
		AWS DevOps

Task	Description	Skills required
	`"details": " Error: The pod named crashme terminated because the container named crashme crashed. \nSolution: Check logs for crashme pod to identify reason for crash. Restart pod or redeploy application to resolve crash.", "parentObject": "" } ] }`	

Check problematic pods.	To check for specific problematic pods, use the following AWS CLI command:
	`kubectl get pods --all-namespaces | grep -v Running`
	Following is an example of the expected output of this command:
	`NAMESPACE NAME READY STATUS RESTARTS AGE`
	`default crashme 0/1 CrashLoopBackOff 260(91s ago) 21h`
		AWS DevOps

Task	Description	Skills required

Get application-specific insights.	This command is particularly useful when:
	
	• You want to focus on a specific application in your cluster.
	• You use labels effectively to organize your Kubernetes resources.
	• You need to quickly check the health of a particular application component.
	
	To get application-specific insights, use the following command:
	
	`k8sgpt analyze --backend amazonbedrock --explain -L app=nginx -n default`
	
	Following is an example of the expected output of this command:
	
	`AI Provider: amazonbedrock`
	
	`No problems detected`

Automatically detect changes and initiate different CodePipeline pipelines for a monorepo in CodeCommit

Helton Ribeiro, Petrus Batalha, and Ricardo Morais, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

Notice: AWS Cloud9 is no longer available to new customers. Existing customers of AWS Cloud9 can continue to use the service as normal. Learn more

This pattern helps you automatically detect changes to the source code of a monorepo-based application in AWS CodeCommit and then initiate a pipeline in AWS CodePipeline that runs the continuous integration and continuous delivery (CI/CD) automation for each microservice. This approach means that each microservice in your monorepo-based application can have a dedicated CI/CD pipeline, which ensures better visibility, easier sharing of code, and improved collaboration, standardization, and discoverability.

The solution described in this pattern doesn't perform any dependency analysis among the microservices inside the monorepo. It only detects changes in the source code and initiates the matching CI/CD pipeline.

The pattern uses AWS Cloud9 as the integrated development environment (IDE) and AWS Cloud Development Kit (AWS CDK) to define an infrastructure by using two AWS CloudFormation stacks: `MonoRepoStack` and `PipelinesStack`. The `MonoRepoStack` stack creates the monorepo in AWS CodeCommit and the AWS Lambda function that initiates the CI/CD pipelines. The `PipelinesStack` stack defines your pipeline infrastructure.

Important

This pattern’s workflow is a proof of concept (PoC). We recommend that you use it only in a test environment. If you want to use this pattern’s approach in a production environment, see Security best practices in IAM in the AWS Identity and Access Management (IAM) documentation and make the required changes to your IAM roles and AWS services.

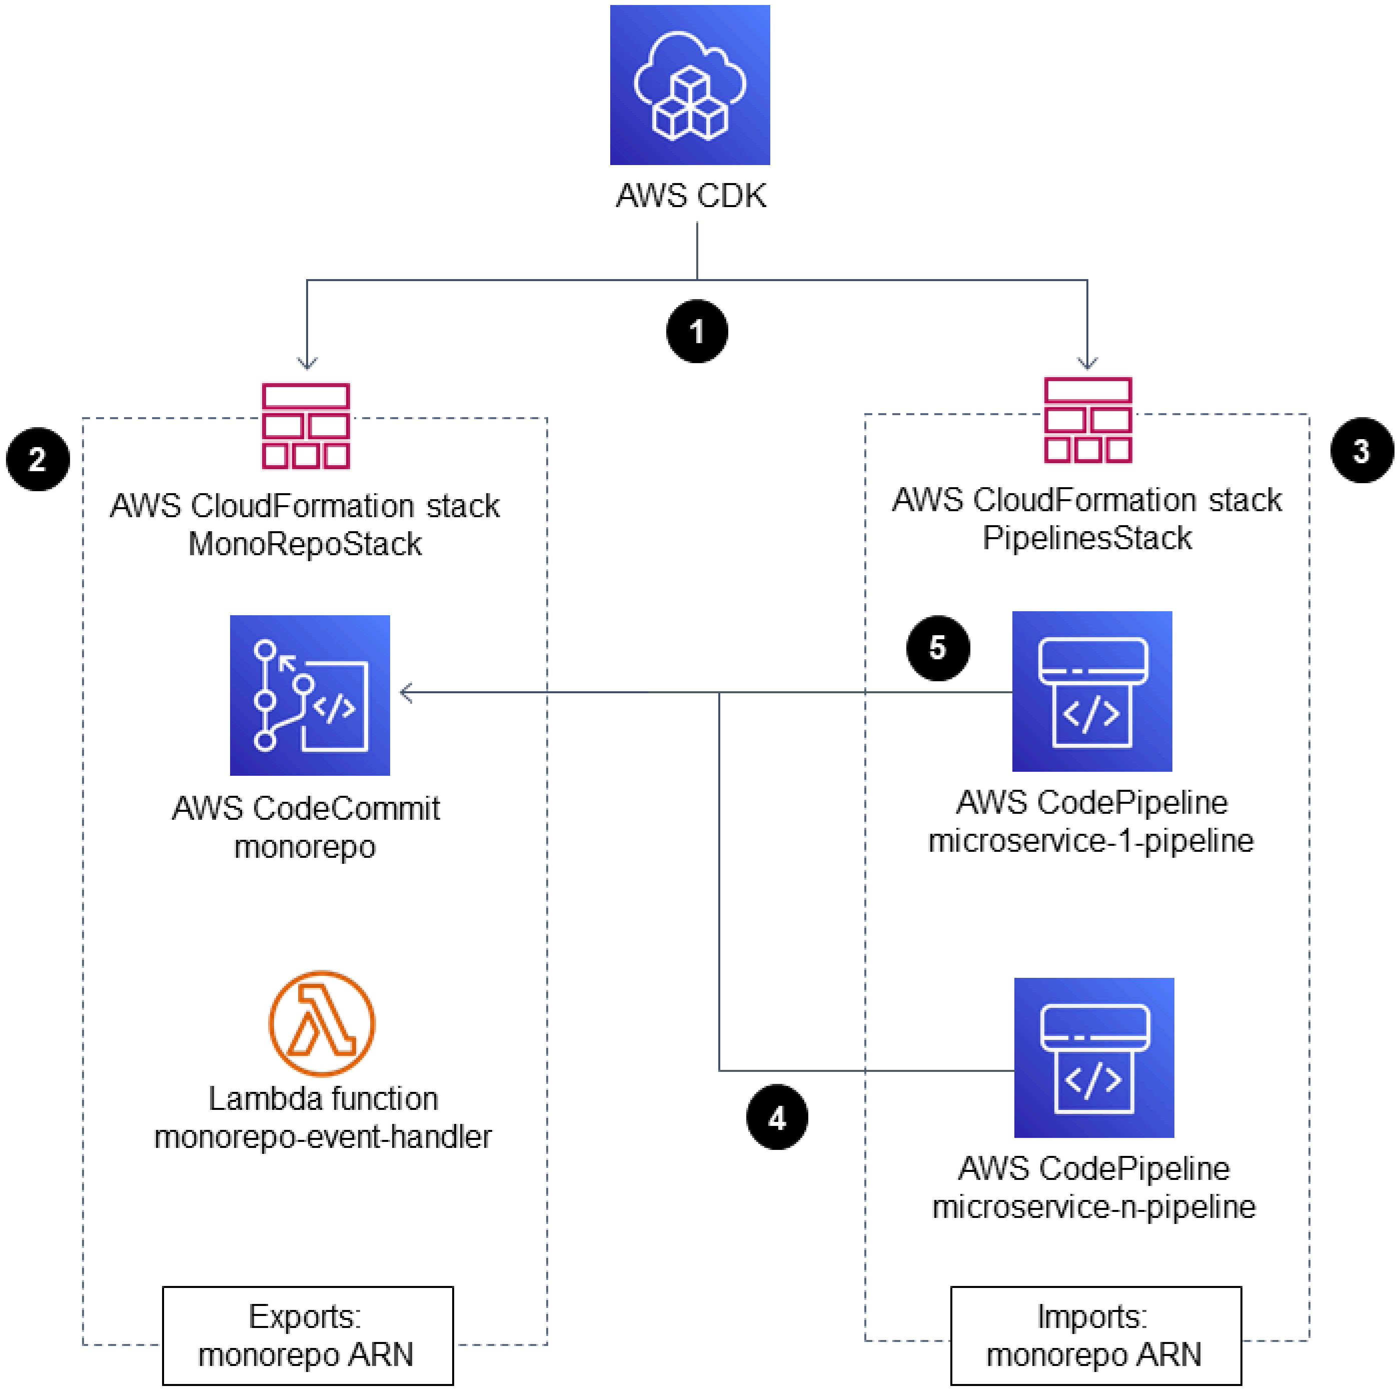
Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- Python 3 and `pip`, installed on your local machine. For more information, see the Python documentation.
- AWS CDK, installed and configured. For more information, see Getting started with the AWS CDK in the AWS CDK documentation.
- An AWS Cloud9 IDE, installed and configured. For more information, see Setting up AWS Cloud9 in the AWS Cloud9 documentation.
- The GitHub AWS CodeCommit monorepo multi-pipeline triggers repository, cloned on your local machine.
- An existing directory containing application code that you want to build and deploy with CodePipeline.
- Familiarity and experience with DevOps best practices on the AWS Cloud. To increase your familiarity with DevOps, you can use the pattern Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9 on the AWS Prescriptive Guidance website.

Architecture

The following diagram shows how to use the AWS CDK to define an infrastructure with two AWS CloudFormation stacks: `MonoRepoStack` and `PipelinesStack`.



The diagram shows the following workflow:

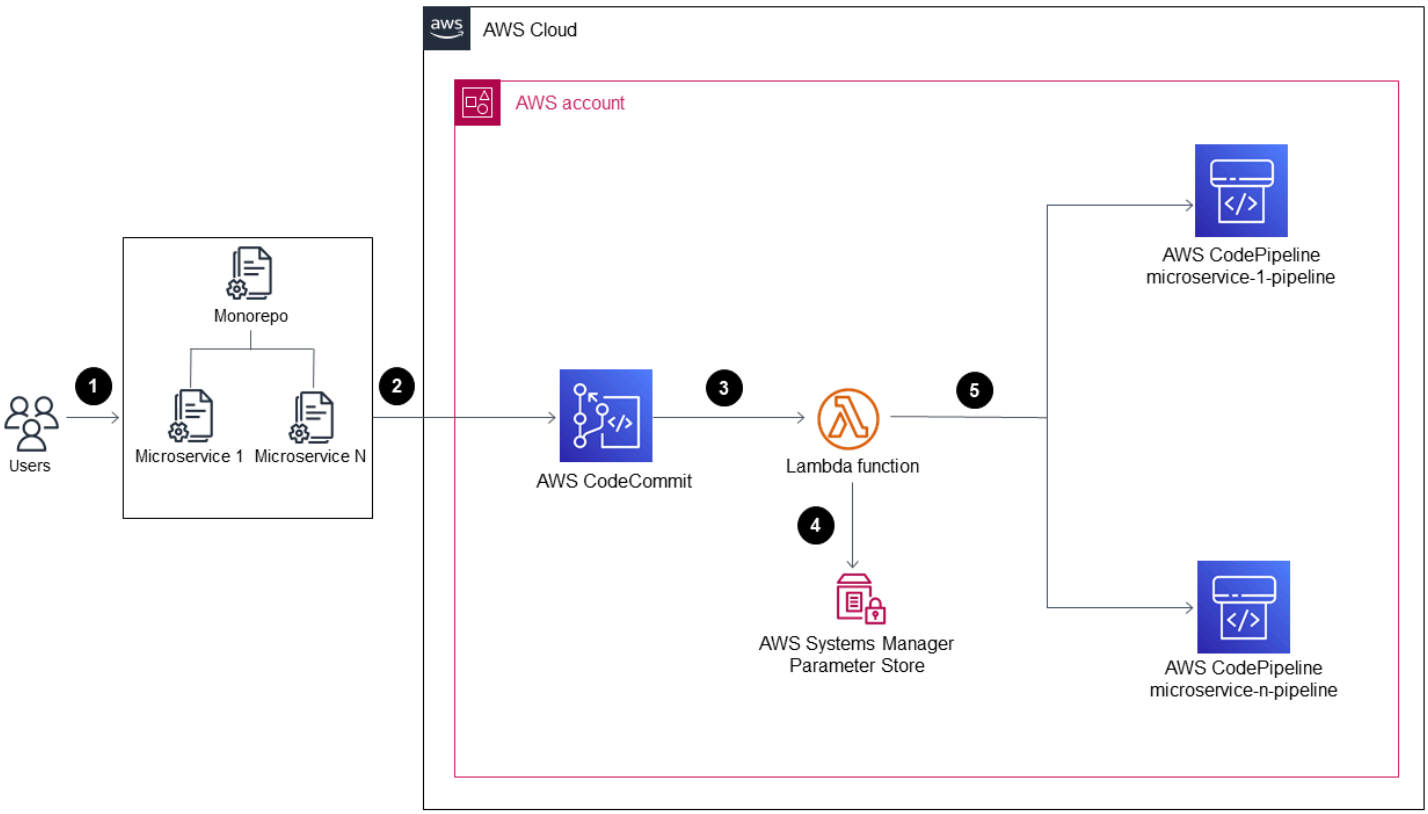
1. The bootstrap process uses the AWS CDK to create the AWS CloudFormation stacks `MonoRepoStack` and `PipelinesStack`.
2. The `MonoRepoStack` stack creates the CodeCommit repository for your application and the `monorepo-event-handler` Lambda function that is initiated after each commit.

3. The `PipelinesStack` stack creates the pipelines in CodePipeline that are initiated by the Lambda function. Each microservice must have a defined infrastructure pipeline.

4. The pipeline for `microservice-n` is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.

5. The pipeline for `microservice-1` is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.

The following diagram shows the deployment of the AWS CloudFormation stacks `MonoRepoStack` and `PipelinesStack` in an account.



1. A user changes code in one of the application's microservices.

2. The user pushes the changes from a local repository to a CodeCommit repository.

3. The push activity initiates the Lambda function that receives all pushes to the CodeCommit repository.

4. The Lambda function reads a parameter in Parameter Store, a capability of AWS Systems Manager, to retrieve the most recent commit ID. The parameter has the naming format: `/MonoRepoTrigger/{repository}/{branch_name}/LastCommit`. If the parameter isn't

found, the Lambda function reads the last commit ID from the CodeCommit repository and saves the returned value in Parameter Store.

5. After identifying the commit ID and the changed files, the Lambda function identifies the pipelines for each microservice directory and initiates the required CodePipeline pipeline.

Tools

- AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- Python is a programming language that lets you work quickly and integrate systems more effectively.

Code

The source code and templates for this pattern are available in the GitHub AWS CodeCommit monorepo multi-pipeline triggers repository.

Best practices

- This sample architecture doesn't include a monitoring solution for the deployed infrastructure. If you want to deploy this solution in a production environment, we recommend that you enable monitoring. For more information, see Monitor your serverless applications with CloudWatch Application Insights in the AWS Serverless Application Model (AWS SAM) documentation.
- When you edit the sample code provided by this pattern, follow the best practices for developing and deploying cloud infrastructure in the AWS CDK documentation.
- When you define your microservice pipelines, review the security best practices in the AWS CodePipeline documentation.
- You can also check your AWS CDK code for best practices by using the cdk-nag utility. This tool uses a set of rules, grouped by packs, to evaluate your code. The available packs are:
  - AWS Solutions Library
  - Health Insurance Portability and Accountability Act (HIPAA) security
  - National Institute of Standards and Technology (NIST) 800-53 rev 4
  - NIST 800-53 rev 5
  - Payment Card Industry Data Security Standard (PCI DSS) 3.2.1

Epics

Set up the environment

Task	Description	Skills required
Create a virtual Python envionment.	In your AWS Cloud9 IDE, create a virtual Python environment and install the required dependencies by running the following command: `make install`	Developer
Bootstrap the AWS account and AWS Region for the AWS CDK.	Bootstrap the required AWS account and Region by running the following command: `make bootstrap account-id=<your-AWS-account-ID> region=<required-region>`	Developer

Add a new pipeline for a microservice

Task	Description	Skills required
Add your sample code to your application directory.	Add the directory that contains your sample application code to the `monorepo-sample` directory in the cloned GitHub AWS CodeCommi	Developer

Task	Description	Skills required
	t monorepo multi-pipeline triggers repository.	
Edit the `monorepo-main.json` file.	Add the directory name of your application's code and the pipeline's name to the `monorepo-main.json` file in the cloned repository .	Developer
Create the pipeline.	In the `Pipelines` directory for the repository, add the pipeline `class` for your application. The directory contains two sample files, `pipeline_hotsite.py` and `pipeline_demo.py` . Each file has three stages: source, build, and deploy. You can copy one of the files and makes changes to it according to your applicati on's requirements.	Developer

Task	Description	Skills required

Edit the `monorepo_config.py` file.	In `service_map`, add the directory name for your application and the class that you created for the pipeline.
	
	For example, the following code shows a pipeline definition in the `Pipelines` directory that uses a file named `pipeline_mysample.py` with a `MySamplePipeline` class:
	
	`...`
	`# Pipeline definition imports`
	`from pipelines.pipeline_demo import DemoPipeline`
	`from pipelines.pipeline_hotsite import HotsitePipeline`
	`from pipelines.pipeline_mysample import MySamplePipeline`
	
	`### Add your pipeline configuration here`
	`service_map: Dict[str, ServicePipeline] = {`
	`    # folder-name -> pipeline-class`
	`    'demo': DemoPipeline(),`
	`    'hotsite': HotsitePipeline(),`
	`    'mysample': MySamplePipeline()`
		Developer

Task	Description	Skills required
	```}```	

Deploy the MonoRepoStack stack

Task	Description	Skills required
Deploy the AWS CloudFormation stack.	Deploy the AWS CloudFormation `MonoRepoStack` stack with default parameter values in the root directory of the cloned repository by running the `make deploy-core` command. You can change the repository's name by running the `make deploy-core monorepo-name=<repo_name>` command. **Note** You can simultaneously deploy both pipelines by using the `make deploy monorepo-name=<repo_name>` command.	Developer
Validate the CodeCommit repository.	Validate that your resources were created by running the `aws codecommit get-repository --reposit`	Developer

Task	Description	Skills required
	`ory-name <repo_name>` command. **Important** Because the AWS CloudFormation stack creates the CodeCommit repository where the monorepo is stored, don't run the `cdk destroy MonoRepoStack` command if you have started to push modifications into it.	
Validate the AWS CloudFormation stack results.	Validate that the AWS CloudFormation `MonoRepoStack` stack is correctly created and configured by running the following command: `aws cloudformation list-stacks --stack-status-filter CREATE_COMPLETE --query 'StackSummaries[?StackName == 'MonoRepoStack']'`	Developer

Deploy the PipelinesStack stack

Task	Description	Skills required
Deploy the AWS CloudFormation stack.	The AWS CloudFormation `PipelinesStack` stack must be deployed after you deploy the `MonoRepoStack` stack. The stack increases in size when new microservices are added to the monorepo's code base and is redeployed when a new microservice is onboarded. Deploy the PipelinesStack stack by running the `make deploy-pipelines` command. **Note** You can also deploy simultaneously deploy both pipelines by running the `make deploy monorepo-name=<repo_name>` command. The following sample output shows how the `PipelinesStacks` deployment prints the URLs for the microservices at the end of the implementation:	Developer

Task	Description	Skills required
	`Outputs: PipelinesStack.demourl = .cloudfront.net PipelinesStack.hotsiteurl = .cloudfront.net`	
Validate the AWS CloudFormation stack results.	Validate that the AWS CloudFormation `PipelinesStacks` stack is correctly created and configured by running the following command: `aws cloudformation list-stacks --stack-status-filter CREATE_COMPLETE UPDATE_COMPLETE --query 'StackSummaries[?StackName == 'PipelinesStack']'`	Developer

Clean up resources

Task	Description	Skills required
Delete your AWS CloudFormation stacks.	Run the `make destroy` command.	Developer
Delete the S3 buckets for your pipelines.	1. Sign in to the [AWS Management Console](#) and open the [Amazon Simple Storage Service (Amazon S3) console](#).	Developer

Task	Description	Skills required
	2. Delete the S3 buckets that are associated with your pipelines and use the following name: `pipelinesstack-codepipeline*`	

Troubleshooting

Issue	Solution
I encountered AWS CDK issues.	See [Troubleshooting common AWS CDK issues](#) in the AWS CDK documentation.
I pushed my microservice code, but the microservice pipeline didn't run.	**Setup validation** *Verify branch configuration:* • Make sure that you are pushing your code to the correct branch. This pipeline is configured to run only when changes are made to the `main` branch. Pushes to other branches don't initiate the pipeline unless they are configured specifically. • After you push your code, check if the commit is visible in AWS CodeCommit to make sure that the push was successful and that the connection between your local environment and the repository is intact. Refresh your credentials if there are issues pushing code. *Validate configuration files:*

Issue	Solution
	• Confirm that the `service_map` variable in `monorepo_config.py` accurately reflects the current directory structure of your microservices. This variable plays a crucial role in mapping your code push to the respective pipeline. • Make sure that `monorepo-main.json` is updated to include the new mapping for your microservice. This file is essential for the pipeline to recognize and correctly handle changes to your microservice. **Troubleshooting on the console** *AWS CodePipeline checks:* • On the AWS Management Console, confirm that you're in the AWS Region where your pipeline is hosted. Open the CodePipeline console and check if the pipeline that corresponds to your microservice has been initiated. **Error analysis**: If the pipeline was initiated but failed, review any error messages or logs provided by CodePipeline to understand what went wrong. *AWS Lambda troubleshooting:* • On the AWS Lambda console, open the `monorepo-event-handler` Lambda function. Verify that the function was initiated in response to the code push.

Issue	Solution
	Log analysis: Examine the Lambda function's logs for any issues. The logs can provide detailed insights into what happened when the function ran and help identify whether the function processed the event as expected.

Issue	Solution
I need to redeploy all my microservices.	There are two approaches to force the redeployment of all microservices. Choose the option that fits your requirements. **Approach 1: Delete a parameter in Parameter Store** This method involves deleting a specific parameter within Systems Manager Parameter Store that tracks the last commit ID used for deployment. When you remove this parameter , the system is forced to redeploy all microserv ices upon the next trigger, because it perceives it as a fresh state. Steps: 1. Locate the specific Parameter Store entry that holds the commit ID or a related deployment marker for your monorepo. The parameter name follows the format: `"/MonoRepoTrigger/{repository}/{branch_name}/LastCommit"` 2. Consider backing up the parameter value if it's critical or if you wish to maintain a record of the deployment state before resetting it. 3. Use the AWS Management Console, AWS CLI, or SDKs to delete the identifie d parameter. This action resets the deployment marker. 4. After deletion, the next push to the repository should cause the system to deploy all microservices, because it looks

Issue	Solution
	for the latest commit to consider for deployment. Pros: • Simple and quick to implement with minimal steps. • Doesn't require making arbitrary code changes to initiate deployments. Cons: • Less granular control over the deployment process. • Potentially risky if the Parameter Store is used for managing other critical configura tions. **Approach 2: Push a commit in each monorepo subfolder** This method involves making a minor change and pushing it in each microservice subfolder within the monorepo to initiate their individua l pipelines. Steps: 1. List all the microservices within the monorepo that need redeployment. 2. For each microservice, make a minimal, non-impactful change in its subfolder. This might be updating a `README` file, adding a comment in a configuration file, or any

Issue	Solution
	change that doesn't affect the service's functionality. 3. Commit these changes with a clear message (such as "Initiate redeployment of microserv ices") and push them to the repository. Make sure that you push the changes to the branch that initiates the deployment. 4. Monitor the pipelines for each microserv ice to confirm that they are initiated and complete successfully. Pros: • Provides granular control over which microservices are redeployed. • Safer because it doesn't involve deleting configuration parameters that might be used for other purposes. Cons: • More time-consuming, especially with a large number of microservices. • Requires making unnecessary code changes that could clutter the commit history.

Integrate a Bitbucket repository with AWS Amplify using AWS CloudFormation

Alwin Abraham, Amazon Web Services

Summary

AWS Amplify helps you to quickly deploy and test static websites without having to set up the infrastructure that is typically required. You can deploy this pattern's approach if your organization wants to use Bitbucket for source control, whether to migrate existing application code or build a new application. By using AWS CloudFormation to automatically set up Amplify, you provide visibility into the configurations that you use.

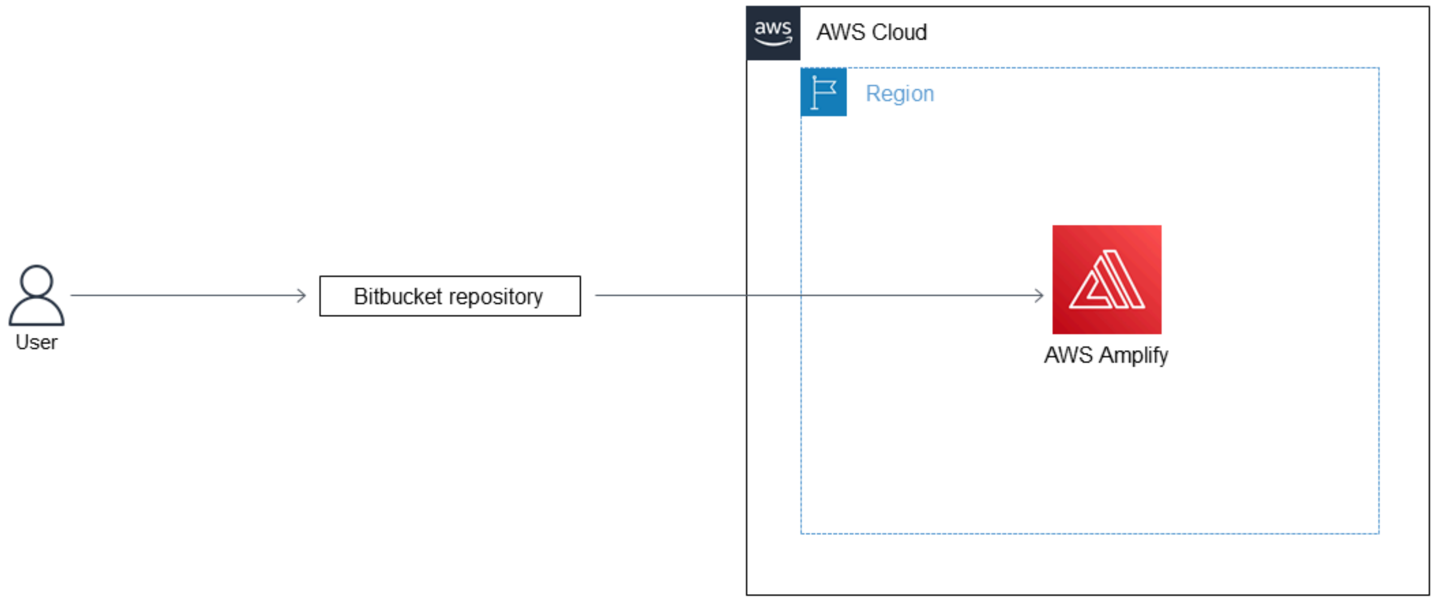
This pattern describes how to create a front-end continuous integration and continuous deployment (CI/CD) pipeline and deployment environment by using AWS CloudFormation to integrate a Bitbucket repository with AWS Amplify. The pattern's approach means that you can build an Amplify front-end pipeline for repeatable deployments.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- An active Bitbucket account with administrator access
- Access to a terminal that uses cURL or the Postman application
- Familiarity with Amplify
- Familiarity with AWS CloudFormation
- Familiarity with YAML-formatted files

Architecture



Technology stack

- Amplify
- AWS CloudFormation
- Bitbucket

Tools

- AWS Amplify – Amplify helps developers to develop and deploy cloud-powered mobile and web apps.
- AWS CloudFormation – AWS CloudFormation is a service that helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
- Bitbucket – Bitbucket is a Git repository management solution designed for professional teams. It gives you a central place to manage Git repositories, collaborate on your source code, and guide you through the development flow.

Code

The `bitbucket-amplify.yml` file (attached) contains the AWS CloudFormation template for this pattern.

Epics

Configure the Bitbucket repository

Task	Description	Skills required
(Optional) Create a Bitbucket repository.	1. Sign in to your Bitbucket account and create a new repository. For more information about this, see Create a Git repository in the Bitbucket documenta tion. 2. Record the workspace's name. **Note** You can also use an existing Bitbucket repository.	DevOps engineer
Open the workspace settings.	1. Open the workspace and choose the **Repository** tab. 2. Choose the repository that you want to integrate with Amplify. 3. Choose the name of the workspace that is above the repository's name. 4. On the sidebar, choose **Settings**.	DevOps engineer
Create an OAuth consumer.	1. In the **Apps and Features** section, choose **OAuth**	DevOps engineer

Task	Description	Skills required
	consumers, and then choose **Add consumer.** 2. Enter a name for your consumer, for example, `Amplify Integration` . 3. Enter a callback URL. Although this field is a required input, it's not used to complete the integrati on so the value could be `http://localhost:3000` 4. Check the box for **This is a private consumer**. 5. Choose the following permissions: • **Project –** `Read` • **Repositories –** `Admin` • **Pull requests –** `Read` • **Webhooks –** `Read and Write` 6. Leave the default choices for all the other fields and choose **Submit**. 7. Record the key and secret that are generated.	

Task	Description	Skills required
Obtain OAuth access token.	1. Open a terminal window and run the following command: `curl -X POST -u "KEY:SECRET" https://bitbucket.org/site/oauth2/access_token -d grant_type=client_credentials` **Important** Replace KEY and SECRET with the key and secret that you recorded earlier. 2. Record the access token without using the quotation marks. The token is only valid for a limited time and the default time is two hours. You must run the AWS CloudFormation template in this timeframe.	DevOps engineer

Create and deploy the AWS CloudFormation stack

Task	Description	Skills required
Download the AWS CloudFormation template.	Download the `bitbucket-amplify.yml` AWS	

Task	Description	Skills required
	CloudFormation template (attached). This template creates the CI/CD pipeline in Amplify, in addition to the Amplify project and branch.	

Task	Description	Skills required
Create and deploy the AWS CloudFormation stack.	1. Sign in to the AWS Management Console in the AWS Region that you want to deploy in and open the AWS CloudFormation console. 2. Choose **Create Stack (with new resources)** and then choose **Upload a Template File**. 3. Upload the `bitbucket-amplify.yml` file. 4. Choose **Next**, enter a stack name, and then enter the following parameters: • **Access token**: Paste the OAuth access token that you created earlier. • **Repository URL**: Add the Bitbucket project repository's URL. The URL is typically in the following format: `https://bitbucket.org/<WORKSPACE_NAME>/<REPO_NAME>` • **Branch name**: This must match the name of a branch in your Bitbucket repository. This branch doesn't need to exist when you run the AWS	DevOps engineer

Task	Description	Skills required
	CloudFormation stack but it is required for deploying code to the environment. • **Project name**: This is the name to associate with the Amplify project. 5. Choose **Next** and then choose **Create Stack**.	

Test the CI/CD pipeline

Task	Description	Skills required
Deploy the code to the branch in your repository.	1. Clone your Bitbucket repository by running the following command: `git clone https://bitbucket.org/<WORKSPACE_NAME>/<REPO_NAME>` 2. Check out the branch name that was used when running the AWS CloudFormation script. To create and check out a new branch, run the `git checkout -b <BRANCH_NAME>` command. To check out an existing branch, run the `git checkout`	App developer

Task	Description	Skills required
	<BRANCH_NAME> command 3. Commit the code into the branch and push it to the remote branch by running the `git commit` and `git push` commands. 4. Amplify then builds and deploys the application. For more information about this, see Basic Git commands in the Bitbucket documentation.

Launch a CodeBuild project across AWS accounts using Step Functions and a Lambda proxy function

Richard Milner-Watts and Amit Anjarlekar, Amazon Web Services

Summary

This pattern demonstrates how to asynchronously launch an AWS CodeBuild project across multiple AWS accounts by using AWS Step Functions and an AWS Lambda proxy function. You can use the pattern's sample Step Functions state machine to test the success of your CodeBuild project.

CodeBuild helps you launch operational tasks using the AWS Command Line Interface (AWS CLI) from a fully-managed runtime environment. You can change the behavior of your CodeBuild project at runtime by overriding environment variables. Additionally, you can use CodeBuild to manage workflows. For more information, see Service Catalog Tools on the AWS Workshop website and Schedule jobs in Amazon RDS for PostgreSQL using AWS CodeBuild and Amazon EventBridge on the AWS Database Blog.

Prerequisites and limitations

Prerequisites

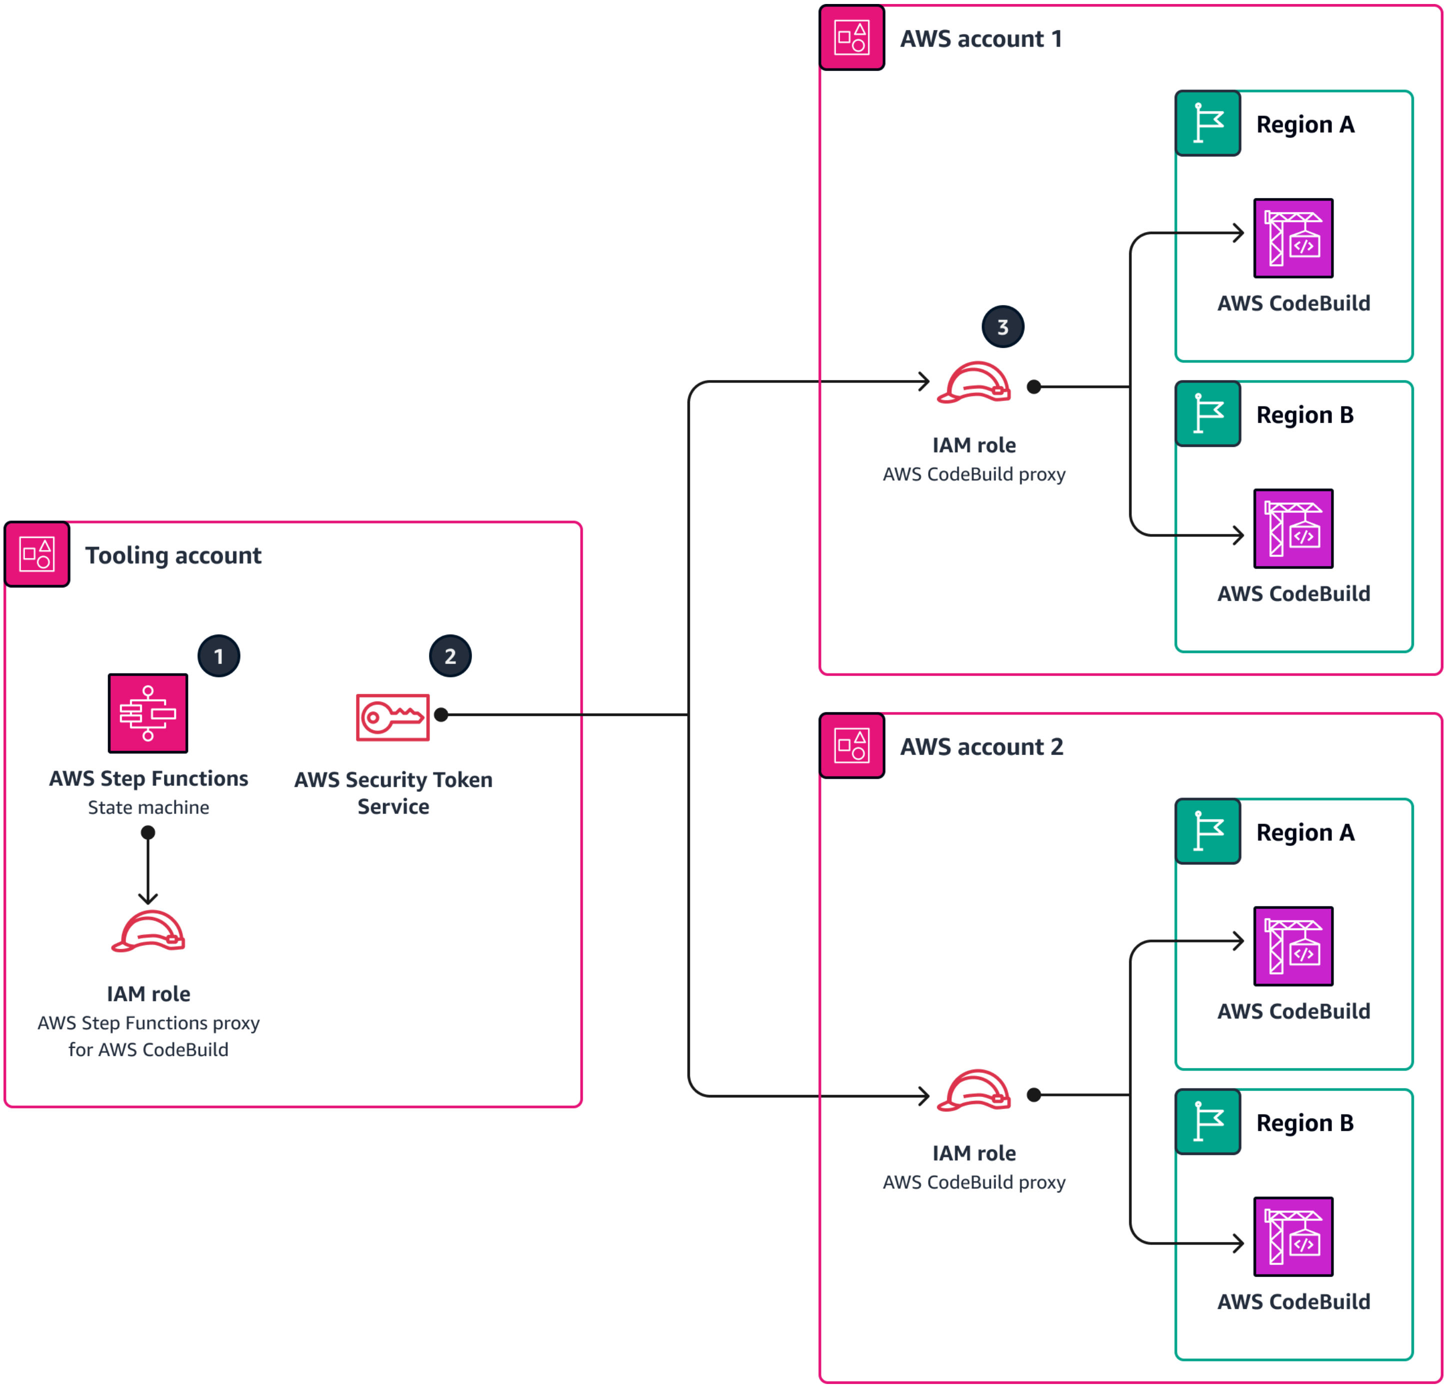
- Two active AWS accounts: a source account for invoking a Lambda proxy function with Step Functions and a target account for building a remote CodeBuild sample project

Limitations

- This pattern cannot be used to copy artifacts between accounts.

Architecture

The following diagram shows the architecture that this pattern builds.

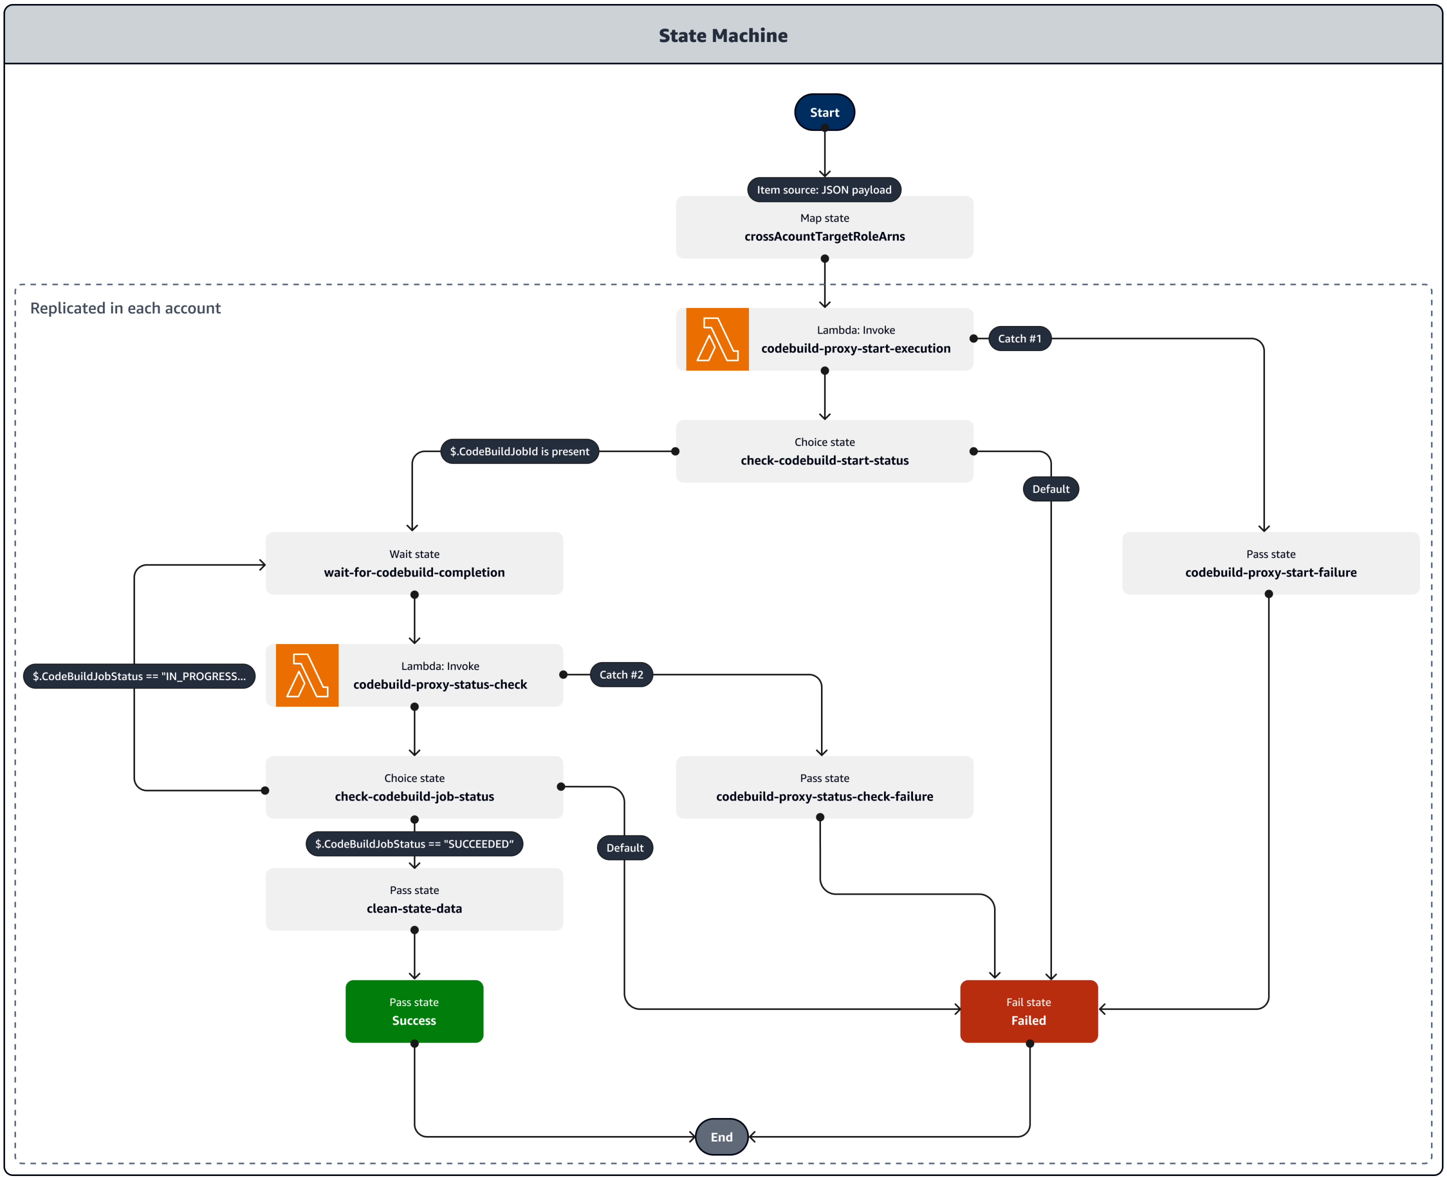


The diagram shows the following workflow:

1. The Step Functions state machine parses the supplied input map and invokes the Lambda proxy function (`codebuild-proxy-lambda`) for each account, Region, and project you defined.
2. The Lambda proxy function uses AWS Security Token Service (AWS STS) to assume an IAM proxy role (`codebuild-proxy-role`), which is associated with an IAM policy (`codebuild-proxy-policy`) in the target account.

3. Using the assumed role, the Lambda function launches the CodeBuild project and returns the CodeBuild job ID. The Step Functions state machine loops and polls the CodeBuild job until receiving a success or failure status.

The state machine logic is shown in the following image.



Technology stack

- AWS CloudFormation
- CodeBuild
- IAM

- Lambda
- Step Functions
- X-Ray

Tools

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CloudFormation Designer provides an integrated JSON and YAML editor that helps you view and edit CloudFormation templates.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- AWS X-Ray helps you collect data about the requests that your application serves, and provides tools that you can use to view, filter, and gain insights into that data to identify issues and opportunities for optimization.

Code

The sample code for this pattern is available in the GitHub Cross Account CodeBuild Proxy repository. This pattern uses the AWS Lambda Powertools for Python library to provide logging and tracing functionality. For more information on this library and its utilities, see Powertools for AWS Lambda (Python).

Best practices

1. Adjust the wait time values in the Step Function state machine to minimize polling requests for job status. Use the expected execution time for the CodeBuild project.

2. Adjust the `MaxConcurrency` property of the map in Step Functions to control how many CodeBuild projects can run in parallel.
3. If required, review the sample code for production readiness. Consider what data might be logged by the solution and whether the default Amazon CloudWatch encryption is sufficient.

Epics

Create the Lambda proxy function and associated IAM role in the source account

Task	Description	Skills required
Record the AWS account IDs.	AWS account IDs are required to set up access across accounts. Record the AWS account ID for your source and target accounts. For more information, see [Finding your AWS account ID](#) in the IAM documentation.	AWS DevOps
Download the AWS CloudFormation templates.	1. Download the `sample_target_codebuild_template.yaml` AWS CloudFormation template from the [GitHub repository](#) for this pattern. 2. Download the `codebuild_lambda_proxy_template.yaml` AWS CloudFormation template from the [GitHub repository](#) for this pattern.	AWS DevOps

Task	Description	Skills required
	Note In the AWS CloudFormation templates, `<SourceAccountId>` is the AWS account ID for the source account, and `<TargetAccountId>` is the AWS account ID for the target account.	

Task	Description	Skills required
Create and deploy the AWS CloudFormation stack.	1. Sign in to the AWS Management Console for your source account, open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/), and then choose **Stacks**. 2. Choose **Create Stack** and then choose **With new resources (standard)**. 3. For **Template source**, choose **Upload a template file**. 4. For **Upload a template** file, choose **file**, and then choose your downloaded `codebuild_lambda_proxy_template.yaml` file. Choose **Next**. 5. For **Stack name**, enter a name for the stack (for example, `codebuild-lambda-proxy`). 6. **Note** Replace the `crossAccountTargetRoleArn` parameter with your `<TargetAccountId>` (for example, `<arn:aws:`	AWS DevOps

Task	Description	Skills required
	`iam::123456789012:role/proxy-lambda-codebuild-role`>). : You aren't required to update the default value for the `targetCodeBuildProject` parameter. 7. Choose **Next**, accept the default stack creation options, and then chose **Next**. 8. Choose the **I acknowledge that AWS CloudFormation might create IAM resources with custom names** check box, and then choose **Create stack**. **Note** You must create the AWS CloudFormation stack for the proxy Lambda function before creating any resources in target accounts. When you create a trust policy in a target account, the	

Task	Description	Skills required
	IAM role is translated from the role name to an internal identifier. This is why the IAM role must already exist.	
Confirm the creation of the proxy function and state machine.	1. Wait for the AWS CloudFormation stack to reach **CREATE_COMPLETE** status. This should take less than one minute. 2. Open the [AWS Lambda console](https://console.aws.amazon.com/lambda/), choose **Functions**, and then find the `lambda-proxy-ProxyLambda-<GUID>` function. 3. Open the [AWS Step Functions console](https://console.aws.amazon.com/states/), choose **state machines**, and then find the `sample-crossaccount-codebuild-state-machine` state machine.	AWS DevOps

Create an IAM role in the target account and launch a sample CodeBuild project

Task	Description	Skills required
Create and deploy the AWS CloudFormation stack.	1. Sign in to the AWS Management Console for your target account, open the [AWS CloudFormation](https://console.aws.amazon.com/cloudformation/)	AWS DevOps

Task	Description	Skills required
	console, and then choose **Stacks**. 2. Choose **Create Stack** and then choose **With new resources (standard)**. 3. For **Template source**, choose **Upload a template file**. 4. For **Upload a template** file, choose **Choose file**, and then choose the sample_target_codebuild_template.yaml file. Choose **Next**. 5. For **Stack name**, enter a name for the stack (for example: sample-codebuild-stack). 6. Replace the crossAccountSourceRoleArn parameter with your <SourceAccountId> (for example, <arn:aws:iam::123456789012:role/codebuild-proxy-lambda-role>). 7. Choose **Next**, accept the default stack creation options, and then choose **Next**. 8. Choose the **I acknowledge that AWS CloudFormation might create IAM**	

Task	Description	Skills required
	resources with custom names check box, and then choose **Create stack**.	
Verify the creation of the sample CodeBuild project.	1. Wait for the AWS CloudFormation stack to reach **CREATE_COMPLETE** status. This should take less than one minute. 2. Open the [AWS CodeBuild console](#) and then find the `sample-codebuild-project` project.	AWS DevOps

Test the cross-account Lambda proxy function

Task	Description	Skills required
Launch the state machine.	1. Sign in to the AWS Management Console for your source account, open the [AWS Step Functions console](#), and then choose **State machines**. 2. Choose the `sample-crossaccount-codebuild-state-machine` state machine and then choose **Start execution**. 3. In the **Input** editor, enter the following JSON, and replace `<TargetAccountID>` with the AWS account ID of the	AWS DevOps

Task	Description	Skills required

	account that contains the CodeBuild project.
	``
	{
	  "crossAccountTargetRoleArns": [
	    {
	      "arn": "arn:aws:iam::<TargetAccountID>:role/proxy-lambda-codebuild-role",
	      "region": "eu-west-1",
	      "codeBuildProject": "sample-codebuild-project",
	      "SampleValue1": "Value1",
	      "SampleValue2": "Value2"
	    }
	  ]
	}
	``
	Note
	The key-value pairs are passed as environment variables from the function in the source account to the CodeBuild project in the target account.
	4. Choose **Start execution**.	

Task	Description	Skills required
	5. On the **Details** tab of the state machine page, check if **Execution Status** is set to **Succeeded**. This confirms that your state machine is running. **Note**: It can take around 30 seconds for the state machine to reach **Succeeded** status. 6. To see the output and input of a step in the state machine, expand that step in the **Execution event history** section. For example, expand the **Lambda - CodeBuild Proxy – Start** step. The output includes details on the overridden environme nt variables, the original payload, and the CodeBuild job ID.	

Task	Description	Skills required
Validate the environment variables.	1. Sign in to the AWS Management Console for your target account. 2. Open the [AWS CodeBuild console](), expand **Build**, and then choose **Build projects**. 3. Choose the `sample-codebuild-project` project, and then choose **View details**. 4. On the **Build history** tab, choose the most recent build of the project, and then choose **View logs**. 5. In the log output, verify that the environment variables printed to STDOUT match the environment variables from the Step Functions sample state machine.	AWS DevOps

Troubleshooting

Issue	Solution
Step Functions execution is taking longer than expected.	Adjust the `MaxConcurrency` property of the map in the Step Function state machine to control how many CodeBuild projects can run in parallel.

Issue	Solution
The execution of the CodeBuild jobs is taking longer than expected.	1. Adjust the wait time values in the Step Functions state machine to minimize polling requests for job status. Use the expected execution time for the CodeBuild project. 2. Consider whether CodeBuild is the appropriate tool to be using. For example, the time required to initialize a CodeBuild job can be significantly longer than AWS Lambda. If high throughput and fast completion times are a requirement, consider migrating the business logic to AWS Lambda and using a fan-out architect ure.

Manage Multi-AZ failover for EMR clusters by using Application Recovery Controller

Aarti Rajput, Ashish Bhatt, Neeti Mishra, and Nidhi Sharma, Amazon Web Services

Summary

This pattern offers an efficient disaster recovery strategy for Amazon EMR workloads to help ensure high availability and data consistency across multiple Availability Zones within a single AWS Region. The design uses Amazon Application Recovery Controller and an Application Load Balancer to manage failover operations and traffic distribution for an Apache Spark-based EMR cluster.

Under standard conditions, the primary Availability Zone hosts an active EMR cluster and application with full read/write functionality. If an Availability Zone fails unexpectedly, traffic is automatically redirected to the secondary Availability Zone, where a new EMR cluster is launched. Both Availability Zones access a shared Amazon Simple Storage Service (Amazon S3) bucket through dedicated gateway endpoints, which ensure consistent data management. This approach minimizes downtime and enables rapid recovery for critical big data workloads during Availability Zone failures. The solution is useful in industries such as finance or retail, where real-time analytics are crucial.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Amazon EMR on Amazon Elastic Compute Cloud (Amazon EC2)
- Access from the master node of the EMR cluster to Amazon S3.
- AWS Multi-AZ infrastructure

Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Product versions

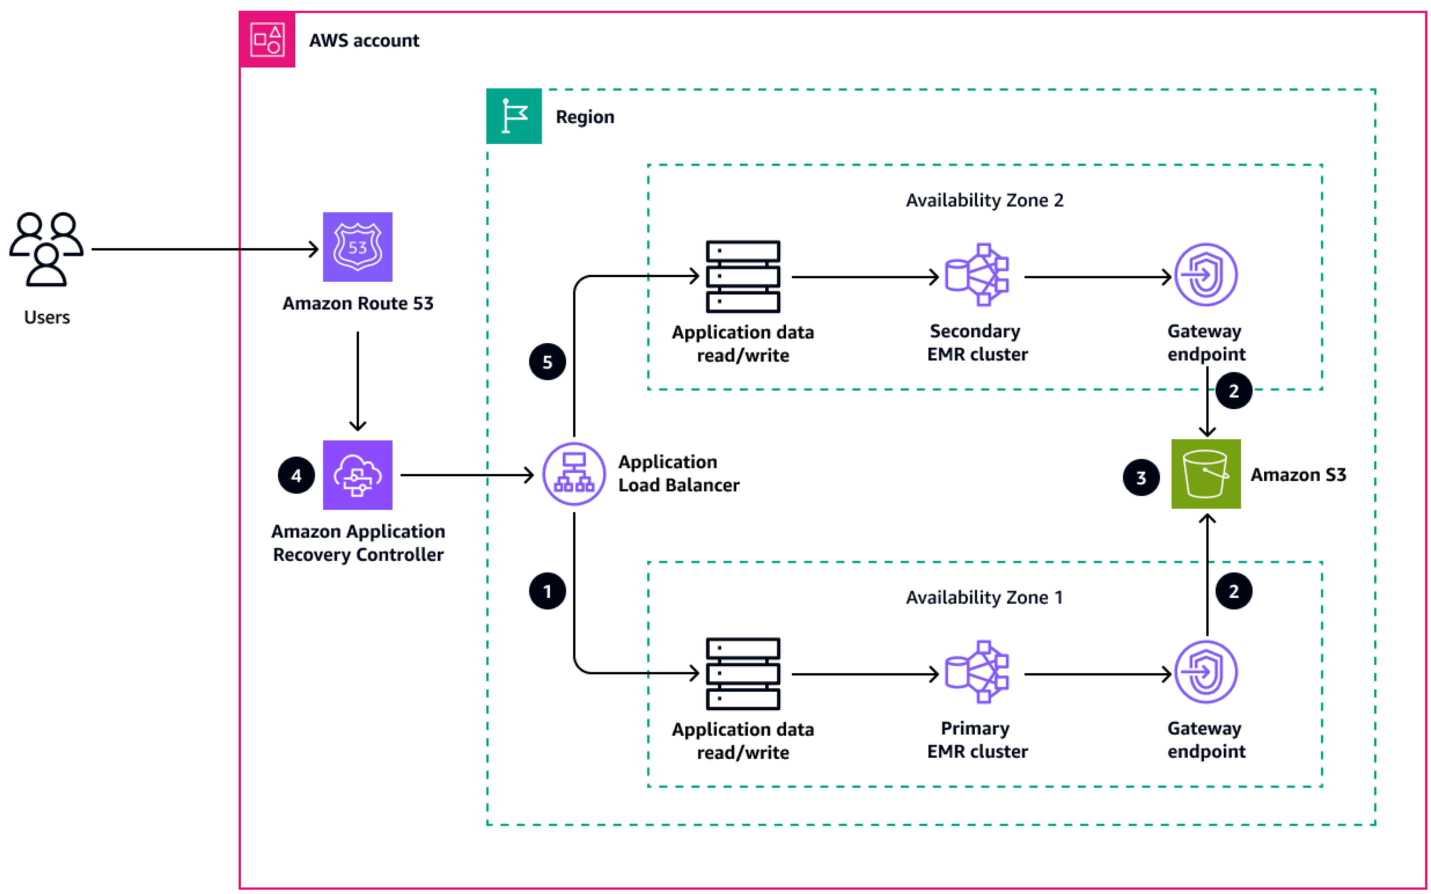
- [Amazon EMR 6.x and later releases]

Architecture

Target technology stack

- Amazon EMR cluster
- Amazon Application Recovery Controller
- Application Load Balancer
- Amazon S3 bucket
- Gateway endpoints for Amazon S3

Target architecture



This architecture provides application resilience by using multiple Availability Zones and implementing an automated recovery mechanism through the Application Recovery Controller.

1. The Application Load Balancer routes traffic to the active Amazon EMR environment, which is typically the primary EMR cluster in the primary Availability Zone.
2. The active EMR cluster processes the application requests and connects to Amazon S3 through its dedicated Amazon S3 gateway endpoint for read and write operations.
3. Amazon S3 serves as a central data repository and is potentially used as a checkpoint or as shared storage between EMR clusters. EMR clusters maintain data consistency when they write directly to Amazon S3 through the `s3://` protocol and the EMR File System (EMRFS).
4. Application Recovery Controller continuously monitors the health of the primary Availability Zone and automatically manages failover operations when necessary.
5. If the Application Recovery Controller detects a failure in the primary EMR cluster, it takes these actions:
    - Initiates the failover process to the secondary EMR cluster in Availability Zone 2.
    - Updates routing configurations to direct traffic to the secondary cluster.

Tools

AWS services

- Amazon Application Recovery Controller helps you manage and coordinate the recovery of your applications across AWS Regions and Availability Zones. This service simplifies the process and improves the reliability of application recovery by reducing the manual steps required by traditional tools and processes.
- Application Load Balancer operates at the application layer, which is the seventh layer of the Open Systems Interconnection (OSI) model. It distributes incoming application traffic across multiple targets, such as EC2 instances, in multiple Availability Zones. This increases the availability of your application.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command line shell.
- Amazon EMR is a big data platform that provides data processing, interactive analysis, and machine learning for open source frameworks such as Apache Spark, Apache Hive, and Presto.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon S3 provides a simple web service interface that you can use to store and retrieve any amount of data, at any time, from anywhere. Using this service, you can easily build applications that make use of cloud native storage.

- Gateway endpoints for Amazon S3 are gateways that you specify in your route table to access Amazon S3 from your virtual private cloud (VPC) over the AWS network.

Best practices

- Follow AWS best practices for security, identity, and compliance to ensure a robust and secure architecture.
- Align the architecture with the AWS Well-Architected Framework.
- Use Amazon S3 Access Grants to manage access from your Spark-based EMR cluster to Amazon S3. For details, see the blog post Use Amazon EMR with S3 Access Grants to Scale Spark access to Amazon S3.
- Improve Spark performance with Amazon S3.

Epics

Set up your environment

Task	Description	Skills required
Sign in to the AWS Management Console.	Sign in to the AWS Management Console as an IAM user. For instructions, see the AWS documentation.	AWS DevOps
Configure the AWS CLI.	Install the AWS CLI or update it to the latest version so you can interact with AWS services in the AWS Management Console. For instructions, see the AWS CLI documentation.	AWS DevOps

Deploy a Spark application on your EMR cluster

Task	Description	Skills required
Create an S3 bucket.	1. Create an S3 bucket to store the input dataset, logs, application, and output data. For instructions, see the [Amazon S3 documentation](). 2. Organize the bucket into separate folders for input data (`dataset`), logs (`logs`), Spark application (`spark-app`), and output data (`output`).	AWS DevOps
Create an EMR cluster.	1. Use the following AWS CLI commands to create an EMR cluster (for example, version 6.12 or later) with instances that span two Availability Zones (such as `us-east-1a` and `us-east-1b`) for high availability. The command specifies the `m4.large` instance type as an example. `aws emr create-cluster \ --ec2-attributes AvailabilityZone=<AZ-name-1> \ --release-label emr-6.12.0 \`	AWS DevOps

Task	Description	Skills required

	``
	    --instance-groups
	  InstanceGroupType=
	MASTER,InstanceCou
	nt=1,InstanceType=
	m4.large InstanceG
	roupType=CORE,Inst
	anceCount=2,Instan
	ceType=m4.large
	``
	``
	aws emr create-cl
	uster \
	    --ec2-attributes
	  AvailabilityZone=<
	AZ-name-2> \
	    --release-label
	  emr-6.12.0 \
	    --instance-groups
	  InstanceGroupType=
	MASTER,InstanceCou
	nt=1,InstanceType=
	m4.large InstanceG
	roupType=CORE,Inst
	anceCount=2,Instan
	ceType=m4.large
	``
	For more information, see the create-cluster command and the Amazon EMR documentation.
	2. Provide the key pair, service role, and instance profile with the required permissions, as necessary.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Configure security settings for the EMR cluster.</td><td>1. Identify the security group associated with the EMR cluster's master node by using the AWS CLI describe-cluster command:
<pre><code>aws emr describe-cluster --cluster-id j-XXXXXXXX</code></pre>2. To enhance security, modify the security group settings to permit SSH access (TCP port 22) to the master node, but restrict it to your specific IP address.

For more information, see the Amazon EMR documentation.</td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required

Connect to the EMR cluster.	Connect to the master node of the EMR cluster through SSH by using the provided key pair.
	
	Ensure that the key pair file is present in the same directory as your application.
	
	Run the following commands to set the correct permissions for the key pair and to establish the SSH connection:
	
	`chmod 400 <key-pair-name>`
	`ssh -i ./<key-pair-name> hadoop@<master-node-public-dns>`
		AWS DevOps

Task	Description	Skills required

Deploy the Spark application.	After you establish the SSH connection, you will be in the Hadoop console.
	
	1. Create or edit the Spark application file (`main.py`) by using a text editor such as vim:
	
	`vim main.py`
	
	For more informati on about creating and modifying the Spark application, see the [Amazon EMR documenta tion](#).
	2. Submit the Spark applicati on to the EMR cluster, specifying the input data and output data locations in the S3 bucket:
	
	`spark-submit main.py —data_source <input-data-folder-in-s3> —output_uri <output-folder-in-s3>`
	
	Here's an example based on the folders you set up earlier:
		AWS DevOps

Task	Description	Skills required

	`spark-submit main.py —data_source dataset —output_uri output`
	3. Monitor the application's progress by checking the application logs:
	`yarn logs -applicationId <application-id>`	

Monitor the Spark application.	1. Open another terminal window and establish an SSH tunnel to the EMR cluster's resource manager web UI: `ssh -i <key-pair-name> -N -L 8157:<resource-manager-public-dns>:8088 hadoop@<resource-manager-public-dns>` 2. To monitor the application, access the resource manager web UI by navigating to `http://localhost:8157` in your web browser.	AWS DevOps

Shift traffic to another Availability Zone

Task	Description	Skills required
Create an Application Load Balancer.	Set up the target group that routes traffic between Amazon EMR master nodes that are deployed across two Availability Zones within an AWS Region. For instructions, see Create a target group for your Application Load Balancer in the Elastic Load Balancing documentation.	AWS DevOps
Configure zonal shift in Application Recovery Controller.	In this step, you'll use the zonal shift feature in Applicati on Recovery Controller to shift traffic to another Availability Zone. 1. Open the Application Recovery Controller console. 2. Under **Getting started**, choose **Zonal shift**, **Start zonal shift**. 3. Select the Availability Zone that you want to shift traffic away from. 4. Select a supported resource (for example, Application Load Balancer) for the zonal shift from the Resources table.	AWS DevOps

Task	Description	Skills required
	5. For **Set zonal shift expiration**, choose or enter an expiration for the zonal shift. You can set a duration between 1 minute and three days (72 hours). All zonal shifts are temporary. You must set an expiration, but you can update active shifts later to set a new expiration period of up to three days. 6. Enter a comment about this zonal shift. 7. Select the check box to acknowledge that starting a zonal shift will reduce available capacity for your application by shifting traffic away from the Availability Zone. 8. Choose **Start**. To use the AWS CLI, see [Examples of using the AWS CLI with zonal shift] in the Application Recovery Controller documentation.	

Task	Description	Skills required

Verify zonal shift configura tion and progress.	1. Verify the resources that are registered with zonal shift:
	`aws arc-zonal-shift list-managed-resou rces --region <AWS-region-name>`
	For example, the following output confirms that the resources are up and running in both Availability Zones.
	`"appliedWeights": { "use1-az1": 1.0, "use1-az2": 1.0 },`
	2. To visualize the zonal shift, use the following AWS CLI command to start the zonal shift:
	`aws arc-zonal-shift start-zonal-shift \ --resource-identif ier <application-load-balancer-arn> \ --away-from <source-AZ> \ --expires-in 10m --comment "testing" \ --region <AWS-regi on-name>`
		AWS DevOps

Task	Description	Skills required

	where `<source-AZ>` is the identifier of the Availability Zone you want to shift traffic away from, and `<application-load-balancer-arn>` is the Amazon Resource Name (ARN) of your Application Load Balancer.
	3. Verify that the traffic has shifted to another Availability Zone.
	`aws arc-zonal-shift get-managed-resource \ --resource-identifier <application-load-balancer-arn> \ --region <AWS-region-name>`
	You can see the zonal shift confirmed by these weights:
	`"appliedWeights": { "use1-az1": 0.0, "use1-az2": 1.0 },`

Manage blue/green deployments of microservices to multiple accounts and Regions by using AWS code services and AWS KMS multi-Region keys

Balaji Vedagiri, Vanitha Dontireddy, Ashish Kumar, Faisal Shahdad, Vivek Thangamuthu, and Anand Krishna Varanasi, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern describes how to deploy a global microservices application from a central AWS account to multiple workload accounts and Regions in accordance with a blue/green deployment strategy. The pattern supports the following:

- Software is developed in a central account, whereas workloads and applications are spread across multiple accounts and AWS Regions.
- A single AWS Key Management System (AWS KMS) multi-Region key is used for encryption and decryption to cover disaster recovery.
- The KMS key is Region-specific and has to be maintained or created in three different Regions for pipeline artifacts. A KMS multi-Region key helps retain the same key ID across Regions.
- The Git workflow branching model is implemented with two branches (development and main) and code is merged by using pull requests (PRs). The AWS Lambda function that is deployed from this stack creates a PR from the development branch to the main branch. The PR merge to the main branch initiates an AWS CodePipeline pipeline, which orchestrates the continuous integration and continuous delivery (CI/CD) flow and deploys the stacks across accounts.

This pattern provides a sample infrastructure as code (IaC) setup through AWS CloudFormation stacks to demonstrate this use case. The blue/green deployment of microservices is implemented by using AWS CodeDeploy.

Prerequisites and limitations

Prerequisites

- Four active AWS accounts:

    - A tools account to manage the code pipeline and maintain the AWS CodeCommit repository.
    - Three workload (test) accounts for deploying the microservices workload.
- This pattern uses the following Regions. If you want to use other Regions, you must make the appropriate modifications to the AWS CodeDeploy and AWS KMS multi-Region stacks.
    - Tools (AWS CodeCommit) account: `ap-south-1`
    - Workload (test) account 1: `ap-south-1`
    - Workload (test) account 2: `eu-central-1`
    - Workload (test) account 3: `us-east-1`
- Three Amazon Simple Storage Service (Amazon S3) buckets for the deployment Regions in each workload account. (These are called `S3BUCKETNAMETESTACCOUNT1`, `S3BUCKETNAMETESTACCOUNT2` and `S3BUCKETNAMETESTACCOUNT3` later in this pattern.)

  For example, you can create these buckets in specific accounts and Regions with unique bucket names as follows (replace *xxxx* with a random number):

```
##In Test Account 1
aws s3 mb s3://ecs-codepipeline-xxxx-ap-south-1 --region ap-south-1
##In Test Account 2
aws s3 mb s3://ecs-codepipeline-xxxx-eu-central-1 --region eu-central-1
##In Test Account 3
aws s3 mb s3://ecs-codepipeline-xxxx-us-east-1 --region us-east-1

#Example
##In Test Account 1
aws s3 mb s3://ecs-codepipeline-18903-ap-south-1 --region ap-south-1
##In Test Account 2
aws s3 mb s3://ecs-codepipeline-18903-eu-central-1 --region eu-central-1
##In Test Account 3
aws s3 mb s3://ecs-codepipeline-18903-us-east-1 --region us-east-1
```

Limitations

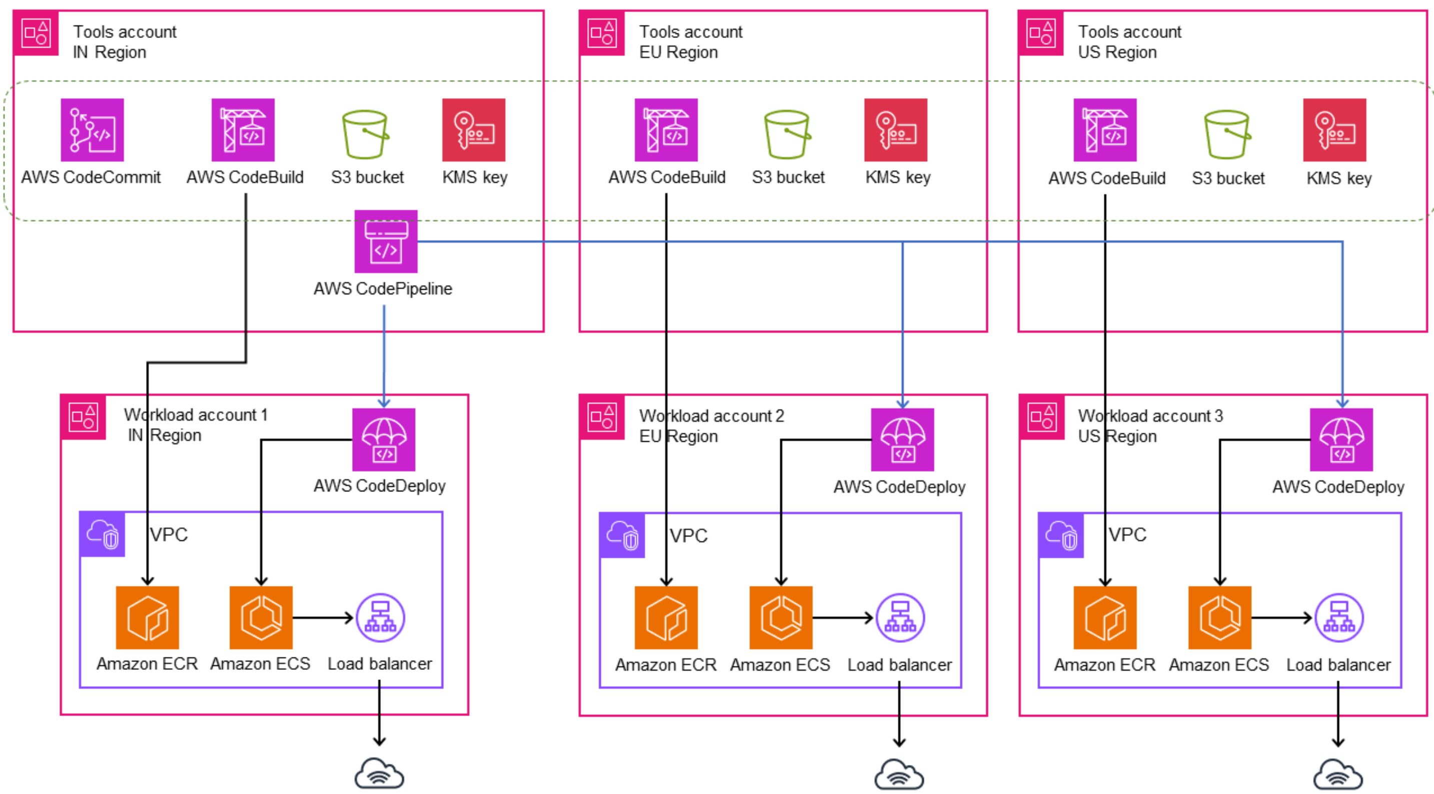
The pattern uses AWS CodeBuild and other configuration files to deploy a sample microservice. If you have a different workload type (for example, serverless), you must update all relevant configurations.

Architecture

Target technology stack

- AWS CloudFormation
- AWS CodeCommit
- AWS CodeBuild
- AWS CodeDeploy
- AWS CodePipeline

Target architecture



Automation and scale

The setup is automated by using AWS CloudFormation stack templates (IaC). It can be easily scaled for multiple environments and accounts.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodeDeploy automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Additional tools

- Git is an open-source, distributed version control system that works with the AWS CodeCommit repository.
- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers. This pattern uses Docker to build and test container images locally.
- cfn-lint and cfn-nag are open-source tools that help you review CloudFormation stacks for any errors and security issues.

Code repository

The code for this pattern is available in the GitHub Global Blue/Green deployments in multiple regions and accounts repository.

Epics

Set up environment variables

Task	Description	Skills required

Export environment variables for CloudFormation stack deployment.	Define environment variables that will be used as input to the CloudFormation stacks later in this pattern.
	
	1. Update the bucket names that you created in the three accounts and Regions as explained earlier in the Prerequisites section:
	
	`export S3BUCKETNAMETESTACCOUNT1=<S3BUCKETACCOUNT1>`
	`export S3BUCKETNAMETESTACCOUNT2=<S3BUCKETACCOUNT2>`
	`export S3BUCKETNAMETESTACCOUNT3=<S3BUCKETACCOUNT3>`
	
	2. Define a random string to create artifact buckets, because bucket names must be unique globally:
	
	`export BUCKETSTARTNAME=ecs-codepipeline-artifacts-19992`
	
	3. Define and export the account IDs and Regions:
		AWS DevOps

Task	Description	Skills required
	``` export TOOLSACCO UNT=<TOOLSACCOUNT> export CODECOMMI TACCOUNT=<CODECOMM ITACCOUNT> export CODECOMMI TREGION=ap-south-1 export CODECOMMI TREPONAME=Poc export TESTACCOU NT1=<TESTACCOUNT1> export TESTACCOU NT2=<TESTACCOUNT2> export TESTACCOU NT3=<TESTACCOUNT3> export TESTACCOU NT1REGION=ap-south -1 export TESTACCOU NT2REGION=eu-centr al-1 export TESTACCOU NT3REGION=us-east-1 export TOOLSACCO UNTREGION=ap-south -1 export ECRREPOSI TORYNAME=web ```	

Package and deploy the CloudFormation stacks for the infrastructure

Task	Description	Skills required
Clone the repository.	Clone the [sample repository](#) into a new repository in your work location: ``` ##In work location ```	AWS DevOps

Task	Description	Skills required
	`git clone https://github.com/aws-samples/ecs-blue-green-global-deployment-with-multiregion-cmk-codepipeline.git`	

Task	Description	Skills required

Package the Cloudformation resources.	In this step, you package the local artifacts that the CloudFormation templates reference to create the infrastructure resources required for services such as Amazon Virtual Private Cloud (Amazon VPC) and Application Load Balancer.
	
	The templates are available in the `Infra` folder of the code repository.
	
	`##In TestAccount1## aws cloudformation package \ --template-file mainInfraStack.yaml \ --s3-bucket $S3BUCKETNAMETESTACCOUNT1 \ --s3-prefix infraStack \ --region $TESTACCOUNT1REGION \ --output-template-file infrastructure_${TESTACCOUNT1}.template`
	
	`##In TestAccount2## aws cloudformation package \ --template-file mainInfraStack.yaml \`
		AWS DevOps

Task	Description	Skills required

	``
	    --s3-bucket
	 $S3BUCKETNAMETESTA
	CCOUNT2 \
	    --s3-prefix
	 infraStack \
	    --region $TESTACCO
	UNT2REGION \
	    --output-template-
	file infrastructure_
	${TESTACCOUNT2}.templ
	ate
	``
	``
	##In TestAccount3##
	aws cloudformation
	 package \
	    --template-file
	 mainInfraStack.yaml \
	    --s3-bucket
	 $S3BUCKETNAMETESTA
	CCOUNT3 \
	    --s3-prefix
	 infraStack \
	    --region $TESTACCO
	UNT3REGION \
	    --output-template-
	file infrastructure_
	${TESTACCOUNT3}.templ
	ate
	``	

Task	Description	Skills required

Validate the package templates.	Validate the package templates:
	`aws cloudformation validate-template \ --template-body file://infrastructure_${TESTACCOUNT1}.template`
	
	`aws cloudformation validate-template \ --template-body file://infrastructure_${TESTACCOUNT2}.template`
	
	`aws cloudformation validate-template \ --template-body file://infrastructure_${TESTACCOUNT3}.template`
		AWS DevOps

Task	Description	Skills required

Deploy the package files into the workload accounts,	1. Update the placeholder values and account names in the `infraParameters.json` script based on your setup.
	2. Deploy the package templates into your three workload accounts.
	<pre>##In TestAccount1##
	aws cloudformation
	 deploy \
	    --template-file
	 infrastructure_${T
	ESTACCOUNT1}.templ
	ate \
	    --stack-name
	 mainInfrastack \
	    --parameter-
	overrides file://in
	fraParameters.json \
	    --region $TESTACCO
	UNT1REGION \
	    --capabilities
	 CAPABILITY_IAM
	 CAPABILITY_NAMED_I
	AM
	
	##In TestAccount2##
	aws cloudformation
	 deploy \
	    --template-file
	 infrastructure_${T
	ESTACCOUNT2}.templ
	ate \
	    --stack-name
	 mainInfrastack \</pre>
		AWS DevOps

Task	Description	Skills required

	`--parameter-overrides file://infraParameters.json \ --region $TESTACCOUNT2REGION \ --capabilities CAPABILITY_IAM CAPABILITY_NAMED_IAM`
	
	`##In TestAccount3## aws cloudformation deploy \ --template-file infrastructure_${TESTACCOUNT3}.template \ --stack-name mainInfrastack \ --parameter-overrides file://infraParameters.json \ --region $TESTACCOUNT3REGION \ --capabilities CAPABILITY_IAM CAPABILITY_NAMED_IAM`	

Push a sample image and scale Amazon ECS

Task	Description	Skills required
Push a sample image to the Amazon ECR repository.	Push a sample (NGINX) image to the Amazon Elastic Container Registry (Amazon ECR) repository named web (as set in parameters). You	AWS DevOps

Task	Description	Skills required

	can customize the image as required.
	
	To log in and set the credentials for pushing an image to Amazon ECR, follow the instructions in the [Amazon ECR documentation](#).
	
	The commands are:
	
	`docker pull nginx`
	`docker images`
	`docker tag <imageid> aws_account_id.dkr.ecr.region.amazonaws.com/<web>:latest`
	`docker push <aws_account_id>.dkr.ecr.<region>.amazonaws.com/<web>:tag`	

Task	Description	Skills required
Scale Amazon ECS and verify access.	1. Scale Amazon ECS to create two replicas: `aws ecs update-service --cluster QA-Cluster --service Poc-Service --desired-count 2` where `Poc-Service` refers to your sample application. 2. Verify that the services are accessible from the Application Load Balancer by using a fully qualified domain name (FQDN) or DNS from a browser or by using the **curl** command.	AWS DevOps

Set up code services and resources

Task	Description	Skills required
Create a CodeCommit repository in the tools account.	Create a CodeCommit repository in the tools account by using the `codecommit.yaml` template, which is in the `code` folder of the GitHub repository. You must create this repository only in the single Region where you plan to develop the code.	AWS DevOps

Task	Description	Skills required
	```aws cloudformation deploy --stack-name codecommitrepoStack --parameter-overrides CodeCommitReponame=$CODECOMMITREPONAME \ ToolsAccount=$TOOLSACCOUNT --template-file codecommit.yaml --region $TOOLSACCOUNTREGION \ --capabilities CAPABILITY_NAMED_IAM```	

Task	Description	Skills required
Create an S3 bucket for managing artifacts generated by CodePipeline.	Create an S3 bucket for managing artifacts generated by CodePipeline by using the `pre-reqs-bucket.yaml` template, which is in the `code` folder of the GitHub repository. The stacks must be deployed in all three workload (test) and tools accounts and Regions. `aws cloudformation deploy --stack-name pre-reqs-artifacts-bucket --parameter-overrides BucketStartName=$BUCKETSTARTNAME \ TestAccount1=$TESTACCOUNT1 TestAccount2=$TESTACCOUNT2 \ TestAccount3=$TESTACCOUNT3 CodeCommitAccount=$CODECOMMITACCOUNT ToolsAccount=$TOOLSACCOUNT \ --template-file pre-reqs_bucket.yaml --region $TESTACCOUNT1REGION --capabilities CAPABILITY_NAMED_IAM`  `aws cloudformation deploy --stack-name pre-reqs-artifacts-bucket --parameter-overrides BucketSta`	AWS DevOps

Task	Description	Skills required
	``` rtName=$BUCKETSTAR TNAME \ TestAccount1=$TE STACCOUNT1 TestAccou nt2=$TESTACCOUNT2 \ TestAccount3=$TE STACCOUNT3 CodeCommi tAccount=$CODECOMM ITACCOUNT ToolsAcco unt=$TOOLSACCOUNT \ --template-file pre- reqs_bucket.yaml --region $TESTACCO UNT2REGION --capabil ities CAPABILIT Y_NAMED_IAM aws cloudformation deploy --stack-name pre-reqs-artifacts -bucket --parameter- overrides BucketSta rtName=$BUCKETSTAR TNAME \ TestAccount1=$TE STACCOUNT1 TestAccou nt2=$TESTACCOUNT2 \ TestAccount3=$TE STACCOUNT3 CodeCommi tAccount=$CODECOMM ITACCOUNT ToolsAcco unt=$TOOLSACCOUNT \ --template-file pre- reqs_bucket.yaml --region $TESTACCO UNT3REGION --capabil ities CAPABILIT Y_NAMED_IAM aws cloudformation deploy --stack-name pre-reqs-artifacts ```	

Task	Description	Skills required
	```-bucket --parameter-overrides BucketStartName=$BUCKETSTARTNAME \ TestAccount1=$TESTACCOUNT1 TestAccount2=$TESTACCOUNT2 \ TestAccount3=$TESTACCOUNT3 CodeCommitAccount=$CODECOMMITACCOUNT ToolsAccount=$TOOLSACCOUNT \ --template-file pre-reqs_bucket.yaml --region $TOOLSACCOUNTREGION --capabilities CAPABILITY_NAMED_IAM```	

Task	Description	Skills required
Set up a multi-Region KMS key.	1. Create a multi-Region KMS key with primary and replica keys that CodePipeline will use. In our example, `ToolsAccount1region - ap-south-1` will be the primary Region. `aws cloudformation deploy --stack-name ecs-codepipeline-pre-reqs-KMS \ --template-file pre-reqs_KMS.yaml --parameter-overrides \ TestAccount1=$TESTACCOUNT1 TestAccount2=$TESTACCOUNT2 \ TestAccount3=$TESTACCOUNT3 CodeCommitAccount=$CODECOMMITACCOUNT ToolsAccount=$TOOLSACCOUNT --region $TOOLSACCOUNTREGION` 2. Set the CMKARN variables to pass to CodeBuild projects. The values are available in the output of the ecs-codepipeline-pre-reqs-KMS template stack (the key ID will be same in all Regions and starts with `mrk-`). Or, you can get the CMKARN values from the	AWS DevOps

Task	Description	Skills required

	tools account. Export them in all account sessions:
	`export CMKARN1=arn:aws:kms:ap-south-1:<TOOLSACCOUNTID>:key/mrk-xxx`
	`export CMKARN2=arn:aws:kms:eu-central-1:<TOOLSACCOUNTID>:key/mrk-xxx`
	`export CMKARN3=arn:aws:kms:us-east-1:<TOOLSACCOUNTID>:key/mrk-xxx`
	`export CMARNTOOLS=arn:aws:kms:ap-south-1:<TOOLSACCOUNTID>:key/mrk-xxx`	

Task	Description	Skills required

Set up the CodeBuild project in the tools account.	1. Use the `codebuild _IAM.yaml` template from the code folder of the GitHub repository to set up AWS Identity and Access Management (IAM) for AWS CodeBuild in a single Region in the tools account:
	```#In ToolsAccount aws cloudformation deploy --stack-name ecs-codebuild-iam \ --template-file codebuild_IAM.yaml --region $TOOLSACCOUNTREGION \ --capabilities CAPABILITY_NAMED_IAM```
	2. Use the `codebuild .yaml` template to set up CodeBuild for your build project. Deploy this template in all three Regions as follows:
	```aws cloudformation deploy --stack-name ecscodebuildstack --parameter-overrides ToolsAccount=$TOOLSACCOUNT \ CodeCommitRepoName=$CODECOMMITREPONAME ECRRepositoryName=```
		AWS DevOps

Task	Description	Skills required
	``` $ECRREPOSITORYNAME APPACCOUNTID=$TEST ACCOUNT1 \ TestAccount3=$TE STACCOUNT3 CodeCommi tRegion=$CODECOMMI TREGION CMKARN=$C MKARN1 \ --template-file codebuild.yaml --region $TESTACCO UNT1REGION --capabil ities CAPABILIT Y_NAMED_IAM aws cloudformation deploy --stack-name ecscodebuildstack -- parameter-overrides ToolsAccount=$TOOL SACCOUNT \ CodeCommitRepoName= $CODECOMMITREPONAME ECRRepositoryName= $ECRREPOSITORYNAME APPACCOUNTID=$TEST ACCOUNT2 \ TestAccount3=$TE STACCOUNT3 CodeCommi tRegion=$CODECOMMI TREGION CMKARN=$C MKARN2 \ --template-file codebuild.yaml --region $TESTACCO UNT2REGION --capabil ities CAPABILIT Y_NAMED_IAM aws cloudformation deploy --stack-name ecscodebuildstack -- ```	

Task	Description	Skills required
	```parameter-overrides ToolsAccount=$TOOLSACCOUNT \ CodeCommitRepoName=$CODECOMMITREPONAME ECRRepositoryName=$ECRREPOSITORYNAME APPACCOUNTID=$TESTACCOUNT3 \ CodeCommitRegion=$CODECOMMITREGION CMKARN=$CMKARN3 \ --template-file codebuild.yaml --region $TESTACCOUNT3REGION --capabilities CAPABILITY_NAMED_IAM```	

Task	Description	Skills required

Set up CodeDeploy in workload accounts.	Use the `codedeploy.yaml` template in the `code` folder of the GitHub repository to set up CodeDeploy in all three workload accounts. The output of `mainInfraStack` includes the Amazon Resource Names (ARNs) of the Amazon ECS cluster and Application Load Balancer listener.
	
	Note
	The values from the infrastructure stacks are exported already, so they are imported by the CodeDeploy stack templates.
	
	`##WorkloadAccount1##`
	`aws cloudformation deploy --stack-name ecscodedeploystack \`

Call and test the pipeline

Task	Description	Skills required
Push changes to the CodeCommit repository.	1. Clone the CodeCommit repository that was created in the `codecommitrepoStack` by using the `git clone` command, as described in the [AWS CodeCommit documentation](). 2. Update the input artifacts with the required details: • JSON file: Update `AccountID` in the file in three places of this file. Rename the three files to include the account IDs. • YAML files: Update the task definition ARN and version. Rename the three files to include the account IDs. 3. Modify the `index.html` file to make a few minor changes to the home page. 4. Copy the following files to the repository and commit:	

Task	Description	Skills required
	``` index.html Dockerfile buildspec.yaml appspec_<accountid>.yaml (3 files - one per account) taskdef<accountid>.json (3 files - one per account) ``` 5. Start or restart the pipeline and verify the results. 6. Access the service from the Application Load Balancer using by using an FQDN or DNS, and verify that the updates have been deployed.	

Clean up

Task	Description	Skills required
Clean up all the deployed resources.	1. Scale down Amazon ECS to zero instances: ``` aws ecs update-service --cluster QA-Cluster --service Poc-Service --desired-count 0 ``` 2. Delete the CloudFormation stacks in each account and Region:	

Task	Description	Skills required
	```##In Tools Account## aws cloudformation delete-stack --stack-name ecscodepipelinestack --region $TOOLSACCOUNTREGION aws cloudformation delete-stack --stack-name ecscodebuildstack --region $TESTACCOUNT1REGION aws cloudformation delete-stack --stack-name ecscodebuildstack --region $TESTACCOUNT2REGION aws cloudformation delete-stack --stack-name ecscodebuildstack --region $TESTACCOUNT3REGION aws cloudformation delete-stack --stack-name ecs-codepipeline-pre-reqs-KMS --region $TOOLSACCOUNTREGION aws cloudformation delete-stack --stack-name codecommitrepoStack --region $TOOLSACCOUNTREGION aws cloudformation delete-stack --stack-name pre-reqs-artifacts-bucket --region $TESTACCOUNT1REGION aws cloudformation delete-stack --stack-name pre-reqs-```	

Task	Description	Skills required
	``` artifacts-bucket --region $TESTACCO UNT2REGION aws cloudformation delete-stack -- stack-name pre-reqs- artifacts-bucket --region $TESTACCO UNT3REGION aws cloudformation delete-stack -- stack-name pre-reqs- artifacts-bucket --region $TOOLSACC OUNTREGION aws cloudformation delete-stack -- stack-name ecs-codeb uild-iam --region $TOOLSACCOUNTREGION ##NOTE: Artifact buckets will not get deleted if there are artifacts so it has to be emptied manually before deleting.## ``` ``` ##In Workload / Test Accounts## ##Account:1## aws cloudformation delete-stack -- stack-name ecscodede ploystack --region $TESTACCOUNT1REGION aws cloudformation delete-stack -- stack-name mainInfra ```	

Task	Description	Skills required
	``` stack --region $TESTACCOUNT1REGION ##Account:2## aws cloudformation delete-stack -- stack-name ecscodede ploystack --region $TESTACCOUNT2REGION aws cloudformation delete-stack -- stack-name mainInfra stack --region $TESTACCOUNT2REGION ##Account:3## aws cloudformation delete-stack -- stack-name ecscodede ploystack --region $TESTACCOUNT3REGION aws cloudformation delete-stack -- stack-name mainInfra stack --region $TESTACCOUNT3REGION ##NOTE: Amazon ECR (web) will not get deleted if the registry still includes images. It can be manually cleaned up if not required. ```	

Troubleshooting

Issue	Solution
Changes that you committed to the repository aren't getting deployed.	• Check the CodeBuild logs for errors in the Docker build action. For more information, see the CodeBuild documentation. • Check the CodeDeploy deployment for any Amazon ECS deployment issues.

Monitor Amazon ECR repositories for wildcard permissions using AWS CloudFormation and AWS Config

Vikrant Telkar, Wassim Benhallam, and Sajid Momin, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that supports private repositories with resource-based permissions using AWS Identity and Access Management (IAM).

IAM supports the "*" wildcard in both the resource and action attributes, which makes it easier to automatically choose multiple matching items. In your testing environment, you can allow all authenticated AWS users to access an Amazon ECR repository by using the `ecr:*` wildcard permission in a principal element for your repository policy statement. The `ecr:*` wildcard permission can be useful when developing and testing in development accounts that can't access your production data.

However, you must make sure that the `ecr:*` wildcard permission is not used in your production environments because it can cause serious security vulnerabilities. This pattern's approach helps you to identify Amazon ECR repositories that contain the `ecr:*` wildcard permission in repository policy statements. The pattern provides steps and an AWS CloudFormation template to create a custom rule in AWS Config. An AWS Lambda function then monitors your Amazon ECR repository policy statements for `ecr:*` wildcard permissions. If it finds non-compliant repository policy statements, Lambda notifies AWS Config to send an event to Amazon EventBridge and EventBridge then initiates an Amazon Simple Notification Service (Amazon SNS) topic. The SNS topic notifies you by email about the non-compliant repository policy statements.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- An existing Amazon ECR repository with an attached policy statement, installed and configured in your testing environment. For more information about this, see Creating a private repository and Setting a repository policy statement in the Amazon ECR documentation.

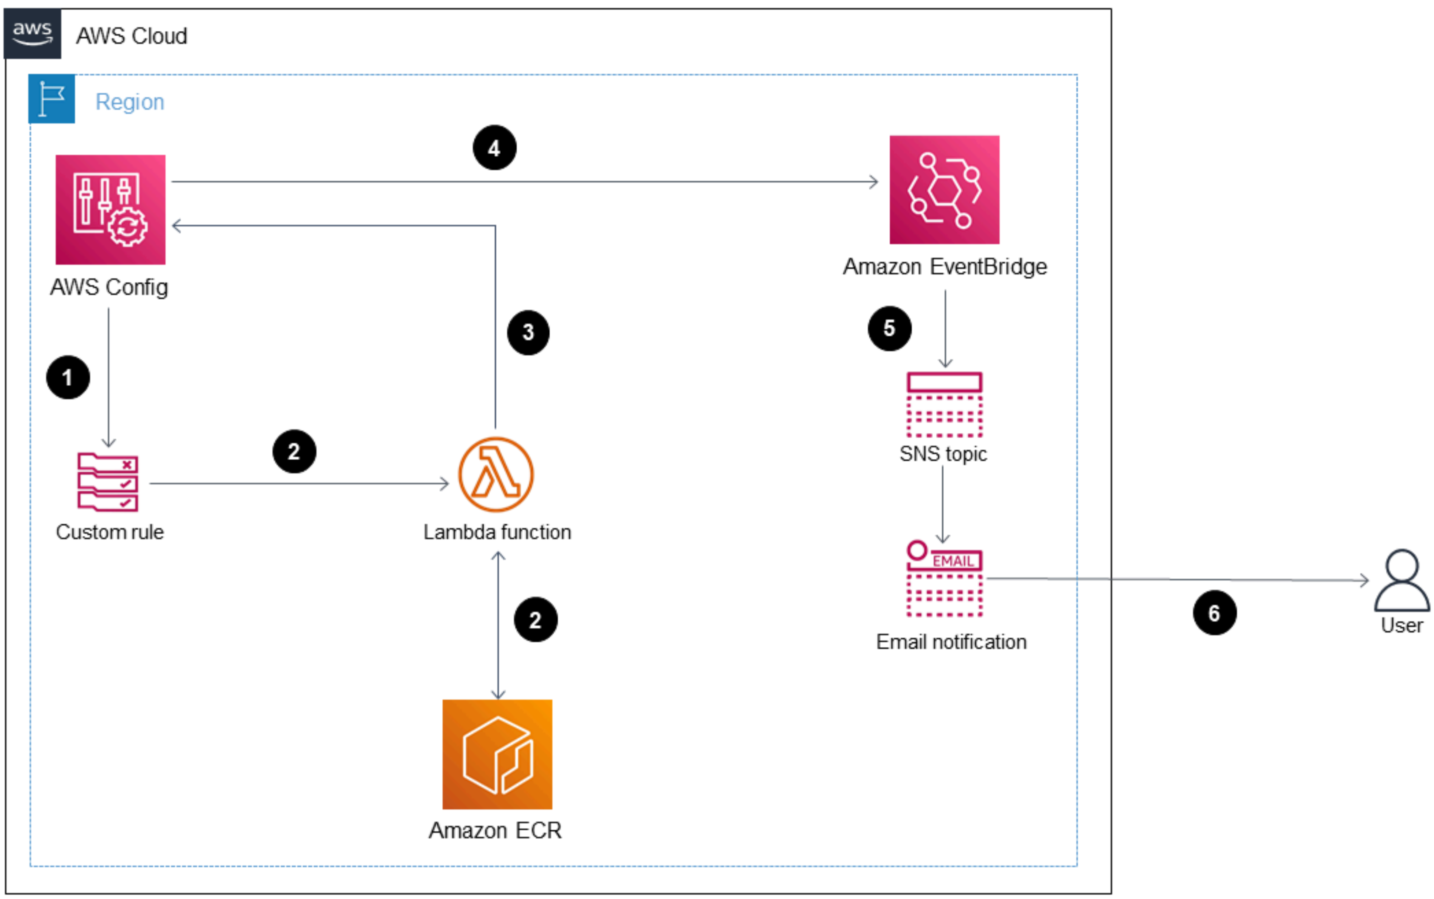
- AWS Config, configured in your preferred AWS Region. For more information about this, see [Getting started with AWS Config](#) in the AWS Config documentation.
- The `aws-config-cloudformation.template` file (attached), downloaded to your local machine.

Limitations

- This pattern's solution is Regional and your resources must be created in the same Region.

Architecture

The following diagram shows how AWS Config evaluates Amazon ECR repository policy statements.



The diagram shows the following workflow:

1. AWS Config initiates a custom rule.
2. The custom rule invokes a Lambda function to evaluate the compliance of the Amazon ECR repository policy statements. The Lambda function then identifies non-compliant repository policy statements.
3. The Lambda function sends the non-compliance status to AWS Config.
4. AWS Config sends an event to EventBridge.
5. EventBridge publishes the non-compliance notifications to an SNS topic.
6. Amazon SNS sends an email alert to you or an authorized user.

Automation and scale

This pattern's solution can monitor any number of Amazon ECR repository policy statements, but all resources that you want to evaluate must be created in the same Region.

Tools

- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- AWS Config – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.
- Amazon EventBridge – Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales

automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- [Amazon SNS](https://docs.aws.amazon.com/sns/latest/dg/welcome.html) – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

Code

The code for this pattern is available in the `aws-config-cloudformation.template` file (attached).

Epics

Create the AWS CloudFormation stack

Task	Description	Skills required
Create the AWS CloudFormation stack.	Create an AWS CloudFormation stack by running the following command in AWS CLI: `$ aws cloudformation create-stack --stack-name=AWSConfigECR \ --template-body file://aws-config-cloudformation.template \ --parameters ParameterKey=<email>,ParameterValue=<myemail@example.com> \ --capabilities CAPABILITY_NAMED_IAM`	AWS DevOps

Test the AWS Config custom rule

Task	Description	Skills required
Test the AWS Config custom rule.	1. Sign in to the AWS Management Console, open the AWS Config console, and then choose **Resources**. 2. On the **Resource inventory** page, you can filter by resource category, resource type, and compliance status. 3. An Amazon ECR repository that contains `ecr:*` is `NON-COMPLIANT?` and an Amazon ECR repository that doesn't contain `ecr:*` is `COMPLIANT` . 4. The email address subscribed to the SNS topic receives notifications if an Amazon ECR repository contains non-compliant policy statements.	AWS DevOps

Optimize multi-account serverless deployments by using the AWS CDK and GitHub Actions workflows

Sarat Chandra Pothula and VAMSI KRISHNA SUNKAVALLI, Amazon Web Services

Summary

Organizations deploying serverless infrastructure across multiple AWS accounts and environments often encounter challenges like code duplication, manual processes, and inconsistent practices. This pattern's solution shows how to use the AWS Cloud Development Kit (AWS CDK) in Go and GitHub Actions reusable workflows to streamline multi-account serverless infrastructure management. This solution demonstrates how you can define cloud resources as code, implement standardized continuous integration/continuous deployment (CI/CD) processes, and create modular, reusable components.

By using these tools, organizations can efficiently manage cross-account resources, implement consistent deployment pipelines, and simplify complex serverless architectures. The approach also enhances security and compliance by enforcing standardized practices for use with AWS accounts, ultimately improving productivity and reducing errors in serverless application development and deployment.

Prerequisites and limitations

Prerequisites

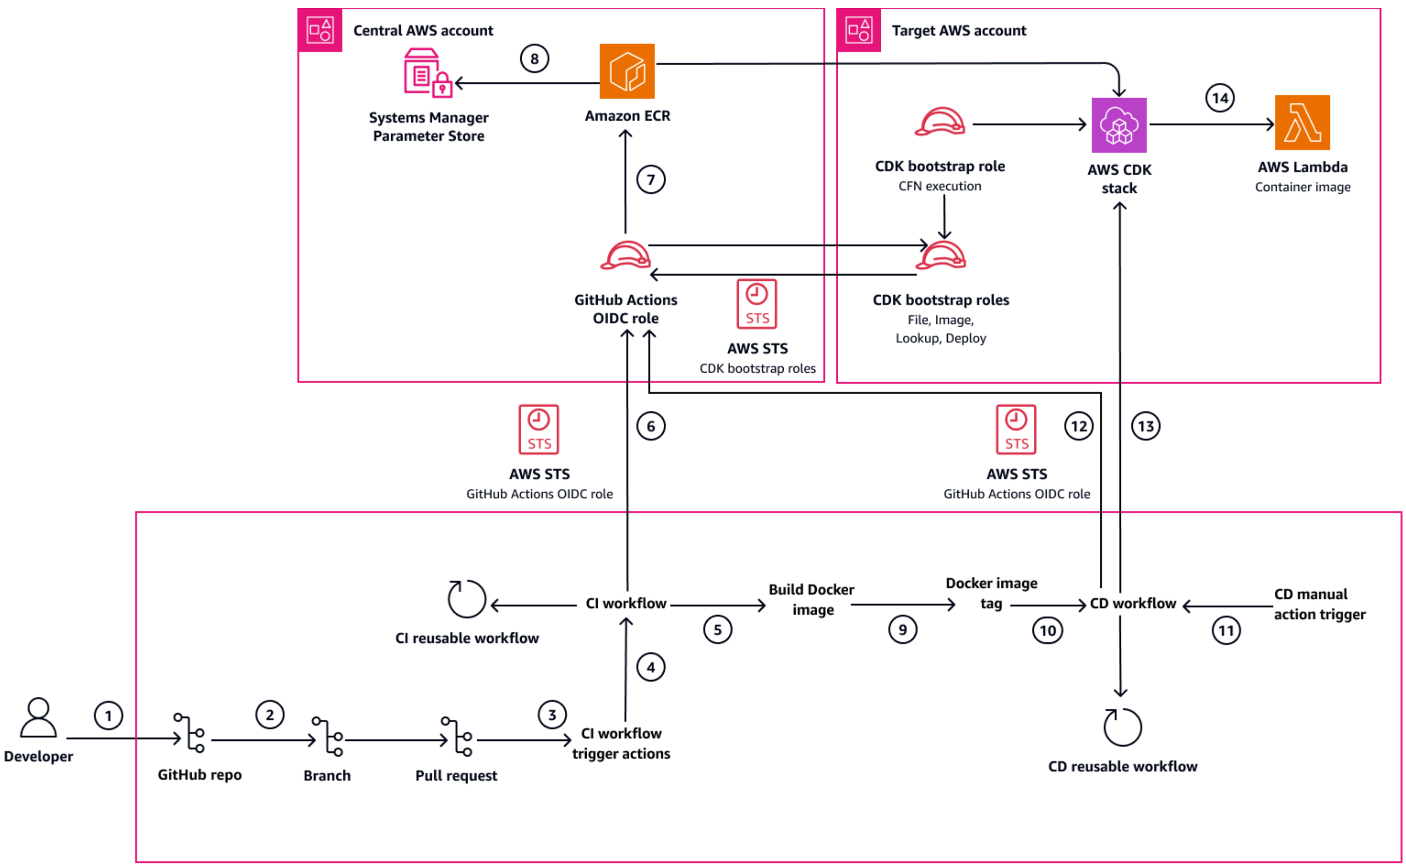
- An active AWS account.
- AWS Identity and Access Management (IAM) roles and permissions are in place for the deployment process. This includes permissions to access Amazon Elastic Container Registry (Amazon ECR) repositories, create AWS Lambda functions, and any other required resources across the target AWS accounts.
- AWS Command Line Interface (AWS CLI) version 2.9.11 or later, installed and configured.
- AWS Cloud Development Kit (AWS CDK) version 2.114.1 or later, installed and bootstrapped.
- Go 1.22 or later, installed.
- Docker 24.0.6 or later, installed.

Limitations

- **Language compatibility –** Go is a popular language for serverless applications. However, in addition to Go, the AWS CDK supports other programming languages, including C#, Java, Python, and TypeScript. If your organization has existing code bases or expertise in other languages, you might need to adapt or learn Go to fully use the solution described in the pattern.
- **Learning curve –** Adopting the AWS CDK, Go (if it's new to the organization), and GitHub reusable workflows might involve a learning curve for developers and DevOps teams. Training and documentation might be required to ensure smooth adoption and effective use of these technologies.

Architecture

The following diagram shows the workflow and architecture components for this pattern.



This solution performs the following steps:

1. The developer clones the repository, creates a new branch, and makes changes to the application code in their local environment.

2. The developer commits these changes and pushes the new branch to the GitHub repository.
3. The developer creates a pull request in the GitHub repository, proposing to merge their feature or new feature branch into the main branch.
4. This pull request triggers the continuous integration (CI) GitHub Actions workflow. The CI and the continuous deployment (CD) workflows in this pattern use reusable workflows, which are predefined, modular templates that can be shared and executed across different projects or repositories. Reusable workflows promote standardization and efficiency in the CI/CD processes.
5. The CI workflow sets up the necessary environment, generates a Docker tag for the image, and builds the Docker image using the application code.
6. The CI workflow authenticates with AWS by using the central AWS account GitHub OIDC role. For CI workflows, the central AWS account GitHub OIDC role uses AWS Security Token Service (AWS STS) to obtain temporary credentials. These credentials allow the role to build and push Docker images to the Amazon ECR repository of the central AWS account.
7. The CI workflow pushes the built Docker image to Amazon ECR.
8. The CI workflow stores the image tag to the Systems Manager Parameter Store.
9. After the CI workflow completes successfully, the Docker image tag is output.
10. When triggering the CD workflow, the developer manually inputs the image tag of the Docker image that they want to deploy. This image tag corresponds to the tag that was generated and pushed to Amazon ECR during the CI workflow.
11. The developer manually triggers the CD workflow, which uses the CD reusable workflow.
12. The CD workflow authenticates with AWS using the central AWS account GitHub OIDC role. For the CD workflow, AWS STS is first used to assume the central AWS account GitHub OIDC role. Then, this role assumes the CDK bootstrap roles for target account deployments.
13. The CD workflow uses the AWS CDK to synthesize AWS CloudFormation templates.
14. The CD workflow deploys the application to the target AWS account by using CDK deploy, using the manually specified image tag for the Lambda function.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions. CloudFormation is an integral part of the AWS CDK deployment process. The CDK synthesizes CloudFormation templates and then uses CloudFormation to create or update the resources in the AWS environment.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Systems Manager Parameter Store provides secure, hierarchical storage for configuration data management and secrets management.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- GitHub Actions is a continuous integration and continuous delivery (CI/CD) platform that's tightly integrated with GitHub repositories. You can use GitHub Actions to automate your build, test, and deployment pipeline.
- Go is an open source programming language that Google supports.

Code repository

The code for this pattern is available in the GitHub aws-cdk-golang-serverless-cicd-github-actions repository.

Best practices

- **Modular design** – Organize your AWS CDK code into modular and reusable constructs or stacks, promoting code reuse and maintainability across multiple accounts and projects.
- **Separation of concerns** – Separate the infrastructure code from the application code, allowing for independent deployment and management of each component.

- **Versioning and immutability** – Treat your infrastructure as code (IaC), and use Git for version control. Embrace immutable infrastructure principles by creating new resources instead of modifying existing ones.
- **Testing and validation** – Implement comprehensive testing strategies, including unit tests, integration tests, and end-to-end tests, to help support the correctness and reliability of your AWS CDK code and deployments.
- **Security and compliance** – Follow AWS security best practices, such as least-privilege access, secure communication, and data encryption. Implement compliance checks and auditing mechanisms to ensure adherence to organizational policies and regulatory requirements. Implement security best practices for container images, such as scanning for vulnerabilities, enforcing image signing, and adhering to compliance requirements for your organization.
- **Monitoring and logging** – Set up monitoring and logging mechanisms to track the health and performance of your serverless applications and infrastructure. Use AWS services like Amazon CloudWatch, AWS CloudTrail, and AWS X-Ray for monitoring and auditing purposes.
- **Automation and CI/CD** – Use GitHub reusable workflows and other CI/CD tools to automate the build, testing, and deployment processes, which can help support consistent and repeatable deployments across multiple accounts.
- **Environment management** – Maintain separate environments (for example, development, staging, and production). Implement strategies for promoting changes between environments, ensuring proper testing and validation before production deployments.
- **Documentation and collaboration** – Document your infrastructure code, deployment processes, and best practices to facilitate knowledge sharing and collaboration within your team.
- **Cost optimization** – Implement cost monitoring and optimization strategies, such as rightsizing resources, making use of auto-scaling, and taking advantage of AWS cost optimization services such as AWS Budgets and AWS Cost Explorer.
- **Disaster recovery and backup** – Plan for disaster recovery scenarios by implementing backup and restore mechanisms for your serverless applications and infrastructure resources.
- **Continuous improvement** – Review regularly and update your practices, tools, and processes to align with the latest best practices, security recommendations, and technological advancements in the serverless ecosystem.
- **Improve security posture** – Use AWS PrivateLink to improve the security posture of your virtual private cloud (VPC) by configuring interface VPC endpoints for Amazon ECR, AWS Lambda, and AWS Systems Manager Parameter Store.

Epics

Set up the environments

Task	Description	Skills required
Create an Amazon ECR repository in the central AWS account.	To share container images across multiple AWS accounts, you must configure cross-account access for Amazon ECR. First, create an Amazon ECR repository in the central AWS account. To create an Amazon ECR repository, run the following command: `aws ecr create-repository --repository-name sample-repo` In a later task, grant pull access to the other AWS accounts that need to use the container image.	AWS DevOps

Add cross-account permissions to the Amazon ECR repository.	To add cross-account permissions to the Amazon ECR repository in the central AWS account, run the following code:
	
	`{`
	`  "Version": "2008-10-17",`
	`  "Statement": [`
	`    {`
		AWS DevOps

Task	Description	Skills required

	``
	      "Sid": "LambdaEC
	RImageRetrievalPol
	icy",
	      "Effect": "Allow",
	      "Principal": {
	        "Service":
	 "lambda.amazonaws.
	com"
	      },
	      "Action": [
	        "ecr:Batc
	hGetImage",
	        "ecr:GetD
	ownloadUrlForLayer",
	      ],
	      "Condition": {
	        "StringLike": {
	          "aws:sour
	ceArn": "arn:aws:
	lambda:<Target_Reg
	ion>:<Target_Accou
	nt_ID>:function:*"
	        }
	      }
	    },
	    {
	      "Sid": "new
	 statement",
	      "Effect": "Allow",
	      "Principal": {
	        "AWS": "arn:aws:
	iam::<Target_Accou
	nt_ID>:root"
	        },
	      "Action": [
	        "ecr:Batc
	hGetImage",
	        "ecr:GetD
	ownloadUrlForLayer",
	      ],
	    }
	  ]
	``	

Task	Description	Skills required
	`}`	
Configure a role for GitHub OIDC role in the central AWS account.	1. Configure AWS to trust GitHub's OIDC as a federated identity, which includes adding the GitHub OIDC provider to AWS and configuring the role and trust policy in IAM. To do so, follow the instructions in [Configuring OpenID Connect in Amazon Web Services](#) in the GitHub documentation. 2. After the role is created, add necessary permissio ns to the role. For example, add permissio ns for Amazon ECR and AWS Systems Manager Parameter Store. For more information, see [Configuri ng a role for GitHub OIDC identity provider](#) in the IAM documentation.	AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Bootstrap the AWS environment in the target AWS accounts.</td><td>Set up a CDK environment in a specific AWS account and AWS Region that enables cross-account deployments from a central account and applies least-privilege principles to the CloudFormation execution role.

To bootstrap an AWS environment, run the following command:

<pre><code>cdk bootstrap aws://<Target_Account_ID>/<Target_Region> --trust <Central_Account_ID> --cloudformation-execution-policies arn:aws:iam::aws:policy/<Least_Privilege_Policy></code></pre></td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required
Grant central AWS account OIDC role access to the target AWS account bootstrap roles.	The CDK bootstrap creates the following IAM roles that are designed to be assumed by the central AWS account during various stages of the CDK deployment process: • File publishing role • Image publishing role • Lookup role • Deployment role Each role has specific permissions tailored to its purpose, following the least-privilege principle. The `Target_Account_ID` and `Target_Region` in each role name help to indicate that these roles are unique across different AWS accounts and Regions. This approach supports clear identification and management in multi-account, multi-Region setups. `Target Account CDK Bootstrap Roles arn:aws:iam::<Target_Account_ID>:role/cdk-deploy-role-<Target_Account_ID>-<Target_Region> arn:aws:iam::<Target_Account_ID>:role/cdk-`	AWS DevOps

Task	Description	Skills required
	``` file-publishing-role- <Target_Account_ID>-< Target_Region> arn:aws:iam::<Target_ Account_ID>:role/cdk- image-publishing-role- <Target_Account_ID>- <Target_Region> arn:aws:iam::<Target _Account_ID>:role/ cdk-lookup-role-<T arget_Account_ID>- <Target_Region> ``` • Update the permissions policy for the OIDC role in the central account to grant it the ability to assume roles in the target account. This configuration enables the deployment of CDK stacks across different AWS accounts. By allowing the central account's OIDC role to adopt the necessary permissions from the target account, you create a secure bridge for cross-account CDK deployments. This approach maintains proper access control while facilitating seamless multi-account infrastructure management.	

Task	Description	Skills required

	To update the permissions policy for the OIDC role in the central AWS account, use the following code:
	``
	{
	    "Version": "2012-10-17",
	    "Statement": [
	        {
	            "Effect": "Allow",
	            "Action": "sts:AssumeRole",
	            "Resource": [
	                "arn:aws:iam::<Target_Account_ID>:role/cdk-deploy-role-<Target_Account_ID>-<Target_Region>",
	                "arn:aws:iam::<Target_Account_ID>:role/cdk-file-publishing-role-<Target_Account_ID>-<Target_Region>",
	                "arn:aws:iam::<Target_Account_ID>:role/cdk-image-publishing-role-<Target_Account_ID>-<Target_Region>",
	                "arn:aws:iam::<Target_Account_ID>:role/cdk-lookup-role-<Target_Account_ID>-<Target_Region>"
	            ]
	``	

Task	Description	Skills required

	``
	        }
	    ]
	}
	``	

Build the Docker image

Task	Description	Skills required
Clone the project repository.	To clone this pattern's [GitHub repository](https://github.com/aws-samples/aws-cdk-golang-serverless-cicd-github-actions), run the following command: `git clone https://github.com/aws-samples/aws-cdk-golang-serverless-cicd-github-actions.git`	AWS DevOps
Go to the Dockerfile path.	To navigate to the Dockerfile path, run the following command: `cd lambda`	AWS DevOps
Authenticate Docker with Amazon ECR.	Amazon ECR requires secure access to your private container repositories. By signing in this way, you're allowing Docker on your local machine or CI/CD environment to interact with Amazon ECR securely.	AWS DevOps

Task	Description	Skills required
	To authenticate Docker with Amazon ECR, run the following command: `aws ecr get-login -password --region <AWS_REGION> | docker login --username AWS --password-stdin <AWS_ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com` Revise the placeholders `AWS_REGION` and `AWS_Account_ID` with your information.	
Build the Docker image.	To build the Docker image, run the following command: `docker build --platform linux/arm64 -t sample-app .`	AWS DevOps

Task	Description	Skills required

Tag and push the Docker Image.	To tag and push the Docker image to the Amazon ECR repository, run the following commands:
	`docker tag sample-app:latest <AWS_ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com/<ECR_REPOSITORY>:<DOCKER_TAG>`
	`docker push <AWS_ACCOUNT_ID>.dkr.ecr.<AWS_REGION>.amazonaws.com/<ECR_REPOSITORY>:<DOCKER_TAG>`
	Revise the placeholders `AWS_Account_ID` , `AWS_REGION` , `ECR_REPOSITORY` , and `DOCKER_TAG` with your information.
		AWS DevOps

Deploy the AWS CDK app

Task	Description	Skills required
Synthesize the CDK stack with environment-specific variables.	To generate the CloudFormation template for your infrastructure as defined in your CDK code, run the following command:	AWS DevOps

Task	Description	Skills required
	```ENV=<environment> IMAGETAG=<image_tag> ECR_ARN=<ecr_repo_arn> cdk synth``` Revise the following placeholders with your information: • `environment` – Replaced with a specific environment name such as `dev`, `staging`, or `prod`. • `image_tag` – Replace with a specific tag for a Docker image such as `v1.0.0` or `latest`. • `ecr_repo_arn` – Replace with the Amazon Resource Name (ARN) of an Amazon ECR repository.	

Task	Description	Skills required
Deploy the CDK stack.	To deploy the CDK stack to your AWS account, run the following command. The `--require-approval never` flag means that the CDK will automatically approve and execute *all* changes. This includes changes that the CDK would normally flag as needing manual review (such as IAM policy changes or removal of resources). Make sure that your CDK code and CI/CD pipeline are well-tested and secure before using the `--require-approval never` flag in production environments. `ENV=<environment> IMAGETAG=<image_tag> ECR_ARN=<ecr_repo_arn> cdk deploy --require-approval never`	AWS DevOps

Automate CI/CD using GitHub Actions workflows

Task	Description	Skills required
Create a feature branch, and add your changes.	Use the cloned repository that you created earlier, create a feature branch, and then add your changes to	AWS DevOps

Task	Description	Skills required

	the application code. Use the following commands:
	`git checkout -b <feature_branch>`
	`git add .`
	`git commit -m "add your changes"`
	`git push origin <feature_branch>`
	
	Following are examples of changes:
	• Changes to the Lambda function logic
	• Adding new features or functionality to Lambda code
	• Fixing bugs or optimizing the existing code within the Lambda function
	
	GitHub Actions will use the reusable workflows and trigger the CI/CD pipelines.	

Merge your changes.	Create a pull request, and merge your changes to main.	AWS DevOps

Troubleshooting

Issue	Solution
`AccessDenied` errors when deploying resources across AWS accounts, for example, `AccessDenied: User not authorized to perform: "sts:AssumeRole"`.	To help resolve this issue, do the following to verify cross-account permissions: • Make sure that the necessary IAM roles and policies are in place for cross-account deployments. • Check that the `assume` role permissions are correctly configured.
Compatibility issues because of version mismatches, for example, `undefined: awscdkStack` error with an outdated CDK version.	To help resolve this issue, do the following to verify that you're using the required versions of the AWS CDK and Go: • Make sure you're using compatible versions of the AWS CDK and Go. • Check for any known issues or breaking changes in recent versions.
CI/CD pipeline failures, for example, `Error: No such file or directory` because of incorrect YAML configuration or `Permission denied` for protected branches.	To help resolve issues with the GitHub Actions configuration, verify that the reusable workflows are properly referenced and configured.

Provision AWS Service Catalog products based on AWS CloudFormation templates by using GitHub Actions

Ashish Bhatt and Ruchika Modi, Amazon Web Services

Summary

This pattern provides organizations with a streamlined approach using AWS Service Catalog products and portfolios to provision standardized and compliant AWS services across teams. AWS CloudFormation helps to combine essential components in Service Catalog products and portfolios for provisioning base network infrastructure on AWS Cloud. This pattern also promotes DevOps practices by integrating infrastructure as code (IaC) into automated development workflows by using GitHub Actions.

AWS Service Catalog enables organizations to create and manage approved IT services on AWS, offering benefits such as standardization, centralized control, self-service provisioning, and cost management. By automating the deployment of Service Catalog portfolios and products through GitHub Actions, companies can do the following:

- Achieve consistent and repeatable deployments.
- Use version control for IaC.
- Integrate cloud resource management with existing development workflows.

This combination streamlines cloud operations, enforces compliance, and accelerates the delivery of approved services while reducing manual errors and improving overall efficiency.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Access to GitHub repository
- Basic understanding of AWS CloudFormation and AWS Service Catalog
- An Amazon Simple Storage Service (Amazon S3) bucket to host CloudFormation templates
- An AWS Identity and Access Management (IAM) role named `github-actions` that is used for connectivity between GitHub and AWS

Limitations

- This pattern's reusable code has been tested only with GitHub Actions.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

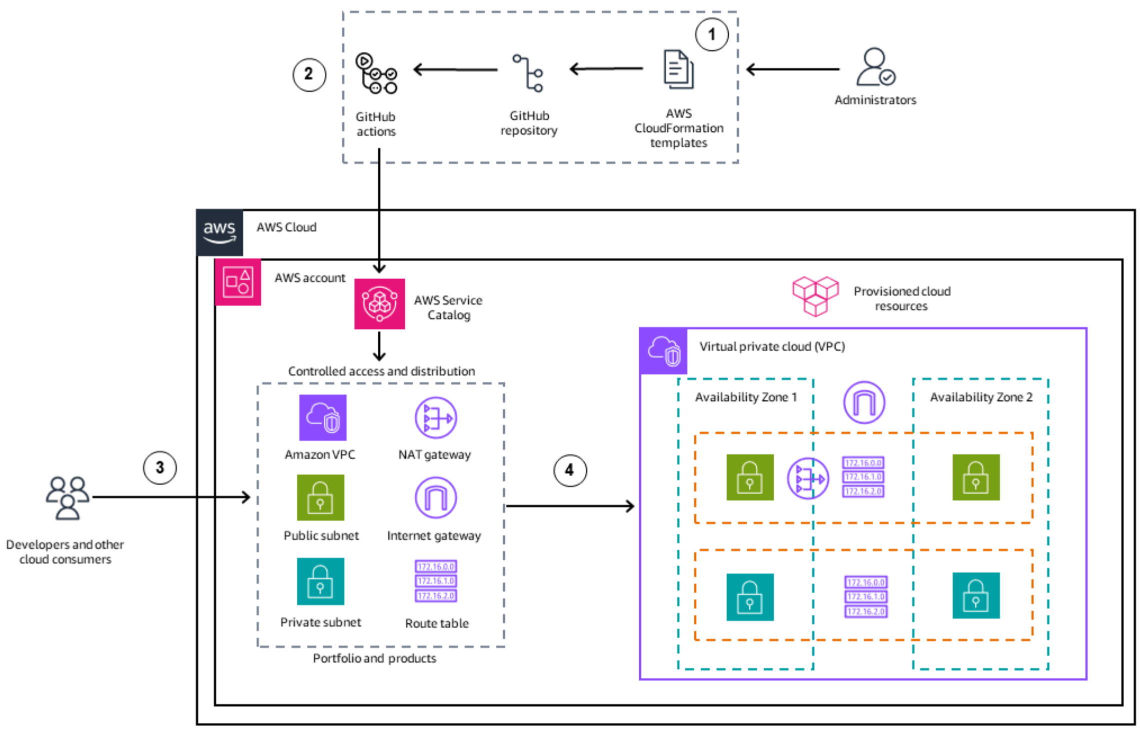
Product versions

This pattern's solution was created by using the following GitHub Marketplace actions and their respective versions:

- `actions/checkout@v4`
- `aws-actions/configure-aws-credentials@v2`
- `aws-actions/aws-cloudformation-github-deploy@v1.2.0`

Architecture

The following diagram shows the architecture for this solution.



1. Administrators or platform engineers push standardized CloudFormation templates to a GitHub repository, where the templates are maintained. The GitHub repo also contains workflows that automate the provisioning of AWS Service Catalog using GitHub Actions.
2. GitHub Actions triggers a workflow that connects to the AWS Cloud using an OpenID Connect (OIDC) provider to provision Service Catalog.
3. Service Catalog contains the portfolio and products that developers can directly use to provision standardized AWS resources. This pattern bundles AWS resources such as virtual private clouds (VPCs), subnets, NAT and internet gateways, and route tables.
4. After the developer creates a Service Catalog product, Service Catalog converts it into pre-configured and standardized AWS resources. As a result, developers save time because they don't need to provision individual resources and configure them manually.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions. It's an infrastructure as code (IaC) service that can be easily used as one of the product types with AWS Service Catalog.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Service Catalog helps you centrally manages catalog of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Others

- GitHub Actions is a continuous integration and continuous delivery (CI/CD) platform that's tightly integrated with GitHub repositories. You can use GitHub Actions to automate your build, test, and deployment pipeline.

Code repository

The code for this pattern is available in the GitHub service-catalog-with-github-actions repository. The repo contains the following files of interest:

- `github/workflows`:
  - `e2e-test.yaml` – This file calls `workflow.yaml`, which is the reusable workflow. This workflow is triggered as soon as there is a commit and push on a branch.
  - `workflow.yaml` – This file contains the reusable workflow for this solution and is configured with `workflow_call` as its trigger. As a reusable workflow, `workflow.yaml` can be called from any other workflow.
- `templates`:
  - `servicecatalog-portfolio.yaml` – This CloudFormation template includes resources that provision the Service Catalog portfolio and Service Catalog product. The template contains a set of parameters that are used while provisioning the Service Catalog portfolio and products. One parameter accepts an Amazon S3 file URL where the template `vpc.yaml` is uploaded. Although this pattern includes the `vpc.yaml` file to provision AWS resources, you can also use the parameter S3 file URL for configuration.
  - `vpc.yaml` – This CloudFormation template contains AWS resources to be added in the Service Catalog product. AWS resources include VPCs, subnets, internet gateways, NAT gateways, and route tables. The `vpc.yaml` template is an example of how you can use any CloudFormation template with a Service Catalog product and portfolio template.

Best practices

- See Security Best Practices for AWS Service Catalog in the AWS Service Catalog documentation.
- See Security hardening for GitHub Actions in the GitHub documentation.

Provision least-privilege IAM roles by deploying a role vending machine solution

Benjamin Morris, Nima Fotouhi, Aman Kaur Gandhi, and Chad Moon, Amazon Web Services

Summary

Over-scoped AWS Identity and Access Management (IAM) role permissions for pipelines can introduce unnecessary risk to an organization. Developers sometimes grant broad permissions during development but neglect to scope down permissions after troubleshooting their code. This causes a problem where powerful roles are present without a business need and may have never been reviewed by a security engineer.

This pattern offers a solution to this problem: the role vending machine (RVM). Using a secure and centralized deployment model, the RVM demonstrates how to provision least-privilege IAM roles for individual GitHub repositories' pipelines with minimal effort from developers. Because the RVM is a central solution, you can configure your security teams as required reviewers to approve changes. This approach allows security to reject over-permissioned pipeline role requests.

The RVM takes Terraform code as input and generates pipeline-ready IAM roles as output. The required inputs are the AWS account ID, GitHub repository name, and permissions policy. The RVM uses these inputs to create the role's trust policy and permissions policy. The resulting trust policy allows the specified GitHub repository to assume the role and use it for pipeline operations.

The RVM uses an IAM role (configured during bootstrap). This role has permissions to assume a role-provisioning-role in each account in the organization. The role is configured through either AWS Control Tower Account Factory for Terraform (AFT) or AWS CloudFormation StackSets. The role-provisioning-roles are the roles that actually create the pipeline roles for developers.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A GitHub organization that is used to deploy infrastructure as code (IaC) through GitHub Actions. (GitHub Enterprise/Premium/Ultimate are *not* required.)
- A multi-account AWS environment. This environment does not need to be part of AWS Organizations.

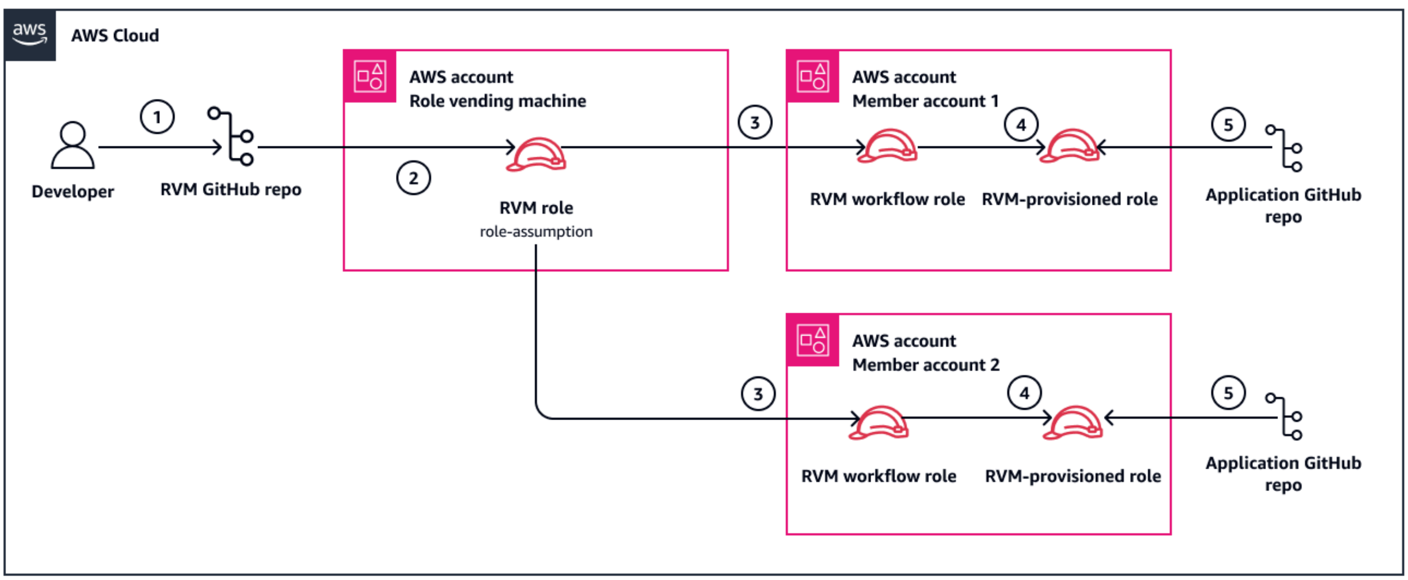
- A mechanism for deploying an IAM role in all AWS accounts (for example, AFT or CloudFormation StackSets).
- Terraform version 1.3 or latter installed and configured.
- Terraform AWS Provider version 4 or later installed and configured.

Limitations

- This pattern's code is specific to GitHub Actions and Terraform. However, the pattern's general concepts can be reused in other continuous integration and delivery (CI/CD) frameworks.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

The following diagram illustrates the workflow for this pattern.



The workflow for the typical usage of the role vending machine consists of the following steps:

1. A developer pushes code that contains Terraform code for a newly requested IAM role to the RVM GitHub repository. This action triggers the RVM GitHub Actions pipeline.
2. The pipeline uses an OpenID Connect (OIDC) trust policy to assume the RVM role-assumption role.

3. As the RVM pipeline runs, it assumes the RVM workflow role in the account in which it's provisioning the developer's new IAM role. (The RVM workflow role was provisioned by using AFT or CloudFormation StackSets.)
4. The RVM creates the developer's IAM role with appropriate permissions and trust, so that the role can be assumed by other application pipelines.
5. App developers can configure their app pipelines to assume this RVM-provisioned role.

The created role includes the permissions requested by the developer and a `ReadOnlyAccess` policy. The role is assumable only by pipelines that run against the `main` branch of the developer's specified repository. This approach helps to ensure that branch protection and reviews can be required to use the role.

Automation and scale

Least-privilege permissions require attention to detail for each role being provisioned. This model reduces the complexity required to create these roles, allowing developers to create the roles they need without much additional learning or effort.

Tools

AWS services

- [AWS Identity and Access Management (IAM)](#) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- [AWS Organizations](#) is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.

Other tools

- [Git](#) is an open source, distributed version control system. It includes the ability to create an [organization account](#).
- [GitHub Actions](#) is a continuous integration and continuous delivery (CI/CD) platform that's tightly integrated with GitHub repositories. You can use GitHub Actions to automate your build, test, and deployment pipeline.
- [Terraform](#) is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub role-vending-machine repository.

Best practices

- **Make the right way easy and the wrong way hard –** Make it easy to do the right thing. If developers are struggling with the RVM provisioning process, they might attempt to create roles through other means, which undermines the central nature of RVM. Make sure that your security team provides clear guidance about how to use the RVM securely and effectively.

  You should also make it hard for developers to do the wrong thing. Use service control policies (SCPs) or permission boundaries to restrict what roles can create other roles. This approach can help limit role creation to just RVM and other trusted sources.
- **Provide good examples –** Inevitably, some developers will adapt existing roles in the RVM repository as informal templates for granting permissions to their new roles. If you have least-permissions examples that they can copy from, that can reduce the risk of developers requesting broad, wildcard-heavy permissions. If you start with highly permissioned roles with lots of wildcards, that problem can multiply as time goes on.
- **Use naming conventions and conditions –** Even if a developer doesn't know all the resource names that their application will create, they should still limit role permissions by using a naming convention. For example, if they're creating Amazon S3 buckets, their resource key's value might look like `arn:aws:s3:::myorg-myapp-dev-*` so that their role doesn't have permissions beyond buckets matching that name. Enforcing naming convention through an IAM policy has the additional benefit of improving compliance with the naming convention. This improvement occurs because non-matching resources will not be permitted to be created.
- **Require pull request (PR) reviews –** The value of the RVM solution is that it creates a central location where new pipeline roles can be reviewed. However, this design is only useful if there are guardrails that help ensure secure, high-quality code is committed to the RVM. Protect the branches that are used to deploy code (for example, `main`) from direct pushes and require approvals for any merge requests that target them.
- **Configure read-only roles –** By default, the RVM provisions a `readonly` version of each requested role. This role can be used in CI/CD pipelines that don't write data, such as a `terraform plan` pipeline workflow. This approach helps prevent unwanted changes if a read-only workflow misbehaves.

By default, the AWS managed `ReadOnlyAccess` policy is attached to both the read-only roles and read-write roles. This policy reduces the need for iteration when determining required permissions, but it might be overly permissive for some organizations. If you want, you can remove the policy from the Terraform code.

- **Grant minimum permissions** – Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the IAM documentation.

Prepare environment

Task	Description	Skills required
Copy the sample repository to your GitHub organization.	Clone this pattern's repository or fork this repository to your GitHub organization so that you can adapt it for your needs. • If you choose to clone this repository, you can use the following command: `git clone https://github.com/aws-samples/role-vending-machine` • If you choose to fork the repository to your GitHub organization, you can use the following command: `gh repo fork aws-samples/role-vending-machine`	DevOps engineer

Task	Description	Skills required
	`--org YOUR_ORGA NIZATION_NAME`	
Determine the AWS account for the RVM.	Determine which infrastru cture deployment AWS account to use for the RVM. Don’t use the management or root account.	Cloud architect

Task	Description	Skills required
(Optional) Allow the organization's pipelines to create PRs.	**Note** This step is only necessary if you want to allow the `generate_providers_and_account_vars` workflow to create PRs. To allow your organization’s pipelines to create PRs, use the following steps: 1. Go to `https://github.com/organizations/YOUR_ORG/settings/actions` . 2. Select **Allow GitHub Actions to create and approve pull requests**. For more information, see [Managing GitHub Actions settings for a repository](#) in the GitHub documentation.	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Grant read-only permissions to the RVM account.</td><td>

Create a delegation policy in your management account that grants your RVM account read-only permissions. This allows your RVM GitHub workflows to dynamically pull a list of your AWS organization's accounts when the `generate_providers_and_account_vars.py` script runs.

Use the following code and replace `<YOUR RVM Account ID>` with the AWS account ID that you selected in Step 2:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Statement",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::<YOUR RVM Account ID>:root"
      },
      "Action": [
        "organizations:ListAccounts",
        "organizations:DescribeOrganization",
```

</td><td>Cloud administrator</td></tr>
</table>

Task	Description	Skills required
	`"organizations:DescribeOrganizationalUnit", "organizations:ListRoots", "organizations:ListAWSServiceAccessForOrganization", "organizations:ListDelegatedAdministrators" ], "Resource": "*" } ] }`	
Update default values from the sample repo.	To configure the RVM to operate in your specific environment and AWS Region, do the following: 1. Update `scripts/generate_providers_and_account_vars.py` and other files (such as the `bootstrap` folder) with the appropriate Region that you operate in. 2. Update the `.github/workflows/.env` file with the AWS account ID, Region, and any other variables that you want to specify.	DevOps engineer

Initialize infrastructure

Task	Description	Skills required
Bootstrap the RVM repo.	This step is necessary to create the OIDC trust and IAM roles used by the RVM pipeline itself, so that it can start operating and vending other roles. In the context of your RVM account, manually run a `terraform apply` command from the `scripts/bootstrap` directory. Provide any required values based on variable documentation.	DevOps engineer

Configure operations

Task	Description	Skills required
Deploy the `github-workflow-rvm` and `github-workflow-rvm-readonly` roles to all accounts.	Choose a deployment method that aligns with your organization's practices, such as AFT or StackSets. Use that method to deploy the two IAM roles in the `scripts/assumed_role/main.tf` file (default names `github-workflow-rvm` and `github-workflow-rvm-readonly`) to each account where you want the RVM to	AWS administrator

Task	Description	Skills required
	be able to create pipeline roles. These IAM roles have trust policies that allows the RVM account's role-assumption role (or its `readonly` equivalent) to assume it. The roles also have IAM permission policies that allow them to read and write (unless using the `readonly` role) roles that match `github-workflow-role-*` .	

Task	Description	Skills required
Run the `generate_providers_and_account_vars` workflow.	To configure your RVM so that it's ready to create pipeline roles, do the following: 1. Run the `generate_providers_and_account_vars` workflow by using [workflow_dispatch](https://docs.github.com/en/actions/using-workflows/events-that-trigger-workflows#workflow_dispatch). 2. Merge the PR that the workflow creates. After the workflow completes , the RVM is ready to: • Accept requests for new pipeline roles. • Create either read-only or read-write roles as requested. • Deploy roles to the specified AWS accounts.	DevOps engineer

Troubleshooting

Issue	Solution
I created a role by using the RVM, but GitHub isn't able to assume it.	Verify that the name of the GitHub repository matches the name provided to the `github_workflow_roles` module. Roles are scoped so that only one repository can assume them. Similarly, verify that the branch used in the GitHub pipeline matches the name of

Issue	Solution
	the branch provided to the `github_workflow_roles` module. Typically, RVM-created roles with write permissions can only be used by workflows scoped to the `main` branch (that is, deployments sourced from `main`).
My read-only role is failing to run its pipeline because it lacks permissions to read a specific resource.	Although the `ReadOnlyAccess` policy provides broad read-only permissions, the policy doesn't have some read actions (for example, certain AWS Security Hub actions). You can add specific action permissions by using the `inline_policy_readonly` parameter of the `github-workflow-roles` module.

- Policy best practices

Additional information

Using GitHub environments

GitHub environments are an alternative approach to branch-based restrictions for role access. If you prefer to use a GitHub environment, following is an example of the syntax for an additional condition in the IAM trust policy. This syntax specifies that the role can be used only when the GitHub action is running in the `Production` environment.

```
"StringLike": {
```

```
    "token.actions.githubusercontent.com:sub": "repo:octo-org/octo-
repo:environment:Production"
}
```

The example syntax uses the following placeholder values:

- `octo-org` is the GitHub organization name.
- `octo-repo` is the repository name.
- `Production` is the specific GitHub environment name.

Publish Amazon CloudWatch metrics to a CSV file

Abdullahi Olaoye, Amazon Web Services

Summary

This pattern uses a Python script to retrieve Amazon CloudWatch metrics and to convert the metrics information into a comma-separated values (CSV) file for improved readability. The script takes the AWS service whose metrics should be retrieved as a required argument. You can specify the AWS Region and AWS credential profile as optional arguments. If you don't specify those arguments, the script uses the default Region and profile that are configured for the workstation where the script is run. After the script runs, it generates and stores a CSV file in the same directory.

See the *Attachments* section for the script and associated files provided with this pattern.

Prerequisites and limitations

Prerequisites

- Python 3.x
- AWS Command Line Interface (AWS CLI)

Limitations

The script currently supports the following AWS services:

- AWS Lambda
- Amazon Elastic Compute Cloud (Amazon EC2)
  - By default, the script doesn't collect Amazon Elastic Block Store (Amazon EBS) volume metrics. To collect Amazon EBS metrics, you must modify the attached `metrics.yaml` file.
- Amazon Relational Database Service (Amazon RDS)
  - However, the script doesn't support Amazon Aurora.
- Application Load Balancer
- Network Load Balancer
- Amazon API Gateway

Tools

- [Amazon CloudWatch](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/WhatIsCloudWatch.html) is a monitoring service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides data and actionable insights to help you monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, and provides a unified view of AWS resources, applications, and services that run on AWS and on-premises servers.

Epics

Install and configure the prerequisites

Task	Description	Skills required
Install the prerequisites.	Run the following command: `$ pip3 install -r requirements.txt`	Developer
Configure the AWS CLI.	Run the following command: `$ aws configure`	Developer

Configure the Python script

Task	Description	Skills required
Open the script.	To change the default configuration of the script, open `metrics.yaml` .	Developer
Set the period for the script.	This is the time period to fetch. The default period is 5 minutes (300 seconds). You can change the time	Developer

Task	Description	Skills required
	period, but note the following limitations: • If the hours value that you specify is between 3 hours and 15 days ago, use a multiple of 60 seconds (1 minute) for the period. • If the hours value that you specify is between 15 hours and 63 days ago, use a multiple of 300 seconds (5 minutes) for the period. • If the hours value that you specify is greater than 63 days ago, use a multiple of 3,600 seconds (1 hour) for the period. Otherwise, the API operation won't return any data points.	
Set the hours for the script.	This value specifies how many hours of metrics you want to fetch. The default is 1 hour. To retrieve multiple days of metrics, provide the value in hours. For example, for 2 days, specify 48.	Developer

Task	Description	Skills required
Change statistics values for the script.	(Optional) The global statistics value is `Average`, which is used when fetching metrics that do not have a specific statistics value assigned. The script supports the statistics values `Maximum`, `SampleCount`, and `Sum`.	Developer

Run the Python script

Task	Description	Skills required
Run the script.	Use the following command: `$ python3 cwreport.py <service>` To see a list of service values and the optional `region` and `profile` parameters, run the following command: `$ python3 cwreport.py -h` For more information about the optional parameters, see the *Additional information* section.	Developer

- Using Amazon CloudWatch metrics
- Amazon CloudWatch documentation
- EC2 CloudWatch Metrics
- AWS Lambda Metrics
- Amazon RDS Metrics
- Application Load Balancer Metrics
- Network Load Balancer Metrics
- Amazon API Gateway Metrics

Additional information

Script usage

```
$ python3 cwreport.py -h
```

Example syntax

```
python3 cwreport.py <service> <--region=Optional Region> <--profile=Optional credential
 profile>
```

Parameters

- **service (required)** – The service you want to run the script against. The script currently supports these services: AWS Lambda, Amazon EC2, Amazon RDS, Application Load Balancer, Network Load Balancer, and API Gateway.
- **region (optional)** – The AWS Region to fetch metrics from. The default Region is `ap-southeast-1`.
- **profile (optional)** – The AWS CLI named profile to use. If this parameter isn't specified, the default configured credential profile is used.

Examples

- To use the default Region `ap-southeast-1` and default configured credentials to fetch Amazon EC2 metrics: `$ python3 cwreport.py ec2`

- To specify a Region and fetch API Gateway metrics: `$ python3 cwreport.py apigateway --region us-east-1`
- To specify an AWS profile and fetch Amazon EC2 metrics: `$ python3 cwreport.py ec2 --profile testprofile`
- To specify both Region and profile to fetch Amazon EC2 metrics: `$ python3 cwreport.py ec2 --region us-east-1 --profile testprofile`

Remove Amazon EC2 entries across AWS accounts from AWS Managed Microsoft AD by using AWS Lambda automation

Dr. Rahul Sharad Gaikwad and Tamilselvan P, Amazon Web Services

Summary

Active Directory (AD) is a Microsoft scripting tool that manages domain information and user interactions with network services. It's widely used among managed services providers (MSPs) to manage employee credentials and access permissions. Because AD attackers can use inactive accounts to try and hack into an organization, it's important to find inactive accounts and disable them on a routine maintenance schedule. With AWS Directory Service for Microsoft Active Directory, you can run Microsoft Active Directory as a managed service. This pattern can help you to configure AWS Lambda automation to quickly find and remove inactive accounts.

If the following scenarios apply to your organization, this pattern can assist you:

- **Centralized AD management –** If your organization has multiple AWS accounts, each with its own AD deployment, it can be challenging to manage user accounts and access permissions consistently across all accounts. With an across-accounts AD cleanup solution, you can disable or remove inactive accounts from all AD instances in a centralized manner.
- **AD restructuring or migration –** If your organization plans to restructure or migrate its AD deployment, an across-accounts AD cleanup solution can help you prepare the environment. The solution can help you remove unnecessary or inactive accounts, simplify the migration process, and reduce potential conflicts or issues.

When you use this pattern, you can get the following benefits:

- Improve database and server performance, and fix vulnerabilities in your security from inactive accounts.
- If your AD server is hosted in the cloud, removing inactive accounts can also reduce storage costs while improving performance. Your monthly bills might decrease because bandwidth charges and compute resources can both drop.
- Keep potential attackers at bay with a clean Active Directory.

Prerequisites and limitations

Prerequisites

- An active parent AWS account and one or multiple child accounts. In this pattern, a *parent account* is where Active Directory is created. *Child accounts* host Windows servers and are joined through the parent account Active Directory.
- Git installed and configured on a local workstation.
- Terraform installed and configured on a local workstation.
- AWS Managed Microsoft AD directory configured in the parent account and shared to all child accounts. For more details, see Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 domain-join in the *AWS Directory Service Administration Guide*.
- A virtual private cloud (VPC) peering connection or AWS Transit Gateway connection available between the VPC of AWS Directory Service (parent account) and the VPC of the Amazon Elastic Compute Cloud (Amazon EC2) instances (child accounts). For more details, see Configure a VPC peering connection between the directory owner and the directory consumer account in the *AWS Directory Service Administration Guide*.
- A Windows machine configured with the `EC2WindowsUserdata` script on all the parent and child accounts. The script file is available in the root of this pattern's code repository.
- A cross-account AWS Identity and Access Management (IAM) role available on each child account that's configured with a trust policy to allow the use of an AWS Lambda function from the parent account. For more information, see Sending and receiving events between AWS accounts in Amazon EventBridge in the *Amazon EventBridge User Guide*.
- The following secrets values available in AWS Systems Manager Parameter Store of the parent account:
  - `domainJoinUser` – Username of the directory service
  - `domainJoinPassword` – Password of the directory service

  For more information about secrets, see Create an AWS Secrets Manager secret in the *AWS Secrets Manager User Guide*.

Limitations

- Creating a resource in a child account isn't automated with Terraform. You must create the following resources manually by using the AWS Management Console:

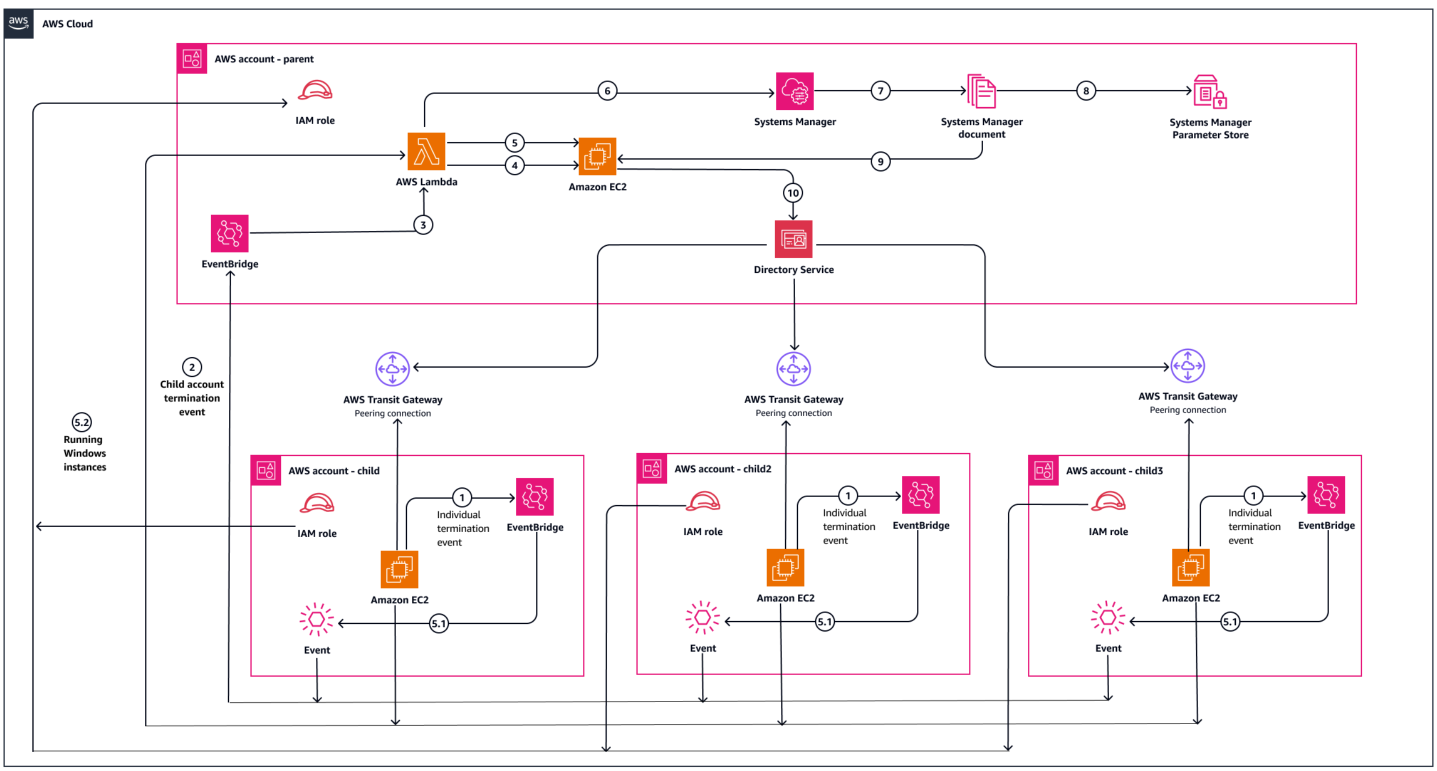
  - Amazon EventBridge rule to send the Amazon EC2 termination events to the parent account
  - Amazon EC2 cross-account role creation in the child account with trust policy
  - VPC peering or Transit Gateway connection
- Some AWS services aren't available in all AWS Regions. For Region availability, see [AWS services by Region](). For specific endpoints, see [Service endpoints and quotas](), and choose the link for the service.

Product versions

- [Terraform version 1.1.9 or later]()
- [Terraform AWS Provider version 3.0 or higher]()

Architecture

The following diagram displays the high-level architecture of the solution.



The architecture diagram illustrates the following process:

1. In child accounts, the EventBridge rule collects all the Amazon EC2 termination events. The rule sends those events to EventBridge which is present in the parent account.

2. From the parent account, EventBridge collects all the events and contains the rule to trigger the Lambda function `ADcleanup-Lambda`.
3. The parent account receives any termination events from the parent or child account and triggers the Lambda function.
4. The Lambda function makes the call to Amazon EC2 Auto Scaling groups using the Python boto module and gets the random instance ID. The instance ID is used to execute Systems Manager commands.
5. The Lambda function makes another call to Amazon EC2 using the boto module. The Lambda function gets the private IP addresses of the running Windows servers and stores the addresses in a temporary variable. In steps 5.1 and 5.2, the running Windows EC2 instances are collected from child accounts.
6. The Lambda function makes another call to Systems Manager to get the computer information that is connected to AWS Directory Service.
7. An AWS Systems Manager document helps to execute the PowerShell command on Amazon EC2 Windows servers to get the private IP addresses of the computers which are connected to AD. (The Systems Manager document uses the instance ID that was obtained in step 4.)
8. The AD domain username and passwords are stored in the AWS Systems Manager Parameter Store. AWS Lambda and Systems Manager make a call to Parameter Store and get the username and password values to use to connect to AD.
9. Using the Systems Manager document, the PowerShell script is executed on the Amazon EC2 Windows server using the instance id obtained earlier in step 4.
10. Amazon EC2 connects to AWS Directory Service by using PowerShell commands and remove the computers that are not in use or inactive.

Tools

AWS services

- AWS Directory Service provides multiple ways to use Microsoft Active Directory (AD) with other AWS services such as Amazon Elastic Compute Cloud (Amazon EC2), Amazon Relational Database Service (Amazon RDS) for SQL Server, and Amazon FSx for Windows File Server.
- AWS Directory Service for Microsoft Active Directory enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

- Amazon EventBridge is a serverless event bus service that that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them. With IAM, you can specify who or what can access services and resources in AWS, centrally manage fine-grained permissions, and analyze access to refine permissions across AWS.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.
- AWS Systems Manager documents define the actions that Systems Manager performs on your managed instances. Systems Manager includes more than 100 pre-configured documents that you can use by specifying parameters at runtime.
- AWS Systems Manager Parameter Store is a capability of AWS Systems Manager and provides secure, hierarchical storage for configuration data management and secrets management.

Other tools

- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.
- PowerShell is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.
- Python is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub aws-lambda-ad-cleanup-terraform-samples repository.

Best practices

- **Automatically join domains.** When you launch a Windows instance that's to be part of an AWS Directory Service domain, join the domain during the instance creation process instead of manually adding the instance later. To automatically join a domain, select the correct directory from the **Domain join directory** dropdown list when launching a new instance. For more details, see [Seamlessly join an Amazon EC2 Windows instance to your AWS Managed Microsoft AD Active Directory]() in the *AWS Directory Service Administration Guide*.

- **Delete unused accounts.** It's common to find accounts in AD that have never been used. Like disabled or inactive accounts that remain in the system, neglected unused accounts can slow down your AD system or make your organization vulnerable to data breaches.
- **Automate Active Directory cleanups.** To help mitigate security risks and prevent obsolete accounts from impacting AD performance, conduct AD cleanups should at regular intervals. You can accomplish most AD management and cleanup tasks by writing scripts. Example tasks include removing disabled and inactive accounts, deleting empty and inactive groups, and locating expired user accounts and passwords.

Epics

Set up child accounts

Task	Description	Skills required
Create a cross-account role in the child account.	To create a cross-account role in a child account, do the following: 1. For each child account, create a role named `ec2crossaccountrole` by using the managed policy named `AmazonEC2ReadOnlyAccess`. (For more information, see [Create a role using custom trust policies]() in the IAM documentation.) 2. In the **Custom trust policy** section, add the following code:	DevOps engineer

Task	Description	Skills required

	``{
	    "Version":
	 "2012-10-17",
	    "Statement": [
	        {
	            "Effect":
	 "Allow",
	            "Principa
	l": {
	
	 "Service": "ec2.amaz
	onaws.com"
	            },
	            "Action":
	 "sts:AssumeRole"
	        },
	        {
	            "Effect":
	 "Allow",
	            "Principa
	l": {
	                "AWS":
	 "arn:aws:iam::${Pa
	rentaccountid}:rol
	e/ADcleanuprole"
	            },
	            "Action":
	 "sts:AssumeRole"
	        }
	    ]
	}```	

Task	Description	Skills required

Create an event rule in the child account.	To create an EventBridge rule for each child account, do the following:
	
	1. Sign in to the child AWS account, and then open the Amazon EventBridge console at https://console.aws.amazon.com/events/.
	2. In the navigation pane, choose **Rules**.
	3. Choose **Create rule**.
	4. Enter a **Name** and, optionally, a description for the rule.
	5. For **Event bus**, select **AWS default event bus**.
	6. For **Rule type**, choose **Rule with an event pattern**.
	7. Choose **Next**.
	8. For **Event pattern**, paste the following code:
	
	`{`
	`  "source": ["aws.ec2"],`
	`  "detail-type": ["EC2 Instance State-change Notification"],`
	`  "detail": {`
	`    "state": ["terminated"]`
	`  }`
		DevOps engineer

Task	Description	Skills required
	`}` 9. Choose **Next**. 10. For **Target type**, choose **Event bus in a different account or Region.** For **Event bus as target**, enter the event bus Amazon Resource Name (ARN) for the parent account. 11. For **Execution role**, choose **Create a new role for this specific resource.** 12. Choose **Next** to review the details for the new rule, and then choose **Create**. For more details, see [Creating rules that react to events in Amazon EventBridge] in the *Amazon EventBridge User Guide*.	

Task	Description	Skills required
Create an EC2 instance and join to AD.	To create an EC2 instance for Windows, do the following: 1. Use the `EC2WindowsUserdata` script that's available in this pattern's [code repository](#). 2. In the user data script, revise the following code to use your `Directory service addresses` values from the parent account: `set-DnsClientServerAddress -InterfaceIndex 6 -ServerAddresses $(Directory service addresses)`	DevOps engineer

Set up the local workstation

Task	Description	Skills required
Create a project folder and add the files.	To clone the repository and create a project folder, do the following: 1. Open this pattern's [GitHub repository](#). 2. Choose the **Code** button to see the options to clone in the **Clone** dropdown.	DevOps engineer

Task	Description	Skills required

	3. On the **HTTPS** tab, copy the URL provided in **Clone using the web URL**.
	4. Create a folder on your machine, and name it with your project name.
	5. Open a terminal in your local machine, and navigate to this folder.
	6. To clone the git repository, use the following command.
	`git clone <repository-URL>.git`
	7. After the repository has been cloned, use the following command to go to the cloned directory.
	`cd <directory name>/terraform-aws-lambda-ad-cleanup/multiple-account-cleanup`
	8. In the cloned repository, open this project in an integrated development environment (IDE) of your choice.	

Task	Description	Skills required
Build the `adcleanup.zip` file.	To compress the `lambda_function.py` file, run the following command: `zip -r adcleanup.zip lambda_function.py`	DevOps engineer

Provision the target architecture using the Terraform configuration

Task	Description	Skills required
Provide values for the Terraform variables.	For the child account, provide values for the following `arn` variables as string types in the `terraform.tfvars` file: • `lambda_env_cross_role_arn` • `child_account_cross_role_arn`	DevOps engineer
Initialize the Terraform configuration.	To initialize your working directory that contains the Terraform files, run the following command: `terraform init`	DevOps engineer
Preview changes.	You can preview the changes that Terraform will make to the infrastructure before your infrastructure is deployed. To validate that Terraform will	DevOps engineer

Task	Description	Skills required
	make the changes as required, run the following command: `terraform plan -- var-file=examples/ terraform.tfvars`	
Execute the proposed actions.	To verify that the results from the `terraform plan` command are as expected, do the following: 1. Run the following command: `terraform apply` 2. Sign in to the AWS Management Console, and verify that the resources are present.	DevOps engineer

Verify the deployment

Task	Description	Skills required
Execute and test the Lambda function.	To verify that the deploymen t occurred successfully, do the following: 1. Sign in to the AWS Management Console, and open the Lambda console. Open the **Functions** page, and select the function name that begins with **ADcleanup-Lambda-***.	DevOps engineer

Task	Description	Skills required
	2. On the function overview page, choose **Test** on the **Code** tab in the **Code source** section. 3. To save the test event, provide a name for the event and choose **Save**. To test the event, choose **Test** again. The execution results show the output of the function.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>View results of EventBridge rule execution from parent account.</td><td>To view the results of the EventBridge rule that’s based on Amazon EC2 terminati on events from the parent account, do the following:
Terminate EC2 instances from the parent account.
Open the Lambda console of the parent account. Open the Functions page, and select the function name that begins with ADcleanup-Lambda-*.
Choose the Monitor tab, and choose View CloudWatch logs.
In the CloudWatch console, the Log groups page shows the results of the Lambda function.</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
View results of EventBridge rule execution from the child account.	To view the results of the EventBridge rule that's based on Amazon EC2 termination events from the child account, do the following: 1. Terminate EC2 instances from the child account. 2. Open the Lambda console of the parent account. Open the **Functions** page, and select the function name that begins with **ADcleanup-Lambda-***. 3. Choose the **Monitor** tab, and choose **View CloudWatch logs**. In the CloudWatch console, the **Log groups** page shows the results of the Lambda function.	DevOps engineer

Clean up infrastructure after use

Task	Description	Skills required
Clean up the infrastructure.	To clean up the infrastructure that you created, use the following command: `terraform destroy`	DevOps engineer

Task	Description	Skills required
	To confirm the `destroy` command, type `yes`.	
Verify after cleanup.	Verify that the resources are successfully removed.	DevOps engineer

Troubleshooting

Issue	Solution
Connection issue between AWS Directory Service (parent account) and Amazon EC2 instance (child account) – You are unable to join the child account's computers to AD even though VPC peering is available.	Add routing in the VPCs. For instructions, see Configure a VPC peering connection between the directory owner and the directory consumer account in the AWS Directory Service documentation.

Remove Amazon EC2 entries in the same AWS account from AWS Managed Microsoft AD by using AWS Lambda automation

Dr. Rahul Sharad Gaikwad and Tamilselvan P, Amazon Web Services

Summary

Active Directory (AD) is a Microsoft scripting tool that manages domain information and user interactions with network services. It's widely used among managed services providers (MSPs) to manage employee credentials and access permissions. Because AD attackers can use inactive accounts to try and hack into an organization, it's important to find inactive accounts and disable them on a routine maintenance schedule. With AWS Directory Service for Microsoft Active Directory, you can run Microsoft Active Directory as a managed service.

This pattern can help you to configure AWS Lambda automation to quickly find and remove inactive accounts. When you use this pattern, you can get the following benefits:

- Improve database and server performance, and fix vulnerabilities in your security from inactive accounts.
- If your AD server is hosted in the cloud, removing inactive accounts can also reduce storage costs while improving performance. Your monthly bills might decrease because bandwidth charges and compute resources can both drop.
- Keep potential attackers at bay with a clean Active Directory.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Git installed and configured on a local workstation.
- Terraform installed and configured on a local workstation.
- Windows computer with Active Directory modules (`ActiveDirectory`).
- A directory in AWS Managed Microsoft AD and credentials stored in a parameter in AWS Systems Manager Parameter Store.
- AWS Identity and Access Management (IAM) role with permissions to the AWS services listed in Tools. For more information about IAM, see Related resources.

Limitations

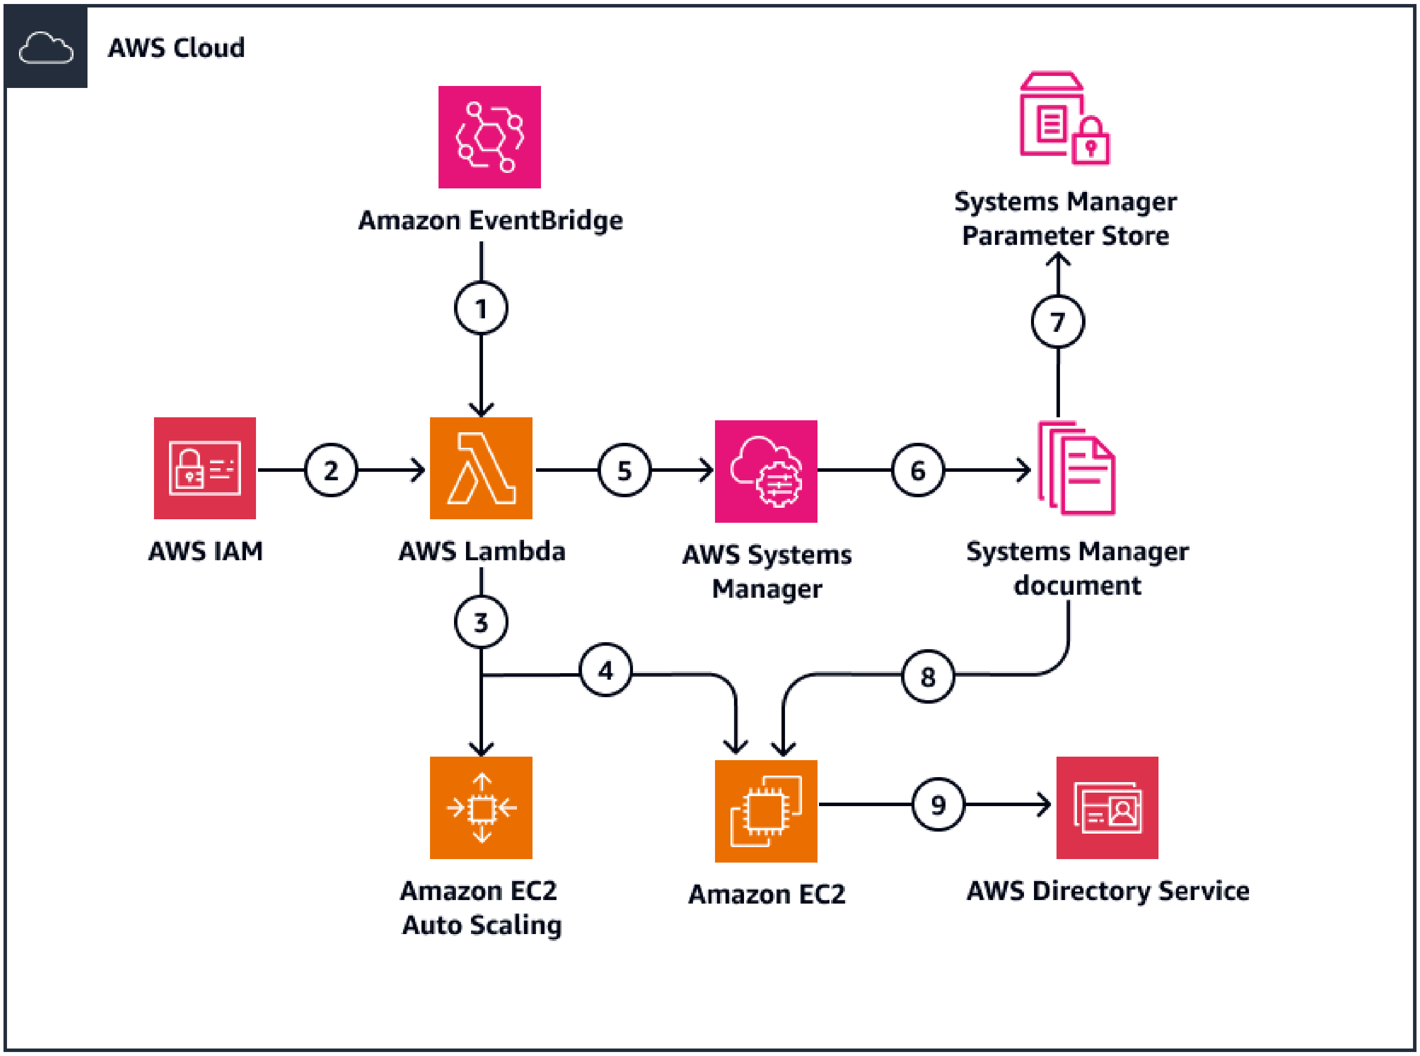
- This pattern doesn't support cross-account setup.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- Terraform version 1.1.9 or later
- Terraform AWS Provider version 3.0 or higher

Architecture

The following diagram shows the workflow and architecture components for this pattern.



The diagram shows the following workflow:

1. Amazon EventBridge triggers the AWS Lambda function based on a cron expression. (For this pattern, the cron expression schedule is once per day.)
2. The required IAM role and policy are created and attached to AWS Lambda through Terraform.
3. The AWS Lambda function is executed and calls to Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling Groups by using the Python boto module. The Lambda function gets the random instance id. The instance id is used to execute AWS Systems Manager commands.
4. AWS Lambda makes another call to Amazon EC2 using the boto module and gets the private IP addresses of the running Windows servers and stores the addresses in a temporary variable.
5. AWS Lambda makes another call to Systems Manager to get the computer information that is connected to AWS Directory Service.

6. An AWS Systems Manager document helps to execute the PowerShell script on Amazon EC2 Windows servers to get the private IP addresses of the computers which are connected with AD.
7. The AD domain username and passwords are stored in the AWS Systems Manager Parameter Store. AWS Lambda and Systems Manager make a call to Parameter Store and get the username and password values to use to connect AD.
8. Using the Systems Manager document, the PowerShell script is executed on the Amazon EC2 Windows server using the instance id obtained earlier in step 3.
9. Amazon EC2 connects AWS Directory Service by using PowerShell commands and removes the computers which are not in use or inactive.

Tools

AWS services

- AWS Directory Service provides multiple ways to use Microsoft Active Directory (AD) with other AWS services such as Amazon Elastic Compute Cloud (Amazon EC2), Amazon Relational Database Service (Amazon RDS) for SQL Server, and Amazon FSx for Windows File Server.
- AWS Directory Service for Microsoft Active Directory enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon EventBridge is a serverless event bus service that that helps you connect your applications with real-time data from a variety of sources. For example, AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other AWS accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWSresources by controlling who is authenticated and authorized to use them. With IAM, you can specify who or what can access services and resources in AWS, centrally manage fine-grained permissions, and analyze access to refine permissions across AWS.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale.

- [AWS Systems Manager documents](#) define the actions that Systems Manager performs on your managed instances. Systems Manager includes more than 100 pre-configured documents that you can use by specifying parameters at runtime.
- [AWS Systems Manager Parameter Store](#) is a capability of AWS Systems Manager and provides secure, hierarchical storage for configuration data management and secrets management.

Other tools

- [HashiCorp Terraform](#) is an open source infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.
- [PowerShell](#) is a Microsoft automation and configuration management program that runs on Windows, Linux, and macOS.
- [Python](#) is a general-purpose computer programming language.

Code repository

The code for this pattern is available in the GitHub [Custom AD Cleanup Automation solution](#) repository.

Best practices

- **Automatically join domains.** When you launch a Windows instance that's to be part of an AWS Directory Service domain, join the domain during the instance creation process instead of manually adding the instance later. To automatically join a domain, select the correct directory from the **Domain join directory** dropdown list when launching a new instance. For more details, see [Seamlessly join an Amazon EC2 Windows instance to your AWS Managed Microsoft AD Active Directory](#) in the *AWS Directory Service Administration Guide*.
- **Delete unused accounts.** It's common to find accounts in AD that have never been used. Like disabled or inactive accounts that remain in the system, neglected unused accounts can slow down your AD system or make your organization vulnerable to data breaches.
- **Automate Active Directory cleanups.** To help mitigate security risks and prevent obsolete accounts from impacting AD performance, conduct AD cleanups should at regular intervals. You can accomplish most AD management and cleanup tasks by writing scripts. Example tasks include removing disabled and inactive accounts, deleting empty and inactive groups, and locating expired user accounts and passwords.

Epics

Set up your environment

Task	Description	Skills required

Create a project folder, and add the files.	To clone the repository and create a project folder, do the following:
	
	1. Open this pattern’s [GitHub repository](#).
	2. Choose the **Code** button to see the options to clone in the **Clone** dropdown.
	3. On the **HTTPS** tab, copy the URL provided in **Clone using the web URL**.
	4. Create a folder on your machine, and name it with your project name.
	5. Open a terminal in your local machine, and navigate to this folder.
	6. To clone the git repository, use the following command.
	`git clone <repository-URL>.git`
	7. After the repository has been cloned, use the following command to go to the cloned directory.
	`cd <directory name>`
		DevOps engineer

Task	Description	Skills required
	8. In the cloned repository, open this project in an integrated development environment (IDE) of your choice.	

Provision the target architecture by using the Terraform configuration

Task	Description	Skills required
Initialize the Terraform configuration.	To initialize your working directory that contains the Terraform files, run the following command. `terraform init`	DevOps engineer
Preview changes.	You can preview the changes that Terraform will make to the infrastructure before your infrastructure is deployed. To validate that Terraform will make the changes as required, run the following command. `terraform plan`	DevOps engineer
Execute the proposed actions.	To verify that the results from the `terraform plan` command are as expected, do the following: 1. Run the following command. `terraform apply`	DevOps engineer

Task	Description	Skills required
	2. Sign in to the AWS Management Console, and verify that the resources are present.	
Clean up the infrastructure.	To clean up the infrastructure that you created, use the following command. `terraform destroy` To confirm the destroy command, type `yes`.	DevOps engineer

Verify the deployment

Task	Description	Skills required
Execute and test the Lambda function.	To verify that the deploymen t occurred successfully, do the following: 1. Sign in to the AWS Management Console and open the console. Open the **Functions** page, and select the function name that begins with **ADcleanup-Lambda-***. 2. On the function overview page, choose **Test** on the **Code** tab in the **Code source** section. 3. To save the test event, provide a name for the	DevOps engineer

Task	Description	Skills required
	event and choose **Save**. Then to test the event, choose **Test** again. The execution results show the output of the function.	
View the results of the Lambda function.	In this pattern, an EventBrid ge rule executes the Lambda function once per day. To view the results of the Lambda function, do the following: 1. Sign in to the AWS Management Console and open the AWS Lambda console. Open the **Functions** page and select the function name that begins with **ADcleanup-Lambda-***. 2. Choose the **Monitor** tab and choose **View CloudWatch logs**. In the CloudWatch console, the **Log groups** page shows the results of the Lambda function.	DevOps engineer

Clean up infrastructure after use

Task	Description	Skills required
Clean up infrastructure.	To clean up the infrastructure that you created, use the following command. `terraform destroy` To confirm the destroy command, type `yes`.	DevOps engineer
Verify after cleanup.	Verify that the resources are successfully removed.	DevOps engineer

Troubleshooting

Issue	Solution
If you try to remove the AD computer, you get an "Access Denied" message. The AD computer can't be removed because, by default, the action tries to remove two private IP addresses which are connected as a part of the AD services.	To avoid this error, use the following Python operation to ignore the first two computers when you list the differences between an AD computer output and the output of your machine running Windows. `Difference = Difference[2:]`
When Lambda executes a PowerShell script on a Windows server, it expects Active Directory modules to be available by default. If the modules are not available, a Lambda function creates an error that states "Get-AdComputer is not installed on instance".	To avoid this error, install the required modules by using the user data of the EC2 instances. Use the EC2WindowsUserdata script that's in this pattern's GitHub repository.

Run unit tests for Python ETL jobs in AWS Glue using the pytest framework

Praveen Kumar Jeyarajan and Vaidy Sankaran, Amazon Web Services

Summary

You can run unit tests for Python extract, transform, and load (ETL) jobs for AWS Glue in a local development environment, but replicating those tests in a DevOps pipeline can be difficult and time consuming. Unit testing can be especially challenging when you're modernizing mainframe ETL process on AWS technology stacks. This pattern shows you how to simplify unit testing, while keeping existing functionality intact, avoiding disruptions to key application functionality when you release new features, and maintaining high-quality software. You can use the steps and code samples in this pattern to run unit tests for Python ETL jobs in AWS Glue by using the pytest framework in AWS CodePipeline. You can also use this pattern to test and deploy multiple AWS Glue jobs.

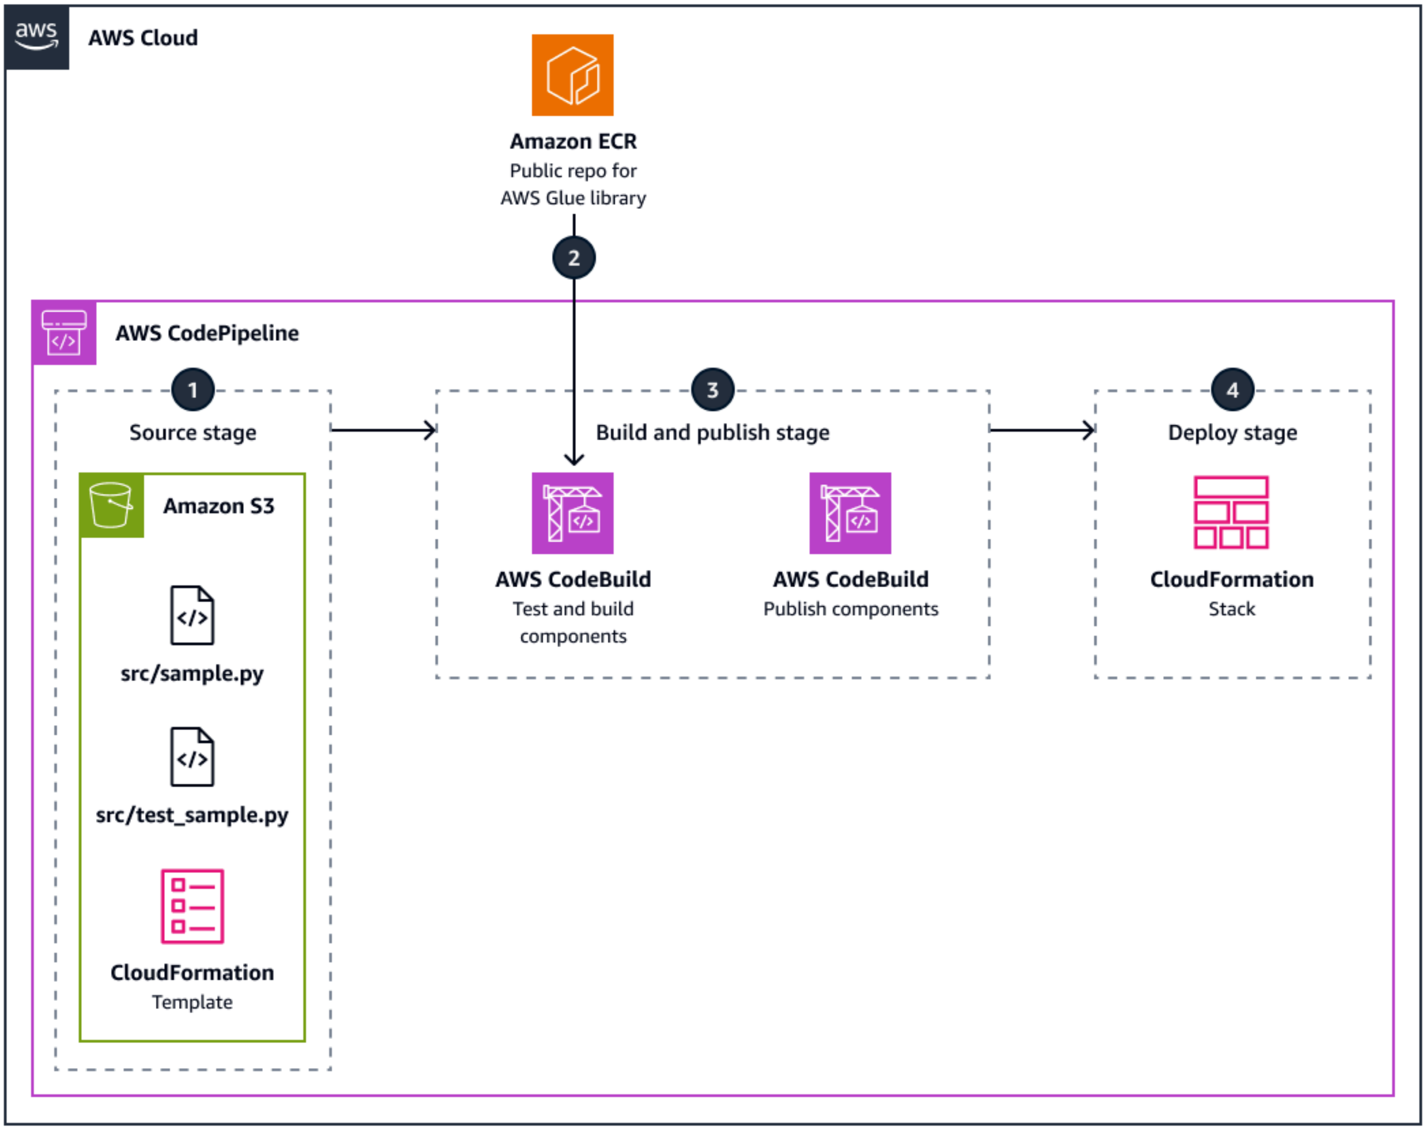
Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Elastic Container Registry (Amazon ECR) image URI for your AWS Glue library, downloaded from the Amazon ECR Public Gallery
- Bash terminal (on any operating system) with a profile for the target AWS account and AWS Region
- Python 3.10 or later
- Pytest
- Moto Python library for testing AWS services

Architecture

The following diagram describes how to incorporate unit testing for AWS Glue ETL processes that are based on Python into a typical enterprise-scale AWS DevOps pipeline.



The diagram shows the following workflow:

1. In the source stage, AWS CodePipeline uses a versioned Amazon Simple Storage Service (Amazon S3) bucket to store and manage source code assets. These assets include a sample Python ETL job (`sample.py`), a unit test file (`test_sample.py`), and an AWS CloudFormation template. Then, CodePipeline transfers the most recent code from the main branch to the AWS CodeBuild project for further processing.
2. In the build and publish stage, the most recent code from the previous source stage is unit tested with the help of an AWS Glue public Amazon ECR image. Then, the test report is published to CodeBuild report groups. The container image in the public Amazon ECR repository for AWS Glue libraries includes all the binaries required to run and unit test [PySpark-based](#) ETL tasks in AWS Glue locally. The public container repository has three image tags, one for

each version supported by AWS Glue. For demonstration purposes, this pattern uses the `glue_libs_4.0.0_image_01` image tag. To use this container image as a runtime image in CodeBuild, copy the image URI that corresponds to the image tag that you intend to use, and then update the `pipeline.yml` file in the GitHub repository for the `TestBuild` resource.

3. In the deploy stage, the CodeBuild project is launched and it publishes the code to an Amazon S3 bucket if all the tests pass.
4. The user deploys the AWS Glue task by using the CloudFormation template in the `deploy` folder.

Tools

AWS services

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that's secure, scalable, and reliable.
- AWS Glue is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- Amazon Simple Storage Service (Amazon S3) is an object storage service offering industry-leading scalability, data availability, security, and performance.

Other tools

- Python is a high-level, interpreted general purpose programming language.
- Moto is a Python library for testing AWS services.
- Pytest is a framework for writing small unit tests that scale to support complex functional testing for applications and libraries.
- Python ETL library for AWS Glue is a repository for Python libraries that are used in the local development of PySpark batch jobs for AWS Glue.

Code repository

The code for this pattern is available in the GitHub aws-glue-jobs-unit-testing repository. The repository includes the following resources:

- A sample Python-based AWS Glue job in the `src` folder
- Associated unit test cases (built using the pytest framework) in the `tests` folder
- A CloudFormation template (written in YAML) in the `deploy` folder

Best practices

Security for CodePipeline resources

It’s a best practice to use encryption and authentication for the source repositories that connect to your pipelines in CodePipeline. For more information, see Security best practices in the CodePipeline documentation.

Monitoring and logging for CodePipeline resources

It’s a best practice to use AWS logging features to determine what actions users take in your account and what resources they use. The log files show the following:

- Time and date of actions
- Source IP address of actions
- Which actions failed due to inadequate permissions

Logging features are available in AWS CloudTrail and Amazon CloudWatch Events. You can use CloudTrail to log AWS API calls and related events made by or on behalf of your AWS account. For more information, see Logging CodePipeline API calls with AWS CloudTrail in the CodePipeline documentation.

You can use CloudWatch Events to monitor your AWS Cloud resources and applications running on AWS. You can also create alerts in CloudWatch Events. For more information, see Monitoring CodePipeline events in the CodePipeline documentation.

Epics

Deploy the source code

Task	Description	Skills required

Prepare the code archive for deployment.	1. Download `code.zip` from the GitHub [aws-glue-jobs-unit-testing](https://github.com/aws-samples/aws-glue-jobs-unit-testing) repository, or create the .zip file yourself by using a command-line tool. For example, you can create the .zip file on Linux or Mac by running the following commands in the terminal:
	`git clone https://github.com/aws-samples/aws-glue-jobs-unit-testing.git`
	`cd aws-glue-jobs-unit-testing`
	`git checkout master`
	`zip -r code.zip src/ tests/ deploy/`
	2. Sign in to the AWS Management Console and choose the AWS Region of your choice.
	3. Create an Amazon S3 bucket, and then upload the .zip package and `code.zip` file (downloaded earlier) to the Amazon S3 bucket that you created.
		DevOps engineer

Task	Description	Skills required
Create the CloudFormation stack.	1. Sign in to the AWS Management Console and then open the [CloudFormation console](#). 2. Choose **Create stack**, and then choose **With existing resources (import resources)**. 3. In the **Specify template** section of the **Create stack** page, choose **Upload a template file**, and then choose the **pipeline.yml** template (downloaded from the GitHub repository). Then, choose **Next**. 4. For **Stack name**, enter **glue-unit-testing-pipeline**, or choose a stack name of your choice. 5. For **ApplicationStackName**, use the prepopulated **glue-codepipeline-app** name. This is the name of the CloudFormation stack that's created by the pipeline. 6. For **BucketName**, use the prepopulated **aws-glue-artifacts-us-east-1** bucket name. This is the name of the Amazon S3 bucket that contains the .zip file and	AWS DevOps, DevOps engineer

Task	Description	Skills required
	is used by the pipeline to store code artifacts. 7. For **CodeZipFile**, use the prepopulated **code.zip** value. This is the key name of the sample code Amazon S3 object. The object should be a .zip file. 8. For **TestReportGroupName**, use the prepopulated **glue-unittest-report** name. This is the name of the CodeBuild test report group that's created to store the unit test reports. 9. Choose **Next**, and then choose **Next** again on the **Configure stack options** page. 10. On the **Review** page, under **Capabilities**, choose the **I acknowledge that CloudFormation might create IAM resources with custom names** option. 11. Choose **Submit**. After the stack creation is complete, you can see the created resources on the **Resources** tab. The stack creation takes approximately 5-7 minutes.	

Task	Description	Skills required
	The stack creates a CodePipeline view using Amazon S3 as the source. In the steps above, the pipeline is **aws-glue-unit-test-pipeline**.	

Run the unit tests

Task	Description	Skills required
Run the unit tests in the pipeline.	1. To test the deployed pipeline, sign in to the AWS Management Console, and then open the [CodePipeline console](). 2. Select the pipeline created by the CloudFormation stack, and then choose **Release change**. The pipeline starts running (using the most recent code in the Amazon S3 bucket). 3. After the **Test_and_Build** phase is finished, choose the **Details** tab, and then examine the logs. 4. Choose the **Reports** tab, and then choose the test report from **Report history** to view the unit test results.	AWS DevOps, DevOps engineer

Task	Description	Skills required
	5. After the deployment stage is complete, run and monitor the deployed AWS Glue job on the AWS Glue console. For more information, see [Monitoring AWS Glue]() in the AWS Glue documentation.	

Clean up all AWS resources

Task	Description	Skills required
Clean up the resources in your environment.	To avoid additional infrastructure costs, make sure that you delete the stack after experimenting with the examples provided in this pattern. 1. Open the [CloudFormation console](), and then select the stack that you created. 2. Choose **Delete**. This deletes all the resources that your stack created, including AWS Identity and Access Management (IAM) roles, IAM policies, and CodeBuild projects.	AWS DevOps, DevOps engineer

Troubleshooting

Issue	Solution
The CodePipeline service role cannot access the Amazon S3 bucket.	• For the policy attached to your CodePipeline service role, add `s3:ListBucket` to the list of actions in your policy. For instructions on viewing the service role policy, see View the pipeline ARN and service role ARN (console). Edit the policy statement for your service role as detailed in Add permissions to the CodePipeline service role. • For the resource-based policy that is attached to the Amazon S3 artifact bucket for your pipeline, also called the *artifact bucket policy*, add a statement that allows the CodePipeline service role to use the `s3:ListBucket` permission.
CodePipeline returns an error that the Amazon S3 bucket is not versioned.	CodePipeline requires that the source Amazon S3 bucket be versioned. Enable versioning on your Amazon S3 bucket. For instructions, see Enabling versioning on buckets.

Additional information

Additionally, you can deploy the AWS CloudFormation templates by using the AWS Command Line Interface (AWS CLI). For more information, see Quickly deploying templates with transforms in the CloudFormation documentation.

Set up a Helm v3 chart repository in Amazon S3

Abhishek Sharma, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern helps you to manage Helm v3 charts efficiently by integrating the Helm v3 repository into Amazon Simple Storage Service (Amazon S3) on the Amazon Web Services (AWS) Cloud. To use this pattern, you must be familiar with Kubernetes and with Helm, which is a Kubernetes package manager. Using Helm repositories to store charts and control chart versions can improve mean time to restore (MTTR) during outages.

This pattern uses AWS CodeCommit for Helm repository creation, and it uses an S3 bucket as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Python version 2.7.12 or later
- pip
- A virtual private cloud (VPC) with subnets and an Amazon Elastic Compute Cloud (Amazon EC2) instance
- Git installed on the EC2 instance
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmatic or role) access to Amazon S3 from the client machine
- AWS CodeCommit repository
- AWS Command Line Interface (AWS CLI)

Product versions

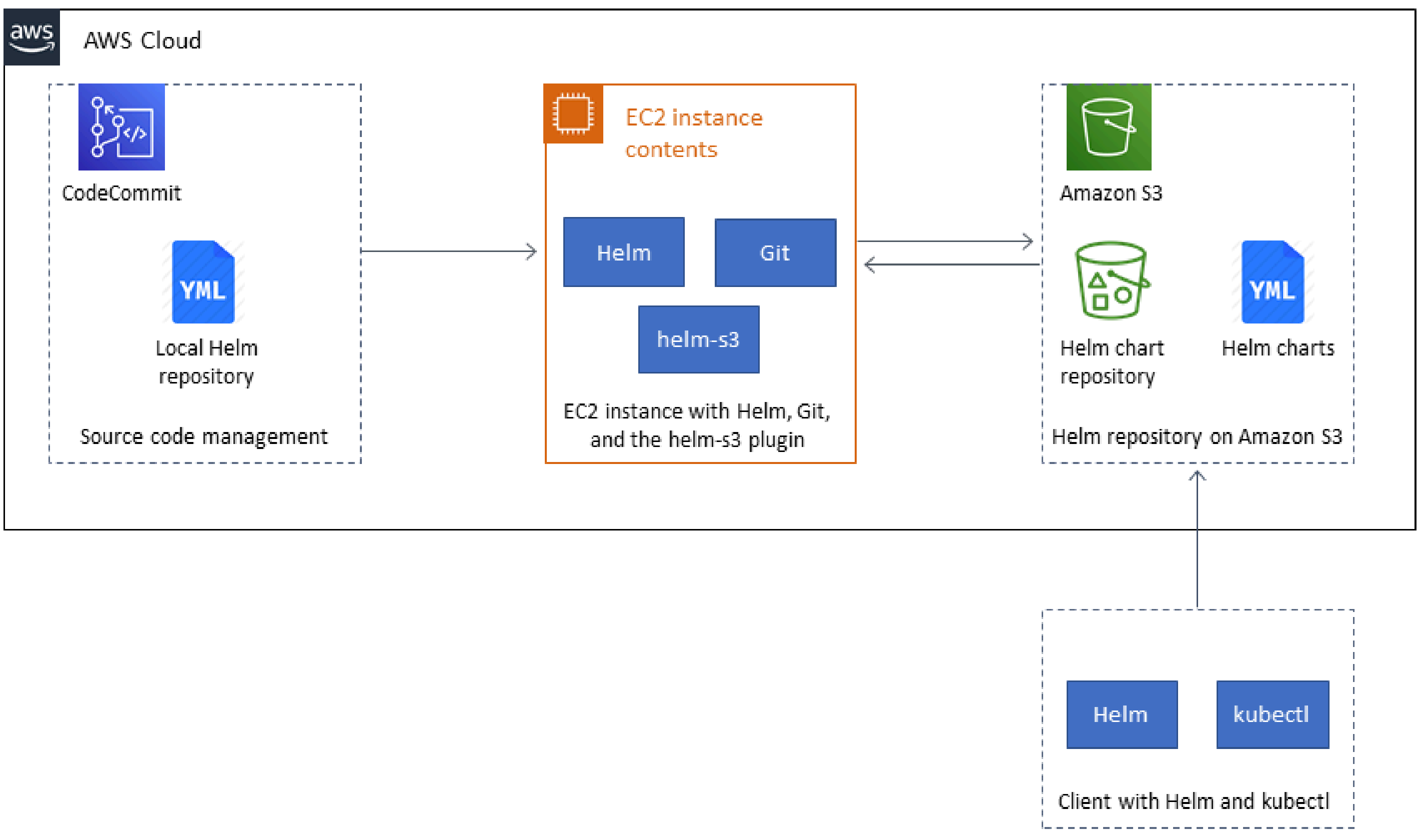
- Helm v3
- Python version 2.7.12 or later

Architecture

Target technology stack

- Amazon S3
- AWS CodeCommit
- Helm
- Kubectl
- Python and pip
- Git
- helm-s3 plugin

Target architecture



Automation and scale

- You can incorporate Helm into your existing continuous integration/continuous delivery (CI/CD) automation tool to automate the packaging and version control of Helm charts (out of scope for this pattern).
- GitVersion or Jenkins build numbers can be used to automate version control of the charts.

Tools

- Helm – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- helm-s3 plugin – The helm-s3 plugin supports interaction with Amazon S3. It can be used with either Helm v2 or Helm v3.

Epics

Install and validate Helm v3

Task	Description	Skills required
Install the Helm v3 client.	To download and install the Helm client on your local system, run the following command: `sudo curl https://raw.githubusercontent.com/helm/helm/main/scripts/get-helm-3 | bash`	Cloud Administrator, DevOps Engineer
Validate the Helm installation.	To validate the Helm client, run the following command: `helm version --short`	Cloud Administrator, DevOps Engineer

Initialize an S3 bucket as a Helm repository

Task	Description	Skills required
Create an S3 bucket for Helm charts.	Create a unique S3 bucket. In the bucket, create a folder called `stable/myapp` . The example in this pattern uses `s3://my-helm-charts/stable/myapp` as the target chart repository.	Cloud Administrator, DevOps Engineer
Install the helm-s3 plugin for Amazon S3.	To install the helm-s3 plugin on your client machine, run the following command: `helm plugin install https://github.com/hypnoglow/helm-s3.git`	Cloud Administrator, DevOps Engineer
Initialize the Amazon S3 Helm repository.	To initialize the target folder as a Helm repository, use the following command: `helm s3 init s3://my-helm-charts/stable/myapp` The command creates an `index.yaml` file in the target to track all the chart information that is stored at that location.	Cloud Administrator, DevOps Engineer
Verify the newly created Helm repository.	To verify that the `index.yaml` file was created, run the following command: `aws s3 ls s3://my-helm-charts/stable/myapp/`	Cloud Administrator, DevOps Engineer

Task	Description	Skills required
Add the Amazon S3 repository to Helm on the client machine.	To add the target repository alias to the Helm client machine, use the following command: `helm repo add stable-myapp s3://my-helm-charts/stable/myapp/`	Cloud Administrator, DevOps Engineer

Package and publish charts in the Amazon S3 Helm repository

Task	Description	Skills required
Clone your Helm charts.	If no local Helm charts are present on in your CodeCommit repository, clone them from your GitHub repo by running the following command: `git clone <url_of_your_helm_source_code>.git`	Cloud Administrator, DevOps Engineer
Package the local Helm chart.	To package the chart that you created or cloned, use the following command: `helm package ./my-app` As an example, this pattern uses the `my-app` chart. The command packages all the contents of the `my-app` chart folder into an archive file, which is named using the version number that is	Cloud Administrator, DevOps Engineer

Task	Description	Skills required
	mentioned in the `Chart.yaml` file.	
Store the local package in the Amazon S3 Helm repository.	To upload the local package to the Helm repository in Amazon S3, run the following command: `helm s3 push ./my-app-0.1.0.tgz stable-myapp` In the command, `my-app` is your chart folder name, `0.1.0` is the chart version mentioned in `Chart.yaml`, and `stable-myapp` is the target repository alias.	Cloud Administrator, DevOps Engineer
Search for the Helm chart.	To confirm that the chart appears both locally and in the Amazon S3 Helm repository, run the following command: `helm search repo stable-myapp`	Cloud Administrator, DevOps Engineer

Upgrade your Helm repository

Task	Description	Skills required
Modify and package the chart.	In `values.yaml`, set the `replicaCount` value to 1, and then package the chart, this time changing the version in `Chart.yaml` to `0.1.1`. Version control is ideally	Cloud Administrator, DevOps Engineer

Task	Description	Skills required
	achieved through automation by using tools like GitVersion or Jenkins build numbers in a CI/CD pipeline. Automating the version number is out of scope for this pattern. To package the chart, run the following command: `helm package ./my-app/`	
Push the new version to the Helm repository in Amazon S3.	To push the new package, version of 0.1.1, to the *my-helm-charts* Helm repository in Amazon S3, run the following command: `helm s3 push ./my-app-0.1.1.tgz stable-myapp`	Cloud Administrator, DevOps Engineer

Verify the updated Helm chart.	To confirm that the updated chart appears both locally and in the Amazon S3 Helm repository, run the following commands.
	
	`helm repo update`
	
	`helm search repo stable-myapp`
		Cloud Administrator, DevOps Engineer

Search for and install a chart from the Amazon S3 Helm repository

Task	Description	Skills required
Search for all versions of the my-app chart.	To view all the available versions of a chart, run the following command with the `--versions` flag: `helm search repo my-app --versions` Without the flag, Helm by default displays the latest uploaded version of a chart.	DevOps Engineer
Install a chart from the Amazon S3 Helm repository.	Automated installation is out of scope for this pattern, but you can manually install. The search results from the previous task show the multiple versions of the `my-app` chart. To install the new version (0.1.1) from the Amazon S3 Helm repository, use the following command: `helm upgrade --install my-app-release stable-myapp/my-app --version 0.1.1 --namespace dev`	DevOps Engineer

Roll back to a previous version by using Helm

Task	Description	Skills required
Review the details for a specific revision.	Automated rollback is out of scope for this pattern,	DevOps Engineer

Task	Description	Skills required
	but you can roll back to an earlier version manually. Before you switch or roll back to a working version, and for an additional layer of validation before installin g a revision, view which values were passed to each of the revisions by using the following command: `helm get values --revisio n=2 my-app-release`	
Roll back to a previous version.	Automated rollback is out of scope for this pattern. To manually roll back to a previous revision, use the following command: `helm rollback my-app-re lease 1` This example is rolling back to revision number 1.	DevOps Engineer

Set up a CI/CD pipeline by using AWS CodePipeline and AWS CDK

Konstantin Zarudaev, Yasha Dabas, Lars Kinder, and Cizer Pereira, Amazon Web Services

Home

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more Automating your software build and release process with continuous integration and continuous delivery (CI/CD) supports repeatable builds and rapid delivery of new features to your users. You can quickly and easily test each code change, and you can catch and fix bugs before releasing your software. By running each change through your staging and release process, you can verify the quality of your application or infrastructure code. CI/CD embodies a culture, a set of operating principles, and a collection of practices that help application development teams to deliver code changes more frequently and reliably. The implementation is also known as the *CI/CD pipeline*.

This pattern defines a reusable continuous integration and continuous delivery (CI/CD) pipeline on Amazon Web Services (AWS) with an AWS CodeCommit repository. The AWS CodePipeline pipeline is written using AWS Cloud Development Kit (AWS CDK) v2.

Using CodePipeline, you can model the different stages of your software release process through the AWS Management Console interface, the AWS Command Line Interface (AWS CLI), AWS CloudFormation, or the AWS SDKs. This pattern demonstrates the implementation of CodePipeline and its components using AWS CDK. In addition to construct libraries, AWS CDK includes a toolkit (the CLI command `cdk`), which is the primary tool for interacting with your AWS CDK app. Among other functions, the toolkit provides the ability to convert one or more stacks to CloudFormation templates and deploy them to an AWS account.

The pipeline includes tests to validate the security of your third-party libraries, and it helps ensure expedited, automated release in the specified environments. You can increase the overall security of your applications by putting them through a validation process.

The intent of this pattern is to accelerate your use of CI/CD pipelines to deploy your code while ensuring the resources you deploy adhere to DevOps best practices. After you implement the example code, you will have an AWS CodePipeline with linting, testing, a security check, deployment, and post-deployment processes. This pattern also includes steps for Makefile. Using a Makefile, developers can reproduce CI/CD steps locally and increase the velocity of the development process.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A basic understanding in the following:
  - AWS CDK
  - AWS CloudFormation
  - AWS CodePipeline
  - TypeScript

Limitations

This pattern uses AWS CDK for TypeScript only. It doesn't cover other languages supported by AWS CDK.

Product versions

Use the latest versions of the following tools:

- AWS Command Line Interface (AWS CLI)
- cfn_nag
- git-remote-codecommit
- Node.js

Architecture

Target technology stack

- AWS CDK
- AWS CloudFormation
- AWS CodeCommit
- AWS CodePipeline

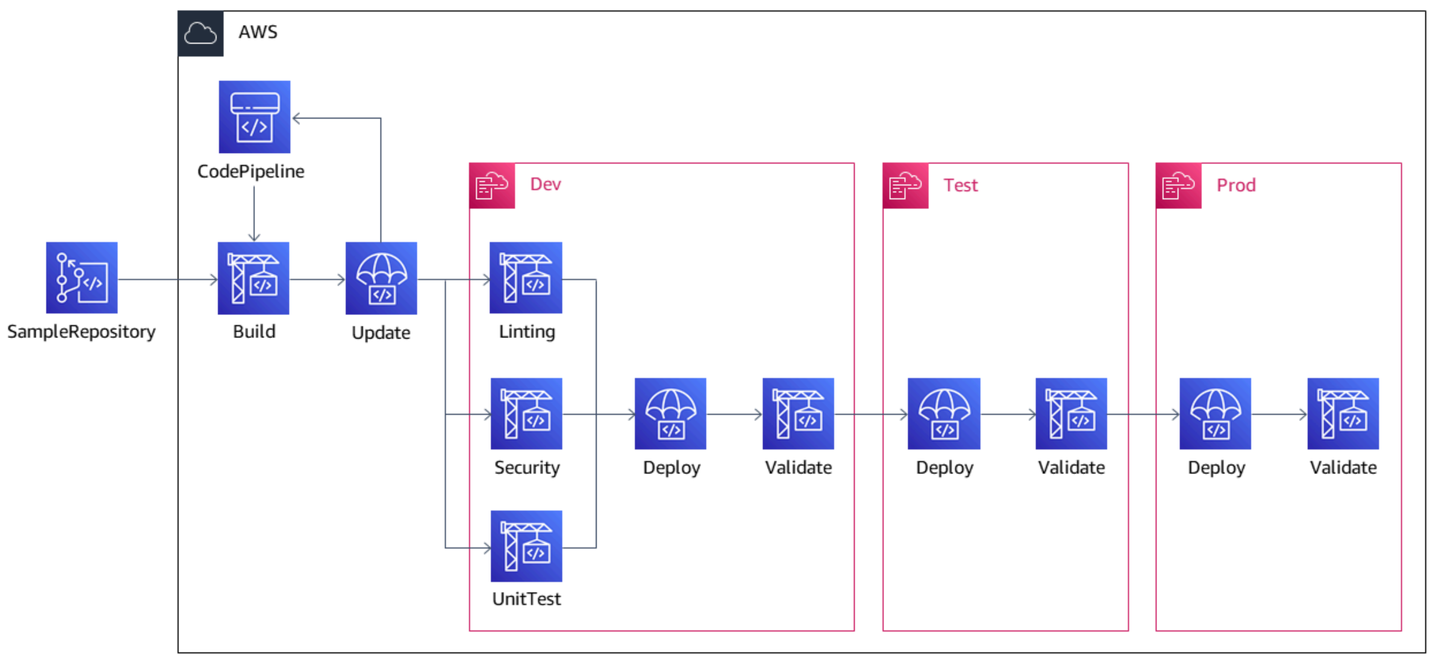
Target architecture

The pipeline is triggered by a change in the AWS CodeCommit repository (`SampleRepository`). In the beginning, CodePipeline builds artifacts, updates itself, and starts the deployment process. The resulting pipeline deploys a solution to three independent environments:

- Dev – Three-step code check in the active development environment
- Test – Integration and regression test environment
- Prod – Production environment

The three steps included in the Dev stage are linting, security, and unit tests. These steps run in parallel to speed up the process. To ensure that the pipeline provides only working artifacts, it will be stop running whenever a step in the process fails. After a Dev stage deployment, the pipeline runs validation tests to verify the results. In the case of success, the pipeline will then deploy the artifacts to the Test environment, which contains post-deployment validation. The final step is to deploy the artifacts to the Prod environment.

The following diagram shows the workflow from the CodeCommit repository to the build and update processes performed by CodePipeline, the three Dev environment steps, and subsequent deployment and validation in each of the three environments.



Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions. In this pattern CloudFormation templates can be used to create a CodeCommit repository and a CodePipeline CI/CD pipeline.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodePipeline is a CI/CD service that helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Other tools

- cfn_nag is an open-source tool that looks for patterns in CloudFormation templates to identify potential security issues.
- git-remote-codecommit is a utility for pushing and pulling code from CodeCommit repositories by extending Git.
- Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.

Code

The code for this pattern is available in the GitHub AWS CodePipeline with CI/CD practices repository.

Best practices

Review resources, such as AWS Identity and Access Management (IAM) policies, to confirm that they align with your organizational best practices.

Epics

Install tools

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install tools on macOS or Linux.</td><td>If you are using MacOS or Linux, you can install the tools by running the following command in your preferred terminal or using Homebrew for Linux.<pre><code>brew install
brew install git-remote-codecommit
brew install ruby brew-gem
brew-gem install cfn-nag</code></pre></td><td>DevOps engineer</td></tr>
<tr><td>Set up AWS CLI.</td><td>To set up AWS CLI, use the instructions for your operating system:
Windows: Setup steps for HTTPS connections to AWS CodeCommit repositories on Windows with the AWS CLI credential helper
Linux, macOS, Unix: Setup steps for HTTPS connections to AWS CodeCommit repositories on Linux, macOS, or Unix with the AWS CLI credential helper</td><td>DevOps engineer</td></tr>
</table>

Set up the initial deployment

Task	Description	Skills required

Download or clone the code.	To get the code that is used by this pattern, do one of the following:
	
	• Download the latest source code from releases in the GitHub repo, and unzip the downloaded file into a folder.
	• Clone the project by running the following command.
	
	`git clone --depth 1 https://github.com/aws-samples/aws-codepipeline-cicd.git`
	
	Remove the `.git` directory from the cloned repository.
	
	`cd ./aws-codepipeline-cicd`
	`rm -rf ./.git`
	
	Later, you will use a newly created AWS CodeCommit repository as a remote origin.
		DevOps engineer

Connect to the AWS account.	You can connect by using a temporary security token or landing zone authentication. To confirm that you are using	DevOps engineer

Task	Description	Skills required
	the correct account and AWS Region, run the following commands. ``` AWS_REGION="eu-west-1" ACCOUNT_NUMBER=$(aws sts get-caller-identity --query Account --output text) echo "${ACCOUNT_NUMBER}" ```	
Bootstrap the environment.	To bootstrap an AWS CDK environment, run the following commands. ``` npm install npm run cdk bootstrap "aws://${ACCOUNT_NUMBER}/${AWS_REGION}" ``` After you successfully bootstrap the environment, the following output should be displayed. ``` # Bootstrapping environment aws://{account}/{region}... # Environment aws://{account}/{region} bootstrapped ``` For more information about AWS CDK bootstrapping, see the [AWS CDK documentation]().	DevOps engineer

Task	Description	Skills required

Synthesize a template.	To synthesize an AWS CDK app, use the `cdk synth` command.
	`npm run cdk synth`
	You should see the following output.
	`Successfully synthesized to <path-to-directory>/aws-codepipeline-cicd/cdk.out`
	`Supply a stack id (CodePipeline, Dev-MainStack) to display its template.`
		DevOps engineer

Task	Description	Skills required

Deploy the CodePipeline stack.	Now that you bootstrapped and synthesized the CloudFormation template, you can deploy it. The deployment will create the CodePipeline pipeline and a CodeCommit repository, which will be the source and trigger of the pipeline.
	
	`npm run cdk -- deploy CodePipeline --require-approval never`
	
	After you run the command, you should see a successful deployment of the CodePipeline stack and output information. The `CodePipeline.RepositoryName` gives you the name of the CodeCommit repository in the AWS account.
	
	`CodePipeline: deploying ...`
	`CodePipeline: creating CloudFormation changeset...`
	`#  CodePipeline Outputs:`
	`CodePipeline.RepositoryName = SampleRepository`
	`Stack ARN:`
	`arn:aws:cloudformation:REGION:ACCOUNT-ID`
		DevOps engineer

Task	Description	Skills required
	`:stack/CodePipeline/ STACK-ID`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Set up the remote CodeCommit repository and branch.</td><td>After a successful deployment, CodePipeline will initiate the first run of the pipeline, which you can find in the AWS CodePipeline console. Because AWS CDK and CodeCommit don’t initiate a default branch, this initial pipeline run will fail and return the following error message.
<pre><code>The action failed because no branch named main was found in the selected AWS CodeCommit repository SampleRepository. Make sure you are using the correct branch name, and then try again. Error: null</code></pre>
To fix this error, set up a remote origin as <code>SampleRepository</code> , and create the required <code>main</code> branch.
<pre><code>RepoName=$(aws cloudformation describe-stacks --stack-name CodePipeline --query "Stacks[0].Outputs[?OutputKey=='RepositoryName'].OutputValue" --output text)
echo "${RepoName}"
#</code></pre></td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	``` git init git branch -m master main git remote add origin codecommit://${Rep oName} git add . git commit -m "Initial commit" git push -u origin main ```	

Test the deployed CodePipeline pipeline

Task	Description	Skills required
Commit a change to activate the pipeline.	After a successful initial deployment, you should have a complete CI/CD pipeline with a `main` branch for `SampleRepository` as a source branch. As soon as you commit changes to the `main` branch, the pipeline will initiate and run the following sequence of actions: 1. Get your code from the CodeCommit repository. 2. Build your code. 3. Update the pipeline itself (`UpdatePipeline`). 4. Run three parallel jobs for linting, security and unit test checks.	DevOps engineer

Task	Description	Skills required
	5. In the case of success, the pipeline will deploy the `Main` stack from `./lib/main-stack.ts` to the Dev environment. 6. Run a post-deployment check for deployed resources. You can follow all CodePipeline steps and results in the CodePipeline console. 7. In the case of success, the pipeline will repeat deployment and validation for the Test and Prod environments.	

Test locally by using a Makefile

Task	Description	Skills required
Run the development process by using a Makefile.	You can run the whole pipeline locally by using the `make` command, or you can run an individual step (for example, `make linting`). To test using `make`, perform the following actions: • Implement the local pipeline: `make` • Run only unit testing: `make unittest`	App developer, DevOps engineer

Task	Description	Skills required
	• Deploy to the current account: `make deploy` • Clean up the environment: `make clean`	

Clean up resources

Task	Description	Skills required
Delete AWS CDK app resources.	To clean up your AWS CDK app, run the following command. `cdk destroy --all` Be aware that the Amazon Simple Storage Service (Amazon S3) buckets that are created during bootstrapping aren't automatically deleted. They need a retention policy that allows deletion, or you need to delete them manually in your AWS account.	DevOps engineer

Troubleshooting

Issue	Solution
The template isn’t working as expected.	If something goes wrong and template is not working, make sure that you have the following: • The proper versions of the tools.

Issue	Solution
	• Access to the target AWS account (network connectivity). • Enough permissions to the target AWS account.

Set up centralized logging at enterprise scale by using Terraform

Aarti Rajput, Yashwant Patel, and Nishtha Yadav, Amazon Web Services

Summary

Centralized logging is vital for an organization's cloud infrastructure, because it provides visibility into its operations, security, and compliance. As your organization scales its AWS environment across multiple accounts, a structured log management strategy becomes fundamental for running security operations, meeting audit requirements, and achieving operational excellence.

This pattern provides a scalable, secure framework for centralizing logs from multiple AWS accounts and services, to enable enterprise-scale logging management across complex AWS deployments. The solution is automated by using Terraform, which is an infrastructure as code (IaC) tool from HashiCorp that ensures consistent and repeatable deployments, and minimizes manual configuration. By combining Amazon CloudWatch Logs, Amazon Data Firehose, and Amazon Simple Storage Service (Amazon S3), you can implement a robust log aggregation and analysis pipeline that delivers:

- Centralized log management across your organization in AWS Organizations
- Automated log collection with built-in security controls
- Scalable log processing and durable storage
- Simplified compliance reporting and audit trails
- Real-time operational insights and monitoring

The solution collects logs from Amazon Elastic Kubernetes Service (Amazon EKS) containers, AWS Lambda functions, and Amazon Relational Database Service (Amazon RDS) database instances through CloudWatch Logs. It automatically forwards these logs to a dedicated logging account by using CloudWatch subscription filters. Firehose manages the high-throughput log streaming pipeline to Amazon S3 for long-term storage. Amazon Simple Queue Service (Amazon SQS) is configured to receive Amazon S3 event notifications upon object creation. This enables integration with analytics services, including:

- Amazon OpenSearch Service for log search, visualization, and real-time analytics
- Amazon Athena for SQL-based querying
- Amazon EMR for large-scale processing
- Lambda for custom transformation

- Amazon QuickSight for dashboards

All data is encrypted by using AWS Key Management Service (AWS KMS), and the entire infrastructure is deployed by using Terraform for consistent configuration across environments.

This centralized logging approach enables organizations to improve their security posture, maintain compliance requirements, and optimize operational efficiency across their AWS infrastructure.

Prerequisites and limitations

Prerequisites

- A landing zone for your organization that's built by using AWS Control Tower
- Account Factory for Terraform (AFT), deployed and configured with required accounts
- Terraform for provisioning the infrastructure
- AWS Identity and Access Management (IAM) roles and policies for cross-account access

For instructions for setting up AWS Control Tower, AFT, and Application accounts, see the Epics section.

Required accounts

Your organization in AWS Organizations should include these accounts:

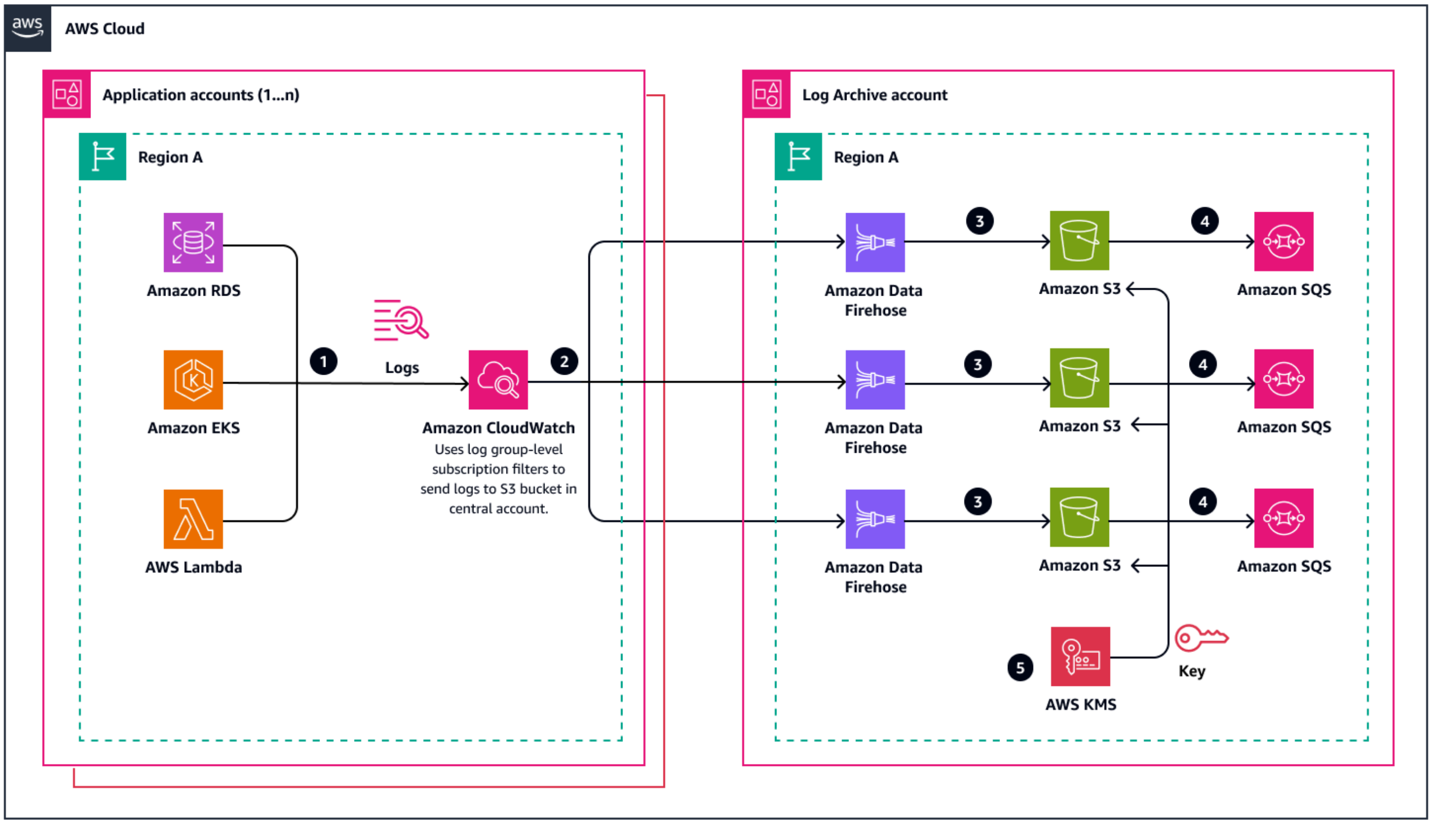
- **Application account** – One or more source accounts where the AWS services (Amazon EKS, Lambda, and Amazon RDS) run and generate logs
- **Log Archive account** – A dedicated account for centralized log storage and management

Product versions

- AWS Control Tower version 3.1 or later
- Terraform version 0.15.0 or later

Architecture

The following diagram illustrates an AWS centralized logging architecture that provides a scalable solution for collecting, processing, and storing logs from multiple Application accounts into a dedicated Log Archive account. This architecture efficiently handles logs from AWS services, including Amazon RDS, Amazon EKS, and Lambda, and routes them through a streamlined process to Regional S3 buckets in the Log Archive account.



The workflow includes five processes:

1. **Log flow process**
   - The log flow process begins in the Application accounts, where AWS services generate various types of logs, such as general, error, audit, slow query logs from Amazon RDS, control plane logs from Amazon EKS, and function execution and error logs from Lambda.
   - CloudWatch serves as the initial collection point. It gathers these logs at the log group level within each application account.
   - In CloudWatch, subscription filters determine which logs should be forwarded to the central account. These filters give you granular control over log forwarding, so you can specify exact log patterns or complete log streams for centralization.
2. **Cross-account log transfer**
   - Logs move to the Log Archive account. CloudWatch subscription filters facilitate the cross-account transfer and preserve Regional context.

- The architecture establishes multiple parallel streams to handle different log sources efficiently, to ensure optimal performance and scalability.

3. **Log processing in the Log Archive account**
   - In the Log Archive account, Firehose processes the incoming log streams.
   - Each Region maintains dedicated Firehose delivery streams that can transform, convert, or enrich logs as needed.
   - These Firehose streams deliver the processed logs to S3 buckets in the Log Archive account, which is located in the same Region as the source Application accounts (Region A in the diagram) to maintain data sovereignty requirements.
4. **Notifications and additional workflows**
   - When logs reach their destination S3 buckets, the architecture implements a notification system by using Amazon SQS.
   - The Regional SQS queues enable asynchronous processing and can trigger additional workflows, analytics, or alerting systems based on the stored logs.
5. **AWS KMS for security**

   The architecture incorporates AWS KMS for security. AWS KMS provides encryption keys for the S3 buckets. This ensures that all stored logs maintain encryption at rest while keeping the encryption Regional to satisfy data residency requirements.

Tools

AWS services

- Amazon CloudWatch is a monitoring and observability service that collects monitoring and operational data in the form of logs, metrics, and events. It provides a unified view of AWS resources, applications, and services that run on AWS and on-premises servers.
- CloudWatch Logs subscription filters are expressions that match a pattern in incoming log events and deliver matching log events to the specified AWS resource for further processing or analysis.
- AWS Control Tower Account Factory For Terraform (AFT) sets up a Terraform pipeline to help you provision and customize accounts in AWS Control Tower. AFT provides Terraform-based account provisioning while allowing you to govern your accounts with AWS Control Tower.
- Amazon Data Firehose delivers real-time streaming data to destinations such as Amazon S3, Amazon Redshift, and Amazon OpenSearch Service. It automatically scales to match the throughput of your data and requires no ongoing administration.

- Amazon Elastic Kubernetes Service (Amazon EKS) is a managed container orchestration service that makes it easy to deploy, manage, and scale containerized applications by using Kubernetes. It automatically manages the availability and scalability of the Kubernetes control plane nodes.
- AWS Key Management Service (AWS KMS) creates and controls encryption keys for encrypting your data. AWS KMS integrates with other AWS services to help you protect the data you store with these services.
- AWS Lambda is a serverless compute service that lets you run code without provisioning or managing servers. It automatically scales your applications by running code in response to each trigger, and charges only for the compute time that you use.
- Amazon Relational Database Service (Amazon RDS) is a managed relational database service that makes it easy to set up, operate, and scale a relational database in the cloud. It provides cost-efficient and resizable capacity while automating time-consuming administration tasks.
- Amazon Simple Queue Service (Amazon SQS) is a message queuing service that enables you to decouple and scale microservices, distributed systems, and serverless applications. It eliminates the complexity of managing and operating message-oriented middleware.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that offers scalability, data availability, security, and performance. It can store and retrieve any amount of data from anywhere on the web.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code

The code for this pattern are available in the GitHub Centralized logging repository.

Best practices

- Use multiple AWS accounts in a single organization in AWS Organizations. This practice enables centralized management and standardized logging across accounts.
- Configure S3 buckets with versioning, lifecycle policies, and cross-Region replication. Implement encryption and access logging for security and compliance.
- Implement common logging standards by using JSON format with standard timestamps and fields. Use a consistent prefix structure and correlation IDs for easy tracking and analysis.

- Enable security controls with AWS KMS encryption and least privilege access. Maintain AWS CloudTrail monitoring and regular key rotation for enhanced security.
- Set up CloudWatch metrics and alerts for delivery tracking. Monitor costs and performance with automated notifications.
- Configure Amazon S3 retention policies to meet compliance requirements and enable Amazon S3 server access logging to track all requests made to your S3 buckets. Maintain documentation for S3 bucket policies and lifecycle rules. Conduct periodic reviews of access logs, bucket permissions, and storage configurations to help ensure compliance and security best practices.

Epics

Set up AWS Control Tower, AFT, and Application accounts

Task	Description	Skills required
Set up an AWS Control Tower environment with AFT.	1. Deploy AWS Control Tower by following the instructi ons in the AWS Control Tower documentation. 2. Deploy AFT by following the instructions in the AWS Control Tower documenta tion.	AWS administrator
Enable resource sharing for the organization.	1. Configure AWS Command Line Interface (AWS CLI) with management account credentials, which provide administrative permissio ns to manage AWS Control Tower. 2. Run the following AWS CLI command in any AWS Region:	AWS administrator

Task	Description	Skills required
	```aws ram enable-sharing-with-aws-organization``` This enables resource sharing within your organization in AWS Organizations across all Regions that support AWS Resource Access Manager (AWS RAM).	
Verify or provision Application accounts.	To provision new Application accounts for your use case, create them through AFT. For more information, see [Provision a new account with AFT] in the AWS Control Tower documentation.	AWS administrator

Set up configuration files for Application accounts

Task	Description	Skills required
Copy `Application_account` folder contents into the `aft-account-customizations` repository.	1. Create a folder named `Application_account` in the root path of the `aft-account-customizations` repository. This repository is created automatically when you set up AFT (see the previous epic).	DevOps engineer

Task	Description	Skills required
	2. Navigate to the root directory of the [centralised-logging-at-enterprise-scale-using-terraform](https://github.com/aws-samples/centralised-logging-at-enterprise-scale-using-terraform) repository, copy the contents of the `aft/account` directory, and then paste them into the `Application_account` directory that you created in step 1 in the `aft-account-customizations` repository. 3. From the root directory of the `centralised-logging-at-enterprise-scale-using-terraform` repository, copy the contents of the `Application_account` directory into the `Application_account/terraform` directory in the `aft-account-customizations` repository. 4. In the `aft-account-customizations/Application_account/terraform.tfvars` file, confirm that all parameters are passed as arguments in the correspon	

Task	Description	Skills required
	ding Terraform configura tion files.	

Task	Description	Skills required
Review and edit the input parameters for setting up the Application account.	In this step, you set up the configuration file for creating resources in Application accounts, including CloudWatch log groups, CloudWatch subscription filters, IAM roles and policies, and configuration details for Amazon RDS, Amazon EKS, and Lambda functions. In your `aft-account-customizations` repository, in the `Application_account` folder, configure the input parameters in the `terraform.tfvars` file based on your organization's requirements: • `environment` : The name of the environment (for example, `prod`, `dev`, `staging`) where the resources will be deployed. • `account_name` : The name of the AWS account where the resources will be created. • `log_archive_account_id` : The AWS account ID where logs will be archived. • `admin_role_name` : The name of the administrative	DevOps engineer

Task	Description	Skills required
	role that will be used for managing resources. • `tags`: A map of key-value pairs that represent common tags to be applied to all resources. • `rds_config` : An object that contains configuration details for Amazon RDS instances. • `allowed_cidr_blocks` : A list of CIDR blocks that are allowed to access the resources. • `destination_name`: A variable that is used to create the Amazon Resource Name (ARN) of the CloudWatch destination where logs will be streamed. • `rds_parameters`: An object that contains Amazon RDS parameter group settings. • `vpc_config` : An object that contains VPC configuration details. • `eks_config` : An object that contains configuration details for Amazon EKS clusters.	

Task	Description	Skills required
	• `lambda_config` : An object that contains configuration details for Lambda functions. • `restrictive_cidr_range` : A list of restrictive CIDR ranges for security group rules. • `target_account_id` : The AWS account ID of the target Log Archive account where resources will be deployed.	

Set up configuration files for the Log Archive account

Task	Description	Skills required
Copy `Log_archive_account` folder contents into the `aft-account-customizations` repository.	1. Create a folder named `Log_archive_account` in the root path of the `aft-account-customizations` repository, This repository is created automatically when you set up AFT. 2. Navigate to the root directory of the `centralised-logging-at-enterprise-scale-using-terraform` repository, copy the contents of the `aft/`	DevOps engineer

Task	Description	Skills required
	`account` directory, and then paste them into the `Log_archive_account` directory that you created in the previous step in the `aft-account-customizations` repository. 3. From the root directory of the `centralised-logging-at-enterprise-scale-using-terraform` repository, copy the contents of the `Log_archive_account` directory into the `Log_archive_account/terraform` directory in the `aft-account-customizations` repository. 4. In the `aft-account-customizations/Log_archive_account/terraform.tfvars` file, confirm that all parameters are passed as arguments in the corresponding Terraform configuration files.	

Task	Description	Skills required
Review and edit the input parameters for setting up the Log Archive account.	In this step, you set up the configuration file for creating resources in the Log Archive account, including Firehose delivery streams, S3 buckets, SQS queues, and IAM roles and policies. In the `Log_archive_account` folder of your `aft-account-customizations` repository, configure the input parameters in the `terraform.tfvars` file based on your organization's requirements: • `environment` : The name of the environment (for example, `prod`, `dev`, `staging`) where the resources will be deployed. • `destination_name` : A variable that is used to create the ARN of the CloudWatch destination where logs will be streamed. • `source_account_ids` : A list of AWS account IDs that are allowed to put subscription filters on the log destination. You can input as many account IDs	DevOps engineer

Task	Description	Skills required
	as you want to enable for centralized logging.	

Run Terraform commands to provision resources

Task	Description	Skills required

Option 1 - Deploy the Terraform configuration files from AFT.	In AFT, the AFT pipeline is triggered after you push the code with the configuration changes to the GitHub `aft-account-customizations` repository. AFT automatically detects the changes and initiates the account customization process.
	
	After you make changes to your Terraform (`terraform.tfvars`) files, commit and push your changes to your `aft-account-customizations` repository:
	
	`$ git add *`
	`$ git commit -m "update message"`
	`$ git push origin main`
	
	Note
	If you're using a different branch (such as `dev`), replace `main`
		DevOps engineer

Task	Description	Skills required
	with your branch name.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Option 2 - Deploy the Terraform configuration file manually.</td><td>If you aren't using AFT or you want to deploy the solution manually, you can use the following Terraform commands from the <code>Application_account</code> and <code>Log_archive_account</code> folders:

1. Clone the GitHub repository and configure the input parameters in the <code>terraform.tfvars</code> file.
2. Run the following command:
<pre>$ terraform init</pre>3. Preview changes:
<pre>$ terraform plan</pre>This command evaluates the Terraform configuration to determine the desired state of the resources and compares it with the current state of your infrastructure.
4. Apply changes:
<pre>$ terraform apply</pre>5. Review the planned changes and type yes at</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	the prompt to proceed with the application.	

Validate resources

Task	Description	Skills required
Verify subscription filters.	To verify that the subscription filters forward logs correctly from the Application account log groups to the Log Archive account: 1. In the Application account, open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/). 2. In the left navigation pane, choose **Log groups**. 3. Select each log group (`/aws/rds`, `/aws/eks`, `/aws/lambda`) and choose the **Subscription filters** tab. You should see active subscription filters that point to the destination ARN, based on the name that you specified in the Terraform configuration file. 4. Choose any subscription filter to verify its configura tion and status.	DevOps engineer

Task	Description	Skills required

Verify Firehose streams.	To verify that the Firehose streams in the Log Archive account process application logs successfully:
	
	1. In the Log Archive account, open the [Firehose console](https://console.aws.amazon.com/firehose/).
	2. In the left navigation pane, choose **Firehose streams**.
	3. Choose any **Firehose streams** and verify the following:
	  • The destination shows the correct S3 bucket.
	  • The **Monitoring** tab shows successful delivery metrics.
	  • The recent delivery timestamp is current.
		DevOps engineer

Task	Description	Skills required
Validate the centralized S3 buckets.	To verify that the centralized S3 buckets receive and organize logs properly: 1. In the Log Archive account, open the [Amazon S3 console](https://console.aws.amazon.com/s3/). 2. Select each central logging bucket. 3. Navigate through the folder structure: **AWSLogs/AccountID/Region/Service**. You should see log files organized by timestamp (**YYYY/MM/DD/HH**). 4. Choose any recent log file and verify its format and data integrity.	DevOps engineer

Task	Description	Skills required
Validate SQS queues.	To verify that the SQS queues receive notifications for new log files: 1. In the Log Archive account, open the [Amazon SQS console](https://console.aws.amazon.com/sqs/). 2. In the left navigation pane, choose **Queues**. 3. Select each configured queue and choose **Send and receive messages**. You should see messages that contain **S3 event notifications** for new log files. 4. Choose any message to verify that it contains the correct S3 object informati on.	DevOps engineer

Clean up resources

Task	Description	Skills required
Option 1 - Decommission the Terraform configuration file from AFT.	When you remove the Terraform configuration files and push the changes, AFT automatically initiates the resource removal process.	DevOps engineer

Task	Description	Skills required

	1. Navigate to the `aft-account-customizations` repository.
	2. Go to the `terraform` directory.
	3. Delete the following files:
	• `modules` directory
	• `iam.tf`
	• `versions.tf`
	• `variables.tf`
	• `outputs.tf`
	• `terraform.tfvars`
	4. Clear the contents of the `main.tf` file.
	5. Push your changes to the repository:
	`# Stage all changes`
	`$ git add *`
	
	`# Commit cleanup changes`
	`$ git commit -m "Remove AFT customizations"`
	
	`# Push to repository`
	`$ git push origin main`
	
	Note
	If you're using a different branch (such as dev),	

Task	Description	Skills required
	replace `main` with your branch name.	

Option 2 – Clean up Terraform resources manually.	If you aren't using AFT or you want to clean up resources manually, use the following Terraform commands from the `Application_account` and `Log_archive_account` folders:
	
	1. Initialize the Terraform configuration:
	`$ terraform init`
	This command initializes Terraform and ensures access to the current state.
	2. Preview cleanup changes:
	`$ terraform destroy`
	This command evaluates which resources will be destroyed and compares the desired state with the current state of your infrastructure.
	3. Run cleanup. When you're prompted, type **yes** to confirm and run the destruction plan.
		DevOps engineer

Troubleshooting

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td>The CloudWatch Logs destination wasn't created or is inactive.</td><td>Validate the following:

In the Log Archive account, verify that the destination policy includes:

The correct source account principal.
The correct action (<code>logs:PutSubscriptionFilter</code>).
A valid destination ARN.

Confirm that the Firehose stream exists and is active.
Verify that the IAM role that's attached to the destination has permissions for Firehose.
</td></tr>
<tr><td>The subscription filter failed or is stuck in pending status.</td><td>Check the following:

In the Application account, verify that the IAM role has:

Permissions to call <code>PutSubscriptionFilter</code>.
A trust relationship with CloudWatch Logs.

Confirm that the destination ARN is correct.
Check CloudWatch Logs for specific error messages.
</td></tr>
<tr><td>The Firehose delivery stream shows no incoming records.</td><td>Verify the following:

Confirm that the Firehose IAM role has:

Permissions to write to Amazon S3.
Access to the AWS KMS key if encryption is enabled.

</td></tr>
</table>

Issue	Solution
	2. Review CloudWatch metrics for: • `IncomingRecords` • `DeliveryToS3.Records` 3. Verify buffer settings and delivery configura tions.

Set up end-to-end encryption for applications on Amazon EKS using cert-manager and Let's Encrypt

Mahendra Revanasiddappa and Vasanth Jeyaraj, Amazon Web Services

Summary

Implementing end-to-end encryption can be complex and you need to manage certificates for each asset in your microservices architecture. Although you can terminate the Transport Layer Security (TLS) connection at the edge of the Amazon Web Services (AWS) network with a Network Load Balancer or Amazon API Gateway, some organizations require end-to-end encryption.

This pattern uses NGINX Ingress Controller for ingress. This is because when you create a Kubernetes ingress, the ingress resource uses a Network Load Balancer. The Network Load Balancer doesn't permit uploads of client certificates. Therefore, you can't achieve mutual TLS with Kubernetes ingress.

This pattern is intended for organizations that require mutual authentication between all microservices in their applications. Mutual TLS reduces the burden of maintaining user names or passwords and can also use the turnkey security framework. This pattern’s approach is compatible if your organization has a large number of connected devices or must comply with strict security guidelines.

This pattern helps increase your organization's security posture by implementing end-to-end encryption for applications running on Amazon Elastic Kubernetes Service (Amazon EKS). This pattern provides a sample application and code in the GitHub End-to-end encryption on Amazon EKS repository to show how a microservice runs with end-to-end encryption on Amazon EKS. The pattern's approach uses cert-manager, an add-on to Kubernetes, with Let's Encrypt as the certificate authority (CA). Let's Encrypt is a cost-effective solution to manage certificates and provides free certificates that are valid for 90 days. Cert-manager automates the on-demand provisioning and rotating of certificates when a new microservice is deployed on Amazon EKS.

Intended audience

This pattern is recommended for users who have experience with Kubernetes, TLS, Amazon Route 53, and Domain Name System (DNS).

Prerequisites and limitations

Prerequisites

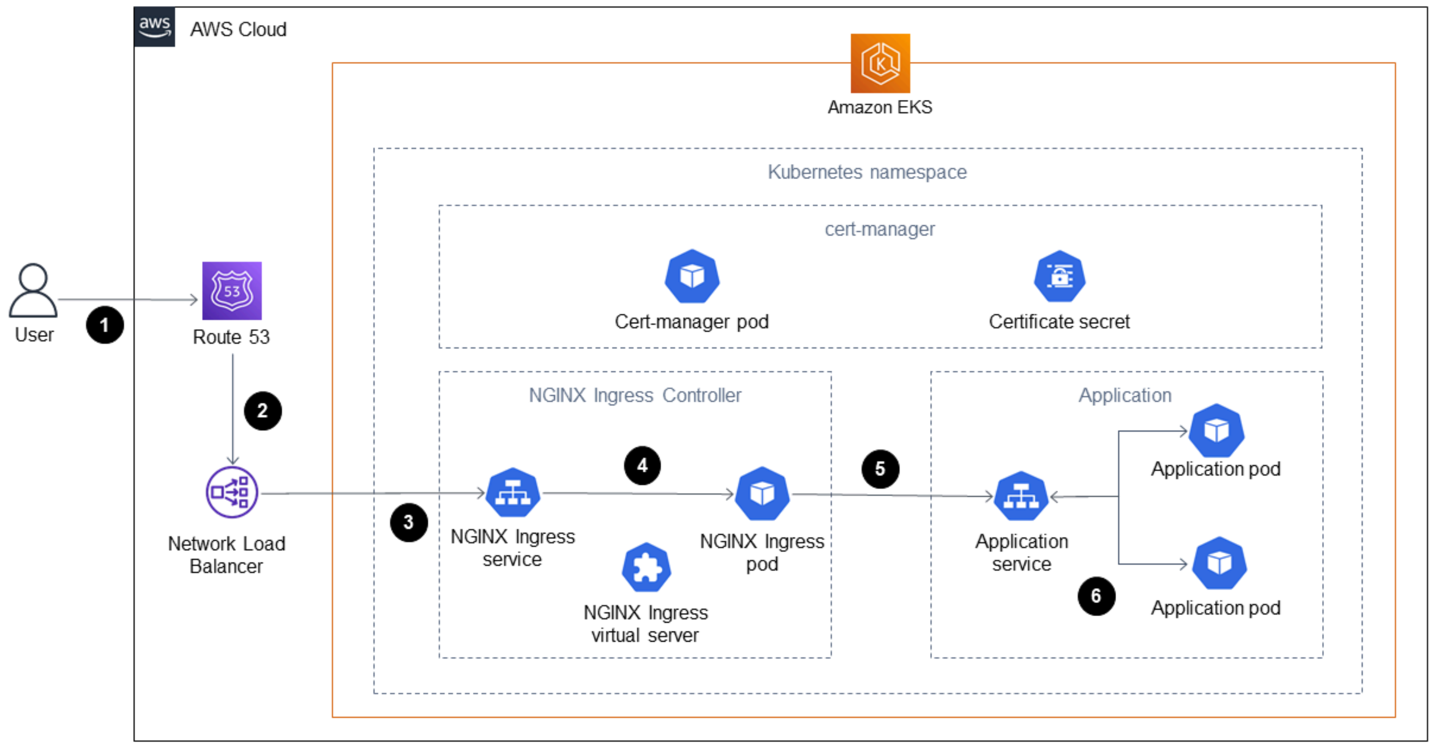
- An active AWS account.
- An existing Amazon EKS cluster.
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
- The `kubectl` command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see Installing kubectl in the Amazon EKS documentation.
- An existing DNS name to test the application. For more information about this, see Registering domain names using Amazon Route 53 in the Amazon Route 53 documentation.
- The latest Helm version, installed on your local machine. For more information about this, see Using Helm with Amazon EKS in the Amazon EKS documentation and the GitHub Helm repository.
- The GitHub End-to-end encryption on Amazon EKS repository, cloned to your local machine.
- Replace the following values in the `policy.json` and `trustpolicy.json` files from the cloned GitHub End-to-end encryption on Amazon EKS repository:
  - `<account number>` – Replace with the AWS account ID for the account that you want to deploy the solution in.
  - `<zone id>` – Replace with the domain name's Route 53 zone ID.
  - `<node_group_role>` – Replace with the name of the AWS Identity and Access Management (IAM) role associated with the Amazon EKS nodes.
  - `<namespace>` – Replace with the Kubernetes namespace in which you deploy the NGINX Ingress Controller and the sample application.
  - `<application-domain-name>` – Replace with the DNS domain name from Route 53.

Limitations

- This pattern doesn't describe how to rotate certificates and only demonstrates how to use certificates with microservices on Amazon EKS.

Architecture

The following diagram shows the workflow and architecture components for this pattern.



The diagram shows the following workflow:

1. A client sends a request to access the application to the DNS name.
2. The Route 53 record is a CNAME to the Network Load Balancer.
3. The Network Load Balancer forwards the request to the NGINX Ingress Controller that is configured with a TLS listener. Communication between the NGINX Ingress Controller and the Network Load Balancer follows HTTPS protocol.
4. The NGINX Ingress Controller carries out path-based routing based on the client's request to the application service.
5. The application service forwards the request to the application pod. The application is designed to use the same certificate by calling secrets.
6. Pods run the sample application using the cert-manager certificates. The communication between the NGINX Ingress Controller and the pods uses HTTPS.

Note: Cert-manager runs in its own namespace. It uses a Kubernetes cluster role to provision certificates as secrets in specific namespaces. You can attach those namespaces to application pods and NGINX Ingress Controller.

Tools

AWS services

- Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.
- Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, containers, and IP addresses.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Route 53 is a highly available and scalable DNS web service.

Other tools

- cert-manager is an add-on to Kubernetes that requests certificates, distributes them to Kubernetes containers, and automates certificate renewal.
- NGINX Ingress Controller is a traffic management solution for cloud-native apps in Kubernetes and containerized environments.

Epics

Create and configure a public hosted zone with Route 53

Task	Description	Skills required
Create a public hosted zone in Route 53.	Sign in to the AWS Management Console, open the Amazon Route 53 console, choose **Hosted zones**, and then choose **Create hosted zone**. Create a public hosted zone and record the zone ID. For more information about this, see Creating a public hosted	AWS DevOps

Task	Description	Skills required
	zone in the Amazon Route 53 documentation. **Note** ACME DNS01 uses the DNS provider to post a challenge for cert-manager to issue the certificate. This challenge asks you to prove that you control the DNS for your domain name by putting a specific value in a TXT record under that domain name. After Let's Encrypt gives your ACME client a token, your client creates a TXT record derived from that token and your account key, and it puts that record at `_acme-challenge.<YOURDOMAIN>`. Then Let's Encrypt queries the DNS for that record. If it finds a match, you can proceed to issue a certificate.	

Configure an IAM role to allow cert-manager to access the public hosted zone

Task	Description	Skills required
Create the IAM policy for cert-manager.	An IAM policy is required to provide cert-manager with permission to validate that you own the Route 53 domain. The `policy.json` sample IAM policy is provided in the `1-IAMRole` directory in the cloned GitHub [End-to-end encryption on Amazon EKS](#) repository. Enter the following command in AWS CLI to create the IAM policy. `aws iam create-policy \ --policy-name PolicyForCertManager \ --policy-document file://policy.json`	AWS DevOps
Create the IAM role for cert-manager.	After you create the IAM policy, you must create an IAM role. The `trustpolicy.json` sample IAM role is provided in the `1-IAMRole` directory. Enter the following command in AWS CLI to create the IAM role. `aws iam create-role \`	AWS DevOps

Task	Description	Skills required

	``
	  --role-name RoleForCe
	rtManager \
	  --assume-role-poli
	cy-document file://tr
	ustpolicy.json
	``	

Attach the policy to the role.	Enter the following command in AWS CLI to attach the IAM policy to the IAM role. Replace `AWS_ACCOUNT_ID` with the ID of your AWS account.
	
	``
	aws iam attach-role-
	policy \
	  --policy-arn
	 arn:aws:iam::AWS_A
	CCOUNT_ID:policy/P
	olicyForCertManager \
	  --role-name RoleForCe
	rtManager
	``
		AWS DevOps

Set up the NGINX Ingress Controller in Amazon EKS

Task	Description	Skills required
Deploy the NGINX Ingress Controller.	Install the most recent version of `nginx-ingress` using Helm. You can modify the `nginx-ingress` configuration according to your requirements before deploying it. This pattern uses an annotated, internal-facing Network Load Balancer and that is available in the	AWS DevOps

Task	Description	Skills required
	`5-Nginx-Ingress-Controller` directory. Install the NGINX Ingress Controller by running the following Helm command from the `5-Nginx-Ingress-Controller` directory. `helm install test-nginx nginx-stable/nginx-ingress -f 5-Nginx-Ingress-Controller/values_internal_nlb.yaml`	
Verify that the NGINX Ingress Controller is installed.	Enter the `helm list` command. The output should show that the NGINX Ingress Controller is installed.	AWS DevOps

Task	Description	Skills required

Create a Route 53 A record.	The A record points to the Network Load Balancer created by NGINX Ingress Controller.
	
	1. Get the DNS name of the Network Load Balancer. For instructions, see Getting the DNS name for an ELB load balancer.
	2. On the Amazon Route 53 console, choose **Hosted Zones**.
	3. Select the public hosted zone that you want to create the record in, and then choose **Create record**.
	4. Enter a name for the record.
	5. In **Record type**, choose **A - Routes traffic to IPv4 and some AWS resources**.
	6. Enable **Alias**.
	7. In **Route traffic to**, do the following:
	  a. Choose **Alias to Network Load Balancer**.
	  b. Choose the AWS Region in which the Network Load Balancer is deployed.
		AWS DevOps

Task	Description	Skills required
	c. Enter the DNS name of the Network Load Balancer. 8. Choose **Create records**.	

Set up NGINX VirtualServer on Amazon EKS

Task	Description	Skills required
Deploy NGINX VirtualServer.	The NGINX VirtualServer resource is a load balancing configuration that is an alternative to the ingress resource. The configuration to create the NGINX VirtualServer resource is available in the `nginx_virtualserver.yaml` file in the `6-Nginx-Virtual-Server` directory. Enter the following command in `kubectl` to create the NGINX VirtualServer resource. `kubectl apply -f nginx_virtualserver.yaml` **Important** Make sure that you update the application domain name, certificate secret,	AWS DevOps

Task	Description	Skills required
	and application service name in the `nginx_virtualserver.yaml` file.	
Verify that NGINX VirtualServer is created.	Enter the following command in `kubectl` to verify that the NGINX VirtualServer resource was successfully created. `kubectl get virtualserver` **Note** Verify that the `Host` column matches your application's domain name.	AWS DevOps

Task	Description	Skills required
Deploy the NGINX web server with TLS enabled.	This pattern uses a NGINX web server with TLS enabled as the application for testing end-to-end encryption. The configuration files required to deploy the test applicati on are available in the `demo-webserver` directory. Enter the following command in `kubectl` to deploy the test application. `kubectl apply -f nginx-tls-ap.yaml`	AWS DevOps

Task	Description	Skills required
Verify that the test application resources are created.	Enter the following commands in `kubectl` to verify that the required resources are created for the test application: • `kubectl get deployments` **Note:** Validate the `Ready` column and `Available` column. • `kubectl get pods | grep -i example-deploy` **Note:** Pods should be in `running` state. • `kubectl get configmap` • `kubectl get svc`	AWS DevOps

Task	Description	Skills required
Validate the application.	1. Enter the following command by replacing the `<application-domain-name>` with the Route53 DNS name that you created earlier. `curl --verbose https://<application-domain-name>` 2. Verify that you can access the application.	AWS DevOps

Simplify Amazon EKS multi-tenant application deployment by using Flux

Nadeem Rahaman, Aditya Ambati, Aniket Dekate, and Shrikant Patil, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

Many companies that offer products and services are data-regulated industries that are required to maintain data barriers between their internal business functions. This pattern describes how you can use the multi-tenancy feature in Amazon Elastic Kubernetes Service (Amazon EKS) to build a data platform that achieves logical and physical isolation between tenants or users that share a single Amazon EKS cluster. The pattern provides isolation through the following approaches:

- Kubernetes namespace isolation
- Role-based access control (RBAC)
- Network policies
- Resource quotas
- AWS Identity and Access Management (IAM) roles for service accounts (IRSA)

In addition, this solution uses Flux to keep the tenant configuration immutable when you deploy applications. You can deploy your tenant applications by specifying the tenant repository that contains the Flux `kustomization.yaml` file in your configuration.

This pattern implements the following:

- An AWS CodeCommit repository, AWS CodeBuild projects, and an AWS CodePipeline pipeline, which are created by manually deploying Terraform scripts.
- Network and compute components required for hosting the tenants. These are created through CodePipeline and CodeBuild by using Terraform.
- Tenant namespaces, network policies, and resource quotas, which are configured through a Helm chart.
- Applications that belong to different tenants, deployed by using Flux.

We recommend that you carefully plan and build your own architecture for multi-tenancy based on your unique requirements and security considerations. This pattern provides a starting point for your implementation.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2.11.4 or later, installed and configured
- Terraform version 0.12 or later installed on your local machine
- Terraform AWS Provider version 3.0.0 or later
- Kubernetes Provider version 2.10 or later
- Helm Provider version 2.8.0 or later
- Kubectl Provider version 1.14 or later

Limitations

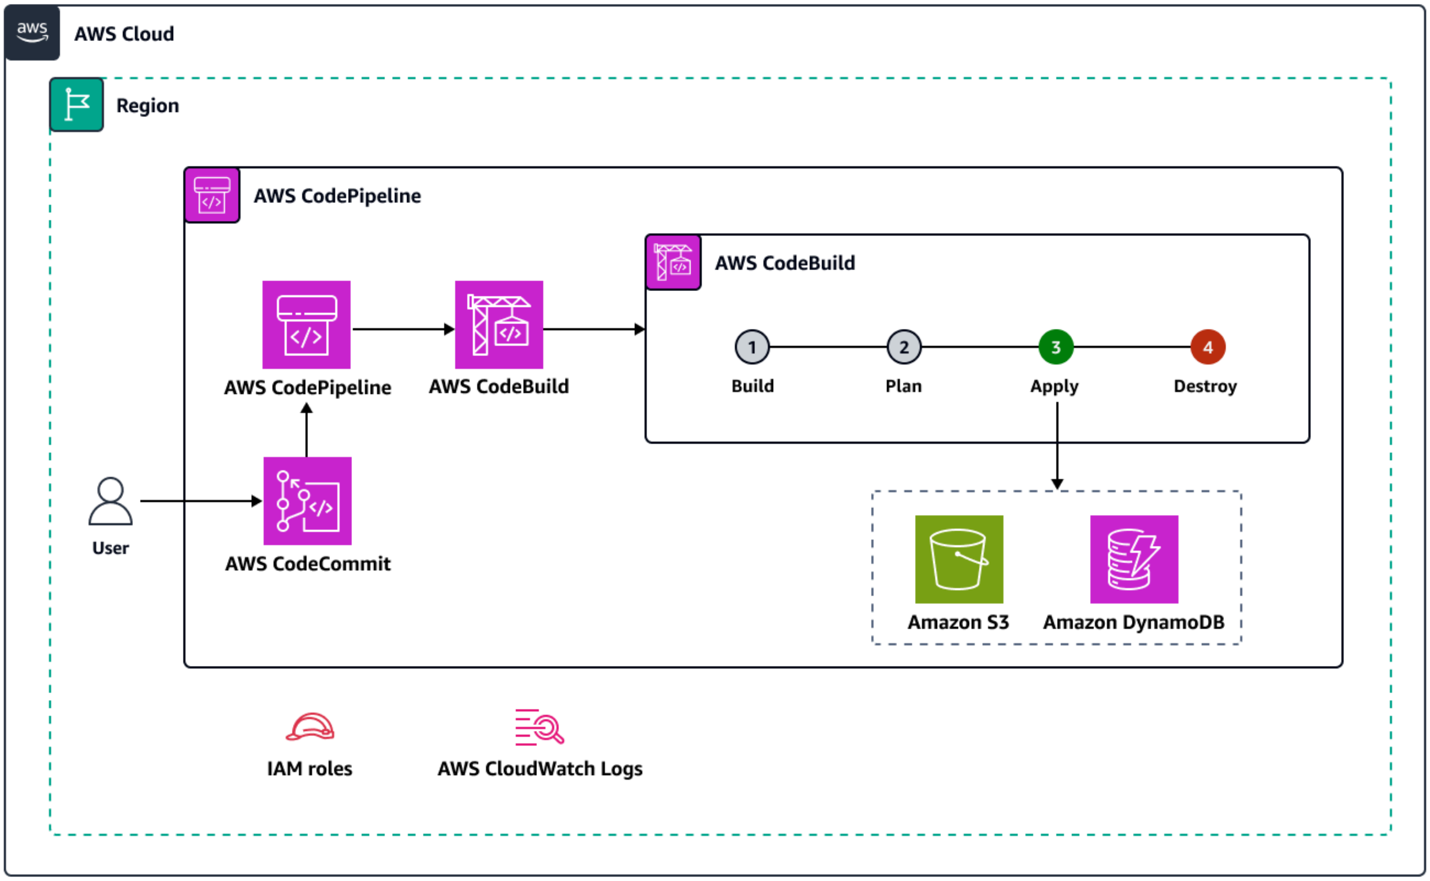
- **Dependency on Terraform manual deployments:** The workflow's initial setup, including creating CodeCommit repositories, CodeBuild projects, and CodePipeline pipelines, relies on manual Terraform deployments. This introduces a potential limitation in terms of automation and scalability, because it requires manual intervention for infrastructure changes.
- **CodeCommit repository dependency:** The workflow relies on CodeCommit repositories as the source code management solution and is tightly coupled with AWS services.

Architecture

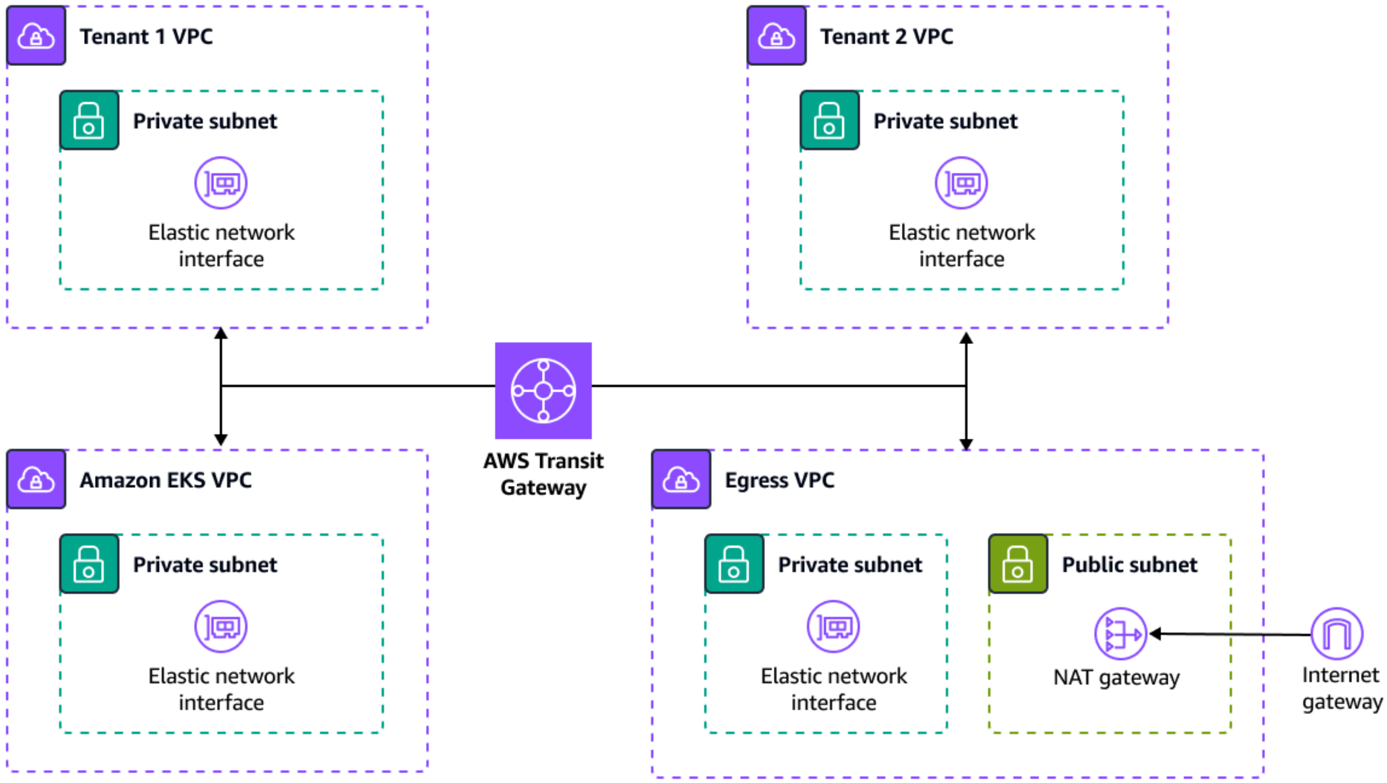
Target architectures

This pattern deploys three modules to build the pipeline, network, and compute infrastructure for a data platform, as illustrated in the following diagrams.

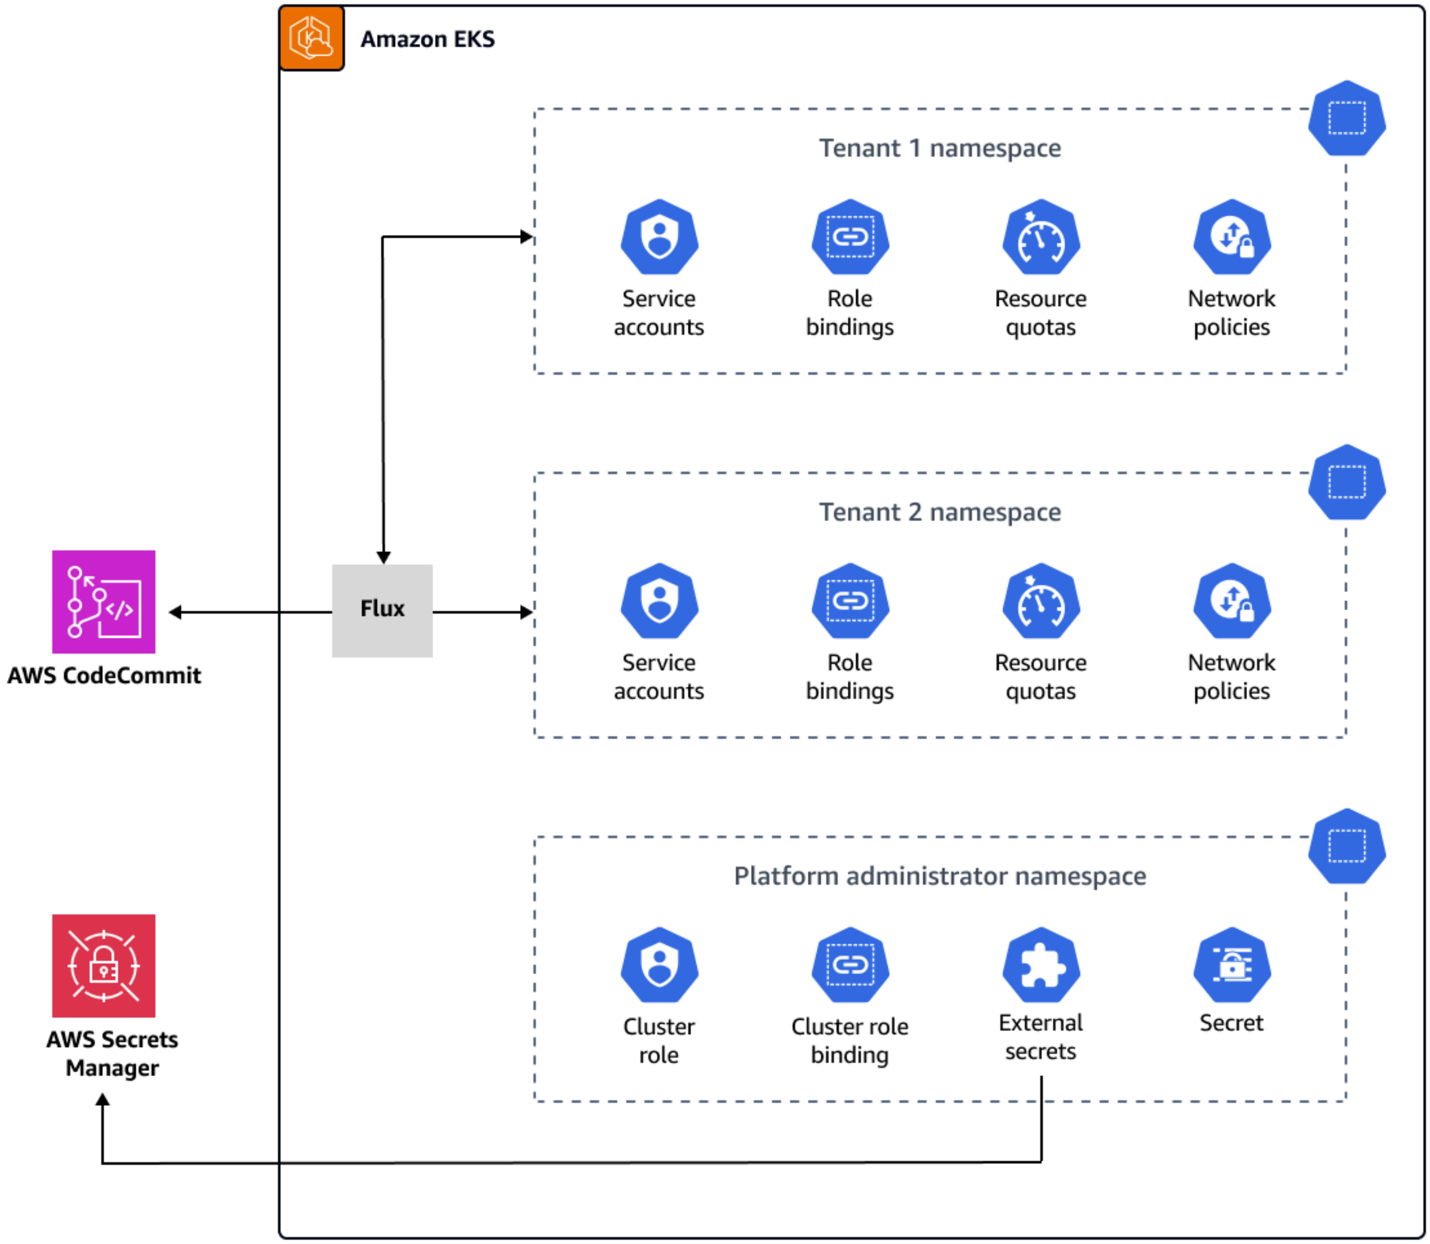
Pipeline architecture:



Network architecture:



Compute architecture:



Tools

AWS services

- [AWS CodeBuild](#) is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- [AWS CodeCommit](#) is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.

- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Transit Gateway is a central hub that connects virtual private clouds (VPCs) and on-premises networks.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- Cilium Network Policies support Kubernetes L3 and L4 networking policies. They can be extended with L7 policies to provide API-level security for HTTP, Kafka, and gRPC, and other similar protocols.
- Flux is a Git-based continuous delivery (CD) tool that automates application deployments on Kubernetes.
- Helm is an open source package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Code repository

The code for this pattern is available in the GitHub EKS Multi-Tenancy Terraform Solution repository.

Best practices

For guidelines and best practices for using this implementation, see the following:

- Amazon EKS multi-tenancy best practices
- Flux documentation

Epics

Create pipelines for Terraform build, test, and deploy stages

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Clone the project repository.</td><td>Clone the GitHub EKS Multi-Tenancy Terraform Solution repository by running the following command in a terminal window:
<pre><code>git clone https://github.com/aws-samples/aws-eks-multitenancy-deployment.git</code></pre></td><td>AWS DevOps</td></tr>
<tr><td>Bootstrap the Terraform S3 bucket and Amazon DynamoDB.</td><td>1. In the <code>bootstrap</code> folder, open the <code>bootstrap.sh</code> file and update the variable values for the S3 bucket name, DynamoDB table name, and AWS Region:
<pre><code>S3_BUCKET_NAME="<S3_BUCKET_NAME>"
DYNAMODB_TABLE_NAME="<DYNAMODB_NAME>"
REGION="<AWS_REGION>"</code></pre>2. Run the <code>bootstrap.sh</code> script. The script requires the AWS CLI, which you installed as part of prerequisites.
<pre><code>cd bootstrap</code></pre></td><td>AWS DevOps</td></tr>
</table>

Task	Description	Skills required
	`./bootstrap.sh`	

Task	Description	Skills required

Update the `run.sh` and `locals.tf` files.	1. After the bootstrap process completes successfully, copy the S3 bucket and DynamoDB table name from the `variables` section of the `bootstrap.sh` script:
	`# Variables`
	`S3_BUCKET_NAME="<S3_BUCKET_NAME>"`
	`DYNAMODB_TABLE_NAME="<DYNAMODB_NAME"`
	2. Paste those values to the `run.sh` script, which is in the root directory of the project:
	`BACKEND_BUCKET_ID="<SAME_NAME_AS_S3_BUCKET_NAME>"`
	`DYNAMODB_ID="<SAME_NAME_AS_DYNAMODB_NAME>"`
	3. Upload the project code to a CodeCommit repository. You can automatically create this repository through Terraform by setting the following variable to `true` in the `demo/pipeline/locals.tf` file:
		AWS DevOps

Task	Description	Skills required
	`create_new_repo = true` 4. Update the `locals.tf` file according to your requirements to create pipeline resources.	

Deploy the pipeline module.	To create pipeline resources, run the following Terraform commands manually. There is no orchestration for running these commands automatically.
	`./run.sh -m pipeline -e demo -r <AWS_REGION> -t init`
	`./run.sh -m pipeline -e demo -r <AWS_REGION> -t plan`
	`./run.sh -m pipeline -e demo -r <AWS_REGION> -t apply`
		AWS DevOps

Create the network infrastructure

Task	Description	Skills required
Start the pipeline.	1. In the `templates` folder, make sure that the `buildspec` files have the following variable set to `network`:	AWS DevOps

Task	Description	Skills required
	`TF_MODULE_TO_BUILD: "network"` 2. On the CodePipeline console, on the pipeline details page, start the pipeline by choosing **Release change**. After this first run, the pipeline starts automatically whenever you commit a change to the CodeCommit repository main branch. The pipeline includes the following stages: • `validate` initializes Terraform, runs Terraform security scans by using the checkov and tfsec tools, and uploads the scan reports to the S3 bucket. • `plan` shows the Terraform plan and uploads the plan to the S3 bucket. • `apply` applies the Terraform plan output from the S3 bucket and creates AWS resources. • `destroy` removes the AWS resources created during the `apply` stage. To enable	

Task	Description	Skills required
	this optional stage, set the following variable to `true` in the `demo/pipeline/locals.tf` file: `enable_destroy_stage = true`	

Task	Description	Skills required
Validate the resources created through the network module.	Confirm that the following AWS resources were created after the pipeline deployed successfully: • An egress VPC with three public and three private subnets, internet gateway, and NAT gateway. • An Amazon EKS VPC with three private subnets. • Tenant 1 and Tenant 2 VPCs with three private subnets each. • A transit gateway with all VPC attachments and routes to each private subnet. • A static transit gateway route for the Amazon EKS egress VPC with a destination CIDR block of `0.0.0.0/0` . This is required to enable all VPCs to have outbound internet access through the Amazon EKS egress VPC.	AWS DevOps

Create the compute infrastructure

Task	Description	Skills required

Update `locals.tf` to enable the CodeBuild project's access to the VPC.	To deploy the add-ons for the Amazon EKS private cluster, the CodeBuild project must be attached to the Amazon EKS VPC.
	
	1. In the `demo/pipeline` folder, open the `locals.tf` file, and set the `vpc_enabled` variable to `true`.
	2. Run the `run.sh` script to apply the changes to the pipeline module:
	
	`demo/pipeline/locals.tf`
	`./run.sh -m pipeline -env demo -region <AWS_REGION> -tfcmd init`
	`./run.sh -m pipeline -env demo -region <AWS_REGION> -tfcmd plan`
	`./run.sh -m pipeline -env demo -region <AWS_REGION> -tfcmd apply`
		AWS DevOps

Update the `buildspec` files to build the compute module.	In the `templates` folder, in all `buildspec` YAML files, set the value of the `TF_MODULE_TO_BUILD`	AWS DevOps

Task	Description	Skills required
	variable from `network` to `compute`: `TF_MODULE_TO_BUILD: "compute"`	

Task	Description	Skills required

Update the `values` file for the tenant management Helm chart.	1. Open the `values.yaml` file in the following location:
	`cd cfg-terraform/demo/compute/cfg-tenant-mgmt`
	The file looks like this:
	`---`
	`global:`
	`  clusterRoles:`
	`    operator: platform-tenant`
	`    flux: flux-tenant-applier`
	`  flux:`
	`    tenantCloneBaseUrl: ${TEANT_BASE_URL}`
	`    repoSecret: ${TENANT_REPO_SECRET}`
	`tenants:`
	`  tenant-1:`
	`    quotas:`
	`      limits:`
	`        cpu: 1`
	`        memory: 1Gi`
	`    flux:`
	`      path: overlays/tenant-1`
	`  tenant-2:`
	`    quotas:`
	`      limits:`
	`        cpu: 1`
	`        memory: 2Gi`
	`    flux:`
		AWS DevOps

Task	Description	Skills required
	`path: overlays/tenant-2` 2. In the `global` and `tenants` sections, update the configuration based on your requirements: • `tenantCloneBaseUrl` – Path to the repository that hosts the code for all tenants (we use the same Git repository for all tenants) • `repoSecret` – Kubernetes secret that holds the SSH keys and known hosts to authenticate to the global tenant Git repository • `quotas` – Kubernetes resources quotas that you want to apply for each tenant • `flux path` – Path to the tenant application YAML files in the global tenant repository	

Task	Description	Skills required
Validate compute resources.	After you update the files in the previous steps, CodePipeline starts automatically. Confirm that it created the following AWS resources for the compute infrastructure: • Amazon EKS cluster with private endpoint • Amazon EKS worker nodes • Amazon EKS add-ons: external secrets, `aws-loadbalancer-controller` , and `metrics-server` • GitOps module, Flux Helm chart, Cilium Helm chart, and tenant management Helm chart	AWS DevOps

Check tenant management and other resources

Task	Description	Skills required
Validate the tenant management resources in Kubernetes.	Run the following commands to check that tenant management resources were created successfully with the help of Helm. 1. Tenant namespaces were created, as specified in `values.yaml` :	AWS DevOps

Task	Description	Skills required

	`kubectl get ns -A`
	2. Quotas are assigned to each tenant namespace, as specified in `values.yaml` :
	`kubectl get quota --namespace=<tenant_namespace>`
	3. Details of quotas are correct for each tenant namespace:
	`kubectl describe quota cpu-memory-resource-quota-limit -n <tenant_namespace>`
	4. Cilium Network Policies were applied to each tenant namespace:
	`kubectl get CiliumNetworkPolicy -A`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Verify tenant application deployments.</td><td>Run the following commands to verify that the tenant applications were deployed.

1. Flux is able to connect to the CodeCommit repository that's specified in the GitOps module:

<code>kubectl get gitrepositories -A</code>

2. The Flux kustomization controller has deployed the YAML files in the CodeCommit repository:

<code>kubectl get kustomizations -A</code>

3. All application resources are deployed in their tenant namespaces:

<code>kubectl get all -n <tenant_namespace></code>

4. An ingress has been created for each tenant:

<code>kubectl get ingress -n <tenant_namespace></code></td><td></td></tr>
</table>

Troubleshooting

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td>

You encounter an error message that's similar to the following:

```
Failed to checkout and determine
revision: unable to clone unknown
error: You have successfully
authenticated over SSH. You
can use Git to interact with AWS
CodeCommit.
```

</td><td>

Follow these steps to troubleshoot the issue:

1. Verify the tenant application repository: An empty or misconfigured repository might be causing the error. Make sure that the tenant application repository contains the required code.
2. Redeploy the `tenant_mgmt` module: In the `tenant_mgmt` module configuration file, locate the `app` block, and then set the `deploy` parameter to `0`:

   ```
   deploy = 0
   ```

   After you run the Terraform `apply` command, change the `deploy` parameter value back to `1`:

   ```
   deploy = 1
   ```

3. Recheck the status: After you run the previous steps, use the following command to check whether the issue persists:

   ```
   kubectl get gitrepositories -A
   ```

   If it persists, consider diving deeper into the Flux logs for more details or refer to the Flux general troubleshooting guide.

</td></tr>

Subscribe multiple email endpoints to an SNS topic by using a custom resource

Ricardo Morais, Amazon Web Services

Summary

Note, August 2022: AWS CloudFormation now supports the subscription of multiple resources through the **AWS::SNS::Topic** object and its **Subscription** attribute.

This pattern describes how to subscribe multiple email addresses to receive notifications from an Amazon Simple Notification Service (Amazon SNS) topic. It uses an AWS Lambda function as a custom resource in an AWS CloudFormation template. The Lambda function is associated with an input parameter that specifies the email endpoints for the SNS topic.

Currently, you can use the AWS CloudFormation template objects AWS::SNS::Topic and AWS::SNS::Subscription to subscribe single endpoints to SNS topics. To subscribe multiple endpoints, you have to invoke the object multiple times. By using the Lambda function as a custom resource, you can subscribe multiple endpoints through an input parameter. You can use this Lambda function as a custom resource in any AWS CloudFormation template.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An AWS profile configured in your local environment with an access key and secret key.
- Permissions for the following:
  - AWS Identity and Access Management (IAM) role and policy
  - AWS Lambda function
  - Amazon Simple Storage Service (Amazon S3) for uploading the Lambda function
  - Amazon SNS topic and policy
  - AWS CloudFormation stacks

Limitations

- The code supports Linux and macOS workstations.

Product versions

- AWS Command Line Interface (AWS CLI) version 2 or later.

Architecture

Target technology stack

- AWS CloudFormation
- Amazon SNS
- AWS Lambda

Tools

Tools

- [AWS CLI version 2]

Code

The attachment includes the following files:

- Lambda function: `lambda_function.py`
- AWS CloudFormation template: `template.yaml`
- Two parameter files to handle multiple or single email endpoint subscriptions: `parameters-multiple-values.json` (used as the default) and `parameters-one-value.json`

To deploy the stack, you can use either parameter file. To specify multiple email endpoints:

```
./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION>
```

To specify a single email endpoint:

```
./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION> -f parameters-one-value.json
```

Epics

Option 1 - Deploy an SNS topic with one email subscription

Task	Description	Skills required
Configure the email endpoint for SNS topic subscriptions.	Edit the file `parameters-one-value.json` (attached), and change the value of the `pSNSNotificationsEmail` parameter to reflect the email address you want to use, such as `someone@example.com`.	
Deploy the AWS CloudFormation stack that creates the resources and subscription.	Run the **deploy.sh** command with your AWS profile name, AWS Region, and the `parameters-one-value.json` file. `./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION> -f parameters-one-value.json`	IAM role with proper permissions

Option 2 - Deploy an SNS topic with two or more email subscriptions

Task	Description	Skills required
Configure the email endpoints for SNS topic subscriptions.	Edit the file `parameters-multiple-values.json` (attached), and change the value of the `pSNSNotificationsE`	

Task	Description	Skills required
	`mail` parameter to reflect the email addresses you want to use, separated by commas, as follows: `someone1@example.com, someone2@example.com` .	
Deploy the AWS CloudFormation stack that creates the resources and subscription.	Run the **deploy.sh** command with your AWS profile name and AWS Region. You don't have to specify the `parameters-multiple-values.json` file because it's used by default. `./deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION>`	IAM role with proper permissions

Option 3 - Deploy an SNS topic through an AWS CloudFormation template

Task	Description	Skills required
Create an SNS topic.	Create an SNS topic through an AWS CloudFormation template, without specifying subscription endpoints in the `AWS::SNS::Topic` template object. You can use `template.yaml` in the attachment as a starting point.	IAM role with proper permissions

Task	Description	Skills required
Create an SNS topic policy.	Create an SNS topic policy in the AWS CloudFormation template.	IAM role with proper permissions
Subscribe the email endpoints list to the SNS topic.	Based on the list of email endpoints (one or more), subscribe the endpoints to the SNS topic you created.	IAM role with proper permissions

Coordinate resource dependency and task execution by using the AWS Fargate WaitCondition hook construct

Stan Fan, Amazon Web Services

Summary

This pattern describes the WaitCondition hook (`waitcondition-hook-for-aws-fargate-task`) npm package, which is a cloud-native solution designed for orchestrating AWS Fargate tasks in Amazon Elastic Container Service (Amazon ECS) clusters.

The WaitCondition hook is an AWS Cloud Development Kit (AWS CDK) construct that's specifically tailored for integration with AWS CloudFormation. The WaitCondition hook provides the following key capabilities:

- Acts as a wait condition mechanism, pausing CloudFormation stack execution until a specified Fargate task completes, which helps with orderly deployments and resource provisioning.
- Supports TypeScript and Python, making it ideal for AWS CDK projects.
- Allows developers and architects to orchestrate deployments by coordinating task completion and resource management for containerized applications on AWS.
- Enables running Fargate tasks with one or multiple containers embedded in a CloudFormation lifecycle. and can handle task failures and roll back the CloudFormation stack after a task failure.
- Provides flexibility to add dependencies between resources and the Fargate task execution results, enabling custom tasks or invoking other endpoints. For instance, you can pause a CloudFormation stack and wait for a database migration (done by a Fargate task) and provision other resources that might depend on the success of the database migration.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Cloud Development Kit (AWS CDK) Command Line Interface (CLI) installed on a local workstation. For more information, see AWS CDK CLI reference in the AWS CDK documentation.
- Node package manager (npm), installed on a local workstation and configured for the AWS CDK in TypeScript. For more information, see Downloading and installing Node.js and npm in the npm documentation.

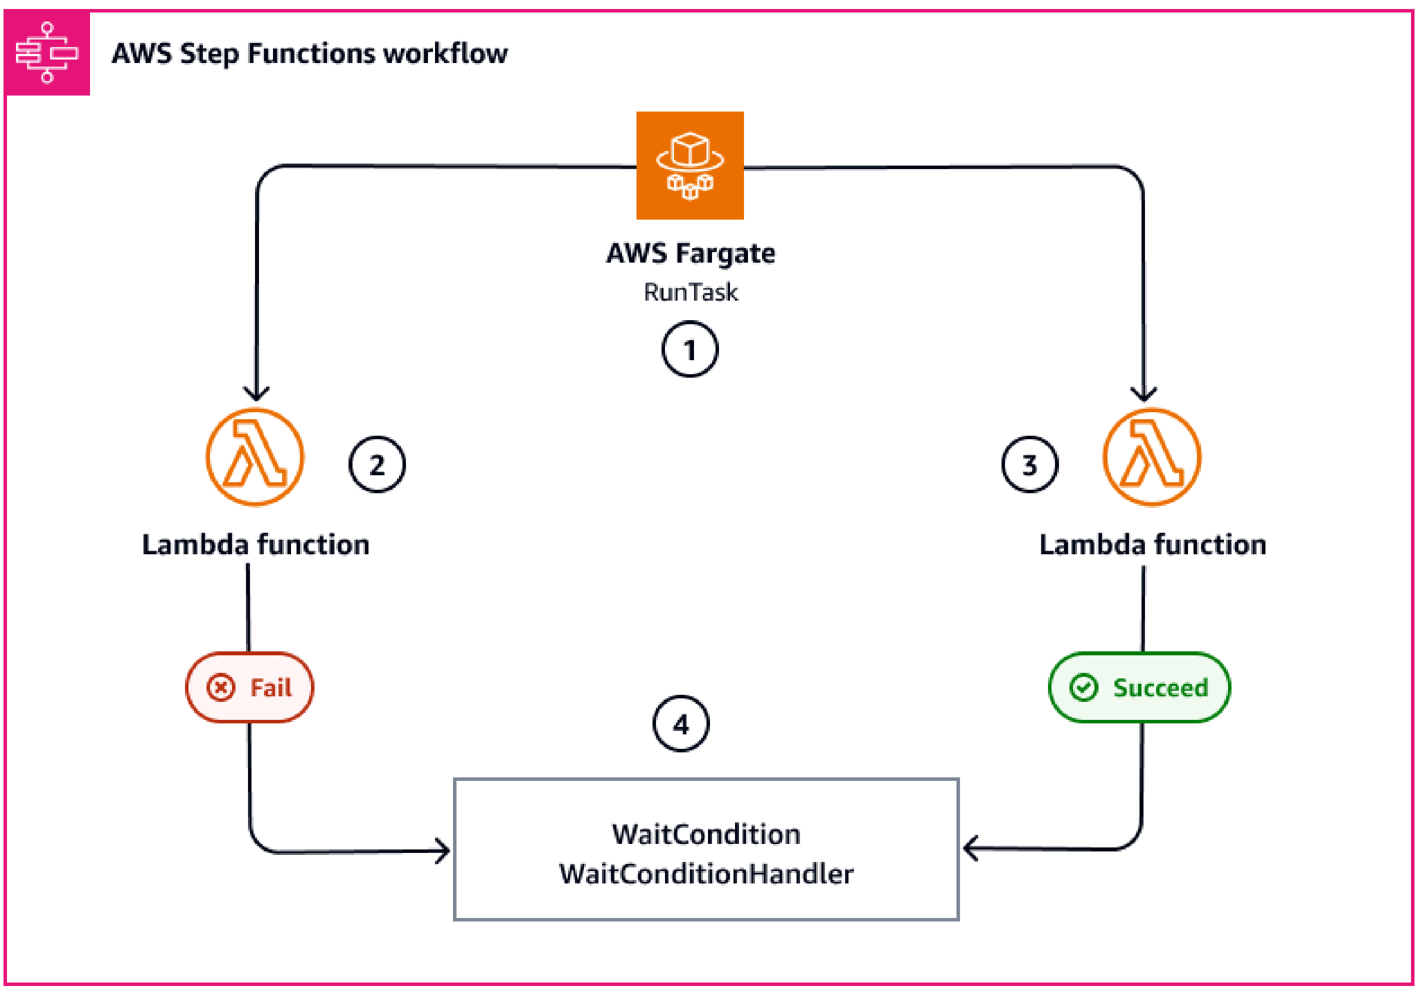
- Yarn installed on a local workstation. For more information, see Installation in the Yarn documentation.

Limitations

- This solution is deployed to a single AWS account.
- The expected return code of the container is `0` for success. Any other return code indicates failure, and the CloudFormation stack will roll back.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Architecture

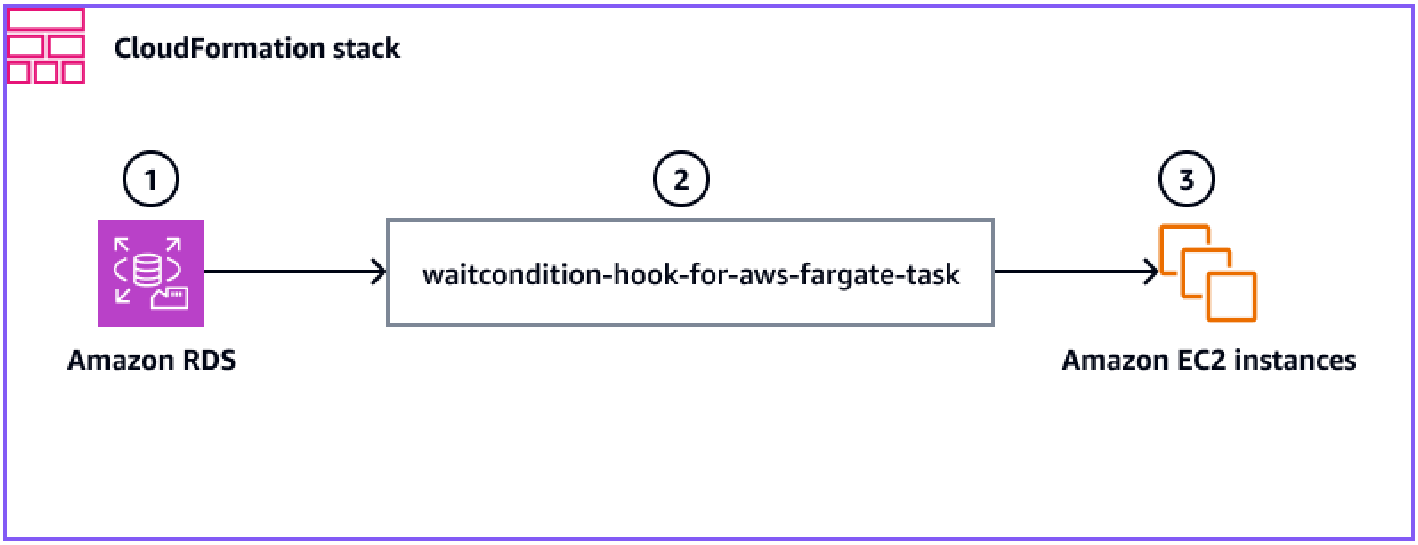
The following diagram shows the construct architecture.



The diagram shows the workflow of `waitcondition-hook-for-aws-fargate-task`:

1. `WaitCondition` and `WaitConditionHandler` are provisioned to listen to the response from the AWS Lambda functions.
2. Depending on the result of the task, either the `CallbackFunction` or the `ErrorHandlerFunction` is triggered by the finish of the Fargate task.
3. The Lambda function sends a SUCCEED or FAILURE signal to `WaitConditionHandler`.
4. `WaitConditionHandler` continues to provision the resources if the execution result of the Fargate task succeeds, or rolls back the stack if the task failed.

The following diagram shows an example of a workflow to perform a database migration.



The example workflow uses the `waitcondition-hook-for-aws-fargate-task` construct to perform a database migration, as follows:

1. An Amazon Relational Database Service (Amazon RDS) instance is provisioned.
2. The `waitcondition-hook-for-aws-fargate-task` construct runs the database migration task and pauses the stack as an Amazon Elastic Compute Cloud (Amazon EC2) instance.
3. If the migration task finishes successfully, it sends a Succeed signal to CloudFormation. Otherwise, it sends a Fail signal to CloudFormation and rolls back the stack.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define cloud infrastructure in code and provision it through AWS CloudFormation.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon Elastic Container Service (Amazon ECS) is a fast and scalable container management service that helps you run, stop, and manage containers on a cluster.
- AWS Fargate helps you run containers without needing to manage servers or Amazon EC2 instances. It's used in conjunction with Amazon ECS.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you would operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.
- Yarn is an open source package manager that you can use to manage dependencies in JavaScript projects. Yarn can assist you with installing, updating, configuring, and removing packages dependencies.

Code repository

The code for this pattern is available in the GitHub waitcondition-hook-for-aws-fargate-task repository.

Best practices

- When building your AWS CDK app, follow the Best practices for developing and deploying cloud infrastructure with the AWS CDK in the AWS CDK v2 documentation.
- For the AWS Fargate task, follow the Best practices for Amazon ECS container images in the Amazon ECS documentation.

Epics

Set up the AWS CDK

Task	Description	Skills required
Install the AWS CDK.	To install the AWS CDK on your local machine or other environment, run the following command: `npm install -g aws-cdk@latest`	Cloud architect, App developer
Bootstrap the AWS CDK.	Bootstrapping is the process of preparing an environment for deployment. To bootstrap your AWS CDK toolkit for the target AWS account and AWS Region, run the following command: `cdk bootstrap aws://ACCOUNT-NUMBER-1/REGION-1` This command creates a CloudFormation stack named `CDKToolkit` .	Cloud architect

Run the WaitCondition hook for AWS Fargate tasks construct

Task	Description	Skills required
Create the CDK project.	Create a CDK project using the language that you prefer. This pattern uses TypeScript. To create a CDK project using TypeScript, run the following command: `cdk init app —language typescript`	Cloud architect
Install the package.	Execute `npm install` on the root path of your CDK project. After the CDK library has been installed, run the following command to install `waitcondition-hook-for-aws-fargate-task` : `yarn add waitcondition-hook-for-aws-fargate-task`	Cloud architect
Build your CDK application and Amazon ECS components.	Build your CDK project. An Amazon ECS task definition resource is required. For information about creating a task definition, see [Amazon ECS task definitions](#) in the Amazon ECS documentation. The following example uses this construct:	Cloud architect

Task	Description	Skills required

	<pre>import * as cdk from
	 'aws-cdk-lib';
	import { Vpc } from
	 'aws-cdk-lib/aws-e
	c2';
	import * as ecr from
	 'aws-cdk-lib/aws-e
	cr';
	import * as ecs from
	 'aws-cdk-lib/aws-e
	cs';
	import { Construct }
	 from 'constructs';
	import { FargateRu
	nner } from 'waitcond
	ition-hook-for-aws-
	fargate-task';
	import { Queue } from
	 'aws-cdk-lib/aws-s
	qs';
	
	export class FargateRu
	nnerStack extends
	 cdk.Stack {
	    constructor(scope:
	 Construct, id: string,
	 props?: cdk.Stack
	Props) {
	        super(scope,
	 id, props);
	        // Define the
	 VPC
	        const vpc = new
	 Vpc(this, 'MyVpc')
	        // Define the
	 Fargate Task
	        const taskDefin
	ition = new ecs.Farga
	teTaskDefinition(t
	his, 'MyTask', {});</pre>	

Task	Description	Skills required
	``` // Import exiting ecr repo const repo = ecr.Repository.fro mRepositoryName(this, 'MyRepo', 'RepoName'); // Add a container to the task taskDefin ition.addContainer ('MyContainer', { image: ecs.ContainerImage .fromEcrRepository (repo), }); // Create the Fargate runner const myFargate Runner = new FargateRu nner(this, 'MyRunner ', { fargateTa skDef: taskDefinition, timeout: ` ${60 * 5}`, vpc: vpc, }); // Create the SQS queue const myQueue = new Queue(this, 'MyQueue', {}); // Add dependenc y myQueue.n ode.addDependency(myFargateRunner); } } ```	

Task	Description	Skills required

Synth and launch the CDK application.	1. To generate the assets and CloudFormation template, run the following command in your CDK root path:
	`cdk synth`
	2. After the `synth` command is successful, run the following command to deploy the resources:
	`cdk deploy`
	
	The `waitcondition-hook-for-aws-fargate-task` construct runs the Fargate task.
		Cloud architect

Clean up

Task	Description	Skills required
Clean up resources.	To clean up the resources provisioned from the previous step, run the following command: `cdk destroy`	Cloud architect

Troubleshooting

Issue	Solution
General CloudFormation stack failure	To help troubleshoot general CloudFormation stack failures, add the `--no-rollback` flag as shown in the following example: `cdk deploy --no-rollback` This command will pause the CloudForm ation stack from rolling back, which gives you resources to troubleshoot. For more informati on, see Choose how to handle failures when provisioning resources in the AWS CloudForm ation documentation.
AWS Step Functions failure	An AWS Step Functions state machine might fail to execute for different reasons. With –`disable-rollback` configured, use the following steps to troubleshoot: 1. Sign in to the AWS Management Console, enter **Step Functions** in the **Search** field, and then choose the Step Functions service. 2. In the left navigation pane, choose **State machines** and then select the state machine that is provisioned by the CloudFormation stack. 3. In **Executions**, choose the name of the execution that failed unexpectedly. 4. In the **Event** view, choose the failed step. For more information, see Troubleshooting issues in Step Functions and Viewing

Issue	Solution
	execution details in the Step Functions console in the AWS Step Functions documentation.
AWS Lambda function failure	This construct provisions two Lambda functions: `CallbackFunction` and `ErrorhandlerFunction` . They can fail for various reasons such as unhandled exceptions. Use the following steps to troubleshoot: 1. Sign in to the AWS Management Console, enter **CloudWatch** in the **Search** field, and then choose the CloudWatch service. 2. In the left navigation pane, choose **Log groups**. 3. In the **Search** field, enter the name of the Lambda function. 4. Choose the log group name that's associate d with the Lambda function. 5. To go to the Lambda function execution result, choose the latest log stream. For more information, see Troubleshooting issues in Lambda in the AWS Lambda documentation.

Use third-party Git source repositories in AWS CodePipeline

Kirankumar Chandrashekar, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern describes how to use AWS CodePipeline with third-party Git source repositories.

AWS CodePipeline is a continuous delivery service that automates tasks for building, testing, and deploying your software. The service currently supports Git repositories managed by GitHub, AWS CodeCommit, and Atlassian Bitbucket. However, some enterprises use third-party Git repositories that are integrated with their single sign-on (SSO) service and Microsoft Active Directory for authentication. You can use these third-party Git repositories as sources for CodePipeline by creating custom actions and webhooks.

A webhook is an HTTP notification that detects events in another tool, such as a GitHub repository, and connects those external events to a pipeline. When you create a webhook in CodePipeline, the service returns a URL that you can use in your Git repository webhook. If you push code to a specific branch of the Git repository, the Git webhook initiates the CodePipeline webhook through this URL, and sets the source stage of the pipeline to **In Progress**. When the pipeline is in this state, a job worker polls CodePipeline for the custom job, runs the job, and sends a success or failure status to CodePipeline. In this case, because the pipeline is in the source stage, the job worker gets the contents of the Git repository, zips the contents, and uploads it to the Amazon Simple Storage Service (Amazon S3) bucket where artifacts for the pipeline are stored, using the object key provided by the polled job. You can also associate a transition for the custom action with an event in Amazon CloudWatch, and initiate the job worker based on the event. This setup enables you to use third-party Git repositories that the service doesn't natively support as sources for CodePipeline.

Prerequisites and limitations

Prerequisites

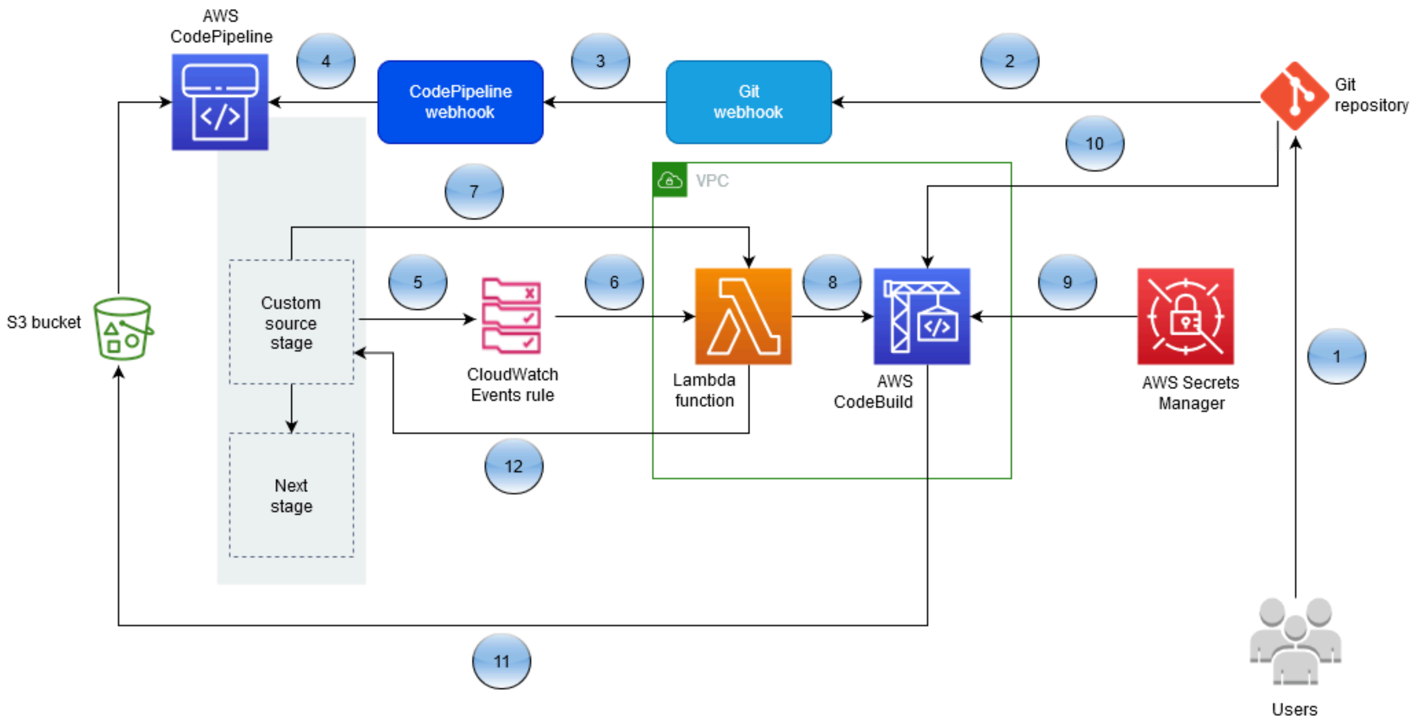
- An active AWS account
- A Git repository that supports webhooks and can connect to a CodePipeline webhook URL through the internet

- AWS Command Line Interface (AWS CLI) installed and configured to work with the AWS account

Architecture

The pattern involves these steps:

1. The user commits code to a Git repository.
2. The Git webhook is called.
3. The CodePipeline webhook is called.
4. The pipeline is set to **In Progress**, and the source stage is set to the **In Progress** state.
5. The source stage action initiates a CloudWatch Events rule, indicating that it was started.
6. The CloudWatch event initiates a Lambda function.
7. The Lambda function gets the details of the custom action job.
8. The Lambda function initiates AWS CodeBuild and passes it all the job-related information.
9. CodeBuild gets the public SSH key or user credentials for HTTPS Git access from Secrets Manager.
10. CodeBuild clones the Git repository for a specific branch.
11. CodeBuild zips the archive and uploads it to the S3 bucket that serves as the CodePipeline artifact store.



Tools

- [AWS CodePipeline](#) – AWS CodePipeline is a fully managed [continuous delivery](#) service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deployment phases of your release process for each code change, based on the release model you define. This enables you to rapidly and reliably deliver features and updates. You can integrate AWS CodePipeline with third-party services such as GitHub or with your own custom plugin.
- [AWS Lambda](#) – AWS Lambda lets you run code without provisioning or managing servers. With Lambda, you can run code for virtually any type of application or backend service with no administration necessary. You upload your code and Lambda takes care of everything required to run and scale your code with high availability. You can set up your code to automatically initiate from other AWS services or call it directly from any web or mobile app.
- [AWS CodeBuild](#) – AWS CodeBuild is a fully managed [continuous integration](#) service that compiles source code, runs tests, and produces software packages that are ready to deploy. With CodeBuild, you don't need to provision, manage, and scale your own build servers. CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left waiting in a queue. You can get started quickly by using prepackaged build environments, or you can create custom build environments that use your own build tools.

- AWS Secrets Manager – AWS Secrets Manager helps you protect secrets needed to access your applications, services, and IT resources. The service enables you to rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, without having to hardcode sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon Relational Database Service (Amazon RDS), Amazon Redshift, and Amazon DocumentDB. The service can be extended to support other types of secrets, including API keys and OAuth tokens. In addition, Secrets Manager lets you control access to secrets by using fine-grained permissions, and audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on-premises environments.
- Amazon CloudWatch – Amazon CloudWatch is a monitoring and observation service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides you with data and actionable insights to monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, providing you with a unified view of AWS resources, applications, and services that run on AWS and on-premises servers. You can use CloudWatch to detect anomalous behavior in your environments, set alarms, visualize logs and metrics side by side, take automated actions, troubleshoot issues, and discover insights to keep your applications running smoothly.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is an object storage service that lets you store and protect any amount of data for a range of use cases, such as websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. Amazon S3 provides easy-to-use management features to help you organize your data and configure finely tuned access controls to meet your specific business, organizational, and compliance requirements.

Epics

Create a custom action in CodePipeline

Task	Description	Skills required
Create a custom action using AWS CLI or AWS CloudForm ation.	This step involves creating a custom source action that can be used in the source	General AWS

Task	Description	Skills required
	stage of a pipeline in your AWS account in a particula r region. You must use AWS CLI or AWS CloudForm ation (not the console) to create the custom source action. For more informati on about the commands and steps described in this and other epics, see the "Related resources" section at the end of this pattern. In AWS CLI, use the create-custom-action-type command. Use --configu ration-properties to provide all the parameters required for the job worker to process when it polls CodePipeline for a job. Make sure to note the values provided to the --provider and --action-version options, so that you can use the same values when creating the pipeline with this custom source stage. You can also create the custom source action in AWS CloudForm ation by using the resource type AWS::CodePipeline::CustomActionType.	

Set up authentication

Task	Description	Skills required
Create an SSH key pair.	Create a Secure Shell (SSH) key pair. For instructions, see the GitHub documentation.	Systems/DevOps engineer
Create a secret in AWS Secrets Manager.	Copy the contents of the private key from the SSH key pair and create a secret in AWS Secrets Manager. This secret is used for authentic ation when accessing the Git repository.	General AWS
Add the public key to the Git repository.	Add the public key from the SSH key pair to the Git repository account settings, for authentication against the private key.	Systems/DevOps engineer

Create a pipeline and webhook

Task	Description	Skills required
Create a pipeline that includes the custom source action.	Create a pipeline in CodePipel ine. When you configure the source stage, choose the custom source action that you created previously. You can do this in the AWS CodePipel ine console or in AWS CLI. CodePipeline prompts you for the configuration propertie s that you set on the custom action. This information is	General AWS

Task	Description	Skills required
	required for the job worker to process the job for the custom action. Follow the wizard and create the next stage for the pipeline.	
Create a CodePipeline webhook.	Create a webhook for the pipeline you created with the custom source action. You must use AWS CLI or AWS CloudFormation (not the console) to create the webhook. In AWS CLI, run the put-webhook command and provide the appropria te values for the webhook options. Make a note of the webhook URL that the command returns. If you're using AWS CloudFormation to create the webhook, use the resource type AWS::Code Pipeline::Webhook. Make sure to output the webhook URL from the created resource, and make a note of it.	General AWS

Task	Description	Skills required
Create a Lambda function and CodeBuild project.	In this step, you use Lambda and CodeBuild to create a job worker that will poll CodePipeline for job requests for the custom action, run the job, and return the status result to CodePipeline. Create a Lambda function that is initiated by an Amazon CloudWatch Events rule when the custom source action stage of the pipeline transitions to "In Progress." When the Lambda function is initiated, it should get the custom action job details by polling for jobs. You can use the PollForJobs API to return this information. After the polled job information is obtained, the Lambda function should return an acknowledgment, and then process the information with the data it obtains from the configuration properties for the custom action. When the worker is ready to talk to the Git repository, you might initiate a CodeBuild project, because it's convenient to handle Git tasks by using the SSH client.	General AWS, code developer

Create an event in CloudWatch

Task	Description	Skills required
Create a CloudWatch Events rule.	Create a CloudWatch Events rule that initiates the Lambda function as a target whenever the pipeline's custom action stage transitions to "In Progress."	General AWS

Create a CI/CD pipeline to validate Terraform configurations by using AWS CodePipeline

Aromal Raj Jayarajan and Vijesh Vijayakumaran Nair, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

This pattern shows how to test HashiCorp Terraform configurations by using a continuous integration and continuous delivery (CI/CD) pipeline deployed by AWS CodePipeline.

Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources. The solution provided in this pattern creates a CI/CD pipeline that helps you validate the integrity of your Terraform configurations by running five CodePipeline stages:

1. `"checkout"` pulls the Terraform configuration that you're testing from an AWS CodeCommit repository.
2. `"validate"` runs infrastructure as code (IaC) validation tools, including tfsec, TFLint, and checkov. The stage also runs the following Terraform IaC validation commands: `terraform validate` and `terraform fmt`.
3. `"plan"` shows what changes will be applied to the infrastructure if the Terraform configuration is applied.
4. `"apply"` uses the generated plan to provision the required infrastructure in a test environment.
5. `"destroy"` removes the test infrastructure that was created during the `"apply"` stage.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), installed and configured
- Git, installed and configured on your local machine
- Terraform, installed and configured on your local machine

Limitations

- This pattern's approach deploys AWS CodePipeline into one AWS account and AWS Region only. Configuration changes are required for multi-account and multi-Region deployments.
- The AWS Identity and Access Management (IAM) role that this pattern provisions (**codepipeline_iam_role**) follows the principle of least privilege. This IAM role's permissions must be updated based on the specific resources that your pipeline needs to create.

Product versions

- AWS CLI version 2.9.15 or later
- Terraform version 1.3.7 or later

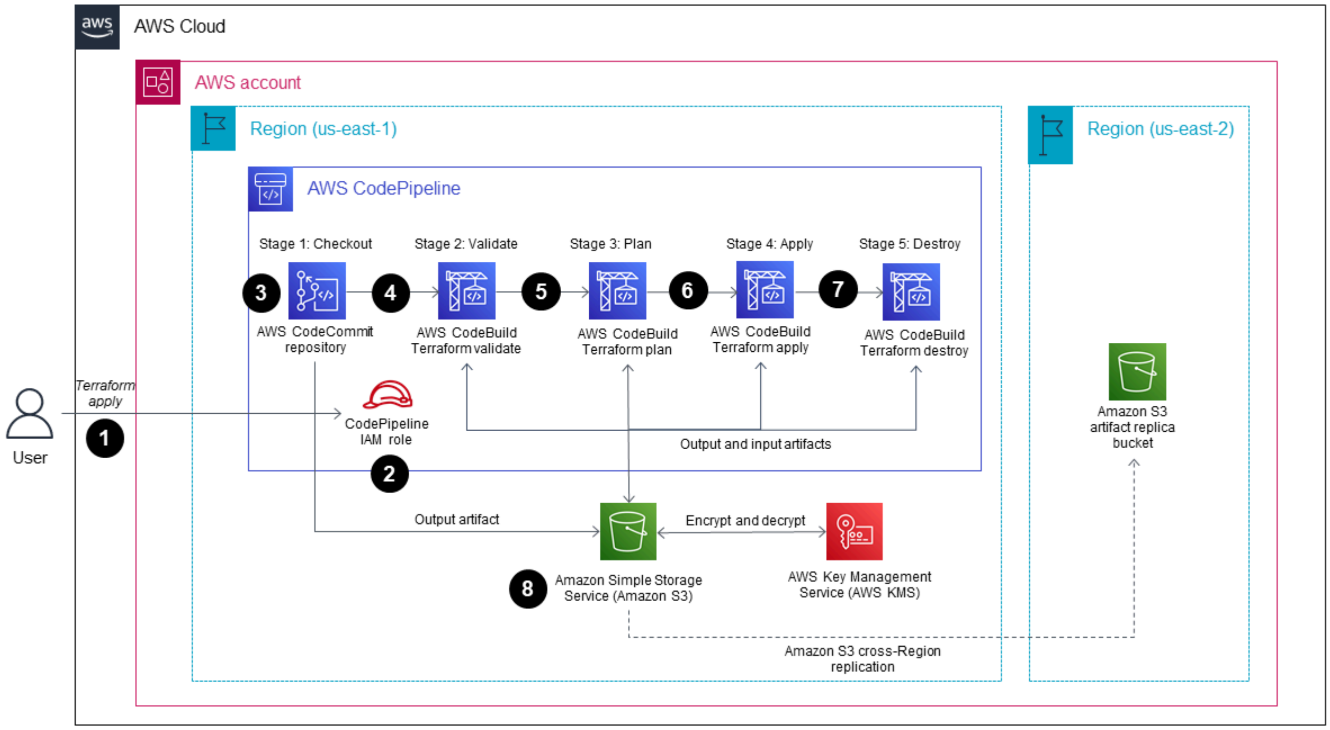
Architecture

Target technology stack

- AWS CodePipeline
- AWS CodeBuild
- AWS CodeCommit
- AWS IAM
- Amazon Simple Storage Service (Amazon S3)
- AWS Key Management Service (AWS KMS)
- Terraform

Target architecture

The following diagram shows an example CI/CD pipeline workflow for testing Terraform configurations in CodePipeline.



The diagram shows the following workflow:

1. In CodePipeline, an AWS user initiates the actions proposed in a Terraform plan by running the `terraform apply` command in the AWS CLI.
2. AWS CodePipeline assumes an IAM service role that includes the policies required to access CodeCommit, CodeBuild, AWS KMS, and Amazon S3.
3. CodePipeline runs the `"checkout"` pipeline stage to pull the Terraform configuration from an AWS CodeCommit repository for testing.
4. CodePipeline runs the `"validate"` stage to test the Terraform configuration by running IaC validation tools and running Terraform IaC validation commands in a CodeBuild project.
5. CodePipeline runs the `"plan"` stage to create a plan in the CodeBuild project based on the Terraform configuration. The AWS user can review this plan before the changes are applied to the test environment.
6. Code Pipeline runs the `"apply"` stage to implement the plan by using the CodeBuild project to provision the required infrastructure in the test environment.
7. CodePipeline runs the `"destroy"` stage, which uses CodeBuild to remove the test infrastructure that was created during the `"apply"` stage.

8. An Amazon S3 bucket stores pipeline artifacts, which are encrypted and decrypted by using an AWS KMS customer managed key.

Tools

Tools

AWS services

- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Other services

- HashiCorp Terraform is a command-line interface application that helps you use code to provision and manage cloud infrastructure and resources.

Code

The code for this pattern is available in the GitHub aws-codepipeline-terraform-cicdsamples repository. The repository contains the Terraform configurations required to create the target architecture outlined in this pattern.

Epics

Provision the solution components

Task	Description	Skills required
Clone the GitHub repository.	Clone the GitHub [aws-codepipeline-terraform-cicdsamples](https://github.com/aws-samples/aws-codepipeline-terraform-cicd-samples) repository by running the following command in a terminal window: `git clone https://github.com/aws-samples/aws-codepipeline-terraform-cicd-samples.git` For more information, see [Cloning a repository](#) in the GitHub documentation.	DevOps engineer
Create a Terraform variable definitions file.	Create a `terraform.tfvars` file based on your use case requirements. You can update the variables in the `examples/terraform.tfvars` file that's in the cloned repository. For more information, see [Assigning values to root module variables](#) in the Terraform documentation. **Note** The repository's `Readme.md` file	DevOps engineer

Task	Description	Skills required
	includes more information on the required variables.	
Configure AWS as the Terraform provider.	1. In a code editor, open the cloned repository's `main.tf` file. 2. Add the necessary configurations for establishing connectivity to the target AWS account. For more information, see AWS provider in the Terraform documentation.	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Update the Terraform provider configuration for creating the Amazon S3 replication bucket.</td><td>
1. Open the repository’s S3 directory by running the following command:
<code>cd ./modules/s3</code>
2. Update the Terraform provider configuration for creating the Amazon S3 replication bucket by updating the <code>region</code> value in the <code>tf</code> file. Make sure that you enter the Region that you want Amazon S3 to replicate objects to.
3. (Optional) By default, Terraform uses local state files for state managemen t. If you want to add Amazon S3 as the remote backend, you must update the Terraform configura tion. For more informati on, see Backend configura tion in the Terraform documentation.
Note
Replication activates automatic, asynchron ous copying of objects
</td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
	across Amazon S3 buckets.	
Initialize the Terraform configuration.	To initialize your working directory that contains the Terraform configuration files, run the following command in the cloned repository's root folder: `terraform init`	DevOps engineer
Create the Terraform plan.	To create a Terraform plan, run the following command in the cloned repository's root folder: `terraform plan --var-file=terraform.tfvars -out=tfplan` **Note** Terraform evaluates the configuration files to determine the target state for the declared resources. It then compares the target state against the current state and creates a plan.	DevOps engineer

Task	Description	Skills required
Verify the Terraform plan.	Review the Terraform plan and confirm that it configure s the required architecture in your target AWS account.	DevOps engineer
Deploy the solution.	1. To apply the Terraform plan, run the following command in the cloned repository’s root folder: `terraform apply "tfplan"` 2. Enter **yes** to confirm that you want to deploy the resources. **Note** Terraform creates, updates, or destroys infrastructure to achieve the target state declared in the configuration files.	DevOps engineer

Validate Terraform configurations by running the pipeline

Task	Description	Skills required
Set up the source code repository.	1. From the Terraform output, get the **source repository** details for the repository that contains the Terraform	DevOps engineer

Task	Description	Skills required
	configurations that you want to validate. 2. Sign in to the AWS Management Console. Then, open the [CodeCommit console](). 3. Create a new branch in the source repository named `main`. For instructions, see [Create a branch in AWS CodeCommit]() in the CodeCommit documentation. 4. Clone the `main` branch of the **source repository** to your local workstation. For instructions, see [Setup steps for HTTPS connections to AWS CodeCommit repositories on Windows with the AWS CLI credential helper]() in the CodeCommit documentation. 5. Copy the `templates` folder from the GitHub [aws-codepipeline-terraform-cicdsamples]() repository by running the following command: `cp -r templates $YOUR_CODECOMMIT_REPO_ROOT`	

Task	Description	Skills required
	Note The `templates` folder contains the build specification files and the validation script for the root directory of the source repository. 6. Add your required Terraform IaC configurations to the root folder of the **source repository**. 7. Add the details for the remote backend in your project's Terraform configuration. For more information, see S3 in the Terraform documentation. 8. **(Optional)** Update the variables in the `templates` folder to either activate or deactivate the preconfigured scans, tool change versions, and to specify your directory in custom script files. For more information, see the *Additional information* section of this pattern.	

Task	Description	Skills required
	9. Push the changes to the `main` branch of the **source repository**.	

Task	Description	Skills required
Validate the pipeline stages.	1. Sign in to the AWS Management Console and open the [CodePipeline console](). 2. In the output generated from the `terraform apply "tfplan"` command in the previous Epic section, find the name of the generated **CodePipeline**. 3. Open the pipeline in the CodePipeline console and choose **Release change**. 4. Review each pipeline stage and confirm it's working as expected. For more information, see [View pipeline details and history (console)]() in the *AWS CodePipeline User Guide*. **Important** When a change is committed to the main branch of the source repository, the test pipeline is activated automatic ally.	DevOps engineer

Task	Description	Skills required
Verify the report output.	1. On the [CodePipeline console](#), in the left navigation pane, choose **Build**. Then, choose **Report history**. 2. Review the tfsec and checkov scan reports that the pipeline generates. These reports can help you identify issues through visualizations and graphical representations. **Note** The `<project_name>-validate` CodeBuild project generates vulnerability reports for your code during the `"validate"` stage.	DevOps engineer

Clean up your resources

Task	Description	Skills required
Clean up the pipeline and associated resources.	To delete the test resources from your AWS account, run the following command in the cloned repository's root folder:	DevOps engineer

Task	Description	Skills required
	`terraform destroy --var-file=terraform.tfvars`	

Troubleshooting

Issue	Solution
You receive an **AccessDenied** error during the `"apply"` stage.	1. Review the execution logs of the CodeBuild project associated with the `"apply"` stage to identify any missing IAM permissions. For more information, see View build details in AWS CodeBuild in the *AWS CodeBuild User Guide*. 2. In a code editor, open the cloned repository's `modules` folder. Then, navigate to the `iam-role` folder and open the `main.tf` file that's in that folder. 3. In the `codepipeline_policy` statement, add the IAM policies that are required for provisioning resources in your AWS account.

Additional information

Custom Terraform modules

The following is a list of custom Terraform modules that are used in this pattern:

- `codebuild_terraform` creates the CodeBuild projects that form each stage of the pipeline.
- `codecommit_infrastructure_source_repo` captures and creates the source CodeCommit repository.
- `codepipeline_iam_role` creates the required IAM roles for the pipeline.
- `codepipeline_kms` creates the required AWS KMS key for Amazon S3 object encryption and decryption.
- `codepipeline_terraform` creates the test pipeline for the source CodeCommit repository.
- `s3_artifacts_bucket` creates an Amazon S3 bucket to manage pipeline artifacts.

Build specification files

The following is a list of build specification (buildspec) files that this pattern uses to run each pipeline stage:

- `buildspec_validate.yml` runs the "`validate`" stage.
- `buildspec_plan.yml` runs the "`plan`" stage.
- `buildspec_apply.yml` runs the "`apply`" stage.
- `buildspec_destroy.yml` runs the "`destroy`" stage.

Build specification file variables

Each buildspec file uses the following variables to activate different build-specific settings:

Variable	Default value	Description
`CODE_SRC_DIR`	"."	Defines the source CodeCommit directory

`TF_VERSION`	"1.3.7"	Defines the Terraform version for the build environment

The `buildspec_validate.yml` file also supports the following variables to activate different build-specific settings:

Variable	Default value	Description
`SCRIPT_DIR`	"./templates/scripts"	Defines the script directory
`ENVIRONMENT`	"dev"	Defines the environment name
`SKIPVALIDATIONFAILURE`	"Y"	Skips validation on failures
`ENABLE_TFVALIDATE`	"Y"	Activates Terraform validate
`ENABLE_TFFORMAT`	"Y"	Activates Terraform format
`ENABLE_TFCHECKOV`	"Y"	Activates checkov scan
`ENABLE_TFSEC`	"Y"	Activates tfsec scan
`TFSEC_VERSION`	"v1.28.1"	Defines the tfsec version

More patterns

- Access container applications privately on Amazon EKS using AWS PrivateLink and a Network Load Balancer
- Associate an AWS CodeCommit repository in one AWS account with Amazon SageMaker AI Studio Classic in another account
- Automate account creation by using the Landing Zone Accelerator on AWS
- Automate adding or updating Windows registry entries using AWS Systems Manager
- Automate backups for Amazon RDS for PostgreSQL DB instances by using AWS Batch
- Automate deployment of nested applications using AWS SAM
- Automate deployment of Node Termination Handler in Amazon EKS by using a CI/CD pipeline
- Automate RabbitMQ configuration in Amazon MQ
- Automate the replication of Amazon RDS instances across AWS accounts
- Automatically build and deploy a Java application to Amazon EKS using a CI/CD pipeline
- Automatically generate a PynamoDB model and CRUD functions for Amazon DynamoDB by using a Python application
- Automatically validate and deploy IAM policies and roles by using CodePipeline, IAM Access Analyzer, and AWS CloudFormation macros
- Back up Sun SPARC servers in the Stromasys Charon-SSP emulator on the AWS Cloud
- Build a data pipeline to ingest, transform, and analyze Google Analytics data using the AWS DataOps Development Kit
- Build a Micro Focus Enterprise Server PAC with Amazon EC2 Auto Scaling and Systems Manager
- Build a pipeline for hardened container images using EC2 Image Builder and Terraform
- Build an MLOps workflow by using Amazon SageMaker AI and Azure DevOps
- Centralize DNS resolution by using AWS Managed Microsoft AD and on-premises Microsoft Active Directory
- Chain AWS services together using a serverless approach
- Clean up AWS Account Factory for Terraform (AFT) resources safely after state file loss
- Configure logging for .NET applications in Amazon CloudWatch Logs by using NLog
- Continuously deploy a modern AWS Amplify web application from an AWS CodeCommit repository

- Create a custom Docker container image for SageMaker and use it for model training in AWS Step Functions
- Create a pipeline in AWS Regions that don't support AWS CodePipeline
- Create alarms for custom metrics using Amazon CloudWatch anomaly detection
- Customize default role names by using AWS CDK aspects and escape hatches
- Deploy a pipeline that simultaneously detects security issues in multiple code deliverables
- Deploy and manage a serverless data lake on the AWS Cloud by using infrastructure as code
- Deploy Kubernetes resources and packages using Amazon EKS and a Helm chart repository in Amazon S3
- Deploy multiple-stack applications using AWS CDK with TypeScript
- Deploy SQL Server failover cluster instances on Amazon EC2 and Amazon FSx by using Terraform
- Deploy the Security Automations for AWS WAF solution by using Terraform
- Develop advanced generative AI chat-based assistants by using RAG and ReAct prompting
- Enable Amazon GuardDuty conditionally by using AWS CloudFormation templates
- Set up event-driven auto scaling in Amazon EKS by using Amazon EKS Pod Identity and KEDA
- Generate personalized and re-ranked recommendations using Amazon Personalize
- Get Amazon SNS notifications when the key state of an AWS KMS key changes
- Govern permission sets for multiple accounts by using Account Factory for Terraform
- Identify duplicate container images automatically when migrating to an Amazon ECR repository
- Implement path-based API versioning by using custom domains in Amazon API Gateway
- Improve operational performance by enabling Amazon DevOps Guru across multiple AWS Regions, accounts, and OUs with the AWS CDK
- Install SSM Agent on Amazon EKS worker nodes by using Kubernetes DaemonSet
- Integrate Stonebranch Universal Controller with AWS Mainframe Modernization
- Mainframe modernization: DevOps on AWS with Rocket Software Enterprise Suite
- Manage AWS IAM Identity Center permission sets as code by using AWS CodePipeline
- Manage AWS permission sets dynamically by using Terraform
- Manage on-premises container applications by setting up Amazon ECS Anywhere with the AWS CDK
- Manage AWS Organizations policies as code by using AWS CodePipeline and Amazon Bedrock
- Migrate DNS records in bulk to an Amazon Route 53 private hosted zone

- Monitor use of a shared Amazon Machine Image across multiple AWS accounts
- Orchestrate an ETL pipeline with validation, transformation, and partitioning using AWS Step Functions
- Automate blue/green deployments of Amazon Aurora global databases by using IaC principles
- Preserve routable IP space in multi-account VPC designs for non-workload subnets
- Provision a Terraform product in AWS Service Catalog by using a code repository
- Replicate filtered Amazon ECR container images across accounts or Regions
- Rotate database credentials without restarting containers
- Run AWS Systems Manager Automation tasks synchronously from AWS Step Functions
- Set up a CI/CD pipeline for hybrid workloads on Amazon ECS Anywhere by using AWS CDK and GitLab
- Set up a CI/CD pipeline for database migration by using Terraform
- Set up Multi-AZ infrastructure for a SQL Server Always On FCI by using Amazon FSx
- Set up UiPath RPA bots automatically on Amazon EC2 by using AWS CloudFormation
- Simplify application authentication with mutual TLS in Amazon ECS by using Application Load Balancer
- Tenant onboarding in SaaS architecture for the silo model using C# and AWS CDK
- Use Terraform to automatically enable Amazon GuardDuty for an organization
- Use Amazon Bedrock agents to automate creation of access entry controls in Amazon EKS through text-based prompts
- Validate Account Factory for Terraform (AFT) code locally
- Visualize AI/ML model results using Flask and AWS Elastic Beanstalk

Infrastructure

Topics

- Access a bastion host by using Session Manager and Amazon EC2 Instance Connect
- Centralize DNS resolution by using AWS Managed Microsoft AD and on-premises Microsoft Active Directory
- Centralize monitoring by using Amazon CloudWatch Observability Access Manager
- Check EC2 instances for mandatory tags at launch
- Clean up AWS Account Factory for Terraform (AFT) resources safely after state file loss
- Connect to an Amazon EC2 instance by using Session Manager
- Create a pipeline in AWS Regions that don't support AWS CodePipeline
- Customize default role names by using AWS CDK aspects and escape hatches
- Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing
- Extend VRFs to AWS by using AWS Transit Gateway Connect
- Get Amazon SNS notifications when the key state of an AWS KMS key changes
- Preserve routable IP space in multi-account VPC designs for non-workload subnets
- Provision a Terraform product in AWS Service Catalog by using a code repository
- Register multiple AWS accounts with a single email address by using Amazon SES
- Set up DNS resolution for hybrid networks in a single-account AWS environment
- Set up UiPath RPA bots automatically on Amazon EC2 by using AWS CloudFormation
- Set up a highly available PeopleSoft architecture on AWS
- Set up disaster recovery for Oracle JD Edwards EnterpriseOne with AWS Elastic Disaster Recovery
- Set up AWS CloudFormation drift detection in a multi-Region, multi-account organization
- Successfully import an S3 bucket as an AWS CloudFormation stack
- Synchronize data between Amazon EFS file systems in different AWS Regions by using AWS DataSync
- Test AWS infrastructure by using LocalStack and Terraform Tests
- Upgrade SAP Pacemaker clusters from ENSA1 to ENSA2
- Use consistent Availability Zones in VPCs across different AWS accounts
- Use user IDs in IAM policies for access control and automation
- Validate Account Factory for Terraform (AFT) code locally

- More patterns

Access a bastion host by using Session Manager and Amazon EC2 Instance Connect

Piotr Chotkowski and Witold Kowalik, Amazon Web Services

Summary

A *bastion host*, sometimes called a *jump box*, is a server that provides a single point of access from an external network to the resources located in a private network. A server exposed to an external public network, such as the internet, poses a potential security risk for unauthorized access. It's important to secure and control access to these servers.

This pattern describes how you can use Session Manager and Amazon EC2 Instance Connect to securely connect to an Amazon Elastic Compute Cloud (Amazon EC2) bastion host deployed in your AWS account. Session Manager is a capability of AWS Systems Manager. The benefits of this pattern include:

- The deployed bastion host doesn't have any open, inbound ports exposed to the public internet. This reduces the potential attack surface.
- You don't need to store and maintain long-term Secure Shell (SSH) keys in your AWS account. Instead, each user generates a new SSH key pair each time they connect to the bastion host. AWS Identity and Access Management (IAM) policies that are attached to the user's AWS credentials control access to the bastion host.

Intended audience

This pattern is intended for readers who have experience with basic understanding of Amazon EC2, Amazon Virtual Private Cloud (Amazon VPC), and Hashicorp Terraform.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, installed and configured
- Session Manager plugin for the AWS CLI, installed
- Terraform CLI, installed

- Storage for the Terraform state, such as an Amazon Simple Storage Service (Amazon S3) bucket and an Amazon DynamoDB table that serve as a remote backend to store the Terraform state. For more information on using remote backends for the Terraform state, see Amazon S3 Backends (Terraform documentation). For a code sample that sets up remote state management with an Amazon S3 backend, see remote-state-s3-backend (Terraform Registry). Note the following requirements:
  - The Amazon S3 bucket and DynamoDB table must be in the same AWS Region.
  - When creating the DynamoDB table, the partition key must be `LockID` (case-sensitive), and the partition key type must be `String`. All other table settings must be at their default values. For more information, see About primary keys and Create a table in the DynamoDB documentation.
- An SSH client, installed

Limitations

- This pattern is intended as a proof of concept (PoC) or as a basis for further development. It should not be used in its current form in production environments. Before deployment, adjust the sample code in the repository to meet your requirements and use case.
- This pattern assumes that the target bastion host uses Amazon Linux 2 as its operating system. While it is possible to use other Amazon Machine Images (AMIs), other operating systems are out of scope for this pattern.

> **Note**
>
> Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs.

- In this pattern, the bastion host is located in a private subnet without an NAT gateway and internet gateway. This design isolates the Amazon EC2 instance from the public internet. You can add a specific network configuration that allows it to communicate with the internet. For more information, see Connect your virtual private cloud (VPC) to other networks in the Amazon VPC documentation. Similarly, following the principle of least privilege, the bastion host doesn't have access to any other resources in your AWS account unless you explicitly grant permissions. For more information, see Resource-based policies in the IAM documentation.

Product versions

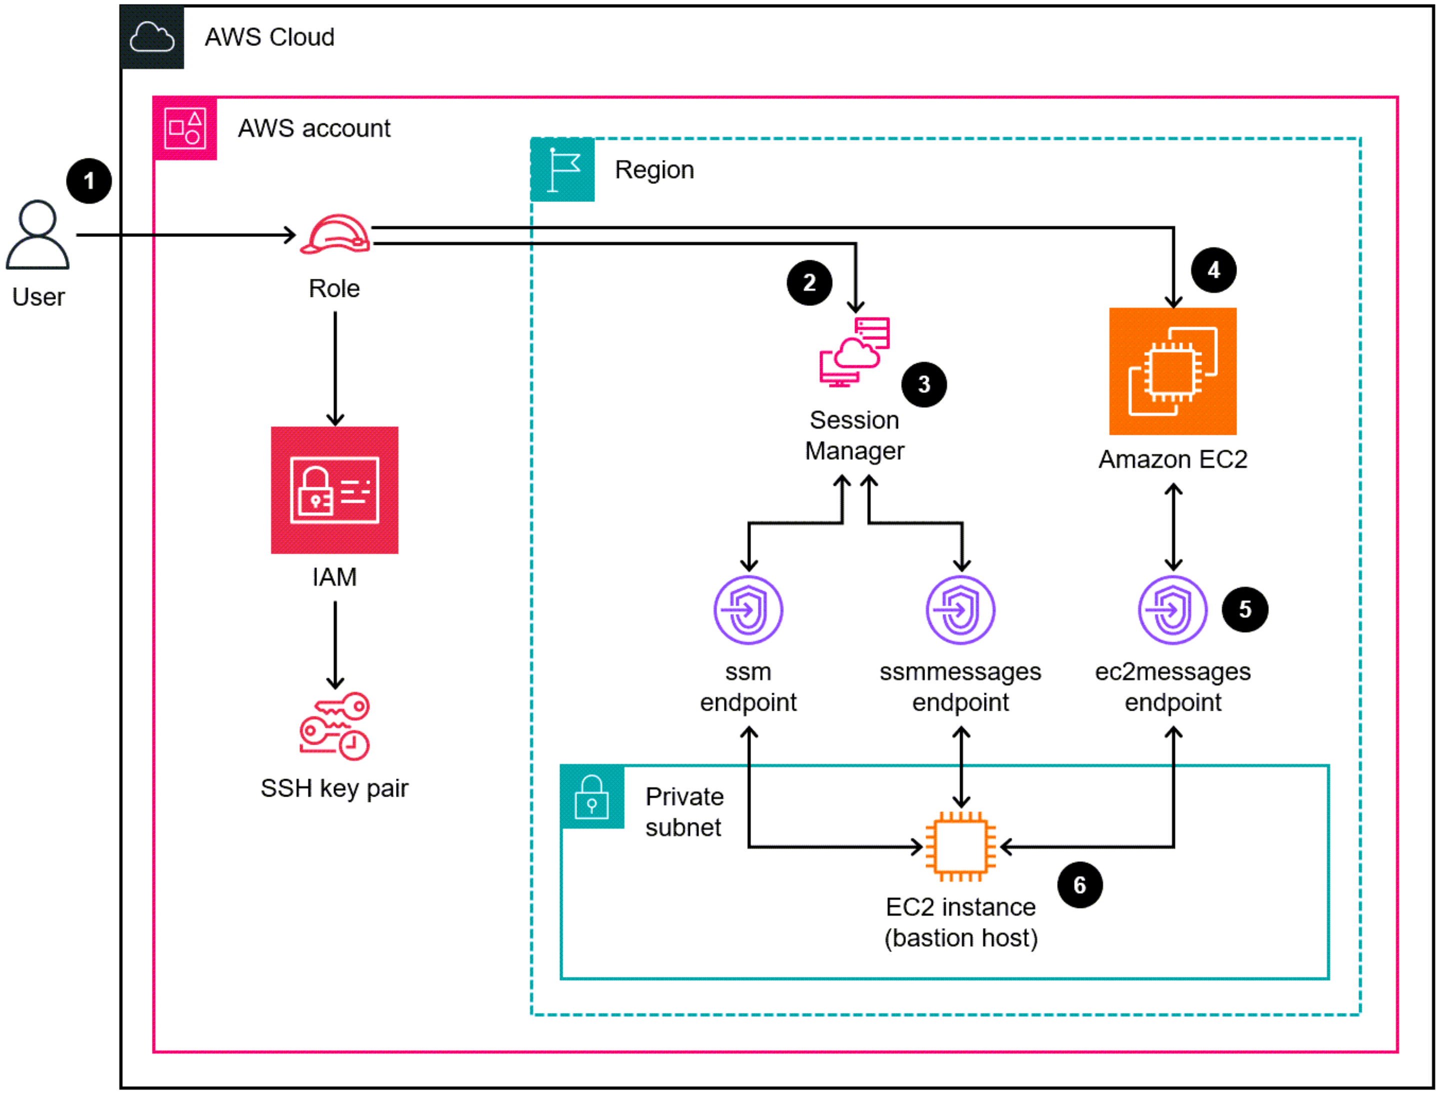
- AWS CLI version 2
- Terraform version 1.3.9

Architecture

Target technology stack

- A VPC with a single private subnet
- The following interface VPC endpoints:
  - `amazonaws.<region>.ssm` – The endpoint for the AWS Systems Manager service.
  - `amazonaws.<region>.ec2messages` – Systems Manager uses this endpoint to make calls from SSM Agent to the Systems Manager service.
  - `amazonaws.<region>.ssmmessages` – Session Manager uses this endpoint to connect to your Amazon EC2 instance through a secure data channel.
- A `t3.nano` Amazon EC2 instance running Amazon Linux 2
- IAM role and instance profile
- Amazon VPC security groups and security group rules for the endpoints and Amazon EC2 instance

Target architecture



The diagram shows the following process:

1. The user assumes an IAM role that has permissions to do the following:
   - Authenticate, authorize, and connect to the Amazon EC2 instance
   - Start a session with Session Manager
2. The user initiates an SSH session through Session Manager.
3. Session Manager authenticates the user, verifies the permissions in the associated IAM policies, checks the configuration settings, and sends a message to SSM Agent to open a two-way connection.
4. The user pushes the SSH public key to the bastion host through Amazon EC2 metadata. This must be done before each connection. The SSH public key remains available for 60 seconds.

5. The bastion host communicates with the interface VPC endpoints for Systems Manager and Amazon EC2.
6. The user accesses the bastion host through Session Manager by using a TLS 1.2 encrypted bidirectional communication channel.

Automation and scale

The following options are available to automate deployment or to scale this architecture:

- You can deploy the architecture through a continuous integration and continuous delivery (CI/CD) pipeline.
- You can modify the code to change the instance type of the bastion host.
- You can modify the code to deploy multiple bastion hosts. In the `bastion-host/main.tf` file, in the `aws_instance` resource block, add the `count` meta-argument. For more information, see the Terraform documentation.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses Session Manager, a capability of Systems Manager.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- HashiCorp Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. This pattern uses Terraform CLI.

Code repository

The code for this pattern is available in the GitHub Access a bastion host by using Session Manager and Amazon EC2 Instance Connect repository.

Best practices

- We recommend using automated code-scanning tools to improve the security and quality of the code. This pattern was scanned by using Checkov, a static code-analysis tool for IaC. At a minimum, we recommend that you perform basic validation and formatting checks by using the `terraform validate` and `terraform fmt -check -recursive` Terraform commands.
- It's a good practice to add automated tests for IaC. For more information about the different approaches for testing Terraform code, see Testing HashiCorp Terraform (Terraform blog post).
- During deployment, Terraform uses the replaces the Amazon EC2 instance each time a new version of the Amazon Linux 2 AMI is detected. This deploys the new version of the operating system, including patches and upgrades. If the deployment schedule is infrequent, this can pose a security risk because the instance doesn't have the latest patches. It is important to frequently update and apply security patches to deployed Amazon EC2 instances. For more information, see Update management in Amazon EC2.
- Because this pattern is a proof of concept, it uses AWS managed policies, such as `AmazonSSMManagedInstanceCore`. AWS managed policies cover common use cases but don't grant least-privilege permissions. As needed for your use case, we recommend that you create custom policies that grant least-privilege permissions for the resources deployed in this architecture. For more information, see Get started with AWS managed policies and move toward least-privilege permissions.
- Use a password to protect access to SSH keys and store keys in a secure location.
- Set up logging and monitoring for the bastion host. Logging and monitoring are important parts of maintaining systems, from both an operational and security perspective. There are multiple ways to monitor connections and activity in your bastion host. For more information, see the following topics in the Systems Manager documentation:
  - Monitoring AWS Systems Manager
  - Logging and monitoring in AWS Systems Manager
  - Auditing session activity

- Logging session activity

Epics

Deploy the resources

Task	Description	Skills required
Clone the code repository.	1. In a command-line interface, change your working directory to the location where you want to store the sample files. 2. Enter the following command. `git clone https://github.com/aws-samples/secured-bastion-host-terraform.git`	DevOps engineer, Developer
Initialize the Terraform working directory.	This step is necessary for only the first deployment. If you are redeploying the pattern, skip to the next step. In the root directory of the cloned repository, enter the following command, where: • `$S3_STATE_BUCKET` is the name of Amazon S3 bucket that contains the Terraform state • `$PATH_TO_STATE_FILE` is the key to the Terraform	DevOps engineer, Developer, Terraform

Task	Description	Skills required
	state file, such as `infra/bastion-host/tetfstate` • `$AWS_REGION` is the Region where the Amazon S3 bucket is deployed `terraform init \ -backend-config="bucket=$S3_STATE_BUCKET" \ -backend-config="key=$PATH_TO_STATE_FILE" \ -backend-config="region=$AWS_REGION` **Note** Alternatively, you can open the **config.tf** file and, in the `terraform` section, manually provide these values.	

Task	Description	Skills required
Deploy the resources.	1. In the root directory of the cloned repository, enter the following command. `terraform apply -var-file="dev.tfvars"` 2. Review the list of all changes that will be applied to your AWS account, and then confirm the deployment. 3. Wait until all resources are deployed.	DevOps engineer, Developer, Terraform

Set up the local environment

Task	Description	Skills required
Configure the SSH connection.	Update the SSH configuration file to allow SSH connections through Session Manager. For instructions, see [Allowing SSH connections for Session Manager](). This allows authorized users to enter a proxy command that starts a Session Manager session and transfers all data through a two-way connection.	DevOps engineer
Generate the SSH keys.	Enter the following command to generate a local private and public SSH key pair. You	DevOps engineer, Developer

Task	Description	Skills required
	use this key pair to connect to the bastion host. `ssh-keygen -t rsa -f my_key`	

Connect to the bastion host by using Session Manager

Task	Description	Skills required
Get the instance ID.	1. In order to connect to the deployed bastion host, you need the ID of the Amazon EC2 instance. Do one of the following to locate the ID: • Open the [Amazon EC2 console](). In the navigation pane, choose **Instances** . Locate the bastion host instance. • In the AWS CLI, enter the following command. `aws ec2 describe-instances` To filter the results, enter the following command, where `$BASTION_HOST_TAG` is the tag you assigned to the bastion host. The default value for this tag is	General AWS

Task	Description	Skills required

	sandbox-dev-bastion-host .
	
	`aws ec2 describe-instances \`
	`    --filters "Name=tag:Name,Values=$BASTION_HOST_TAG" \`
	`    --output text \`
	`    --query 'Reservations[*].Instances[*].InstanceId' \`
	`    --output text`
	
	2. Copy the ID of the Amazon EC2 instance. You use this ID later.	

Task	Description	Skills required
Send the SSH public key.	**Note** In this section, you upload the public key to the instance metadata of the bastion host. After the key is uploaded, you have 60 seconds to start a connection with the bastion host. After 60 seconds, the public key is removed. For more informati on, see the Troublesh ooting section of this pattern. Complete the next steps quickly to prevent the key from being removed before you connect to the bastion host. 1. Send the SSH key to the bastion host by using Amazon EC2 Instance Connect. Enter the following command, where: • `$INSTANCE_ID` is the ID of the Amazon EC2 instance	General AWS

Task	Description	Skills required
	• `$PUBLIC_KEY_FILE` is the path to your public key file, such as `my_key.pub` **Important** Be sure to use the public key and not the private key. `aws ec2-instance-connect send-ssh-public-key \ --instance-id $INSTANCE_ID \ --instance-os-user ec2-user \ --ssh-public-key file://$PUBLIC_KEY_FILE` 2. Wait until you receive a message indicating that the key has been successfully uploaded. Continue to the next step immediately.	

Task	Description	Skills required
Connect to the bastion host.	1. Enter the following command to connect to the bastion host through Session Manager, where: • `$PRIVATE_KEY_FILE` is the path to your private key, such as `my_key` • `$INSTANCE_ID` is the ID of the Amazon EC2 instance `ssh -i $PRIVATE_KEY_FILE ec2-user@$INSTANCE_ID` 2. Confirm the connection by entering `yes`. This opens an SSH connection by using Session Manager. **Note** There are other options for opening an SSH connection with the bastion host. For more information, see *Alternative approaches to establish an SSH connection with the bastion host* in the [Additional informati	General AWS

Task	Description	Skills required
	on section of this pattern.	

(Optional) Clean up

Task	Description	Skills required
Remove the deployed resources.	1. In order to remove all deployed resources, run the following command from the root directory of the cloned repository. `terraform destroy -var-file="dev.tfvars"` 2. Confirm the removal of the resources.	DevOps engineer, Developer, Terraform

Troubleshooting

Issue	Solution
`TargetNotConnected` error when trying to connect to the bastion host	1. Reboot the bastion host according to the instructions in Reboot your instance in the Amazon EC2 documentation. 2. After the instance has successfully rebooted, resend the public key to the bastion host and reattempt the connection.
`Permission denied` error when trying to connect to the bastion host	After the public key is uploaded to the bastion host, you have only 60 seconds to start the connection. After 60 seconds, the key is

Issue	Solution
	automatically removed, and you can't use it to connect to the instance. If this occurs, you can repeat the step to resend the key to the instance.

Additional information

Alternative approaches to establish an SSH connection with the bastion host

Port forwarding

You can use the `-D 8888` option to open an SSH connection with dynamic port forwarding. For more information, see the [instructions](#) at explainshell.com. The following is an example of a command to open an SSH connection by using port forwarding.

```
ssh -i $PRIVATE_KEY_FILE -D 8888 ec2-user@$INSTANCE_ID
```

This is kind of connection opens a SOCKS proxy that can forward traffic from your local browser through the bastion host. If you are using Linux or MacOS, to see all options, enter `man ssh`. This displays the SSH reference manual.

Using the provided script

Instead of manually running the steps described in *Connect to the bastion host by using Session Manager* in the Epics section, you can use the **connect.sh** script included in the code repository. This script generates the SSH key pair, pushes the public key to the Amazon EC2 instance, and initiates a connection with the bastion host. When you run the script, you pass the tag and key name as arguments. The following is an example of the command to run the script.

```
./connect.sh sandbox-dev-bastion-host my_key
```

Centralize DNS resolution by using AWS Managed Microsoft AD and on-premises Microsoft Active Directory

Brian Westmoreland, Amazon Web Services

Summary

This pattern provides guidance for centralizing DNS resolution within an AWS multi-account environment by using both AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) and Amazon Route 53. In this pattern the AWS DNS namespace is a subdomain of the on-premises DNS namespace. This pattern also provides guidance on how to configure the on-premises DNS servers to forward queries to AWS when the on-premises DNS solution uses Microsoft Active Directory.

Prerequisites and limitations

Prerequisites

- An AWS multi-account environment set up by using AWS Organizations.
- Network connectivity established between AWS accounts.
- Network connectivity established between AWS and the on-premises environment (by using AWS Direct Connect or any type of VPN connection).
- AWS Command Line Interface (AWS CLI) configured on a local workstation.
- AWS Resource Access Manager (AWS RAM) used to share Route 53 rules between accounts. Therefore, sharing must be enabled within the AWS Organizations environment, as described in the Epics section.

Limitations

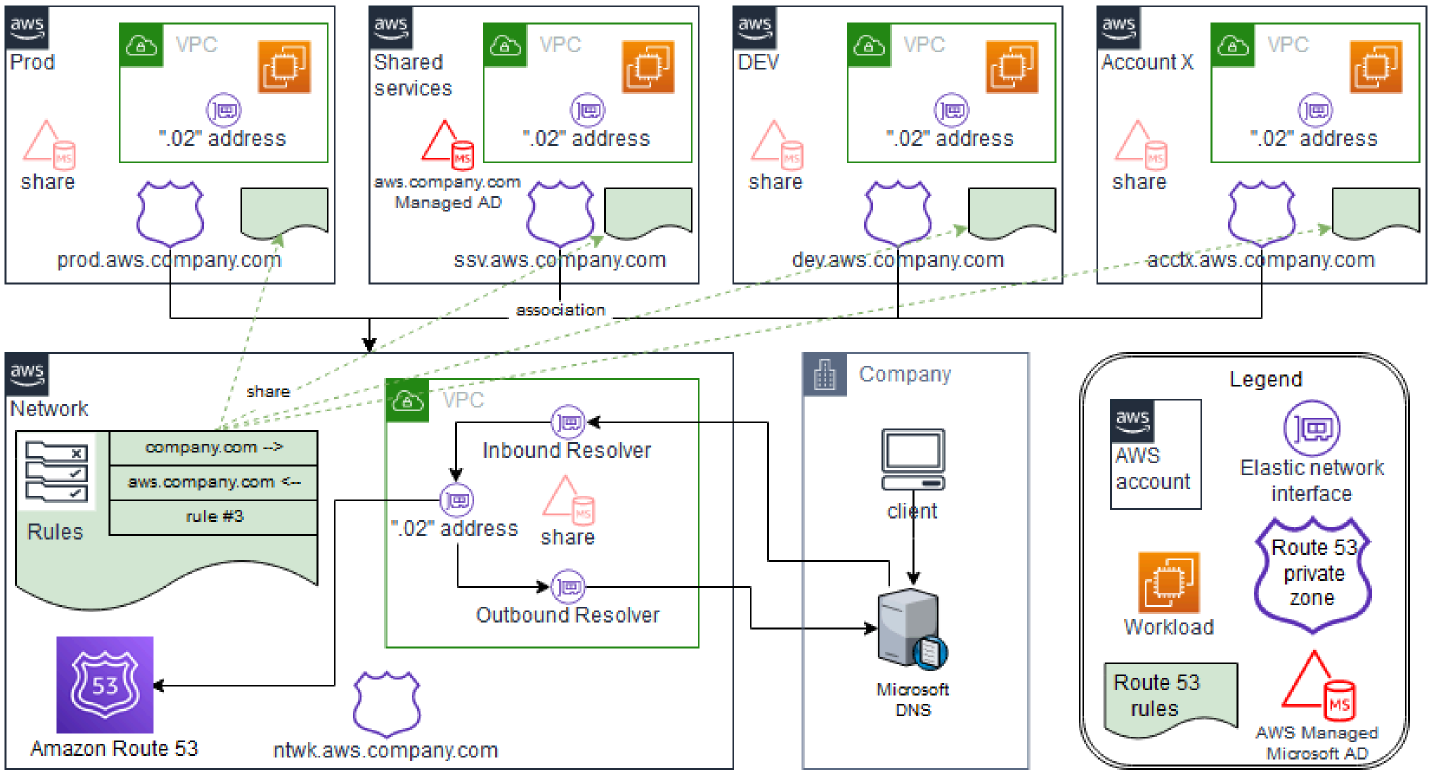
- AWS Managed Microsoft AD Standard Edition has a limit of 5 shares.
- AWS Managed Microsoft AD Enterprise Edition has a limit of 125 shares.
- The solution in this pattern is limited to AWS Regions that support sharing through AWS RAM.

Product versions

- Microsoft Active Directory running on Windows Server 2008, 2012, 2012 R2, or 2016.

Architecture

Target architecture



In this design, AWS Managed Microsoft AD is installed in the shared services AWS account. Although it is not a requirement, this pattern assumes this configuration. If you configure AWS Managed Microsoft AD in a different AWS account, you might have to modify the steps in the Epics section accordingly.

This design uses Route 53 Resolvers to support name resolution through the use of Route 53 rules. If the on-premises DNS solution uses Microsoft DNS, creating a conditional forwarding rule for the AWS namespace (`aws.company.com`), which is a subdomain of the company DNS namespace (`company.com`), is not straightforward. If you try to create a traditional conditional forwarder, it will result in an error. This is because Microsoft Active Directory is already considered authoritative for any subdomain of `company.com`. To get around this error, you must first create a delegation for `aws.company.com` to delegate authority of that namespace. You can then create the conditional forwarder.

The virtual private cloud (VPC) for each spoke account can have its own unique DNS namespace based on the root AWS namespace. In this design, each spoke account appends an abbreviation of the account name to the base AWS namespace. After the private hosted zones in the spoke account have been created, the zones are associated with the local VPC in the spoke account as well as with the VPC in the central AWS network account. This enables the central AWS network account to answer DNS queries related to the spoke accounts. This way, both Route 53 and AWS Managed Microsoft AD work together to share the responsibility of managing the AWS namespace (`aws.company.com`).

Automation and scale

This design uses Route 53 Resolver endpoints to scale DNS queries between AWS and your on-premises environment. Each Route 53 Resolver endpoint comprises multiple elastic network interfaces (spread across multiple Availability Zones), and each network interface can handle up to 10,000 queries per second. Route 53 Resolver supports up to 6 IP addresses per endpoint, so altogether this design supports up to 60,000 DNS queries per second spread across multiple Availability Zones for high availability.

Additionally, this pattern automatically accounts for future growth within AWS. The DNS forwarding rules configured on premises do not have to be modified to support new VPCs and their associated private hosted zones that are added to AWS.

Tools

AWS services

- AWS Directory Service for Microsoft Active Directory enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Resource Access Manager (AWS RAM) helps you securely share your resources across AWS accounts to reduce operational overhead and provide visibility and auditability.
- Amazon Route 53 is a highly available and scalable DNS web service.

Tools

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell. In this pattern, the AWS CLI is used to configure Route 53 authorizations.

Epics

Create and share an AWS Managed Microsoft AD directory

Task	Description	Skills required
Deploy AWS Managed Microsoft AD.	1. Create and configure a new directory. For detailed steps, see [Creating your AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*. 2. Record the IP addresses of the AWS Managed Microsoft AD domain controllers. These will be referenced in a later step.	AWS administrator
Share the directory.	After the directory has been built, share it with other AWS accounts in the AWS organization. For instructions, see [Share your directory](#) in the *AWS Directory Service Administration Guide*. **Note** AWS Managed Microsoft AD Standard Edition has a limit of 5 shares. Enterprise Edition has a limit of 125 shares.	AWS administrator

Configure Route 53

Task	Description	Skills required
Create Route 53 Resolvers.	Route 53 Resolvers facilitate DNS query resolution between AWS and the on-premises data center. 1. Install Route 53 Resolvers by following the instructions in the *Route 53 Developer Guide*. 2. Configure Route 53 Resolvers in private subnets in at least two Availability Zones within the central AWS network account VPC for high availability. **Note** Although using the central AWS network account VPC isn't a requirement, the remaining steps assume this configuration.	AWS administrator
Create Route 53 rules.	Your specific use case might require a large number of Route 53 rules, but you will need to configure the following rules as a baseline:	AWS administrator

Task	Description	Skills required

	• An outgoing rule for the on-premises namespace (`company.com`) by using the central network account outbound Route 53 Resolvers. The target IP addresses are the on-premises DNS servers.
	  ◦ Associate this rule with the central network account VPC.
	• An outgoing rule for the AWS namespace (`aws.company.com`) by using the central network account outbound Route 53 Resolvers. The target IP addresses are the central network account inbound Route 53 Resolver IP addresses.
	  ◦ **Do not** associate this rule with the central AWS network account VPC (which houses the Route 53 Resolvers).
	• A second outgoing rule for the AWS namespace (`aws.company.com`) that points to the AWS Managed Microsoft AD domain controllers (use the IPs from the previous epic).	

Task	Description	Skills required
	• Associate this rule with the central AWS network account VPC (which houses the Route 53 Resolvers). • **Do not** share or associate this rule with other AWS accounts. For more information, see [Managing forwarding rules]() in the *Route 53 Developer Guide*.	

Task	Description	Skills required
Configure a Route 53 Profile.	A Route 53 Profile is used to share the rules with spoke accounts. 1. Create a new Route 53 Profile in the central networking account by following the [instructions](#) in the *Route 53 Developer Guide*. 2. Add the rule for the on-premises namespace (`company.com`) to the Profile. 3. Add the first rule for the AWS namespace (`aws.company.com`), which targets the IP addresses of the Route 53 inbound resolvers, to the Profile. 4. Share the Route 53 Profile with the AWS organization. 5. Accept the Route 53 Profile resource share in each spoke account. 6. Associate the Route 53 Profile with each spoke account VPC.	AWS administrator

Configure on-premises Active Directory DNS

Task	Description	Skills required
Create the delegation.	Use the Microsoft DNS snap-in (`dnsmgmt.msc`) to create a new delegation for the `company.com` namespace within Active Directory. The name of the delegated domain should be `aws`. This makes the fully qualified domain name (FQDN) of the delegation `aws.company.com` . Use the IP addresses of the AWS Managed Microsoft AD domain controllers for the name server IP values, and use `server.aws.company.com` for the name. (This delegation is only for redundancy, because a conditional forwarder will be created for this namespace that takes precedence over the delegation.)	Active Directory
Create the conditional forwarder.	Use the Microsoft DNS snap-in (`dnsmgmt.msc`) to create a new conditional forwarder for `aws.company.com` . Use the IP addresses of the AWS inbound Route 53 Resolvers in the central DNS	Active Directory

Task	Description	Skills required
	AWS account for the target of the conditional forwarder.	

Create Route 53 private hosted zones for spoke AWS accounts

Task	Description	Skills required
Create the Route 53 private hosted zones.	Create a Route 53 private hosted zone in each spoke account. Associate this private hosted zone with the spoke account VPC. For detailed steps, see [Creating a private hosted zone](#) in the *Route 53 Developer Guide*.	AWS administrator
Create authorizations.	Use the AWS CLI to create an authorization for the central AWS network account VPC. Run this command from the context of each spoke AWS account: `aws route53 create-vpc-association-authorization --hosted-zone-id <hosted-zone-id> \ --vpc VPCRegion=<region>,VPCId=<vpc-id>` where:	AWS administrator

Task	Description	Skills required
	• `<hosted-zone-id>` is the Route 53 private hosted zone in the spoke account. • `<region>` and `<vpc-id>` are the AWS Region and VPC ID of the central AWS network account VPC.	
Create associations.	Create the Route 53 private hosted zone association for the central AWS network account VPC by using the AWS CLI. Run this command from the context of the central AWS network account: `aws route53 associate-vpc-with-hosted-zone --hosted-zone-id <hosted-zone-id> \ --vpc VPCRegion=<region>,VPCId=<vpc-id>` where: • `<hosted-zone-id>` is the Route 53 private hosted zone in the spoke account. • `<region>` and `<vpc-id>` are the AWS Region and VPC ID of the central AWS network account.	AWS administrator

Centralize monitoring by using Amazon CloudWatch Observability Access Manager

Anand Krishna Varanasi, JAGDISH KOMAKULA, Ashish Kumar, Jimmy Morgan, Sarat Chandra Pothula, Vivek Thangamuthu, and Balaji Vedagiri, Amazon Web Services

Summary

Observability is crucial to monitoring, understanding, and troubleshooting applications. Applications that span multiple accounts, as with AWS Control Tower or landing zone implementations, generate a large number of logs and trace data. To quickly troubleshoot problems or understand user analytics or business analytics, you need a common observability platform across all accounts. The Amazon CloudWatch Observability Access Manager gives you access to, and control over, multiple account logs from a central location.

You can use the Observability Access Manager to view and manage observability data logs generated by source accounts. Source accounts are individual AWS accounts that generate observability data for their resources. Observability data is shared between source accounts and monitoring accounts. The shared observability data can include metrics in Amazon CloudWatch, logs in Amazon CloudWatch Logs, and traces in AWS X-Ray. For more information, see the Observability Access Manager documentation.

This pattern is for users who have applications or infrastructure that run in multiple AWS accounts and need a common place to view logs. It explains how you can set up Observability Access Manager by using Terraform, to monitor the status and health of these applications or infrastructure. You can install this solution in multiple ways:

- As a standalone Terraform module that you set up manually
- By using a continuous integration and continuous delivery (CI/CD) pipeline
- By integrating with other solutions such as AWS Control Tower Account Factory for Terraform (AFT)

The instructions in the Epics section cover the manual implementation. For AFT installation steps, see the README file for the GitHub Observability Access Manager repository.

Prerequisites and limitations

Prerequisites

- Terraform installed or referenced in your system or in automated pipelines. (We recommend that you use the latest version.)
- An account that you can use as a central monitoring account. Other accounts create links to the central monitoring account in order to view logs.
- (Optional) A source code repository such as GitHub, AWS CodeCommit, Atlassian Bitbucket, or similar system. A source code repository isn't necessary if you're using automated CI/CD pipelines.
- (Optional) Permissions to create pull requests (PRs) for code review and code collaboration in GitHub.

Limitations

Observability Access Manager has the following service quotas, which cannot be changed. Consider these quotas before you deploy this feature. For more information, see CloudWatch service quotas in the CloudWatch documentation.

- **Source account links**: You can link each source account to a maximum of five monitoring accounts.
- **Sinks**: You can build multiple sinks for an account, but only one sink per AWS Region is allowed.

In addition:

- Sinks and links must be created in the same AWS Region; they cannot be cross-Region.

Cross-Region and cross-account monitoring

For cross-Region, cross-account monitoring, you can choose one of these options:

- Create cross-account and cross-Region CloudWatch dashboards for alarms and metrics. This option doesn't support logs and traces.
- Implement centralized logging by using Amazon OpenSearch Service.
- Create one sink per Region from all tenant accounts, push metrics to a centralized monitoring account (as described in this pattern), and then use CloudWatch metric streams to send the data to a common external destination or to third-party monitoring products such as Datadog, Dynatrace, Sumo Logic, Splunk, or New Relic.

Architecture

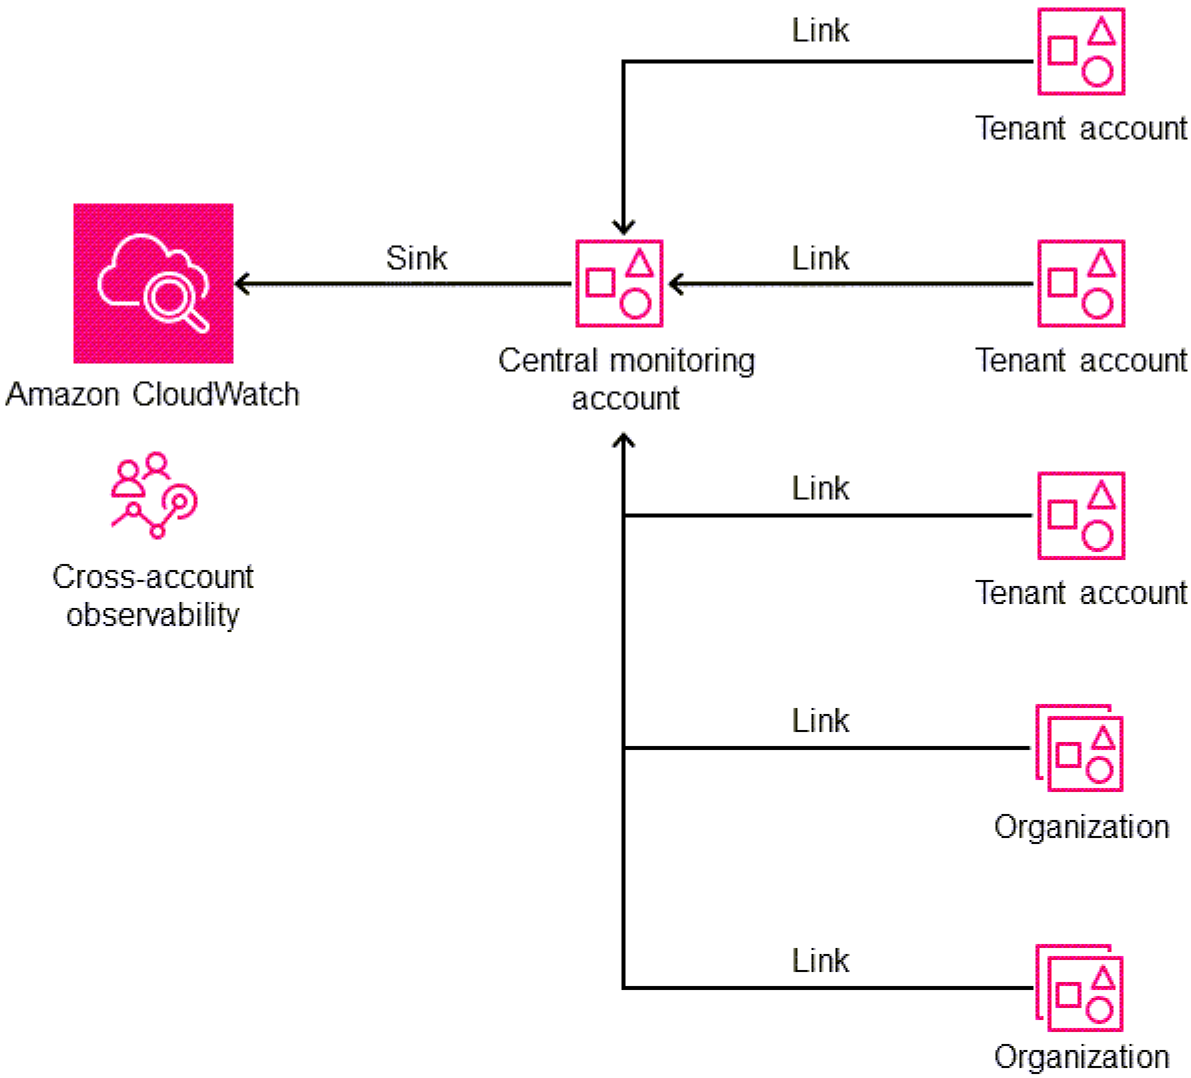
Components

CloudWatch Observability Access Manager consists of two major components that enable cross-account observability:

- A *sink* provides the ability for source accounts to send observability data to the central monitoring account. A sink basically provides a gateway junction for source accounts to connect to. There can be only one sink gateway or connection, and multiple accounts can connect to it.
- Each source account has a *link* to the sink gateway junction, and observability data is sent through this link. You must create a sink before you create links from each source account.

Architecture

The following diagram illustrates Observability Access Manager and its components.



Tools

AWS services

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- AWS Organizations is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.
- AWS Control Tower Account Factory for Terraform (AFT) sets up a Terraform pipeline to help you provision and customize accounts in AWS Control Tower. You can optionally use AFT to set up Observability Access Manager at scale across multiple accounts.

Code repository

The code for this pattern is available in the GitHub Observability Access Manager repository.

Best practices

- In AWS Control Tower environments, mark the logging account as the central monitoring account (sink).
- If you have multiple organizations with multiple accounts in AWS Organizations, we recommend that you include the organizations instead of individual accounts in the configuration policy. If you have a small number of accounts or if the accounts aren't part of an organization in the sink configuration policy, you might decide to include individual accounts instead.

Epics

Set up the sink module

Task	Description	Skills required
Clone the repository.	Clone the GitHub Observability Access Manager repository: `git clone https://github.com/aws-samples/cloudwatch-obervability-access-manager-terraform`	AWS DevOps, Cloud administrator, AWS administrator
Specify property values for the sink module.	In the `main.tf` file (in the `deployments/aft-ac`	AWS DevOps, Cloud administrator, AWS administrator

Task	Description	Skills required
	`count-customizations/LOGGING/terraform/` folder of the repository), specify values for the following properties: • `sink_name` : The name of the CloudWatch sink. • `allowed_oam_resource_types` : Observability Access Manager currently supports CloudWatch metrics, log groups, and AWS X-Ray traces. • `allowed_source_accounts` : The source accounts that are allowed to send logs to the central CloudWatch sink account. • `allowed_source_organizations` : The source AWS Control Tower organizations that are allowed to send logs to the central CloudWatch sink account. For more information, see AWS::Oam::Sink in the AWS CloudFormation documentation.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Install the sink module.</td><td>Export the credentials of the AWS account that you have selected as the monitorin g account, and install the Observability Access Manager sink module:
<pre><code>Terraform Init
Terrafom Plan
Terraform Apply</code></pre></td><td>AWS DevOps, Cloud administr ator, AWS administrator</td></tr>
</table>

Set up the link module

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Specify property values for the link module.</td><td>In the <code>main.tf</code> file (in the <code>deployments/aft-ac count-customizatio ns/LOGGING/terrafo rm/</code> folder of the repositor y), specify values for the following properties:
<code>account_label</code> : Use one of the following values:
<code>$AccountName</code> : The name of the account.
<code>$AccountEmail</code> : A globally unique email address, which includes the email domain (for example, <code>hello@exa mple.com</code>)</td><td>AWS DevOps, Cloud administr ator, Cloud architect</td></tr>
</table>

Task	Description	Skills required
	• `$AccountEmailNoDomain` : An email address without the domain name. • `allowed_oam_resource_types` : Observability Access Manager currently supports CloudWatch metrics, log groups, and AWS X-Ray traces. For more information, see AWS::Oam::Link in the AWS CloudFormation documentation.	

Install the link module for individual accounts.	Export the credentials of individual accounts and install the Observability Access Manager link module:
	`Terraform Plan`
	`Terraform Apply`
	You can set up the link module individually for each account, or use AFT to automatically install this module across a large number of accounts.
		AWS DevOps, Cloud administrator, Cloud architect

Approve sink-to-link connections

Task	Description	Skills required
Check the status message.	1. Sign in to the monitoring account. 2. Open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/). 3. In the left navigation pane, choose **Settings**. On the right, you should see the status message **Monitoring account enabled** with a green checkmark. This means that the monitoring account has an Observability Access Manager sink that the links of other accounts will connect to.	
Approve the link-to-sink connections.	1. Choose the **Resources to link accounts** option below the status message. The information confirms that this is the monitoring account, lists the data that is shared from the tenant source accounts (**Logs**, **Metrics, Traces**), and shows the account label as **$AccountName.** This screen provides two options for linking tenant accounts to the monitoring account: organization-	AWS DevOps, Cloud administrator, Cloud architect

Task	Description	Skills required
	level approval or account-level approval. For each option, you can choose to download an AWS CloudFormation template for the approval or approve each account individually. 2. For simplicity, choose **Any Account** to approve at each account level. This option provides an approval link for the account. 3. Choose **Copy URL** to copy the link. 4. Sign in to each source account. 5. In a browser window, paste the link, and choose **Approve link connect to sink**. 6. Repeat for additional source accounts. For more information, see Link monitoring accounts with source accounts in the CloudWatch documentation.	

Verify cross-account observability data

Task	Description	Skills required
View cross-account data.	1. Sign in to the central monitoring account. 2. Open the [CloudWatch console](#). 3. In the left navigation pane, choose options to view cross-account logs, metrics, and traces.	AWS DevOps, Cloud administr ator, Cloud architect

(Optional) Enable source accounts to trust monitoring account

Task	Description	Skills required
View metrics, dashboards, logs, widgets, and alarms from other accounts.	As an additional feature, you can share the CloudWatc h metrics, dashboards, logs, widgets, and alarms with other accounts. Each account uses an IAM role called **CloudWatch-CrossAc countSharingRole** to gain access to this data. Source accounts that have a trust relationship with the central monitoring account can assume this role and view data from the monitoring account. CloudWatch provides a sample CloudFormation script	AWS DevOps, Cloud administr ator, Cloud architect

Task	Description	Skills required
	to create the role. Choose **Manage role in IAM and** run this script in the accounts where you want to view data. `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Principal": { "AWS": [ "arn:aws:iam::XXXXXXXXX:root", "arn:aws:iam::XXXXXXXXX:root", "arn:aws:iam::XXXXXXXXX:root", "arn:aws:iam::XXXXXXXXX:root" ] }, "Action": "sts:AssumeRole" } ] }` For more information, see [Enabling cross-account functionality in CloudWatc]()	

Task	Description	Skills required
	h in the CloudWatch documentation.	

(Optional) View cross-account cross-Region from the monitoring account

Task	Description	Skills required
Set up cross-account, cross-Region access.	In the central monitoring account, you can optionally add an account selector to easily switch between accounts and view their data without having to authenticate. 1. Sign in to the central monitoring account. 2. Open the CloudWatch console. 3. In the left navigation pane, choose **Settings**. 4. In the **View cross-account cross-region** section, choose **Configure**. 5. Choose **Enable**, and then select the **Show selector in the console** check box. 6. Choose one of these options: • **Account Id Input:** This option prompts you to manually input the account ID whenever you	AWS DevOps, Cloud administrator, Cloud architect

Task	Description	Skills required
	want to change accounts to view cross-account data. • **AWS Organization account selector:** If you have integrated CloudWatch with AWS Organizations, this option provides a dropdown selector with a complete list of accounts in the organization. • **Custom account selector:** This option lets you manually input a list of account IDs to populate the selector. 7. Choose **Save changes.** For more information, see Cross-account cross-Region CloudWatch console in the CloudWatch documentation.

Check EC2 instances for mandatory tags at launch

Susanne Kangnoh and Archit Mathur, Amazon Web Services

Summary

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster.

You can use tagging to categorize your AWS resources in different ways. EC2 instance tagging is useful when you have many resources in your account and you want to quickly identify a specific resource based on the tags. You can assign custom metadata to your EC2 instances by using tags. A tag consists of a user-defined key and value. We recommend that you create a consistent set of tags to meet your organization's requirements.

This pattern provides an AWS CloudFormation template to help you monitor EC2 instances for specific tags. The template creates an Amazon CloudWatch Events event that watches for the AWS CloudTrail **TagResource** or **UntagResource** events, to detect new EC2 instance tagging or tag removal. If a predefined tag is missing, it calls an AWS Lambda function, which sends out a violation message to an email address that you provide, by using Amazon Simple Notification Service (Amazon SNS).

Prerequisites and limitations

Prerequisites

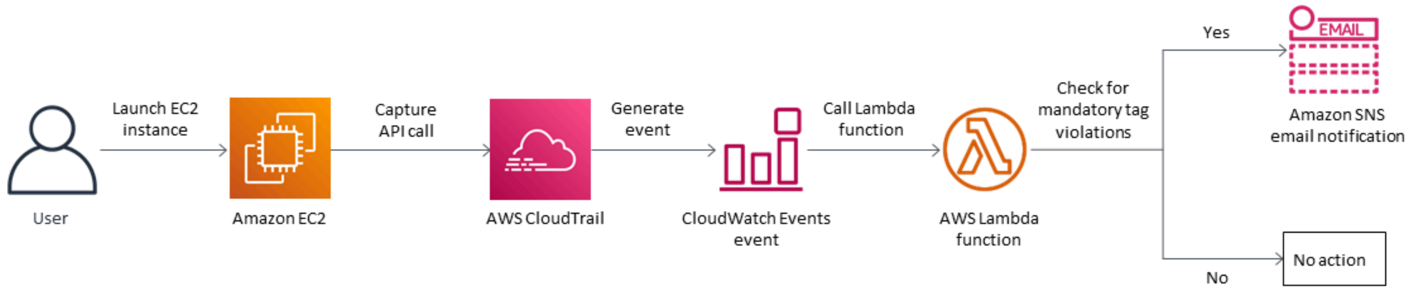
- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code.
- An email address where you would like to receive violation notifications.

Limitations

- This solution supports CloudTrail **TagResource** or **UntagResource** events. It does not create notifications for any other events.
- This solution checks only for tag keys. It does not monitor key values.

Architecture

Workflow architecture



Automation and scale

- You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

Tools

AWS services

- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides secure, resizable compute capacity in the cloud. It is designed to make web-scale cloud computing easier for developers.
- AWS CloudTrail – CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or AWS service are recorded as events in CloudTrail.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
- AWS Lambda – Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

- [Amazon S3](#) – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- [Amazon SNS](#) – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

Code

This pattern includes an attachment with two files:

- `index.zip` is a compressed file that includes the Lambda code for this pattern.
- `ec2-require-tags.yaml` is a CloudFormation template that deploys the Lambda code.

See the *Epics* section for information about how to use these files.

Epics

Deploy the Lambda code

Task	Description	Skills required
Upload the code to an S3 bucket.	Create a new S3 bucket or use an existing S3 bucket to upload the attached `index.zip` file (Lambda code). This bucket must be in the same AWS Region as the resources (EC2 instances) that you want to monitor.	Cloud architect
Deploy the CloudFormation template.	Open the Cloudformation console in the same AWS Region as the S3 bucket, and deploy the `ec2-require-tags.yaml` file that's provided in the attachment. In the next epic, provide	Cloud architect

Task	Description	Skills required
	values for the template parameters.	

Complete the parameters in the CloudFormation template

Task	Description	Skills required
Provide the S3 bucket name.	Enter the name of the S3 bucket that you created or selected in the first epic. This S3 bucket contains the .zip file for the Lambda code and must be in the same AWS Region as the CloudForm ation template and the EC2 instances that you want to monitor.	Cloud architect
Provide the S3 key.	Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, `index.zip` or `controls/index.zip`).	Cloud architect
Provide an email address.	Provide an active email address where you want to receive violation notifications.	Cloud architect
Define a logging level.	Specify the logging level and verbosity. `Info` designate s detailed informational messages on the applicati on's progress and should be used only for debugging	Cloud architect

Task	Description	Skills required
	. `Error` designates error events that could still allow the application to continue running. `Warning` designates potentially harmful situation s.	
Enter the required tag keys.	Enter the tag keys that you want to check for. If you want to specify multiple keys, separate them with commas, without spaces. (For example, `ApplicationId,Crea tedBy,Environment, Organization` searches for four keys.) The CloudWatc h Events event searches for these tag keys and sends a notification if they are not found.	Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the email subscript ion.	When the CloudFormation template deploys successfu lly, it sends a subscription email message to the email address you provided. To receive notifications, you must confirm this email subscription.	Cloud architect

Clean up AWS Account Factory for Terraform (AFT) resources safely after state file loss

Gokendra Malviya, Amazon Web Services

Summary

When you use AWS Account Factory for Terraform (AFT) to manage your AWS Control Tower environment, AFT generates a Terraform state file to track the state and configuration of the resources created by Terraform. Losing the Terraform state file can create significant challenges for resource management and cleanup. This pattern provides a systematic approach to safely identify and remove AFT-related resources while maintaining the integrity of your AWS Control Tower environment.

The process is designed to ensure proper removal of all AFT components, even without the original state file reference. This process provides a clear path to successfully re-establish and reconfigure AFT in your environment, to help ensure minimal disruption to your AWS Control Tower operations.

For more information about AFT, see the [AWS Control Tower documentation](#).

Prerequisites and limitations

Prerequisites

- A thorough understanding of [AFT architecture](#).
- Administrator access to the following accounts:
  - AFT Management account
  - AWS Control Tower Management account
  - Log Archive account
  - Audit account
- Verification that no service control policies (SCPs) contain restrictions or limitations that would block the deletion of AFT-related resources.

Limitations

- This process can clean up resources effectively, but it cannot recover lost state files, and some resources might require manual identification.

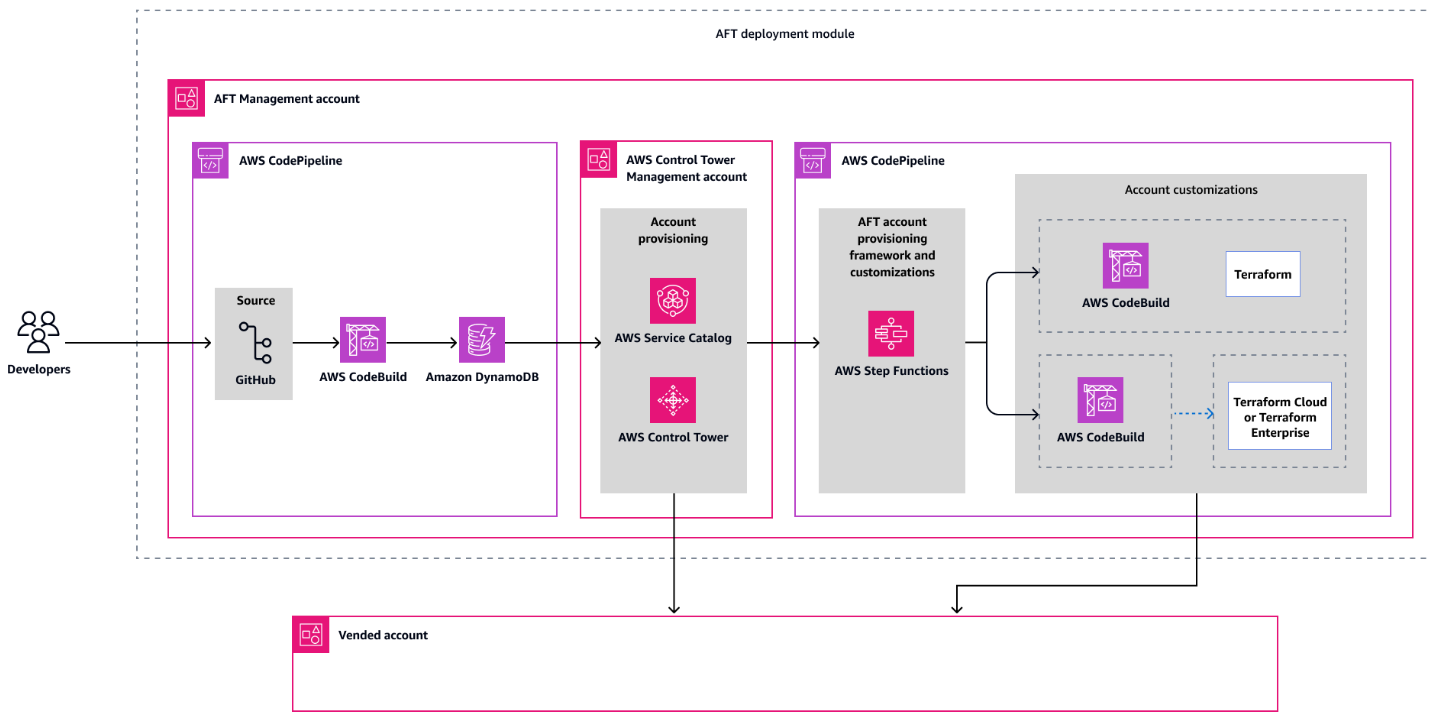
- The duration of the cleanup process depends on your environment's complexity and might take several hours.
- This pattern has been tested with AFT version 1.12.2 and deletes the following resources. If you're using a different version of AFT, you might have to delete additional resources.

Service name	Number of resources
AWS CodeBuild	6
AWS CodeCommit	4
AWS CodePipeline	4
Amazon DynamoDB	5
Amazon Elastic Compute Cloud (Amazon EC2)	16
Amazon EventBridge	4
AWS Identity and Access Management (IAM) roles	40
AWS Key Management Service (AWS KMS)	2
AWS Lambda	17
Amazon Simple Storage Service (Amazon S3)	2
Amazon Simple Notification Service (Amazon SNS)	2
Amazon Simple Queue Service (Amazon SQS)	2
AWS Systems Manager	62
AWS Step Functions	4

> **Important**
>
> The resources that are deleted by the steps in this pattern cannot be recovered. Before you follow these steps, verify the resource names carefully and make sure that they were created by AFT.

Architecture

The following diagram shows the AFT components and high-level workflow. AFT sets up a Terraform pipeline that helps you provision and customize your accounts in AWS Control Tower. AFT follows a GitOps model to automate the processes of account provisioning in AWS Control Tower. You create a Terraform file for an account request and commit it to a repository, which provides the input that triggers the AFT workflow for account provisioning. After account provisioning is complete, AFT can run additional customization steps automatically.



In this architecture:

- **AWS Control Tower Management account** is an AWS account that's dedicated to the AWS Control Tower service. This is also typically referred to as the *AWS payer account* or *AWS Organizations Management account*.

- **AFT Management account** is an AWS account that's dedicated to AFT management operations. This is different from your organization's management account.
- **Vended account** is an AWS account that contains all the baseline components and controls that you selected. AFT uses AWS Control Tower to vend a new account.

For additional information about this architecture, see Introduction to AFT in the AWS Control Tower workshop.

Tools

AWS services

- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices.
- AWS Account Factory for Terraform (AFT) sets up a Terraform pipeline to help you provision and customize accounts and resources in AWS Control Tower.
- AWS Organizations helps you centrally manage and govern your environment as you grow and scale your AWS resources. Using Organizations, you can create accounts and allocate resources, group accounts to organize your workflows, apply policies for governance, and simplify billing by using a single payment method for all your accounts.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them. This pattern requires IAM roles and permissions.

Other tools

- Terraform is an infrastructure as code (IaC) tool from HashiCorp that helps you create and manage cloud and on-premises resources.

Best practices

- For AWS Control Tower, see Best practices for AWS Control Tower administrators in the AWS Control Tower documentation.
- For IAM, see Security best practices in the IAM documentation.

Epics

Delete AFT resources in the AFT Management account

Task	Description	Skills required
Delete resources that are identified by the AFT tag.	1. Sign in to the AFT management account with administrator permissions. 2. Open the [AWS Resource Groups console](https://console.aws.amazon.com/resource-groups/). 3. Select the Region where AWS Control Tower has been deployed. 4. In the navigation pane, choose **Tag Editor**. 5. For **Resource types**, choose **All supported resource types**. 6. For **Tags**, type **managed_b y** as the tag key and **AFT** as the tag value. 7. Choose **Search resources**. This search displays all resources that were created by AFT. 8. Identify the resource names and delete them by using the correspon ding service consoles. For example, to delete Parameter Store resources: a. Open the [AWS Systems Manager console](https://console.aws.amazon.com/systems-manager/).	AWS administrator, AWS DevOps, DevOps engineer

Task	Description	Skills required
	b. In the navigation pane, choose **Parameter Store**. c. In the search box, click to display the dropdown, choose **Name**, choose **equals**, and then type **/aft**. d. Delete the parameters in batches of 10. (This is the maximum number you can delete at the same time.) For AFT version 1.12.2, there will be approximately 62 Parameter Store resources to delete. All parameter names will start with **/aft**. However, not all resources can be identified by AWS Resource Groups. In the following steps, you will find and delete the remaining resources.	

Task	Description	Skills required
Delete IAM roles.	1. Sign in to the AFT management account with administrator permissions. 2. Open the IAM console. 3. Delete these roles in the order listed (the order is important because of dependencies): • `aft-*` • `AWSAFTAdmin` • `AWSAFTExecution` • `AWSAFTService` • `codebuild_trigger_role`	AWS administrator, AWS DevOps, DevOps engineer
Delete the AWS Backup backup vault.	1. Open the AWS Backup console. 2. Locate the backup vault named `aws_backup_vault` . 3. Confirm that the vault doesn't contain any active backups. 4. Delete `aws_backup_vault` .	AWS administrator, AWS DevOps, DevOps engineer

Task	Description	Skills required
Delete Amazon CloudWatch resources.	1. Open the [CloudWatch console](). 2. Delete the following resources in the order listed: a. Event bus: Delete `aws_cloudwatch_event_bus` . b. Logs: Search for the prefix **AFT** and delete all related log groups. c. Query definitions: Delete the following queries: • `Customization Logs by Account ID` • `Customization Logs by Customization Request ID`	AWS administrator, AWS DevOps, DevOps engineer
Delete AWS KMS resources.	1. Switch to the secondary Region, which serves as the backend for state tracking of AFT's own state. 2. Open the [AWS KMS console](). 3. Delete the alias named **AFT**.	AWS administrator, AWS DevOps, DevOps engineer

Delete AFT resources in the Log Archive account

Task	Description	Skills required
Delete S3 buckets.	1. Sign in to the Log Archive account with administrator permissions. 2. Open the [Amazon S3 console](https://console.aws.amazon.com/s3/). 3. Empty the following buckets: • `aws-aft-logs-471112509802-us-east-1` • `aws-aft-s3-access-logs-471112509802-us-east-1` (Replace 111122223333 with your account ID.) 4. Delete the two buckets.	AWS administrator, AWS DevOps, DevOps engineer
Delete IAM roles.	1. Open the [IAM console](https://console.aws.amazon.com/iam/). 2. Verify that the following roles aren't being used by any active services: • `AWSAFTService` • `AWSAFTExecution` 3. Delete the two roles.	AWS administrator, AWS DevOps, DevOps engineer

Delete AFT resources in the Audit account

Task	Description	Skills required
Delete IAM roles.	1. Sign in to the Audit account with administrator permissions. 2. Open the [IAM console](https://console.aws.amazon.com/iam/). 3. Verify that the following roles aren't being used by any active services: • `AWSAFTService` • `AWSAFTExecution` 4. Delete the two roles.	AWS administrator, AWS DevOps, DevOps engineer

Delete AFT resources in the AWS Control Tower Management account

Task	Description	Skills required
Delete IAM roles.	1. Sign in to the AWS Control Tower Management account with administrator permissions. 2. Open the [IAM console](https://console.aws.amazon.com/iam/). 3. Verify that the following roles aren't being used by any active services: • `AWSAFTService` • `AWSAFTExecution` • `aft-control-tower-events-rule` 4. Delete the three roles.	AWS administrator, AWS DevOps, DevOps engineer

Task	Description	Skills required
Delete EventBridge rules.	1. Open the [Amazon EventBridge console](). 2. In the left navigation pane, choose **Rules**. 3. Find and select the rule named `aft-capture-ct-events` . 4. Choose **Delete** and confirm the deletion when prompted.	AWS administrator, AWS DevOps, DevOps engineer

Troubleshooting

Issue	Solution
Detaching the internet gateway was unsuccessful.	While you're deleting resources that are identified by the **AFT** tag, if you encounter this issue when you detach or delete the internet gateway, you first have to delete VPC endpoints: 1. Sign in to the AFT Management account, and then open the [Amazon VPC console](). 2. In the navigation pane, in the **Filter by VPC** list, choose the VPC named **aft-management-vpc**. 3. In the navigation pane, choose **Endpoints**. 4. Select the endpoints that are associated with the VPC **aft-management-vpc**. • Double-check the VPC ID column before deletion to avoid removing the wrong endpoints.

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td></td><td>Be careful to delete only the endpoints that are associated with the AFT VPC.
<ol start="5">
Choose Actions, Delete VPC endpoints.
In the confirmation dialog box, type delete and then choose Delete.
Wait for the endpoint status to change to Deleted.

Deletion might take a few minutes to complete.</td></tr>
<tr><td>You're unable to find the specified CloudWatc h queries.</td><td>If you are unable to find the CloudWatch queries that were created by AFT, follow these steps:
Sign in to the AFT Management account, and then open the CloudWatch console.
In the navigation pane, under Logs, choose Logs Insights.
In the upper-right corner, choose the Saved and sample queries icon.

You should now be able to see AFT queries. For a screenshot, see the Additional information section.
Select the following queries, and then choose Actions, Delete to remove them.
<code>Customization Logs by Account ID</code>
<code>Customization Logs by Customization Request ID</code></td></tr>
</table>

Connect to an Amazon EC2 instance by using Session Manager

Jason Cornick, Abhishek Bastikoppa, and Yaniv Ron, Amazon Web Services

Summary

This pattern describes how to connect to an Amazon Elastic Compute Cloud (Amazon EC2) instance by using the Session Manager, a capability of AWS Systems Manager. Using this pattern, you can run bash commands on an EC2 instance through a web browser. Session Manager doesn't require that you open inbound ports and doesn't require public IP addresses for EC2 instances. Additionally, it removes the need to maintain bastion hosts with different Secure Shell (SSH) keys. You can govern access to Session Manager with AWS Identity and Access Management (IAM) policies and configure logging, which records important information, such as instance access and actions.

In this pattern, you configure an IAM role and associate it to a Linux EC2 instance that you provision by using an Amazon Machine Image (AMI). You then configure logging in Amazon CloudWatch Logs and use Session Manager to start a session with the instance.

Although this pattern connects to a Linux EC2 instance in the Amazon Web Services (AWS) Cloud, you could use this approach to use Session Manager for connections with other servers, such as on-premises servers or other virtual machines.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Permissions to access the managed node. For instructions, see Control user session access to managed nodes.
- VPC endpoints for `ssm`, `ec2`, `ec2messages`, `ssmmessages`, and `s3`. For instructions, see Create VPC endpoints in the Systems Manager documentation.

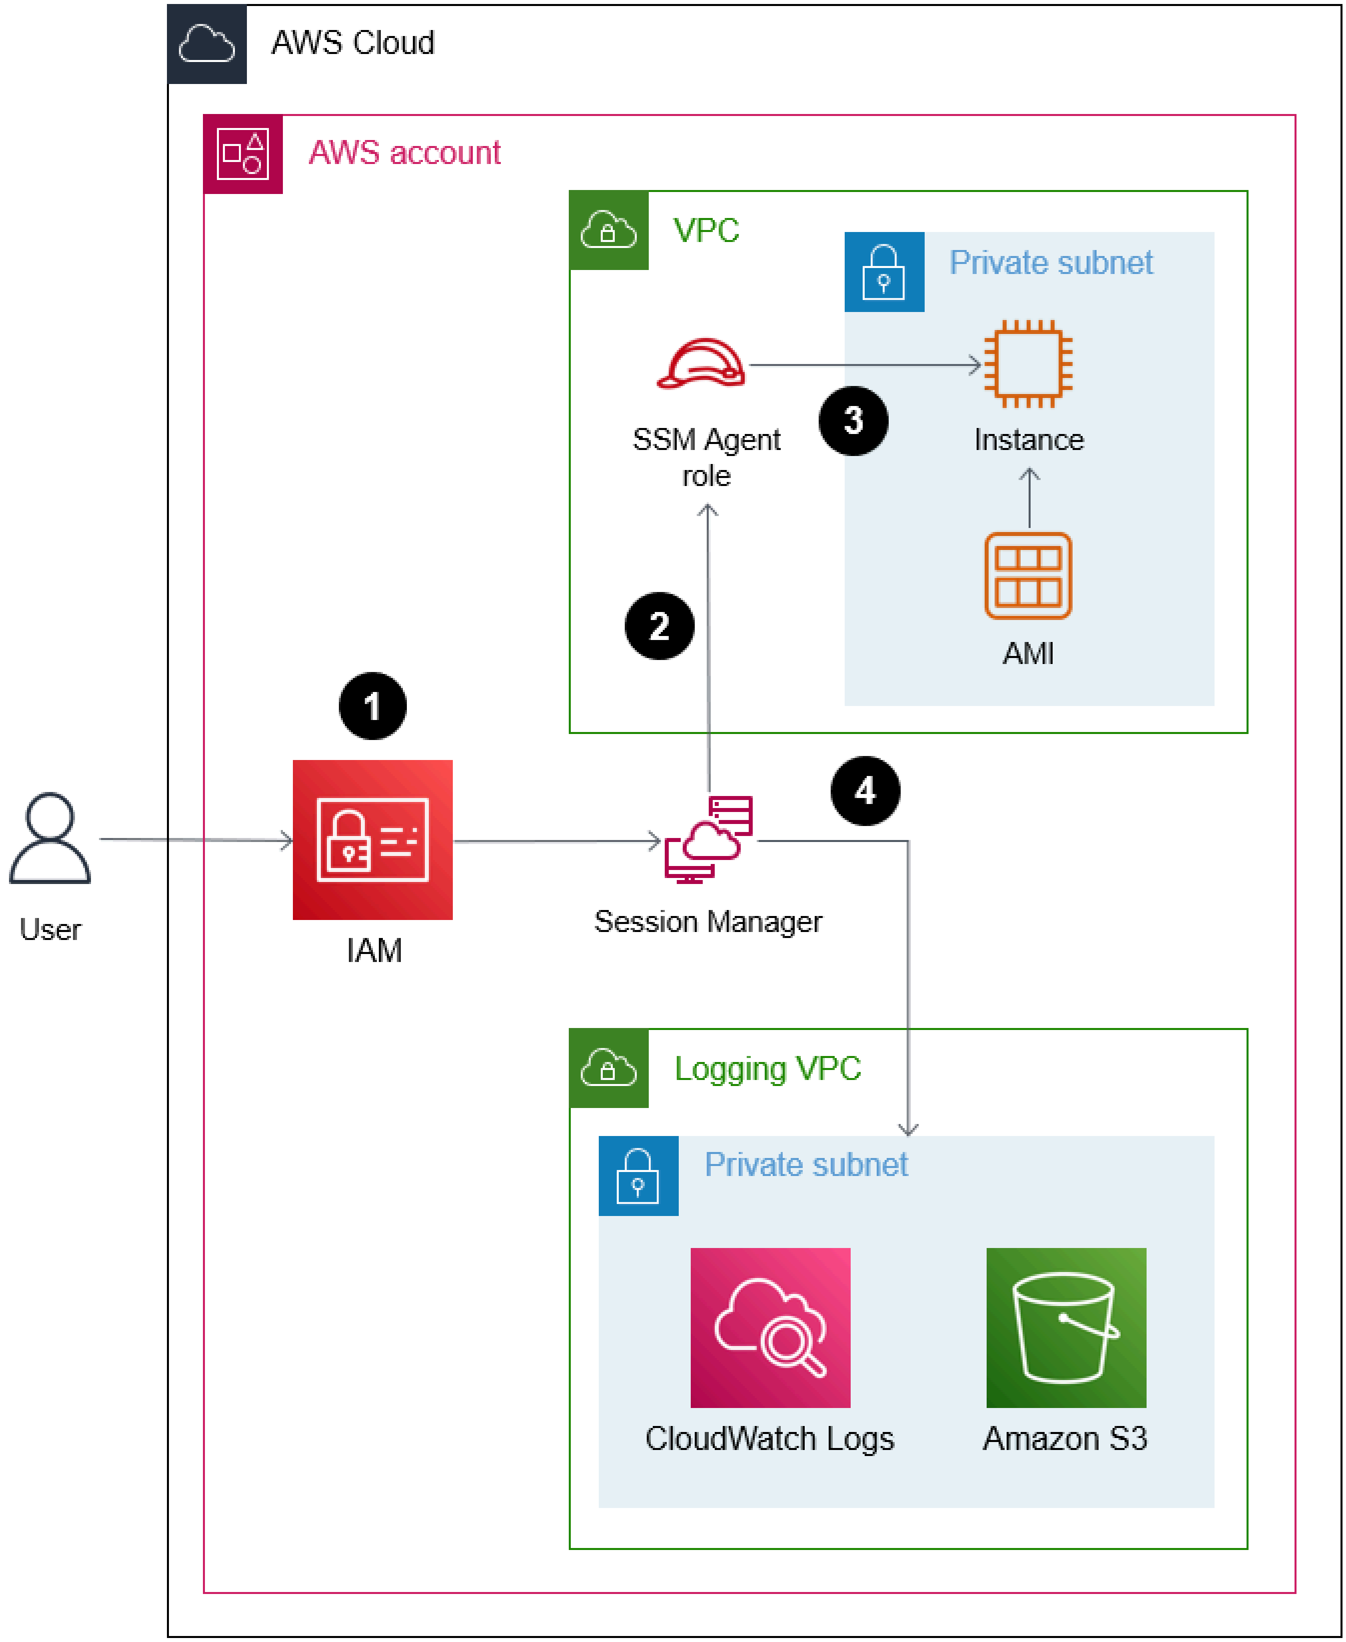
Architecture

Target technology stack

- Session Manager

- Amazon EC2
- CloudWatch Logs

Target architecture



AWS Cloud
AWS account
VPC
Private subnet
SSM Agent role
3
Instance
AMI
2
1
User
IAM
Session Manager
4
Logging VPC
Private subnet
CloudWatch Logs
Amazon S3

1. The user authenticates their identity and credentials through IAM.
2. The user initiates an SSH session through Session Manager and sends API calls to the EC2 instance.
3. The AWS Systems Manager SSM Agent, which is installed on the EC2 instance, connects to Session Manager and runs the commands.
4. For auditing and monitoring purposes, Session Manager sends the logging data to CloudWatch Logs. Alternatively, you can send log data to an Amazon Simple Storage Service (Amazon S3) bucket. For more information, see Logging session data using Amazon S3 (Systems Manager documentation).

Tools

AWS services

- Amazon CloudWatch Logs helps you centralize the logs from all your systems, applications, and AWS services so you can monitor them and archive them securely.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down. This pattern uses an Amazon Machine Image (AMI) to provision a Linux EC2 instance.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses Session Manager, a capability of Systems Manager.

Best practices

We recommend that you read more about the security pillar of the AWS Well-Architected Framework and explore encryption options and apply the security recommendations in Setting up Session Manager (Systems Manager documentation).

Epics

Set up the infrastructure

Task	Description	Skills required
Create the IAM role.	Create the IAM role for the SSM Agent. Follow the instructions in [Creating a role for an AWS service](#) (IAM documentation) and note the following: 1. For the AWS service, choose **EC2**. 2. For **Permissions Policies**, choose `AmazonSSMManagedInstanceCore` . 3. In **Role Name**, enter `EC2_SSM_Role` .	AWS systems administrator
Create the EC2 instance.	1. Create the EC2 instance. Follow the instructions in [Launch an instance](#) (Amazon EC2 documentation) and note the following: a. In the **Name and tags** section, choose **Add additional tags**. In **Key**, enter `Name`, and in **Value**, enter `Production_Server_One` . b. Choose an Amazon Linux AMI that has the SSM Agent preinstalled.	AWS systems administrator

Task	Description	Skills required
	For a complete list, see AMIs with SSM Agent preinstalled (Systems Manager documentation). c. In the **Advanced details** section, in **IAM instance profile**, choose **EC2_SSM_Role**. 2. Open the Systems Manager console at https://console.aws.amazon.com/systems-manager/. 3. In the navigation pane, choose **Fleet Manager**. 4. Verify that the instance appears in the list of managed nodes.	

Task	Description	Skills required
Set up logging.	1. Create a log group in CloudWatch Logs. Follow the instructions in [Create a log group](#) (CloudWatch Logs documentation). Name the new log group `SessionManager` . 2. Configure logging for Session Manager. Follow the instructions in [Logging session data using Amazon CloudWatch Logs](#) (Systems Manager documentation) and note the following: a. Don't select **Allow only encrypted CloudWatch log groups**. b. In **Choose a log group from the list**, choose **SessionManager**.	AWS systems administrator

Connect to the instance

Task	Description	Skills required
Connect to the EC2 instance.	1. Start a session in the Systems Manager console. For instructions, see [Start a session](#) (Systems Manager documentation). For **Target instances**, choose the option button to the	AWS systems administrator

Task	Description	Skills required
	left of the **Production_Server_One** instance. 2. After the connection is made, run several bash commands. 3. In the Systems Manager console, end the session. For instructions, see [End a session](#) (Systems Manager documentation).	
Validate logging.	1. In CloudWatch Logs, open the log stream for the log group. For instructions, see [View log data](#) (CloudWatch Logs documentation). 2. In the log data, confirm that the commands you ran in the previous story are listed.	AWS systems administrator

Troubleshooting

Issue	Solution
IAM issues	For support, see Troubleshooting (IAM documentation).

Create a pipeline in AWS Regions that don’t support AWS CodePipeline

Anand Krishna Varanasi, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more

AWS CodePipeline is a continuous delivery (CD) orchestration service that’s part of a set of DevOps tools from Amazon Web Services (AWS). It integrates with a large variety of sources (such as version control systems and storage solutions), continuous integration (CI) products and services from AWS and AWS Partners, and open-source products to provide an end-to-end workflow service for fast application and infrastructure deployments.

However, CodePipeline isn’t supported in all AWS Regions, and it’s useful to have an invisible orchestrator that connects AWS CI/CD services. This pattern describes how to implement an end-to-end workflow pipeline in AWS Regions where CodePipeline isn’t yet supported by using AWS CI/CD services such as AWS CodeCommit, AWS CodeBuild, and AWS CodeDeploy.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Cloud Development Kit (AWS CDK) CLI version 2.28 or later

Architecture

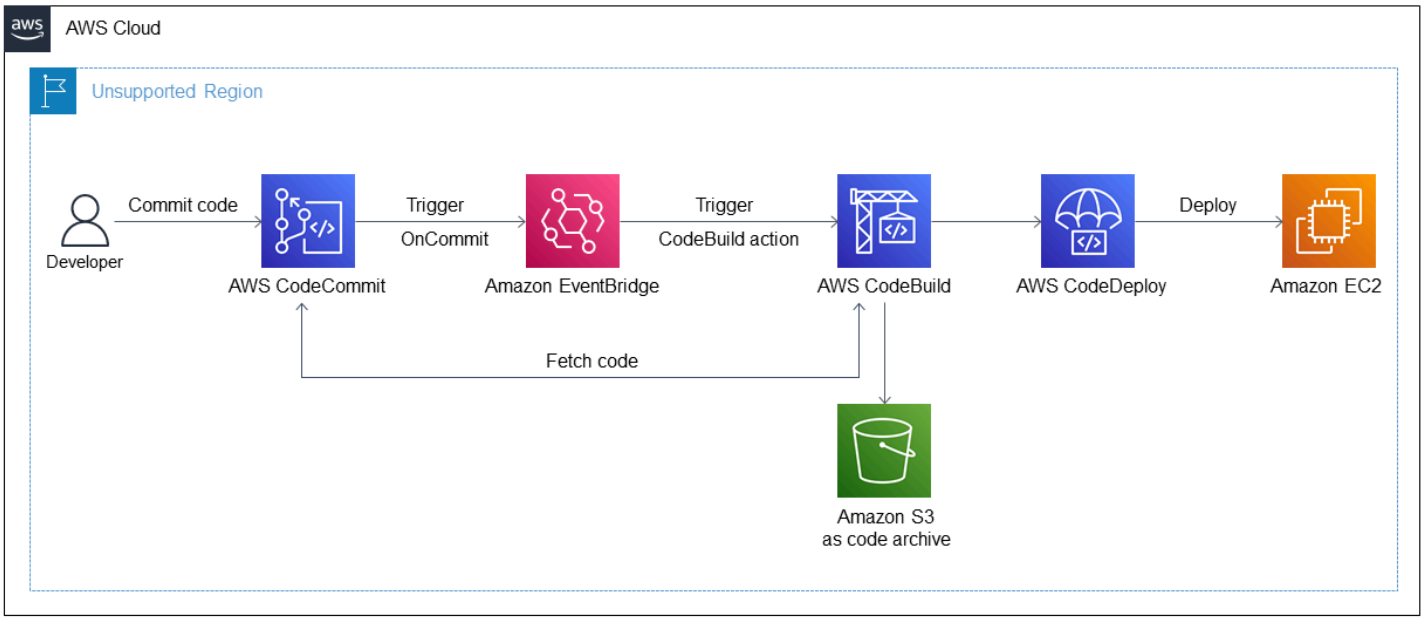
Target technology stack

The following diagram shows a pipeline that was created in a Region that doesn’t support CodePipeline, such as the Africa (Cape Town) Region. A developer pushes the CodeDeploy configuration files (also called *deployment lifecycle hook scripts*) to the Git repository that’s hosted by CodeCommit. (See the GitHub repository provided with this pattern.) An Amazon EventBridge rule automatically initiates CodeBuild.

The CodeDeploy configuration files are fetched from CodeCommit as part of the source stage of the pipeline and transferred to CodeBuild.

In the next phase, CodeBuild performs these tasks:

1. Downloads the application source code TAR file. You can configure the name of this file by using Parameter Store, a capability of AWS Systems Manager.
2. Downloads the CodeDeploy configuration files.
3. Creates a combined archive of application source code and CodeDeploy configuration files that are specific to the application type.
4. Initiates CodeDeploy deployment to an Amazon Elastic Compute Cloud (Amazon EC2) instance by using the combined archive.



Tools

AWS services

- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodeDeploy automates deployments to Amazon EC2 or on-premises instances, AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.

Code

The code for this pattern is available in the GitHub CodePipeline Unsupported Regions repository.

Epics

Set up your developer workstation

Task	Description	Skills required
Install the AWS CDK CLI.	For instructions, see the AWS CDK documentation.	AWS DevOps
Install a Git client.	To create commits, you can use a Git client installed on your local computer, and then push your commits to the CodeCommit repository. To set up CodeCommit with your Git client, see the CodeCommit documentation.	AWS DevOps
Install npm.	Install the **npm** package manager. For more information, see the npm documentation.	AWS DevOps

Set up the pipeline

Task	Description	Skills required
Clone the code repository.	Clone the GitHub CodePipeline Unsupported Regions repository to your local	DevOps engineer

Task	Description	Skills required
	machine by running the following command. `git clone https://github.com/aws-samples/invisible-codepipeline-unsupported-regions`	

Task	Description	Skills required
Set parameters in cdk.json.	Open the `cdk.json` file and provide values for the following parameters: `"pipeline_account" :"XXXXXXXXXXXX", "pipeline_region":" us-west-2", "repo_name": "app-dev-repo", "ec2_tag_key": "test-vm", "configName" : "cbdeployconfig", "deploymentGroupName": "cbdeploygroup", "applicationName" : "cbdeployapplication", "projectName" : "CodeBuildProject"` where: • `pipeline_account` is the AWS account where the pipeline will be built. • `pipeline_region` is the AWS Region where the pipeline will be built. • `repo_name` is the name of the CodeCommit repository. • `ec2_tag_key` is the tag attached to the EC2 instance that you want to deploy the code to.	AWS DevOps

Task	Description	Skills required
	• `configName` is the name of the CodeDeploy configuration file. • `deploymentGroupName` is the name of the CodeDeploy deployment group. • `applicationName` is the CodeDeploy application name. • `projectName` is the CodeBuild project name.	

Set up the AWS CDK construct library.	In the cloned GitHub repository, use the following commands to install the AWS CDK construct library, build your application, and synthesize to generate the AWS CloudFormation template for the application.
	`npm i aws-cdk-lib`
	`npm run build`
	`cdk synth`
		AWS DevOps

Deploy the sample AWS CDK application.	Deploy the code by running the following command in an unsupported Region (such as `af-south-1`). `cdk deploy`	AWS DevOps

Set up the CodeCommit repository for CodeDeploy

Task	Description	Skills required
Set up CI/CD for the applicati on.	Clone the CodeCommit repository that you specified in the `cdk.json` file (this is called `app-dev-repo` by default) to set up the CI/CD pipeline for the application. `git clone https://git-codecommit.us-west-2.amazonaws.com/v1/repos/app-dev-repo` where the repository name and Region depend on the values you provided in the `cdk.json` file.	AWS DevOps

Test the pipeline

Task	Description	Skills required
Test the pipeline with deployment instructions.	The `CodeDeploy_Files` folder of the GitHub [CodePipeline Unsupported Regions](#) repository includes sample files that instruct CodeDeploy to deploy the application. The `appspec.yml` file is a CodeDeploy configuration file that contains hooks to control the flow of application deployment. You can use	AWS DevOps

Task	Description	Skills required
	the sample files `index.html`, `start_server.sh`, `stop_server.sh`, and `install_dependencies.sh` to update a website that's hosted on Apache. These are examples—you can use the code in the GitHub repository to deploy any type of application. When the files are pushed to the CodeCommit repository, the invisible pipeline is initiated automatically. For deployment results, check the results of individual phases in the CodeBuild and CodeDeploy consoles.

Customize default role names by using AWS CDK aspects and escape hatches

SANDEEP SINGH and James Jacob, Amazon Web Services

Summary

This pattern demonstrates how to customize the default names of roles that are created by AWS Cloud Development Kit (AWS CDK) constructs. Customizing role names is often necessary if your organization has specific constraints based on naming conventions. For example, your organization might set AWS Identity and Access Management (IAM) permissions boundaries or service control policies (SCPs) that require a specific prefix in role names. In such cases, the default role names generated by AWS CDK constructs might not meet these conventions and might have to be altered. This pattern addresses those requirements by using escape hatches and aspects in the AWS CDK. You use escape hatches to define custom role names, and aspects to apply a custom name to all roles, to ensure adherence to your organization's policies and constraints.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Prerequisites specified in the AWS CDK documentation

Limitations

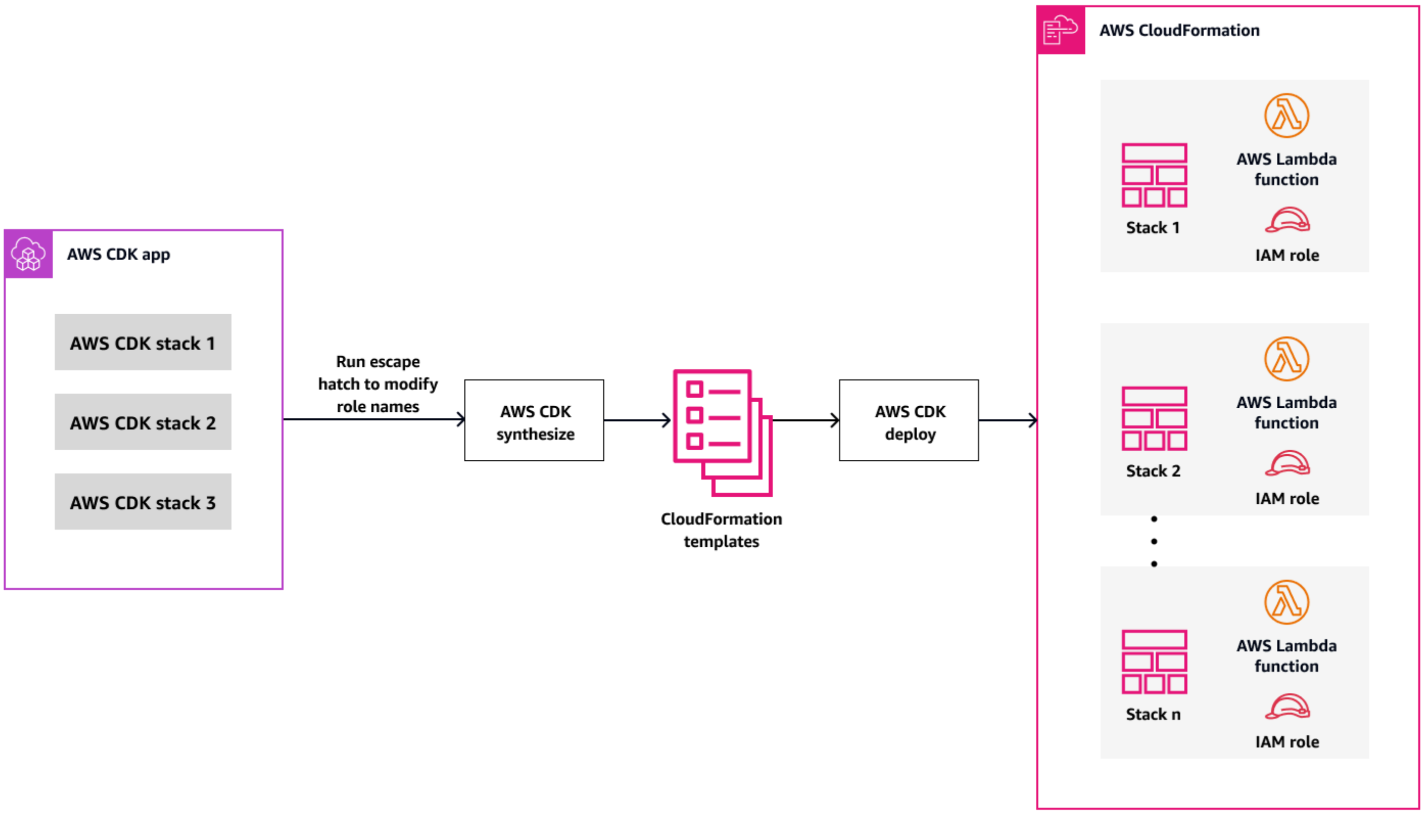
- Aspects filter resources based on resource types, so all roles share the same prefix. If you require different role prefixes for different roles, additional filtering based on other properties is necessary. For example, to assign different prefixes to roles that are associated with AWS Lambda functions, you could filter by specific role attributes or tags, and apply one prefix for Lambda-related roles and a different prefix for other roles.
- IAM role names have a maximum length of 64 characters, so modified role names have to be trimmed to meet this restriction.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

Target technology stack

- AWS CDK
- AWS CloudFormation

Target architecture



- An AWS CDK app consists of one or more AWS CloudFormation stacks, which are synthesized and deployed to manage AWS resources.
- To modify a property of an AWS CDK-managed resource that isn't exposed by a layer 2 (L2) construct, you use an escape hatch to override the underlying CloudFormation properties (in this case, the role name), and an aspect to apply the role to all resources in the AWS CDK app during the AWS CDK stack synthesis process.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CDK Command Line Interface (AWS CDK CLI) (also referred to as the AWS CDK Toolkit) is a command line cloud development kit that helps you interact with your AWS CDK app. The CLI `cdk` command is the primary tool for interacting with your AWS CDK app. It runs your app, interrogates the application model you defined, and produces and deploys the CloudFormation templates that are generated by the AWS CDK.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.

Code repository

The source code and templates for this pattern are available in the GitHub CDK Aspects Override repository.

Best practices

See Best practices for using the AWS CDK in TypeScript to create IaC projects on the AWS Prescriptive Guidance website.

Epics

Install the AWS CDK CLI

Task	Description	Skills required
Install the AWS CDK CLI.	To install the AWS CDK CLI globally, run the command: `npm install -g aws-cdk`	AWS DevOps
Verify the version.	Run the command: `cdk --version` Confirm that you're using version 2 of the AWS CDK CLI.	AWS DevOps

Task	Description	Skills required
Bootstrap the AWS CDK environment.	Before you deploy the AWS CloudFormation templates, prepare the account and AWS Region that you want to use. Run the command: `cdk bootstrap <account>/<Region>` For more information, see [AWS CDK bootstrapping] in the AWS documentation.	AWS DevOps

Deploy the AWS CDK app to demonstrate the use of aspects

Task	Description	Skills required

Set up the project.	1. Clone the GitHub repository for this pattern to your local computer:
	`git clone https://github.com/aws-samples/cdk-aspects-override`
	2. Navigate to the project directory on your local computer.
	3. Install the project dependencies:
	`npm ci`
		AWS DevOps

Task	Description	Skills required
Deploy stacks with default role names assigned by the AWS CDK.	Deploy two CloudFormation stacks (`ExampleStack1` and `ExampleStack2`) that contain the Lambda functions and their associated roles: `npm run deploy:ExampleAppWithoutAspects` The code doesn't explicitly pass role properties, so the role names will be constructed by the AWS CDK. For example output, see the Additional information section.	AWS DevOps

Task	Description	Skills required

Deploy stacks with aspects.	In this step, you apply an aspect that enforces a role name convention by adding a prefix to all IAM roles that are deployed in the AWS CDK project. The aspect is defined in the `lib/aspects.ts` file. The aspect uses an escape hatch to override the role name by adding a prefix. The aspect is applied to the stacks in the `bin/app-with-aspects.ts` file. The role name prefix used in this example is `dev-unicorn`.
	
	1. Edit the `bin/app-with-aspects.ts` file.
	2. In the file, update the variable `ROLE_NAME_PREFIX` with the prefix `dev-unicorn`:
	
	`const app = new cdk.App();`
	
	`// Define a prefix for the role names`
	`const ROLE_NAME_PREFIX = 'dev-unicorn';`
	
	`// Instantiate the RoleNamingConventionAspect with the desired prefix`
		AWS DevOps

Task	Description	Skills required

	`const roleNamingConventionAspect = new RoleNamingConventionAspect(ROLE_NAME_PREFIX);`
	3. Deploy the AWS CDK app with aspects:
	`npm run deploy:ExampleAppWithAspects`
	
	For example output, see the Additional information section.	

Clean up resources

Task	Description	Skills required
Delete your AWS CloudFormation stacks.	After you finish using this pattern, run the following command to clean up resources to avoid incurring additional costs: `cdk destroy --all -f && cdk --app npx ts-node bin/app-with-aspects.ts' destroy --all -f`	AWS DevOps

Troubleshooting

Issue	Solution
You encounter problems using the AWS CDK.	See Troubleshooting common AWS CDK issues in the AWS CDK documentation.

Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing

Dipin Jain, Amazon Web Services

Summary

The private IP of an Amazon Elastic Compute Cloud (Amazon EC2) instance is retained throughout its lifecycle. However, the private IP might change during a planned or unplanned system crash; for example, during an Amazon Machine Image (AMI) upgrade. In some scenarios, retaining a private static IP can enhance the performance and recovery time of workloads. For example, using a static IP for an Apache Cassandra seed node prevents the cluster from incurring a rebalancing overhead.

This pattern describes how to attach a secondary elastic network interface to EC2 instances to keep the IP static during rehosting. The pattern focuses on Cassandra clusters, but you can use this implementation for any architecture that benefits from private static IPs.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Service (AWS) account

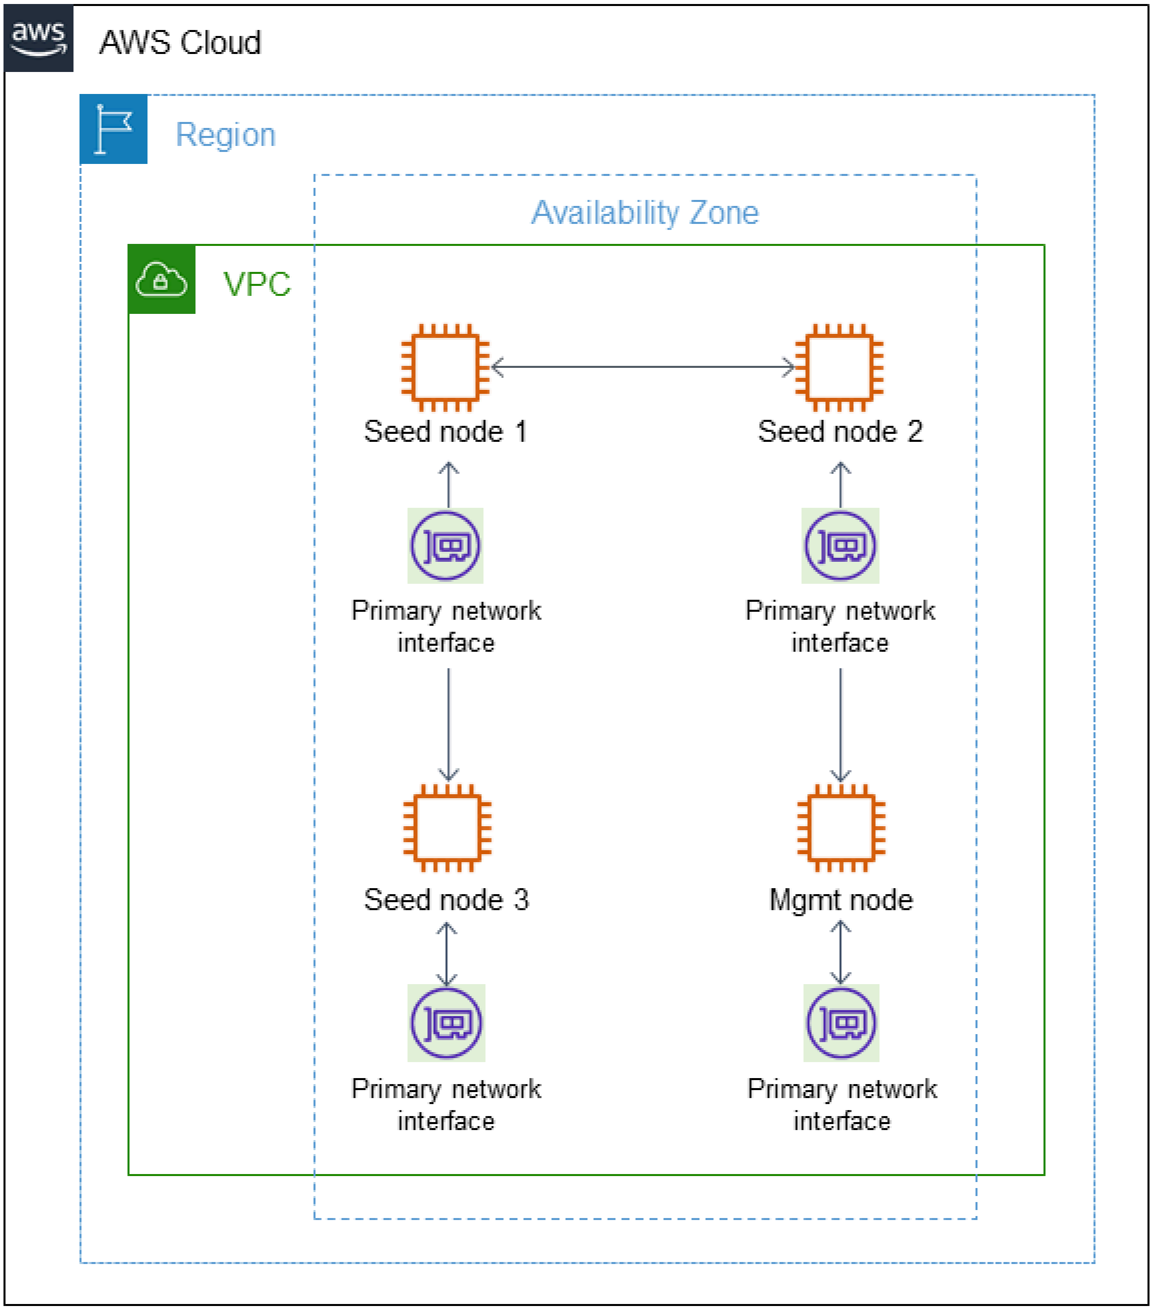
Product versions

- DataStax version 5.11.1
- Operating system: Ubuntu 16.04.6 LTS

Architecture

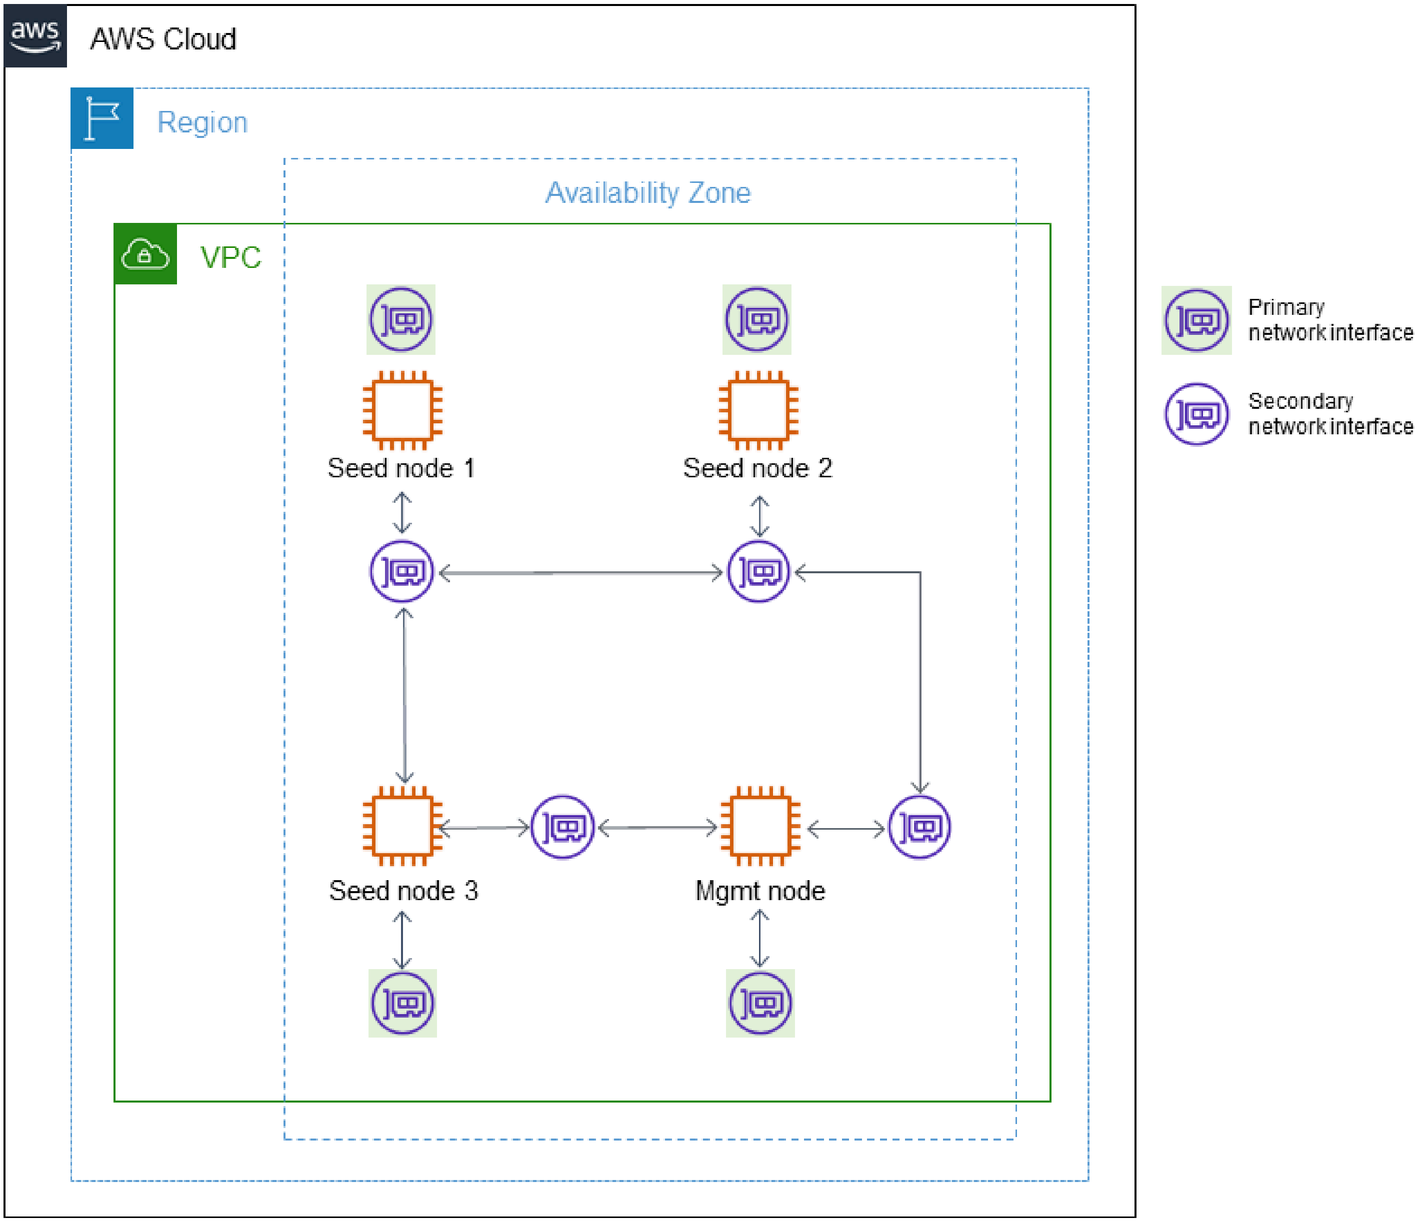
Source architecture

The source could be a Cassandra cluster on an on-premises virtual machine (VM) or on EC2 instances in the AWS Cloud. The following diagram illustrates the second scenario. This example includes four cluster nodes: three seed nodes and one management node. In the source architecture, each node has a single network interface attached.



Target architecture

The destination cluster is hosted on EC2 instances with a secondary elastic network interface attached to each node, as illustrated in the following diagram.



Automation and scale

You can also automate attaching a second elastic network interface to an EC2 Auto Scaling group, as described in an AWS Knowledge Center video.

Epics

Configure a Cassandra cluster on Amazon EC2

Task	Description	Skills required
Launch EC2 nodes to host a Cassandra cluster.	On the Amazon EC2 console, launch four EC2 instances for your Ubuntu nodes in your AWS account. Three (seed) nodes are used for the Cassandra cluster, and the fourth node acts as a cluster management node where you will install DataStax Enterprise (DSE) OpsCenter . For instructions, see the Amazon EC2 documentation.	Cloud engineer
Confirm node communica tions.	Make sure that the four nodes can communicate with one another over the database and cluster management ports.	Network engineer
Install DSE OpsCenter on the management node.	Install DSE OpsCenter 6.1 from the Debian package on the management node. For instructions, see the DataStax documentation.	DBA
Create a secondary network interface.	Cassandra generates a universal unique identifie r (UUID) for each node based on the IP address of the EC2 instance for that node. This UUID is used for distributing virtual nodes	Cloud Engineer

Task	Description	Skills required
	(vnodes) on the ring. When Cassandra is deployed on EC2 instances, IP addresses are assigned automatically to the instances as they are created. In the event of a planned or unplanned outage, the IP address for the new EC2 instance changes, the data distribution changes, and the entire ring has to be rebalanced. This is not desirable. To preserve the assigned IP address, use a [secondary elastic network interface]() with a fixed IP address. 1. On the [Amazon EC2 console](), choose **Network Interfaces**, **Create network interface**. 2. For **Subnet**, select the subnet that you created the EC2 instance in. 3. For **Private IPv4 address**, choose **Auto-assign**. 4. For **Security groups**, select a security group, and then choose **Create network interface**. For more information about creating a network interface	

Task	Description	Skills required
	, see the Amazon EC2 documentation.	
Attach the secondary network interface to cluster nodes.	1. On the Amazon EC2 console, choose **Instances**. 2. Select the checkbox for the EC2 instance you created earlier. 3. Choose **Actions**, **Networking**, **Attach network interface**. 4. Select the network interface you created in the previous step, and then choose **Attach**. For more information about attaching a network interface, see the Amazon EC2 documentation.	Cloud engineer

Task	Description	Skills required
Add routes in Amazon EC2 to address asymmetric routing.	When you attach the second network interface, the network will very likely perform asymmetric routing. To avoid this, you can add routes for the new network interfaces. For an in-depth explanati on and remediation of asymmetric routing, see the [AWS Knowledge Center video] or [Overcoming Asymmetri c Routing on Multi-Hom e Servers] (article in *Linux Journal* by Patrick McManus, April 5, 2004).	Network engineer
Update DNS entries to point to the secondary network interface IP.	Point the fully qualified domain name (FQDN) of the node to the IP of the secondary network interface.	Network engineer
Install and configure the Cassandra cluster by using DSE OpsCenter.	When the cluster nodes are ready with the secondary network interfaces, you can install and configure the Cassandra cluster.	DBA

Recover cluster from node failure

Task	Description	Skills required
Create an AMI for the cluster seed node.	Make a backup of the nodes so you can restore them with	Backup administrator

Task	Description	Skills required
	database binaries in case of node failure. For instructi ons, see Create an AMI in the Amazon EC2 documentation.	
Recover from node failure.	Replace the failed node with a new EC2 instance launched from the AMI, and attach the secondary network interface of the failed node.	Backup administrator
Verify that the Cassandra cluster is healthy.	When the replacement node is up, verify cluster health in DSE OpsCenter.	DBA

Extend VRFs to AWS by using AWS Transit Gateway Connect

Adam Till, Yashar Araghi, Vikas Dewangan, and Mohideen HajaMohideen, Amazon Web Services

Summary

Virtual routing and forwarding (VRF) is a feature of traditional networks. It uses isolated logical routing domains, in the form of route tables, to separate network traffic within the same physical infrastructure. You can configure AWS Transit Gateway to support VRF isolation when you connect your on-premises network to AWS. This pattern uses a sample architecture to connect on-premises VRFs to different transit gateway route tables.

This pattern uses transit virtual interfaces (VIFs) in AWS Direct Connect and transit gateway Connect attachments to extend the VRFs. A transit VIF is used to access one or more Amazon VPC transit gateways that are associated with Direct Connect gateways. A transit gateway Connect attachment connects a transit gateway with a third-party virtual appliance that is running in a VPC. A transit gateway Connect attachment supports the Generic Routing Encapsulation (GRE) tunnel protocol for high performance, and it supports Border Gateway Protocol (BGP) for dynamic routing.

The approach described in this pattern has the following benefits:

- Using Transit Gateway Connect, you can advertise up to 1,000 routes to the Transit Gateway Connect peer and receive up to 5,000 routes from it. Using the Direct Connect transit VIF feature without Transit Gateway Connect is limited to 20 prefixes per transit gateway.
- You can maintain the traffic isolation and use Transit Gateway Connect to provide hosted services on AWS, regardless of the IP address schemas your customers are using.
- The VRF traffic doesn't need to traverse a public virtual interface. This makes it easier to adhere to compliance and security requirements in many organizations.
- Each GRE tunnel supports up to 5 Gbps, and you can have up to four GRE tunnels per transit gateway Connect attachment. This is faster than many other connection types, such as AWS Site-to-Site VPN connections that support up to 1.25 Gbps.

Prerequisites and limitations

Prerequisites

- The required AWS accounts have been created (see the architecture for details)

- Permissions to assume an AWS Identity and Access Management (IAM) role in each account.
- The IAM roles in each account must have permissions to provision AWS Transit Gateway and AWS Direct Connect resources. For more information, see Authentication and access control for your transit gateways and see Identity and access management for Direct Connect.
- The Direct Connect connections have successfully been created. For more information, see Create a connection using the Connection wizard.

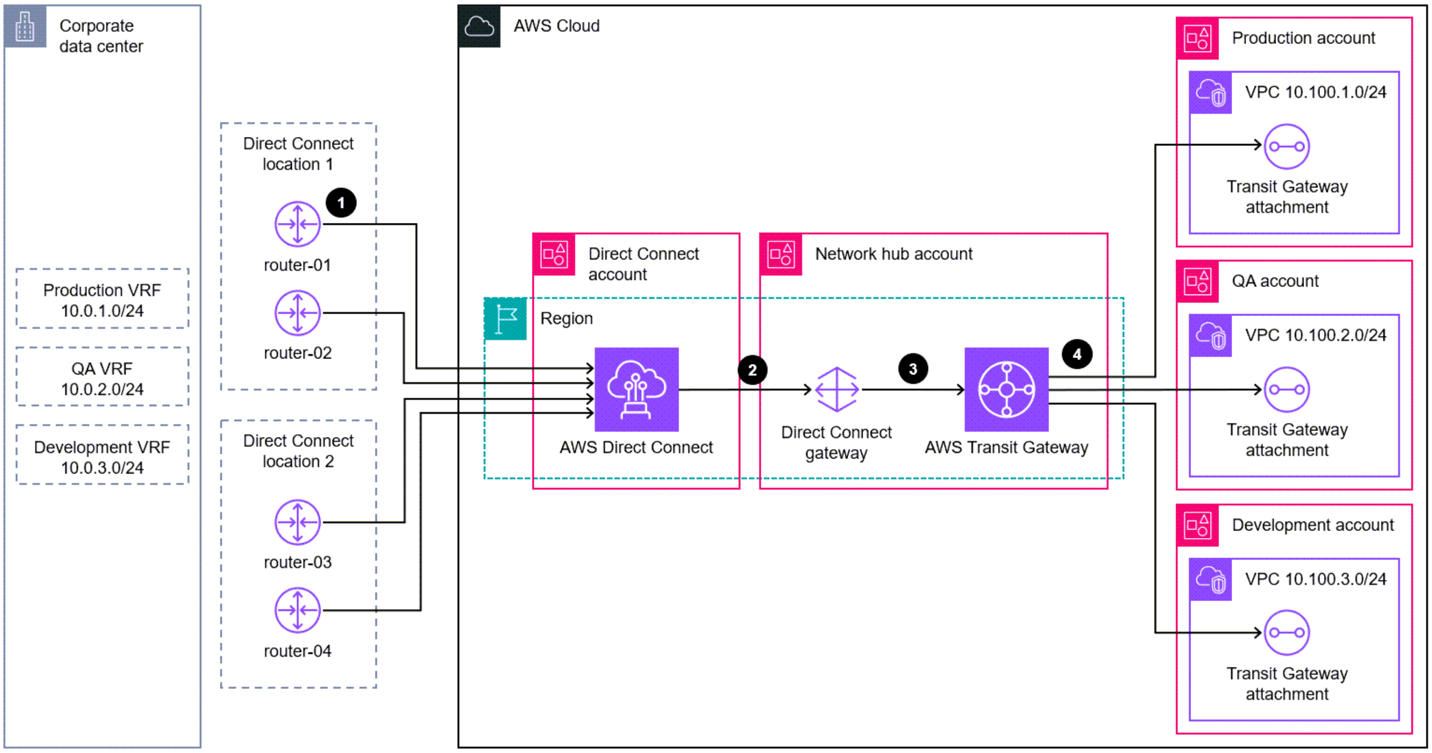
Limitations

- There are limits for transit gateway attachments to the VPCs in the production, QA, and development accounts. For more information, see Transit gateway attachments to a VPC.
- There are limits for creating and using Direct Connect gateways. For more information, see AWS Direct Connect quotas.

Architecture

Target architecture

The following sample architecture provides a reusable solution to deploy transit VIFs with transit gateway Connect attachments. This architecture provides resilience by using multiple Direct Connect locations. For more information, see Maximum resiliency in the Direct Connect documentation. The on-premises network has production, QA, and development VRFs that are extended to AWS and isolated by using dedicated route tables.

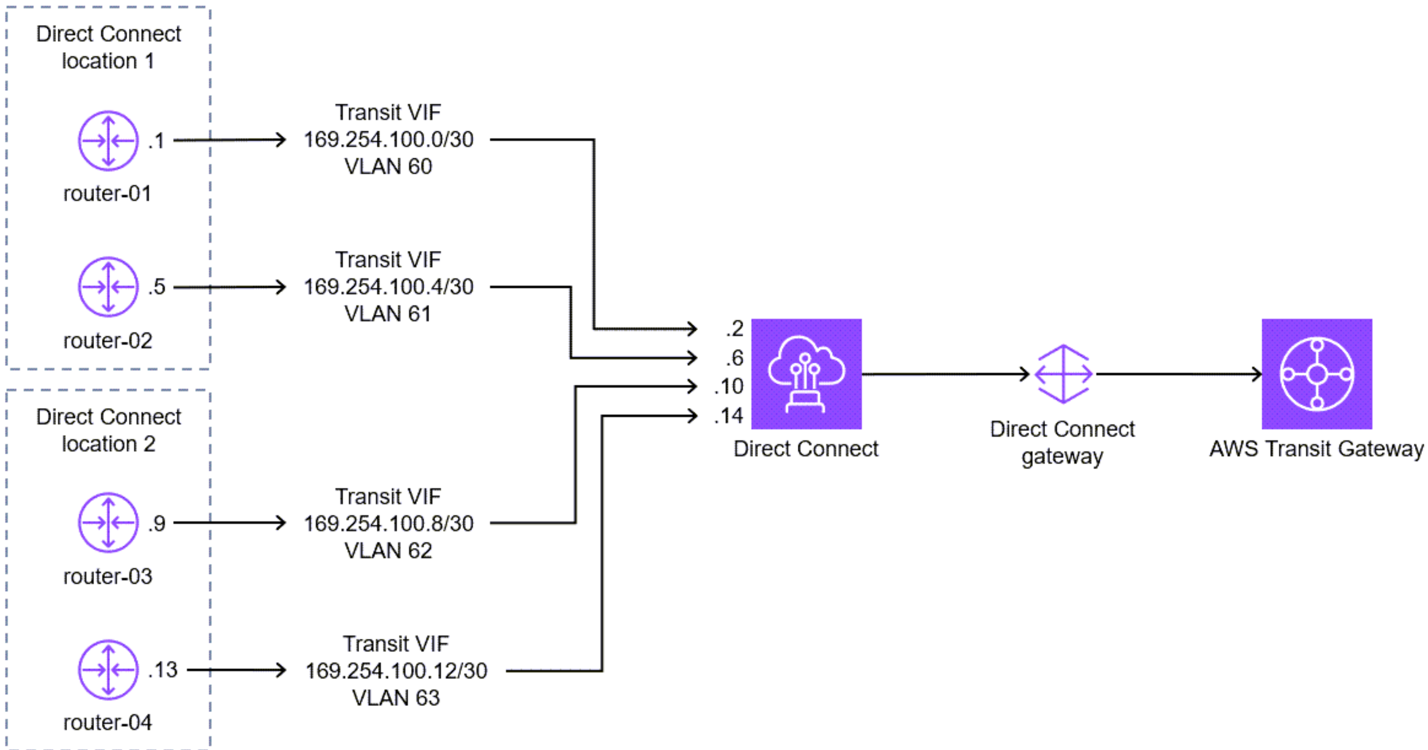


In the AWS environment, two accounts are dedicated to extending the VRFs: a *Direct Connect account* and a *network hub account*. The Direct Connect account contains the connection and the transit VIFs for each router. You create the transit VIFs from the Direct Connect account but deploy them to the network hub account so that you can associate them with the Direct Connect gateway in the network hub account. The network hub account contains the Direct Connect gateway and transit gateway. The AWS resources are connected as follows:

1. Transit VIFs connect the routers in the Direct Connect locations with AWS Direct Connect in the Direct Connect account.
2. A transit VIF connects Direct Connect with the Direct Connect gateway in the network hub account.
3. A transit gateway association connects the Direct Connect gateway with the transit gateway in the network hub account.
4. Transit gateway Connect attachments connect the transit gateway with the VPCs in the production, QA, and development accounts.

Transit VIF architecture

The following diagram shows the configuration details for the transit VIFs. This sample architecture uses a VLAN for the tunnel source, but you could also use a loopback.

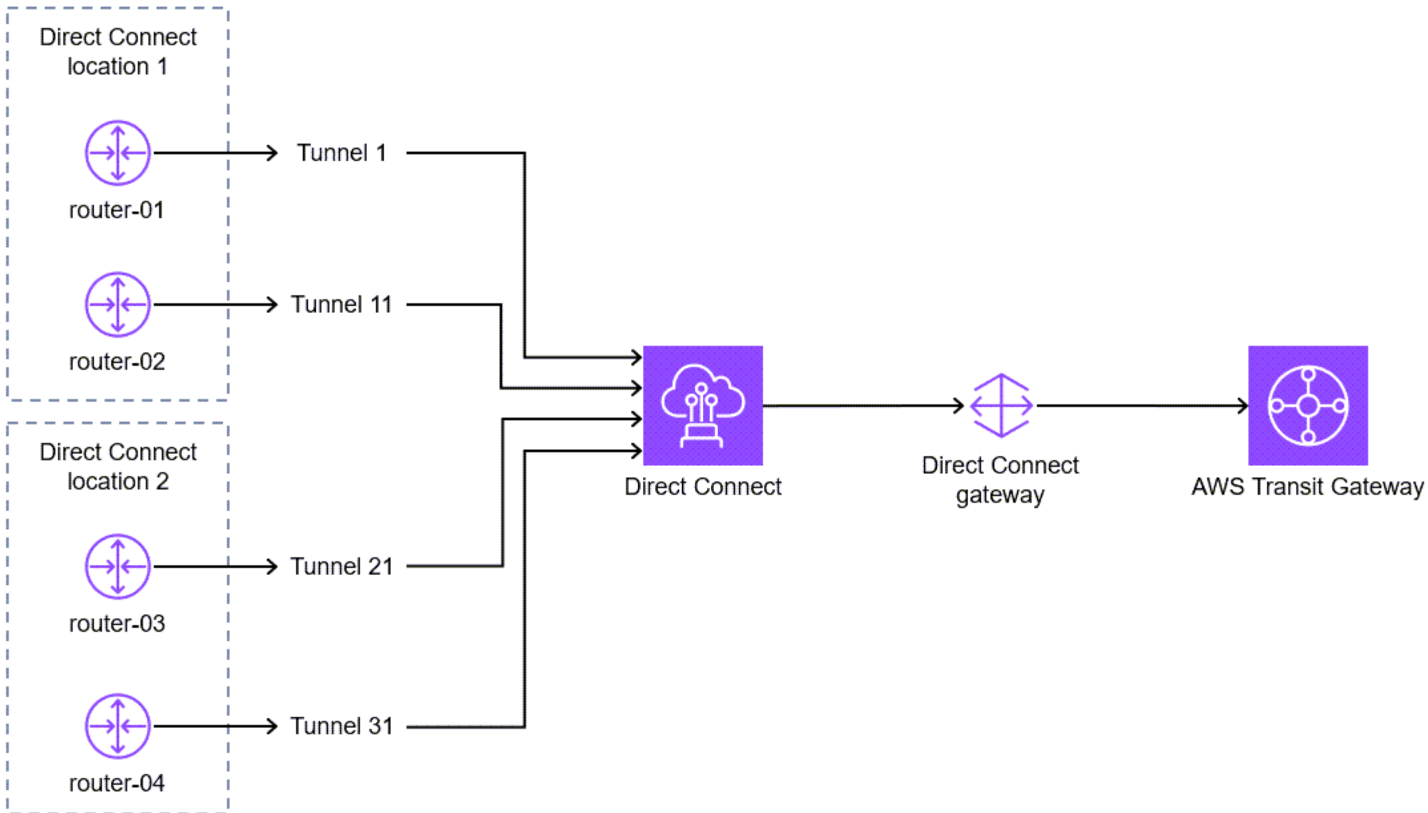


The following are the configuration details, such as autonomous system numbers (ASNs), for the transit VIFs.

Resource	Item	Detail
router-01	ASN	65534
router-02	ASN	65534
router-03	ASN	65534
router-04	ASN	65534
Direct Connect gateway	ASN	64601
Transit gateway	ASN	64600
	CIDR block	10.100.254.0/24

Transit gateway Connect architecture

The following diagram and tables describe how to configure a single VRF through a transit gateway Connect attachment. For additional VRFs, assign unique tunnel IDs, transit gateway GRE IP addresses, and BGP inside CIDR blocks. The peer GRE IP address matches the router peer IP address from the transit VIF.



The following table contains router configuration details.

Router	Tunnel	IP address	Source	Destination
router-01	Tunnel 1	169.254.101.17	VLAN 60 169.254.100.1	10.100.254.1
router-02	Tunnel 11	169.254.101.81	VLAN 61 169.254.100.5	10.100.254.11
router-03	Tunnel 21	169.254.1 01.145	VLAN 62	10.100.254.21

			169.254.100.9	
router-04	Tunnel 31	169.254.101.209	VLAN 63 169.254.100.13	10.100.254.31

The following table contains transit gateway configuration details.

Tunnel	Transit gateway GRE IP address	Peer GRE IP address	BGP inside CIDR blocks
Tunnel 1	10.100.254.1	VLAN 60 169.254.100.1	169.254.101.16/29
Tunnel 11	10.100.254.11	VLAN 61 169.254.100.5	169.254.101.80/29
Tunnel 21	10.100.254.21	VLAN 62 169.254.100.9	169.254.101.144/29
Tunnel 31	10.100.254.31	VLAN 63 169.254.100.13	169.254.101.208/29

Deployment

The Epics section describes how to deploy a sample configuration for a single VRF across multiple customer routers. After steps 1–5 are complete, you can create new transit gateway Connect attachments by using steps 6–7 for every new VRF that you're extending into AWS:

1. Create the transit gateway.
2. Create a Transit Gateway route table for each VRF.
3. Create the transit virtual interfaces.
4. Create the Direct Connect gateway.

5. Create the Direct Connect gateway virtual interface and gateway associations with allowed prefixes.
6. Create the transit gateway Connect attachment.
7. Create the Transit Gateway Connect peers.
8. Associate the transit gateway Connect attachment with the route table.
9. Advertise routes to the routers.

Tools

AWS services

- AWS Direct Connect links your internal network to a Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services while bypassing internet service providers in your network path.
- AWS Transit Gateway is a central hub that connects virtual private clouds (VPCs) and on-premises networks.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Plan the architecture

Task	Description	Skills required
Create custom architecture diagrams.	1. In the Attachments section, download the diagram template. 2. Open the attached diagram in Microsoft Office PowerPoint. 3. On the **Architecture overview** slide, customize the architecture diagram	Cloud architect, Network administrator

Task	Description	Skills required
	for your environment. Identify the on-premises VRFs that need to be extended into your AWS environment. 4. On the **Transit VIF** slide, customize the architecture diagram. Identify the AS numbers of the routers, the Direct Connect gateway, and the transit gateway. Identify the IP addresses at each end of the transit VIF. 5. On the **Transit Gateway Connect** slide, customize an architecture diagram for each VRF. Identify all required IP addresses necessary to configure the routers and the Transit Gateway Connect peers.	

Create the Transit Gateway resources

Task	Description	Skills required
Create the transit gateway.	1. Sign in to the network hub account. 2. Follow the instructions in [Create a transit gateway](). Note the following for this pattern:	Network administrator, Cloud architect

Task	Description	Skills required
	• For **Amazon side Autonomous System Number (ASN)**, enter a unique ASN. For the purposes of this example, the ASN is `64600`. • Select **DNS support**. • For this sample architecture, **VPN ECMP support**, **Default route table association**, **Default route table prorogation**, and **Multicast support** are not required. • For **Transit gateway CIDR blocks**, enter the IPv4 CIDR blocks for your transit gateway. For the purposes of this example, the CIDR block is `10.100.254.0/24` .	

Task	Description	Skills required
Create the transit gateway route table.	Follow the instructions in [Create a transit gateway route table](). Note the following for this pattern: • For **Name tag**, provide a name for the transit gateway route table. We recommend using a name that corresponds to the VRF, such as `routetable-dev-vrf` . • For **Transit gateway ID**, choose the transit gateway that you created previously.	Cloud architect, Network administrator

Create the transit virtual interfaces

Task	Description	Skills required
Create the transit virtual interfaces.	1. Sign in to the Direct Connect account. 2. Follow the instructions in [Create a transit virtual interface to the Direct Connect gateway](). Note the following for this pattern: • For **Virtual interface name**, enter a name for the transit VIF. We recommend using a name that corresponds to the router, such as	Cloud architect, Network administrator

Task	Description	Skills required

	`transit-vif-router 01` .
	• For **Connection**, select the router, such as `router-01` .
	• For **Virtual interface owner**, enter the account ID of the network hub account. For instructions, see [View your AWS account ID](#).
	• For **Direct Connect gateway**, do not make any selection. You attach the Direct Connect gateway in a subsequent step.
	• For **VLAN**, enter the VLAN of the router, such as `60`.
	• For **BGP ASN**, enter the ASN of the router, such as `65534`.
	• Under **Additional** Settings, do the following:
	  • Choose **IPv4**.
	  • For **Your router peer ip**, enter the router peer IP address, such as `169.254.100.1` .
	  • For **Amazon router peer ip**. enter the	

Task	Description	Skills required
	Amazon router peer IP, such as `169.254.100.2` . • For **BGP authentication key**, a password is required. If this is left blank, AWS creates a key that is only accessible in this account. 3. Repeat these instructions to create all transit VIFs for the VRF.	

Create the Direct Connect resources

Task	Description	Skills required
Create a Direct Connect gateway.	1. Sign in to the network hub account. 2. Follow the instructions in [Creating a Direct Connect gateway](). Note the following for this pattern: • For **Amazon side ASN**, enter the ASN of the Direct Connect gateway, such as `64601`. • Do not choose a virtual private gateway.	Cloud architect, Network administrator
Attach the Direct Connect gateway to the transit VIFs.	1. In the network hub account, open the AWS Direct Connect console	Cloud architect, Network administrator

Task	Description	Skills required
	at https://console.aws.amazon.com/directconnect/v2/. 2. In the navigation pane, choose **Virtual Interfaces**. 3. Select a new transit VIF, and then choose **Accept**. 4. Choose the Direct Connect gateway you created. 5. Repeat these instructions for each transit VIF.	
Create the Direct Connect gateway associations with allowed prefixes.	In the network hub account, follow the instructions in To associate a transit gateway. Note the following for this pattern: • For **Gateways**, choose the transit gateway you created previously. • For **Allowed prefixes**, enter the CIDR block assigned to the transit gateway, such as `10.100.254.0/24` . Creating this association automatically creates a Transit Gateway attachment that has a Direct Connect Gateway resource type. This attachment does not need to be associated with a transit gateway route table.	Cloud architect, Network administrator

Task	Description	Skills required
Create the transit gateway Connect attachment.	1. In the network hub account, open the Amazon VPC console at https://console.aws.amazon.com/vpc/. 2. In the navigation pane, choose **Transit gateway attachments**. 3. Choose **Create transit gateway attachment**. 4. For **Name tag**, enter a name for the attachmen t. We recommend using a name that corresponds to the VRF, such as `PROD-VRF`. 5. For **Transit gateway ID**, choose the transit gateway you created previously. 6. For **Attachment type**, choose **Connect**. 7. For **Transport attachmen t ID**, choose the Direct Connect gateway you created previously. 8. Choose **Create transit gateway attachment**. 9. Repeat this step for each VRF that you are extending .	Cloud architect, Network administrator

Task	Description	Skills required
Create the Transit Gateway Connect peers.	1. In the network hub account, follow the instructions in [Create a Transit Gateway Connect peer (GRE tunnel)](). Note the following for this pattern: • For **Name tag**, enter a name for the Transit Gateway Connect peer. We recommending using a name that corresponds with the router, such as `connectpeer-router 01` . • For **Transit gateway GRE address**, enter the assigned IP address from the transit gateway CIDR block, such as `10.100.254.1` . • For **Peer GRE address**, enter the IP address assigned to the VLAN created on the router for the transit VIF, such as `169.254.1 00.1` . Provided that AWS can reach the IP address, you can use any interface, such as VLAN or Loopback, for the peer GRE address. • For **BGP Inside CIDR Blocks (IPv4)**, enter	

Task	Description	Skills required
	the BGP inside CIDR block IP address, such as `169.254.101.16/29` . • For **Peer ASN**, enter the ASN of the router, such as `65534`. 2. Repeat these instructions to create a GRE tunnel for each router.	

Advertise routes to the routers

Task	Description	Skills required
Advertise the routes.	Associate the new transit gateway Connect attachmen t with the route table you created previously for this VRF. For example, associate the production transit gateway Connect attachment with the `Production-VRF` route table. Create a static route for the prefix that is advertised to the routers. 1. Sign in to the network hub account. 2. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.	Network administrator, Cloud architect

Task	Description	Skills required
	3. In the navigation pane, under **Transit Gateways**, choose **Transit gateway route tables**. 4. Select the `Production-VRF` route table. 5. On the **Actions** menu, choose **Create static route**. 6. For **CIDR**, enter the CIDR block for the advertise d route to the transit gateway attachment in the target VPC, such as `10.100.1.0/24` . 7. For **Choose Attachmen t**, choose the relevant transit gateway Connect attachment. 8. Choose **Create static route**.

Get Amazon SNS notifications when the key state of an AWS KMS key changes

Shubham Harsora, Aromal Raj Jayarajan, and Navdeep Pareek, Amazon Web Services

Summary

The data and metadata associated with an AWS Key Management Service (AWS KMS) key is lost when that key is deleted. The deletion is irreversible and you can't recover lost data (including encrypted data). You can prevent data loss by setting up a notification system to alert you of status changes to [key states](#) of your AWS KMS keys.

This pattern shows you how to monitor status changes to AWS KMS keys by using Amazon EventBridge and Amazon Simple Notification Service (Amazon SNS) to issue automated notifications whenever the key state of an AWS KMS key changes to `Disabled` or `PendingDeletion`. For example, if a user tries to disable or delete an AWS KMS key, you will receive an email notification with details about the attempted status change. You can also use this pattern to schedule the deletion of AWS KMS keys.

Prerequisites and limitations

Prerequisites

- An active AWS account with an AWS Identity and Access Management (IAM) user
- An [AWS KMS key](#)

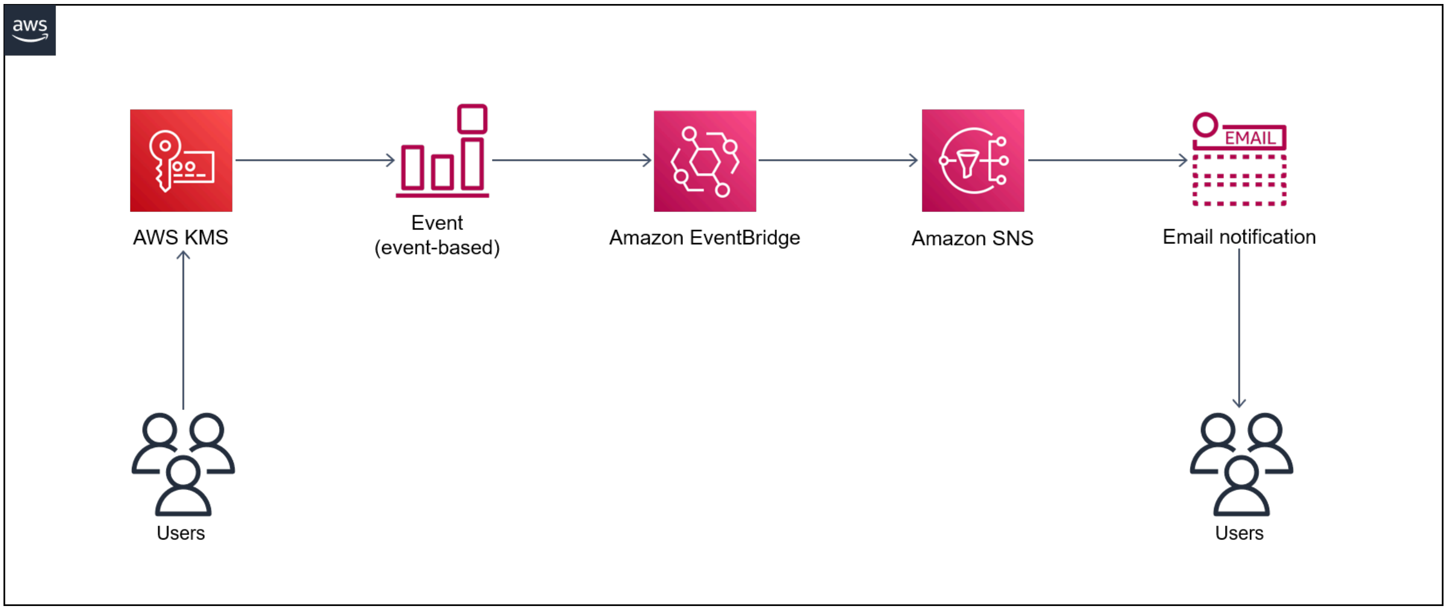
Architecture

Technology stack

- Amazon EventBridge
- AWS Key Management Service (AWS KMS)
- Amazon Simple Notification Service (Amazon SNS)

Target architecture

The following diagram shows an architecture for building an automated monitoring and notification process for detecting any changes to the state of an AWS KMS key.



The diagram shows the following workflow:

1. A user disables or schedules the deletion of an AWS KMS key.
2. An EventBridge rule evaluates the scheduled `Disabled` or `PendingDeletion` event.
3. The EventBridge rule invokes the Amazon SNS topic.
4. Amazon SNS sends an email notification message to the users.

> **Note**
>
> You can customize the email message to meet your organization's needs. We recommend including information about the entities where the AWS KMS key is used. This can help users understand the impact of deleting the AWS KMS key. You can also schedule a reminder email notification that's sent one or two days before the AWS KMS key is deleted.

Automation and scale

The AWS CloudFormation stack deploys all the necessary resources and services for this pattern to work. You can implement the pattern independently in a single account, or by using [AWS CloudFormation StackSets] for multiple independent accounts or [organizational units] in AWS Organizations.

Tools

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and AWS Regions. The CloudFormation template for this pattern describes all the AWS resources that you want, and CloudFormation provisions and configures those resources for you.
- Amazon EventBridge is a serverless event bus service that helps you connect your applications with real-time data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications and AWS services, and it routes that data to targets such as AWS Lambda. EventBridge simplifies the process of building event-driven architectures.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

Code

The code for this pattern is available in the GitHub Monitor AWS KMS keys disable and scheduled deletion repository.

Epics

Deploy the CloudFormation template

Task	Description	Skills required
Clone the repository.	Clone the GitHub Monitor AWS KMS keys disable and scheduled deletion repository to your local machine by running the following command: `git clone https://github.com/aws-samp`	AWS administrator, Cloud architect

Task	Description	Skills required
	`les/aws-kms-deletion-notification`	
Update the template's parameters.	In a code editor, open the `Alerting-KMS-Events.yaml` CloudFormation template that you cloned from the repository, and then update the following parameters: • For `DestinationEmailAddress` , enter an active email address that you plan to use for receiving the SNS notification. • For `SNSTopicName` , enter a name for your SNS topic.	AWS administrator, Cloud architect

Task	Description	Skills required
Deploy the CloudFormation template.	1. Sign in to the AWS Management Console and open the [CloudFormation console](). 2. In the navigation pane, choose **Create stack**, and then choose **With new resources (standard)**. 3. On the **Identify resources** page, choose **Next**. 4. On the **Specify template** page, for **Template source**, select **Upload a template file**. 5. Choose **Choose file**, select the `Alerting-KMS-Events.yaml` file from your cloned GitHub repository, and then choose **Next**. 6. For **Stack name**, enter your stack name. 7. Choose **Submit**.	AWS administrator, Cloud architect

Confirm the subscription

Task	Description	Skills required
Confirm the subscription email.	After the CloudFormation template successfully deploys, Amazon SNS sends a subscription confirmation message to the email address	AWS administrator, Cloud architect

Task	Description	Skills required
	that you provided in the CloudFormation template. To receive notifications, you must confirm this email subscription. For more information, see Confirm the subscription in the Amazon SNS Developer Guide.	

Test the subscription notification

Task	Description	Skills required
Disable AWS KMS keys.	1. Sign in to the AWS Management Console and open the AWS KMS console. 2. To change the Region, choose the name of the currently displayed Region, and then choose the Region to which you want to switch. 3. In the navigation pane, choose **Customer managed keys**. 4. Select the check box for the AWS KMS key that you want to enable or disable. 5. To disable the AWS KMS key, choose **Key actions**, and then choose **Disable**.	AWS administrator

Task	Description	Skills required
Validate the subscription.	Confirm that you received the Amazon SNS notification email.	AWS administrator

Clean up resources

Task	Description	Skills required
Delete the CloudFormation stack.	1. Sign in to the AWS Management Console and open the [CloudFormation console](). 2. In the navigation pane, choose **Stacks**. 3. Select that stack that you created previously, and then choose **Delete**.	AWS administrator

Related resources

- AWS CloudFormation (AWS documentation)
- Creating a stack on the AWS CloudFormation console (AWS CloudFormation documentation)
- Building event-driven architectures on AWS (AWS Workshop Studio documentation)
- AWS Key Management Service Best Practices (AWS Whitepaper)

Additional information

Amazon SNS provides in-transit encryption by default. To align with security best practices, you can also enable server-side encryption for Amazon SNS by using an AWS KMS customer managed key.

Preserve routable IP space in multi-account VPC designs for non-workload subnets

Adam Spicer, Amazon Web Services

Summary

Amazon Web Services (AWS) has published best practices that recommend using dedicated subnets in a virtual private cloud (VPC) for both transit gateway attachments and Gateway Load Balancer endpoints (to support AWS Network Firewall or third-party appliances). These subnets are used to contain elastic network interfaces for these services. If you use both AWS Transit Gateway and a Gateway Load Balancer, two subnets are created in each Availability Zone for the VPC. Because of the way VPCs are designed, these extra subnets can't be smaller than a /28 mask and can consume precious routable IP space that could otherwise be used for routable workloads. This pattern demonstrates how you can use a secondary, non-routable Classless Inter-Domain Routing (CIDR) range for these dedicated subnets to help preserve routable IP space.

Prerequisites and limitations

Prerequisites

- Multi-VPC strategy for routable IP space
- A non-routable CIDR range for the services you're using (transit gateway attachments and Gateway Load Balancer or Network Firewall endpoints)

Architecture

Target architecture

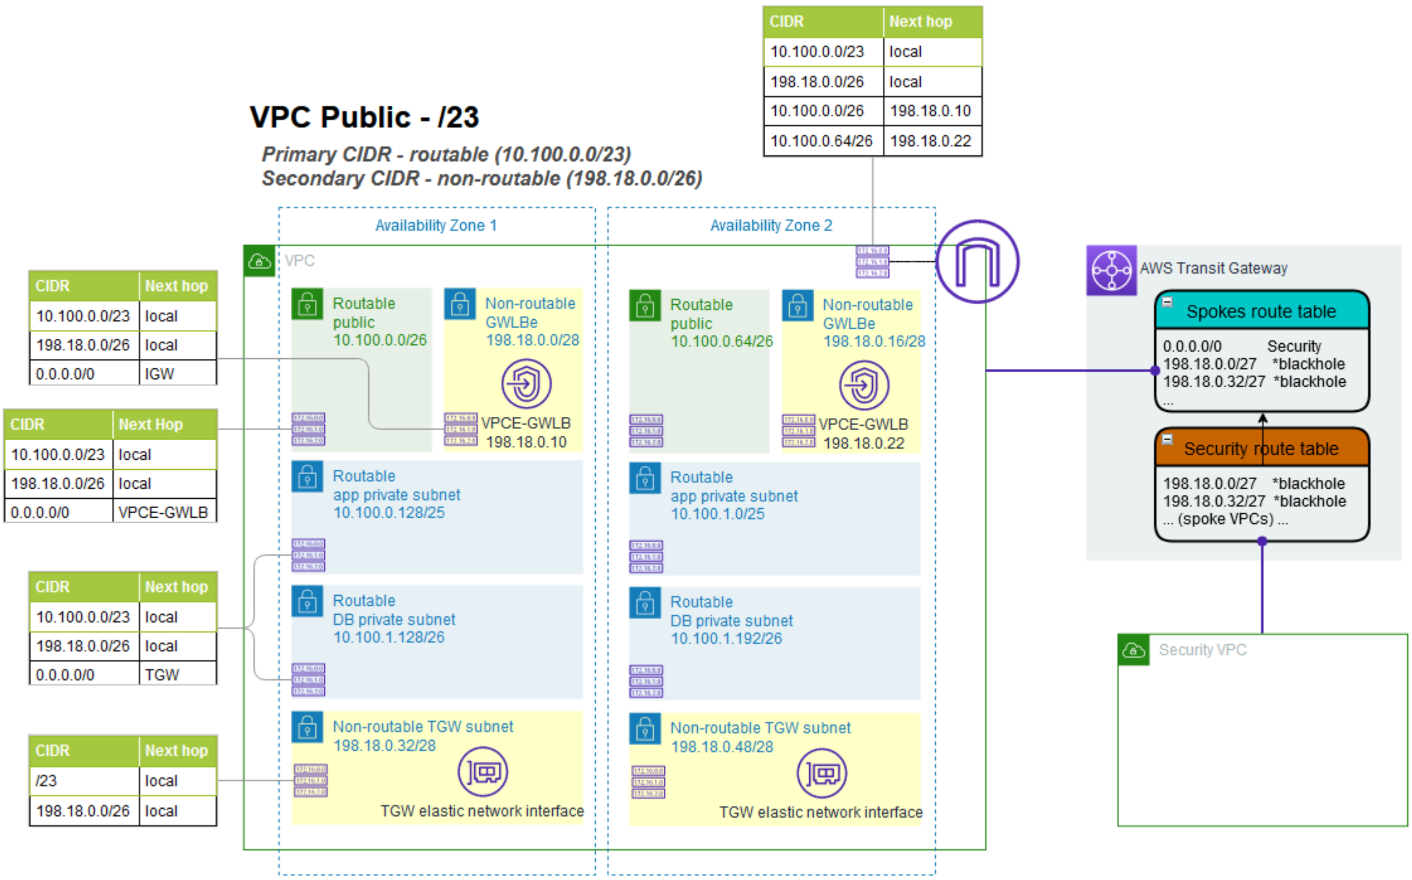
This pattern includes two reference architectures: one architecture has subnets for transit gateway (TGW) attachments and a Gateway Load Balancer endpoint (GWLBe), and the second architecture has subnets for TGW attachments only.

Architecture 1 ‒ TGW-attached VPC with ingress routing to an appliance

The following diagram represents a reference architecture for a VPC that spans two Availability Zones. On ingress, the VPC uses an ingress routing pattern to direct traffic destined for the public subnet to a bump-in-the-wire appliance for firewall inspection. A TGW attachment supports egress from the private subnets to a separate VPC.

This pattern uses a non-routable CIDR range for the TGW attachment subnet and the GWLBe subnet. In the TGW routing table, this non-routable CIDR is configured with a blackhole (static) route by using a set of more specific routes. If the routes were to get propagated to the TGW routing table, these more specific blackhole routes would apply.

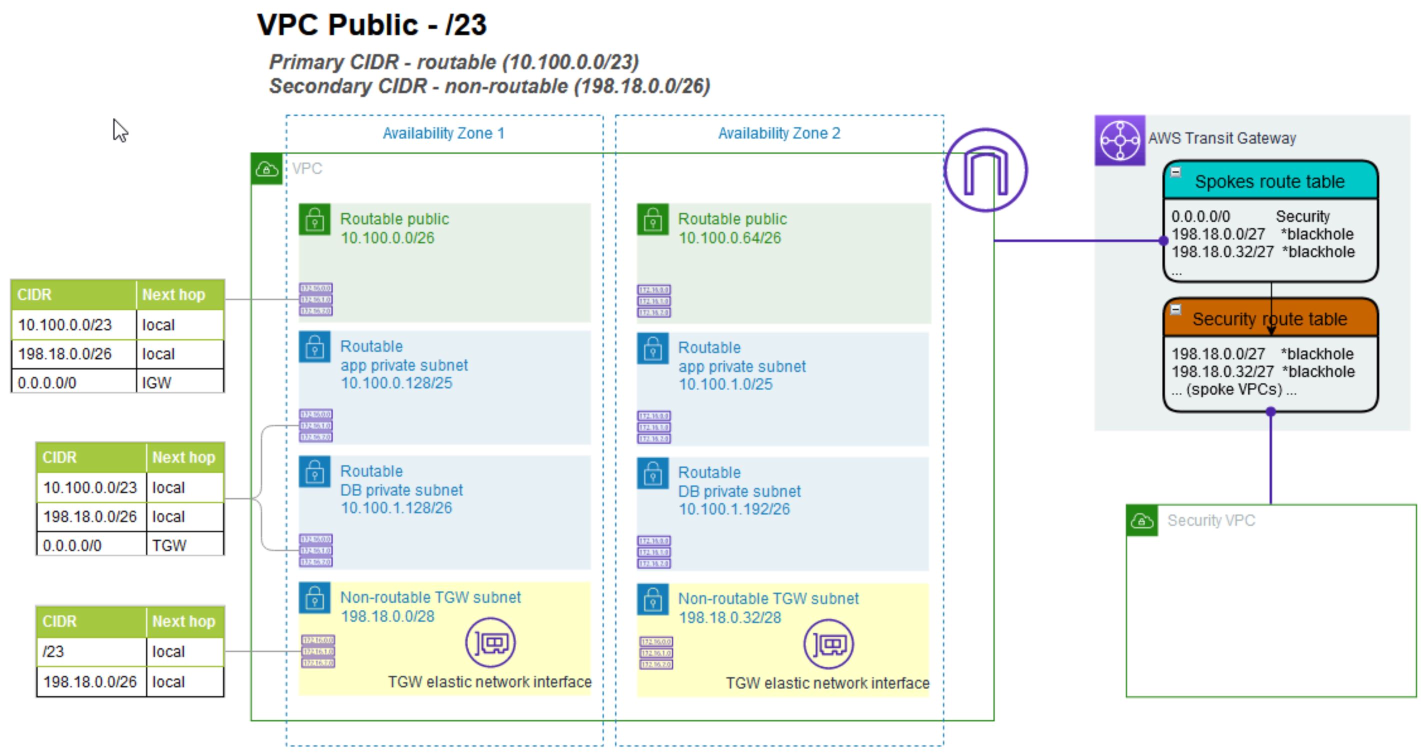
In this example, the /23 routable CIDR is divided up and fully allocated to routable subnets.



Architecture 2 – TGW-attached VPC

The following diagram represents another reference architecture for a VPC that spans two Availability Zones. A TGW attachment supports outbound traffic (egress) from the private subnets to a separate VPC. It uses a non-routable CIDR range only for the TGW attachments subnet. In the TGW routing table, this non-routable CIDR is configured with a blackhole route by using a set of more specific routes. If the routes were to get propagated to the TGW routing table, these more specific blackhole routes would apply.

In this example, the /23 routable CIDR is divided up and fully allocated to routable subnets.



Tools

AWS services and resources

- [Amazon Virtual Private Cloud (Amazon VPC)](#) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. In this pattern, VPC secondary CIDRs are used to preserve routable IP space in workload CIDRs.
- [Internet gateway ingress routing](#) (edge associations) can be used along with Gateway Load Balancer endpoints for dedicated non-routable subnets.
- [AWS Transit Gateway](#) is a central hub that connects VPCs and on-premises networks. In this pattern, VPCs are centrally attached to a transit gateway, and the transit gateway attachments are in a dedicated non-routable subnet.
- [Gateway Load Balancers](#) help you deploy, scale, and manage virtual appliances, such as firewalls, intrusion detection and prevention systems, and deep packet inspection systems. The gateway serves as a single entry and exit point for all traffic. In this pattern, endpoints for a Gateway Load Balancer can be used in a dedicated non-routable subnet.

- [AWS Network Firewall](#) is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud. In this pattern, endpoints for an firewall can be used in a dedicated non-routable subnet.

Code repository

A runbook and AWS CloudFormation templates for this pattern are available in the GitHub Non-Routable Secondary CIDR Patterns repository. You can use the sample files to set up a working lab in your environment.

Best practices

AWS Transit Gateway

- Use a separate subnet for each transit gateway VPC attachment.
- Allocate a /28 subnet from the secondary non-routable CIDR range for the transit gateway attachment subnets.
- In each transit gateway routing table, add a static, more specific route for the non-routable CIDR range as a blackhole.

Gateway Load Balancer and ingress routing

- Use ingress routing to direct traffic from the internet to the Gateway Load Balancer endpoints.
- Use a separate subnet for each Gateway Load Balancer endpoint.
- Allocate a /28 subnet from the secondary non-routable CIDR range for the Gateway Load Balancer endpoint subnets.

Epics

Create VPCs

Task	Description	Skills required
Determine non-routable CIDR range.	Determine a non-routable CIDR range that will be used for the transit gateway attachment subnet and	Cloud architect

Task	Description	Skills required
	(optionally) for any Gateway Load Balancer or Network Firewall endpoint subnets. This CIDR range will be used as the secondary CIDR for the VPC. It must **not be routable** from the VPC's primary CIDR range or the larger network.	
Determine routable CIDR ranges for VPCs.	Determine a set of routable CIDR ranges that will be used for your VPCs. This CIDR range will be used as the primary CIDR for your VPCs.	Cloud architect
Create VPCs.	Create your VPCs and attach them to the transit gateway. Each VPC should have a primary CIDR range that is routable and a secondary CIDR range that is non-routa ble, based on the ranges you determined in the previous two steps.	Cloud architect

Configure Transit Gateway blackhole routes

Task	Description	Skills required
Create more specific non-routable CIDRs as blackholes.	Each transit gateway routing table needs to have a set of blackhole routes created for the non-routable CIDRs. These are configured to ensure that any traffic from	Cloud architect

Task	Description	Skills required
	the secondary VPC CIDR remains non-routable and doesn't leak into the larger network. These routes should be more specific than the non-routable CIDR that is set as the secondary CIDR on the VPC. For example, if the secondary non-routa ble CIDR is 100.64.0.0/26, the blackhole routes in the transit gateway routing table should be 100.64.0.0/27 and 100.64.0.32/27.	

Related resources

- Best practices for deploying Gateway Load Balancer
- Distributed Inspection Architectures with Gateway Load Balancer
- Networking Immersion Day – Internet to VPC Firewall Lab
- Transit gateway design best practices

Additional information

The non-routable secondary CIDR range can also be useful when working with larger scaled container deployments that require a large set of IP addresses. You can use this pattern with a private NAT Gateway to use a non-routable subnet to host your container deployments. For more information, see the blog post How to solve Private IP exhaustion with Private NAT Solution.

Provision a Terraform product in AWS Service Catalog by using a code repository

Dr. Rahul Sharad Gaikwad and Tamilselvan P, Amazon Web Services

Summary

AWS Service Catalog supports self-service provisioning with governance for your HashiCorp Terraform configurations. If you use Terraform, you can use Service Catalog as the single tool to organize, govern, and distribute your Terraform configurations within AWS at scale. You can access Service Catalog key features, including cataloging of standardized and pre-approved infrastructure as code (IaC) templates, access control, cloud resources provisioning with least privilege access, versioning, sharing to thousands of AWS accounts, and tagging. End users, such as engineers, database administrators, and data scientists, see a list of products and versions they have access to, and they can deploy them through a single action.

This pattern helps you deploy AWS resources by using Terraform code. The Terraform code in the GitHub repository is accessed through Service Catalog. Using this approach, you integrate the products with your existing Terraform workflows. Administrators can create Service Catalog portfolios and add AWS Launch Wizard products to them by using Terraform.

The following are the benefits of this solution:

- Because of the rollback feature in Service Catalog, if any issues occur during deployment, you can revert the product to a previous version.
- You can easily identify the differences between product versions. This helps you resolve issues during deployment.
- You can configure a repository connection in Service Catalog, such as to GitHub or GitLab. You can make product changes directly through the repository.

For information about the overall benefits of AWS Service Catalog, see What is Service Catalog.

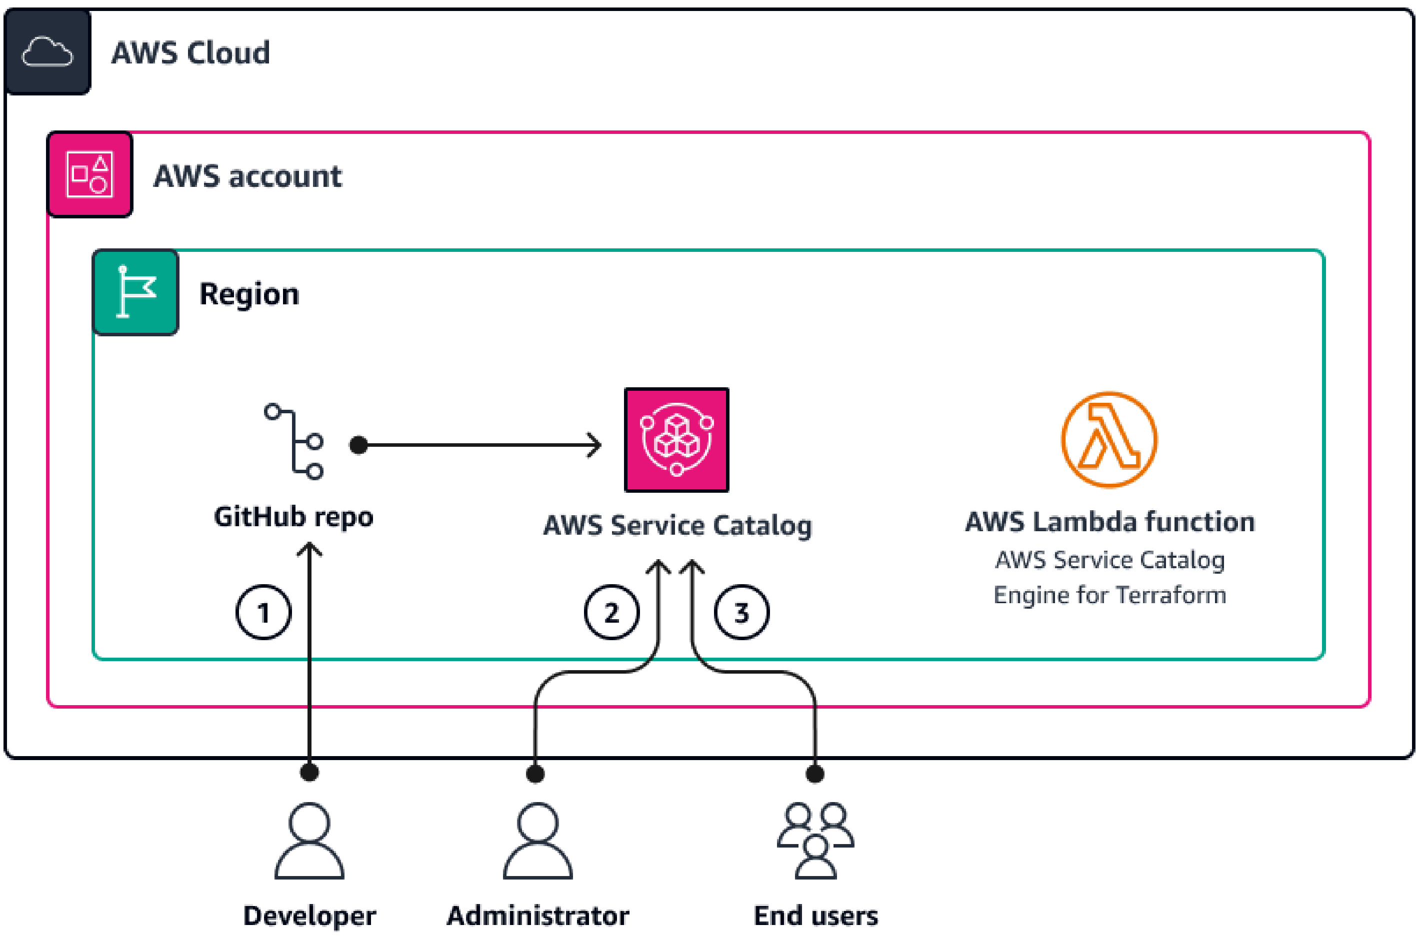
Prerequisites and limitations

Prerequisites

- An active AWS account.
- A GitHub, BitBucket, or other repository that contains Terraform configuration files in ZIP format.

- AWS Serverless Application Model Command Line Interface (AWS SAM CLI), installed.
- AWS Command Line Interface (AWS CLI), installed and configured.
- Go, installed.
- Python version 3.9 , installed. AWS SAM CLI requires this version of Python.
- Permissions to write and run AWS Lambda functions and permissions to access and manage Service Catalog products and portfolios.

Architecture



The diagram shows the following workflow:

1. When a Terraform configuration is ready, a developer creates a .zip file that contains all of the Terraform code. The developer uploads the .zip file into the code repository that is connected to Service Catalog.

2. An administrator associates the Terraform product to a portfolio in Service Catalog. The administrator also creates a launch constraint that allows end users to provision the product.
3. In Service Catalog, end users launch AWS resources by using the Terraform configuration. They can choose which product version to deploy.

Tools

AWS services

- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Service Catalog helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

Other services

- Go is an open source programming language that Google supports.
- Python is a general-purpose computer programming language.

Code repository

If you require sample Terraform configurations that you can deploy through Service Catalog, you can use the configurations in the GitHub Amazon Macie Organization Setup Using Terraform repository. Use of the code samples in this repository is not required.

Best practices

- Instead of providing the values for variables in the Terraform configuration file (`terraform.tfvars`), configure variable values when launching product through Service Catalog.
- Grant access to the portfolio only to specific users or administrators.
- Follow the principle of least privilege and grant the minimum permissions required to perform a task. For more information, see Grant least privilege and Security best practices in the AWS Identity and Access Management (IAM) documentation.

Epics

Set up your local workstation

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>(Optional) Install Docker.</td><td>If you want to run the AWS Lambda functions in your development environment, install Docker. For instructions, see Install Docker Engine in the Docker documentation.</td><td>DevOps engineer</td></tr>
<tr><td>Install the AWS Service Catalog Engine for Terraform.</td><td>1. Enter the following command to clone the AWS Service Catalog Engine for Terraform repository.
<pre>git clone https://github.com/aws-samples/service-catalog-engine-for-terraform-os.git</pre>2. Navigate to the the root directory of the cloned repository.
3. Enter the following command. This installs the engine.
<pre>run ./bin/bash/deploy-tre.sh -r</pre>The AWS Region set in your default profile is not used during the automated</td><td>DevOps engineer, AWS administrator</td></tr>
</table>

Task	Description	Skills required
	installation. Instead, you provide the Region when you run this command.	

Connect the GitHub repository

Task	Description	Skills required
Create a connection to the GitHub repository.	1. Sign in to the AWS Management Console, and then open the **Developer Tools** console. You can access the Developer Tools console by choosing a service such as AWS CodePipeline or AWS CodeDeploy. 2. In the left navigation pane, choose **Settings**, and then choose **Connections**. 3. Choose **Create connection**. 4. Select the repository where you maintain the Terraform source code. For example, you can choose **Bitbucket**, **GitHub**, or **GitHub Enterprise Server**. 5. Enter a name for the connection, and then choose **Connect**. 6. When you are prompted, authenticate the repositor y.	AWS administrator

Task	Description	Skills required
	After authentication is complete, the connection is created and the status changes to **active**.	

Create a Terraform product in Service Catalog

Task	Description	Skills required
Create the Service Catalog product.	1. Open the [AWS Service Catalog console](https://console.aws.amazon.com/servicecatalog/). 2. Navigate to the **Administration** section, and then choose **Product list**. 3. Choose **Create product**. 4. On the **Create product** page in the **Product details** section, choose the **External** product type. Service Catalog uses this product type to support Terraform Community Edition products. 5. Enter a name and owner for the Service Catalog product. 6. Select **Specify your code repository using a CodeStar provider**. 7. Enter the following information for your repository:	AWS administrator

Task	Description	Skills required
	Connect to your provider using AWS CodeConnections – Select the connection you created previously. **Repository –** Select the repository. **Branch –** Select the branch. **Template file path –** Choose the path where the code template file is stored. The file name should end with `tar.gz`. 8. Under **Version name and description**, provide information about the product version. 9. Choose **Create product**.	

Task	Description	Skills required
Create a portfolio.	1. Open the [AWS Service Catalog console](). 2. Navigate to the **Administr ation** section, and then choose, choose **Portfolios**. 3. Choose **Create portfolio**. 4. Enter the following values: • **Portfolio name** – `Sample terraform` • **Portfolio description** – `Sample portfolio for Terraform configurations` • **Owner** – Your contact information, such as an email address 5. Choose **Create**.	AWS administrator

Task	Description	Skills required
Add the Terraform product to the portfolio.	1. Open the [AWS Service Catalog console](). 2. Navigate to the **Administr ation** section, and then choose **Product list**. 3. Select the Terraform product that you created previously. 4. Choose **Actions**, and then choose **Add product to portfolio**. 5. Choose the `Sample terraform` portfolio. 6. Choose **Add product to portfolio**.	AWS administrator

Task	Description	Skills required
Create the access policy.	1. Open the [AWS Identity and Access Management (IAM) console](). 2. In the navigation pane, choose **Policies**. 3. In the content pane, choose **Create policy**. 4. Choose the **JSON** option. 5. Enter the sample JSON policy in *Access policy* in the [Additional information]() section of this pattern. 6. Choose **Next**. 7. On the **Review and create** page, in the **Policy name** box, enter `TerraformResourceCreationAndArtifactAccessPolicy` . 8. Choose **Create policy**.	AWS administrator

Task	Description	Skills required
Create a custom trust policy.	1. Open the IAM console. 2. In the navigation pane, choose **Roles**. 3. Choose **Create role**. 4. Under **Trusted entity type**, choose **Custom trust policy**. 5. In the JSON policy editor, enter the sample JSON policy in *Trust policy* in the Additional information section of this pattern. 6. Choose **Next**. 7. Under **Permissions policies**, choose the `TerraformResourceCreationAndArtifactAccessPolicy` that you previously created. 8. Choose **Next**. 9. Under **Role details**, in the **Role name** box, enter `SCLaunch-product` . **Important** The role name must begin with `SCLaunch`. 10. Choose **Create role**.	AWS administrator

Task	Description	Skills required
Add a launch constraint to the Service Catalog product.	1. Sign in to the AWS Management Console as a user with administrative permissions. 2. Open the [AWS Service Catalog console](https://console.aws.amazon.com/servicecatalog/). 3. In the navigation pane, choose **Portfolios**. 4. Choose the portfolio that you created previously. 5. On the **Portfolio details** page, choose the **Constraints** tab, and then choose **Create constraint**. 6. For **Product**, select the Terraform product you created previously. 7. Under **Launch constraint**, for **Method**, choose **Enter role name**. 8. In the **Role name** box, enter `SCLaunch-product` . 9. Choose **Create**.	AWS administrator

Task	Description	Skills required
Grant access to the product.	1. Open the [AWS Service Catalog console](). 2. In the navigation pane, choose **Portfolios**. 3. Choose the portfolio that you created previously. 4. Choose the **Access** tab, and then choose **Grant access**. 5. Choose the **Roles** tab, and then select the role that should have access to deploy this product. 6. Choose **Grant Access**.	AWS administrator
Launch the product.	1. Sign in to the AWS Management Console as a user with permissions to deploy the Service Catalog product. 2. Open the [AWS Service Catalog console](). 3. In the navigation pane, choose **Products**. 4. Choose the produce you created previously, and then choose **Launch product**. 5. Enter a product name and define any required parameters. 6. Choose **Launch product**.	DevOps engineer

Verify the deployment

Task	Description	Skills required
Validate the deployment.	There are two AWS Step Functions state machines for the Service Catalog provisioning workflow: • `ManageProvisionedProductStateMachine` – Service Catalog invokes this state machine when provisioning a new Terraform product and when updating an existing Terraform provisioned product. • `TerminateProvisionedProductStateMachine` – Service Catalog invokes this state machine when terminating an existing Terraform provisioned product. You check the logs for the `ManageProvisionedProductStateMachine` state machine to confirm that the product was provisioned. 1. Sign in to the AWS Management Console, and then open the [AWS Step Functions console](https://console.aws.amazon.com/states/home).	DevOps engineer

Task	Description	Skills required
	2. In the left navigation pane, choose **State machines**. 3. Choose `ManageProvisionedProductStateMachine` . 4. In the **Executions** list, enter the provisioned product ID to locate the execution. **Note** The state file backend bucket names start with `sc-terraform-engine-state-`. 5. Validate that all the required resources have been created in the account.	

Clean up infrastructure

Task	Description	Skills required
Delete provisioned products.	1. Sign in to the AWS Management Console as a user with permissions to deploy the Service Catalog product. 2. Open the [AWS Service Catalog console]().	DevOps engineer

Task	Description	Skills required
	3. In the left navigation, choose **Provisioned products**. 4. Select the product you created. 5. In the **Actions** list, choose **Terminate**. 6. In the confirmation text box, enter `terminate`, and then choose **Terminate provisioned product**. 7. Repeat these steps to terminate all provisioned products.	

Task	Description	Skills required
Remove the AWS Service Catalog Engine for Terraform.	1. Sign in to the AWS Management Console as a user with administrative permissions. 2. Open the [Amazon Simple Storage Service (Amazon S3) console](https://console.aws.amazon.com/s3/). 3. In the navigation pane, choose **Buckets**. 4. Select the `sc-terraform-engine-logging-XXXX` bucket. 5. Choose **Empty**. 6. Repeat steps 4–5 for the following buckets: • `sc-terraform-engine-state-XXXX` • `terraform-engine-bootstrap-XXXX` 7. Open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/), and then validate you're in the correct AWS Region. 8. In the left navigation, choose **Stacks**. 9. Select `SAM-TRE`, and then choose **Delete**. Wait until the stack has been deleted. 10. Select `Bootstrap-TRE`, and then choose **Delete**. Wait until the stack has been deleted.	AWS administrator

Register multiple AWS accounts with a single email address by using Amazon SES

Joe Wozniak and Shubhangi Vishwakarma, Amazon Web Services

Summary

This pattern describes how you can decouple real email addresses from the email address that's associated with an AWS account. AWS accounts require a unique email address to be provided at the time of account creation. In some organizations, the team that manages AWS accounts must take on the burden of managing many unique email addresses with their messaging team. This can be difficult for large organizations that manage many AWS accounts. Additionally, if your email system doesn't allow *plus addressing* or *sub-addressing* as defined in Sieve Email Filtering: Subaddress Extension (RFC 5233)—by adding a plus sign (+) and an identifier to the end of the local part of the email address, such as `admin+123456789123@example.com`—this pattern can help overcome this limitation.

This pattern provides a unique email address vending solution that enables AWS account owners to associate one email address with multiple AWS accounts. The real email addresses of AWS account owners are then associated with these generated email addresses in a table. The solution handles all incoming email for the unique email accounts, looks up the owner of each account, and then forwards any received messages to the owner.

Prerequisites and limitations

Prerequisites

- Administrative access to an AWS account.
- Access to a development environment.
- (Optional) Familiarity with AWS Cloud Development Kit (AWS CDK) workflows and the Python programming language will help you troubleshoot any issues or make modifications.

Limitations

- Overall vended email address length of 64 characters. For details, see CreateAccount in the *AWS Organizations API reference*.

Product versions

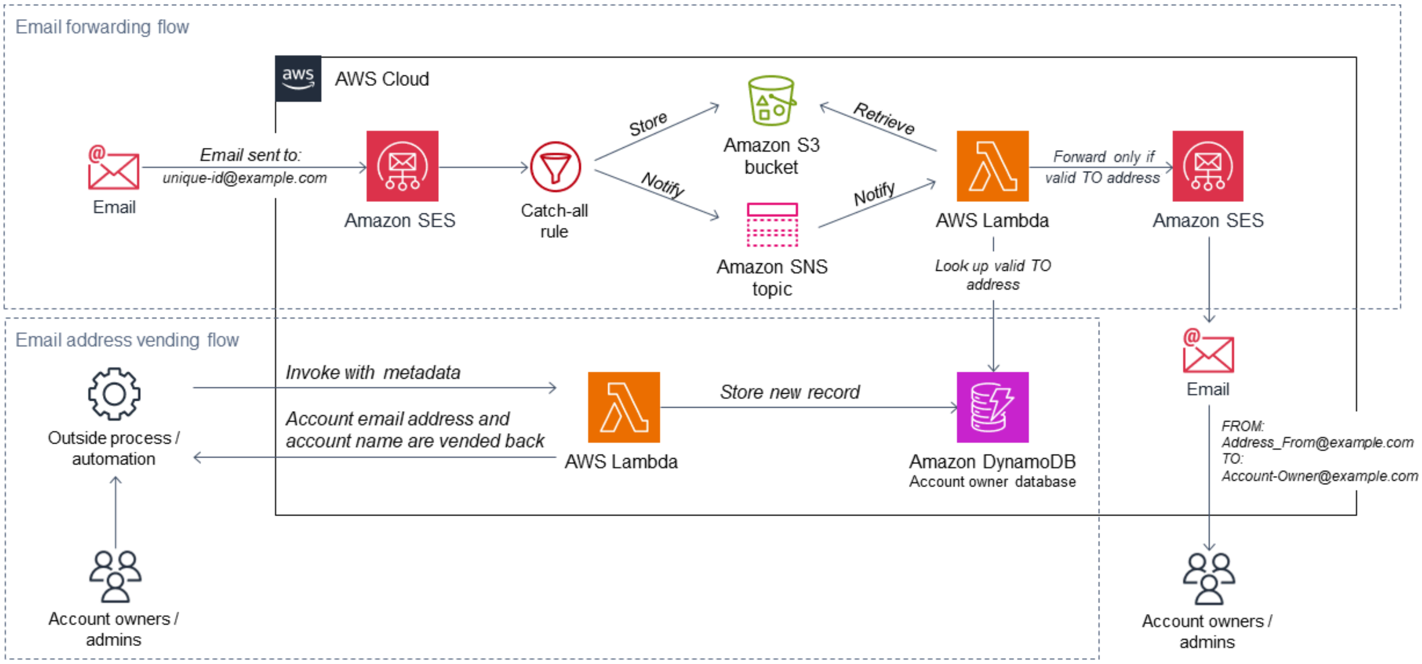
- Node.js version 22.x or later
- Python 3.13 or later
- Python packages **pip** and **virtualenv**
- AWS CDK CLI version 2.1019.2 or later
- Docker 20.10.x or later

Architecture

Target technology stack

- AWS CloudFormation stack
- AWS Lambda functions
- Amazon Simple Email Service (Amazon SES) rule and rule set
- AWS Identity and Access Management (IAM) roles and policies
- Amazon Simple Storage Service (Amazon S3) bucket and bucket policy
- AWS Key Management Service (AWS KMS) key and key policy
- Amazon Simple Notification Service (Amazon SNS) topic and topic policy
- Amazon DynamoDB table

Target architecture



This diagram shows two flows:

- **Email address vending flow:** In the diagram, the email address vending flow (lower section) begins typically with an account vending solution or outside automation, or is invoked manually. In the request, a Lambda function is called with a payload that contains the needed metadata. The function uses this information to generate a unique account name and email address, stores it in a DynamoDB database, and returns the values to the caller. These values can then be used to create a new AWS account (typically by using AWS Organizations).
- **Email forwarding flow:** This flow is illustrated in the upper section of the previous diagram. When an AWS account is created by using the account email generated from the email address vending flow, AWS sends various emails, such as account registration confirmation and periodic notifications, to that email address. By following the steps in this pattern, you configure your AWS account with Amazon SES to receive emails for the entire domain. This solution configures forwarding rules that allow Lambda to process all incoming emails, check to see if the TO address is in the DynamoDB table, and forward the message to the account owner's email address instead. Using this process gives account owners the ability to associate multiple accounts with one email address.

Automation and scale

This pattern uses the AWS CDK to fully automate the deployment. The solution uses AWS managed services that will (or can be configured to) scale automatically to meet your needs. The Lambda functions might require additional configuration to meet your scaling needs. For more information, see Understanding Lambda function scaling in the Lambda documentation.

Tools

AWS services

- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to help protect your data.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Email Service (Amazon SES) helps you send and receive emails by using your own email addresses and domains.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Tools needed for deployment

- Development environment with the AWS CLI and IAM access to your AWS account. For details, see the links in the Related resources section.
- On your development system, install the following:
  - Git command line tool, available from the Git downloads website.

- The AWS CLI to configure access credentials for the AWS CDK. For more information, see the AWS CLI documentation.
- Python version 3.13 or later, available from the Python downloads website.
- UV for Python package management. For installation instructions, see the UV installation guide.
- Node.js version 22.x or later. For installation instructions, see the Node.js documentation.
- AWS CDK CLI version 2.1019.2 or later. For installation instructions, see the AWS CDK documentation.
- Docker version 20.10.x or later. For installation instructions, see the Docker documentation.

Code

The code for this pattern is available in the GitHub AWS account factory email repository.

Epics

Allocate a target deployment environment

Task	Description	Skills required
Identify or create an AWS account.	Identify an existing or new AWS account to which you have full administrative access, to deploy the email solution.	AWS administrator, Cloud administrator
Set up a deployment environment.	Configure an easy to use deployment environment and set up dependencies by following these steps: 1. Set up your development environment with the tools listed in the Tools section. 2. Clone the GitHub AWS account factory email repository code base	AWS DevOps, App developer

Task	Description	Skills required

	to your development environment by using the command:
	`git clone https://github.com/aws-samples/aws-account-factory-email`
	3. In the `requirements.in` file (in the root of the repository), update the line that starts with `aws-cdk-lib==` to match the latest version of the AWS CDK. To identify what the latest version is, run `npm view aws-cdk-lib` and look for the keyword "latest:".
	4. If you made an update to the version in `requirements.in`, run the following command to update the `requirements.txt` file by using UV:
	`uv pip compile requirements.in -o requirements.txt --python-version 3.13`	

Set up a verified domain

Task	Description	Skills required
Identify and allocate a domain.	The email forwarding functionality requires a dedicated domain. Identify and allocate a domain or subdomain that you can verify with Amazon SES. This domain should be available to receive incoming email within the AWS account where the email forwarding solution is deployed. Domain requirements: • The domain should be a standard domain or subdomain. • The domain should be externally DNS resolvable, because it will be used to receive emails from outside the organization.	Cloud administrator, Network administrator, DNS administr ator
Verify the domain.	Verify that the identified domain can be used to accept incoming email. Complete the instructions in [Verifying your domain for Amazon SES email receiving](#) in the Amazon SES documentation. This will require coordination with the person or team who is	App developer, AWS DevOps

Task	Description	Skills required
	responsible for the domain's DNS records.	
Set up MX records.	Set up your domain with MX records that point to the Amazon SES endpoints in your AWS account and Region. For more informati on, see [Publishing an MX record for Amazon SES email receiving](#) in the Amazon SES documentation.	Cloud administrator, Network administrator, DNS administr ator

Deploy the email vending and forwarding solution

Task	Description	Skills required
Modify the default values in `cdk.json`.	Edit some of the default values in the `cdk.json` file (in the root of the repositor y) so that the solution will operate correctly after it is deployed. 1. Modify the `SES_DOMAIN_NAME` value to match the domain name you verified previously. 2. Modify the `ADDRESS_FROM` value to include the same domain that is in `SES_DOMAIN_NAME`. The local part of the address should be determined by your cloud team. This	App developer, AWS DevOps

Task	Description	Skills required
	address becomes the `FROM` address for every email that's forwarded through the solution. 3. Modify the `ADDRESS_ADMIN` value to match the email address that any non-matching incoming messages will be forwarded to. This value must be a valid and operating email address.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Deploy the email vending and forwarding solution.</td><td>
1. Create a Python virtual environment:
<pre>uv venv --python 3.13</pre>
2. Activate the Python virtual environment:
<pre>source .venv/bin/
activate</pre>
Or, on the Windows platform, use:
<pre>% .venv\Scripts\acti
vate.bat</pre>
3. Install all Python requirements with no errors:
<pre>uv pip install -r
 requirements.txt</pre>
4. Synthesize the CloudFormation template:
<pre>cdk synth</pre>
Confirm that there are no errors and that the full CloudFormation template contains the expected output.
5. (Optional) If you are deploying the AWS CDK
</td><td>App developer, AWS DevOps</td></tr>
</table>

Task	Description	Skills required

	code into the current AWS account or Region for the first time, bootstrap the environment. For more information, see [AWS CDK Bootstrapping](#) in the AWS CDK documentation.
	`cdk bootstrap aws://AWS-ACCOUNT-NUMBER/REGION`
	Replace `AWS-ACCOUNT-NUMBER` and `REGION` with actual values.
	6. Deploy the solution:
	`cdk bootstrap`
	`cdk deploy`
	The commands should complete without errors.	

Task	Description	Skills required
Verify that the solution has been deployed.	Verify that the solution deployed successfully before you begin testing: 1. Open the [AWS CloudFormation console](#) and look for a CloudFormation stack that contains the name `AwsMailFwdStack` . 2. Confirm that this `AwsMailFwdStack` stack has the following resources : • Lambda functions • Amazon SES rule and rule set • IAM roles and policies • Amazon S3 bucket and bucket policy • AWS KMS key and key policy • Amazon SNS topic and topic policy • DynamoDB table	App developer, AWS DevOps

Verify that email vending and forwarding operate as expected

Task	Description	Skills required
Verify that the API is working.	In this step, you submit test data to the solution's API and confirm that the solution produces the expected output	App developer, AWS DevOps

Task	Description	Skills required
	and that backend operation s have been performed as expected. Manually run the **Vend Email** Lambda function by using test input. (For an example, see the sample_vend_reques t.json file.) For `OwnerAddr ess` , use a valid email address. The API should return an account name and account email with values as expected.	

Task	Description	Skills required
Verify that email is being forwarded.	In this step, you send a test email through the system and verify that the email is forwarded to the expected recipient. 1. Obtain the account email from the last step. 2. Send an email to this address with a test subject and body text. 3. Confirm that you received the email at the account owner's email address. 4. Confirm that the email you received has a `FROM` address that matches the `ADDRESS_FROM` setting in `cdk.json`. 5. Confirm that the received email's subject and body are the same as the original sent message.	App developer, AWS DevOps

Troubleshooting

Issue	Solution
The system doesn’t forward email as expected.	Verify that your setup is correct: 1. You should have completed the [Amazon SES verification process]() for your domain.

Issue	Solution
	2. Your domain should be set up properly with MX records pointing to the Amazon SES endpoints in your AWS account and Region. For more information, see [Publishing an MX record for Amazon SES email receiving]() in the Amazon SES documentation. After you verify your domain setup, follow these steps: 1. Open the [Amazon CloudWatch console]() for the account and Region where you deployed the solution, and navigate to CloudWatch log groups in the navigation pane. 2. Search the list of log groups for `SesMailForwardLogGroup` . 3. Investigate the logs in this group to see if any errors are generated during the email vending and forwarding process.

Issue	Solution
When you try to deploy the AWS CDK stack, you receive an error similar to: "Template format error: Unrecognized resource types"	In most instances, this error message means that the Region you're targeting doesn't have all the available AWS services. If you're using an Amazon EC2 instance to deploy the solution, you might be targeting a Region that is different from the Region where the instance is running. **Note** By default, the AWS CDK deploys to the Region and account that you configured in the AWS CLI. Possible solutions: 1. Investigate if all the services needed for this solution (see the Target technology stack section earlier in this pattern) are in the AWS Region you are targeting by reviewing AWS Services by Region. 2. If you are using an EC2 instance and targeting a Region that's different from the Region where your instance is running, make sure to set the `AWS_DEFAULT_REGION` environment variable, or set a Region with the AWS CLI before you deploy the solution. For more information, see the Configuring environment variables for the AWS CLI in the AWS CLI documentation. Alternatively, you can modify the `app.py` file in the root of the repository to include a hard-coded account ID and Region

Issue	Solution
	by following the instructions in the [AWS CDK documentation for environments]().
When you deploy the solution, you receive the error message: "Deployment failed: Error: AwsMailFwdStack: SSM parameter /cdk-bootstrap/hnb659fds/version not found. Has the environment been bootstrapped? Please run 'cdk bootstrap'"	If you have never deployed any AWS CDK resources to the AWS account and Region you're targeting, you will have to first run the `cdk bootstrap` command as the error indicates. If you continue to receive this error after you run the bootstrapping command, you might be trying to deploy the solution to a Region that's different from the Region where your development environment is running. To solve this problem, set the `AWS_DEFAULT_REGION` environment variable or set a Region with the AWS CLI before you deploy the solution. Alternatively, you can modify the `app.py` file in the root of the repository to include a hard-coded account ID and Region by following the instructions in the AWS CDK documentation for environments.

- For help with the AWS CDK, see Getting started with the AWS CDK.

Additional information

Costs

When you deploy this solution, the AWS account holder might incur costs that are associated with the use of the following services. It is important for you to understand how these services are billed so you are aware of any potential charges. For pricing information, see the following pages:

- Amazon SES pricing
- Amazon S3 pricing
- AWS KMS pricing
- AWS Lambda pricing
- Amazon DynamoDB pricing

Set up DNS resolution for hybrid networks in a single-account AWS environment

Abdullahi Olaoye, Amazon Web Services

Summary

This pattern describes how to set up a fully hybrid Domain Name System (DNS) architecture that enables end-to-end DNS resolution of on-premise resources, AWS resources, and internet DNS queries, without administrative overhead. The pattern describes how to set up Amazon Route 53 Resolver forwarding rules that determine where a DNS query that originates from AWS should be sent, based on the domain name. DNS queries for on-premises resources are forwarded to on-premises DNS resolvers. DNS queries for AWS resources and internet DNS queries are resolved by Route 53 Resolver.

This pattern covers hybrid DNS resolution in an AWS single-account environment. For information about setting up outbound DNS queries in an AWS multi-account environment, see the pattern Set up DNS resolution for hybrid networks in a multi-account AWS environment.

Prerequisites and limitations

Prerequisites

- An AWS account
- A virtual private cloud (VPC) in your AWS account
- A network connection between the on-premises environment and your VPC, through AWS Virtual Private Network (AWS VPN) or AWS Direct Connect
- IP addresses of your on-premises DNS resolvers (reachable from your VPC)
- Domain/subdomain name to forward to on-premises resolvers (for example, onprem.mydc.com)
- Domain/subdomain name for the AWS private hosted zone (for example, myvpc.cloud.com)

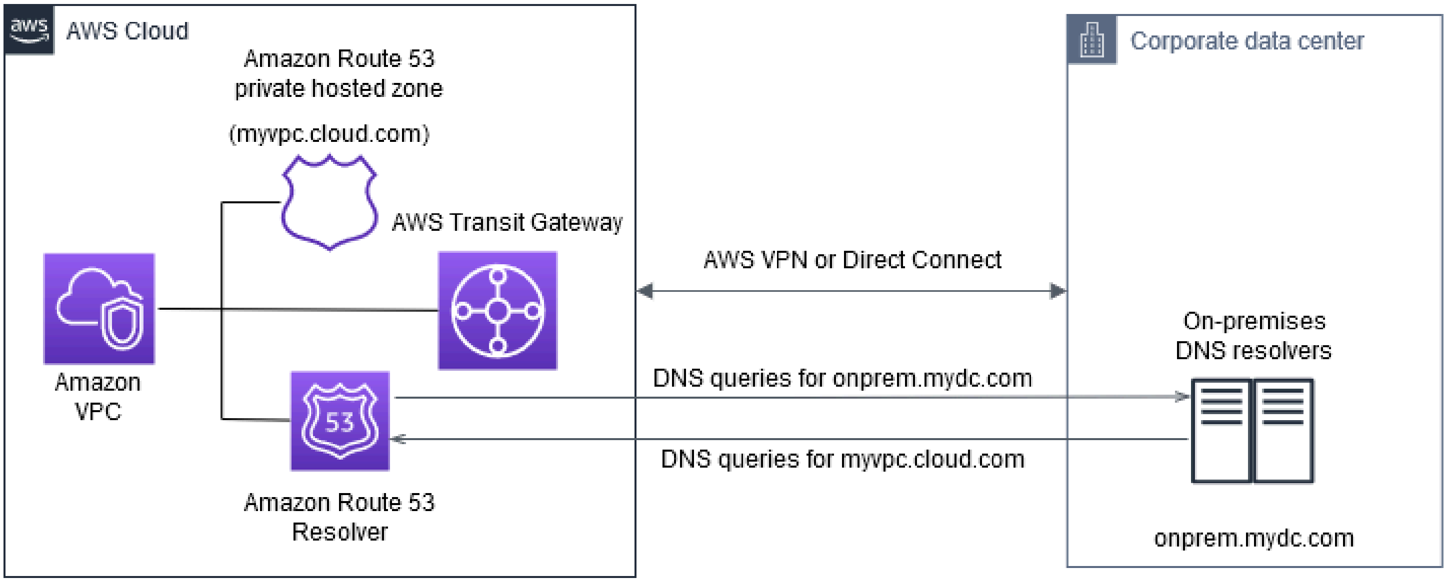
Architecture

Target technology stack

- Amazon Route 53 private hosted zone
- Amazon Route 53 Resolver
- Amazon VPC

- AWS VPN or Direct Connect

Target architecture



Tools

- Amazon Route 53 Resolver makes hybrid cloud easier for enterprise customers by enabling seamless DNS query resolution across your entire hybrid cloud. You can create DNS endpoints and conditional forwarding rules to resolve DNS namespaces between your on-premises data center and your VPCs.
- Amazon Route 53 private hosted zone is a container that holds information about how you want Route 53 to respond to DNS queries for a domain and its subdomains within one or more VPCs that you create with the Amazon VPC service.

Epics

Configure a private hosted zone

Task	Description	Skills required
Create a Route 53 private hosted zone for an AWS	This zone holds the DNS records for AWS resources that should be resolved from	Network admin, System admin

Task	Description	Skills required
reserved domain name such as myvpc.cloud.com.	the on-premises environment. For instructions, see Creating a private hosted zone in the Route 53 documentation.	
Associate the private hosted zone with your VPC.	To enable resources in your VPC to resolve DNS records in this private hosted zone, you must associate your VPC with the hosted zone. For instructions, see Creating a private hosted zone in the Route 53 documentation.	Network admin, System admin

Set up Route 53 Resolver endpoints

Task	Description	Skills required
Create an inbound endpoint.	Route 53 Resolver uses the inbound endpoint to receive DNS queries from on-premises DNS resolvers. For instructions, see Forwarding inbound DNS queries to your VPCs in the Route 53 documentation. Make a note of the inbound endpoint IP address.	Network admin, System admin
Create an outbound endpoint.	Route 53 Resolver uses the outbound endpoint to send DNS queries to on-premises DNS resolvers. For instructions, see Forwarding outbound DNS queries to your network in the Route 53	Network admin, System admin

Task	Description	Skills required
	documentation. Make a note of the output endpoint ID.	

Set up a forwarding rule and associate it with your VPC

Task	Description	Skills required
Create a forwarding rule for the on-premises domain.	This rule will instruct Route 53 Resolver to forward any DNS queries for on-premises domains (such as onprem.mydc.com) to on-premises DNS resolvers. To create this rule, you will need the IP addresses of the on-premises DNS resolvers and the outbound endpoint ID for Route 53 Resolver. For instructions, see Managing forwarding rules in the Route 53 documentation.	Network admin, System admin
Associate the forwarding rule with your VPC.	For the forwarding rule to take effect, you must associate the rule with your VPC. Route 53 Resolver then takes the rule into consideration when resolving a domain. For instructions, see Managing forwarding rules in the Route 53 documentation.	Network admin, System admin

Configure on-premises DNS resolvers

Task	Description	Skills required
Configure conditional forwarding in the on-premise DNS resolvers.	For DNS queries to be sent to the Route 53 private hosted zone from the on-premises environment, you must configure condition al forwarding in the on-premises DNS resolvers. This instructs the DNS resolvers to forward all DNS queries for the AWS domain (for example, for myvpc.clo ud.com) to the inbound endpoint IP address for Route 53 Resolver.	Network admin, System admin

Test end-to-end DNS resolution

Task	Description	Skills required
Test DNS resolution from AWS to the on-premises environment.	From a server in the VPC, perform a DNS query for an on-premises domain (such as server1.onprem.mydc.com).	Network admin, System admin
Test DNS resolution from the on-premises environment to AWS.	From an on-premises server, perform DNS resolution for an AWS domain (such as server1.myvpc.cloud.com).	Network admin, System admin

Set up UiPath RPA bots automatically on Amazon EC2 by using AWS CloudFormation

Dr. Rahul Sharad Gaikwad and Tamilselvan P, Amazon Web Services

Summary

This pattern explains how you can deploy robotic process automation (RPA) bots on Amazon Elastic Compute Cloud (Amazon EC2) instances. It uses an EC2 Image Builder pipeline to create a custom Amazon Machine Image (AMI). An AMI is a preconfigured virtual machine (VM) image that contains the operating system (OS) and preinstalled software to deploy EC2 instances. This pattern uses AWS CloudFormation templates to install UiPath Studio Community edition on the custom AMI. UiPath is an RPA tool that helps you set up robots to automate your tasks.

As part of this solution, EC2 Windows instances are launched by using the base AMI, and the UiPath Studio application is installed on the instances. The pattern uses the Microsoft System Preparation (Sysprep) tool to duplicate the customized Windows installation. After that, it removes the host information and creates a final AMI from the instance. You can then launch the instances on demand by using the final AMI with your own naming conventions and monitoring setup.

Note: This pattern doesn't provide any information about using RPA bots. For that information, see the UiPath documentation. You can also use this pattern to set up other RPA bot applicati ons by customizing the installation steps based on your requirements.

This pattern provides the following automations and benefits:

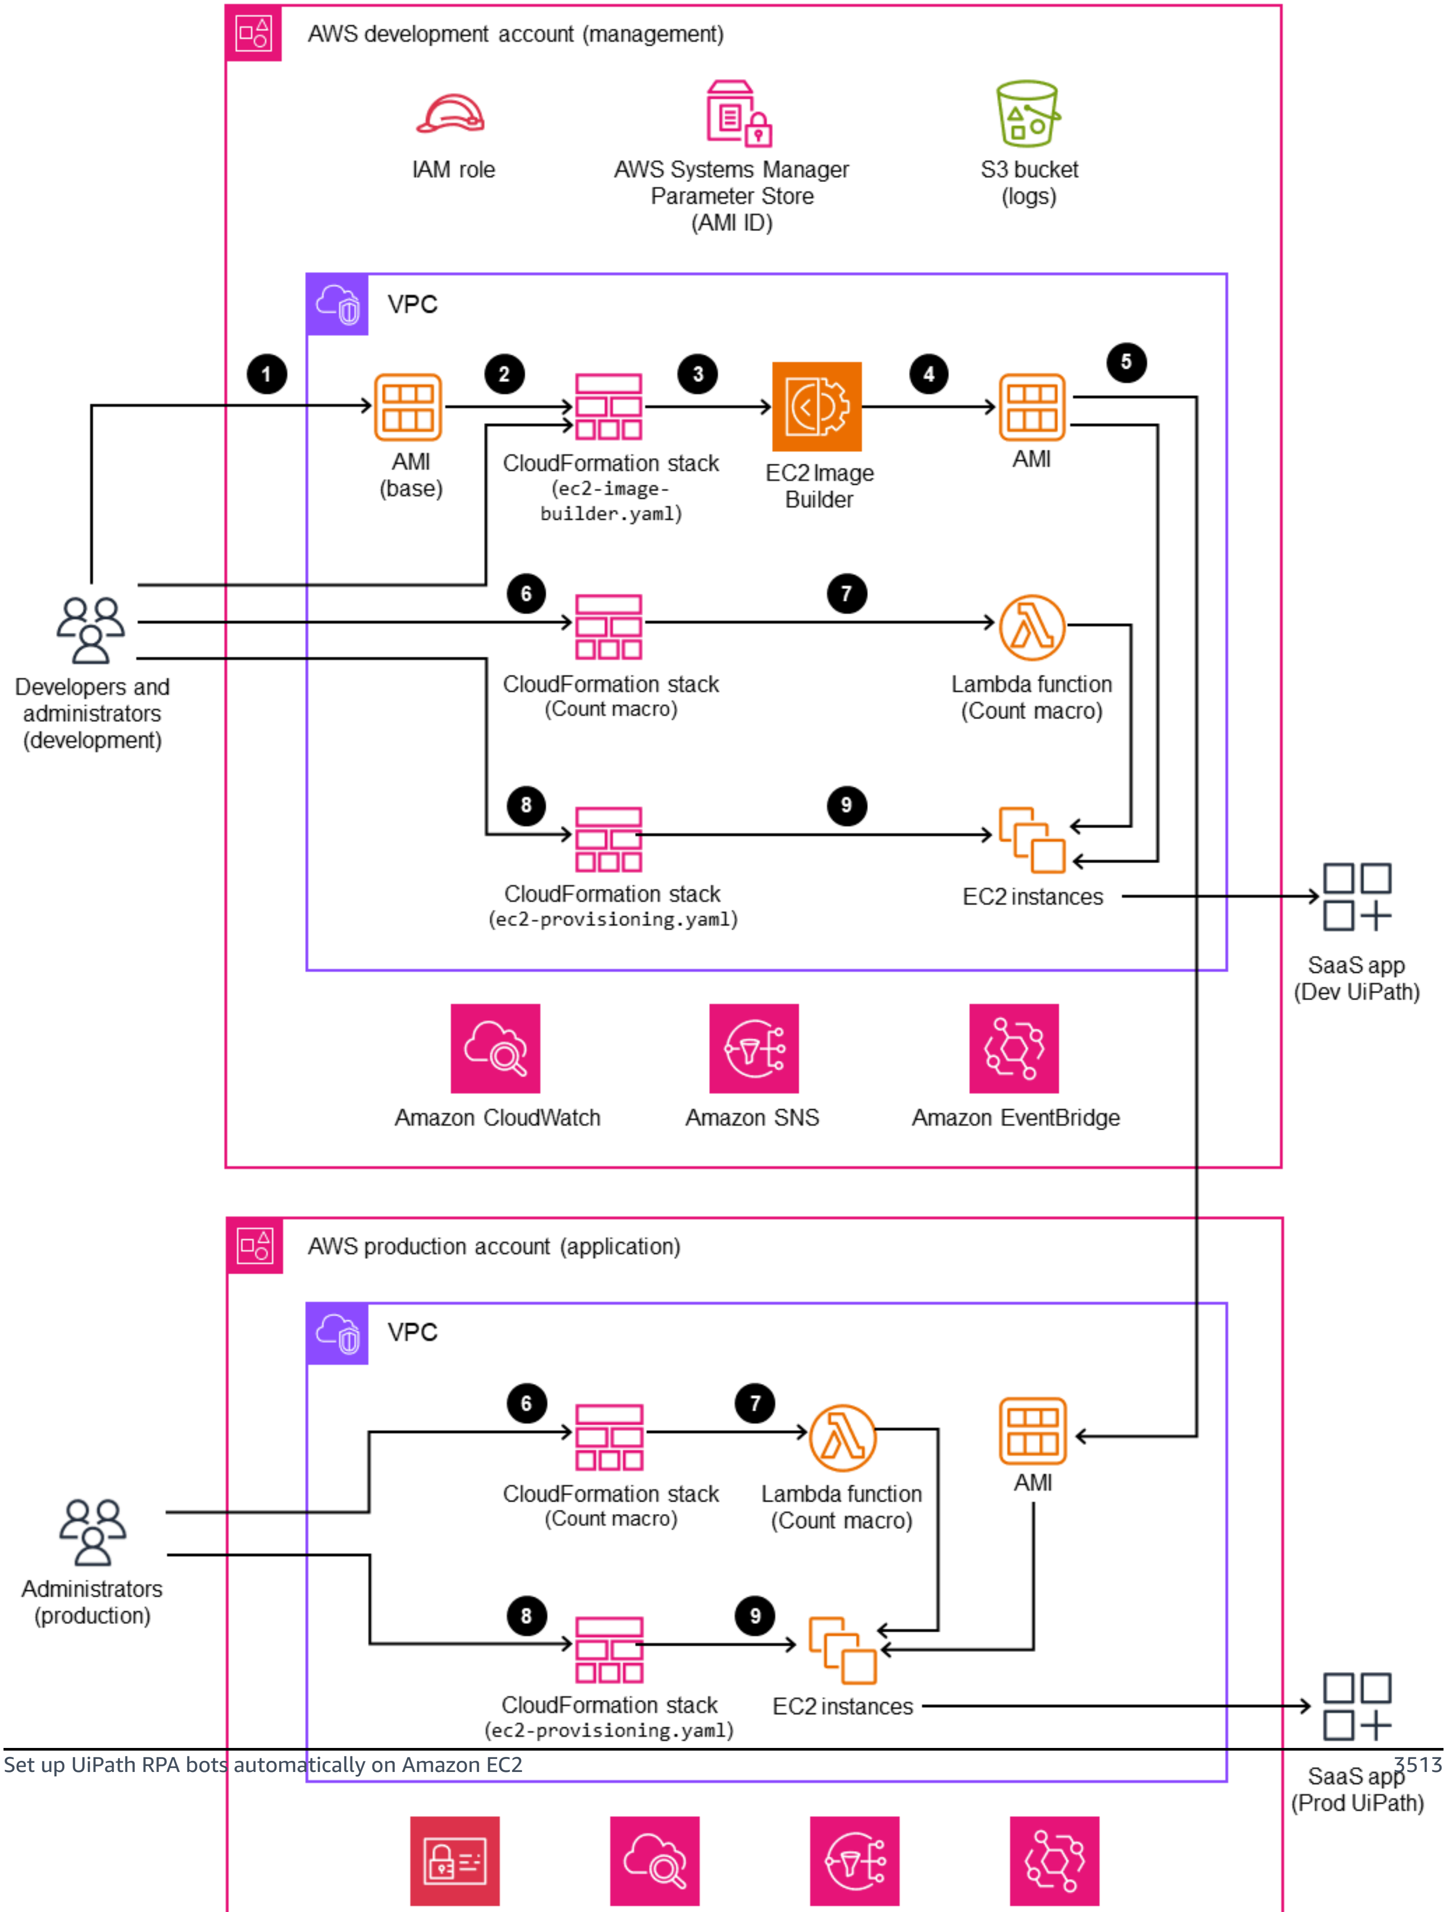
- Application deployment and sharing: You can build Amazon EC2 AMIs for application deployment and share them across multiple accounts through an EC2 Image Builder pipeline, which uses AWS CloudFormation templates as infrastructure as code (IaC) scripts.
- Amazon EC2 provisioning and scaling: CloudFormation IaC templates provide custom computer name sequences and Active Directory join automation.
- Observability and monitoring: The pattern sets up Amazon CloudWatch dashboards to help you monitor Amazon EC2 metrics (such as CPU and disk usage).
- RPA benefits for your business: RPA improves accuracy because robots can perform assigned tasks automatically and consistently. RPA also increases speed and productivity because it removes operations that don't add value and handles repetitious activities.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Identity and Access Management (IAM) permissions for deploying CloudFormation templates
- IAM policies to set up cross-account AMI distribution with EC2 Image Builder

Architecture



1. The administrator provides the base Windows AMI in the `ec2-image-builder.yaml` file and deploys the stack in the CloudFormation console.
2. The CloudFormation stack deploys the EC2 Image Builder pipeline, which includes the following resources:
   - `Ec2ImageInfraConfiguration`
   - `Ec2ImageComponent`
   - `Ec2ImageRecipe`
   - `Ec2AMI`
3. The EC2 Image Builder pipeline launches a temporary Windows EC2 instance by using the base AMI and installs the required components (in this case, UiPath Studio).
4. The EC2 Image Builder removes all the host information and creates an AMI from Windows Server.
5. You update the `ec2-provisioning yaml` file with the custom AMI and launch a number of EC2 instances based on your requirements.
6. You deploy the Count macro by using a CloudFormation template. This macro provides a **Count** property for CloudFormation resources so you can specify multiple resources of the same type easily.
7. You update the name of the macro in the CloudFormation `ec2-provisioning.yaml` file and deploy the stack.
8. The administrator updates the `ec2-provisioning.yaml` file based on requirements and launches the stack.
9. The template deploys EC2 instances with the UiPath Studio application.

Tools

AWS services

- AWS CloudFormation helps you model and manage infrastructure resources in an automated and secure manner.
- Amazon CloudWatch helps you observe and monitor resources and applications on AWS, on premises, and on other clouds.
- Amazon Elastic Compute Cloud (Amazon EC2) provides secure and resizable compute capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

- EC2 Image Builder simplifies the building, testing, and deployment of virtual machines and container images for use on AWS or on premises.
- Amazon EventBridge helps you build event-driven applications at scale across AWS, existing systems, or software as a service (SaaS) applications.
- AWS Identity and Access Management (IAM) helps you securely control access to AWS resources. With IAM, you can centrally manage permissions that control which AWS resources users can access. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- AWS Lambda is a serverless, event-driven compute service that lets you run code for virtually any type of application or backend service without provisioning or managing servers. You can call Lambda functions from over 200 AWS services and SaaS applications, and pay only for what you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data..
- AWS Systems Manager Agent (SSM Agent) helps Systems Manager update, manage, and configure EC2 instances, edge devices, on-premises servers, and virtual machines (VMs).

Code repositories

The code for this pattern is available in the GitHub UiPath RPA bot setup using CloudFormation repository. The pattern also uses a macro that's available from the AWS CloudFormation Macros repository.

Best practices

- AWS releases new Windows AMIs each month. These contain the latest OS patches, drivers, and launch agents. We recommend that you use the latest AMI when you launch new instances or when you build your own custom images.
- Apply all available Windows or Linux security patches during image builds.

Epics

Deploy an image pipeline for the base image

Task	Description	Skills required
Set up an EC2 Image Builder pipeline.	1. Clone the UiPath RPA bot setup using CloudFormation repository, or download the `ec2-image-builder.yaml` template from the repository. 2. Sign in to the AWS Management Console, and open the AWS CloudFormation console. 3. Choose **Create stack**. 4. In the **Specify template** section, choose **Upload a template file**. 5. Locate and upload the `ec2-image-builder.yaml` template from your computer, and then choose **Next**. 6. Provide input parameters for your stack or accept the default values. Choose **Next**. **Note** The number and values of parameters might	AWS DevOps

Task	Description	Skills required
	vary depending on your input values. 7. Optionally, configure stack options, and then choose **Next**. 8. Review your stack details. 9. At the end of the screen, select the check box to acknowledge capabilities, and then choose **Submit**. 10. Monitor the stack's progress. When the status is `CREATE_COMPLETE` , the deployment is ready.	

Task	Description	Skills required
View EC2 Image Builder settings.	The EC2 Image Builder settings include infrastru cture configuration, distribut ion settings, and security scanning settings. To view the settings: 1. Open the EC2 Image Builder console. 2. From the navigation pane, navigate to various Image Builder settings. **Note** As a best practice, you should make any updates to EC2 Image Builder through the CloudFormation template only.	AWS DevOps

Task	Description	Skills required
View the image pipeline.	To view the deployed image pipeline: 1. On the EC2 Image Builder console, choose **Image pipelines** from the navigation pane. 2. Select the image pipeline you created. 3. View the configuration details of the output images, image recipe, infrastructure configura tion, distribution settings, Amazon EventBridge rules, and tags.	AWS DevOps

Task	Description	Skills required
View Image Builder logs.	EC2 Image Builder logs are aggregated in CloudWatch log groups. To view the logs in CloudWatch: 1. Open the [CloudWatch console](https://console.aws.amazon.com/cloudwatch/). 2. In the navigation pane, choose **Logs**, **Log groups**. 3. Choose the log group name. EC2 Image Builder logs are aggregated in the log group `/aws/imagebuilder/XXX` . 4. Check the latest logs in the respective log stream for any errors encountered when running the image pipeline. EC2 Image Builder logs are also stored in an S3 bucket. To view the logs in the bucket: 1. Open the [Amazon S3 console](https://console.aws.amazon.com/s3/). 2. In the **Buckets** list, choose the bucket name. The logs are aggregated in the S3 bucket `<stack-name>-XXXXXX` .	AWS DevOps

Task	Description	Skills required
Upload the UiPath file to an S3 bucket.	1. Download the `.msi` file for UiPath Studio from the location https://download.uipath.com/UiPathStudioCommunity.msi. 2. Upload the file to an S3 bucket. 3. Update the bucket name and file key in the `ec2-image-builder.yaml` template, in the user data section, line number 310.	AWS DevOps

Deploy and test the Count macro

Task	Description	Skills required
Deploy the Count macro.	1. Clone or download the Count CloudFormation macro. 2. Navigate to the `Count` folder. 3. You will need an S3 bucket to store the CloudFormation artifacts. If you don't have an S3 bucket already, create one with the name `aws s3 mb s3://<bucket name> .` 4. Package the Count macro template. The template uses the AWS Serverless Application Model (SAM),	DevOps engineer

Task	Description	Skills required

so it must be transformed before you can deploy it.

```
aws cloudformation
 package \
    --template-file
 template.yaml \
    --s3-bucket <your
 bucket name here> \
    --output-
template-file
 packaged.yaml
```

For example:

```
aws cloudformation
 package \
    --template-file
 template.yaml \
    --s3-bucket
 count-macro-ec2 \
    --output-
template-file
 packaged.yaml
```

5. Deploy the packaged template to create a CloudFormation stack.

```
aws cloudformation
 deploy \
    --stack-name
 Count-macro \
    --template-file
 packaged.yaml \
    --capabilities
 CAPABILITY_IAM
```

Task	Description	Skills required
	If you want to use the console, follow the instructions in the previous epic or in the [CloudFormation documentation]().	
Test the Count macro.	To test the macro's capabilities, try launching the example template that's provided with the macro. `aws cloudformation deploy \ --stack-name Count-test \ --template-file test.yaml \ --capabilities CAPABILITY_IAM`	DevOps engineer

Deploy the CloudFormation stack to provision instances with the custom image

Task	Description	Skills required
Deploy the Amazon EC2 provisioning template.	To deploy EC2 Image Pipeline by using CloudFormation: 1. Download the `ec2-provisioning.yaml` template from the [GitHub repository](), or locate it on your computer if you cloned the repository. 2. Open the [CloudFormation console]().	AWS DevOps

Task	Description	Skills required
	3. Repeat the steps from the first epic (or follow the instructions in the [CloudFormation documentation](#)) to deploy `ec2-provisioning.yaml` .	
View Amazon EC2 settings.	Amazon EC2 settings include security, networking, storage, status checks, monitoring, and tags configurations. To view these configurations: 1. Open the [Amazon EC2 console](#). 2. In the navigation pane, choose **Instances**, and then select the EC2 instance that was created by the Amazon EC2 provisioning template. 3. In the instance summary, select the tabs to view the corresponding Amazon EC2 settings.	AWS DevOps

Task	Description	Skills required
View the CloudWatch dashboard.	1. Open the [CloudWatch console](). 2. In the navigation pane, choose **Dashboards**. 3. Choose the dashboard that has your stack name. **Note** After you provision the stack, it takes time to populate the dashboard with metrics. The dashboard provides these metrics: `CPUUtilization` , `DiskUtilization` , `MemoryUtilization` , `NetworkIn` , `NetworkOut` , `StatusCheckFailed` .	AWS DevOps
View custom metrics for memory and disk usage.	1. On the [CloudWatch console](), choose **Dashboards**. 2. In the navigation pane, choose **Metrics**, **All metrics**. 3. Choose **Custom namespaces**, **CWAgent**.	AWS DevOps

Task	Description	Skills required
View alarms for memory and disk usage.	1. On the CloudWatch console, in the navigation pane, choose **Dashboards**. 2. Choose **All alarms**.	AWS DevOps
Verify the snapshot lifecyle rule.	1. Open the Amazon EC2 console. 2. In the navigation pane, choose **Lifecycle Manager**. 3. Verify the settings for the AMI lifecycle.	AWS DevOps

Delete the environment (optional)

Task	Description	Skills required
Delete the stacks.	When your PoC or pilot project is complete, we recommend that you delete the stacks you created to make sure that you aren't charged for these resources. 1. Open the AWS CloudFormation console. 2. In the navigation pane, choose **Stacks**, and then select one or both stacks you created earlier that you want to delete. The stack must be currently running. 3. In the stack details pane, choose **Delete**.	AWS DevOps

Task	Description	Skills required
	4. When prompted, choose **Delete stack**. ⚠ **Important** The stack deletion operation can't be stopped after it begins. The stack proceeds to the `DELETE_IN_PROGRESS` state. If the deletion fails, the stack will be in the `DELETE_FAILED` state. For solutions, see Delete stack fails in the AWS CloudFormation troubleshooting documentation. For information about protecting stacks from being accidentally deleted, see Protecting a stack from being deleted in the AWS CloudFormation documentation.	

Troubleshooting

Issue	Solution
When you deploy the Amazon EC2 provision ing template, you get the error: *Received malformed response from transform 123xxxx::Count*.	This is a known issue. (See the custom solution and PR in the AWS CloudFormation macros repository.) To fix this issue, open the AWS Lambda console and update `index.py` with the content from the GitHub repository.

Set up a highly available PeopleSoft architecture on AWS

Ramanathan Muralidhar, Amazon Web Services

Summary

When you migrate your PeopleSoft workloads to AWS, resiliency is an important objective. It ensures that your PeopleSoft application is always highly available and able to recover from failures quickly.

This pattern provides an architecture for your PeopleSoft applications on AWS to ensure high availability (HA) at the network, application, and database tiers. It uses an Amazon Relational Database Service (Amazon RDS) for Oracle or Amazon RDS for SQL Server database for the database tier. This architecture also includes AWS services such as Amazon Route 53, Amazon Elastic Compute Cloud (Amazon EC2) Linux instances, Amazon Elastic Block Storage (Amazon EBS), Amazon Elastic File System (Amazon EFS), and an Application Load Balancer, and is scalable.

Oracle PeopleSoft provides a suite of tools and applications for workforce management and other business operations.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A PeopleSoft environment with the necessary licenses for setting it up on AWS
- A virtual private cloud (VPC) set up in your AWS account with the following resources:
  - At least two Availability Zones
  - One public subnet and three private subnets in each Availability Zone
  - A NAT gateway and an internet gateway
  - Route tables for each subnet to route the traffic
  - Network access control lists (network ACLs) and security groups defined to help ensure the security of the PeopleSoft application in accordance with your organization’s standards

Limitations

- This pattern provides a high availability (HA) solution. It doesn't support disaster recovery (DR) scenarios. In the rare occurrence that the entire AWS Region for the HA implementation goes down, the application will become unavailable.

Product versions

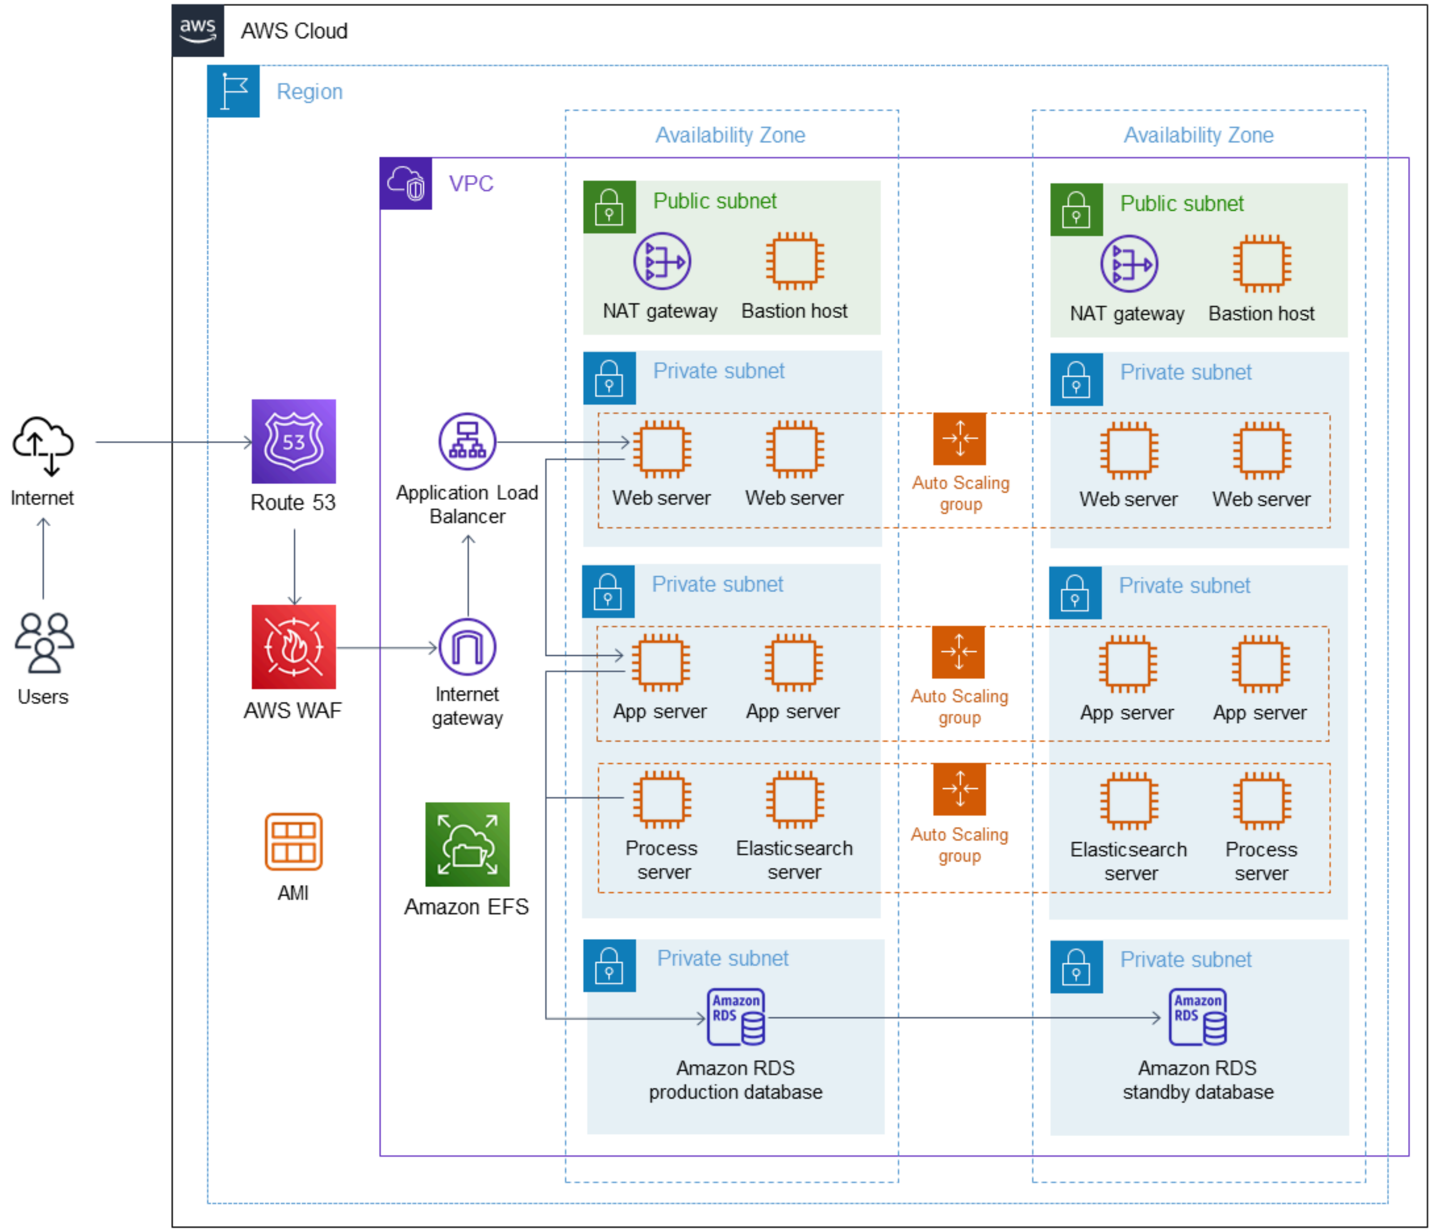
- PeopleSoft applications running PeopleTools 8.52 and later

Architecture

Target architecture

Downtime or outage of your PeopleSoft production application impacts the availability of the application and causes major disruptions to your business.

We recommend that you design your PeopleSoft production application so that it is always highly available. You can achieve this by eliminating single points of failure, adding reliable crossover or failover points, and detecting failures. The following diagram illustrates an HA architecture for PeopleSoft on AWS.



This architecture deployment uses Amazon RDS for Oracle as the PeopleSoft database, and EC2 instances that are running on Red Hat Enterprise Linux (RHEL). You can also use Amazon RDS for SQL Server as the Peoplesoft database.

This architecture contains the following components:

- Amazon Route 53 is used as the Domain Name Server (DNS) for routing requests from the internet to the PeopleSoft application.

- AWS WAF helps you protect against common web exploits and bots that can affect availability, compromise security, or consume excessive resources. AWS Shield Advanced (not illustrated) provides much broader protection.
- An Application Load Balancer load-balances HTTP and HTTPS traffic with advanced request routing targeted at the web servers.
- The web servers, application servers, process scheduler servers, and Elasticsearch servers that support the PeopleSoft application run in multiple Availability Zones and use Amazon EC2 Auto Scaling.
- The database used by the PeopleSoft application runs on Amazon RDS in a Multi-AZ configuration.
- The file share used by the PeopleSoft application is configured on Amazon EFS and is used to access files across instances.
- Amazon Machine Images (AMIs) are used by Amazon EC2 Auto Scaling to ensure that PeopleSoft components are cloned quickly when needed.
- The NAT gateways connect instances in a private subnet to services outside your VPC, and ensure that external services cannot initiate a connection with those instances.
- The internet gateway is a horizontally scaled, redundant, and highly available VPC component that allows communication between your VPC and the internet.
- The bastion hosts in the public subnet provide access to the servers in the private subnet from an external network, such as the internet or on-premises network. The bastion hosts provide controlled and secure access to the servers in the private subnets.

Architecture details

The PeopleSoft database is housed in an Amazon RDS for Oracle (or Amazon RDS for SQL Server) database in a Multi-AZ configuration. The Amazon RDS Multi-AZ feature replicates database updates across two Availability Zones to increase durability and availability. Amazon RDS automatically fails over to the standby database for planned maintenance and unplanned disruptions.

The PeopleSoft web and middle tier are installed on EC2 instances. These instances are spread across multiple Availability Zones and tied by an Auto Scaling group. This ensures that these components are always highly available. A minimum number of required instances are maintained to ensure that the application is always available and can scale when required.

We recommend that you use a current generation EC2 instance type for the OEM EC2 instances. Current generation instance types, such as instances built on the AWS Nitro System, support hardware virtual machines (HVMs). The HVM AMIs are required to take advantage of enhanced networking, and they also offer increased security. The EC2 instances that are part of each Auto Scaling group use their own AMI when replacing or scaling up instances. We recommend that you select EC2 instance types based on the load you want your PeopleSoft application to handle and the minimum values recommended by Oracle for your PeopleSoft application and PeopleTools release. For more information about hardware and software requirements, see the Oracle support website.

The PeopleSoft web and middle tier share an Amazon EFS mount to share reports, data files, and (if needed) the `PS_HOME` directory. Amazon EFS is configured with mount targets in each Availability Zone for performance and cost reasons.

An Application Load Balancer is provisioned to support the traffic that accesses the PeopleSoft application and load-balances the traffic among the web servers across different Availability Zones. An Application Load Balancer is a network device that provides HA in at least two Availability Zones. The web servers distribute the traffic to different application servers by using a load balancing configuration. Load balancing among the web server and application server ensures that load is distributed evenly across the instances, and helps avoid bottlenecks and service disruptions due to overloaded instances.

Amazon Route 53 is used as the DNS service to route traffic to the Application Load Balancer from the internet. Route 53 is a highly available and scalable DNS web service.

HA details

- Databases: The Multi-AZ feature of Amazon RDS operates two databases in multiple Availability Zones with synchronous replication. This creates a highly available environment with automatic failover. Amazon RDS has failover event detection and initiates automated failover when these events occur. You can also initiate manual failover through the Amazon RDS API. For a detailed explanation, see the blog post Amazon RDS Under The Hood: Multi-AZ. The failover is seamless and the application automatically reconnects to the database when it happens. However, any process scheduler jobs during the failover generate errors and have to be resubmitted.
- PeopleSoft application servers: The application servers are spread across multiple Availability Zones and have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the application server template. Specifically, *jolt pooling* is enabled, so when an application server

instance goes down, the sessions automatically fail over to another application server, and the Auto Scaling group automatically spins up another instance, brings up the application server, and registers it in the Amazon EFS mount. The newly created application server is automatically added to the web servers by using the `PSSTRSETUP.SH` script in the web servers. This ensures that the application server is always highly available and recovers from failure quickly.

- Process schedulers: The process schedulers servers are spread across multiple Availability Zones and have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the process scheduler server template. Specifically, when a process scheduler instance goes down, the Auto Scaling group automatically spins up another instance and brings up the process scheduler. Any jobs that were running when the instance failed must be resubmitted. This ensures that the process scheduler is always highly available and recovers from failure quickly.
- Elasticsearch servers: The Elasticsearch servers have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the Elasticsearch server template. Specifically, when an Elasticsearch instance goes down, the Application Load Balancer that serves requests to it detects the failure and stops sending traffic to it. The Auto Scaling group automatically spins up another instance and brings up the Elasticsearch instance. When the Elasticsearch instance is back up, the Application Load Balancer detects that it's healthy and starts sending requests to it again. This ensures that the Elasticsearch server is always highly available and recovers from failure quickly.
- Web servers: The web servers have an Auto Scaling group defined for them. If an instance fails, the Auto Scaling group immediately replaces it with a healthy instance that's cloned from the AMI of the web server template. Specifically, when a web server instance goes down, the Application Load Balancer that serves requests to it detects the failure and stops sending traffic to it. The Auto Scaling group automatically spins up another instance and brings up the web server instance. When the web server instance is back up, the Application Load Balancer detects that it's healthy and starts sending requests to it again. This ensures that the web server is always highly available and recovers from failure quickly.

Tools

AWS services

- Application Load Balancers distribute incoming application traffic across multiple targets, such as EC2 instances, in multiple Availability Zones.

- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with Amazon Elastic Compute Cloud (Amazon EC2) instances.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.
- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
- Amazon Route 53 is a highly available and scalable DNS web service.

Best practices

Operational best practices

- When you run PeopleSoft on AWS, use Route 53 to route the traffic from the internet and locally. Use the failover option to reroute traffic to the disaster recovery (DR) site if the primary DB instance isn't available.
- Always use an Application Load Balancer in front of the PeopleSoft environment. This ensures that traffic is load-balanced to the web servers in a secure fashion.
- In the Application Load Balancer target group settings, make sure that stickiness is turned on with a load balancer generated cookie.

> **Note**
>
> You might need to use an application-based cookie if you use external single sign-on (SSO). This ensures that connections are consistent across the web servers and application servers.

- For a PeopleSoft production application, the Application Load Balancer idle timeout must match what is set in the web profile you use. This prevents user sessions from expiring at the load balancer layer.
- For a PeopleSoft production application, set the application server recycle count to a value that minimizes memory leaks.
- If you're using an Amazon RDS database for your PeopleSoft production application, as described in this pattern, run it in Multi-AZ format for high availability.

- If your database is running on an EC2 instance for your PeopleSoft production application, make sure that a standby database is running on another Availability Zone for high availability.
- For DR, make sure that your Amazon RDS database or EC2 instance has a standby configured in a separate AWS Region from the production database. This ensures that in event of a disaster in the Region, you can switch the application over to another Region.
- For DR, use Amazon Elastic Disaster Recovery to set up application-level components in a separate Region from production components. This ensures that in the event of a disaster in the Region, you can switch the application over to another Region.
- Use Amazon EFS (for moderate I/O requirements) or Amazon FSx (for high I/O requirements) to store your PeopleSoft reports, attachments, and data files. This ensures that the content is stored in one central location and can be accessed from anywhere within the infrastructure.
- Use Amazon CloudWatch (basic and detailed) to monitor the AWS Cloud resources that your PeopleSoft application is using in near real time. This ensures that you are alerted of issues instantly and can address them quickly before they affect the availability of the environment.
- If you're using an Amazon RDS database as the PeopleSoft database, use Enhanced Monitoring. This feature provides access to over 50 metrics, including CPU, memory, file system I/O, and disk I/O.
- Use AWS CloudTrail to monitor API calls on the AWS resources that your PeopleSoft application is using. This helps you perform security analysis, resource change tracking, and compliance auditing.

Security best practices

- To protect your PeopleSoft application from common exploits such as SQL injection or cross-site scripting (XSS), use AWS WAF. Consider using AWS Shield Advanced for tailored detection and mitigation services.
- Add a rule to the Application Load Balancer to redirect traffic from HTTP to HTTPS automatically to help secure your PeopleSoft application.
- Set up a separate security group for the Application Load Balancer. This security group should allow only HTTPS/HTTP inbound traffic and no outbound traffic. This ensures that only intended traffic is allowed and helps secure your application.
- Use private subnets for the application servers, web servers, and database, and use NAT gateways for outbound internet traffic. This ensures that the servers that support the application aren't reachable publicly, while providing public access only to the servers that need it.

- Use different VPCs to run your PeopleSoft production and non-production environments. Use AWS Transit Gateway, VPC peering, network ACLs, and security groups to control the traffic flow between the VPCs and, if necessary, your on-premises data center.
- Follow the principle of least privilege. Grant access to the AWS resources used by the PeopleSoft application only to users who absolutely need it. Grant only the minimum privileges required to perform a task. For more information, see the security pillar of the AWS Well-Architected Framework.
- Wherever possible, use AWS Systems Manager to access the EC2 instances that the PeopleSoft application uses.

Reliability best practices

- When you use an Application Load Balancer, register a single target for each enabled Availability Zone. This makes the load balancer most effective.
- We recommend that you have three distinct URLs for each PeopleSoft production environment: one URL to access the application, one to serve the integration broker, and one to view reports. If possible, each URL should have its own dedicated web servers and application servers. This design helps make your PeopleSoft application more secure, because each URL has a distinct functionality and controlled access. It also minimizes the scope of impact if the underlying services fail.
- We recommend that you configure health checks on the load balancer target groups for your PeopleSoft application. The health checks should be performed on the web servers instead of the EC2 instances running those servers. This ensures that if the web server crashes or the EC2 instance that hosts the web server goes down, the Application Load Balancer reflects that information accurately.
- For a PeopleSoft production application, we recommend that you spread the web servers across at least three Availability Zones. This ensures that the PeopleSoft application is always highly available even if one of the Availability Zones goes down.
- For a PeopleSoft production application, enable jolt pooling (`joltPooling=true`). This ensures that your application fails over to another application server if a server is down for patching purposes or because of a VM failure.
- For a PeopleSoft production application, set `DynamicConfigReload` to 1. This setting is supported in PeopleTools version 8.52 and later. It adds new application servers to the web server dynamically, without restarting the servers.

- To minimize downtime when you apply PeopleTools patches, use the blue/green deployment method for your Auto Scaling group launch configurations for the web and application servers. For more information, see the Overview of deployment options on AWS whitepaper.
- Use AWS Backup to back up your PeopleSoft application on AWS. AWS Backup is a cost-effective, fully managed, policy-based service that simplifies data protection at scale.

Performance best practices

- Terminate the SSL at the Application Load Balancer for optimal performance of the PeopleSoft environment, unless your business requires encrypted traffic throughout the environment.
- Create interface VPC endpoints for AWS services like such as Amazon Simple Notification Service (Amazon SNS) and CloudWatch so that traffic is always internal. This is cost-effective and helps keep your application secure.

Cost optimization best practices

- Tag all the resources used by your PeopleSoft environment, and enable cost allocation tags. These tags help you view and manage your resource costs.
- For a PeopleSoft production application, set up Auto Scaling groups for the web servers and the application servers. This maintains a minimal number of web and application servers to support your application. You can use Auto Scaling group policies to scale the the servers up and down as required.
- Use billing alarms to get alerts when costs exceed a budget threshold that you specify.

Sustainability best practices

- Use infrastructure as code (IaC) to maintain your PeopleSoft environments. This helps you build consistent environments and maintain change control.

Epics

Migrate your PeopleSoft database to Amazon RDS

Task	Description	Skills required
Create a DB subnet group.	On the Amazon RDS console, in the navigation pane, choose **Subnet groups**, and then create an Amazon RDS DB subnet group with subnets in multiple Availabil ity Zones. This is required for the Amazon RDS database to run in a Multi-AZ configura tion.	Cloud administrator
Create the Amazon RDS database.	Create an Amazon RDS database in an Availability Zone of the AWS Region you selected for the PeopleSof t HA environment. When you create the Amazon RDS database, make sure to select the Multi-AZ option (**Create a standby instance**) and the database subnet group you created in the previous step. For more information, see the Amazon RDS documentation.	Cloud administrator, Oracle database administrator
Migrate your PeopleSoft database to Amazon RDS.	Migrate your existing PeopleSoft database into the Amazon RDS database by using AWS Database Migration Service (AWS DMS). For more information, see the AWS DMS documentation and	Cloud administrator, PeopleSoft DBA

Task	Description	Skills required
	the AWS blog post [Migrating Oracle databases with near-zero downtime using AWS DMS]().	

Set up your Amazon EFS file system

Task	Description	Skills required
Create a file system.	On the [Amazon EFS console](), create a file system and mount targets for each Availability Zone. For instructions, see the [Amazon EFS documentation](). When the file system has been created, note its DNS name. You will use this information when you mount the file system.	Cloud administrator

Set up your PeopleSoft application and file system

Task	Description	Skills required
Launch an EC2 instance.	Launch an EC2 instance for your PeopleSoft application. For instructions, see the [Amazon EC2 documentation](). • For **Name**, enter `APP_TEMPLATE` . • For **OS images**, choose **Red Hat**.	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
	• For **Instance type**, choose the instance type that's appropriate for your PeopleSoft application. For more information, see *Architecture details* in the [Architecture](#) section.	
Install PeopleSoft on the instance.	Install your PeopleSoft application and PeopleToo ls on the EC2 instance you created. For instructions, see the [Oracle documentation](#).	Cloud administrator, PeopleSoft administrator
Create the application server.	Create the application server for the AMI template and make sure that it connects successfully to the Amazon RDS database.	Cloud administrator, PeopleSoft administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Mount the Amazon EFS file system.</td><td>Log in to the EC2 instance as the root user and run the following commands to mount the Amazon EFS file system to a folder called PSFTMNT on the server.
<pre><code>sudo su –
mkdir /psftmnt
cat /etc/fstab</code></pre>
Append the following line to the <code>/etc/fstab</code> file. Use the DNS name you noted when you created the file system.
<pre><code>fs-09e064308f11453
88.efs.us-east-1.a
mazonaws.com:/ /
psftmnt nfs4 nfsvers=4
.1,rsize=1048576,w
size=1048576,hard,
timeo=600,retrans=
2,noresvport,_netdev
 0 0
mount -a</code></pre></td><td>Cloud administrator, PeopleSoft administrator</td></tr>
<tr><td>Check permissions.</td><td>Make sure that the PSFTMNT folder has the proper permissions so that the PeopleSoft user can access it properly.</td><td>Cloud administrator, PeopleSoft administrator</td></tr>
</table>

Task	Description	Skills required
Create additional instances.	Repeat the previous steps in this epic to create template instances for the process scheduler, web server, and Elasticsearch server. Name these instances `PRCS_TEMPLATE`, `WEB_TEMPLATE`, and `SRCH_TEMPLATE`. For the web server, set `joltPooling=true` and `DynamicConfigReload=1`.	Cloud administrator, PeopleSoft administrator

Create scripts to set up servers

Task	Description	Skills required

Create a script to install the application server.	In the Amazon EC2 `APP_TEMPLATE` instance, as the PeopleSoft user, create the following script. Name it `appstart.sh` and place it in the PS_HOME directory. You will use this script to bring up the application server and also record the server name on the Amazon EFS mount.
	
	`#!/bin/ksh`
	`. /usr/homes/hcmdemo/.profile.`
	`psadmin -c configure -d HCMDEMO`
	`psadmin -c parallelboot -d HCMDEMO`
		PeopleSoft administrator

Task	Description	Skills required
	`touch /psftmnt/`echo $HOSTNAME``	

Create a script to install the process scheduler server.	In the Amazon EC2 `PRCS_TEMPLATE` instance, as the PeopleSoft user, create the following script. Name it `prcsstart.sh` and place it in the `PS_HOME` directory. You will use this script to bring up the process scheduler server.
	
	`#!/bin/ksh`
	`. /usr/homes/hcmdemo/.profile`
	`/* The following line ensures that the process scheduler always has a unique name during replacement or scaling activity. */`
	`sed -i "s/.*PrcsServerName.*/`hostname -I | awk -F. '{print "PrcsServerName=PSUNX"$3$4}'`/" $HOME/appserv/prcs/*/psprcs.cfg`
	`psadmin -p configure -d HCMDEMO`
	`psadmin -p start -d HCMDEMO`
		PeopleSoft administrator

Task	Description	Skills required

Create a script to install the Elasticsearch server.	In the Amazon EC2 `SRCH_TEMPLATE` instance, as the Elasticsearch user, create the following script. Name it `srchstart.sh` and place it in the `HOME` directory.
	
	`#!/bin/ksh`
	`/* The following line ensures that the correct IP is indicated in the elasticsearch.yaml file. */`
	`sed -i "s/.*network.host.*/`hostname -I | awk '{print "host:"$0}'`/" $ES_HOME_DIR/config/elasticsearch.yaml`
	`nohup $ES_HOME_DIR/bin/elasticsearch &`
		PeopleSoft administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a script to install the web server.</td><td>

In the Amazon EC2 `WEB_TEMPLATE` instance, as the web server user, create the following scripts in the `HOME` directory.

`renip.sh`: This script ensures that the web server has the correct IP when cloned from the AMI.

```
#!/bin/ksh
hn=`hostname`
/* On the following line, change the IP with the hostname with the hostname of the web template. */
for text_file in `find * -type f -exec grep -l '<hostname-of-the-web-template>' {} \;`
do
sed -e 's/<hostname-of-the-web-template>/'$hn'/g' $text_file > temp
mv -f temp $text_file
done
```

`psstrsetup.sh` : This script ensures that the web server uses the correct application server IPs that are currently running. It tries to connect to each application server on the jolt port and adds it to the configuration file.

</td><td>PeopleSoft administrator</td></tr>
</table>

Task	Description	Skills required
	<pre>#!/bin/ksh c2="" for ctr in `ls -1 / psftmnt/*.internal` do c1=`echo $ctr | awk -F  "/" '{print $3}'` /* In the following lines, 9000 is the jolt port. Change it if necessary. */ if nc -z $c1 9000 2> / dev/null; then if [[$c2 = ""]]; then c2="psserver="`echo  $c1`":9000" else c2=`echo $c2`","`echo  $c1`":9000" fi fi done</pre> `webstart.sh` : This script runs the two previous scripts and starts the web servers. <pre>#!/bin/ksh /* Change the path in the following if necessary. */ cd /usr/homes/hcmdemo ./renip.sh ./psstrsetup.sh webserv/peoplesoft/ bin/startPIA.sh</pre>	

Task	Description	Skills required
Add a crontab entry.	In the Amazon EC2 `WEB_TEMPLATE` instance, as the web server user, add the following line to **crontab**. Change the time and path to reflect the values you need. This entry ensures that your web server always has the correct application server entries in the `configuration.properties` file. `* * * * * /usr/homes/hcmdemo/psstrsetup.sh`	PeopleSoft administrator

Create AMIs and Auto Scaling group templates

Task	Description	Skills required
Create an AMI for the application server template.	On the Amazon EC2 console, create an AMI image of the Amazon EC2 `APP_TEMPLATE` instance. Name the AMI `PSAPPSRV-SCG-VER1` . For instructions, see the [Amazon EC2 documentation]().	Cloud administrator, PeopleSoft administrator
Create AMIs for the other servers.	Repeat the previous step to create AMIs for the process scheduler, Elasticsearch server, and web server.	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required

Create a launch template for the application server Auto Scaling group.	Create a launch template for the application server Auto Scaling group. Name the template `PSAPPSRV_TEMPLATE.` In the template, choose the AMI you created for the `APP_TEMPLATE` instance. For instructions, see the [Amazon EC2 documentation]().
	• In the launch template, select the instance type based on your requirements.
	• In the **User data** field of the **Advanced details** section, add the following entries. Make sure that the path and user information are correct. You created the `appstart.sh` script in a previous step.
	`#! /bin/ksh`
	`su -c "/usr/homes/hcmdemo/appstart.sh" - hcmdemo`
		Cloud administrator, PeopleSoft administrator

Task	Description	Skills required

Create a launch template for the process scheduler server Auto Scaling group.	Repeat the previous step to create a launch template for the process scheduler server Auto Scaling group. Name the template `PSPRCS_TEMPLATE` . In the template, choose the AMI you created for the process scheduler.
	
	• In the **User data** field of the **Advanced details** section, add the following entries. Make sure that the path and user information are correct. You created the `prcsstart.sh` script in a previous step.
	
	`#! /bin/ksh`
	`su -c "/usr/homes/hcmdemo/prcsstart.sh" - hcmdemo`
		Cloud administrator, PeopleSoft administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a launch template for the Elasticsearch server Auto Scaling group.</td><td>Repeat the previous steps to create a launch template for the Elasticsearch server Auto Scaling group. Name the template <code>SRCH_TEMPLATE</code> . In the template, choose the AMI you created for the search server.
In the User data field of the Advanced details section, add the following entries. Make sure that the path and user information are correct. You created the <code>srchstart.sh</code> script in a previous step.<pre><code>#! /bin/ksh
su -c "/usr/homes/essearch/srchstart.sh" - essearch</code></pre></td><td>Cloud administrator, PeopleSoft administrator</td></tr>
</table>

Task	Description	Skills required

Create a launch template for the web server Auto Scaling group.	Repeat the previous steps to create a launch template for the web server Auto Scaling group. Name the template `WEB_TEMPLATE` . In the template, choose the AMI you created for the web server.
	• In the **User data** field of the **Advanced details** section, add the following entries. Make sure that the path and user information are correct. You created the `webstart.sh` script in a previous step.
	`#! /bin/ksh`
	`su -c "/usr/homes/hcmdemo/webstart.sh" - hcmdemo`
		Cloud administrator, PeopleSoft administrator

Create Auto Scaling groups

Task	Description	Skills required
Create an Auto Scaling group for the application server.	On the Amazon EC2 console, create an Auto Scaling group called PSAPPSRV_ASG for the application server by using the `PSAPPSRV_TEMPLATE` template. For instructions, see the [Amazon EC2 documentation]().	Cloud administrator, PeopleSoft administrator

Task	Description	Skills required
	• On the **Choose instance launch options** page, select the correct VPC and then select multiple subnets from different Availability Zones. • On the **Configure advanced options** page, do not select a load balancer. • On the **Configure group size and scaling policies** page, choose settings depending on how much load you want to architect your system for and whether you want to use a scaling policy. We recommend that you set the desired and minimum capacity to 2 at a minimum so that at least one instance is available to service the traffic at any point in time. For more information about Auto Scaling policies, see the [Amazon EC2 documentation]().	
Create Auto Scaling groups for the other servers.	Repeat the previous step to create Auto Scaling groups for the process scheduler, Elasticsearch server, and web server.	Cloud administrator, PeopleSoft administrator

Create and configure target groups

Task	Description	Skills required
Create a target group for the web server.	On the Amazon EC2 console, create a target group for the web server. For instructions, see the [Elastic Load Balancing documentation](). Set the port to the port that the web server is listening on.	Cloud administrator
Configure health checks.	Confirm that the health checks have the correct values to reflect your business requirements. For more information, see the [Elastic Load Balancing documentation]().	Cloud administrator
Create a target group for the Elasticsearch server.	Repeat the previous steps to create a target group called `PSFTSRCH` for the Elasticsearch server, and set the correct Elasticsearch port.	Cloud administrator
Add target groups to Auto Scaling groups.	Open the web server Auto Scaling group called `PSPIA_ASG` that you created earlier. On the **Load balancing** tab, choose **Edit** and then add the `PSFTWEB` target group to the Auto Scaling group. Repeat this step for the Elasticsearch Auto Scaling group `PSSRCH_ASG` to add	Cloud administrator

Task	Description	Skills required
	the target group PSFTSRCH you created earlier.	
Set session stickiness.	In the target group PSFTWEB, choose the **Attributes** tab, choose **Edit**, and set the session stickiness. For stickiness type, choose **Load balancer generated cookie**, and set the duration to 1. For more information, see the Elastic Load Balancing documentation. Repeat this step for the target group PSFTSRCH.	Cloud administrator

Create and configure application load balancers

Task	Description	Skills required
Create a load balancer for the web servers.	Create an Application Load Balancer named PSFTLB to load-balance traffic to the web servers. For instructions, see the Elastic Load Balancing documentation. • Provide the load balancer name. • For **Scheme**, choose **Internet-facing**. • In the **Network mapping** section, select the correct VPC and at least two public	Cloud administrator

Task	Description	Skills required
	subnets from different Availability Zones. • In the **Listeners and routing** section, select the target group PSFTWEB and specify the correct protocol and port number.	
Create a load balancer for the Elasticsearch servers.	Create an Application Load Balancer named PSFTSCH to load-balance traffic to the Elasticsearch servers. • Provide the load balancer name. • For **Scheme**, choose **Internal**. • In the **Network mapping** section, select the correct VPC and private subnets. • In the **Listeners and routing** section, select the target group PSFTSRCH and specify the correct protocol and port number.	Cloud administrator
Configure Route 53.	On the [Amazon Route 53 console](), create a record in the hosted zone that will service the PeopleSoft applicati on. For instructions, see the [Amazon Route 53 documenta tion](). This ensures that all the traffic passes through the PSFTLB load balancer.	Cloud administrator

Set up disaster recovery for Oracle JD Edwards EnterpriseOne with AWS Elastic Disaster Recovery

Thanigaivel Thirumalai, Amazon Web Services

Summary

Disasters that are triggered by natural catastrophes, application failures, or disruption of services harm revenue and cause downtime for corporate applications. To reduce the repercussions of such events, planning for disaster recovery (DR) is critical for firms that adopt JD Edwards EnterpriseOne enterprise resource planning (ERP) systems and other mission-critical and business-critical software.

This pattern explains how businesses can use AWS Elastic Disaster Recovery as a DR option for their JD Edwards EnterpriseOne applications. It also outlines the steps for using Elastic Disaster Recovery failover and failback to construct a cross-Region DR strategy for databases hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance in the AWS Cloud.

> **Note**
>
> This pattern requires the primary and secondary Regions for the cross-Region DR implementation to be hosted on AWS.

Oracle JD Edwards EnterpriseOne is an integrated ERP software solution for midsize to large companies in a wide range of industries.

AWS Elastic Disaster Recovery minimizes downtime and data loss with fast, reliable recovery of on-premises and cloud-based applications by using affordable storage, minimal compute, and point-in-time recovery.

AWS provides four core DR architecture patterns. This document focuses on setup, configuration, and optimization by using the pilot light strategy. This strategy helps you create a lower-cost DR environment where you initially provision a replication server for replicating data from the source database, and you provision the actual database server only when you start a DR drill and recovery. This strategy removes the expense of maintaining a database server in the DR Region. Instead, you pay for a smaller EC2 instance that serves as a replication server.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A JD Edwards EnterpriseOne application running on Oracle Database or Microsoft SQL Server with a supported database in a running state on a managed EC2 instance. This application should include all JD Edwards EnterpriseOne base components (Enterprise Server, HTML Server, and Database Server) installed in one AWS Region.
- An AWS Identity and Access Management (IAM) role to set up the Elastic Disaster Recovery service.
- The network for running Elastic Disaster Recovery configured according to the required connectivity settings.

Limitations

- You can use this pattern to replicate all tiers, unless the database is hosted on Amazon Relational Database Service (Amazon RDS), in which case we recommend that you use the cross-Region copy functionality of Amazon RDS.
- Elastic Disaster Recovery isn't compatible with CloudEndure Disaster Recovery, but you can upgrade from CloudEndure Disaster Recovery. For more information, see the FAQ in the Elastic Disaster Recovery documentation.
- Amazon Elastic Block Store (Amazon EBS) limits the rate at which you can take snapshots. You can replicate a maximum number of 300 servers in a single AWS account by using Elastic Disaster Recovery. To replicate more servers, you can use multiple AWS accounts or multiple target AWS Regions. (You will have to set up Elastic Disaster Recovery separately for each account and Region.) For more information, see Best practices in the Elastic Disaster Recovery documentation.
- The source workloads (the JD Edwards EnterpriseOne application and database) must be hosted on EC2 instances. This pattern doesn't support workloads that are on premises or in other cloud environments.
- This pattern focuses on the JD Edwards EnterpriseOne components. A full DR and business continuity plan (BCP) should include other core services, including:
  - Networking (virtual private cloud, subnets, and security groups)
  - Active Directory
  - Amazon WorkSpaces

- Elastic Load Balancing
- A managed database service such as Amazon Relational Database Service (Amazon RDS)

For additional information about prerequisites, configurations, and limitations, see the Elastic Disaster Recovery documentation.

Product versions

- Oracle JD Edwards EnterpriseOne (Oracle and SQL Server supported versions based on Oracle Minimum Technical Requirements)

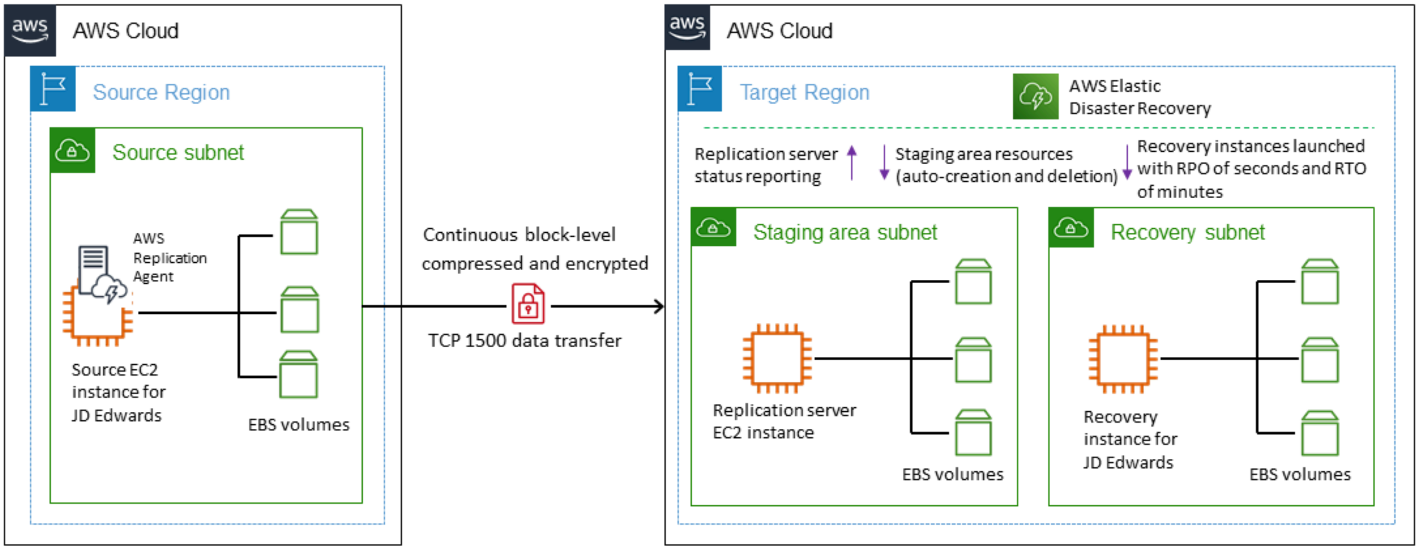
Architecture

Target technology stack

- A single Region and single virtual private cloud (VPC) for production and non-production, and a second Region for DR
- Single Availability Zones to ensure low latency between servers
- An Application Load Balancer that distributes network traffic to improve the scalability and availability of your applications across multiple Availability Zones
- Amazon Route 53 to provide Domain Name System (DNS) configuration
- Amazon WorkSpaces to provide users with a desktop experience in the cloud
- Amazon Simple Storage Service (Amazon S3) for storing backups, files, and objects
- Amazon CloudWatch for application logging, monitoring, and alarms
- Amazon Elastic Disaster Recovery for disaster recovery

Target architecture

The following diagram shows the cross-Region disaster recovery architecture for JD Edwards EnterpriseOne using Elastic Disaster Recovery.



Procedure

Here is a high-level review of the process. For details, see the *Epics* section.

- Elastic Disaster Recovery replication begins with an initial sync. During the initial sync, the AWS Replication Agent replicates all the data from the source disks to the appropriate resource in the staging area subnet.
- Continuous replication continues indefinitely after the initial sync is complete.
- You review the launch parameters, which include service-specific configurations and an Amazon EC2 launch template, after the agent has been installed and replication has started. When the source server is indicated as being ready for recovery, you can start instances.
- When Elastic Disaster Recovery issues a series of API calls to begin the launch operation, the recovery instance is immediately launched on AWS according to your launch settings. The service automatically spins up a conversion server during startup.
- The new instance is spun up on AWS after the conversion is complete and is ready for use. The source server state at the time of launch is represented by the volumes associated with the launched instance. The conversion process involves changes to the drivers, network, and operating system license to ensure that the instance boots natively on AWS.
- After the launch, the newly created volumes are no longer kept in sync with the source servers. The AWS Replication Agent continues to routinely replicate changes made to your source servers to the staging area volumes, but the launched instances do not reflect those changes.
- When you start a new drill or recovery instance, the data is always reflected in the most recent state that has been replicated from the source server to the staging area subnet.

- When the source server is marked as being prepared for recovery, you can start instances.

> **Note**
>
> The process works both ways: for failover from a primary AWS Region to a DR Region, and to fail back to the primary site, when it has been recovered. You can prepare for failback by reversing the direction of data replication from the target machine back to the source machine in a fully orchestrated way.

The benefits of this process described in this pattern include:

- Flexibility: Replication servers scale out and scale in based on dataset and replication time, so you can perform DR tests without disrupting source workloads or replication.
- Reliability: The replication is robust, non-disruptive, and continuous.
- Automation: This solution provides a unified, automated process for test, recovery, and failback.
- Cost optimization: You can replicate only the needed volumes and pay for them, and pay for compute resources at the DR site only when those resources are activated. You can use a cost-optimized replication instance (we recommend that you use a compute-optimized instance type) for multiple sources or a single source with a large EBS volume.

Automation and scale

When you perform disaster recovery at scale, the JD Edwards EnterpriseOne servers will have dependencies on other servers in the environment. For example:

- JD Edwards EnterpriseOne application servers that connect to a JD Edwards EnterpriseOne supported database on boot have dependencies on that database.
- JD Edwards EnterpriseOne servers that require authentication and need to connect to a domain controller on boot to start services have dependencies on the domain controller.

For this reason, we recommend that you automate failover tasks. For example, you can use AWS Lambda or AWS Step Functions to automate the JD Edwards EnterpriseOne startup scripts and load balancer changes to automate the end-to-end failover process. For more information, see the blog post [Creating a scalable disaster recovery plan with AWS Elastic Disaster Recovery](#).

Tools

AWS services

- Amazon Elastic Block Store (Amazon EBS) provides block-level storage volumes for use with EC2 instances.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Elastic Disaster Recovery minimizes downtime and data loss with fast, reliable recovery of on-premises and cloud-based applications using affordable storage, minimal compute, and point-in-time recovery.
- Amazon Virtual Private Cloud (Amazon VPC) gives you full control over your virtual networking environment, including resource placement, connectivity, and security.

Best practices

General best practices

- Have a written plan of what to do in the event of a real recovery event.
- After you set up Elastic Disaster Recovery correctly, create an AWS CloudFormation template that can create the configuration on demand, should the need arise. Determine the order in which servers and applications should be launched, and record this in the recovery plan.
- Perform a regular drill (standard Amazon EC2 rates apply).
- Monitor the health of the ongoing replication by using the Elastic Disaster Recovery console or programmatically.
- Protect the point-in-time snapshots and confirm before terminating the instances.
- Create a IAM role for AWS Replication Agent installation.
- Enable termination protection for recovery instances in a real DR scenario.
- Do not use the **Disconnect from AWS** action in the Elastic Disaster Recovery console for servers that you launched recovery instances for, even in the case of a real recovery event. Performing a disconnect terminates all replication resources related to these source servers, including your point-in-time (PIT) recovery points.
- Change the PIT policy to change the number of days for snapshot retention.
- Edit the launch template in Elastic Disaster Recovery launch settings to set the correct subnet, security group, and instance type for your target server.

- Automate the end-to-end failover process by using Lambda or Step Functions to automate JD Edwards EnterpriseOne startup scripts and load balancer changes.

JD Edwards EnterpriseOne optimization and considerations

- Move **PrintQueue** into the database.
- Move **MediaObjects** into the database.
- Exclude the logs and temp folder from batch and logic servers.
- Exclude the temp folder from Oracle WebLogic.
- Create scripts for startup after the failover.
- Exclude the tempdb for SQL Server.
- Exclude the temp file for Oracle.

Epics

Perform initial tasks and configuration

Task	Description	Skills required
Set up the replication network.	Implement your JD Edwards EnterpriseOne system in the primary AWS Region and identify the AWS Region for DR. Follow the steps in the Replication network requirements section of the Elastic Disaster Recovery documentation to plan and set up your replication and DR network.	AWS administrator
Determine RPO and RTO.	Identify the recovery time objective (RTO) and recovery point objective (RPO) for	Cloud architect, DR architect

Task	Description	Skills required
	your application servers and database.	
Enable replication for Amazon EFS.	If applicable, enable replicati on from the AWS primary to DR Region for shared file systems such as Amazon Elastic File System (Amazon EFS) by using AWS DataSync, **rsync**, or another appropriate tool.	Cloud administrator
Manage DNS in case of DR.	Identify the process to update the Domain Name System (DNS) during the DR drill or actual DR.	Cloud administrator
Create an IAM role for setup.	Follow the instructions in the [Elastic Disaster Recovery initialization and permissions](#) section of the Elastic Disaster Recovery documentation to create an IAM role to initialize and manage the AWS service.	Cloud administrator
Set up VPC peering.	Make sure that the source and target VPCs are peered and accessible to each other. For configuration instructions, see the [Amazon VPC documenta tion](#).	AWS administrator

Configure Elastic Disaster Recovery replication settings

Task	Description	Skills required
Initialize Elastic Disaster Recovery.	Open the [Elastic Disaster Recovery console](), choose the target AWS Region (where you will replicate data and launch recovery instances), and then choose **Set default replication settings**.	AWS administrator
Set up replication servers.	1. In the **Set up replication servers** pane, enter the staging area subnet and replication server instance type. The `t3.small` instance type is selected by default. Configure this setting based on your requirements, and remember to consider instance pricing. For more information, see [Amazon EC2 pricing](). 2. In the **Service access** section, choose **View details** to review the service linked role and additional policies created during service initialization. 3. Choose **Next**.	AWS administrator
Configure volumes and security groups.	1. In the **Volumes and security groups** pane, select the EBS volume type for the replication	AWS administrator

Task	Description	Skills required
	server and set Amazon EBS encryption to **Default.** 2. Select **Always use AWS Elastic Disaster Recovery security group** so that Elastic Disaster Recovery automatically attaches and monitors the default security group. 3. Choose **Next**.	

Task	Description	Skills required
Configure additional settings.	1. In the **Additional settings** pane, configure data routing and throttling, PIT policy, and tags. • Data routing and throttling control how data flows from the external server to the replication servers. Choose **Use private IP for data replication**. Otherwise, replication servers will be automatic ally assigned a public IP, and data will flow over the public internet. • In the **Point in time (PIT) policy** section, configure a retention policy that determine s the duration after which snapshots are not required. The default retention period is seven days. • In the **Tags** section, add custom tags to resources created by Elastic Disaster Recovery in your AWS account. 2. Choose **Next**, review the settings in the next pane, and then choose **Create**	AWS administrator

Task	Description	Skills required
	default to create the default template.	

Install the AWS Replication Agent

Task	Description	Skills required
Create an IAM role.	Create an IAM role that contains the `AWSElasticDisasterRecoveryAgentInstallationPolicy` policy. In the **Select AWS access type** section, enable programmatic access. Note the access key ID and secret access key. You will need this information during the installation of the AWS Replication Agent.	AWS administrator
Check requirements.	Check and complete the [prerequisites](#) in the Elastic Disaster Recovery documentation for installing the AWS Replication Agent.	AWS administrator
Install the AWS Replication Agent.	Follow the [installation instructions](#) for your operating system and install the AWS Replication Agent. • For Microsoft Windows: Download the setup files and run the .exe file as an administrator. Respond to	AWS administrator

Task	Description	Skills required

	the prompts to complete the installation.
	• For Linux: Copy the following commands (in the order presented) and paste them into your Secure Shell (SSH) session. The first command downloads the installer and the second command runs it.
	`wget -O ./aws-replication-installer-init.py https://aws-elastic-disaster-recovery-us-west-2.s3.amazonaws.com/latest/linux/aws-replication-installer-init.py`
	`sudo python3 aws-replication-installer-init.py`
	Respond to the prompts to complete the installation.
	Note
	Change the URL to reflect your Region.
	
	Repeat these steps for the remaining server.	

Task	Description	Skills required
Monitor the replication.	Return to the Elastic Disaster Recovery **Source servers** pane to monitor the replication status. The initial sync will take some time depending on the size of the data transfer. When the source server is fully synced, the server status will be updated to **Ready**. This means that a replicati on server has been created in the staging area, and the EBS volumes have been replicated from the source server to the staging area.	AWS administrator

Configure launch settings

Task	Description	Skills required
Edit launch settings.	To update the launch settings for the drill and recovery instances, on the [Elastic Disaster Recovery console](https://console.aws.amazon.com/drs/home), select the source server, and then choose **Actions**, **Edit launch settings**. Or you can choose your replicati ng source machines from the **Source servers** page, and then choose the **Launch Settings** tab. This tab has two sections: **General launch**	AWS administrator

Task	Description	Skills required
	settings and **EC2 launch template**.	
Configure general launch settings.	Revise the general launch settings according to your requirements. • **Instance type right sizing**: If you choose **Basic**, Elastic Disaster Recovery bypasses the instance type you selected in the Amazon EC2 launch template and automatically chooses the instance type based on the operating system, CPU, and RAM of the source server. • **Copy private IP**: Choose whether you want Elastic Disaster Recovery to ensure that the private IP used by the drill or recovery instance matches the private IP used by the source server. If you chose **Yes**, make sure that the IP range of the subnet you set in the Amazon EC2 launch template includes the private IP address. For more information, see General launch settings in the Elastic Disaster Recovery documentation.	AWS administrator

Task	Description	Skills required
Configure the Amazon EC2 launch template.	Elastic Disaster Recovery uses Amazon EC2 launch templates to launch drill and recovery instances for each source server. The launch template is created automatically for each source server that you add to Elastic Disaster Recovery after you install the AWS Replication Agent. You must set the Amazon EC2 launch template as the default launch template if you want to use it with Elastic Disaster Recovery. For more information, see EC2 Launch Template in the Elastic Disaster Recovery documentation.	AWS administrator

Initiate DR drill and failover

Task	Description	Skills required
Initiate Drill	1. On the Elastic Disaster Recovery console, open the **Source servers** page and verify that the status of the source server is **Ready**.	AWS administrator

Task	Description	Skills required
	2. Select all the source servers that you want to perform the DR drill for. 3. From the **Initiate recovery job** menu, choose **Initiate drill** and select the appropriate point-in-time snapshot. This starts a recovery job for the selected source servers. You can monitor the status of the job on the **Recovery job history** tab. The launched drill instance also appears on the **Recovery instances** page. **Note** Further changes to the source server will be synced to the replication server, not to the drill instance. 4. Test and verify the DR drill instance. 5. On the **Recovery instances** page, select the drill instance, and then choose **Actions**, **Disconnect from AWS**. This deletes the AWS Replication	

Task	Description	Skills required
	Agent from the recovery instance and removes all resources associated with the recovery instance from Elastic Disaster Recovery. 6. Choose **Delete recovery instances**. This deletes the representation of the instance from the Elastic Disaster Recovery console and completely disassociates the instance from the Elastic Disaster Recovery service. It does not delete the underlying EC2 instance. 7. Terminate the DR drill instance from the Amazon EC2 console. For more information, see [Preparing for failover] in the Elastic Disaster Recovery documentation.	

Task	Description	Skills required
Validate the drill.	In the previous step, you launched new target instances in the DR Region. The target instances are replicas of the source servers based on the snapshot taken when you initiated the launch. In this procedure, you connect to your Amazon EC2 target machines to confirm that they're running as expected. 1. Open the Amazon EC2 console. 2. Choose **Instances (running)**. 3. Select the target instance and note its private IPv4 address. 4. Make sure that you can connect to the EC2 instance and that the JD Edwards EnterpriseOne and related components are replicated as expected.	

Task	Description	Skills required
Initiate a failover.	A failover is the redirection of traffic from a primary system to a secondary system. Elastic Disaster Recovery helps you perform a failover by launching recovery instances on AWS. When the recovery instances have been launched, you redirect the traffic from your primary systems to these instances. 1. On the [Elastic Disaster Recovery console](#), open the **Source servers** page and verify that the **Ready for recovery** column for the source server shows **Ready**, and the **Data replication status** column shows **Healthy**. 2. Select the source server. From the **Initiate recovery job** menu, choose **Initiate recovery**. 3. Select the point-in-time snapshot from which to launch the recovery instance, and then choose **Initiate recovery**. This starts a recovery job. You can monitor the status of the job on the **Recovery instances** page.	AWS administrator

Task	Description	Skills required
	4. Test and verify the recovery instance. If required, adjust the DNS configuration and connect your JD Edwards Enterpris eOne application to the database. 5. You can now disconnec t and decommission the source JD Edwards EnterpriseOne server, because all changes have been written to the new recovery instance. 6. Register the recovery instance as the source server in the DR Region by following the process described in the *Install the AWS Replication Agent* epic. For more information, see [Performing a failover](#) in the Elastic Disaster Recovery documentation.	

Task	Description	Skills required
Initiate a failback.	The process for initiating a failback is similar to the process for initiating failover. 1. Open the [Elastic Disaster Recovery console]() in the primary Region. Navigate to the **Recovery instances** page, select the drill instance, and then choose **Actions**, **Disconnect from AWS**, **Delete recovery instances**. 2. Open the Elastic Disaster Recovery console in the DR Region. Register your new JD Edwards EnterpriseOne server as the source server in the DR Region by installing the AWS Replication Agent. The data will be synced with a new replication server provisioned in the new staging subnet. **Note** When the new JD Edwards EnterpriseOne server is registered as a source server, you might see two source servers in the Elastic Disaster	AWS administrator

Task	Description	Skills required
	Recovery console: one server that was created from the primary EC2 instance, and the new server that was created from the recovery instance. We recommend that you tag the servers correctly to avoid confusion, and preferably add the new server to the launch template. 3. To restart DR replication from the primary Region, disassociate the launched recovery instance from the Elastic Disaster Recovery console in the DR Region, and register the host as a source server in the primary Region. For more information, see Performing a failback in the Elastic Disaster Recovery documentation.	

Task	Description	Skills required
Start JD Edwards EnterpriseOne components.	1. Start the JD Edwards EnterpriseOne database by logging in to the database server. 2. When the database is running, start the JD Edwards EnterpriseOne logic and batch servers. 3. Start WebLogic on the web servers, and start a JAS instance on the JAS servers. 4. Start WebLogic on the provision server and on the server for the SM console. 5. Start SM Agent on the servers. 6. Confirm that the login to JD Edwards EnterpriseOne works correctly. You will need to make incorporate the changes in Route 53 and Application Load Balancer for the JD Edwards EnterpriseOne link to work. You can automate these steps by using Lambda, Step Functions, and Systems Manager (Run Command).	JD Edwards EnterpriseOne CNC

Task	Description	Skills required
	Note Elastic Disaster Recovery performs block-level replication of the source EC2 instance EBS volumes that host the operating system and file systems. Shared file systems that were created by using Amazon EFS aren't part of this replication. You can replicate shared file systems to the DR Region by using AWS DataSync, as noted in the first epic, and then mount these replicated file systems in the DR system.	

Troubleshooting

Issue	Solution
Source server data replication status is **Stalled** and replication lags. If you check details, the data replication status displays **Agent not seen**.	Check to confirm that the stalled source server is running.

Issue	Solution
	Note If the source server goes down, the replication server is automatically terminated. For more information about lag issues, see Replication lag issues in the Elastic Disaster Recovery documentation.
Installation of AWS Replication Agent in source EC2 instance fails in RHEL 8.2 after scanning the disks. `aws_replication_agent_installer.log` reveals that kernel headers are missing.	Before you install the AWS Replication Agent on RHEL 8, CentOS 8, or Oracle Linux 8, run: `sudo yum install elfutils-libelf-devel` For more information, see Linux installation requirements in the Elastic Disaster Recovery documentation.
On the Elastic Disaster Recovery console, you see the source server as **Ready** with a lag and data replication status as **Stalled**. Depending on how long the AWS Replication Agent has been unavailable, the status might indicate high lag, but the issue remains the same.	Use an operating system command to confirm that the AWS Replication Agent is running in the source EC2 instance, or confirm that the instance is running. After you correct any issues, Elastic Disaster Recovery will restart scanning. Wait until all data has been synced and the replication status is **Healthy** before you start a DR drill.

Issue	Solution
Initial replication with high lag. On the Elastic Disaster Recovery console, you can see that the initial sync status is extremely slow for a source server.	Check for the replication lag issues documente d in the Replication lag issues section of the Elastic Disaster Recovery documentation. The replication server might be unable to handle the load because of intrinsic compute operations. In that case, try upgrading the instance type after consulting with the AWS Technical Support team.

Set up AWS CloudFormation drift detection in a multi-Region, multi-account organization

Ram Kandaswamy, Amazon Web Services

Summary

Amazon Web Services (AWS) users often look for an efficient way to detect resource configuration mismatches, including drift in AWS CloudFormation stacks, and fix them as soon as possible. This is especially the case when AWS Control Tower is used.

This pattern provides a prescriptive solution that efficiently solves the problem by using consolidated resource configuration changes and acting on those changes to generate results. The solution is designed for scenarios where there are several AWS CloudFormation stacks created in more than one AWS Region, or in more than one account, or a combination of both. The goals of the solution are the following:

- Simplify the drift detection process
- Set up notification and alerting
- Set up consolidated reporting

Prerequisites and limitations

Prerequisites

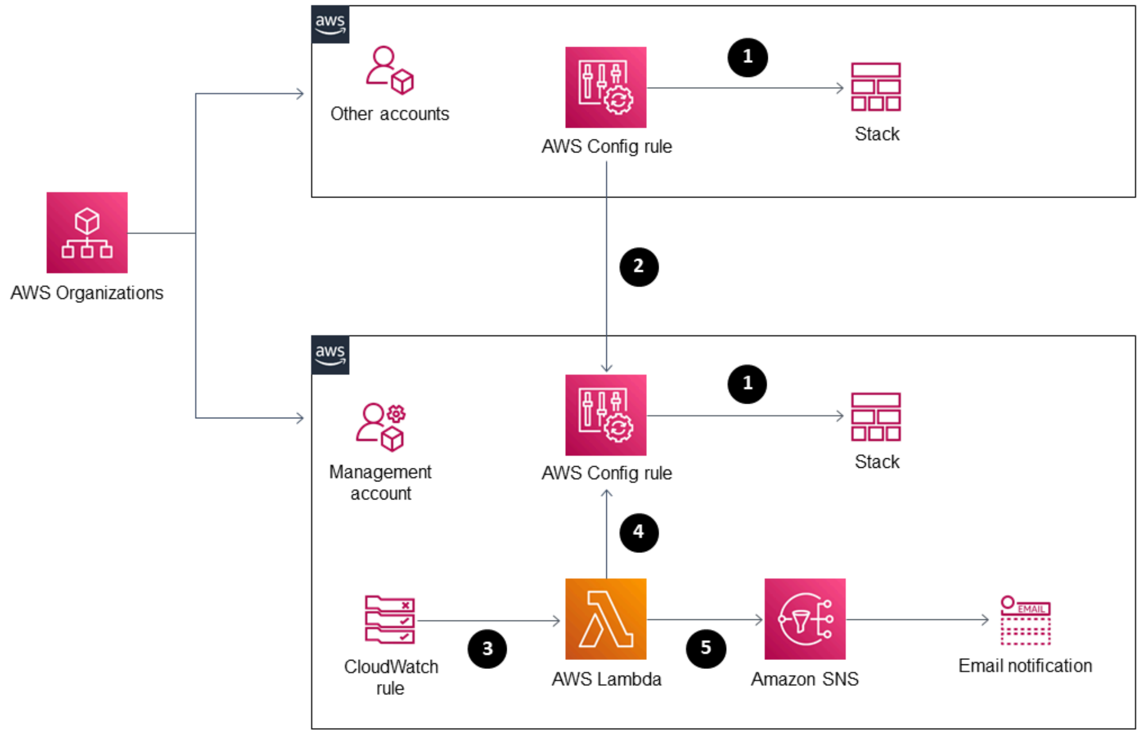
- AWS Config enabled in all the Regions and accounts that must be monitored

Limitations

- The report generated supports only the comma-separated values (CSV) and JSON output formats.

Architecture

The following diagram shows AWS Organizations set up with multiple accounts. AWS Config rules communicate between the accounts.



The workflow includes the following steps:

1. The AWS Config rule detects drift.
2. Drift detection results that are found in other accounts are sent to the management account.
3. The Amazon CloudWatch rule calls an AWS Lambda function.
4. The Lambda function queries the AWS Config rule for aggregated results.
5. The Lambda function notifies Amazon Simple Notification Service (Amazon SNS), which sends email notification of the drift.

Automation and scale

The solution presented here can scale for both additional Regions and accounts.

Tools

AWS services

- AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

Epics

Automate drift detection for AWS CloudFormation

Task	Description	Skills required
Create the aggregator.	1. Sign in to the AWS Management Console and open the AWS Config console at https://console.aws.amazon.com/config. 2. Create an aggregator in the management account. 3. Ensure that data replication is turned on so that AWS Config can fetch data from the source accounts. 4. Select all applicable Regions and accounts. You can select accounts based on AWS Organizations. We recommend this approach	Cloud architect

Task	Description	Skills required
	because new accounts in the organization are automatically part of the aggregator.	
Create an AWS managed rule.	Add the `cloudformation-stack-drift-detection-check` AWS managed rule. The rule needs one parameter value: `cloudformationArn` . Enter the IAM role Amazon Resource Name (ARN) that has permissions to detect stack drift. The role must have a trust policy that enables AWS Config to assume the role.	Cloud architect
Create the advanced query section of the aggregator.	To fetch drifted stacks from multiple sources, create the following query: `SELECT resourceId, configuration.driftInformation.stackDriftStatus WHERE resourceType = 'AWS::CloudFormation::Stack' AND configuration.driftInformation.stackDriftStatus IN ('DRIFTED')`	Cloud architect, Developer

Task	Description	Skills required
Automate running the query and publish.	1. Create a Lambda function by using the code that is attached. Lambda will publish the results to an SNS topic that is provided as an environment variable in the Lambda function. 2. To receive alerts, create an email subscription to the SNS topic.	Cloud architect, Developer
Create a CloudWatch rule.	Create a schedule-based CloudWatch rule to call the Lambda function, which is responsible for alerting.	Cloud architect

Resources

- What Is AWS Config?
- Multi-account multi-Region data aggregation
- Detecting unmanaged configuration changes to stacks and resources
- IAM: Pass an IAM role to a specific AWS service
- What is Amazon SNS?

Additional information

Considerations

We recommend using the solution presented in this pattern instead of using custom solutions that involve API calls at specific intervals to initiate drift detection on each CloudFormation stack or stack set. Custom solutions that use API calls at specific intervals can lead to a large number API calls and affect performance. Because of the number of API calls, throttling can occur. Another potential issue is a delay in detection if resource changes are identified based on schedule only.

Because stack sets are made of stacks, you can use this solution. Stack instance details are also available as part of the solution.

Successfully import an S3 bucket as an AWS CloudFormation stack

Ram Kandaswamy, Amazon Web Services

Summary

If you use Amazon Web Services (AWS) resources, such as Amazon Simple Storage Service (Amazon S3) buckets, and want to use an infrastructure as code (IaC) approach, then you can import your resources into AWS CloudFormation and manage them as a stack.

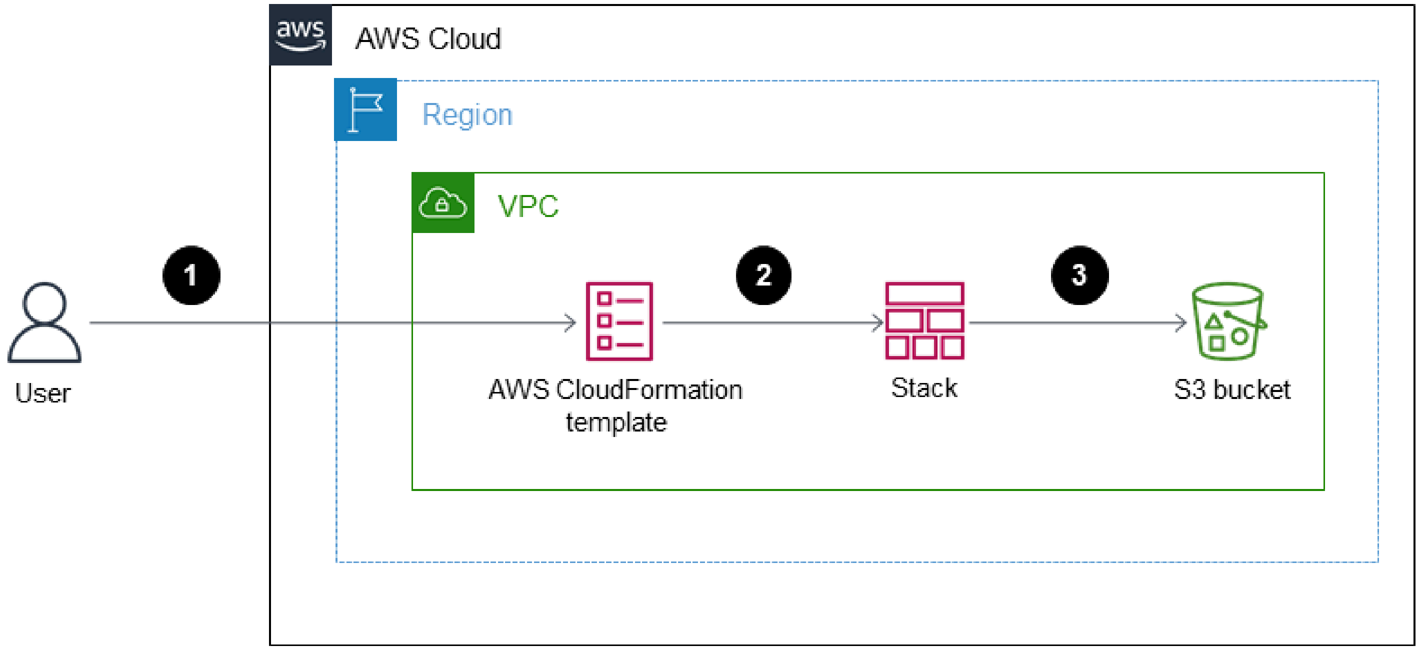
This pattern provides steps to successfully import an S3 bucket as an AWS CloudFormation stack. By using this pattern's approach, you can avoid possible errors that might occur if you import your S3 bucket in a single action.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing S3 bucket and S3 bucket policy. For more information about this, see What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only in the AWS Knowledge Center.
- An existing AWS Key Management Service (AWS KMS) key and its alias. For more information about this, see Working with aliases in the AWS KMS documentation.
- The sample `CloudFormation-template-S3-bucket` AWS CloudFormation template (attached), downloaded to your local computer.

Architecture



The diagram shows the following workflow:

1. The user creates a JSON or YAML-formatted AWS CloudFormation template.
2. The template creates an AWS CloudFormation stack to import the S3 bucket.
3. The AWS CloudFormation stack manages the S3 bucket that you specified in the template.

Technology stack

- AWS CloudFormation
- AWS Identity and Access Management (IAM)
- AWS KMS
- Amazon S3

Tools

- AWS CloudFormation – AWS CloudFormation helps you to create and provision AWS infrastructure deployments predictably and repeatedly.

- [AWS Identity and Access Management (IAM)] – IAM is a web service for securely controlling access to AWS services.
- [AWS KMS] – AWS Key Management Service (AWS KMS) is an encryption and key management service scaled for the cloud.
- [Amazon S3] – Amazon Simple Storage Service (Amazon S3) is storage for the Internet.

Epics

Import an S3 bucket with AWS KMS key-based encryption as an AWS CloudFormation stack

Task	Description	Skills required

Create a template to import the S3 bucket and KMS key.	On your local computer, create a template to import your S3 bucket and KMS key by using the following sample template:
	``
	AWSTemplateFormatVersion: 2010-09-09
	Parameters:
	  bucketName:
	    Type: String
	Resources:
	  S3Bucket:
	    Type: 'AWS::S3::Bucket'
	    DeletionPolicy: Retain
	    Properties:
	``
		AWS DevOps

Task	Description	Skills required

	``
	      BucketName: !Ref
	 bucketName
	
	      BucketEncryption:
	
	        ServerSid
	eEncryptionConfigu
	ration:
	
	          - ServerSid
	eEncryptionByDefault:
	
	              SSEAlgori
	thm: 'aws:kms'
	
	              KMSMaster
	KeyID: !GetAtt
	
	                -
	 KMSS3Encryption
	
	                - Arn
	
	  KMSS3Encryption:
	
	    Type: 'AWS::KMS
	::Key'
	
	    DeletionPolicy:
	 Retain
	
	    Properties:
	
	      Enabled: true
	
	      KeyPolicy: !Sub
	 |-
	
	        {
	
	            "Id": "key-
	consolepolicy-3",
	``	

Task	Description	Skills required
| | ```
 "Version": "2012-10-17",
 "Statement": [
 {
 "Sid": "Enable IAM User Permissions",
 "Effect": "Allow",
 "Principal": {
 "AWS": ["arn:aws:iam::${AWS::AccountId}:root"]
 },
 "Action": "kms:*",
 "Resource": "*"
 }
 }
 ]
 }
``` | |
```

Task	Description	Skills required
	`EnableKey` `Rotation: true`	
Create the stack.	1. Sign in to the AWS Management Console, open the AWS CloudFormation console, choose **View stack**, choose **Create stack**, and then choose **With existing resources (import resources)**. 2. Choose **Upload a template file** and then upload the template file that you created earlier. 3. Enter a name for your stack and configure the remaining options according to your requirements. 4. Choose **Create stack** and wait for the stack's status to change to `IMPORT_COMPLETE` .	AWS DevOps

Task	Description	Skills required

Create the KMS key alias.	1. On the AWS CloudFormation console, choose **Stacks**, choose the name of the stack that you created earlier, choose the **Template** pane, and then choose **View in Designer**.
	2. Add the following snippet to the `Resource` section of your template, and then choose **Create stack** and complete the wizard:
	
	`KMSS3EncryptionAlias:`
	`    Type: 'AWS::KMS::Alias'`
	`    DeletionPolicy: Retain`
	`    Properties:`
	`    AliasName: alias/S3BucketKey`
	`    TargetKeyId: !Ref KMSS3Encryption`
	
	For more information about this, see [AWS CloudFormation stack updates](#) in the AWS CloudFormation documentation.
		AWS DevOps

Task	Description	Skills required

Update the stack to include the S3 bucket policy.	1. On the AWS CloudFormation console, choose **Stacks**, choose the name of the stack that you created earlier, choose the **Template** pane, and then choose **View in Designer**.
	2. Add the following snippet to the `Resource` section of the template, and then choose **Create stack** and complete the wizard:
	<pre>S3BucketPolicy:
	
	  Type: 'AWS::S3::BucketPolicy'
	
	  Properties:
	
	    Bucket: !Ref S3Bucket
	
	    PolicyDocument: !Sub |-
	
	      {
	
	 "Version": "2008-10-17",
	
	                  "Id": "restricthttp",
	
	 "Statement": [</pre>
		AWS DevOps

Task	Description	Skills required

	``
	                    {
	
	  "Sid": "denyhttp",
	
	  "Effect": "Deny",
	
	  "Principal": {
	
	      "AWS": "*"
	
	  },
	
	  "Action": "s3:*",
	
	  "Resource": ["arn:aws
	:s3:::${S3Bucket}"
	,"arn:aws:s3:::${S
	3Bucket}/*"],
	
	  "Condition": {
	
	      "Bool": {
	
	             "aws:Secu
	reTransport": "false"
	
	      }
	
	  }
	``	

Task	Description	Skills required

	``
	}
	]
	}
	``
	Note
	This S3 bucket policy has a deny statement that restricts API calls that are not secure.	

Update the key policy.	1. On the AWS CloudFormation console, choose **Stacks**, choose the name of the stack that you created earlier, choose the **Template** pane, and then choose **View in Designer**. 2. Modify the template's KMS resource to include the key policy that allows administrators to administer the KMS key. 3. Choose **Create stack**, choose **Next**, and then complete the wizard according to your requirements. For more information, see [Key policies in AWS KMS]() in the AWS KMS documentation.	AWS administrator

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add resource-level tags.</td><td>1. On the AWS CloudFormation console, choose Stacks, choose the name of the stack that you created earlier, choose the Template pane, and then choose View in Designer.
2. Add the following snippet to the Amazon S3 resource <code>Properties</code> section of the template, and then choose Create stack and complete the wizard:
<pre>Tags:

  - Key: createdBy

    Value: Cloudformation</pre></td><td>AWS DevOps</td></tr>

Synchronize data between Amazon EFS file systems in different AWS Regions by using AWS DataSync

Sarat Chandra Pothula and Aditya Ambati, Amazon Web Services

Summary

This solution provides a robust framework for efficient and secure data synchronization between Amazon Elastic File System (Amazon EFS) instances in different AWS Regions. This approach is scalable and provides controlled, cross-Region data replication. This solution can enhance your disaster recovery and data redundancy strategies.

By using the AWS Cloud Development Kit (AWS CDK), this pattern uses as an infrastructure as code (IaC) approach to deploy the solution resources. The AWS CDK application deploys the essential AWS DataSync, Amazon EFS, Amazon Virtual Private Cloud (Amazon VPC), and Amazon Elastic Compute Cloud (Amazon EC2) resources. This IaC provides a repeatable and version-controlled deployment process that is fully aligned with AWS best practices.

Prerequisites and limitations

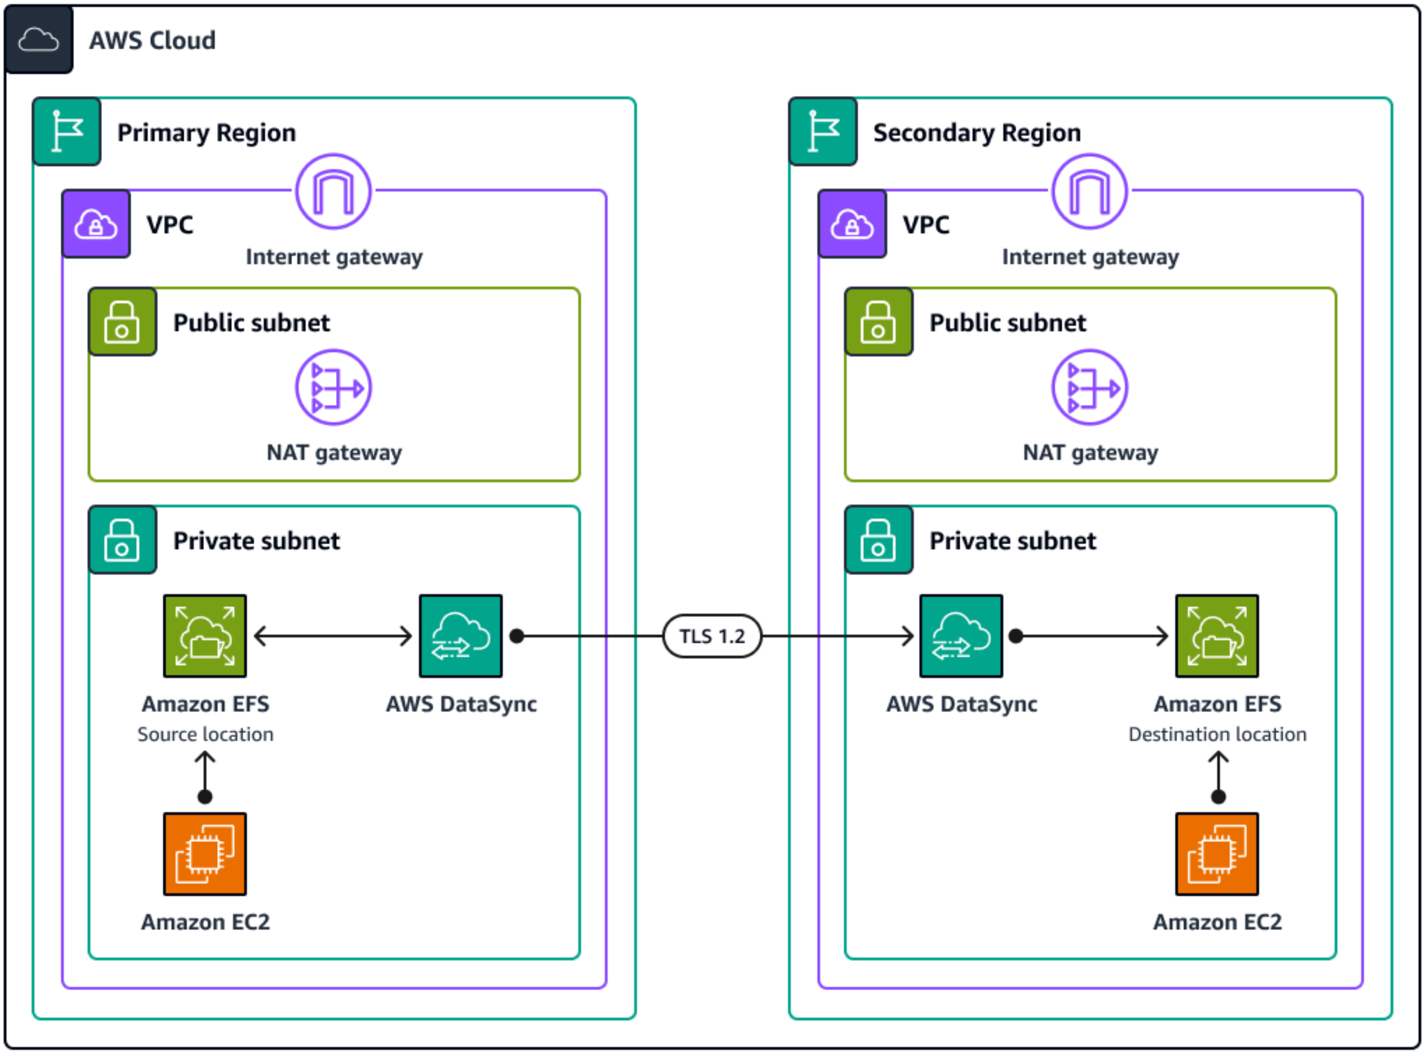
Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2.9.11 or later, installed and configured
- AWS CDK version 2.114.1 or later, installed and bootstrapped
- NodeJS version 20.8.0 or later, installed

Limitations

- The solution inherits limitations from DataSync and Amazon EFS, such as data transfer rates, size limitations, and regional availability. For more information, see AWS DataSync quotas and Amazon EFS quotas.
- This solution supports Amazon EFS only. DataSync supports other AWS services, such as Amazon Simple Storage Service (Amazon S3) and Amazon FSx for Lustre. However, this solution requires modification to synchronize data with these other services.

Architecture



This solution deploys the following AWS CDK stacks:

- **Amazon VPC stack –** This stack sets up virtual private cloud (VPC) resources, including subnets, an internet gateway, and a NAT gateway in both the primary and secondary AWS Regions.
- **Amazon EFS stack –** This stack deploys Amazon EFS file systems into the primary and secondary Regions and connects them to their respective VPCs.
- **Amazon EC2 stack –** This stack launches EC2 instances in the primary and secondary Regions. These instances are configured to mount the Amazon EFS file system, which allows them to access the shared storage.
- **DataSync location stack –** This stack uses a custom construct called `DataSyncLocationConstruct` to create DataSync location resources in the primary and secondary Regions. These resources define endpoints for data synchronization.

- **DataSync task stack –** This stack uses a custom construct called `DataSyncTaskConstruct` to create a DataSync task in the primary Region. This task is configured to synchronize data between the primary and secondary Regions by using the DataSync source and destination locations.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS DataSync is an online data transfer and discovery service that helps you move files or object data to, from, and between AWS storage services.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Elastic File System (Amazon EFS) helps you create and configure shared file systems in the AWS Cloud.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Code repository

The code for this pattern is available in the GitHub Amazon EFS Cross-Region DataSync Project repository.

Best practices

Follow the best practices described in Best practices for using the AWS CDK in TypeScript to create IaC projects.

Epics

Deploy the AWS CDK app

Task	Description	Skills required
Clone the project repository.	Enter the following command to clone the [Amazon EFS Cross-Region DataSync Project](https://github.com/aws-samples/aws-efs-crossregion-datasync) repository. `git clone https://github.com/aws-samples/aws-efs-crossregion-datasync.git`	AWS DevOps
Install the npm dependencies.	Enter the following command. `npm ci`	AWS DevOps

Choose the primary and secondary Regions.	In the cloned repository, navigate to the `src/infa` directory. In the `Launcher.ts` file, update the `PRIMARY_AWS_REGION` and `SECONDARY_AWS_REGION` values. Use the corresponding Region codes.
	`const primaryRegion = { account: account, region: '<PRIMARY_AWS_REGION>' };`
	`const secondaryRegion = { account: account, region: '<SECONDARY_AWS_REGION>' };`
		AWS DevOps

Task	Description	Skills required
Bootstrap the environment.	Enter the following command to bootstrap the AWS account and AWS Region that you want to use. `cdk bootstrap <aws_account>/<aws_region>` For more information, see [Bootstrapping](#) in the AWS CDK documentation.	AWS DevOps
List the AWS CDK stacks.	Enter the following command to view a list of the AWS CDK stacks in the app. `cdk ls`	AWS DevOps
Synthesize the AWS CDK stacks.	Enter the following command to produce an AWS CloudFormation template for each stack defined in the AWS CDK app. `cdk synth`	AWS DevOps
Deploy the AWS CDK app.	Enter the following command to deploy all of the stacks to your AWS account, without requiring manual approval for any changes. `cdk deploy --all --require-approval never`	AWS DevOps

Validate the deployment

Task	Description	Skills required
Log in to the EC2 instance in the primary Region.	1. Using Session Manager, a capability of AWS Systems Manager, log in to the EC2 instance in the primary Region. For instructions, see [Connect to your Linux instance with AWS Systems Manager Session Manager](). 2. Change directories to the Amazon EFS mount path. `cd /mnt/efs`	AWS DevOps

Create a temporary file.	Enter the following command to create a temporary file in the Amazon EFS mount path.
	 `sudo dd if=/dev/zero \`
	`of=tmptst.dat \`
	`bs=1G \`
	`seek=5 \`
	`count=0`
	
	`ls -lrt tmptst.dat`
		AWS DevOps

Start the DataSync task.	Enter the following command to replicate the temporary file from the primary Region to the secondary Region, where `<ARN-task>` is the Amazon Resource Name (ARN) of your DataSync task.	AWS DevOps

Task	Description	Skills required

	``
	aws datasync start-tas
	k-execution \
	    --task-arn <ARN-
	task>
	``
	
	The command returns the ARN of the task execution in the following format.
	
	`arn:aws:datasync:<region>:<account-ID>:task/task-execution/<exec-ID>`	

Check the status of the data transfer.	Enter the following command to describe the DataSync execution task, where `<ARN-task-execution>` is the ARN of the task execution. ``` aws datasync describe- task-execution \ --task-execution-a rn <ARN-task-executio n> ``` The DataSync task is complete when `PrepareStatus` , `TransferStatus` , and `VerifyStatus` all have the value SUCCESS.	AWS DevOps

Task	Description	Skills required
Log in to the EC2 instance in the secondary Region.	1. Using Session Manager, a capability of AWS Systems Manager, log in to the EC2 instance in the secondary Region. For instructions, see [Connect to your Linux instance with AWS Systems Manager Session Manager](). 2. Change directories to the Amazon EFS mount path. `cd /mnt/efs`	AWS DevOps
Validate the replication.	Enter the following command to verify that the temporary file exists in the Amazon EFS file system. `ls -lrt tmptst.dat`	AWS DevOps

Test AWS infrastructure by using LocalStack and Terraform Tests

Ivan Girardi and Ioannis Kalyvas, Amazon Web Services

Summary

This pattern helps you locally test infrastructure as code (IaC) for AWS in Terraform without the need to provision infrastructure in your AWS environment. It integrates the Terraform Tests framework with LocalStack. The LocalStack Docker container provides a local development environment that emulates various AWS services. This helps you test and iterate on infrastructure deployments without incurring costs in the AWS Cloud.

This solution provides the following benefits:

- **Cost optimization –** Running tests against LocalStack eliminates the need to use AWS services. This prevents you from incurring costs that are associated with creating, operating, and modifying those AWS resources.
- **Speed and efficiency –** Testing locally is also typically faster than deploying the AWS resources. This rapid feedback loop accelerates development and debugging. Because LocalStack runs locally, you can develop and test your Terraform configuration files without an internet connection. You can debug Terraform configuration files locally and receive immediate feedback, which streamlines the development process.
- **Consistency and reproducibility –** LocalStack provides a consistent environment for testing. This consistency helps make sure that tests yield the same results, regardless of external AWS changes or network issues.
- **Isolation –** Testing with LocalStack prevents you from accidentally affecting live AWS resources or production environments. This isolation makes it safe to experiment and test various configurations.
- **Automation –** Integration with a continuous integration and continuous delivery (CI/CD) pipeline helps you automatically test Terraform configuration files. The pipeline thoroughly tests the IaC before deployment.
- **Flexibility –** You can simulate different AWS Regions, AWS accounts, and service configurations to match your production environments more closely.

Prerequisites and limitations

Prerequisites

- Install Docker
- Enable access to the default Docker socket (`/var/run/docker.sock`). For more information, see the LocalStack documentation.
- Install Docker Compose
- Install Terraform version 1.6.0 or later
- Install Terraform CLI
- Configure the Terraform AWS Provider
- (Optional) Install and configure the AWS Command Line Interface (AWS CLI). For an example of how to use the AWS CLI with LocalStack, see the GitHub Test AWS infrastructure using LocalStack and Terraform Tests repository.

Limitations

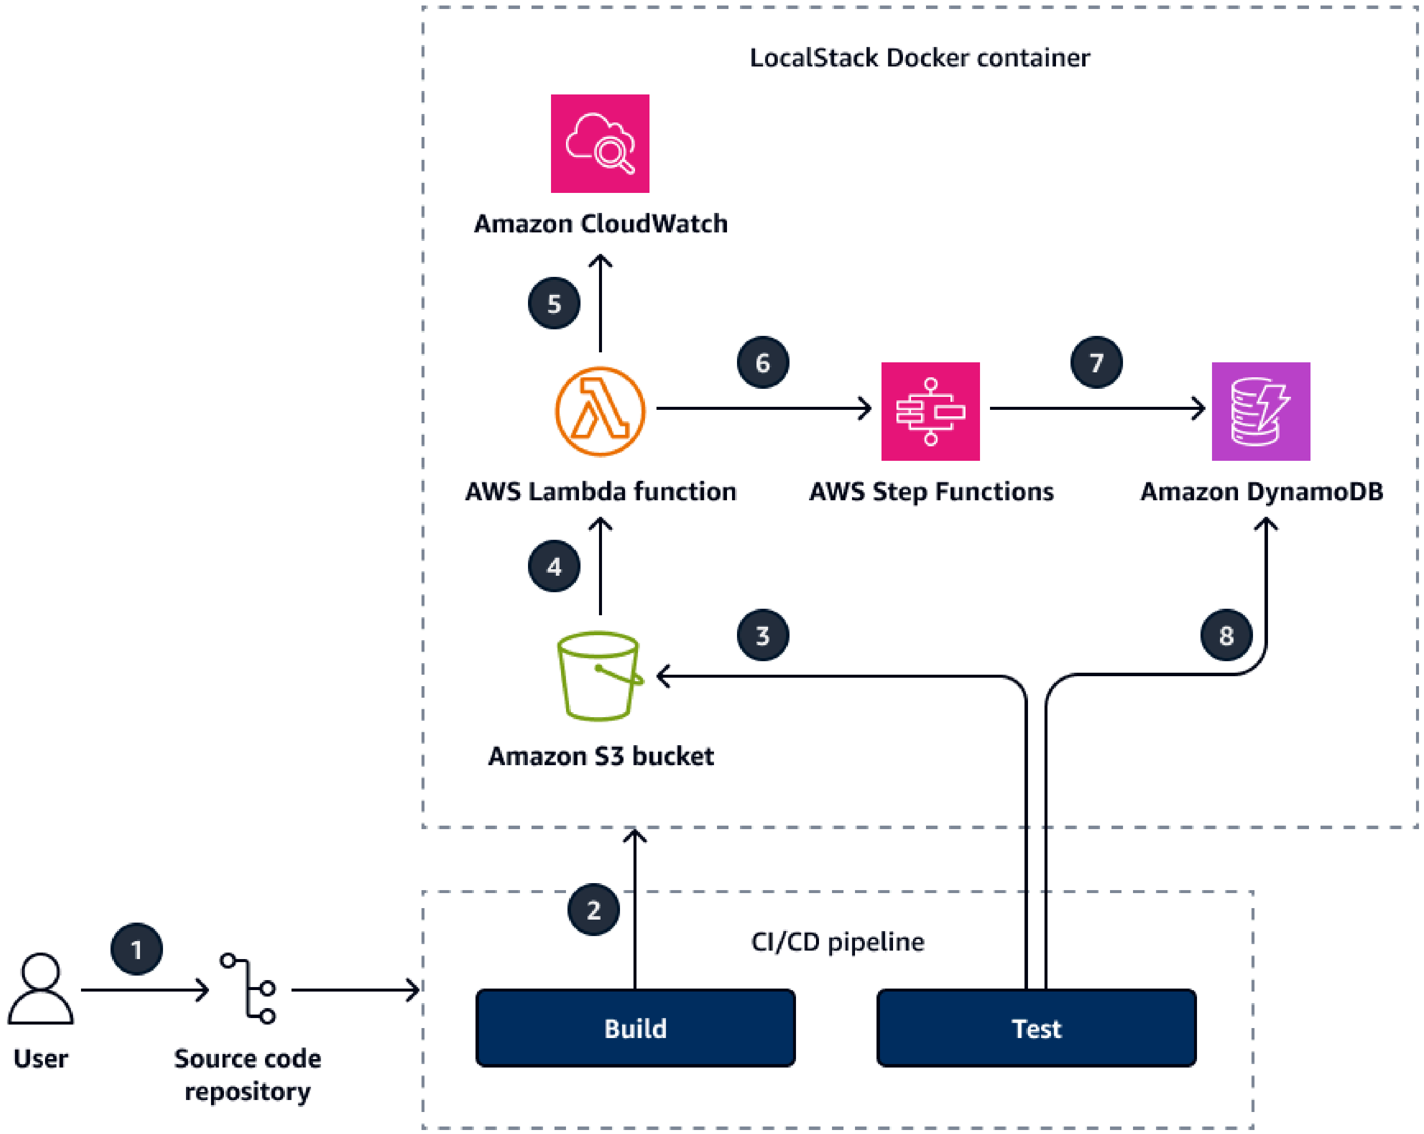
- This pattern provides explicit examples for testing Amazon Simple Storage Service (Amazon S3), AWS Lambda, AWS Step Functions, and Amazon DynamoDB resources. However, you can extend this solution to include additional AWS resources.
- This pattern provides instructions to run Terraform Tests locally, but can you can integrate testing into any CI/CD pipeline.
- This pattern provides instructions for using the LocalStack Community image. If you're using the LocalStack Pro image, see the LocalStack Pro documentation.
- LocalStack provides emulation services for different AWS APIs. For a complete list, see AWS Service Feature Coverage. Some advanced features might require a subscription for LocalStack Pro.

Architecture

The following diagram shows the architecture for this solution. The primary components are a source code repository, a CI/CD pipeline, and a LocalStack Docker container. The LocalStack Docker Container hosts the following AWS services locally:

- An Amazon S3 bucket for storing files
- Amazon CloudWatch for monitoring and logging
- An AWS Lambda function for running serverless code
- An AWS Step Functions state machine for orchestrating multi-step workflows

- An Amazon DynamoDB table for storing NoSQL data



The diagram shows the following workflow:

1. You add and commit a Terraform configuration file to the source code repository.
2. The CI/CD pipeline detects the changes and initiates a build process for static Terraform code analysis. The pipeline builds and runs the LocalStack Docker container. Then the pipeline starts the test process.
3. The pipeline uploads an object into an Amazon S3 bucket that is hosted in the LocalStack Docker container.
4. Uploading the object invokes an AWS Lambda function.

5. The Lambda function stores the Amazon S3 event notification in a CloudWatch log.
6. The Lambda function starts an AWS Step Functions state machine.
7. The state machine writes the name of the Amazon S3 object into a DynamoDB table.
8. The test process in the CI/CD pipeline verifies that the name of the uploaded object matches the entry in the DynamoDB table. It also verifies that the S3 bucket is deployed with the specified name and that the AWS Lambda function has been successfully deployed.

Tools

AWS services

- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.

Other tools

- Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.
- Docker Compose is a tool for defining and running multi-container applications.
- LocalStack is a cloud service emulator that runs in a single container. By using LocalStack, you can run workloads on your local machine that use AWS services, without connecting to the AWS Cloud.
- Terraform is an IaC tool from HashiCorp that helps you create and manage cloud and on-premises resources.
- Terraform Tests helps you validate Terraform module configuration updates through tests that are analogous to integration or unit testing.

Code repository

The code for this pattern is available in the GitHub Test AWS infrastructure using LocalStack and Terraform Tests repository.

Best practices

- This solution tests AWS infrastructure that is specified in Terraform configuration files, and it does not deploy those resources in the AWS Cloud. If you want to deploy the resources, follow the principle of least-privilege (IAM documentation) and properly configure the Terraform backend (Terraform documentation).
- When integrating LocalStack in a CI/CD pipeline, we recommend that you don't run the LocalStack Docker container in privilege mode. For more information, see Runtime privilege and Linux capabilities (Docker documentation) and Security for self-managed runners (GitLab documentation).

Epics

Deploy the solution

Task	Description	Skills required
Clone the repository.	In a bash shell, enter the following command. This clones the Test AWS infrastructure using LocalStack and Terraform Tests repository from GitHub: `git clone https://github.com/aws-samples/localstack-terraform-test.git`	DevOps engineer
Run the LocalStack container.	1. Enter the following command to navigate into the cloned repository:	DevOps engineer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>cd localstack-terrafo
rm-test</code></pre>
2. Enter the following command to start the LocalStack Docker container in detached mode:
<pre><code>docker-compose up -d</code></pre>
3. Wait until the LocalStack Docker container is operational.</td><td></td></tr>
<tr><td>Initialize Terraform.</td><td>Enter the following command to initialize Terraform:
<pre><code>terraform init</code></pre></td><td>DevOps engineer</td></tr>
<tr><td>Run Terraform Tests.</td><td>1. Enter the following command to run Terraform Tests:
<pre><code>terraform test</code></pre>
2. Verify that all tests completed successfully. The output should be similar to the following:
<pre><code>Success! 3 passed, 0
 failed.</code></pre></td><td>DevOps engineer</td></tr>
</table>

Task	Description	Skills required
Clean up resources.	Enter the following command to destroy the LocalStack container: `docker-compose down`	DevOps engineer

Troubleshooting

Issue	Solution

`Error: reading DynamoDB Table Item (Files|README.md): empty` result when running the `terraform test` command.	1. Reenter the `terraform test` command.
	2. If that doesn't resolve the error, edit the **main.tf** file to increase the sleep timeout to a value greater than 15 seconds:
	`resource "time_sleep" "wait" {`
	`  create_duration = "15s"`
	`  triggers = {`
	`    s3_object = local.key_json`
	`  }`
	`}`

Additional information

Integration with GitHub Actions

You can integrate LocalStack and Terraform Tests in a CI/CD pipeline by using GitHub Actions. For more information, see the [GitHub Actions documentation](). The following is a sample GitHub Actions configuration file:

```
name: LocalStack Terraform Test

on:
  push:
    branches:
      - '**'

  workflow_dispatch: {}

jobs:
  localstack-terraform-test:
    runs-on: ubuntu-latest

    steps:
    - uses: actions/checkout@v4

    - name: Build and Start LocalStack Container
      run: |
        docker compose up -d

    - name: Setup Terraform
      uses: hashicorp/setup-terraform@v3
      with:
        terraform_version: latest

    - name: Run Terraform Init and Validation
      run: |
        terraform init
        terraform validate
        terraform fmt --recursive --check
        terraform plan
        terraform show

    - name: Run Terraform Test
      run: |
```

```
        terraform test

    - name: Stop and Delete LocalStack Container
      if: always()
      run: docker compose down
```

Upgrade SAP Pacemaker clusters from ENSA1 to ENSA2

Gergely Cserdi and Balazs Sandor Skublics, Amazon Web Services

Summary

This pattern explains the steps and considerations for upgrading an SAP Pacemaker cluster that is based on Standalone Enqueue Server (ENSA1) to ENSA2. The information in this pattern applies to both SUSE Linux Enterprise Server (SLES) and Red Hat Enterprise Linux (RHEL) operating systems.

Pacemaker clusters on SAP NetWeaver 7.52 or S/4HANA 1709 and earlier versions run on an ENSA1 architecture and are configured specifically for ENSA1. If you run your SAP workloads on Amazon Web Services (AWS) and you're interested in moving to ENSA2, you might find that the SAP, SUSE, and RHEL documentation doesn't provide comprehensive information. This pattern describes the technical steps required to reconfigure SAP parameters and Pacemaker clusters to upgrade from ENSA1 to ENSA2. It provides examples of SUSE systems, but the concept is the same for RHEL clusters.

Notes: ENSA1 and ENSA2 are concepts that pertain to SAP applications only, so the information in this pattern doesn't apply to SAP HANA or other types of clusters.

Technically, ENSA2 can be used with or without Enqueue Replicator 2. However, high availability (HA) and failover automation (through a cluster solution) require Enqueue Replicator 2. This pattern uses the term *ENSA2 clusters* to refer to clusters with Standalone Enqueue Server 2 and Enqueue Replicator 2.

Prerequisites and limitations

Prerequisites

- A working ENSA1-based cluster that uses Pacemaker and Corosync on SLES or RHEL.
- At least two Amazon Elastic Compute Cloud (Amazon EC2) instances where the (ABAP) SAP Central Services (ASCS/SCS) and Enqueue Replication Server (ERS) instances are running.
- Knowledge of managing SAP applications and clusters.
- Access to the Linux environment as root user.

Limitations

- ENSA1-based clusters support a two-node architecture only.
- ENSA2-based clusters cannot be deployed to SAP NetWeaver versions before 7.52.
- EC2 instances in clusters should be in different AWS Availability Zones.

Product versions

- SAP NetWeaver version 7.52 or later
- Starting with S/4HANA 2020, only ENSA2 clusters are supported
- Kernel 7.53 or later, which supports ENSA2 and Enqueue Replicator 2
- SLES for SAP Applications version 12 or later
- RHEL for SAP with High Availability (HA) version 7.9 or later

Architecture

Source technology stack

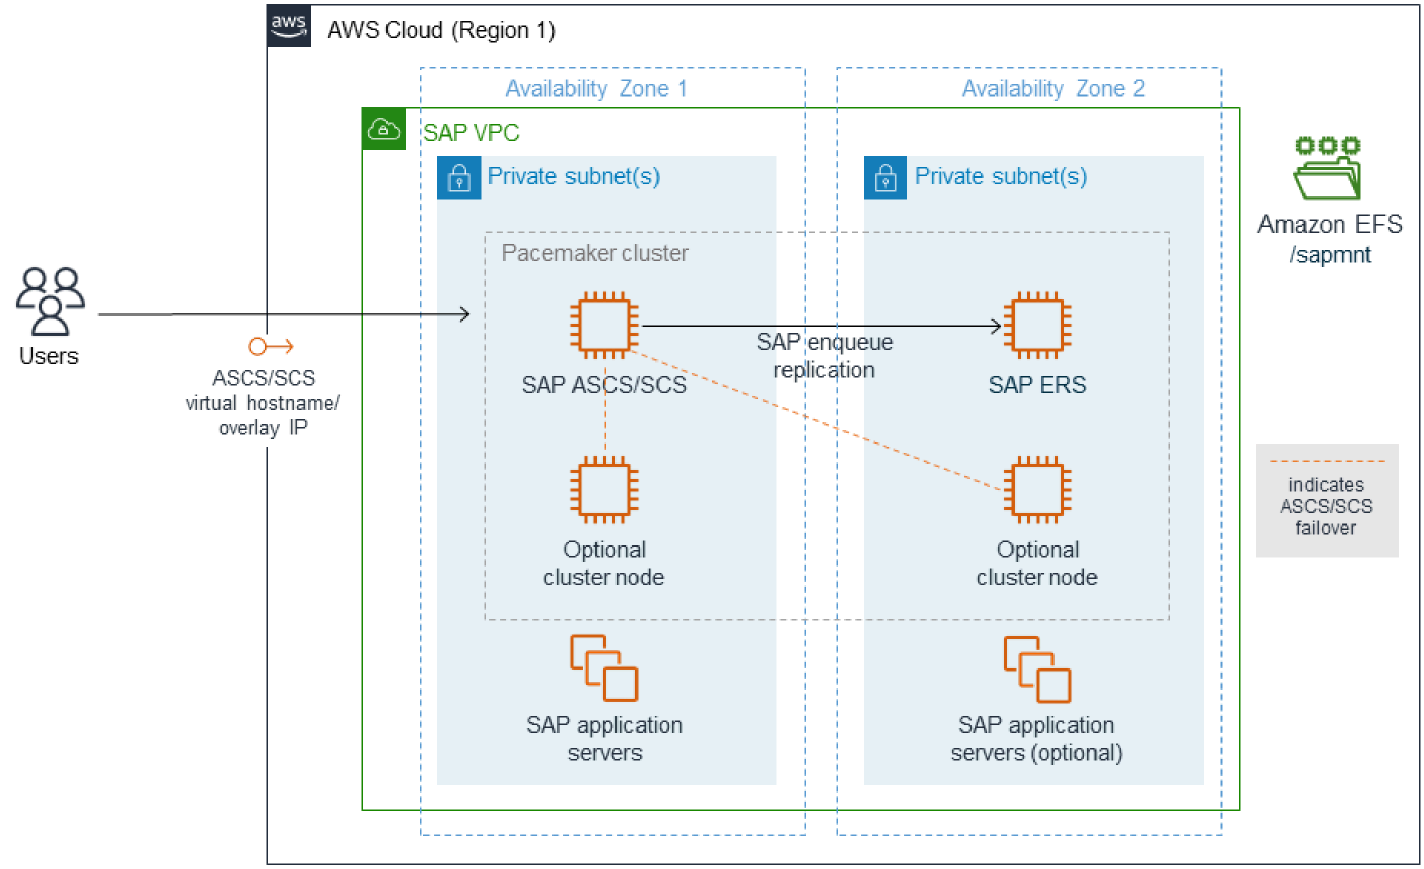
- SAP NetWeaver 7.52 with SAP Kernel 7.53 or later
- SLES or RHEL operating system

Target technology stack

- SAP NetWeaver 7.52 with SAP Kernel 7.53 or later, including S/4HANA 2020 with ABAP platform
- SLES or RHEL operating system

Target architecture

The following diagram shows an HA configuration of ASCS/SCS and ERS instances based on an ENSA2 cluster.



Comparison of ENSA1 and ENSA2 clusters

SAP introduced ENSA2 as the successor to ENSA1. An ENSA1-based cluster supports a two-node architecture where the ASCS/SCS instance fails over to ERS when an error occurs. This limitation stems from how the ASCS/SCS instance regains the lock table information from the shared memory of the ERS node after failover. ENSA2-based clusters with Enqueue Replicator 2 eliminate this limitation, because the ASCS/SCS instance can collect the lock information from the ERS instance over the network. ENSA2-based clusters can have more than two nodes, because the ASCS/SCS instance is no longer required to fail over to the ERS node. (However, in a two-node ENSA2 cluster environment, the ASCS/SCS instance will still fail over to the ERS node because there are no other nodes in the cluster to fail over to.) ENSA2 is supported starting with SAP Kernel 7.50 with some limitations. For HA setup that supports Enqueue Replicator 2, the minimum requirement is NetWeaver 7.52 (see SAP OSS Note 2630416). S/4HANA 1809 comes with ENSA2 architecture recommended by default, whereas S/4HANA supports only ENSA2 starting with version 2020.

Automation and scale

The HA cluster in the target architecture makes ASCS fail over to other nodes automatically.

Scenarios for moving to ENSA2-based clusters

There are two main scenarios for upgrading to ENSA2-based clusters:

- Scenario 1: You choose to upgrade to ENSA2 without an accompanying SAP upgrade or S/4HANA conversion, assuming that your SAP release and Kernel version support ENSA2.
- Scenario 2: You move to ENSA2 as part of an upgrade or conversion (for example, to S/4HANA 1809 or later) by using SUM.

The Epics section covers the steps for these two scenarios. The first scenario requires you to manually set up SAP-related parameters before you change the cluster configuration for ENSA2. In the second scenario, the binaries and SAP-related parameters are deployed by SUM, and your only remaining task is to update the cluster configuration for HA. We still recommend that you validate SAP parameters after you use SUM. In most cases, S/4HANA conversion is the main reason for a cluster upgrade.

Tools

- For OS package managers, we recommend the Zypper (for SLES) or YUM (for RHEL) tools.
- For cluster management, we recommend **crm** (for SLES) or **pcs** (for RHEL) shells.
- SAP instance management tools such as SAPControl.
- (Optional) SUM tool for S/4HANA conversion upgrade.

Best practices

- For best practices for using SAP workloads on AWS, see the SAP Lens for the AWS Well-Architected Framework.
- Consider the number of cluster nodes (odd or even) in your ENSA2 multi-node architecture.
- Set up the ENSA2 cluster for SLES 15 in alignment with the SAP S/4-HA-CLU 1.0 certification standard.
- Always save or back up your existing cluster and application state before upgrading to ENSA2.

Epics

Configure SAP parameters manually for ENSA2 (scenario 1 only)

Task	Description	Skills required
Configure the parameters in the default profile.	If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the parameters in the default profile (DEFAULT.PFL file) to the following values. ```enq/enable=TRUE enq/serverhost=sapascsvirt enq/serverinst=10 (instance number of ASCS/SCS instance) enque/process_location=REMOTESA enq/replicatorhost=sapersvirt enq/replicatorinst=11 (instance number of ERS instance)``` where `sapascsvirt` is the virtual hostname for the ASCS instances, and `sapersvirt` is the virtual hostname for the ERS instances. You can change these to fit your target environment.	SAP

Task	Description	Skills required
	Note To use this upgrade option, your SAP release and Kernel version must support ENSA2 and Enqueue Replicator 2.	

Task	Description	Skills required

Configure the ASCS/SCS instance profile.	If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the following parameters in the ASCS/SCS instance profile.
	
	The section of the profile where ENSA1 is defined looks something like the following.
	
	`#-----------------------------------------------------------------------------------`
	`Start SAP enqueue server`
	`#-----------------------------------------------------------------------------------`
	`_EN = en.sap$(SAPSYSTEMNAME)$(INSTANCE_NAME)`
	`Execute_04 = local rm -f $(_EN)`
	`Execute_05 = local ln -s -f $(DIR_EXECUTABLE)/enserver$(FT_EXE) $(_EN)`
	`Start_Program_01 = local $(_EN) pf=$(_PF)`
	
	To reconfigure this section for ENSA2:
		SAP

Task	Description	Skills required

	1. Change the _EN program prefix to _ENQ based on the latest information from SAP (OSS Note 2501860; requires an [SAP ONE Support Launchpad user account](#)).
	2. Change the binary for enqueue server from `enserver` to `enq_server` .
	3. Set the new parameter `enq/server/replication/enable` to TRUE.
	4. Make sure that `Autostart = 0`.
	
	This profile section would look something like the following after your changes.
	
	`#-----------------------------------------------------`
	`Start SAP enqueue server`
	`#-------------------------------------------------------`
	`_ENQ = enq.sap$(SAPSYSTEMNAME)$(INSTANCE_NAME)`
	`Execute_04 = local rm -f $(_ENQ)`	

Task	Description	Skills required
	``` Execute_05 = local ln - s -f $(DIR_EXECUTABLE)/ enq_server$(FT_EXE) $(_ENQ) Start_Program_01 = local $(_ENQ) pf= $(_PF) ... enq/server/replic ation/enable = TRUE Autostart = 0 ``` **Important** _ENQ must not have the restart option enabled. If `RestartProgram_01` is set for _ENQ, change it to `StartProgram_01`. This prevents SAP from restarting the service or interfering with cluster-managed resources.	

Task	Description	Skills required

Configure the ERS profile.	If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the following parameters in the ERS instance profile.
	
	Find the section where the enqueue replicator is defined. It will be similar to the following.
	
	`#----------------------------------------------------- Start enqueue replication server`
	`#-----------------------------------------------------`
	`_ER = er.sap$(SAPSYSTEMNAME)$(INSTANCE_NAME)`
	`Execute_03 = local rm -f $(_ER)`
	`Execute_04 = local ln -s -f $(DIR_EXECUTABLE)/enrepserver$(FT_EXE) $(_ER)`
	`Start_Program_00 = local $(_ER) pf=$(_PF) NR=$(SCSID)`
	
	To reconfigure this section for Enqueue Replicator 2:
		SAP

Task	Description	Skills required

	1. Change the _ER program prefix to _ENQR based on the latest notes from SAP (OSS Note 2501860; requires an SAP ONE Support Launchpad user account).
	2. Change the binary for the enqueue replicator to `enq_replicator` instead of `enrepserver` .
	3. Make sure that `Autostart = 0`.
	
	This profile section should look something like the following after your changes.
	
	`#-----------------------------------------------------Start enqueue replication server`
	`#----------------------------------------------------`
	`_ENQR = enqr.sap$(SAPSYSTEMNAME)$(INSTANCE_NAME)`
	`Execute_01 = local rm -f $(_ENQR)`
	`Execute_02 = local ln -s -f $(DIR_EXECUTABLE)/enq_replicator$(FT_EXE) $(_ENQR)`	

Task	Description	Skills required

	<pre>Start_Program_00 =
	 local $(_ENQR) pf=
	$(_PF) NR=$(SCSID)
	…
	Autostart = 0</pre> **Important** _ENQR must not have the restart option enabled. If `RestartProgram_01` is set for _ENQR, change it to `StartProgram_01` . This prevents SAP from restarting the service or interfering with cluster-managed services.	

Task	Description	Skills required

Restart SAP Start Services.	After you change the profiles described previously in this epic, restart SAP Start Services for both ASCS/SCS and ERS.
	
	`sapcontrol -nr 10 -function RestartService SCT`
	
	`sapcontrol -nr 11 -function RestartService SCT`
	
	where SCT refers to the SAP system ID, and assuming that 10 and 11 are the instance numbers for ASCS/SCS and ERS instances, respectively.
		SAP

Reconfigure the cluster for ENSA2 (required for both scenarios)

Task	Description	Skills required
Verify version numbers in SAP resource agents.	When you use SUM to upgrade SAP to S/4HANA 1809 or later, SUM handles the parameter changes in the SAP profiles. Only the cluster requires manual adjustment. However, we recommend that you verify the parameter settings before you make any changes to the cluster.	AWS systems administrator

Task	Description	Skills required

	Note
	
	The examples in this epic assume that you're using the SUSE operating system. If you're using RHEL, you will need to use tools such as YUM and the **pcs** shell instead of Zypper and **crm**.
	
	Check both nodes in the architecture to confirm that the `resource-agents` package matches the minimum version recommended by SAP. For SLES, check SAP OSS Note 2641019. For RHEL, check SAP OSS Note 2641322. (SAP Notes require an [SAP ONE Support Launchpad user account](https://me.sap.com/).)
	
	`sapers:sctadm 23> zypper search -s -i resource-agents`
	`Loading repository data...`
	`Reading installed packages...`
	`S | Name | Type | Version | Arch | Repository`
	`--+-------------`
	`----+---------+---`	

Task	Description	Skills required
	``` ------------------ ---------------+-- ------+----------- ------------------ i | resource-agents | package | 4.8.0+git 30.d0077df0-150300 .8.28.1 | x86_64 | SLE-Product-HA15-SP3- Updates ``` Update the `resource-agents` version if necessary.	
Back up cluster configuration.	Back up the CRM cluster configuration as follows. `crm configure show > /tmp/cluster_config_backup.txt`	AWS systems administrator
Set maintenance mode.	Set the cluster to maintenance mode. `crm configure property maintenance-mode="true"`	AWS systems administrator

Task	Description	Skills required

Check cluster configuration.	Check the current cluster configuration.
	
	`crm configure show`
	
	Here is an excerpt from the full output:
	
	`node 1: sapascs`
	`node 2: sapers`
	`...`
	`primitive rsc_sap_SCT_ASCS10 SAPInstance \`
	`operations $id=rsc_sap_SCT_ASCS10-operations \`
	`op monitor interval=120 timeout=60 on-fail=restart \`
	`params InstanceName=SCT_ASCS10_sapascsvirt START_PROFILE="/sapmnt/SCT/profile/SCT_ASCS10_sapascsvirt" \`
	`   AUTOMATIC_RECOVER=false \`
	`meta resource-stickiness=5000 failure-timeout=60 migration-threshold=1 priority=10`
	`primitive rsc_sap_SCT_ERS11 SAPInstance \`
	`operations $id=rsc_sap_SCT_ERS11-operations \`
	`op monitor interval=120 timeout=60 on-fail=restart \`
		AWS systems administrator

Task	Description	Skills required
	``` params InstanceN ame=SCT_ERS11_sape rsvirt START_PRO FILE="/sapmnt/SCT/ profile/SCT_ERS11_ sapersvirt" \ AUTOMATIC_RECOVER= false IS_ERS=true \ meta priority=1000 ... colocation col_sap_S CT_no_both -5000: grp_SCT_ERS11 grp_SCT_ASCS10 location loc_sap_S CT_failover_to_ers rsc_sap_SCT_ASCS10 \ rule 2000: runs_ers_SCT eq 1 order ord_sap_S CT_first_start_asc s Optional: rsc_sap_S CT_ASCS10:start rsc_sap_SCT_ERS11: stop symmetrical=false ... ``` where `sapascsvirt` refers to the virtual hostname for the ASCS instances, `sapersvirt` refers to the virtual hostname for the ERS instances, and SCT refers to the SAP system ID.	

Task	Description	Skills required
Remove failover colocation constraint.	In the previous example, the location constraint `loc_sap_SCT_failover_to_ers` specifies that the ENSA1 feature of ASCS should always follow the ERS instance upon failover. With ENSA2, ASCS should be able to fail over freely to any participating nodes, so you can remove this constraint. `crm configure delete loc_sap_SCT_failover_to_ers`	AWS systems administrator

Task	Description	Skills required
Adjust primitives.	You will also need to make minor changes to the ASCS and ERS SAPInstance primitives. Here is an example of an ASCS SAPInstance primitive that is configured for ENSA1. `primitive rsc_sap_SCT_ASCS10 SAPInstance \ operations $id=rsc_sap_SCT_ASCS10-operations \ op monitor interval=120 timeout=60 on-fail=restart \ params InstanceName=SCT_ASCS10_sapascsvirt START_PROFILE="/sapmnt/SCT/profile/SCT_ASCS10_sapascsvirt" \ AUTOMATIC_RECOVER=false \ meta resource-stickiness=5000 failure-timeout=60 migration-threshold=1 priority=10`  To upgrade to ENSA2, change this configuration to the following.  `primitive rsc_sap_SCT_ASCS10 SAPInstance \`	AWS systems administrator

Task	Description	Skills required

	``
	operations $id=rsc_s
	ap_SCT_ASCS10-oper
	ations \
	op monitor interval=120
	 timeout=60 on-fail=r
	estart \
	params InstanceN
	ame=SCT_ASCS10_sap
	ascsvirt START_PRO
	FILE="/sapmnt/SCT/
	profile/SCT_ASCS10
	_sapascsvirt" \
	   AUTOMATIC_RECOVER=
	false \
	meta resource-stickines
	s=3000
	``
	This is an example of an ERS SAPInstance primitive that is configured for ENSA1.
	``
	primitive rsc_sap_S
	CT_ERS11 SAPInstance \
	operations $id=rsc_s
	ap_SCT_ERS11-opera
	tions \
	op monitor interval=120
	 timeout=60 on-fail=r
	estart \
	params InstanceN
	ame=SCT_ERS11_sape
	rsvirt START_PRO
	FILE="/sapmnt/SCT/
	profile/SCT_ERS11_
	sapersvirt" \
	   AUTOMATIC_RECOVER=
	false IS_ERS=true \
	meta priority=1000
	``	

Task	Description	Skills required

	To upgrade to ENSA2, change this configuration to the following.
	`primitive rsc_sap_SCT_ERS11 SAPInstance \`
	`operations $id=rsc_sap_SCT_ERS11-operations \`
	`op monitor interval=120 timeout=60 on-fail=restart \`
	`params InstanceName=SCT_ERS11_sapersvirt START_PROFILE="/sapmnt/SCT/profile/SCT_ERS11_sapersvirt" \`
	`   AUTOMATIC_RECOVER=false IS_ERS=true`
	
	You can change primitives in various ways. For example, you can revise them in an editor such as vi, as in the following example.
	
	`crm configure edit rsc_sap_SCT_ERS11`	

Task	Description	Skills required
Disable maintenance mode.	Disable maintenance mode on the cluster. `crm configure property maintenance-mode=" false"` When the cluster is out of maintenance mode, it attempts to bring the ASCS and ERS instances online with the new ENSA2 settings.	AWS systems administrator

(Optional) Add cluster nodes

Task	Description	Skills required
Review best practices.	Before you add more nodes, make sure to understand best practices such as whether to use an odd or even number of nodes.	AWS systems administrator
Add nodes.	Adding more nodes involves a series of tasks, such as updating the operating system, installing software packages that match the existing nodes, and making mounts available. You can use the **Prepare Additional Host** option in SAP Software Provisioning Manager (SWPM) to create an SAP-specific baseline of the host. For	AWS systems administrator

Task	Description	Skills required
	more information, see the SAP guides listed in the next section.

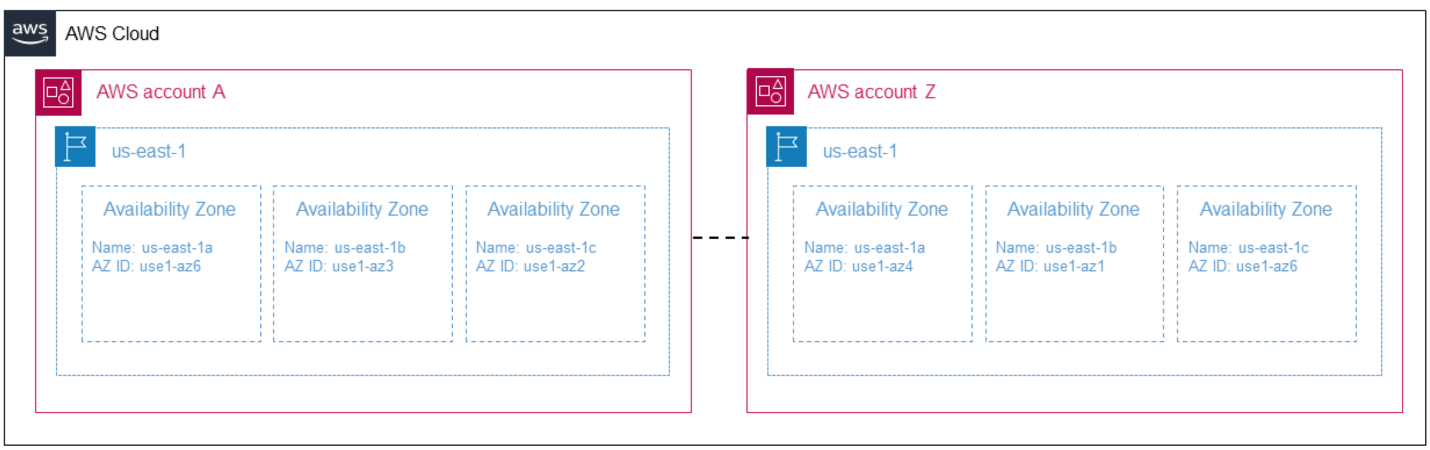
Use consistent Availability Zones in VPCs across different AWS accounts

Adam Spicer, Amazon Web Services

Summary

On the Amazon Web Services (AWS) Cloud, an Availability Zone has a name that can vary between your AWS accounts and an Availability Zone ID (AZ ID) that identifies its location. If you use AWS CloudFormation to create virtual private clouds (VPCs), you must specify the Availability Zone's name or ID when creating the subnets. If you create VPCs in multiple accounts, the Availability Zone name is randomized, which means that subnets use different Availability Zones in each account.

To use the same Availability Zone across your accounts, you must map the Availability Zone name in each account to the same AZ ID. For example, the following diagram shows that the `use1-az6` AZ ID is named `us-east-1a` in AWS account A and `us-east-1c` in AWS account Z.



This pattern helps ensure zonal consistency by providing a cross-account, scalable solution for using the same Availability Zones in your subnets. Zonal consistency ensures that your cross-account network traffic avoids cross-Availability Zone network paths, which helps reduce data transfer costs and lower network latency between your workloads.

This pattern is an alternative approach to the AWS CloudFormation AvailabilityZoneId property.

Prerequisites and limitations

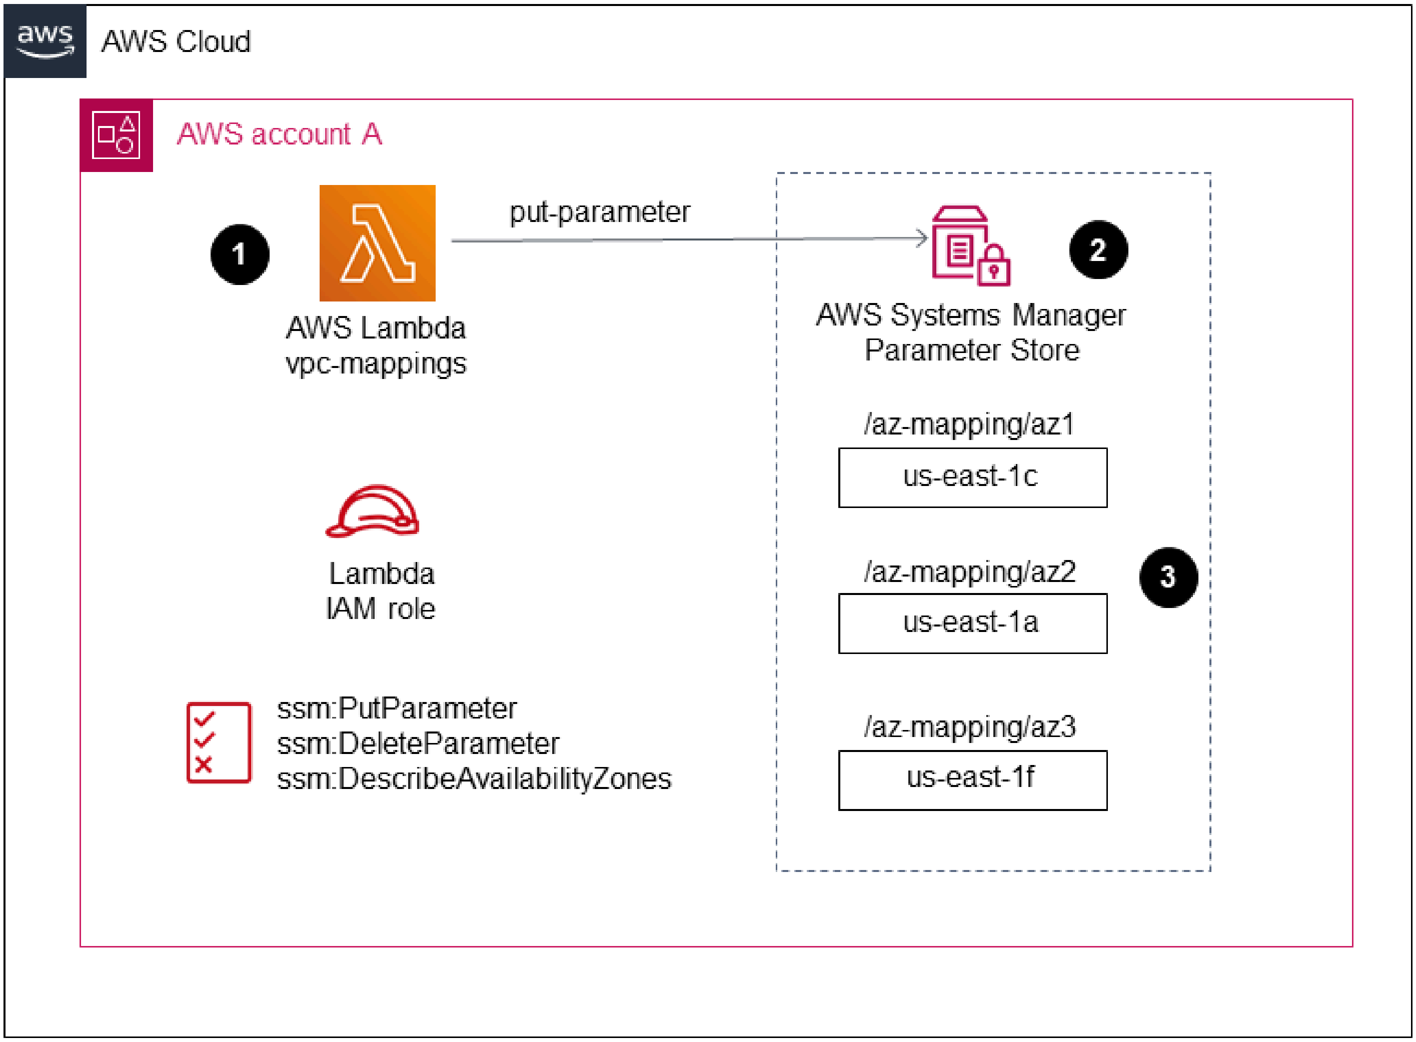
Prerequisites

- At least two active AWS accounts in the same AWS Region.

- Evaluate how many Availability Zones are needed to support your VPC requirements in the Region.
- Identify and record the AZ ID for each Availability Zone that you need to support. For more information about this, see [Availability Zone IDs for your AWS resources]() in the AWS Resource Access Manager documentation.
- An ordered, comma-separated list of your AZ IDs. For example, the first Availability Zone on your list is mapped as `az1`, the second Availbility Zone is mapped as `az2`, and this mapping structure continues until your comma-separated list is fully mapped. There is no maximum number of AZ IDs that can be mapped.
- The `az-mapping.yaml` file from the GitHub [Multi-account Availability Zone mapping]() repository, copied to your local machine

Architecture

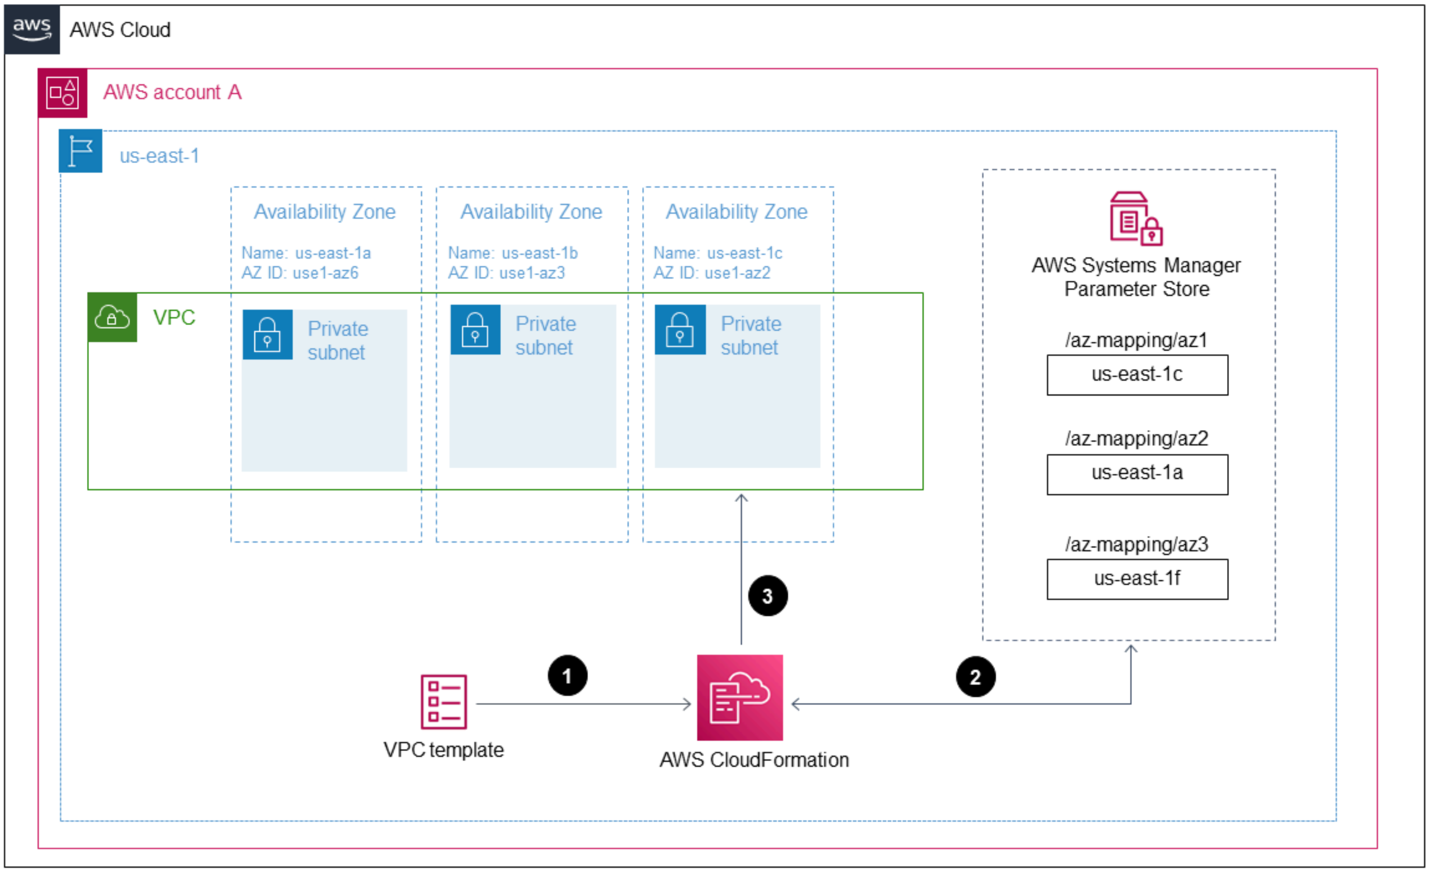
The following diagram shows the architecture that is deployed in an account and that creates AWS Systems Manager Parameter Store values. These Parameter Store values are consumed when you create a VPC in the account.



The diagram shows the following workflow:

1. This pattern’s solution is deployed to all accounts that require zonal consistency for a VPC.
2. The solution creates Parameter Store values for each AZ ID and stores the new Availability Zone name.
3. The AWS CloudFormation template uses the Availability Zone name stored in each Parameter Store value and this ensures zonal consistency.

The following diagram shows the workflow for creating a VPC with this pattern's solution.



The diagram shows the following workflow:

1. Submit a template for creating a VPC to AWS CloudFormation.
2. AWS CloudFormation resolves the Parameter Store values for each Availability Zone and returns the Availability Zone name for each AZ ID.
3. A VPC is created with the correct AZ IDs required for zonal consistency.

After you deploy this pattern's solution, you can create subnets that reference the Parameter Store values. If you use AWS CloudFormation, you can reference the Availability Zone mapping parameter values from the following YAML-formatted sample code:

```
Resources:
    PrivateSubnet1AZ1:
        Type: AWS::EC2::Subnet
        Properties:
            VpcId: !Ref VPC
            CidrBlock: !Ref PrivateSubnetAZ1CIDR
            AvailabilityZone:
```

```
                  !Join
                      - ''
                      - - '{{resolve:ssm:/az-mapping/az1:1}}'
```

This sample code is contained in the `vpc-example.yaml` file from the GitHub [Multi-account Availability Zone mapping] repository. It shows you how to create a VPC and subnets that align to the Parameter Store values for zonal consistency.

Technology stack

- AWS CloudFormation
- AWS Lambda
- AWS Systems Manager Parameter Store

Automation and scale

You can deploy this pattern to all your AWS accounts by using AWS CloudFormation StackSets or the Customizations for AWS Control Tower solution. For more information, see Working with AWS CloudFormation StackSets in the AWS Cloudformation documentation and Customizations for AWS Control Tower in the AWS Solutions Library.

After you deploy the AWS CloudFormation template, you can update it to use the Parameter Store values and deploy your VPCs in pipelines or according to your requirements.

Tools

AWS services

- AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- AWS Systems Manager Parameter Store is a capability of AWS Systems Manager. It provides secure, hierarchical storage for configuration data management and secrets management.

Code

The code for this pattern is provided in the GitHub [Multi-account Availability Zone mapping] repository.

Epics

Deploy the az-mapping.yaml file

Task	Description	Skills required
Determine the required Availability Zones for the Region.	1. Determine the AZ IDs that must be consistently used in your Region. 2. Record these AZ IDs in a comma-separated list and in the order that you want them applied in. For example, the first Availabil ity Zone on your list is mapped as `az1` and the second is mapped as `az2`. There is no maximum number of AZ IDs that can be mapped.	Cloud architect
Deploy the az-mapping.yaml file.	Use the `az-mapping.yaml` file to create an AWS CloudFormation stack in all required AWS accounts. In the `AZIds` parameter, use the comma-separated list that you created earlier. We recommend that you use AWS CloudFormation StackSets or the Customiza	Cloud architect

Task	Description	Skills required
	tions for AWS Control Tower Solution.	

Deploy the VPCs in your accounts

Task	Description	Skills required
Customize the AWS CloudFormation templates.	When you create the subnets using AWS CloudFormation, customize the templates to use the Parameter Store values that you created earlier. For a sample template, see the `vpc-example.yaml` file in the GitHub Multi-account Availability Zone mapping repository.	Cloud architect
Deploy the VPCs.	Deploy the customized AWS CloudFormation templates into your accounts. Each VPC in the Region then has zonal consistency in the Availability Zones used for the subnets	Cloud architect

Use user IDs in IAM policies for access control and automation

Srinivas Ananda Babu and Ram Kandaswamy, Amazon Web Services

Summary

This pattern explains the potential pitfalls of using username-based policies in AWS Identity and Access Management (IAM), the benefits of using user IDs, and how to integrate this approach with AWS CloudFormation for automation.

In the AWS Cloud, the IAM service helps you manage user identities and access control with precision. However, reliance on usernames in IAM policy creation can lead to unforeseen security risks and access control issues. For example, consider this scenario: A new employee, John Doe, joins your team, and you create an IAM user account with the username `j.doe`, which grants them permissions through IAM policies that reference usernames. When John leaves the company, the account is deleted. The trouble begins when a new employee, Jane Doe, joins your team, and the `j.doe` username is recreated. The existing policies now grant Jane Doe the same permissions as John Doe. This creates a potential security and compliance nightmare.

Manually updating each policy to reflect new user details is a time-consuming, error-prone process, especially as your organization grows. The solution is to use a unique and immutable user ID. When you create an IAM user account, AWS assigns the IAM user a unique user ID (or principal ID). You can use these user IDs in your IAM policies to ensure consistent and reliable access control that isn't affected by username changes or reuse.

For example, an IAM policy that uses a user ID might look like this:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::example-bucket",
            "Principal": { "AWS": "arn:aws:iam::123456789012:user/abcdef01234567890" }
        }
      ]
}
```

The benefits of using user IDs in IAM policies include:

- **Uniqueness.** User IDs are unique across all AWS accounts, so they provide correct and consistent permission application.
- **Immutability.** User IDs cannot be changed, so they provide a stable identifier for referencing users in policies.
- **Auditing and compliance.** AWS services often include user IDs in logs and audit trails, which makes it easy to trace actions back to specific users.
- **Automation and integration.** Using user IDs in AWS APIs, SDKs, or automation scripts ensures that processes remain unaffected by username changes.
- **Future-proofing.** Using user IDs in policies from the start can prevent potential access control issues or extensive policy updates.

Automation

When you use infrastructure as code (IaC) tools such as AWS CloudFormation, the pitfalls of username-based IAM policies can still cause issues. The IAM user resource returns the username when you call the `Ref` intrinsic function. As your organization's infrastructure evolves, the cycle of creating and deleting resources, including IAM user accounts, can lead to unintended access control issues if you reuse usernames.

To address this issue, we recommend that you incorporate user IDs into your CloudFormation templates. However, obtaining user IDs for this purpose can be challenging. This is where custom resources can be helpful. You can use CloudFormation custom resources to extend the service's functionality by integrating with AWS APIs or external services. By creating a custom resource that fetches the user ID for a given IAM user, you can make the user ID available within your CloudFormation templates. This approach streamlines the process of referencing user IDs and ensures that your automation workflows remain robust and future-proof.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An IAM role for a cloud administrator to run the AWS CloudFormation template

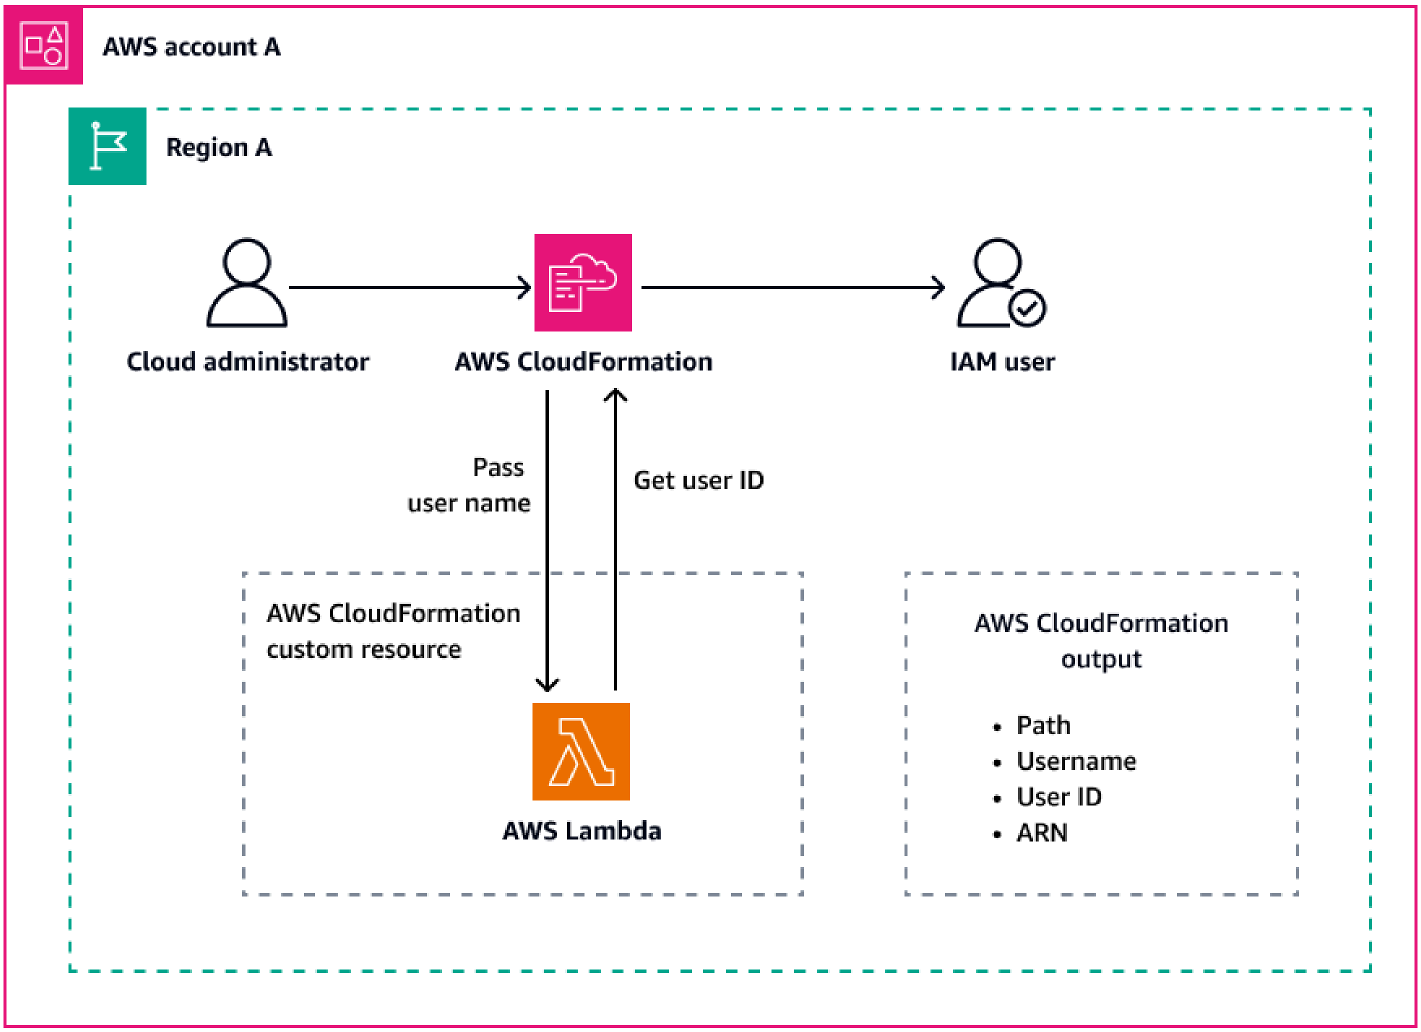
Limitations

- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS services by Region. For specific endpoints, see the Service endpoints and quotas page, and choose the link for the service.

Architecture

Target architecture

The following diagram shows how AWS CloudFormation uses a custom resource backed by AWS Lambda to retrieve the IAM user ID.



Automation and scale

You can use the CloudFormation template multiple times for different AWS Regions and accounts. You need to run it only once in each Region or account.

Tools

AWS services

- IAM – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run on AWS. You create a template that describes the AWS resources that you want, and CloudFormation takes care of provisioning and configuring those resources for you.
- AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

Best practices

If you're starting from scratch or planning a greenfield deployment, we strongly recommend that you use AWS IAM Identity Center for centralized user management. IAM Identity Center integrates with your existing identity providers (such as Active Directory or Okta) to federate user identities on AWS, which eliminates the need to create and manage IAM users directly. This approach not only ensures consistent access control but also simplifies user lifecycle management and helps enhance security and compliance across your AWS environment.

Epics

Validate permissions

Task	Description	Skills required
Validate your AWS account and IAM role.	Confirm that you have an IAM role with permissions to deploy CloudFormation templates in your AWS account. If you're planning to use the AWS CLI instead of the	Cloud architect

Task	Description	Skills required
	CloudFormation console to deploy the template in the last step of this procedure , you should also set up temporary credentials to run AWS CLI commands. For instructions, see the IAM documentation.	

Build a CloudFormation template

Task	Description	Skills required
Create a CloudFormation template.	1. Create a CloudFormation template by following the instructions in the CloudFormation documentation. You can use either JSON or YAML format. This pattern assumes that you're using YAML format. 2. Save the template with the name `get_unique_user_id.yaml` .	AWS DevOps, Cloud architect

Add an input parameter for the username.	Add the following code to the `Parameters` section of the CloudFormation template:
	`Parameters:`
	`  NewIamUserName:`
	`    Type: String`
		AWS DevOps, Cloud architect

Task	Description	Skills required
	<pre> Description: Unique username for the new IAM user</pre> This parameter prompts the user for the username.	

Add a custom resource to create an IAM user.	Add the following code to the `Resources` section of the CloudFormation template: <pre>Resources:
	  rNewIamUser:
	    Type: 'AWS::IAM
	::User'
	    Properties:
	      UserName: !Ref
	 NewIamUserName</pre> This code adds a CloudFormation resource that creates an IAM user with the name provided by the `NewIamUserName` parameter.
		AWS DevOps, Cloud architect

Task	Description	Skills required
Add an execution role for the Lambda function.	In this step, you create an IAM role that grants an AWS Lambda function permission to get the IAM `UserId`. Specify the following minimum required permissions for Lambda to run: • `logs:CreateLogStream` • `logs:PutLogEvents` • `CreateLogGroup` • `iam:GetUser` • `AssumeRole` for `lambda.amazonaws.com` For instructions on creating an execution role, see the [Lambda documentation](). You will reference this role in the next step, when you create the Lambda function.	AWS administrator, Cloud architect

Task	Description	Skills required

Add a Lambda function to get the unique IAM `UserId`.	In this step, you define a Lambda function with a Python runtime to get the unique IAM `UserId`. To do this, add the following code to the `Resources` section of the CloudFormation template. Replace `<<ROLENAME>>` with the name of the execution role that you created in the last step.
	`GetUserLambdaFunction:`
	`Type: 'AWS::Lambda::Function'`
	`Properties:`
	`Handler: index.handler`
	`Role: <<ROLENAME>>`
	`Timeout: 30`
	`Runtime: python3.11`
	`Code:`
	`ZipFile: |`
	`import cfnresponse, boto3`
	`def handler(event, context):`
	`try:`
	`print(event)`
	`user = boto3.client('iam').get_user(UserName=event['ResourceP`
		AWS DevOps, Cloud architect

Task	Description	Skills required
	```roperties']['NewIa mUserName'])['User'] cfnrespon se.send(event, context, cfnrespon se.SUCCESS, {'NewIamU serId': user['Use rId'], 'NewIamUs erPath': user['Pat h'], 'NewIamUserArn': user['Arn']}) except Exception as e: cfnrespon se.send(event, context, cfnrespon se.FAILED, {'NewIamU ser': str(e)})```	

Task	Description	Skills required

Add a custom resource.	Add the following code to the `Resources` section of the CloudFormation template:
	`rCustomGetUniqueUserId:`
	`Type: 'Custom::rCustomGetUniqueUserIdWithLambda'`
	`Properties:`
	`ServiceToken: !GetAtt GetUserLambdaFunction.Arn`
	`NewIamUserName: !Ref NewIamUserName`
	This custom resource calls the Lambda function to get the IAM `UserID`.
		AWS DevOps, Cloud architect

Define CloudFormation outputs.	Add the following code to the `Outputs` section of the CloudFormation template:
	`Outputs:`
	`NewIamUserId:`
	`Value: !GetAtt rCustomGetUniqueUserId.NewIamUserId`
	This displays the IAM `UserID` for the new IAM user.
		AWS DevOps, Cloud architect

Save the template.	Save your changes to the CloudFormation template.	AWS DevOps, Cloud architect

Deploy the CloudFormation template

Task	Description	Skills required
Deploy the CloudFormation template.	To deploy the `get_unique_user_id.yaml` template by using the CloudFormation console, follow the instructions in the [CloudFormation documentation](). Alternatively, you can run the following AWS CLI command to deploy the template: `aws cloudformation create-stack \ --stack-name DemoNewUser \ --template-body file://get_unique_user_id.yaml \ --parameters ParameterKey=NewIamUserName,ParameterValue=demouser \ --capabilities CAPABILITY_NAMED_IAM`	AWS DevOps, Cloud architect

Validate Account Factory for Terraform (AFT) code locally

Alexandru Pop and Michal Gorniak, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. [Learn more]

This pattern shows how to locally test HashiCorp Terraform code that's managed by AWS Control Tower Account Factory for Terraform (AFT). Terraform is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources. AFT sets up a Terraform pipeline that helps you provision and customize multiple AWS accounts in AWS Control Tower.

During code development, it can be helpful to test your Terraform infrastructure as code (IaC) locally, outside of the AFT pipeline. This pattern shows how to do the following:

- Retrieve a local copy of the Terraform code that's stored in the AWS CodeCommit repositories in your AFT management account.
- Simulate the AFT pipeline locally by using the retrieved code.

This procedure can also be used to run Terraform commands that aren't part of the normal AFT pipeline. For example, you can use this method to run commands such as `terraform validate`, `terraform plan`, `terraform destroy`, and `terraform import`.

Prerequisites and limitations

Prerequisites

- An active AWS multi-account environment that uses AWS Control Tower
- A fully deployed of AFT environment
- AWS Command Line Interface (AWS CLI), installed and configured
- AWS CLI credential helper for AWS CodeCommit, installed and configured
- Python 3.x
- Git, installed and configured on your local machine
- `git-remote-commit` utility, installed and configured

- Terraform, installed and configured (the local Terraform package version must match the version that's used in the AFT deployment)

Limitations

- This pattern doesn't cover the deployment steps required for AWS Control Tower, AFT, or any specific Terraform modules.
- The output that's generated locally during this procedure isn't saved in the AFT pipeline runtime logs.

Architecture

Target technology stack

- AFT infrastructure deployed within an AWS Control Tower deployment
- Terraform
- Git
- AWS CLI version 2

Automation and scale

This pattern shows how to locally invoke Terraform code for AFT global account customizations in a single AFT-managed AWS account. After your Terraform code is validated, you can apply it to the remaining accounts in your multi-account environment. For more information, see Re-invoke customizations in the AWS Control Tower documentation.

You can also use a similar process to run AFT account customizations in a local terminal. To locally invoke Terraform code from AFT account customizations, clone the **aft-account-customizations** repository instead of **aft-global-account-customizations** repository from CodeCommit in your AFT management account.

Tools

AWS services

- AWS Control Tower helps you set up and govern an AWS multi-account environment, following prescriptive best practices.

- [AWS Command Line Interface (AWS CLI)](#) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Other services

- [HashiCorp Terraform](#) is an infrastructure as code (IaC) tool that helps you use code to provision and manage cloud infrastructure and resources.
- [Git](#) is an open-source, distributed version control system.

Code

The following is an example bash script that can be used to locally run Terraform code that's managed by AFT. To use the script, follow the instructions in the Epics section of this pattern.

```
#! /bin/bash
# Version: 1.1 2022-06-24 Unsetting AWS_PROFILE since, when set, it interferes with
 script operation
#          1.0 2022-02-02 Initial Version
#
# Purpose: For use with AFT: This script runs the local copy of TF code as if it were
 running within AFT pipeline.
#        * Facilitates testing of what the AFT pipline will do
#           * Provides the ability to run terraform with custom arguments (like 'plan'
 or 'move') which are currently not supported within the pipeline.
#
# © 2021 Amazon Web Services, Inc. or its affiliates. All Rights Reserved.
# This AWS Content is provided subject to the terms of the AWS Customer Agreement
# available at http://aws.amazon.com/agreement or other written agreement between
# Customer and either Amazon Web Services, Inc. or Amazon Web Services EMEA SARL or
 both.
#
# Note: Arguments to this script are passed directly to 'terraform' without parsing nor
 validation by this script.
#
# Prerequisites:
#    1. local copy of ct GIT repositories
#    2. local backend.tf and aft-providers.tf filled with data for the target account
 on which terraform is to be run
#       Hint: The contents of above files can be obtain from the logs of a previous
 execution of the AFT pipeline for the target account.
#    3. 'terraform' binary is available in local PATH
```

```
#    4. Recommended: .gitignore file containing 'backend.tf', 'aft_providers.tf' so the
 local copy of these files are not pushed back to git

readonly credentials=$(aws sts assume-role \
    --role-arn arn:aws:iam::$(aws sts get-caller-identity --query "Account" --output
 text ):role/AWSAFTAdmin \
    --role-session-name AWSAFT-Session \
    --query Credentials )

unset AWS_PROFILE
export AWS_ACCESS_KEY_ID=$(echo $credentials | jq -r '.AccessKeyId')
export AWS_SECRET_ACCESS_KEY=$(echo $credentials | jq -r '.SecretAccessKey')
export AWS_SESSION_TOKEN=$(echo $credentials | jq -r '.SessionToken')
terraform "$@"
```

Epics

Save the example code as a local file

Task	Description	Skills required
Save the example code as a local file.	1. Copy the example bash script that's in the *Code* section of this pattern and paste it into a code editor. 2. Name the file `ct_terraform.sh`, and then save the file locally inside a dedicated folder, such as `~/scripts` or `~/bin`.	AWS administrator
Make the example code runnable.	Open a terminal window and authenticate into your AWS AFT management account by doing one of the following: • Use an existing [AWS CLI profile](#) that's configured with the permissions required to access the AFT	AWS administrator

Task	Description	Skills required
	management account. To use the profile, you can run the following command: `export AWS_PROFILE=<aft account profile name>` • If your organization uses SSO to access AWS, enter the credentials for your AFT management account on your organization's SSO page. **Note** Your organization might also have a custom tool to provide authentication credentials to your AWS environment.	

Task	Description	Skills required

Verify access to AFT management account in the correct AWS Region.	**Important**
	Make sure that you use the same terminal session with which you authenticated into your AFT management account.
	
	1. Navigate to your AFT deployment's AWS Region by running the following command:
	`export AWS_REGION=<aft_region>`
	2. Make sure that you're in the correct account.
	a. Run the following command:
	`aws code-commit list-repositories`
	b. Verify that the repositories listed in the output match the names of the repositories that are in your AFT management account.
		AWS administrator

Task	Description	Skills required

Create a new, local directory to store the AFT repository code.	In the same terminal session, run the following commands:
	`mkdir my_aft`
	`cd my_aft`
		AWS administrator

Task	Description	Skills required

Clone the remote AFT repository code.	1. In your local terminal, run the following command:
	`git clone codecommit::$AWS_REGION://aft-global-customizations`
	Note
	For simplicity, this procedure and AFT use a main code branch only. To use code branching, you can enter code branching commands here as well. However, any applied changes from the non-main branch will be rolled back when AFT automation applies code from the main branch.
	2. Navigate into the cloned directory:
	`cd aft-global-customizations/terraform`
		AWS administrator

Create the Terraform configuration files required for the AFT pipeline to run locally

Task	Description	Skills required
Open a previously run AFT pipeline and copy the Terraform configuration files to a local folder.	**Note** The `backend.tf` and `aft-providers.tf` configuration files that are created in this epic are needed for the AFT pipeline to run locally. These files are created automatically within the cloud-based AFT pipeline, but must be created manually for the pipeline to run locally. Running the AFT pipeline locally requires one set of files that represent running the pipeline within a single AWS account. 1. Using your AWS Control Tower management account credentials, sign in to the AWS Management Console, and open the [AWS CodePipeline console](https://console.aws.amazon.com/codesuite/codepipeline/home). Make sure that you're in the same AWS Region where you deployed AFT.	AWS administrator

Task	Description	Skills required
	2. In the left navigation pane, choose **Pipelines**. 3. Choose **############-customizations-pipeline**. (The **############** is the AWS account ID that you're using to run Terraform code locally.) 4. Make sure that **Most Recent Execution Marked** shows a **Succeeded** value. If it the value is different , you must re-invoke your customizations in the AFT pipeline. For more information, see Re-invoke customizations in the AWS Control Tower documenta tion. 5. Choose the most recent runtime to bring up its details. 6. In the **Apply-AFT-Global-Customizations** section, find the **Apply-Ter raform** stage. 7. Select the **Details** section of the **Apply-Terraform** stage. 8. Find the runtime log for the **Apply-Terraform** stage.	

Task	Description	Skills required

	9. In the runtime log, look for the section that begins and ends with the following lines:
	`"\n\n aft-provi ders.tf ... "\n \n backend.tf"`
	10. Copy the output between these two labels and save them as a local file named `aft-provi ders.tf` within the local Terraform folder (your terminal session's current working directory).
	Example auto generated providers.tf statement
	`## Autogenerated providers.tf ## ## Updated on: 2022-05-31 16:27:45 ## provider "aws" { region = "us-east-2" assume_role { role_arn = "arn:aws:iam::############:role/AWSAFTExecution" } default_tags { tags = {`	

Task	Description	Skills required

	``
	        managed_by
	               = "AFT"
	      }
	    }
	}
	``
	11. In the runtime log, look for the section that begins and ends with the following lines:
	``
	"\n\n tf
	...
	"\n \n backend.tf"
	``
	12. Copy the output between these two labels and save them as a local file named `tf` within the local Terraform folder (your terminal session's current working directory).
	
	Example auto-generated backend.tf statement
	``
	## Autogenerated
	 backend.tf ##
	## Updated on: 2022-05-3
	1 16:27:45 ##
	terraform {
	  required_version =
	 ">= 0.15.0"
	  backend "s3" {
	    region =
	 "us-east-2"
	    bucket =
	 "aft-backend-#####
	``	

Task	Description	Skills required

	``
	#######-primary-re
	gion"
	    key =
	 "############-aft-
	global-customizati
	ons/terraform.tfst
	ate"
	    dynamodb_table =
	 "aft-backend-#####
	#######"
	    encrypt =
	 "true"
	    kms_key_id =
	 "########-####-####-
	####-############"
	    role_arn =
	 "arn:aws:iam::####
	#########:role/AWS
	AFTExecution"
	  }
	}
	``
	
	Note
	
	The `backend.tf` and `aft-providers.tf` files are tied to a specific AWS account, AFT deployment, and folder. These files are also different , depending on whether they're in the **aft-global-customizations** and **aft-account-customizations** repository within the	

Task	Description	Skills required
	same AFT deployment. Make sure that you generate both files from the same runtime listing.	

Run the AFT pipeline locally by using the example bash script

Task	Description	Skills required
Implement the Terraform configuration changes that you want to validate.	1. Navigate to the cloned **aft-global-customizations** repository by running the following command: `cd aft-global-customizations/terraform` **Note** The files `backend.tf` and `aft-providers.tf` are in this directory. The directory also contains Terraform files from the **aft-global-customizations** repository. 2. Incorporate the Terraform code changes that you	AWS administrator

Task	Description	Skills required
	want to test locally into the configuration files.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Run the <code>ct_terraform.sh</code> script and review the output.</td><td>
1. Navigate to the local folder that contains the sh script.
2. To validate your modified Terraform code, run the <code>ct_terraform.sh</code> script by running the following command:
<pre>~/scripts/ct_terraform.sh apply</pre>
<pre>terraform --help</pre>
Note
You can run any Terraform command during this step. To see a complete list of Terraform commands, run the following command:
3. Review the command output, and then debug the code changes locally before committing and pushing the changes back to the AFT repository.
</td><td>AWS administrator</td></tr>
</table>

Task	Description	Skills required
	⚠ **Important** • Any changes made locally and not pushed back to the remote repository are temporary and might be undone at any time by a running AFT pipeline automation. • AFT automation can run at any time, because it can be invoked by other users and AFT automation triggers. • AFT will always apply code from the main branch of the repository, undoing any uncommitted changes.	

Push your local code changes back to the AFT repository

Task	Description	Skills required
Add references to the `backend.tf` and `aft-providers.tf` files to a `.gitignore` file.	Add the `backend.tf` and `aft-providers.tf` files that you created to a `.gitignore` file by running the following commands: `echo backend.tf >> .gitignore`	AWS administrator

Task	Description	Skills required
	`echo aft-providers.tf >>.gitignore` **Note** Moving the files to the `.gitignore` file ensures that they don't get committed and pushed back to the remote AFT repository.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Commit and push your code changes to the remote AFT repository.</td><td>
1. To add any new Terraform configuration files to the repository, run the following command:
<pre><code>git add <filename></code></pre>
2. To commit your changes and push them to the remote AFT repository in CodeCommitt, run the following commands:
<pre><code>git commit -a
git push</code></pre>
Important
The code changes that you introduce by following this procedure up until this point are applied to one AWS account only.
</td><td>AWS administrator</td></tr>
</table>

Roll out the changes to multiple accounts

Task	Description	Skills required
Roll out the changes to all of your accounts that are managed by AFT.	To roll out the changes to multiple AWS accounts that are managed by AFT, follow	AWS administrator

Task	Description	Skills required
	the instructions in Re-invoke customizations in the AWS Control Tower documenta tion.	

More patterns

- Add HA to Oracle PeopleSoft on Amazon RDS Custom by using a read replica

- Automate RabbitMQ configuration in Amazon MQ
- Automate the replication of Amazon RDS instances across AWS accounts
- Automatically attach an AWS managed policy for Systems Manager to EC2 instance profiles using Cloud Custodian and AWS CDK
- Automatically build CI/CD pipelines and Amazon ECS clusters for microservices using AWS CDK
- Automatically detect changes and initiate different CodePipeline pipelines for a monorepo in CodeCommit
- Automatically re-enable AWS CloudTrail by using a custom remediation rule in AWS Config
- Build a data pipeline to ingest, transform, and analyze Google Analytics data using the AWS DataOps Development Kit
- Build a Micro Focus Enterprise Server PAC with Amazon EC2 Auto Scaling and Systems Manager
- Build and push Docker images to Amazon ECR using GitHub Actions and Terraform
- Centralize IAM access key management in AWS Organizations by using Terraform
- Centralize software package distribution in AWS Organizations by using Terraform
- Chain AWS services together using a serverless approach
- Configure a data center extension to VMware Cloud on AWS using Hybrid Linked Mode
- Configure model invocation logging in Amazon Bedrock by using AWS CloudFormation
- Configure read-only routing in an Always On availability group in SQL Server on AWS
- Configure VMware vRealize Automation to provision VMs on VMware Cloud on AWS

- Create a portal for micro-frontends by using AWS Amplify, Angular, and Module Federation
- Create a cross-account Amazon EventBridge connection in an organization
- Create dynamic CI pipelines for Java and Python projects automatically
- Deploy an Amazon API Gateway API on an internal website using private endpoints and an Application Load Balancer
- Deploy and debug Amazon EKS clusters
- Deploy and manage AWS Control Tower controls by using AWS CDK and CloudFormation
- Deploy and manage AWS Control Tower controls by using Terraform
- Deploy CloudWatch Synthetics canaries by using Terraform
- Deploy a Lustre file system for high-performance data processing by using Terraform and DRA
- Deploy a RAG use case on AWS by using Terraform and Amazon Bedrock
- Deploy resources in an AWS Wavelength Zone by using Terraform
- Deploy SQL Server failover cluster instances on Amazon EC2 and Amazon FSx by using Terraform
- Deploy the Security Automations for AWS WAF solution by using Terraform
- Detect Amazon RDS and Aurora database instances that have expiring CA certificates
- Document your AWS landing zone design
- Ensure that an IAM profile is associated with an EC2 instance
- Export AWS Backup reports from across an organization in AWS Organizations as a CSV file
- Generate personalized and re-ranked recommendations using Amazon Personalize
- Govern permission sets for multiple accounts by using Account Factory for Terraform
- Identify and alert when Amazon Data Firehose resources are not encrypted with an AWS KMS key
- Implement Account Factory for Terraform (AFT) by using a bootstrap pipeline
- Implement path-based API versioning by using custom domains in Amazon API Gateway
- Install SSM Agent on Amazon EKS worker nodes by using Kubernetes DaemonSet
- Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands
- Integrate VMware vRealize Network Insight with VMware Cloud on AWS
- Manage AWS IAM Identity Center permission sets as code by using AWS CodePipeline
- Manage AWS permission sets dynamically by using Terraform
- Manage AWS Service Catalog products in multiple AWS accounts and AWS Regions

- Manage on-premises container applications by setting up Amazon ECS Anywhere with the AWS CDK
- Manage AWS Organizations policies as code by using AWS CodePipeline and Amazon Bedrock
- Migrate DNS records in bulk to an Amazon Route 53 private hosted zone
- Migrate Oracle PeopleSoft to Amazon RDS Custom
- Migrate RHEL BYOL systems to AWS License-Included instances by using AWS MGN
- Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX
- Set up a minimum viable data space to share data between organizations
- Monitor Amazon ElastiCache clusters for at-rest encryption
- Monitor application activity by using CloudWatch Logs Insights
- Monitor ElastiCache clusters for security groups
- Monitor SAP RHEL Pacemaker clusters by using AWS services
- Optimize multi-account serverless deployments by using the AWS CDK and GitHub Actions workflows
- Provision AWS Service Catalog products based on AWS CloudFormation templates by using GitHub Actions
- Provision least-privilege IAM roles by deploying a role vending machine solution
- Remove Amazon EC2 entries across AWS accounts from AWS Managed Microsoft AD by using AWS Lambda automation
- Remove Amazon EC2 entries in the same AWS account from AWS Managed Microsoft AD by using AWS Lambda automation
- Rotate database credentials without restarting containers
- Secure file transfers by using Transfer Family, Amazon Cognito, and GuardDuty
- Send a notification when an IAM user is created
- Send logs from VMware Cloud on AWS to Splunk by using VMware Aria Operations for Logs
- Set up a serverless cell router for a cell-based architecture
- Set up a CI/CD pipeline for hybrid workloads on Amazon ECS Anywhere by using AWS CDK and GitLab
- Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database
- Set up DNS resolution for hybrid networks in a multi-account AWS environment
- Set up Multi-AZ infrastructure for a SQL Server Always On FCI by using Amazon FSx

- Set up Oracle UTL_FILE functionality on Aurora PostgreSQL-Compatible
- Simplify application authentication with mutual TLS in Amazon ECS by using Application Load Balancer
- Simplify private certificate management by using AWS Private CA and AWS RAM
- Streamline machine learning workflows from local development to scalable experiments by using SageMaker AI and Hydra
- Tag Transit Gateway attachments automatically using AWS Organizations
- Transition roles for an Oracle PeopleSoft application on Amazon RDS Custom for Oracle
- Use Amazon Q Developer as a coding assistant to increase your productivity

Authenticate existing React application users by using Amazon Cognito and AWS Amplify UI

Daniel Kozhemyako, Amazon Web Services

Summary

This pattern shows how to add authentication capabilities to an existing frontend React application by using an AWS Amplify UI library and an Amazon Cognito user pool.

The pattern uses Amazon Cognito to provide authentication, authorization, and user management for the application. It also uses a component from Amplify UI, an open-source library that extends the capabilities of AWS Amplify to user interface (UI) development. The Authenticator UI component manages login sessions and runs the cloud-connected workflow that authenticates users through Amazon Cognito.

After you implement this pattern, users can sign in by using any of the following credentials:

- User name and password
- Social identity providers, such as Apple, Facebook, Google, and Amazon
- Enterprise identity providers that are either SAML 2.0 compatible or OpenID Connect (OIDC) compatible

> **Note**
>
> To create a custom authentication UI component, you can run the Authenticator UI component in headless mode.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A React 18.2.0 or later web application
- Node.js and npm 6.14.4 or later, installed

Limitations

- This pattern applies to React web applications only.
- This pattern uses a prebuilt Amplify UI component. The solution doesn't cover the steps required to implement a custom UI component.

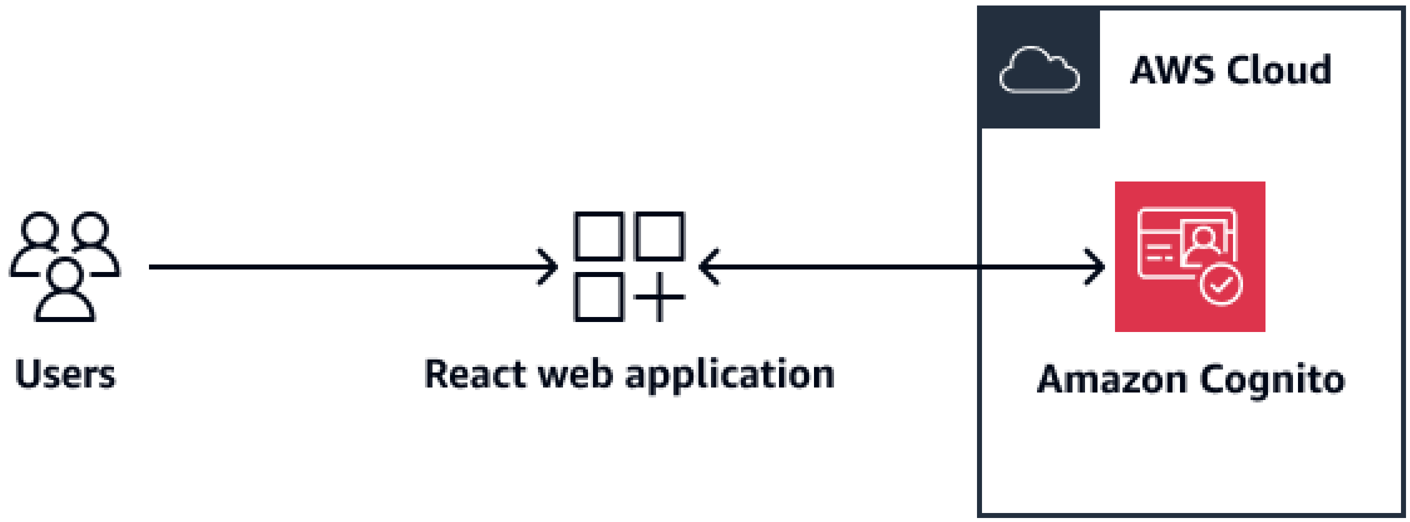
Product versions

- Amplify UI 6.1.3 or later (Gen 1)
- Amplify 6.0.16 or later (Gen 1)

Architecture

Target architecture

The following diagram shows an architecture that uses Amazon Cognito to authenticate users for a React web application.



Tools

AWS services

- [Amazon Cognito](https://docs.aws.amazon.com/cognito/latest/developerguide/what-is-amazon-cognito.html) provides authentication, authorization, and user management for web and mobile apps.

Other tools

- Amplify UI is an open-source UI library that provides customizable components that you can connect to the cloud.
- Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.

Best practices

If you're building a new application, we recommend that you use Amplify Gen 2.

Epics

Create an Amazon Cognito user pool

Task	Description	Skills required
Create a user pool.	Create an Amazon Cognito user pool. Configure the user pool's sign-in options and security requirements to fit your use case.	App developer
Add an app client.	Configure a user pool app client. This client is required for your application to interact with the Amazon Cognito user pool.	App developer

Integrate your Amazon Cognito user pool with the Authenticator UI component

Task	Description	Skills required
Install dependencies.	To install the `aws-amplify` and `@aws-amplify/ui-react` packages, run	App developer

Task	Description	Skills required
	the following command from your application's root directory: `npm i @aws-amplify/ui-react aws-amplify`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Configure the user pool.</td><td>Based on the following example, create an <code>aws-exports.js</code> file and save in the <code>src</code> folder. The file should include the following information:

AWS Region that your Amazon Cognito user pool is in
Amazon Cognito user pool ID
App client ID

<pre><code>// replace the user pool region, id, and app client id details
const awsmobile = {
    "aws_project_region": "put_your_region_here",
    "aws_cognito_region": "put_your_region_here",
    "aws_user_pools_id": "put_your_user_pool_id_here",
    "aws_user_pools_web_client_id": "put_your_user_pool_app_id_here"
}

export default awsmobile;</code></pre></td><td>App developer</td></tr>
</table>

Task	Description	Skills required

Import and configure the Amplify service.	1. In the application's entry point file (for example, `App.js`), import and load the `aws-exports.js` file by entering the following lines of code:
	`import { Amplify } from 'aws-amplify'; import awsExports from './aws-exports';`
	2. Based on the following example, configure the Amplify client by using the `aws-exports.js` file:
	`// Configure Amplify in index file or root file Amplify.configure({ ...awsExports });`
	For more information, see [Configure Amplify categories] in the Amplify documentation.
		App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add the Authenticator UI component.</td><td>To display the <code>Authenticator</code> UI component, add the following lines of code to the application's entry point file (<code>App.js</code>):<pre><code>import { Authenticator } from '@aws-amplify/ui-react';
import '@aws-amplify/ui-react/styles.css';</code></pre>Note
The example code snippet imports the <code>Authenticator</code> UI component and the Amplify UI styles.css file, which is required when using the component's prebuilt themes.

The <code>Authenticator</code> UI component provides two return values:
User details
A function that can be invoked to sign the user out
See the following example component:</td><td>App developer</td></tr>
</table>

Task	Description	Skills required

	<pre>function App() {
	    return (
	        <Authenticator>
	            {({ signOut,
	 user }) => (
	
	  Welcome {user.use
	rname}
	
	  <button onClick={
	signOut}>Sign out</
	button>
	
	            )}
	        </Authent
	icator>
	    );
	}</pre> **Note** For an example `App.js` file, see the Additional information section of this pattern.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>(Optional) Retrieve session information.</td><td>After a user is authenticated, you can retrieve data from the Amplify client about their session. For example, you can retrieve the JSON web token (JWT) from a user’s session so that you can authenticate the requests from their session to a backend API.

See the following example of a request header that includes a JWT:

<pre>import { fetchAuth
Session } from 'aws-
amplify/auth';
(await fetchAuth
Session()).tokens?
.idToken?.toString();</pre></td><td>App developer</td></tr>
</table>

Troubleshooting

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td>New users can’t sign up for the application.</td><td>As follows, make sure that your Amazon Cognito user pool is configured to allow users to sign themselves up to be in the user pool:
Sign in to the AWS Management Console, and then open the Amazon Cognito console.
In the left navigation pane, choose User pools.
Choose your user pool from the list.</td></tr>
</table>

Issue	Solution
	• Under **General Settings**, choose **Policies**. • Choose **Allow users to sign themselves up**.
Auth component stopped working after upgrading from v5 to v6.	The `Auth` category has moved to a functional approach and named parameters in Amplify v6. You must now import the functional APIs directly from the `aws-amplify/auth` path. For more information, see Migrate from v5 to v6 in the Amplify documentation.

Related resources

- Getting started with Amazon Cognito (AWS website)
- Create a new React app (React documentation)
- What is Amazon Cognito? (Amazon Cognito documentation)
- Amplify UI library (Amplify documentation)

Additional information

The `App.js` file should contain the following code:

```
import './App.css';
import { Amplify } from 'aws-amplify';
import awsExports from './aws-exports';
import { fetchAuthSession } from 'aws-amplify/auth';
import { Authenticator } from '@aws-amplify/ui-react';
import '@aws-amplify/ui-react/styles.css';
Amplify.configure({ ...awsExports });
let token = (await fetchAuthSession()).tokens?.idToken?.toString();
function App() {
  return (
      <Authenticator>
        {({ signOut, user }) => (
            <div>
              <p>Welcome {user.username}</p>
                <p>Your token is: {token}</p>
```

```
              <button onClick={signOut}>Sign out</button>
            </div>
        )}
      </Authenticator>
  );
}

export default App;
```

Continuously deploy a modern AWS Amplify web application from an AWS CodeCommit repository

Deekshitulu Pentakota and Sai Katakam, Amazon Web Services

Summary

Notice: AWS CodeCommit is no longer available to new customers. Existing customers of AWS CodeCommit can continue to use the service as normal. Learn more.

Modern web applications are constructed as single-page applications (SPAs) that package all application components into static files. By using AWS Amplify Hosting, you can build a continuous integration and continuous deployment (CI/CD) pipeline that builds, deploys, and hosts a modern web application that is managed in a Git-based repository. When you connect Amplify Hosting to the code repository, each commit initiates a single workflow to deploy the application frontend and backend. The benefit of this approach is that the web application is updated only after the deployment is successfully completed, which prevents inconsistencies between the frontend and backend.

In this pattern, you use an AWS CodeCommit repository to manage your modern web application. The sample web application in these instructions uses the React SPA framework. However, Amplify Hosting supports many other SPA frameworks, such as Angular, Vue, Next.js, and it also support single-site generators, such as Gatsby, Hugo, and Jekyll.

This pattern is intended for AWS builders who have experience with the following services and concepts:

- AWS CodeCommit
- AWS Amplify Hosting
- React
- JavaScript
- Node.js
- npm
- Git

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Permissions to create resources in Amplify and CodeCommit. For more information, see Identity and Access Management for Amplify and Identity and Access Management for AWS CodeCommit.
- AWS Command Line Interface (AWS CLI), installed and configured.
- A text editor or code editor.
- CodeCommit, set up for HTTPS users using Git credentials.
- An IAM service role for Amplify.
- npm and Node.js, installed (npm documentation).

Limitations

- This pattern doesn't discuss development and integration of a backend for the Amplify application, such as an API, authentication, or database. For more information about backends, see Create a backend in the Amplify documentation.

Product versions

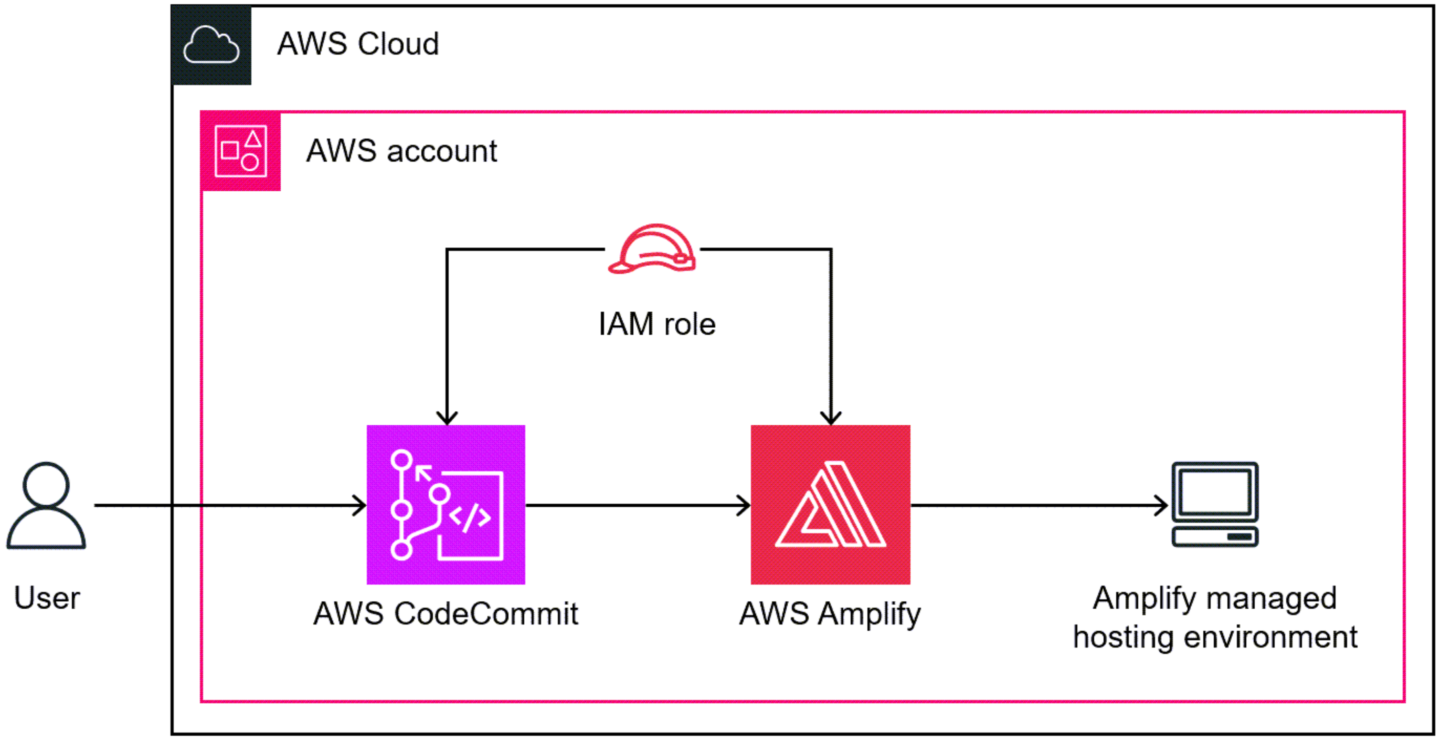
- AWS CLI version 2.0
- Node.js version 16.x or later

Architecture

Target technology stack

- AWS CodeCommit repository containing a React SPA
- AWS Amplify Hosting workflow

Target architecture



Tools

AWS services

- AWS Amplify Hosting provides a Git-based workflow for hosting full-stack serverless web applications with continuous deployment.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Other tools

- Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.

Epics

Create a CodeCommit repository

Task	Description	Skills required
Create a repository.	For instructions, see Create an AWS CodeCommit repository in the CodeCommit documentation.	AWS DevOps
Clone the repository.	For instructions, see Connect to the CodeCommit repository by cloning the repository in the CodeCommit documentation. If you are prompted, provide the Git credentials.	App developer

Create a React application

Task	Description	Skills required
Create a new React application.	1. Enter the following command to navigate into cloned repo. Replace `<repo name>` with the name of your CodeCommit repo. `$ cd <repo name>` 2. Enter the following command to create a new React application in the cloned repository.	App developer

Task	Description	Skills required

	`$ npx create-react-app .`
	3. Code the application, and then enter the following command to start it.
	`$ npm start`
	
	For more information about creating a custom React application, see the Create React App instructions in the *Create React App* documentation. You can also deploy a sample React application to your Amplify account by following the instructions in Deploy a frontend in the Amplify documentation.	

Task	Description	Skills required

Create a branch and push the code.	1. Enter the following command to create a new branch locally, where `<branch>` is the name you want to assign to the new branch.
	`$ git checkout -b <branch>`
	2. Enter the following command to push the branch to the CodeCommit repository, where `<branch>` is the name you assigned in the previous step. For more information, see [Working with commits](#).
	`$ git push --set-upstream origin <branch>`
		App developer

Deploy the application in AWS Amplify Hosting

Task	Description	Skills required
Connect Amplify to the repository.	For instructions, see [Connect a repository](#) in the Amplify Hosting documentation. Select AWS CodeCommit and the repository and branch you created previously.	App developer
Define the frontend build settings.	For instructions, see [Confirm build settings for the](#)	App developer

Task	Description	Skills required

	frontend in the Amplify Hosting documentation. Accept the defaults or enter the following.
	
	`Build settings:`
	`version: 0.1`
	`frontend:`
	`  phases:`
	`    preBuild:`
	`      commands:`
	`        - npm ci`
	`    build:`
	`      commands:`
	`        - npm run build`
	`  artifacts:`
	`    baseDirectory: build`
	`    files:`
	`      - '**/*'`
	`  cache:`
	`    paths:`
	`      - node_modules/**/*`	

Review and deploy.	For instructions, see Save and deploy in the Amplify Hosting documentation. Wait until the deployment process is complete.	App developer

Validate continuous deployment

Task	Description	Skills required
Verify initial deployment.	When the deployment process is complete, under	App developer

Task	Description	Skills required
	Domain, choose the link. Verify that the application is operating as expected.	
Push a change to the code repository.	Edit the code on your local workstation and push the changes to CodeCommit repository. Amplify Hosting detects the change in the repository and automatically starts the build and deployment process. Confirm that the application updates are visible on the domain.	App developer

Create a React app by using AWS Amplify and add authentication with Amazon Cognito

Rishi Singla, Amazon Web Services

Summary

This pattern demonstrates how to use AWS Amplify to create a React-based app and how to add authentication to the frontend by using Amazon Cognito. AWS Amplify consists of a set of tools (open source framework, visual development environment, console) and services (web app and static website hosting) to accelerate the development of mobile and web apps on AWS.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Node.js and npm installed on your machine

Product versions

- Node.js version 10.x or later (to verify your version, run `node -v` in a terminal window)
- npm version 6.x or later (to verify your version, run `npm -v` in a terminal window)

Architecture

Target technology stack

- AWS Amplify
- Amazon Cognito

Tools

- Amplify Command Line Interface (CLI)
- Amplify Libraries (open source client libraries)
- Amplify Studio (visual interface)

Epics

Install AWS Amplify CLI

Task	Description	Skills required

Install the Amplify CLI.	The Amplify CLI is a unified toolchain for creating AWS Cloud services for your React app. To install the Amplify CLI, run:
	`npm install -g @aws-amplify/cli`
	npm will notify you if a new major version is available . If so, use the following command to upgrade your version of npm:
	`npm install -g npm@9.8.0`
	where 9.8.0 refers to the version you want to install.
		App developer

Create a React app

Task	Description	Skills required
Create a React app.	To create a new React app, use the command: `npx create-react-app amplify-react-application`	App developer

Task	Description	Skills required
	where `ampify-react-application` is the name of the app. When the app has been created successfully, you will see the message: `Success! Created amplify-react-application` A directory with various subfolders will be created for the React app.	
Launch the app on your local machine.	Go to the directory `amplify-react-application` that was created in the previous step and run the command: `amplify-react-application% npm start` This launches the React app on your local machine.	App developer

Configure the Amplify CLI

Task	Description	Skills required
Configure Amplify to connect to your AWS account.	Configure Amplify by running the command:	General AWS, App developer

Task	Description	Skills required
	```amplify-react-appl ication % amplify configure``` The Amplify CLI asks you to follow these steps to set up access to your AWS account: 1. Sign in to your AWS administrator account. 2. Specify the AWS Region you want to use. 3. Create an AWS Identity and Access Management (IAM) user with programmatic access, and attach the `AdministratorAccess-Amplify` permissions policy to the user. 4. Create and then copy the access key ID and secret access key. 5. Enter these details in the terminal. 6. Create a profile name or use the default profile. **Warning** This scenario requires IAM users with programmatic access and long-term credentials, which	

Task	Description	Skills required

	present a security risk. To help mitigate this risk, we recommend that you provide these users with only the permissions they require to perform the task and that you remove these users when they are no longer needed. Access keys can be updated if necessary. For more information, see [Updating access keys](#) in the *IAM User Guide*.
	
	These steps appear in the terminal as follows.
	
	`Follow these steps to set up access to your AWS account:`
	`Sign in to your AWS administrator account:`
	`https://console.aws.amazon.com/`
	`Press Enter to continue`
	`Specify the AWS Region`
	`? region:  us-east-1`
	`Follow the instructions at`
	`https://docs.amplify.aws/cli/start/`	

Task	Description	Skills required
	``` install/#configure- the-amplify-cli to complete the user creation in the AWS console https://console.aws .amazon.com/iamv2/ home#/users/create Press Enter to continue Enter the access key of the newly created user: ? accessKeyId: ******************** ? secretAccessKey: ****************** ****************** **** This would update/cr eate the AWS Profile in your local machine ? Profile Name: new Successfully set up the new user. ``` For more information about these steps, see the documentation in the Amplify Dev Center.	

Initialize Amplify

Task	Description	Skills required
Initialize Amplify.	1. To initialize Amplify in the new directory, run: `amplify init`	App developer, General AWS

Task	Description	Skills required
	Amplify prompts you for the project name and configuration parameters 2. Specify all parameters, and then press **Y** to initializ e the project with the specified configuration. `Project information	Name: amplifyre actproject	Environment: dev	Default editor: Visual Studio Code	App type: javascrip t	Javascript framework: react	Source Directory Path: src	Distribution Directory Path: build	Build Command: npm run-script build	Start Command: npm run-script start` 3. Select the profile you created in the previous step. The resources will be deployed into the `dev`	

Task	Description	Skills required

	environment in the Amplify project you created.
	4. To confirm that the resources have been created, you can open the [AWS Amplify console](#) and view the AWS CloudFormation template that was used to create the resources and the details.
	`Deploying root stack amplifyreactproject [ ==================================---- ] 2/4 amplify-amplifyreactproject-d… AWS::CloudFormation::Stack CREATE_IN_PROGRESS`
	
	`UnauthRole AWS::IAM::Role CREATE_COMPLETE`
	
	`DeploymentBucket AWS::S3::Bucket CREATE_IN_PROGRESS`
	
	`AuthRole AWS::IAM:`	

Task	Description	Skills required
	`:Role CREATE_COMPLETE`	

Add authentication to the frontend

Task	Description	Skills required
Adding authentication.	You can use the `amplify add <category>` command to add features such as a user login or a backend API. In this step you will use the command to add authentication. Amplify provides a backend authentication service with Amazon Cognito, frontend libraries, and a drop-in Authenticator UI component . Features include user sign-up, user sign-in, multi-fac tor authentication, user sign-out, and passwordless sign-in. You can also authentic ate users by integrating with federated identity providers such as Amazon, Google, and Facebook. The Amplify authentication category integrates seamlessly with other Amplify categories such as API, analytics, and storage, so you can define authoriza	App developer, General AWS

Task	Description	Skills required

	tion rules for authenticated and unauthenticated users.
	
	1. To configure authentic ation for your React app, run the command:
	
	`amplify-react-appl ication1 % amplify add auth`
	
	This displays the following information and prompts. You can choose the appropriate configura tion depending on your business and security requirements.
	
	`Using service: Cognito, provided by: awscloudformation The current configure d provider is Amazon Cognito. Do you want to use the default authentic ation and security configuration? (Use arrow keys)`
	
	`# Default configura tion`
	
	`Default configura tion with Social Provider (Federati on)`	

Task	Description	Skills required

	``
	  Manual configura
	tion
	
	  I want to learn
	 more.
	``
	2. For a simple example, choose the default configuration and then select the sign-in mechanism for users (in this case, email):
	``
	How do you want users
	 to be able to sign
	 in?
	 Username
	
	# Email
	
	  Phone Number
	
	  Email or Phone
	 Number
	
	  I want to learn
	 more.
	``
	3. Bypass the advanced settings to complete adding authentication resources:
	``
	Do you want to
	 configure advanced
	 settings? (Use arrow
	 keys)
	# No, I am done.
	``	

Task	Description	Skills required

	``
	 Yes, I want to make
	 some additional
	 changes.
	``
	4. Build your local backend resources and provision them in the cloud:
	``
	amplify-react-appl
	ication1 % amplify
	 push
	``
	This command makes the appropriate changes to the Congito user pools in your account.
	5. Press **Y** to configure the `auth` resource by using CloudFormation.
	This configures the following resources:
	``
	UserPool
	           AWS::Cogn
	ito::UserPool
	  CREATE_COMPLETE
	UserPoolClientWeb
	            AWS::Cogn
	ito::UserPoolClient
	   CREATE_COMPLETE
	
	UserPoolClientWeb
	            AWS::Cogn
	ito::UserPoolClient
	   CREATE_COMPLETE
	
	UserPoolClientRole
	            AWS::IAM:
	``	

Task	Description	Skills required

	``
	:Role
	 CREATE_COMPLETE
	
	UserPoolClientLambda
	           AWS::Lamb
	da::Function
	  CREATE_COMPLETE
	UserPoolClientLam
	bdaPolicy
	 AWS::IAM::Policy
	            CREATE_CO
	MPLETE
	
	UserPoolClientLog
	Policy
	 AWS::IAM::Policy
	            CREATE_IN
	_PROGRESS
	``
	
	You can also use the [AWS Cognito console](https://console.aws.amazon.com/cognito/) to view these resources (look for Cognito user pools and identity pools).
	
	This step updates the `aws-exports.js` file in the `src` folder for your React app with the Cognito user pool and identity pool configurations.	

Change the App.js file

Task	Description	Skills required

Change the App.js file.	In the `src` folder, open and revise the `App.js` file. The modified file should look like this:
	<pre>{ App.Js File after
	 modifications:
	import React from
	 'react';
	import logo from './
	logo.svg';
	import './App.css';
	import { Amplify } from
	 'aws-amplify';
	import { withAuthe
	nticator, Button,
	 Heading } from '@aws-
	amplify/ui-react';
	import awsconfig from
	 './aws-exports';
	Amplify.configure(a
	wsconfig);
	function
	 App({ signOut }) {
	  return (
	      <div>
	      <h1>Thankyou for
	 doing verification</
	h1>
	      <h2>My Content</
	h2>
	       <button onClick={
	signOut}>Sign out</
	button>
	    </div>
	  );
	}</pre>
		App developer

Task	Description	Skills required
	```export default withAuthenticator(App);```	
Import React packages.	The `App.js` file imports two React packages. Install these packages by using the command: ```amplify-react-application1 % npm install --save aws-amplify @aws-amplify/ui-react```	App developer

Launch the React app and check authentication

Task	Description	Skills required
Launch the app.	Launch the React app on your local machine: ```amplify-react-application1 % npm start```	App developer, General AWS
Check authentication.	Check whether the app prompts for authentication parameters. (In our example, we've configured email as the sign-in method.) The frontend UI should prompt you for sign-in credentials and provide an option to create an account.	App developer, General AWS

Task	Description	Skills required
	You can also configure the Amplify build process to add the backend as part of a continuous deploymen t workflow. However, this pattern doesn’t cover that option.

Create a portal for micro-frontends by using AWS Amplify, Angular, and Module Federation

Milena Godau and Pedro Garcia, Amazon Web Services

Summary

A micro-frontend architecture enables multiple teams to work on different parts of a frontend application independently. Each team can develop, build, and deploy a fragment of the frontend without interfering with other parts of the application. From the end user's perspective, it appears to be a single, cohesive application. However, they are interacting with several independent applications that are published by different teams.

This document describes how to create a micro-frontend architecture by using AWS Amplify, the Angular frontend framework, and Module Federation. In this pattern, the micro-frontends are combined on the client side by a shell (or *parent*) application. The shell application acts as a container that retrieves, displays, and integrates the micro-frontends. The shell application handles the global routing, which loads different micro-frontends. The @angular-architects/module-federation plugin integrates Module Federation with Angular. You deploy the shell application and micro-frontends by using AWS Amplify. End users access the application through a web-based portal.

The portal is split vertically. This means that the micro-frontends are entire views or groups of views, instead of parts of the same view. Therefore the shell application loads only one micro-frontend at a time.

The micro-frontends are implemented as remote modules. The shell application lazily loads these remote modules, which defers the micro-frontend initialization until it is required. This approach optimizes application performance by loading only the necessary modules. This reduces the initial load time and improves the overall user experience. Additionally, you share common dependencies across modules through the webpack configuration file (**webpack.config.js**). This practice promotes code reuse, reduces duplication, and streamlines the bundling process.

Prerequisites and limitations

Prerequisites

- An active AWS account

- Node.js and npm, installed
- Amplify CLI, installed
- Angular CLI, installed
- Permissions to use AWS Amplify
- Familiarity with Angular

Product versions

- Angular CLI version 13.1.2 or later
- @angular-architects/module-federation version 14.0.1 or later
- webpack version 5.4.0 or later
- AWS Amplify Gen 1

Limitations

A micro-frontend architecture is a powerful approach for building scalable and resilient web applications. However, it's crucial to understand the following potential challenges before adopting this approach:

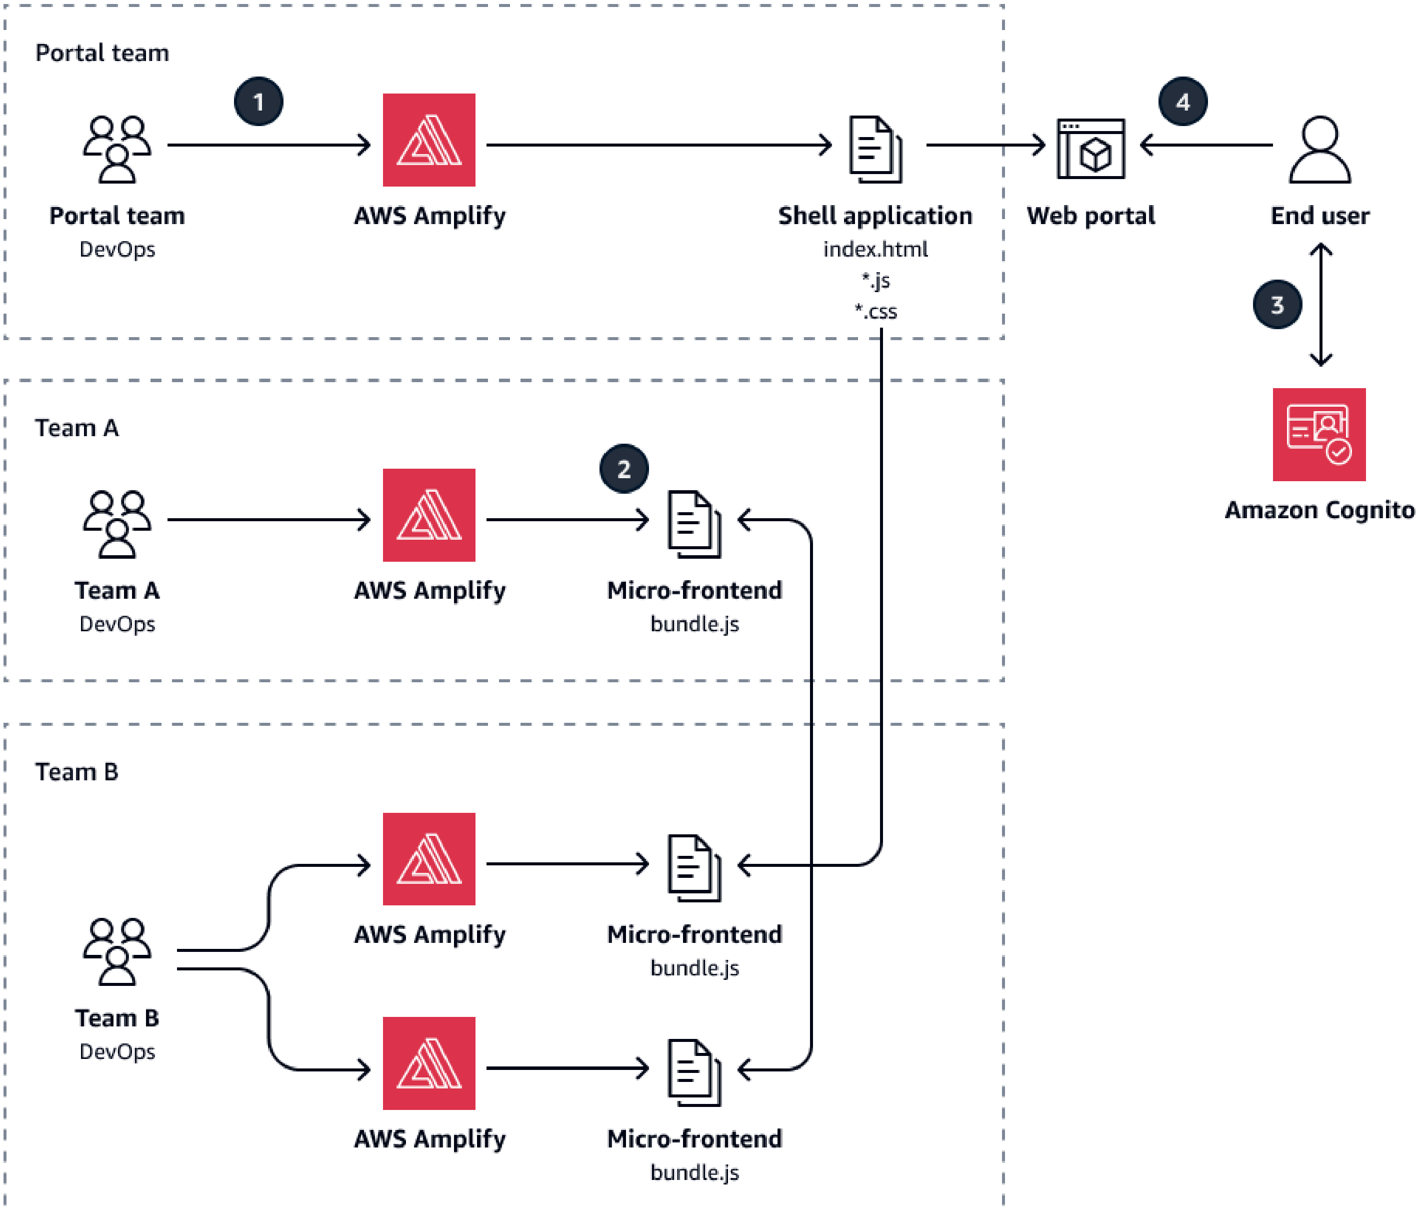
- **Integration –** One of the key challenges is the potential increase in complexity compared to monolithic frontends. Orchestrating multiple micro-frontends, handling communication between them, and managing shared dependencies can be more intricate. Additionally, there may be a performance overhead associated with communication between the micro-frontends. This communication can increase latency and reduce performance. This needs to be addressed through efficient messaging mechanisms and data-sharing strategies.
- **Code duplication –** Because each micro-frontend is developed independently, there is a risk of duplicating code for common functionality or shared libraries. This can increase the overall application size and introduce maintenance challenges.
- **Coordination and management –** Coordinating the development and deployment processes across multiple micro-frontends can be challenging. Ensuring consistent versioning, managing dependencies, and maintaining compatibility between components becomes more critical in a distributed architecture. Establishing clear governance, guidelines, and automated testing and deployment pipelines is essential for seamless collaboration and delivery.
- **Testing –** Testing micro-frontend architectures can be more complex than testing monolithic frontends. It requires additional effort and specialized testing strategies to perform cross-

component integration testing and end-to-end testing, and to validate consistent user experiences across multiple micro-frontends.

Before committing to the micro-frontend approach, we recommend that you review Understanding and implementing micro-frontends on AWS.

Architecture

In a micro-frontend architecture, each team develops and deploys features independently. The following image shows how multiple DevOps teams work together. The portal team develops the shell application. The shell application acts as a container. It retrieves, displays, and integrates the micro-frontend applications that are published by other DevOps teams. You use AWS Amplify to publish the shell application and micro-frontend applications.



The architecture diagram shows the following workflow:

1. The portal team develops and maintains the shell application. The shell application orchestrates the integration and rendering of the micro-frontends in order to compose the overall portal.
2. Teams A and B develop and maintain one or more micro-frontends or features that are integrated into the portal. Each team can work independently on their respective micro-frontends.
3. The end user authenticates by using Amazon Cognito.

4. The end user accesses the portal, and the shell application is loaded. As the user navigates, the shell application deals with the routing and retrieves the requested micro-frontend, loading its bundle.

Tools

AWS services

- AWS Amplify is a set of purpose-built tools and features that helps frontend web and mobile developers quickly build full-stack applications on AWS. In this pattern, you use the Amplify CLI to deploy the Amplify micro-frontend applications.
- AWS Command Line Interface (AWS CLI) is an open source tool that helps you interact with AWS services through commands in your command-line shell.

Other tools

- @angular-architects/module-federation is a plugin that integrates Angular with Module Federation.
- Angular is an open source web application framework for building modern, scalable, and testable single-page applications. It follows a modular and component-based architecture that promotes code reuse and maintenance.
- Node.js is an event-driven JavaScript runtime environment designed that is for building scalable network applications.
- npm is a software registry that runs in a Node.js environment and is used to share or borrow packages and manage deployment of private packages.
- Webpack Module Federation helps you load code that is independently compiled and deployed, such as micro-frontends or plugins, into an application.

Code repository

The code for this pattern is available in the Micro-frontend portal using Angular and Module Federation GitHub repository. This repository contains the following two folders:

- `shell-app` contains the code for the shell application.
- `feature1-app` contains a sample micro-frontend. The shell application fetches this micro-frontend and displays it as a page within the portal application.

Best practices

Micro-frontend architectures offer numerous advantages, but they also introduce complexity. The following are some best practices for smooth development, high-quality code, and a great user experience:

- **Planning and communication –** To streamline collaboration, invest in upfront planning, design, and clear communication channels.
- **Design consistency –** Enforce a consistent visual style across micro-frontends by using design systems, style guides, and component libraries. This provides a cohesive user experience and accelerates development.
- **Dependency management –** Because micro-frontends evolve independently, adopt standardized contracts and versioning strategies to manage dependencies effectively and prevent compatibility issues.
- **Micro-frontend architecture –** To enable independent development and deployment, each micro-frontend should have a clear and well-defined responsibility for an encapsulated functionality.
- **Integration and communication –** To facilitate smooth integration and minimize conflicts, define clear contracts and communication protocols between micro-frontends, including APIs, events, and shared data models.
- **Testing and quality assurance –** Implement test automation and continuous integration pipelines for micro-frontends. This improves the overall quality, reduces manual testing effort, and validates functionality between micro-frontend interactions.
- **Performance optimization –** Continuously monitor performance metrics and track dependencies between micro-frontends. This helps you identify bottlenecks and maintain optimal application performance. Use performance monitoring and dependency analysis tools for this purpose.
- **Developer experience –** Focus on the developer experience by providing clear documentation, tooling, and examples. This helps you streamline development and onboard new team members.

Epics

Create the shell application

Task	Description	Skills required

Create the shell application.	1. In the Angular CLI, enter the following command:
	`ng new shell --routing`
	2. Enter the following command to navigate to the project folder:
	`cd shell`
	Note
	The folder and project structure for the shell and micro-frontend applications can be totally independent. They can be handled as independent Angular applications.
		App developer

Install the plugin.	In the Angular CLI, enter the following command to install the [@angular-architects/module-federation](https://www.npmjs.com/package/@angular-architects/module-federation) plugin:	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>
<pre><code>ng add @angular-
architects/module-
federation --project
 shell --port 4200</code></pre>
</td><td></td></tr>
<tr><td>Add the micro-frontend URL as an environment variable.</td><td>
1. Open the environment.ts file.
2. Add <code>mfe1URL: 'http://localhost:5000'</code> to the <code>environment</code> object:
<pre><code>export const environme
nt = {
  production: false,
  mfe1URL: 'http://l
ocalhost:5000',
};</code></pre>
3. Save and close the environment.ts file.
</td><td>App developer</td></tr>
</table>

Task	Description	Skills required

Define routing.	1. Open the **app-routi ng.module.ts** file.
	2. In the Angular CLI, enter the following command to import the `loadRemot eModule` module from the @angular-architects/ module-federation plugin:
	`import { loadRemot eModule } from '@angular-architec ts/module-federati on';`
	3. Set the default route as the following:
	`{ path: '', pathMatch: 'full', redirectTo: 'mfe1' },`
	4. Set the route for the micro-frontend:
	`{ path: 'mfe1', loadChildren: () => loadRemot eModule({ type: 'module', remoteEntry: `${environment.mfe`
		App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

```
1URL}/remoteEntry.
js`,
        exposedMo
dule: './Module'
      })
      .then(m =>
 m.Mfe1Module)
  },
```

5. Save and close the **app-routing.module.ts** file.</td><td></td></tr>
<tr><td>Declare the `mfe1` module.</td><td>

1. In the `src` folder, create a new file named **decl.d.ts**.
2. Open the **decl.d.ts** file.
3. Add the following to the file:

```
declare module 'mfe1/
Module';
```

4. Save and close the **decl.d.ts** file.</td><td>App developer</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Prepare preloading for the micro-frontend.</td><td>Preloading the micro-frontend helps the webpack properly negotiate the shared libraries and packages.

1. Open the main.ts file.
2. Replace the content with the following:
<pre><code>import { loadRemoteEntry } from
 '@angular-architects/module-federation';

Promise.all([
    loadRemoteEntry(`${environment.mfe1URL}/remoteEntry.js`, 'mfe1'),
])
.catch(err =>
 console.error('Error loading remote
 entries', err))
.then(() => import('./bootstrap'))
.catch(err =>
 console.error(err)
);</code></pre>3. Save and close the main.ts file.</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
Adjust the HTML content.	1. Open the **app.component.html** file. 2. Replace the content with the following: `<h1>Shell application is running!</h1> <router-outlet></router-outlet>` 3. Save and close the **app.component.html** file.	App developer

Create the micro-frontend application

Task	Description	Skills required

Create the micro-frontend.	1. In the Angular CLI, enter the following command:
	`ng new mfe1 --routing`
	2. Enter the following command to navigate to the project folder:
	`cd mfe1`
		App developer

Install the plugin.	Enter the following command to install the @angular-architects/module-federation plugin: `ng add @angular-architects/module-`	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td><pre><code>federation --project
 mfe1 --port 5000</code></pre></td><td></td></tr>
<tr><td>Create a module and component.</td><td>Enter the following commands to create a module and component and export them as the remote entry module:<pre><code>ng g module mfe1 --
routing
ng g c mfe1</code></pre></td><td>App developer</td></tr>
<tr><td>Set the default routing path.</td><td>Open the mfe-routi ng.module.ts file.
Set the default route as the following:<pre><code>{
    path: '',
    component:
 Mfe1Component
  },</code></pre>
Save and close the mfe-routing.module.ts file.</td><td>App developer</td></tr>
</table>

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add the <code>mfe1</code> route.</td><td>
1. Open the app-routing.module.ts file.
2. Set the default route as the following:
<pre><code>{
    path: '',
    pathMatch: 'full',
    redirectTo: 'mfe1'
  },</code></pre>
3. Add the following <code>mfe1</code> route:
<pre><code>{
    path: 'mfe1',
    loadChildren: () =>
      import('./mfe1/mfe1.module').then((m) => m.Mfe1Module),
  },</code></pre>
4. Save and close the app-routing.module.ts file.
</td><td>App developer</td></tr>
</table>

Task	Description	Skills required

Edit the **webpack.config.js** file.	1. Open the **webpack.config.js** file.
	2. Edit the `For remotes` section to match the following:
	<pre>// For remotes (please adjust)
	    name: "mfe1",
	    filename: "remoteEntry.js",
	    exposes: {
	        './Module': './src/app/mfe1/mfe1.module.ts',
	    },</pre>3. In the `shared` section, add any dependencies that the `mfe1` application shares with the shell application:
	<pre>shared: share({
	        "@angular/core": { singleton: true, strictVersion: true, requiredVersion: 'auto' },
	        "@angular/common": { singleton: true, strictVersion: true, requiredVersion: 'auto' },
	        "@angular/common/http": { singleton: true, strictVersion: true, requiredVersion: 'auto' },</pre>
		App developer

Task	Description	Skills required

	``
	        "@angular/
	router": { singleton
	: true, strictVer
	sion: true, requiredV
	ersion: 'auto' },
	
	        ...shared
	Mappings.getDescri
	ptors()
	    })
	``
	4. Save and close the **webpack.config.js** file.	

Adjust the HTML content.	1. Open the **app.compo nent.html** file. 2. Replace the contents with the following: `<router-outlet></router-outlet>` 3. Save and close the **app.component.html** file.	App developer

Run the applications locally

Task	Description	Skills required
Run the `mfe1` application.	1. Enter the following command to start the `mfe1` application: `npm start`	App developer

Task	Description	Skills required
	2. In a web browser, access `http://localhost:5000`. 3. Verify that the micro-frontend can be run standalone. The `mfe1` application should properly render without any errors.	
Run the shell application.	1. Enter the following command to start the shell application: `npm start` 2. In a web browser, access `http://localhost:4200/mfe1`. 3. Verify that the `mfe1` micro-frontend is embedded in the shell application. The portal application should properly render without any errors, and the `mfe1` application should be embedded within it.	App developer

Refactor the shell application to handle a micro-frontend loading error

Task	Description	Skills required
Create a module and component.	In the root folder of the shell application, enter the following commands	App developer

Task	Description	Skills required

	to create a module and component for an error page:
	`ng g module error-page --routing`
	`ng g c error-page`	

Adjust the HTML content.	1. Open the **error-page.component.html** file. 2. Replace the contents with the following: `<p>Sorry, this page is not available.</p>` 3. Save and close the **error-page.component.html** file.	App developer
Set the default routing path.	1. Open the **error-page-routing.module.ts** file. 2. Set the default route as the following: `{ path: '', component: ErrorPageComponent },` 3. Save and close the **error-page-routing.module.ts** file.	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create a function to load micro-frontends.</td><td>

1. Open the **app-routi ng.module.ts** file.
2. Create the following function:

```
function loadMFE(url:
 string) {
    return loadRemot
eModule({
        type:
 'module',
        remoteEntry:
 `${url}/remoteEntr
y.js`,
        exposedMo
dule: './Module'
    })
    .then(m =>
 m.Mfe1Module)
    .catch(
        () =>
 import('./error-pa
ge/error-page.modu
le').then(m =>
 m.ErrorPageModule)
    );
}
```

3. Modify the `mfe1` route to be the following:

```
{
    path: 'mfe1',
    loadChildren:
 () => loadMFE(e
nvironment.mfe1URL)
},
```

</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
	4. Save and close the **app-routing.module.ts** file.	

Test the error handling.	1. If it is not already running, enter the following command to start the shell application:
	`npm start`
	2. In a web browser, access `http://localhost:4200/mfe1` .
	3. Verify that the error page is rendered. You should see the following text:
	`Sorry, this page is not available.`
		App developer

Deploy the applications by using AWS Amplify

Task	Description	Skills required
Deploy the micro-frontend.	1. In the Amplify CLI, navigate to the root folder of the micro-frontend application. 2. Enter the following command to initialize Amplify: `amplify init`	App developer, AWS DevOps

Task	Description	Skills required
	3. When you are prompted to enter a name for your Amplify project, press **Enter**. This re-uses the name from the **package.json** file. 4. When you are prompted to initialize the project with the above configuration, enter `Yes`. 5. When you are prompted to select an authentication method, choose `AWS Profile`. 6. Select the profile you want to use. 7. Wait for Amplify to initialize the project. When this process is complete, you receive a confirmation message in the terminal. 8. Enter the following command to add an Amplify hosting category to the micro-frontend: `amplify add hosting` 9. When you are prompted to select the plugin module, choose `Hosting with Amplify Console`.	

Task	Description	Skills required

	10. When you are prompted to choose a type, choose `Manual deployment` .
	11. Install the project npm dependencies by entering the following command:
	`npm install`
	12. Publish the application to the Amplify console by entering the following command:
	`amplify publish -y`
	When publishing is complete, Amplify returns the URL of the micro-frontend.
	13. Copy the URL. You need this value to update the shell application.	

Task	Description	Skills required

Deploy the shell application.	1. In the **src/app/environments** folder, open the **environments.prod.ts** file.
	2. Replace the `mfe1URL` value with the URL of the deployed micro-frontend:
	`export const environment = {`
	`   production: true,`
	`   mfe1URL: 'https://<env>.<Amplify-app-ID>.amplifyapp.com'`
	` };`
	3. Save and close the **environments.prod.ts** file.
	4. In the Amplify CLI, navigate to the root folder of the shell application.
	5. Enter the following command to initialize Amplify:
	`amplify init`
	6. When you are prompted to enter a name for your Amplify project, press **Enter**. This re-uses the name from the **package.json** file.
	7. When you are prompted to initialize the project with
		App developer, App owner

Task	Description	Skills required

	the above configuration, enter `Yes`.
	8. When you are prompted to select an authentication method, choose `AWS Profile`.
	9. Select the profile you want to use.
	10. Wait for Amplify to initialize the project. When this process is complete, you receive a confirmation message in the terminal.
	11. Add an Amplify hosting category to the shell application:
	`amplify add hosting`
	12. When you are prompted to select the plugin module, choose `Hosting with Amplify Console`.
	13. When you are prompted to choose a type, choose `Manual deployment` .
	14. Install project npm dependencies by entering the following command:
	`npm install`
	15. Publish the shell application to the Amplify console	

Task	Description	Skills required
	by entering the following command: `amplify publish -y` When publishing is complete, Amplify returns the URL of the deployed shell application. 16. Make note of the URL for the shell application.	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Enable CORS.</td><td>Because the shell and micro-frontend applications are hosted independently on different domains, you must enable cross-origin resource sharing (CORS) on the micro-frontend. This allows the shell application to load the content from a different origin. To enable CORS, you add custom headers.

1. In the Amplify CLI, navigate to the root folder of the micro-frontend.
2. Enter the following command:
<pre><code>amplify configure hosting</code></pre>3. When you are prompted to configure custom settings, enter Y.
4. Sign in to the AWS Management Console, and then open the Amplify console.
5. Choose the micro-frontend.
6. In the navigation pane, choose Hosting, and then choose Custom headers.
7. Choose Edit.</td><td>App developer, AWS DevOps</td></tr>
</table>

Task	Description	Skills required

	8. In the **Edit custom headers** window, enter the following:
	``customHeaders:
	  - pattern: '*.js'
	    headers:
	      - key: Access-Control-Allow-Origin
	        value: '*'
	      - key: Access-Control-Allow-Methods
	        value: 'GET, OPTIONS'
	      - key: Access-Control-Allow-Headers
	        value: '*'```
	9. Choose **Save**.
	10. Redeploy the micro-frontend to apply the new custom headers.	

Task	Description	Skills required
Create a rewrite rule on the shell application.	The Angular shell application is configured to use HTML5 routing. If the user performs a hard refresh, Amplify tries to load a page from the current URL. This generates a 403 error. To avoid this, you add a rewrite rule in the Amplify console. To create the rewrite rule, follow these steps: 1. In the Amplify CLI, navigate to the root folder of the shell application. 2. Enter the following command: `amplify configure hosting` 3. When you are prompted to configure custom settings, enter Y. 4. Open the [Amplify console](https://console.aws.amazon.com/amplify/). 5. Choose the shell applicati on. 6. In the navigation pane, choose **Hosting**, and then choose **Rewrites and redirects**. 7. On the **Rewrites and redirects** page, choose **Manage redirects**.	App developer, AWS DevOps

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td></td><td>

8. Choose **Open text editor**.
9. In the JSON editor, enter the following redirect:

```
[
    {
        "source": "/<*>",
        "target": "/index.html",
        "status": "404-200",
        "condition": null
    }
]
```

10. Choose **Save**.

</td><td></td></tr>
<tr><td>Test the web portal.</td><td>

1. In a web browser, enter the URL of the deployed shell application.
2. Verify that the shell application and the micro-frontend load properly.

</td><td>App developer</td></tr>
</table>

Clean up resources

Task	Description	Skills required
Delete the applications.	If you no longer need the shell and micro-frontend applications, delete them. This helps prevent charges for resources that you aren't using.	General AWS

Task	Description	Skills required
	1. Sign in to the AWS Management Console, and then open the [Amplify console](). 2. Choose the micro-fro ntend. 3. In the navigation pane, choose **App settings**, and then choose **General settings**. 4. Choose **Delete app**. 5. In the confirmation window, enter `delete`, and then choose **Delete app**. 6. Repeat these steps to delete the shell applicati on.	

Troubleshooting

Issue	Solution
No AWS profile available when running the `amplify init` command	If you don't have an AWS profile configure d, you can still proceed with the `amplify init` command. However, you need to select the `AWS access keys` option when you're prompted for the authentication method. Have your AWS access key and secret key available. Alternatively, you can configure a named profile for the AWS CLI. For instructions, see

Issue	Solution
	Configuration and credential file settings in the AWS CLI documentation.
Error loading remote entries	If you encounter an error when loading the remote entries in the **main.ts** file of the shell application, make sure that the `environment.mfe1URL` variable is set correctly. The value of this variable should be the URL of the micro-frontend.
404 error when accessing the micro-frontend	If you get a 404 error when trying to access the local micro-frontend, such as at `http://localhost:4200/mfe1`, check the following: • For the shell application, make sure that the routing configuration in the **app-routing.module.ts** file is set up correctly, and make sure that the `loadRemoteModule` function is properly calling the micro-frontend. • For the micro-frontend, verify that the **webpack.config.js** file has the correct `exposes` configuration, and make sure that the **remoteEntry.js** file is being generated correctly.

Deploy a React-based single-page application to Amazon S3 and CloudFront

Jean-Baptiste Guillois, Amazon Web Services

Summary

A single-page application (SPA) is a website or web application that dynamically updates the contents of a displayed webpage by using JavaScript APIs. This approach enhances the user experience and performance of a website because it updates only new data instead of reloading the entire webpage from the server.

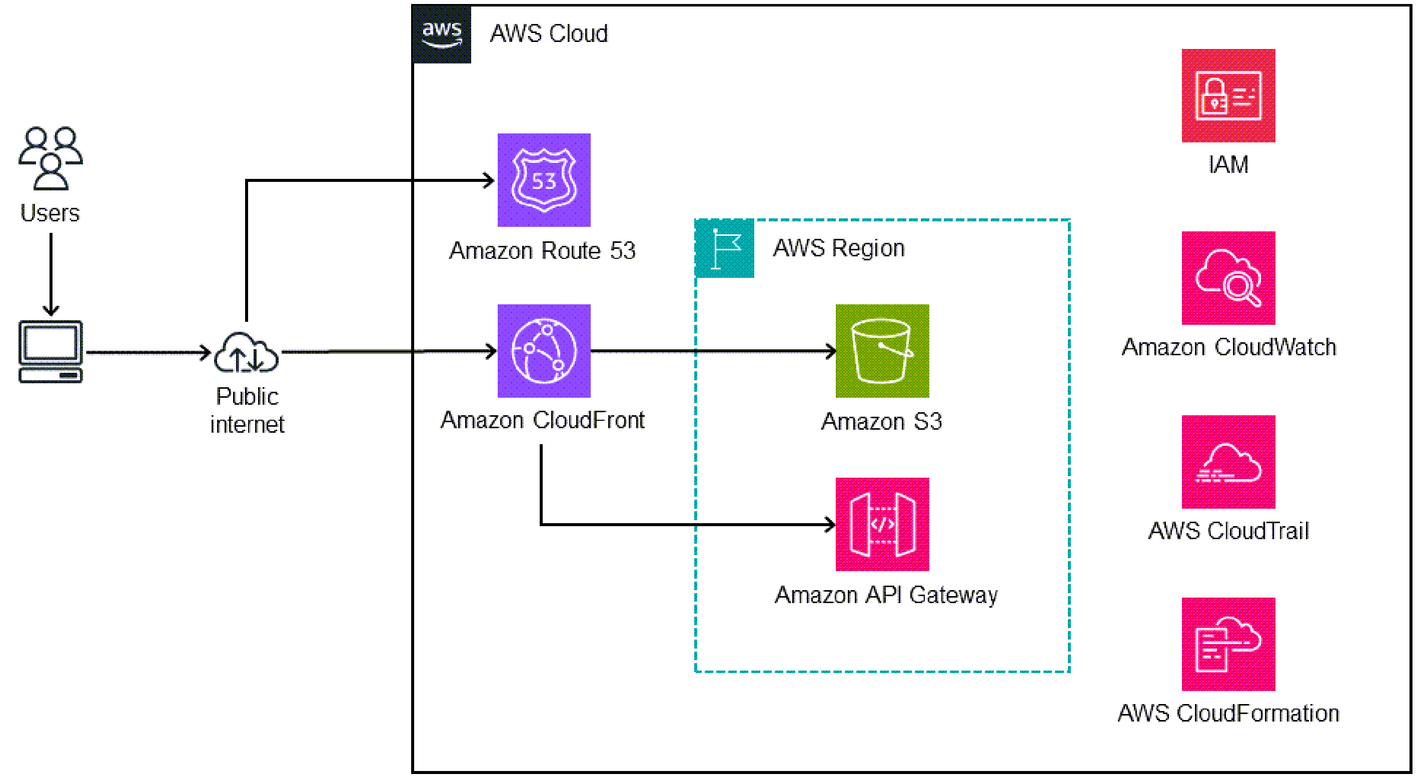
This pattern provides a step-by-step approach to coding and hosting an SPA that's written in React on Amazon Simple Storage Service (Amazon S3) and Amazon CloudFront. The SPA in this pattern uses a REST API that's configured in Amazon API Gateway and exposed through an Amazon CloudFront distribution to simplify cross-origin resource sharing (CORS) management.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Node.js and `npm`, installed and configured. For more information, see the Downloads section of the Node.js documentation.
- Yarn, installed and configured. For more information, see the Yarn documentation.
- Git, installed and configured. For more information, see the Git documentation.

Architecture



This architecture is automatically deployed by using AWS CloudFormation (infrastructure as code). It uses Regional services such as Amazon S3 to store the static assets and Amazon CloudFront with Amazon API Gateway to expose Regional API (REST) endpoints. The application logs are collected by using Amazon CloudWatch. All AWS API calls are audited in AWS CloudTrail. All security configuration (for example, identities and permissions) is managed in AWS Identity and Access Management (IAM). Static content is delivered through the Amazon CloudFront content delivery network (CDN), and DNS queries are handled by Amazon Route 53.

Tools

AWS services

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- Amazon CloudFront speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.

- AWS CloudTrail helps you audit the governance, compliance, and operational risk of your AWS account.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- Amazon Route 53 is a highly available and scalable DNS web service.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Code

This pattern's sample application code is available in the GitHub React-based CORS single-page application repository.

Best practices

By using Amazon S3 object storage, you can store your application’s static assets in a secure, highly resilient, performant, and cost-effective way. There is no need to use a dedicated container or an Amazon Elastic Compute Cloud (Amazon EC2) instance for this task.

By using the Amazon CloudFront content delivery network, you can reduce the latency your users might experience when they access your application. You can also attach a web application firewall (AWS WAF) to protect your assets from malicious attacks.

Epics

Locally build and deploy your application

Task	Description	Skills required
Clone the repository.	Run the following command to clone the sample application's repository: `git clone https://github.com/aws-samples/react-cors-spa`	App developer, AWS DevOps

Task	Description	Skills required
	`react-cors-spa && cd react-cors-spa`	
Locally deploy the application.	1. In the project directory, run the `npm install` command to initiate the application dependencies. 2. Run the `yarn dev` command to start the application locally.	App developer, AWS DevOps
Locally access the application.	Open a browser window and enter the `http://localhost:3000` URL to access the application.	App developer, AWS DevOps

Deploy the application

Task	Description	Skills required
Deploy the AWS CloudFormation template.	1. Sign in to the AWS Management Console, and then open the [AWS CloudFormation console](https://console.aws.amazon.com/cloudformation/). 2. Choose **Create Stack**, and then choose **With new resources (standard)**. 3. Choose **Upload a template file**. 4. Choose **Choose file**, choose the `react-cors-spa-stack.yaml` file from the cloned repository, and then choose **Next**.	App developer, AWS DevOps

Task	Description	Skills required
	5. Enter a name for your stack, and then choose **Next**. 6. Keep all default options, and then choose **Next**. 7. Review the final settings for your stack, and then choose **Create stack**.	
Customize your application source files.	1. After your stack is deployed, open the **Output** tab and identify the `Bucket` name and `APIDomain` value. 2. Copy the CloudFront distribution domain for the REST API. 3. Navigate to `<project_root>/src/pages/index.tsx`, and then insert or paste this domain into the `APIEndPoint` variable value on line 13 of the `index.tsx` file.	App developer
Build the application package.	In your project directory, run the `yarn build` command to build the application package.	App developer

Task	Description	Skills required
Deploy the application package.	1. Open the [Amazon S3 console](https://console.aws.amazon.com/s3/). 2. Identify and choose the S3 bucket that was created earlier by the CloudFormation stack. 3. Choose **Upload**, and then choose **Add files**. 4. Choose the content of your `out` folder. 5. Choose **Add folder**, and then choose the `_next` directory. **Important** Choose the `_next` directory, not the contents. 6. Choose **Upload** to upload the files and directory to your S3 bucket.	App developer, AWS DevOps

Test the application

Task	Description	Skills required
Access and test the application.	Open a browser window, and then paste the CloudFront distribution domain (the `SPADomain` output from the CloudFormation stack that	App developer, AWS DevOps

Task	Description	Skills required
	you deployed previously) to access the application.	

Clean up the resources

Task	Description	Skills required
Delete the S3 bucket contents.	1. Open the [Amazon S3 console](#) and choose the bucket that was created earlier by the stack (the first bucket whose name starts with `react-cors-spa-`). 2. Choose **Empty** to delete the bucket’s contents. 3. Choose the second bucket that was created earlier by the stack (the second bucket whose name starts with `react-cors-spa-` and ends with `-logs`). 4. Choose **Empty** to delete the bucket’s contents.	AWS DevOps, App developer
Delete the AWS CloudFormation stack.	1. Open the [AWS CloudFormation console](#) and choose the stack that you created earlier. 2. Choose **Delete** to delete the stack and all related resources.	AWS DevOps, App developer

Related resources

To deploy and host your web application, you can also use [AWS Amplify Hosting](), which provides a Git-based workflow for hosting full-stack, serverless web apps with continuous deployment. Amplify Hosting is part of [AWS Amplify](), which provides a set of purpose-built tools and features that enable frontend web and mobile developers to quickly and easily build full-stack applications on AWS.

Additional information

To handle invalid URLs requested by the user that might generate 403 errors, a custom error page that's configured in the CloudFront distribution catches 403 errors and redirects them to the application entry point (`index.html`).

To simplify the management of CORS, the REST API is exposed through a CloudFront distribution.

Deploy an Amazon API Gateway API on an internal website using private endpoints and an Application Load Balancer

Saurabh Kothari, Amazon Web Services

Summary

This pattern shows you how to deploy an Amazon API Gateway API on an internal website that's accessible from an on-premises network. You learn to create a custom domain name for a private API by using an architecture that's designed with private endpoints, an Application Load Balancer, AWS PrivateLink, and Amazon Route 53. This architecture prevents the unintended consequences of using a custom domain name and proxy server to help with domain-based routing on an API. For example, if you deploy a virtual private cloud (VPC) endpoint in a non-routable subnet, your network can't reach API Gateway. A common solution is to use a custom domain name and then deploy the API in a routable subnet, but this can break other internal sites when the proxy configuration passes traffic (`execute-api.{region}.vpce.amazonaws.com`) to AWS Direct Connect. Finally, this pattern can help you meet organizational requirements for using a private API that's unreachable from the internet and a custom domain name.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Server Name Indication (SNI) certificate for your website and API
- A connection from an on-premises environment to an AWS account that's set up by using AWS Direct Connect or AWS Site-to-Site VPN
- A private hosted zone with a corresponding domain (for example, domain.com) that's resolved from an on-premises network and forwards DNS queries to Route 53
- A routable private subnet that's reachable from an on-premises network

Limitations

For more information about quotas (formerly referred to as limits) for load balancers, rules, and other resources, see Quotas for your Application Load Balancers in the Elastic Load Balancing documentation.

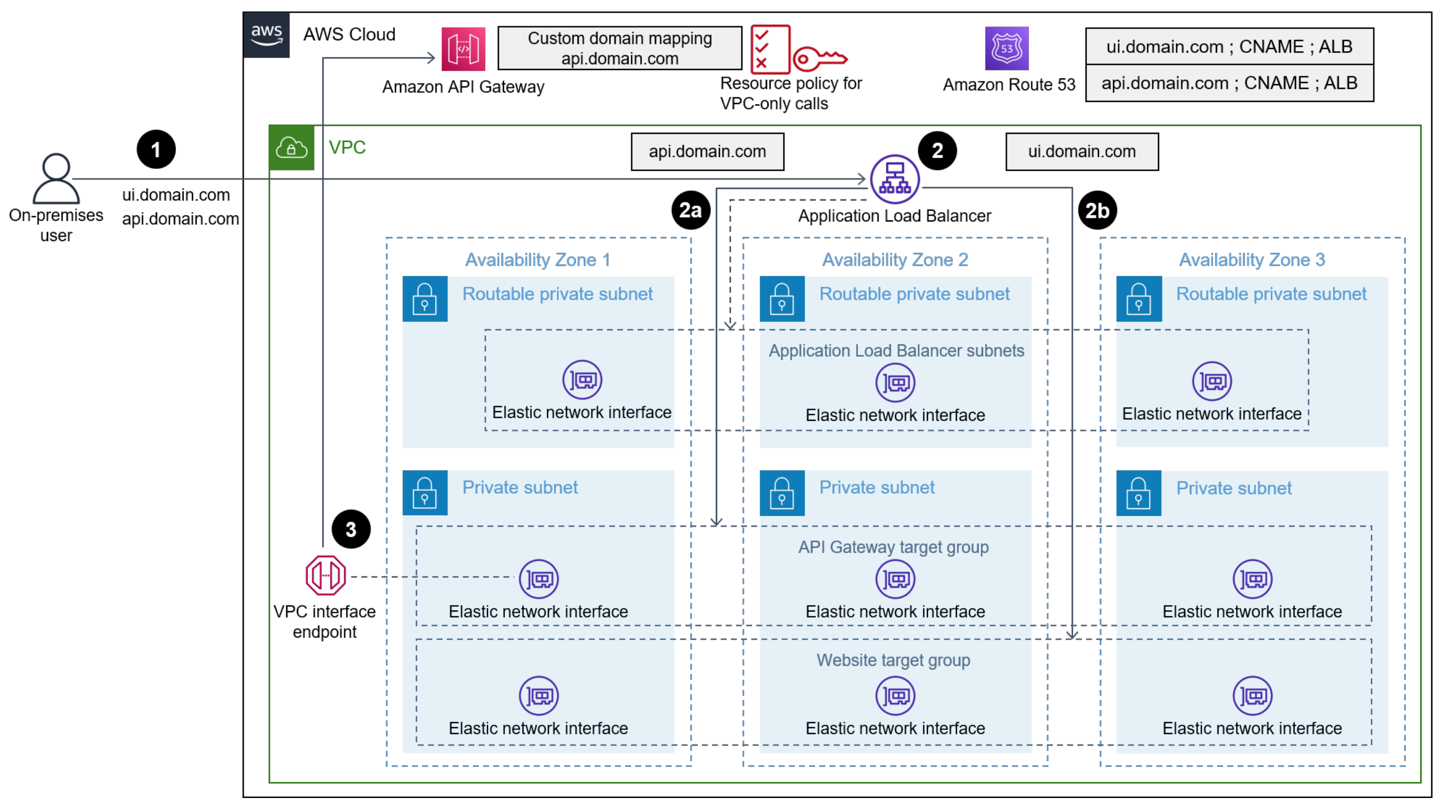
Architecture

Technology stack

- Amazon API Gateway
- Amazon Route 53
- Application Load Balancer
- AWS Certificate Manager
- AWS PrivateLink

Target architecture

The following diagram shows how an Application Load Balancer is deployed in a VPC that directs web traffic to a website target group or API Gateway target group based on Application Load Balancer listener rules. The API Gateway target group is a list of IP addresses for the VPC endpoint in API Gateway. API Gateway is configured to make the API private with its resource policy. The policy denies all calls that are not from a specific VPC endpoint. Custom domain names in API gateway are updated to use api.domain.com for the API and its stage. Application Load Balancer rules are added to route traffic based on the host name.



The diagram shows the following workflow:

1. A user from an on-premises network tries to access an internal website. The request is sent to ui.domain.com and api.domain.com. Then, the request is resolved to the internal Application Load Balancer of the routable private subnet. The SSL is terminated at the Application Load Balancer for ui.domain.com and api.domain.com.
2. Listener rules, configured on the Application Load Balancer, check for the host header.

   a. If the host header is api.domain.com, the request is forwarded to the API Gateway target group. The Application Load Balancer initiates a new connection to API Gateway over port 443.

   b. If the host header is ui.domain.com, the request is forwarded to the website target group.
3. When the request reaches API Gateway, the custom domain mapping configured in API Gateway determines the hostname and which API to run.

Automation and scale

The steps in this pattern can be automated by using AWS CloudFormation or the AWS Cloud Development Kit (AWS CDK). To configure the target group of the API Gateway calls, you must use a custom resource to retrieve the IP address of the VPC endpoint. API calls to describe-vpc-endpoints and describe-network-interfaces return the IP addresses and the security group, which can be used to create the API target group of IP addresses.

Tools

- Amazon API Gateway helps you create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs at any scale.
- Amazon Route 53 is a highly available and scalable DNS web service.
- AWS Certificate Manager (ACM) helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS PrivateLink helps you create unidirectional, private connections from your VPCs to services outside of the VPC.

Epics

Create an SNI certificate

Task	Description	Skills required
Create an SNI certificate and import the certificate into ACM.	1. Create an SNI certificate for ui.domain.com and api.domain.com. For more information, see [Choosing how CloudFront serves HTTPS requests] in the Amazon CloudFront documentation. 2. Import the SNI certificates into AWS Certificate Manager (ACM). For more information, see [Importing certificates into AWS Certificate Manager] in the ACM documentation.	Network administrator

Deploy a VPC endpoint in a non-routable private subnet

Task	Description	Skills required
Create an interface VPC endpoint in API Gateway.	To create an interface VPC endpoint, follow the instructions from [Access an AWS service using an interface VPC endpoint] in the Amazon Virtual Private Cloud (Amazon VPC) documentation.	Cloud administrator

Configure the Application Load Balancer

Task	Description	Skills required
Create a target group for your application.	Create a target group for the UI resources of your applicati on.	Cloud administrator
Create a target group for the API Gateway endpoint.	1. Create a target group with an IP address type, and then add the IP address of the VPC endpoint for the API Gateway endpoint to the target group. 2. Configure health checks for your target groups with success code 403. 403 is required because the VPC endpoint for the API Gateway returns a 403 code when it is invoked without any headers by the target group health check.	Cloud administrator
Create an Application Load Balancer.	1. Create an Application Load Balancer (internal) in a routable private subnet. 2. Add the 443 listener to the Application Load Balancer, and the choose the certificate from ACM.	Cloud administrator
Create listeners rules.	Create listener rules to do the following:	Cloud administrator

Task	Description	Skills required
	1. Forward the host api.domain.com to the API Gateway target group 2. Forward the host ui.domain.com to the target group for the UI resources	

Configure Route 53

Task	Description	Skills required
Create a private hosted zone.	[Create a private hosted zone](#) for domain.com.	Cloud administrator
Create domain records.	[Create CNAME records](#) for the following: • An API with the value set to the DNS name of the Application Load Balancer • A UI with the value set to the DNS name of the Application Load Balancer	Cloud administrator

Create a private API endpoint in API Gateway

Task	Description	Skills required
Create and configure a private API endpoint.	1. To create a private API endpoint, follow the instructions from [Creating a private API in Amazon](#)	App developer, Cloud administrator

Task	Description	Skills required
	API Gateway in the API Gateway documentation. 2. Configure the resource policy to allow calls to only the API from the VPC endpoint. For more information, see Controlling access to an API with API Gateway resource policies in the API Gateway documentation.	
Create a custom domain name.	1. Create a custom domain name for api.domain.com. For more information, see Setting up custom domain names for REST APIs in the API Gateway documentation. 2. Select the created API and stage. For more information, see Working with API mappings for REST APIs in the API Gateway documentation.	Cloud administrator

Embed an Amazon QuickSight dashboard in a local Angular application

Sean Griffin and Milena Godau, Amazon Web Services

Summary

This pattern provides guidance for embedding an Amazon QuickSight dashboard into a locally hosted Angular application for development or testing. The embedded analytics feature in QuickSight doesn't support this functionality natively. It requires an QuickSight account with an existing dashboard and knowledge of Angular.

When you work with embedded QuickSight dashboards, you would typically have to host your application on a web server to view the dashboard. This makes development more difficult, because you have to continuously push your changes to the web server to make sure everything is behaving correctly. This pattern shows how to run a locally hosted server and use QuickSight embedded analytics to make the development process easier and more streamlined.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- An active QuickSight account with session capacity pricing
- QuickSight Embedding SDK installed
- Angular CLI installed
- Familiarity with Angular
- mkcert installed

Limitations

- This pattern provides guidance on embedding a QuickSight dashboard by using the `ANONYMOUS` (publicly accessible) authentication type. If you are using AWS Identity and Access Management (IAM) or QuickSight authentication with your embedded dashboards, the provided code won't apply. However, the steps for hosting the Angular application in the Epics section are still valid.
- Using the **GetDashboardEmbedUrl** API with the `ANONYMOUS` identity type requires a QuickSight capacity pricing plan.

Versions

- Angular CLI version 13.3.4
- QuickSight Embedding SDK version 2.3.1

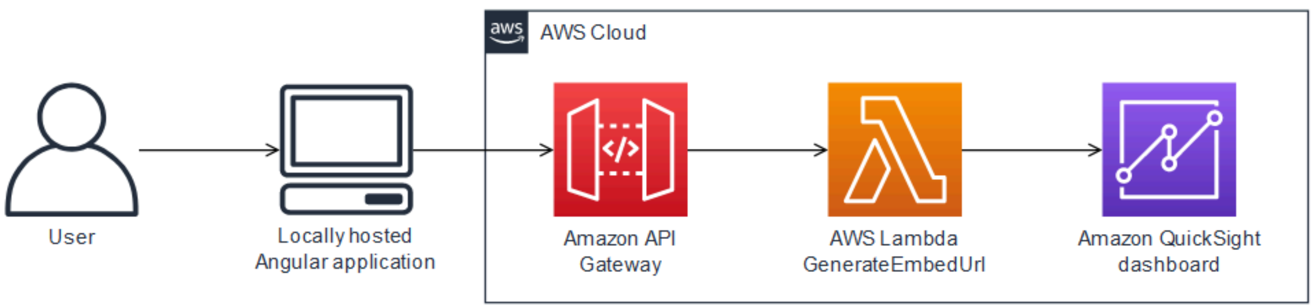
Architecture

Technology stack

- Angular frontend
- AWS Lambda and Amazon API Gateway backend

Architecture

In this architecture, the HTTP APIs in API Gateway enable the local Angular application to call the Lambda function. The Lambda function returns the URL for embedding the QuickSight dashboard.



Automation and scale

You can automate the backend deployment by using AWS CloudFormation or AWS Serverless Application Model (AWS SAM).

Tools

Tools

- Angular CLI is a command-line interface tool that you use to initialize, develop, scaffold, and maintain Angular applications directly from a command shell.
- QuickSight Embedding SDK is used to embed QuickSight dashboards into your HTML.

- mkcert is a simple tool for creating locally trusted development certificates. It requires no configuration. mkcert is required because QuickSight allows only HTTPS requests for embedding dashboards.

AWS services

- Amazon API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.
- AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- Amazon QuickSight is a business analytics service for building visualizations, performing ad hoc analyses, and getting business insights from your data.

Epics

Generate EmbedURL

Task	Description	Skills required
Create an EmbedUrl policy.	Create an IAM policy named **QuicksightGetDashboardEmbedUrl** that has the following properties. `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow", "Action": [ "quicksight:GetDashboardEmbedUrl",`	AWS administrator

Task	Description	Skills required

	``
	   "quickSight:GetAno
	nymousUserEmbedUrl"
	                  ],
	
	 "Resource": "*"
	            }
	      ]
	}
	``	

Task	Description	Skills required

Create the Lambda function.	1. On the Lambda console, open the [Functions page](https://console.aws.amazon.com/lambda/home#/functions).
	
	2. Choose **Create Function**.
	
	3. Choose **Author from scratch**.
	
	4. For **Function name**, enter `get-qs-embed-url` .
	
	5. For **Runtime**, choose **Python 3.9**.
	
	6. Choose **Create Function**.
	
	7. On the **Code** tab, copy the following code into the Lambda function.
	
	`import json`
	`import boto3`
	`from botocore.exceptions import ClientError`
	`import time`
	`from os import environ`
	
	`qs = boto3.client('quicksight',region_name='us-east-1')`
	`sts = boto3.client('sts')`
	
	`ACCOUNT_ID = boto3.client('sts').get_caller_identity().get('Account')`
		App developer

Task	Description	Skills required

	``
	DASHBOARD_ID =
	 environ['DASHBOARD
	_ID']
	
	def getDashboardURL(ac
	countId, dashboardId,
	 quicksightNamespac
	e, resetDisabled,
	 undoRedoDisabled):
	  try:
	    response = qs.get_da
	shboard_embed_url(
	      AwsAccountId =
	 accountId,
	      DashboardId =
	 dashboardId,
	      Namespace =
	 quicksightNamespace,
	      IdentityType =
	 'ANONYMOUS',
	      SessionLi
	fetimeInMinutes = 600,
	      UndoRedoDisabled
	 = undoRedoDisabled,
	      ResetDisabled =
	 resetDisabled
	    )
	    return response
	
	  except ClientError as
	 e:
	    print(e)
	    return "Error
	 generating embeddedU
	RL: " + str(e)
	
	def lambda_handler(eve
	nt, context):
	  url = getDashbo
	ardURL(ACCOUNT_ID,
	 DASHBOARD_ID,
	``	

Task	Description	Skills required

	``
	 "default", True, True)
	['EmbedUrl']
	  return {
	      'statusCode':
	 200,
	      'url': url
	  }
	``
	8. Choose **Deploy**.	

Task	Description	Skills required
Add the dashboard ID as an environment variable.	Add `DASHBOARD_ID` as an environment variable to your Lambda function: 1. On the **Configuration** tab, choose **Environment variables**, **Edit**, **Add environment variable**. 2. Add an environment variable with the key `DASHBOARD_ID`. 3. To get the value of `DASHBOARD_ID`, navigate to your dashboard in QuickSight and copy the UUID at the end of the URL in your browser. For example, if the URL is `https://us-east-1.quicksight.aws.amazon.com/sn/dashboards/<dashboard-id>`, specify the `<dashboard-id>` part of the URL as the key value. 4. Choose **Save**.	App developer

Task	Description	Skills required
Add permissions for the Lambda function.	Modify the execution role of the Lambda function and add the **QuicksightGetDashboardEmbedUrl** policy to it. 1. On the **Configuration** tab, choose **Permissions**, and then choose the role name. 2. Choose **Attach policies**, search for `QuicksightGetDashboardEmbedUrl` , select its check box, and then choose **Attach policy**.	App developer

Task	Description	Skills required
Test the Lambda function.	Create and run a test event. You can use the "Hello World" template, because the function won't use any of the data in the test event. 1. Choose the **Test** tab. 2. Give your test event a name, and then choose **Save**. 3. To test your Lambda function, choose **Test**. The response should look similar to the following. `{ "statusCode": 200, "url": "\"https://us-east-1.quicksight.aws.amazon.com/embed/f1acc0786687783b9a4543a05ba929b3a/dashboards/... }` **Note** As mentioned in the *Prerequisites and limitations* section, your QuickSight account must be under a session capacity pricing plan. Otherwise, this step	App developer

Task	Description	Skills required
	will display an error message.	

Task	Description	Skills required
Create an API in API Gateway.	1. On the [API Gateway console](), choose **Create API**, and then choose **REST API**, **Build**. • For API name, enter `qs-embed-api` . • Choose **Create API**. 2. In **Actions**, choose **Create Method**. • Choose **GET** and confirm by choosing the checkmark. • Choose **Lambda Function** as the integrati on type. • For **Lambda Function**, enter `get-qs-embed-url`. • Choose **Save**. • In the **Add Permission to Lambda Function** box, choose **OK**. 3. Enable CORS. • In **Actions**, choose **Enable CORS**. • For **Access-Control-Allow-Origin**, enter `'https://my-qs-app.net:4200'` . • Choose **Enable CORS and replace existing**	App developer

Task	Description	Skills required
	CORS headers, and confirm. 4. Deploy the API. • For **Actions**, choose **Deploy API**. • For **Deployment stage**, choose **[New Stage]**. • For **Stage name**, enter `dev`. • Choose **Deploy**. • Copy the **Invoke URL**. **Note** `my-qs-app.net` can be any domain. If you want to use a different domain name, make sure to update the **Access-Control-Allow-Origin** information in step 3, and change `my-qs-app.net` in subsequent steps.	

Create the Angular application

Task	Description	Skills required
Create the application with the Angular CLI.	1. Create the application.	App developer

Task	Description	Skills required

	``
	ng new quicksight-app
	 --defaults
	cd quicksight-app/src
	/app
	``
	2. Create the dashboard component.
	``
	ng g c dashboard
	``
	3. Navigate to your `src/environments/environment.ts` file and add `apiUrl: '<Invoke URL from previous steps>'` to the environment object.
	``
	export const environme
	nt = {
	  production: false,
	  apiUrl: '<Invoke
	 URL from previous
	 steps>',
	};
	``	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Add the QuickSight Embedding SDK.</td><td>1. Install the QuickSight Embedding SDK by running the following command in your project's root folder.
<pre>npm i amazon-quicksight-embedding-sdk</pre>2. Create a new <code>decl.d.ts</code> file in the <code>src</code> folder with the following content.
<pre>declare module 'amazon-quicksight-embedding-sdk';</pre></td><td>App developer</td></tr>
</table>

Task	Description	Skills required

Add code to your dashboard .component.ts file.	```
	import { Component,
	 OnInit } from '@angular
	/core';
	import { HttpClient }
	 from '@angular/common/
	http';
	import * as Quicksigh
	tEmbedding from
	 'amazon-quicksight-
	embedding-sdk';
	import { environme
	nt } from "../../en
	vironments/environ
	ment";
	import { take } from
	 'rxjs';
	import { Embedding
	Context } from 'amazon-
	quicksight-embedding-
	sdk/dist/types';
	import { createEmb
	eddingContext } from
	 'amazon-quicksight-
	embedding-sdk';
	
	@Component({
	  selector: 'app-dash
	board',
	  templateUrl: './
	dashboard.compo
	nent.html',
	  styleUrls: ['./dashb
	oard.component.scss']
	})

	ronment.apiUrl)
	    .pipe(
	      take(1),
	    )
	    .subscribe((data:
	 any) => this.Dash
	board(data.url));
	  }
	
	  public async Dashboard
	(embeddedURL: any) {
	    var containerDiv
	 = document.getElemen
	tById("dashboardCo
	ntainer") || '';
	    const frameOptions
	 = {
	      url: embeddedURL,
	      container:
	 containerDiv,
	      height: "850px",
	      width: "100%",
	      resizeHei
	ghtOnSizeChangedEv
	ent: true,
	  }
	    const embedding
	Context: Embedding
	Context = await
	 createEmbeddingCon
	text();
	``	

Task	Description	Skills required

	``
	    this.dashboard =
	  embeddingContext.e
	mbedDashboard(fram
	eOptions);
	  }
	}
	``	

Add code to your dashboard .component.html file.	Add the following code to your `src/app/dashboard/dashboard.component.html` file. `<div id="dashboardContainer"></div>`	App developer
Modify your app.component.html file to load your dashboard component.	1. Delete the contents of the `src/app/app.component.html` file. 2. Add the following. `<app-dashboard></app-dashboard>`	App developer
Import HttpClientModule into your app.module.ts file.	1. At the top of the `src/app/app.module.ts` file, add the following. `import { HttpClientModule } from '@angular/common/http';` 2. Add `HttpClientModule` in the `imports` array for your `AppModule` .	App developer

Host the Angular application

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Configure mkcert.</td><td>

Note

The following commands are for Unix or MacOS machines. If you're using Windows, see the [Additional information](#) section for the equivalent **echo** command.

1. Create a local certificate authority (CA) on your machine.

```
mkcert -install
```

2. Configure `my-qs-app.net` to always redirect to your local PC.

```
echo "127.0.0.1 my-qs-app.net" | sudo tee -a /private/etc/hosts
```

3. Make sure that you're in the `src` directory of the Angular project.

```
mkcert my-qs-app.net 127.0.0.1
```

- QuickSight Embedding SDK
- mkcert tool

Additional information

If you're using Windows, run the Command Prompt window as an administrator, and configure `my-qs-app.net` to always redirect to your local PC by using the following command.

```
echo 127.0.0.1 my-qs-app.net >> %WINDIR%\System32\Drivers\Etc\Hosts
```

Explore full-stack cloud-native web application development with Green Boost

Ben Stickley and Amiin Samatar, Amazon Web Services

Summary

In response to the evolving needs of developers, Amazon Web Services (AWS) recognizes the critical demand for an efficient approach to developing cloud-native web applications. The AWS focus is on helping you to overcome common roadblocks associated with deploying web apps on the AWS Cloud. By harnessing the capabilities of modern technologies such as TypeScript, AWS Cloud Development Kit (AWS CDK), React, and Node.js, this pattern aims to streamline and expedite the development process.

Underpinned by the Green Boost (GB) toolkit, the pattern offers a practical guide to constructing web applications that fully use the extensive capabilities of AWS. It acts as a comprehensive roadmap, leading you through the process of deploying a fundamental CRUD (Create, Read, Update, Delete) web application integrated with Amazon Aurora PostgreSQL-Compatible Edition. This is accomplished by using the Green Boost command line interface (Green Boost CLI) and establishing a local development environment.

Following the successful deployment of the application, the pattern delves into key components of the web app, including infrastructure design, backend and frontend development, and essential tools such as cdk-dia for visualization, facilitating efficient project management.

Prerequisites and limitations

Prerequisites

- Git installed
- Visual Studio Code (VS Code) installed
- AWS Command Line Interface (AWS CLI) installed
- AWS CDK Toolkit installed
- Node.js 18 installed, or Node.js 18 with pnpm activated
- pnpm installed, if it isn't part of your Node.js installation
- Basic familiarity with TypeScript, AWS CDK, Node.js, and React
- An active AWS account

- An AWS account bootstrapped by using AWS CDK in `us-east-1`. The `us-east-1` AWS Region is required for support of the Amazon CloudFront Lambda@Edge functions.
- AWS security credentials, including `AWS_ACCESS_KEY_ID`, correctly configured in your terminal environment
- For Windows users, a terminal in administrator mode (to accommodate the way pnpm handles node modules)

Product versions

- AWS SDK for JavaScript version 3
- AWS CDK version 2
- AWS CLI version 2.2
- Node.js version 18
- React version 18

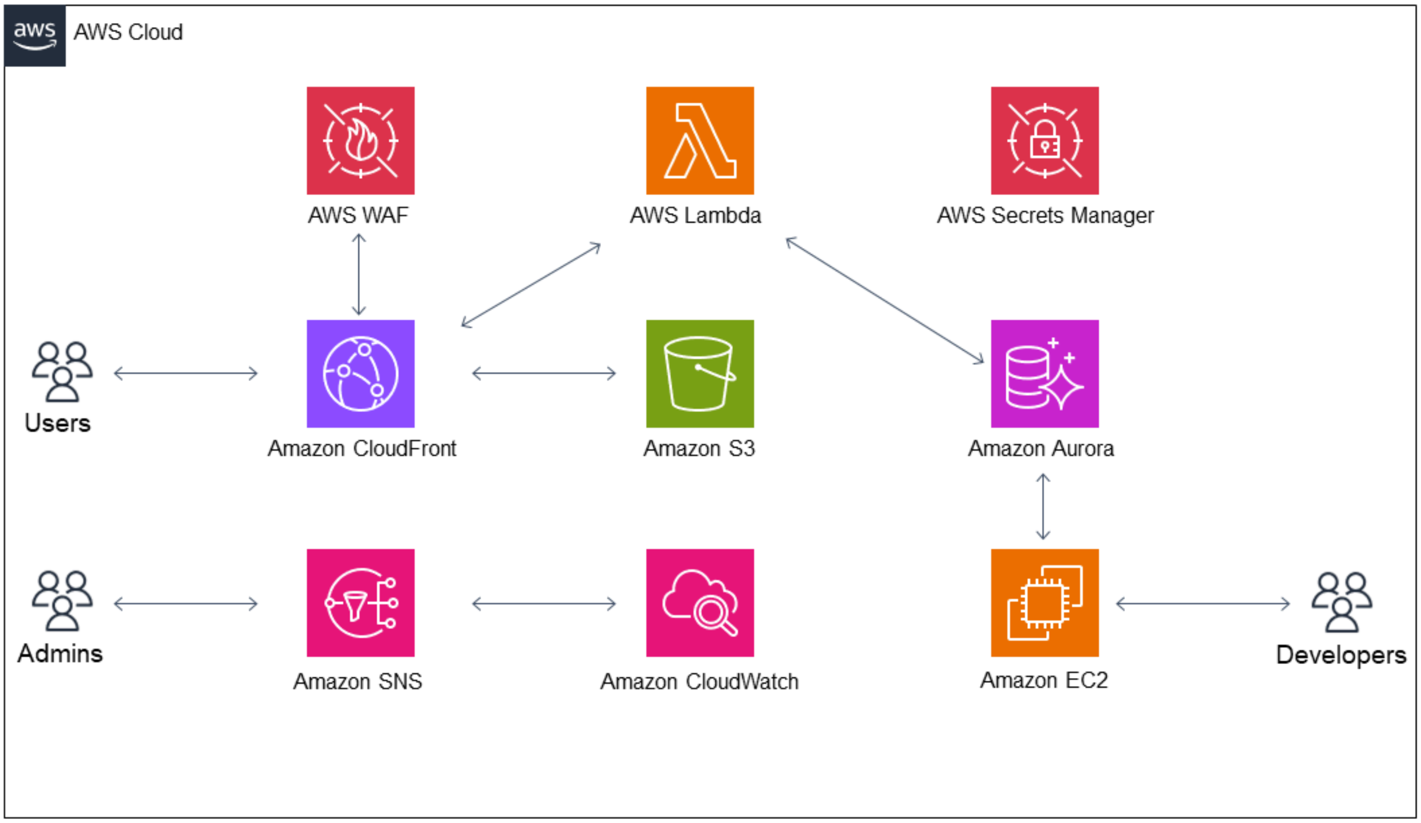
Architecture

Target technology stack

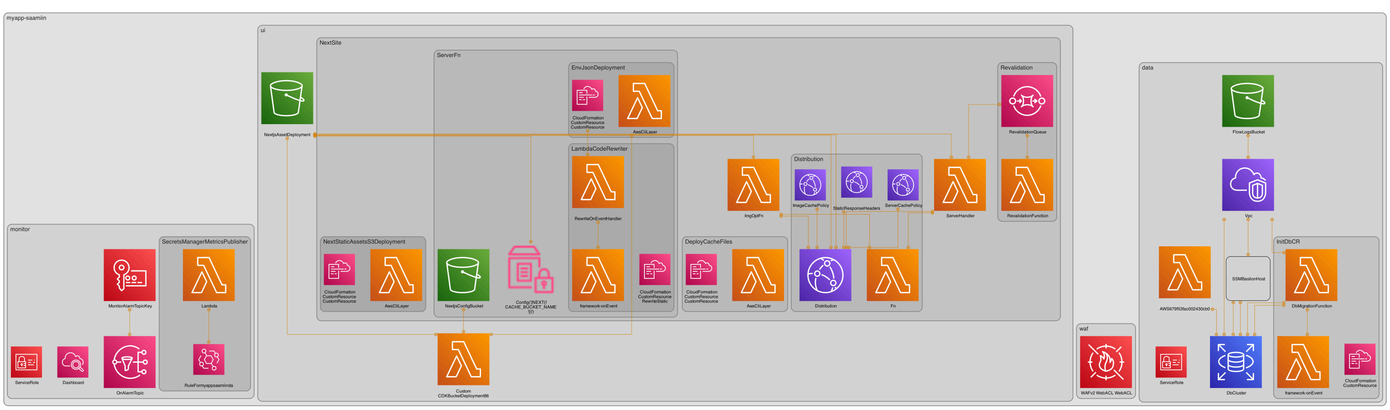
- Amazon Aurora PostgreSQL-Compatible Edition
- Amazon CloudFront
- Amazon CloudWatch
- Amazon Elastic Compute Cloud (Amazon EC2)
- AWS Lambda
- AWS Secrets Manager
- Amazon Simple Notification Service (Amazon SNS)
- Amazon Simple Storage Service (Amazon S3)
- AWS WAF

Target Architecture

The following diagram shows that user requests pass through Amazon CloudFront, AWS WAF, and AWS Lambda before interacting with an S3 bucket, an Aurora database, an EC2 instance, and ultimately reaching developers. Administrators, on the other hand, use Amazon SNS and Amazon CloudWatch for notifications and monitoring purposes.



To gain a more in-depth look at the application after deployment, you can create diagram by using [cdk-dia](https://github.com/pistazie/cdk-dia), as shown in the following example.



These diagrams showcase the web application architecture from two distinct angles. The cdk-dia diagram offers a detailed technical view of the AWS CDK infrastructure, highlighting specific AWS services such as Amazon Aurora PostgreSQL-Compatible and AWS Lambda. In contrast, the other diagram takes a broader perspective, emphasizing the logical flow of data and user interactions.

The key distinction lies in the level of detail: The cdk-dia delves into technical intricacies, while the first diagram provides a more user-centric view.

Creation of the cdk-dia diagram is covered in the epic *Understand the app infrastructure by using AWS CDK*.

Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- Amazon CloudFront speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- Amazon CloudWatch helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.
- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- AWS Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- AWS Systems Manager helps you manage your applications and infrastructure running in the AWS Cloud. It simplifies application and resource management, shortens the time to detect and resolve operational problems, and helps you manage your AWS resources securely at scale. This pattern uses AWS Systems Manager Session Manager.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.Amazon Simple Notification Service (Amazon SNS) helps you coordinate and manage the exchange of messages between publishers and clients, including web servers and email addresses.

- AWS WAF is a web application firewall that helps you monitor HTTP and HTTPS requests that are forwarded to your protected web application resources

Other tools

- Git is an open-source, distributed version control system.
- Green Boost is a toolkit for building web apps on AWS.
- Next.js is a React framework for adding features and optimizations.
- Node.js is an event-driven JavaScript runtime environment designed for building scalable network applications.
- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
- pnpm is a package manager for Node.js project dependencies.

Best practices

See the Epics section for more information about the following recommendations:

- Monitor infrastructure by using Amazon CloudWatch Dashboards and alarms.
- Enforce AWS best practices by using cdk-nag to run static infrastructure as code (IaC) analysis.
- Establish DB port forwarding through SSH (Secure Shell) tunneling with Systems Manager Session Manager, which is more secure than having a publicly exposed IP address.
- Manage vulnerabilities by running `pnpm audit`.
- Enforce best practices by using ESLint to perform static TypeScript code analysis, and Prettier to standardize code formatting.

Epics

Deploy a CRUD web app with Aurora PostgreSQL-Compatible

Task	Description	Skills required
Install the Green Boost CLI.	To install Green Boost CLI, run the following command.	App developer

Task	Description	Skills required
	`pnpm add -g gboost`	
Create a GB app.	1. To create an app by using Green Boost, run the command `gboost create`. 2. Choose the `CRUD App with Aurora PostgreSQL` template.	App developer

Task	Description	Skills required
Install dependencies and deploy the app.	1. Navigate to the project directory: `cd <your directory>` . 2. To install dependencies, run the command `pnpm i`. 3. Navigate to the infra directory: `cd infra`. 4. To deploy the app locally, run the command `pnpm deploy:local` . This is an alias for a `cdk deploy ...` command defined in `infra/package.json` . Wait for deployment to finish (approximately 20 minutes). While you're waiting, monitor AWS CloudFormation stacks in the CloudFormation console. Notice how the constructs defined in the code map to the resource deployed. Review the [CDK Construct tree view](#) in the CloudFormation console.	App developer

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Access the app.</td><td>After deploying your GB app locally, you can access it using the CloudFront URL. The URL is printed in the terminal output, but it can be a bit overwhelming to find. To find it more quickly, use the following steps:

1. Open the terminal where you ran the <code>pnpm deploy:local</code> command.
2. Look for a section in the terminal output that resembles the following text.

<pre>myapp5stickbui9C39A55A.CloudFrontDomainName = d1q16n5pof924c.cloudfront.net</pre>
The URL will be unique to your deployment.

Alternatively, you can find the CloudFront URL by accessing the Amazon CloudFront console:

1. Sign in to the AWS Management Console and</td><td>App developer</td></tr>
</table>

Task	Description	Skills required
	navigate to the CloudFront service. 2. Look for the latest deployed distribution in the list. Copy the **Domain Name** that is associated with the distribution. It will look similar to `your-unique-id.cloudfront.net` .	

Monitor by using Amazon CloudWatch

Task	Description	Skills required
View the CloudWatch Dashboard.	1. Open the CloudWatc h console and choose **Dashboards**. 2. Select the dashboard that has the name **<appId>-<stageName>-dashboard**. 3. Review the dashboard . What resources are being monitored? What metrics are being recorded? This dashboard is made possible by the open-sour ce construct [cdk-monit oring-constructs]().	App developer
Enable alerts.	A CloudWatch Dashboard helps you to actively monitor your web app. To passively	App developer

Task	Description	Skills required

	monitor your web app, you can enable alerting.
	
	1. Navigate to `/infra/src/app/stateless/monitor-stack.ts` , which defines the monitor stack.
	2. Uncomment the following line, and replace `admin@example.com` with your email address.
	
	`onAlarmTopic.addSubscription(new EmailSubscription("admin@example.com"));`
	
	3. Add the following import information to the top of the file.
	
	`import { EmailSubscription } from "aws-cdk-lib/aws-sns-subscriptions";`
	
	4. Within `infra/`, run the following command.
	
	`cdk deploy "*/monitor" --exclusively.`
	
	5. To confirm your subscription to the SNS topic that is intitated when a monitoring alarm is initiated, choose	

Task	Description	Skills required
	the link in the email message.	

Understand the app infrastructure by using AWS CDK

Task	Description	Skills required
Create an architecture diagram.	Generate an architecture diagram of your web app by using cdk-dia. Visualizing the architecture helps improve understanding and communication among team members. It provides a clear overview of the system's components and their relationships. 1. Install Graphviz. 2. Within `infra/`, run the command `pnpm cdk-dia`. 3. View your `infra/diagram.png` .	App developer
Use cdk-nag to enforce best practices.	Use cdk-nag to help you maintain secure and compliant infrastructure by enforcing best practices, reducing the risk of security vulnerabilities and misconfigurations. 1. Explore cdk-nag's best practice enforcement through its rules section,	App developer

Task	Description	Skills required
	including checks from the AWS Solutions Library's Rules Pack. 2. To see how cdk-nag enforces rules, make a change in the code. For example, in `infra/src/app/stateful/data-stacks.ts`, change `storageEncrypted: true` to `storageEncrypted: false`. 3. Within `infra/`, run the command `cdk synth "*/data"`. During synthesis, you will encounter a build error that indicates a rule violation. `AwsSolutions-RDS2: The RDS instance or Aurora DB cluster does not have storage encryption enabled.` This error showcases how cdk-nag is a security mechanism for enforcing infrastructure best practices and preventing security misconfigurations. 4. If needed, you can also [suppress rules](https://github.com/cdklabs/cdk-nag) at different	

Task	Description	Skills required

	scopes. For example, to suppress AwsSolutions-RDS2, add the following code below the instantiation of `DbIamCluster` .
	
	`NagSuppressions.addResourceSuppressions(`
	`  cluster.node.findChild("Resource"),`
	`  [`
	`    {`
	`      id: "AwsSolutions-RDS2",`
	`      reason: "Customer requirement necessitates having unencrypted DB storage",`
	`    },`
	`  ],`
	`);`
	
	5. After suppression, run `cdk synth "*/data"` again. Your AWS CDK app should now synthesize successfully. You can find all suppressed rules in `infra/cdk.out/assembly-<appId>-<stageName>/AwsSolutions-<appId>-<stageName>-${stackId}-NagReport.csv` .	

Evaluate the database configuration and schema

Task	Description	Skills required
Acquire environment variables.	To obtain the required environment variables, use the following steps: 1. To find the `DB_BASTION_ID`, sign in to the console, and navigate to the EC2 console. Choose **Instances (running)**, and find the row that contains **<stageName>-ssm-db-bastion Name**. The instance ID starts with **i-**. 2. To find the `DB_ENDPOINT`, on the Amazon Relational Database Service (Amazon RDS) console, choose **DB Instances**, and select the regional cluster that has a DB identifier starting with **<appId>-<stageName>-data-**. Locate the writer instance endpoint, which ends with **rds.amazonaws.com**.	App developer
Establish port forwarding.	To establish port forwarding, use the following steps:	App developer

Task	Description	Skills required
	1. Install the AWS Systems Manager [Session Manager plugin](). 2. Start port forwarding by running `pnpm db:connect` within `core/` to establish a secure connection through the bastion host. 3. After you see the text `Waiting for connections...,` in your terminal, an SSH tunnel has been successfully established between your local machine and the Aurora server through the EC2 bastion host.	
Adjust the Systems Manager Session Manager timeout.	(Optional) If the default 20-minute session timeout is too short, you can increase it up to 60 minutes in the Systems Manager console by choosing **Session Manager**, **Preferences**, **Edit**, **Idle session timeout**.	App developer

Task	Description	Skills required
Visualize the database.	pgAdmin is a user-frie ndly open-source tool for managing PostgreSQ L databases. It simplifies database tasks, allowing you to efficiently create, manage, and optimize databases. This section guides you through [installing pgAdmin](#) and using its features for PostgreSQL database management. 1. In the Object Explorer, open the context (right-click) menu for **Servers**, and then choose **Register**, **Server**. 2. On the **General** tab, enter **<appId>-<stageName>** for the **Name** field. 3. To fetch the DB password, open the AWS Secrets Manager console, select the secret that has the description **Generated by the CDK for the stack: <appId>-<stageName >-data**, and choose the **Secret Value** card. Choose **Retrieve Secret Value**, and copy the **Secret value** with a key of **password**. 4. On the **Connection** tab, enter **0.0.0** for the **Host**	App developer

Task	Description	Skills required
	name/address field, and enter **<appId>_admin** for the **Username** field. For the **Password** field, use the secret that you fetched previously. Choose **yes** for the **Save password?** field. 5. Choose **Save**. 6. To view the tables, navigate to **<appId>-< stageName>**, **Databases** , **<appId>_db**, **Schemas**, **<appId>**, **Tables**. 7. Open the context (right-click) menu for the **item** table, and then select **View/Edit Data**, **All Rows**. 8. Explore the table.	

Debug with Node.js

Task	Description	Skills required
Debug the create item use case.	To debug the create item use case, follow these steps: 1. Open the `core/src/modules/item/create-item.use-case.ts` file, and insert the following code.	App developer

Task	Description	Skills required

	``
	import { fileURLTo
	Path } from "node:url
	";
	
	// existing create-it
	em.use-case.ts code
	 here
	
	if (process.argv[1]
	 === fileURLTo
	Path(import.meta.u
	rl)) {
	  createItemUseCase(
	{
	    description:
	 "Item 1's Descripti
	on",
	    name: "Item 1",
	  });
	}
	``
	2. The code added in the previous step ensures the `createItemUseCase` function will be called when this module is run directly. Set [breakpoints](#) on the lines within this code block where you want to initiate line-by-line debugging.
	
	1. Open the [VS Code JavaScript Debug Terminal](#), and then run `pnpm tsx core/src/modules/item/create-item.us`	

Task	Description	Skills required
	`e-case.ts` to run the code with line-by-line debugging. Alternatively, you can use `console.log` statements, but print statements can be inadequate when you're working with complex business logic. Line-by-line debugging gives you more context.	

Develop the frontend

Task	Description	Skills required
Set up the development server.	1. Navigate to `ui/`, and run `pnpm dev` to start the [Next.js](https://nextjs.org/) development server. 2. Access your web app locally at `http://localhost:3000`. The Next.js development server is set up with [Fast Refresh](https://nextjs.org/docs/architecture/fast-refresh) instantaneous feedback on edits made to your React components. 3. Experiment with customizing the app bar color. Open the `ui/src/components/theme/theme.tsx` file and locate the section that defines	App developer

Task	Description	Skills required
	the theme for the app bar. In the `colorSchemes.light.palette.primary` section, update the main value from `colors.lagoon` to `colors.carrot`. After making this change, save the file and observe the update in your browser. 4. Experiment by modifying text, components, and adding new pages.	

Tooling with Green Boost

Task	Description	Skills required
Set up monorepo and the pnpm package manager.	1. Review `pnpm-workspace.yaml` in the root of your GB repository, and notice how workspaces are defined. For more information about workspaces, see the pnpm documentation. 2. Review `ui/package.json`, and notice how it references the workspace in `core/` with the package name `"<appId>/core": "workspace:^",`.	App developer

Task	Description	Skills required
	3. Observe how TypeScript and ESLint configuration is centralized in utility packages defined within `packages/` . This configuration is then used by application packages such as `core/`, `infra/`, and `ui/`. This is helpful when your app scales and you define more application packages, which can reference the utility packages without duplicating configuration code.	

Task	Description	Skills required
Run pnpm scripts.	Run the following commands in the root of your repository: 1. Run `pnpm lint`. This command runs static code analysis with ESLint. 2. Run `pnpm typecheck .` This command runs the TypeScript compiler to check the types of your code. 3. Run `pnpm test`. This command runs Vitest to run unit tests. Notice how these commands are run in all workspaces. The commands are defined in each workspace's `package.json#scripts` field.	App developer

Task	Description	Skills required
Use ESLint for static code analysis.	To test the static code analysis capability of ESLint, do the following: 1. First, ensure the [VS Code ESLint extension]() (ID: `dbaeumer.vscode-eslint`) is installed. We recommend also installing [VS Code Error Lens]() (ID: `usernamehw.errorlens`) to see errors inline. 2. In your code, purposefully include a line of code that uses the `eval()` function, as shown in the following example. `const userInput = "import("fs").then((fs) => console.log(fs.readFileSync("/etc/passwd", { encoding: "utf8" })))"; eval(userInput);` **Important** This is for testing purposes only. Using `eval()` is considered potentially dangerous and should be avoided	App developer

Task	Description	Skills required
	because of security risks. 3. After you include the `eval()` line, open your code editor to confirm that ESLint indicated the code smell by using red squiggles. 4. Review ESLint plugins and configuration at `packages/eslint-config-{node,next}/.eslintrc.cjs` .	
Manage dependencies and vulnerabilities.	1. To identify any Common Vulnerabilities and Exposures (CVEs), run `pnpm audit` in the root of your repository. You should see **No known vulnerabilities found.** 2. Install an intentionally vulnerable package within `core/` by running `pnpm add minimist@0.2.3` , and then run `pnpm audit`. Notice the vulnerability being reported. 3. Uninstall the vulnerable package within `core/` by running `pnpm remove minimist`.	App developer

Task	Description	Skills required
Pre-commit hooks with Husky.	1. Make a couple small changes in TypeScript files throughout the repository. The changes can be as basic as adding comments. 2. Stage and commit these changes by using `git add -A` and then `git commit -m "test husky"`. The Husky pre-commit hook trigger, which is defined in `.husky/pre-commit`, runs the command `pnpm lint-staged`. 3. Observe how lint-staged runs commands specified in `*/.lintstagedrc.js` files throughout the repository on files that have been staged by Git. These tools are mechanisms to help prevent bad code from making its way into your application.	App developer

Tear down the infrastructure

Task	Description	Skills required
Remove the deployment from your account.	1. To tear down the infrastructure that you provisioned in the first epic, by run `pnpm destroy:local` in `infra/`. 2. Wait 15 minutes after `pnpm destroy:local` is complete, and then delete the retained Lambda@Edge function by searching for your app ID in the Lambda console. Lambda@Edge functions are replicated., which makes them difficult to delete. For more information about deleting Lambda@Edge functions, see the [CloudFront documentation]().	App developer

Troubleshooting

Issue	Solution
Unable to establish port forwarding	Ensure that your AWS credentials are properly configured and have the necessary permissions. Double-check that the bastion host ID (`DB_BASTION_ID`) and database endpoint

Issue	Solution
	(`DB_ENDPOINT`) environment variables are correctly set. If you still encounter issues, see the AWS documentation for [troubleshooting SSH connections and Session Manager]().
Website isn't loading on `localhost:3000`	Confirm that the terminal output indicates successful port forwarding, including the forwarding address. Ensure there are no conflicting processes using port 3000 on your local machine. Verify that the Green Boost application is properly configured and running on the expected port (3000). Check your web browser for any security extensions or settings that might block local connections.
Error messages during local deployment (`pnpm deploy:local`)	Review the error messages carefully to identify the cause of the issue. Verify that the necessary environment variables and configuration files are correctly set.

Run unit tests for a Node.js application from GitHub by using AWS CodeBuild

Thomas Scott and Jean-Baptiste Guillois, Amazon Web Services

Summary

This pattern provides sample source code and key unit test components for a Node.js game API. It also includes instructions for running these unit tests from a GitHub repository by using AWS CodeBuild, as part of your continuous integration and continuous delivery (CI/CD) workflow.

Unit testing is a software development process in which different parts of an application, called *units*, are individually and independently tested for correct operation. Tests validate the quality of the code and confirm that it functions as expected. Other developers can also easily gain familiarity with your code base by consulting the tests. Unit tests reduce future refactoring time, help engineers get up to speed on your code base more quickly, and provide confidence in the expected behavior.

Unit testing involves testing individual functions, including AWS Lambda functions. To create unit tests, you need a testing framework and a way of validating tests (assertions). The code examples in this pattern use the Mocha testing framework and the Chai assertion library.

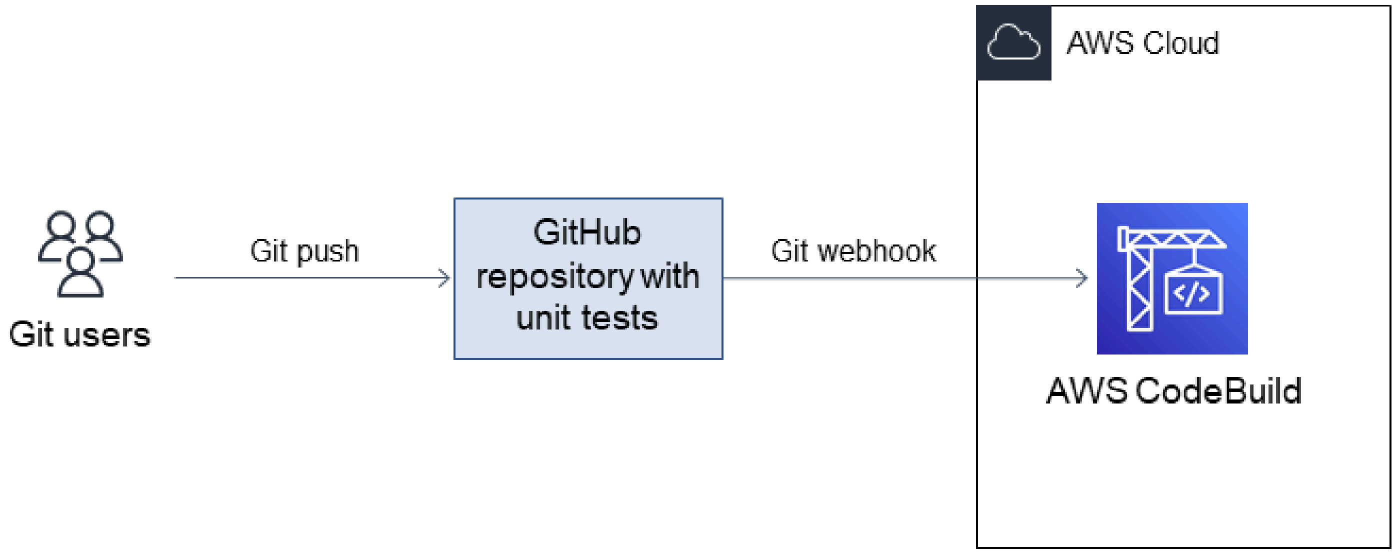
For more information about unit testing and examples of test components, see the Additional information section.

Prerequisites and limitations

- An active AWS account with correct CodeBuild permissions
- A GitHub account (see instructions for signing up)
- Git (see installation instructions)
- A code editor to make changes and push your code to GitHub

Architecture

This pattern implements the architecture that is shown in the following diagram.



Tools

Tools

- Git is a version control system that you can use for code development.
- AWS CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy. With CodeBuild, you don't need to provision, manage, and scale your own build servers. CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left waiting in a queue. You can get started quickly by using prepackaged build environments, or you can create custom build environments that use your own build tools. With CodeBuild, you are charged by the minute for the compute resources you use.

Code

The source code for this pattern is available on GitHub, in the Sample game unit test application repository. You can create your own GitHub repository from this sample (option 1) or use the sample repository directly (option 2) for this pattern. Follow the instructions for each option in the next section. The option you follow will depend on your use case.

Epics

Option 1 - Run unit tests on your personal GitHub repository with CodeBuild

Task	Description	Skills required
Create your own GitHub repository based on the sample project.	1. Log in to GitHub. 2. Create a new repository. For instructions, see the [GitHub documentation](#). 3. Clone and push the [sample repository](#) into the new repository in your account.	App developer, AWS administrator, AWS DevOps
Create a new CodeBuild project.	1. Sign in to the AWS Management Console and open the CodeBuild console at https://console.aws.amazon.com/codesuite/codebuild/home. 2. Choose **Create build project**. 3. In the **Project configura tion** section, for **Project name**, type **aws-tests-sample-node-js**. 4. In the **Source** section, for **Source provider**, choose **GitHub**. 5. For **Repository**, choose **Repository in my GitHub account**, and then paste the URL to your newly created GitHub repository.	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	6. In the **Primary source webhook events** section, select **Rebuild every time a code change is pushed to this repository**. 7. For event type, choose **PUSH.** 8. In the **Environment** section, choose **Managed image**, Amazon Linux, and the latest image. 9. Leave the default settings for all other options, and then choose **Create build project**.	
Start the build.	On the **Review** page, choose **Start build** to run the build.	App developer, AWS administrator, AWS DevOps

Option 2 - Run unit tests on a public repository with CodeBuild

Task	Description	Skills required
Create a new CodeBuild build project.	1. Sign in to the AWS Management Console and open the CodeBuild console at https://console.aws.amazon.com/codesuite/codebuild/home. 2. Choose **Create build project**.	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	3. In the **Project configuration** section, for **Project name**, type **aws-tests-sample-node-js**. 4. In the **Source** section, for **Source provider**, choose **GitHub**. 5. For **Repository**, choose **Public repository**, and then paste the URL: https://github.com/aws-samples/node-js-tests-sample. 6. In the **Environment** section, choose **Managed image**, Amazon Linux, and the latest image. 7. Leave the default settings for all other options, and then choose **Create build project.**	
Start the build.	On the **Review** page, choose **Start build** to run the build.	App developer, AWS administrator, AWS DevOps

Analyze the unit tests

Task	Description	Skills required
View test results.	In the CodeBuild console, review the unit test results from the CodeBuild job. They should match the results	App developer, AWS administrator, AWS DevOps

Task	Description	Skills required
	shown in the Additional information section. These results validate the GitHub repository integration with CodeBuild.	
Apply a webhook.	You can now apply a webhook, so you can automatically start a build whenever you push code changes to the main branch of your repository. For instructions, see the CodeBuild documentation.	App developer, AWS administrator, AWS DevOps

Related resources

- Sample game unit test application (GitHub repository with sample code)
- AWS CodeBuild documentation
- GitHub webhook events (CodeBuild documentation)
- Creating a new repository (GitHub documentation)

Additional information

Unit test results

In the CodeBuild console, you should see the following test results after the project builds successfully.

```
> node-game-unit-tests@1.0.0 test /codebuild/output/src813991724/src/github.com/aws-samples/node-js-tests-sample
> mocha

  Game Function Group
    Initialize Game
      ✓ Check that the game ID is between 0 and 1000
      ✓ Check that the play date is today
    Start Game
      ✓ Check that the game has two competitors
      ✓ Check that the two competitors have different names
    End Game
      ✓ Check that there are no more competitors after the game ends
    Game ID Stubs and Mocks
      ✓ Check that an out of range game ID is returned with Stub
      ✓ Using a mock check that the function was called and returns 9

  7 passing (9ms)
```

Example unit test components

This section describes the four types of test components that are used in unit testing: assertions, spies, stubs, and mocks. It includes a brief explanation and code example of each component.

Assertions

An assertion is used to verify an expected result. This is an important test component because it validates the expected response from a given function. The following sample assertion validates that the returned ID is between 0 and 1000 when initializing a new game.

```
const { expect }  = require('chai');
const { Game } = require('../src/index');

describe('Game Function Group', () => {
 it('Check that the Game ID is between 0 and 1000', function() {
      const game = new Game();
      expect(game.id).is.above(0).but.below(1000)
 });
});
```

Spies

A spy is used to observe what is happening when a function is running. For example, you might want to validate that the function has been called correctly. The following example shows that start and stop methods are called on a **Game** class object.

```
const { expect }  = require('chai');
const { spy } = require('sinon');
```

```
const { Game } = require('../src/index');

describe('Game Function Group', () => {
   it('should verify that the correct function is called', () => {
      const spyStart = spy(Game.prototype, "start");
      const spyStop = spy(Game.prototype, "stop");

      const game = new Game();
      game.start();
      game.stop();

      expect(spyStart.called).to.be.true
      expect(spyStop.called).to.be.true
    });
});
```

Stubs

A stub is used to override a function’s default response. This is especially useful when the function makes an external request, because you want to avoid making external requests from unit tests. (External requests are better suited for integration tests, which can physically test requests between different components.) In the following example, a stub forces a return ID from the **getId** function.

```
const { expect }  = require('chai');
const {.stub } = require('sinon');

const { Game } = require('../src/index');

describe('Game Function Group', () =>  {
   it('Check that the Game ID is between 0 and 1000', function() {
      let generateIdStub = stub(Game.prototype, 'getId').returns(999999);

      const game = new Game();

      expect(game.getId).is.equal(999999);

      generateIdStub.restore();
    });
});
```

Mocks

A mock is a fake method that has a pre-programmed behavior for testing different scenarios. A mock can be considered an extended form of a stub and can carry out multiple tasks simultaneously. In the following example, a mock is used to validate three scenarios:

- Function is called
- Function is called with arguments
- Function returns the integer 9

```
const { expect }  = require('chai');
const {.mock } = require('sinon');

const { Game } = require('../src/index');

describe('Game Function Group', () =>  {
   it('Check that the Game ID is between 0 and 1000', function() {
      let mock = mock(Game.prototype).expects('getId').withArgs().returns(9);

      const game = new Game();
      const id = get.getId();

      mock.verify();
      expect(id).is.equal(9);
    });
});
```

Structure a Python project in hexagonal architecture using AWS Lambda

Furkan Oruc, Dominik Goby, Darius Kunce, and Michal Ploski, Amazon Web Services

Summary

This pattern shows how to structure a Python project in hexagonal architecture by using AWS Lambda. The pattern uses the AWS Cloud Development Kit (AWS CDK) as the infrastructure as code (IaC) tool, Amazon API Gateway as the REST API, and Amazon DynamoDB as the persistence layer. Hexagonal architecture follows domain-driven design principles. In hexagonal architecture, software consists of three components: domain, ports, and adapters. For detailed information about hexagonal architectures and their benefits, see the guide Building hexagonal architectures on AWS.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Experience in Python
- Familiarity with AWS Lambda, AWS CDK, Amazon API Gateway, and DynamoDB
- A GitHub account (see instructions for signing up)
- Git (see installation instructions)
- A code editor for making changes and pushing your code to GitHub (for example, Visual Studio Code or JetBrains PyCharm)
- Docker installed, and the Docker daemon up and running

Product versions

- Git version 2.24.3 or later
- Python version 3.7 or later
- AWS CDK v2
- Poetry version 1.1.13 or later
- AWS Lambda Powertools for Python version 1.25.6 or later
- pytest version 7.1.1 or later

- Moto version 3.1.9 or later
- pydantic version 1.9.0 or later
- Boto3 version 1.22.4 or later
- mypy-boto3-dynamodb version 1.24.0 or later

Architecture

Target technology stack

The target technology stack consists of a Python service that uses API Gateway, Lambda, and DynamoDB. The service uses a DynamoDB adapter to persist data. It provides a function that uses Lambda as the entry point. The service uses Amazon API Gateway to expose a REST API. The API uses AWS Identity and Access Management (IAM) for the authentication of clients.

Target architecture

To illustrate the implementation, this pattern deploys a serverless target architecture. Clients can send requests to an API Gateway endpoint. API Gateway forwards the request to the target Lambda function that implements the hexagonal architecture pattern. The Lambda function performs create, read, update, and delete (CRUD) operations on a DynamoDB table.

> **Important**
>
> This pattern was tested in a PoC environment. You must conduct a security review to identify the threat model and create a secure code base before you deploy any architect ure to a production environment.

The API supports five operations on a product entity:

- `GET /products` returns all products.
- `POST /products` creates a new product.
- `GET /products/{id}` returns a specific product.
- `PUT /products/{id}` updates a specific product.
- `DELETE /products/{id}` deletes a specific product.

You can use the following folder structure to organize your project to follow the hexagonal architecture pattern:

```
app/  # application code
|--- adapters/  # implementation of the ports defined in the domain
     |--- tests/  # adapter unit tests
|--- entrypoints/  # primary adapters, entry points
     |--- api/  # api entry point
          |--- model/  # api model
          |--- tests/  # end to end api tests
|--- domain/  # domain to implement business logic using hexagonal architecture
     |--- command_handlers/  # handlers used to execute commands on the domain
     |--- commands/  # commands on the domain
     |--- events/  # events triggered via the domain
     |--- exceptions/  # exceptions defined on the domain
     |--- model/  # domain model
     |--- ports/  # abstractions used for external communication
     |--- tests/  # domain tests
|--- libraries/  # List of 3rd party libraries used by the Lambda function
infra/  # infrastructure code
simple-crud-app.py  # AWS CDK v2 app
```

Tools

AWS services

- [Amazon API Gateway](https://docs.aws.amazon.com/apigateway/latest/developerguide/welcome.html) is a fully managed service that makes it easy for developers to create, publish, maintain, monitor, and secure APIs at any scale.
- [Amazon DynamoDB](https://docs.aws.amazon.com/amazondynamodb/latest/developerguide/Introduction.html) is a fully managed, serverless, key-value NoSQL database that is designed to run high-performance applications at any scale.
- [AWS Lambda](https://docs.aws.amazon.com/lambda/latest/dg/welcome.html) is a serverless, event-driven compute service that lets you run code for virtually any type of application or backend service without provisioning or managing servers. You can launch

Lambda functions from over 200 AWS services and software as a service (SaaS) applications, and only pay for what you use.

Tools

- Git is used as the version control system for code development in this pattern.
- Python is used as the programming language for this pattern. Python provides high-level data structures and an approach to object-oriented programming. AWS Lambda provides a built-in Python runtime that simplifies the operation of Python services.
- Visual Studio Code is used as the IDE for development and testing for this pattern. You can use any IDE that supports Python development (for example, PyCharm).
- AWS Cloud Development Kit (AWS CDK) is an open-source software development framework that lets you define your cloud application resources by using familiar programming languages. This pattern uses the CDK to write and deploy cloud infrastructure as code.
- Poetry is used to manage dependencies in the pattern.
- Docker is used by the AWS CDK to build the Lambda package and layer.

Code

The code for this pattern is available in the GitHub Lambda hexagonal architecture sample repository.

Best practices

To use this pattern in a production environment, follow these best practices:

- Use customer managed keys in AWS Key Management Service (AWS KMS) to encrypt Amazon CloudWatch log groups and Amazon DynamoDB tables.
- Configure AWS WAF for Amazon API Gateway to allow access only from your organization's network.
- Consider other options for API Gateway authorization if IAM doesn’t meet your needs. For example, you can use Amazon Cognito user pools or API Gateway Lambda authorizers.
- Use DynamoDB backups.
- Configure Lambda functions with a virtual private cloud (VPC) deployment to keep network traffic inside the cloud.

- Update the allowed origin configuration for cross-origin resource sharing (CORS) preflight to restrict access to the requesting origin domain only.
- Use cdk-nag to check the AWS CDK code for security best practices.
- Consider using code scanning tools to find common security issues in the code. For example, Bandit is a tool that's designed to find common security issues in Python code. Pip-audit scans Python environments for packages that have known vulnerabilities.

This pattern uses AWS X-Ray to trace requests through the application's entry point, domain, and adapters. AWS X-Ray helps developers identify bottlenecks and determine high latencies to improve application performance.

Epics

Initialize the project

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Create your own repository.</td><td>1. Log in to GitHub.
2. Create a new repository. For instructions, see the GitHub documentation.
3. Clone and push the sample repository for this pattern into the new repository in your account.</td><td>App developer</td></tr>
<tr><td>Install dependencies.</td><td>1. Install Poetry.
<pre>pip install poetry</pre>2. Install packages from the root directory. The following command installs the application and AWS CDK packages. It also installs development packages that are required</td><td>App developer</td></tr>
</table>

Task	Description	Skills required

	for running unit tests. All installed packages are placed in a new virtual environment.
	
	`poetry install`
	
	3. To see a graphical representation of the installed packages, run the following command.
	
	`poetry show --tree`
	
	4. Update all dependencies.
	
	`poetry update`
	
	5. Open a new shell within the newly created virtual environment. It contains all installed dependencies.
	
	`poetry shell`	

Task	Description	Skills required
Configure your IDE.	We recommend Visual Studio Code, but you can use any IDE of your choice that supports Python. The following steps are for Visual Studio Code. 1. Update the `.vscode/settings` file. `{ "python.testing.pytestArgs": [ "app/adapters/tests", "app/entrypoints/api/tests", "app/domain/tests" ], "python.testing.unittestEnabled": false, "python.testing.pytestEnabled": true, "python.envFile": "${workspaceFolder}/.env", }` 2. Create an `.env` file in the root directory of the project. This ensures that the root directory of the project is included in the `PYTHONPATH` so that `pytest` can find it	App developer

Task	Description	Skills required
	and properly discover all packages. `PYTHONPATH=.`	
Run unit tests, option 1: Use Visual Studio Code.	1. Choose the Python interpreter of the virtual environment that's managed by Poetry. 2. Run tests from Test Explorer.	App developer

Run unit tests, option 2: Use shell commands.	1. Start a new shell within the virtual environment.
	`poetry shell`
	2. Run the `pytest` command from the root directory.
	`python -m pytest`
	Alternatively you can run the command directly from Poetry.
	`poetry run python -m pytest`
		App developer

Deploy and test the application

Task	Description	Skills required
Request temporary credentials.	To have AWS credentials on the shell when you run `cdk`	App developer, AWS DevOps

Task	Description	Skills required
	`deploy`, create temporary credentials by using AWS IAM Identity Center (successor to AWS Single Sign-On). For instructions, see the blog post [How to retrieve short-term credentials for CLI use with AWS IAM Identity Center]().	

Deploy the application.	1. Install the AWS CDK v2.
	`npm install -g aws-cdk`
	For more information, see the [AWS CDK documentation]().
	2. Bootstrap the AWS CDK into your account and Region.
	`cdk bootstrap aws://12345678900/us-east-1 --profile aws-profile-name`
	3. Deploy the application as an AWS CloudFormation stack by using an AWS profile.
	`cdk deploy --profile aws-profile-name`
		App developer, AWS DevOps

Task	Description	Skills required
Test the API, option 1: Use the console.	Use the API Gateway console to test the API. For more information about API operations and request/r esponse messages, see the API usage section of the readme file in the GitHub repository.	App developer, AWS DevOps
Test the API, option 2: Use Postman.	If you want to use a tool such as Postman: 1. Install Postman as a standalone application or browser extension. 2. Copy the endpoint URL for the API Gateway. It will be in the following format. `https://{api-id}.execute-api.{region}.amazonaws.com/{stage}/{path}` 3. Configure the AWS signature in the authoriza tion tab. For instructions, see the AWS re:Post article on activating IAM authentic ation for API Gateway REST APIs. 4. Use Postman to send requests to your API endpoint.	App developer, AWS DevOps

Develop the service

Task	Description	Skills required

Write unit tests for the business domain.	1. Create a Python file in the `app/domain/tests` folder by using the `test_` file name prefix.
	2. Create a new test method to test the new business logic by using the following example.
	<pre>def test_create_product_should_store_in_repository():
	    # Arrange
	    command = create_product_command.CreateProductCommand(
	        name="Test Product",
	        description="Test Description",
	    )
	    # Act
	    create_product_command_handler.handle_create_product_command(
	        command=command, unit_of_work=mock_unit_of_work
	    )
	    # Assert</pre>
		App developer

Task	Description	Skills required
	3. Create a command class in the `app/domain/commands` folder. 4. If the functionality is new, create a stub for the command handler in the `app/domain/command_handlers` folder. 5. Run the unit test to see it fail, because there is still no business logic. `python -m pytest`	

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Implement commands and command handlers.</td><td>

Implement business logic in the newly created command handler file.
For every dependency that interacts with external systems, declare an abstract class in the <code>app/domain/ports</code> folder.

<pre><code>class ProductsRepository(ABC):
    @abstractmethod
    def add(self, product: product.Product) -> None:
        ...

class UnitOfWork(ABC):
    products: ProductsRepository

    @abstractmethod
    def commit(self) -> None:
        ...

    @abstractmethod
    def __enter__(self) -> typing.Any:
        ...

    @abstractmethod
    def __exit__(self, *args) -> None:
        ...
</code></pre>
</td><td>App developer</td></tr>
</table>

Task	Description	Skills required

	3. Update the command handler signature to accept the newly declared dependencies by using the abstract port class as type annotation.
	
	`def handle_create_product_command(`
	`    command: create_product_command.CreateProductCommand,`
	`    unit_of_work: unit_of_work.UnitOfWork,`
	`) -> str:`
	`    ...`
	
	4. Update the unit test to simulate the behavior of all declared dependencies for the command handler.
	
	`    # Arrange`
	`    mock_unit_of_work = unittest.mock.create_autospec(`
	`        spec=unit_of_work.UnitOfWork, instance=True`
	`    )`
	`    mock_unit_of_work.products = unittest.mock.create_autospec(`
	`        spec=unit_of_work.ProductsRepository, instance=True`	

Task	Description	Skills required

	``
	    )
	``
	5. Update the assertion logic in the test to check for the expected dependency invocations.
	``
	  # Assert
	    mock_unit_of_work.commit.assert_called_once()
	    product = mock_unit_of_work.products.add.call_args.args[0]
	
	    assertpy.assert_that(product.name).is_equal_to("Test Product")
	    assertpy.assert_that(product.description).is_equal_to("Test Description")
	``
	6. Run the unit test to see it succeed.
	``
	python -m pytest
	``	

Task	Description	Skills required

Write integration tests for secondary adapters.	1. Create a test file in the `app/adapters/tests` folder by using `test_` as a file name prefix.
	2. Use the Moto library to mock AWS services.
	`@pytest.fixture def mock_dynamodb(): with moto.mock _dynamodb(): yield boto3.res ource("dynamodb", region_name="eu-ce ntral-1")`
	3. Create a new test method for an integration test of the adapter.
	`def test_add_ and_commit_should_ store_product(mock _dynamodb): # Arrange unit_of_work = dynamodb_unit_of_w ork.DynamoDBUnitOf Work( table_nam e=TEST_TABLE_NAME, dynamodb_client=mo ck_dynamodb.meta.c lient ) current_time = datetime.datetime. now(datetime.timez`

Extract and query AWS IoT SiteWise metadata attributes in a data lake

Ambarish Dongaonkar, Amazon Web Services

Summary

AWS IoT SiteWise uses asset models and hierarchies to represent your industrial equipment, processes, and facilities. Each model or asset can have multiple attributes that are specific to your environment. Example metadata attributes include the site or physical location of the asset, plant details, and equipment identifiers. These attribute values complement asset measurement data to maximize the business value. Machine learning (ML) can provide additional insights into this metadata and streamline engineering tasks.

However, metadata attributes can't be queried directly from the AWS IoT SiteWise service. To make the attributes queryable, you must extract and ingest them into a data lake. This pattern uses a Python script to extract the attributes for all AWS IoT SiteWise assets and ingest them into a data lake in an Amazon Simple Storage Service (Amazon S3) bucket. When you have completed this process, you can use SQL queries in Amazon Athena to access the AWS IoT SiteWise metadata attributes and other datasets, such as measurement datasets. The metadata attribute information is also useful when working with AWS IoT SiteWise monitors or dashboards. You can also build an Amazon QuickSight dashboard by using the extracted attributes in the Amazon S3 bucket.

The pattern has reference code, and you can you can implement the code by using the best compute services for your use case, such as AWS Lambda or AWS Glue.

Prerequisites and limitations

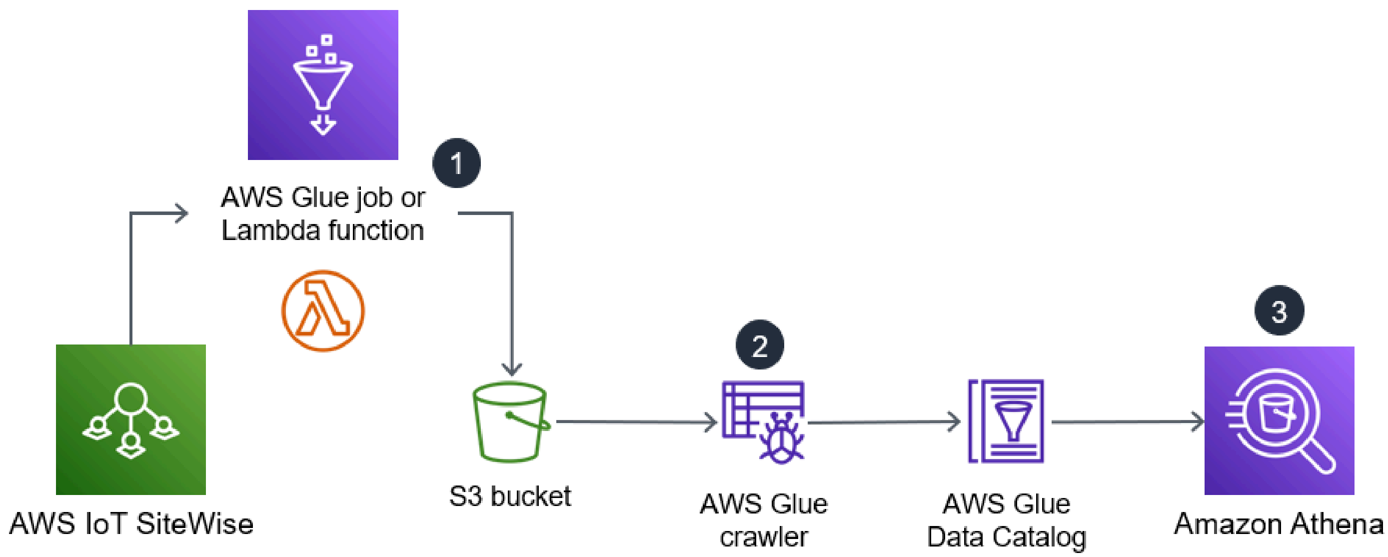
Prerequisites

- An active AWS account.
- Permissions to set up AWS Lambda functions or AWS Glue jobs.
- An Amazon S3 bucket.
- The asset models and hierarchies are set up in AWS IoT SiteWise. For more information, see Creating asset models in the AWS IoT SiteWise documentation.

Architecture

You can use a Lambda function or an AWS Glue job to complete this process. We recommend using Lambda if you have less than 100 models and each model has an average of 15 or fewer attributes. For all other use cases, we recommend using AWS Glue.

The solution architecture and workflow are shown in the following diagram.



1. The scheduled AWS Glue job or Lambda function runs. It extracts the asset metadata attributes from AWS IoT SiteWise and ingests them into an Amazon S3 bucket.
2. An AWS Glue crawler crawls the extracted data in the Amazon S3 bucket and creates tables in an AWS Glue Data Catalog.
3. Using standard SQL, Amazon Athena queries the tables in the AWS Glue Data Catalog.

Automation and scale

You can schedule the Lambda function or AWS Glue job to run daily or weekly, according to the update frequency of your AWS IoT SiteWise asset configurations.

There is no limit to the number of AWS IoT SiteWise assets that the sample code can process, but a large number of assets can increase the amount of time required to complete the process.

Tools

- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- AWS Glue is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS IoT SiteWise helps you collect, model, analyze, and visualize data from industrial equipment at scale.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- Amazon Simple Storage Service (Amazon S3) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- AWS SDK for Python (Boto3) is a software development kit that helps you integrate your Python application, library, or script with AWS services.

Epics

Set up the job or function

Task	Description	Skills required
Configure permissions in IAM.	In the IAM console, grant permissions to the IAM role assumed by the Lambda function or AWS Glue job to do the following: • Read from the AWS IoT SiteWise service • Write to the Amazon S3 bucket	General AWS

Task	Description	Skills required
	For more information, see Creating a role for an AWS service in the IAM documenta tion.	
Create the Lambda function or AWS Glue job.	If you are using Lambda, create a new Lambda function. For **Runtime**, choose **Python**. For more information, see Building Lambda functions with Python in the Lambda documentation. If you are using AWS Glue, create a new Python shell job in the AWS Glue console. For more information, see Adding Python shell jobs in the AWS Glue documentation.	General AWS
Update the Lambda function or AWS Glue job.	Modify the new Lambda function or AWS Glue job, and enter the code sample in the Additional information section. Modify the code as needed for your use case. For more information, see Edit code using the console editor in the Lambda documenta tion and see Working with scripts in theAWS Glue documentation.	General AWS

Run the job or function

Task	Description	Skills required
Run the Lambda function or AWS Glue job.	Run the Lambda function or AWS Glue job. For more information, see Invoke the Lambda function in the Lambda documentation or see Starting jobs using triggers in the AWS Glue documentation. This extracts the metadata attributes for the assets and models in the AWS IoT SiteWise hierarchy and stores them in the specified Amazon S3 bucket.	General AWS
Set up an AWS Glue crawler.	Set up an AWS Glue crawler with the necessary format classifier for a CSV-forma tted file. Use the Amazon S3 bucket and prefix details used in the Lambda function or AWS Glue job. For more information, see Defining crawlers in the AWS Glue documentation.	General AWS
Run the AWS Glue crawler.	Run the crawler to process the data file created by the Lambda function or AWS Glue job. The crawler creates a table in the specified AWS Glue Data Catalog. For more information, see or Starting	General AWS

Task	Description	Skills required
	crawlers using triggers in the AWS Glue documentation.	
Query the metadata attribute s.	Using Amazon Athena, use standard SQL to query the AWS Glue Data Catalog as needed for your use case. You can join the metadata attribute table with other databases and tables. For more information, see Getting Started in the Amazon Athena documentation.	General AWS

Additional information

Code

The sample code provided is for reference, and you can customize this code as needed for your use case.

```
# Following code can be used in an AWS Lambda function or in an AWS Glue Python shell
 job.
# IAM roles used for this job need read access to the AWS IoT SiteWise service and
 write access to the S3 bucket.
sw_client = boto3.client('iotsitewise')
s3_client = boto3.client('s3')
output = io.StringIO()

attribute_list=[]
bucket = '{3_bucket name}'
prefix = '{s3_bucket prefix}'
output.write("model_id,model_name,asset_id,asset_name,attribuet_id,attribute_name,attribute_val
\n")

m_resp = sw_client.list_asset_models()
for m_rec in m_resp['assetModelSummaries']:
     model_id = m_rec['id']
     model_name = m_rec['name']

     attribute_list.clear()
     dam_response = sw_client.describe_asset_model(assetModelId=model_id)
     for rec in dam_response['assetModelProperties']:
         if 'attribute' in rec['type']:
            attribute_list.append(rec['name'])

     response = sw_client.list_assets(assetModelId=model_id, filter='ALL')
     for asset in response['assetSummaries']:
         asset_id = asset['id']
         asset_name = asset['name']
         resp = sw_client.describe_asset(assetId=asset_id)
         for rec in resp['assetProperties']:
            if rec['name'] in attribute_list:
                p_resp = sw_client.get_asset_property_value(assetId=asset_id,
 propertyId=rec['id'])
                if 'propertyValue' in p_resp:
                    if p_resp['propertyValue']['value']:
                        if 'stringValue' in p_resp['propertyValue']['value']:
                             output.write(model_id + "," + model_name + ","
 + asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
```

```
 str(p_resp['propertyValue']['value']['stringValue']) + "\n")

                       if 'doubleValue' in p_resp['propertyValue']['value']:
                            output.write(model_id + "," + model_name + ","
 + asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
 str(p_resp['propertyValue']['value']['doubleValue']) + "\n")
                       if 'integerValue' in p_resp['propertyValue']['value']:
                            output.write(model_id + "," + model_name + ","
 + asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
 str(p_resp['propertyValue']['value']['integerValue']) + "\n")
                        if 'booleanValue' in p_resp['propertyValue']['value']:
                            output.write(model_id + "," + model_name + ","
 + asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," +
 str(p_resp['propertyValue']['value']['booleanValue']) + "\n")

output.seek(0)
s3_client.put_object(Bucket=bucket, Key= prefix + '/data.csv', Body=output.getvalue())
output.close()
```

Configure logging and monitoring for security events in an AWS IoT environment

Prateek Prakash, Amazon Web Services

Summary

Ensuring that your Internet of Things (IoT) environments are secure is an important priority, particularly because organizations are connecting billions of devices to their IT environments. This pattern provides a reference architecture that you can use to implement logging and monitoring for security events across your IoT environment on the AWS Cloud. Typically, an IoT environment on the AWS Cloud has the following three layers:

- IoT devices that generate relevant telemetry data.
- AWS IoT services (for example, AWS IoT Core, AWS IoT Device Management, or AWS IoT Device Defender) that connect your IoT devices to other devices and AWS services.
- Backend AWS services that help process telemetry data and provide useful insights for your different business use cases.

The best practices provided by the AWS IoT Lens - AWS Well-Architected Framework whitepaper can help you review and improve your cloud-based architecture and better understand the business impact of your design decisions. An important recommendation is that you analyze application logs and metrics on your devices and in the AWS Cloud. You can achieve this by leveraging different approaches and techniques (for example, threat modeling) to identify metrics and events that must be monitored to detect potential security issues.

This pattern describes how to use AWS IoT and security services to design and implement a security logging and monitoring reference architecture for an IoT environment on the AWS Cloud. This architecture builds on existing AWS security best practices and applies them to your IoT environment.

Prerequisites and limitations

Prerequisites

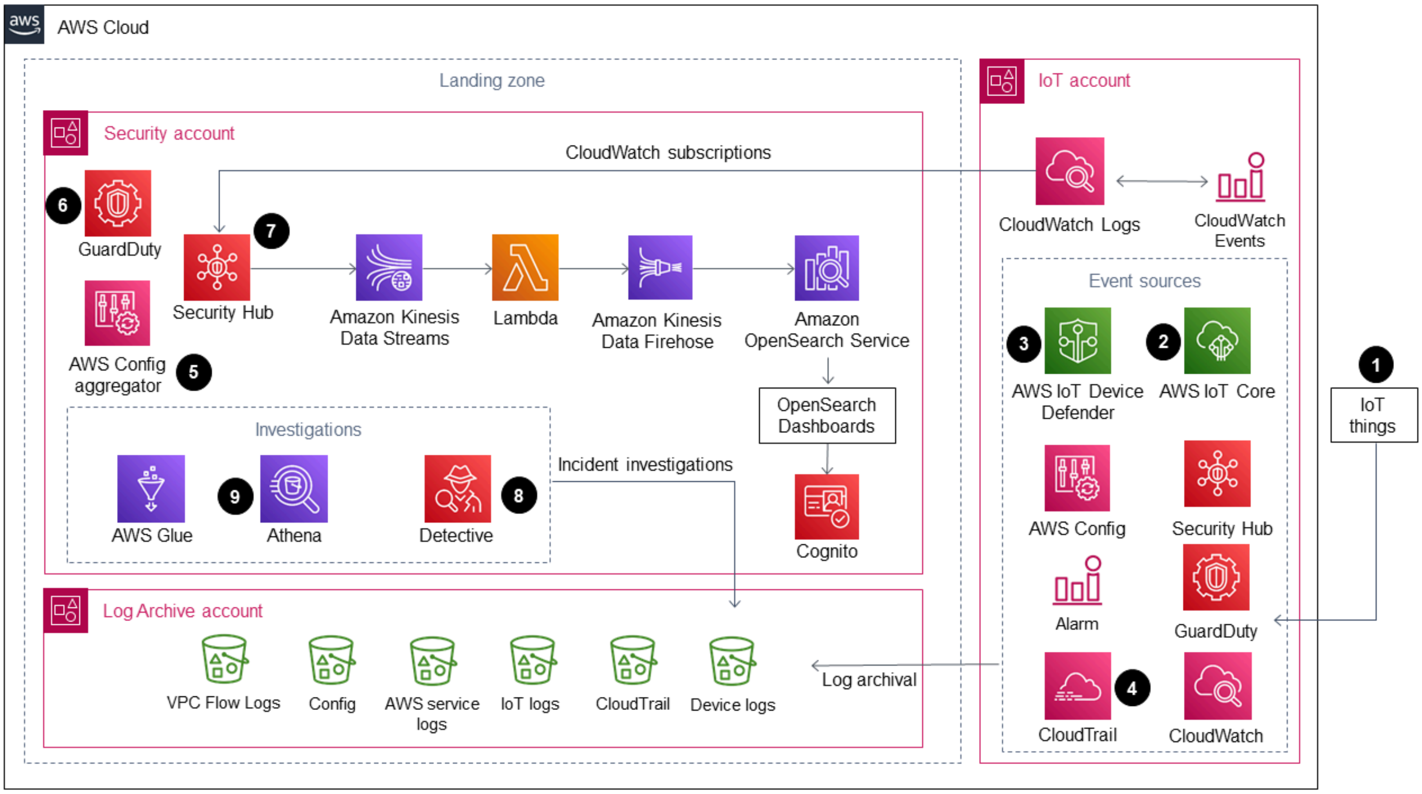
- An existing landing zone environment. For more information about this, see the guide Setting up a secure and scalable multi-account AWS environment on the AWS Prescriptive Guidance website.

- The following accounts must be available in your landing zone:
  - **Log Archive account** – This account is for users that need to access the logging information for accounts in your landing zone's organizational units (OUs). For more information about this, see the Security OU – Log Archive account section of the guide AWS Security Reference Architecture on the AWS Prescriptive Guidance website.
  - **Security account** – Your security and compliance teams use this account for auditing or to perform emergency security operations. This account is also designated as the administrator account for Amazon GuardDuty. Users from the administrator account can configure GuardDuty, in addition to viewing and managing GuardDuty findings for their own account and all member accounts. For more information about this, see Managing multiple accounts in GuardDuty in the GuardDuty documentation.
  - **IoT account** – This account is for your IoT environment.

Architecture

This pattern extends the Centralized Logging solution from the AWS Solutions Library to collect and process security-related IoT events. The Centralized Logging solution is deployed in the Security account and helps collect, analyze, and display Amazon CloudWatch logs in a single dashboard. This solution consolidates, manages, and analyzes log files from multiple sources. Finally, the Centralized Logging solution also uses Amazon OpenSearch Service and OpenSearch Dashboards to show a unified view of all log events.

The following architecture diagram shows the key components of an IoT security logging and reference architecture on the AWS Cloud.



The diagram shows the following workflow:

1. IoT things are the devices that must be monitored for anomalous security events. These devices run an agent to publish security events or metrics to AWS IoT Core and AWS IoT Device Defender.
2. When AWS IoT logging is enabled, AWS IoT sends progress events about each message as it passes from your devices through the message broker and rules engine to Amazon CloudWatch Logs. You can use CloudWatch Logs subscriptions to push events to a Centralized Logging solution. For more information about this, see AWS IoT metrics and dimensions in the AWS IoT Core documentation.
3. AWS IoT Device Defender helps monitor insecure configurations and security metrics for your IoT devices. When an anomaly is detected, alarms notify Amazon Simple Notification Service (Amazon SNS), which has an AWS Lambda function as a subscriber. The Lambda function sends the alarm as a message to CloudWatch Logs. You can use CloudWatch Logs subscriptions to push events to your Centralized Logging solution. For more information about this, see Audit checks, Upload device-side logs to CloudWatch, and Configure AWS IoT logging in the AWS IoT Core documentation.

4. AWS CloudTrail logs AWS IoT Core control plane actions that make changes (for example, creating, updating, or attaching APIs). When CloudTrail is set up as part of a landing zone implementation, it sends events to CloudWatch Logs. You can use subscriptions to push events to your Centralized Logging solution.
5. AWS Config managed rules or custom rules evaluate resources that are part of your IoT environment. Monitor your [compliance change notifications](#) using CloudWatch Events with CloudWatch Logs as the target. After compliance change notifications are sent to CloudWatch Logs, you can use subscriptions to push events to your Centralized Logging solution.
6. Amazon GuardDuty continuously analyzes CloudTrail management events and helps identify API calls made to AWS IoT Core endpoints from known malicious IP addresses, unusual geolocations, or anonymizing proxies. Monitor GuardDuty notifications using CloudWatch Events with log groups in CloudWatch Logs as the target. When GuardDuty notifications are sent to CloudWatch Logs, you can use subscriptions to push events to your Centralized Monitoring solution or use the GuardDuty console in your Security account to view the notifications.
7. AWS Security Hub monitors your IoT account by using security best practices. Monitor Security Hub notifications by using CloudWatch Events with log groups in CloudWatch Logs as the target. When Security Hub notifications are sent to CloudWatch Logs, use subscriptions to push events to your Centralized Monitoring solution or use the Security Hub console in your Security account to view the notifications.
8. Amazon Detective evaluates and analyzes information to isolate the root cause and take action on security findings for unusual calls to AWS IoT endpoints or other services in your IoT architecture.
9. Amazon Athena queries logs stored in your Log Archive account to enhance your understanding of security findings and identify trends and malicious activities.

Tools

- Amazon Athena is an interactive query service that makes it easy to analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL.
- AWS CloudTrail helps you enable governance, compliance, and operational and risk auditing of your AWS account.
- Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.

- Amazon CloudWatch Logs centralizes the logs from all your systems, applications, and AWS services that you use. You can view and monitor the logs, search them for specific error codes or patterns, filter them based on specific fields, or archive them securely for future analysis.
- AWS Config provides a detailed view of the configuration of AWS resources in your AWS account.
- Amazon Detective makes it easy to analyze, investigate, and quickly identify the root cause of security findings or suspicious activities.
- AWS Glue is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.
- Amazon GuardDuty is a continuous security monitoring service.
- AWS IoT Core provides secure, bi-directional communication for Internet-connected devices (such as sensors, actuators, embedded devices, wireless devices, and smart appliances) to connect to the AWS Cloud over MQTT, HTTPS, and LoRaWAN.
- AWS IoT Device Defender is a security service that allows you to audit the configuration of your devices, monitor connected devices to detect abnormal behavior, and mitigate security risks.
- Amazon OpenSearch Service is a managed service that makes it easy to deploy, operate, and scale OpenSearch clusters in the AWS Cloud.
- AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.
- AWS Security Hub provides a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices.
- Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you've defined. This virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Epics

Set up an IoT account in your landing zone environment

Task	Description	Skills required
Validate the security guardrail s in the IoT account.	Validate that the guardrails for CloudTrail, AWS Config,	AWS administrator

Task	Description	Skills required
	GuardDuty, and Security Hub are enabled in your IoT account.	
Validate that your IoT account is configured as a member account of your Security account.	Validate that your IoT account is configured and associate d as a member account for GuardDuty and Security Hub in your Security account. For more information about this, see Managing GuardDuty accounts with AWS Organizat ions in the GuardDuty documentation and Managing administrator and member accounts in the Security Hub documentation.	AWS administrator
Validate log archiving.	Validate that CloudTrail, AWS Config, and VPC Flow Logs are stored in the Log Archive account.	AWS administrator

Set up the Centralized Logging solution

Task	Description	Skills required
Set up the Centralized Logging solution in your Security account.	Sign in to the AWS Management Console for your Security account and set up the Centralized Logging solution from the AWS Solutions Library to collect, analyze, and display	AWS administrator

Task	Description	Skills required
	CloudWatch Logs in Amazon OpenSearch Service and OpenSearch Dashboards. For more information about this, see Collect, analyze, and display Amazon CloudWatch Logs in a single dashboard with the Centralized Logging solution from the Centralized Logging implementation guide in the AWS Solutions Library.	

Set up and configure AWS resources in your IoT account

Task	Description	Skills required
Set up AWS IoT logging.	Sign in to the AWS Management Console for your IoT account. Set up and configure AWS IoT Core to send logs to CloudWatch Logs. For more information about this, see Configure AWS IoT logging and Monitor AWS IoT using CloudWatch Logs in the AWS IoT Core documentation.	AWS administrator
Set up AWS IoT Device Defender.	Set up AWS IoT Device Defender to audit your IoT resources and detect anomalies.	AWS administrator

Task	Description	Skills required
	For more information about this, see Getting started with AWS IoT Device Defender in the AWS IoT Core documenta tion.	
Set up CloudTrail.	Set up CloudTrail to send events to CloudWatch Logs. For more information about this, see Sending events to CloudWatch Logs in the CloudTrail documentation.	AWS administrator
Set up AWS Config and AWS Config rules.	Set up AWS Config and the required AWS Config rules. For more information about this, see Setting up AWS Config with the console and Adding AWS Config rules in the AWS Config documenta tion.	AWS administrator
Set up GuardDuty.	Set up and configure GuardDuty to send findings to Amazon CloudWatch Events with log groups in CloudWatc h Logs as the target. For more information about this, see Creating custom responses to GuardDuty findings with Amazon CloudWatch Events in the GuardDuty documentation.	AWS administrator

Task	Description	Skills required
Set up Security Hub.	Set up Security Hub and enable the CIS AWS Foundations Benchmark and AWS Foundational Security Best Practices standards. For more information about this, see Automated response and remediation in the Security Hub documentation.	AWS administrator
Set up Amazon Detective.	Set up Detective to facilitate analysis of security findings. For more information about this, see Getting started with Amazon Detective in the Amazon Detective documenta tion.	AWS administrator
Set up Amazon Athena and AWS Glue.	Set up Athena and AWS Glue to query the AWS service logs that conduct security incident investigations. For more information about this, see Querying AWS service logs in the Amazon Athena documentation.	AWS administrator

Set up and troubleshoot AWS IoT Greengrass with client devices

Marouane Sefiani and Akalanka De Silva, Amazon Web Services

Summary

AWS IoT Greengrass is an open-source edge runtime and cloud service for building, deploying, and managing Internet of Things (IoT) software on edge devices. Use cases for AWS IoT Greengrass include:

- Smart homes where an AWS IoT Greengrass gateway is used as a hub for home automation
- Smart factories where AWS IoT Greengrass can facilitate ingestion and local processing of data from the shop floor

AWS IoT Greengrass can act as a secure, authenticated, MQTT connection endpoint for other edge devices (also known as *client devices*), which otherwise would typically connect directly to AWS IoT Core. This capability is useful when client devices do not have direct network access to the AWS IoT Core endpoint.

You can set up AWS IoT Greengrass for use with client devices for the following use cases:

- For client devices to send data to AWS IoT Greengrass
- For AWS IoT Greengrass to forward data to AWS IoT Core
- To take advantage of advanced AWS IoT Core rules engine features

These capabilities require installing and configuring the following components on the AWS IoT Greengrass device:

- MQTT broker
- MQTT bridge
- Client device authentication
- IP detector

In addition, published messages from client devices must be in JSON format or Protocol Buffers (protobuf) format.

This pattern describes how to install and configure these required components, and provides troubleshooting tips and best practices.

Prerequisites and limitations

Prerequisites

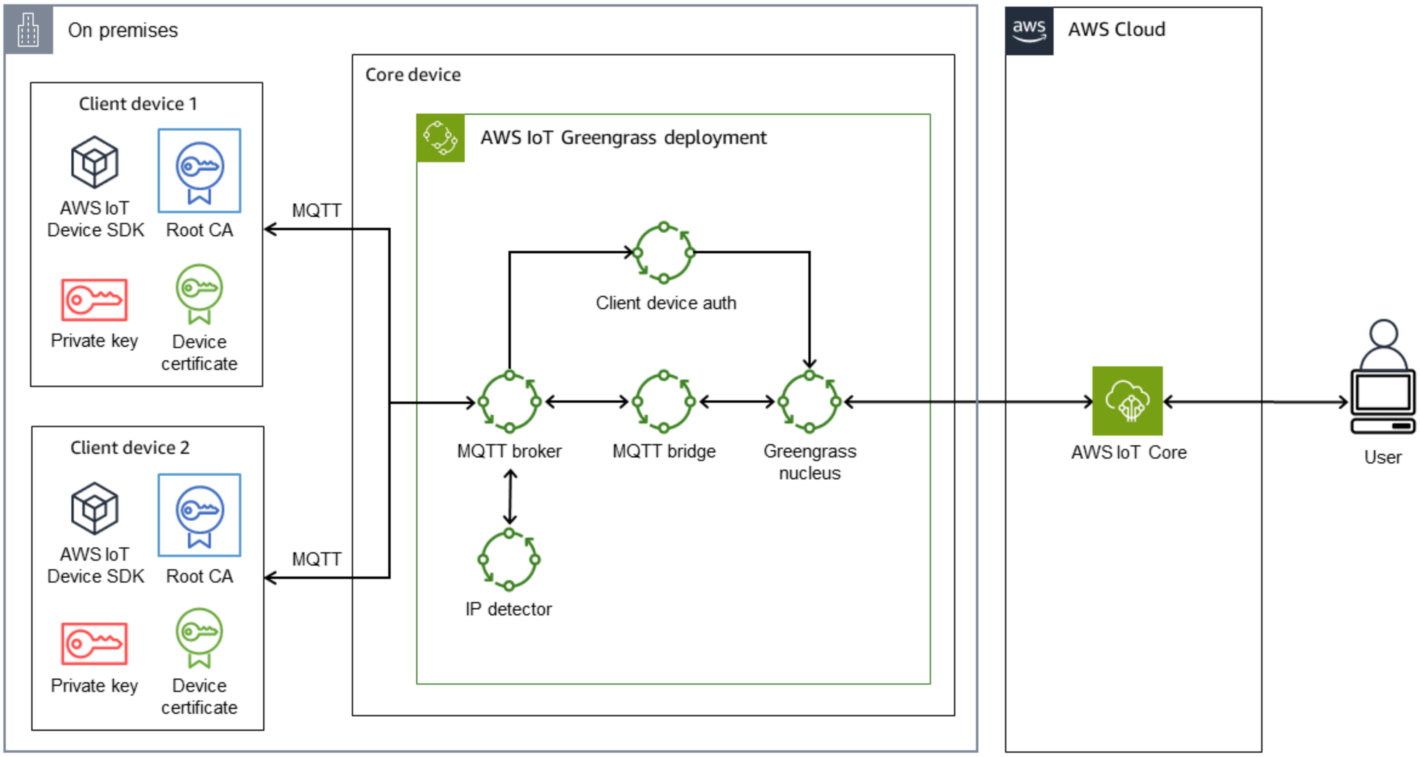
- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2
- Two client devices running Python 3.7 or later
- One core device running Java Runtime Environment (JRE) version 8 or later, and Amazon Corretto 11 or OpenJDK 11

Limitations

- You must choose an AWS Region where AWS IoT Core is available. For the current list of Regions for AWS IoT Core, see AWS Services by Region.
- The core device must have at least 172 MB RAM and 512 MB of disk space.

Architecture

The following diagram shows the solution architecture for this pattern.



The architecture includes:

- Two client devices. Each device contains a private key, a device certificate, and a root certificate authority (CA) certificate. The AWS IoT Device SDK, which contains an MQTT client, is also installed on each client device.
- A core device that has AWS IoT Greengrass deployed with the following components:
  - MQTT broker
  - MQTT bridge
  - Client device authentication
  - IP detector

This architecture supports the following scenarios:

- Client devices can use their MQTT client to communicate with one another through the core device's MQTT broker.
- Client devices can also communicate with AWS IoT Core in the cloud through the core device's MQTT broker and the MQTT bridge.

- AWS IoT Core in the cloud can send messages to client devices through the MQTT test client and the core device's MQTT bridge and MQTT broker.

For more information about the communications between client devices and the core device, see the Additional information section.

Tools

AWS services

- AWS IoT Greengrass is an open source Internet of Things (IoT) edge runtime and cloud service that helps you build, deploy, and manage IoT applications on your devices.
- AWS IoT Core provides secure, bidirectional communication for internet-connected devices to connect to the AWS Cloud.
- AWS IoT Device SDK is a software development kit that includes open-source libraries, developer guides with samples, and porting guides so that you can build innovative IoT products or solutions on your choice of hardware platforms.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Best practices

- The payload of the messages from client devices should be in either JSON or Protobuf format in order to take advantage of the advanced features of the AWS IoT Core rules engine, such as transformation and conditional actions.
- Configure the MQTT bridge to allow bidirectional communication.
- Configure and deploy the IP detector component in AWS IoT Greengrass to ensure that the core device's IP addresses are included in the subject alternative name (SAN) field of the MQTT broker certificate.

Task	Description	Skills required

	``
	              "Action":
	 [
	
	 "iot:*"
	              ],
	              "Resource
	": "*"
	        },
	        {
	              "Sid":
	 "GreengrassActions
	",
	              "Effect":
	 "Allow",
	              "Action":
	 [
	
	 "greengrass:*"
	              ],
	              "Resource
	": "*"
	        }
	    ]
	}
	``
	2. Attach the policy to the Greengrass service role. To get the service role, use the command:
	``
	aws greengrassv2
	 get-service-role-f
	or-account --region
	 <region>
	``
	where `<region>` refers to your AWS Region.	

Task	Description	Skills required
Configure and deploy required components in the AWS IoT Greengrass core device.	Configure and deploy the following components: • `greengrass.clientdevices.mqtt.Moquette` (see configuration details) • `greengrass.clientdevices.mqtt.Bridge` (see configuration details and the next task) • `greengrass.clientdevices.Auth` (see configuration details and the task after the next one) • `aws.greengrass.clientdevices.IPDetector` (see configuration details)	AWS IoT Greengrass

Task	Description	Skills required

Confirm that the MQTT bridge allows bidirectional communication.	To relay MQTT messages between client devices and AWS IoT Core, configure and deploy the MQTT bridge component and specify the topics to relay. Here's an example:
	``
	{
	  "mqttTopicMapping":
	 {
	    "ClientDevicesToCl
	oud": {
	      "topic": "dt/#",
	      "source":
	 "LocalMqtt",
	      "target":
	 "IotCore"
	    },
	    "CloudToClientDevi
	ces": {
	      "topic": "cmd/#",
	      "source":
	 "IotCore",
	      "target":
	 "LocalMqtt"
	    }
	  }
	}
	``
		AWS IoT Greengrass

Task	Description	Skills required
Confirm that the auth component allows client devices to connect and publish or subscribe to topics.	The following `aws.greengrass.clientdevices.Auth` configuration allows all client devices to connect, publish messages, and subscribe to all topics. `{ "deviceGroups": { "formatVersion": "2021-03-05", "definitions": { "MyPermissiveDeviceGroup": { "selectionRule": "thingName: *", "policyName": "MyPermissivePolicy" } }, "policies": { "MyPermissivePolicy": { "AllowAll": { "statementDescription": "Allow client devices to perform all actions.", "operations": ["*"], "resources": ["*"] } } }`	AWS IoT Greengrass

Task	Description	Skills required

	``
	  }
	}
	``	

Set up client devices

Task	Description	Skills required
Install the AWS IoT Device SDK.	Install the AWS IoT Device SDK on client devices. For a full list of supported languages and the associated SDKs, see the [AWS IoT Core documentation]. For example, the AWS IoT Device SDK for Python SDK is [located on GitHub]. To install this SDK: 1. Confirm that Python 3.7 or later is installed, as instructed on the [Prerequisites page] of the GitHub repository. 2. Use the **pip** command to install the SDK. For MacOS and Linux:: `python3 -m pip install awsiotsdk` For Windows:	General AWS IoT

Task	Description	Skills required

	```python -m pip install awsiotsdk```
	
	Alternatively, you can install the SDK from the source repository:
	
	```# Create a workspace directory to hold all the SDK files mkdir sdk-workspace cd sdk-workspace # Clone the repository git clone https://github.com/aws/aws-iot-device-sdk-python-v2.git # Install using Pip (use 'python' instead of 'python3' on Windows) python3 -m pip install ./aws-iot-device-sdk-python-v2```	

Task	Description	Skills required

Create a thing.	1. In the [AWS IoT console](https://console.aws.amazon.com/iot/home), if a **Get started** button appears, choose it. Otherwise, in the navigation pane, choose **Security**, **Policies**.
	2. If the **You don't have any policies yet** dialog box appears, choose **Create a policy**. Otherwise, choose **Create**.
	3. Enter a name for the AWS IoT policy (for example, `ClientDevicePolicy`).
	4. In the **Add statements** section, replace the existing policy with the following JSON code. Replace `<region>` and `<account>` with your AWS Region and AWS account number.
	
	`{`
	`  "Version": "2012-10-17",`
	`  "Statement": [{`
	`      "Effect": "Allow",`
	`      "Action": "iot:Connect",`
	`      "Resource": "arn:aws:iot:region:account:client/*"`
	`    },`
		AWS IoT Core

	``	

Task	Description	Skills required

	``
	}
	``
	5. Choose **Create**.
	6. On the [AWS IoT console,](https://console.aws.amazon.com/iot/home) in the navigation pane, choose **Manage**, **Things**.
	7. If the **You don't have any things yet** dialog box is displayed, choose **Register a thing**. Otherwise, choose **Create**.
	8. On the **Creating AWS IoT things** page, choose **Create a single thing**.
	9. On the **Add your device to the device registry** page, enter a name for your IoT thing (for example, `ClientDevice1`), and then choose **Next**.
	
	Note
	You can't change the name of a thing after you create it. To change the name, you must create a new thing, give it the new name, and then delete the old thing.	

Task	Description	Skills required
	10. On the **Add a certificate for your thing** page, choose **Create certificate**. 11. Choose the **Download** links to download the certificate, private key, and root CA certificate. **Important** This is your only opportunity to download your certificate and private key. 12. To activate the certificate, choose **Activate**. The certificate must be active for a device to connect to AWS IoT. 13. Choose **Attach a policy**. 14. For **Add a policy for your thing**, choose **ClientDevicePolicy**, **Register Thing**.	

Task	Description	Skills required
Download the CA certificate from the Greengrass core device.	If you expect the Greengrass core device to work in offline environments, you have to make the Greengrass core CA certificate available to the client device so it can verify the MQTT broker's certificate (which is issued by the Greengrass core CA). Therefore, it is important to obtain a copy of this certificate. Use one of the following approaches to download the CA certificate: • If you have network access to the AWS IoT Greengrass device from your PC, enter `https://<device IP>:8883` in your web browser and view the MQTT broker certificate and the CA certificate. You can also save the CA certificate to the client device. • Alternatively, you can use the OpenSSL command line: `openssl s_client -showcerts -connect <device IP>:8883`	General AWS

Task	Description	Skills required
Copy credentials in the client devices.	Copy the Greengrass core CA certificate, the device certifica te, and the private key in the client devices.	General AWS

Task	Description	Skills required
Associate client devices with the core device.	Associate client devices with a core device so that they can discover the core device. The client devices can then use the [Greengrass discovery API](#) to retrieve connectivity information and certificates for their associated core devices. For more information, see [Associate client devices](#) in the AWS IoT Greengrass documentation. 1. On the [AWS IoT Greengrass console](#), choose **Core devices**. 2. Choose the core device to manage. 3. On the core device's details page, choose the **Client devices** tab. 4. In the **Associated client devices** section, choose **Associate client devices**. 5. In the **Associate client devices with core device** modal, do the following for each client device to associate: a. Enter the name of the AWS IoT thing to associate as a client device. b. Choose **Add**.	AWS IoT Greengrass

Task	Description	Skills required
	6. Choose **Associate**. The client devices that you associated can now use the Greengrass discovery API to discover this core device.	

Send and receive data

Task	Description	Skills required
Send data from one client device to another client device.	Use the MQTT client in your device to publish a message on the `dt/client1/sensor` topic.	General AWS
Send data from the client device to AWS IoT Core.	Use the MQTT client in your device to publish a message on the `dt/client1/sensor` topic. In the MQTT test client, subscribe to the topic that the device is sending messages on, or subscribe to **#** for all topics (see details).	General AWS
Send messages from AWS IoT Core to client devices.	On the MQTT test client page, in the **Publish to a topic** tab, in the **Topic name** field, enter the topic name of your message. In this example, use `cmd/client1` for the topic.	General AWS

Troubleshooting

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td>

Unable to verify server certificate error

</td><td>

This error occurs when the MQTT client cannot verify the certificate that's presented by the MQTT broker during the TLS handshake. The most common reason is that the MQTT client doesn't have the CA certificate. Follow these steps to make sure that the CA certificate is provided to the MQTT client.

1. If you have network access to the AWS IoT Greengrass device from your PC, enter `https://<device IP>:8883` in a browser window to view the MQTT broker certificate and the CA certificate. You can also save the CA certificate to the client device.

   Alternatively use the OpenSSL command line:

   ```
   openssl s_client -showcerts -connect
    <device IP>:8883
   ```

2. Save the contents of the Moquette CA and Greengrass Core CA certificates into files, and then view the decoded contents by using the command:

   ```
   openssl x509 -in <Name of CA>.pem -
   text
   ```

   The Moquette CA certificate should show the SAN field as in this example:

</td></tr>
</table>

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td></td><td><pre><code>X509v3 Subject Alternative Name:
 IP Address:XXX.XXX.XXX.XXX, IP
Address:127.0.0.1, DNS:localhost</code></pre></td></tr>
<tr><td>Unable to verify server name error</td><td> This errors occurs when the MQTT client can’t verify that it’s connecting to the correct server. The most common reason is that the IP address of the Greengrass device isn’t listed in the SAN field of the certificate. Follow the instructions in the previous solution to obtain the MQTT broker certifica te and verify that the SAN field contains the IP address of the AWS IoT Greengrass device, as explained in the Additional information section. If not, confirm that the IP detector component is installed correctly and restart the core device. </td></tr>
<tr><td>Unable to verify server name only when connecting from an embedded client device</td><td>Mbed TLS, which is a popular TLS library used in embedded devices, currently supports DNS name verification only in the SAN field of the certificate, as shown in the Mbed TLS library code. Because the core device doesn’t have its own domain name and depends on the IP address, TLS clients that use Mbed TLS will fail the server name verification during the TLS handshake, causing a connection failure. We recommend that you add the SAN IP address verification to your Mbed TLS library at the x509_crt_check_san function.</td></tr>

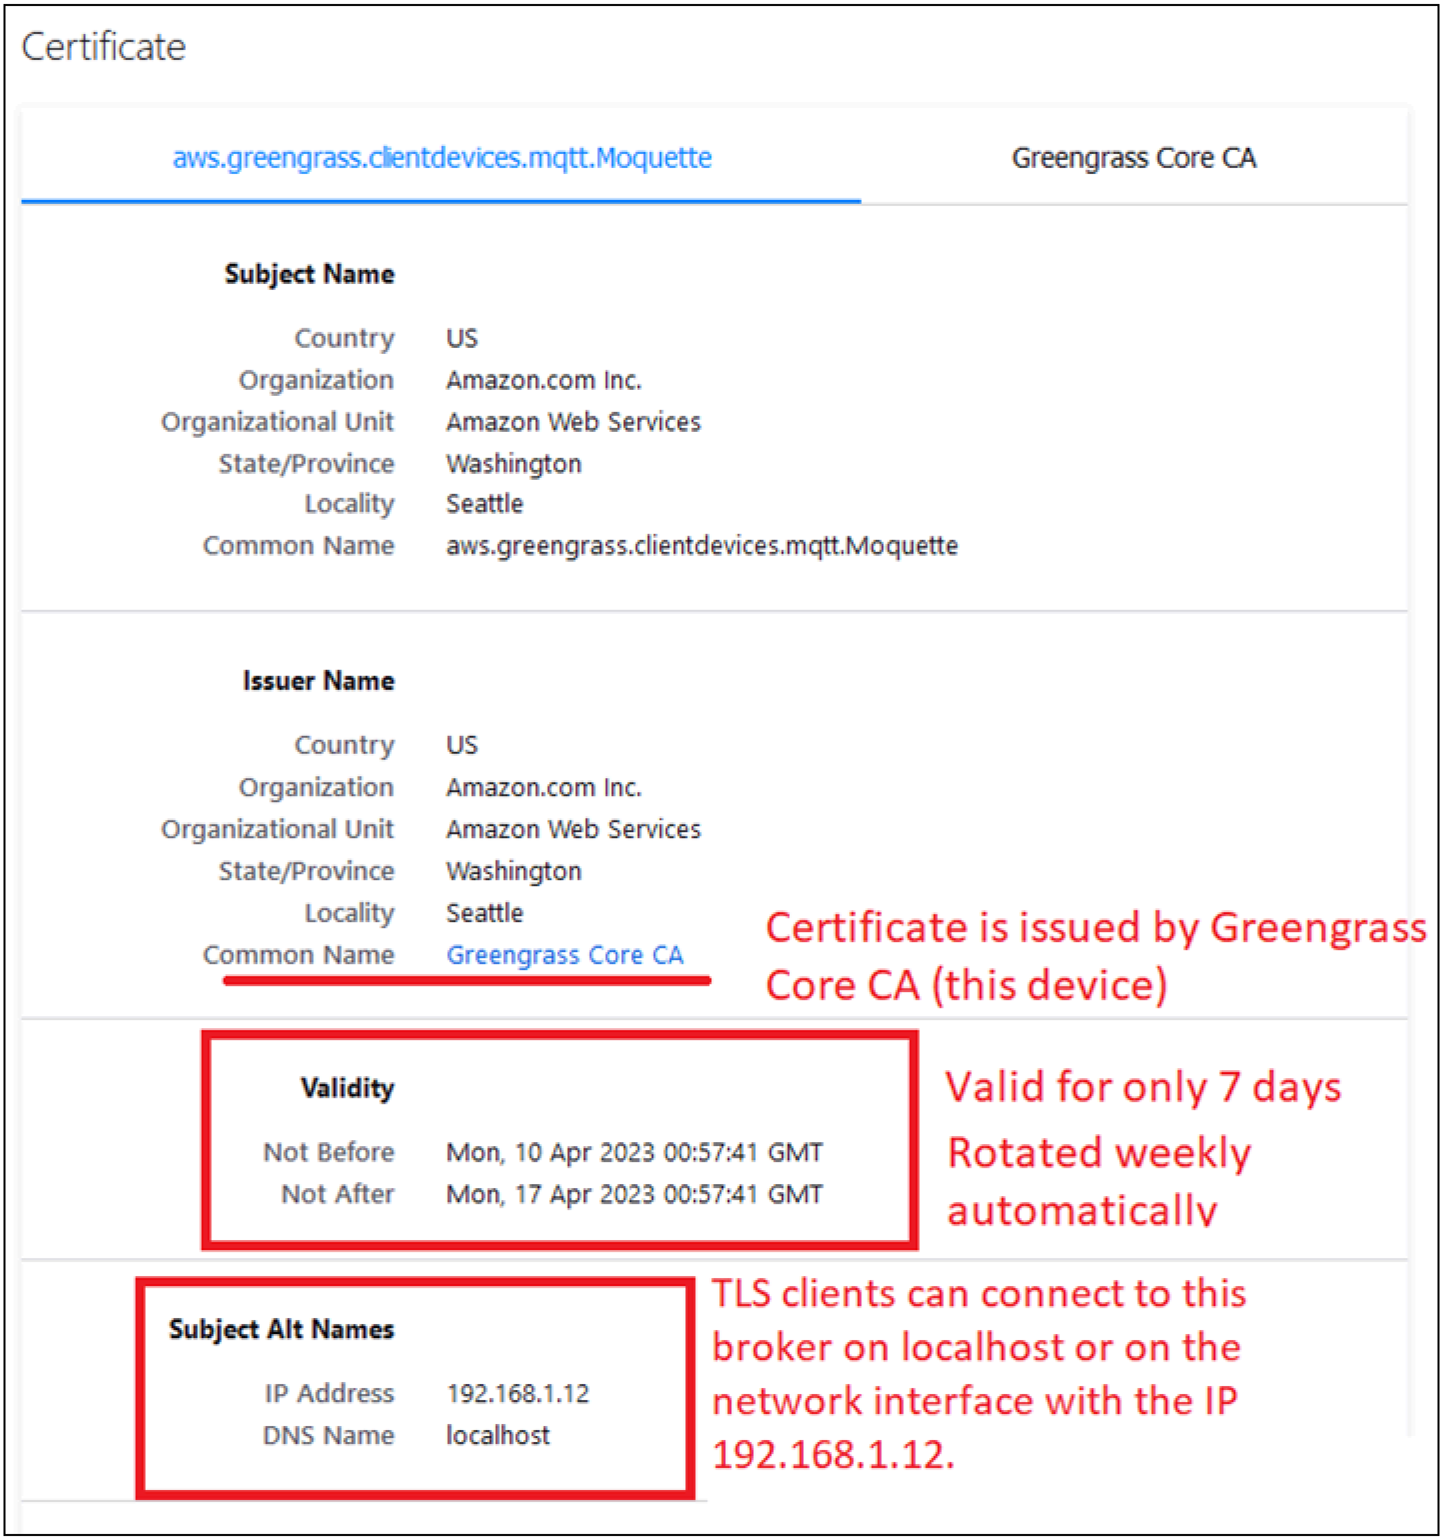
- RFC 5280 – Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile

Additional information

This section provides additional information about the communications between the client devices and the core device.

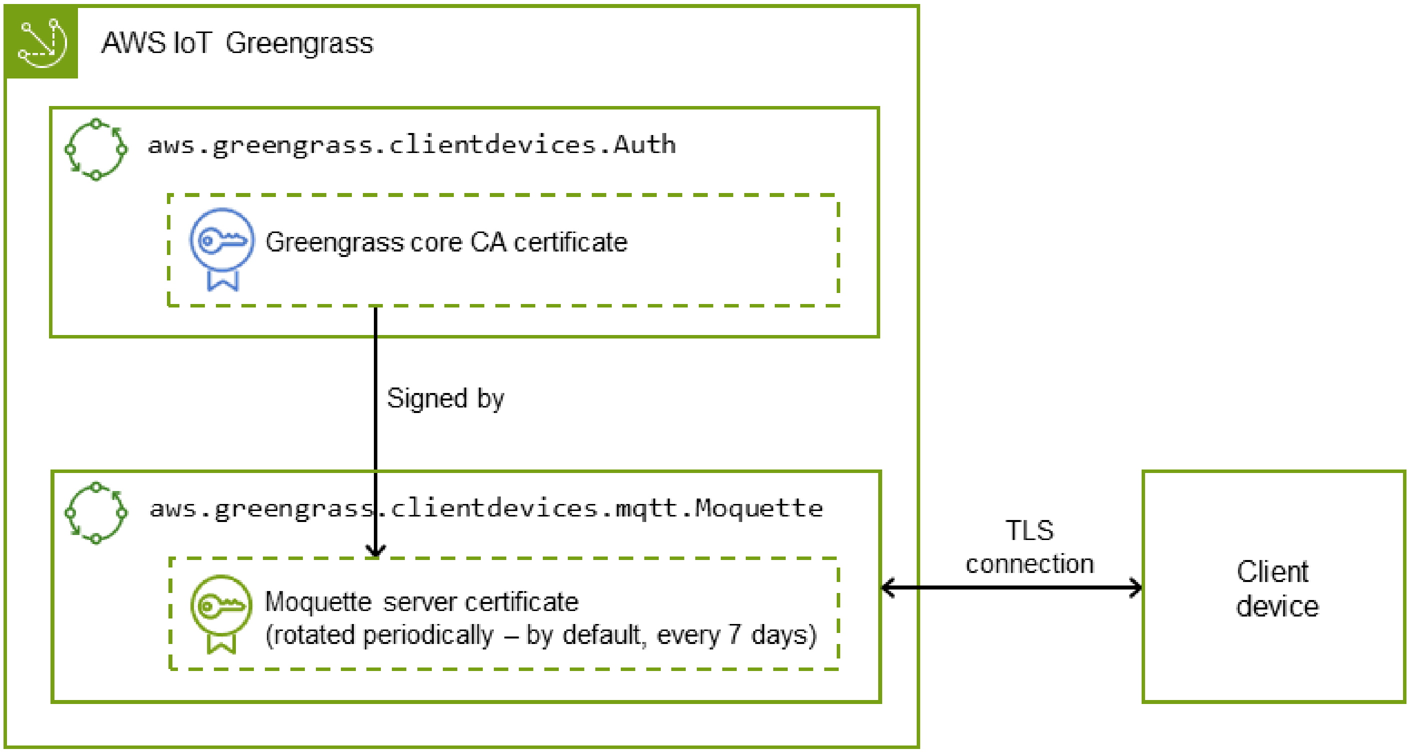
The MQTT broker listens on port 8883 in the core device for a TLS client connection attempt. The following illustration shows an example MQTT broker's server certificate.



The example certificate displays the following details:

- The certificate is issued by the AWS IoT Greengrass Core CA, which is local and specific to the core device; that is, it acts as a local CA.

- This certificate is automatically rotated every week by the client auth component as shown in the following illustration. You can set this interval in the client auth component configuration.



- The subject alternative name (SAN) plays a critical role in the server name verification on the TLS client end. It helps the TLS client ensure that it connects to the correct server and helps avoid man-in-the-middle attacks during TLS session setup. In the example certificate, the SAN field indicates that this server is listening on localhost (the local Unix domain socket), and the network interface has the IP address 192.168.1.12.

The TLS client uses the SAN field in the certificate to verify that it's connecting to a legitimate server during server verification. In contrast, during a typical TLS handshake between an HTTP server and a browser, the domain name in the common name (CN) field or SAN field is used to cross-check the domain that the browser is actually connecting to during the server verification process. If the core device doesn't have a domain name, the IP address included in the SAN field serves the same purpose. For more information, see the [Subject Alternative Name section](#) of *RFC 5280 – Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile*.

Th IP detector component in AWS IoT Greengrass ensures that the correct IP addresses are included in the SAN field of the certificate.

The certificate in the example is signed by the AWS IoT Greengrass device acting as a local CA. The TLS client (MQTT client) isn't aware of this CA, so we must provide a CA certificate that looks like the following.

Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel and Python

Venkata Naveen Koppula, Amazon Web Services

Summary

This pattern outlines steps for automatically creating AWS CloudFormation templates for AWS Database Migration Service (AWS DMS) using Microsoft Excel and Python.

Migrating databases using AWS DMS often involves creation of AWS CloudFormation templates to provision AWS DMS tasks. Previously, creating AWS CloudFormation templates required knowledge of the JSON or YAML programming language. With this tool, you only need basic knowledge of Excel and how to run a Python script using a terminal or command window.

As input, the tool takes an Excel workbook that includes the names of the tables to be migrated, Amazon Resource Names (ARNs) of AWS DMS endpoints, and AWS DMS replication instances. The tool then generates AWS CloudFormation templates for the required AWS DMS tasks.

For detailed steps and background information, see the blog post Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel in the AWS Database blog.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Microsoft Excel version 2016 or later
- Python version 2.7 or later
- The **xlrd** Python module (installed at a command prompt with the command: **pip install xlrd**)
- AWS DMS source and target endpoints and AWS DMS replication instance

Limitations

- The names of schemas, tables, and associated columns are transformed into lowercase characters at the destination endpoints.
- This tool doesn’t address the creation of AWS DMS endpoints and replication instances.

- Currently, the tool supports only one schema for each AWS DMS task.

Architecture

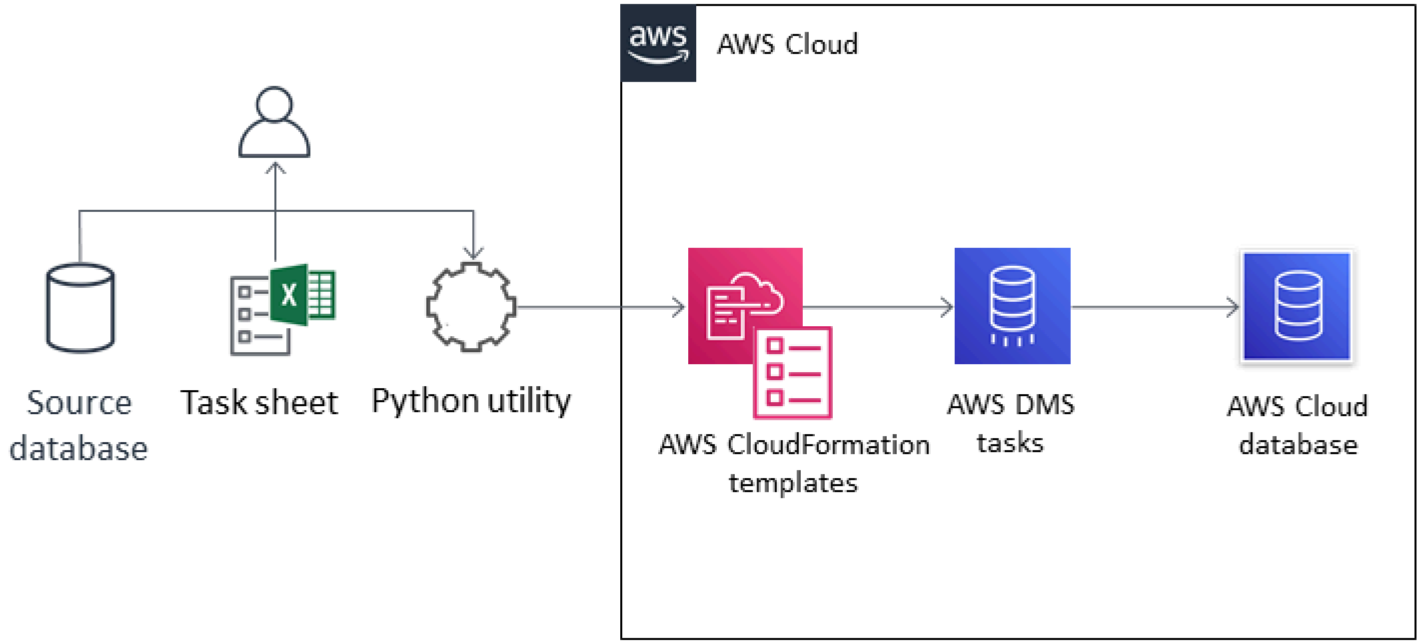
Source technology stack

- An on-premises database
- Microsoft Excel

Target technology stack

- AWS CloudFormation templates
- A database in the AWS Cloud

Architecture



Tools

- [Pycharm IDE](), or any integrated development environment (IDE) that supports Python version 3.6
- Microsoft Office 2016 (for Microsoft Excel)

Epics

Configure the network, AWS DMS replication instance, and endpoints

Task	Description	Skills required
If necessary, request a service quota increase.	Request a service quota increase for the AWS DMS tasks if needed.	General AWS
Configure the AWS Region, virtual private clouds (VPCs), CIDR ranges, Availability Zones, and subnets.		General AWS
Configure the AWS DMS replication instance.	The AWS DMS replication instance can connect to both on-premises and AWS databases.	General AWS
Configure AWS DMS endpoints.	Configure endpoints for both the source and target databases.	General AWS

Prepare the worksheets for AWS DMS tasks and tags

Task	Description	Skills required
Configure the tables list.	List all tables involved in the migration.	Database
Prepare the tasks worksheet.	Prepare the Excel worksheet using the tables list you configured.	General AWS, Microsoft Excel
Prepare the tags worksheet.	Detail the AWS resource tags to attach to the AWS DMS tasks.	General AWS, Microsoft Excel

Download and run the tool

Task	Description	Skills required
Download and extract the template generation tool from the GitHub repository.	GitHub repository: https://github.com/aws-samples/dms-cloudformation-templates-generator/	
Run the tool.	Follow the detailed instructions in the blog post listed under "References and help."

Get started with automated portfolio discovery

Pratik Chunawala and Rodolfo Jr. Cerrada, Amazon Web Services

Summary

Assessing the portfolio and collecting metadata is a critical challenge when migrating applications and servers to the Amazon Web Services (AWS) Cloud, especially for large migrations that have more than 300 servers. Using an automated portfolio discovery tool can help you collect information about your applications, such as the number of users, frequency of use, dependencies, and information about the application's infrastructure. This information is essential when planning migration waves so that you can properly prioritize and group applications with similar traits. Using a discovery tool streamlines communication between the portfolio team and the application owners because the portfolio team can validate the results of the discovery tool rather than manually collecting the metadata. This pattern discusses key considerations for selecting an automated discovery tool and information about how to deploy and test one in your environment.

This pattern includes a template, which is a starting point for building your own checklist of high-level activities. Next to the checklist is template for a responsible, accountable, consulted, informed (RACI) matrix. You can use this RACI matrix to determine who is responsible for each task in your checklist.

Epics

Select a discovery tool

Task	Description	Skills required
Determine whether a discovery tool is appropriate for your use case.	A discovery tool might not be the best solution for your use case. Consider the amount of time required to select, procure, prepare, and deploy a discovery tool. It can take 4–8 weeks to set up the scanning appliance for an agentless discovery tool in your environment or to	Migration lead, Migration engineer

Task	Description	Skills required
	install agents to all in-scope workloads. Once deployed, you must allow 4–12 weeks for the discovery tool to collect metadata by scanning the application workloads and performing application stack analysis. If you are migrating fewer than 100 servers, you might be able to manually collect the metadata and analyze dependencies faster than the time required to deploy and collect metadata with an automated discovery tool.	
Select a discovery tool.	Review the **Considerations for selecting an automated discovery tool** in the Additional information section. Determine the appropriate criteria for selecting a discovery tool for your use case, and then evaluate each tool against those criteria. For a comprehensive list of automated discovery tools, see Discovery, Planning, and Recommendation migration tools.	Migration lead, Migration engineer

Prepare for installation

Task	Description	Skills required
Prepare the pre-deployment checklist.	Create a checklist of the tasks you must complete before deploying the tool. For an example, see Predeployment Checklist on the Flexera documentation website.	Build lead, Migration engineer, Migration lead, Network administrator
Prepare the network requirements.	Provision the ports, protocols , IP addresses, and routing necessary for the tool to run and access the target servers. For more information, see the installation guide for your discovery tool. For an example, see Deployment Requirements on the Flexera documentation website.	Migration engineer, Network administrator, Cloud architect
Prepare the account and credential requirements.	Identify the credentials you need to access the target servers and to install all of the tool's components.	Cloud administrator, General AWS, Migration engineer, Migration lead, Network administrator, AWS administrator
Prepare the appliances on which you will install the tool.	Ensure that the appliances on which you will install the tool components meet the specifications and platform requirements for the tool.	Migration engineer, Migration lead, Network administrator
Prepare the change orders.	According to the change management process in your organization, prepare the any change orders needed, and	Build lead, Migration lead

Task	Description	Skills required
	ensure these change orders are approved.	
Send requirements to stakeholders.	Send the pre-deployment checklist and network requirements to the stakeholders. Stakeholders should review, evaluate, and prepare the necessary requirements before proceeding with the deployment.	Build lead, Migration lead

Deploy the tool

Task	Description	Skills required
Download the installer.	Download the installer or the virtual machine image. Virtual machine images typically come in Open Virtualization Format (OVF).	Build lead, Migration lead
Extract the files.	If you are using an installer, you must download and run the installer on an on-premises server.	Build lead, Migration lead
Deploy the tool on the servers.	Deploy the discovery tool on the target, on-premises servers as follows: • If your source file is a virtual machine image, deploy it into your virtual	Build lead, Migration lead, Network administrator

Task	Description	Skills required
	machine environment, such as VMware. • If your source file is an installer, run the installer to install and set up the tool.	
Log in to the discovery tool.	Follow the on-screen prompts, and log in to get started with the tool.	Migration lead, Build lead
Activate the product.	Enter your license key.	Build lead, Migration lead
Configure the tool.	Enter any credentials necessary to access the target servers, such as credentia ls for Windows, VMware, Simple Network Managemen t Protocol (SNMP), and Secure Shell Protocol (SSH), or databases.	Build lead, Migration lead

Test the tool

Task	Description	Skills required
Select test servers.	Identify a small set of non-production subnets or IP addresses that you can use to test the discovery tool. This helps you validate the scans quickly, identify and troubleshoot any errors quickly, and isolate your tests from production environme nts.	Build lead, Migration lead, Network administrator

Task	Description	Skills required
Start scanning the selected test servers.	For an agentless discovery tool, enter the subnets or IP addresses for the selected test servers in the discovery tool console, and start the scan. For an agent-based discovery tool, install the agent on the selected test servers.	Build lead, Migration lead, Network administrator
Review the scan results.	Review the scan results for the test servers. If any errors are found, troubleshoot and fix the errors. Document the errors and solutions. You reference this information in the future, and you can add this information to your portfolio runbook.	Build lead, Migration lead, Network administrator
Rescan the test servers.	Once the rescan is complete, repeat the scan until there are no errors.	Build lead, Migration lead, Network administrator

Additional information

Considerations for selecting an automated discovery tool

Each discovery tool has benefits and limitations. When selecting the appropriate tool for your use case, consider the following:

- Select a discovery tool that can collect most, if not all, of the metadata you need to achieve your portfolio assessment goal.
- Identify any metadata you need to gather manually because the tool doesn't support it.
- Provide the discovery tool requirements to stakeholders so they can review and assess the tool based on their internal security and compliance requirements, such as server, network, and credential requirements.
  - Does the tool require that you install an agent in the in-scope workload?
  - Does the tool require that you set up a virtual appliance in your environment?
- Determine your data residency requirements. Some organizations don't want to store their data outside of their environment. To address this, you might need to install some components of the tool in the on-premises environment.
- Make sure the tool supports the operating system (OS) and OS version of the in-scope workload.
- Determine whether your portfolio includes mainframe, mid-range, and legacy servers. Most of the discovery tools can detect these workloads as dependencies, but some tools might not be able to get device details, such as utilization and server dependencies. Device42 and modernizeIT discovery tools both support mainframe and mid-range servers.

Migrate on-premises Cloudera workloads to Cloudera Data Platform on AWS

Battulga Purevragchaa and Nidhi Gupta, Amazon Web Services

Nijjwol Lamsal, Partner

Summary

This pattern describes the high-level steps for migrating your on-premises Cloudera Distributed Hadoop (CDH), Hortonworks Data Platform (HDP), and Cloudera Data Platform (CDP) workloads to CDP Public Cloud on AWS. We recommend that you partner with Cloudera Professional Services and a systems integrator (SI) to implement these steps.

There are many reasons Cloudera customers want to move their on-premises CDH, HDP, and CDP workloads to the cloud. Some typical reasons include:

- Streamline adoption of new data platform paradigms such as data lakehouse or data mesh
- Increase business agility, democratize access and inference on existing data assets
- Lower the total cost of ownership (TCO)
- Enhance workload elasticity
- Enable greater scalability; drastically reduce time to provision data services compared with legacy, on-premises install base
- Retire legacy hardware; significantly reduce hardware refresh cycles
- Take advantage of pay-as-you-go pricing, which is extended to Cloudera workloads on AWS with the Cloudera licensing model (CCU)
- Take advantage of faster deployment and improved integration with continuous integration and continuous delivery (CI/CD) platforms
- Use a single unified platform (CDP) for multiple workloads

Cloudera supports all major workloads, including Machine Learning, Data Engineering, Data Warehouse, Operational Database, Stream Processing (CSP), and data security and governance. Cloudera has offered these workloads for many years on premises, and you can migrate these workloads to the AWS Cloud by using CDP Public Cloud with Workload Manager and Replication Manager.

Cloudera Shared Data Experience (SDX) provides a shared metadata catalog across these workloads to facilitate consistent data management and operations. SDX also includes comprehensive, granular security to protect against threats, and unified governance for audit and search capabilities for compliance with standards such as Payment Card Industry Data Security Standard (PCI DSS) and GDPR.

CDP migration at a glance

Workload	Source workload	CDH, HDP, and CDP Private Cloud
	Source environment	• Windows, Linux • On-premises, colocation, or any non-AWS environment
	Destination workload	CDP Public Cloud on AWS
	Destination environment	• Deployment model: customer account • Operating model: customer/Cloudera control plane
Migration	Migration strategy (7Rs)	Rehost, replatform, or refactor
	Is this an upgrade in the workload version?	Yes
	Migration duration	• Deployment: About 1 week to create customer account, virtual private cloud (VPC), and CDP Public Cloud customer-managed environment. • Migration duration: 1-4 months, depending on the

complexity and size of the workload.

Cost	Cost of running the workload on AWS	• At a high level, the cost of a CDH workload migration to AWS assumes that you will establish a new environment on AWS. It includes accounting for personnel time and effort as well as provisioning computing resources and licensing software for the new environment. • The Cloudera cloud consumption-based pricing model gives you the flexibility to take advantage of bursting and automatic scaling capabilities. For more information, see CDP Public Cloud service rates on the Cloudera website. • Cloudera Enterprise Data Hub is based on Amazon Elastic Compute Cloud (Amazon EC2) and closely models traditional clusters. Data Hub can be customized, but this will affect costs. • CDP Public Cloud Data Warehouse, Cloudera Machine Learning, and Cloudera Data Engineering (CDE) are container-based and can be configured to scale automatically.

Infrastructure agreements and framework	System requirements	See the Prerequisites section.
	SLA	See Cloudera Service Level Agreement for CDP Public Cloud.
	DR	See Disaster Recovery in the Cloudera documentation.
	Licensing and operating model (for target AWS account)	Bring Your Own License (BYOL) model
Compliance	Security requirements	See Cloudera Security Overview in the Cloudera documentation.
	Other compliance certifications	See the information on the Cloudera website about General Data Protection Regulation (GDPR) compliance and the CDP Trust Center.

Prerequisites and limitations

Prerequisites

- AWS account requirements, including accounts, resources, services, and permissions, such as AWS Identity and Access Management (IAM) roles and policies setup
- Prerequisites for deploying CDP from the Cloudera website

The migration requires the following roles and expertise:

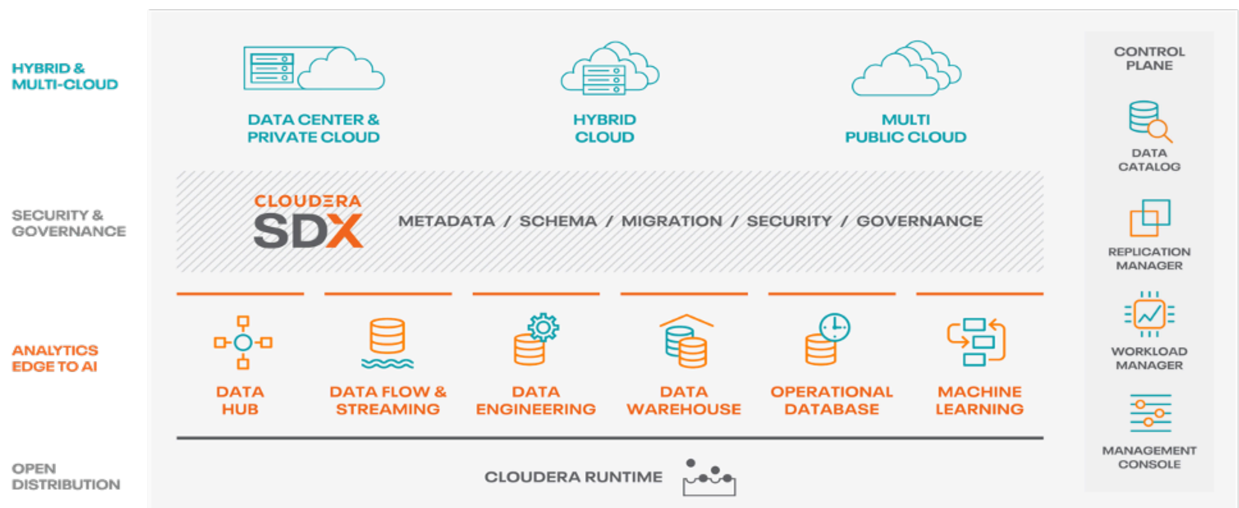
Role	Skills and responsibilities
Migration lead	Ensures executive support, team collaboration, planning, implementation, and assessment

Cloudera SME	Expert skills in CDH, HDP, and CDP administration, system administration, and architecture
AWS architect	Skills in AWS services, networking, security, and architectures

Architecture

Building to the appropriate architecture is a critical step to ensure that migration and performance meet your expectations. For your migration effort to meet this playbook's assumptions, your target data environment in the AWS Cloud, either on virtual private cloud (VPC) hosted instances or CDP, must be an equivalent match to your source environment in terms of operating system and software versions as well as major machine specifications.

The following diagram (reproduced with permission from the Cloudera Shared Data Experience data sheet) shows the infrastructure components for the CDP environment and how the tiers or infrastructure components interact.



The architecture includes the following CDP components:

- Data Hub is a service for launching and managing workload clusters powered by Cloudera Runtime. You can use the cluster definitions in Data Hub to provision and access workload clusters for custom use cases and define custom cluster configurations. For more information, see the Cloudera website.
- Data Flow and Streaming addresses the key challenges enterprises face with data in motion. It manages the following:

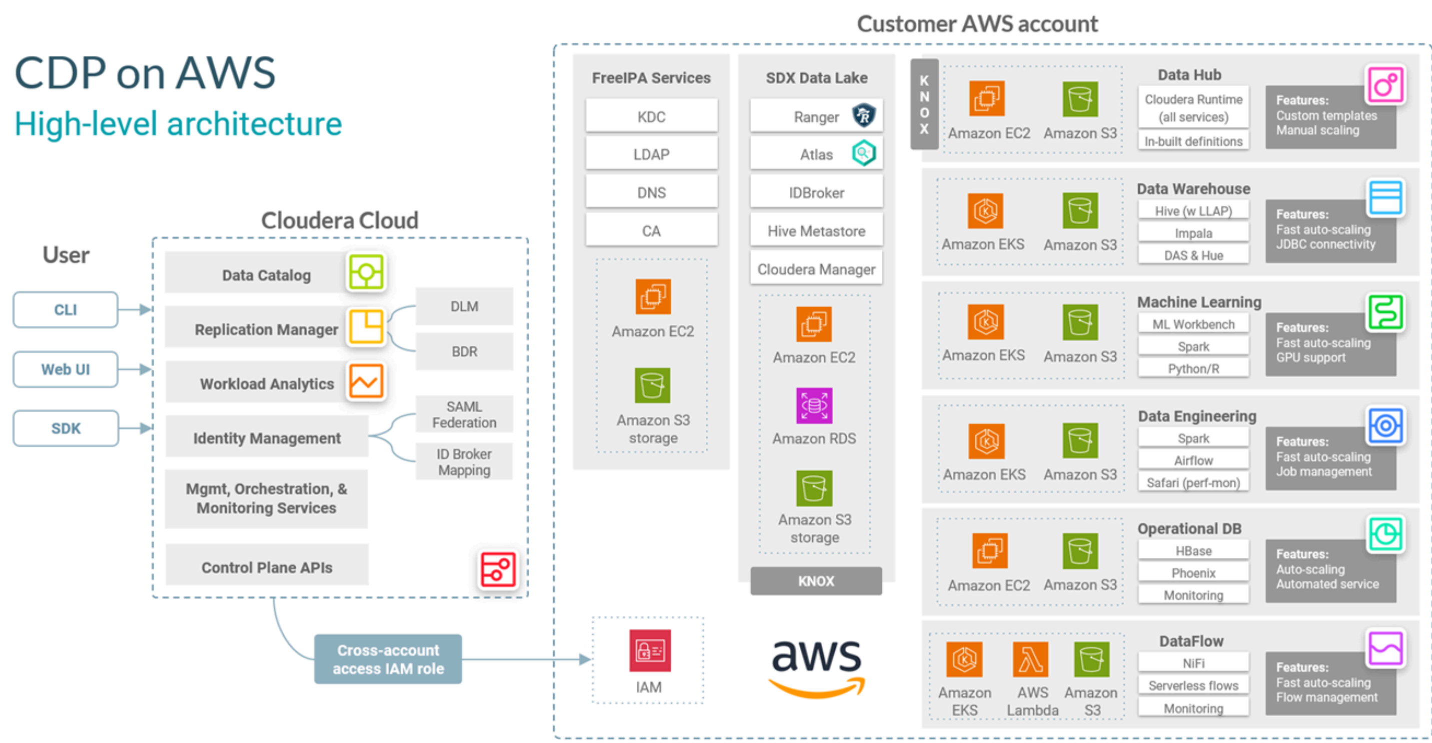
  - Processing real-time data streaming at high volume and high scale
  - Tracking data provenance and lineage of streaming data
  - Managing and monitoring edge applications and streaming sources

  For more information, see Cloudera DataFlow and CSP on the Cloudera website.

- Data Engineering includes data integration, data quality, and data governance, which help organizations build and maintain data pipelines and workflows. For more information, see the Cloudera website. Learn about support for spot instances to facilitate cost savings on AWS for Cloudera Data Engineering workloads.
- Data Warehouse enables you to create independent data warehouses and data marts that automatically scale to meet workload demands. This service provides isolated compute instances and automated optimization for each data warehouse and data mart, and helps you save costs while meeting SLAs. For more information, see the Cloudera website. Learn about managing costs and auto-scaling for Cloudera Data Warehouse on AWS.
- Operational Database in CDP provides a reliable and flexible foundation for scalable, high-performance applications. It delivers a real-time, always available, scalable database that serves traditional structured data alongside new, unstructured data within a unified operational and warehousing platform. For more information, see the Cloudera website.
- Machine Learning is a cloud-native machine learning platform that merges self-service data science and data engineering capabilities into a single, portable service within an enterprise data cloud. It enables scalable deployment of machine learning and artificial intelligence (AI) on data anywhere. For more information, see the Cloudera website.

CDP on AWS

The following diagram (adapted with permission from the Cloudera website) shows the high-level architecture of CDP on AWS. CDP implements its own security model to manage both accounts and data flow. These are integrated with IAM through the use of cross-account roles.



The CDP control plane resides in a Cloudera master account in its own VPC. Each customer account has its own sub-account and unique VPC. Cross-account IAM roles and SSL technologies route management traffic to and from the control plane to customer services that reside on internet-routable public subnets within each customer VPC. On the customer's VPC, the Cloudera Shared Data Experience (SDX) provides enterprise-strength security with unified governance and compliance so you can get insights from your data faster. SDX is a design philosophy incorporated into all Cloudera products. For more information about SDX and the CDP Public Cloud network architecture for AWS, see the Cloudera documentation.

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

- [Amazon Relational Database Service (Amazon RDS)](#) helps you set up, operate, and scale a relational database in the AWS Cloud.
- [Amazon Simple Storage Service (Amazon S3)](#) is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

Automation and tooling

- For additional tooling, you can use Cloudera Backup Data Recovery (BDR), AWS Snowball, and AWS Snowmobile to help migrate data from on-premises CDH, HDP, and CDP to AWS-hosted CDP.
- For new deployments, we recommend that you use the AWS Partner Solution for CDP.

Epics

Prepare for migration

Task	Description	Skills required
Engage the Cloudera team.	Cloudera pursues a standardized engagement model with its customers and can work with your systems integrator (SI) to promote the same approach. Contact the Cloudera customer team so they can provide guidance and the necessary technical resources to get the project started. Contacting the Cloudera team ensures that all necessary teams can prepare for the migration as its date approaches. You can contact Cloudera Professional Services to move your	Migration lead

Task	Description	Skills required
	Cloudera deployment from pilot to production quickly, at lower cost, and with peak performance. For a complete list of offerings, see the Cloudera website.	
Create a CDP Public Cloud environment on AWS for your VPC.	Work with Cloudera Professional Services or your SI to plan and deploy CDP Public Cloud into a VPC on AWS.	Cloud architect, Cloudera SME

Task	Description	Skills required
Prioritize and assess workloads for migration.	Evaluate all your on-premises workloads to determine the workloads that are the easiest to migrate. Applications that aren't mission-critical are the best to move first, because they will have minimal impact on your customers. Save the mission-critical workloads for last, after you successfully migrate other workloads. **Note** Transient (CDP Data Engineering) workloads are easier to migrate than persistent (CDP Data Warehouse) workloads. It's also important to consider data volume and locations when migrating. Challenge s can include replicati ng data continuously from an on-premises environment to the cloud, and changing the data ingestion pipelines to import data directly to the cloud.	Migration lead

Task	Description	Skills required
Discuss CDH, HDP, CDP, and legacy application migration activities.	Consider and start planning for the following activitie s with Cloudera Workload Manager: • Data and workloads to copy to your AWS environment • Cloud-ready data • Noisy neighbors, which use up resources and create issues for other tenants • Elastic workloads • Small clusters with high operational overhead	Migration lead

Task	Description	Skills required
Complete the Cloudera Replication Manager requirements and recommendations.	Work with Cloudera Professional Services and your SI to prepare to migrate workloads to your CDP Public Cloud environment on AWS. Understanding the following requirements and recommendations can help you avoid common issues during and after you install the Replication Manager service. • Review Replication Manager supporting documents to confirm that you meet the environment and system requirements. For more information, see [Support matrix for CDP Public Cloud Replication Manager]() on the Cloudera website. • You don't need root access to the nodes on which the Replication Manager App and Data Lifecycle Manager (DLM) engine will be installed. • Install Apache Hive during the initial installation of Replication Manager, unless you are certain that you won't use Hive replication	Migration lead

Task	Description	Skills required
	in the future. If you decide to install Hive after creating HDFS replication policies in Replication Manager, you have to delete and then recreate all HDFS replicati on policies after you add Hive. • Clusters used in Replicati on Manager must have symmetrical configurations. Each cluster in a replicati on relationship must be configured exactly the same for security (Kerberos), user management (LDAP/AD), and Knox Proxy. Cluster services such as Hadoop Distribut ed File System (HDFS), Apache Hive, Apache Knox, Apache Ranger, and Apache Atlas can have different configurations for high availability (HA). For example, source and target clusters might have separate HA and non-HA configurations.	

Migrate CDP to AWS

Task	Description	Skills required
Migrate the first workload for dev/test environments by using Cloudera Workload Manager.	Your SI can help you migrate your first workload to the AWS Cloud. This should be an application that isn't customer-facing or mission-critical. Ideal candidates for dev/test migration are applications that have data that the cloud can easily ingest, such as CDP Data Engineering workloads. This is a transient workload that usually has fewer users accessing it, compared with a persistent workload such as a CDP Data Warehouse workload that could have many users who need uninterrupted access. Data Engineering workloads aren't persistent, which minimizes the business impact if something goes wrong. However, these jobs could be critical for productio n reporting, so prioritize low-impact Data Engineering workloads first.	Migration lead
Repeat migration steps as necessary.	Cloudera Workload Manager helps identify workloads that are best suited for the cloud. It provides metrics	Cloudera SME

Task	Description	Skills required
	such as cloud performance ratings, sizing/capacity plans for the target environment, and replication plans. The best candidates for migration are seasonal workloads, ad hoc reporting, and intermittent jobs that don't consume many resources. Cloudera Replication Manager moves data from on premises to the cloud, and from the cloud to on premises. Proactively optimize workloads, applications, performance, and infrastructure capacity for data warehousing, data engineering, and machine learning by using Workload Manager. For a complete guide on how to modernize a data warehouse, see the Cloudera website.

Resolve connection errors after migrating Microsoft SQL Server to the AWS Cloud

Premkumar Chelladurai, Amazon Web Services

Summary

After you migrate Microsoft SQL Server running on Windows Server 2008 R2, 2012, or 2012 R2 to Amazon Elastic Compute Cloud (Amazon EC2) instances on the Amazon Web Services (AWS) Cloud, the connection to SQL Server fails and the following errors appear:

- `[Microsoft][ODBC SQL Server Driver][DBNETLIB] General Network error`
- `ERROR [08S01] [Microsoft][SQL Native Client]Communication link failure. System.Data.SqlClient.SqlException: A transport-level error has occurred when sending the request to the server. (provider: TCP Provider, error: 0 - An existing connection was forcibly closed by the remote host.)`
- `TCP Provider: The semaphore timeout period has expired`

This pattern describes how you can resolve these errors by turning off the Windows Scalable Networking Pack (SNP) features at the operating system (OS) and network interface level for SQL Server running on Windows Server 2008 R2, 2012, or 2012 R2.

Prerequisites and limitations

Prerequisites

- Administrator privileges for Windows Server.
- If you used AWS Application Migration Service as your migration tool, you require one of the following Windows Server versions:
  - Windows Server 2008 R2 Service Pack 1, 2012, or 2012 R2
- If you used CloudEndure Migration as your migration tool, you require one of the following Windows Server versions:
  - Windows Server 2003 R2 Service Pack 3, 2008, 2008 R2 Service Pack 1, 2012, or 2012 R2

Tools

- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- [Windows Server](#) – Windows Server is a platform for building an infrastructure of connected applications, networks, and web services.

Epics

Turn off SNP features at the OS and elastic network interface levels

Task	Description	Skills required
Turn off SNP features at the OS level.	1. Sign in to Windows Server and open a command prompt as an administr ator. 2. Run the `netsh int tcp show global` command. 3. In the output, check if either `Receive-Side Scaling` or `Chimney Offload` is in `enabled` mode. If either of them is `enabled`, run the following commands: • `netsh int tcp set global chimney=d isabled` • `netsh int tcp set global rss=disab led`	AWS administrator, AWS systems administrator, Migration engineer, Cloud administrator

Task	Description	Skills required
Turn off SNP features at the elastic network interface level.	1. Choose **Start**, enter `ncpa.cpl`, and then press **Enter**. 2. Right-click **Elastic Network Adapter**. 3. In the popup menu, choose **Properties**. 4. In the **Ethernet Adapter Properties** window, choose **Configure**. 5. In the **Amazon Elastic Network Adapter Properties** popup window, choose the **Advanced** tab. 6. In the **Property** section, turn off all offloads and RSS.	AWS administrator, Cloud administrator, AWS systems administrator

Restart the AWS Replication Agent automatically without disabling SELinux after rebooting a RHEL source server

Anil Kunapareddy, Venkatramana Chintha, and Shanmugam Shanker, Amazon Web Services

Summary

AWS Application Migration Service helps simplify, expedite, and automate the migration of your Red Hat Enterprise Linux (RHEL) workload to the Amazon Web Services (AWS) Cloud. To add source servers to Application Migration Service, you install the AWS Replication Agent on the servers.

Application Migration Service provides real-time, asynchronous, block-level replication. This means that you can continue normal IT operations during the entire replication process. These IT operations might require that you reboot or restart your RHEL source server during the migration. If this happens, the AWS Replication Agent will not restart automatically, and your data replication will stop. Typically, you can set Security-Enhanced Linux (SELinux) to **disabled** or **permissive** mode to automatically restart AWS Replication Agent. However, your organization's security policies might prohibit disabling SELinux, and you might also have to relabel your files.

This pattern describes how to automatically restart the AWS Replication Agent without turning off SELinux when your RHEL source server reboots or restarts during a migration.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An on-premises RHEL workload that you want to migrate to the AWS Cloud.
- Application Migration Service initialized from the Application Migration Service console. Initialization is required only the first time you use this service. For instructions, see the Application Migration Service documentation.
- An existing AWS Identity and Access Management (IAM) policy for Application Migration Service. For more information, see the Application Migration Service documentation.

Versions

- RHEL version 7 or later

Tools

AWS services

- AWS Application Migration Service is a highly automated lift-and-shift (rehost) solution that simplifies, expedites, and reduces the cost of migrating applications to AWS.

Linux commands

The following table provides a list of Linux commands that you will run on your RHEL source server. These are also described in the epics and stories for this pattern.

Command	Description
`#systemctl –version`	Identifies the system version.
`#systemctl list-units --type=service`	Lists all active services that are available on the RHEL server.
`#systemctl list-units --type=service | grep running`	Lists all services that are currently running on the RHEL server.
`#systemctl list-units --type=service | grep failed`	Lists all services that failed to load after the RHEL server rebooted or restarted.
`restorecon -Rv /etc/rc.d/init.d/aws-replication-service`	Changes the context to `aws-replication-service` .
`yum install policycoreutils*`	Installs the policy core utilities that are required for the operation of the SELinux system.
`ausearch -c "insmod" --raw | audit2allow -M my-modprobe`	Searches the audit log and creates a module for policies.
`semodule -i my-modprobe.pp`	Activates the policy.
`cat my-modprobe.te`	Displays the contents of the `my-modprobe.te` file.

`semodule -l | grep my-modprobe`	Checks whether the policy has been loaded to the SELinux module.

Epics

Install the AWS Replication Agent and reboot the RHEL source server

Task	Description	Skills required
Create an Application Migration Service user with an access key and a secret access key.	To install the AWS Replicati on Agent, you must create an Application Migration Service user with the required AWS credentials. For instructions, see the [Application Migration Service documentation]().	Migration engineer
Install the AWS Replication Agent.	1. Sign in to the AWS Management Console and open the AWS Migration Service console at https://console.aws.amazon.com/mgn/home. 2. Configure replication settings by following the instructions in the [Applicati on Migration Service documentation](). 3. Install the AWS Replicati on Agent by following the instructions in the [Application Migration Service documentation](). 4. On the **Source Servers** page, choose the RHEL source server, and then	Migration engineer

Task	Description	Skills required
	choose **Replication** to start the initial replication. For more information, see the [Application Migration Service documentation]().	
Restart or reboot the RHEL source server.	Restart or reboot your RHEL source server when its **Data replication status** displays **Stalled** on the [Migration dashboard]().	Migration engineer
Check data replication status.	Wait for one hour and then check the **Data replication status** again on the Migration dashboard. It should be in the **Healthy** state.	Migration engineer

Check AWS Replication Agent status on the RHEL source server

Task	Description	Skills required
Identify the system version.	Open the command line interface for your RHEL source server and run the following command to identify the system version: `#systemctl -version`	Migration engineer
List all active services.	To list all active services available on the RHEL server, run the command:	Migration engineer

Task	Description	Skills required
	#systemctl list-unit s --type=service	
List all running services.	To list all services that are currently running on the RHEL server, use the command: #systemctl list-unit s --type=service | grep running	Migration engineer
List all services that failed to load.	To list all services that failed to load after the RHEL server rebooted or restarted, run the command: #systemctl list-unit s --type=service | grep failed	Migration engineer

Create and run the SELinux module

Task	Description	Skills required
Change the security context.	In the command line interface for your RHEL source server, run the following command to change the security context to the AWS replicati on service: restorecon -Rv /etc/ rc.d/init.d/aws- replication-service	Migration engineer

Task	Description	Skills required
Install core utilities.	To install the core utilities required for the operation of the SELinux system and its policies, run the command: `yum install policycoreutils*`	Migration engineer
Search the audit log and create a module for policies.	Run the command: `ausearch -c "insmod" --raw | audit2allow -M my-modprobe`	Migration engineer
Display the contents of the my-modprobe-te file.	The `my-modprobe.te` file is generated by the **audit2allow** command. It includes the SELinux domains, policy source directory, and subdirectories, and specifies the access vector rules and transitions associated with the domains. To display the contents of the file, run the command: `cat my modprobe.te`	Migration engineer
Activate the policy.	To insert the module and make the policy package active, run the command: `semodule -i my-modprobe.pp`	Migration engineer

Task	Description	Skills required
Check whether the module has been loaded.	Run the command: `semodule -l | grep my-modprobe` After the SELinux module is loaded, you will no longer have to set SELinux to **disabled** or **permissive** mode during your migration.	Migration engineer
Reboot or restart the RHEL source server and verify the data replication status.	Open the AWS Migration Service console, navigate to **Data replication progress**, and then reboot or restart your RHEL source server. Data replication should now resume automatically after the RHEL source server reboots.	Migration engineer

Convert VARCHAR2(1) data type for Oracle to Boolean data type for Amazon Aurora PostgreSQL

Naresh Damera, Amazon Web Services

Summary

During a migration from Amazon Relational Database Service (Amazon RDS) for Oracle to Amazon Aurora PostgreSQL-Compatible Edition, you might encounter a data mismatch when validating the migration in AWS Database Migration Service (AWS DMS). To prevent this mismatch, you can convert VARCHAR2(1) data type to Boolean data type.

VARCHAR2 data type stores variable-length text strings, and VARCHAR2(1) indicates that the string is 1 character in length or 1 byte. For more information about VARCHAR2, see Oracle built-in data types (Oracle documentation).

In this pattern, in the sample source data table column, the VARCHAR2(1) data is either a **Y**, for *Yes*, or **N**, for *No*. This pattern includes instructions for using AWS DMS and AWS Schema Conversion Tool (AWS SCT) to convert this data type from the **Y** and **N** values in VARCHAR2(1) to **true** or **false** values in Boolean.

Intended audience

This pattern is recommended for those who have experience migrating Oracle databases to Aurora PostgreSQL-Compatible by using AWS DMS. As you complete the migration, adhere to the recommendations in Converting Oracle to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL (AWS SCT documentation).

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Confirm that your environment is prepared for Aurora, including setting up credentials, permissions, and a security group. For more information, see Setting up your environment for Amazon Aurora (Aurora documentation).
- A source Amazon RDS for Oracle database that contains a table column with VARCHAR2(1) data.
- A target Amazon Aurora PostgreSQL-Compatible database instance. For more information, see Creating a database cluster and connecting to a database on an Aurora PostgreSQL database cluster (Aurora documentation).

Product versions

- Amazon RDS for Oracle version 12.1.0.2 or later.
- AWS DMS version 3.1.4 or later. For more information, see Using an Oracle database as a source for AWS DMS and Using a PostgreSQL database as a target for AWS DMS (AWS DMS documentation). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- AWS Schema Conversion Tool (AWS SCT) version 1.0.632 or later. We recommend that you use the latest version of AWS SCT for the most comprehensive version and feature support.
- Aurora supports the PostgreSQL versions listed in Database Engine Versions for Aurora PostgreSQL-Compatible (Aurora documentation).

Architecture

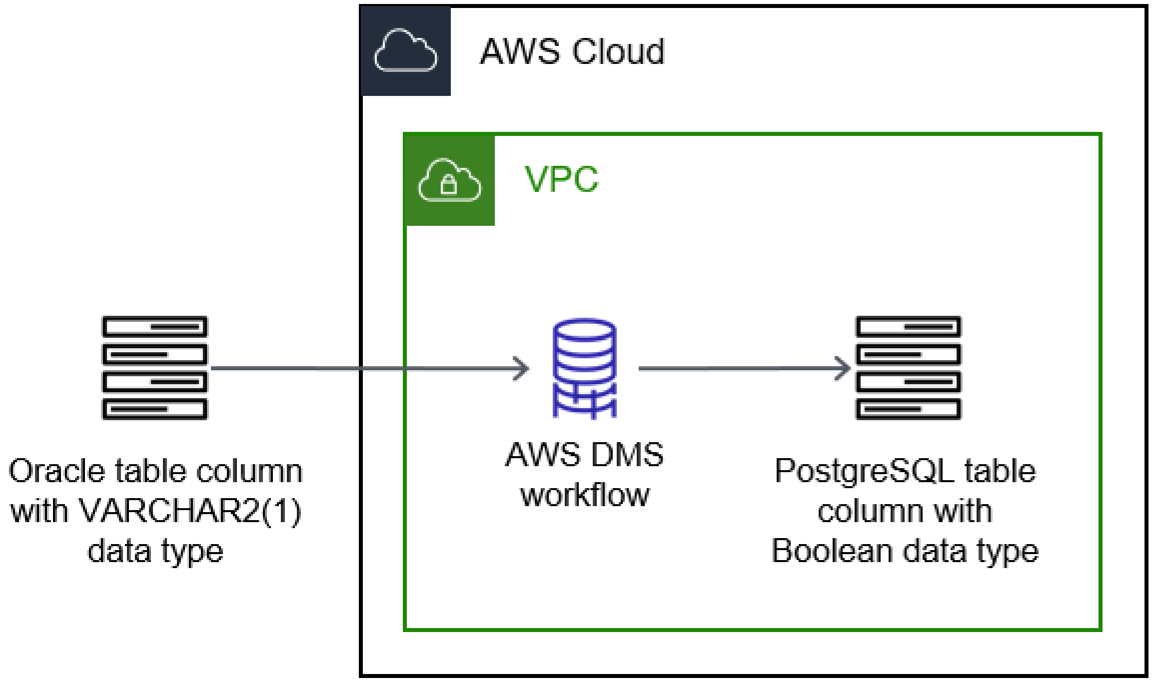
Source technology stack

Amazon RDS for Oracle database instance

Target technology stack

Amazon Aurora PostgreSQL-Compatible database instance

Source and target architecture



Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Relational Database Service (Amazon RDS) for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

Other services

- Oracle SQL Developer is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments. In this pattern, you use this tool to connect to the Amazon RDS for Oracle database instance and query the data.

- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects. In this pattern, you use this tool to connect to the Aurora database instance and query the data.

Epics

Prepare for the migration

Task	Description	Skills required
Create database migration report.	1. In AWS SCT, create a database migration assessment report. For more information, see Creating migration assessment reports. 2. Review and perform the action items in the migration assessment report. For more informati on, see Assessment report action items.	DBA, Developer
Disable foreign key constrain ts on the target database.	In PostgreSQL, foreign keys are implemented by using triggers. During the full load phase, AWS DMS loads each table one at a time. We strongly recommend that you disable foreign key constraints during a full load by using one of the following methods: • Temporarily disable all triggers from the instance, and finish the full load.	DBA, Developer

Task	Description	Skills required
	• Use the `session_replication_role` parameter in PostgreSQL. If disabling foreign key constraints is not feasible, create an AWS DMS migration task for the primary data that is specific to the parent table and child table.	

Disable the primary keys and unique keys on the target database.	Using the following commands, disable the primary keys and constraints on the target database. This helps improve the performance of the initial load task.
	
	`ALTER TABLE <table> DISABLE PRIMARY KEY;`
	
	`ALTER TABLE <table> DISABLE CONSTRAINT <constraint_name>;`
		DBA, Developer

Create the initial load task.	In AWS DMS, create the migration task for the initial load. For instructions, see Creating a task. For the migration method, choose **Migrate existing data**. This migration method is called `Full Load` in the API. Do not start this task yet.	DBA, Developer

Task	Description	Skills required
Edit task settings for the initial load task.	Edit the task settings to add data validation. These validation settings must be created in a JSON file. For instructions and examples, see Specifying task settings. Add the following validations: • To validate that the VARCHAR2(1) data is accurately converted to Boolean in the target database, add the code in *Data validation script* in the Additional information section of this pattern. The validation script converts the Boolean values of **1** to **Y** and **0** to **N** in the target table, and then it compares the values in the target table to the source table. To validate the rest of the data migration, enable data validation in the task. For more information, see Data validation task settings.	AWS administrator, DBA

Task	Description	Skills required
Create the ongoing replicati on task.	In AWS DMS, create the migration task that keeps the target database in sync with the source database. For instructions, see [Creating a task](). For the migration method, choose **Replicate data changes only**. Do not start this task yet.	DBA

Test the migration tasks

Task	Description	Skills required
Create sample data for testing.	In the source database, create a sample table with data for testing purposes.	Developer
Confirm there are no conflicti ng activities.	Use the `pg_stat_a ctivity` to check for any activity on the server that might affect the migration. For more information, see [The Statistics Collector]() (PostgreS QL documentation).	AWS administrator
Start the AWS DMS migration tasks.	In the AWS DMS console, on the **Dashboard** page, start the initial load and ongoing replication tasks that you created in the previous epic.	AWS administrator
Monitor the tasks and table load states.	During the migration, monitor the [task status]() and the [table states](). When the initial load	AWS administrator

Task	Description	Skills required
	task is complete, on the **Table statistics** tab: • The **Load state** should be **Table completed**. • The **Validation state** should be **Validated**.	
Verify the migration results.	Using pgAdmin, query the table on target database. A successful query indicates that the data was migrated successfully.	Developer
Add primary keys and foreign keys on the target database.	Create the primary key and foreign key on the target database. For more information, see [ALTER TABLE](#) (PostgreSQL website).	DBA
Clean up the test data.	On the source and target databases, clean up data that was created for unit testing.	Developer

Cut over

Task	Description	Skills required
Complete the migration.	Repeat the previous epic, *Test the migration tasks*, using the real source data. This migrates the data from the source to the target database.	Developer
Validate that the source and target databases are in sync.	Validate that the source and target databases are in sync.	Developer

Task	Description	Skills required
	For more information and instructions, see AWS DMS data validation.	
Stop the source database.	Stop the Amazon RDS for Oracle database. For instructi ons, see Stopping an Amazon RDS DB instance temporari ly. When you stop the source database, the initial load and ongoing replication tasks in AWS DMS are automatic ally stopped. No additiona l action is required to stop these tasks.	Developer

- Getting Started With Amazon RDS
- Introduction to AWS DMS (Video)
- Understanding Amazon RDS (Video)

Additional information

Data validation script

The following data validation script converts **1** to **Y** and **0** to **N**. This helps the AWS DMS task successfully complete and pass the table validation.

```
{
"rule-type": "validation",
"rule-id": "5",
"rule-name": "5",
"rule-target": "column",
"object-locator": {
"schema-name": "ADMIN",
"table-name": "TEMP_CHRA_BOOL",
"column-name": "GRADE"
},
"rule-action": "override-validation-function",
"target-function": "case grade when '1' then 'Y' else 'N' end"
        }
```

The `case` statement in the script performs the validation. If validation fails, AWS DMS inserts a record in the **public.awsdms_validation_failures_v1** table on the target database instance. This record includes the table name, error time, and details about the mismatched values in the source and target tables.

If you do not add this data validation script to the AWS DMS task and the data is inserted in the target table, the AWS DMS task shows validation state as **Mismatched Records**.

During AWS SCT conversion, the AWS DMS migration task changes the data type of VARCHAR2(1) data type to Boolean and adds a primary key constraint on the `"NO"` column.

Create application users and roles in Aurora PostgreSQL-Compatible

Abhishek Verma, Amazon Web Services

Summary

When you migrate to Amazon Aurora PostgreSQL-Compatible Edition, the database users and roles that exist on the source database must be created in the Aurora PostgreSQL-Compatible database. You can create the users and roles in Aurora PostgreSQL-Compatible by using two different approaches:

- Use similar users and roles in the target as in the source database. In this approach, the data definition languages (DDLs) are extracted for users and roles from the source database. Then they are transformed and applied to the target Aurora PostgreSQL-Compatible database. For example, the blog post Use SQL to map users, roles, and grants from Oracle to PostgreSQL covers using extraction from an Oracle source database engine.
- Use standardized users and roles that are commonly used during development, administration, and for performing other related operations in the database. This includes read-only, read/write, development, administration, and deployment operations performed by the respective users.

This pattern contains the grants required for users and roles creation in Aurora PostgreSQL-Compatible required for the standardized users and roles approach. The user and role creation steps are aligned to the security policy of granting least privilege to the database users. The following table lists the users, their corresponding roles, and their details on the database.

Users	Roles	Purpose
`APP_read`	`APP_RO`	Used for read-only access on the schema APP
`APP_WRITE`	`APP_RW`	Used for the write and read operations on the schema APP
`APP_dev_user`	`APP_DEV`	Used for the developme nt purpose on the schema APP_DEV, with read-only access on the schema APP

`Admin_User`	`rds_superuser`	Used for performing administrator operations on the database
`APP`	`APP_DEP`	Used for creating the objects under the APP schema and for deployment of objects in the APP schema

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- A PostgreSQL database, Amazon Aurora PostgreSQL-Compatible Edition database, or Amazon Relational Database Service (Amazon RDS) for PostgreSQL database

Product versions

- All versions of PostgreSQL

Architecture

Source technology stack

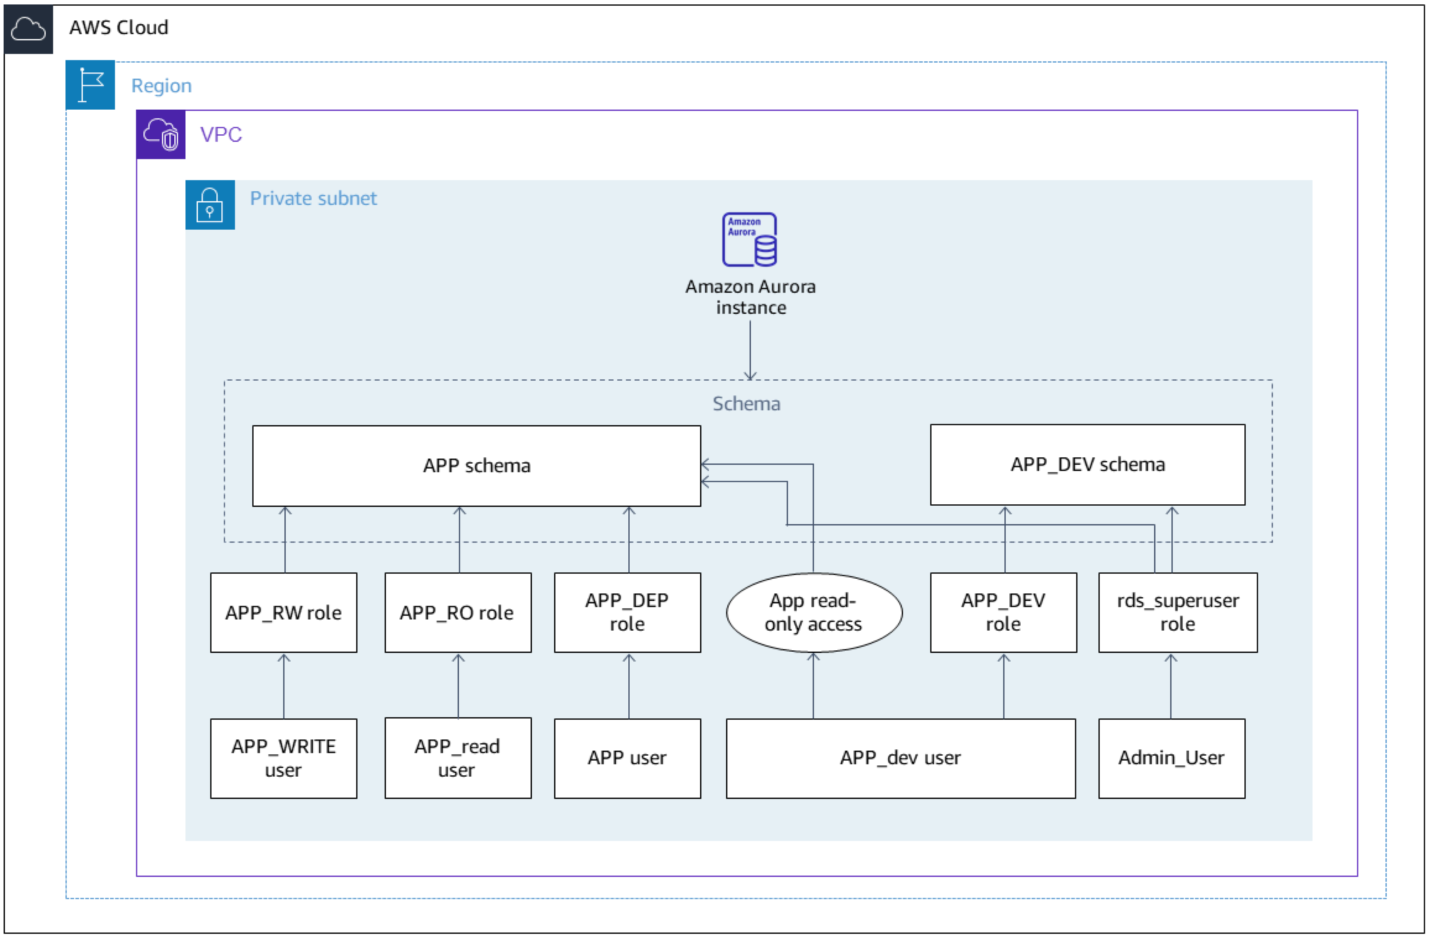
- Any database

Target technology stack

- Amazon Aurora PostgreSQL-Compatible

Target architecture

The following diagram shows user roles and the schema architecture in the Aurora PostgreSQL-Compatible database.



Automation and scale

This pattern contains the users, roles, and schema creation script, which you can run multiple times without any impact to existing users of the source or target database.

Tools

AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](https://docs.aws.amazon.com/AmazonRDS/latest/AuroraUserGuide/Aurora.AuroraPostgreSQL.html) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

Other services

- psql is a terminal-based front-end tool that is installed with every PostgreSQL Database installation. It has a command line interface for running SQL, PL-PGSQL, and operating system commands.
- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Epics

Create the users and roles

Task	Description	Skills required

Create the deployment user.	The deployment user APP will be used to create and modify the database objects during deployments. Use the following scripts to create the deployment user role APP_DEP in the schema APP. Validate access rights to make sure this user has only the privilege to create objects in the required schema APP.
	
	1. Connect to the admin user, and create the schema.
	`CREATE SCHEMA APP;`
	2. Create the user.
	`CREATE USER APP WITH PASSWORD <password > ;`
	3. Create the role.
	`CREATE ROLE APP_DEP ;`
		DBA

Task	Description	Skills required

	<pre>GRANT all on schema
	 APP to APP_DEP ;
	GRANT USAGE ON SCHEMA
	 APP to APP_DEP ;
	GRANT connect on
	 database <db_name>
	 to APP_DEP ;
	GRANT APP_DEP to APP;</pre>
	4. To test the privileges, connect to APP and create the tables.
	<pre>set search_path to
	 APP;
	SET
	CREATE TABLE test(id
	 integer) ;
	CREATE TABLE</pre>
	5. Check the privileges.
	<pre>select schemaname ,
	 tablename , tableowne
	r from pg_tables
	 where tablename like
	 'test' ;
	schemaname
	 | tablename |
	 tableowner
	APP |
	 test | APP</pre>	

Task	Description	Skills required

Create the read-only user.	The read-only user `APP_read` will be used for performing the read-only operation in the schema APP. Use the following scripts to create the read-only user. Validate access rights to make sure that this user has privilege only to read the objects in the schema APP and for automatically granting read access for any new objects created in the schema APP.
	
	1. Create the user `APP_read`.
	`create user APP_read ;`
	`alter user APP_read with password 'your_password' ;`
	2. Create the role.
	`CREATE ROLE APP_ro ;`
	`GRANT SELECT ON ALL TABLES IN SCHEMA  APP  TO  APP_RO   ;`
	`GRANT USAGE ON SCHEMA APP   TO APP_RO`
	`GRANT CONNECT ON DATABASE  testdb  TO APP_RO ;`
	`GRANT APP_RO TO APP_read;`
	3. To test the privileges, log in using the `APP_read` user.
		DBA

Task	Description	Skills required
	``` set search_path to APP ; create table test1(id integer) ; ERROR: permission denied for schema APP LINE 1: create table test1(id integer) ; insert into test values (34) ; ERROR: permission denied for table test SQL state: 42501 select from test no rows selected ```	

Task	Description	Skills required

Create the read/write user.	The read/write user `APP_WRITE` will be used to perform read and write operations on the schema APP. Use the following scripts to create the read/write user and grant it the `APP_RW` role. Validate access rights to make sure that this user has read and write privileges only on the objects in the schema APP and for automatically granting read and write access for any new object created in schema APP.
	
	1. Create the user.
	
	`CREATE USER APP_WRITE ; alter user APP_WRITE with password 'your_password' ;`
	
	2. Create the role.
	
	`CREATE ROLE APP_RW; GRANT SELECT, INSERT, UPDATE, DELETE ON ALL TABLES IN SCHEMA APP TO APP_RW ; GRANT CONNECT ON DATABASE postgres to APP_RW ; GRANT USAGE ON SCHEMA APP to APP_RW ;`	

Task	Description	Skills required
	``` ALTER DEFAULT PRIVILEGES IN SCHEMA APP GRANT SELECT, INSERT, UPDATE, DELETE ON TABLES TO APP_RW ; GRANT APP_RW to APP_WRITE ``` 3. To test the privileges, log in using the `APP_WRITE` user. ``` SET SEARCH_PATH to APP; CREATE TABLE test1(id integer) ; ERROR: permission denied for schema APP LINE 1: create table test1(id integer) ; SELECT * FROM test ; id ---- 12 INSERT INTO test values (31) ; INSERT 0 1 ```	

Task	Description	Skills required

Create the admin user.	The admin user `Admin_User` will be used to perform admin operations on the database. Examples of these operations are `CREATE ROLE` and `CREATE DATABASE`. `Admin_User` uses the built-in role `rds_superuser` to perform admin operations on the database. Use the following scripts to create and test the privilege for the admin user `Admin_User` in the database.
	
	1. Create the user and grant the role.
	
	`create user Admin_User WITH PASSWORD 'Your password'`
	`ALTER user Admin_user CREATEDB;`
	`ALTER user Admin_user CREATEROLE;`
	
	2. To test the privilege, log in from the `Admin_User` user.
	
	`SELECT * FROM APP.test ;`
	`id`
	`----`
	`31`
	`CREATE ROLE TEST ;`
		DBA

Task	Description	Skills required
	``` CREATE DATABASE test123 ; ```	

Task	Description	Skills required

Create the development user.	The development user `APP_dev_user` will have rights to create the objects in its local schema APP_DEV and read access in the schema APP. Use the following scripts to create and test the privileges of the user `APP_dev_user` in the database.
	
	1. Create the user.
	`CREATE USER APP1_dev_user with password 'your password';`
	2. Create the APP_DEV schema for the `App_dev_user` .
	`CREATE SCHEMA APP1_DEV ;`
	3. Create the APP_DEV role.
	`CREATE ROLE APP1_DEV ;`
	`GRANT APP1_RO to APP1_DEV ;`
	`GRANT SELECT ON ALL TABLES IN SCHEMA APP1_DEV to APP1_dev_user`
	`GRANT USAGE, CREATE ON SCHEMA APP1_DEV to APP1_DEV_USER`
	`GRANT APP1_DEV to APP1_DEV_USER ;`
		DBA

Task	Description	Skills required

	4. To test the privileges, log in from `APP_dev_user` .
	
	`CREATE TABLE APP1_dev.test1( id integer ) ;`
	`CREATE TABLE`
	`INSERT into APP1_dev.test1 ( select * from APP1.test );`
	`INSERT 0 1`
	`CREATE TABLE APP1.test4 ( id int) ;`
	`ERROR:   permission denied for schema APP1`
	`LINE 1: create table APP1.test4 ( id int) ;`

- CREATE USER
- Predefined Roles

Additional information

PostgreSQL 14 enhancement

PostgreSQL 14 provides a set of predefined roles that give access to certain commonly needed, privileged capabilities and information. Administrators (including roles that have the `CREATE ROLE` privilege) can grant these roles or other roles in their environment to users, providing them with access to the specified capabilities and information.

Administrators can grant users access to these roles using the GRANT command. For example, to grant the pg_signal_backend role to Admin_User, you can run the following command.

```
GRANT pg_signal_backend TO Admin_User;
```

The pg_signal_backend role is intended to allow administrators to enable trusted, non-superuser roles to send signals to other backends. For more information, see PostgreSQL 14 enhancement.

Fine-tuning access

In some cases, it might be necessary to provide more granular access to the users (for example, table-based access or column-based access). In such cases, additional roles can be created to grant those privileges to the users. For more information, see PostgreSQL Grants.

Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database

HariKrishna Boorgadda, Amazon Web Services

Summary

Best practices for Enterprise disaster recovery (DR) basically consist of designing and implementing fault-tolerant hardware and software systems that can survive a disaster (*business continuance*) and resume normal operations (*business resumption*), with minimal intervention and, ideally, with no data loss. Building fault-tolerant environments to satisfy Enterprise DR objectives can be expensive and time consuming and requires a strong commitment by the business.

Oracle Database provides three different approaches to DR that provide the highest level of data protection and availability compared to any other approach for protecting Oracle data.

- Oracle Zero Data Loss Recovery Appliance
- Oracle Active Data Guard
- Oracle GoldenGate

This pattern provides a way to emulate the Oracle GoldenGate DR by using an Amazon Aurora global database. The reference architecture uses Oracle GoldenGate for DR across three AWS Regions. The pattern walks through the replatforming of the source architecture to the cloud-native Aurora global database based on Amazon Aurora PostgreSQL–Compatible Edition.

Aurora global databases are designed for applications with a global footprint. A single Aurora database spans multiple AWS Regions with as many as five secondary Regions. Aurora global databases provide the following features:

- Physical storage-level replication
- Low-latency global reads
- Fast disaster recovery from Region-wide outages
- Fast cross-Region migrations
- Low replication lag across Regions
- Little-to-no performance impact on your database

For more information about Aurora global database features and advantages, see Using Amazon Aurora global databases. For more information about unplanned and managed failovers, see Using failover in an Amazon Aurora global database.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Java Database Connectivity (JDBC) PostgreSQL driver for application connectivity
- An Aurora global database based on Amazon Aurora PostgreSQL-Compatible Edition
- An Oracle Real Application Clusters (RAC) database migrated to the Aurora global database based on Aurora PostgreSQL–Compatible

Limitations of Aurora global databases

- Aurora global databases aren't available in all AWS Regions. For a list of supported Regions, see Aurora global databases with Aurora PostgreSQL.
- For information about features that aren't supported and other limitations of Aurora global databases, see the Limitations of Amazon Aurora global databases.

Product versions

- Amazon Aurora PostgreSQL–Compatible Edition version 10.14 or later

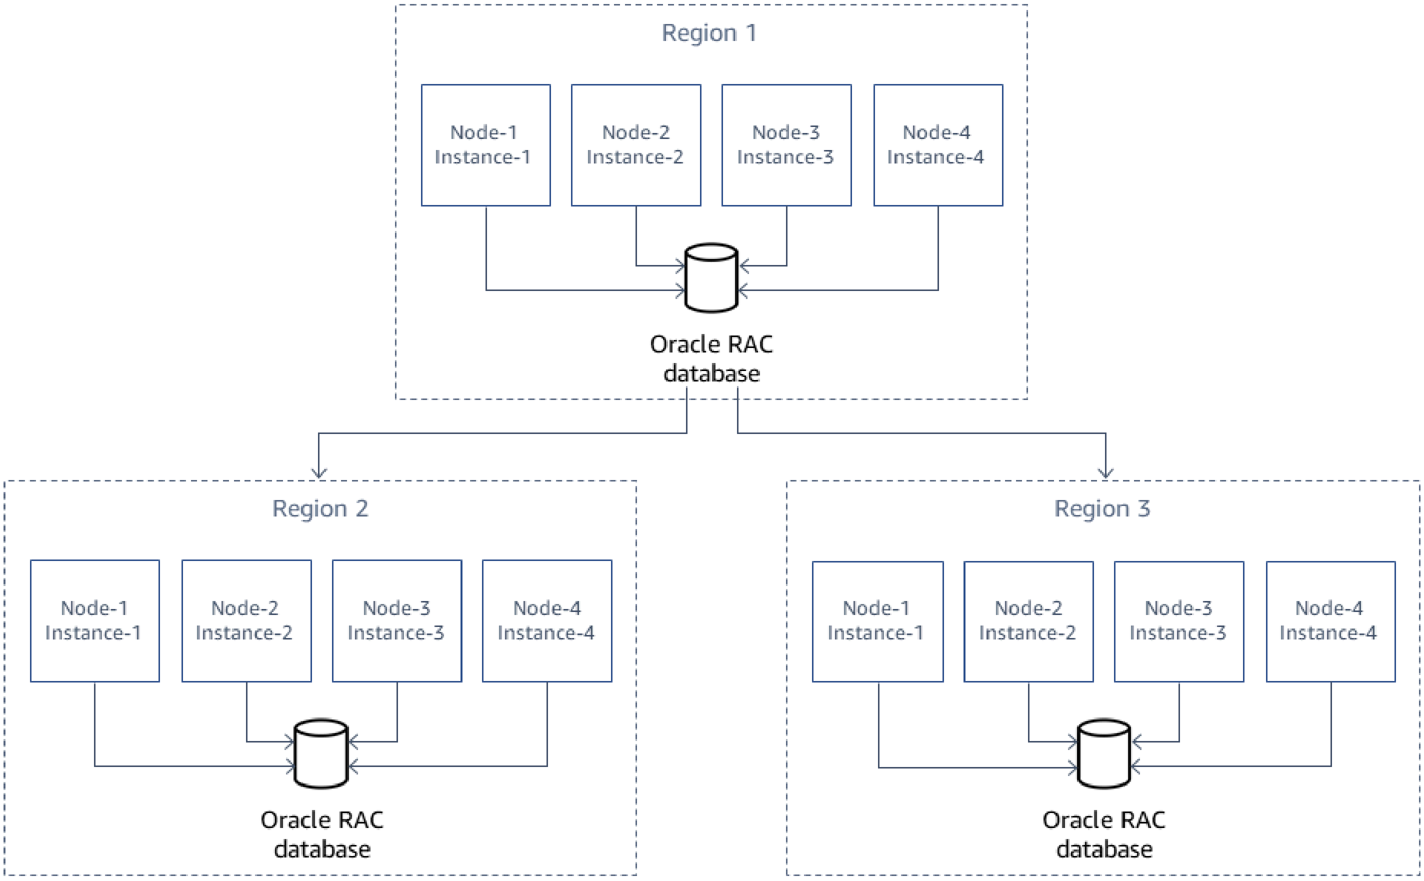
Architecture

Source technology stack

- Oracle RAC four-node database
- Oracle GoldenGate

Source architecture

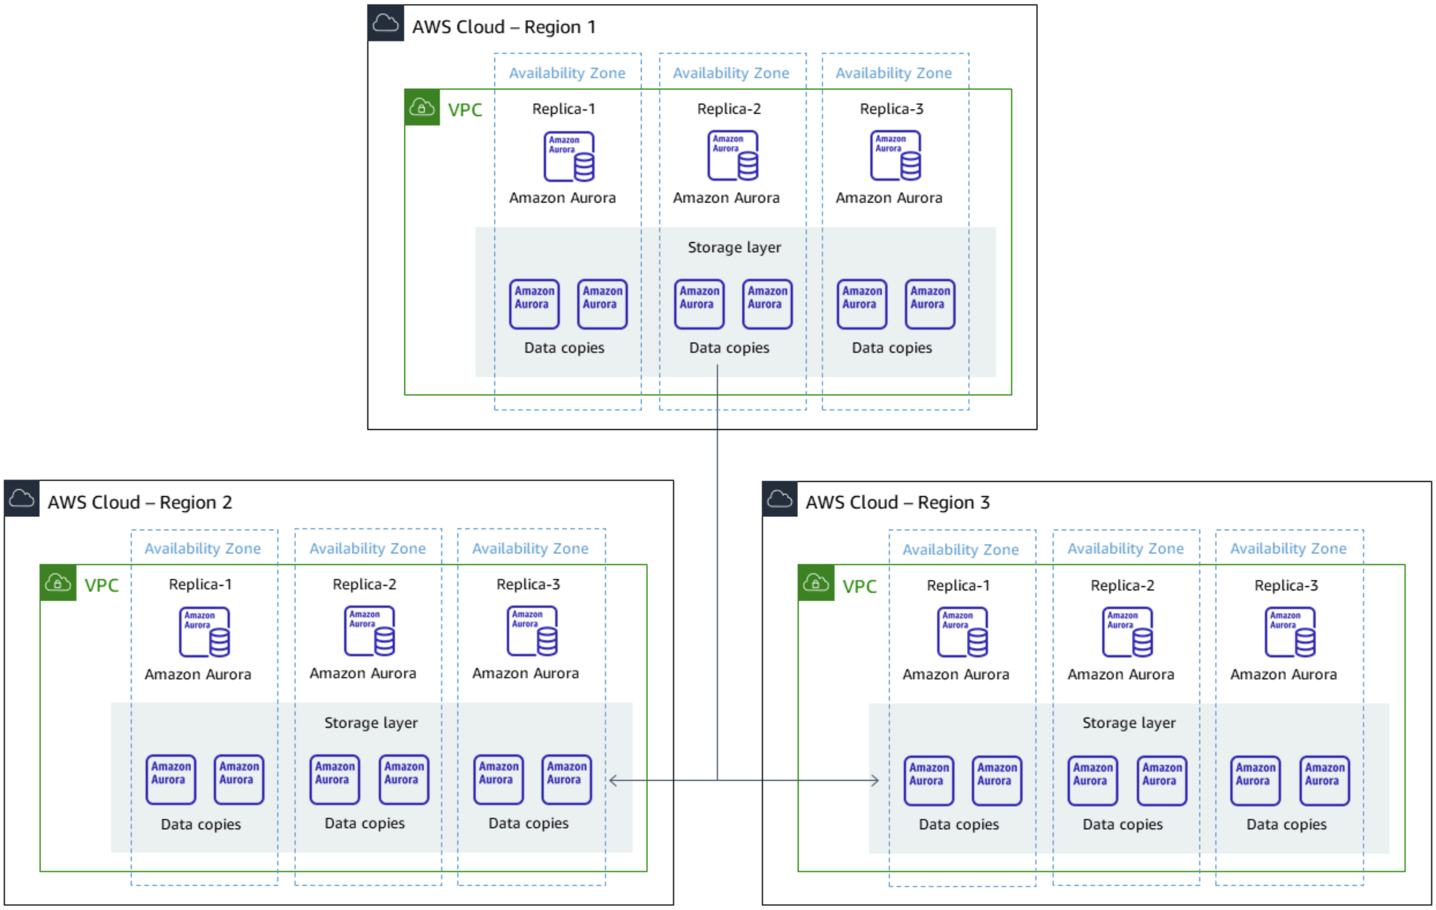
The following diagram shows three clusters with four-node Oracle RAC in different AWS Regions replicated using Oracle GoldenGate.



Target technology stack

- A three-cluster Amazon Aurora global database based on Aurora PostgreSQL–Compatible, with one cluster in the primary Region, two clusters in different secondary Regions

Target architecture



Tools

AWS services

- [Amazon Aurora PostgreSQL-Compatible Edition](#) is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [Amazon Aurora global databases](#) span multiple AWS Regions, providing low latency global reads and fast recovery from the rare outage that might affect an entire AWS Region.

Epics

Add Regions with reader DB instances

Task	Description	Skills required
Attach one or more secondary Aurora clusters.	On the AWS Managemen t Console, choose Amazon	DBA

Task	Description	Skills required
	Aurora. Select the primary cluster, choose **Actions**, and choose **Add region** from the dropdown list.	
Select the instance class.	You can change the instance class of the secondary cluster. However, we recommend keeping it the same as the primary cluster instance class.	DBA
Add the third Region.	Repeat the steps in this epic to add a cluster in the third Region.	DBA

Fail over the Aurora global database

Task	Description	Skills required
Remove the primary cluster from the Aurora global database.	1. On the Databases page, choose the primary cluster. 2. Choose **Remove from Global** to fail over to a secondary cluster.	DBA
Reconfigure your application to divert write traffic to the newly promoted cluster.	Modify the endpoint in the application with that of the newly promoted cluster.	DBA
Stop issuing any write operations to the unavailable cluster.	Stop the application and any data manipulation language (DML) activity to the cluster that you removed.	DBA
Create a new Aurora global database.	Now you can create an Aurora global database with the	DBA

Task	Description	Skills required
	newly promoted cluster as the primary cluster.	

Start the primary cluster

Task	Description	Skills required
Select the primary cluster to be started from the global database.	On the Amazon Aurora console, in the Global Database setup, choose the primary cluster.	DBA
Start the cluster.	On the **Actions** dropdown list, choose **Start**. This process might take some time. Refresh the screen to see the status, or check the **Status** column for the current state of the cluster after the operation is completed.	DBA

Clean up the resources

Task	Description	Skills required
Delete the remaining secondary clusters.	After the failover pilot is completed, remove the secondary clusters from the global database.	DBA
Delete the primary cluster.	Remove the cluster.	DBA

Implement SHA1 hashing for PII data when migrating from SQL Server to PostgreSQL

Rajkumar Raghuwanshi and Jagadish Kantubugata, Amazon Web Services

Summary

This pattern describes how to implement Secure Hash Algorithm 1 (SHA1) hashing for email addresses when migrating from SQL Server to either Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL-Compatible. An email address is an example of *personally identifiable information* (PII). PII is information that, when viewed directly or paired with other related data, can be used to reasonably infer the identity of an individual.

This pattern covers the challenges of maintaining consistent hash values across different database collations and character encodings, and provides a solution using PostgreSQL functions and triggers. Although this pattern focuses on SHA1 hashing, it can be adapted for other hashing algorithms supported by PostgreSQL's `pgcrypto` module. Always consider the security implications of your hashing strategy and consult with security experts if handling sensitive data.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Source SQL Server database
- Target PostgreSQL database (Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible)
- PL/pgSQL coding expertise

Limitations

- This pattern requires database-level collation changes based on use cases.
- The performance impact on large datasets has not been evaluated.
- Some AWS services aren't available in all AWS Regions. For Region availability, see AWS Services by Region. For specific endpoints, see Service endpoints and quotas, and choose the link for the service.

Product versions

- Microsoft SQL Server 2012 or later

Architecture

Source technology stack

- SQL Server
- .NET Framework

Target technology stack

- PostgreSQL
- `pgcrypto` extension

Automation and scale

- Consider implementing the hashing function as a stored procedure for easier maintenance.
- For large datasets, evaluate performance and consider batch processing or indexing strategies.

Tools

AWS services

- [Amazon Aurora PostgreSQL-Compatible] is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- [AWS Database Migration Service (AWS DMS)] helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Relational Database Service Amazon RDS for PostgreSQL] helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- [AWS Schema Conversion Tool (AWS SCT)] supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

Other tools

- pgAdmin is an open source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
- SQL Server Management Studio (SSMS) is an integrated environment for managing any SQL infrastructure.

Best practices

- Use appropriate collation settings for handling special characters on the target database side.
- Test thoroughly with a variety of email addresses, including addresses with non-ASCII characters.
- Maintain consistency in uppercase and lowercase handling between the application and database layers.
- Benchmark performance of queries using the hashed values.

Epics

Analyze source hashing implementation

Task	Description	Skills required
Review SQL Server code.	To review SQL Server code that generates SHA1 hashes, do the following: • Analyze the existing SQL Server implementation of SHA1 hashing. • Identify the exact methods used for hash generation. • Document the input parameters and output format. • Review any data type conversions or transform ations.	Data engineer, DBA, App developer

Task	Description	Skills required
	• Examine collation settings and their impact.	
Document the hashing algorithm and data transform ations.	To document the exact hashing algorithm and data transformations, do the following: • Create detailed technical documentation of the hashing process. • Document the step-by-step transformation logic. • Specify input and output formats and data types. • Include edge cases and special character handling.	App developer, Data engineer, DBA

Create PostgreSQL hashing function

Task	Description	Skills required
Create `pgcrypto` extension.	To create the `pgcrypto` extension, use `pgAdmin/psql` to run the following command: `CREATE EXTENSION pgcrypto;`	DBA, Data engineer
Implement a PostgreSQL function.	Implement the following PostgreSQL function to replicate the SQL Server hashing logic. At a high	Data engineer, DBA, App developer

Task	Description	Skills required

	level, this function uses the following steps:
	
	1. Optionally converts the input to uppercase.
	2. Creates an SHA1 hash of the input.
	3. Takes the last 10 bytes (80 bits) of this hash.
	4. Converts these bytes to a 64-bit integer.
	
	`CREATE OR REPLACE FUNCTION utility.hex_to_bigint (`
	`     par_val character varying,`
	`     par_upper character varying DEFAULT 'lower'::character varying)`
	`RETURNS bigint`
	`LANGUAGE 'plpgsql'`
	`AS $BODY$`
	`DECLARE`
	`    retnumber bigint;`
	`    digest_bytes bytea;`
	`BEGIN`
	`    if lower(par_upper) = 'upper'`
	`    then`
	`        digest_bytes := digest(upper(par_val), 'sha1');`
	`    else`
	`        digest_bytes := digest((par_val), 'sha1');`	

Task	Description	Skills required

	``
	    end if;
	    retnumber := ('x'
	 || encode(substring(d
	igest_bytes, length(di
	gest_bytes)-10+1),
	 'hex'))::bit(64)::
	bigint;
	    RETURN retnumber;
	END;
	$BODY$;
	``	

Test the function.	To test the function, use sample data from SQL Server to verify matching hash values. Run the following command: ``` select 'alejandr o_rosalez@example. com' as Email, utility.hex_to_big int('alejandro_ros alez@example.com', 'upper') as HashValue; --OUTPUT /* email hashvalue "alejandro_rosale z@example.com" 451 397011176045063 */ ```	App developer, DBA, Data engineer

Implement triggers for automatic hashing

Task	Description	Skills required

Create triggers on relevant tables.	To create triggers on relevant tables to automatically generate hash values on insert or update, run the following command:
	`CREATE OR REPLACE FUNCTION update_email_hash() RETURNS TRIGGER AS $$ BEGIN NEW.email_hash = utility.hex_to_bigint(NEW.email, 'upper'); RETURN NEW; END; $$ LANGUAGE plpgsql;`
	`CREATE TRIGGER email_hash_trigger BEFORE INSERT OR UPDATE ON users FOR EACH ROW EXECUTE FUNCTION update_email_hash();`
		App developer, Data engineer, DBA

Migrate existing data

Task	Description	Skills required
Develop a migration script or use AWS DMS.	Develop a migration script or use AWS DMS to populate hash values for existing	Data engineer, App developer , DBA

Task	Description	Skills required
	data (including hash values stored as `BIGINT` in the source system.) Complete the following tasks: • Create migration scripts for data transfer with hash values. • Configure AWS DMS tasks with appropriate transformation rules. • Set up source and target endpoints in AWS DMS. • Implement error handling and logging mechanisms. • Design a batch processing strategy for large datasets. • Create validation queries for data verification.	
Use the new PostgreSQL hashing function.	To use the new PostgreSQL hashing function to ensure consistency, do the following: • Implement validation procedures to verify hash consistency. • Create comparison scripts between the source and target systems. • Set up automated testing for hash value verification. • Document any discrepancies and resolution steps.	App developer, DBA, DevOps engineer

Update application queries

Task	Description	Skills required
Identify application queries.	To identify application queries that use hashed values, do the following: • Analyze the application codebase for queries using hash values. • Review stored procedure s and functions that reference hash operations. • Document query performan ce metrics and execution plans. • Identify dependencies on hash-based lookups. • Map out affected applicati on components.	App developer, DBA, Data engineer
Modify queries.	If necessary, modify queries to use the new PostgreSQ L hashing function. Do the following: • Refactor existing queries to use the PostgreSQL hashing function. • Update stored procedures and functions. • Implement and test new query patterns. • Optimize modified queries for performance.	App developer, DBA, Data engineer

Test and validate

Task	Description	Skills required
Perform testing.	To perform thorough testing with a subset of production data, do the following: • Create a test plan for data subset validation. • Extract representative sample of production data. • Set up a test environment with proper configurations. • Execute data loading and transformation tests. • Perform volume and stress testing.	App developer, Data engineer, DBA
Validate that hash values match.	To validate that hash values match between SQL Server and PostgreSQL, do the following: • Develop comparison scripts for hash values. • Create validation reports for hash matching. • Implement automated verification procedures. • Document any discrepan cies found. • Analyze and resolve hash mismatches.	App developer, Data engineer, DBA

Task	Description	Skills required
Verify application functiona lity.	To verify application functionality by using the migrated data and the new hashing implementation, do the following: • Execute end-to-end application testing. • Validate all application features using hashed data. • Test application performan ce with the new implement ation. • Verify API integrations and dependencies.	App developer, DBA, Data engineer

Troubleshooting

Issue	Solution
Hash values don't match.	Verify character encodings and collation s between source and target. For more information, see Manage collation changes in PostgreSQL on Amazon Aurora and Amazon RDS (AWS Blog).

Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT

Pinesh Singal, Amazon Web Services

Summary

Many migration strategies and approaches run in multiple phases that can last from a few weeks to several months. During this time, you can experience delays because of patching or upgrades in the source Oracle DB instances that you want to migrate to PostgreSQL DB instances. To avoid this situation, we recommend that you incrementally migrate the remaining Oracle database code to PostgreSQL database code.

This pattern provides an incremental migration strategy with no downtime for a multi-terabyte Oracle DB instance that has a high number of transactions performed after your initial migration and that must be migrated to a PostgreSQL database. You can use this pattern's step-by-step approach to incrementally migrate an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance without signing in to the Amazon Web Services (AWS) Management Console.

The pattern uses Oracle SQL Developer to find the differences between two schemas in the source Oracle database. You then use AWS Schema Conversion Tool (AWS SCT) to convert the Amazon RDS for Oracle database schema objects to Amazon RDS for PostgreSQL database schema objects. You can then run a Python script in the Windows Command Prompt to create AWS SCT objects for the incremental changes to the source database objects.

> **Note**
>
> Before you migrate your production workloads, we recommend that you run a proof of concept (PoC) for this pattern's approach in a testing or non-production environment.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon RDS for Oracle DB instance.
- An existing Amazon RDS for PostgreSQL DB instance.

- AWS SCT, installed and configured with JDBC drivers for Oracle and PostgreSQL database engines. For more information about this, see Installing AWS SCT and Installing the required database drivers in the AWS SCT documentation.
- Oracle SQL Developer, installed and configured. For more information about this, see the Oracle SQL Developer documentation.
- The `incremental-migration-sct-sql.zip` file (attached), downloaded to your local computer.

Limitations

- The minimum requirements for your source Amazon RDS for Oracle DB instance are:
  - Oracle versions 10.2 and later (for versions 10.x), 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c for the Enterprise, Standard, Standard One, and Standard Two editions
- The minimum requirements for your target Amazon RDS for PostgreSQL DB instance are:
  - PostgreSQL versions 9.4 and later (for versions 9.x), 10.x, and 11.x
- This pattern uses Oracle SQL Developer. Your results might vary if you use other tools to find and export schema differences.
- The SQL scripts generated by Oracle SQL Developer can raise transformation errors, which means that you need to perform a manual migration.
- If the AWS SCT source and target test connections fail, make sure that you configure the JDBC driver versions and inbound rules for the virtual private cloud (VPC) security group to accept incoming traffic.

Product versions

- Amazon RDS for Oracle DB instance version 12.1.0.2 (version 10.2 and later)
- Amazon RDS for PostgreSQL DB instance version 11.5 (version 9.4 and later)
- Oracle SQL Developer version 19.1 and later
- AWS SCT version 1.0.632 and later

Architecture

Source technology stack

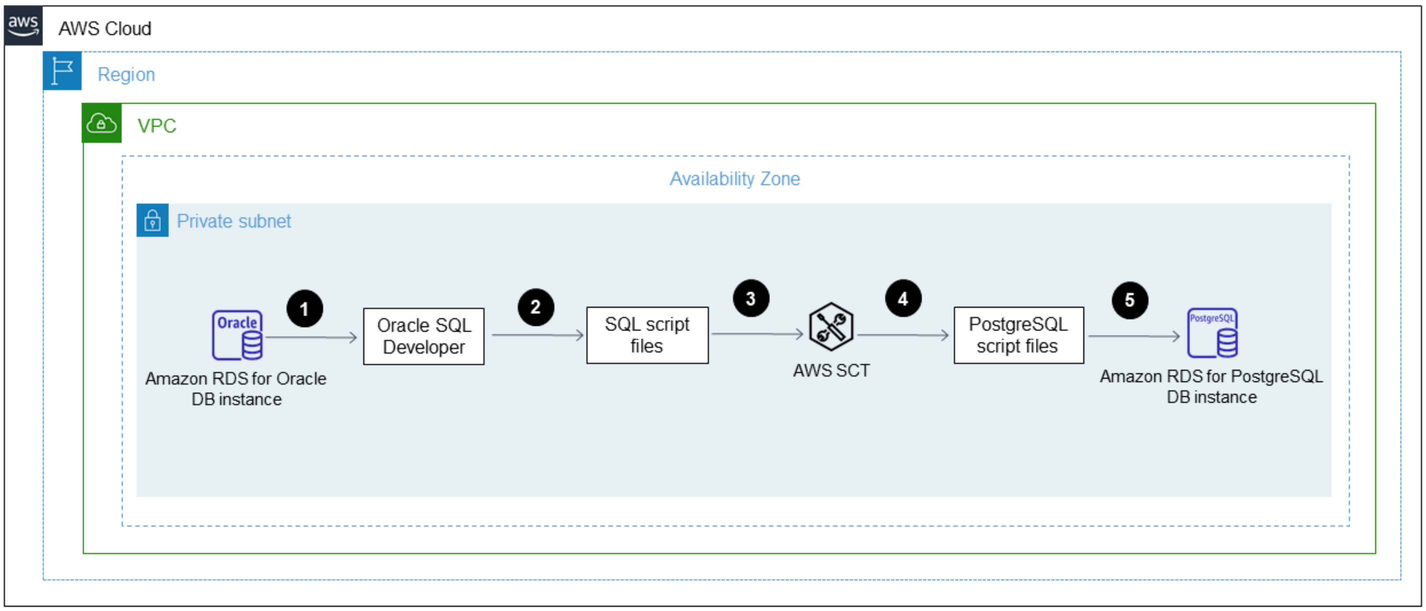
- Amazon RDS for Oracle DB instance

Target technology stack

- Amazon RDS for PostgreSQL DB instance

Source and target architecture

The following diagram shows the migration of an Amazon RDS for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance.



The diagram shows the following migration workflow:

1. Open Oracle SQL Developer and connect to the source and target databases.
2. Generate a diff report and then generate the SQL scripts file for the schema difference objects. For more information about diff reports, see Detailed diff reports in the Oracle documentation.
3. Configure AWS SCT and run the Python code.
4. The SQL scripts file converts from Oracle to PostgreSQL.
5. Run the SQL scripts file on the target PostgreSQL DB instance.

Automation and scale

You can automate this migration by adding additional parameters and security-related changes for multiple functionalities in a single program to your Python script.

Tools

- [AWS SCT](#) – AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another.
- [Oracle SQL Developer](#) – Oracle SQL Developer is an integrated development environment (IDE) that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.

Code

The `incremental-migration-sct-sql.zip` file (attached) contains the complete source code for this pattern.

Epics

Create the SQL scripts file for the source database schema differences

Task	Description	Skills required
Run Database Diff in Oracle SQL Developer.	1. Sign in to your source Oracle DB instance, choose **Tools**, and then choose **Database Diff**. 2. Choose your source database in **Source Connection**. 3. Choose the updated or patched source database in **Destination Connection**. 4. Configure the remaining options according to your requirements, choose **Next**, and then choose **Finish** to generate the diff report.	DBA
Generate the SQL scripts file.	Choose **Generate Script** to generate the differences in the SQL files.	DBA

Task	Description	Skills required
	This generates the SQL scripts file that AWS SCT uses to convert your database from Oracle to PostgreSQL.	

Use the Python script to create the target DB objects in AWS SCT

Task	Description	Skills required
Configure AWS SCT with the Windows Command Prompt.	1. Copy the `AWSSchemaConversionToolBatch.jar` file from your pre-installed AWS SCT folder and paste it into your working directory. 2. Deploy the Python code from the `run_aws_sct_sql.py` file from the `incremental-migration-sct-sql.zip` folder (attached). This creates .xml files and .sct files in the `projects` directory with your source and target database environment configuration details. It also reads the SQL scripts file that you generated in Oracle SQL Developer. Finally, it creates .sql file objects in the `output` directory.	DBA

Task	Description	Skills required

	3. Configure the source and target environment configuration details in the `database_migration.txt` file by using the following format:
	
	`#source_vendor,source_hostname,source_dbname,source_user,source_pwd,source_schema,source_port,source_sid,target_vendor,target_hostname,target_user,target_pwd,target_dbname,target_port`
	
	`ORACLE,myoracledb.cokmvis0v46q.us-east-1.rds.amazonaws.com,ORCL,orcl,orcl1234,orcl,1521,ORCL,POSTGRESQL,mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com,pguser,pgpassword,pgdb,5432`
	
	4. Modify the AWS SCT configuration parameters according to your requirements and then copy the SQL scripts file into your working directory in the `input` subdirectory.	

Task	Description	Skills required
Run the Python script.	1. Run the Python script by using the following command: `$ python run_aws_sct_sql.py database_migration .txt` 2. This creates the DB objects SQL file. Non-converted codes with transformation errors can be manually converted.	DBA
Create the objects in Amazon RDS for PostgreSQL	Run the SQL files and create objects in your Amazon RDS for PostgreSQL DB instance.	DBA

Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible

Bhanu Ganesh Gudivada and Jeevan Shetty, Amazon Web Services

Summary

Often during migration, there are cases where you have to process unstructured and structured data that is loaded from files on a local file system. The data might also be in a character set that differs from the database character set.

These files hold the following types of data:

- **Metadata –** This data describes the file structure.
- **Semi-structured data –** These are textual strings in a specific format, such as JSON or XML. You might be able to make assertions about such data, such as "will always start with '<' " or "does not contain any newline characters."
- **Full text –** This data usually contains all types of characters, including newline and quote characters. It might also consist of multibyte characters in UTF-8.
- **Binary data –** This data might contain bytes or combinations of bytes including, nulls and end-of-file markers.

Loading a mixture of these types of data can be a challenge.

The pattern can be used with on-premises Oracle databases , Oracle databases that are on Amazon Elastic Compute Cloud (Amazon EC2) instances on the Amazon Web Services (AWS) Cloud, and Amazon Relational Database Service (Amazon RDS) for Oracle databases. As an example, this pattern is using Amazon Aurora PostgreSQL-Compatible Edition.

In Oracle Database, with the help of a `BFILE` (binary file) pointer, the `DBMS_LOB` package, and Oracle system functions, you can load from file and convert to CLOB with character encoding. Because PostgreSQL does not support the BLOB data type when migrating to an Amazon Aurora PostgreSQL-Compatible Edition database, these functions must be converted to PostgreSQL-compatible scripts.

This pattern provides two approaches for loading a file into a single database column in an Amazon Aurora PostgreSQL-Compatible database:

- Approach 1 – You import data from your Amazon Simple Storage Service (Amazon S3) bucket by using the `table_import_from_s3` function of the `aws_s3` extension with the encode option.
- Approach 2 – You encode to hexadecimal outside of the database, and then you decode to view `TEXT` inside the database.

We recommend using Approach 1 because Aurora PostgreSQL-Compatible has direct integration with the `aws_s3` extension.

This pattern uses the example of loading a flat file that contains an email template, which has multibyte characters and distinct formatting, into an Amazon Aurora PostgreSQL-Compatible database.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS instance or an Aurora PostgreSQL-Compatible instance
- A basic understanding of SQL and Relational Database Management System (RDBMS)
- An Amazon Simple Storage Service (Amazon S3) bucket.
- Knowledge of system functions in Oracle and PostgreSQL
- RPM Package HexDump-XXD-0.1.1 (included with Amazon Linux 2)

> **Note**
>
> Amazon Linux 2 is nearing end of support. For more information, see the [Amazon Linux 2 FAQs](#).

Limitations

- For the `TEXT` data type, the longest possible character string that can be stored is about 1 GB.

Product versions

- Aurora supports the PostgreSQL versions listed in [Amazon Aurora PostgreSQL updates](#).

Architecture

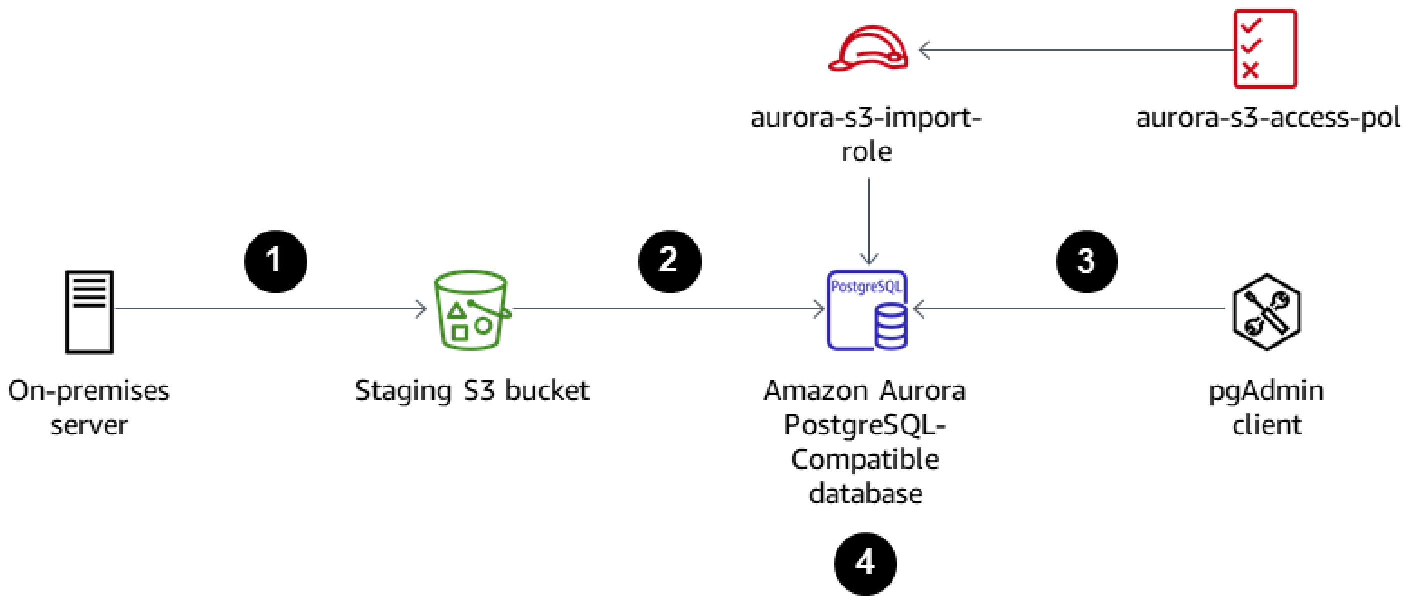
Target technology stack

- Aurora PostgreSQL-Compatible

Target architecture

Approach 1 – Using aws_s3.table_import_from_s3

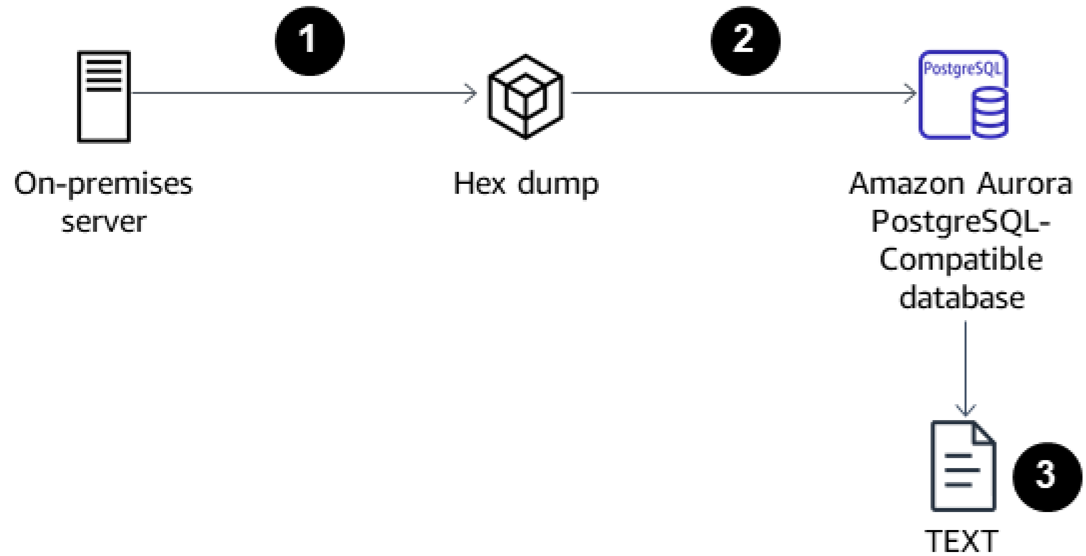
From an on-premises server, a file containing an email template with multibyte characters and custom formatting is transferred to Amazon S3. The custom database function provided by this pattern uses the `aws_s3.table_import_from_s3` function with `file_encoding` to load files into the database and return query results as the TEXT data type.



1. Files are transferred to the staging S3 bucket.
2. Files are uploaded to the Amazon Aurora PostgreSQL-Compatible database.
3. Using the pgAdmin client, the custom function `load_file_into_clob` is deployed to the Aurora database.
4. The custom function internally uses `table_import_from_s3` with file_encoding. The output from the function is obtained by using `array_to_string` and `array_agg` as TEXT output.

Approach 2 – Encoding to hexadecimal outside of the database and decoding to view TEXT inside the database

A file from an on-premises server or a local file system is converted into a hex dump. Then the file is imported into PostgreSQL as a TEXT field.



1. Convert the file to a hex dump in the command line by using the `xxd -p` option.
2. Upload the hex dump files into Aurora PostgreSQL-Compatible by using the `\copy` option, and then decode the hex dump files to binary.
3. Encode the binary data to return as TEXT.

Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Other tools

- pgAdmin4 is an open source administration and development platform for PostgreSQL. pgAdmin4 can be used on Linux, Unix, mac OS, and Windows to manage PostgreSQL.

Epics

Approach 1: Import data from Amazon S3 to Aurora PostgreSQL-Compatible

Task	Description	Skills required
Launch an EC2 instance.	For instructions on launching an instance, see [Launch your instance]().	DBA
Install the PostgreSQL client pgAdmin tool.	Download and install [pgAdmin]().	DBA

Create an IAM policy.	Create an AWS Identity and Access Management (IAM) policy named `aurora-s3-access-pol` that grants access to the S3 bucket where the files will be stored. Use the following code, replacing <bucket-name> with the name of your S3 bucket.
	`{`
	`    "Version": "2012-10-17",`
	`    "Statement": [`
	`        {`
	`            "Effect": "Allow",`
	`            "Action": [`
	`                "s3:GetObject",`
	`                "s3:AbortMultipartUpload",`
	`                "s3:DeleteObject",`
	`                "s3:ListMultipartUploadParts",`
		DBA

Task	Description	Skills required

	<pre>"s3:PutObject",
	
	"s3:ListBucket"
	            ],
	            "Resource":
	[
	
	"arn:aws:s3:::<buc
	ket-name>/*",
	
	"arn:aws:s3:::<buc
	ket-name>"
	            ]
	        }
	    ]
	}</pre>	

Task	Description	Skills required
Create an IAM role for object import from Amazon S3 to Aurora PostgreSQL-Compatible.	Use the following code to create an IAM role named `aurora-s3-import-role` with the [AssumeRole](https://docs.aws.amazon.com/STS/latest/APIReference/API_AssumeRole.html) trust relationship. `AssumeRole` allows Aurora to access other AWS services on your behalf. `{ "Version": "2012-10-17", "Statement": [ { "Effect": "Allow","Principal": { "Service": "rds.amazonaws.com" },"Action": "sts:AssumeRole" } ] }`	DBA

<table>
<tr><th>Task</th><th>Description</th><th>Skills required</th></tr>
<tr><td>Associate the IAM role to the cluster.</td><td>To associate the IAM role with the Aurora PostgreSQL-Compatible database cluster, run the following AWS CLI command. Change <code><Account-ID></code> to the ID of the AWS account that hosts the Aurora PostgreSQL-Compatible database. This enables the Aurora PostgreSQL-Compatible database to access the S3 bucket.

<pre><code>aws rds add-role-to-db-cluster --db-cluster-identifier aurora-postgres-cl
--feature-name s3Import
 --role-arn arn:aws:iam::<Account-ID>:role/aurora-s3-import-role</code></pre></td><td>DBA</td></tr>
<tr><td>Upload the example to Amazon S3.</td><td>1. In the Additional information section of this pattern, copy the email template code into a file named <code>salary.event.notification.email.vm</code>.
2. Upload to the file to the S3 bucket.</td><td>DBA, App owner</td></tr>
</table>

Task	Description	Skills required
Deploy the custom function.	1. From the *Additional information* section, copy the custom function `load_file_into_clob` SQL file content into a temporary table. 2. Log in to the Aurora PostgreSQL-Compatible database and deploy it into the database schema by using the pgAdmin client.	App owner, DBA

Task	Description	Skills required

Run the custom function for importing the data into the database.	Run the following SQL command, replacing the items in angle brackets with the appropriate values.
	`select load_file _into_clob('aws-s3 -import-test'::tex t,'us-west-1'::tex t,'employee.salary .event.notificatio n.email.vm'::text);`
	Replace the items in angle brackets with the appropria te values, as shown in the following example, before running the command.
	`Select load_file _into_clob('aws-s3 -import-test'::tex t,'us-west-1'::tex t,'employee.salary .event.notificatio n.email.vm'::text);`
	The command loads the file from Amazon S3 and returns the output as TEXT.
		App owner, DBA

Approach 2: Convert the template file into a hex dump in a local Linux system

Task	Description	Skills required
Convert the template file into a hex dump.	**Note** The Hexdump utility displays the contents of binary files in hexadecimal, decimal, octal, or ASCII. The `hexdump` command is part of the `util-linux` package and comes pre-installed in Linux distributions. The Hexdump RPM package is part of Amazon Linux 2 as well. (: Amazon Linux 2 is nearing end of support. For more information, see the Amazon Linux 2 FAQs.) To convert the file contents into a hex dump, run the following shell command. `xxd -p </path/file.vm> | tr -d '\n' > </path/file.hex>` Replace the path and file with the appropriate values,	DBA

Task	Description	Skills required
	as shown in the following example. ``` xxd -p employee.salary.event.notification.email.vm | tr -d '\n' > employee.salary.event.notification.email.vm.hex ```	

Task	Description	Skills required

Load the hexdump file into the database schema.	Use the following commands to load the hexdump file into the Aurora PostgreSQL-Compatible database.
	
	1. Log in to Aurora PostgreSQL database, and create a new table called `email_template_hex` .
	`CREATE TABLE email_template_hex(hex_data TEXT);`
	2. Load the files from the local file system into the DB schema by using the following command.
	`\copy email_template_hex FROM '/path/file.hex';`
	Replace the path with the location on your local file system.
	`\copy email_template_hex FROM '/tmp/employee.salary.event.notification.email.vm.hex';`
	3. Create one more table called `email_template_bytea` .
		DBA

Task	Description	Skills required
	``` CREATE TABLE email_template_bytea(hex_data bytea); ``` 4. Insert the data from `email_template_hex` into `email_template_bytea` . ``` INSERT INTO email_template_bytea (hex_data) (SELECT decode(hex_data, 'hex') FROM email_template_hex limit 1); ``` 5. To return hex bytea code as TEXT data, run the following command. ``` SELECT encode(hex_data::bytea, 'escape') FROM email_template_bytea; ```

Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation

Pinesh Singal, Amazon Web Services

Summary

This pattern shows how to migrate a multi-terabyte Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance by using the AWS Command Line Interface (AWS CLI). The approach provides minimal downtime and doesn't require signing in to the AWS Management Console.

This pattern helps avoid manual configurations and individual migrations by using the AWS Schema Conversion Tool (AWS SCT) and AWS Database Migration Service (AWS DMS) consoles. The solution sets up a one-time configuration for multiple databases and performs the migrations by using AWS SCT and AWS DMS in the AWS CLI.

The pattern uses AWS SCT to convert database schema objects from Amazon RDS for Oracle to Amazon RDS for PostgreSQL, and then uses AWS DMS to migrate the data. Using Python scripts in AWS CLI, you create AWS SCT objects and AWS DMS tasks with an AWS CloudFormation template.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon RDS for Oracle DB instance.
- An existing Amazon RDS for PostgreSQL DB instance.
- An Amazon Elastic Compute Cloud (Amazon EC2) instance or local machine with Windows or Linux OS for running scripts.
- An understanding of the following AWS DMS migration task types: `full-load`, `cdc`, `full-load-and-cdc`. For more information, see Creating a task in the AWS DMS documentation.
- AWS SCT, installed and configured with Java Database Connectivity (JDBC) drivers for Oracle and PostgreSQL database engines. For more information, see Installing and configuring AWS SCT in the AWS SCT documentation.
- The `AWSSchemaConversionToolBatch.jar` file from the installed AWS SCT folder, copied to your working directory.

- The `cli-sct-dms-cft.zip` file (attached), downloaded and extracted in your working directory.
- The most recent AWS DMS replication instance engine version. For more information, see [How do I create an AWS DMS replication instance](#) in the AWS Support documentation and [AWS DMS release notes](#).
- AWS CLI version 2, installed and configured with your access key ID, secret access key, and default AWS Region name for the EC2 instance or OS where the scripts are run. For more information, see [Installing or updating to the latest version of the AWS CLI](#) and [Configuring settings for the AWS CLI](#) in the AWS CLI documentation.
- Familiarity with AWS CloudFormation templates. For more information, see [How AWS CloudFormation works](#) in the AWS CloudFormation documentation.
- Python version 3, installed and configured on the EC2 instance or OS where the scripts are run. For more information, see the [Python documentation](#).

Limitations

- The minimum requirements for your source Amazon RDS for Oracle DB instance are:
  - Oracle versions 12c (12.1.0.2, 12.2.0.1), 18c (18.0.0.0), and 19c (19.0.0.0) for the Enterprise, Standard, Standard One, and Standard Two editions.
  - Although Amazon RDS supports Oracle 18c (18.0.0.0), this version is on a deprecation path because Oracle no longer provides patches for 18c after the end-of-support date. For more information, see [Amazon RDS for Oracle](#) in the Amazon RDS documentation.
  - Amazon RDS for Oracle 11g is no longer supported.
- The minimum requirements for your target Amazon RDS for PostgreSQL DB instance are:
  - PostgreSQL versions 9 (9.5 and 9.6), 10.x, 11.x, 12.x, and 13.x

Product versions

- Amazon RDS for Oracle DB instance version 12.1.0.2 and later
- Amazon RDS for PostgreSQL DB instance version 11.5 and later
- AWS CLI version 2
- The latest version of AWS SCT
- The latest version of Python 3

Architecture

Source technology stack

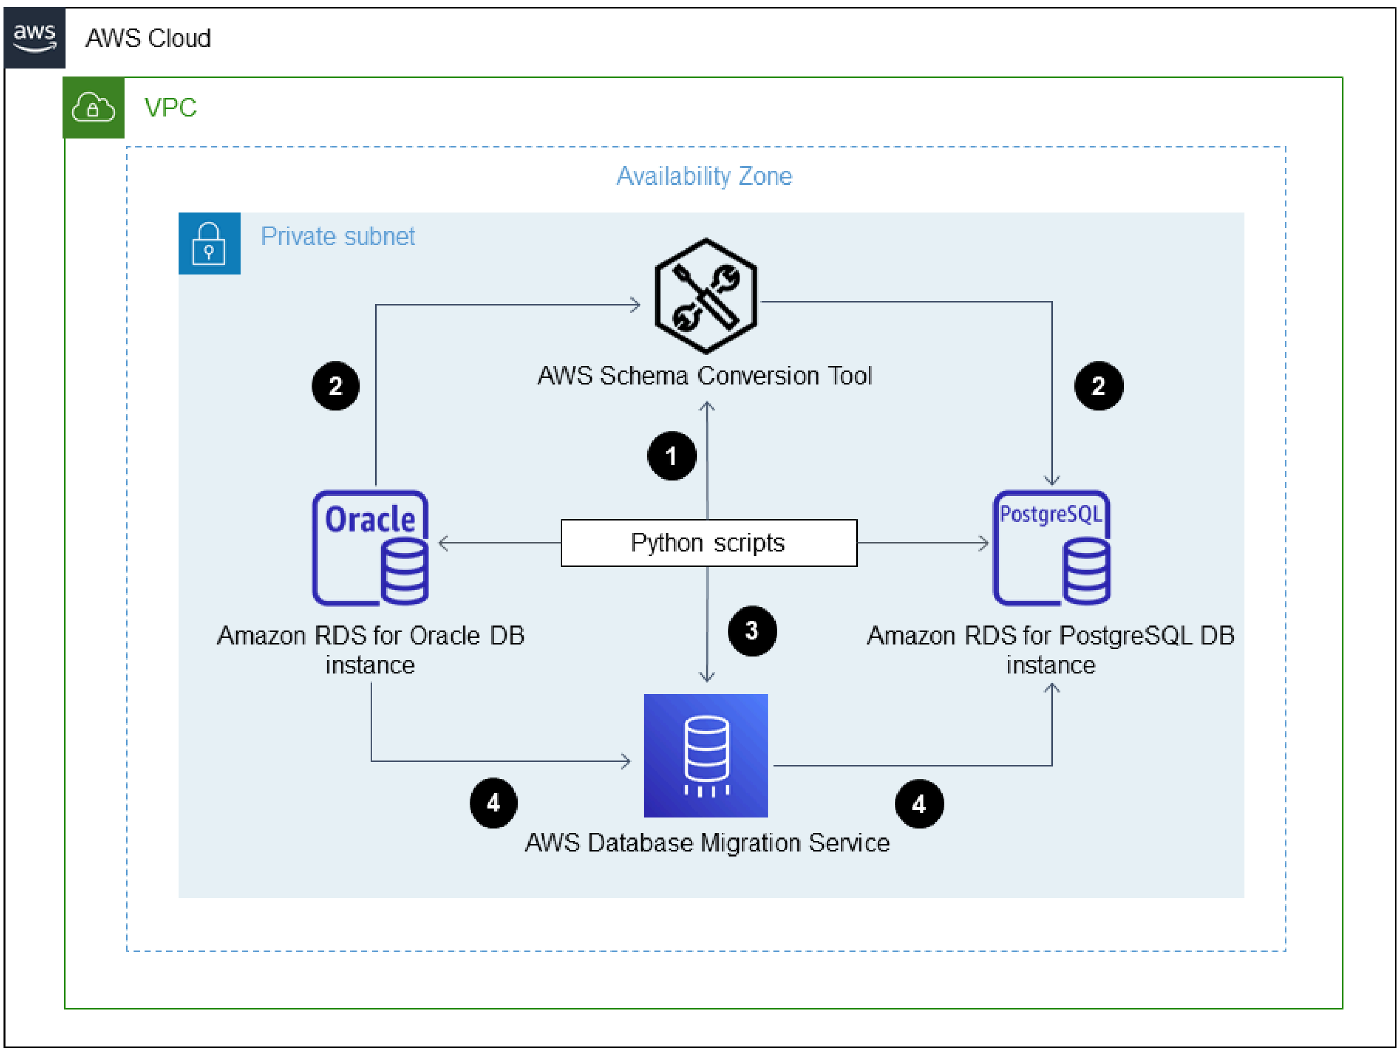
- Amazon RDS for Oracle

Target technology stack

- Amazon RDS for PostgreSQL

Source and target architecture

The following diagram shows the migration of an Amazon RDS for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance using AWS DMS and Python scripts.



The diagram shows the following migration workflow:

1. The Python script uses AWS SCT to connect to the source and target DB instances.
2. The user starts AWS SCT with the Python script, converts the Oracle code to PostgreSQL code, and runs it on the target DB instance.
3. The Python script creates AWS DMS replication tasks for the source and target DB instances.
4. The user deploys Python scripts to start the AWS DMS tasks and then stops the tasks after the data migration is complete.

Automation and scale

You can automate this migration by adding parameters and security-related changes to your Python script, to provide additional functionality.

Tools

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command line shell.
- AWS CloudFormation helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions. This pattern converts the `.csv` input file to a `.json` input file by using a Python script. The `.json` file is used in AWS CLI commands to create an AWS CloudFormation stack that creates multiple AWS DMS replication tasks with Amazon Resource Names (ARNs), migration types, task settings, and table mappings.
- AWS Database Migration Service (AWS DMS) helps you migrate data stores to the AWS Cloud or between combinations of cloud and on-premises setups. This pattern uses AWS DMS to create, start, and stop tasks with a Python script that runs on the command line, and to create the AWS CloudFormation template.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. This patterns requires the `AWSSchemaConversionToolBatch.jar` file from the installed AWS SCT directory.

Code

The `cli-sct-dms-cft.zip` file (attached) contains the complete source code for this pattern.

Epics

Configure AWS SCT and create database objects in the AWS CLI

Task	Description	Skills required

Configure AWS SCT to run from the AWS CLI.	1. Configure the source and target environment configuration details in the `database_migration.txt` file by using the following format:
	 `#source_vendor,source_hostname,source_dbname,source_user,source_pwd,source_schema,source_port,source_sid,target_vendor,target_hostname,target_user,target_pwd,target_dbname,target_port`
	 `ORACLE,myoracledb.cokmvis0v46q.us-east-1.rds.amazonaws.com,ORCL,orcl,orcl1234,orcl,1521,ORCL,POSTGRESQL,mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com,pguser,pgpassword,pgdb,5432`
	 2. Modify the AWS SCT configuration parameters according to your requirements in the following files: `project_s`
		DBA

Task	Description	Skills required
	`ettings.xml` , `Oracle_PG_Test_Batch.xml` , and `ORACLE-orcl-to-POSTGRESQL.xml` .	
Run the `run_aws_sct.py` Python script.	Run the `run_aws_sct.py` Python script by using the following command: `$ python run_aws_sct.py database_migration.txt` The Python script converts the database objects from Oracle to PostgreSQL and creates SQL files in PostgreSQL format. The script also creates the PDF file `Database migration assessment report` , which provides you with detailed recommendations and conversion statistics for database objects.	DBA
Create objects in Amazon RDS for PostgreSQL.	1. Manually modify the SQL files generated by AWS SCT, if required. 2. Run the SQL files and create objects in your Amazon RDS for PostgreSQL DB instance.	DBA

Configure and create AWS DMS tasks by using the AWS CLI and AWS CloudFormation

Task	Description	Skills required
Create an AWS DMS replication instance.	Sign in to the AWS Management Console, open the AWS DMS console, and create a replication instance that is configured according to your requirements. For more information, see Creating a replication instance in the AWS DMS documentation and How do I create an AWS DMS replication instance in the AWS Support documentation.	DBA
Create the source endpoint.	On the AWS DMS console, choose **Endpoints** and then create a source endpoint for the Oracle database according to your requirements. **Note** The extra connection attribute must be `numberDataTypeScale` with a `-2` value. For more information, see Creating source and target	DBA

Task	Description	Skills required
	endpoints in the AWS DMS documentation.	
Create the target endpoint.	On the AWS DMS console, choose **Endpoints** and then create a target endpoint for the PostgreSQL database according to your requireme nts. For more information, see Creating source and target endpoints in the AWS DMS documentation.	DevOps engineer

Task	Description	Skills required
Configure the AWS DMS replication details to run from the AWS CLI.	Configure the AWS DMS source and target endpoints and replication details in the `dms-arn-list.txt` file with the source endpoint ARN, target endpoint ARN, and the replication instance ARN by using the following format: `#sourceARN,targetARN,repARN arn:aws:dms:us-east-1:123456789012:endpoint:EH7AINRUDZ5GOYIY6HVMXECMCQ arn:aws:dms:us-east-1:123456789012:endpoint:HHJVUV57N7O3CQF4PJZKGIOYY5 arn:aws:dms:us-east-1:123456789012:rep:LL57N77AQQAHHJF4PJFHNEDZ5G`	DBA

Task	Description	Skills required
Run the `dms-create-task.py` Python script to create the AWS DMS tasks.	1. Run the `dms-create-task.py` Python script by using the following command: `$ python dms-create-task.py database_migration.txt dms-arn-list.txt <cft-stack-name> <migration-type>` where: • `database_migration.txt` is the database migration text file. • `dms-arn-list.txt` is the ARN list for AWS DMS. • `<cft-stack-name>` is the user-defined AWS CloudFormation stack name. • `<migration-type>` is `full-load`, `cdc`, or `full-load-and-cdc`. 2. Depending on your migration type, you can use the following commands to create three types of AWS DMS tasks: • `$ python dms-create-task.py database_migration`	DBA

Task	Description	Skills required
	.txt dms-arn-l ist.txt dms-cli-c ft-stack full-load • `$ python dms-create-task.py database_migration.txt dms-arn-list.txt dms-cli-cft-stack cdc` • `$ python dms-create-task.py database_migration.txt dms-arn-list.txt dms-cli-cft-stack full-load-and-cdc`	
Verify that AWS DMS tasks are ready.	On the AWS DMS console, check that your AWS DMS tasks are in `Ready` status in the **Status** section.	DBA

Start and stop the AWS DMS tasks by using the AWS CLI

Task	Description	Skills required
Start the AWS DMS tasks.	Run the `dms-start-task.py` Python script by using the following command:	DBA

Task	Description	Skills required
	`$ python dms-start-task.py start '<cdc-start-datetime>'` **Note** The start date and time must be in the `'DD-MON-YYYY'` or `'YYYY-MM-DDTHH:MI:SS'` format (for example, `'01-Dec-2019'` or `'2018-03-08T12:12:12'`). You can review the AWS DMS task status in the **Table statistics** tab on the **Tasks** page of the AWS DMS console.	

Task	Description	Skills required
Validate the data.	1. After the full-load migration is complete, the task is continuously kept running for CDC. 2. When CDC is complete or no more changes need to be migrated, review and validate the migration task results and data in your Oracle and PostgreSQL databases. You can validate your data by checking status and count columns (`Validation state`, `Validation pending`, `Validation failed`, `Validation suspended`, and `Validation details`) in the **Table statistics** tab of your database migration task on the **Tasks** page of the AWS DMS console. For more information, see [AWS DMS data validation](#) in the AWS DMS documentation.	DBA

Task	Description	Skills required
Stop the AWS DMS tasks.	Run the Python script by using the following command: `$ python dms-start-task.py stop` **Note** AWS DMS tasks might stop with a `failed`status, depending on the validation status. For more information, see the next section.	DBA

Troubleshooting

Issue	Solution
AWS SCT source and target test connections fail.	Configure the JDBC driver versions and VPC security group inbound rules to accept the incoming traffic.
Source or target endpoint test run fails.	Check if the endpoint settings and replication instance are in `Available` status. Check if the endpoint connection status is `Successful`. For more information, see [How do I troubleshoot AWS DMS endpoint connectivity failures](https://repost.aws/knowledge-center/dms-endpoint-connectivity-failures) in the AWS Support documentation.

Issue	Solution
Full-load run fails.	Check if the source and target databases have matching data types and sizes. For more information, see Troubleshooting migration tasks in AWS DMS in the AWS DMS documentation.
You encounter validation run errors.	Check if the table has a primary key because non-primary key tables are not validated. If the table has a primary key and errors, check that the extra connection attribute in the source endpoint has `numberDataTypeScale=-2` . For more information, see Endpoint settings when using Oracle as a source for AWS DMS, OracleSettings, and Troubleshooting in the AWS DMS documentation.

Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL in SSL mode by using AWS DMS

Pinesh Singal, Amazon Web Services

Summary

This pattern provides guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle database instance to an Amazon RDS for PostgreSQL database on the Amazon Web Services (AWS) Cloud. To encrypt connections between the databases, the pattern uses certificate authority (CA) and SSL mode in Amazon RDS and AWS Database Migration Service (AWS DMS).

The pattern describes an online migration strategy with little or no downtime for a multi-terabyte Oracle source database with a high number of transactions. For data security, the pattern uses SSL when transferring the data.

This pattern uses AWS Schema Conversion Tool (AWS SCT) to convert the Amazon RDS for Oracle database schema to an Amazon RDS for PostgreSQL schema. Then the pattern uses AWS DMS to migrate data from the Amazon RDS for Oracle database to the Amazon RDS for PostgreSQL database.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Amazon RDS database certificate authority (CA) configured with ***rds-ca-rsa2048-g1*** only
  - The ***rds-ca-2019*** certificate expired in August 2024.
  - The ***rds-ca-2015*** certificate expired on March 5, 2020.
- AWS SCT
- AWS DMS
- pgAdmin
- SQL tools (for example, SQL Developer or SQL*Plus)

Limitations

- Amazon RDS for Oracle database – The minimum requirement is for Oracle versions 19c for the Enterprise and Standard Two editions.
- Amazon RDS for PostgreSQL database – The minimum requirement is for PostgreSQL version 12 and later (for versions 9.x and later).

Product versions

- Amazon RDS for Oracle database version 12.1.0.2 instance
- Amazon RDS for PostgreSQL database version 11.5 instance

Architecture

Source technology stack

- An Amazon RDS for Oracle database instance with version 12.1.0.2.v18.

Target technology stack

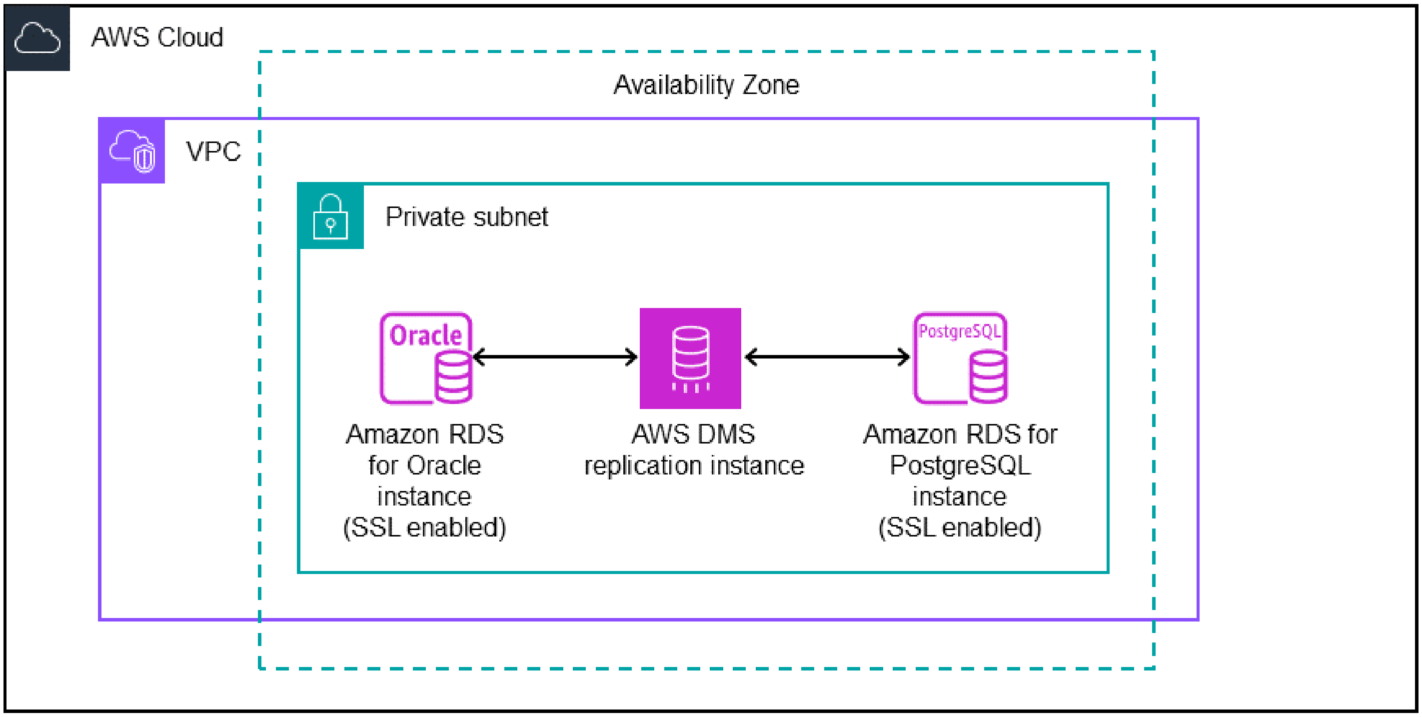
- AWS DMS
- An Amazon RDS for PostgreSQL database instance with version 11.5.

Target architecture

The following diagram shows the architecture for data migration architecture between Oracle (source) and PostgreSQL (target) databases. The architecture includes the following:

- A virtual private cloud (VPC)
- An Availability Zone
- A private subnet
- An Amazon RDS for Oracle database
- An AWS DMS replication instance
- An RDS for PostgreSQL database

To encrypt connections for source and target databases, CA and SSL mode must be enabled in Amazon RDS and AWS DMS.



Tools

AWS services

- AWS Database Migration Service (AWS DMS) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- Amazon Relational Database Service (Amazon RDS) for Oracle helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.

Other services

- pgAdmin is an open source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Best practices

Amazon RDS provides new CA certificates as an AWS security best practice. For information about the new certificates and the supported AWS Regions, see Using SSL/TLS to encrypt a connection to a DB instance or cluster.

If your RDS instance is currently on CA certificate `rds-ca-2019`, and you want to upgrade to `rds-ca-rsa2048-g1`, follow the instructions in Updating your CA certificate by modifying your DB instance or cluster or Updating your CA certificate by applying maintenance.

Epics

Configure the Amazon RDS for Oracle instance

Task	Description	Skills required
Create the Oracle database instance.	Sign in to your AWS account, open the AWS Managemen t Console, and navigate to the Amazon RDS console. On the console, choose **Create database**, and then choose **Oracle**.	General AWS, DBA
Configure security groups.	Configure inbound and outbound security groups.	General AWS
Create an option group.	Create an option group in the same VPC and security group as the Amazon RDS for Oracle database. For **Option**, choose **SSL**. For **Port**, choose **2484** (for SSL connections).	General AWS
Configure the option settings.	Use the following settings: • `SQLNET.CIPHER_SUITE :SSL_RSA_WITH_AES_256_CBC_SHA`	General AWS

Task	Description	Skills required
	• `SQLNET.SSL_VERSION : 1.2 or 1.0`	
Modify the RDS for Oracle DB instance.	Set the CA certificate as **rds-ca-rsa2048-g1**. Under **Option group**, attach the previously created option group.	DBA, General AWS

Task	Description	Skills required

Confirm that the RDS for Oracle DB instance is available.	Make sure that the Amazon RDS for Oracle database instance is up and running and that the database schema is accessible.
	
	To connect to the RDS for Oracle DB, use the `sqlplus` command from the command line.
	
	`$ sqlplus orcl/****@myoracledb.cokmvis0v46q.us-east-1.rds.amazonaws.com:1521/ORCL`
	`SQL*Plus: Release 12.1.0.2.0 Production on Tue Oct 15 18:11:07 2019`
	`Copyright (c) 1982, 2016, Oracle.  All rights reserved.`
	`Last Successful login time: Mon Dec 16 2019 23:17:31 +05:30`
	`Connected to:`
	`Oracle Database 12c Enterprise Edition Release 12.1.0.2.0 - 64bit Production`
	`With the Partitioning, OLAP, Advanced Analytics and Real Application Testing options`
	`SQL>`
		DBA

Task	Description	Skills required
Create objects and data in the RDS for Oracle database.	Create objects and insert data in the schema.	DBA

Configure the Amazon RDS for PostgreSQL instance

Task	Description	Skills required
Create the RDS for PostgreSQL database.	On the Amazon RDS console **Create database** page, choose **PostgreSQL** to create an Amazon RDS for PostgreSQL database instance.	DBA, General AWS
Configure security groups.	Configure inbound and outbound security groups.	General AWS
Create a parameter group.	If you are using PostgreSQL version 11.x, create a parameter group to set SSL parameters. In PostgreSQL version 12, the SSL parameter group is enabled by default.	General AWS
Edit parameters.	Change the `rds.force_ssl` parameter to 1 (on). By default, the `ssl` parameter is 1 (on). By setting the `rds.force_ssl` parameter to 1, you force all connections to connect through SSL mode only.	General AWS

Task	Description	Skills required
Modify the RDS for PostgreSQL DB instance.	Set the CA certificate as **rds-ca-rsa2048-g1**. Attach the default parameter group or the previously created parameter group, depending on your PostgreSQL version.	DBA, General AWS

Task	Description	Skills required

Confirm that the RDS for PostgreSQL DB instance is available.	Make sure that the Amazon RDS for PostgreSQL database is up and running.
	
	The `psql` command establishes an SSL connection with `sslmode` set from the command line.
	
	One option is to set `sslmode=1` in the parameter group and use a `psql` connection without including the `sslmode` parameter in the command.
	
	The following output shows that the SSL connection is established.
	
	`$ psql -h mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com -p 5432 "dbname=pgdb user=pguser"`
	`Password for user pguser:`
	`psql (11.3, server 11.5)`
	`SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256, compression: off)`
	`Type "help" for help.`
	`pgdb=>`
		DBA

Task	Description	Skills required
	A second option is to set `sslmode=1` in the parameter group and to include the `sslmode` parameter in the `psql` command. The following output shows that the SSL connection is established. `$ psql -h mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com -p 5432 "dbname=pgdb user=pguser sslmode=require" Password for user pguser: psql (11.3, server 11.5) SSL connection (protocol: TLSv1.2, cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256, compression: off) Type "help" for help. pgdb=>`	

Configure and run AWS SCT

Task	Description	Skills required
Install AWS SCT.	Install the latest version of the AWS SCT application.	General AWS

Task	Description	Skills required
Configure AWS SCT with JDBC drivers.	Download the Java Database Connectivity (JDBC) drivers for Oracle (ojdbc8.jar) and PostgreSQL (postgresql-42.2.5.jar). To configure the drivers in AWS SCT, choose **Settings**, **Global settings**, **Drivers**.	General AWS

Task	Description	Skills required
Create the AWS SCT project.	Create the AWS SCT project and report, using Oracle as the source DB engine and Amazon RDS for PostgreSQL as the target DB engine: 1. Test connections to the source Oracle database and target Amazon RDS for PostgreSQL database by providing connection details. For the source Oracle database, the following permissions or privileges are required: • CONNECT • SELECT_CATALOG_ROLE • SELECT ANY DICTIONARY • SELECT on SYS.USER$ TO <sct_user> For more information, see Using Oracle Database as a source for AWS SCT. Both source and target connections must be successful before AWS SCT can start the migration report.	General AWS

Task	Description	Skills required
	2. After the report, enter the schema to be converted, and choose **Finish**.	
Validate database objects.	1. Choose **Load schema**. AWS SCT displays the source and the converted target objects, including objects that that have errors. Update any incorrect objects on the target database. 2. Review the errors, and clear them by using manual intervention. 3. After all errors are cleared, choose **Load schema** again. 4. Choose **Apply to database**. 5. Connect to pgAdmin, or any tool that supports a PostgreSQL DB connection, and check the schema and objects.	DBA, General AWS

Configure and run AWS DMS

Task	Description	Skills required
Create a replication instance.	1. Sign in to your account, open the AWS Managemen t Console, and navigate to the AWS DMS console.	General AWS

Task	Description	Skills required
	2. Create a replication instance with valid settings for the VPC, security group, Availability Zone, and extra connection attributes.	
Import the certificate.	Download the [certificate bundle (PEM)]() for your AWS Region. The bundle contains both the `rds-ca-2019` intermediate and root certificates. The bundle also contains the `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, and `rds-ca-ecc384-g1` root CA certificates. Your application trust store needs to register only the root CA certificate.	General AWS

Task	Description	Skills required
Create the source endpoint.	1. Create a source endpoint for Amazon RDS for Oracle by choosing **Select RDS DB instance** and then selecting the RDS for Oracle DB instance that you created. The endpoint configuration details will be automatically populated . 2. Choose **Provide access information manually**. For **Port**, make sure that you enter **2484**. 3. Under **Secure Socket Layer (SSL) mode**, choose `verify-ca` , and then choose the CA certificate that you created previousl y. 4. Under **Endpoint settings**, add the extra connectio n attribute `NumberDat aTypeScale=-2` to support the `NUMBER` data type with no size. For more information, see [Using an Oracle database as a source for AWS Database Migration Service]().	General AWS

Task	Description	Skills required
Create the target endpoint.	1. Create a target endpoint for Amazon RDS for PostgreSQL by choosing **Select RDS DB instance** and then selecting your RDS for PostgreSQL DB instance. The endpoint configuration details will be automatically populated . 2. Choose **Provide access information manually**. For **Port**, make sure that you enter **2484**. For more information, see [Using a PostgreSQL database as a target for AWS Database Migration Service]().	General AWS
Test the endpoints.	1. Test the source and target endpoints to confirm that both are successful and available. 2. If a test fails, make sure that the security group inbound rules are valid.	General AWS

Task	Description	Skills required
Create migration tasks.	To create a migration task for full load and change data capture (CDC) or for data validation, do the following: 1. To create a database migration task, choose the replication instance, source database endpoint, target database endpoint. Specify the migration type as one of the following: • **Migrate existing data** (full load) • **Replicate data changes only (CDC)** • **Migrate existing data and replicate ongoing changes** (full load and CDC) 2. Under **Table mappings**, you can configure selection rules and transformation rules in GUI or JSON formats: • Under **Selection rules**, select the schema, enter the table name, and select the action (Include or Exclude) to be configured; for example, Schema ORCL, Table name %, Action Include.	General AWS

Task	Description	Skills required

	- Under **Transformation rules**, do one of the following: - Select the schema and choose the action (case, prefix, suffix); for example, Target Schema ORCL, Action Make lowercase. - Select the schema, enter the table name, and choose the action (case, prefix, suffix); for example, Target Schema ORCL, Table %, Action Make lowercase. 3. Turn on Amazon CloudWatch Logs monitoring.
	4. For the mapping rules, add the following JSON code.
	<pre>{
	    "rules": [
	        {
	            "rule-type": "transformation",
	            "rule-id": "1",
	            "rule-name": "1",
	            "rule-target": "table",</pre>	

Task	Description	Skills required

	``
	            "object-l
	ocator": {
	
	 "schema-name": "%",
	
	 "table-name": "%"
	            },
	            "rule-
	action": "convert-
	lowercase",
	            "value":
	 null,
	            "old-valu
	e": null
	        },
	        {
	            "rule-
	type": "transfor
	mation",
	            "rule-id"
	: "2",
	            "rule-nam
	e": "2",
	            "rule-tar
	get": "schema",
	            "object-l
	ocator": {
	
	 "schema-name":
	 "ORCL",
	
	 "table-name": "%"
	            },
	            "rule-
	action": "convert-
	lowercase",
	            "value":
	 null,
	            "old-valu
	e": null
	        },
	        {
	``	

Task	Description	Skills required

	            },
	            "rule-act
	ion": "include",
	            "filters"
	: []
	        }
	    ]
	}
	``	

Plan the production run.	Confirm downtime with stakeholders such as applicati on owners to run AWS DMS in production systems.	Migration lead

Task	Description	Skills required
Run the migration task.	1. Start the AWS DMS task that has a status of **Ready**, and monitor the migration task logs in Amazon CloudWatch for any errors. If you chose **Migrate existing data and replicate ongoing changes** as the migration type, and the status is **Load complete ongoing replication**, the full load with CDC data migration is completed and validation is ongoing. 2. After you start the migration, you can obtain additional SSL-connection information in CloudWatch. For Oracle, CloudWatch shows the following connection string. `2019-12-17T09:15:11 [SOURCE_UNLOAD ]I: Connecting to Oracle: Beginning session (oracle_endpoint_conn.c:834)` The PostgreSQL connection string will be similar to the following example.	General AWS

Task	Description	Skills required
	`2019-12-17T09:15:11 [TARGET_LOAD ]I: Going to connect to ODBC connection string: PROTOCOL=7.4-0;DRIVER={PostgreSQL};SERVER=mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com;DATABASE=pgdb;PORT=5432;sslmode=require;UID=pguser;(odbc_endpoint_imp.c:2218)`	
Validate the data.	Review migration task results and data in the source Oracle and target PostgreSQL databases: 1. Connect to pgAdmin and check the data in your PostgreSQL database with schema `ORCL`. 2. For CDC, check the ongoing changes by inserting or updating data in the source Oracle database.	DBA
Stop the migration task.	After you successfully complete the data validation, stop the migration task.	General AWS

Clean up the resources

Task	Description	Skills required
Delete the AWS DMS tasks.	1. On the AWS DMS console, navigate to **Database migration tasks**, and stop any ongoing or running AWS DMS task. 2. Select the task or tasks, choose **Actions**, and choose **Delete**.	General AWS
Delete the AWS DMS endpoints.	Select the source and target endpoints that you created, choose **Actions**, and choose **Delete**.	General AWS
Delete the AWS DMS replicati on instance.	Choose the replication instance, choose **Actions**, and then choose **Delete**.	General AWS
Delete the PostgreSQL database.	1. On the Amazon RDS console, choose **Databases**. 2. Select the PostgreSQL database instance that you created, choose **Actions**, and then choose **Delete**.	General AWS
Delete the Oracle database.	On the Amazon RDS console, select the Oracle database instance, choose **Actions**, and then choose **Delete**.	General AWS

Troubleshooting

Issue	Solution
AWS SCT source and target test connections are failing.	Configure JDBC driver versions and VPC security group inbound rules to accept the incoming traffic.
The Oracle source endpoint test run fails.	Check the endpoint settings and whether the replication instance is available.
The AWS DMS task full-load run fails.	Check whether the source and target databases have matching data types and sizes.
The AWS DMS validation migration task returns errors.	1. Check whether the table has a primary key. Tables without a primary key are not validated. 2. If the table has a primary key but returns errors, check the extra connection attribute in the source endpoint. The extra connection attribute must have `numberDataTypeScale=-2` to support the `NUMBER` data type with no size dynamically based on data available in table.

Additional information

Amazon RDS Certificate Authority certificates `rds-ca-2019` expired in August 2024. If you use or plan to use SSL or TLS with certificate verification to connect to your RDS DB instances or Multi-

AZ DB clusters, consider using one of the new CA certificates: `rds-ca-rsa2048-g1`, `rds-ca-rsa4096-g1`, or `rds-ca-ecc384-g1`.

Migrate Oracle SERIALLY_REUSABLE pragma packages into PostgreSQL

Vinay Paladi, Amazon Web Services

Summary

This pattern provides a step-by-step approach for migrating Oracle packages that are defined as SERIALLY_REUSABLE pragma to PostgreSQL on Amazon Web Services (AWS). This approach maintains the functionality of the SERIALLY_REUSABLE pragma.

PostgreSQL doesn't support the concept of packages and the SERIALLY_REUSABLE pragma. To get similar functionality in PostgreSQL, you can create schemas for packages and deploy all the related objects (such as functions, procedures, and types) inside the schemas. To achieve the functionality of the SERIALLY_REUSABLE pragma, the example wrapper function script that's provided in this pattern uses an AWS Schema Conversion Tool (AWS SCT) extension pack.

For more information, see SERIALLY_REUSABLE Pragma in the Oracle documentation.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The latest version of AWS SCT and the required drivers
- An Amazon Aurora PostgreSQL-Compatible Edition database or an Amazon Relational Database Service (Amazon RDS) for PostgreSQL database

Product versions

- Oracle Database version 10g and later

Architecture

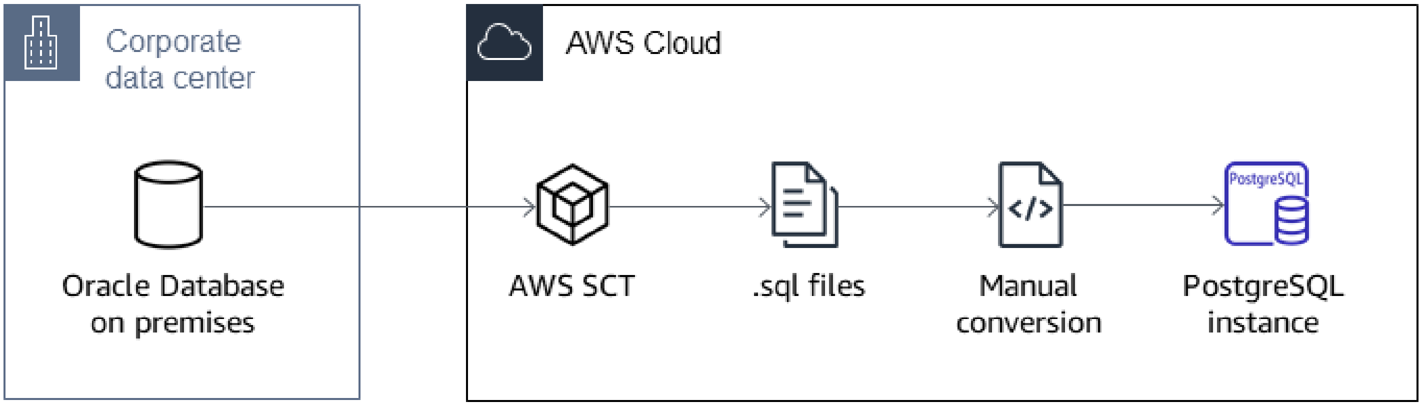
Source technology stack

- Oracle Database on premises

Target technology stack

- Aurora PostgreSQL-Compatible or Amazon RDS for PostgreSQL
- AWS SCT

Migration architecture



Tools

AWS services

- AWS Schema Conversion Tool (AWS SCT) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database.
- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- Amazon Relational Database Service (Amazon RDS) for PostgreSQL helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.

Other tools

- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

Epics

Migrate the Oracle package by using AWS SCT

Task	Description	Skills required
Set up AWS SCT.	Configure AWS SCT connectiv ity to the source database. For more information, see [Using Oracle Database as a source for AWS SCT]().	DBA, Developer
Convert the script.	Use AWS SCT to convert the Oracle package by selecting the target database as Aurora PostgreSQL-Compatible.	DBA, Developer
Save the .sql files.	Before you save the .sql file, modify the **Project Settings** option in AWS SCT to **Single file per stage**. AWS SCT will separate the .sql file into multiple .sql files based on object type.	DBA, Developer
Change the code.	Open the `init` function generated by AWS SCT, and change it as shown in the example in the *Additional information* section. It will add a variable to achieve the functionality `pg_serialize = 0` .	DBA, Developer
Test the conversion.	Deploy the `init` function to the Aurora PostgreSQL-Compatible database, and test the results.	DBA, Developer

Additional information

```
Source Oracle Code:

CREATE OR REPLACE PACKAGE test_pkg_var
IS
PRAGMA SERIALLY_REUSABLE;
PROCEDURE function_1
 (test_id number);
PROCEDURE function_2
 (test_id number
 );
END;

CREATE OR REPLACE PACKAGE BODY test_pkg_var
IS
PRAGMA SERIALLY_REUSABLE;
v_char VARCHAR2(20) := 'shared.airline';
v_num number := 123;

PROCEDURE function_1(test_id number)
IS
begin
dbms_output.put_line( 'v_char-'|| v_char);
dbms_output.put_line( 'v_num-'||v_num);
v_char:='test1';
function_2(0);
END;

PROCEDURE function_2(test_id number)
is
begin
dbms_output.put_line( 'v_char-'|| v_char);
dbms_output.put_line( 'v_num-'||v_num);
```

```
END;
END test_pkg_var;

Calling the above functions

set serveroutput on

EXEC test_pkg_var.function_1(1);

EXEC test_pkg_var.function_2(1);

Target Postgresql Code:

CREATE SCHEMA test_pkg_var;

CREATE OR REPLACE FUNCTION test_pkg_var.init(pg_serialize IN INTEGER DEFAULT 0)

RETURNS void
AS
$BODY$

DECLARE

BEGIN

if aws_oracle_ext.is_package_initialized( 'test_pkg_var' ) AND pg_serialize = 0

then

return;

end if;

PERFORM aws_oracle_ext.set_package_initialized( 'test_pkg_var' );

PERFORM aws_oracle_ext.set_package_variable( 'test_pkg_var', 'v_char',
 'shared.airline.basecurrency'::CHARACTER

VARYING(100));
```

```
PERFORM aws_oracle_ext.set_package_variable('test_pkg_var', 'v_num', 123::integer);

END;

$BODY$

LANGUAGE plpgsql;

CREATE OR REPLACE FUNCTION test_pkg_var.function_1(pg_serialize int default 1)

RETURNS void
AS

$BODY$
DECLARE

BEGIN

PERFORM test_pkg_var.init(pg_serialize);

raise notice 'v_char%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_char');

raise notice 'v_num%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_num');

PERFORM aws_oracle_ext.set_package_variable( 'test_pkg_var', 'v_char',
 'test1'::varchar);

PERFORM test_pkg_var.function_2(0);
END;

$BODY$
LANGUAGE plpgsql;

CREATE OR REPLACE FUNCTION test_pkg_var.function_2(IN pg_serialize integer default 1)

RETURNS void

AS

$BODY$

DECLARE
```

```
BEGIN

PERFORM test_pkg_var.init(pg_serialize);

raise notice 'v_char%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_char');

raise notice 'v_num%',aws_oracle_ext.get_package_variable( 'test_pkg_var', 'v_num');

END;
$BODY$
LANGUAGE plpgsql;

Calling the above functions

select test_pkg_var.function_1()

 select test_pkg_var.function_2()
```

Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible

anuradha chintha and Rakesh Raghav, Amazon Web Services

Summary

External tables give Oracle the ability to query data that is stored outside the database in flat files. You can use the ORACLE_LOADER driver to access any data stored in any format that can be loaded by the SQL*Loader utility. You can't use Data Manipulation Language (DML) on external tables, but you can use external tables for query, join, and sort operations.

Amazon Aurora PostgreSQL-Compatible Edition doesn't provide functionality similar to external tables in Oracle. Instead, you must use modernization to develop a scalable solution that meets functional requirements and is frugal.

This pattern provides steps for migrating different types of Oracle external tables to Aurora PostgreSQL-Compatible Edition on the Amazon Web Services (AWS) Cloud by using the `aws_s3` extension.

We recommend thoroughly testing this solution before implementing it in a production environment.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI)
- An available Aurora PostgreSQL-Compatible database instance.
- An on-premises Oracle database with an external table
- pg.Client API
- Data files

Limitations

- This pattern doesn't provide the functionality to act as a replacement for Oracle external tables. However, the steps and sample code can be enhanced further to achieve your database modernization goals.

- Files should not contain the character that is passing as a delimiter in `aws_s3` export and import functions.

Product versions

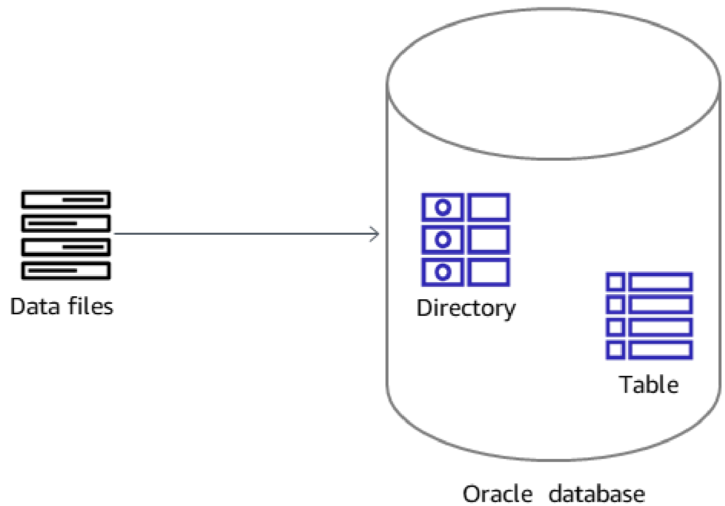
- To import from Amazon S3 into RDS for PostgreSQL the database must be running PostgreSQL version 10.7 or later.

Architecture

Source technology stack

- Oracle

Source architecture

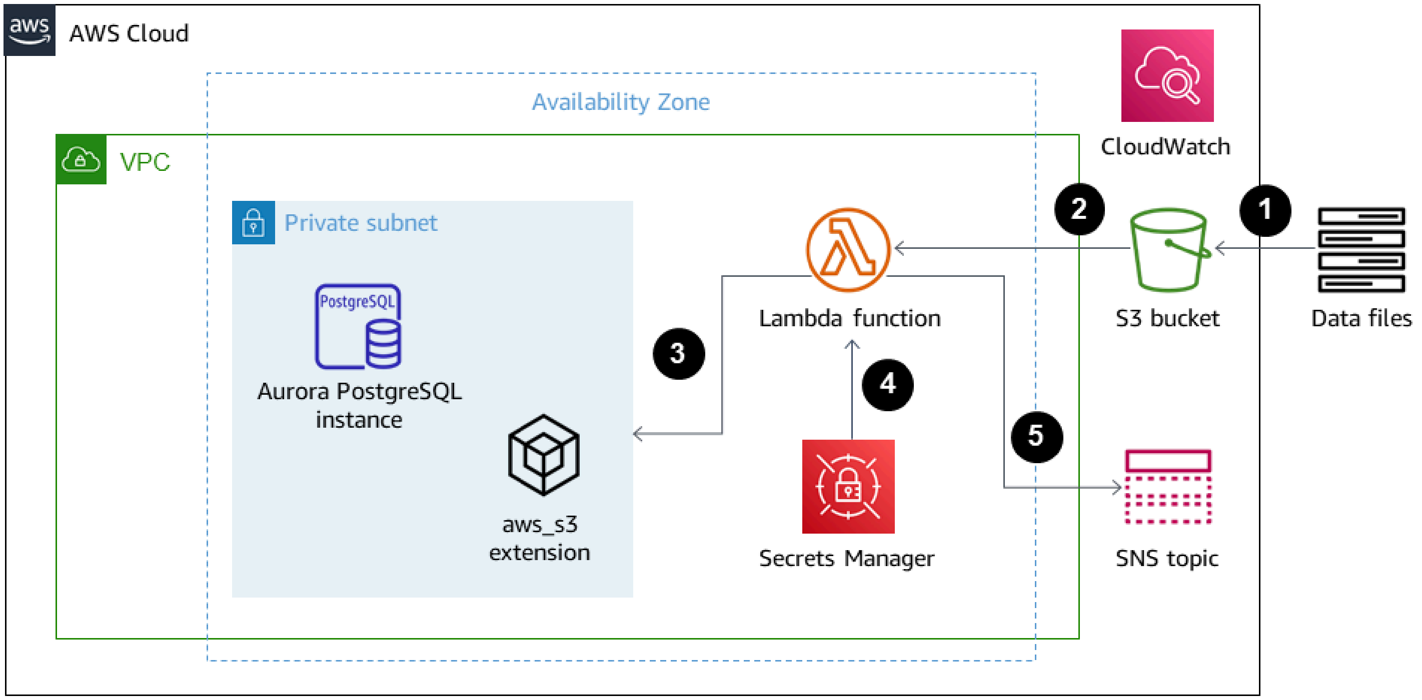


Target technology stack

- Amazon Aurora PostgreSQL-Compatible
- Amazon CloudWatch
- AWS Lambda
- AWS Secrets Manager
- Amazon Simple Notification Service (Amazon SNS)
- Amazon Simple Storage Service (Amazon S3)

Target architecture

The following diagram shows a high-level representation of the solution.



1. Files are uploaded to the S3 bucket.
2. The Lambda function is initiated.
3. The Lambda function initiates the DB function call.
4. Secrets Manager provides the credentials for database access.
5. Depending on the DB function, an SNS alarm is created.

Automation and scale

Any additions or changes to the external tables can be handled with metadata maintenance.

Tools

- Amazon Aurora PostgreSQL-Compatible – Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases.

- AWS CLI – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. With only one tool to download and configure, you can control multiple AWS services from the command line and automate them through scripts.
- Amazon CloudWatch – Amazon CloudWatch monitors Amazon S3 resources and utilization.
- AWS Lambda – AWS Lambda is a serverless compute service that supports running code without provisioning or managing servers, creating workload-aware cluster scaling logic, maintaining event integrations, or managing runtimes. In this pattern, Lambda runs the database function whenever a file is uploaded to Amazon S3.
- AWS Secrets Manager – AWS Secrets Manager is a service for credential storage and retrieval. Using Secrets Manager, you can replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) provides a storage layer to receive and store files for consumption and transmission to and from the Aurora PostgreSQL-Compatible cluster.
- aws_s3 – The `aws_s3` extension integrates Amazon S3 and Aurora PostgreSQL-Compatible.
- Amazon SNS – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients. In this pattern, Amazon SNS is used to send notifications.

Code

Whenever a file is placed in the S3 bucket, a DB function must be created and called from the processing application or the Lambda function. For details, see the code (attached).

Epics

Create an external file

Task	Description	Skills required
Add an external file to the source database.	Create an external file, and move it to the `oracle` directory.	DBA

Configure the target (Aurora PostgreSQL-Compatible)

Task	Description	Skills required
Create an Aurora PostgreSQL database.	Create a DB instance in your Amazon Aurora PostgreSQL-Compatible cluster.	DBA
Create a schema, aws_s3 extension, and tables.	Use the code under `ext_tbl_scripts` in the *Additional information* section. The tables include actual tables, staging tables, error and log tables, and a metatable.	DBA, Developer
Create the DB function.	To create the DB function, use the code under `load_external_table_latest` function in the *Additional information* section.	DBA, Developer

Create and configure the Lambda function

Task	Description	Skills required
Create a role.	Create a role with permissions to access Amazon S3 and Amazon Relational Database Service (Amazon RDS). This role will be assigned to Lambda for running the pattern.	DBA
Create the Lambda function.	Create a Lambda function that reads the file name from Amazon S3 (for example,	DBA

Task	Description	Skills required
	`file_key = info.get('object', {}).get('key')`) and calls the DB function (for example, `curs.callproc("load_external_tables", [file_key])`) with the file name as the input parameter. Depending on the function call result, an SNS notification will be initiated (for example, `client.publish(TopicArn='arn:',Message='fileloadsuccess',Subject='fileloadsuccess')`). Based on your business needs, you can create a Lambda function with extra code if required. For more information, see the [Lambda documentation]().	
Configure an S3 bucket event trigger.	Configure a mechanism to call the Lambda function for all object creation events in the S3 bucket.	DBA
Create a secret.	Create a secret name for the database credentials by using Secrets Manager. Pass the secret in the Lambda function.	DBA

Task	Description	Skills required
Upload the Lambda supporting files.	Upload a .zip file that contains the Lambda support packages and the attached Python script for connecting to Aurora PostgreSQL-Compatible. The Python code calls the function that you created in the database.	DBA
Create an SNS topic.	Create an SNS topic to send mail for the success or failure of the data load.	DBA

Add integration with Amazon S3

Task	Description	Skills required
Create an S3 bucket.	On the Amazon S3 console, create an S3 bucket with a unique name that does not contain leading slashes. An S3 bucket name is globally unique, and the namespace is shared by all AWS accounts.	DBA
Create IAM policies.	To create the AWS Identity and Access Management (IAM) policies, use the code under `s3bucketpolicy_for_import` in the *Additional information* section.	DBA
Create roles.	Create two roles for Aurora PostgreSQL-Compatible,	DBA

Task	Description	Skills required
	one role for Import and one role for Export. Assign the corresponding policies to the roles.	
Attach the roles to the Aurora PostgreSQL-Compatible cluster.	Under **Manage roles**, attach the Import and Export roles to the Aurora PostgreSQL cluster.	DBA
Create supporting objects for Aurora PostgreSQL-Compatible.	For the table scripts, use the code under `ext_tbl_scripts` in the *Additional information* section. For the custom function, use the code under `load_external_Table_latest` in the *Additional information* section.	DBA

Process a test file

Task	Description	Skills required
Upload a file into the S3 bucket.	To upload a test file into the S3 bucket, use the console or the following command in AWS CLI. `aws s3 cp /Users/Desktop/ukpost/exttbl/"testing files"/aps s3://s3importtest/inputext/aps`	DBA

Task	Description	Skills required
	As soon as the file is uploaded, a bucket event initiates the Lambda function, which runs the Aurora PostgreSQL-Compatible function.	
Check the data and the log and error files.	The Aurora PostgreSQL-Compatible function loads the files into the main table, and it creates `.log` and `.bad` files in the S3 bucket.	DBA
Monitor the solution.	In the Amazon CloudWatch console, monitor the Lambda function.	DBA

Migrate function-based indexes from Oracle to PostgreSQL

Veeranjaneyulu Grandhi and Navakanth Talluri, Amazon Web Services

Summary

Indexes are a common way to enhance database performance. An index allows the database server to find and retrieve specific rows much faster than it could without an index. But indexes also add overhead to the database system as a whole, so they should be used sensibly. Function-based indexes, which are based on a function or expression, can involve multiple columns and mathematical expressions. A function-based index improves the performance of queries that use the index expression.

Natively, PostgreSQL doesn't support creating function-based indexes using functions that have volatility defined as stable. However, you can create similar functions with volatility as `IMMUTABLE` and use them in index creation.

An `IMMUTABLE` function cannot modify the database, and it's guaranteed to return the same results given the same arguments forever. This category allows the optimizer to pre-evaluate the function when a query calls it with constant arguments.

This pattern helps in migrating the Oracle function-based indexes when used with functions such as `to_char`, `to_date`, and `to_number` to the PostgreSQL equivalent.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- A source Oracle database instance with the listener service set up and running
- Familiarity with PostgreSQL databases

Limitations

- Database size limit is 64 TB.
- Functions used in index creation must be IMMUTABLE.

Product versions

- All Oracle database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c
- PostgreSQL versions 9.6 and later

Architecture

Source technology stack

- An Oracle database on premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance, or an Amazon RDS for Oracle DB instance

Target technology stack

- Any PostgreSQL engine

Tools

- **pgAdmin 4** is an open source management tool for Postgres. The pgAdmin 4 tool provides a graphical interface for creating, maintaining, and using database objects.
- **Oracle SQL Developer** is an integrated development environment (IDE) for developing and managing Oracle Database in both traditional and cloud deployments.

Epics

Create a function-based index using a default function

Task	Description	Skills required

Create a function-based index on a column using the to_char function.	Use the following code to create the function-based index.
	`postgres=# create table funcindex( col1 timestamp without time zone);`
	`CREATE TABLE`
		DBA, App developer

Task	Description	Skills required

	<pre>postgres=# insert
	 into funcindex values
	 (now());
	INSERT 0 1
	postgres=# select *
	 from funcindex;
	            col1
	---------------------- 	
	------ 	
	 2022-08-09 16:00:57.
	77414
	(1 rows)
	
	postgres=# create
	 index funcindex_idx
	 on funcindex(to_char(
	col1,'DD-MM-YYYY
	 HH24:MI:SS'));
	ERROR: functions in
	 index expression must
	 be marked IMMUTABLE</pre> **Note** PostgreSQL doesn’t allow creating a function-based index without the `IMMUTABLE` clause.	

Check the volatility of the function.	To check the function volatility, use the code in the *Additional information* section.	DBA

Create function-based indexes using a wrapper function

Task	Description	Skills required
Create a wrapper function.	To create a wrapper function, use the code in the *Additional information section*.	PostgreSQL developer
Create an index by using the wrapper function.	Use the code in the *Additional information* section to create a user-defined function with the keyword `IMMUTABLE` in the same schema as the application, and refer to it in the index-creation script. If a user-defined function is created in a common schema (from the previous example), update the `search_path` as shown. `ALTER ROLE <ROLENAME> set search_path=$user, COMMON;`	DBA, PostgreSQL developer

Validate index creation

Task	Description	Skills required
Validate index creation.	Validate that the index needs to be created, based on query access patterns.	DBA
Validate that the index can be used.	To check whether the function-based index is picked up by the PostgreSQ	DBA

Task	Description	Skills required
	L Optimizer, run an SQL statement using explain or explain analyze. Use the code in the *Additional information* section. If possible, gather the table statistics as well. **Note** If you notice the explain plan, PostgreSQL optimizer has chosen a function-based index because of the predicate condition.	

Related resources

- PostgreSQL search_path (PostgreSQL documentation)
- Oracle Database 19c to Amazon Aurora PostgreSQL Migration Playbook

Additional information

Create a wrapper function

```
CREATE OR REPLACE FUNCTION myschema.to_char(var1 timestamp without time zone, var2
 varchar) RETURNS varchar AS $BODY$ select to_char(var1, 'YYYYMMDD'); $BODY$ LANGUAGE
 sql IMMUTABLE;
```

Create an index by using the wrapper function

```
postgres=# create function common.to_char(var1 timestamp without time zone, var2
 varchar) RETURNS varchar AS $BODY$ select to_char(var1, 'YYYYMMDD'); $BODY$ LANGUAGE
 sql IMMUTABLE;
CREATE FUNCTION
postgres=# create index funcindex_idx on funcindex(common.to_char(col1,'DD-MM-YYYY
 HH24:MI:SS'));
CREATE INDEX
```

Check the volatility of the function

```
SELECT DISTINCT p.proname as "Name",p.provolatile as "volatility" FROM
 pg_catalog.pg_proc p
 LEFT JOIN pg_catalog.pg_namespace n ON n.oid = p.pronamespace
 LEFT JOIN pg_catalog.pg_language l ON l.oid = p.prolang
 WHERE n.nspname OPERATOR(pg_catalog.~) '^(pg_catalog)$' COLLATE pg_catalog.default AND
 p.proname='to_char'GROUP BY p.proname,p.provolatile
ORDER BY 1;
```

Validate that the index can be used

```
explain analyze <SQL>

postgres=# explain select col1 from funcindex where common.to_char(col1,'DD-MM-YYYY
 HH24:MI:SS') = '09-08-2022 16:00:57';
                                                       QUERY PLAN
-----------------------------------------------------------------------------------------------------
 Index Scan using funcindex_idx on funcindex  (cost=0.42..8.44 rows=1 width=8)
   Index Cond: ((common.to_char(col1, 'DD-MM-YYYY HH24:MI:SS'::character
 varying))::text = '09-08-2022 16:00:57'::text)
(2 rows)
```

Migrate Oracle native functions to PostgreSQL using extensions

Pinesh Singal, Amazon Web Services

Summary

This migration pattern provides step-by-step guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle database instance to an Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition database by modifying the `aws_oracle_ext` and `orafce` extensions to PostgreSQL (`psql`) native built-in code. This will save processing time.

The pattern describes an offline manual migration strategy with no downtime for a multi-terabyte Oracle source database with a high number of transactions.

The migration process uses AWS Schema Conversion Tool (AWS SCT) with the `aws_oracle_ext` and `orafce` extensions to convert an Amazon RDS for Oracle database schema to an Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database schema. Then the code is manually changed to PostgreSQL supported native `psql` built-in code. This is because the extension calls impact code processing on the PostgreSQL database server, and not all the extension code is fully complaint or compatible with PostgreSQL code.

This pattern primarily focuses on manually migrating SQL codes using AWS SCT and the extensions `aws_oracle_ext` and `orafce`. You convert the already used extensions into native PostgreSQL (`psql`) built-ins. Then you remove all references to the extensions and convert the codes accordingly.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Operating system (Windows or Mac) or Amazon EC2 instance (up and running)
- Orafce

Limitations

Not all Oracle functions using `aws_oracle_ext` or `orafce` extensions can be converted to native PostgreSQL functions. It might need manual rework so as to compile it with PostgreSQL libraries.

One drawback of using AWS SCT extensions is its slow performance in running and fetching the results. Its cost can be understood from simple [PostgreSQL EXPLAIN plan] (execution plan of a statement) on the Oracle `SYSDATE` function migration to the PostgreSQL `NOW()` function between all three codes (`aws_oracle_ext`, `orafce`, and `psql` default), as explained in the *Performance comparison check* section in the attached document.

Product versions

- **Source:** Amazon RDS for Oracle database 10.2 and later (for 10.x), 11g (11.2.0.3.v1 and later) and up to 12.2, 18c, and 19c (and later) for Enterprise Edition, Standard Edition, Standard Edition 1, and Standard Edition 2
- **Target**: Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database 9.4 and later (for 9.x), 10.x, 11.x, 12.x, 13.x, and 14.x (and later)
- **AWS SCT**: Latest version (this pattern was tested with 1.0.632)
- **Orafce**: Latest version (this pattern was tested with 3.9.0)

Architecture

Source technology stack

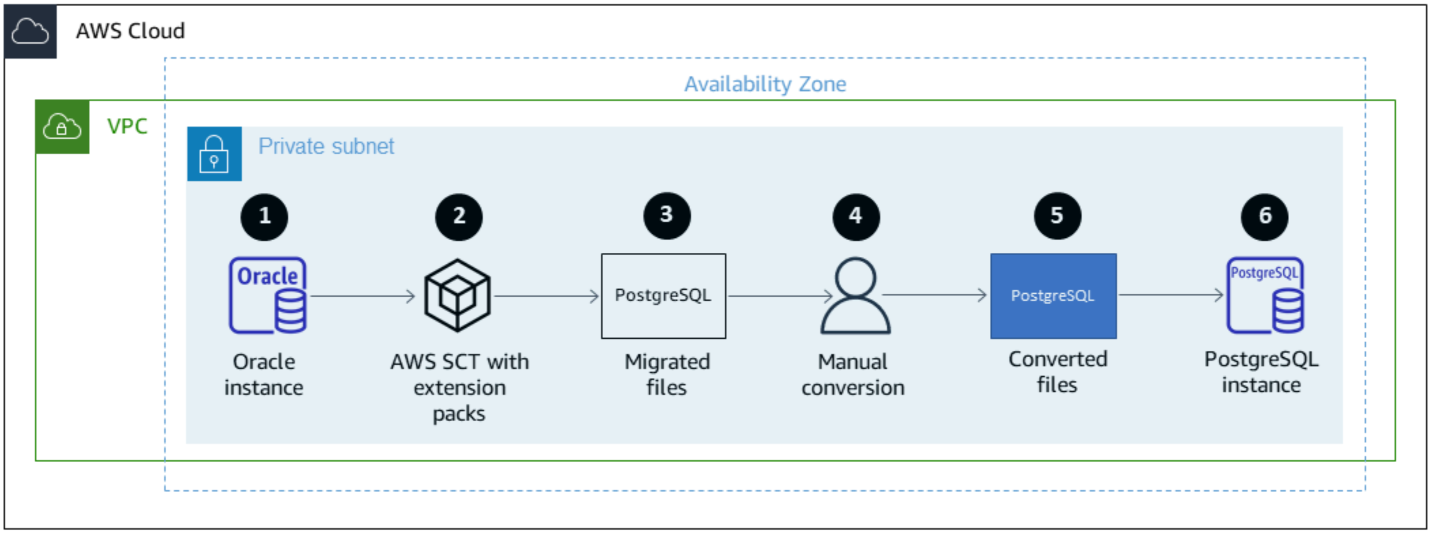
- An Amazon RDS for Oracle database instance with version 12.1.0.2.v18

Target technology stack

- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database instance with version 11.5

Database migration architecture

The following diagram represents the database migration architecture between the source Oracle and target PostgreSQL databases. The architecture involves AWS Cloud, a virtual private cloud (VPC), Availability Zones, a private subnet, an Amazon RDS for Oracle database, AWS SCT, an Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database, extensions for Oracle (`aws_oracle_ext` and `orafce`), and structured query language (SQL) files.



1. Launch Amazon RDS for Oracle DB instance (source DB).
2. Use AWS SCT with the `aws_oracle_ext` and `orafce` extension packs to convert the source code from Oracle to PostreSQL.
3. The conversion produces PostgreSQL-supported migrated .sql files.
4. Manually convert the non-converted Oracle extension codes to PostgreSQL (`psql`) codes.
5. The manual conversion produces PostgreSQL-supported converted .sql files.
6. Run these .sql files on your Amazon RDS for PostgreSQL DB instance (target DB).

Tools

Tools

AWS services

- AWS SCT - AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another. You can convert relational Online Transactional Processing (OLTP) schema, or data warehouse schema. Your converted schema is suitable for an Amazon RDS for MySQL DB instance, an Amazon Aurora DB cluster, an Amazon RDS for PostgreSQL DB instance, or an Amazon Redshift cluster. The converted schema can also be used with a database on an Amazon EC2 instance or stored as data in an Amazon S3 bucket.

  AWS SCT provides a project-based user interface to automatically convert the database schema of your source database into a format compatible with your target Amazon RDS instance.

You can use AWS SCT to do migration from an Oracle source database to any of the targets listed preceding. Using AWS SCT, you can export the source database object definitions such as schema, views, stored procedures, and functions.

You can use AWS SCT to convert data from Oracle to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition.

In this pattern, you use AWS SCT to convert and migrate Oracle code into PostgreSQL using the extensions `aws_oracle_ext` and `orafce`, and manually migrating the extension codes into `psql` default or native built-in code.

- The AWS SCT extension pack is an add-on module that emulates functions present in the source database that are required when converting objects to the target database. Before you can install the AWS SCT extension pack, you need to convert your database schema.

  When you convert your database or data warehouse schema, AWS SCT adds an additional schema to your target database. This schema implements SQL system functions of the source database that are required when writing your converted schema to your target database. This additional schema is called the extension pack schema.

  The extension pack schema for OLTP databases is named according to the source database. For Oracle databases, the extension pack schema is `AWS_ORACLE_EXT`.

Other tools

- Orafce – Orafce is a module that implements Oracle compatible functions, data types, and packages. It's an open-source tool with a Berkeley Source Distribution (BSD) license so that anyone can use it. The `orafce` module is useful for migrating from Oracle to PostgreSQL because it has many Oracle functions implemented in PostgreSQL.

Code

For a list of all commonly used and migrated code from Oracle to PostgreSQL to avoid AWS SCT extension code usage, see the attached document.

Epics

Configure the Amazon RDS for Oracle source database

Task	Description	Skills required
Create the Oracle database instance.	Create an Amazon RDS for Oracle or Aurora PostgreSQL-Compatible database instance from the Amazon RDS console.	General AWS, DBA
Configure the security groups.	Configure inbound and outbound security groups.	General AWS
Create the database.	Create the Oracle database with needed users and schemas.	General AWS, DBA
Create the objects.	Create objects and insert data in schema.	DBA

Configure the Amazon RDS for PostgreSQL target database

Task	Description	Skills required
Create the PostgreSQL database instance.	Create an Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL database instance from the Amazon RDS console.	General AWS, DBA
Configure the security groups.	Configure inbound and outbound security groups.	General AWS
Create the database.	Create the PostgreSQL database with needed users and schemas.	General AWS, DBA

Task	Description	Skills required
Validate the extensions.	Make sure that `aws_oracle_ext` and `orafce` are installed and configured correctly in the PostgreSQL database.	DBA
Verify that the PostgreSQL database is available.	Make sure that the PostgreSQL database is up and running.	DBA

Migrate the Oracle schema into PostgreSQL using AWS SCT and the extensions

Task	Description	Skills required
Install AWS SCT.	Install the latest version of AWS SCT.	DBA
Configure AWS SCT.	Configure AWS SCT with Java Database Connectivity (JDBC) drivers for Oracle (`ojdbc8.jar`) and PostgreSQL (`postgresql-42.2.5.jar`).	DBA
Enable the AWS SCT extension pack or template.	Under AWS SCT **Project Settings**, enable built-in function implementation with the `aws_oracle_ext` and `orafce` extensions for the Oracle database schema.	DBA
Convert the schema.	In AWS SCT, choose **Convert Schema** to convert the schema from Oracle to PostgreSQL and generate the .sql files.	DBA

Convert AWS SCT extension code to psql code

Task	Description	Skills required
Manually convert the code.	Manually convert each line of extension-supported code into `psql` default built-in code, as detailed in the attached document. For example, change `AWS_ORACLE_EXT.SYSDATE()` or `ORACLE.SYSDATE()` to `NOW()`.	DBA
Validate the code	(Optional) Validate each line of code by temporary running it in the PostgreSQL database.	DBA
Create objects in the PostgreSQL database.	To create objects in the PostgreSQL database, run the .sql files that were generated by AWS SCT and modified in the previous two steps.	DBA

Migrate a Db2 database from Amazon EC2 to Aurora MySQL-Compatible by using AWS DMS

Pinesh Singal, Amazon Web Services

Summary

After you migrate your IBM Db2 for LUW database to Amazon Elastic Compute Cloud (Amazon EC2), consider re-architecting the database by moving to an Amazon Web Services (AWS) cloud-native database. This pattern covers migrating an IBM Db2 for LUW database running on an Amazon EC2 instance to an Amazon Aurora MySQL-Compatible Edition database on AWS.

The pattern describes an online migration strategy with minimal downtime for a multi-terabyte Db2 source database with a high number of transactions.

This pattern uses AWS Schema Conversion Tool (AWS SCT) to convert the Db2 database schema to an Aurora MySQL-Compatible schema. Then the pattern uses AWS Database Migration Service (AWS DMS) to migrate data from the Db2 database to the Aurora MySQL-Compatible database. Manual conversions will be required for the code that isn't converted by AWS SCT.

Prerequisites and limitations

Prerequisites

- An active AWS account with a virtual private cloud (VPC)
- AWS SCT
- AWS DMS

Product versions

- AWS SCT latest version
- Db2 for Linux version 11.1.4.4 and later

Architecture

Source technology stack

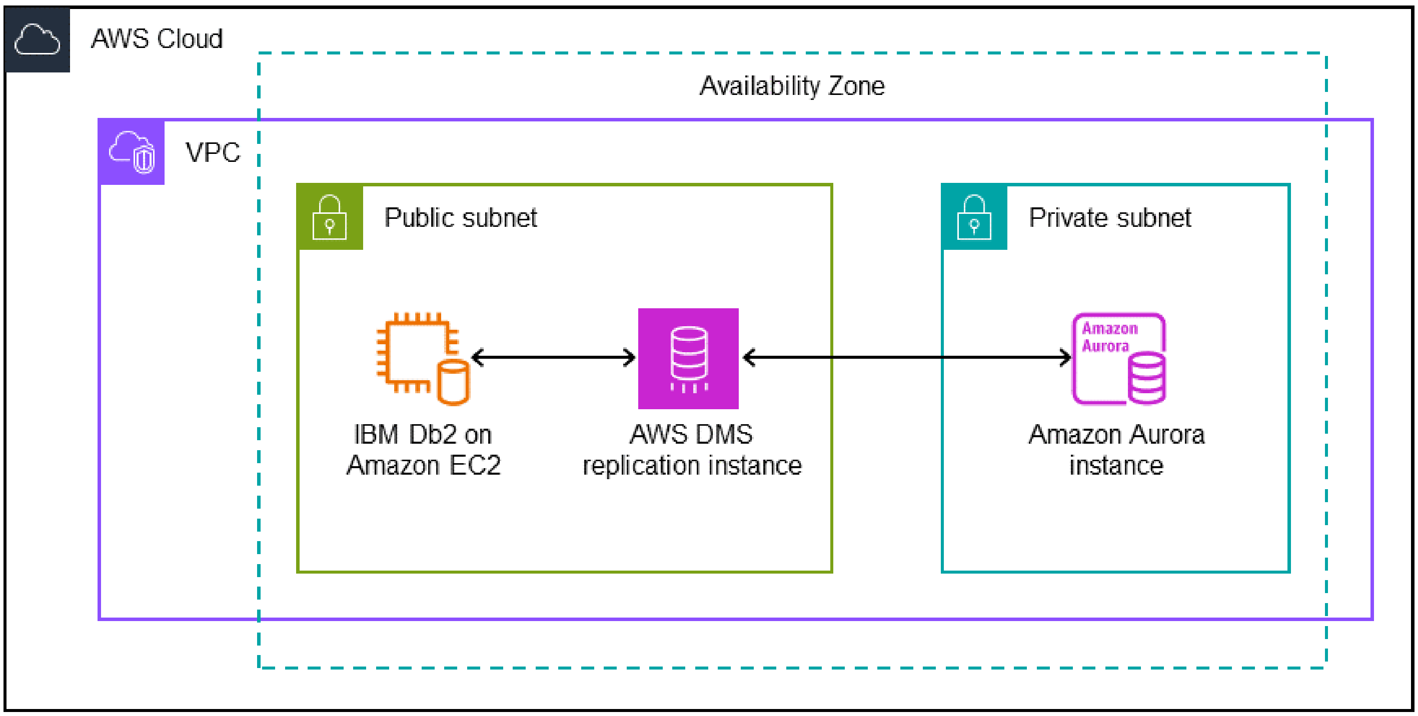
- DB2/Linux x86-64 bit mounted on an EC2 instance

Target technology stack

- An Amazon Aurora MySQL-Compatible Edition database instance

Source and target architecture

The following diagram shows the data migration architecture between the source Db2 and target Aurora MySQL-Compatible databases. The architecture on the AWS Cloud includes a virtual private cloud (VPC) (Virtual Private Cloud), an Availability Zone, a public subnet for the Db2 instance and the AWS DMS replication instance, and a private subnet for the Aurora MySQL-Compatible database.



Tools

AWS services

- [Amazon Aurora](#) is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- [AWS Database Migration Service (AWS DMS)](#) helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- [Amazon Elastic Compute Cloud (Amazon EC2)](#) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need and quickly scale them up or down.

- [AWS Schema Conversion Tool (AWS SCT)](#) supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format that's compatible with the target database. AWS SCT supports as a source IBM Db2 for LUW versions 9.1, 9.5, 9.7, 10.1, 10.5, 11.1, and 11.5.

Best practices

For best practices, see Best practices for AWS Database Migration Service.

Epics

Configure the source IBM Db2 database

Task	Description	Skills required
Create the IBM Db2 database on Amazon EC2.	You can create an IBM Db2 database on an EC2 instance by using an Amazon Machine Image (AMI) from AWS Marketplace or by installin g Db2 software on an EC2 instance. Launch an EC2 instance by selecting an AMI for IBM Db2 (for example, IBM Db2 v11.5.7 RHEL 7.9), which is similar to an on-premises database.	DBA, General AWS
Configure security groups.	Configure the VPC security group inbound rules for SSH (Secure Shell) and TCP with port 22 and 50000, respectiv ely.	General AWS
Create the database instance.	Create a new instance (user) and database (schema), or use the default `db2inst1`	DBA

Task	Description	Skills required
	instance and sample database. 1. Connect to the EC2 instance by using the terminal to connect to the Db2 database. Alternatively, you can install any DB client software that will connect to the Db2 database. 2. To set the password of the db2inst1 user, run the command `sudo passwd db2inst1`. 3. To connect to the db2inst1 instance, run the command `sudo su - db2inst1`. 4. To connect to the Db2 database, run the command `db2`. 5. To connect to the sample database, use the command `connect to sample`. Alternatively, connect to the database that you created. 6. After you connect to the database instance, create objects and insert data into these objects by using Db2 SQL statements.	

Task	Description	Skills required
Confirm that the Db2 DB instance is available.	To confirm that the Db2 database instance is up and running, use the `Db2pd -` command.	DBA

Configure the target Aurora MySQL-Compatible database

Task	Description	Skills required
Create the Aurora MySQL-Compatible database.	Create an Amazon Aurora with MySQL compatibility Database from AWS RDS service • Create a database on Amazon Aurora with MySQL compatibility and version of your choice, e.g. Aurora (MySQL)–5.6.10a • Install MySQL Workbench application or your preferred DB client software which allows you to connect to MySQL database	DBA, General AWS
Configure security groups.	Configure the VPC security group inbound rules for SSH and TCP connections.	General AWS
Confirm that the Aurora database is available.	To make sure that the Aurora MySQL-Compatible database is up and running, do the following:	DBA

Task	Description	Skills required
	1. Connect to the EC2 instance through SSH. 2. Configure and connect to the Aurora MySQL-Compatible instance from MySQL Workbench. Use the endpoint as the hostname, as shown in the following example. `mysql-cluster-instance-1.cokmvis0v46q.us-east-1.rds.amazonaws.com` 3. Create and connect to the new schema (for example, `mysql-sample-db2`). 4. Run the MySQL statements to check the schemas and objects in the database.	

Configure and run AWS SCT

Task	Description	Skills required
Install AWS SCT.	Download and install the latest version of [AWS SCT](https://docs.aws.amazon.com/SchemaConversionTool/latest/userguide/CHAP_Installing.html) (the current latest version 1.0.628).	General AWS
Configure AWS SCT.	1. Download the Java Database Connectivity (JDBC) drivers for IBM Db2	General AWS

Task	Description	Skills required
	(4.22.X version) and MySQL (8.x). 2. To configure the drivers in AWS SCT, choose **Settings**, **Global settings**, **Drivers**.	
Create an AWS SCT project.	Create an AWS SCT project and report that uses Db2 for LUW as the source DB engine and Aurora MySQL-Compatible for the target DB engine. To identify the privileges needed to connect to a Db2 for LUW database, see [Using Db2 LUW as a source for AWS SCT]().	General AWS

Task	Description	Skills required
Validate the objects.	Choose **Load schema**, validate the objects. Update any incorrect objects on the target database: 1. Connect to the Amazon Aurora MySQL-Compatible server by providing the connection details, and choose **Test connection**. Both source and target connections must be successful before AWS SCT can start the migration report. 2. After the report is completed, enter the schema to be converted, and choose **Finish**. AWS SCT lists any source and target objects that are converted and have errors. 3. Review the errors, and clear them manually. 4. After all errors are cleared, open the context (right-cl ick) menu for the schema, and choose **Load schema**. 5. Choose **Apply to database**. 6. In MySQL Workbench , connect to the Aurora MySQL-Compatible	DBA, General AWS

Task	Description	Skills required
	database, and check the schema and objects.	

Configure and run AWS DMS

Task	Description	Skills required
Create a replication instance.	Sign in to the AWS Management Console, navigate to the AWS DMS service, and create a replicati on instance with valid settings for the VPC security group that you configure d for the source and target databases.	General AWS
Create endpoints.	Create the source endpoint for the Db2 database, and create the target endpoint for the Aurora MySQL-Com patible database: 1. Create an endpoint for IBM Db2 as the source by choosing **Select RDS DB instance** and then choosing the Db2 instance that you created. The endpoint configuration details will be automatic ally populated. 2. In the endpoint-specific settings, add the following	General AWS

Task	Description	Skills required
	extra connection attributes. `CurrentLSN=<scan>; MaxKBytesPerRead=64; SetDataCaptureChanges=true` If you don’t mention these attributes, the source endpoint test connection will not be successful. For more information, see Using IBM Db2 LUW as a source for AWS DMS. 3. Create an endpoint for Aurora MySQL-Compatible as the target by choosing **Select RDS DB instance** and then choosing the Aurora MySQL-Compatible instance that you created. The endpoint configuration details will be automatically populated. For more information, see Using a MySQL-compatible database as a target for AWS Database Migration Service. 4. Test the source and target endpoints. Confirm that both are successful and available	

Task	Description	Skills required
	5. If the test fails, make sure that the security group inbound rules are valid.	

Task	Description	Skills required
Create migration tasks.	Create a single migration task or multiple migration tasks for full load and CDC or Data validation: 1. To create a database migration task, choose the replication instance, source database endpoint, target database endpoint. Specify the migration type as **Migrate existing data** (full load), **Replicate data changes only (CDC)**, or **Migrate existing data and replicate ongoing changes** (full load and CDC). 2. Under **Table mappings**, you can configure selection rules and transformation rules in GUI or JSON formats. 3. Under **Selection rules**, select the schema, enter table name, and select Action (Include/Exclude) to be configured (for example, Schema: SAMPLE; Table name: %, Action: Include). 4. Under **Transformation rules**, select the target (Schema, Table, or Column). Select the schema name, and choose	General AWS

Task	Description	Skills required
	the action (case, prefix, suffix); for example, Target: Schema; `mysql-sample-db`; Action: Make lowercase. 5. Turn on Amazon CloudWatch Logs monitoring.	
Plan the production run.	Confirm downtime with stakeholders such as applicati on owners to run AWS DMS in production systems.	Migration lead
Run the migration tasks.	1. Start the AWS DMS task that has a status of **Ready**. 2. Monitor the migration task logs in Amazon CloudWatc h Logs for any errors.	General AWS

Task	Description	Skills required
Validate the data.	Review migration task results and data in the source Db2 and target MySQL databases: 1. If the status is **Load complete ongoing replication**, the full load with CDC data migration is completed, and validation is ongoing. 2. Connect to the Aurora MySQL-Compatible database, and check the data. 3. Check the ongoing changes by inserting or updating data in the Db2 database.	DBA
Stop migration tasks.	After data validation is successfully completed, stop the validation migration tasks.	General AWS

Troubleshooting

Issue	Solution
AWS SCT source and target test connections are failing.	Configure JDBC driver versions and VPC security group inbound rules to accept the incoming traffic.
The Db2 source endpoint test run fails.	Configure the extra connection setting `CurrentLSN=<scan>;` .

<table>
<tr><th>Issue</th><th>Solution</th></tr>
<tr><td>The AWSDMS task fails to connect to the Db2 source, and the following error is returned.

<code>database is recoverable if either or both of the database configura tion parameters LOGARCHMETH1 and LOGARCHMETH2 are set to ON</code></td><td>To avoid the error, run the following commands:

1. <code>$ db2 update db cfg for sample using LOGARCHMETH1 DISK:/home/db2inst1/logs</code>
2. <code>$ db2stop</code>
3. <code>$ db2start</code>
4. <code>$ db2 connect to sample</code>
<pre>SQL1116N A connection to or
 activation of database "SAMPLE"
 cannot be made because of BACKUP
 PENDING. SQLSTATE=57019</pre>5. <code>$ db2 backup database sample to ../logs</code>
<pre>SQL2036N The path for the file or
 device "../logs" is not valid</pre>6. <code>$ cd</code>
7. <code>$ pwd</code>
<pre> /home/db2inst1</pre>8. <code>$ mkdir /tmp/backup</code>

Migrate a Microsoft SQL Server database from Amazon EC2 to Amazon DocumentDB by using AWS DMS

Umamaheswara Nooka, Amazon Web Services

Summary

This pattern describes how to use AWS Database Migration Service (AWS DMS) to migrate a Microsoft SQL Server database hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon DocumentDB (with MongoDB compatibility) database.

The AWS DMS replication task reads the table structure of the SQL Server database, creates the corresponding collection in Amazon DocumentDB, and performs a full-load migration.

You can also use this pattern to migrate an on-premises SQL Server or an Amazon Relational Database Service (Amazon RDS) for SQL Server DB instance to Amazon DocumentDB. For more information, see the guide Migrating Microsoft SQL Server databases to the AWS Cloud on the AWS Prescriptive Guidance website.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing SQL Server database on an EC2 instance.
- Fixed database (**db_owner**) role assigned to AWS DMS in the SQL Server database. For more information, see Database-level roles in the SQL Server documentation.
- Familiarity with using the `mongodump`, `mongorestore`, `mongoexport`, and `mongoimport` utilities to move data in and out of an Amazon DocumentDB cluster.
- Microsoft SQL Server Management Studio, installed and configured.

Limitations

- The cluster size limit in Amazon DocumentDB is 64 TB. For more information, see Cluster limits in the Amazon DocumentDB documentation.
- AWS DMS doesn't support the merging of multiple source tables into a single Amazon DocumentDB collection.

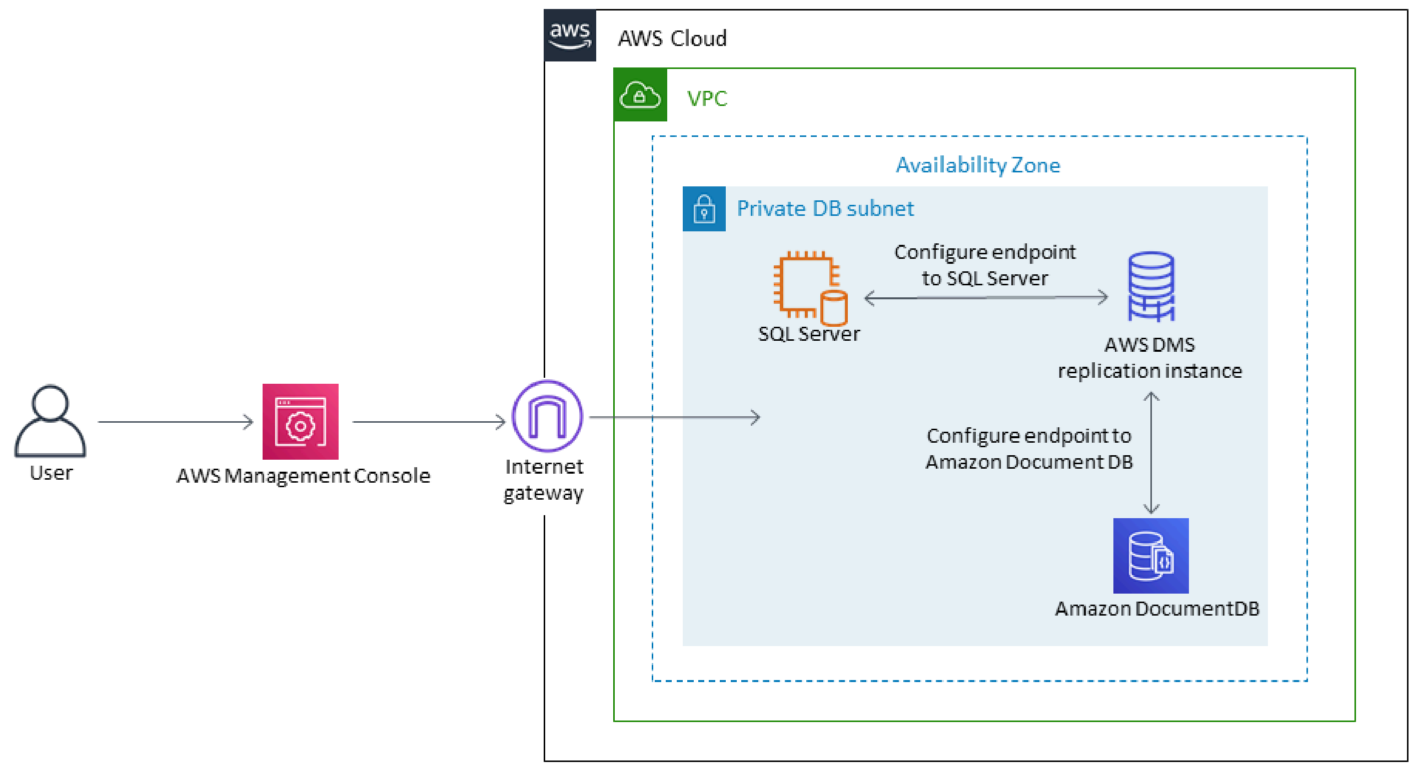
- If AWS DMS processes any changes from a source table without a primary key, it will ignore large object (LOB) columns in the source table.

Architecture

Source technology stack

- Amazon EC2

Target architecture



Target technology stack

- Amazon DocumentDB

Tools

- [AWS DMS](#) – AWS Database Migration Service (AWS DMS) helps you migrate databases easily and securely.

- [Amazon DocumentDB](#) – Amazon DocumentDB (with MongoDB compatibility) is a fast, reliable, and fully managed database service.
- [Amazon EC2](#) – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- [Microsoft SQL Server](#) – SQL Server is a relational database management system.
- [SQL Server Management Studio (SSMS)](#) – SSMS is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.

Epics

Create and configure a VPC

Task	Description	Skills required
Create a VPC.	Sign in to the AWS Management Console and open the Amazon VPC console. Create a virtual private cloud (VPC) with an IPv4 CIDR block range.	System administrator
Create security groups and network ACLs.	On the Amazon VPC console, create security groups and network access control lists (network ACLs) for your VPC, according to your requireme nts. You can also use the default settings for these configurations. For more information about this and other stories, see the "Related resources" section.	System administrator

Create and configure the Amazon DocumentDB cluster

Task	Description	Skills required
Create an Amazon DocumentDB cluster.	Open the Amazon DocumentDB console and choose "Clusters." Choose "Create," and create an Amazon DocumentDB cluster with one instance. Important : Make sure you configure this cluster with your VPC's security groups.	System administrator
Install the mongo shell.	The mongo shell is a command-line utility that you use to connect to and query your Amazon DocumentD B cluster. To install it, run the "/etc/yum.repos.d/ mongodb-org-3.6.repo" command to create the repository file. Run the "sudo yum install -y mongodb-o rg-shell" command to install the mongo shell. To encrypt data in transit, download the public key for Amazon DocumentDB, and then connect to your Amazon DocumentDB instance. For more information about these steps, see the "Related resources" section.	System administrator
Create a database in the Amazon DocumentDB cluster.	Run the "use" command with the name of your database	System administrator

Task	Description	Skills required
	to create a database in your Amazon DocumentDB cluster.	

Create and configure the AWS DMS replication instance

Task	Description	Skills required
Create the AWS DMS replicati on instance.	Open the AWS DMS console and choose "Create replicati on instance." Enter a name and description for your replication task. Choose the instance class, engine version, storage, VPC, Multi-AZ, and make it publicly accessibl e. Choose the "Advanced" tab to set the network and encryption settings. Specify the maintenance settings, and then choose "Create replicati on instance."	System administrator
Configure the SQL Server database.	Log in to Microsoft SQL Server and add an inbound rule for communication between the source endpoint and the AWS DMS replication instance. Use the replication instance's private IP address as the source. Important : The replication instance and target endpoint should be on the same VPC. Use an alternative source in the security group if the VPCs are	System administrator

Task	Description	Skills required
	different for the source and replication instances.	

Create and test the source and target endpoints in AWS DMS

Task	Description	Skills required
Create the source and target database endpoints.	Open the AWS DMS console and choose "Connect source and target database endpoints." Specify the connection information for the source and target databases. If required, choose the "Advanced" tab to set values for "Extra connection attributes." Download and use the certificate bundle in your endpoint configuration.	System administrator
Test the endpoint connection.	Choose "Run test" to test the connection. Troubleshoot any error messages by verifying the security group settings and the connections to the AWS DMS replication instance from both the source and target database instances.	System administrator

Migrate data

Task	Description	Skills required
Create the AWS DMS migration task.	On the AWS DMS console, choose "Tasks," "Create task." Specify the task options, including the source and destination endpoint names, and replication instance names. Under "Migratio n type" choose "Migrate existing data," and "Replicat e data changes only." Choose "Start task."	System administrator
Run the AWS DMS migration task.	Under "Task settings," specify the settings for the table preparation mode, such as "Do nothing," "Drop tables on target," "Truncate," and "Include LOB columns in replication." Set a maximum LOB size that AWS DMS will accept and choose "Enable logging." Leave the "Advanced settings" at their default values and choose "Create task."	System administrator
Monitor the migration.	On the AWS DMS console, choose "Tasks" and choose your migration task. Choose "Task monitoring" to monitor your task. The task stops when the full-load migration	System administrator

Task	Description	Skills required
	is complete and cached changes are applied.	

Test and verify the migration

Task	Description	Skills required
Connect to the Amazon DocumentDB cluster by using the mongo shell.	Open the Amazon DocumentDB console, choose your cluster under "Clusters." In the "Connecti vity and Security" tab, choose "Connect to this cluster with the mongo shell."	System administrator
Verify the results of your migration.	Run the "use" command with the name of your database and then run the "show collections" command. Run the "db. .count();" command with the name of your database. If the results match your source database, then your migration was successfu l.	System administrator

Migrate an on-premises ThoughtSpot Falcon database to Amazon Redshift

Battulga Purevragchaa and Antony Prasad Thevaraj, Amazon Web Services

Summary

On-premises data warehouses require significant administration time and resources, particularly for large datasets. The financial cost of building, maintaining, and growing these warehouses is also very high. To help manage costs, keep extract, transform, and load (ETL) complexity low, and deliver performance as your data grows, you must constantly choose which data to load and which data to archive.
