Amazon Web Services (AWS) Prescriptive Guidance patterns provide step-by-step instructions, architecture, tools, and code for implementing specific cloud migration, modernization, and deployment scenarios. These patterns, which are vetted by subject matter experts at AWS, are meant for builders and hands-on users who are planning to, or are in the process of, migrating to AWS. They also support users who are already on AWS and are looking for ways to optimize or modernize their cloud operations.

You can use these patterns to move your on-premises or cloud workloads of varying complexity to AWS and to accelerate your cloud adoption, optimization, and modernization efforts, regardless of whether you're in the proof of concept, planning, or implementation phase of your project. For example, for a cloud migration project:

- In the planning phase, you can evaluate the different options available to migrate to AWS. You can choose the right pattern that fits your needs, depending on whether you want to relocate, rehost, replatform, rearchitect, or repurchase. You can also understand the different tools available for migration, and start planning to procure licenses or start initial conversations with vendors.
- In the proof of concept and implementation phases, you can follow the step-by-step instructions provided in the pattern to migrate your workload to AWS. Each pattern includes details such as assumptions and prerequisites, target reference architectures, tools, lists of tasks, and code.
- If you're already using the AWS Cloud you can find patterns that will help you modernize, optimize, scale, and secure your use of cloud resources.

For more information about how to plan your migration to the AWS Cloud, see Mobilize your organization to accelerate large-scale migrations. To view all publications, including guides, strategies, and patterns, see the AWS Prescriptive Guidance home page.
Analyze Amazon Redshift data in Microsoft SQL Server Analysis Services

Created by Sunil Vora (AWS)

### Environment: PoC or pilot  
Source: Amazon Redshift  
Target: Microsoft SQL Server Analysis Services

<table>
<thead>
<tr>
<th>R Type: N/A</th>
<th>Workload: Microsoft</th>
<th>Technologies: Analytics</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: Amazon Redshift</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Summary

This pattern describes how to connect and analyze Amazon Redshift data in Microsoft SQL Server Analysis Services, by using the Intellisoft OLE DB Provider or CData ADO.NET Provider for database access.

Amazon Redshift is a fully managed, petabyte-scale data warehouse service in the cloud. SQL Server Analysis Services is an online analytical processing (OLAP) tool that you can use to analyze data from data marts and data warehouses such as Amazon Redshift. You can use SQL Server Analysis Services to create OLAP cubes from your data for rapid, advanced data analysis.

Prerequisites and limitations

Assumptions

- This pattern describes how to set up SQL Server Analysis Services and Intellisoft OLE DB Provider or CData ADO.NET Provider for Amazon Redshift on an Amazon Elastic Compute Cloud (Amazon EC2) instance. Alternatively, you can install both on a host in your corporate data center.

Prerequisites

- An active AWS account
- An Amazon Redshift cluster with credentials

Architecture

Source technology stack

- An Amazon Redshift cluster

Target technology stack

- Microsoft SQL Server Analysis Services

Source and target architecture
Tools

- Microsoft Visual Studio 2019 (Community Edition)
- Intellisoft OLE DB Provider for Amazon Redshift (Trial) or CData ADO.NET Provider for Amazon Redshift (Trial)

Epics

Analyze tables

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Analyze the tables and data to be imported.</td>
<td>Identify the Amazon Redshift tables to be imported and their sizes.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

Set up EC2 instance and install tools

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up an EC2 instance.</td>
<td>In your AWS account, create an EC2 instance in a private or public subnet.</td>
<td>Systems administrator</td>
</tr>
<tr>
<td>Install tools for database access.</td>
<td>Download and install the Intellisoft OLE DB Provider for Amazon Redshift (or CData ADO.NET Provider for Amazon Redshift).</td>
<td>Systems administrator</td>
</tr>
</tbody>
</table>
Install Visual Studio.
Skills required: Systems administrator

Install extensions.
Install the Microsoft Analysis Services Projects extension in Visual Studio.
Skills required: Systems administrator

Create a project.
Create a new tabular model project in Visual Studio to store your Amazon Redshift data. In Visual Studio, choose the Analysis Services Tabular Project option when creating your project.
Skills required: DBA

Create data source and import tables

Create an Amazon Redshift data source.
Create an Amazon Redshift data source by using the Intellisoft OLE DB Provider for Amazon Redshift (or CData ADO.NET Provider for Amazon Redshift) and your Amazon Redshift credentials.
Skills required: Amazon Redshift, DBA

Import tables.
Select and import tables and views from Amazon Redshift into your SQL Server Analysis Services project.
Skills required: Amazon Redshift, DBA

Clean up after migration

Delete the EC2 instance.
Delete the EC2 instance you launched previously.
Skills required: Systems administrator

Automate data loading from Amazon S3 to Amazon Redshift using AWS Data Pipeline

Created by Burada Kiran (AWS)

<table>
<thead>
<tr>
<th>Created by: AWS</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Storage &amp; backup; Databases; Analytics</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon S3;</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Amazon Redshift</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern walks you through the AWS data migration process from an Amazon Simple Storage Service (Amazon S3) bucket to Amazon Redshift using AWS Data Pipeline.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An S3 source bucket with the right privileges

Architecture

Source technology stack

- An S3 bucket with CSV files

Target technology stack

- An Amazon Redshift cluster

Data migration architecture
**Tools**

- **Data Pipeline** - You can use AWS Data Pipeline to automate the movement and transformation of data. With Data Pipeline, you can define data-driven workflows so that tasks can proceed after the successful completion of previous tasks.

**Epics**

**Plan the migration**

Build an ETL service pipeline to load data incrementally from Amazon S3 to Amazon Redshift using AWS Glue

Created by Rohan Jamadagni (AWS) and Arunabha Datta (AWS)

<table>
<thead>
<tr>
<th>Created by: AWS</th>
<th>Environment: Production</th>
<th>Technologies: Data lakes; Storage &amp; backup; Analytics</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: Amazon Redshift; Amazon S3; AWS Glue; AWS Lambda</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides guidance on how to configure Amazon Simple Storage Service (Amazon S3) for optimal data lake performance, and then load incremental data changes from Amazon S3 into Amazon Redshift by using AWS Glue, performing extract, transform, and load (ETL) operations.

The source files in Amazon S3 can have different formats, including comma-separated values (CSV), XML, and JSON files. This pattern describes how you can use AWS Glue to convert the source files into a cost-optimized and performance-optimized format like Apache Parquet. You can query Parquet files directly from Amazon Athena and Amazon Redshift Spectrum. You can also load Parquet files into Amazon Redshift, aggregate them, and share the aggregated data with consumers, or visualize the data by using Amazon QuickSight.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An S3 source bucket that has the right privileges and contains CSV, XML, or JSON files.

Assumptions

- The CSV, XML, or JSON source files are already loaded into Amazon S3 and are accessible from the account where AWS Glue and Amazon Redshift are configured.
- Best practices for loading the files, splitting the files, compression, and using a manifest are followed, as discussed in the Amazon Redshift documentation.
- The source file structure is unaltered.
- The source system is able to ingest data into Amazon S3 by following the folder structure defined in Amazon S3.
• The Amazon Redshift cluster spans a single Availability Zone. (This architecture is appropriate because AWS Lambda, AWS Glue, and Amazon Athena are serverless.) For high availability, cluster snapshots are taken at a regular frequency.

Limitations
• The file formats are limited to those that are currently supported by AWS Glue.
• Real-time downstream reporting isn't supported.

Architecture

Source technology stack
• S3 bucket with CSV, XML, or JSON files

Target technology stack
• S3 data lake (with partitioned Parquet file storage)
• Amazon Redshift

Target architecture
Tools

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **AWS Lambda** – AWS Lambda lets you run code without provisioning or managing servers. AWS Lambda is an event-driven service; you can set up your code to automatically initiate from other AWS services.
- **Amazon Redshift** – Amazon Redshift is a fully managed, petabyte-scale data warehouse service. With Amazon Redshift, you can query petabytes of structured and semi-structured data across your data warehouse and your data lake using standard SQL.
- **AWS Glue** – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics. AWS Glue discovers your data and stores the associated metadata (for example, table definitions and schema) in the AWS Glue Data Catalog. Your cataloged data is immediately searchable, can be queried, and is available for ETL.
- **AWS Secrets Manager** – AWS Secrets Manager facilitates protection and central management of secrets needed for application or service access. The service stores database credentials, API keys, and other secrets, and eliminates the need to hardcode sensitive information in plaintext format. Secrets Manager also offers key rotation to meet security and compliance needs. It has built-in integration for Amazon Redshift, Amazon Relational Database Service (Amazon RDS), and Amazon DocumentDB. You can store and centrally manage secrets by using the Secrets Manager console, the command-line interface (CLI), or Secrets Manager API and SDKs.
- **Amazon Athena** – Amazon Athena is an interactive query service that makes it easy to analyze data that's stored in Amazon S3. Athena is serverless and integrated with AWS Glue, so it can directly query the data that's cataloged using AWS Glue. Athena is elastically scaled to deliver interactive query performance.

Epics

Create S3 buckets and folder structure

<table>

<td>Data engineer</td>
</tr>
</tbody>
</table>
**Create an AWS Glue job to process source data.**

The AWS Glue job can be a Python shell or PySpark to standardize, deduplicate, and cleanse the source data files. To optimize performance and avoid having to query the entire S3 source bucket, partition the S3 bucket by date, broken down by year, month, day, and hour as a pushdown predicate for the AWS Glue job. For more information, see the AWS Glue documentation. Load the processed and transformed data to the processed S3 bucket partitions in Parquet format. You can query the Parquet files from Athena.

**Create an AWS Glue job to load data into Amazon Redshift.**

The AWS Glue job can be a Python shell or PySpark to load the data by upserting the data, followed by a complete refresh. For details, see the AWS Glue documentation and the Additional information section.

(Optional) **Schedule AWS Glue jobs by using triggers as necessary.**

The incremental data load is primarily driven by an Amazon S3 event that causes an AWS Lambda function to call the AWS Glue job. Use AWS Glue trigger-based scheduling for any data loads that demand time-based instead of event-based scheduling.

**Additional information**

**Detailed approach for upsert and complete refresh**

**Upsert:** This is for datasets that require historical aggregation, depending on the business use case. Follow one of the approaches described in Updating and inserting new data (Amazon Redshift documentation) based on your business needs.

**Complete refresh:** This is for small datasets that don't need historical aggregations. Follow one of these approaches:
1. Truncate the Amazon Redshift table.
2. Load the current partition from the staging area

or:

1. Create a temporary table with current partition data.
2. Drop the target Amazon Redshift table.
3. Rename the temporary table to the target table.

**Calculate value at risk (VaR) by using AWS services**

*Created by Sumon Samanta (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Analytics; Serverless</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon Kinesis Data Streams; AWS Lambda; Amazon SQS; Amazon ElastiCache</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern describes how to implement a value at risk (VaR) calculation system by using AWS services. In an on-premises environment, most VaR systems use a large, dedicated infrastructure and in-house or commercial grid scheduling software to run batch processes. This pattern presents a simple, reliable, and scalable architecture to handle VaR processing in the AWS Cloud. It builds a serverless architecture that uses Amazon Kinesis Data Streams as a streaming service, Amazon Simple Queue Service (Amazon SQS) as a managed queue service, Amazon ElastiCache as a caching service, and AWS Lambda to process orders and calculate risk.

VaR is a statistical measure that traders and risk managers use to estimate potential loss in their portfolio beyond a certain confidence level. Most VaR systems involve running a large number of mathematical and statistical calculations and storing the results. These calculations require significant compute resources, so VaR batch processes have to be broken into smaller sets of compute tasks. Splitting a large batch into smaller tasks is possible because these tasks are mostly independent (that is, calculations for one task don’t depend other tasks).

Another important requirement for a VaR architecture is compute scalability. This pattern uses a serverless architecture that automatically scales in or out based on compute load. Because the batch or online compute demand is difficult to predict, dynamic scaling is required to complete the process within the timeline imposed by a service-level agreement (SLA). Also, a cost-optimized architecture should be able to scale down each compute resource as soon as the tasks on that resource are complete.

AWS services are well-suited for VaR calculations because they offer scalable compute and storage capacity, analytics services for processing in a cost-optimized way, and different types of schedulers to run your risk management workflows. Also, you pay only for the compute and storage resources that you use on AWS.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
• Input files, which depend on your business requirements. A typical use case involves the following input files:
  • Market data file (input to the VaR calculation engine)
  • Trade data file (unless trade data comes through a stream).
  • Configuration data file (model and other static configuration data)
  • Calculation engine model files (quantitative libraries)
  • Time series data file (for historical data such as the stock price for the last five years)
  • If the market data or other input comes in through a stream, Amazon Kinesis Data Streams set up, and Amazon Identity and Access Management (IAM) permissions configured to write to the stream.

This pattern builds an architecture in which trade data is written from a trading system to a Kinesis data stream. Instead of using a streaming service, you can save your trade data in small batch files, store them in an Amazon Simple Storage Service (Amazon S3) bucket, and invoke an event to start processing the data.

Limitations

• Kinesis data stream sequencing is guaranteed on each shard, so trade orders that are written to multiple shards are not guaranteed to be delivered in the same order as write operations.
• The AWS Lambda runtime limit is currently 15 minutes. (For more information, see the Lambda FAQ.)

Architecture

Target architecture

The following architecture diagram displays the AWS services and workflows for the risk assessment system.
The diagram illustrates the following:

1. Trades stream in from the order management system.
2. The *ticket position netting* Lambda function processes the orders and writes consolidated messages for each ticker to a risk queue in Amazon SQS.
3. The *risk calculation engine* Lambda function processes the messages from Amazon SQS, performs risk calculations, and updates the VaR profit and loss (PnL) information in the risk cache in Amazon ElastiCache.
4. The *read ElastiCache data* Lambda function retrieves the risk results from ElastiCache and stores them in a database and S3 bucket.

For more information about these services and steps, see the *Epics* section.

**Automation and scale**

You can deploy the entire architecture by using the AWS Cloud Development Kit (AWS CDK) or AWS CloudFormation templates. The architecture can support both batch processing and intraday (real-time) processing.

Scaling is built into the architecture. As more trades are written into the Kinesis data stream and are waiting to be processed, additional Lambda functions can be invoked to process those trades and can then scale down after processing is complete. Processing through multiple Amazon SQS risk calculation queues is also an option. If strict ordering or consolidation is required across queues, processing cannot be parallelized. However, for an end-of-the-day batch or a mini intraday batch, the Lambda functions can process in parallel and store the final results in ElastiCache.

**Tools**

**AWS services**

- **Amazon Aurora MySQL-Compatible Edition** is a fully managed, MySQL-compatible relational database engine that helps you set up, operate, and scale MySQL deployments. This pattern uses MySQL as an example, but you can use any RDBMS system to store data.
- **Amazon ElastiCache** helps you set up, manage, and scale distributed in-memory cache environments in the AWS Cloud.
- **Amazon Kinesis Data Streams** helps you collect and process large streams of data records in real time.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **Amazon Simple Queue Service (Amazon SQS)** provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.

**Code**

This pattern provides an example architecture for a VaR system in the AWS Cloud and describes how you can use Lambda functions for VaR calculations. To create your Lambda functions, see the code examples in the Lambda documentation. For assistance, contact AWS Professional Services.

**Best practices**

- Keep each VaR compute task as small and lightweight as possible. Experiment with different numbers of trades in each compute task to see which one is most optimized for compute time and cost.
• Store reusable objects in Amazon ElastiCache. Use a framework such as Apache Arrow to reduce serialization and deserialization.

• Consider Lambda’s time limitation. If you think your compute tasks might exceed 15 minutes, try to break them down into smaller tasks to avoid the Lambda timeout. If this is not possible, you might consider a container orchestration solution with AWS Fargate, Amazon Elastic Container Service (Amazon ECS), and Amazon Elastic Kubernetes Service (Amazon EKS).

Convert the Teradata NORMALIZE temporal feature to Amazon Redshift SQL

*Created by Po Hong (AWS)*

**Source**: Teradata data warehouse  
**Target**: Amazon Redshift  
**R Type**: Re-architect  
**Environment**: Production  
**Technologies**: Analytics; Databases; Migration  
**Workload**: All other workloads  
**AWS services**: Amazon Redshift

### Summary

NORMALIZE is a Teradata extension to the ANSI SQL standard. When a SQL table includes a column that has a PERIOD data type, NORMALIZE combines values that meet or overlap in that column, to form a single period that consolidates multiple, individual period values. To use NORMALIZE, at least one column in the SQL SELECT list must be of Teradata's temporal PERIOD data type. For more information about NORMALIZE, see the Teradata documentation.

Amazon Redshift doesn't support NORMALIZE, but you can implement this functionality by using native SQL syntax and the LAG window function in Amazon Redshift. This pattern focuses on using the Teradata NORMALIZE extension with the ON MEETS OR OVERLAPS condition, which is the most popular format. It explains how this feature works in Teradata and how it can be converted into Amazon Redshift native SQL syntax.

### Prerequisites and limitations

**Prerequisites**

- Basic Teradata SQL knowledge and experience
- Amazon Redshift knowledge and experience
Architecture

Source technology stack

- Teradata data warehouse

Target technology stack

- Amazon Redshift

Target architecture

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents. The migration doesn't automatically convert the Teradata normalize phrase to Amazon Redshift SQL. You can convert this Teradata extension by following the guidelines in this pattern.

Tools

Code

To illustrate the concept and functionality of normalize, consider the following table definition in Teradata:

```
CREATE TABLE systest.project
(
  emp_id INTEGER,
  project_name VARCHAR(20),
  dept_id INTEGER,
  duration PERIOD(DATE)
);
```

Run the following SQL code to insert sample data into the table:

```
BEGIN TRANSACTION;
INSERT INTO systest.project VALUES (10, 'First Phase', 1000, PERIOD(DATE '2010-01-10', DATE '2010-03-20'));
INSERT INTO systest.project VALUES (10, 'First Phase', 2000, PERIOD(DATE '2010-03-20', DATE '2010-07-15'));
INSERT INTO systest.project VALUES (10, 'Second Phase', 2000, PERIOD(DATE '2010-06-15', DATE '2010-08-18'));
INSERT INTO systest.project VALUES (20, 'First Phase', 1000, PERIOD(DATE '2020-05-10', DATE '2020-09-20'));
@end transaction;
```

Results:

```
select * from systest.project order by 1,2,3;
*** Query completed. 4 rows found. 4 columns returned.
*** Total elapsed time was 1 second.
```
### Teradata NORMALIZE use case

Now add the Teradata `NORMALIZE` SQL clause to the `SELECT` statement:

```sql
SELECT NORMALIZE ON MEETS OR OVERLAPS emp_id, duration
FROM systest.project
ORDER BY 1,2;
```

This `NORMALIZE` operation is performed on a single column (emp_id). For emp_id=10, the three overlapping period values in duration coalesce into a single period value, as follows:

<table>
<thead>
<tr>
<th>emp_id</th>
<th>duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>('10/01/10', '10/08/18')</td>
</tr>
<tr>
<td>20</td>
<td>('10/03/10', '10/07/20')</td>
</tr>
<tr>
<td>20</td>
<td>('20/05/10', '20/09/20')</td>
</tr>
</tbody>
</table>

The following `SELECT` statement performs a `NORMALIZE` operation on project_name and dept_id. Note that the `SELECT` list contains only one `PERIOD` column, duration.

```sql
SELECT NORMALIZE project_name, dept_id, duration
FROM systest.project;
```

Output:

<table>
<thead>
<tr>
<th>project_name</th>
<th>dept_id</th>
<th>duration</th>
</tr>
</thead>
<tbody>
<tr>
<td>First Phase</td>
<td>1000</td>
<td>('10/01/10', '10/03/20')</td>
</tr>
<tr>
<td>Second Phase</td>
<td>1000</td>
<td>('20/05/10', '20/09/20')</td>
</tr>
<tr>
<td>First Phase</td>
<td>2000</td>
<td>('10/03/10', '10/07/20')</td>
</tr>
<tr>
<td>Second Phase</td>
<td>2000</td>
<td>('10/06/15', '10/08/18')</td>
</tr>
</tbody>
</table>

### Amazon Redshift equivalent SQL

Amazon Redshift currently doesn't support the `PERIOD` data type in a table. Instead, you need to divide a Teradata `PERIOD` data field into two parts: start_date, end_date, as follows:

```sql
CREATE TABLE systest.project
(
    emp_id INTEGER,
    project_name VARCHAR(20),
    dept_id INTEGER,
    start_date DATE,
    end_date DATE
);
```

Insert sample data into the table:

```sql
BEGIN TRANSACTION;
```
To rewrite Teradata's **NORMALIZE** clause, you can use the **LAG window function** in Amazon Redshift. This function returns the values for a row at a given offset above (before) the current row in the partition.

You can use the **LAG** function to identify each row that begins a new period by determining if a period meets or overlaps with the previous period (0 if yes and 1 if no). When this flag is cumulatively summed up, it provides a group identifier that can be used in the outer **GROUP BY** clause to arrive at the desired result in Amazon Redshift.

Here's a sample Amazon Redshift SQL statement that uses **LAG()**:  

```sql
SELECT emp_id, start_date, end_date,
     (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag
FROM systest.project
ORDER BY 1,2;
```

Output:

```
emp_id | start_date |  end_date  | groupstartflag
--------+------------+------------+----------------
10  | 2010-01-10 | 2010-03-20 | 1
10  | 2010-03-20 | 2010-07-15 | 0
10  | 2010-06-15 | 2010-08-18 | 0
20  | 2010-03-10 | 2010-07-20 | 1
20  | 2020-05-10 | 2020-09-20 | 1
(5 rows)
```

The following Amazon Redshift SQL statement normalizes only on the emp_id column:

```sql
SELECT T2.emp_id, MIN(T2.start_date) as new_start_date, MAX(T2.end_date) as new_end_date
FROM
( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY emp_id ORDER BY start_date ROWS UNBOUNDED PRECEDING) As GroupID
```

```
```
FROM ( SELECT emp_id, start_date, end_date, (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY emp_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag FROM systest.project ) T1 ) T2 GROUP BY T2.emp_id, T2.GroupID ORDER BY 1,2;

Output:

<table>
<thead>
<tr>
<th>emp_id</th>
<th>new_start_date</th>
<th>new_end_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>2010-01-10</td>
<td>2010-08-18</td>
</tr>
<tr>
<td>20</td>
<td>2010-03-10</td>
<td>2010-07-20</td>
</tr>
<tr>
<td>20</td>
<td>2020-05-10</td>
<td>2020-09-20</td>
</tr>
</tbody>
</table>

The following Amazon Redshift SQL statement normalizes on both the project_name and dept_id columns:

SELECT T2.project_name, T2.dept_id, MIN(T2.start_date) as new_start_date, MAX(T2.end_date) as new_end_date FROM ( SELECT T1.*, SUM(GroupStartFlag) OVER (PARTITION BY project_name, dept_id ORDER BY start_date ROWS UNBOUNDED PRECEDING) AS GroupID FROM ( SELECT project_name, dept_id, start_date, end_date, (CASE WHEN start_date <= LAG(end_date) OVER (PARTITION BY project_name, dept_id ORDER BY start_date, end_date) THEN 0 ELSE 1 END) AS GroupStartFlag FROM systest.project ) T1 ) T2 GROUP BY T2.project_name, T2.dept_id, T2.GroupID ORDER BY 1,2,3;

Output:

<table>
<thead>
<tr>
<th>project_name</th>
<th>dept</th>
<th>new_start_date</th>
<th>new_end_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>First Phase</td>
<td>1000</td>
<td>2010-01-10</td>
<td>2010-03-20</td>
</tr>
<tr>
<td>First Phase</td>
<td>2000</td>
<td>2010-03-10</td>
<td>2010-07-20</td>
</tr>
<tr>
<td>Second Phase</td>
<td>1000</td>
<td>2020-05-10</td>
<td>2020-09-20</td>
</tr>
<tr>
<td>Second Phase</td>
<td>2000</td>
<td>2010-06-15</td>
<td>2010-08-18</td>
</tr>
</tbody>
</table>

Convert the Teradata RESET WHEN feature to Amazon Redshift SQL

*Created by Po Hong (AWS)*

| Source: Teradata data warehouse | Target: Amazon Redshift | R Type: Re-architect |
| Environment: Production | Technologies: Analytics; Databases; Migration | Workload: All other workloads |

AWS services: Amazon Redshift

Summary

RESET WHEN is a Teradata feature used in SQL analytical window functions. It is an extension to the ANSI SQL standard. RESET WHEN determines the partition over which an SQL window function operates based on some specified condition. If the condition evaluates to TRUE, a new, dynamic sub-partition is created inside the existing window partition. For more information about RESET WHEN, see the Teradata documentation.

Amazon Redshift doesn't support RESET WHEN in SQL window functions. To implement this functionality, you have to convert RESET WHEN to the native SQL syntax in Amazon Redshift, and use
multiple, nested functions. This pattern demonstrates how you can use the Teradata **RESET WHEN**
feature and how you can convert it to Amazon Redshift SQL syntax.

**Prerequisites and limitations**

**Prerequisites**

- Basic knowledge of the Teradata data warehouse and its SQL syntax
- Good understanding of Amazon Redshift and its SQL syntax

**Architecture**

**Source technology stack**

- Teradata data warehouse

**Target technology stack**

- Amazon Redshift

**Architecture**

For a high-level architecture for migrating a Teradata database to Amazon Redshift, see the pattern
*Migrate a Teradata database to Amazon Redshift using AWS SCT data extraction agents*. The migration
doesn't automatically convert the Teradata **RESET WHEN** phrase to Amazon Redshift SQL. You can
convert this Teradata extension by following the guidelines in the next section.

**Tools**

**Code**

To illustrate the concept of **RESET WHEN**, consider the following table definition in Teradata:

```sql
create table systest.f_account_balance
( account_id integer NOT NULL,
  month_id integer,
  balance integer )
unique primary index (account_id, month_id);
```

Run the following SQL code to insert sample data into the table:

```sql
BEGIN TRANSACTION;
Insert Into systest.f_account_balance values (1,1,60);
Insert Into systest.f_account_balance values (1,2,99);
Insert Into systest.f_account_balance values (1,3,94);
Insert Into systest.f_account_balance values (1,4,90);
Insert Into systest.f_account_balance values (1,5,80);
Insert Into systest.f_account_balance values (1,6,88);
Insert Into systest.f_account_balance values (1,7,90);
Insert Into systest.f_account_balance values (1,8,92);
Insert Into systest.f_account_balance values (1,9,10);
Insert Into systest.f_account_balance values (1,10,60);
Insert Into systest.f_account_balance values (1,11,80);
```

```sql
```
The sample table has the following data:

<table>
<thead>
<tr>
<th>account_id</th>
<th>month_id</th>
<th>balance</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>60</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>99</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>94</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>90</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>80</td>
</tr>
<tr>
<td>1</td>
<td>6</td>
<td>88</td>
</tr>
<tr>
<td>1</td>
<td>7</td>
<td>90</td>
</tr>
<tr>
<td>1</td>
<td>8</td>
<td>92</td>
</tr>
<tr>
<td>1</td>
<td>9</td>
<td>10</td>
</tr>
<tr>
<td>1</td>
<td>10</td>
<td>60</td>
</tr>
<tr>
<td>1</td>
<td>11</td>
<td>80</td>
</tr>
<tr>
<td>1</td>
<td>12</td>
<td>10</td>
</tr>
</tbody>
</table>

For each account, let’s say that you want to analyze the sequence of consecutive monthly balance increases. When one month’s balance is less than, or equal to, the previous month’s balance, the requirement is to reset the counter to zero and restart.

**Teradata `RESET WHEN` use case**

To analyze this data, Teradata SQL uses a window function with a nested aggregate and a `RESET WHEN` phrase, as follows:

```sql
SELECT account_id, month_id, balance,
     ( ROW_NUMBER() OVER (PARTITION BY account_id ORDER BY month_id
     RESET WHEN balance <= SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING) ) -1 ) as balance_increase
FROM systest.f_account_balance
ORDER BY 1,2;
```

Output:

<table>
<thead>
<tr>
<th>account_id</th>
<th>month_id</th>
<th>balance</th>
<th>balance_increase</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>60</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>99</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>94</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>90</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>80</td>
<td>0</td>
</tr>
</tbody>
</table>
The query is processed as follows in Teradata:

1. The \texttt{SUM(balance)} aggregate function calculates the sum of all balances for a given account in a given month.
2. We check to see if a balance in a given month (for a given account) is greater than the balance of the previous month.
3. If the balance increased, we track a cumulative count value. If the \texttt{RESET WHEN} condition evaluates to \textit{false}, which means that the balance has increased over successive months, we continue to increase the count.
4. The \texttt{ROW_NUMBER()} ordered analytical function calculates the count value. When we reach a month whose balance is less than, or equal to, the balance of the previous month, the \texttt{RESET WHEN} condition evaluates to \textit{true}. If so, we start a new partition and \texttt{ROW_NUMBER()} restarts the count from 1. We use \texttt{ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING} to access the value of the previous row.
5. We subtract 1 to ensure that the count value starts with 0.

\textit{Amazon Redshift equivalent SQL}

Amazon Redshift doesn't support the \textit{RESET WHEN} phrase in an SQL analytical window function. To produce the same result, you must rewrite the Teradata SQL using Amazon Redshift native SQL syntax and nested sub-queries, as follows:

\begin{verbatim}
SELECT account_id, month_id, balance, 
    (ROW_NUMBER() OVER(PARTITION BY account_id, new_dynamic_part ORDER BY month_id) -1) as balance_increase 
FROM 
( SELECT account_id, month_id, balance, prev_balance, 
    SUM(dynamic_part) OVER (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) As new_dynamic_part 
FROM ( SELECT account_id, month_id, balance, 
    SUM(balance) over (PARTITION BY account_id ORDER BY month_id ROWS BETWEEN 1 PRECEDING AND 1 PRECEDING) as prev_balance, 
    (CASE When balance <= prev_balance Then 1 Else 0 END) as dynamic_part 
FROM systest.f_account_balance ) A 
) B 
ORDER BY 1,2;
\end{verbatim}

Because Amazon Redshift doesn't support nested window functions in the \texttt{SELECT} clause of a single SQL statement, you must use two nested sub-queries.

- In the inner sub-query (alias A), a dynamic partition indicator (\texttt{dynamic_part}) is created and populated. \texttt{dynamic_part} is set to 1 if one month's balance is less than or equal to the preceding month's balance; otherwise, it's set to 0.
• In the next layer (alias B), a `new_dynamic_part` attribute is generated as the result of a `SUM` window function.
• Finally, you add `new_dynamic_part` as a new partition attribute (`dynamic_partition`) to the existing partition attribute (`account_id`) and apply the same `ROW_NUMBER()` window function as in Teradata (and minus one).

After these changes, Amazon Redshift SQL generates the same output as Teradata.

**Enforce tagging of Amazon EMR clusters at launch**

*Created by Priyanka Chaudhary (AWS)*
Summary

This pattern provides a security control that ensures that Amazon EMR clusters are tagged when they are created.

Amazon EMR is an Amazon Web Services (AWS) service for processing and analyzing vast amounts of data. Amazon EMR offers an expandable, low-configuration service as an easier alternative to running in-house cluster computing. You can use tagging to categorize AWS resources in different ways, such as by purpose, owner, or environment. For example, you can tag your Amazon EMR clusters by assigning custom metadata to each cluster. A tag consists of a key and value that you define. We recommend that you create a consistent set of tags to meet your organization’s requirements. When you add a tag to an Amazon EMR cluster, the tag is also propagated to each active Amazon Elastic Compute Cloud (Amazon EC2) instance that is associated with the cluster. Similarly, when you remove a tag from an Amazon EMR cluster, that tag is removed from each associated, active EC2 instance as well.

The detective control monitors API calls and initiates an Amazon CloudWatch Events event for the RunJobFlow, AddTags, RemoveTags, and CreateTags APIs. The event calls AWS Lambda, which runs a Python script. The Python function gets the Amazon EMR cluster ID from the JSON input from the event and performs the following checks:

- Check if the Amazon EMR cluster is configured with tag names that you specify.
- If not, send an Amazon Simple Notification Service (Amazon SNS) notification to the user with the relevant information: the Amazon EMR cluster name, violation details, AWS Region, AWS account, and Amazon Resource Name (ARN) for Lambda that this notification is sourced from.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code. Or, you can create an S3 bucket for this purpose, as described in the Epics section.
- An active email address where you would like to receive violation notifications.
- A list of mandatory tags you want to check for.

Limitations

- This security control is regional. You must deploy it in each AWS Region that you want to monitor.

Product versions

- Amazon EMR release 4.8.0 and later.

Architecture

Workflow architecture
**Automation and scale**

- If you are using **AWS Organizations**, you can use **AWS Cloudformation StackSets** to deploy this template in multiple accounts that you want to monitor.

**Tools**

**AWS services**

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **Amazon CloudWatch Events** - Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.

- **Amazon EMR** - Amazon EMR is a web service that simplifies running big data frameworks and processing vast amounts of data efficiently.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Code**

This pattern includes the following attachments:

- **EMRTagValidation.zip** – The Lambda code for the security control.
- **EMRTagValidation.yml** – The CloudFormation template that sets up the event and Lambda function.

<th>Workload:</th>
<th>Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS services:</strong></td>
<td>Amazon EMR; Amazon S3; Amazon SNS; Amazon CloudWatch</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern provides a security control that monitors logging configuration for Amazon EMR clusters running on Amazon Web Services (AWS).

Amazon EMR is an AWS tool for big data processing and analysis. Amazon EMR offers the expandable low-configuration service as an alternative to running in-house cluster computing. Amazon EMR provides two types of EMR clusters.

- **Transient Amazon EMR clusters**: Transient Amazon EMR clusters automatically shut down and stop incurring costs when processing is finished.
- **Persistent Amazon EMR clusters**: Persistent Amazon EMR clusters continue to run after the data processing job is complete.

Amazon EMR and Hadoop both produce log files that report status on the cluster. By default, these are written to the master node in the `/mnt/var/log/` directory. Depending on how you configure the cluster when you launch it, you can also save these logs to Amazon Simple Storage Service (Amazon S3) and view them through the graphical debugging tool. Note that Amazon S3 logging can be specified only when the cluster is launched. With this configuration, logs are sent from the primary node to the Amazon S3 location every 5 minutes. For transient clusters, Amazon S3 logging is important because the clusters disappear when processing is complete, and these log files can be used to debug any failed jobs.

The pattern uses an AWS CloudFormation template to deploy a security control that monitors for API calls and starts Amazon CloudWatch Events on "RunJobFlow." The trigger invokes AWS Lambda, which runs a Python script. The Lambda function retrieves the EMR cluster ID from the event JSON input and also checks for an Amazon S3 log URI. If an Amazon S3 URI is not found, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification detailing the EMR cluster name, violation details, AWS Region, AWS account, and the Lambda Amazon Resource Name (ARN) that the notification is sourced from.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An S3 bucket for the Lambda code .zip file
- An email address where you want to receive the violation notification
Limitations

- This detective control is regional and must be deployed in the AWS Regions you intend to monitor.

Product versions

- Amazon EMR release 4.8.0 and later

Architecture

Target technology stack

- Amazon CloudWatch Events event
- Amazon EMR
- Lambda function
- S3 bucket
- Amazon SNS

Target architecture

Automation and scale

- If you are using AWS Organizations, you can use AWS CloudFormation StackSets to deploy this template in multiple accounts that you want to monitor.

Tools

Tools

- AWS CloudFormation – AWS CloudFormation helps you model and set up AWS resources using infrastructure as code.
- AWS Cloudwatch Events – AWS CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- Amazon EMR – Amazon EMR is a managed cluster platform that simplifies running big data frameworks.
- AWS Lambda – AWS Lambda supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
• **Amazon S3** – Amazon S3 is a web services interface that you can use to store and retrieve any amount of data from anywhere on the web.

• **Amazon SNS** – Amazon SNS is a web service that coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses.

Generate test data using an AWS Glue job and Python

Created by Moinul Al-Mamun

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Analytics; Cloud-native; Data lakes; Software development &amp; testing; Serverless; Big data</td>
</tr>
<tr>
<td>AWS services:</td>
<td>AWS Glue; Amazon S3</td>
</tr>
</tbody>
</table>

Summary

This pattern shows you how to quickly and easily generate millions of sample files concurrently by creating an AWS Glue job written in Python. The sample files are stored in an Amazon Simple Storage Service (Amazon S3) bucket. The ability to quickly generate a large number of sample files is important for testing or evaluating services in the AWS Cloud. For example, you can test the performance of AWS Glue Studio or AWS Glue DataBrew jobs by performing data analysis on millions of small files in an Amazon S3 prefix.

Although you can use other AWS services to generate sample datasets, we recommend that you use AWS Glue. You don’t need to manage any infrastructure because AWS Glue is a serverless data processing service. You can just bring your code and run it in an AWS Glue cluster. Additionally, AWS Glue provisions, configures, and scales the resources required to run your jobs. You pay only for the resources that your jobs use while running.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI), installed and configured to work with the AWS account

Product versions

- Python 3.9
- AWS CLI version 2

Limitations

The maximum number of AWS Glue jobs per trigger is 50. For more information, see AWS Glue endpoints and quotas.
Architecture

The following diagram depicts an example architecture centered around an AWS Glue job that writes its output (that is, sample files) to an S3 bucket.

The diagram includes the following workflow:

1. You use the AWS CLI, AWS Management Console, or an API to initiate the AWS Glue job. The AWS CLI or API enables you to automate the parallelization of the invoked job and reduce the runtime for generating sample files.
2. The AWS Glue job generates file content randomly, converts the content into CSV format, and then stores the content as an Amazon S3 object under a common prefix. Each file is less than a kilobyte. The AWS Glue job accepts two user-defined job parameters: START_RANGE and END_RANGE. You can use these parameters to set file names and the number of files generated in Amazon S3 by each job run. You can run multiple instances of this job in parallel (for example, 100 instances).

Tools

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- **AWS Glue** is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Best practices

Consider the following AWS Glue best practices as you implement this pattern:

- **Use the right AWS Glue worker type to reduce cost.** We recommend that you understand the different properties of worker types, and then choose the right worker type for your workload based on CPU and memory requirements. For this pattern, we recommend that you use a Python shell job as your job type to minimize DPU and reduce cost. For more information, see Adding jobs in AWS Glue in the AWS Glue Developer Guide.

- **Use the right concurrency limit to scale your job.** We recommend that you base the maximum concurrency of your AWS Glue job on your time requirement and required number of files.
• Start generating a small number of files at first. To reduce cost and save time when you build your AWS Glue jobs, start with a small number of files (such as 1,000). This can make troubleshooting easier. If generating a small number of files is successful, then you can scale to a larger number of files.

• Run locally first. To reduce cost and save time when you build your AWS Glue jobs, start the development locally and test your code. For instructions on setting up a Docker container that can help you write AWS Glue extract, transform, and load (ETL) jobs both in a shell and in an integrated development environment (IDE), see the Developing AWS Glue ETL jobs locally using a container post on the AWS Big Data Blog.

For more AWS Glue best practices, see Best practices in the AWS Glue documentation.

Epics

Create a destination S3 bucket and IAM role

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an S3 bucket for storing the files. | Create an S3 bucket and a prefix within it.  
Note: This pattern uses the s3://{your-s3-bucket-name}/small-files/ location for demonstration purposes. | App developer |

Create and configure an IAM role.

You must create an IAM role that your AWS Glue job can use to write to your S3 bucket.

1. Create an IAM role (for example, called "AWSGlueServiceRole-smallfiles").
2. Choose AWS Glue as the policy's trusted entity.
3. Attach an AWS managed policy called "AWSGlueServiceRole" to the role.
4. Create an inline policy or customer managed policy called "s3-small-file-access" based on the following configuration. Replace "{bucket}" with your bucket name.

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [------------------
```
5. Attach the "s3-small-file-access" policy to your role.

Create and configure an AWS Glue job to handle concurrent runs

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an AWS Glue job.</td>
<td>You must create an AWS Glue job that generates your content and stores it in an S3 bucket.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

Create an AWS Glue job, and then configure your job by completing the following steps:

1. Sign in to the AWS Management Console and open the AWS Glue console.
2. In the navigation pane, under Data Integration and ETL, choose Jobs.
3. In the Create job section, choose Python Shell script editor.
4. In the Options section, select Create a new script with boilerplate code, and then choose Create.
5. Choose Job details.
6. For Name, enter create_small_files.
7. For IAM Role, select the IAM role that you created earlier.
8. In the This job runs section, choose A new script to be authored by you.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>For <strong>Maximum concurrency</strong>, enter <strong>100</strong> for demonstration purposes. <strong>Note:</strong> Maximum concurrency defines how many instances of the job that you can run in parallel.</td>
<td></td>
</tr>
<tr>
<td>11</td>
<td>Choose <strong>Save</strong>.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
| Update the job code. | 1. Open the [AWS Glue console](https://aws.amazon.com/glue/).  <br>2. In the navigation pane, choose Jobs.  <br>3. In the Your jobs section, choose the job that you created earlier.  <br>4. Choose the Script tab, and then update the script based on the following code. Update the BUCKET_NAME, PREFIX, and text_str variables with your values.  
```python
from awsglue.utils import getResolvedOptions
import sys
import boto3
from random import randrange

# Two arguments
args = getResolvedOptions(sys.argv, ['START_RANGE', 'END_RANGE'])

START_RANGE = int(args['START_RANGE'])
END_RANGE = int(args['END_RANGE'])

BUCKET_NAME = '{BUCKET_NAME}'
PREFIX = 'small-files/input/

s3 = boto3.resource('s3')
for x in range(START_RANGE, END_RANGE):
    # generate file name
    file_name = f"input_{x}.txt"
    # generate text
    text_str = str(randrange(100000)) + ',' + str(randrange(10000000)) + ',' + str(randrange(10000))
    # write in s3
    s3.Object(BUCKET_NAME, PREFIX + file_name).put(Body=text_str)
```
|  | 5. Choose Save. | App developer |
### Run the AWS Glue job from the command line or console

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the AWS Glue job from the command line.</td>
<td>To run your AWS Glue job from the AWS CLI, run the following command using your values:</td>
<td>App developer</td>
</tr>
</tbody>
</table>

```bash
# command to run AWS Glue job

cmd:$ aws glue start-job-run --job-name create_small_files --arguments '{"--START_RANGE":0,"--END_RANGE":1000000}"

cmd:$ aws glue start-job-run --job-name create_small_files --arguments '{"--START_RANGE":1000000,"--END_RANGE":2000000}"

**Note:** For instructions on running the AWS Glue job from the AWS Management Console, see the *Run the AWS Glue job in the AWS Management Console* story in this pattern.

**Tip:** We recommend using the AWS CLI to run AWS Glue jobs if you want to run multiple executions at a time with different parameters, as shown in the example above.

To generate all AWS CLI commands that are required to generate a defined number of files using a certain parallelization factor, run the following bash code (using your values):

```bash
# define parameters
NUMBER_OF_FILES=10000000;
PARALLELIZATION=50;

# initialize
_SB=0;

# generate commands
for i in $(seq 1 $PARALLELIZATION); do
echo aws glue start-job-run --job-name create_small_files --arguments "{"--START_RANGE":"$((NUMBER_OF_FILES/";}}
```

...
If you use the script above, consider the following:

- The script simplifies the invocation and generation of small files at scale.
- Update `NUMBER_OF_FILES` and `PARALLELIZATION` with your values.
- The script above prints a list of commands that you must run. Copy those output commands, and then run them in your terminal.
- If you want to run the commands directly from within the script, remove the `echo` statement in line 11.

**Note:** To see an example of output from the above script, see *Shell script output* in the *Additional information* section of this pattern.

Run the AWS Glue job in the AWS Management Console.

1. Sign in to the AWS Management Console and open the **AWS Glue console**.
2. In the navigation pane, under **Data Integration and ETL**, choose **Jobs**.
3. In the **Your jobs** section, choose your job.
4. In the **Parameters (optional)** section, update your parameters.
5. Choose **Action**, and then choose **Run job**.
6. Repeat steps 3-5 as many times as you require. For example, to create 10 million files, repeat this process 10 times.
Task | Description | Skills required
--- | --- | ---
Check the status of your AWS Glue job. | 1. Open the [AWS Glue console](https://aws.amazon.com/glue/).  
2. In the navigation pane, choose Jobs.  
3. In the Your jobs section, choose the job that you created earlier (that is, `create_small_files`).  
4. For insight into the progress and generation of your files, review the Run ID, Run Status, and other columns. | App developer

- [Adding jobs in AWS Glue](https://docs.aws.amazon.com.glue/latest/dg/)
- [Getting started with AWS Glue](https://docs.aws.amazon.com/glue/latest/dg/)

#### Guides and patterns

- [AWS Glue best practices](https://docs.aws.amazon.com/glue/latest/dg/)
- [Load testing applications](https://docs.aws.amazon.com/glue/latest/dg/)

### Additional information

#### Benchmarking test

This pattern was used to generate 10 million files using different parallelization parameters as part of a benchmarking test. The following table shows the output of the test:

<table>
<thead>
<tr>
<th>Parallelization</th>
<th>Number of files generated by a job run</th>
<th>Job duration</th>
<th>Speed</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>1,000,000</td>
<td>6 hours, 40 minutes</td>
<td>Very slow</td>
</tr>
<tr>
<td>50</td>
<td>200,000</td>
<td>80 minutes</td>
<td>Moderate</td>
</tr>
<tr>
<td>100</td>
<td>100,000</td>
<td>40 minutes</td>
<td>Fast</td>
</tr>
</tbody>
</table>

If you want to make the process faster, you can configure more concurrent runs in your job configuration. You can easily adjust the job configuration based on your requirements, but keep in mind that there is an AWS Glue service quota limit. For more information, see [AWS Glue endpoints and quotas](https://docs.aws.amazon.com/glue/latest/dg/).

#### Shell script output

---

47
The following example shows the output of the shell script from the Run the AWS Glue job from the command line story in this pattern.

```bash
user@MUC-1234567890 MINGW64 ~
$ # define parameters
NUMBER_OF_FILES=10000000;
PARALLELIZATION=50;
# initialize
_SB=0;

# generate commands
for i in $(seq 1 $PARALLELIZATION);
   do
echo aws glue start-job-run --job-name create_small_files --arguments "'{-"'"START_RANGE":"'$(((NUMBER_OF_FILES/PARALLELIZATION)  (i-1) + SB))'","ENDRANGE":"'$(((NUMBER_OF_FILES/PARALLELIZATION) (i)))'"'}"';
   _SB=1;
done

aws glue start-job-run --job-name create_small_files --arguments '{"START_RANGE":"0","END_RANGE":"200000"}'
aws glue start-job-run --job-name create_small_files --arguments '{"START_RANGE":"200001","END_RANGE":"400000"}'
aws glue start-job-run --job-name create_small_files --arguments '{"START_RANGE":"400001","END_RANGE":"600000"}'
aws glue start-job-run --job-name create_small_files --arguments '{"START_RANGE":"600001","END_RANGE":"800000"}'
aws glue start-job-run --job-name create_small_files --arguments '{"START_RANGE":"800001","END_RANGE":"1000000"}'

user@MUC-1234567890 MINGW64 ~

FAQ

How many concurrent runs or parallel jobs should I use?

The number of concurrent runs and parallel jobs depend on your time requirement and desired number of test files. We recommend that you check the size of the files that you’re creating. First, check how much time an AWS Glue job takes to generate your desired number of files. Then, use the right number of concurrent runs to meet your goals. For example, if you assume that 100,000 files takes 40 minutes to
Launch a Spark job in Amazon EMR using a Lambda function

Summary

This pattern uses the Amazon EMR RunJobFlow API action to launch a transient cluster to run a Spark job from a Lambda function. A transient EMR cluster is designed to terminate as soon as the job is complete or if any error occurs. A transient cluster provides cost savings because it runs only during the computation time, and it provides scalability and flexibility in a cloud environment.

The transient EMR cluster is launched using the Boto3 API and the Python programming language in a Lambda function. The Lambda function, which is written in Python, provides the added flexibility of initiating the cluster when it is needed.

To demonstrate a sample batch computation and output, this pattern will launch a Spark job in an EMR cluster from a Lambda function and run a batch computation against the example sales data of a fictional company. The output of the Spark job will be a comma-separated values (CSV) file in Amazon Simple Storage Service (Amazon S3). The input data file, Spark .jar file, a code snippet, and an AWS CloudFormation template for a virtual private cloud (VPC) and AWS Identity and Access Management (IAM) roles to run the computation are provided as an attachment.

Prerequisites and limitations

Prerequisites

- An AWS account

Limitations

What type of content can I create using this pattern?

You can create any type of content, such as text files with different delimiters (for example, PIPE, JSON, or CSV). This pattern uses Boto3 to write to a file and then saves the file in an S3 bucket.

What level of IAM permission do I need in the S3 bucket?

You must have an identity-based policy that allows Write access to objects in your S3 bucket. For more information, see Amazon S3: Allows read and write access to objects in an S3 bucket in the Amazon S3 documentation.
• Only one Spark job can be initiated from the code at a time.

Product versions
• Tested on EMR 5.0.0+

Architecture

Target technology stack
• Amazon EMR
• AWS Lambda
• Amazon S3
• Apache Spark

Target architecture

Automation and scale
To automate the Spark-EMR batch computation, you can use either of the following options.

• Implement an Amazon CloudWatch event rule that can initiate the Lambda function in a cron schedule. For more information, see Tutorial: Schedule AWS Lambda functions using CloudWatch Events.
• Configure Amazon S3 event notifications to initiate the Lambda function on file arrival.

Tools

AWS services
• Amazon EMR – Amazon EMR is the industry-leading cloud big data platform for processing vast amounts of data using open source tools such as Apache Spark, Apache Hive, Apache HBase, Apache Flink, Apache Hudi, and Presto.
• AWS Lambda – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code isn't running. With Lambda, you can run code for virtually any type of
application or backend service with zero administration. AWS Lambda runs your code on a high-
availability compute infrastructure and manages all the compute resources, including server and
operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and
logging.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) provides storage for the internet. You can
use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

### Code

```python
import json
import boto3

client = boto3.client('emr')

def lambda_handler(event, context):
    response = client.run_job_flow(
        Name= 'spark_job_cluster',
        LogUri= 's3://your-bucket-name/prefix/logs',
        ReleaseLabel= 'emr-6.0.0',
        Instances={
            'MasterInstanceType': 'm5.xlarge',
            'SlaveInstanceType': 'm5.large',
            'InstanceCount': 1,
            'KeepJobFlowAliveWhenNoSteps': False,
            'TerminationProtected': False,
            'Ec2SubnetId': 'subnet-XXXXXXXXXXXXXX'
        },
        Applications = [ {'Name': 'Spark'} ],
        Configurations = [
            {'Classification': 'spark-hive-site',
             'Properties': {

### Additional information

To launch the EMR cluster in a Lambda function, a VPC and IAM roles are needed. You can set up the VPC and IAM roles by using the AWS CloudFormation template in the Attachments section of this pattern, or you can manually create them by using the links below.

The following IAM roles are required to run Lambda and Amazon EMR.

**Lambda execution role**

A Lambda function's execution role grants it permission to access AWS services and resources.

**Service role for Amazon EMR**

The Amazon EMR role defines the allowable actions for Amazon EMR when provisioning resources and performing service-level tasks that are not performed in the context of an Amazon Elastic Compute Cloud (Amazon EC2) instance running within a cluster. For example, the service role is used to provision EC2 instances when a cluster launches.

**Service role for EC2 instances**

The service role for cluster EC2 instances (also called the EC2 instance profile for Amazon EMR) is a special type of service role that is assigned to every EC2 instance in an Amazon EMR cluster when the instance launches. Application processes that run on top of the Hadoop ecosystem assume this role for permissions to interact with other AWS services.

**VPC and subnet creation**

You can create a VPC from the VPC console.

Migrate Apache Cassandra workloads to Amazon Keyspaces using AWS Glue

*Created by Nikolai Kolesnikov (AWS), Karthiga Priya Chandran (AWS), and Samir Patel (AWS)*

</tr>
</tbody>
</table>

Summary

This pattern shows you how to migrate your existing Apache Cassandra workloads to Amazon Keyspaces (for Apache Cassandra) by using AWS Glue. You can use extract, transform, and load (ETL) jobs in AWS Glue to minimize the replication lag of migrating your workloads down to a matter of minutes. You also learn how to use an Amazon Simple Storage Service (Amazon S3) bucket to store data required for the migration, including Apache Parquet files, configuration files, and scripts. This pattern assumes that your Cassandra workloads are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances in a virtual private network (VPC).

Prerequisites and limitations

**Prerequisites**

- Cassandra cluster with a source table
- Target table in Amazon Keyspaces to replicate the workload
- S3 bucket to store intermediate Parquet files that contain incremental data changes
- S3 bucket to store job configuration files and scripts

**Limitations**

AWS Glue requires some time to provision Data Processing Units (DPUs) for the Cassandra workloads. The replication lag between the Cassandra cluster and the target keyspace and table in Amazon Keyspaces is likely to last for only a matter of minutes.

Architecture

**Source technology stack**

- Apache Cassandra
• DataStax
• ScyllaDB

Target technology stack
• Amazon Keyspaces

Migration architecture
The following diagram shows an example architecture where a Cassandra cluster is hosted on Amazon EC2 instances and spread across three Availability Zones. The Cassandra nodes are hosted in private subnets. The AWS Glue ETL jobs are hosted on Amazon Virtual Private Cloud (Amazon VPC).

The diagram shows the following workflow:
1. An AWS Glue job reads the job configuration and scripts in an S3 bucket.
2. The AWS Glue job connects through port 9042 to read data from the Cassandra cluster.
3. The AWS Glue job connects through port 9142 to write data to Amazon Keyspaces.

Tools

AWS services and tools
• **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
• **AWS Glue** is a fully managed ETL service that helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
• **AWS Glue Studio** is a graphical interface that makes it easy to create, run, and monitor ETL jobs in AWS Glue.
• **Amazon Keyspaces Console** is a scalable, highly available, and managed database service that’s compatible with Apache Cassandra.
Code

The code for this pattern is available in the GitHub Amazon Keyspaces (for Apache Cassandra) Examples and Migration to Amazon Keyspaces from Apache Cassandra repositories.

Epics

Prepare the migration environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a target keyspace and table. | Create a **keyspace and table** in Amazon Keyspaces.  
**Note:** For more information on write capacity, see *Write unit calculations* in the Additional information section of this pattern.  
You can also create a keyspace by using the Cassandra Query Language (CQL). For more information, see *Create a keyspace using CQL* in the Additional information section of this pattern.  
**Note:** After you create the table, consider switching the table to on-demand capacity mode to avoid unnecessary charges.  
To update to throughput mode, run the following script:  
```sql
ALTER TABLE target_keyspace.target_table WITH CUSTOM_PROPERTIES = { 'capacity_mode': { 'throughput_mode':'PAY_PER_REQUEST'} }
``` | App owner, AWS administrator, DBA, App developer |
| Create a network connection for AWS Glue. | To create a new **AWS Glue connection** that connects the Cassandra cluster to the keyspace and table that you created earlier, use the following script:  
```bash
aws glue create-connection --connection-input '{  "Name":"conn-cassandra-custom",  "Description":"Connection to Cassandra cluster",  "ConnectionType":"NETWORK",  "ConnectionProperties":{  "DBC_ENFORCE_SSL": "false"
``` | AWS administrator, Data engineer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the Cassandra driver to connect to Cassandra.</td>
<td>Use the following configuration script:</td>
<td>DBA</td>
</tr>
</tbody>
</table>

```java
Datastax-java-driver {
    basic.request.consistency = "LOCAL_QUORUM"
    basic.contact-points = ["127.0.0.1:9042"]
    advanced.reconnect-on-init = true
    basic.load-balancing-policy {
        local-datacenter = "datacenter1"
    }
    advanced.auth-provider = {
        class =PlainTextAuthProvider
        username = "user-at-sample"
        password = "S@MPLE=PASSWORD="
    }
}
```

**Note:** The preceding script uses the Spark Cassandra Connector. For more information, see the GitHub Migration to Amazon Keyspaces from Apache Cassandra repository.

    max-requests-per-second = 1000  
    max-queue-size = 50000  
    drain-interval = 1 millisecond  
  }  
  advanced.ssl-engine-factory {  
    class = DefaultSslEngineFactory  
    hostname-validation = false  
  }  
  advanced.connection.pool.local.size = 1  
}  

**Note:** The preceding script uses the Spark Cassandra Connector. For more information, see the GitHub Migration to Amazon Keyspaces from Apache Cassandra repository.

When you use the script, consider the following:

- RateLimitingRequestThrottler ensures that the request
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|      | doesn’t exceed the configured capacity in Amazon Keyspaces.  
• The G1.X DPU creates one executor per worker.  
• The RateLimitingRequestThrottler in the preceding example is set to 1000 requests per second. With this configuration and G.1X DPU, you can achieve 1000 requests per AWS Glue worker.  
• Adjust the max-requests-per-second value to fit your workload.  
• Increase the number of workers to scale throughput to a table. | AWS administrator, AWS DevOps |

Create an S3 bucket to store job artifacts.  
The AWS Glue ETL job must access jar dependencies, the driver configuration, and the Scala script.  
To create an S3 bucket, run the following command:

```bash
MIGRATION_BUCKET=aws-migration-$(dbus-uuidgen) aws s3 mb s3://$MIGRATION_BUCKET
```

**Note:** You can use the same S3 bucket to store backups.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upload the job artifacts to the S3 bucket.</td>
<td>To upload the artifacts required by the AWS Glue job to the S3 bucket, run the following commands:</td>
<td>AWS administrator, AWS DevOps</td>
</tr>
</tbody>
</table>

```
curl -L -O https://repo1.maven.org/maven2/com/datastax/spark/spark-cassandra-connector-assembly_2.12/3.2.0/spark-cassandra-connector-assembly_2.12-3.2.0.jar
aws s3api put-object --bucket $MIGRATION_BUCKET --key jars/spark-cassandra-connector-assembly_2.12-3.2.0.jar --body spark-cassandra-connector-assembly_2.12-3.2.0.jar
aws s3api put-object --bucket $MIGRATION_BUCKET --key conf/KeyspacesConnector.conf --body KeyspacesConnector.conf
aws s3api put-object --bucket $MIGRATION_BUCKET --key conf/CassandraConnector.conf --body CassandraConnector.conf
aws s3api put-object --bucket $MIGRATION_BUCKET --key scripts/CassandraToS3.scala --body CassandraToS3.scala
aws s3api put-object --bucket $MIGRATION_BUCKET --key scripts/S3toKeyspaces.scala --body S3toKeyspaces.scala
```

The artifacts include the following:

- `spark-cassandra-connector` allows reads from Amazon Keyspaces
- `CassandraConnector.conf` and `KeyspacesConnector.conf` contain the Cassandra driver configuration that's required for accessing Cassandra and Amazon Keyspaces
- `CassandraToS3.scala` and `S3toKeyspaces.scala` scripts contain the migration code

**Create the AWS Glue jobs for migration**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an AWS Glue job to export the Cassandra workload to S3 in Parquet format.</td>
<td>Create an AWS Glue job based on the CassandraToS3.scala example from the GitHub amazon-keyspaces-examples repository. The example reads from Cassandra and writes the table to the S3 bucket.</td>
<td>App developer, App owner, Migration engineer</td>
</tr>
<tr>
<td>Create an AWS Glue job to import the incremental workload to Amazon Keyspaces.</td>
<td>Create an AWS Glue job based on the S3toKeyspaces.scala example from the GitHub amazon-keyspaces-examples repository.</td>
<td>App developer, App owner, Migration engineer</td>
</tr>
</tbody>
</table>

**Additional information**

**Migration considerations**

You can use AWS Glue to migrate your Cassandra workload to Amazon Keyspaces, while keeping your Cassandra source databases completely functional during the migration process. After the replication is complete, you can choose to cut over your applications to Amazon Keyspaces with minimal replication lag (less than minutes) between the Cassandra cluster and Amazon Keyspaces. To maintain data consistency, you can also use a similar pipeline to replicate the data back to the Cassandra cluster from Amazon Keyspaces.
Write unit calculations

As an example, consider that you intend to write 500,000,000 with the row size 1 KiB during one hour. The total number of Amazon Keyspaces write units (WCUs) that you require is based on this calculation:

\[(\text{number of rows}/60 \text{ mins} \times 60\text{s}) \times 1 \text{ WCU per row} = (500,000,000/(60\times60\text{s}) \times 1 \text{ WCU}) = 69,444 \text{ WCUs required}\]

69,444 WCUs per second is the rate for 1 hour, but you could add some cushion for overhead. For example, 69,444 \times 1.10 = 76,388 WCUs has 10 percent overhead.

Create a keyspace using CQL

To create a keyspace by using CQL, run the following commands:

```sql
CREATE KEYSPACE target_keyspace WITH replication = {'class': 'SingleRegionStrategy'}
CREATE TABLE target_keyspace.target_table (userid uuid, level text, gameid int, description text, nickname text, zip text, email text, updatetime text, PRIMARY KEY (userid, level, gameid) ) WITH default_time_to_live = 0 AND CUSTOM_PROPERTIES = {'capacity_mode':{ 'throughput_mode':'PROVISIONED', 'write_capacity_units':76388, 'read_capacity_units':3612 }} AND CLUSTERING ORDER BY (level ASC, gameid ASC)
```

Migrate Oracle Business Intelligence 12c to the AWS Cloud from on-premises servers

*Created by Lanre showunmi (AWS) and Patrick Huang (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Source: On-premises</th>
<th>Target: Amazon EC2, Amazon RDS, Amazon ALB, Amazon EFS</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>R Type</strong>: Replatform</td>

<tr>
<td><strong>AWS services</strong>: Amazon EBS; Amazon EC2; Amazon EFS; AWS CloudFormation; Elastic Load Balancing (ELB); AWS Certificate Manager (ACM)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern shows how to migrate Oracle Business Intelligence Enterprise Edition 12c from on-premises servers to the AWS Cloud by using AWS CloudFormation. It also describes how you can use other AWS services to implement Oracle BI 12c components that deliver high availability, security, flexibility, and the ability to dynamically scale.

For a list of best practices related to migrating Oracle BI 12c to the AWS Cloud, see the Additional information section of this pattern.

**Note:** It's a best practice to run multiple test migrations before transferring your existing Oracle BI 12c data to the cloud. These tests help you fine tune your migration approach, identify and fix potential issues, and estimate downtime requirements more accurately.
Prerequisites and limitations

Prerequisites

- An active AWS account
- Secure network connectivity between your on-premises servers and AWS through either AWS Virtual Private Network (AWS VPN) services or AWS Direct Connect
- Software licenses for your Oracle operating system, Oracle BI 12c, Oracle Database, Oracle WebLogic Server, and Oracle HTTP Server

Limitations

For information about storage size limits, see the Amazon Relational Database Service (Amazon RDS) for Oracle documentation.

Product versions

- Oracle Business Intelligence Enterprise Edition 12c
- Oracle WebLogic Server 12c
- Oracle HTTP Server 12c
- Oracle Database 12c (or newer)
- Oracle Java SE 8

Architecture

The following diagram shows an example architecture for running Oracle BI 12c components in the AWS Cloud:
This diagram shows the following architecture:

1. Amazon Route 53 provides domain name service (DNS) configuration.
2. Elastic Load Balancing (ELB) distributes network traffic to improve the scalability and availability of the Oracle BI 12c components across multiple Availability Zones.
3. Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling groups host the Oracle HTTP Servers, Weblogic Admin server, and managed BI servers across multiple Availability Zones.
4. Amazon Relational Database Service (Amazon RDS) for Oracle database store BI Server metadata across multiple Availability Zones.
5. Amazon Elastic File System (Amazon EFS) is mounted to every Oracle BI 12c component for shared file storage.

**Technology stack**
- Amazon Elastic Block Store (Amazon EBS)
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Elastic File System (Amazon EFS)
- Amazon RDS for Oracle
- AWS Certificate Manager (ACM)
- Elastic Load Balancing (ELB)
- Oracle BI 12c
- Oracle WebLogic Server 12c
- Oracle HTTP Server (OHS)

**Tools**
- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS Certificate Manager (ACM)** helps you create, store, and renew public and private SSL/TLS X.509 certificates and keys that protect your AWS websites and applications.
- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- **Amazon Elastic Compute Cloud (Amazon EC2)** provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- **Amazon EC2 Auto Scaling** helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- **Amazon Elastic File System (Amazon EFS)** helps you create and configure shared file systems in the AWS Cloud.
- **Elastic Load Balancing** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.
- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.
- **Oracle Data Pump** helps you move data and metadata from one database to another at high speeds.
- **Oracle Fusion Middleware** is a suite of application development tools and integration solutions to identity management, collaboration, and business intelligence reporting.

- **Oracle GoldenGate** helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.

- **Oracle WebLogic Scripting Tool (WLST)** provides a command line interface that helps you horizontally scale out your WebLogic clusters.

## Epics

### Assess the source environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Gather software inventory information. | Identify versions and patch levels for each of your source technology stack's software components, including the following:  
- Oracle operating system  
- Oracle Database  
- Oracle BI 12c  
- Oracle WebLogic Server  
- Oracle HTTP Server  
- Java | Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator |
| Gather compute and storage inventory information. | In your source environment, review current and historical utilization metrics for the following:  
- CPU usage  
- Memory usage  
- Storage usage | Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator, System Administrator |
| Gather information about the source environment’s architecture and its requirements. | Obtain a full understanding of your source environment’s architecture and its requirements, including knowledge of the following:  
- Oracle WebLogic Server domain configuration  
- Clustering  
- Load balancing  
- Connectivity  
- Availability | Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator |
### Identify Java Database Connectivity (JDBC) data sources.

**Description:** Gather information about your source environment's JDBC data sources and drivers for each database engine that it uses.

**Skills required:** Migration Architect, Application Owner, Oracle BI Administrator, Database Engineer or Administrator

---

### Gather information about environment-specific settings.

**Description:** Collect information about settings and configurations that are specific to your source environment, including the following:

- Custom startup and shutdown scripts
- Java and other environment variables
- Certificates

**Skills required:** Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

---

### Identify any dependencies on other applications.

**Description:** Collect information about integrations in your source environment that create dependencies with other applications.**Important:** Make sure that you identify any Lightweight Directory Access Protocol (LDAP) integrations and other networking requirements.

**Skills required:** Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator

---

### Design your target environment

**Task** | **Description** | **Skills required**
--- | --- | ---
Create a high-level design document. | Create a target architecture design document. Make sure that you use the information that you collected when assessing your source environment to inform the design document. | Solutions Architect, Application Architect, Database Engineer, Migration Architect

Obtain approval for the design document. | Review the design document with stakeholders and obtain the required approvals. | Application or Service Owner, Solutions Architect, Application Architect
## Deploy the infrastructure

</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> Conduct additional testing and validation as required.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Disconnect traffic to the on-premises Oracle BI 12c environment.

- At the appointed cutover window, stop all traffic to the on-premises Oracle BI 12c environment.
- **Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator**

#### Resynchronize the new Oracle BI 12c repository database with the source database.

- Resynchronize the Amazon RDS Oracle Oracle BI 12c repository database with the on-premises database.
- To synchronize the databases, you can either use an Oracle Data Pump refresh or an AWS DMS change data capture (CDC).
- **Oracle BI Administrator, Database Engineer/Administrator**

#### Switch your Oracle BI 12c URLs to point to the new AWS environment.

- Update the Oracle BI 12c URLs on your internal DNS servers so that they point to the new AWS installation.
- **Migration Architect, Solutions Architect, Application Owner, Oracle BI Administrator**

#### Monitor the new environment.

- Monitor the new Oracle BI 12c environment by using any of the following tools:
  - **Amazon CloudWatch**
  - **Amazon RDS Performance Insights**
  - **Oracle Enterprise Manager**
- **Oracle BI Administrator, Database Engineer/Administrator, Application Administrator**

#### Get sign-off on the project.

- Review the testing results with stakeholders and obtain the required approvals to wrap up the migration.
- **Application Owner, Service Owner, Cloud Infrastructure Architect, Migration Architect, Oracle BI Architect**
Additional information

The following is a list of best practices related to migrating Oracle BI 12c to the AWS Cloud.

Repository databases

It’s a best practice to host Oracle BI 12c database schemas on an Amazon RDS for Oracle instance. This instance type provides cost-efficient and resizable capacity while automating administration tasks, such as hardware provisioning, database setup, patching, and backups.

For more information, see Using the Oracle Repository Creation Utility on RDS for Oracle in the Amazon RDS User Guide.

Web and application tiers

Memory optimized Amazon EC2 instances are often well suited for Oracle BI 12c servers. Whatever instance type you choose, make sure that the instances that you provision meet your system's memory usage requirements. Also, make sure that you configure a sufficient WebLogic Java Virtual Machine (JVM) heap size based on your Amazon EC2 instance's available memory.

Local storage

I/O plays an important part in the overall performance of your Oracle BI 12c application. Amazon Elastic Block Store (Amazon EBS) offers different storage classes that are optimized for different workload patterns. Make sure that you choose an Amazon EBS volume type that fits your use case.

For more information about EBS volume types, see Amazon EBS features in the Amazon EBS documentation.

Shared storage

A clustered Oracle BI 12c domain requires shared storage for the following resources:

- Configuration files
- Oracle BI 12c singleton data directory (SDD)
- Oracle global cache
- Oracle BI Scheduler scripts
- Oracle WebLogic Server binaries

You can meet this shared storage requirement by using Amazon EFS, which provides a scalable, fully managed elastic Network File System (NFS) file system.

Fine tuning shared storage performance

Amazon EFS has two throughput modes: Provisioned and Bursting. The service also has two performance modes: General Purpose and Max I/O.

To fine tune performance, start by testing your workloads in the General Purpose performance mode and Provisioned throughput mode. Doing these tests will help you determine if those baseline modes are sufficient to meet your desired service levels.

For more information, see Amazon EFS performance in the Amazon EFS User Guide.

Availability and disaster recovery

It's a best practice to deploy Oracle BI 12c components across multiple Availability Zones to protect those resources in the event of an Availability Zone failure. The following is a list of availability and disaster recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:
• **Oracle BI 12c repository databases**: Deploy a multi-AZ Amazon RDS database instance to your Oracle BI 12c repository database. In a multi-AZ deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different AZ. Running an Oracle BI 12c repository database instance across Availability Zones can enhance availability during planned system maintenance and help protect your databases against instance and Availability Zone failures.

• **Oracle BI 12c Managed Servers**: To achieve fault tolerance, it’s a best practice to deploy Oracle BI 12c system components on Managed Servers in an Amazon EC2 Auto Scaling Group configured to span multiple Availability Zones. Auto Scaling replaces faulty instances based on Amazon EC2 health checks. In the event of an Availability Zone failure, Oracle HTTP Servers continue to direct traffic to Managed Servers in the functioning Availability Zone. Then, Auto Scaling launches instances to keep up with your host count requirements. Activating HTTP session state replication is recommended to help make sure that there’s a smooth failover of the existing sessions to the functioning Managed Servers.

• **Oracle BI 12c Administration Servers**: To make sure that your Administration Server has high availability, host it in an Amazon EC2 Auto Scaling group configured to span multiple Availability Zones. Then, set the minimum and maximum size of the group set to 1. If an Availability Zone failure occurs, Amazon EC2 Auto Scaling starts up a replacement Administration Server in an alternate Availability Zone. To recover any failed underlying hosts within the same Availability Zone, you can activate Amazon EC2 Auto Recovery.

• **Oracle Web Tier servers**: It’s a best practice to associate your Oracle HTTP Server with your Oracle WebLogic Server domain. For high availability, deploy your Oracle HTTP Server in an Amazon EC2 Auto Scaling group configured to span multiple Availability Zones. Then, place the server behind an ELB elastic load balancer. To provide additional protection against host failure, you can activate Amazon EC2 Auto Recovery.

**Scalability**

The elasticity of the AWS Cloud helps you scale applications either horizontally or vertically in response to workload requirements.

*Vertical scaling*

To vertically scale your application, you can change the size and type of the Amazon EC2 instances that are running your Oracle BI 12c components. You don't need to over-provision instances at the start of your deployment and incur unnecessary cost.

*Horizontal scaling*

Amazon EC2 Auto Scaling helps you horizontally scale your application by automatically adding or removing Managed Servers based on workload requirements.

**Note:** Horizontal scaling with Amazon EC2 Auto Scaling requires scripting skills and thorough testing to implement.

**Backup and recovery**

The following is a list of backup and recovery best practices for specific Oracle BI 12c resources hosted in the AWS Cloud:

• **Oracle Business Intelligence metadata repositories**: Amazon RDS automatically creates and saves backups of your database instances. These backups are retained for a period of time that you specify. Make sure that you configure your Amazon RDS backup duration and retention settings based on your data protection requirements. For more information, see Amazon RDS backup and restore.

• **Managed Servers, Administration Servers, and Web Tier servers**: Make sure that you configure Amazon EBS snapshots based on your data protection and retention requirements.

• **Shared storage**: You can manage backup and recovery for files stored in Amazon EFS by using AWS Backup. The AWS Backup service can also be deployed to centrally manage backup and recovery of
other services, including Amazon EC2, Amazon EBS, and Amazon RDS. For more information, see What is AWS Backup? in the AWS Backup Developer Guide.

Security and compliance

The following is a list of security best practices and AWS services that can help you protect your Oracle BI 12c applications in the AWS Cloud:

- **Encryption at rest:** Amazon RDS, Amazon EFS, and Amazon EBS all support industry standard encryption algorithms. You can use AWS Key Management Service (AWS KMS) to create and manage cryptographic keys and control their use across AWS services and in your applications. You can also configure Oracle Transparent Data Encryption (TDE) on the Amazon RDS for Oracle database instance that’s hosting your Oracle BI 12c repository database.

- **Encryption in transit:** It’s a best practice to activate either SSL or TLS protocols to protect data in transit between the various layers of your Oracle BI 12c installation. You can use AWS Certificate Manager (ACM) to provision, manage, and deploy public and private SSL and TLS certificates for your Oracle BI 12c resources.

- **Network security:** Make sure that you deploy your Oracle BI 12c resources in an Amazon VPC that has the appropriate access controls configured for your use case. Configure your security groups to filter inbound and outbound traffic from the Amazon EC2 instances that are running your installation. Also, make sure that you configure Network Access Control Lists (NACLs) that allow or deny traffic based on defined rules.

- **Monitoring and logging:** You can use AWS CloudTrail to track API calls to your AWS infrastructure, including your Oracle BI 12c resources. This functionality is useful when tracking changes to infrastructure or when conducting a security analysis. You can also use Amazon CloudWatch to view operational data that can provide you with actionable insight into the performance and health of your Oracle BI 12c application. You can configure alarms and take automated actions based on those alarms, too. Amazon RDS provides additional monitoring tools, including Enhanced Monitoring and Performance Insights.

---

Migrate an ELK Stack to Elastic Cloud on AWS

*Created by Battulga Purevragchaa (AWS), Uday Theepireddy (Elastic), and Antony Prasad Thevaraj (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Source: Elasticsearch</th>
<th>Target: Elastic Cloud</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>R Type:</strong> Replatform</td>
<td><strong>Workload:</strong> All other workloads</td>
<td><strong>Technologies:</strong> Analytics; Security, identity, compliance</td>
</tr>
</tbody>
</table>

| AWS services: Amazon EC2; Amazon EC2 Auto Scaling; Elastic Load Balancing (ELB); Amazon S3; Amazon Route 53 |

**Summary**

Elastic has provided services for many years, with their users and customers typically managing Elastic themselves on premises. Elastic Cloud, the managed Elasticsearch service, provides a way to consume the Elastic Stack (ELK Stack) and solutions for enterprise search, observability, and security. You can access Elastic solutions with apps such as Logs, Metrics, APM (application performance monitoring), and SIEM.
(security information and event management). You can use integrated features such as machine learning, index lifecycle management, Kibana Lens (for drag-and-drop visualizations).

When you move from self-managed Elasticsearch to Elastic Cloud, the Elasticsearch service takes care of the following:

- Provisioning and managing the underlying infrastructure
- Creating and managing Elasticsearch clusters
- Scaling clusters up and down
- Upgrades, patching, and taking snapshots

This gives you more time to focus on solving other challenges.

This pattern defines how to migrate on-premises Elasticsearch 7.13 to Elasticsearch on Elastic Cloud on Amazon Web Services (AWS). Other versions might require slight modifications to the processes described in this pattern. For more information, contact your Elastic representative.

**Prerequisites and limitations**

**Prerequisites**

- An active [AWS account](https://aws.amazon.com) with access to [Amazon Simple Storage Service](https://aws.amazon.com/s3) (Amazon S3) for snapshots
- A secure, sufficiently high-bandwidth [private link](https://aws.amazon.com/private-links) for copying snapshot data files to Amazon S3
- [Amazon S3 Transfer Acceleration](https://aws.amazon.com/s3-accelerate/)
- [Elastic Snapshot policies](https://aws.amazon.com) to ensure that data ingestion is archived regularly, either to a sufficiently large local data store or to remote storage (Amazon S3)

You must understand how large your snapshots and the [lifecycle policies](https://aws.amazon.com) for accompanying indexes are on premises before initiating your migration. For more information, contact Elastic.

**Roles and skills**

The migration process also requires the roles and expertise described in the following table.

<table>
<thead>
<tr>
<th>Role</th>
<th>Expertise</th>
<th>Responsibilities</th>
</tr>
</thead>
<tbody>
<tr>
<td>App support</td>
<td>Familiarity with Elastic Cloud and Elastic on premises</td>
<td>All Elastic related tasks</td>
</tr>
<tr>
<td>Systems administrator or DBA</td>
<td>In-depth knowledge of the on-premises Elastic environment and its configuration</td>
<td>The ability to provision storage, install and use the AWS Command Line Interface (AWS CLI), and identify all data sources feeding Elastic on premises</td>
</tr>
<tr>
<td>Network administrator</td>
<td>Knowledge of on-premises to AWS network connectivity, security, and performance</td>
<td>Establishment of network links from on premises to Amazon S3, with an understanding of connectivity bandwidth</td>
</tr>
</tbody>
</table>

**Limitations**
Elasticsearch on Elastic Cloud is available only in supported AWS Regions (September 2021).

Product versions
- Elasticsearch 7.13

Architecture

Source technology stack

On-premises Elasticsearch 7.13 or later:

- Cluster snapshots
- Index snapshots
- Beats configuration

Source technology architecture

The following diagram shows a typical on-premises architecture with different ingestion methods, node types, and Kibana. The different node types reflect the Elasticsearch cluster, authentication, and visualization roles.

1. Ingestion from Beats to Logstash
2. Ingestion from Beats to Apache Kafka messaging queue
3. Ingestion from Filebeat to Logstash
4. Ingestion from Apache Kafka messaging queue to Logstash
5. Ingestion from Logstash to an Elasticsearch cluster
6. Elasticsearch cluster
7. Authentication and notification node
8. Kibana and blob nodes
Target technology stack

Elastic Cloud is deployed to your software as a service (SaaS) account in multiple AWS Regions with cross-cluster replication.

- Cluster snapshots
- Index snapshots
- Beats configurations
- Elastic Cloud
- Network Load Balancer
- Amazon Route 53
- Amazon S3

Target architecture

The managed Elastic Cloud infrastructure is:

- Highly available, being present in multiple Availability Zones and multiple AWS Regions.
- Region failure tolerant because data (indexes and snapshots) is replicated using Elastic Cloud cross-cluster replication (CCR)
- Archival, because snapshots are archived in Amazon S3
- Network partition tolerant through a combination of Network Load Balancers and Route 53
- Data ingestion originating from (but not limited to) Elastic APM, Beats, Logstash

High-level migration steps

Elastic has developed its own prescriptive methodology for migrating on-premises Elastic Cluster to Elastic Cloud. The Elastic methodology is directly aligned and complementary to the AWS migration guidance and best practices, including Well-Architected Framework and AWS Migration Acceleration Program (MAP). Typically, the three AWS migration phases are the following:
Elastic follows similar migration phases with complementary terminology:

- Initiate
- Plan
- Implement
- Deliver
- Close

Elastic uses the Elastic Implementation Methodology to facilitate the delivery of project outcomes. This is inclusive by design to ensure that the Elastic, consulting teams, and customer teams work together with clarity to jointly deliver intended outcomes.

The Elastic methodology combines traditional waterfall phasing with Scrum within the implementation phase. Configurations of technical requirements are delivered iteratively in a collaborative manner while minimizing risk.

**Tools**

- **Elastic Load Balancing** – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones.
- **Amazon Route 53** – Amazon Route 53 is a highly available and scalable Domain Name System (DNS) web service. You can use Route 53 to perform three main functions in any combination: domain registration, DNS routing, and health checking.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web. This pattern uses an S3 bucket and **Amazon S3 Transfer Acceleration**.
- **Beats** – Beats ship data from Logstash or Elasticsearch
- **Elastic Cloud** – Elastic Cloud is a managed service for hosting Elasticsearch.
- **Elasticsearch** – Elasticsearch is a search and analytics engine that uses the Elastic Stack to centrally store your data for search and analytics that scale. This pattern also uses snapshot creation and cross-cluster replication.
Logstash – Logstash is a server-side data processing pipeline that ingests data from multiple sources, transforms it, and then sends it to your data storage.

## Epics

### Prepare the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identify servers running the on-premises Elastic solution.</td>
<td>Confirm that Elastic migration is supported.</td>
<td>App owner</td>
</tr>
<tr>
<td>Understand the on-premises server configuration.</td>
<td>To understand the server configuration needed to drive workloads successfully on premises, find the server hardware footprint, network configuration, and storage characteristics that are currently in use.</td>
<td>App Support</td>
</tr>
<tr>
<td>Gather user and app account information.</td>
<td>Identify the user names and app names that are used by the on-premises Elastic environment.</td>
<td>Systems administrator, App support</td>
</tr>
<tr>
<td>Document Beats and data shipper configuration.</td>
<td>To document the configurations, look at existing data sources and sinks. For more information, see the Elastic documentation.</td>
<td>App support</td>
</tr>
<tr>
<td>Determine the velocity and volume of data.</td>
<td>Establish a baseline for how much data the cluster is handling.</td>
<td>Systems administrator, App support</td>
</tr>
<tr>
<td>Document RPO and RTO scenarios.</td>
<td>Document recovery point objective (RPO) and recovery time objective (RTO) scenarios in terms of outages and service level agreements (SLAs).</td>
<td>App owner, Systems administrator, App support</td>

Migrate data to the AWS Cloud by using Starburst

_Created by Antony Prasad Thevaraj (AWS), Shaun Van Staden (Starburst), and Suresh Veeragoni (AWS)_

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Analytics; Data lakes; Databases</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon EKS</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

_Summary_
Starburst helps accelerate your data migration journey to Amazon Web Services (AWS) by providing an enterprise query engine that brings existing data sources together in a single access point. You can run analytics across multiple data sources to get valuable insights, before finalizing any migration plans. Without disrupting business-as-usual analytics, you can migrate the data by using the Starburst engine or a dedicated extract, transform, and load (ETL) application.

_Prerequisites and limitations_

Prerequisites
• An active AWS account
• A virtual private cloud (VPC)
• An Amazon Elastic Kubernetes Service (Amazon EKS) cluster
• An Amazon Elastic Compute Cloud (Amazon EC2) Auto Scaling group
• A list of current system workloads that need to be migrated
• Network connectivity from AWS to your on-premises environment

Architecture

Reference architecture

The following high-level architecture diagram shows the typical deployment of Starburst Enterprise in the AWS Cloud:

1. The Starburst Enterprise cluster runs inside your AWS account.
2. A user authenticates by using Lightweight Directory Access Protocol (LDAP) or Open Authorization (OAuth) and interacts directly with the Starburst cluster.
3. Starburst can connect to several AWS data sources, such as AWS Glue, Amazon Simple Storage Service (Amazon S3), Amazon Relational Database Service (Amazon RDS), and Amazon Redshift. Starburst provides federated query capabilities across data sources in the AWS Cloud, on premises, or in other cloud environments.
4. You launch Starburst Enterprise in an Amazon EKS cluster by using Helm charts.
5. Starburst Enterprise uses Amazon EC2 Auto Scaling groups and Amazon EC2 Spot Instances to optimize infrastructure.
6. Starburst Enterprise connects directly to your existing on-premises data sources to read data real-time. In addition, if you have an existing Starburst Enterprise deployment in this environment, you can directly connect your new Starburst cluster in the AWS Cloud to this existing cluster.
Please note the following:

- Starburst is not a data virtualization platform. It is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.
- When Starburst is deployed as part of a migration, it has direct connectivity to the existing on-premises infrastructure.
- Starburst provides several built-in enterprise and open-source connectors that facilitate connectivity to a variety of legacy systems. For a full list of connectors and their capabilities, see Connectors in the Starburst Enterprise user guide.
- Starburst can query data in real-time from on-premises data sources. This prevents interruptions of regular business operations while data is being migrated.
• If you are migrating from an existing on-premises Starburst Enterprise deployment, you can use a special connector, *Starburst Stargate*, to connect your Starburst Enterprise cluster in AWS directly to your on-premises cluster. This provides additional performance benefits when business users and data analysts are federating queries from the AWS Cloud to your on-premises environment.

**High-level process overview**

You can accelerate data migration projects by using Starburst because Starburst enables insights across all of your data, prior to migrating it. The following image shows the typical process for migrating data by using Starburst.

---

**Roles**

The following roles are typically required to complete a migration using Starburst:

- **Cloud administrator** – Responsible for making cloud resources available to run the Starburst Enterprise application
- **Starburst administrator** – Responsible for installing, configuring, managing, and supporting the Starburst application
- **Data engineer** – Responsible for:
  - Migrating the legacy data to the cloud
  - Building semantic views to support analytics
- **Solution or system owner** – Responsible for the overall solution implementation
Tools

AWS services

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service for running Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

Other tools

- **Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.

- **Starburst Enterprise** – Starburst Enterprise is a SQL-based massively parallel processing (MPP) query engine that forms the basis of an overall data mesh strategy for analytics.

- **Starburst Stargate** – Starburst Stargate links catalogs and data sources in one Starburst Enterprise environment, such as a cluster in an on-premises data center, to the catalogs and data sources in another Starburst Enterprise environment, such as a cluster in the AWS Cloud.

Epics

Assess the data

### Optimize the ETL ingestion of input file size on AWS

*Created by Apoorva Patrikar (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Analytics; Data lakes</td>
</tr>
<tr>
<td>Workload:</td>
<td>Open-source</td>
</tr>
</tbody>
</table>

| AWS services: | AWS Glue; Amazon S3 |
Summary

This pattern shows you how to optimize the ingestion step of the extract, transform, and load (ETL) process for big data and Apache Spark workloads on AWS Glue by optimizing file size before processing your data. Use this pattern to prevent or resolve the small files problem. That is, when a large number of small files slows down data processing due to the aggregate size of the files. For example, hundreds of files that are only a few hundred kilobytes each can significantly slow down data processing speeds for your AWS Glue jobs. This is because AWS Glue must perform internal list functions on Amazon Simple Storage Service (Amazon S3) and YARN (Yet Another Resource Negotiator) must store a large amount of metadata. To improve data processing speeds, you can use grouping to enable your ETL tasks to read a group of input files into a single in-memory partition. The partition automatically groups smaller files together. Alternatively, you can use custom code to add batch logic to your existing files.

Prerequisites and limitations

Prerequisites

- An active AWS account
- One or more AWS glue jobs
- One or more big data or Apache Spark workloads
- An S3 bucket

Architecture

The following pattern shows how data in different formats is processed by an AWS Glue job and then stored in an S3 bucket to get visibility into performance.
The diagram shows the following workflow:

1. An AWS Glue job converts small files in CSV, JSON, and Parquet format to dynamic frames. **Note**: The size of the input file has the most significant impact on the performance of the AWS Glue job.

2. The AWS Glue job performs internal list functions in an S3 bucket.

**Tools**

- **AWS Glue** is a fully managed ETL service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.

- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
# Epics

## Use grouping to optimize ETL ingestion

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the group size.</td>
<td>If you have more than 50,000 files, grouping is done by default. However, you can also use grouping for less than 50,000 files by specifying the group size in the connectionOptions parameter. The connectionOptions parameter is in the create_dynamic_frame.from_options method.</td>
<td>Data engineer</td>
</tr>
<tr>
<td>Write the grouping code.</td>
<td>Use the create_dynamic_frame method to create a dynamic frame. For example:</td>
<td>Data engineer</td>
</tr>
</tbody>
</table>
|                                     | ```python
S3bucket_node1 =
glueContext.create_dynamic_frame.from_options(
    format_options={"multiline": False},
    connection_type="s3",
    format="json",
    connection_options={
        "paths": ["s3://bucket/prefix/file.json"],
        "recurse": True,
        "groupFiles": 'inPartition',
        "groupBy": "inPartition",
        "groupSize": 1048576
    },
    transformation_ctx="S3bucket_node1",
)
```
| Note: Use groupFiles to group files in an Amazon S3 partition group. Use groupSize to set the target size of the group to be read in memory. Specify groupSize in bytes (1048576 = 1 MB). |                                                                                                                                           |                 |
| Add the code to the workflow.       | Add the grouping code to your job workflow in AWS Glue.                                                                                                                                            | Data engineer   |

Additional information

Determining file size

There is no straightforward way to determine if a file size is too big or too small. The impact of file size on processing performance depends on the configuration of your cluster. In core Hadoop, we recommend that you use files that are 128 MB or 256 MB to make the most of the block size.

For most text file workloads on AWS Glue, we recommended a file size between 100 MB and 1 GB for a 5-10 DPU cluster. To figure out the best size of input files, monitor the preprocessing section of your AWS Glue job, and then check the CPU utilization and memory utilization of the job.

Additional considerations

If performance in the early ETL stages is a bottleneck, consider grouping or merging the data files before processing. If you have complete control on the file generation process, it can be even more efficient to aggregate data points on the source system itself before the raw data is sent to AWS.

Orchestrate an ETL pipeline with validation, transformation, and partitioning using AWS Step Functions

Created by Sandip Gangopadhyay (AWS)
**Summary**

This pattern describes how to build a serverless extract, transform, and load (ETL) pipeline to validate, transform, compress, and partition a large CSV dataset for performance and cost optimization. The pipeline is orchestrated by AWS Step Functions and includes error handling, automated retry, and user notification features.

When a CSV file is uploaded to an Amazon Simple Storage Service (Amazon S3) bucket source folder, the ETL pipeline starts to run. The pipeline validates the content and the schema of the source CSV file, transforms the CSV file to a compressed Apache Parquet format, partitions the dataset by year, month, and day, and stores it in a separate folder for analytics tools to process.

The code that automates this pattern is available on GitHub, in the ETL Pipeline with AWS Step Functions repository.

### Prerequisites and limitations

**Prerequisites**

- An active AWS account.
- AWS Command Line Interface (AWS CLI) installed and configured with your AWS account, so that you can create AWS resources by deploying an AWS CloudFormation stack. AWS CLI version 2 is recommended. For installation instructions, see [Installing, updating, and uninstalling the AWS CLI version 2](https://docs.aws.amazon.com/cli/latest/userguide/cli-install-howto.html) in the AWS CLI documentation. For AWS CLI configuration instructions, see [Configuration and credential file settings](https://docs.aws.amazon.com/cli/latest/userguide/cli-configure-files.html) in the AWS CLI documentation.
- An Amazon S3 bucket.
- A CSV dataset with the correct schema. (The code repository included with this pattern provides a sample CSV file with the correct schema and data type that you can use.)
- A web browser that is supported for use with the AWS Management Console. (See the list of supported browsers.)
- AWS Glue console access.
- AWS Step Functions console access.

**Limitations**

- In AWS Step Functions, the maximum limit for keeping history logs is 90 days. For more information, see [Quotas](https://docs.aws.amazon.com/stepfunctions/latest/concept/quota.html) and [Quotas for standard workflows](https://docs.aws.amazon.com/stepfunctions/latest/concept/quota.html) in the AWS Step Functions documentation.

**Product versions**

- Python 3 for AWS Lambda
- AWS Glue version 2.0

### Architecture
The workflow illustrated in the diagram consists of these high-level steps:

1. The user uploads a CSV file into the source folder in Amazon S3.
2. An Amazon S3 notification event initiates an AWS Lambda function that starts the Step Functions state machine.
3. The Lambda function validates the schema and data type of the raw CSV file.
4. Depending on the validation results:
   a. If validation of the source file succeeds, the file moves to the stage folder for further processing.
   b. If validation fails, the file moves to the error folder, and an error notification is sent through Amazon Simple Notification Service (Amazon SNS).
5. An AWS Glue crawler creates the schema of the raw file from the stage folder in Amazon S3.
6. An AWS Glue job transforms, compresses, and partitions the raw file into Parquet format.
7. The AWS Glue job also moves the file to the transform folder in Amazon S3.
8. The AWS Glue crawler creates the schema from the transformed file. The resulting schema can be used by any analytics job. You can also use Amazon Athena to run ad-hoc queries.
9. If the pipeline completes without errors, the schema file is moved to the archive folder. If any errors are encountered, the file is moved to the error folder instead.
10. Amazon SNS sends a notification that indicates success or failure based on the pipeline completion status.

All the AWS resources used in this pattern are serverless. There are no servers to manage.

**Tools**

**AWS services**

- **AWS Glue** – AWS Glue is a fully managed ETL service that makes it easy for customers to prepare and load their data for analytics.
- **AWS Step Functions** – AWS Step Functions is a serverless orchestration service that lets you combine AWS Lambda functions and other AWS services to build business-critical applications. Through the AWS Step Functions graphical console, you see your application’s workflow as a series of event-driven steps.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers industry-leading scalability, data availability, security, and performance.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a highly available, durable, secure, fully managed pub/sub messaging service that enables you to decouple microservices, distributed systems, and serverless applications.

- **AWS Lambda** – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

**Code**

The code for this pattern is available on GitHub, in the [ETL Pipeline with AWS Step Functions](https://github.com) repository. The code repository contains the following files and folders:

- `template.yml` – AWS CloudFormation template for creating the ETL pipeline with AWS Step Functions.
- `parameter.json` – Contains all parameters and parameter values. You update this file to change parameter values, as described in the *Epics* section.
- `myLayer/python` folder – Contains Python packages needed to create the required AWS Lambda layer for this project.
- `lambda` folder – Contains the following Lambda functions:
  - `move_file.py` – Moves the source dataset to the archive, transform, or error folder.
  - `check_crawler.py` – Checks the status of the AWS Glue crawler as many times as configured by the `RETRYLIMIT` environment variable before it sends a failure message.
  - `start_crawler.py` – Starts the AWS Glue crawler.
  - `start_step_function.py` – Starts AWS Step Functions.
  - `start_codebuild.py` – Starts the AWS CodeBuild project.
  - `validation.py` – Validates the input raw dataset.
  - `s3object.py` – Creates the required directory structure inside the S3 bucket.
  - `notification.py` – Sends success or error notifications at the end of the pipeline.

To use the sample code, follow the instructions in the *Epics* section.

**Epics**

**Prepare the source files**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>

| Clone the sample code repository. | 1. Open the [ETL Pipeline with AWS Step Functions repository](https://github.com).  
2. Choose **Code** on the main repository page, above the file list, and copy the URL listed under **Clone with HTTPS**.  
3. Change your working directory to the location where you want to store the sample files.  
4. At a terminal or command prompt, type the command: | Developer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>git clone <code>&lt;repoURL&gt;</code></td>
<td>where <code>&lt;repoURL&gt;</code> refers to the URL you copied in step 2.</td>
<td>Developer</td>
</tr>
<tr>
<td>Update parameter values.</td>
<td>In your local copy of the repository, edit the <code>parameter.json</code> file and update the default parameter values as follows:</td>
<td>Developer</td>
</tr>
<tr>
<td></td>
<td>• <code>pS3BucketName</code> — The name of the S3 bucket for storing the datasets. The template will create this bucket for you. The bucket name must be globally unique.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>pSourceFolder</code> — The name of the folder inside the S3 bucket that will be used to upload the source CSV file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>pStageFolder</code> — The name of the folder inside the S3 bucket that will be used as the staging area during the process.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>pTransformFolder</code> — The name of the folder inside the S3 bucket that will be used to store transformed and partitioned datasets.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>pErrorFolder</code> — The folder inside the S3 bucket that the source CSV file will be moved to if it can't be validated.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>pArchiveFolder</code> — The name of the folder inside the S3 bucket that will be used to archive the source CSV file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>pEmailforNotification</code> — A valid email address for receiving success/error notifications.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>pDatasetSchema</code> — The dataset schema that the source file will be validated against. The Cerberus Python package is used for source dataset validation. For more information, see the Cerberus website.</td>
<td></td>
</tr>
</tbody>
</table>

</tr>
</thead>
</table>
| Upload the source code to the S3 bucket. | Before you deploy the CloudFormation template that automates the ETL pipeline, you must package the source files for the CloudFormation template and upload them to an S3 bucket. To do this, run the following AWS CLI command with your preconfigured profile: ```
aws cloudformation package --template-file template.yml --s3-bucket <bucket_name> --output-template-file packaged.template --profile <profile_name>``` where:  
* `<bucket_name>` is the name of an existing S3 bucket in the AWS Region where you want to deploy the stack. This bucket is used to store the source code package for the CloudFormation template.  
* `<profile_name>` is a valid AWS CLI profile that you preconfigured when you set up AWS CLI. | Developer |

### Create the stack

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the CloudFormation template. | To deploy the CloudFormation template, run the following AWS CLI command: ```
aws cloudformation deploy --stack-name <stack_name> --template-file packaged.template --parameter-overrides file://parameter.json --capabilities CAPABILITY_IAM --profile <profile_name>``` where:  
* `<stack_name>` is a unique identifier for the CloudFormation stack. | Developer |
### Check progress.

On the [AWS CloudFormation console](https://aws.amazon.com/cloudformation/), check the progress of stack development. When the status is `CREATE_COMPLETE`, the stack has been deployed successfully.

### Note the AWS Glue database name.

The **Outputs** tab for the stack displays the name of the AWS Glue database. The key name is `GlueDBOutput`.

### Test the pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Start the ETL pipeline.** | 1. Navigate to the source folder (`source`, or the folder name you set in the `parameter.json` file) inside the S3 bucket.  
2. Upload a sample CSV file to this folder. (The code repository provides a sample file called `Sample_Bank_Transaction_Raw_Dataset.csv` that you can use.) Uploading the file will start the ETL pipeline through Step Functions.  
3. On the [Step Functions console](https://console.aws.amazon.com/stepfunctions/), check the ETL pipeline status. | Developer |
| **Check for the partitioned dataset.** | When the ETL pipeline completes, verify that the partitioned dataset is available in the Amazon S3 transform folder (`transform`, or the folder name you set in the `parameter.json` file). | Developer |
| **Check for the partitioned AWS Glue database.** | 1. On the [AWS Glue console](https://console.aws.amazon.com/glue/), select the AWS Glue database created by the stack (this is the database that you noted in the previous epic).  
2. Verify that the partitioned table is available in the AWS Glue Data Catalog. | Developer |
### Task

**Run queries.**

(Optional) Use Amazon Athena to run ad-hoc queries on the partitioned and transformed database. For instructions, see [Running SQL Queries Using Amazon Athena](#) in the AWS documentation.

**Skills required**

- Database analyst

### Additional information

The following diagram shows the AWS Step Functions workflow for a successful ETL pipeline, from the Step Functions **Inspector** panel.
The following diagram shows the AWS Step Functions workflow for an ETL pipeline that fails because of an input validation error, from the Step Functions Inspector panel.
Perform advanced analytics using Amazon Redshift ML
Summary

On the Amazon Web Services (AWS) Cloud, you can use Amazon Redshift machine learning (Amazon Redshift ML) to perform ML analytics on data stored in either an Amazon Redshift cluster or on Amazon Simple Storage Service (Amazon S3). Amazon Redshift ML supports supervised learning, which is typically used for advanced analytics. Use cases for Amazon Redshift ML include revenue forecasting, credit card fraud detection, and customer lifetime value (CLV) or customer churn predictions.

Amazon Redshift ML makes it easy for database users to create, train, and deploy ML models by using standard SQL commands. Amazon Redshift ML uses Amazon SageMaker Autopilot to automatically train and tune the best ML models for classification or regression based on your data, while you retain control and visibility.

All interactions between Amazon Redshift, Amazon S3, and Amazon SageMaker are abstracted away and automated. After the ML model is trained and deployed, it becomes available as a user-defined function (UDF) in Amazon Redshift and can be used in SQL queries.

This pattern complements the Create, train, and deploy ML models in Amazon Redshift using SQL with Amazon Redshift ML from the AWS Blog, and the Build, train, and deploy an ML model with Amazon SageMaker tutorial from the Getting Started Resource Center.

Prerequisites and limitations

Prerequisites

• An active AWS account
• Existing data in an Amazon Redshift table

Skills

• Familiarity with terms and concepts used by Amazon Redshift ML, including machine learning, training, and prediction. For more information about this, see Training ML models in the Amazon Machine Learning (Amazon ML) documentation.
• Experience with Amazon Redshift user setup, access management, and standard SQL syntax. For more information about this, see Getting started with Amazon Redshift in the Amazon Redshift documentation.
• Knowledge and experience with Amazon S3 and AWS Identity and Access Management (IAM).
• Experience running commands in AWS Command Line Interface (AWS CLI) is also beneficial but not required.

Limitations

• The Amazon Redshift cluster and S3 bucket must be located in the same AWS Region.
• This pattern’s approach only supports supervised learning models such as regression, binary classification, and multiclass classification.
The following steps explain how Amazon Redshift ML works with SageMaker to build, train, and deploy an ML model:

1. Amazon Redshift exports training data to an S3 bucket.
2. SageMaker Autopilot automatically preprocesses the training data.
3. After the `CREATE MODEL` statement is invoked, Amazon Redshift ML uses SageMaker for training.
4. SageMaker Autopilot searches for and recommends the ML algorithm and optimal hyper-parameters that optimize the evaluation metrics.
5. Amazon Redshift ML registers the output ML model as a SQL function in the Amazon Redshift cluster.
6. The ML model's function can be used in a SQL statement.

**Technology stack**

- Amazon Redshift
- SageMaker
- Amazon S3

**Tools**

- **Amazon Redshift** – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- **Amazon Redshift ML** – Amazon Redshift machine learning (Amazon Redshift ML) is a robust, cloud-based service that makes it easy for analysts and data scientists of all skill levels to use ML technology.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- **Amazon SageMaker** – SageMaker is a fully managed ML service.
- **Amazon SageMaker Autopilot** – SageMaker Autopilot is a feature-set that automates key tasks of an automatic machine learning (AutoML) process.
Code

You can create a supervised ML model in Amazon Redshift by using the following code:

```
"CREATE MODEL customer_churn_auto_model
FROM (SELECT state, account_length, area_code, total_charge/account_length AS average_daily_spend, cust_serv_calls/account_length AS average_daily_cases, churn
FROM customer_activity
WHERE record_date < '2020-01-01'
)
TARGET churn
FUNCTION ml_fn_customer_churn_auto
IAM_ROLE 'arn:aws:iam::XXXXXXXXXXXX:role/Redshift-ML'
SETTINGS (S3_BUCKET 'your-bucket');"
```

**Note:** The SELECT state can refer to Amazon Redshift regular tables, Amazon Redshift Spectrum external tables, or both.

Access, query, and join Amazon DynamoDB tables using Athena
Summary

This pattern shows you how to set up a connection between Amazon Athena and Amazon DynamoDB by using the Amazon Athena DynamoDB connector. The connector uses an AWS Lambda function to query the data in DynamoDB. You don’t need to write any code to set up the connection. After the connection is established, you can quickly access and analyze DynamoDB tables by using Athena Federated Query to run SQL commands from Athena. You can also join one or more DynamoDB tables to each other or to other data sources, such as Amazon Redshift or Amazon Aurora.

Prerequisites and limitations

Prerequisites

- An active AWS account with permissions to manage DynamoDB tables, Athena Data sources, Lambda, and AWS Identity and Access Management (IAM) roles
- An Amazon Simple Storage Service (Amazon S3) bucket where Athena can store query results
- An S3 bucket where the Athena DynamoDB Connector can save the data in the short term
- An AWS Region that supports Athena engine version 2
- IAM permissions to access Athena and the required S3 buckets
- Amazon Athena DynamoDB Connector, installed

Limitations

There is a cost for querying DynamoDB tables. Table sizes exceeding a few gigabytes (GBs) can incur a high cost. We recommend that you consider cost before performing any full table SCAN operation. For more information, see Amazon DynamoDB pricing. To reduce costs and achieve high performance, we recommend that you always use LIMIT in your query (for example, SELECT * FROM table1 LIMIT 10). Also, before you perform a JOIN or GROUP BY query in a production environment, consider the size of your tables. If your tables are too large, consider alternative options such as migrating the table to Amazon S3.

Architecture

The following diagram shows how a user can run a SQL query to a DynamoDB table from Athena.
The diagram shows the following workflow:

1. A user runs a SQL query to a DynamoDB table from Athena.
2. Athena initiates a Lambda function.
3. The Lambda function queries the requested data in the DynamoDB table.
4. DynamoDB returns the requested data to the Lambda function, which in turn transfers the query results to the user through Athena.
5. The Lambda function stores data in the S3 bucket.

**Technology stack**
- Amazon Athena
- Amazon DynamoDB
- Amazon S3
- AWS Lambda

**Tools**
- Amazon Athena is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- Amazon Athena DynamoDB Connector is an AWS tool that enables Athena to connect with DynamoDB and access your tables by using SQL queries.
- Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- AWS Lambda is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.

</table>
### Create a data source in Athena for DynamoDB

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Set up the data source connector. | Create a data source for DynamoDB, and then create a Lambda function to connect to that data source:  
1. Sign in to the AWS Management Console and open the Athena console.  
2. In the navigation pane, choose Data sources, and                                                          | Developer       |
| Insert sample data into the second table. | 1. Open the DynamoDB console.  
2. On the navigation pane, choose Table, and then choose your table in the Name column.  
3. Choose Actions, and then choose Create item.  
4. Choose JSON.  
5. In the Attributes editor, enter the following sample data:  

```json
{  
  "PK2": "1234",  
  "SK2": "bonus",  
  "Bonus": "500"
}
{  
  "PK2": "1235",  
  "SK2": "bonus",  
  "Bonus": "1000"
}
```  

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| 4. For Partition key, enter PK2. | 5. For Sort key, enter SK2.  
6. In the Table settings section, choose Customize settings.  
7. In the Table class section, choose DynamoDB Standard.  
8. In the Read/write capacity settings section, for Capacity mode, choose On-demand.  
9. In the Encryption at rest section, choose Owned by Amazon DynamoDB.  
10. Choose Create table. |                |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>then choose Create data source.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. Choose the Amazon DynamoDB data source, and then choose Next.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. In the Data source details section, for Data source name, enter testDynamoDB.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. In the Connection details section, select a Lambda function that's already deployed or choose Create Lambda function if you don't have a Lambda function to use for this pattern. <strong>Note:</strong> For more information on creating a Lambda function, see Getting started with Lambda in the Lambda Developer Guide.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6. (Optional) If you choose Create Lambda function, then you must configure the AWS CloudFormation template that's included by the Java application before deploying that stack. The template includes ApplicationName, SpillBucket, AthenaCatalogName, and other application settings. <strong>Note:</strong> After you deploy this Java-based application, the stack creates a Lambda function that enables Athena to communicate with DynamoDB. This makes your tables accessible through SQL commands.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>7. Deploy your Lambda function.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>8. Choose Next.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Task: Verify that the Lambda function can access the S3 spill bucket.

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Open the <a href="https://console.aws.amazon.com/lambda">Lambda console</a>.</td>
<td>Developer</td>
</tr>
<tr>
<td>2. In the navigation pane, choose <a href="https://console.aws.amazon.com/lambda">Functions</a>, and then choose the function that you created earlier.</td>
<td></td>
</tr>
<tr>
<td>3. Choose the <a href="https://console.aws.amazon.com/lambda">Configuration</a> tab.</td>
<td></td>
</tr>
<tr>
<td>4. In the left pane, choose <a href="https://console.aws.amazon.com/lambda">Environment variables</a>, and then confirm that the value for the key is <code>spill_bucket</code>.</td>
<td></td>
</tr>
<tr>
<td>5. In the left pane, choose <a href="https://console.aws.amazon.com/lambda">Permissions</a>, and then in the Execution role section, choose the attached IAM role.</td>
<td></td>
</tr>
<tr>
<td><strong>Note:</strong> You are directed to the IAM role that's attached to your Lambda function in the IAM console.</td>
<td></td>
</tr>
<tr>
<td>6. Confirm that you have write permission on <code>spill_bucket</code> bucket.</td>
<td></td>
</tr>
</tbody>
</table>

If you experience any errors, see the *Additional information* section in this pattern for guidance.

### Task: Access DynamoDB tables from Athena

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query the DynamoDB tables.</td>
<td>Developer</td>
</tr>
<tr>
<td>1. Sign in to the AWS Management Console and open the <a href="https://console.aws.amazon.com/athena">Athena console</a>.</td>
<td></td>
</tr>
<tr>
<td>2. In the navigation pane, choose <a href="https://console.aws.amazon.com/athena">Data sources</a>, and then choose Create data source.</td>
<td></td>
</tr>
<tr>
<td>3. In the navigation pane, choose <a href="https://console.aws.amazon.com/athena">Query editor</a>.</td>
<td></td>
</tr>
<tr>
<td>4. On the Editor tab, in the Data section, for Data source, choose your data source for Data source.</td>
<td></td>
</tr>
<tr>
<td>5. For Database, choose your database.</td>
<td></td>
</tr>
<tr>
<td>6. For Query 1, enter the following query: <code>SELECT * FROM dydbtable1 t1;</code></td>
<td></td>
</tr>
</tbody>
</table>

---

- [Amazon Athena DynamoDB Connector](https://aws.amazon.com) (AWS Labs)
- [Query any data source with Amazon Athena's new federated query](https://aws.amazon.com) (AWS Big Data Blog)
- [Athena engine version reference](https://docs.aws.amazon.com) (Athena User Guide)
- [Simplify Amazon DynamoDB data extraction and analysis by using AWS Glue and Amazon Athena](https://aws.amazon.com) (AWS Database Blog)

### Additional information

If you run a query in Athena with `spill_bucket` in the `{bucket_name}/folder_name/` format, then you can receive the following error message:

```
This query ran against the "default" database, unless qualified by the query. Please post the error message on our forum or contact customer support with Query Id: 0acc5858-69a4-41d6-b8ab-84d163a7cb00"
```

To resolve this error, update the Lambda function's environment variable `spill_bucket` to `{bucket_name_only}`, and then update the following Lambda IAM policy for bucket write access:

```json
{}
```
Set up SSO for Amazon QuickSight by using IAM Identity Center and identity federation

"Action": [
    "s3:GetObject",
    "s3:ListBucket",
    "s3:GetBucketLocation",
    "s3:GetObjectVersion",
    "s3:PutObject",
    "s3:PutObjectAcl",
    "s3:GetLifecycleConfiguration",
    "s3:PutLifecycleConfiguration",
    "s3:DeleteObject"
],
"Resource": [
    "arn:aws:s3:::spill_bucket",
    "arn:aws:s3:::spill_bucket/*"
],
"Effect": "Allow"

Alternatively, you can remove the Athena data source connector that you created earlier, and recreate it by using only `{bucket_name}` for spill_bucket.

Set up SSO for Amazon QuickSight by using IAM Identity Center and identity federation

*Created by Arpit Gupta and Parijat Bhide (AWS)*

| Environment: Production | Technologies: Analytics; Security, identity, compliance | AWS services: AWS Identity and Access Management; AWS Organizations; Amazon QuickSight |

**Summary**

This pattern shows you how to set up single sign-on (SSO) for Amazon QuickSight applications in the Amazon Web Services (AWS) Cloud by using AWS IAM Identity Center (successor to AWS Single Sign-On) and identity federation with Security Assertion Markup Language (SAML) 2.0. You can deliver a better user experience and improve security by centrally managing accounts and access control from IAM Identity Center. Your users can sign in to QuickSight applications by using their IAM Identity Center accounts, and they won't be prompted for credentials each time.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An active QuickSight subscription
- An organization in AWS Organizations *(Note: If you don't already have an organization, IAM Identity Center automatically creates an organization for you when you set up IAM Identity Center.)*
- An IAM Identity Center identity source with a built-in identity store *(Note: You can also use AWS Directory Service for Microsoft Active Directory, also known as AWS Managed Microsoft AD, or an on-premises Active Directory (AD) that uses AD Connector as the identity store.)*
Product versions
This pattern is tested on AWS Managed Microsoft AD with Active Directory Federation Services, but it will work the same way with other identity federation services.

Architecture
The following diagram shows how users get SSO access to a QuickSight application through an architecture that uses IAM Identity Center and identity federation with SAML 2.0.

The diagram shows the following workflow:
1. The user provides AD authentication credentials in the web endpoint URL.
2. AWS Managed Microsoft AD authenticates users and then posts the SAML assertion to the IAM Identity Center sign-in endpoint.
3. The sign-in endpoint receives the SAML request, processes the request, and then creates temporary credentials.
4. The temporary credentials are validated in the member account by the AWS Identity and Access Management (IAM) roles that are provisioned by IAM Identity Center.
5. The IAM roles authenticate the permissions and pass them to QuickSight.

Technology Stack
- AWS Identity and Access Management (IAM)
- AWS IAM Identity Center (successor to AWS Single Sign-On)
- AWS Managed Microsoft AD
- AWS Organizations
- Amazon QuickSight
**Tools**

- **AWS Directory Service for Microsoft Active Directory**, also known as AWS Managed Microsoft Active Directory (AD), enables your directory-aware workloads and AWS resources to use managed AD in AWS.
- **AWS IAM Identity Center (successor to AWS Single Sign-On)** is a cloud-based SSO service that makes it easy to centrally manage SSO access to all of your AWS accounts and cloud applications.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Organizations** is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- **Amazon QuickSight** is a cloud-scale business intelligence (BI) service that helps you visualize, analyze, and report your data in a single dashboard.

**Epics**

**Configure IAM Identity Center in the AWS Organizations management account**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Add QuickSight as an application in the management account. | 1. Sign in to the AWS Management Console and open the IAM Identity Center console.  
2. In the navigation pane, choose Applications, and then choose Add application.  
3. On the Select an application page, for Preintegrated applications, search for and select Amazon QuickSight, and then choose Next.  
4. On the Configure application page, in the Configure application section, for Display name, enter a unique display name for your application (for example, Amazon QuickSight).  
5. In the IAM Identity Center metadata section, choose Download for IAM Identity Center SAML metadata file.  
6. Choose Submit. | Cloud administrator |
| Create a SAML identity provider in the member account. | 1. Sign in to the AWS Management Console and open the IAM console.  
2. In the navigation pane, choose Identity providers, and then choose Add provider. | Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.</td>
<td>For <strong>Provider type</strong>, choose SAML.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>For <strong>Provider name</strong>, enter a name for the identity provider.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>For <strong>Metadata document</strong>, choose <strong>Choose file</strong>, and then choose the SAML metadata document that you downloaded earlier.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>(Optional) For <strong>Add tags</strong>, add key–value pairs to help you identify and organize your identity providers.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>Note the Amazon Resource Name (ARN) of the identity provider. You will use it later when you configure attributes in the SSO application.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>Choose <strong>Add provider</strong>.</td>
<td></td>
</tr>
</tbody>
</table>
### Create a SAML 2.0 federation IAM role in the member account.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Open the IAM console.</td>
<td></td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>2. In the navigation pane, choose Roles, and then choose Create role.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. For Trusted entity type, select SAML 2.0 federation.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. In the SAML 2.0 provider section, under SAML 2.0–based provider, choose the SAML provider that you created earlier, select Allow programmatic and AWS Management Console access, and then choose Next.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. On the Add Permissions page, attach the appropriate policies to limit the role permissions to QuickSight only by attaching an inline policy to the role. For an example policy, see IAM policy in the Additional information section of this pattern.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6. Choose Next.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>7. On the Name, review, and create page, under Role details, enter a name for Role name.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>8. (Optional) For Add tags, add key–value pairs to help you identify and organize your roles.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>9. Note the ARN of this role. You will use it later when you configure attributes in your SSO application.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>10. Choose Create role.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------</td>
</tr>
</tbody>
</table>
| Configure attributes in the application. | 1. Sign back in to the management account and open the IAM Identity Center console.  
2. In the navigation pane, choose Applications, and then select the application that you created earlier.  
3. Choose Actions, and then choose Edit attribute mappings.  
5. For Maps to this string value or user attribute in IAM Identity Center, enter <IDP ARN>,<Role ARN>. **Note:** These ARNs are intended for the identity provider and IAM role that you created earlier in the member account.  
6. Choose Save changes. | Cloud administrator |

| Assign users to the application. | 1. In the IAM Identity Center console, choose Assign Users.  
2. On the Users tab, add your required users, and then choose Assign Users.  
3. On the Groups tab, add your required groups, and then choose Assign Users.  

**Note:** If no users or groups are available, you can create a user and group for testing purposes. Open the IAM Identity Center console, choose Users from the navigation pane, and then create a user. For example, create a user named Analyst01. To create a group, choose Groups in the navigation pane, and then create a group called Analyst. Then, you can assign the Analyst01 user to the Analyst group. | Cloud administrator |

**Additional information**

IAM policy
The following IAM policy enables you to access QuickSight and create both author accounts and reader accounts.

```json
{
  "Statement": [
    {
      "Action": ["quicksight:CreateUser"],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:quicksight::<YOUR_AWS_ACCOUNT_ID>:user/${aws:userid}"]
    }
  ],
  "Version": "2012-10-17"
}
```

**Subscribe a Lambda function to event notifications from S3 buckets in different AWS Regions**

*Created by Suresh Konathala (AWS) and Arindom Sarkar (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Analytics</th>
<th>AWS services: AWS Lambda; Amazon S3; Amazon SNS; Amazon SQS</th>
</tr>
</thead>
</table>

**Summary**

Amazon Simple Storage Service (Amazon S3) Event Notifications publishes notifications for certain events in your S3 bucket (for example, object created events, object removal events, or restore object events). You can use an AWS Lambda function to process these notifications according to your application's requirements. However, the Lambda function can't directly subscribe to notifications from S3 buckets that are hosted in different AWS Regions.

This pattern's approach deploys a **fanout scenario** to process Amazon S3 notifications from cross-Region S3 buckets by using an Amazon Simple Notification Service (Amazon SNS) topic for each Region. These Regional SNS topics send the Amazon S3 event notifications to an Amazon Simple Queue Service (Amazon SQS) queue in a central Region that also contains your Lambda function. The Lambda function subscribes to this SQS queue and processes the event notifications according to your organization's requirements.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- Existing S3 buckets in multiple Regions, including a central Region to host the Amazon SQS queue and Lambda function.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see [Installing, updating, and uninstalling the AWS CLI](https://docs.aws.amazon.com/cli/latest/userguide/) in the AWS CLI documentation.
• Familiarity with the fanout scenario in Amazon SNS. For more information about this, see Common Amazon SNS scenarios in the Amazon SNS documentation.

Architecture

The following diagram shows the architecture for this pattern's approach.

The diagram shows the following workflow:

1. Amazon S3 sends event notifications about S3 buckets (for example, object created, object removed, or object restored) to an SNS topic in the same Region.
2. The SNS topic publishes the event to an SQS queue in the central Region.
3. The SQS queue is configured as the event source for your Lambda function and buffers the event messages for the Lambda function.
4. The Lambda function polls the SQS queue for messages and processes the Amazon S3 event notifications according to your application's requirements.

Technology stack

• Lambda
• Amazon SNS
• Amazon SQS
• Amazon S3

Tools

• **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS
CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

- **Amazon SQS** – Amazon Simple Queue Service (Amazon SQS) offers a secure, durable, and available hosted queue that lets you integrate and decouple distributed software systems and components. Amazon SQS supports both standard and FIFO queues.

## Epics

### Create the SQS queue and Lambda function in your central Region

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an SQS queue with a Lambda trigger. | Sign in to the AWS Management Console and use the instructions from the tutorial Using Lambda with Amazon SQS in the AWS Lambda documentation to create the following resources in your central Region:  
  - A Lambda execution role  
  - A Lambda function to process the Amazon S3 events  
  - An SQS queue  
  **Note:** Make sure that you configure the SQS queue as the event source for your Lambda function. | AWS DevOps, Cloud architect |

### Create an SNS topic and set up event notifications for the S3 buckets in each required Region

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an SNS topic to receive Amazon S3 event notifications.</td>
<td>Create an SNS topic in a Region that you want to receive Amazon S3 event notifications from. For</td>
<td>AWS DevOps, Cloud architect</td>
</tr>
</tbody>
</table>
### Task: Subscribe the SNS topic to the central SQS queue.

Subscribe your SNS topic to the SQS queue hosted by your central Region. For more information about this, see [Subscribing to an SNS topic](#) in the Amazon SNS documentation.

**Important:** Make sure that you record your SNS topic’s Amazon Resource Name (ARN).

**Skills required:** AWS DevOps, Cloud architect

### Task: Update the SNS topic’s access policy.

1. Open the Amazon SNS console, choose **Topics**, and then choose the SNS topic that you created earlier.
2. Choose **Edit** and then expand the **Access policy - optional** section.
3. Attach the following access policy to your SNS topic to allow `sns:publish` permission for Amazon S3 and then choose **Save**:

   ```json
   {  
     "Version": "2012-10-17",
     "Statement": [
       {  
         "Sid": "0",
         "Effect": "Allow",
         "Principal": {
           "Service": "s3.amazonaws.com"
         },
         "Action": "sns:Publish",
         "Resource": "arn:aws:sns:us-west-2::s3Events-SNSTopic-us-west-2"
       }
     ]
   }
   ```

**Skills required:** AWS DevOps, Cloud architect
### Task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up notifications for each S3 bucket in the Region.</td>
<td>Set up event notifications for each S3 bucket in the Region. For more information about this, see <a href="https://docs.aws.amazon.com/AmazonS3/latest/userguide/Event-Notification-Enable.html">Enabling and configuring event notifications using the Amazon S3 console</a> in the Amazon S3 documentation. <strong>Note:</strong> In the <strong>Destination</strong> section, choose <strong>SNS topic</strong> and specify the ARN of the SNS topic that you created earlier.</td>
<td>AWS DevOps, Cloud architect</td>
</tr>
</tbody>
</table>

**Important:** Repeat the tasks in this epic for each Region that you want to receive Amazon S3 event notifications from, including your central Region.

 AWS DevOps, Cloud architect

### Three AWS Glue ETL job types for converting data to Apache Parquet

*Created by Adnan Alvee (AWS)*

**Environment:** PoC or pilot  
**Technologies:** Analytics  
**Workload:** All other workloads  
**AWS services:** AWS Glue

### Summary

On the Amazon Web Services (AWS) Cloud, AWS Glue is a fully managed extract, transform, and load (ETL) service. AWS Glue makes it cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.

This pattern provides different job types in AWS Glue and uses three different scripts to demonstrate authoring ETL jobs.

You can use AWS Glue to write ETL jobs in a Python shell environment. You can also create both batch and streaming ETL jobs by using Python (PySpark) or Scala in a managed Apache Spark environment. To get you started with authoring ETL jobs, this pattern focuses on batch ETL jobs using Python shell,
PySpark, and Scala. Python shell jobs are meant for workloads requiring lesser compute power. The managed Apache Spark environment is meant for workloads requiring high compute power.

Apache Parquet is built to support efficient compression and encoding schemes. It can speed up your analytics workloads because it stores data in a columnar fashion. Converting data to Parquet can save you both storage space, cost and time in the longer run. To learn more about Parquet, see the blog post Apache Parquet: How to be a hero with the open-source columnar data format on Google, Azure, and Amazon cloud.

**Prerequisites and limitations**

**Prerequisites**

- AWS Identity and Access Management (IAM) role

**Architecture**

**Target technology stack**

- AWS Glue
- Amazon Simple Storage Service (Amazon S3)
- Apache Parquet

**Automation and scale**

*AWS Glue workflows* support full automation of an ETL pipeline.

You can change the number of data processing units (DPUs), or worker types, to scale horizontally and vertically.

**Tools**

**Tools**

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) provides storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **AWS Glue** – AWS Glue is a fully managed ETL service for categorizing, cleaning, enriching, and moving your data between various data stores and data streams.

**Configuration**

Following are the settings for configuring the compute power of AWS Glue ETL. To reduce costs, use the minimal settings when you run the workload that is provided in this pattern.

- **Python shell** – You can use 1 DPU to utilize 16 GB of memory or 0.0625 DPU to utilize 1 GB of memory. This pattern uses 0.0625 DPU, which is the default in the AWS Glue console.
- **Python or Scala for Spark** – If you choose the Spark-related job types in the console, AWS Glue by default uses 10 workers and the G.1X worker type. This pattern uses two workers, which is the minimum number allowed, with the standard worker type, which is sufficient and cost effective.

The following table displays the different AWS Glue worker types for the Apache Spark environment. Because a Python shell job does not use the Apache Spark environment to run Python, it is not included in the table.
AWS Prescriptive Guidance Patterns
Tools

<table>
<thead>
<tr>
<th></th>
<th>Standard</th>
<th>G.1X</th>
<th>G.2X</th>
</tr>
</thead>
<tbody>
<tr>
<td>vCPU</td>
<td>4</td>
<td>4</td>
<td>8</td>
</tr>
<tr>
<td>Memory</td>
<td>16 GB</td>
<td>16 GB</td>
<td>32 GB</td>
</tr>
<tr>
<td>Disk space</td>
<td>50 GB</td>
<td>64 GB</td>
<td>128 GB</td>
</tr>
<tr>
<td>Executor per worker</td>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

**Code**

When you create the AWS Glue jobs, you can use either the IAM role that is attached or an existing role.

**AWS Glue Python shell**

The Python code uses the Pandas and PyArrow libraries to convert data to Parquet. The Pandas library is already available. The PyArrow library is downloaded when you run the pattern, because it is a one-time run. You can use wheel files to convert PyArrow to a library and provide the file as a library package. For more information about packaging wheel files, see [Providing your own Python library](#).

```python
from io import BytesIO
import pandas as pd
import boto3
import os
import io
import site
from importlib import reload
from setuptools.command import easy_install
install_path = os.environ['GLUE_INSTALLATION']
easy_install.main( ["--install-dir", install_path, "pyarrow"] )
reload(site)
import pyarrow
input_loc = "bucket-name/prefix/sample_data.csv"
output_loc = "bucket-name/prefix/"

input_bucket = input_loc.split('/', 1)[0]
object_key = input_loc.split('/', 1)[1]

output_loc_bucket = output_loc.split('/', 1)[0]
output_loc_prefix = output_loc.split('/', 1)[1]

s3 = boto3.client('s3')
obj = s3.get_object(Bucket=input_bucket, Key=object_key)
df = pd.read_csv(io.BytesIO(obj['Body'].read()))

parquet_buffer = BytesIO()
s3_resource = boto3.resource('s3')
df.to_parquet(parquet_buffer, index=False)
s3_resource.Object(output_loc_bucket, output_loc_prefix + 'data' + '.parquet').put(Body=parquet_buffer.getvalue())
```

**AWS Glue Spark job with Python**

To use an AWS Glue Spark job type with Python, choose **Spark** as the job type. Choose **Spark 2.4, Python 3 with improved job startup time (Glue Version 2.0)** as the AWS Glue version.
import sys
from pyspark.context import SparkContext
from awsglue.context import GlueContext
from awsglue.transforms import *
from awsglue.dynamicframe import DynamicFrame
from awsglue.utils import getResolvedOptions
from awsglue.job import Job

sc = SparkContext()
glueContext = GlueContext(sc)
spark = glueContext.spark_session
job = Job(glueContext)

input_loc = "bucket-name/prefix/sample_data.csv"
output_loc = "bucket-name/prefix/"

inputDyf = glueContext.create_dynamic_frame_from_options(
    connection_type = "s3",
    connection_options = {
        "paths": [input_loc],
        "format": "csv",
        "withHeader": True,
        "separator": "",
    },
)

outputDF = glueContext.write_dynamic_frame.from_options(
    frame = inputDyf,
    connection_type = "s3",
    connection_options = {
        "path": output_loc,
        "format": "parquet",
    },
)

AWS Glue Spark job with Scala

To use an AWS Glue Spark job type with Scala, choose Spark as the job type. Choose Spark 2.4, Scala 2 with improved job startup time (Glue Version 2.0) as the AWS Glue version. To save on storage space, the following AWS Glue with Scala sample also uses the applyMapping feature to convert data types.

import com.amazonaws.services.glue.GlueContext
import com.amazonaws.services.glue.MappingSpec
import com.amazonaws.services.glue.DynamicFrame
import com.amazonaws.services.glue.errors.CallSite
import com.amazonaws.services.glue.util.GlueArgParser
import com.amazonaws.services.glue.util.JsonOptions
import org.apache.spark.SparkContext
import scala.collection.JavaConverters

object GlueScalaApp {
  def main(sysArgs: Array[String]) {
    @transient val spark: SparkContext = SparkContext.getOrCreate()
    val glueContext: GlueContext = new GlueContext(spark)

    val inputLoc = "s3://bucket-name/prefix/sample_data.csv"
    val outputLoc = "s3://bucket-name/prefix/"

    val readCSV = glueContext.getSource("csv", JsonOptions(Map("paths" -> Set(inputLoc)))).getDynamicFrame()
val applyMapping = readCSV.applyMapping(mappings = Seq(("_c0", "string", "date", "string"), ("_c1", "string", "sales", "long"), ("_c2", "string", "profit", "double")), caseSensitive = false)

val formatPartition = applyMapping.toDF().coalesce(1)

val dynamicFrame = DynamicFrame(formatPartition, glueContext)

val dataSink = glueContext.getSinkWithFormat(
  connectionType = "s3",
  options = JsonOptions(Map("path" -> outputLoc )),
  transformationContext = "dataSink", format = "parquet").writeDynamicFrame(dynamicFrame)
}

- What is AWS Glue?

Additional information

Parameter configuration

You can use the following snippets to set parameters for your ETL job. AWS Glue uses four argument names internally:

- --conf
- --debug
- --mode
- --JOB_NAME

The --JOB_NAME parameter must be explicitly entered on the AWS Glue console. Choose Jobs, Edit Job, Security configuration, script libraries, and job parameters (optional). Enter --JOB_NAME as the key and provide a value. You can also use the AWS Command Line Interface (AWS CLI) or the AWS Glue API to set this parameter. The --JOB_NAME parameter is used by Spark and is not needed in a Python shell environment job.

You must add -- before every parameter name; otherwise, the code will not work. For example, for the following code snippets, the location parameters must be invoked by --input_loc and --output_loc.

AWS Glue Python shell

```python
from awsglue.utils import getResolvedOptions
args = getResolvedOptions(sys.argv, ['input_loc', 'output_loc'])
```

AWS Glue Python

```python
from awsglue.utils import getResolvedOptions
args = getResolvedOptions(sys.argv, ['JOB_NAME', 'input_loc', 'output_loc'])
```

AWS Glue Scala

```scala
import com.amazonaws.services.glue.util.GlueArgParser
val args = GlueArgParser.getResolvedOptions(sysArgs, Seq("JOB_NAME", "inputLoc", "outputLoc ").toArray)
```
Visualize Amazon Redshift audit logs using Amazon Athena and Amazon QuickSight

Created by Sanket Sirsikar (AWS) and Gopal Krishna Bhatia (AWS)

Environment: PoC or pilot  Technologies: Analytics; Big data; Data lakes  AWS services: Amazon Athena; Amazon Redshift; Amazon S3; Amazon QuickSight

Summary

Security is an integral part of database operations on the Amazon Web Services (AWS) Cloud. Your organization should ensure that it monitors database user activities and connections to detect potential security incidents and risks. This pattern helps you monitor your databases for security and troubleshooting purposes, which is a process known as database auditing.

This pattern provides a SQL script that automates the creation of an Amazon Athena table and views for a reporting dashboard in Amazon QuickSight that helps you audit Amazon Redshift logs. This ensures that users responsible for monitoring database activities have convenient access to data security features.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon Redshift cluster. For more information about this, see Create an Amazon Redshift cluster in the Amazon Redshift documentation.
- Access to an existing Athena workgroup. For more information, see How workgroups work in the Amazon Athena documentation.
- An existing Amazon Simple Storage Service (Amazon S3) source bucket with the required AWS Identity and Access Management (IAM) permissions. For more information, see Bucket permissions for Amazon Redshift audit logging from Database audit logging in the Amazon Redshift documentation.

Architecture
Technology stack

- Athena
- Amazon Redshift
- Amazon S3
- QuickSight

Tools

- **Amazon Athena** – Athena is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- **Amazon QuickSight** – QuickSight is a scalable, serverless, embeddable, machine learning-powered business intelligence (BI) service.
- **Amazon Redshift** – Amazon Redshift is an enterprise-level, petabyte scale, fully managed data warehousing service.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

Epics

Configure the Amazon Redshift cluster

<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Enable logging in the Amazon Redshift cluster parameter group.</td>
<td>You can enable auditing of connection logs, user logs, and user activity logs at the same time by using the AWS Management Console, the Amazon Redshift API reference, or AWS Command Line Interface (AWS CLI).&lt;br&gt;&lt;br&gt;For auditing of user activity logs, you must enable the <code>enable_user_activity_logging</code> database parameter. If you only enable the audit logging feature but not the associated parameter, the database audit logs the logging information for the connection and user logs but not for the user activity logs. The <code>enable_user_activity_logging</code> parameter is not enabled by default, but you can enable it by changing it from <code>false</code> to <code>true</code>.</td>
<td>DBA, Data engineer</td>
</tr>
</tbody>
</table>
## Configure S3 bucket permissions for Amazon Redshift cluster logging.

**Task**: Configure S3 bucket permissions for Amazon Redshift cluster logging.

**Description**: When you enable logging, Amazon Redshift collects logging information and uploads it to log files stored in an S3 bucket. You can use an existing S3 bucket or create a new bucket.

**Important**: Make sure that Amazon Redshift has the required IAM permissions to access the S3 bucket. For more information about this, see [Bucket permissions for Amazon Redshift audit logging](https://docs.aws.amazon.com/redshift/latest/dg/bucket-permissions.html) from [Database audit logging](https://docs.aws.amazon.com/redshift/latest/dg/) in the Amazon Redshift documentation.

**Skills required**: DBA, Data engineer

## Create the Athena table and views

**Task**: Create the Athena table and views to query Amazon Redshift audit log data from the S3 bucket.

**Description**: Open the Amazon Athena console and use the data definition language (DDL) query from the `AuditLogging.sql` SQL script (attached) to create the table and views for user activity logs, user logs, and connection logs.

For more information and instructions, see the [Create tables and run queries](https://docs.aws.amazon.com/athena/latest/ug/quickstart-database-query.html) tutorial from the Amazon Athena Workshop.

**Skills required**: Data engineer

## Set up log monitoring in the QuickSight dashboard

**Task**: Set up log monitoring in the QuickSight dashboard.

**Description**: Open the Amazon QuickSight console and create a QuickSight dashboard by following the instructions in the [Visualize with QuickSight using Athena](https://docs.aws.amazon.com/quicksight/latest/devguide/visualize-with-athena.html) tutorial from the Amazon Athena Workshop.

**Skills required**: DBA, Data engineer

Build a video processing pipeline by using Amazon Kinesis Video Streams and AWS Fargate

Created by Piotr Chotkowski (AWS)

<table>
<thead>
<tr>
<th>Environment</th>
<th>Technologies</th>
<th>AWS services</th>
</tr>
</thead>
<tbody>
<tr>
<td>PoC or pilot</td>
<td>Cloud-native; Software development &amp; testing; Media services</td>
<td>AWS Fargate; Amazon Kinesis; Amazon S3</td>
</tr>
</tbody>
</table>

Summary

This pattern demonstrates how to use Amazon Kinesis Video Streams and AWS Fargate to extract frames from a video stream and store them as image files for further processing in Amazon Simple Storage Service (Amazon S3).

The pattern provides a sample application in the form of a Java Maven project. This application defines the AWS infrastructure by using the AWS Cloud Development Kit (AWS CDK). Both the frame processing logic and the infrastructure definitions are written in the Java programming language. You can use this sample application as a basis for developing your own real-time video processing pipeline or to build the video preprocessing step of a machine learning pipeline.

Prerequisites and limitations

Prerequisites
• An active AWS account
• Java SE Development Kit (JDK) 11, installed
• Apache Maven, installed
• AWS Cloud Development Kit (AWS CDK), installed
• AWS Command Line Interface (AWS CLI) version 2, installed
• Docker (required for building Docker images to use in AWS Fargate task definitions), installed

Limitations
This pattern is intended as a proof of concept, or as a basis for further development. It should not be used in its current form in production deployments.

Product versions
• This pattern was tested with the AWS CDK version 1.77.0 (see AWS CDK versions)
• JDK 11
• AWS CLI version 2

Architecture

Target technology stack

• Amazon Kinesis Video Streams
• AWS Fargate task
• Amazon Simple Queue Service (Amazon SQS) queue
• Amazon S3 bucket

Target architecture

The user creates a Kinesis video stream, uploads a video, and sends a JSON message that contains details about the input Kinesis video stream and the output S3 bucket to an SQS queue. AWS Fargate, which is running the main application in a container, pulls the message from the SQS queue and starts extracting frames. Each frame is saved in an image file and stored in the target S3 bucket.

Automation and scale

The sample application can scale both horizontally and vertically within a single AWS Region. Horizontal scaling can be achieved by increasing the number of deployed AWS Fargate tasks that read from the SQS queue. Vertical scaling can be achieved by increasing the number of frame-splitting and image-publishing threads in the application. These settings are passed as environment variables to the application in the definition of the QueueProcessingFargateService resource in the AWS CDK. Due to the nature of AWS CDK stack deployment, you can deploy this application in multiple AWS Regions and accounts with no additional effort.

Tools
AWS Prescriptive Guidance Patterns
Epics

- **AWS CDK** – The AWS Cloud Development Kit (AWS CDK) is a software development framework for defining your cloud infrastructure and resources by using programming languages such as TypeScript, JavaScript, Python, Java, and C#/.Net.

- **Amazon Kinesis Video Streams** – Amazon Kinesis Video Streams is a fully managed AWS service that you can use to stream live video from devices to the AWS Cloud, or build applications for real-time video processing or batch-oriented video analytics.

- **AWS Fargate** – AWS Fargate is a serverless compute engine for containers. Fargate removes the need to provision and manage servers, and lets you focus on developing your applications.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that offers scalability, data availability, security, and performance.

- **Amazon SQS** – Amazon Simple Queue Service (Amazon SQS) is a fully managed message queuing service that enables you to decouple and scale microservices, distributed systems, and serverless applications.

**Code**

- A .zip file of the sample application project (frame-splitter-code.zip) is attached.

**Epics**

**Deploy the infrastructure**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start the Docker daemon.</td>
<td>Start the Docker daemon on your local system. The AWS CDK uses Docker to build the image that is used in the AWS Fargate task. You must run Docker before you proceed to the next step.</td>
<td>Developer, DevOps engineer</td>
</tr>
<tr>
<td>Build the project.</td>
<td>Download the frame-splitter-code sample application (attached) and extract its contents into a folder on your local machine. Before you can deploy the infrastructure, you have to build the Java Maven project. At a command prompt, navigate to the root directory of the project, and build the project by running the command: mvn clean install</td>
<td>Developer, DevOps engineer</td>
</tr>
<tr>
<td>Bootstrap the AWS CDK.</td>
<td>(First-time AWS CDK users only) If this is the first time you're using the AWS CDK, you might have to bootstrap the environment by running the AWS CLI command:</td>

<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Deploy the AWS CDK stack.</td>
<td>In this step, you create the required infrastructure resources (SQS queue, S3 bucket, AWS Fargate task definition) in your AWS account, build the Docker image that is required for the AWS Fargate task, and deploy the application. At a command prompt, navigate to the root directory of the project, and run the command: <code>cdk deploy --profile &quot;$AWS_PROFILE_NAME&quot;</code> where <code>$AWS_PROFILE_NAME</code> holds the name of the AWS profile from your AWS credentials. Or, you can remove this parameter to use the default profile. Confirm the deployment. Note the QueueUrl and Bucket values from the CDK deployment output; you will need these in later steps. The AWS CDK creates the assets, uploads them to your AWS account, and creates all infrastructure resources. You can observe the resource creation process in the AWS CloudFormation console at <a href="https://console.aws.amazon.com/cloudformation/">https://console.aws.amazon.com/cloudformation/</a>. For more information, see the AWS CloudFormation documentation and the AWS CDK documentation.</td>
<td>Developer, DevOps engineer</td>
</tr>
</tbody>
</table>
## AWS Prescriptive Guidance Patterns

### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a video stream.</td>
<td>In this step, you create a Kinesis video stream that will serve as an input stream for video processing. Make sure that you have the AWS CLI installed and configured. In the AWS CLI, run:</td>
<td>Developer, DevOps engineer</td>
</tr>
</tbody>
</table>

```bash
aws kinesisvideo --profile "$AWS_PROFILE_NAME" create-stream --stream-name "$STREAM_NAME" --data-retention-in-hours "24"
```

where `$AWS_PROFILE_NAME` holds the name of the AWS profile from your AWS credentials (or remove this parameter to use the default profile) and `$STREAM_NAME` is any valid stream name.

Alternatively, you can create a video stream by using the Kinesis console by following the steps in the [Kinesis Video Streams documentation](https://docs.aws.amazon.com/kinesis-video-streams/latest/devguide/). Note the AWS Resource Name (ARN) of the created stream; you will need it later.

### Run an example

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upload the video to the stream.</td>
<td>In the project folder for the sample frame-splitter-code application, open the <code>ProcessingTaskTest.java</code> file in the <code>src/test/java/amazon/awscdk/examples/splitter</code> folder. Replace the <code>profileName</code> and <code>streamName</code> variables with the values you used in the previous steps. To upload the example video to the Kinesis video stream you created in the previous step, run:</td>
<td>Developer, DevOps engineer</td>
</tr>
</tbody>
</table>

```java
amazon.awscdk.examples.splitter.ProcessingTaskTest#testExample
```

Alternatively, you can upload your video by using one of the
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Initiate video processing.    | Now that you have uploaded a video to the Kinesis video stream, you can start processing it. To initiate the processing logic, you have to send a message with details to the SQS queue that the AWS CDK created during deployment. To send a message by using the AWS CLI, run:  

```bash
aws sqs --profile "$AWS_PROFILE_NAME" send-message --queue-url QUEUE_URL --message-body MESSAGE
```

where `$AWS_PROFILE_NAME` holds the name of the AWS profile from your AWS credentials (remove this parameter to use the default profile), `QUEUE_URL` is the QueueUrl value from the AWS CDK output, and `MESSAGE` is a JSON string in the following format:

```json
{
  "streamARN": "STREAM_ARN",
  "bucket": "BUCKET_NAME",
  "s3Directory": "test-output"
}
```

where `STREAM_ARN` is the ARN of the video stream you created in an earlier step and `BUCKET_NAME` is the `Bucket` value from the AWS CDK output.

Sending this message initiates video processing. Alternatively, you can send a message by using the Amazon SQS console, as described in the Amazon SQS documentation. | Developer, DevOps engineer |
**Task** | **Description** | **Skills required**
--- | --- | ---
View images of the video frames. | You can see the resulting images in the S3 output bucket `s3://BUCKET_NAME/test-output` where `BUCKET_NAME` is the *Bucket* value from the AWS CDK output. | Developer, DevOps engineer

**Related resources**

- AWS CDK documentation
- AWS CDK API reference
- AWS CDK introductory workshop
- Amazon Kinesis Video Streams documentation
- Example: Identifying Objects in Video Streams Using SageMaker
- Example: Parsing and Rendering Kinesis Video Streams Fragments

- AWS Fargate Getting Started

**Additional information**

**Choosing an IDE**

We recommend that you use your favorite Java IDE to build and explore this project.

**Cleaning up**

After you finish running this example, remove all deployed resources to avoid incurring additional AWS infrastructure costs.

To remove the infrastructure and the video stream, use these two commands in the AWS CLI:

```
cdk destroy --profile "$AWS_PROFILE_NAME" --all
```

```
aws kinesisvideo --profile "$AWS_PROFILE_NAME" delete-stream --stream-arn "$STREAM_ARN"
```

Alternatively, you can remove the resources manually by using the AWS CloudFormation console to remove the AWS CloudFormation stack, and the Kinesis console to remove the Kinesis video stream. Note that `cdk destroy` doesn't remove the output S3 bucket or the images in Amazon Elastic Container Registry (Amazon ECR) repositories (`aws-cdk/assets`). You have to remove them manually.

Copy data from an S3 bucket in one account and Region to another account and Region

Created by Appasaheb Bagali (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Cloud-native; Security, identity, compliance; Storage &amp; backup; Migration</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: Amazon S3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to copy data from an Amazon Simple Storage Service (Amazon S3) bucket in an Amazon Web Services (AWS) account and AWS Region to an S3 bucket in another account and Region.

This pattern uses a source account and a destination account in different Regions. You attach a bucket policy to your source S3 bucket that grants the destination account access through AWS Identity and Access Management (IAM). You then create an IAM policy in your destination account that allows a user to perform PutObject and GetObject actions on the source S3 bucket. Finally, you run copy and sync commands to transfer data from the source S3 bucket to the destination S3 bucket.

Accounts own the objects that they upload to S3 buckets. If you copy objects across different accounts and Regions, you grant the destination account ownership of the copied objects. You can change the ownership of an object by changing its access control list (ACL) to bucket-owner-full-control. However, we recommend that you grant programmatic cross-account permissions to the destination account because ACLs can be difficult to manage for multiple objects.

Prerequisites and limitations

Prerequisites

- Two active AWS accounts in different AWS Regions.
- An existing S3 bucket in the source account.
- AWS Command Line Interface (AWS CLI), installed and configured.
- If your source or destination S3 bucket has default encryption enabled, you must modify the AWS Key Management Service (AWS KMS) key permissions. For more information, see Allow users to download from and upload to an S3 bucket with default encryption in the AWS Knowledge Center.
- Familiarity with cross-account permissions.

Architecture
Tools

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services.
- **IAM** – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources.

**Code**

**Copy**

```bash
```

**Synchronize**

```bash
```
## Epics

### Create and attach the S3 bucket policy in the source account

**Successfully import an S3 bucket as an AWS CloudFormation stack**

*Created by Ram Kandaswamy (AWS)*
## Summary

If you use Amazon Web Services (AWS) resources, such as Amazon Simple Storage Service (Amazon S3) buckets, and want to use an infrastructure as code (IaC) approach, then you can import your resources into AWS CloudFormation and manage them as a stack.

This pattern provides steps to successfully import an S3 bucket as an AWS CloudFormation stack. By using this pattern's approach, you can avoid possible errors that might occur if you import your S3 bucket in a single action.

## Prerequisites and limitations

**Prerequisites**

- An active AWS account.
- An existing S3 bucket and S3 bucket policy. For more information about this, see [What S3 bucket policy should I use to comply with the AWS Config rule s3-bucket-ssl-requests-only](https://aws.amazon.com/knowledge-center) in the AWS Knowledge Center.
- An existing AWS Key Management Service (AWS KMS) key and its alias. For more information about this, see [Working with aliases](https://docs.aws.amazon.com/kms/latest/developerguide/) in the AWS KMS documentation.
- The sample CloudFormation-template-S3-bucket AWS CloudFormation template (attached), downloaded to your local computer.

## Architecture

![Diagram showing the following workflow:](diagram)

The diagram shows the following workflow:

1. The user creates a JSON or YAML-formatted AWS CloudFormation template.
2. The template creates an AWS CloudFormation stack to import the S3 bucket.
3. The AWS CloudFormation stack manages the S3 bucket that you specified in the template.
Technology stack

- AWS CloudFormation
- AWS Identity and Access Management (IAM)
- AWS KMS
- Amazon S3

Tools

- AWS CloudFormation – AWS CloudFormation helps you to create and provision AWS infrastructure deployments predictably and repeatedly.
- AWS Identity and Access Management (IAM) – IAM is a web service for securely controlling access to AWS services.
- AWS KMS – AWS Key Management Service (AWS KMS) is an encryption and key management service scaled for the cloud.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the Internet.

Epics

Import an S3 bucket with CMK-based encryption as an AWS CloudFormation stack

Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer

Created by Kirankumar Chandrashekar (AWS)

**Environment:** Production

**Technologies:** Containers & microservices; Networking; Security, identity, compliance; Websites & web apps

**Workload:** All other workloads

**AWS services:** Amazon EC2; Amazon EC2 Auto Scaling; AWS EC2 Container Registry; Amazon EFS; Amazon RDS; Amazon VPC; Amazon ECS; Elastic Load Balancing (ELB); AWS Lambda

### Summary

This pattern describes how to privately host a Docker container application on Amazon Elastic Container Service (Amazon ECS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). Amazon Elastic File System (Amazon EFS) is used if the application requires persistent storage.

The Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

You can also use AWS Fargate instead of an Amazon EC2 Auto Scaling group. For more information, see Access container applications privately on Amazon ECS by using AWS Fargate, AWS PrivateLink, and a Network Load Balancer.

### Prerequisites and limitations

**Prerequisites**

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows
- Docker, installed and configured on Linux, macOS, or Windows
- An application running on Docker

### Architecture
Technology stack

- Amazon CloudWatch
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon EC2 Auto Scaling
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Lambda
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

Automation and scale

- You can use AWS CloudFormation to create this pattern by using Infrastructure as Code.

Tools

- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- Amazon EC2 Auto Scaling – Amazon EC2 Auto Scaling helps you ensure that you have the correct number of Amazon EC2 instances available to handle the load for your application.
- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- Amazon EFS – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- AWS Lambda – Lambda is a compute service for running code without provisioning or managing servers.
- Amazon RDS – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- AWS Secrets Manager – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, by providing an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon VPC – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you’ve defined.
- Elastic Load Balancing – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon EC2 instances, containers, and IP addresses, in multiple Availability Zones.
- Docker – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.
## Epics

### Create networking components

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a VPC. | 1. Sign in to the AWS Management Console and open the Amazon VPC console. Choose **Create VPC**, and choose **VPC and more**.  
2. Enter a name for your VPC, and choose an appropriate CIDR block range.  
3. Specify two Availability Zones, two public subnets, four private subnets. Two private subnets are for Amazon ECS tasks, and two private subnets are for Amazon RDS databases.  
4. Specify one NAT gateway for each Availability Zone.  
5. Choose **Create VPC**. | Cloud administrator |

### Create the load balancers

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a Network Load Balancer. | 1. Open the Amazon EC2 console and choose the AWS Region that contains your VPC.  
2. Under **Load balancing**, choose **Load balancers**, and choose **Create load balancer**.  
3. Choose **Network Load Balancer**, and choose **Create**.  
4. On the **Configure load balancer** page, configure your Network Load Balancer and listener. **Important:** Make sure you choose your Network Load Balancer’s scheme as **Internal**.  
5. Choose the applicable security settings, configure a security group and a target group. Choose **Instance** or **IP** as the **Target type** in the **Configure routing** section. | Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Make sure you do not register a target.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>6.</td>
<td>When you have configured all the settings, choose <strong>Next: Review</strong>, and then choose <strong>Create</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

**Create an Application Load Balancer.**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>On the Amazon EC2 console, choose the same Region that contains your VPC.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>2.</td>
<td>Under <strong>Load balancing</strong>, choose <strong>Load balancers</strong>, and choose <strong>Create load balancer</strong>.</td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Choose <strong>Application Load Balancer</strong>, and choose <strong>Create</strong>.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>Configure your Application Load Balancer and its listener. <strong>Important:</strong> Make sure you choose your Application Load Balancer's scheme as <strong>Internal</strong>.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>Choose the applicable security settings, configure a security group and a target group. Choose <strong>Instance</strong> or <strong>IP</strong> as the <strong>Target type</strong> in the <strong>Configure routing</strong> section. Make sure you do not register a target.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>When you have configured all the settings, choose <strong>Next: Review</strong>, and then choose <strong>Create</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

**Create an Amazon EFS file system**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1. Open the Amazon EFS console, and choose <strong>Create file system</strong>.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td></td>
<td>2. In the <strong>Create file system</strong> dialog box, enter a name for your file system, and choose your VPC.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Choose <strong>Create</strong> to create the file system.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Set up and configure your Amazon EFS file system.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1. Return to the Amazon EFS console, and choose <strong>File</strong></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to privately host a Docker container application on the Amazon Web Services (AWS) Cloud by using Amazon Elastic Container Service (Amazon ECS) with an AWS Fargate launch type, behind a Network Load Balancer, and access the application by using AWS PrivateLink. Amazon Relational Database Service (Amazon RDS) hosts the relational database for the application running on Amazon ECS with high availability (HA). You can use Amazon Elastic File System (Amazon EFS) if the application requires persistent storage.

This pattern uses a Fargate launch type for the Amazon ECS service running the Docker applications, with a Network Load Balancer at the front end. It can then be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

You can use Fargate with Amazon ECS to run containers without having to manage servers or clusters of Amazon Elastic Compute Cloud (Amazon EC2) instances. You can also use an Amazon EC2 Auto Scaling group instead of Fargate. For more information, see Access container applications privately on Amazon ECS by using AWS PrivateLink and a Network Load Balancer.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows
- Docker, installed and configured on Linux, macOS, or Windows
- An application running on Docker

Architecture
AWS Prescriptive Guidance Patterns
Architecture
Technology stack

- Amazon CloudWatch
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon ECS
- Amazon EFS
- Amazon RDS
- Amazon Simple Storage Service (Amazon S3)
- AWS Fargate
- AWS Lambda
- AWS PrivateLink
- AWS Secrets Manager
- Application Load Balancer
- Network Load Balancer
- VPC

Automation and scale

- You can use AWS CloudFormation to create this pattern by using Infrastructure as Code.

Tools

- Amazon ECS – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast, container management service that makes it easy to run, stop, and manage containers on a cluster.
- Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
- Amazon EFS – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- AWS Fargate – AWS Fargate is a technology that you can use with Amazon ECS to run containers without having to manage servers or clusters of Amazon EC2 instances.
- AWS Lambda – Lambda is a compute service that lets you run code without provisioning or managing servers.
- Amazon RDS – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.
- AWS Secrets Manager – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
- Amazon VPC – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you've defined.
- Elastic Load Balancing – Elastic Load Balancing (ELB) distributes incoming application or network traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in multiple Availability Zones.
- Docker – Docker helps developers to easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

</tr>
</tbody>
</table>

Summary

This pattern describes how to privately host a Docker container application on Amazon Elastic Kubernetes Service (Amazon EKS) behind a Network Load Balancer, and access the application by using AWS PrivateLink. You can then use a private network to securely access services on the Amazon Web Services (AWS) Cloud.

The Amazon EKS cluster running the Docker applications, with a Network Load Balancer at the front end, can be associated with a virtual private cloud (VPC) endpoint for access through AWS PrivateLink. This VPC endpoint service can then be shared with other VPCs by using their VPC endpoints.

The setup described by this pattern is a secure way to share application access among VPCs and AWS accounts. It requires no special connectivity or routing configurations, because the connection between the consumer and provider accounts is on the global AWS backbone and doesn’t traverse the public internet.

Prerequisites and limitations

Prerequisites

- Docker, installed and configured on Linux, macOS, or Windows.
- An application running on Docker.
- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured on Linux, macOS, or Windows.
- An existing Amazon EKS cluster with tagged private subnets and configured to host applications. For more information, see Subnet tagging in the Amazon EKS documentation.
- Kubectl, installed and configured to access resources on your Amazon EKS cluster. For more information, see Installing kubectl in the Amazon EKS documentation.

Architecture
Tools

- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.

- **Elastic Load Balancing** – Elastic Load Balancing distributes incoming application or network traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you’ve defined.

- **Kubectl** – Kubectl is a command line utility for running commands against Kubernetes clusters.

</tr>
</thead>
</table>
| Record the Network Load Balancer's name. | Run the following command to retrieve the name of the Network Load Balancer:  

```bash
kubectl get svc sample-service -o wide
```

Record the Network Load Balancer's name, which is required to create an AWS PrivateLink endpoint.  

| DevOps engineer               |                                                                                                                                            |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| Create an AWS PrivateLink endpoint. | Sign in to the AWS Management Console, open the Amazon VPC console, and then create an AWS PrivateLink endpoint. Associate this endpoint with                                                                 | Cloud administrator   |

---

188
the Network Load Balancer, this makes the application privately available to customers. For more information, see VPC endpoint services (AWS PrivateLink) in the Amazon VPC documentation.

**Important:** If the consumer account requires access to the application, the consumer account’s AWS account ID must be added to the allowed principals list for the AWS PrivateLink endpoint configuration. For more information, see Adding and removing permissions for your endpoint service in the Amazon VPC documentation.

Create a VPC endpoint.

On the Amazon VPC console, choose **Endpoint Services**, and then choose **Create Endpoint Service**. Create a VPC endpoint for the AWS PrivateLink endpoint.

The VPC endpoint’s fully qualified domain name (FQDN) points to the FQDN for the AWS PrivateLink endpoint. This creates an elastic network interface to the VPC endpoint service that the DNS endpoints can access.

**Activate mTLS in AWS App Mesh using AWS Private CA on Amazon EKS**

*Created by Omar Kahil (AWS), Emmanuel Saliu (AWS), and Muhammad Shahzad (AWS)*
Summary

This pattern shows how to implement Mutual Transport Layer Security (mTLS) on Amazon Web Services (AWS) using certificates from AWS Private Certificate Authority (AWS Private CA) in AWS App Mesh. It uses the Envoy secret discovery service (SDS) API through the Secure Production Identity Framework for Everyone (SPIFFE). SPIFFE is a Cloud Native Computing Foundation (CNCF) open-source project with wide community support that provides fine-grained and dynamic workload identity management. To implement SPIFFE standards, use the SPIRE SPIFFE runtime environment.

Using mTLS in App Mesh offers two-way peer authentication, because it adds a layer of security over TLS and allows services in the mesh to verify the client that's making the connection. The client in the client-server relationship also provides an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client. This helps to verify if the certificate is issued by a trusted certificate authority (CA) and if the certificate is a valid one.

Prerequisites and limitations

Prerequisites

• An Amazon Elastic Kubernetes Service (Amazon EKS) cluster with self-managed or managed node groups
• App Mesh controller deployed on the cluster with SDS activated
• A private certificate from AWS Certificate Manager (ACM) that is issued by AWS Private CA

Limitations

• SPIRE cannot be installed on AWS Fargate because the SPIRE Agent must be run as a Kubernetes DaemonSet.

Product versions

• AWS App Mesh Controller chart 1.3.0 or later

Architecture

The following diagram shows the EKS cluster with App Mesh in the VPC. The SPIRE server in one worker node communicates with the SPIRE Agents in other worker nodes, and with AWS Private CA. Envoy is used for mTLS communication between the SPIRE Agent worker nodes.
The diagram illustrates the following steps:

1. Certificate is issued.
2. Request cert signing and certificate.

**Tools**

**AWS services**

- **AWS Private CA** – AWS Private Certificate Authority (AWS Private CA) enables creation of private certificate authority (CA) hierarchies, including root and subordinate CAs, without the investment and maintenance costs of operating an on-premises CA.

- **AWS App Mesh** – AWS App Mesh is a service mesh that makes it easier to monitor and control services. App Mesh standardizes how your services communicate, giving you consistent visibility and network traffic controls for every service in an application.

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

**Other tools**

- **Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster. This pattern uses Helm to deploy AWS App Mesh Controller.

- **AWS App Mesh Controller chart** – AWS App Mesh Controller chart is used by this pattern to enable AWS App Mesh on Amazon EKS.
## Epics

### Set up the environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up App Mesh with Amazon EKS.</td>
<td>Follow base deployment steps that are provided in the repository.</td>

<tr>
<td>Install the AWS Private CA certificate.</td>
<td>Create and install a certificate for your private root CA by following the instructions in the AWS documentation.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Grant permissions to the cluster node instance role.</td>
<td>To attach policies to the cluster node instance role, use the code that's in the Additional information (p. 194) section.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Add the SPIRE plugin for AWS Private CA.</td>
<td>To add the plugin to the SPIRE server configuration, use the code that's in the Additional information (p. 194) section. Replace the <code>certificate_authority_arn</code> Amazon Resource Name (ARN) to your private CA ARN. The signing algorithm used must be the same as the signing algorithm on the private CA. Replace your <code>region</code> with your AWS Region. For more information about the plugin, see Server plugin: UpstreamAuthority &quot;aws_pca&quot;.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Update bundle.cert.</td>
<td>After you create the SPIRE server, a spire-bundle.yaml file will be created. Change the bundle.crt value in the spire-bundle.yaml file from the private CA to the public certificate.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
## Deploy and register the workloads

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register node and workload entries with SPIRE.</td>
<td>To register node and workload (services) with SPIRE Server, use the code in the repository.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Create a mesh in App Mesh with mTLS activated.</td>
<td>Create a new mesh in App Mesh with all the components for your microservices application (for example, virtual service, virtual router, and virtual nodes).</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Inspect the registered entries.</td>
<td>You can inspect the registered entries for your nodes and workloads by running the following command.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```
kubectl exec -n spire spire-server-0 -- /opt/spire/bin/spire-server entry show
```

This will show the entries for the SPIRE Agents.

## Verify mTLS traffic

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify mTLS traffic.</td>
<td>1. From the frontend service, send an HTTP header to the backend service, and verify a successful response with the services that are registered in SPIRE. 2. For mutual TLS authentication, you can inspect the ssl.handshake statistic by running the following command.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```
kubectl exec -it $POD -n $NAMESPACE -c envoy -- curl http://localhost:9901/stats | grep ssl.handshake
```

After running the previous command, you should see the listener ssl.handshake count, which will look similar to the following example:
**Task**

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify that certificates are being issued from AWS Private CA.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

You can check that the plugins have been configured correctly and certificates are being issued from your upstream private CA by viewing the logs in your SPIRE server. Run the following command.

```
kubectl logs spire-server-0 -n spire
```

Then view the logs that are produced. This code assumes that your server is named `spire-server-0` and is hosted in your `spire` namespace. You should see successful loading of the plugins and a connection being made to your upstream private CA.

Automate backups for Amazon RDS for PostgreSQL DB instances by using AWS Batch

Created by Kirankumar Chandrashekar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Containers &amp; microservices; Databases; DevOps</th>
<th>Workload:</th>
<th>All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon RDS; AWS Batch; Amazon CloudWatch; AWS Lambda; Amazon S3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Backing up your PostgreSQL databases is an important task and can typically be completed with the pg_dump utility, which uses the COPY command by default to create a schema and data dump of a PostgreSQL database. However, this process can become repetitive if you require regular backups for multiple PostgreSQL databases. If your PostgreSQL databases are hosted in the cloud, you can also take advantage of the automated backup feature provided by Amazon Relational Database Service (Amazon RDS) for PostgreSQL as well. This pattern describes how to automate regular backups for Amazon RDS for PostgreSQL DB instances using the pg_dump utility.

Note: The instructions assume that you’re using Amazon RDS. However, you can also use this approach for PostgreSQL databases that are hosted outside Amazon RDS. To take backups, the AWS Lambda function must be able to access your databases.

A time-based Amazon CloudWatch Events event initiates a Lambda function that searches for specific backup tags applied to the metadata of the PostgreSQL DB instances on Amazon RDS. If the PostgreSQL DB instances have the bkp:AutomatedDBDump = Active tag and other required backup tags, the Lambda function submits individual jobs for each database backup to AWS Batch.
AWS Batch processes these jobs and uploads the backup data to an Amazon Simple Storage Service (Amazon S3) bucket. This pattern uses a Dockerfile and an entrypoint.sh file to build a Docker container image that is used to make backups in the AWS Batch job. After the backup process is complete, AWS Batch records the backup details to an inventory table on Amazon DynamoDB. As an additional safeguard, a CloudWatch Events event initiates an Amazon Simple Notification Service (Amazon SNS) notification if a job fails in AWS Batch.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing managed or unmanaged compute environment. For more information, see Managed and unmanaged compute environments in the AWS Batch documentation.
- AWS Command Line Interface (CLI) version 2 Docker image, installed and configured.
- Existing Amazon RDS for PostgreSQL DB instances.
- An existing S3 bucket.
- Docker, installed and configured on Linux, macOS, or Windows.
- Familiarity with coding in Lambda.

Architecture

Technology stack

- Amazon CloudWatch Events
- Amazon DynamoDB
- Amazon Elastic Container Registry (Amazon ECR)
- Amazon RDS
• Amazon SNS
• Amazon S3
• AWS Batch
• AWS Key Management Service (AWS KMS)
• AWS Lambda
• AWS Secrets Manager
• Docker

Tools

• Amazon CloudWatch Events – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
• Amazon DynamoDB – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
• Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is a managed AWS container image registry service that is secure, scalable, and reliable.
• Amazon RDS – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
• Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.
• Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
• AWS Batch – AWS Batch helps you run batch computing workloads on the AWS Cloud.
• AWS KMS – AWS Key Management Service (AWS KMS) is a managed service that makes it easy for you to create and control the encryption keys used to encrypt your data.
• AWS Lambda – Lambda is a compute service that helps you run code without provisioning or managing servers.
• AWS Secrets Manager – Secrets Manager helps you replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
• Docker – Docker helps developers easily pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Your PostgreSQL DB instances on Amazon RDS must have tags applied to their metadata. The Lambda function searches for tags to identify DB instances that should be backed up, and the following tags are typically used.

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bkp:AutomatedDBDump = Active</td>
<td>Identifies an Amazon RDS DB instance as a candidate for backups.</td>
</tr>
<tr>
<td>bkp:AutomatedBackupSecret = &lt;secret_name&gt;</td>
<td>Identifies the Secrets Manager secret that contains the Amazon RDS login credentials.</td>
</tr>
<tr>
<td>bkp:AutomatedDBDumpS3Bucket = &lt;s3_bucket_name&gt;</td>
<td>Identifies the S3 bucket to send backups to.</td>
</tr>
<tr>
<td>bkp:AutomatedDBDumpFrequency</td>
<td>Identify the frequency and times when databases should be backed up.</td>
</tr>
<tr>
<td>bkp:AutomatedDBDumpTime</td>
<td></td>
</tr>
</tbody>
</table>
Epics

Create an inventory table in DynamoDB

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>

### Build a Docker image and push it to an Amazon ECR repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon ECR repository.</td>
<td>Open the Amazon ECR console and choose the AWS Region in which you want to create your repository. Choose <strong>Repositories</strong>, and then choose <strong>Create repository</strong>. Configure the repository according to your requirements.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Write a Dockerfile.</td>
<td>Sign in to Docker and use the “Sample Dockerfile” and “Sample entrypoint.sh file” from the Additional information section to build a Dockerfile.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Create a Docker image and push it to the Amazon ECR repository.</td>
<td>Build the Dockerfile into a Docker image and push it to the Amazon ECR repository. For help with this story, see the Related resources section.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

### Create the AWS Batch components

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an AWS Batch job definition.</td>
<td>Open the AWS Batch console and create a job definition that includes the Amazon ECR repository’s Uniform Resource Identifier (URI) as the property Image.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Configure the AWS Batch job queue.</td>
<td>On the AWS Batch console, choose <strong>Job queues</strong>, and then choose <strong>Create queue</strong>. Create a job queue that will store jobs until AWS Batch runs them on the resources within your compute environment. Important: Make sure you write logic for AWS Batch to record the backup details to the DynamoDB inventory table.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>
## Create and schedule a Lambda function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a Lambda function to search for tags.</td>
<td>Create a Lambda function that searches for tags on your PostgreSQL DB instances and identifies backup candidates. Make sure your Lambda function can identify the <code>bkp:AutomatedDBDump = Active</code> tag and all other required tags. Important: The Lambda function must also be able to add jobs to the AWS Batch job queue.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Create a time-based CloudWatch Events event.</td>
<td>Open the Amazon CloudWatch console and create a CloudWatch Events event that uses a cron expression to run your Lambda function on a regular schedule. Important: All scheduled events use the UTC time zone.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

## Test the backup automation

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon KMS key.</td>
<td>Open the Amazon KMS console and create a KMS key that can be used to encrypt the Amazon RDS credentials stored in AWS Secrets Manager.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Create an AWS Secrets Manager secret.</td>
<td>Open the AWS Secrets Manager console and store your Amazon RDS for PostgreSQL database credentials as a secret.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Add the required tags to the PostgreSQL DB instances.</td>
<td>Open the Amazon RDS console and add tags to the PostgreSQL DB instances that you want to automatically back up. You can use the tags from the table in the Tools section. If you require backups from multiple PostgreSQL databases within the same Amazon RDS instance, then use <code>-d test:-d test1</code> as the value for the <code>bkp:pgdumpcommand</code> tag. <strong>Important:</strong> <code>test</code> and <code>test1</code> are database names. Make sure that</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>
Verify the backup automation. To verify the backup automation, you can either invoke the Lambda function or wait for the backup schedule to begin. After the backup process is complete, check that the DynamoDB inventory table has a valid backup entry for your PostgreSQL DB instances. If they match, then the backup automation process is successful. Cloud administrator

Automate deployment of Node Termination Handler in Amazon EKS by using a CI/CD pipeline

Created by Sandip Gangapadhyay (AWS), Pragtideep Singh (AWS), Sandeep Gawande (AWS), and Viyoma Sachdeva (AWS)
AWS Prescriptive Guidance Patterns

Summary

On the Amazon Web Services (AWS) Cloud, you can use AWS Node Termination Handler, an open-source project, to handle Amazon Elastic Compute Cloud (Amazon EC2) instance shutdown within Kubernetes gracefully. AWS Node Termination Handler helps to ensure that the Kubernetes control plane responds appropriately to events that can cause your EC2 instance to become unavailable. Such events include the following:

- EC2 instance scheduled maintenance
- Amazon EC2 Spot Instance interruptions
- Auto Scaling group scale in
- Auto Scaling group rebalancing across Availability Zones
- EC2 instance termination through the API or the AWS Management Console

If an event isn't handled, your application code might not stop gracefully. It also might take longer to recover full availability, or it might accidentally schedule work to nodes that are going down. The aws-node-termination-handler (NTH) can operate in two different modes: Instance Metadata Service (IMDS) or Queue Processor. For more information about the two modes, see the Readme file.

This pattern automates the deployment of NTH by using Queue Processor through a continuous integration and continuous delivery (CI/CD) pipeline.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- A web browser that is supported for use with the AWS Management Console. See the list of supported browsers.
- AWS Cloud Development Kit (AWS CDK) installed.
- kubectl, the Kubernetes command line tool, installed.
- eksctl, the AWS Command Line Interface (AWS CLI) for Amazon Elastic Kubernetes Service (Amazon EKS), installed.
- A running EKS cluster with version 1.20 or later.
- A self-managed node group attached to the EKS cluster. To create an Amazon EKS cluster with a self-managed node group, run the following command.

```bash
eksctl create cluster --managed=false --region <region> --name <cluster_name>
```

For more information on eksctl, see the eksctl documentation.
- AWS Identity and Access Management (IAM) OpenID Connect (OIDC) provider for your cluster. For more information, see Creating an IAM OIDC provider for your cluster.

Limitations

- You must use an AWS Region that supports the Amazon EKS service.
Product versions

- Kubernetes version 1.20 or later
- eksctl version 0.107.0 or later
- AWS CDK version 2.27.0 or later

Architecture

Target technology stack

- A virtual private cloud (VPC)
- An EKS cluster
- Amazon Simple Queue Service (Amazon SQS)
- IAM
- Kubernetes

Target architecture

The following diagram shows the high level view of the end-to-end steps when the node termination is started.
The workflow shown in the diagram consists of the following high-level steps:

1. The automatic scaling EC2 instance terminate event is sent to the SQS queue.
2. The NTH Pod monitors for new messages in the SQS queue.
3. The NTH Pod receives the new message and does the following:
   • Cordons the node so that new pod does not run on the node.
   • Drains the node, so that the existing pod is evacuated
   • Sends a lifecycle hook signal to the Auto Scaling group so that the node can be terminated.

Automation and scale

- Code is managed and deployed by AWS CDK, backed by AWS CloudFormation nested stacks.
- The Amazon EKS control plane runs across multiple Availability Zones to ensure high availability.
- For automatic scaling, Amazon EKS supports the Kubernetes Cluster Autoscaler and Karpenter.

Tools

AWS services

- AWS Cloud Development Kit (AWS CDK) is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- AWS CodeBuild is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- AWS CodeCommit is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- AWS CodePipeline helps you quickly model and configure the different stages of a software release and automate the steps required to release software changes continuously.
- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- Amazon EC2 Auto Scaling helps you maintain application availability and allows you to automatically add or remove Amazon EC2 instances according to conditions you define.
- Amazon Simple Queue Service (Amazon SQS) provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.

Other tools

- kubectl is a Kubernetes command line tool for running commands against Kubernetes clusters. You can use kubectl to deploy applications, inspect and manage cluster resources, and view logs.

Code

The code for this pattern is available in the deploy-nth-to-eks repo on GitHub.com. The code repo contains the following files and folders.

- nth folder – The Helm chart, values files, and the scripts to scan and deploy the AWS CloudFormation template for Node Termination Handler.
- config/config.json – The configuration parameter file for the application. This file contains all the parameters needed for CDK to be deployed.
- cdk – AWS CDK source code.
- setup.sh – The script used to deploy the AWS CDK application to create the required CI/CD pipeline and other required resources.
• uninstall.sh – The script used to clean up the resources.

To use the example code, follow the instructions in the Epics section.

**Best practices**

For best practices when automating AWS Node Termination Handler, see the following:

- EKS Best Practices Guides
- Node Termination Handler - Configuration

Additional information

1. Find the NTH Pod name.

```bash
kubectl get pods -n kube-system |grep aws-node-termination-handler
aws-node-termination-handler-65445555-kbqc7 1/1 Running 0  26m
```

2. Check the logs. An example log looks like the following. It shows that the node has been cordoned and drained before sending the Auto Scaling group lifecycle hook completion signal.

```bash
kubectl -n kube-system logs aws-node-termination-handler-65445555-kbqc7
022/07/17 20:20:43 INF Adding new event to the event store
  event={"AutoScalingGroupName":"eksctl-my-cluster-target-nodegroup-ng-18d99c89-NodeGroup-ZME36IGAP701","Description":"ASG Lifecycle Termination event received. Summary

This pattern describes how to create a continuous integration and continuous delivery (CI/CD) pipeline that automatically builds and deploys a Java application to an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the Amazon Web Services (AWS) Cloud. This pattern uses a greeting application developed with a Spring Boot Java framework and that uses Apache Maven.

You can use this pattern's approach to build the code for a Java application, package the application artifacts as a Docker image, security scan the image, and upload the image as a workload container on Amazon EKS. This pattern's approach is useful if you want to migrate from a tightly coupled monolithic architecture to a microservices architecture. The approach also helps you to monitor and manage the entire lifecycle of a Java application, which ensures a higher level of automation and helps avoid errors or bugs.

Prerequisites and limitations

**Prerequisites**

- An active AWS account.
- AWS Command Line Interface (AWS CLI) version 2, installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI version 2 in the AWS CLI documentation.
• AWS CLI version 2 must be configured with the same IAM user that creates the Amazon EKS cluster because only they are authorized to add other IAM users, groups, or roles to the `aws-auth` ConfigMap. For information and steps to configure AWS CLI, see Configuration basics in the AWS CLI documentation.

• AWS Identity and Access Management (IAM) roles and permissions with full access to AWS CloudFormation. For more information about this, see Controlling access with IAM in the AWS CloudFormation documentation.

• An existing Amazon EKS cluster.

• Kubernetes Cluster Autoscaler, installed and configured in your Amazon EKS cluster. For more information about this, see Cluster Autoscaler in the Amazon EKS documentation.

• The `java-cicd-eks-cfn.zip` file (attached), downloaded to your local computer.

Limitations

• This pattern’s approach doesn’t implement container-specific logging and monitoring tools, such as Fluentd, Amazon CloudWatch, Grafana, or Prometheus.

• This approach doesn’t deploy containers to Amazon EKS clusters across multiple accounts.

Product versions

• Helm version 3.4.2 or later

• Apache Maven version 3.6.3 or later

Architecture

The diagram shows the following workflow:

1. Users commit the Java application code changes to an AWS CodeCommit repository.
2. An Amazon CloudWatch Events event is generated by the new commit.
3. The CloudWatch Events event initiates AWS CodePipeline.
4. CodePipeline runs the build phase (continuous integration).

5. CodeBuild builds the artifact, packages the artifact to a Docker image, scans the image for security vulnerabilities by using Aqua Security Trivy, and stores the image in Amazon Elastic Container Registry (Amazon ECR).

6. After the continuous integration phases are complete, CodePipeline enters the deployment phase (continuous delivery).

7. The Docker image is deployed to Amazon EKS as a container workload using Helm charts.

Tools

- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources.
- **AWS CodeBuild** – CodeBuild is a fully managed build service in the cloud.
- **AWS CodeCommit** – CodeCommit is a version control service hosted that you can use to privately store and manage assets.
- **AWS CodePipeline** – CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.
- **AWS Identity and Access Management** – IAM is a web service that helps you securely control access to AWS resources.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- **Aqua Security Trivy** – Trivy is a simple and comprehensive scanner for vulnerabilities in container images, file systems, and Git repositories, in addition to configuration issues.
- **Apache Maven** – Apache Maven is a software project management and comprehension tool.
- **Helm** – Helm helps you manage Kubernetes applications.

Code

The `java-cicd-eks-cfn.zip` file (attached) contains the build scripts, Helm chart configuration files, and IAM roles and policies required for this pattern. The code has the following structure, with 15 directories and 22 files.

```bash
### README

### app_code (Java application code)

# # # # app
# # # # Dockerfile (the Docker file to package the application artifact)
# # # # pom.xml
# # # # src
# # # # main
# # # # java
# # # # org
```
# aws

Epics

Create the AWS resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an S3 bucket.                | 1. Sign in to the AWS Management Console, open the Amazon S3 console, and then create an S3 bucket.  
2. Create a folder in the S3 bucket. We recommend naming this folder “Code.”  
3. Open the java-cicd-eks-cfn.zip file (attached) and upload the app_code/app_code.zip to the Code folder that you created in the S3 bucket.  
For more information about this, see Creating a bucket in the Amazon S3 documentation. | AWS DevOps, DevOps     |

Create an AWS CloudFormation stack.  
1. Open the AWS CloudFormation console and choose Create stack.  
2. In Specify template, choose Upload a template file, upload the cf_templates/codecommit.yaml file, and then choose Next.  
3. In Specify stack details, enter the stack name, and then provide the following input parameter values:  
   - CodeCommitRepositoryBranchName – The default value is the main branch name but any other branch name can be provided.  
   - CodeCommitRepositoryName – The name for your CodeCommit repository.  
   - CodeCommitRepositoryS3Bucket – The name of the S3 bucket that you created earlier.  
   - CodeCommitRepositoryS3BucketObjKey – The value for this is code/app_code.zip. | AWS DevOps, DevOps     |
### Configure the Helm charts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure the Helm charts of your Java application. | Open the app_code/aws-proserve-java-greeting folder. The values.dev.yaml file is the input file that can be modified for your container deployments to Amazon EKS. Change the Docker repository with the following parameter by replacing AWS account ID, AWS Region, and Amazon ECR repository information:  

```yaml
image:
  repository: <account-id>.dkr.ecr.<region>.amazonaws.com/aws-proserve-java-docker
```

The Java pod's service type is set to LoadBalancer. If you need to change it to another service (for example, NodePort), you can modify the following parameters:

```yaml
service:
  type: LoadBalancer
  port: 80
  targetPort: 8080
  path: /hello
```  | DevOps                                           |
The Kubernetes Horizontal Pod Autoscaler can be turned on by modifying the following parameters:

```
autoscaling:
  enabled: false
  minReplicas: 1
  maxReplicas: 100
  targetCPUUtilizationPercentage: 80
# targetMemoryUtilizationPercentage: 80
```

This means that you can turn on different features for the Kubernetes workloads by changing the values in the .{ENV}.yaml file, in which ENV can be your development, production, UAT, or QA environments.

### Set up the CI/CD pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the CI/CD pipeline.    | 1. Open the AWS CloudFormation console and choose Create stack.  
2. In Specify template, choose Upload a template file, upload the cf_templates/build_deployment.yaml template, and then choose Next.  
3. In Specify stack details, specify the Stack name, and then provide the following values for the input parameters:  
   - CodeBranchName – The default value is the main branch where the Java application code, Docker file, and Helm charts are located.  
   - EKSClusterName – The name of the Amazon EKS cluster.                                                                                                                                                                                                                                                                                                                                                   | AWS DevOps      |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|     | • EKSCodeBuildAppName – The name of the Java application. This pattern uses aws-proserve-java-greeting.  
     |     | • EcrDockerRepository – The name of your Amazon ECR repository.  
     |     | • EnvType – Your environment type.  
     |     | • SourceRepoName – The name of your CodeCommit repository.  
     |     | 4. Choose **Next**. Use the default settings in **Configure stack options** and then choose **Next**.  
     |     | 5. In the **Review** section, verify the AWS CloudFormation template and stack details. Choose **Next** and then choose **Create stack**.  
     |     | 6. After the stack is created, open the **Outputs** tab of the stack, and then record the Amazon Resource Name (ARN) value for the EksCodeBuildkubeRoleARN output key.  
<pre><code> |     | | Allow CodeBuild to run Helm or kubectl commands | | |
</code></pre>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Allow CodeBuild to run Helm or kubectl commands in the Amazon EKS cluster. | 1. CodeBuild needs to authenticate with the Amazon EKS cluster to use Helm or kubectl commands. The aws-auth ConfigMap in the Amazon EKS cluster is responsible for authenticating IAM users, groups, or roles, which must be added to the aws-auth ConfigMap.  
     | | 2. Open the cf_templates/kube_aws_auth_configmap_patch.sh shell script in your Amazon Linux or macOS environment. | DevOps |
### task | description | skills required
--- | --- | ---
3. Authenticate to the Amazon EKS cluster by running the following command: `aws eks --region <aws-region> update-kubeconfig --name <eks-cluster-name>`
4. Run the shell script with the following command: `bash cf_templates/kube_aws_auth_configmap_patch.sh <rolearn-eks-codebuild-kubectl>` **Note:** Replace `<rolearn-eks-codebuild-kubectl>` with the ARN value of `EksCodeBuildkubeRoleARN` that you recorded earlier.
5. The `aws_auth` ConfigMap is configured and access is granted.

**Validate the CI/CD pipeline**

<table>
<thead>
<tr>
<th>task</th>
<th>description</th>
<th>skills required</th>
</tr>
</thead>
</table>
| Verify that the CI/CD pipeline automatically initiates. | The build phase in the pipeline will initially fail when Trivy scans the Docker image for vulnerabilities. This is intentional and is caused by an old version of the `spring-boot-starter-parent` in the `app_code/app/pom.xml` file that validates that the Docker image is tested against well-known application and Docker common vulnerabilities and exposures (CVEs).

Use the following steps to resolve this build failure:

1. Update the `spring-boot-starter-parent` version to the most recent version in the file `app_code/app/pom.xml` file in your CodeCommit repository. You can find the most recent version in the Maven Spring Boot Starter Parent repository. | DevOps |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>2. Commit the changes to the CodeCommit repository. 3. The pipeline automatically initiates and the build phase is successful.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For more information about this, see Start a pipeline execution in CodePipeline, Start a pipeline manually, and Start a pipeline on a schedule from the AWS CodePipeline documentation.</td>
<td></td>
</tr>
<tr>
<td>Approve the deployment.</td>
<td>After the build phase is complete, there is a deployment approval gate. The reviewer or a release manager should inspect the build and, if all requirements are met, approve it. When approved, the pipeline implements the deployment phase.</td>
<td>DevOps</td>
</tr>
</tbody>
</table>

Create an Amazon ECS task definition and mount a file system on EC2 instances using Amazon EFS

Created by Durga Prasad Cheepuri (AWS)

| Environment: | PoC or pilot | Technologies: | Containers & microservices; Cloud-native; Management & governance; Storage & backup; Websites & web apps | AWS services: | Amazon ECS; Amazon EFS |
Summary

This pattern provides code samples and steps to create an Amazon Elastic Container Service (Amazon ECS) task definition that runs on Amazon Elastic Compute Cloud (Amazon EC2) instances in the Amazon Web Services (AWS) Cloud, while using Amazon Elastic File System (Amazon EFS) to mount a file system on those EC2 instances. Amazon ECS tasks that use Amazon EFS automatically mount the file systems that you specify in the task definition and make these file systems available to the task's containers across all Availability Zones in an AWS Region.

To meet your persistent storage and shared storage requirements, you can use Amazon ECS and Amazon EFS together. For example, you can use Amazon EFS to store persistent user data and application data for your applications with active and standby ECS container pairs running in different Availability Zones for high availability. You can also use Amazon EFS to store shared data that can be accessed in parallel by ECS containers and distributed job workloads.

To use Amazon EFS with Amazon ECS, you can add one or more volume definitions to a task definition. A volume definition includes an Amazon EFS file system ID, access point ID, and a configuration for AWS Identity and Access Management (IAM) authorization or Transport Layer Security (TLS) encryption in transit. You can use container definitions within task definitions to specify the task definition volumes that get mounted when the container runs. When a task that uses an Amazon EFS file system runs, Amazon ECS ensures that the file system is mounted and available to the containers that need access to it.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router
- (Recommended) Amazon ECS container agent 1.38.0 or later for compatibility with Amazon EFS access points and IAM authorization features (For more information, see the AWS blog post New for Amazon EFS – IAM Authorization and Access Points.)

Limitations

- Amazon ECS container agent versions earlier than 1.35.0 don't support Amazon EFS file systems for tasks that use the EC2 launch type.

Architecture

The following diagram shows an example of an application that uses Amazon ECS to create a task definition and mount an Amazon EFS file system on EC2 instances in ECS containers.
The diagram shows the following workflow:

1. Create an Amazon EFS file system.
2. Create a task definition with a container.
3. Configure the container instances to mount the Amazon EFS file system. The task definition references the volume mounts, so the container instance can use the Amazon EFS file system. ECS tasks have access to the same Amazon EFS file system, regardless of which container instance those tasks are created on.
4. Create an Amazon ECS service with three instances of the task definition.

**Technology stack**

- Amazon EC2
- Amazon ECS
- Amazon EFS

**Tools**

- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of EC2 instances that you manage.
- **Amazon EFS** – Amazon Elastic File System (Amazon EFS) provides a simple, scalable, fully managed elastic NFS file system for use with AWS Cloud services and on-premises resources.
- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS
CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

Epics

Create an Amazon EFS file system

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an Amazon EFS file system by using the AWS Management Console. | 1. Create an Amazon EFS file system and choose the VPC that includes your containers. **Note:** If you use a different VPC, set up a VPC peering connection.  
2. Note the file system ID. | AWS DevOps |

Create an Amazon ECS task definition by using either an Amazon EFS file system or the AWS CLI

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a task definition using an Amazon EFS file system. | Create a task definition by using the new Amazon ECS console or classic Amazon ECS console with the following configurations:  
• If you use the new console, choose Amazon EC2 instances for App environment. If you use the classic console, choose EC2 as the launch type.  
• Add a volume. Enter a name for the volume, choose EFS for volume type, and then choose the file system ID that you noted earlier. For the root directory, choose the Amazon EFS file system path that you want to host on the Amazon ECS container host. | AWS DevOps |
| Create a task definition using the AWS CLI. | 1. To create a JSON template with input parameter placeholders for your task definition, run the following command:  
```
aws ecs register-task-definition --generate-cli-skeleton
```
 | AWS DevOps |
### Task

### Deploy CoreDNS on Amazon EKS with Fargate automatically using Terraform and Python

*Created by Kevin Vaughan and Lorenzo Couto (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Containers &amp; microservices; Infrastructure</th>
<th>Workload:</th>
<th>Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS services:</strong></td>
<td>Amazon EKS; AWS Fargate</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Summary

This pattern describes the steps to automate the deployment of Kubernetes CoreDNS pods onto an Amazon Elastic Kubernetes Service (Amazon EKS) cluster on the Amazon Web Services (AWS) Cloud.
using AWS Fargate when not creating the cluster using eksctl. CoreDNS is a flexible, extensible Domain Name System (DNS) server that can serve as the Kubernetes Cluster DNS. The CoreDNS pods provide name resolution for all pods in the cluster. When you launch an Amazon EKS cluster with at least one node, two replicas of the CoreDNS image are deployed by default, regardless of the number of nodes deployed in your cluster.

If you want to run your pods only on Fargate in your cluster, you need to modify the CoreDNS deployment to remove the eks.amazonaws.com/compute-type : ec2 annotation. To do this manually, use the following kubectl command line interface (CLI) commands, in sequential order, after you create the Amazon EKS cluster:

1. kubectl patch deployment coredns -n kube-system --type=json -p='{"op": "remove", "path": "/spec/template/metadata/annotations", "value": "eks.amazonaws.com/compute-type"}"
2. kubectl rollout restart -n kube-system deployment coredns

However, if because of an organizational policy or other situation, CLI-based access is not available, you might need to use automation to perform these changes. This pattern adds new Hashicorp Terraform and Python resources to automate an existing Terraform based infrastructure as code (IaC) Amazon EKS cluster deployment when the deployment is running in a continuous integration and continuous delivery (CI/CD) pipeline.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An existing Amazon EKS cluster deployment template based on Terraform

**Limitations**

This pattern has been designed to support Amazon EKS cluster deployments deployed using Terraform. The Python script (main.py) can also be used for Amazon EKS cluster deployments deployed using AWS CloudFormation, when applied using the appropriate CloudFormation template resources.

**Product versions**

- Terraform version 13 or later
- Python 3.7

**Architecture**

**Technology stack**

- Amazon EKS
- AWS Fargate
- AWS Lambda
- Hashicorp Terraform
- Python

**Target architecture**
The following diagram illustrates the architecture of an Amazon EKS in the Amazon EKS cluster control pane, with Fargate and CoreDNS deployed in an Auto Scaling group, and an AWS Lambda function.

- A Lambda function is initiated after the Fargate profile has been created on the Amazon EKS cluster.
- A Python script is called to run the automated kubectl commands that deploy the CoreDNS pods onto the Amazon EKS cluster.

**Automation and scale**

This pattern automates the manual CLI-based steps that can be used to deploy the CoreDNS pods.

**Tools**

**AWS services**

- **Amazon EKS** - Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

- **AWS Fargate** - AWS Fargate is a serverless compute engine for containers that works with both Amazon Elastic Container Service (Amazon ECS) and Amazon Elastic Kubernetes Service (Amazon EKS). Fargate removes the need to provision and manage servers, lets you specify and pay for resources for each application, and it improves security through application isolation by design.

- **AWS Lambda** - AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

**Other tools**
• **Hashicorp Terraform** - Hashicorp Terraform is an open-source IaC software tool that provides a consistent CLI workflow to manage cloud services. Terraform codifies cloud APIs into declarative configuration files.

• **Python** - Python is an interpreted high-level general-purpose programming language.

**Code**

The code for this pattern is in the *Additional information* section.

**Epics**

**Deploy the Terraform file**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>

Summary

This pattern provides guidance for deploying containerized Java microservices on Amazon Elastic Container Service (Amazon ECS) using AWS Fargate. The pattern doesn't use Amazon Elastic Container Registry (Amazon ECR) for container management; instead, Docker images are pulled in from the on-premises environment.

Microservices are an architectural and organizational approach to software development where software is composed of small independent services that communicate over well-defined APIs. These architectures make applications easier to scale and faster to develop, enabling innovation and accelerating time-to-market for new features.

Amazon ECS is a highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS.

AWS Fargate is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters.

Prerequisites and limitations

Prerequisites

- An existing Java microservices application on a Docker hub
- A public Docker repository
- An active AWS account
- Familiarity with AWS services, including Amazon ECS and Fargate
- Docker, Java, and Spring Boot framework
- Amazon Relational Database Service (Amazon RDS) up and running (optional)
- A virtual private cloud (VPC) if the application requires Amazon RDS (optional)

Limitations

- Fargate is currently supported only in Amazon ECS.

Architecture

Source technology stack
• Java microservices (for example, implemented in Spring Boot) and deployed on Docker

Source architecture

Target technology stack
• An Amazon ECS cluster that hosts each microservice using Fargate
• A VPC network to host the Amazon ECS cluster and associated security groups
• A cluster/task definition for each microservice that spins up containers using Fargate

Target architecture
Tools

Tools

- **Amazon ECS** – Amazon ECS eliminates the need to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.
- **AWS Fargate** – With the AWS Fargate compute engine, you no longer have to provision, configure, and scale clusters of virtual machines to run containers, choose server types, decide when to scale your clusters, or optimize cluster packing.
- **Docker file** – Docker is a software platform that allows you to build, test, and deploy applications quickly. Docker packages software into standardized units called containers that have everything the software needs to run, including libraries, system tools, code, and runtime.

Docker code

The following DockerFile specifies the Java Development Kit (JDK) version that is used, where the Java archive (JAR) file exists, the port number that is exposed, and the entry point for the application.

```
FROM openjdk:8
ADD target/Spring-docker.jar Spring-docker.jar
EXPOSE 8080
ENTRYPOINT ["java","-jar","Spring-docker.jar"]
```

Epics

Set up a VPC

- Amazon ECS
- AWS Fargate

Target architecture
AWS Prescriptive Guidance Patterns
Tools

Tools

- **Amazon ECR** - Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can reliably deploy containers for your applications. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

- **Amazon ECS** - Amazon Elastic Container Service (Amazon ECS) is a highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS. Amazon ECS eliminates the need for you to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.

- **AWS Fargate** - AWS Fargate is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters. With AWS Fargate, you no longer have to provision, configure, and scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

- **Docker** - Docker is a platform that lets you build, test, and deliver applications in packages called containers.

**Code**

The following DockerFile specifies the Java Development Kit (JDK) version that is used, where the Java archive (JAR) file exists, the port number that is exposed, and the entry point for the application.

```
FROM openjdk:8
ADD target/Spring-docker.jar Spring-docker.jar
EXPOSE 8080
ENTRYPOINT ["java","-jar","Spring-docker.jar"]
```

**Epics**

Create an Amazon ECR repository

<table>
<thead>
<tr>
<th>Task</th>

<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>Choose the cluster type based on your requirements. In our example, we selected a networking cluster. Provide a name for the cluster and choose whether you want to create a new virtual private cloud (VPC) to use for Fargate tasks.</td>
<td></td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Create a service.</td>
<td>Inside the cluster, choose Create service.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Choose the launch type.</td>
<td>Choose Fargate as the launch type.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Choose task definition, revision, and platform version.</td>
<td>Choose the task that you want to run, followed by the revision of the task definition and the platform version.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Select the cluster.</td>
<td>Select the cluster in which to create your service from the dropdown list.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Provide a service name.</td>
<td>Provide a unique name for the service that you are creating.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Specify the number of tasks.</td>
<td>Configure the number of tasks that should run when the service launches. If you're launching with two or more tasks, a load balancer is required to balance the tasks. The minimum number of tasks to be configured is One.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Set the minimum and maximum healthy percentages.</td>
<td>Configure the minimum and maximum healthy percentages for the application, or accept the default option that is provided.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Configure deployment settings.</td>
<td>Choose the deployment type based on your requirements. You can choose a rolling update or a blue/green deployment.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Configure the cluster VPC, subnets, and security groups.</td>
<td>Configure the cluster VPC, the subnets on which you want to deploy the application, and the security groups (HTTP, HTTPS, and port 8080) for providing access to inbound/outbound connections.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td>Configure public IP settings.</td>
<td>Enable or disable the public IP, depending on whether you want to use a public IP address for Fargate tasks.</td>
<td>Developer, System Admin</td>
</tr>
</tbody>

**Deploy Java microservices on Amazon ECS using Amazon ECR and load balancing**

*Created by Durga Prasad Cheepuri (AWS)*

242
Summary

This pattern outlines steps for deploying a containerized Java microservices architecture on Amazon Elastic Container Service (Amazon ECS) to make it easier to scale and faster to develop your applications. This helps enable innovation and accelerates time-to-market for new features.

The pattern also uses Amazon Elastic Container Registry (Amazon ECR) to store and manage the Docker-based containers, and an AWS CloudFormation template with a Python script to automate the setup of your infrastructure. The pattern is based on the post Deploying Java Microservices on Amazon Elastic Container Service, which is published on the AWS Compute blog.

Microservices provide an architectural and organizational approach to software development, where software is composed of small, independent services that communicate over well-defined application programming interfaces (APIs). Small, self-contained teams own these services.

Amazon ECS is a highly scalable, high-performance container orchestration service. It supports Docker containers and enables you to run and scale containerized applications on AWS quickly. With Amazon ECS, you no longer have to install and operate your container orchestration software, manage and scale a cluster of virtual machines (VMs), or schedule containers on those VMs.

With simple API calls, you can launch and stop Docker-enabled applications, query the complete state of your request, and access many natural features, such as AWS Identity and Access Management (IAM) roles, security groups, load balancers, Amazon CloudWatch Events, AWS CloudFormation templates, and AWS CloudTrail logs.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Java microservices source code, with Java Development Kit version 1.7 or later
- An access key and secret access key for a user in the account
- AWS Command Line Interface (AWS CLI)
- Java, AWS Software Development Kit (SDK) for Python (Boto3), and Docker software
- Familiarity with the use of the preceding technologies
- Familiarity with AWS services such as Amazon ECS, AWS CloudFormation, and Elastic Load Balancing

Architecture

Source technology stack

- Microservices implemented in Java and deployed on Apache Tomcat in an on-premises environment

Target technology stack
- The Application Load Balancer that inspects the client request. Based on routing rules, the load balancer directs the request to an instance and port from the target group that matches the state.

- A target group for each microservice. The target groups are used by the corresponding services to register available container instances. Each target group has a path, so when you call the way for a particular microservice, it maps to the correct target group. This enables you to use one Application Load Balancer to serve all the microservices, accessed by the path. For example, https://owner/* would map and direct to the Owner microservice.

- An Amazon ECS cluster that hosts the containers for each microservice.

- An Amazon Virtual Private Cloud (Amazon VPC) network for hosting the Amazon ECS cluster and associated security groups.

- An Amazon Elastic Container Registry (Amazon ECR) repository for each microservice.

- A service or task definition for each microservice, which spins up containers on the instances of the Amazon ECS cluster.

**Target architecture**
Tools

- **Amazon ECS** – Amazon ECS lets you launch and stop container-based applications with simple API calls, enables you to get the state of your cluster from a centralized service, and gives you access to many familiar Amazon Elastic Compute Cloud (Amazon EC2) features.

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR
hosts your images in a highly available and scalable architecture so you can reliably deploy containers for your applications. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

Epics

Create an AWS CloudFormation template to set up an Amazon ECS cluster to host the Java microservices

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provision an Amazon EC2 Linux instance, install Docker, and create a Docker file for each microservice.</td>
<td>Use the Python script at <a href="https://github.com/awslabs/amazon-ecs-java-microservices/blob/master/2_ECS_Java_Spring_PetClinic_Microservices/setup.py">https://github.com/awslabs/amazon-ecs-java-microservices/blob/master/2_ECS_Java_Spring_PetClinic_Microservices/setup.py</a> to invoke the AWS CloudFormation template you created earlier. This template creates the AWS infrastructure you need for the target environment.</td>
<td>Ops</td>
</tr>
<tr>
<td>Set up Docker images on Amazon ECR.</td>
<td>Use the Dockerfile for the image to push, build the image, and tag it for your new repository. Do the same for each microservice. Push the newly tagged images to the repository.</td>
<td>Ops</td>
</tr>
<tr>
<td>Create an AWS CloudFormation template.</td>
<td>Create an AWS CloudFormation template to provision the virtual private cloud (VPC), Amazon ECS cluster, and Amazon Relational Database Service (Amazon RDS).</td>
<td>Ops</td>
</tr>
</tbody>
</table>

Provision AWS services

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the AWS infrastructure by using the CloudFormation template you created earlier.</td>
<td>Create Amazon ECR repositories, tasks, services, the Application Load Balancer, and target groups. The Python script reads the outputs of the AWS CloudFormation template and uses BOTO3 API calls to create Amazon ECR repositories, tasks, services, the Application Load Balancer, and target groups.</td>
<td>Ops</td>
</tr>
</tbody>
</table>
Deploy Kubernetes resources and packages using Amazon EKS and a Helm chart repository in Amazon S3

Created by Sagar Panigrahi (AWS)

| Environment: | PoC or pilot | Technologies: | Containers & microservices; DevOps | AWS services: | Amazon EKS |

Summary

This pattern helps you to manage Kubernetes applications efficiently, regardless of their complexity. The pattern integrates Helm into your existing continuous integration and continuous delivery (CI/CD) pipelines to deploy applications into a Kubernetes cluster. Helm is a Kubernetes package manager that helps you manage Kubernetes applications. Helm charts help to define, install, and upgrade complex Kubernetes applications. Charts can be versioned and stored in Helm repositories, which improves mean time to restore (MTTR) during outages.

This pattern uses Amazon Elastic Kubernetes Service (Amazon EKS) for the Kubernetes cluster. It uses Amazon Simple Storage Service (Amazon S3) as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account with a virtual private cloud (VPC)
- An Amazon EKS cluster
- Worker nodes set up within the Amazon EKS cluster and ready to take workloads
- Kubectl for configuring the Amazon EKS kubeconfig file for the target cluster in the client machine
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmatic or role) access to Amazon S3 from the client machine
- Source code management and a CI/CD pipeline

Limitations
• There is no support at this time for upgrading, deleting, or managing custom resource definitions (CRDs).
• If you are using a resource that refers to a CRD, the CRD must be installed separately (outside of the chart).

Product versions
• Helm v3.6.3

Architecture

Target technology stack
• Amazon EKS
• Amazon VPC
• Amazon S3
• Source code management
• Helm
• Kubectl

Target architecture

Automation and scale
• AWS CloudFormation can be used to automate the infrastructure creation. One option is to use the Modular and Scalable Amazon EKS Architecture Quick Start.
• Helm is to be incorporated into your existing CI/CD automation tool to automate the packaging and versioning of Helm charts (out of scope for this pattern).
• GitVersion or Jenkins build numbers can be used to automate the versioning of charts.
Tools

**Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service for running Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

**Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.

**Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

**Kubectl** – Kubectl is a command line utility for running commands against Kubernetes clusters.

---

Code

The example code is attached.

Epics

**Configure and initialize Helm**

<table>

</tr>
</tbody>
</table>
**AWS Prescriptive Guidance Patterns**

### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deactivate service account creation in the chart.</strong></td>
<td>In values.yaml, under the serviceAccount section, set the create key to false. This is turned off because there is no requirement to create a service account for this pattern.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td><strong>Validate (lint) the modified chart for syntactical errors.</strong></td>
<td>To validate the chart for any syntactical error before installing it in the target cluster, run helm lint my-nginx/.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td><strong>Install the chart to deploy Kubernetes resources.</strong></td>
<td>To run the Helm chart installation, use the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>helm install --name my-nginx-release --debug my-nginx/ --namespace helm-space</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The optional debug flag outputs all debug messages during the installation. The namespace flag specifies the namespace in which the resources part of this chart will be created.</td>
<td></td>
</tr>
<tr>
<td><strong>Review the resources in the Amazon EKS cluster.</strong></td>
<td>To review the resources that were created as part of the Helm chart in the helm-space namespace, use the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>kubectl get all -n helm-space</td>
<td></td>
</tr>
</tbody>
</table>

### Roll back to a previous version of a Kubernetes application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Modify and upgrade the release.</strong></td>
<td>To modify the chart, in values.yaml, change the replicaCount value to 2. Then upgrade the already installed release by running the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>helm upgrade my-nginx-release my-nginx/ --namespace helm-space</td>
<td></td>
</tr>
</tbody>
</table>
Initialize an S3 bucket as a Helm repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an S3 bucket for Helm charts.</td>
<td>Create a unique S3 bucket. In the bucket, create a folder called charts. The example in this pattern uses s3://my-helm-charts/charts as the target chart repository.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Install the Helm plugin for Amazon S3.</td>
<td>To install the helm-s3 plugin on your client machine, use the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>helm plugin install <a href="https://github.com/hypnoglow/helm-s3.git">https://github.com/hypnoglow/helm-s3.git</a> --version 0.10.0</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Note: Helm V3 support is available with plugin version 0.9.0 and above.</td>
<td></td>
</tr>
</tbody>
</table>
### Initialize the Amazon S3 Helm repository.

**Task**: Initialize the Amazon S3 Helm repository.

**Description**: To initialize the target folder as a Helm repository, use the following command.

```
helm s3 init s3://my-helm-charts/charts
```

The command creates an `index.yaml` file in the target to track all the chart information that is stored at that location.

**Skills required**: DevOps engineer

### Add the Amazon S3 repository to Helm.

**Task**: Add the Amazon S3 repository to Helm.

**Description**: To add the repository in the client machine, use the following command.

```
helm repo add my-helm-charts s3://my-helm-charts/charts
```

This command adds an alias to the target repository in the Helm client machine.

**Skills required**: DevOps engineer

### Review the repository list.

**Task**: Review the repository list.

**Description**: To view the list of repositories in the Helm client machine, run `helm repo list`.

**Skills required**: DevOps engineer

### Package and store charts in the Amazon S3 Helm repository

#### Task: Package the chart.

**Description**: To package the `my-nginx` chart that you created, run `helm package ./my-nginx/`. The command packages all the contents of the `my-nginx` chart folder into an archive file, which is named using the version number that is mentioned in the `Chart.yaml` file.

**Skills required**: DevOps engineer

#### Task: Store the package in the Amazon S3 Helm repository.

**Description**: To upload the package to the Helm repository in Amazon S3, run the following command, using the correct name of the `.tgz` file.

```
helm s3 push ./my-nginx-0.1.0.tgz my-helm-charts
```

**Skills required**: DevOps engineer
### Modify, version, and package a chart

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify and package the chart.</td>
<td>In <code>values.yaml</code>, set the <code>replicaCount</code> value to 1. Then package the chart by running <code>helm package ./my-nginx/</code>, this time changing the version in <code>Chart.yaml</code> to 0.1.1. The versioning is ideally updated through automation using tools such as GitVersion or Jenkins build numbers in a CI/CD pipeline. Automating the version number is out of scope for this pattern.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Push the new version to the Helm repository in Amazon S3.</td>
<td>To push the new package with version of 0.1.1 to the <code>my-helm-charts</code> Helm repository in Amazon S3, run the following command.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search for all versions of the my-nginx chart.</td>
<td>To view all the available versions of a chart, run the following command with the <code>--versions</code> flag.</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
Without the flag, Helm by default displays the latest uploaded version of a chart.

Install a chart from the Amazon S3 Helm repository. The search results from the previous task show the multiple versions of the my-nginx chart. To install the new version (0.1.1) from the Amazon S3 Helm repository, use the following command.

```
helm upgrade my-nginx-release my-helm-charts/my-nginx --version 0.1.1 --namespace helm-space
```

### Deploy Lambda functions with container images

*Created by Ram Kandaswamy (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Containers &amp; microservices; Business productivity; Cloud-native; Cost management; Software development &amp; testing; Modernization; Serverless</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
</table>

**AWS services:** AWS EC2

Container Registry; AWS Lambda

### Summary
AWS Lambda supports containers images as a deployment model. This pattern shows how to deploy Lambda functions through container images.
Lambda is a serverless, event-driven compute service that you can use to run code for virtually any type of application or backend service without provisioning or managing servers. With container image support for Lambda functions, you get the benefits of up to 10 GB of storage for your application artifact and the ability to use familiar container image development tools.

**Prerequisites and limitations**

**Prerequisites**
- Amazon Elastic Container Registry (Amazon ECR) activated
- Application code
- Docker images with the runtime interface client

**Limitations**
- Maximum image size supported is 10 GB.
- Maximum runtime for a Lambda based container deployment is 15 minutes.

**Architecture**

**Target technology stack**
- AWS CodeBuild
- AWS CodeCommit
- Docker image
- Amazon Elastic Container Registry (Amazon ECR)
- AWS Identity and Access Management (IAM)
- AWS Lambda
- Amazon CloudWatch Logs

**Target architecture**
1. You create a repository and commit the application code using CodeCommit.
2. The CodeBuild project is created, using CodeCommit as the source provider.
3. The CodeBuild run creates the Docker image.
4. CodeBuild publishes the image to Amazon ECR.
5. You create the Lambda function using the image in Amazon ECR.

Automation and scale

This pattern can be automated by using AWS CloudFormation, AWS Cloud Development Kit (AWS CDK), or API operations from an SDK. Lambda can automatically scale based on the number of requests, and you can tune it by using the concurrency parameters.

Tools

**Tools**

- **AWS CloudFormation Designer** integrated JSON and YAML editor – AWS CloudFormation Designer provides an integrated JSON and YAML editor for viewing and editing template details. For example, you can use the integrated editor to define the properties of a resource or to change a template parameter.
- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- **AWS CodeCommit** – AWS CodeCommit is a version control service hosted by AWS. You can use CodeCommit to privately store and manage assets (such as documents, source code, and binary files) in the cloud.
- **AWS CodeStar** or another development environment – AWS CodeStar is a cloud-based service for creating, managing, and working with software development projects on AWS.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- **Docker** – Docker is a software platform that for building, testing, and deploying applications quickly. Docker packages software into standardized units called containers that have everything the software needs to run, including libraries, system tools, code, and runtime.

Epics

Create a project in CodeBuild

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a CodeCommit repository.</td>
<td>The following approach uses Python as the underlying programming language, but you can use other languages, such as Java, Node.js, or Go. To store the configuration file and the files that will contain</td>
<td>Developer</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Create a CodeBuild project.</td>
<td>On the CodeBuild console, create a new project. Provide values for project name and description. Specify a source provider. This example uses CodeCommit. Other options include GitHub, Bitbucket, or Amazon Simple Storage Service (Amazon S3).</td>
<td>Developer</td>
</tr>
<tr>
<td>Edit the Dockerfile.</td>
<td>The Dockerfile should be located in the top-level directory where you're developing the application. The Python code should be in the src folder. When you create the image, use the official Lambda supported images. Otherwise, a bootstrap error will occur, making the packing process more difficult. For details, see the Additional information section.</td>
<td>Developer</td>
</tr>
<tr>
<td>Add the image in Amazon ECR.</td>
<td>Build the image and publish it to the image repository. Use CodeBuild to perform the image build process. Then push the image to Amazon ECR registry. For details and the code, see the Additional information section.</td>
<td>Developer</td>
</tr>
<tr>
<td>Verify that the image is in the repository.</td>
<td>To verify that the image is in the repository, on the Amazon ECR console, choose Repositories. The image should be listed, with tags and with the results of a vulnerability scan report if that feature was turned on in the Amazon ECR settings.</td>
<td>Developer</td>
</tr>
<tr>
<td>Create the Lambda function.</td>
<td>On the Lambda console, choose Create function, and then choose Container image. Enter the function name and the URI for the image that is in the Amazon ECR repository, and then choose Create function.</td>
<td>Developer</td>
</tr>
<tr>
<td>Test the Lambda function.</td>
<td>To invoke and test the function, choose Test.</td>
<td>Developer</td>
</tr>
</tbody>
</table>

- Runtime support for Lambda container images

Additional information

Edit the Dockerfile

The following screenshot shows the commands for editing the Dockerfile.

```
# first stage
FROM public.ecr.aws/lambda/python:3.8
COPY requirements.txt .

# install dependencies to the local user directory (eg. /root/.local)
RUN pip install --user -r requirements.txt

# Copy function code
COPY src/server.py ${LAMBDA_TASK_ROOT}

# Set the CMD to your handler (could also be done as a parameter override outside of the Dockerfile)
CMD [ "server.lambda_handler" ]
```

The FROM command value corresponds to the Python 3.8 base image that is using the Lambda function in the public Amazon ECR image repository.

The COPY requirements.txt command captures the dependencies necessary for the code.

The RUN pip install --user -r requirements.txt command installs the dependencies to the local user directory.

The COPY src/server.py ${LAMBDA_TASK_ROOT} command copies the code to the task root directory, which the Lambda function will use. This command uses the environment variable so we don't have to worry about the actual path. The function to be run is passed as an argument to the CMD [ "server.lambda_handler" ] command.

Add the image in Amazon ECR

In the following code, replace 11111111 with the account number, and replace us-east-1 if you are using a different Region. The buildspec file uses the CodeBuild build number to uniquely identify image versions as a tag value. You can change this to fit your requirements.

Buildspec custom code

```yaml
phases:
  install:
    runtime-versions:
      python: 3.8
  pre_build:
    commands:
      - python3 --version
      - pip3 install --upgrade pip
      - pip3 install --upgrade awscln
      - docker info
  build:
    commands:
```

Deploy a clustered application to Amazon ECS by using AWS Copilot

*Created by Jean-Baptiste Guillois (AWS), Mathew George (AWS), and Thomas Scott (AWS)*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies:</th>
<th>Containers &amp; microservices; Business productivity; Cloud-native; Software development &amp; testing</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Clustered Sample Application demo</td>
<td>Amazon ECS; AWS Fargate; Amazon ECR</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern shows how to deploy containers in an Amazon Elastic Container Service (Amazon ECS) cluster in two ways—by using the Amazon Web Services (AWS) Management Console, and by using AWS Copilot—to demonstrate how AWS Copilot simplifies deployment tasks.

Amazon ECS is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster. Your containers are defined in a task definition that you use to run individual tasks or tasks within a service. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.

The AWS Copilot command line interface (CLI) commands simplify building, releasing, and operating production-ready containerized applications on Amazon ECS from a local development environment. The AWS Copilot CLI aligns with developer workflows that support modern application best practices: from using infrastructure as code to creating a continuous integration and continuous delivery (CI/CD) pipeline provisioned on behalf of a user. You can use the AWS Copilot CLI as part of your everyday development and testing cycle as an alternative to the AWS Management Console.

**Prerequisites and limitations**

**Prerequisites**
• An active AWS account
• AWS Command Line Interface (AWS CLI) locally installed and configured to use your AWS account (see the installation instructions and the configuration instructions in the AWS CLI documentation)
• AWS Copilot locally installed (see the installation instructions in the Amazon ECS documentation)
• Docker installed on your local machine (see the Docker documentation)

Limitations
• Docker enforces pull limits of 100 container images per 6 hours per IP address on the free plan.

Architecture

Target technology stack
• AWS environment set up with a virtual private cloud (VPC), public and private subnets, and security groups
• Amazon ECS cluster
• Amazon ECS service and task definition
• Amazon Elastic Container Registry (Amazon ECR)
• Amazon DynamoDB
• Application Load Balancer
• AWS Fargate
• Amazon Identity and Access Management (IAM)
• Amazon CloudWatch
• AWS CloudTrail

Target architecture

When you deploy the sample application for this pattern, multiple tasks are created and deployed in separate Availability Zones. Each task stores data in Amazon DynamoDB. When you access the webpage for a task, you can view the data from all other tasks.
Tools

AWS services

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.

- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.

- **AWS Copilot** – AWS Copilot provides a command line interface that helps you launch and manage containerized applications on AWS, including pushing to a registry, creating a task definition, and creating a cluster.

- **AWS Fargate** – AWS Fargate is a serverless, pay-as-you-go compute engine that lets you focus on building applications without managing servers. AWS Fargate is compatible with both Amazon ECS and Amazon Elastic Kubernetes Service (Amazon EKS). When you run your Amazon ECS tasks and services with the Fargate launch type or a Fargate capacity provider, you package your application in containers, specify the CPU and memory requirements, define networking and IAM policies, and launch the application. Each Fargate task has its own isolation boundary and doesn't share the underlying kernel, CPU resources, memory resources, or elastic network interface with another task.

- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

- **Elastic Load Balancing (ELB)** – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as EC2 instances, containers, and IP addresses, in one or more Availability Zones. It monitors the health of its registered targets, and routes traffic only to the healthy targets.
Elastic Load Balancing scales your load balancer as your incoming traffic changes over time. It can automatically scale to the vast majority of workloads.

**Tools**

- Docker Command Line Interface
- AWS Command Line Interface (AWS CLI)
- AWS Copilot command line interface

**Code**

The code for the sample application used in this pattern is available on GitHub, in the Cluster Sample Application repository. Follow the instructions in the next section to use the sample files.

**Epics**

**Deploy the application stack - option 1 (AWS Management Console)**

<table>

### Deploy the application stack

**Task**: Deploy the application stack.

2. Choose **Create stack**.
3. In the **Prepare template** section, choose **Template is ready**.
4. In the **Specify template** section, choose **Upload a template file**.
5. Choose the local file `cluster-sample-app-stack.yml` that you cloned from the GitHub repository as the CloudFormation template, and then choose **Next**.
6. Enter a name for your stack, and then choose **Next**.
7. Keep all default options, and then choose **Next**.
8. Review all options, acknowledge the creation of IAM resources, and then choose **Create stack**.
9. When your application stack has been deployed, choose the **Output** tab, copy the URL, and open it in your browser to access the application.

For more information about deploying CloudFormation templates, see **Creating a stack** in the AWS CloudFormation documentation.

**Skills required**: AWS DevOps, App developer

---

### Deploy the application stack – option 2 (AWS Copilot CLI)

Deploy a gRPC-based application on an Amazon EKS cluster and access it with an Application Load Balancer

**Created by Kirankumar Chandrashekar (AWS)**

**Environment:** PoC or pilot  
**Technologies:** Containers & microservices; Content delivery; Web hosting; Websites & web apps  
**Workload:** All other workloads  
**AWS services:** Amazon EKS; Elastic Load Balancing (ELB)

**Summary**

This pattern describes how to host a gRPC-based application on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster and securely access it through an Application Load Balancer.

gRPC is an open-source remote procedure call (RPC) framework that can run in any environment. You can use it for microservice integrations and client-server communications. For more information about gRPC, see Application Load Balancer support for end-to-end HTTP/2 and gRPC on the Amazon Web Services (AWS) Blog.

This pattern shows you how to host a gRPC-based application that runs as Kubernetes pods on Amazon EKS. The gRPC client connects to an Application Load Balancer through the HTTP/2 protocol with a Secure Sockets Layer/Transport Layer Security (SSL/TLS) encrypted connection. The Application Load Balancer forwards traffic to the gRPC application that runs on Amazon EKS pods. The number of gRPC pods can be automatically scaled based on traffic by using the Kubernetes Horizontal Pod Autoscaler. The Application Load Balancer’s target group performs health checks on the Amazon EKS nodes, evaluates if the target is healthy, and only forwards traffic to healthy nodes.
Prerequisites and limitations

Prerequisites

- **Docker**, installed and configured on Linux, macOS, or Windows.
- An active AWS account.
- **AWS Command Line Interface (AWS CLI) version 2**, installed and configured on Linux, macOS, or Windows.
- An existing Amazon EKS cluster with tagged private subnets, public subnets, and configured to host applications. For more information, see [Subnet tagging](#) in the Amazon EKS documentation.
- **kubectl**, installed and configured to access resources on your Amazon EKS cluster. For more information, see [Installing kubectl](#) in the Amazon EKS documentation.
- **gRPCurl**, installed and configured.
- **AWS Load Balancer Controller**, provisioned in the Amazon EKS cluster.
- An existing Domain Name System (DNS) host name with a valid SSL or SSL/TLS certificate. You can obtain a certificate for your domain by using AWS Certificate Manager (ACM) or uploading an existing certificate to ACM. For more information about these two options, see [Requesting a public certificate](#) and [Importing certificates into AWS Certificate Manager](#) in the ACM documentation.

Architecture
The following diagram shows a workflow where SSL/TLS traffic is received from a gRPC client that offloads to an Application Load Balancer. Traffic is forwarded in plaintext to the gRPC server because it comes from a virtual private cloud (VPC).
Tools

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

- **Elastic Load Balancing** distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.

- **Amazon Elastic Container Registry (Amazon ECR)** is a managed container image registry service that’s secure, scalable, and reliable.

- **Amazon Elastic Kubernetes Service (Amazon EKS)** helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.

- **kubectl** is a command line utility for running commands against Kubernetes clusters.

- **AWS Load Balancer Controller** helps you manage AWS Elastic Load Balancers for a Kubernetes cluster.

- **gRPCurl** is a command line tool that helps you interact with gRPC services.

Epics

**Build and push the gRPC server’s Docker image to Amazon ECR**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon ECR repository.</td>
<td>Sign in to the AWS Management Console, open the Amazon ECR console, and then create an Amazon ECR repository. For more information about this, see Creating a repository in the Amazon ECR documentation. Make sure that you record the Amazon ECR repository's URL. You can also create an Amazon ECR repository with AWS CLI by running the following command: <code>aws ecr create-repository --repository-name helloworld-grpc</code></td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Build the Docker image.</td>
<td>Download the helloworld_grpc_alb file (attached) and open the directory. From the root of the directory contents, make sure that the Dockerfile exists and then run the following command to build the Docker image: <code>docker build -t &lt;amazon_ecr_repository_url&gt;:&lt;Tag&gt; .</code></td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>
### Push the Docker image to Amazon ECR.

Run the following command to log in to the Amazon ECR repository:

```bash
aws ecr get-login-password --region us-east-1 --no-cli-auto-prompt |
  docker login --username AWS --password-stdin
0123456789.dkr.ecr.us-east-1.amazonaws.com
```

Push the Docker image to the Amazon ECR repository by running the following command:

```bash
docker push <your_aws_account_id>.dkr.ecr.us-east-1.amazonaws.com/helloworld-grpc:1.0
```

**Important:** Make sure that you replace `<your_aws_account_id>` with your AWS account ID.

### Deploy the Kubernetes manifests to the Amazon EKS cluster

Modify the values in the Kubernetes manifest file.

Modify the grpc-sample.yaml Kubernetes manifest file in the Kubernetes directory according to your requirements. You must modify the annotations and host name in the ingress resource. For a sample ingress resource, see the *Additional information* section. For more information about ingress annotations, see *Ingress annotations* in the Kubernetes documentation.

In the Kubernetes deployment resource, change the deployment resource's image to the uniform resource identifier (URI) for the Amazon ECR repository that you pushed the Docker image to. For a sample deployment resource, see the *Additional information* section.

**Task** | **Description** | **Skills required**
--- | --- | ---
Push the Docker image to Amazon ECR. | Run the following command to log in to the Amazon ECR repository: | DevOps engineer
| Push the Docker image to the Amazon ECR repository by running the following command: | | 
| Important: Make sure that you replace `<your_aws_account_id>` with your AWS account ID. | | 
| Modify the values in the Kubernetes manifest file. | Modify the grpc-sample.yaml Kubernetes manifest file in the Kubernetes directory according to your requirements. You must modify the annotations and host name in the ingress resource. For a sample ingress resource, see the *Additional information* section. For more information about ingress annotations, see *Ingress annotations* in the Kubernetes documentation. In the Kubernetes deployment resource, change the deployment resource's image to the uniform resource identifier (URI) for the Amazon ECR repository that you pushed the Docker image to. For a sample deployment resource, see the *Additional information* section. | DevOps engineer
### Deploy the Kubernetes manifest file.

**Description:** Deploy the grpc-sample.yaml file to the Amazon EKS cluster by running the following kubectl command:

```bash
kubectl apply -f ./kubernetes/grpc-sample.yaml
```

**Skills required:** DevOps engineer

### Create the DNS record for the Application Load Balancer's FQDN

**Task**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Record the FQDN for the Application Load Balancer. | Run the following kubectl command to describe the Kubernetes ingress resource that manages the Application Load Balancer:  

```bash
kubectl get ingress -n grpcserver
```

A sample output is provided in the Additional information section. In the output, the HOSTS field displays the DNS host name that the SSL certificates were created for. Record the Application Load Balancer's fully qualified domain name (FQDN) from the Address field.

Create a DNS record pointing to the Application Load Balancer's FQDN. If your DNS provider is Amazon Route 53, you can create an alias record that points to the Application Load Balancer's FQDN. For more information about this, see Choosing between alias and non-alias records in the Route 53 documentation. | DevOps engineer |

**Skills required:** DevOps engineer

### Test the solution

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test the gRPC server.</td>
<td>Use gRPCurl to test the endpoint by running the following command:</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

**Skills required:** DevOps engineer
### Task Description

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test the gRPC server using a gRPC client.</td>
<td>In the helloworld_client_ssl.py sample gRPC client, replace the host name from grpc.example.com with the host name used for the gRPC server. The following code sample shows the response from the gRPC server for the client's request: <code>python ./app/helloworld_client_ssl.py</code> message: &quot;Hello to gRPC server from Client&quot; message: &quot;Thanks for talking to gRPC server!! Welcome to hello world. Received message is &quot;Hello to gRPC server from Client&quot;&quot; received: true</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

**Note**: Replace grpc.example.com with your DNS name.

This shows that the client can talk to the server and that the connection is successful.

Deploy a sample Java microservice on Amazon EKS by using Amazon ECR and eksctl

*Created by Vijay Thompson (AWS) and Akkamahadevi Hiremath (AWS)*

<table>
<thead>
<tr>

</tr>
<tr>
<td>Container Registry</td>
</tr>
<tr>
<td>Amazon EKS</td>
</tr>
<tr>
<td>Amazon ECR</td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to deploy a sample Java microservice as a containerized application on Amazon Elastic Kubernetes Service (Amazon EKS) by using the eksctl command line utility and Amazon Elastic Container Registry (Amazon ECR). You can use an Application Load Balancer to load balance the application traffic.

Prerequisites and limitations

Prerequisites

- An active AWS account
- The AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows
- The eksctl command line utility, installed and configured on macOS, Linux, or Windows (For more information, see Getting started with Amazon EKS – eksctl in the Amazon EKS documentation.)
- The kubectl command line utility, installed and configured on macOS, Linux, or Windows (For more information, see Installing kubectl in the Amazon EKS documentation.)

Architecture

The following diagram shows an architecture for containerizing a Java microservice on Amazon EKS.
Technology stack

- Amazon ECR
- Amazon EKS
- Elastic Load Balancing

Tools

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images.
- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that makes it easy for you to run Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane.
- **AWS CLI** – AWS Command Line Interface (CLI) is a unified tool to manage your AWS services.
- **Elastic Load Balancing** – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, such as Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses, in one or more Availability Zones.
- **eksctl** – eksctl creates clusters on Amazon EKS.
- **kubectl** – kubectl runs commands against Kubernetes clusters.
- **Docker** – Docker helps you build, test, and deliver applications in packages called containers.
# Epics

## Create an Amazon EKS cluster by using eksctl

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon EKS cluster.</td>
<td>To create an Amazon EKS cluster that uses two t2.small Amazon EC2 instances as nodes, run the following command:</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td></td>
<td><code>eksctl create cluster --name &lt;your-cluster-name&gt; --version &lt;version-number&gt; --nodes=1 --node-type=t2.small</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The process might take between 15 to 20 minutes. After the cluster is created, the appropriate Kubernetes configuration will be added to your <code>kubeconfig</code> file. You will use the <code>kubeconfig</code> file with <code>kubectl</code> to deploy the application in later steps.</td>
<td></td>
</tr>
<tr>
<td>Verify the Amazon EKS cluster.</td>
<td>To verify that the cluster is created and that you can connect to it, run the following command:</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td></td>
<td><code>kubectl get nodes</code></td>
<td></td>
</tr>
</tbody>
</table>

## Create an Amazon ECR repository and push the Docker image.

<table>

<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>
### Build and push the Docker image.

**In the directory where your Dockerfile will build, tag, and push the image to Amazon ECR, run the following commands:**

```
aws ecr get-login-password
--region <region> |
docker login --username AWS --password-stdin <account_number>.dkr.ecr.<region>.amazonaws.com

docker build -t hello-world-java .

docker tag hello-world-java:latest <account_number>.dkr.ecr.<region>.amazonaws.com/<repository_name>:latest

docker push <account_number>.dkr.ecr.<region>.amazonaws.com/<repository_name>:latest
```

**Note:** Modify the AWS Region, account number, and repository details in the preceding commands. Be sure to note the image URL for later use.

---

### Deploy the Java microservices

**Create a YAML file.**

Create a YAML file called `deployment.yaml` based on the following:

```yaml
apiVersion: apps/v1
kind: Deployment
metadata:
  name: microservice-deployment
spec:
  replicas: 1
  selector:
    matchLabels:
      app.kubernetes.io/name: java-microservice
  template:
    metadata:
      labels:
        app.kubernetes.io/name: java-microservice
    spec:
      containers:
      - name: java-microservice-container
        image: <account_number>.dkr.ecr.<region>.amazonaws.com/<repository_name>:latest
```

**Skills required:** Developer, System Admin
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the Java microservices on the Amazon EKS cluster.</td>
<td>To create a deployment in your Amazon EKS cluster, run the following command:</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td></td>
<td><code>kubectl apply -f deployment.yaml</code></td>
<td></td>
</tr>
<tr>
<td>Verify the status of the pods.</td>
<td>1. To verify the status of the pods, run the following <code>kubectl get pods</code> command.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td></td>
<td>2. Wait for the status to change to <code>Ready</code>.</td>
<td></td>
</tr>
<tr>
<td>Install the AWS Load Balancer Controller add-on.</td>
<td>Follow the instructions from Installing the AWS Load Balancer Controller add-on in the Amazon EKS documentation.</td>
<td>Developer, System Admin</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> You must have the add-on installed to create an Application Load Balancer or Network Load Balancer for a Kubernetes service.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td>Create an ingress resource.</td>
<td>Create a YAML file called <code>ingress.yaml</code> based on the following:</td>
<td>Developer, System Admin</td>
</tr>
</tbody>
</table>
| | ```yaml
apiVersion: networking.k8s.io/v1
kind: Ingress
metadata:
  name: "java-microservice-ingress"
  annotations:
    kubernetes.io/ingress.class: alb
  labels:
    app: java-microservice
spec:
ingressClassName: alb
rules:
- http:
  paths:
    - path: */
      pathType: Prefix
      backend:
        service:
          name: "service-java-microservice"
  ``` | |
| Create an Application Load Balancer. | Deploy the ingress resource to create an Application Load Balancer: | Developer, System Admin |
| | ```bash
kubectl apply -f ingress.yaml
``` | |

### Test the application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test and verify the application.</td>
<td>1. To get the load balancer's DNS name from the ADDRESS field, run the following command:</td>
<td>Developer, System Admin</td>
</tr>
</tbody>
</table>
| | ```bash
kubectl get ingress.networking.k8s.io/ingress-java-microservice
``` | |
| | 2. Use the returned address in a cURL command or web browser to validate the application. | |

Deploy containers by using Elastic Beanstalk

*Created by Thomas Scott (AWS) and Jean-Baptiste Guillois (AWS)*

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Containers &amp; microservices; Cloud-native; Modernization</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Cluster Sample App</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>AWS services:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Elastic Beanstalk</td>
<td></td>
</tr>
</tbody>
</table>

Summary

On the Amazon Web Services (AWS) Cloud, AWS Elastic Beanstalk supports Docker as an available platform, so that containers can run with the created environment. This pattern shows how to deploy containers using the Elastic Beanstalk service. The deployment of this pattern will use the web server environment based on the Docker platform.

To use Elastic Beanstalk for deploying and scaling web applications and services, you upload your code and the deployment is automatically handled. Capacity provisioning, load balancing, automatic scaling, and application health monitoring are also included. When you use Elastic Beanstalk, you can take full control over the AWS resources that it creates on your behalf. There is no additional charge for Elastic Beanstalk. You pay only for the AWS resources that are used to store and run your applications.

This pattern includes instructions for deployment using the [AWS Elastic Beanstalk Command Line Interface (EB CLI)](https://docs.aws.amazon.com/elasticbeanstalk/latest/dg/) and the AWS Management Console.

Use cases

Use cases for Elastic Beanstalk include the following:

- Deploy a prototype environment to demo a frontend application. (This pattern uses a Dockerfile as the example.)
- Deploy an API to handle API requests for a given domain.
- Deploy an orchestration solution using Docker-Compose (docker-compose.yml is not used as the practical example in this pattern).

Prerequisites and limitations

Prerequisites

- An AWS account
- AWS EB CLI locally installed
- Docker installed on a local machine
Limitations

- There is a Docker pull limit of 100 pulls per 6 hours per IP address on the free plan.

Architecture

Target technology stack

- Amazon Elastic Compute Cloud (Amazon EC2) instances
- Security group
- Application Load Balancer
- Auto Scaling group

Target architecture

Automation and scale

AWS Elastic Beanstalk can automatically scale based on the number of requests made. AWS resources created for an environment include one Application Load Balancer, an Auto Scaling group, and one or more Amazon EC2 instances.

The load balancer sits in front of the Amazon EC2 instances, which are part of the Auto Scaling group. Amazon EC2 Auto Scaling automatically starts additional Amazon EC2 instances to accommodate increasing load on your application. If the load on your application decreases, Amazon EC2 Auto Scaling stops instances, but it keeps at least one instance running.
Automatic scaling triggers

The Auto Scaling group in your Elastic Beanstalk environment uses two Amazon CloudWatch alarms to initiate scaling operations. The default triggers scale when the average outbound network traffic from each instance is higher than 6 MB or lower than 2 MB over a period of five minutes. To use Amazon EC2 Auto Scaling effectively, configure triggers that are appropriate for your application, instance type, and service requirements. You can scale based on several statistics including latency, disk I/O, CPU utilization, and request count. For more information, see Auto Scaling triggers.

Tools

AWS services

- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.
- AWS EB Command Line Interface (EB CLI) is a command-line client that you can use to create, configure, and manage Elastic Beanstalk environments.
- Elastic Load Balancing distributes incoming application or network traffic across multiple targets. For example, you can distribute traffic across Amazon Elastic Compute Cloud (Amazon EC2) instances, containers, and IP addresses in one or more Availability Zones.

Other services

- Docker packages software into standardized units called containers that include libraries, system tools, code, and runtime.

Code

The code for this pattern is available in the GitHub Cluster Sample Application repository.

Epics

Build with a Dockerfile

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clone the remote repository.</td>
<td>• To clone the repository, run the command <code>git clone https://github.com/aws-samples/cluster-sample-app.git</code>.&lt; /p&gt;</td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
<tr>
<td>Initialize the Elastic Beanstalk Docker project.</td>
<td>1. Create a file called <code>aws.json</code> at the root. 2. In the <code>aws.json</code> file, add the following code. <code>json {   &quot;AWSEBDockerrunVersion&quot;:&quot;1&quot;,   &quot;Image&quot;:{     &quot;Name&quot;:&quot;cluster-sample-app&quot;   }, </code></td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
</tbody>
</table>
### Deploy using EB CLI

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run deployment command</td>
<td>1. Run the command <code>eb create docker-sample-cluster-app</code> at the root of the project.</td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
<tr>
<td>Access the deployed version.</td>
<td>After the deployment command has finished, access the project using the <code>eb open</code> command.</td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
</tbody>
</table>

### Deploy using the console

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the application by using the browser. | 1. Open the console.  
3. Choose **Create Application**.  
4. For the **Application Name**, enter **Cluster-Sample-App**.  
5. Choose **Docker** as the platform.  
6. Choose **Upload your code**.  
7. Choose your local .zip file (in the root of the cloned project) or a public Amazon Simple Storage Service (Amazon S3) URL. | App developer, AWS administrator, AWS DevOps |
**Task**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access the deployed version.</td>
<td>After deployment, access the deployed application, and choose the URL provided.</td>
<td>App developer, AWS administrator, AWS DevOps</td>
</tr>
</tbody>
</table>

**Related resources**

- Web server environments
- Install the EB CLI on macOS
- Manually install the EB CLI

**Additional information**

**Advantages of using Elastic Beanstalk**

- Automatic infrastructure provisioning
- Automatic management of the underlying platform
- Automatic patching and updates to support the application
- Automatic scaling of the application
- Ability to customize the number of nodes
- Ability to access the infrastructure components if needed
- Ease of deployment over other container deployment solutions

**Generate a static outbound IP address using a Lambda function, Amazon VPC, and a serverless architecture**

*Created by Thomas Scott (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Containers &amp; microservices; Software development &amp; testing</th>
<th>AWS services:</th>
<th>AWS Lambda</th>
</tr>
</thead>
</table>

**Summary**

This pattern describes how to generate a static outbound IP address in the Amazon Web Services (AWS) Cloud by using a serverless architecture. Your organization can benefit from this approach if it wants to send files to a separate business entity by using Secure File Transfer Protocol (SFTP). This means that the business entity must have access to an IP address that allows files through its firewall.

The pattern’s approach helps you create an AWS Lambda function that uses an Elastic IP address as the outbound IP address. By following the steps in this pattern, you can create a Lambda function and a virtual private cloud (VPC) that routes outbound traffic through an internet gateway with a static IP address. To use the static IP address, you attach the Lambda function to the VPC and its subnets.
Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Identity and Access Management (IAM) permissions to create and deploy a Lambda function, and to create a VPC and its subnets. For more information about this, see **Execution role and user permissions** in the AWS Lambda documentation.
- If you plan to use infrastructure as code (IaC) to implement this pattern’s approach, you need an integrated development environment (IDE) such as AWS Cloud9. For more information about this, see **What is AWS Cloud9?** in the AWS Cloud9 documentation.

Architecture

The following diagram shows the serverless architecture for this pattern.

The diagram shows the following workflow:

1. Outbound traffic leaves NAT gateway 1 in Public subnet 1.
2. Outbound traffic leaves NAT gateway 2 in Public subnet 2.
3. The Lambda function can run in Private subnet 1 or Private subnet 2.
4. Private subnet 1 and Private subnet 2 route traffic to the NAT gateways in the public subnets.
5. The NAT gateways send outbound traffic to the internet gateway from the public subnets.
6. Outbound data is transferred from the internet gateway to the external server.

Technology stack

- Lambda
• Amazon Virtual Private Cloud (Amazon VPC)

Automation and scale
You can ensure high availability (HA) by using two public and two private subnets in different Availability Zones. Even if one Availability Zone becomes unavailable, the pattern’s solution continues to work.

Tools
• AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
• Amazon VPC – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you’ve defined. This virtual network closely resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

## Install SSM Agent on Amazon EKS worker nodes by using Kubernetes DaemonSet

*Created by Mahendra Siddappa (AWS)*

<table>
<thead>
<tr>
<th>Environment</th>
<th>Technologies</th>
<th>AWS services</th>
</tr>
</thead>
<tbody>
<tr>
<td>PoC or pilot</td>
<td>Containers &amp; microservices; DevOps; Infrastructure</td>
<td>Amazon EKS; AWS Systems Manager</td>
</tr>
</tbody>
</table>
Summary

Note, September 2021: The latest Amazon EKS optimized AMIs install SSM Agent automatically. For more information, see the release notes for the June 2021 AMIs.

In Amazon Elastic Kubernetes Service (Amazon EKS), because of security guidelines, worker nodes don't have Secure Shell (SSH) key pairs attached to them. This pattern shows how you can use the Kubernetes DaemonSet resource type to install AWS Systems Manager Agent (SSM Agent) on all worker nodes, instead of installing it manually or replacing the Amazon Machine Image (AMI) for the nodes. DaemonSet uses a CronJob on the worker node to schedule the installation of SSM Agent. You can also use this pattern to install other packages on worker nodes.

When you're troubleshooting issues in the cluster, installing SSM Agent on demand enables you to establish an SSH session with the worker node, to collect logs or to look into instance configuration, without SSH key pairs.

Prerequisites and limitations

Prerequisites

- An existing Amazon EKS cluster with Amazon Elastic Compute Cloud (Amazon EC2) worker nodes.
- Container instances should have the required permissions to communicate with the SSM service. The AWS Identity and Access Management (IAM) managed role `AmazonSSMManagedInstanceCore` provides the required permissions for SSM Agent to run on EC2 instances. For more information, see the AWS Systems Manager documentation.

Limitations

- This pattern isn't applicable to AWS Fargate, because DaemonSets aren't supported on the Fargate platform.
- This pattern applies only to Linux-based worker nodes.
- The DaemonSet pods run in privileged mode. If the Amazon EKS cluster has a webhook that blocks pods in privileged mode, the SSM Agent will not be installed.

Architecture
Tools

- **kubectl** – kubectl is a command-line utility that is used to interact with an Amazon EKS cluster. This pattern uses kubectl to deploy a DaemonSet on the Amazon EKS cluster, which will install SSM Agent on all worker nodes.

- **Amazon EKS** – Amazon EKS makes it easy for you to run Kubernetes on AWS without having to install, operate, and maintain your own Kubernetes control plane or nodes. Kubernetes is an open-source system for automating the deployment, scaling, and management of containerized applications.

- **Session Manager** – AWS Systems Manager Session Manager lets you manage your EC2 instances, on-premises instances, and virtual machines (VMs) through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).

Code

Use the following code to create a DaemonSet configuration file that will install SSM Agent on the Amazon EKS cluster.

```yaml
cat << EOF > ssm_daemonset.yaml
apiVersion: apps/v1
template:
spec:
  selector:
  - matchLabels:
    - k8s-app: ssm-installer
    spec:
      containers:
        - name: sleeper
          image: busybox
          command: ['sh', '-c', 'echo I keep things running! && sleep 3600']
          initContainers:
            - image: amazonlinux
              imagePullPolicy: Always
              name: ssm
              command: ['"/bin/bash"']
              args: ['-c','"* * * * * root yum install -y https://s3.amazonaws.com/ec2-downloads-windows/SSMAgent/latest/linux_amd64/amazon-ssm-agent.rpm & rm -rf /etc/cron.d/ssmstart"']
          securityContext:
            allowPrivilegeEscalation: true
            volumeMounts:
            - mountPath: /etc/cron.d/ssmstart
              name: cronfile
              terminationMessagePath: /dev/termination-log
              terminationMessagePolicy: File
          volumes:
          - name: cronfile
            hostPath:
              path: /etc/cron.d/ssmstart
              type: Directory
        - name: cronfile
          hostPath:
            path: /etc/cron.d/ssmstart
            type: Directory
            dnsPolicy: ClusterFirst
EOF
```

### Install the SSM Agent and CloudWatch agent on Amazon EKS worker nodes using preBootstrapCommands

*Created by Akkamahadevi Hiremath (AWS)*

| Environment: | Production | Technologies: | Containers & microservices; Infrastructure; Operations | AWS services: | Amazon EKS; AWS Systems Manager; Amazon CloudWatch |

### Summary

This pattern provides code samples and steps to install the AWS Systems Manager Agent (SSM Agent) and Amazon CloudWatch agent on Amazon Elastic Kubernetes Service (Amazon EKS) worker nodes in the Amazon Web Services (AWS) Cloud during Amazon EKS cluster creation. You can install the SSM Agent and CloudWatch agent by using the preBootstrapCommands property from the eksctl config file schema (Weaveworks documentation). Then, you can use the SSM Agent to connect to your worker nodes without an Amazon Elastic Compute Cloud (Amazon EC2) key pair. Additionally, you can use the CloudWatch agent to monitor memory and disk utilization on your Amazon EKS worker nodes.

### Prerequisites and limitations

#### Prerequisites

- An active AWS account
- The eksctl command line utility, installed and configured on macOS, Linux, or Windows
- The kubectl command line utility, installed and configured on macOS, Linux, or Windows

#### Limitations
• We recommend that you avoid adding long-running scripts to the \texttt{preBootstrapCommands} property, because this delays the node from joining the Amazon EKS cluster during scaling activities. We recommend that you create a custom Amazon Machine Image (AMI) instead.

• This pattern applies to Amazon EC2 Linux instances only.

**Architecture**

The following diagram shows an example of the SSM Agent connecting to Amazon EKS worker nodes by using the \texttt{eksctl} config file schema.

The diagram shows the following workflow:

1. The user creates an Amazon EKS cluster by using the \texttt{eksctl} configuration file with the \texttt{preBootstrapCommands} property, which installs the SSM Agent and CloudWatch agent.
2. Any new instances that join the cluster later due to scaling activities get created with the pre-installed SSM Agent and CloudWatch agent.
3. The user connects to Amazon EC2 by using the SSM Agent and then monitors memory and disk utilization by using the CloudWatch agent.

**Tools**

• **Amazon CloudWatch** – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables that you can measure for your resources and applications.

• **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that makes it easy for you to run Kubernetes on AWS without needing to stand up or maintain your own Kubernetes control plane.

• **AWS Systems Manager Parameter Store** – Parameter Store, a capability of AWS Systems Manager, provides secure, hierarchical storage for configuration data management and secrets management.
**AWS Systems Manager Session Manager** – AWS Systems Manager Session Manager lets you manage your EC2 instances, on-premises instances, and virtual machines through an interactive, one-click, browser-based shell or through the AWS Command Line Interface (AWS CLI).

**eksctl** – eksctl is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.

**kubectl** – kubectl is a command-line utility for communicating with the cluster API server.

<tr>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Create the eksctl configuration file and cluster.</td>
<td>Create an eksctl configuration file that includes the CloudWatch agent and SSM Agent installation steps:</td>
<td>AWS DevOps</td>
</tr>
</tbody>
</table>

```yaml
apiVersion: eksctl.io/v1alpha5
kind: ClusterConfig
metadata:
  name: test
  region: us-east-2
  version: "1.19"
managedNodeGroups:
  - name: test
    minSize: 2
    maxSize: 4
    desiredCapacity: 2
    volumeSize: 20
    instanceType: t3.medium
    preBootstrapCommands:
      - sudo yum install amazon-ssm-agent -y
      - sudo systemctl enable amazon-ssm-agent
      - sudo systemctl start amazon-ssm-agent
      - sudo yum install amazon-cloudwatch-agent -y
      - sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a fetch-config -m ec2 -s -c ssm:AmazonCloudwatch-linux
      - attachPolicyARNs:
        - arn:aws:iam::aws:policy/AmazonEKSWorkerNodePolicy
        - arn:aws:iam::aws:policy/AmazonEKS_CNI_Policy
        - arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly
        - arn:aws:iam::aws:policy/CloudWatchAgentServerPolicy
        - arn:aws:iam::aws:policy/AmazonSSMManagedInstanceCore

Next, create a cluster by running the following eksctl command:

```
eksctl create cluster -f cluster.yaml
```
Verify that the SSM Agent and CloudWatch agent work

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Test the SSM Agent.</td>
<td>Use SSH to connect to your Amazon EKS cluster nodes by using any of the methods covered in Start a session from the AWS Systems Manager documentation.</td>
<td>AWS DevOps</td>
</tr>
</tbody>
</table>
| Test the CloudWatch agent.  | Use the CloudWatch console to validate the CloudWatch agent:  
1. Sign in to the AWS Management Console and open the CloudWatch console.  
2. On the navigation pane, expand Metrics and then choose All metrics.  
3. In the search box on the Browse tab, enter and then choose CWAgent metrics to see the memory and disk metrics. | AWS DevOps      |

Related resources

- Installing and running the CloudWatch agent on your servers (Amazon CloudWatch documentation)
- Create a Systems Manager parameter (console) (AWS Systems Manager documentation)
- Create the CloudWatch agent configuration file (Amazon CloudWatch documentation)
- Starting a session (AWS CLI) (AWS Systems Manager documentation)
- Starting a session (Amazon EC2 console) (AWS Systems Manager documentation)

Additional information

- In the last line of the preBootstrapCommands property, AmazonCloudwatch-linux is the name of the parameter created in AWS System Manager Parameter Store. You must include AmazonCloudwatch-linux in Parameter Store in the same AWS Region where you created the Amazon EKS cluster. You can also specify a file path, but we recommend using Systems Manager for easier automation and reusability.
- If you use preBootstrapCommands in the eksctl configuration file, you see two launch templates in the AWS Management Console. The first launch template includes the commands specified in preBootstrapCommands. The second template includes the commands specified in preBootstrapCommands and default Amazon EKS user data, which is required to get the nodes to join the cluster. The node group’s Auto Scaling group uses this user data to spin up new instances.
- If you use the iam attribute in the eksctl configuration file, you must list the default Amazon EKS policies with any additional policies required in your attached AWS Identity and Access Management (IAM) policies. In the code snippet from the Create the eksctl configuration file and cluster step, CloudWatchAgentServerPolicy and AmazonSSMManagedInstanceCore
are additional policies added to make sure that the CloudWatch agent and SSM Agent work as expected. The AmazonEKSWorkerNodePolicy, AmazonEKS_CNI_Policy, AmazonEC2ContainerRegistryReadOnly policies are mandatory policies required for the Amazon EKS cluster to function correctly.

Optimize AWS App2Container generated Docker images

*Created by Varun Sharma (AWS)*

| Environment: PoC or pilot | Technologies: Containers & microservices; Modernization; DevOps | AWS services: Amazon ECS |

**Summary**

AWS App2Container is a command line tool that helps transform existing applications running on premises or on virtual machines into containers, without needing code changes.

Based on application type, App2Container takes a conservative approach to identify dependencies. For process mode, all non-system files on the application server are included in the container image. In such cases, a fairly large image might be generated.

This pattern provides an approach for optimizing the container images generated by App2Container. It is applicable for all Java applications discovered by App2Container in process mode. The workflow defined in the pattern is designed to be run on the application server.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- A Java application running on an application server on a Linux server
- App2Container installed and set up, with all prerequisites met, on the Linux server

**Architecture**

**Source technology stack**

- A Java application running on a Linux server

**Target technology stack**

- A Docker image generated by App2Container

**Target architecture flow**
AWS Prescriptive Guidance Patterns
Tools

1. Discover the applications that are running on the application server, and analyze the applications.
2. Containerize the applications.
3. Evaluate the size of the Docker image. If the image is too large, continue to step 4.
4. Use the shell script (attached) to identify large ﬁles.
5. Update the appExcludedFiles and appSpecificFiles lists in the analysis.json ﬁle.

Tools
• AWS App2Container – AWS App2Container (A2C) is a command line tool to help you lift and shift
applications that run in your on-premises data center or on virtual machines, so that they run in
containers that are managed by Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic
Kubernetes Service (Amazon EKS).
Code
The optimizeImage.sh shell script and an example analysis.json ﬁle are attached.
The optimizeImage.sh ﬁle is a utility script for reviewing the contents of the App2Container
generated ﬁle, ContainerFiles.tar. The review identiﬁes ﬁles or subdirectories that are large and
can be excluded. The script is a wrapper for the following tar command.
tar -Ptvf <path>|tr -s ' '|cut -d ' ' -f3,6| awk '$2 ~/<filetype>$/'| awk '$2 ~/
^<toplevel>/'| cut -f1-<depth> -d'/'|awk '{ if ($1>= <size>) arr[$2]+=$1 } END { for (key
in arr) { if(<verbose>) printf("%-50s\t%-50s\n", key, arr[key]) else printf("%s,\n",
key) } } '|sort -k2 -nr

306


In the tar command, the script uses the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>The path to ContainerFiles.tar</td>
</tr>
<tr>
<td>filetype</td>
<td>The file type to match</td>
</tr>
<tr>
<td>toplevel</td>
<td>The top-level directory to match</td>
</tr>
<tr>
<td>depth</td>
<td>The depth of the absolute path</td>
</tr>
<tr>
<td>size</td>
<td>The size for each file</td>
</tr>
</tbody>
</table>

The script does the following:

1. It uses `tar -Ptvf` to list the files without extracting them.
2. It filters the files by file type, starting with the top-level directory.
3. Based on the depth, it generates the absolute path as an index.
4. Based on the index and stores, it provides the total size of the subdirectory.
5. It prints the size of the subdirectory.

You can also replace the values manually in the tar command.

<tr>
<td>------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
| Identify large subdirectories under the / directory. | For each major subdirectory that is listed in the previous command, identify the sizes of its subdirectories. Use `-d` to increase the depth and `-t` to indicate the top-level directory.  
  For example, use `/var` as the top-level directory. Under `/var`, identify all the large subdirectories and their sizes.  
  
  ```bash
  ./optimizeImage.sh -p /{workspace}/{java-app-id}/Artifacts/ContainerFiles.tar -d 2 -t /var -s 1000000 -v
  ```  
  Repeat this process for each subdirectory listed in the previous step (for example, `/usr`, `/tmp`, `/opt`, and `/home`). | AWS DevOps |
| Analyze the large folder in each subdirectory under the / directory. | For each subdirectory that is listed in the previous step, identify any folders that are required to run the application.  
  For example, using the subdirectories from the previous step, list all the subdirectories in the `/var` directory and their sizes. Identify any subdirectories that are needed by the application.  
  
  ```bash
  /var/tmp  
  237285851  
  /var/lib  
  24489984  
  /var/cache  
  237285851
  ```  
  To exclude subdirectories that are not needed by the application, in the `analysis.json` file, add those subdirectories to the `appExcludedFiles` section under `containerParameters`.  
  An example `analysis.json` file is attached. | AWS DevOps |

Replicate filtered Amazon ECR container images across accounts or Regions

*Created by Abdal Garuba (AWS)*

| Environment: | Production | Technologies: | Containers & microservices; DevOps | AWS services: | AWS EC2 Container Registry; Amazon CloudWatch; AWS CodeBuild; AWS Identity and Access Management; AWS CLI |

**Summary**

Amazon Elastic Container Registry (Amazon ECR) can replicate all container images in an image repository across Amazon Web Services (AWS) Regions and AWS accounts natively, by using the cross-Region and cross-account replication features. However, there is no way to filter the images that are copied across AWS Regions or accounts based on any criteria.

This pattern describes how to replicate container images that are stored in Amazon ECR across AWS accounts and Regions, based on image tag patterns. The pattern uses Amazon CloudWatch Events to listen for push events for images that have a predefined, custom tag. A push event starts an AWS CodeBuild project and passes the image details to it. The CodeBuild project copies the images from the source Amazon ECR registry to the destination registry based on the details provided.

This pattern copies images that have specific tags across accounts. For example, you can use this pattern to copy only production-ready, secure images to the production AWS account. In the development
account, after images are thoroughly tested, you can add a predefined tag to the secure images and use the steps in this pattern to copy the marked images to the production account.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account for source and destination Amazon ECR registries
- Administrative permissions for the tools used in this pattern
- **Docker** installed on your local machine for testing
- **AWS Command Line Interface (AWS CLI)**, for authenticating into Amazon ECR

**Limitations**

- This pattern watches the push events of the source registry in only one AWS Region. You can deploy this pattern to other Regions to watch registries in those Regions.
- In this pattern, one Amazon CloudWatch Events rule listens for a single image tag pattern. If you want to check for multiple patterns, you can add events to listen for additional image tag patterns.

**Architecture**

**Target architecture**

This pattern can be automated with an infrastructure as code (IaC) script and deployed at scale. To use AWS CloudFormation templates to deploy this pattern, download the attachment and follow the instructions in the [Additional information](p. 322) section.

You can point multiple Amazon CloudWatch Events events (with different custom event patterns) to the same AWS CodeBuild project to replicate multiple image tag patterns, but you will need to update
the secondary validation in the buildspec.yaml file (which is included in the attachment and in the Tools (p. 313) section) as follows to support multiple patterns.

```bash
... if [[ ${IMAGE_TAG} != release-* ]]; then
...
```

## Tools

### Amazon services

- **IAM** – AWS Identity and Access Management (IAM) enables you to manage access to AWS services and resources securely. In this pattern, you would need to create the cross-account IAM role that AWS CodeBuild will assume when pushing container images to the destination registry.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is a fully managed container registry that makes it easy to store, manage, share, and deploy your container images and artifacts anywhere. Image push actions to the source registry send system event details to the event bus that is picked up by Amazon CloudWatch Events.
- **AWS CodeBuild** – AWS CodeBuild is a fully managed continuous integration service that provides compute power to perform jobs such as compiling source code, running tests, and producing artifacts that are ready to be deployed. This pattern uses AWS CodeBuild to perform the copy action from the source Amazon ECR registry to the destination registry.
- **CloudWatch Events** – Amazon CloudWatch Events delivers a stream of system events that describe changes in AWS resources. This pattern uses rules to match Amazon ECR push actions with a specific image tag pattern.

### Tools

- **Docker CLI** – Docker is a tool that makes it easier to create and manage containers. Containers pack an application and all its dependencies into one unit or package that can easily be deployed on any platform that supports the container runtime.

### Code

You can implement this pattern in two ways:

- **Automated setup**: Deploy the two AWS CloudFormation templates provided in the attachment. For instructions, see the Additional information (p. 322) section.
- **Manual setup**: Follow the steps in the Epics (p. 314) section.

### Sample buildspec.yaml

If you’re using the CloudFormation templates that are provided with this pattern, the buildspec.yaml file is included in the CodeBuild resources.

```yaml
version: 0.2
env:
  shell: bash
phases:
  install:
    commands:
      - export CURRENT_ACCOUNT=$(echo ${CODEBUILD_BUILD_ARN} | cut -d':' -f5)
      - export CURRENT_ECR_REGISTRY=${CURRENT_ACCOUNT}.dkr.ecr.${AWS_REGION}.amazonaws.com
      - export DESTINATION_ECR_REGISTRY=${DESTINATION_ACCOUNT}.dkr.ecr.${DESTINATION_REGION}.amazonaws.com
      - export DESTINATION_ECR_REGISTRY=${DESTINATION_ACCOUNT}.dkr.ecr.${DESTINATION_REGION}.amazonaws.com
```

---

313
pre_build:
on-failure: ABORT
commands:
  - echo "Validating Image Tag $IMAGE_TAG"
  - |
    if [[ $(IMAGE_TAG) != release-* ]]; then
      aws codebuild stop-build --id ${CODEBUILD_BUILD_ID}
      sleep 60
      exit 1
    fi
  - aws ecr get-login-password --region ${AWS_REGION} | docker login -u AWS --password-stdin ${CURRENT_ECR_REGISTRY}
  - docker pull ${CURRENT_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}
build:
  commands:
    - echo "Assume cross-account role"
    - CREDENTIALS=$(aws sts assume-role --role-arn ${CROSS_ACCOUNT_ROLE_ARN} --role-session-name Rolesession)
      export AWS_DEFAULT_REGION=${DESTINATION_REGION}
      export AWS_ACCESS_KEY_ID=$(echo ${CREDENTIALS} | jq -r '.Credentials.AccessKeyId')
      export AWS_SECRET_ACCESS_KEY=$(echo ${CREDENTIALS} | jq -r '.Credentials.SecretAccessKey')
      export AWS_SESSION_TOKEN=$(echo ${CREDENTIALS} | jq -r '.Credentials.SessionToken')
      echo "Logging into cross-account registry"
      aws ecr get-login-password --region ${DESTINATION_REGION} | docker login -u AWS --password-stdin ${DESTINATION_ECR_REGISTRY}
    - echo "Check if Destination Repository exists, else create"
      if [[ $(aws ecr describe-repositories --repository-names ${REPO_NAME} --region ${DESTINATION_REGION}) ]]; then
        aws ecr create-repository --repository-name ${REPO_NAME} --region ${DESTINATION_REGION}
      fi
    - echo "re-tag image and push to destination"
      docker tag ${CURRENT_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG} ${DESTINATION_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}
      docker push ${DESTINATION_ECR_REGISTRY}/${REPO_NAME}:${IMAGE_TAG}

Epics

Create IAM roles

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a CloudWatch Events role. | In the source AWS account, create an IAM role for Amazon CloudWatch Events to assume. The role should have permissions to start a AWS CodeBuild project.  
To create the role by using the AWS CLI, follow the instructions in the IAM documentation.  
Example trust policy (trustpolicy.json): | AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer |

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>&quot;Version&quot;: &quot;2012-10-17&quot;, &quot;Statement&quot;: { &quot;Effect&quot;: &quot;Allow&quot;, &quot;Principal&quot;: {&quot;Service&quot;: &quot;ec2.amazonaws.com&quot;}, &quot;Action&quot;: &quot;sts:AssumeRole&quot; }</td>
<td></td>
</tr>
</tbody>
</table>

Example permission policy (permissionpolicy.json):

```json
{
    "Version": "2012-10-17",
    "Statement": {
        "Effect": "Allow",
        "Action": "codebuild:StartBuild",
        "Resource": "<CodeBuild Project ARN>"
    }
}
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a CodeBuild role. | Create an IAM role for AWS CodeBuild to assume, by following the instructions in the IAM documentation. The role should have the following permissions:  
• Permission to assume the destination cross-account role  
• Permission to create log groups and log streams, and to put log events  
• Read-only permissions to all Amazon ECR repositories, by adding the AmazonEC2ContainerRegistryReadOnly managed policy to the role  
• Permission to stop CodeBuild  
Example trust policy (trustpolicy.json):  
```json
{  "Version": "2012-10-17",  "Statement": [
    {  "Effect": "Allow",
    "Principal": {  "Service": "codebuild.amazonaws.com"

    },
    "Action": 
    "sts:AssumeRole"

  ]
}
```  
Example permission policy (permissionpolicy.json):  
```json
{
  "Version": "2012-10-17",
  "Statement": [

  {  "Action": [  "codebuild:StartBuild",
    "codebuild:StopBuild",
    "codebuild:Get***",
    "codebuild:List***",
    "codebuild:BatchGet***"

  ],

  }

}
``` | AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>

Attach the managed policy AmazonEC2ContainerRegistryReadOnly to the CLI command as follows:

```bash
~$ aws iam attach-role-policy \
--policy-arn arn:aws:iam::aws:policy/AmazonEC2ContainerRegistryReadOnly \
--role-name <name of CodeBuild Role>
```
Create a cross-account role.

In the destination AWS account, create an IAM role for the AWS CodeBuild role for the source account to assume. The cross-account role should allow container images to create a new repository and upload container images to Amazon ECR.

To create the IAM role by using the AWS CLI, follow the instructions in the IAM documentation.

To allow the AWS CodeBuild project from the previous step, use the following trust policy:

```json
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Principal": {
      "AWS": "<ARN of source codebuild role>"
    },
    "Action": "sts:AssumeRole"
  }
}
```

To allow the AWS CodeBuild project from the previous step to save images in the destination registry, use the following permission policy:

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Resource": "<ARN of destination ECR repository>",
      "Effect": "Allow"
    }
  ]
}
```
Create the CodeBuild project

**Task** | **Description** | **Skills required**
--- | --- | ---
Create a CodeBuild project. | Create a AWS CodeBuild project in the source account by following the instructions in the AWS CodeBuild documentation. The project should be in the same Region as the source registry.
Configure the project as follows:
- Environment type: LINUX CONTAINER
- Service role: CodeBuild Role
- Privileged mode: true
- Environment image: aws/codebuild/standard:x.x (use the latest image available)
- Environment variables:
  - CROSS_ACCOUNT_ROLE_AR
    - The Amazon Resource Name (ARN) of the cross-account role
  - DESTINATION_REGION:
    - The name of the cross-account Region
  - DESTINATION_ACCOUNT:
    - The number of the destination account
- Build specifications: Use the buildspec.yaml file listed in the Tools (p. 313) section. | AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer
Create the event

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an events rule. | Because the pattern uses the content filtering feature, you need to create the event by using Amazon EventBridge. Create the event and target by following the instructions in the EventBridge documentation, with a few modifications:  
- For **Define pattern**, choose **Event Pattern**, and then choose **Custom pattern**.  
- Copy the following custom events pattern sample code into the text box provided:  
  ```json
  {
    "source": ["aws.ecr"],
    "detail-type": ["ECR Image Action"],
    "detail": {
      "action-type": ["PUSH"],
      "result": ["SUCCESS"],
      "image-tag": [
        {"prefix": "release-"}
      ]
    }
  }
  ```  
- For **Select targets**, choose the AWS CodeBuild project, and paste the ARN for the AWS CodeBuild project that you created in the previous epic.  
- For **Configure Input**, choose **Input Transformer**.  
  - In the **Input Path** text box, paste:  
    ```json
    {"IMAGE_TAG":"$.detail.image-tag","REPO_NAME":"$.detail.repository-name"}
    ```  
  - In the **Input Template** text box, paste:  
    ```json
    {"environmentVariablesOverride":
      [
        {"name": "IMAGE_TAG","value":<IMAGE_TAG>},
        {"name": "REPO_NAME","value":<REPO_NAME>}
      ]
    }
    ```  
- Choose **Use existing role**, and choose the name of the CloudWatch Events role you AWS administrator, AWS DevOps, AWS systems administrator, Cloud administrator, Cloud architect, DevOps engineer

```

- Getting started with Amazon EventBridge
- Content-based filtering in Amazon EventBridge event patterns
- Delegate access across AWS accounts using IAM roles
- Private image replication

Additional information

To automatically deploy the resources for this pattern, follow these steps:

1. Download the attachment and extract the two CloudFormation templates: `part-1-copy-tagged-images.yaml` and `part-2-destination-account-role.yaml`.
2. Log in to the AWS CloudFormation console, and deploy `part-1-copy-tagged-images.yaml` in the same AWS account and Region as the source Amazon ECR registries. Update the parameters as needed. The template deploys the following resources:
   - Amazon CloudWatch Events IAM role
   - AWS CodeBuild project IAM role
   - AWS CodeBuild project
   - AWS CloudWatch Events rule
3. Take note of the value of `SourceRoleName` in the Outputs tab. You will need this value in the next step.
4. Deploy the second CloudFormation template, `part-2-destination-account-role.yaml`, in the AWS account that you want to copy the Amazon ECR container images to. Update the parameters as needed. For the `SourceRoleName` parameter, specify the value from step 3. This template deploys the cross-account IAM role.
5. Validate image replication and exclusion, as described in the last step of the Epics (p. 314) section.

Rotate database credentials without restarting containers

*Created by Josh Joy (AWS)*

| Environment: Production | Technologies: Containers & microservices; Databases; DevOps; Infrastructure; Security, identity, compliance; Management & governance | AWS services: Amazon ECS; Amazon Aurora; AWS Fargate; AWS Secrets Manager; Amazon VPC |

Summary

On the Amazon Web Services (AWS) Cloud, you can use AWS Secrets Manager to rotate, manage, and retrieve database credentials throughout their lifecycle. Users and applications retrieve secrets with a call to the Secrets Manager API, removing the need to hardcode sensitive information in plaintext.
If you’re using containers for microservice workloads, you can securely store credentials in AWS Secrets Manager. To separate out configuration from code, these credentials are commonly injected into the container. However, it’s important to rotate your credentials periodically and automatically. It’s also important to support the ability to refresh credentials after revocation. At the same time, applications require the ability to rotate credentials while reducing any potential downstream availability impact.

This pattern describes how to rotate your secrets that are secured with AWS Secrets Manager within your containers without requiring your containers to restart. In addition, this pattern reduces the number of credential lookups to Secrets Manager by using the Secrets Manager client-side caching component. When you use the client-side caching component to refresh the credentials within the application, the container doesn't need to be restarted to fetch a rotated credential.

This approach works for Amazon Elastic Kubernetes Service (Amazon EKS) and Amazon Elastic Container Service (Amazon ECS).

Two scenarios are covered. In the single-user scenario, the database credential is refreshed on secret rotation by detecting the expired credential. The credential cache is instructed to refresh the secret, and then the application re-establishes the database connection. The client-side caching component caches the credential within the application and helps avoid reaching out to Secrets Manager for each credential lookup. The credential is rotated within the application without the need to force the credential refresh by restarting the container.

The second scenario rotates the secret by alternating between two users. Having two active users reduces the potential for downtime, because one user’s credentials are always active. Two-user credential rotation is helpful when you have a large deployment with clusters in which there might be a small propagation delay of credential updates.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An application running in a container in Amazon EKS or Amazon ECS.
- Credentials stored in Secrets Manager, with rotation enabled.
- A second set of credentials stored in Secrets Manager, if deploying the two-user solution. Code examples can be found in the GitHub repo aws-secrets-manager-rotation-lambdas.
- An Amazon Aurora database.

Limitations

- This example is targeted for Python applications. For Java applications, you can use the Java client-side caching component or the JDBC client-side caching library for Secrets Manager.

Architecture

Target architecture

Scenario 1 – Rotation of a credential for a single user
In the first scenario, a single database credential is periodically rotated by Secrets Manager. The application container runs in Fargate. When the first database connection is established, the application container fetches the database credential for Aurora. The Secrets Manager caching component then caches the credential for future connection establishment. When rotation period has elapsed, the credential expires and the database returns an authentication error. The application then fetches the rotated credential, invalidates the cache, and updates the credential cache via the Secrets Manager client-side caching component.

In this scenario, there might be a minimal disruption while the credential is being rotated and stale connections are using the outdated credential. This concern can be addressed by using the two-user scenario.

**Scenario 2 – Rotation of credentials for two users**

In the second scenario, two database user credentials (Alice’s and Bob’s) are periodically rotated by Secrets Manager. The application container runs in a Fargate cluster. When the first database connection is established, the application container fetches the Aurora database credential for the first user (Alice). The Secrets Manager caching component then caches the credential for future connection establishment.
Although there are two users and credentials, one only active credential is managed by Secrets Manager. In this case, the caching component periodically expires and fetches the latest credential. If the Secrets Manager rotation period is longer than the cache timeout, the caching component picks up the rotated credential for the second user (Bob). For example, if the cache expiration is measured in minutes and the rotation period is measured in days, the caching component fetches the new credential as part of its periodic cache refresh. In this way, the downtime is minimized because each user's credential is active for one Secrets Manager rotation.

Automation and scale

You can use AWS CloudFormation to deploy this pattern by using infrastructure as code. This builds and creates the application container, creates the Fargate task, deploys the container into Fargate, and sets up and configure Secrets Manager with Aurora. For step-by-step deployment instructions, see the readme file.

Tools

• Secrets Manager – AWS Secrets Manager enables the replacement of hardcoded credentials, including passwords, with an API call to Secrets Manager to retrieve the secret. Because Secrets Manager can automatically rotate the secret according to a schedule, you can replace long-term secrets with short-term ones, reducing the risk of compromise.

• Docker – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Code

Example Python code

This pattern uses the Python client-side caching component for Secrets Manager to retrieve the authentication credentials when establishing the database connection. The client-side caching component helps avoid reaching out to Secrets Manager each time.

Now, when the rotation period elapses, the cached credential will be expired, and connecting to the database will result in an authentication error. For MySQL, the authentication error code is 1045. This example uses Amazon Aurora for MySQL, though you could use another engine such as PostgreSQL. Upon the authentication error, the database connection exception handling code catches the error. It then informs the Secrets Manager client-side caching component to refresh the secret, then to reauthenticate and re-establish the database connection. If you are using PostgreSQL or another engine, you must look up the corresponding authentication error code.

The container application can now update the database password with the rotated password without restarting the container.

Place the following code in your application code that handles database connections. This example uses Django, and it subclasses the database backend with a database wrapper for connections. If you are using a different programming language or database connection library, see your database connection library to review how to subclass database connection retrieval.

```python
def get_new_connection(self, conn_params):
    try:
        logger.info("get connection")
        databasecredentials.get_conn_params_from_secrets_manager(conn_params)
        conn = super(DatabaseWrapper, self).get_new_connection(conn_params)
        return conn
    except MySQLdb.OperationalError as e:
        error_code=e.args[0]
```

325
if error_code!=1045:
    raise e

logger.info("Authentication error. Going to refresh secret and try again.")
databasecredentials.refresh_now()
databasecredentials.get_conn_params_from_secrets_manager(conn_params)
conn=super(DatabaseWrapper,self).get_new_connection(conn_params)
logger.info("Successfully refreshed secret and established new database connection.")
return conn

Run Amazon ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere

*Created by Akash Kumar (AWS)*

<table>
<thead>

Summary

Amazon Elastic Container Service (Amazon ECS) Anywhere supports the deployment of Amazon ECS tasks in any environment, including Amazon Web Services (AWS) managed infrastructure and customer managed infrastructure. You can do this while using a fully AWS managed control plane that’s running in the cloud and always up to date.

Enterprises often use Amazon WorkSpaces for developing container-based applications. This has required Amazon Elastic Compute Cloud (Amazon EC2) or AWS Fargate with an Amazon ECS cluster to test and run ECS tasks. Now, by using Amazon ECS Anywhere, you can add Amazon WorkSpaces as external instances directly to an ECS cluster, and you can run your tasks directly. This reduces your development time, because you can test your container with an ECS cluster locally on Amazon WorkSpaces. You can also save the cost of using EC2 or Fargate instances for testing your container applications.

This pattern showcases how to deploy ECS tasks on Amazon WorkSpaces with Amazon ECS Anywhere. It sets up the ECS cluster and uses AWS Directory Service Simple AD to launch the WorkSpaces. Then the example ECS task launches NGINX in the WorkSpaces.
Prerequisites and limitations

- An active AWS account
- AWS Command Line Interface (AWS CLI)
- AWS credentials configured on your machine

Architecture

Target technology stack

- A virtual private cloud (VPC)
- An Amazon ECS cluster
- Amazon WorkSpaces
- AWS Directory Service with Simple AD

Target architecture

The architecture includes the following services and resources:

- An ECS cluster with public and private subnets in a custom VPC
- Simple AD in the VPC to provide user access to Amazon WorkSpaces
- Amazon WorkSpaces provisioned in the VPC using Simple AD
- AWS Systems Manager activated for adding Amazon WorkSpaces as managed instances
- Using Amazon ECS and AWS Systems Manager Agent (SSM Agent), Amazon WorkSpaces added to Systems Manager and the ECS cluster
• An example ECS task to run in the WorkSpaces in the ECS cluster

**Tools**

- **Simple AD** – AWS Directory Service Simple Active Directory (Simple AD) is a standalone managed directory powered by a Samba 4 Active Directory Compatible Server. Simple AD provides a subset of the features offered by AWS Managed Microsoft AD, including the ability to manage user accounts and to securely connect to Amazon EC2 instances.

- **Amazon ECS** – Amazon Elastic Container Service is a highly scalable, fast container management service that for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon EC2 instances that you manage.

- **AWS Identity and Access Management** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

- **AWS Systems Manager** – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting on (or taking corrective action on) any policy violations it detects.

- **Amazon WorkSpaces** – Amazon WorkSpaces enables the provisioning of virtual, cloud-based Microsoft Windows or Amazon Linux desktops for your users, known as WorkSpaces. WorkSpaces eliminates the need to procure and deploy hardware or install complex software.

AWS services: Amazon EC2; Elastic Load Balancing (ELB)

Summary

This pattern is for people who are starting to containerize their applications on the Amazon Web Services (AWS) Cloud. When you begin to containerize apps on cloud, usually there are no container orchestrating platforms set up. This pattern helps you quickly set up infrastructure on AWS to test your containerized applications without needing an elaborate container orchestrating infrastructure.

The first step in the modernization journey is to transform the application. If it's a legacy .NET Framework application, you must first change the runtime to ASP.NET Core. Then do the following:

- Create the Docker container image
- Run the Docker container using the built image
- Validate the application before deploying it on any container orchestration platform, such as Amazon Elastic Container Service (Amazon ECS) or Amazon Elastic Kubernetes Service (Amazon EKS).

This pattern covers the build, run, and validate aspects of modern application development on an Amazon Elastic Compute Cloud (Amazon EC2) Linux instance.

Prerequisites and limitations

Prerequisites
• An active Amazon Web Services (AWS) account
• An AWS Identity and Access Management (IAM) role with sufficient access to create AWS resources for this pattern
• Visual Studio Community 2022 or later downloaded and installed
• A .NET Framework project modernized to ASP.NET Core
• A GitHub repository

Product versions
• Visual Studio Community 2022 or later

Architecture

Target architecture
This pattern uses an AWS CloudFormation template to create the highly available architecture shown in the following diagram. An Amazon EC2 Linux instance is launched in a private subnet. AWS Systems Manager Session Manager is used to access the private Amazon EC2 Linux instance and to test the API running in the Docker container.

1. Access to the Linux instance through Session Manager

Tools

AWS services
• AWS Command Line Interface – AWS Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services through commands in your command line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console.
• AWS Management Console – The AWS Management Console is a web application that comprises and refers to a broad collection of service consoles for managing AWS resources. When you first sign in,
you see the console home page. The home page provides access to each service console and offers a single place to access the information you need to perform your AWS related tasks.

- **AWS Systems Manager Session Manager** – Session Manager is a fully managed AWS Systems Manager capability. With Session Manager, you can manage your Amazon Elastic Compute Cloud (Amazon EC2) instances. Session Manager provides secure and auditable node management without the need to open inbound ports, maintain bastion hosts, or manage SSH keys.

**Other tools**

- **Visual Studio 2022** – Visual Studio 2022 is an integrated development environment (IDE).
- **Docker** – Docker is a set of platform as a service (PaaS) products that use virtualization at the operating-system level to deliver software in containers.

**Epics**

**Develop the ASP.NET Core web API**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create an example ASP.NET Core web API using Visual Studio. | To create an example ASP.NET Core web API, do the following:  
2. Choose Create a new project.  
3. Select the ASP.NET Core Web API project template, and choose Next.  
4. For the project name, enter DemoNetCoreWebAPI, and choose Next.  
5. Choose Create. | App developer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.</td>
<td>To run the project locally, press F5.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>Verify that the default <strong>WeatherForecast</strong> API endpoint is returning the results using <strong>Swagger</strong>.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>Open the command prompt, navigate to the .csproj project folder, and run the following commands to push the new web API to your GitHub repository.</td>
<td></td>
</tr>
</tbody>
</table>
|      | `git add --all`  
|      | `git commit -m "Initial Version"`  
|      | `git push` | App developer |

**Create a Dockerfile.**

To create a Dockerfile, do one of the following:

- Create the Dockerfile manually using the sample Dockerfile in the **Code** section. Based on the requirements, select the appropriate .NET base image. For information about .NET and ASP.NET Core related images, see **Docker hub**.

- Create the Dockerfile using Visual Studio and **Docker Desktop**. In the solution explorer, right click on the project, choose **Add->Docker Support**. For **Target OS**, select **Linux**. Ensure that the new Dockerfile is in the same path as the solution file (.sln).

To push the changes to your GitHub repository, run the following command.

```
git add --all  
git commit -m "Dockerfile added"  
git push
```
Set up the Amazon EC2 Linux instance

<table>

## Task 1: Build and run the Docker container.

To build the Docker image and run the container inside the Amazon EC2 Linux instance, do the following:

1. To create the Docker image, run the following command:
   ```bash
docker build -t aspnetcorewebapiimage -f Dockerfile .
   ```

2. To view all the Docker images, run the following command:
   ```bash
docker images
   ```

3. To create and run the container, run the following command:
   ```bash
docker run -d -p 80:80 --name aspnetcorewebapicontainer aspnetcorewebapiimage
   ```

### Skills required:
App developer, AWS administrator, AWS DevOps

## Test the web API

### Task 2: Test the web API using the curl command.

To test the web API, run the following command:

```bash
curl -X GET "http://localhost/WeatherForecast" -H "accept: text/plain"
```

Verify the API response.

**Note:** You can get the curl commands for each endpoint from Swagger when you are running it locally.

### Skills required:
App developer

## Clean up resources

### Task 3: Delete all resources.

Delete the stack to remove all the resources. This ensures

### Skills required:
AWS administrator, AWS DevOps
Run message-driven workloads at scale by using AWS Fargate

Created by Stan Zubarev

Environment: PoC or pilot
Technologies: Containers & microservices; Messaging & communications; Databases
AWS services: AWS Fargate; Amazon SQS; Amazon DynamoDB

Summary

This pattern shows how to run message-driven workloads at scale in the AWS Cloud by using containers and AWS Fargate.

Using containers to process data can be helpful when the amount of data an application processes exceeds the limitations of function-based serverless compute services. For example, if an application requires more compute capacity or processing time than what AWS Lambda offers, using Fargate can improve performance.

The following example setup uses the AWS Cloud Development Kit (AWS CDK) in TypeScript to configure and deploy the following resources in the AWS Cloud:

- A Fargate service
- An Amazon Simple Queue Service (Amazon SQS) queue
- An Amazon DynamoDB table.
- An Amazon CloudWatch dashboard

The Fargate service receives and processes messages from the Amazon SQS queue, then stores them in the Amazon DynamoDB table. You can monitor how many Amazon SQS messages are processed and how many DynamoDB items are created by Fargate by using the CloudWatch dashboard.

Note: You can also use this pattern’s example code to build more complex data processing workloads in event-driven serverless architectures. For more information, see Run event-driven and scheduled workloads at scale with AWS Fargate.

Prerequisites and limitations

Prerequisites
• An active AWS account
• The latest version of the AWS Command Line Interface (AWS CLI), installed and configured on your local machine
• Git, installed and configured on your local machine
• The AWS CDK, installed and configured on your local machine
• Go, installed and configured on your local machine
• Docker, installed and configured on your local machine

Architecture

Target technology stack

• Amazon SQS
• AWS Fargate
• Amazon DynamoDB

Target architecture

The following diagram shows an example workflow for running message-driven workloads at scale in the AWS Cloud by using Fargate:

The diagram shows the following workflow:
1. The Fargate service uses Amazon SQS long polling to receive messages from an Amazon SQS queue.
2. The Fargate service then processes the Amazon SQS messages and stores them in a DynamoDB table.

Automation and scale
To automate scaling your Fargate task count, you can configure Amazon Elastic Container Service (Amazon ECS) Service Auto Scaling. It’s a best practice to configure the scaling policy based on the number of visible messages in your application's Amazon SQS queue.

For more information, see Scaling based on Amazon SQS in the Amazon EC2 Auto Scaling User Guide.

**Tools**

**AWS services**

- **AWS Fargate** helps you run containers without needing to manage servers or Amazon Elastic Compute Cloud (Amazon EC2) instances. It’s used in conjunction with Amazon Elastic Container Service (Amazon ECS).
- **Amazon Simple Queue Service (Amazon SQS)** provides a secure, durable, and available hosted queue that helps you integrate and decouple distributed software systems and components.
- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications you run on AWS in real time.

**Code**

The code for this pattern is available in the GitHub sqs-fargate-ddb-cdk-go repository.

**Epics**

Create and deploy the resources by using the AWS CDK

</thead>
<tbody>
<tr>
<td>in AWS CLI and export it as an <code>AWS_PROFILE</code> environment variable. For more information, see <a href="https://docs.aws.amazon.com/cli/latest/userguide/cli-aws-profiles.html">Creating named profiles</a> in the <strong>AWS CLI User Guide for Version 2</strong>. Note: If you haven’t used the AWS CDK in your AWS account before, you must first provision the required AWS CDK resources. For more information, see <a href="https://docs.aws.amazon.com/cdk/v2/guide/quickstart.html">Bootstrapping</a> in the <strong>AWS CDK v2 Developer Guide</strong>.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

---

### Deploy the AWS CDK stack to your AWS account.

1. Build a container image by running the following AWS CLI command:
   ```sh
docker build -t go-fargate .
```
2. Open the AWS CDK directory by running the following command:
   ```sh
cd cdk
```
3. Install the required npm modules by running the following command:
   ```sh
npm i
```
4. Deploy the AWS CDK pattern to your AWS account by running the following command:
   ```sh
cdk deploy --profile ${AWS_PROFILE}
```

### Test the setup

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Send a test message to the Amazon SQS queue. | For instructions, see [Sending messages to a queue (console)](https://docs.aws.amazon.com/sqs/latest/userguide/sqs-console-send.html) in the **Amazon SQS Developer Guide**. **Test Amazon SQS message example**<br>

```json
{
   "message": "hello, Fargate"
}
``` | App developer |
### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify that the test message appears in the Fargate service's CloudWatch logs.</td>
<td>Follow the instructions in <strong>Viewing CloudWatch Logs</strong> in the <em>Amazon ECS Developer Guide</em>. Make sure that you review the logs for the <strong>go-fargate-service</strong> log group in the <strong>go-service-cluster</strong> ECS cluster.</td>
<td>App developer</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Verify that the test message appears in the DynamoDB table. | 1. Open the **DynamoDB console**.
2. In the left navigation pane, choose Tables. Then, select the following table from the list: **sqs-fargate-ddb-table**.
3. Choose **Explore table items**.
4. Verify that the test message appears in the **Items returned** list. | App developer |

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Verify that the Fargate service is sending messages to CloudWatch Logs. | 1. Open the **CloudWatch console**.
2. In the left navigation pane, choose **Dashboards**.
3. In the Custom Dashboards list, select the dashboard named **go-service-dashboard**.
4. Verify that the test message appears in the logs. | App developer |

**Note:** The AWS CDK creates the CloudWatch dashboard in your AWS account automatically.

### Clean up

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Delete the AWS CDK stack. | 1. Open your AWS CDK directory in the AWS CLI by running the following command:
   ```
cd cdk
   ```
2. Delete the AWS CDK stack by running the following command:
   ```
cdk destroy --profile ${AWS_PROFILE}
   ``` | App developer |
### Task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Verify that the AWS CDK stack is deleted. | To make sure that the stack was deleted, run the following command:  

```bash
aws cloudformation list-stacks --query "StackSummaries[?contains(StackName,'SqsFargate')].StackStatus" --profile ${AWS_PROFILE}
```

The `StackStatus` value returned in the command output is `DELETE_COMPLETE` if the stack is deleted.

For more information, see [Describing and listing your stacks](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/listing-stacks.html) in the AWS CloudFormation User Guide. | App developer |

**Run stateful workloads with persistent data storage by using Amazon EFS on Amazon EKS with AWS Fargate**

*Created by Ricardo Morais (AWS) and Lucio Pereira (AWS)*

**Environment:** PoC or pilot  
**Technologies:** Containers & microservices; Storage & backup  
**Workload:** Open-source

**AWS services:** Amazon EFS; Amazon EKS; AWS Fargate

### Summary

This pattern provides guidance for enabling Amazon Elastic File System (Amazon EFS) as a storage device for containers that are running on Amazon Elastic Kubernetes Service (Amazon EKS), using AWS Fargate to provision your compute resources.
The setup described in this pattern follows security best practices and provides security at rest and security in transit by default. To encrypt your Amazon EFS file system, it uses an AWS Key Management Service (AWS KMS) key, but you can also specify a key alias that dispatches the process of creating a KMS key.

You can follow the steps in this pattern to create a namespace and Fargate profile for a proof-of-concept (PoC) application, install the Amazon EFS Container Storage Interface (CSI) driver that is used to integrate the Kubernetes cluster with Amazon EFS, configure the storage class, and deploy the PoC application. These steps result in an Amazon EFS file system that is shared among multiple Kubernetes workloads, running over Fargate. The pattern is accompanied by scripts that automate these steps.

You can use this pattern whenever you want to ensure data persistence in your containerized applications, and avoid data loss in scale-in or scale-out operations. For example:

- DevOps tools – A common scenario is to use Jenkins as a continuous integration and continuous delivery (CI/CD) tool. In this case, you can use Amazon EFS as a shared file system to store configurations among different instances of the CI/CD tool or to store a cache (for example, an Apache Maven repository) for pipeline stages among different instances of the CI/CD tool.
- Web servers – A common scenario is to use Apache as an HTTP web server. You can use Amazon EFS as a shared file system to store static files that are shared among different instances of the web server. In this example scenario, modifications are applied directly to the file system instead of static files being baked into a Docker image.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An existing Amazon EKS cluster with Kubernetes version 1.17 or later
- Cluster administration permissions
- Context configured to point to the desired Amazon EKS cluster

Limitations

- You have to create the Amazon EFS file system before you can use the CSI driver to mount it inside a container as a persistent volume. Currently, the CSI driver doesn't provision the Amazon EFS file system automatically.
- There are some limitations to consider when you’re using Amazon EKS with Fargate. For example, daemonsets and privileged containers aren't supported. For more information, see AWS Fargate considerations in the Amazon EKS documentation.
- The code provided with this pattern supports workstations that are running Linux or macOS.

Product versions

- AWS Command Line Interface (AWS CLI) version 2 or later
- Amazon EFS CSI driver version 1.0 or later
- eksctl version 0.24.0 or later
- jq version 1.6 or later
- kubectl version 1.17 or later
- Kubernetes version 1.17 or later
The target architecture includes the following services and components, and follows AWS Well-Architected Framework best practices:

- Amazon EFS, which provides a simple, scalable, fully managed elastic NFS file system. This is used as a shared file system among all replications of the PoC application that are running in pods, which are distributed in the private subnets of the chosen Amazon EKS cluster.

- An Amazon EFS mount target for each private subnet. This provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.

- Amazon EKS, which runs the Kubernetes workloads. You must provision an Amazon EKS cluster before you use this pattern, as described in the Prerequisites section.
• AWS KMS, which provides encryption at rest for the content that’s stored in the Amazon EFS file system.
• Fargate, which manages the compute resources for the containers so that you can focus on business requirements instead of infrastructure burden. The Fargate profile is created for all private subnets. It provides redundancy per Availability Zone within the virtual private cloud (VPC) of the cluster.
• Kubernetes pods, for validating that content can be shared, consumed, and written by different instances of an application.

## Tools

### Tools

- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that you can use to interact with AWS services from the command line.
- **eksctl** – eksctl is a command-line utility for creating and managing Kubernetes clusters on Amazon EKS.
- **kubectl** – kubectl is a command-line utility for communicating with the cluster API server.
- **jq** – jq is a command-line tool for parsing JSON.

### AWS services

- **Amazon EFS** – Amazon Elastic File System (Amazon EFS) manages file storage in the AWS Cloud. In this pattern, it provides a simple, scalable, fully managed, and shared file system for use with Amazon EKS.
- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or operate your own clusters.
- **AWS Fargate** – AWS Fargate is a serverless compute engine for Amazon EKS. It creates and manages compute resources for your Kubernetes applications.
- **AWS KMS** – AWS Key Management Service (AWS KMS) is a encryption and key management service that helps you protect your application data.

## Code

The code for this pattern is provided in a [GitHub repo](https://github.com). The scripts are organized by epic, in the folders epic01 through epic06, corresponding to the order in the following section. For information about how to use the scripts to automate the epics in this pattern, see the *Additional information* section.

## Epics

### Create a Kubernetes namespace and a linked Fargate profile

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a Kubernetes namespace for application workloads.</td>
<td>Create a namespace for receiving the application workloads that interact with Amazon EFS. To run a script to automate the steps in this epic, see the <em>Additional information</em> section.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
</tbody>
</table>
## Create a custom Fargate profile.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a custom Fargate profile</td>
<td>Create a custom Fargate profile that is linked to the namespace you created.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
</tbody>
</table>

## Create an Amazon EFS file system

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate an unique token.</td>
<td>Amazon EFS requires a creation token to ensure idempotent operation (calling the operation with the same creation token has no effect). To meet this requirement, you must generate an unique token through an available technique. For example, you can generate an universally unique identifier (UUID) to use as a creation token. After you create a token, you can run a script to automate the remaining steps in this epic; see the Additional information section.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Create a KMS key.</td>
<td>(Optional) Create a unique, symmetric AWS KMS key in your AWS account and AWS Region. This key is used for file system encryption, so that the pattern can use a KMS key for handling encryption at rest. If it is not specified, an AWS managed key is used.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Create an Amazon EFS file system.</td>
<td>Create the file system for receiving the data files that are read and written by the application workloads. You can create an encrypted or non-encrypted file system. (As a best practice, the code for this pattern creates an encrypted system to enable encryption at rest by default.)</td>
<td>System administrator</td>
</tr>
<tr>
<td>Create a security group.</td>
<td>Create a security group to allow the Amazon EKS cluster to access the Amazon EFS file system.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Update the inbound rule for the security group.</td>
<td>Update the inbound rules of the security group to allow incoming traffic for the following settings:</td>
<td>System administrator</td>
</tr>
</tbody>
</table>
## Install Amazon EFS components into the Kubernetes cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deploy the Amazon EFS CSI driver.</strong></td>
<td>Deploy the Amazon EFS CSI driver into the cluster. The driver will provision storage according to persistent volume claims created by applications. To run a script to automate the steps in this epic, see the <em>Additional information</em> section.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
<tr>
<td><strong>Deploy the storage class.</strong></td>
<td>Deploy the storage class into the cluster for the Amazon EFS provisioner (efs.csi.aws.com).</td>
<td>Kubernetes user with granted permissions</td>
</tr>
</tbody>
</table>

## Install the PoC application into the Kubernetes cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deploy the persistent volume.</strong></td>
<td>Deploy the persistent volume, and link it to the created storage class and to the ID of the Amazon EFS file system. The application uses the persistent volume to read and write content. You can specify any size for the persistent volume in the storage field. Kubernetes requires this field, but because Amazon EFS is an elastic file system, it does not enforce any file system capacity. You can deploy the persistent volume with or without encryption. (The Amazon EFS CSI driver enables encryption by default, as a best practice.) To run a script to automate the steps in this epic,</td>
<td>Kubernetes user with granted permissions</td>
</tr>
</tbody>
</table>
## Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy the persistent volume claim requested by the application.</td>
<td>Deploy the persistent volume claim requested by the application, and link it to the storage class. Use the same access mode as the persistent volume you created previously. You can specify any size for the persistent volume claim in the storage field. Kubernetes requires this field, but because Amazon EFS is an elastic file system, it does not enforce any file system capacity.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
<tr>
<td>Deploy workload 1.</td>
<td>Deploy the pod that represents workload 1 of the application. This workload writes content to the file /data/out1.txt.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
<tr>
<td>Deploy workload 2.</td>
<td>Deploy the pod that represents workload 2 of the application. This workload writes content to the file /data/out2.txt.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
</tbody>
</table>

### Validate file system persistence, durability, and shareability

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate that workload 1 can write to the file system.</td>
<td>Validate that workload 1 of the application is writing to the /data/out1.txt file in the Amazon EFS file system. For commands and scripts that automate the steps in this epic, see the Additional information section.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
<tr>
<td>Validate that workload 2 can write to the file system.</td>
<td>Validate that workload 2 of the application is writing to the /data/out2.txt file in the Amazon EFS file system.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
<tr>
<td>Validate that workload 1 can read the file written by workload 2.</td>
<td>Validate that workload 1 of the application is able to read the file /data/out2.txt, written by workload 2 of the application, from the file system.</td>
<td>Kubernetes user with granted permissions</td>
</tr>
<tr>
<td>Validate that workload 2 can read the file written by workload 1.</td>
<td>Validate that workload 2 of the application is able to read the file /data/out1.txt, written by</td>
<td>Kubernetes user with granted permissions</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Validate that files are retained after you remove application components.</td>
<td>Remove application components (persistent volume, persistent volume claim, and pods), and validate that the files /data/out1.txt and /data/out2.txt are retained in the file system. For a script to automate this step, see the Additional information section.</td>
<td>Kubernetes user with granted permissions, System administrator</td>
</tr>
</tbody>
</table>

### Monitor operations

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitor application logs.</td>
<td>As part of a day-two operation, ship the application logs to Amazon CloudWatch for monitoring.</td>
<td>Kubernetes user with granted permissions, System administrator</td>
</tr>
<tr>
<td>Monitor Amazon EKS and Kubernetes containers with Container Insights.</td>
<td>As part of a day-two operation, monitor the Amazon EKS and Kubernetes systems by using Amazon CloudWatch Container Insights. This tool collects, aggregates, and summarizes metrics from containerized applications at different levels and dimensions. For more information, see the links in the Related resources section.</td>
<td>Kubernetes user with granted permissions, System administrator</td>
</tr>
<tr>
<td>Monitor Amazon EFS with CloudWatch.</td>
<td>As part of a day-two operation, monitor the file systems using Amazon CloudWatch, which collects and processes raw data from Amazon EFS into readable, near real-time metrics. For more information, see the Related resources section.</td>
<td>System administrator</td>
</tr>
</tbody>
</table>

### Clean up resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Clean up all created resources for the pattern.</td>
<td>After you complete this pattern, clean up all resources, to avoid incurring AWS charges. To run a script to automate the cleanup</td>

Required tools

- Installing the AWS CLI version 2
- Installing eksctl
- Installing kubectl
- Installing jq

Additional information

The scripts that automate the epics and stories for this pattern are included in a GitHub repo and described in the following sections.

Creating a Kubernetes namespace and a linked Fargate profile

Run the following script to implement these two steps:

```bash
./scripts/epic01/create-k8s-ns-and-linked-fargate-profile.sh -c "MY_CLUSTER_NAME"
```

where MY_CLUSTER_NAME is the name of your Amazon EKS cluster.

Creating an Amazon EKS file system

Use the create-efs.sh script to create an encrypted or non-encrypted Amazon EFS file system, after you generate a unique token for Amazon EFS.
With encryption at rest, without a KMS key:

```bash
./scripts/epic02/create-efs.sh
   -c "MY_CLUSTER_NAME"
   -t "MY_EFS_CREATION_TOKEN"
```

where `MY_CLUSTER_NAME` is the name of your Amazon EKS cluster and `MY_EFS_CREATION_TOKEN` is a unique creation token for the file system.

With encryption at rest, with a KMS key:

```bash
./scripts/epic02/create-efs.sh
   -c "MY_CLUSTER_NAME"
   -t "MY_EFS_CREATION_TOKEN"
   -k "MY_KMS_KEY_ALIAS"
```

where `MY_CLUSTER_NAME` is the name of your Amazon EKS cluster, `MY_EFS_CREATION_TOKEN` is a unique creation token for the file system, and `MY_KMS_KEY_ALIAS` is the alias for the KMS key.

Without encryption:

```bash
./scripts/epic02/create-efs.sh -d
   -c "MY_CLUSTER_NAME"
   -t "MY_EFS_CREATION_TOKEN"
```

where `MY_CLUSTER_NAME` is the name of your Amazon EKS cluster, `MY_EFS_CREATION_TOKEN` is a unique creation token for the file system, and `–d` disables encryption at rest.

Installing Amazon EFS components into the Kubernetes cluster

Run the following script to deploy the Amazon EFS CSI driver and the storage class into the cluster:

```bash
./scripts/epic03/create-k8s-efs-csi-sc.sh
```

This script uses the `kubectl` utility, so make sure that the context has been configured to point to the desired Amazon EKS cluster.

Installing the PoC application

Run the `deploy-poc-app.sh` script to deploy the persistent volume, the persistent volume claim, and the two workloads.

With encryption in transit:

```bash
./scripts/epic04/deploy-poc-app.sh
   -t "MY_EFS_CREATION_TOKEN"
```

where `MY_EFS_CREATION_TOKEN` is the unique creation token for the file system.

Without encryption in transit:

```bash
./scripts/epic04/deploy-poc-app.sh -d
   -t "MY_EFS_CREATION_TOKEN"
```

where `MY_EFS_CREATION_TOKEN` is the unique creation token for the file system, and `–d` disables encryption in transit.
Validating file system persistence, durability, and shareability

To validate that workload 1 is writing to /data/out1.txt:

```
kubectl exec -ti poc-app1 -n poc-efs-eks-fargate -- tail -f /data/out1.txt
```

The results will be similar to the following:

```
...  
Thu Sep  3 15:25:07 UTC 2020 - PoC APP 1  
Thu Sep  3 15:25:12 UTC 2020 - PoC APP 1  
Thu Sep  3 15:25:17 UTC 2020 - PoC APP 1  
...  
```

To validate that workload 2 is writing to /data/out2.txt:

```
kubectl exec -ti poc-app2 -n poc-efs-eks-fargate -- tail -f /data/out2.txt
```

The results will be similar to the following:

```
...  
Thu Sep  3 15:26:48 UTC 2020 - PoC APP 2  
Thu Sep  3 15:26:53 UTC 2020 - PoC APP 2  
Thu Sep  3 15:26:58 UTC 2020 - PoC APP 2  
...  
```

To validate that workload 1 can read the file written by workload 2:

```
kubectl exec -ti poc-app1 -n poc-efs-eks-fargate -- tail -n 3 /data/out2.txt
```

The results will be similar to the following:

```
...  
Thu Sep  3 15:26:48 UTC 2020 - PoC APP 2  
Thu Sep  3 15:26:53 UTC 2020 - PoC APP 2  
Thu Sep  3 15:26:58 UTC 2020 - PoC APP 2  
...  
```

To validate that workload 2 can read the file written by workload 1:

```
kubectl exec -ti poc-app2 -n poc-efs-eks-fargate -- tail -n 3 /data/out1.txt
```

The results will be similar to the following:

```
...  
Thu Sep  3 15:29:22 UTC 2020 - PoC APP 1  
Thu Sep  3 15:29:27 UTC 2020 - PoC APP 1  
Thu Sep  3 15:29:32 UTC 2020 - PoC APP 1  
...  
```

To validate that files are retained after you remove application components:

```
./scripts/epic05/validate-efs-content.sh  
   -t "MY_EFS_CREATION_TOKEN"
```
where MY_EFS_CREATION_TOKEN is the unique creation token for the file system.

The results will be similar to the following:

```
pod/poc-app-validation created
Waiting for pod get Running state...
Waiting for pod get Running state...
Waiting for pod get Running state...
Results from execution of 'find /data' on validation process pod:
/data
/data/out2.txt
/data/out1.txt
```

**Cleaning up resources**

Run the clean-up-resources.sh script to remove all resources after you have finished using the PoC application.

*With encryption at rest, with a KMS key:*

```
./scripts/epic06/clean-up-resources.sh \  
  -c "MY_CLUSTER_NAME" \  
  -t "MY_EFS_CREATION_TOKEN" \  
  -k "MY_KMS_KEY_ALIAS"
```

where MY_CLUSTER_NAME is the name of your Amazon EKS cluster, MY_EFS_CREATION_TOKEN is the creation token for the file system, and MY_KMS_KEY_ALIAS is the alias for the KMS key.

*Without encryption at rest:*

```
./scripts/epic06/clean-up-resources.sh \  
  -c "MY_CLUSTER_NAME" \  
  -t "MY_EFS_CREATION_TOKEN"
```

where MY_CLUSTER_NAME is the name of your Amazon EKS cluster and MY_EFS_CREATION_TOKEN is the creation token for the file system.

Serve static content in an Amazon S3 bucket through a VPC by using Amazon CloudFront

Created by Angel Emmanuel Hernandez Cebrian

Environment: PoC or pilot
Technologies: Content delivery; Security, identity, compliance; Serverless; Web hosting; Networking
AWS services: Amazon CloudFront; Elastic Load Balancing (ELB); AWS Lambda

Summary

When you serve static content that is hosted on Amazon Web Services (AWS), the recommended approach is to use an Amazon Simple Storage Service (S3) bucket as the origin and use Amazon CloudFront to distribute the content. There are two primary benefits of this solution. The first is the convenience of caching static content at edge locations. The second is that you can define web access control lists (web ACLs) for the CloudFront distribution, which helps you secure requests to the content with minimal configuration and administrative overhead.

However, there is a common architectural limitation to the standard, recommended approach. In some environments, you want virtual firewall appliances deployed in a virtual private cloud (VPC) to inspect all content, including static content. The standard approach doesn't route traffic through the VPC for inspection. This pattern provides an alternative architectural solution. You still use a CloudFront distribution to serve static content in an S3 bucket, but the traffic is routed through the VPC by using an Application Load Balancer. An AWS Lambda function then retrieves and returns the content from the S3 bucket.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Static website content hosted in an S3 bucket.

Limitations

- The resources in this pattern must be in a single AWS Region, but they can be provisioned in different AWS accounts.
- Limits apply to the maximum request and response size that the Lambda function can receive and send, respectively. For more information, see Limits in Lambda functions as targets (Elastic Load Balancing documentation).
• It's important to find a good balance between performance, scalability, security, and cost-effectiveness when using this approach. Despite the high scalability of Lambda, if the number of concurrent Lambda invocations exceeds the maximum quota, some requests are throttled. For more information, see Lambda quotas (Lambda documentation). You also need to consider pricing when using Lambda. To minimize Lambda invocations, make sure that you properly define the cache for the CloudFront distribution. For more information, see Optimizing caching and availability (CloudFront documentation).

Architecture

Target technology stack

• CloudFront
• Amazon Virtual Private Cloud (Amazon VPC)
• Application Load Balancer
• Lambda
• Amazon S3

Target architecture

The following image shows the suggested architecture when you need to use CloudFront to serve static content from an S3 bucket through a VPC.

1. The client requests the URL of CloudFront distribution to get a particular website file in the S3 bucket.
2. CloudFront sends the request to AWS WAF. AWS WAF filters the request by using the web ACLs applied to the CloudFront distribution. If the request is determined to be valid, the flow continues. If the request is determined to be invalid, the client receives a 403 error.
3. CloudFront checks its internal cache. If there is a valid key matching the incoming request, the associated value is sent back to the client as a response. If not, the flow continues.
4. CloudFront forwards the request to the URL of the specified Application Load Balancer.
5. The Application Load Balancer has a listener associated with a target group based on a Lambda function. The Application Load Balancer invokes the Lambda function.
6. The Lambda function connects to the S3 bucket, perform a GetObject operation on it, and returns the content as a response.

**Automation and scale**

To automate the deployment of static content using this approach, create CI/CD pipelines to update the Amazon S3 buckets that host websites.

The Lambda function scales automatically to handle the concurrent requests, within the quotas and limitations of the service. For more information, see [Lambda function scaling](https://docs.aws.amazon.com/lambda/latest/dg/function-scaling.html) and [Lambda quotas](https://docs.aws.amazon.com/lambda/latest/dg/lambda-quotas.html) (Lambda documentation). For the other AWS services and features, such as CloudFront and the Application Load Balancer, AWS scales these automatically.

**Tools**

- **Amazon CloudFront** speeds up distribution of your web content by delivering it through a worldwide network of data centers, which lowers latency and improves performance.
- **Elastic Load Balancing (ELB)** distributes incoming application or network traffic across multiple targets. In this pattern, you use an Application Load Balancer provisioned through Elastic Load Balancing to direct traffic to the Lambda function.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

**Epics**

Use CloudFront to serve static content from Amazon S3 through a VPC

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>Create a CloudFront distribution.</td>
<td>Create a CloudFront distribution that points to the Application Load Balancer you created.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

2. Choose **Create Distribution**.

3. On the first page of the **Create Distribution Wizard**, in the **Web** section, choose **Get Started**.

4. Specify settings for your distribution. For more information, see **Values that you specify when you create or update a distribution**. Note the following:
   a. Set the Application Load Balancer as the origin.
   b. In **Distribution settings**, choose existing web ACLs that you want to apply through AWS WAF. For more information, see **AWS WAF web ACL**.

5. Save your changes.

6. After CloudFront creates your distribution, the value of the **Status** column for your distribution changes from **InProgress** to **Deployed**. If you chose to enable the distribution, it will be ready to process requests after the status switches to **Deployed**.

Additional information

Code

The following example Lambda function is written in Node.js. This Lambda function acts as a web server that performs a GetObject operation to an S3 bucket that contains the website resources.

```javascript
/**
* This is an AWS Lambda function created for demonstration purposes.
* It retrieves static assets from a defined Amazon S3 bucket.
* To make the content available through a URL, use an Application Load Balancer with a Lambda integration.
* Set the S3_BUCKET environment variable in the Lambda function definition.
*/

var AWS = require('aws-sdk');
exports.handler = function(event, context, callback) {
  var bucket = process.env.S3_BUCKET;
  var key = event.path.replace('/', '');
  if (key == '') {
    key = 'index.html';
  }
  // Fetch from S3
  var s3 = new AWS.S3();
  return s3.getObject({Bucket: bucket, Key: key},
    function(err, data) {
      if (err) {
        return err;
      }

      var isBase64Encoded = false;
      var encoding = 'utf8';
      if (data.ContentType.indexOf('image/') > -1) {
        isBase64Encoded = true;
        encoding = 'base64'
      }

      var resp = {
        statusCode: 200,
        headers: {
          'Content-Type': data.ContentType,
        },
        body: new Buffer(data.Body).toString(encoding),
        isBase64Encoded: isBase64Encoded
      };
    });
```
callback(null, resp);
}
};

<th>Technologies: Cost management; Analytics</th>
<th>AWS services: AWS Billing and Cost Management; AWS Glue</th>
</tr>
</thead>
</table>

Summary

This pattern shows how to track the usage costs of AWS Glue data integration jobs by configuring user-defined cost allocation tags. You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for jobs across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level.

Prerequisites and limitations

Prerequisites

• An active AWS account
• One or more AWS Glue jobs that have user-defined tags activated

Architecture

Target technology stack

• AWS Glue
• AWS Cost Explorer

The following diagram shows how you can apply tags to track usage costs for AWS Glue jobs.
The diagram shows the following workflow:

1. A data engineer or AWS administrator creates user-defined cost allocation tags for the AWS Glue jobs.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.

**Tools**

- **AWS Glue** is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- **AWS Cost Explorer** helps you view and analyze your AWS costs and usage.

**Epics**

<td>Analytics; Data lakes</td>
<td>Production</td>
<td>Amazon S3;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Amazon CloudWatch; AWS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Lambda; Amazon SNS</td>
</tr>
</tbody>
</table>

Summary

This pattern provides an AWS CloudFormation template that enables you to automatically ingest data from AWS Data Exchange into your data lake in Amazon Simple Storage Service (Amazon S3).

AWS Data Exchange is a service that makes it easy to securely exchange file-based data sets in the AWS Cloud. AWS Data Exchange data sets are subscription-based. As a subscriber, you can also access data set revisions as providers publish new data.

The AWS CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any updates to the data set you have subscribed to. If there is an update, CloudWatch initiates a Lambda function, which copies the data over to the S3 bucket you specify. When the data has been copied successfully, Lambda sends you an Amazon Simple Notification Service (Amazon SNS) notification.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Subscription to a data set in AWS Data Exchange

Limitations

- The AWS CloudFormation template must be deployed separately for each subscribed data set in AWS Data Exchange.
Architecture

Target technology stack

- AWS Lambda
- Amazon S3
- AWS Data Exchange
- Amazon CloudWatch
- Amazon SNS

Target architecture

Automation and scale

You can use the AWS CloudFormation template multiple times for the data sets you want to ingest into the data lake.

Tools

- AWS Data Exchange – A service that makes it easy for AWS customers to securely exchange file-based data sets in the AWS Cloud. As a subscriber, you can find and subscribe to hundreds of products from qualified data providers. Then, you can quickly download the data set or copy it to Amazon S3 for use across a variety of AWS analytics and machine learning services. Anyone with an AWS account can be an AWS Data Exchange subscriber.
- AWS Lambda – A compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code isn’t running. With AWS Lambda, you can run code for virtually any type of application or backend service with zero administration. AWS Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging.
• **Amazon S3** – Storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

• **Amazon CloudWatch Events** – Delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using `cron` or `rate` expressions.

• **Amazon SNS** – A web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud. Amazon SNS provides topics (communication channels) for high-throughput, push-based, many-to-many messaging. Using Amazon SNS topics, publishers can distribute messages to a large number of subscribers for parallel processing, including Amazon Simple Queue Service (Amazon SQS) queues, AWS Lambda functions, and HTTP/S webhooks. You can also use Amazon SNS to send notifications to end users using mobile push, SMS, and email.

</thead>
<tbody>
<tr>
<td>Deploy the AWS CloudFormation template.</td>
<td>Deploy the AWS CloudFormation template that's provided as an attachment to this pattern. Configure the following parameters to correspond to your AWS account, data set, and</td>
<td>General AWS</td>
</tr>
</tbody>
</table>
## Task Description

S3 bucket settings: Dataset AWS Region, Dataset ID, Revision ID, S3 Bucket Name (for example, DOC-EXAMPLE-BUCKET), Folder Prefix (for example, myfolder/), and Email for SNS Notification. You can set the Dataset Name parameter to any name. When you deploy the template, it runs a Lambda function to automatically ingest the first set of data available in the data set. Subsequent ingestion then takes place automatically, as new data arrives in the data set.

## Configure cross-account access to a shared AWS Glue Data Catalog using Amazon Athena

*Created by Denis Avdonin (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: Data lakes; Analytics; Big data</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: Amazon Athena; AWS Glue</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Summary

This pattern provides step-by-step instructions, including AWS Identity and Access Management (IAM) policy samples, to configure cross-account sharing of a dataset stored in an Amazon Simple Storage Service (Amazon S3) bucket through the AWS Glue Data Catalog. You can store the dataset in an S3 bucket. The metadata is collected by an AWS Glue crawler and put into the AWS Glue Data Catalog. The S3 bucket and the AWS Glue Data Catalog reside in an AWS account referred to as the *data account* in this pattern. You can provide access to IAM principals in another AWS account referred to as the *consumer account*. Users can query the data in the consumer account by using the Amazon Athena serverless query engine.
Prerequisites and limitations

Prerequisites

- Two active AWS accounts
- An S3 bucket in one of the AWS accounts
- Athena engine version 2
- AWS Command Line Interface (AWS CLI), installed and configured (or AWS CloudShell for executing AWS CLI commands)

Product versions

This pattern works only with Athena engine version 2. If you can't upgrade from Athena engine version 1 to engine version 2, follow the approach from Cross-account AWS Glue Data Catalog access with Amazon Athena in the AWS Big Data Blog.

Architecture

The following diagram shows an architecture that uses IAM permissions to share data in an S3 bucket through an AWS Glue Data Catalog in one AWS account (the data account) and another AWS account (the consumer account):

The diagram shows the following workflow:

1. The S3 bucket policy in the data account grants permissions to the principals (that is, IAM users and roles) that want to access the AWS Glue Data Catalog through Athena.
2. The AWS Key Management Service (AWS KMS) key policy in the data account encrypts data in the S3 bucket.
3. An AWS Glue crawler in the data account discovers the schema of the data that's stored in the S3 bucket.
4. The resource policy of the catalog in the data account grants access to the principals in the consumer account.
5. An IAM policy grants principals in the consumer account access to resources in the data account.
6. A user creates a named catalog reference in the consumer account by using an AWS CLI command.
7. Consumer account principals access objects in the data catalog by using SQL queries executed by the Athena serverless engine.
Tools

- **Amazon Athena** is an interactive query service that helps you analyze data directly in Amazon S3 by using standard SQL.
- **Amazon Simple Storage Service (Amazon S3)** is a cloud-based object storage service that helps you store, protect, and retrieve any amount of data.
- **AWS Glue** is a fully managed extract, transform, and load (ETL) service. It helps you reliably categorize, clean, enrich, and move data between data stores and data streams.
- **AWS Key Management Service (AWS KMS)** helps you create and control cryptographic keys to protect your data.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.

Epics

Set up permissions in the data account

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Grant principals in the consumer account access to the data.</td>
<td>Create an S3 bucket policy based on the following template and assign it to the bucket where the data is stored:</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

```json
{
   "Version": "2012-10-17",
   "Statement": [
      {
         "Effect": "Allow",
         "Principal": {
            "AWS": [
               "arn:aws:iam::<consumer account id>:user/<user name>",
               "arn:aws:iam::<consumer account id>:role/<role name>",
               "arn:aws:iam::<data account id>:role/service-role/AWSGlueServiceRole-data-bucket-crawler"
            ]
       }
   ]
}
```
The bucket policy grants permissions to the IAM users and roles in the consumer account that are accessing data in the S3 bucket in the data account.

**Note:** It's possible to grant access to all principals in the consumer account (that is, to delegate responsibility for managing access to the data to an administrator in the consumer account). To do so, update the bucket policy by using "arn:aws:iam::<consumer account id>:root" instead of "arn:aws:iam::<consumer account id>:user/<user name>" and "arn:aws:iam::<consumer account id>:role/<role name>". This approach reduces
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>the operational overhead of updating the bucket policy in the data account for every principal in the consumer account. The risk is that the data owner in the data account is no longer in direct control of who in the consumer account receives access to the data because the administrator in the consumer account is free to grant it to any principal in the consumer account. This might result in access that's not authorized by the data owner.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>
| (If required) Grant principals in the consumer account access to the data encryption key. | If the S3 bucket is encrypted by an AWS KMS key, grant kms:Decrypt permission on the key to the principals in the consumer account. Update the key policy with the following statement:  

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      "arn:aws:iam::<consumer account id>:user/<user name>",
      "arn:aws:iam::<consumer account id>:role/<role name>",
      "arn:aws:iam::<data account id>:role/service-role/AWSGlueServiceRole-data-bucket-crawler"
    ],

    "Action": "kms:Decrypt",
    "Resource": "arn:aws:kms::<region>:<data account id>::key/<key id>"
  }
}
``` | Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Grant the crawler access to the data.** | Attach this IAM policy to the crawler's service role:  

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3:GetObject",
            "Resource": "arn:aws:s3:::data-bucket/*"
        },
        {
            "Effect": "Allow",
            "Action": "s3:ListBucket",
            "Resource": "arn:aws:s3:::data-bucket"
        }
    ]
}
``` | Cloud administrator |
| *(If required)* Grant the crawler access to the data encryption key. | If the S3 bucket is encrypted by an AWS KMS key, grant kms:Decrypt permission on the key to the crawler's service role by attaching the following policy to it:  

```json
{
    "Effect": "Allow",
    "Action": "kms:Decrypt",
    "Resource": "arn:aws:kms:<region>:<data account id>:key/<key id>"
}
``` | Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Grant the principals in the consumer account and the crawler access to the data catalog. | 1. Sign in to the AWS Management Console and open the AWS Glue console.  
2. In the navigation pane, under **Data Catalog**, choose **Settings**.  
3. In the **Permissions** section, add the following statement, and then choose **Save**.  

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": [
          "arn:aws:iam::<consumer account id>:user/<username>",
          "arn:aws:iam::<consumer account id>:role/<role name>",
          "arn:aws:iam::<data account id>:role/service-role/AWSGlueServiceRole-data-bucket-crawler"
        ]
      },
      "Action": "glue:**",
      "Resource": [
        "arn:aws:glue:<region>:<data account id>:catalog",
        "arn:aws:glue:<region>:<data account id>:database/**",
        "arn:aws:glue:<region>:<data account id>:table/**"
      ]
    }
  ]
}
```

This policy allows all AWS Glue actions on all databases and tables in the data account. You can customize the policy to grant only required permissions to the consumer principals. For example, you can provide read- | Cloud administrator |

- (AWS CLI) create-data-catalog (AWS CLI Command Reference)
- Cross-account AWS Glue Data Catalog access with Amazon Athena (AWS Big Data Blog)

Additional information

Using Lake Formation as an alternative for cross-account sharing

You can also use AWS Lake Formation to share access to AWS Glue catalog objects across accounts. Lake Formation provides fine-grained access control at the column and row level, tag-based access control, governed tables for ACID transactions, and other functionality. Although Lake Formation is well-integrated with Athena, it does require additional configuration compared to this pattern’s IAM-only approach. We recommend that you consider the decision to use Lake Formation or IAM-only access controls within the wider context of your overall solution architecture. Considerations include what other services are involved and how they integrate with both approaches.

Deploy and manage a serverless data lake on the AWS Cloud by using infrastructure as code

Created by Kirankumar Chandrashekar (AWS) and Abdel Jaidi (AWS)

<table>
<thead>
<tr>

AWS services: Amazon S3; Amazon SQS; AWS CloudFormation; AWS Glue; Amazon CloudWatch; AWS Lambda; AWS Step Functions; Amazon DynamoDB

Summary

This pattern describes how to use serverless computing and infrastructure as code (IaC) to implement and administer a data lake on the Amazon Web Services (AWS) Cloud. This pattern is based on the serverless data lake framework (SDLF) workshop developed by AWS.

SDLF is a collection of reusable resources that accelerate the delivery of enterprise data lakes on the AWS Cloud and helps with faster deployment to production. It is used to implement the foundational structure of a data lake by following best practices.

SDLF implements a continuous integration / continuous deployment (CI/CD) process throughout the code and infrastructure deployment by using AWS services such as AWS CodePipeline, AWS CodeBuild, and AWS CodeCommit.

This pattern uses multiple AWS serverless services to simplify data lake management. These include Amazon Simple Storage Service (Amazon S3) and Amazon DynamoDB for storage, AWS Lambda and
AWS Glue for computing, and Amazon CloudWatch Events, Amazon Simple Queue Service (Amazon SQS), and AWS Step Functions for orchestration.

AWS CloudFormation and AWS code services act as the IaC layer to provide reproducible and fast deployments with easy operations and administration.

## Prerequisites and limitations

### Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured.
- A Git client, installed and configured.
- The SDLF workshop, open in a web browser window and ready to use.

### Architecture

The architecture diagram illustrates an event-driven process with the following steps.
1. After a file is added to the raw data S3 bucket, an Amazon S3 event notification is placed in an SQS queue. Each notification is delivered as a JSON file, which contains metadata such as the S3 bucket name, object key, or timestamp.

2. This notification is consumed by a Lambda function that routes the event to the correct extraction, transformation, and loading (ETL) process based on the metadata. The Lambda function can also use contextual configurations stored in an Amazon DynamoDB table. This step enables decoupling and scaling to multiple applications in the data lake.

3. The event is routed to the first Lambda function in the ETL process, which transforms and moves data from the raw data area to the staging area for the data lake. The first step is to update the comprehensive catalog. This is a DynamoDB table that contains all the file metadata of the data lake. Each row in this table holds operational metadata about a single object stored in Amazon S3. A synchronous call is made to a Lambda function that performs a light transformation, which is a computationally inexpensive operation (such as converting a file from one format to another), on the S3 object. Because a new object has been added to the staging S3 bucket, the comprehensive catalog is updated and a message is sent to the SQS queue waiting for the next phase in the ETL.

4. A CloudWatch Events rule triggers a Lambda function every 5 minutes. This function checks if messages were delivered to the SQS queue from the previous ETL phase. If a message was delivered, the Lambda function begins the second function from AWS Step Functions in the ETL process.

5. A heavy transformation is then applied on a batch of files. This heavy transformation is a computationally expensive operation, such as a synchronous call to an AWS Glue job, AWS Fargate task, Amazon EMR step, or Amazon SageMaker notebook. Table metadata is extracted from the output files by using an AWS Glue crawler, which updates the AWS Glue catalog. File metadata is also added to the comprehensive catalog table in DynamoDB. Finally, a data quality step leveraging Deequ is also run.

**Technology stack**

- Amazon CloudWatch Events
- AWS CloudFormation
- AWS CodePipeline
- AWS CodeBuild
- AWS CodeCommit
- Amazon DynamoDB
- AWS Glue
- AWS Lambda
- Amazon S3
- Amazon SQS
- AWS Step Functions

**Tools**

- **Amazon CloudWatch Events** – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- **AWS CloudFormation** – CloudFormation helps create and provision AWS infrastructure deployments predictably and repeatedly.
- **AWS CodeBuild** – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- **AWS CodeCommit** – CodeCommit is a version control service hosted by AWS that you can use to privately store and manage assets (such as source code and binary files).
- **AWS CodePipeline** – CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software changes continuously.
- **Amazon DynamoDB** – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.
- **AWS Glue** – AWS Glue is a fully managed ETL service that makes it easier to prepare and load data for analytics.
- **AWS Lambda** – Lambda supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service. Amazon S3 can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **AWS Step Functions** - AWS Step Functions is a serverless function orchestrator that makes it easy to sequence AWS Lambda functions and multiple AWS services into business-critical applications.
- **Amazon SQS** – Amazon Simple Queue Service (Amazon SQS) is a fully managed message queuing service that helps you decouple and scale microservices, distributed systems, and serverless applications.
- **Deequ** – Deequ is a tool that helps you compute data quality metrics for large datasets, define and verify data quality constraints, and stay informed about changes in the data distribution.

**Code**

The source code and resources for the SDLF are available in the [AWS Labs GitHub repository](https://github.com/awslabs/sdlf).

Migrate Hadoop data to Amazon S3 by using WANdisco LiveData Migrator

*Created by Tony Velcich*

<table>
<thead>
<tr>
<th>Source: On-premises Hadoop cluster</th>
<th>Target: Amazon S3</th>
<th>R Type: Rehost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment: Production</td>
<td>Technologies: Data lakes; Big data; Hybrid cloud; Migration</td>
<td>Workload: All other workloads</td>
</tr>
<tr>
<td>AWS services: Amazon S3</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern describes the process for migrating Apache Hadoop data from a Hadoop Distributed File System (HDFS) to Amazon Simple Storage Service (Amazon S3). It uses WANdisco LiveData Migrator to automate the data migration process.

**Prerequisites and limitations**

**Prerequisites**

- Hadoop cluster edge node where LiveData Migrator will be installed. The node should meet the following requirements:
  - Minimum specification: 4 CPUs, 16 GB RAM, 100 GB storage.
  - 2 Gbps minimum network.
  - Port 8081 accessible on your edge node to access the WANdisco UI.
  - Java 1.8 64-bit.
  - Hadoop client libraries installed on the edge node.
  - Ability to authenticate as the HDFS superuser (for example, "hdfs").
  - If Kerberos is enabled on your Hadoop cluster, a valid keytab that contains a suitable principal for the HDFS superuser must be available on the edge node.
  - See the release notes for a list of supported operating systems.
  - An active AWS account with access to an S3 bucket.
  - An AWS Direct Connect link established between your on-premises Hadoop cluster (specifically the edge node) and AWS.

**Product versions**

- LiveData Migrator 1.8.6
- WANdisco UI (OneUI) 5.8.0

**Architecture**

Source technology stack
On-premises Hadoop cluster

Target technology stack

- Amazon S3

Architecture

The workflow consists of four primary components for data migration from on-premises HDFS to Amazon S3.

- LiveData Migrator – Automates the migration of data from HDFS to Amazon S3, and resides on an edge node of the Hadoop cluster.
- HDFS – A distributed file system that provides high-throughput access to application data.
- Amazon S3 – An object storage service that offers scalability, data availability, security, and performance.
- AWS Direct Connect – A service that establishes a dedicated network connection from your on-premises data centers to AWS.

Automation and scale

You will typically create multiple migrations so that you can select specific content from your source file system by path or directory. You can also migrate data to multiple, independent file systems at the same time by defining multiple migration resources.

Epics

Configure Amazon S3 storage in your AWS account

## Configure storage through the WANdisco UI

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register your LiveData Migrator account.</td>
<td>Log in to the WANdisco UI through a web browser on port 8081 (on the Hadoop edge node) and provide your details for registration. For example, if you are running LiveData Migrator on a host named myldmhost.example.com, the URL would be: <a href="http://myldmhost.example.com:8081">http://myldmhost.example.com:8081</a></td>
<td>Application owner</td>
</tr>
<tr>
<td>Configure your source HDFS storage.</td>
<td>Provide the configuration details needed for your source HDFS storage. This will include the &quot;fs.defaultFS&quot; value and a user-defined storage name. If Kerberos is enabled, provide the principal and keytab location for LiveData Migrator to use. If NameNode HA is enabled on the cluster, provide a path to the core-site.xml and hdfs-site.xml files on the edge node.</td>
<td>Hadoop administrator, Application owner</td>
</tr>
<tr>
<td>Configure your target Amazon S3 storage.</td>
<td>Add your target storage as the S3a type. Provide the user-defined storage name and the S3 bucket name. Enter &quot;org.apache.hadoop.fs.s3a.SimpleAWSCredentialsProvider&quot; for the Credentials Provider option, and provide the AWS access and secret keys for the S3 bucket. Additional S3a properties will also be needed. For details, see the &quot;S3a Properties&quot; section in the LiveData Migrator documentation at <a href="https://docs.wandisco.com/live-data-migrator/docs/command-reference/#filesystem-add-s3a">https://docs.wandisco.com/live-data-migrator/docs/command-reference/#filesystem-add-s3a</a>.</td>
<td>AWS, Application owner</td>
</tr>
</tbody>
</table>

## Prepare for the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add exclusions (if needed).</td>
<td>If you want to exclude specific datasets from migration, add exclusions for the source HDFS storage. These exclusions can be based on file size, file names</td>
<td>Hadoop administrator, Application owner</td>
</tr>
</tbody>
</table>
## AWS Prescriptive Guidance Patterns

### Additional information

#### Installing LiveData Migrator

You can use the following commands to install LiveData Migrator, assuming that the installer is inside your working directory:

```bash
su - hdfs
chmod +x livedata-migrator.sh && sudo ./livedata-migrator.sh
```

#### Checking the status of LiveData Migrator and other services after installation

Use the following commands to check the status of LiveData Migrator, Hive migrator, and WANdisco UI:

```bash
service livedata-migrator status
service hivemigrator status
service livedata-ui status
```

**Summary**

This pattern describes how to access on-premises Microsoft SQL Server database tables running on Microsoft Windows, from Microsoft SQL Server databases running on Amazon Elastic Compute Cloud (Amazon EC2) Windows or Linux instances by using linked servers.

**Prerequisites and limitations**

**Prerequisites**
- An active AWS account
- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI (Amazon Machine Image)
- AWS Direct Connect between the on-premises Microsoft SQL Server (Windows) server and the Linux EC2 instance

**Architecture**

**Source technology stack**
- On-premises Microsoft SQL Server database running on Windows
- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI

**Target technology stack**
- Amazon EC2 with Microsoft SQL Server running on Amazon Linux AMI
- Amazon EC2 with Microsoft SQL Server running on Windows AMI

**Source and target database architecture**
Tools

- **SSMS** - Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing a SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>In the SSMS query window, run the query: <code>select top 3 * from [sqllin].dms_sample_win.dbo.mlb_data</code>. Note that the FROM clause uses a four-part syntax: <code>computer.database.schema.table</code> (e.g., <code>SELECT name &quot;SQL2 databases&quot; FROM [sqllin].master.sys.databases</code>). In our example, we created an alias for SQL2 in the hosts file, so you don't need to enter the actual NetBIOS name between the square brackets. If you do use the actual NetBIOS names, note that AWS defaults to NetBIOS names like <code>Win-xxxx</code>, and SQL Server requires square brackets for names with dashes.</td>
<td></td>
<td>DBA, Developer</td>
</tr>
</tbody>
</table>

Related resources

- Release notes for SQL Server on Linux

Additional information

**Using stored procedures to create linked servers**

SSMS doesn't support the creation of linked servers for Linux SQL Server, so you have to use these stored procedures to create them:

```sql
EXEC master.sys.sp_addlinkedserver @server= N'SQLLIN' , @srvproduct= N'SQL Server'
EXEC master.dbo.sp_addlinkedsrvlogin @rmtsrvname=N'SQLLIN',@useself=N'False',@locallogin=NULL,@rmtuser=N'username',@rmtpassword='Test123$'
```

Note 1: Enter the user name and password that you created earlier in Windows SQL Server in the stored procedure `master.dbo.sp_addlinkedsrvlogin`.

Note 2: `@server name SQLLIN and host file entry name 172.12.12.4 SQLLIN should be the same.`

You can use this process to create linked servers for the following scenarios:

- Linux SQL Server to Windows SQL Server through a linked server (as specified in this pattern)
- Windows SQL Server to Linux SQL Server through a linked server
- Linux SQL Server to another Linux SQL Server through a linked server
Automatically back up SAP HANA databases using Systems Manager and EventBridge

Created by Ambarish Satarkar (AWS) and Gaurav Rath

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: Production</th>
<th>Technologies: Databases; Storage &amp; backup</th>
</tr>
</thead>
<tbody>
<tr>
<td>HDB_Backup_SSM_Document</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern describes how to automate SAP HANA database backups using AWS Systems Manager, Amazon EventBridge, Amazon Simple Storage Service (Amazon S3), and AWS Backint Agent for SAP HANA.

This pattern provides a shell script-based approach using the BACKUP DATA command and removes the need to maintain scripts and job configurations for each operating system (OS) instance across numerous systems.

**Prerequisites and limitations**

**Prerequisites**

- An existing SAP HANA instance with a supported release in running state on a managed Amazon Elastic Compute Cloud (Amazon EC2) instance that is configured for Systems Manager
- Systems Manager Agent (SSM Agent) 2.3.274.0 or later installed
- An S3 bucket that doesn't have public access enabled
- An hdbuserstore key named SYSTEM
- An AWS Identity and Access Management (IAM) role for the Automation runbook to run on schedule
- AmazonSSMManagedInstanceCore and ssm:StartAutomationExecution policies are attached to Systems Manager Automation service role.

**Limitations**

- AWS Backint Agent for SAP HANA doesn't support deduplication.
- AWS Backint Agent for SAP HANA doesn't support data compression.

**Product versions**

AWS Backint Agent is supported on the following operating systems:

- SUSE Linux Enterprise Server
- SUSE Linux Enterprise Server for SAP
- Red Hat Enterprise Linux for SAP
AWS Backint Agent supports the following databases:

- SAP HANA 1.0 SP12 (single node and multiple nodes)
- SAP HANA 2.0 and later (single node and multiple nodes)

Architecture

Target Technology Stack

- AWS Backint Agent
- Amazon S3
- AWS Systems Manager
- Amazon EventBridge
- SAP HANA

Target Architecture

The following diagram shows the installation scripts that install AWS Backint Agent, the S3 bucket, and Systems Manager and EventBridge, which use a Command document to schedule regular backups.

Automation and Scale

- Multiple AWS Backint Agents can be installed by using a Systems Manager Automation runbook.
- Each run of the Systems Manager runbook can scale to \( n \) number of SAP HANA instances, based on target selection.
- EventBridge can automate SAP HANA backups.

Tools

- **AWS Backint Agent for SAP HANA** is a standalone application that integrates with your existing workflows to back up your SAP HANA database to an S3 bucket that you specify in the configuration file. AWS Backint Agent supports full, incremental, and differential backups of SAP HANA databases. It runs on an SAP HANA database server, where backups and catalogs are transferred from the SAP HANA database to the AWS Backint Agent.
- **Amazon EventBridge** is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your...
applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.

- **Amazon Simple Storage Service (Amazon S3)** is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **AWS Systems Manager** helps you to view and control your infrastructure on AWS. Using the Systems Manager console, you can view operational data from multiple AWS services and automate operational tasks across your AWS resources.

## Code

The code for this pattern is available in the [aws-backint-automated-backup GitHub repository](https://github.com/).

</tr>
</thead>
</table>
| Create an hdbuserstore key. | 1. Navigate to `/usr/sap/<SID>/HDB<Inst No>/exe`.  
                          | 2. Run the following command, with XX as the SAP HANA database instance number.  
                          | `hdbuserstore -i set SYSTEM <hostname>:3XX13@SYSTEMDB SYSTEM`  
                          | For example, for an SAP HANA host saphanadb with instance number 00, run the following command.  
                          | `hdbuserstore -i set SYSTEM saphanadb:30013@SYSTEMDB SYSTEM` | AWS administrator, SAP HANA Administrator |

### Install AWS Backint Agent

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install AWS Backint Agent.</td>
<td>Follow the instructions in <a href="https://aws.amazon.com">Install and configure AWS Backint Agent for SAP HANA</a> in the AWS Backint Agent documentation.</td>
<td>AWS administrator, SAP HANA administrator</td>
</tr>
</tbody>
</table>
Create the Systems Manager Command document

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the Systems Manager Command document. | 1. Sign in to the AWS Management Console and open the AWS Systems Manager Console.  
2. Choose Documents, and choose Owned by me.  
3. Confirm that you are in the same AWS Region as your SAP HANA database.  
4. Choose Create document, Command or session to create your document.  
5. Use a unique and descriptive name, with no spaces (for example, SAP HANA-Backup).  
6. Make sure that Document type is set to Command document.  
7. Under the Content header, there is some sample code. Make sure that you choose the JSON code type, and replace the code with the code from the HDB_Backup_SSM_Document.json file from the GitHub repository.  
8. Choose Create document.  
9. Check your document in the Owned by me section. | AWS administrator, SAP HANA administrator |

Schedule backups on a regular frequency

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Schedule regular backups using Amazon EventBridge. | 1. Open the Amazon EventBridge console, choose Rules, and choose Create rule.  
2. On the Define rule detail screen, enter a unique name and description for your rule, and use the default event bus.  
3. Under Rule type, choose Schedule, and choose Next.  
4. On the Define schedule screen, choose the | AWS administrator, SAP HANA administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>appropriate schedule pattern and cron or rate expression based on the required frequency.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>On the <strong>Select targets</strong> screen, for <strong>Target type</strong>, choose <strong>AWS service</strong>. Under <strong>Select a target</strong>, choose <strong>Systems Manager Run Command</strong>.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>Choose the document that you created earlier.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>Under <strong>Target key</strong> and <strong>Target value</strong>, provide the instance ID. You can use tag names and tag values to add multiple instances.</td>
<td></td>
</tr>
<tr>
<td>8.</td>
<td>Under <strong>Configure automation parameters</strong>, choose <strong>Constant</strong> for incremental or differential backups. If you want full backup, choose <strong>No Parameters</strong>.</td>
<td></td>
</tr>
<tr>
<td>9.</td>
<td>Choose whether to create a new role or to use an existing role. If you use an existing role, make sure that it has the policies required to invoke the target.</td>
<td></td>
</tr>
<tr>
<td>10.</td>
<td>Keep the default additional settings, and choose <strong>Next</strong>.</td>
<td></td>
</tr>
<tr>
<td>11.</td>
<td>The <strong>Configure tags</strong> screen is optional. Choose <strong>next</strong>.</td>
<td></td>
</tr>
<tr>
<td>12.</td>
<td>On the <strong>Review and create</strong> screen, review the rule settings, and choose <strong>Create</strong>. The rule should be successfully created.</td>
<td></td>
</tr>
</tbody>
</table>

You can verify backup success from the S3 bucket path.

```
s3://<your_bucket_name>/<target_folder>/<SID>/usr/sap/<SID>/SYS/global/hdb/backint/DB_<SID>/
```

You can also verify backups from the SAP HANA backup catalog.
Copy Amazon DynamoDB tables across accounts using AWS Backup

*Created by Ramkumar Ramanujam (AWS)*

**Summary**

When working with Amazon DynamoDB on Amazon Web Services (AWS), a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that is in the production environment. As a standard practice, each environment uses a different AWS account.

AWS Backup supports cross-Region and cross-account backup and restore of data for DynamoDB, Amazon Simple Storage Service (Amazon S3), and other AWS services. This pattern provides the steps for using AWS Backup cross-account backup and restore to copy DynamoDB tables between AWS accounts.

**Prerequisites and limitations**

**Prerequisites**

- Two active AWS accounts that belong to the same AWS Organizations organization
- DynamoDB tables in both the accounts.
- AWS Identity and Access Management (IAM) permissions to create and use AWS backup vaults

**Limitations**

- Source and target AWS accounts should be part of the same AWS Organizations organization.

**Architecture**

**Target technology stack**

- AWS Backup
- Amazon DynamoDB

**Target architecture**
1. Create the DynamoDB table backup in the AWS Backup backup vault in the source account.
2. Copy the backup to the backup vault in the target account.
3. Restore the DynamoDB table in the target account using the backup from the target account backup vault.

**Automation and scale**

You can use AWS Backup to schedule backups to run at specific intervals.

**Tools**

- **AWS Backup** – AWS Backup is a fully-managed service for centralizing and automating data protection across AWS services, in the cloud, and on premises. Using this service, you can configure backup policies and monitor activity for your AWS resources in one place. It allows you to automate and consolidate backup tasks that were previously performed service-by-service, and removes the need to create custom scripts and manual processes.
- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.
# Epics

**Turn on AWS Backup features in the source and target accounts**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Turn on advanced features for DynamoDB and cross-account backup. | In both the source and the target AWS accounts, do the following:  
1. On the AWS Management Console, open the AWS Backup console.  
2. Choose Settings.  
3. Under Advanced features for Amazon DynamoDB backups, confirm that Advanced features is enabled, or choose Enable.  
4. Under Cross-account management, for Cross-account backup, choose Enable. | AWS DevOps, Migration engineer |

**Create backup vaults in the source and target accounts**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create backup vaults.    | In both the source and the target AWS accounts, do the following:  
1. On the AWS Backup console, choose Backup vaults.  
2. Choose Create Backup vault.  
3. Copy the Amazon Resource Name (ARN) of the backup vault and save it.  
4. The ARNs of both the source and the target backup vaults will be required when you copying the DynamoDB table backup between the source account and the target account. | AWS DevOps, Migration engineer |
# Perform backup and restore using backup vaults

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| In the source account, create a DynamoDB table backup. | To create a backup for the DynamoDB table in the source account, do the following:  
1. On the AWS Backup Dashboard page, choose Create on-demand backup.  
2. In the Settings section, for Resource type, select DynamoDB, and then select the table name.  
3. In the Backup vault dropdown list, select the backup vault that you created in the source account.  
4. Select the Retention period that you want.  
5. Choose Create on-demand backup.  
   A new backup job is created.  
   To monitor the status of the backup job, on the AWS Backup Jobs page, choose the Backup Jobs tab. All active, in-progress, and completed backup jobs are listed in this tab. | AWS DevOps, DBA, Migration engineer |
| Copy the backup from the source account to the target account. | After the backup job is completed, copy the DynamoDB table backup from the backup vault in the source account to the backup vault in target account.  
To copy the backup vault, in the source account, do the following:  
1. On the AWS Backup console, choose Backup vaults.  
2. Under Backups, choose the DynamoDB table backup.  
3. Choose Actions, Copy.  
4. Enter the AWS Region of the target account.  
5. For External vault ARN, enter the ARN of the backup vault that you created in the target account. | AWS DevOps, Migration engineer, DBA |

</tbody>
</table>

### Summary

When working with Amazon DynamoDB on Amazon Web Services (AWS), a common use case is to copy or sync DynamoDB tables in development, testing, or staging environments with the table data that are in the production environment. As a standard practice, each environment uses a different AWS account.

DynamoDB now supports cross-account backup using AWS Backup. For information about associated storage costs when using AWS Backup, see AWS Backup pricing. When you use AWS Backup to copy across accounts, the source and target accounts must be part of an AWS Organizations organization. There are other solutions for cross-account backup and restore using AWS services such as AWS Data
Pipeline or AWS Glue. Using those solutions, however, increases the application footprint, because there are more AWS services to deploy and maintain.

You can also use Amazon DynamoDB Streams to capture table changes in the source account. Then you can initiate an AWS Lambda function, and make the corresponding changes in the target table in the target account. But that solution applies to use cases in which source and target tables must always be kept in sync. It might not apply to development, testing, and staging environments where data are updated frequently.

This pattern provides steps to implement a custom solution to copy a Amazon DynamoDB table from one account to another. This pattern can be implemented using common programming languages such as C#, Java, and Python. We recommend using a language that is supported by an AWS SDK.

**Prerequisites and limitations**

**Prerequisites**

- Two active AWS accounts
- DynamoDB tables in both the accounts
- Knowledge of AWS Identity and Access Management (IAM) roles and policies
- Knowledge of how to access Amazon DynamoDB tables using any common programming language, such as C#, Java, or Python

**Limitations**

This pattern applies to DynamoDB tables that are around 2 GB or smaller. With additional logic to handle connection or session interruptions, throttling, and failures and retries, it can be used for larger tables.

The DynamoDB scan operation, which reads items from the source table, can fetch only up to 1 MB of data in a single call. For larger tables, greater than 2 GB, this limitation can increase the total time to perform a full table copy.

**Architecture**

**Automation and scale**

This pattern applies to DynamoDB tables that are smaller in size, around 2 GB.

To apply this pattern for larger tables, address the following issues:
• During the table copy operation, two active sessions are maintained, using different security tokens. If the table copy operation takes longer than the token expiration times, you must put in place logic to refresh the security tokens.

• If enough read capacity units (RCUs) and write capacity units (WCUs) are not provisioned, reads or writes on the source or target table might get throttled. Be sure to catch and handle these exceptions.

• Handle any other failures or exceptions and put a retry mechanism in place to retry or continue from where the copy operation failed.

Tools

Tools

• Amazon DynamoDB – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

• The additional tools required will differ based on the programming language that you choose for the implementation. For example, if you use C#, you will need Microsoft Visual Studio and the following NuGet packages:
  
  • AWSSDK
  • AWSSDK.DynamoDBv2

Code

The following Python code snippet deletes and recreates a DynamoDB table using the Boto3 library.

```python
import boto3
import sys
import json

#args = input-parameters = GLOBAL_SEC_INDEXES_JSON_COLLECTION, ATTRIBUTES_JSON_COLLECTION, TARGET_DYNAMODB_NAME, TARGET_REGION, ...

#Input param: GLOBAL_SEC_INDEXES_JSON_COLLECTION
#][{"IndexName":"Test-index","KeySchema":[{"AttributeName":"AppId","KeyType":"HASH"},
{"AttributeName":"AppType","KeyType":"RANGE"}],"Projection":
{"ProjectionType":"INCLUDE","NonKeyAttributes":["PK","SK","OwnerName","AppVersion"]}]

#Input param: ATTRIBUTES_JSON_COLLECTION
#][{"AttributeName":"PK","AttributeType":"S"},{"AttributeName":"SK","AttributeType":"S"},
{"AttributeName":"AppId","AttributeType":"S"},
{"AttributeName":"AppType","AttributeType":"N"}]

region = args['TARGET_REGION']
target_ddb_name = args['TARGET_DYNAMODB_NAME']

global_secondary_indexes = json.loads(args['GLOBAL_SEC_INDEXES_JSON_COLLECTION'])
attribute_definitions = json.loads(args['ATTRIBUTES_JSON_COLLECTION'])

# Drop and create target DynamoDB table
dynamodb_client = boto3.Session(
    aws_access_key_id=args['AWS_ACCESS_KEY_ID'],
    aws_secret_access_key=args['AWS_SECRET_ACCESS_KEY'],
    aws_session_token=args['TEMPORARY_SESSION_TOKEN'],
).client('dynamodb')

# Delete table
print('Deleting table: ' + target_ddb_name + ' ...')
try:
```
dynamodb_client.delete_table(TableName=target_ddb_name)
# Wait for table deletion to complete
waiter = dynamodb_client.get_waiter('table_not_exists')
waiter.wait(TableName=target_ddb_name)
print('Table deleted. ')
except dynamodb_client.exceptions.ResourceNotFoundException:
    print('Table already deleted / does not exist. ')
    pass

print('Creating table: ' + target_ddb_name + ' ...')
table = dynamodb_client.create_table(
    TableName=target_ddb_name,
    KeySchema=[
        {
            'AttributeName': 'PK',
            'KeyType': 'HASH'  # Partition key
        },
        {
            'AttributeName': 'SK',
            'KeyType': 'RANGE'  # Sort key
        }
    ],
    AttributeDefinitions=attribute_definitions,
    GlobalSecondaryIndexes=global_secondary_indexes,
    BillingMode='PAY_PER_REQUEST'
)
waiter = dynamodb_client.get_waiter('table_exists')
waiter.wait(TableName=target_ddb_name)
print('Table created. ')

<tr>
<td></td>
<td>• Perform a scan on the table in the source account, using the source DynamoDB client. Each DynamoDB scan retrieves only 1 MB of data from the table, so you must repeat this operation until all items, or records, are read.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• For each set of scanned items, write the items to the table in the target account, with the target DynamoDB client, using the BatchWriteItem call in AWS SDK for DynamoDB. This reduces the number of PutItem requests made to DynamoDB.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• BatchWriteItem has a limitation of 25 writes or puts, or up to 16 MB. You must add logic to accumulate scanned items in counts of 25 before calling BatchWriteItem. BatchWriteItem returns a list of items that could not be successfully copied. Using this list, add retry logic to perform another BatchWriteItem call with only those items that did not succeed.</td>
<td></td>
</tr>
</tbody>
</table>

For more information, see the reference implementation in C# (for dropping, creating, and populating tables) in the Attachments section. An example table config JavaScript Object Notation (JSON) file is also attached.

Related resources

- Creating an IAM user in your AWS account
- AWS SDKs
Additional information

This pattern was implemented using C# to copy a DynamoDB table with 200,000 items (average item size of 5 KB and table size of 250 MB). The target DynamoDB table was set up with provisioned capacity of 4000 RCUs and 4000 WCUs.

The complete table copy operation (from source account to target account), including dropping and recreating the table, took 5 minutes. Total capacity units consumed: 30,000 RCUs and approximately 400,000 WCUs.

For more information on DynamoDB capacity modes, see Read/Write capacity mode in the AWS documentation.

Create detailed cost and usage reports for Amazon RDS and Amazon Aurora

*Created by Lakshmanan Lakshmanan (AWS) and Sudarshan Narasimhan*

| Environment: Production | Technologies: Databases; Cost management; Analytics | AWS services: Amazon Athena; Amazon Aurora; Amazon RDS; AWS Billing and Cost Management |

Summary

This pattern shows how to track usage costs for Amazon Relational Database Service (Amazon RDS) or Amazon Aurora clusters by configuring user-defined cost allocation tags. You can use these tags to create detailed cost and usage reports in AWS Cost Explorer for clusters across multiple dimensions. For example, you can track usage costs at the team, project, or cost center level, and then analyze the data in Amazon Athena.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- One or more Amazon RDS or Amazon Aurora instances

**Limitations**

For tagging restrictions, see the AWS Billing User Guide.
Architecture

Target technology stack

- Amazon RDS or Amazon Aurora
- AWS Cost and Usage Report
- AWS Cost Explorer
- Amazon Athena

Workflow and architecture

The tagging and analysis workflow consists of these steps:

1. A data engineer, database administrator, or AWS administrator creates user-defined cost allocation tags for the Amazon RDS or Aurora clusters.
2. An AWS administrator activates the tags.
3. The tags report metadata to AWS Cost Explorer.
4. A data engineer, database administrator, or AWS administrator creates a monthly cost allocation report.
5. A data engineer, database administrator, or AWS administrator analyzes the monthly cost allocation report by using Amazon Athena.

The following diagram shows how to apply tags to track usage costs for Amazon RDS or Aurora instances.

The following architecture diagram shows how the cost allocation report is integrated with Amazon Athena for analysis.
The monthly cost allocation report is stored in an Amazon S3 bucket that you specify. When you set up Athena with the AWS CloudFormation template, as described in the Epics section, the template provisions several additional resources, including an AWS Glue crawler, an AWS Glue database, an Amazon Simple Notification System (Amazon SNS) event, AWS Lambda functions, and AWS Identity and Access Management (IAM) roles for the Lambda functions. As new cost data files arrive in the S3 bucket, event notifications are used to forward these files to a Lambda function for processing. The Lambda function initiates an AWS Glue crawler job to create or update the table in the AWS Glue Data Catalog. This table is then used to query data in Athena.

Tools

- **Amazon Athena** is an interactive query service that makes it easy to analyze data in Amazon S3 using standard SQL.
- **Amazon Aurora** is a fully managed relational database engine that's built for the cloud and compatible with MySQL and PostgreSQL.
- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.
- **AWS CloudFormation** is an infrastructure as code (IaC) service that allows you to easily model, provision, and manage AWS and third-party resources.
- **AWS Cost Explorer** helps you view and analyze your AWS costs and usage.

Deploy DataStax Enterprise on AWS

Created by Baji Shaik (AWS)

<table>
<thead>
<tr>
<th>Created by:</th>
<th>APN Partner</th>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Databases</th>
</tr>
</thead>
</table>

Summary

This pattern describes how you can deploy DataStax Enterprise (DSE) automatically into an Amazon Web Services (AWS) Cloud configuration of your choice.

DSE is the always-on data platform for cloud applications powered by Apache Cassandra. The DSE platform is designed to handle big data workloads across multiple nodes with no single point of failure. DSE addresses the problem of failures by employing a peer-to-peer distributed system across homogeneous nodes where data is distributed among all nodes in the cluster. DSE offers advanced functionality designed to accelerate your ability to create intelligent and compelling cloud applications. Integrated within each node of DSE is powerful indexing, search, analytics, and graph functionality, provided by combining Cassandra with Apache Solr, Apache Spark, and DSE Graph. You can write data once, and access it using a variety of workloads or access patterns, all from a single cohesive solution.

This pattern leverages the AWS Quick Start developed by DataStax in collaboration with Amazon Web Services (AWS). DataStax is an AWS Partner Network (APN) Partner.

Prerequisites and limitations

- An active AWS account

Architecture

Source technology stack

- Not applicable

Target technology stack
This target architecture incorporates the following components:

- A highly available architecture that spans three Availability Zones.
- A virtual private cloud (VPC) configured with public and private subnets, to provide you with your own virtual network.
- An internet gateway to allow access to the internet.
- Managed network address translation (NAT) gateways to allow outbound internet access for resources in the private subnets.
- One Amazon Elastic Compute Cloud (Amazon EC2) instance running DSE OpsCenter, which is the DSE cluster-management web console.
- Additional Amazon EC2 instances for DSE data centers and nodes. A DSE data center is a logical grouping of nodes for workload separation.
- One Amazon Elastic Block Store (Amazon EBS) data volume per node instance deployed.

**Target architecture**

**Tools**

- Quick Start: DataStax Enterprise on AWS
Epics

Access and deploy the Quick Start

Emulate Oracle RAC workloads using custom endpoints in Aurora PostgreSQL

Created by HariKrishna Boorgadda (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Databases: Relational</th>
<th>Target:</th>
<th>Aurora PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Replatform</td>
<td>Workload:</td>
<td>Oracle</td>
<td>Technologies:</td>
<td>Databases; Migration</td>
</tr>
</tbody>
</table>
Summary

This pattern describes how to emulate services in an Oracle Real Application Clusters (Oracle RAC) workload by using Amazon Aurora PostgreSQL-Compatible Edition with custom endpoints that distribute workloads across instances within a single cluster. The pattern shows you how to create custom endpoints for Amazon Aurora databases. Custom endpoints enable you to distribute and load balance workloads across different sets of DB instances in your Aurora cluster.

In an Oracle RAC environment, services can span one or more instances and facilitate workload balancing based on transaction performance. Service features include end-to-end unattended recovery, rolling changes by workload, and full location transparency. You can use this pattern to emulate some of these features. For example, you can emulate the ability to route connections for reporting applications.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A PostgreSQL JDBC driver
- An Aurora PostgreSQL-Compatible database
- An Oracle RAC database migrated to an Aurora PostgreSQL-Compatible database

Limitations

- For limitations that apply to custom endpoints, see Specifying properties for custom endpoints in the Amazon RDS documentation.

Architecture

Source technology stack

- A three-node Oracle RAC database

Target technology stack

- An Aurora PostgreSQL-Compatible database with two read replicas

Source architecture

The following diagram shows the architecture of a three-node Oracle RAC database.
Target architecture

The following diagram shows the architecture of an Aurora PostgreSQL-Compatible database with two read replicas. Three different applications/services are using custom endpoints, which serve different application users and redirect the traffic and load between primary and read replicas.
Tools

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon CloudWatch** helps you monitor the metrics of your AWS resources and the applications that you run on AWS in real time.
- **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

### Encrypt an existing Amazon RDS for PostgreSQL DB instance

*Created by Piyush Goyal (AWS), Shobana Raghu (AWS), and Yaser Raja (AWS)*

| Environment: | Production | Technologies: Databases; Security, identity, compliance | AWS services: Amazon RDS; AWS KMS; AWS DMS |
Summary

This pattern explains how to encrypt an existing Amazon Relational Database Service (Amazon RDS) for PostgreSQL DB instance in the Amazon Web Services (AWS) Cloud with minimal downtime. This process works for Amazon RDS for MySQL DB instances as well.

You can enable encryption for an Amazon RDS DB instance when you create it, but not after it's created. However, you can add encryption to an unencrypted DB instance by creating a snapshot of your DB instance, and then creating an encrypted copy of that snapshot. You can then restore a DB instance from the encrypted snapshot to get an encrypted copy of your original DB instance. If your project allows for downtime (at least for write transactions) during this activity, this is all you need to do. When the new, encrypted copy of the DB instance becomes available, you can point your applications to the new database. However, if your project doesn't allow for significant downtime for this activity, you need an alternate approach that helps minimize the downtime. This pattern uses the AWS Database Migration Service (AWS DMS) to migrate and continuously replicate the data so that the cutover to the new, encrypted database can be done with minimal downtime.

Amazon RDS encrypted DB instances use the industry standard AES-256 encryption algorithm to encrypt your data on the server that hosts your Amazon RDS DB instances. After your data is encrypted, Amazon RDS handles authentication of access and decryption of your data transparently, with minimal impact on performance. You don't need to modify your database client applications to use encryption.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An unencrypted Amazon RDS for PostgreSQL DB instance
- Experience working with (creating, modifying, or stopping) AWS DMS tasks (see Working with AWS DMS tasks in the AWS DMS documentation)
- Familiarity with AWS Key Management Service (AWS KMS) for encrypting databases (see the AWS KMS documentation)

Limitations

- You can enable encryption for an Amazon RDS DB instance only when you create it, not after the DB instance is created.
- Data in unlogged tables will not be restored using snapshots. For more information, review Best practices for working with PostgreSQL.
- You can't have an encrypted read replica of an unencrypted DB instance or an unencrypted read replica of an encrypted DB instance.
- You can't restore an unencrypted backup or snapshot to an encrypted DB instance.
- AWS DMS does not automatically transfers the Sequences therefore additional steps are required to handle this.

For more information, see Limitations of Amazon RDS encrypted DB instances in the Amazon RDS documentation.

Architecture

Source architecture

- Unencrypted RDS DB instance
Target architecture

- Encrypted RDS DB instance
  - The destination RDS DB instance is created by restoring the DB snapshot copy of the source RDS DB instance.
  - An AWS KMS key is used for encryption while restoring the snapshot.
  - An AWS DMS replication task is used to migrate the data.

Tools

Tools used to enable encryption:
• AWS KMS key for encryption – When you create an encrypted DB instance, you can choose a customer managed key or the AWS managed key for Amazon RDS to encrypt your DB instance. If you don’t specify the key identifier for a customer managed key, Amazon RDS uses the AWS managed key for your new DB instance. Amazon RDS creates an AWS managed key for Amazon RDS for your AWS account. Your AWS account has a different AWS managed key for Amazon RDS for each AWS Region. For more information about using KMS keys for Amazon RDS encryption, see Encrypting Amazon RDS Resources.

Tools used for ongoing replication:

• AWS DMS – You can use AWS Database Migration Service (AWS DMS) to replicate changes from the source DB to the target DB. It is important to keep the source and target DB in sync to keep downtime to a minimum. For information about setting up AWS DMS and creating tasks, see the AWS DMS documentation.

Epics

Create a snapshot of the source DB instance and encrypt it

</tbody>
</table>

**Summary**

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the Amazon Web Services (AWS) Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

You can use tagging to categorize your AWS resources in different ways. Relational database tagging is useful when you have many resources in your account and you want to quickly identify a specific resource based on the tags. You can use Amazon RDS tags to add custom metadata to your RDS DB instances. A tag consists of a user-defined key and value. We recommend that you create a consistent set of tags to meet your organization's requirements.

This pattern provides an AWS CloudFormation template to help you monitor and tag RDS DB instances. The template creates an Amazon CloudWatch Events event that watches for the AWS CloudTrail CreateDBInstance event. (CloudTrail captures API calls for Amazon RDS as events.) When it detects this event, it calls an AWS Lambda function that automatically applies tag keys and values that you define. The template also sends out a notification that the instance has been tagged, by using Amazon Simple Notification Service (Amazon SNS).
Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the Lambda code.
- An email address where you would like to receive tagging notifications.

Limitations

- The solution supports CloudTrail CreateDBInstance events. It does not create notifications for any other events.

Architecture

Workflow architecture

Automation and scale

- You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

Tools

AWS services

- **AWS CloudTrail** – AWS CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

Code
This pattern includes an attachment with two files:

- `index.zip` is a compressed file that includes the Lambda code for this pattern.
- `rds.yaml` is a CloudFormation template that deploys the Lambda code.

See the Epics section for information about how to use these files.

**Epics**

### Deploy the Lambda code

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Upload the code to an S3 bucket.</td>
<td>Create a new S3 bucket or use an existing S3 bucket to upload the attached <code>index.zip</code> file (Lambda code). This bucket must be in the same AWS Region as the resources (RDS DB instances) that you want to monitor.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Deploy the CloudFormation template.</td>
<td>Open the CloudFormation console in the same AWS Region as the S3 bucket, and deploy the <code>rds.yaml</code> file that's provided in the attachment. In the next epic, provide values for the template parameters.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>

### Complete the parameters in the CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provide the S3 bucket name.</td>
<td>Enter the name of the S3 bucket that you created or selected in the first epic. This S3 bucket contains the .zip file for the Lambda code and must be in the same AWS Region as the CloudFormation template and the RDS DB instances that you want to monitor.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Provide the S3 key.</td>
<td>Provide the location of the Lambda code .zip file in your S3 bucket, without leading slashes (for example, <code>index.zip</code> or <code>controls/index.zip</code>).</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Provide an email address.</td>
<td>Provide an active email address where you want to receive violation notifications.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Specify a logging level.</td>
<td>Specify the logging level and verbosity. Info designates</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
Enter the tag keys and values for your RDS DB instances.

Enter the required tag keys and values that you want to automatically apply to the RDS instance. For more information, see Tagging Amazon RDS resources in the AWS documentation.

Cloud architect

Confirm the email subscription.

When the CloudFormation template deploys successfully, it sends a subscription email message to the email address you provided. To receive notifications when your instances are tagged, you must confirm this email subscription.

Estimate the cost of a DynamoDB table for on-demand capacity
Summary

Amazon DynamoDB is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This Amazon Web Services (AWS) serverless offering is getting popular because of its consistent performance and scalability. You do not need to provision underlying infrastructure. Your single table can grow up to petabytes.

With on-demand capacity mode, you pay per request for the data reads and writes that your application performs on the tables. AWS charges are based on the accumulated read request units (RRUs) and write request units (WRUs) in a month. DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. It supports continuous backup with point-in-time-recovery (PITR). DynamoDB monitors the size of your PITR-enabled tables continuously throughout the month to determine your backup charges.

To estimate the DynamoDB cost for a project, it's important to calculate how much RRU, WRU, and storage will be consumed at different stages of your product lifecycle. For a rough cost estimation, you can use AWS Pricing Calculator, but you must provide an approximate number of RRUs, WRUs, and storage requirements for your table. These can be difficult to estimate at the beginning of the project. AWS Pricing Calculator doesn’t consider data growth rate or item size, and it doesn't consider the number of reads and writes for the base table and global secondary indexes (GSIs) separately. To use AWS Pricing Calculator, you must estimate all those aspects to assume ballpark figures for WRU, RRU, and storage size to obtain your cost estimation.

This pattern provides a mechanism and a re-usable Microsoft Excel template to estimate basic DynamoDB cost factors, such as write, read, storage, backup and recovery cost, for on-demand capacity mode. It is more granular than AWS Pricing Calculator, and it considers base table and GSIs requirements independently. It also considers the monthly item data growth rate and forecasts costs for three years.

Prerequisites and limitations

Prerequisites

• Basic knowledge of DynamoDB and DynamoDB data model design
• Basic knowledge of DynamoDB pricing, WRU, RRU, storage, and backup and recovery (for more information, see Pricing for On-Demand Capacity)
• Knowledge of your data, data model, and item size in DynamoDB
• Knowledge of DynamoDB GSIs

Limitations

• The template provides you with an approximate calculation, but it isn’t appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
• For a more accurate estimate, you must consider the expected number of writes (insert, update, and delete) and reads for each item in an average month.
• This pattern supports estimating only write, read, storage, and backup and recovery costs for next few years based on fixed data growth assumptions.
## Tools

### AWS services

- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

### Other tools

- **AWS Pricing Calculator** is a web-based planning tool that you can use to create estimates for your AWS use cases.

## Best practices

To help keep costs low, consider the following DynamoDB design best practices.

- **Partition key design** – Use a high-cardinality partition key to distribute load evenly.
- **Adjacency list design pattern** – Use this design pattern for managing one-to-many and many-to-many relationships.
- **Sparse index** – Use sparse index for your GSIs. When you create a GSI, you specify a partition key and optionally a sort key. Only items in the base table that contain a corresponding GSI partition key appear in the sparse index. This helps to keep GSIs smaller.
- **Index overloading** – Use the same GSI for indexing various types of items.
- **GSI write sharding** – Shard wisely to distribute data across the partitions for efficient and faster queries.
- **Large items** – Store only metadata inside the table, save the blob in Amazon S3, and keep the reference in DynamoDB. Break large items into multiple items, and efficiently index by using sort keys.

For more design best practices, see the [*Amazon DynamoDB Developer Guide*](#).

## Epics

### Extract item information from your DynamoDB data model

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Get item size.      | 1. Check how many different types of item you are going to store in your table.  
                      | 2. To calculate the size of each item in kilobytes, add the Key and Value size of each attribute.  
                      | 3. Calculate item size for a base table and for each GSI.                      | Data engineer       |
| Estimate the write cost. | To estimate write cost in on-demand capacity mode, first you have to measure how many WRUs will be consumed in a month. For that, you need to consider the following factors: | Data engineer       |
### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|      | • Number of create, update, and delete operations for each item in a month.  
      • Number of available GSIIs. Consider each index independently.  
      • Average size of an index item  
      • Number of synchronization times on an index  
      • How many new things (for example, components or products) will be added in the table each month? The number of added things could be different every month, but you can assume an average growth rate based on your business cases. |
|      | For more information, see the *Additional information* section. | Data engineer, App developer |
| Estimate the read cost. | To estimate read cost in on-demand mode, first you have to measure how many RRUs will be consumed in a month. For that, you need to consider the following factors:  
• Number of available GSIIs. Consider each index independently.  
• Average size of an index item  
• Average number of reads per product per month.  
• Number of total available things (components or products) in the DynamoDB table. |  

### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Estimate the storage size and cost.       | First, estimate the average monthly storage requirement based on your item size in the table. Then calculate storage cost by multiplying storage size by the per GB storage price for your AWS Region. If you already entered data for estimating the write cost, you don't need to enter it again for calculating storage size. Otherwise, to estimate storage size, you need to consider the following factors:  
  - Number of data items in a module (product) based on your table design.  
  - Average item size in kilobytes.  
  - Number of available GSIs. Consider each index independently.  
  - Average size of an index item  
  - How many new products will be added in the table each month? The number of new products could be different every month, but you can assume an average growth rate based on your business cases. This example uses an average of 10 million new products each month. | Data engineer   |

#### Enter the item and object information in the Excel template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Download the Excel template               | 1. Download the Excel template.  
2. Adjust the business module and GSIs, based on your table design.                                                                                                                                          | Data engineer   |
| Enter information in the Excel template.  | 1. Update item information in the sheet. Update data only in orange cells.  
2. Adjust the object numbers: How much could be added into the table each month?                                                                                                                     | Data engineer   |

Guides and patterns

- Modeling data with Amazon DynamoDB
- Estimate storage costs for an Amazon DynamoDB table

Additional information

Write cost calculation example

The DynamoDB data model design shows three items for a product, and an average item size of 4 KB. When you add a new product into the DynamoDB base table, it consumes the number of items * (item size/1 KB write unit) = 3 * (4/1) = 12 WRU. In this example, for writing 1 KB, the product consumes 1 WRU.

Read cost calculation example

To get the RRU estimation, consider the average of how many times each item will be read in a month. For example, the Information item will be read, on average, 10 times in a month, and the metadata item will be read two times, and the relationship item will be read five times. In the example template, total
RRU for all components = number of new components created each month * RRU per component per month = 10 million * 17 RRU = 170 million RRU each month.

Every month, new things (components or products will be added, and the total number of products will grow over time. So, RRU requirements will also grow over time.

- For the first month RRU, consumption will be 170 million.
- For the second month, RRU consumption will be 2 * 170 million = 340 million.
- For the third month RRU consumption will be 3 * 170 million = 510 million.

The following graph shows monthly RRU consumption and cost forecasting.

![MONTHLY RRU COST FORECASTING](image)

Note that prices within the graph are for illustration only. To create accurate forecasts for your use case, check the AWS pricing page, and use those prices in the Excel sheet.

**Storage, backup, and recovery cost calculation examples**

DynamoDB storage, backup and restore all are connected with each other. Backup is directly connected with storage, and recovery is directly connected with backup size. As the table size increases, corresponding storage, backup, and restore costs will increase proportionally.

**Storage size and cost**

Storage cost will increase over time based on your data growth rate. For example, assume that the average size of a component or product in the base table and GSIs is 11 KB, and 10 million new products will be added every month into your database table. In that case, your DynamoDB table size will grow (11 KB * 10 million)/1024/1024 = 105 GB per month. At the first month, your table storage size will be 105 GB, at second month it will be 105 + 105 = 210 GBs, and so on.

- For the first month, storage cost will be 105 GB * storage price per GB for your AWS Region.
- For the second month, storage cost will be 210 GB * storage price per GB for your Region.
- For the third month, storage cost will be 315 GB * storage price per GB for your Region.

For storage size and cost for next three years, see the **Storage size and forecasting** section.
**Backup cost**

Backup cost will increase over time based on your data growth rate. When you turn on continuous backup with point-in-time-recovery (PITR), continuous backup charges are based on average storage GB-Month. In a calendar month, the average backup size would be the same as your table storage size, although the actual size could be a bit different. As new products will be added every month, the total storage size and the backup size will grow over time. For example, for the first month, the average backup size of 105 GB could grow to 210 GB for the second month.

- For the first month, backup cost will be 105 GB-month * continuous backup price per GB for your AWS Region.
- For the second month, backup cost will be 210 GB-month * continuous backup price per GB for your Region.
- For the third month, backup cost will be 315 GB-month * continuous backup price per GB for your Region.
- and, so on

Backup cost is included in the graph in the Storage size and cost forecasting section.

**Recovery cost**

When you are taking continuous backup with PITR enabled, recovery operation charges are based on the size of the restore. Each time that you restore, you pay based on gigabytes of restored data. If your table size is large and you perform restore multiple times in a month, it will be costly.

To estimate restore cost, this example assumes that you perform a PITR recovery one time each month at the end of the month. The example uses the monthly average backup size as the restore data size for that month. For the first month, the average backup size is 105 GB, and for the recovery at end of the month, the restore data size would be 105 GB. For the second month, it would be 210 GBs, and so on.

Recovery cost will increase over time based on your data growth rate.

- For the first month, recovery cost will be 105 GB * restore price per GB for your AWS Region.
- For the second month, recovery cost will be 210 GB * restore price per GB for your Region.
- For the third month, recovery cost will be 315 GB * restore price per GB for your Region.

For more information, see the Storage, backup and recovery tab in the Excel template and the graph in the following section.

**Storage size and cost forecasting**

In the template, actual billable storage size is calculated by subtracting the free tier 25 GB per month for the Standard table class. In the sheet, you will get a forecasting graph broken out into monthly values.

The following example chart forecasts monthly storage size in GB, billable storage cost, on-demand backup cost, and recovery cost for next 36 calendar months. All costs are in USD. From the graph, it’s clear that storage, backup, and recovery costs increase proportionally to increases in storage size.
Note that prices used in the graph are for illustration purposes only. To create accurate prices for your use case, check the AWS pricing page, and use those prices in the Excel template.

**Estimate storage costs for an Amazon DynamoDB table**

*Created by Moinul Al-Mamun*

| Environment: PoC or pilot | Technologies: Databases; Big data; Cost management; Storage & backup | AWS services: Amazon DynamoDB |

**Summary**

Amazon DynamoDB is a NoSQL transactional database that provides single-digit millisecond latency even at petabytes scale. This Amazon Web Services (AWS) serverless offering is getting popular because of its consistent performance and scalability. You do not need to provision storage. Your single table can grow up to petabytes.
DynamoDB monitors the size of your table continuously throughout the month to determine your storage charges. AWS then charges you for the average size of storage in gigabytes. The more that your table grows over time, the more that your storage cost will grow. To calculate storage cost, you can use AWS Pricing Calculator, but you need to provide the approximate size of your table, including global secondary indexes (GSIs), which is really difficult to estimate at the beginning of the project. Also, AWS Pricing Calculator does not consider the data growth rate.

This pattern provides a mechanism and a reusable Microsoft Excel template to calculate DynamoDB storage size and cost. It considers the storage requirements for the base table and the GSIs independently. It calculates storage size by considering the size of your individual items and data growth rate over time.

To get an estimate, insert two pieces of information into the template:

- The individual item size in kilobytes for the base table and GSIs
- How many new objects or products could be added to the table, on average, in a month, (for example, 10 million)

The template will generate a storage and cost forecasting graph for the next three years, which is shown in the following example.

![MONTHLY STORAGE COST FORECASTING](image)

Prerequisites and limitations

Prerequisites

- Basic knowledge of DynamoDB, and DynamoDB storage and pricing
- Knowledge of your data, data model, and item size in DynamoDB
- Knowledge of DynamoDB global secondary indexes (GSIs)

Limitations

- The template provides you with an approximate calculation, but it isn’t appropriate for all configurations. To get a more accurate estimate, you must measure the individual item size for each item in the base table and GSIs.
• This pattern supports estimating only storage size and cost for the next few years based on fixed data growth assumptions.

Tools

AWS services

• Amazon DynamoDB is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.

Other tools

• AWS Pricing Calculator is a web-based planning tool that you can use to create estimates for your AWS use cases.

Epics

Extract item information from your DynamoDB data model

</thead>
<tbody>
<tr>
<td>3.</td>
<td>Update the storage price per GB-month for your AWS Region.</td>
<td></td>
</tr>
</tbody>
</table>

Related resources

- Amazon DynamoDB On-Demand pricing
- AWS Pricing Calculator for DynamoDB

Additional information

Note that the attached template forecasts only storage size and cost for Standard storage table class. Based on the forecast for storage costs, and considering individual item size and product or object growth rate, you can estimate the following:

- Data export cost
- Backup and recovery cost
- Data storage requirements.

Amazon DynamoDB data storage cost

DynamoDB monitors the size of your tables continuously to determine your storage charges. DynamoDB measures the size of your billable data by adding the raw byte size of your data plus a per-item storage overhead that depends on the features you have enabled. For more information, see the DynamoDB Developer Guide.

The price for data storage depends on your table class. The first 25 GB stored each month is free if you’re using the DynamoDB Standard table class. For more information about storage costs for Standard table class and Standard-Infrequent Access table class in different AWS Regions, see Pricing for On-Demand Capacity.

Handle overloaded Oracle functions in Aurora PostgreSQL-Compatible

*Created by Sumana Yanamandra (AWS)*

| Environment: PoC or pilot | Source: Oracle Database | Target: Aurora PostgreSQL-Compatible |
Summary

The code you migrate from an on-premises Oracle database to Amazon Aurora PostgreSQL-Compatible Edition might include overloaded functions. These functions have the same definition—that is, the same function name and the same number and data type of input (IN) parameters—but the data type or the number of output (OUT) parameters might differ.

These parameter mismatches can cause problems in PostgreSQL, because it's difficult to determine which function to run. This pattern illustrates how to handle overloaded functions when you migrate your database code to Aurora PostgreSQL-Compatible.

Prerequisites and limitations

Prerequisites

- An Oracle database instance as your source database
- An Aurora PostgreSQL-Compatible DB instance as your target database (see instructions in the Aurora documentation)

Product versions

- Oracle Database 9i or later
- Oracle SQL Developer version 18.4.0.376
- pgAdmin 4 client
- Aurora PostgreSQL-Compatible version 11 or later (see Identifying versions of Amazon Aurora PostgreSQL in the Aurora documentation)

Tools

AWS services

- Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.

Other tools

- Oracle SQL Developer is a free, integrated development environment for working with SQL in Oracle databases in both traditional and cloud deployments.
- pgAdmin is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.
Create a simple function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a function in PostgreSQL that has one input parameter and one output parameter.</td>
<td>The following example illustrates a function named <code>test_overloading</code> in Aurora PostgreSQL-Compatible. This function has two parameters: one input text parameter and one output text parameter.</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
<tr>
<td>Run the function in PostgreSQL.</td>
<td>Run the function that you created in the previous step.</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
</tbody>
</table>

```
CREATE OR REPLACE FUNCTION public.test_overloading(  
    str1 text,
    OUT str2 text
) LANGUAGE 'plpgsql'  
COST 100  
VOLATILE  
AS $BODY$  
DECLARE  
BEGIN  
str2 := 'Success';  
RETURN ;  
EXCEPTION  
WHEN others THEN  
RETURN ;  
END;  
$BODY$;
```

It should display the following output.

Success

Overload the function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the same function name to create an overloaded function in PostgreSQL.</td>
<td>Create an overloaded function in Aurora PostgreSQL-Compatible that uses the same function name as your previous function. The following example is also named <code>test_overloading</code>, but it has three parameters: one</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
</tbody>
</table>
CREATE OR REPLACE FUNCTION public.test_overloading(
  str1 text,
  OUT str2 text,
  OUT num1 integer)
LANGUAGE 'plpgsql'
COST 100
VOLATILE
AS $BODY$
DECLARE
  str3 text;
BEGIN
  str2 := 'Success';
  num1 := 100;
  RETURN ;
END;
$BODY$;

Run the function in PostgreSQL.
When you run this function, it fails with the following error message.
```
ERROR: cannot change return type of existing function
HINT: Use DROP FUNCTION test_overloading(text) first.
```

This happens because Aurora PostgreSQL-Compatible doesn’t support function overloading directly. It can’t identify which function to run, because the number of output parameters is different in the second version of the function, although the input parameters are the same.

### Apply the workaround

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add INOUT to the first output parameter.</td>
<td>As a workaround, modify the function code by representing str3 as an INOUT parameter.</td>
<td>Data engineer, Aurora PostgreSQL-Compatible</td>
</tr>
</tbody>
</table>
### Task | Description | Skills required
--- | --- | ---
the first output parameter as INOUT. | CREATE OR REPLACE FUNCTION public.test_overloading(  str1 text,  INOUT str2 text,  OUT num1 integer) LANGUAGE 'plpgsql'  COST 100  VOLATILE AS $BODY$  DECLARE  str3 text;  BEGIN  str2 := 'Success';  num1 := 100;  RETURN ;  EXCEPTION  WHEN others THEN  RETURN ;  END;  $BODY$; | Data engineer, Aurora PostgreSQL-Compatible
Run the revised function. | Run the function that you updated by using the following query. You pass a null value as the second argument of this function, because you declared this parameter as INOUT to avoid the error. | Data engineer, Aurora PostgreSQL-Compatible
| select  public.test_overloading('Test', null); | The function is now created successfully. | Success, 100 | Validate the results. | Verify that the code with the overloaded function was converted successfully. | Data engineer, Aurora PostgreSQL-Compatible

Help enforce DynamoDB tagging

*Created by Mansi Suratwala (AWS)*

**Environment:** Production  
**Technologies:** Cloud-native; Security, identity, compliance; Databases  
**Workload:** All other workloads

**AWS services:** Amazon CloudWatch; Amazon DynamoDB; AWS Lambda; Amazon SNS

---

**Summary**

This pattern sets up automatic notifications when a predefined Amazon DynamoDB tag is missing or removed from a DynamoDB resource on the Amazon Web Services (AWS) Cloud.

DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability. DynamoDB lets you offload the administrative burdens of operating and scaling a distributed database. When you use DynamoDB, you don't have to worry about hardware provisioning, setup and configuration, replication, software patching, or cluster scaling.

The pattern uses an AWS CloudFormation template, which creates an Amazon CloudWatch Events event and an AWS Lambda function. The event watches for any new or existing DynamoDB tagging information via AWS CloudTrail. If a predefined tag is missing or removed, CloudWatch triggers a Lambda function, which sends you an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket for the Lambda .zip file that contains the Python script for running the Lambda function

**Limitations**

- The solution works only when the TagResource or UntagResource CloudTrail events occur. It does not create notifications for any other events.

**Architecture**

**Target technology stack**

- Amazon DynamoDB
**Target architecture**

**Automation and scale**

You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

**Tools**

**Tools**

- **Amazon DynamoDB** – DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with scalability.
- **AWS CloudTrail** – CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near-real time stream of system events that describe changes in AWS resources.
- **AWS Lambda** – Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

**Code**

- A .zip file of the project is available as an attachment.

Implement cross-Region disaster recovery with AWS DMS and Amazon Aurora

Created by Mark Hudson (AWS)

| Environment: | Production | Technologies: | Databases | AWS services: | AWS DMS; Amazon RDS; Amazon Aurora |

Summary

Natural or human-induced disasters can occur at any time and can impact the availability of services and workloads running in a given Amazon Web Services (AWS) Region. To mitigate the risks, you must develop a disaster recovery (DR) plan that incorporates the built-in cross-Region capabilities of AWS services. For AWS services that do not inherently provide cross-Region functionality, the DR plan must also provide a solution to handle their failover across AWS Regions.

This pattern guides you through a disaster recovery setup involving two Amazon Aurora MySQL-Compatible Edition database clusters in a single Region. To meet DR requirements, the database clusters are configured to use the Amazon Aurora global database feature, with a single database spanning multiple AWS Regions. An AWS Database Migration Service (AWS DMS) task replicates data between the clusters in the local Region. AWS DMS, however, currently doesn’t support cross-Region tasks. This pattern includes the steps required to work around that limitation and independently configure AWS DMS in both Regions.

Prerequisites and limitations

Prerequisites

- Selected primary and secondary AWS Regions that support Amazon Aurora global databases.
- Two independent Amazon Aurora MySQL-Compatible Edition database clusters in a single account in the primary Region.
- Database instance class db.r5 or higher (recommended).
- An AWS DMS task in the primary Region performing ongoing replication between the existing database clusters.
- DR Region resources in place to meet requirements for creating database instances. For more information, see Working with a DB instance in a VPC.

Limitations

- For the full list of Amazon Aurora global database limitations, see Limitations of Amazon Aurora global databases.

Product versions

- Amazon Aurora MySQL-Compatible Edition 5.6, 5.7, or 8.0. For more information, see Aurora global databases.
Architecture

Target technology stack

- Amazon Aurora MySQL-Compatible Edition global database cluster
- AWS DMS

Target architecture

Automation and scale

You can use AWS CloudFormation to create the prerequisite infrastructure in the secondary Region, such as the virtual private cloud (VPC), subnets, and parameter groups. You can also use AWS CloudFormation to create the secondary clusters in the DR Region and add them to the global database. If you used CloudFormation templates to create the database clusters in the primary Region, you can update or augment them with an additional template to create the global database resource. For more information, see Creating an Amazon Aurora DB cluster with two DB instances and Creating a global database cluster for Aurora MySQL-Compatible.

Finally, you can create the AWS DMS tasks in the primary and secondary Regions using CloudFormation after failover and failback events occur. For more information, see AWS::DMS::ReplicationTask.

Tools

- Amazon Aurora - Amazon Aurora is a fully managed relational database engine that's compatible with MySQL and PostgreSQL. This pattern uses Amazon Aurora MySQL-Compatible Edition.
- Amazon Aurora global databases - Amazon Aurora global databases are designed for globally distributed applications. A single Amazon Aurora global database can span multiple AWS Regions. It replicates your data with no impact on database performance. It also enables fast local reads with low latency in each Region, and it provides disaster recovery from Region-wide outages.
- AWS DMS - AWS Database Migration Service (AWS DMS) provides one-time migration or on-going replication. An on-going replication task keeps your source and target databases in sync. After it is set up, the on-going replication task continuously applies source changes to the target with minimal
latency. All AWS DMS features, such as data validation and transformations, are available for any replication task.

<td>AWS administrator</td>
</tr>
<tr>
<td>Create an AWS DMS task.</td>
<td>Using the console, create an AWS DMS task in the primary Region. In the task, specify a migration method of <strong>Replicate data changes only</strong>. For more information, see <a href="https://docs.aws.amazon.com/aps/latest/userguide/creating-task.html">Creating a task</a>.</td>
<td>AWS administrator, DBA</td>
</tr>
</tbody>
</table>
### Task Description

1. In the task settings, use the wizard and specify the following:
   - **CDC start mode for source transactions** – Enable custom CDC start mode
   - **Custom CDC start point for source transactions** – Specify a recovery checkpoint

2. In the **Recovery checkpoint** box, enter the replication checkpoint value previously obtained through the database query on the `awsdms_txn_state` table.

3. Also within the task settings section, select the JSON editor and set the `TaskRecoveryTableEnabled` parameter to `true`.

4. Finally, set the AWS DMS task **Start migration task** setting to **Automatically on create**.

**Record the AWS DMS task Amazon Resource Name (ARN).**

Use the ARN to obtain the AWS DMS task name for later use. To retrieve the AWS DMS task ARN, run the following command:

```bash
aws dms describe-replication-tasks
```

The task name will be needed when performing another managed failover or during a DR scenario.

**Delete AWS DMS tasks.**

Delete the original (currently stopped) AWS DMS task in the primary Region and the existing AWS DMS task (currently stopped) in the secondary Region.

### Related resources

- Configuring your Amazon Aurora DB cluster
- Using Amazon Aurora global databases
- Working with Amazon Aurora MySQL-Compatible Edition
Additional information

Amazon Aurora global databases are used in this example for DR because they provide an effective recovery time objective (RTO) of 1 second and a recovery point objective (RPO) of less than 1 minute, both lower than traditional replicated solutions and ideal for DR scenarios.

Amazon Aurora global databases offer many other advantages, including the following:

- Global reads with local latency – Global consumers can access information in a local Region, with local latency.
- Scalable secondary Amazon Aurora DB clusters – Secondary clusters can be scaled independently, adding up to 16 read-only replicas.
- Fast replication from primary to secondary Amazon Aurora DB clusters – Replication has little performance impact on the primary cluster. It occurs at the storage layer, with typical cross-Region replication latencies of less than 1 second.

This pattern also uses AWS DMS for replication. Amazon Aurora databases provide the ability to create read replicas, which can simplify the replication process and the DR setup. However, AWS DMS is often used to replicate when data transformations are required or when the target database requires additional indexes that the source database does not have.

Migrate Oracle OUT bind variables to a PostgreSQL database

Created by Bikash Chandra Rout (AWS) and Vinay Paladi (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Source: Database Relational</th>
<th>Target: RDS/Aurora Postgresql</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Workload: Oracle</td>
<td>Technologies: Databases; Migration</td>
</tr>
</tbody>
</table>

AWS services: Amazon Aurora; Amazon RDS; AWS SCT

Summary

This pattern shows how to migrate Oracle Database OUT bind variables to either one of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition
Prerequisites and limitations

PostgreSQL doesn’t support OUT bind variables. To get the same functionality in your Python statements, you can create a custom PL/pgSQL function that uses the GET and SET package variables instead. To apply these variables, the example wrapper function script that’s provided in this pattern uses an AWS Schema Conversion Tool (AWS SCT) extension pack.

**Note:** If the Oracle EXECUTE IMMEDIATE statement is a SELECT statement that can return one row at most, it’s a best practice to do the following:

- Put OUT bind variables (defines) in the INTO clause
- Put IN bind variables in the USING clause

For more information, see [EXECUTE IMMEDIATE statement](https://oracl documentation) in the Oracle documentation.

### Prerequisites and limitations

**Prerequisites**

- An active AWS account
- An Oracle Database 10g (or newer) source database in an on-premises data center
- An Amazon RDS for PostgreSQL DB instance or an Aurora PostgreSQL-Compatible DB instance

**Architecture**

**Source technology stack**

- On-premises Oracle Database 10g (or newer) database

**Target technology stack**

- An Amazon RDS for PostgreSQL DB instance or an Aurora PostgreSQL-Compatible DB instance

**Target architecture**

The following diagram shows an example workflow for migrating Oracle Database OUT bind variables to a PostgreSQL-compatible AWS database:
The diagram shows the following workflow:

1. AWS SCT converts the source database schema and a majority of the custom code to a format compatible with the target PostgreSQL-compatible AWS database.
2. Any database objects that can't be converted automatically are flagged by the PL/pgSQL function. Objects that are flagged are then manually converted to complete the migration.

**Tools**

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- **AWS Schema Conversion Tool (AWS SCT)** supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.
- **pgAdmin** is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects.

**Epics**

Migrate Oracle OUT bind variables by using a custom PL/pgSQL function and AWS SCT

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect to your PostgreSQL-compatible AWS database.</td>
<td>After you've created your DB instance, you can use any standard SQL client application</td>
<td>Migration engineer</td>
</tr>
</tbody>
</table>
### Task Description

**to connect to a database in your DB cluster.** For example, you can use **pgAdmin** to connect to your DB instance.

For more information, see either of the following:

- [Connecting to an Amazon RDS DB instance](https://docs.aws.amazon.com/rds/latest/userguide/rds-connect.html) in the *Amazon RDS User Guide*
- [Connecting to an Amazon Aurora DB cluster](https://docs.aws.amazon.com/aurora/latest/userguide/aurora-connect.html) in the *Amazon Aurora User Guide*

Add the example wrapper function script from this pattern to the target database's main schema.

Copy the example PL/pgSQL wrapper function script from the **Additional information** section of this pattern. Then, add the function to the target database's main schema.

For more information, see **CREATE FUNCTION** in the PostgreSQL documentation.

(Optional) Update the search path in the target database's main schema so that includes the **Test_pg** schema.

To improve performance, you can update the PostgreSQL **search_path** variable so that it includes the **Test_pg** schema name. If you include the schema name in the search path, you don't need to specify the name whenever you call the PL/pgSQL function.

For more information, see section **5.9.3 The Schema Search Path** in the PostgreSQL documentation.

Migrate SAP HANA to AWS using SAP HSR with the same hostname

*Created by Pradeep Puliyampatta (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Source: SAP HANA DB on-premises</th>
<th>Target: SAP HANA DB on AWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Rehost</td>
<td>Workload: SAP</td>
<td>Technologies: Databases; Migration</td>
</tr>
<tr>
<td>AWS services:</td>
<td>AWS Client VPN; AWS Direct Connect; Amazon EBS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

SAP HANA migrations to Amazon Web Services (AWS) can be performed using multiple options, including backup and restore, export and import, and SAP HANA System Replication (HSR). The selection of a particular option depends on the network connectivity between source and target SAP HANA databases, the size of the source database, downtime considerations, and other factors.

The SAP HSR option for migrating SAP HANA workloads to AWS works well when there is a stable network between the source and target systems and the entire database (SAP HANA DB replication...
snapshot) can be completely replicated within 1 day, as stipulated by SAP for network throughput requirements for SAP HSR. The downtime requirements with this approach are limited to performing the takeover on the target AWS environment, SAP HANA DB backup, and post-migration tasks.

SAP HSR supports the use of different hostnames (hostnames mapped to different IP addresses) for replication traffic between the primary, or source, and secondary, or target, systems. You can do this by defining those specific sets of hostnames under the [system_replication_hostname_resolution] section in global.ini. In this section, all hosts of the primary and the secondary sites must be defined on each host. For detailed configuration steps, see the SAP documentation.

One key takeaway from this setup is that the hostnames in the primary system must be different from the hostnames in the secondary system. Otherwise, the following errors can be observed.

- "each site must have a unique set of logical hostnames"
- "remoteHost does not match with any host of the source site. All hosts of source and target site must be able to resolve all hostnames of both sites correctly"

However, the number of post-migration steps can be reduced by using the same SAP HANA DB hostname on the target AWS environment.

This pattern provides a workaround for using the same hostname on source and target environments when using the SAP HSR option. With this pattern, you can use the SAP HANA Hostname Rename option. You assign a temporary hostname to the target SAP HANA DB to facilitate hostname uniqueness for SAP HSR. After the migration completes the takeover milestone on the target SAP HANA environment, you can revert the target system hostname back to the hostname of the source system.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- A virtual private cloud (VPC) with a virtual private network (VPN) endpoint or a router.
- AWS Client VPN or AWS Direct Connect configured to transfer files from the source to the target.
- SAP HANA databases in both the source and the target environment. The target SAP HANA DB patch level should be equal to or higher than the source SAP HANA DB patch level, within the same SAP HANA Platform edition. For example, replication cannot be set up between HANA 1.0 and HANA 2.0 systems. For more information, see question 15 in SAP Note: 1999880 – FAQ: SAP HANA System Replication.
- SAP application servers in the target environment.
- Amazon Elastic Block Store (Amazon EBS) volumes in the target environment.

**Limitations**

The following list of SAP documents covers known issues that are related to this workaround, including constraints regarding SAP HANA dynamic tiering and scale-out migrations:

- 2956397 – Renaming of SAP HANA Database System failed
- 2222694 – When trying to rename the HANA system, the following error appears “Source files are not owned by the original sidadm user (uid = xxxx)”
- 2607227 – hdblcm: register_rename_system: Renaming SAP HANA instance failed
- 2630562 – HANA Hostname Rename failed and HANA does not start up
- 2935639 – sr_register is not using the hostname that is specified under system_replication_hostname_resolution in the global.ini section
• 2710211 – Error: source system and target system have overlapping logical hostnames
• 2693441 – Failed to rename an SAP HANA System due to error
• 2519672 – HANA Primary and Secondary has different system PKI SSFS data and key or unable to check
• 2457129 – SAP HANA System Host Rename is not Permitted when Dynamic Tiering is Part of Landscape
• 2473002 – Using HANA System Replication to migrate scale out system (There are no restrictions provided by SAP in using this hostname rename approach for scale-out SAP HANA systems. However, the procedure must be repeated on each individual host. Other scale-out migration limitations also apply to this approach.)

Product versions

• This solution applies to SAP HANA DB platform edition 1.0 and 2.0.

Architecture

Source setup

An SAP HANA database is installed on the source environment. All the SAP application server connections and DB interfaces use the same hostname for client connections. The following diagram shows the example source hostname hdbhost and its corresponding IP address.

![Diagram showing source setup]

Target setup

The AWS Cloud target environment uses the same hostname to run an SAP HANA database. The target environment on AWS includes the following:

• SAP HANA database
• SAP application servers
• EBS volumes

**Intermediate configuration**

In the following diagram, the hostname on the AWS target environment is temporarily renamed as temp-host so that the hostnames on the source and target are unique. After the migration completes the takeover milestone on the target environment, the target system virtual hostname is renamed using the original name, hdbhost.

The intermediate configuration includes one of the following options:

- AWS Client VPN with a Client VPN endpoint
- AWS Direct Connect connecting to a router
SAP application servers on the AWS target environment can be installed either before replication setup or after the takeover. However, installing the application servers before replication setup can help with reduction of downtime during installation, configuration of high availability, and backups.

**Tools**

**AWS services**

- **AWS Client VPN** – AWS Client VPN is a managed client-based VPN service that enables you to securely access AWS resources and resources in your on-premises network.

- **AWS Direct Connect** – AWS Direct Connect links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services, bypassing internet service providers in your network path.

- **Amazon EBS** – Amazon Elastic Block Store (Amazon EBS) provides block level storage volumes for use with EC2 instances. EBS volumes behave like raw, unformatted block devices. You can mount these volumes as devices on your instances.

**Other tools**

- **SAP application servers** – SAP application servers provide programmers with a way to express business logic. The SAP application server performs the data processing based on the business logic. The actual data is stored in a database, which is a separate component.

- **SAP HANA cockpit** and **SAP HANA Studio** – Both SAP HANA cockpit and SAP HANA Studio provide an administrative interface to the SAP HANA database. In SAP HANA Studio, the SAP HANA Administration console is the system view that provides relevant content for SAP HANA database administration.

- **SAP HANA System Replication** – SAP HANA System Replication (SAP HSR) is the standard procedure provided by SAP for replicating SAP HANA databases. The required executables for SAP HSR are part of the SAP HANA server kernel itself.
## Epics

### Prepare the source and target environments

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install and configure the SAP HANA databases.</td>
<td>In the source and target environments, ensure that the SAP HANA DB is installed and configured according to SAP HANA on AWS best practices. For more information, see <a href="https://aws.amazon.com/saphana/">SAP HANA on AWS</a>.</td>
<td>SAP Basis administration</td>
</tr>
</tbody>
</table>
| Map the IP address.       | In the target environment, ensure that the temporary hostname is assigned to an internal IP address.  
1. Assign a secondary IPv4 address to the Amazon Elastic Compute Cloud (Amazon EC2) instance on the AWS Management Console by navigating to **EC2, Instance, Actions, Networking, Manage IP address, Assign new IP address**.  
2. To assign the same address to the EC2 network adaptor (NIC), from the operating system, as root user, run the command `ip addr add <IP>/32 dev eth0`, replacing `<IP>` with the IP address from step 1.                                                                 | AWS administration                       |
| Resolve target hostnames. | On the secondary SAP HANA DB, confirm that both hostnames (`hdbhost` and `temp-host`) are resolved for the SAP HANA replication networks by updating the relevant hostnames in the `/etc/hosts` file.                                                                                                                      | Linux administration                     |
| Back up the source and target SAP HANA databases. | Use SAP HANA Studio or the SAP HANA cockpit to perform backups on the SAP HANA databases.                                                                                                                                                                                                                                             | SAP Basis administration                  |
| Exchange system PKI certificates. | (Applies only to SAP HANA 2.0 and later) Exchange certificates in the system public key infrastructure (PKI) secure store in the file system (SSFS)                                                                                                                                               | SAP Basis administration                  |
## Rename the target SAP HANA DB

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Stop target client connections.</strong></td>
<td>In the target environment, shut down the SAP application servers and other client connections.</td>
<td>SAP Basis administration</td>
</tr>
</tbody>
</table>
| **Rename the target SAP HANA DB to the temporary hostname.** | 1. As root user, rename the target SAP HANA DB hostname to the temporary hostname by using resident hdblcm.  
   2. Choose option 9 | rename_system | Rename the SAP HANA Database System.  
   3. Provide the new name: temp-host.  
   4. You can validate other options as needed. However, be sure that you don’t mix up the host rename with a SID change (SAP Note 2598814 – hdblcm: SID rename fails).  
   The SAP HANA DB stop and start will be controlled by hdblcm. | SAP Basis administration |
<p>| <strong>Assign replication networks.</strong>   | In the global.ini file of the source system, under the [system_replication_hostname_resolution] header, provide the source and target replication network details. Then copy the entries to the global.ini file on the target system. | SAP Basis administration |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Enable replication on primary. | To enable replication on the source SAP HANA DB, run the following command.  

```
hdbnsutil -sr_enable --name=siteA
```
| SAP Basis administration |
| Register the target SAP HANA DB as a secondary system. | To register the target SAP HANA DB as a secondary system to source for SAP HSR, choose async replication.  

```
(sidadm $> HDB stop  
(sidadm $> hdbnsutil -sr_register --name=siteB --remotehost=hdbhost --remoteInstance=00 --replicationMode=async --operationMode=logreplay  
(sidadm $> HDB start
```
Alternatively, you can choose the -online option to register. In that case, you don’t need to stop and start the SAP HANA DB. |
| SAP Basis administration |
| Validate synchronization. | On the source SAP HANA DB, verify that all the logs are applied on the target system (because it is async replication).  

To verify the replication, on the source, run the following commands.  

```
(sidadm $> cdpy  
(sidadm $> python systemReplicationStatus.py
```
| SAP Basis administration |
| Shut down the source SAP application and SAP HANA DB. | During the migration cutover, perform a shutdown of the source system (the SAP application and SAP HANA database). |
| SAP Basis administration |
| Perform a takeover at the target. | To perform a takeover at the target on AWS, run the command hdbnsutil -sr_takeover. |
| SAP Basis administration |
### On the target SAP HANA DB, turn off replication.

**Description:** To clear the replication metadata, stop replication on the target system by running the command `hdbnsutil -sr_disable`.

**Note:** This is in accordance with SAP Note 2693441 – Failed to rename an SAP HANA System due to error.

**Skills required:** SAP Basis administration

### Back up the target SAP HANA DB.

**Description:** After the takeover is successful, we recommend performing a full SAP HANA DB backup.

**Skills required:** SAP Basis administration

## Revert to the original hostname in the target system

### Revert the target SAP HANA DB hostname to the original.

1. **Description:** To revert the target SAP HANA DB hostname to the original virtual hostname, use resident hdblcm.

   ```
   root $> cd /hana/shared/<SID>/hdblcm
   root $> ./hdblcm
   ```

2. **Description:** Choose option `9 | rename_system | Rename the SAP HANA Database System`.

3. **Description:** Provide the new name: `hdbhost`.

You can validate other options as needed. However, be sure that you don’t mix up the host rename with a SID change (SAP Note 2598814 – hdblcm: SID rename fails).

**Skills required:** SAP Basis administration

### Adjust hdbuserstore.

**Description:** Adapt the hdbuserstore details pointing to the source schema/user details. For detailed steps, see the SAP documentation.

To validate this step, run the command `R3trans -d`. The result should reflect a successful connection to the SAP HANA database.

**Skills required:** SAP Basis administration
Start up client connections.  | In the target environment, start up the SAP application servers and other client connections. | SAP Basis administration

Migrate SQL Server to AWS using distributed availability groups

Created by Praveen Marthala (AWS)

**Source:** SQL Server On-Premises  
**Target:** SQL Server on EC2  
**R Type:** Rehost

**Environment:** PoC or pilot  
**Technologies:** Databases; Migration  
**Workload:** Microsoft

**AWS services:** Amazon EC2

**Summary**

Microsoft SQL Server Always On availability groups provide a high availability (HA) and disaster recovery (DR) solution for SQL Server. An availability group consists of a primary replica that accepts read/write traffic, and up to eight secondary replicas that accept read traffic. An availability group is configured on a Windows Server Failover Cluster (WSFC) with two or more nodes.

Microsoft SQL Server Always On distributed availability groups provide a solution to configure two separate availability groups between two independent WFSCs. The availability groups that are part of the distributed availability group don't have to be in the same data center. One availability group can be on premises, and the other availability group can be on the Amazon Web Services (AWS) Cloud on Amazon Elastic Compute Cloud (Amazon EC2) instances in a different domain.

This pattern outlines steps for using a distributed availability group to migrate on-premises SQL Server databases that are part of an existing availability group to SQL Server with availability groups set up on
Amazon EC2. By following this pattern, you can migrate the databases to the AWS Cloud with minimal downtime during cutover. The databases are highly available on AWS immediately after the cutover. You can also use this pattern to change the underlying operating system from on-premises to AWS while keeping the same version of SQL Server.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- AWS Direct Connect or AWS Site-to-Site VPN
- The same version of SQL Server installed on-premises and on the two nodes on AWS

**Product versions**

- SQL Server version 2016 and later
- SQL Server Enterprise Edition

**Architecture**

**Source technology stack**

- Microsoft SQL Server database with Always On availability groups on premises

**Target technology stack**

- Microsoft SQL Server database with Always On availability groups on Amazon EC2 on the AWS Cloud

**Migration architecture**

**Terminology**

- WSFC 1 – WSFC on premises
• WSFC 2 – WSFC on the AWS Cloud
• AG 1 – First availability group, which is in WSFC 1
• AG 2 – Second availability group, which is in WSFC 2
• SQL Server primary replica – Node in AG 1 that is considered the global primary for all writes
• SQL Server forwarder – Node in AG 2 that receives data asynchronously from the SQL Server primary replica
• SQL Server secondary replica – Nodes in AG 1 or AG 2 that receive data synchronously from the primary replica or the forwarder

**Tools**

• **AWS Direct Connect** – AWS Direct Connect links your internal network to an AWS Direct Connect location over a standard Ethernet fiber-optic cable. With this connection, you can create virtual interfaces directly to public AWS services, bypassing internet service providers in your network path.
• **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can use Amazon EC2 to launch as many or as few virtual servers as you need, and you can scale out or scale in.
• **AWS Site-to-Site VPN** – AWS Site-to-Site VPN supports creating a site-to-site virtual private network (VPN). You can configure the VPN to pass traffic between instances that you launch on AWS and your own remote network.
• **Microsoft SQL Server Management Studio** – Microsoft SQL Server Management Studio (SSMS) is an integrated environment for managing SQL Server infrastructure. It provides a user interface and a group of tools with rich script editors that interact with SQL Server.

</table>
## Fail over to the second availability group

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manually fail over to AG 2.</td>
<td>On the forwarder in AG 2, alter the distributed availability group to allow data loss. Because you already checked and confirmed that the last LSNs on AG 1 and AG 2 match, data loss is not a concern.</td>
<td>DBA, Developer</td>
</tr>
<tr>
<td></td>
<td>When you allow data loss on the forwarder in AG 2, the roles of AG 1 and AG 2 change:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AG 2 becomes the availability group with the primary replica and secondary replica.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AG 1 becomes the availability group with the forwarder and secondary replica.</td>
<td></td>
</tr>
<tr>
<td>Change the availability mode of the distributed availability group on AG 2.</td>
<td>On the primary replica in AG 2, change the availability mode to asynchronous.</td>
<td>DBA, Developer</td>
</tr>
<tr>
<td></td>
<td>This changes the data movement from AG 2 to AG 1, from synchronous to asynchronous. This step is required to avoid network latency between AG 2 and AG 1, if any, and will not impact the performance of the database.</td>
<td></td>
</tr>
<tr>
<td>Start sending traffic to the new primary replica.</td>
<td>Update the connection string to use the listener URL endpoint on AG 2 for sending traffic to the databases.</td>
<td>App owner, Developer</td>
</tr>
<tr>
<td></td>
<td>AG 2 now accepts writes and sends data to the forwarder in AG 1, along with sending data to its own secondary replica in AG 2. Data moves asynchronously from AG 2 to AG 1.</td>
<td></td>
</tr>
</tbody>
</table>

### Perform post-cutover activities

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Drop the distributed availability group on AG 2.</td>
<td>Monitor the migration for the planned amount of time. Then drop the distributed availability group on AG 2 to remove</td>
<td>DBA, Developer</td>
</tr>
</tbody>
</table>

### Migrate from Oracle to a PostgreSQL database by using a standby database

*Created by Dhairya Jindani (AWS) and Sindhusha Paturu (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon RDS for PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Replatform</td>
<td>Workload: Oracle</td>
<td>Technologies: Databases; Migration; Storage &amp; backup</td>
</tr>
</tbody>
</table>

### Summary

This pattern shows how to migrate an Oracle database to a PostgreSQL database by using a standby Oracle database and Oracle Cloud Infrastructure (OCI) GoldenGate. The source Oracle database can be on premises or AWS Cloud based and can be migrated to either of the following PostgreSQL-compatible AWS database services:

- Amazon Relational Database Service (Amazon RDS) for PostgreSQL
- Amazon Aurora PostgreSQL-Compatible Edition

It's a best practice to use this setup when adding processes to a production server during a migration isn't desirable. For example, using a standby database can be helpful when migrating a busy transactional database.
By using Oracle Active Data Guard (ADG) mode, you can configure the Oracle GoldenGate Extract process to connect to a standby database. The Extract process then uses production logs that are transferred from the source Oracle database to the standby database as the data source. To get the data and metadata needed for the migration, Oracle GoldenGate connects to the standby database rather than the source database. No access to the production server is needed during migration.

**Prerequisites and limitations**

**Prerequisites**
- An active AWS account
- An Oracle GoldenGate license
- An Oracle Database 10g (or newer) source database in either an on-premises data center or hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance
- An Oracle Active Data Guard standby database
- Java Database Connectivity (JDBC) driver to connect to the PostgreSQL database
- Schema and tables created with the AWS Schema Conversion Tool (AWS SCT) on the target PostgreSQL database

**Limitations**
- Oracle GoldenGate is used only to replicate existing table data (initial load) and ongoing changes (change data capture or CDC)

**Product versions**
- Oracle GoldenGate 12.2.0.1.1 or newer versions
- Oracle GoldenGate 12.2.0.1.1 for PostgreSQL or newer versions

**Architecture**

**Source technology stack**
- On-premises or AWS Cloud-based Oracle Database 10g (or newer) database

**Target technology stack**
- An Amazon RDS for PostgreSQL DB instance or an Aurora PostgreSQL-Compatible DB instance

**Target architecture**

The following diagram shows an example workflow for migrating an Oracle database to a PostgreSQL-compatible AWS database by using a standby database and Oracle GoldenGate:
The diagram shows the following workflow:

1. The Oracle GoldenGate Extract process runs against the source database to extract data. Then, the GoldenGate Replicat process delivers the extracted data to the Oracle Active Data Guard standby database.

2. The GoldenGate Extract process runs against the standby database to extract data. Then, the GoldenGate Replicat process delivers the extracted data to the target PostgreSQL-compatible AWS database.

Tools

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon Relational Database Service (Amazon RDS) for PostgreSQL** helps you set up, operate, and scale a PostgreSQL relational database in the AWS Cloud.
- **Oracle GoldenGate** helps you design, run, orchestrate, and monitor your data replication and stream data processing solutions in the Oracle Cloud Infrastructure.

Epics

**Download and install Oracle GoldenGate**

**Migrate from Oracle 8i or 9i to Amazon RDS for Oracle using SharePlex and AWS DMS**
Summary

This pattern describes how to migrate an on-premises Oracle 8i or 9i database to an Amazon Relational Database Service (Amazon RDS) for Oracle database. You can use this pattern to complete your migration with reduced downtime by using Quest SharePlex for synchronous replication.

You must use an intermediate Oracle database instance for your migration because AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source environment. You can use SharePlex 7.6.3 to replicate from previous Oracle database versions to later Oracle database versions. The intermediate Oracle database instance is compatible as a target for SharePlex 7.6.3 and supported as a source for AWS DMS or newer releases of SharePlex. This support enables onward replication of data to the Amazon RDS for Oracle target environment.

Consider that several deprecated data types and features can impact a migration from Oracle 8i or 9i to the latest version of Oracle Database. To mitigate this impact, this pattern uses Oracle 11.2.0.4 as an intermediate database version to help optimize the schema code prior to migrating to the Amazon RDS for Oracle target environment.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises environment
- Oracle Database 12c Release 2 (12CR2) for staging on Amazon Elastic Compute Cloud (Amazon EC2)
- Quest SharePlex 7.6.3 (commercial grade)

Limitations

- RDS for Oracle limitations

Product versions

- Oracle 8i or 9i for the source database
- Oracle 12CR2 for the staging database (must match the Amazon RDS for Oracle version)
- Oracle 12CR2 or later for the target database (Amazon RDS for Oracle)

Architecture

Source technology stack

- Oracle 8i or 9i database
Tools

- SharePlex

Target technology stack

- Amazon RDS for Oracle

Migration architecture

The following diagram shows how to migrate an Oracle 8i or 9i database from an on-premises environment to an Amazon RDS for Oracle DB instance in the AWS Cloud.

The diagram shows the following workflow:

1. Enable the Oracle source database with archive log mode, force logging, and supplemental logging.
2. Restore the Oracle staging database from the Oracle source database by using Recovery Manager (RMAN) point-in-time recovery and FLASHBACK_SCN.
3. Configure SharePlex to read redo logs from the Oracle source database by using FLASHBACK_SCN (used in RMAN).
4. Start SharePlex replication to synchronize data from the Oracle source database to the Oracle staging database.
5. Restore the Amazon RDS for Oracle target database by using EXPDP and IMPDP with FLASHBACK_SCN.
6. Configure AWS DMS and its source tasks as the Oracle staging database and Amazon RDS for Oracle as the target database by using FLASHBACK_SCN (used in EXPDP).
7. Start AWS DMS tasks to synchronize data from the Oracle staging database to the Oracle target database.

Tools

- Amazon Relational Database Service (Amazon RDS) helps you set up, operate, and scale a relational database in the AWS Cloud.
• **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

• **Quest SharePlex** is an Oracle-to-Oracle data replication tool for moving data with minimal downtime and no data loss.

• **Recovery Manager (RMAN)** is an Oracle Database client that performs backup and recovery tasks on your databases. It greatly simplifies backing up, restoring, and recovering database files.

• **Data Pump Export** helps you upload data and metadata into a set of operating system files called a dump file set. The dump file set can be imported only by the Data Pump Import utility or the DBMS_DATAPUMP package.

**Monitor Amazon Aurora for instances without encryption**

*Created by Mansi Suratwala (AWS)*
Summary

This pattern provides an Amazon Web Services (AWS) CloudFormation template that you can deploy to set up automatic notifications when an Amazon Aurora instance is created without encryption turned on.

Aurora is a fully managed relational database engine that’s compatible with MySQL and PostgreSQL. With some workloads, Aurora can deliver up to five times the throughput of MySQL and up to three times the throughput of PostgreSQL without requiring changes to most of your existing applications.

The CloudFormation template creates an Amazon CloudWatch Events event and an AWS Lambda function. The event uses AWS CloudTrail to monitor for any Aurora instance creation or a point in time restoration of an existing instance. The Cloudwatch Events event initiates the Lambda function, which checks whether encryption is enabled. If encryption is not turned on, the Lambda function sends an Amazon Simple Notification Service (Amazon SNS) notification informing you of the violation.

Prerequisites and limitations

Prerequisites

- An active AWS account

Limitations

- This service control works with Amazon Aurora instances only. It does not support other Amazon Relational Database Service (Amazon RDS) instances.
- The CloudFormation template must be deployed for CreateDBInstance and RestoreDBClusterToPointInTime only.

Product versions

- PostgreSQL versions that are supported in Amazon Aurora
- MySQL versions that are supported in Amazon Aurora

Architecture

Target technology stack

- Amazon Aurora
- AWS CloudTrail
- Amazon CloudWatch
• AWS Lambda
• Amazon Simple Storage Service (Amazon S3)
• Amazon SNS

Target architecture

Automation and scale
You can use the CloudFormation template multiple times for different Regions and accounts. You need to run it only once in each Region or account.

Tools

Tools

• Amazon Aurora – Amazon Aurora is a fully managed relational database engine that’s compatible with MySQL and PostgreSQL.

• AWS CloudTrail – AWS CloudTrail helps you manage governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, a role, or an AWS service are recorded as events in CloudTrail.

• Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.

• AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

• Amazon S3 – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that you can use for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

• Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery using Lambda, HTTP, email, mobile push notifications, and mobile text messages (SMS).

Replatform Oracle Database Enterprise Edition to Standard Edition Two on Amazon RDS for Oracle

Created by Lanre showunmi (AWS) and Tarun Chawla (AWS)

Environment: Production Source: on-premises Target: Amazon RDS
Summary

Oracle Database Enterprise Edition (EE) is a popular choice for running applications in many enterprises. In some cases, however, applications use few or no Oracle Database EE features, so there is a lack of justification for incurring huge licensing costs. You can achieve cost savings by downgrading such databases to Oracle Database Standard Edition Two (SE2) when you migrate to Amazon RDS.

This pattern describes how to downgrade from Oracle Database EE to Oracle Database SE2 when migrating from on premises to Amazon RDS for Oracle. The steps presented in this pattern also apply if your EE Oracle database is already running on Amazon RDS or on an Amazon Elastic Compute Cloud (Amazon EC2) instance.

For more information, see the AWS Prescriptive Guidance guide on how to Evaluate downgrading Oracle databases to Standard Edition Two on AWS.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Oracle Database Enterprise Edition
- A client tool, such as Oracle SQL Developer or SQL*Plus, for connecting to and running SQL commands on Oracle database
- Database user for performing the assessment; for example, one of the following:
  - User with sufficient privileges for running AWS Schema Conversion Tool (AWS SCT) assessment
  - User with sufficient privileges to run SQL queries on Oracle database dictionary tables
- Database user for performing database migration; for example, one of the following:
  - User with sufficient privileges for running AWS Database Migration Service (AWS DMS)
  - User with sufficient privileges for performing Oracle Data Pump export and import
  - User with sufficient privileges for running Oracle GoldenGate

Limitations

- Amazon RDS for Oracle has a maximum database size. For more information, see Amazon RDS DB instance storage.

Product versions

The general logic described in this document applies to Oracle versions from 9i and later. For supported versions of self-managed and Amazon RDS for Oracle databases, see the AWS DMS documentation.

To identify feature usage in cases where AWS SCT is not supported, run SQL queries on the source database. To migrate from earlier versions of Oracle where AWS DMS and Oracle Data Pump are not supported, use Oracle Export and Import utilities.

For a current list of supported versions and editions, see Oracle on Amazon RDS in the AWS documentation. For details on pricing and supported instance classes, see Amazon RDS for Oracle pricing.
Architecture

Source technology stack

- Oracle Database Enterprise Edition running on premises or on Amazon EC2

Target technology stack using native Oracle tools

- Amazon RDS for Oracle running Oracle Database SE2

1. Export data by using Oracle Data Pump.
2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.

Target technology stack using AWS DMS

- Amazon RDS for Oracle running Oracle Database SE2
- AWS DMS

1. Export data by using Oracle Data Pump with FLASHBACK_SCN.
2. Copy dump files to Amazon RDS through a database link.
3. Import dump files to Amazon RDS by using Oracle Data Pump.
4. Use AWS DMS change data capture (CDC).

## Tools

### AWS services

- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle.

- **AWS SCT** provides a project-based user interface to automatically assess, convert, and copy the database schema of your source Oracle database into a format compatible with Amazon RDS for Oracle. AWS SCT enables you to analyze potential cost savings that can be achieved by changing your license type from Enterprise to Standard Edition of Oracle. The *License Evaluation and Cloud Support* section of the AWS SCT report provides detailed information about Oracle features in use so you can make an informed decision while migrating to Amazon RDS for Oracle.

### Other tools

- Native Oracle import and export utilities support moving Oracle data in and out of Oracle databases. Oracle offers two types of database import and export utilities: *Original Export and Import* (for earlier releases) and *Oracle Data Pump Export and Import* (available in Oracle Database 10g release 1 and later).

- **Oracle GoldenGate** offers real-time replication capabilities so that you can synchronize your target database after an initial load. This option can help reduce application downtime during go-live.

## Epics

### Make a pre-migration assessment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate database requirements for your applications.</td>
<td>Ensure that your applications are certified to run on Standard Edition Two of Oracle Database. Check directly with the software vendor, developer, or application documentation.</td>
<td>App developer, DBA, App owner</td>
</tr>
</tbody>
</table>
| Investigate use of EE features directly in the database. | To determine EE feature use, do one of the following:  
  - Generate an AWS SCT assessment report for your Oracle EE database. The report tells you which features from your current EE database should be removed if you want to change license types. | App owner, DBA, App developer                  |
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>• If you have an Oracle Support account, obtain and run the script <code>options_packs_usage_statistics.sql</code> in <a href="#">Support document 1317265.1</a> to generate a report of options and features that are being used on your Oracle database.</td>
<td><strong>App developer, DBA, App owner</strong></td>
</tr>
<tr>
<td>• Query <code>DBA_FEATURE_USAGE_STATISTICS</code> to display details of all features that are in use.</td>
<td></td>
</tr>
</tbody>
</table>

**Identify use of EE features for operational activities.**  

Database or application administrators sometimes rely on EE-only features for operational activities. Common examples include online maintenance activities (index rebuild, table move) and use of parallelism by batch jobs.

These dependencies can be mitigated by modifying your operations where possible. Identify the use of these features and make a decision based on cost compared with benefits.

Use the [Comparing Oracle Database EE and SE2 features](#) table as a guide to identify features that are available in Oracle Database SE2.
## Review workload patterns of the EE Oracle database.

Oracle Database SE2 automatically restricts usage to a maximum of 16 CPU threads at any time.

If your Oracle EE database is licensed to use the Oracle Diagnostic Pack, use the Automatic Workload Repository (AWR) tool, or DBA_HIST_\* views, to analyze database workload patterns to determine whether the maximum limit of 16 CPU threads will negatively impact service levels when you downgrade to SE2.

Ensure that your assessment covers periods of peak activity, such as end of day, month, or year processing.

### Skills required
- App owner, DBA, App developer

## Prepare the target infrastructure on AWS

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy and configure networking infrastructure.</td>
<td>Create a virtual private cloud (VPC) and subnets, security groups, and network access control lists.</td>
<td>AWS administrator, Cloud architect, Network administrator, DevOps engineer</td>
</tr>
<tr>
<td>Provision the Amazon RDS for Oracle SE2 database.</td>
<td>Provision the target Amazon RDS for Oracle SE2 database to meet your applications’ performance, availability, and security requirements. We recommend Multi-AZ configuration for production workloads. However, to improve migration performance, you can defer enabling Multi-AZ until after data migration.</td>
<td>Cloud administrator, Cloud architect, DBA, DevOps engineer, AWS administrator</td>
</tr>
<tr>
<td>Customize the Amazon RDS environment.</td>
<td>Configure custom parameters and options, and enable additional monitoring. For more information, see Best practices for migrating to Amazon RDS for Oracle.</td>
<td>AWS administrator, AWS systems administrator, Cloud administrator, DBA, Cloud architect</td>
</tr>
</tbody>
</table>
Perform the migration dry run and application testing

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Migrate the data (dry run).  | Migrate data from the source Oracle EE database to the Amazon RDS for Oracle SE2 database instance using the approach best suited to your specific environment. Select a migration strategy based on factors such as size, complexity, and the available downtime window. Use one or a combination of the following:  
  • Native Oracle tools such as Oracle Data Pump (recommended), Oracle Import-Export utilities, and Oracle GoldenGate.  
  • AWS DMS, using the full load with continuous replication through CDC.                                                                                                                                                                                                 | DBA             |
| Validate the target database. | Perform post-migration validation of database storage and code objects. Review migration logs, and fix any identified issues. For more information, see the guide Migrating Oracle databases to the AWS Cloud.                                                                                                                                  | DBA             |
| Test the applications.        | Application and database administrators should conduct functional, performance, and operational tests as appropriate. For more information, see Best practices for migrating to Amazon RDS for Oracle. Lastly, obtain sign-offs on test-results from stakeholders.                                                                                                                    | App developer, App owner, DBA, Migration engineer, Migration lead |

Cut over

<table>
<thead>
<tr>
<th>Task</th>

</table>
Replicate data between Amazon RDS for MySQL and MySQL on Amazon EC2
Summary

This pattern describes how to set up data replication between an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance and a MySQL database on an Amazon Elastic Compute Cloud (Amazon EC2) instance by using native global transaction identifier (GTID) replication.

Prerequisites and limitations

Prerequisites

• Make sure you have access to the Amazon RDS for MySQL DB instance with replication permissions.
• Exclude default Amazon RDS databases.
• Use similar memory and storage for source and target databases.

Restrictions

• This setup requires an internal team to run the read-only queries.
• The source and target MySQL versions should be the same.
• Replication is set up in the same AWS Region and virtual private cloud (VPC).

Product versions

• MySQL versions 5.5, 5.6, 5.7, 8.0. For the latest list of MySQL versions and features supported on Amazon RDS, see MySQL on Amazon RDS in the AWS documentation.

Architecture

Source technology stack

• Amazon RDS for MySQL DB instance

Target technology stack

• MySQL database on an EC2 instance

Data migration architecture
Tools

- Native MySQL GTID replication
- Native MySQL tools: `mysqldump` and `mysql`

Epics

Replication setup

Schedule jobs for Amazon RDS and Aurora PostgreSQL using Lambda and Secrets Manager

Created by Yaser Raja (AWS)

<table>
<thead>
<tr>
<th>R Type: N/A</th>
<th>Source: Databases: Relational</th>
<th>Target: PostgreSQL on AWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Databases</td>

<tr>
<td>Workload: Open-source</td>
<td>AWS services: Amazon RDS; AWS Lambda; AWS Secrets Manager</td>
<td></td>
</tr>
</tbody>
</table>

Summary

For on-premises databases and databases that are hosted on Amazon Elastic Compute Cloud (Amazon EC2) instances, database administrators often use the `cron` utility to schedule jobs.

For example, a job for data extraction or a job for data purging can easily be scheduled using `cron`. For these jobs, database credentials are typically either hard-coded or stored in a properties file. However, when you migrate to Amazon Relational Database Service (Amazon RDS) or Amazon Aurora PostgreSQL-Compatible Edition, you lose the ability to log in to the host instance to schedule `cron` jobs.

This pattern describes how to use AWS Lambda and AWS Secrets Manager to schedule jobs for Amazon RDS for PostgreSQL and Aurora PostgreSQL-Compatible databases after migration.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS for PostgreSQL or Aurora PostgreSQL-Compatible database
Limitations

- A job must complete within 15 minutes, which is the Lambda function timeout limit. For other limits, see the AWS Lambda documentation.
- Job code must be written in a language supported by Lambda.

Architecture

Source technology stack

This stack features jobs written in languages such as Bash, Python, and Java. Database credentials are stored in the properties file, and the job is scheduled using Linux cron.

Target technology stack

This stack has a Lambda function that uses the credentials stored in Secrets Manager to connect to the database and to perform the activity. The Lambda function is initiated at the scheduled interval by using Amazon CloudWatch Events.

Target architecture

Tools

- AWS Lambda – AWS Lambda is a compute service that lets you run code without provisioning or managing servers. AWS Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time you consume; there is no charge when your code is not running. With AWS Lambda, you can run code for virtually any type of application or backend service with zero administration. AWS Lambda runs your code on a high-availability compute infrastructure and manages all the compute resources, including server and operating system maintenance, capacity provisioning and automatic scaling, code monitoring, and logging. All you need to do is provide your code in one of the languages that AWS Lambda supports.
• **CloudWatch Events** – *Amazon CloudWatch Events* delivers a near real-time stream of system events that describe changes in AWS resources. Using simple rules that you can quickly set up, you can match events and route them to one or more target functions or streams. CloudWatch Events becomes aware of operational changes as they occur. It responds to these operational changes and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information. You can also use CloudWatch Events to schedule automated actions that self-initiate at certain times using **cron** or **rate** expressions.

• **Secrets Manager** – *AWS Secrets Manager* helps you protect secrets for accessing your applications, services, and IT resources. You can easily rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, which eliminates the need to hard-code sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon RDS, Amazon Redshift, and Amazon DocumentDB. The service is extensible to other types of secrets, including API keys and OAuth tokens. Secrets Manager enables you to control access to secrets using fine-grained permissions and to audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on-premises.

### Epics

#### Store database credentials in Secrets Manager

<table>
<thead>

Set up an HA/DR architecture for Oracle E-Business Suite on Amazon RDS Custom with an active standby database

*Created by Simon Cunningham (AWS) and Nitin Saxena*

**Environment:** Production  
**Technologies:** Databases; Infrastructure  
**Workload:** Oracle

**AWS services:** Amazon RDS

**Summary**

This pattern describes how you can architect your Oracle E-Business solution on Amazon Relational Database Service (Amazon RDS) Custom for high availability (HA) and disaster recovery (DR) by setting up an Amazon RDS Custom read replica database in another Amazon Web Services (AWS) Availability Zone and converting it to an active standby database. The creation of the Amazon RDS Custom read replica is fully automated through the AWS Management Console.

This pattern doesn’t discuss the steps for adding additional application tiers and shared file systems, which can also be part of an HA/DR architecture. For more information about those topics, see the following Oracle Support Notes: 1375769.1, 1375670.1, and 1383621.1 (section 5, Advanced Cloning Options). (Access requires an Oracle Support account.)
To migrate E-Business Suite system to a single-tier, Single-AZ architecture on Amazon Web Services (AWS), see the pattern Migrate Oracle E-Business Suite to Amazon RDS Custom.

Oracle E-Business Suite is an Enterprise Resource Planning (ERP) solution for automating enterprise-wide processes such as financials, human resources, supply chains, and manufacturing. It has a three-tier architecture: client, application, and database. Previously, you had to run your E-Business Suite database on a self-managed Amazon Elastic Compute Cloud (Amazon EC2) instance, but you can now benefit from Amazon RDS Custom.

Prerequisites and limitations

Prerequisites

- An existing E-Business Suite installation on Amazon RDS Custom; see the pattern Migrate Oracle E-Business Suite to Amazon RDS Custom
- If you want to change the read replica to read-only and use it to offload reporting to the standby, an Oracle Active Data Guard database license (see the Oracle Technology Commercial Price List)

Limitations

- Limitations and unsupported configurations for Oracle databases on Amazon RDS Custom
- Limitations associated with Amazon RDS Custom for Oracle read replicas

Product versions

For Oracle Database versions and instance classes supported by Amazon RDS Custom, see Requirements and limitations for Amazon RDS Custom for Oracle.

Architecture

The following diagram illustrates a representative architecture for E-Business Suite on AWS that includes multiple Availability Zones and application tiers in an active/passive setup. The database uses an Amazon RDS Custom DB instance and Amazon RDS Custom read replica. The read replica uses Active Data Guard to replicate to another Availability Zone. You can also use the read replica to offload read traffic on the primary database and for reporting purposes.
For more information, see Working with read replicas for Amazon RDS Custom for Oracle in the Amazon RDS documentation.

The Amazon RDS Custom read replica is created by default as mounted. However, if you want to offload some of your read-only workloads to the standby database to reduce the load on your primary database, you can manually change the mode of mounted replicas to read-only by following the steps in the Epics (p. 525) section. A typical use case for this would be to run your reports from the standby database. Changing to read-only requires an active standby database license.

When you create a read replica on AWS, the system uses Oracle Data Guard broker under the covers. This configuration is automatically generated and set up in Maximum Performance mode as follows:

```
DGMGRL> show configuration
Configuration - rds_dg
 Protection Mode: MaxPerformance
 Members:
 vis_a - Primary database
       vis_b - Physical standby database
 Fast-Start Failover: DISABLED
 Configuration Status:
 SUCCESS (status updated 58 seconds ago)
```

Tools

**AWS services**

- **Amazon RDS Custom for Oracle** is a managed database service for legacy, custom, and packaged applications that require access to the underlying operating system and database environment. It automates database administration tasks and operations while making it possible for you, as a database administrator, to access and customize your database environment and operating system.

**Other tools**
Oracle Data Guard is a tool that helps you create and manage Oracle standby databases. This pattern uses Oracle Data Guard to set up an active standby database on Amazon RDS Custom.

## Epics

### Create a read replica

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a read replica of the Amazon RDS Custom DB instance.</td>
<td>To create a read replica, follow the instructions in the Amazon RDS documentation and use the Amazon RDS Custom DB instance you created (see the Prerequisites (p. 523) section) as the source database. By default, the Amazon RDS Custom read replica is created as a physical standby and is in the mounted state. This is intentional to ensure compliance with the Oracle Active Data Guard license. Follow the next steps to convert the read replica to read-only mode.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

### Change the read replica to a read-only active standby

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connect to the Amazon RDS Custom read replica.</td>
<td>Use the following commands to convert your physical standby database to an active standby database. <strong>Important:</strong> These commands require an Oracle active standby license. To get a license, contact your Oracle representative.</td>
<td></td>
</tr>
</tbody>
</table>

```sql
$ sudo su - rdsdb
-bash-4.2$ sql
SQL> select process, status, sequence# from v$managed_standby;

<table>
<thead>
<tr>
<th>PROCESS</th>
<th>STATUS</th>
<th>SEQUENCE#</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCH</td>
<td>CLOSING</td>
<td>3956</td>
</tr>
<tr>
<td>ARCH</td>
<td>CONNECTED</td>
<td>0</td>
</tr>
</tbody>
</table>
```
### Task | Description | Skills required

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCH 3955</td>
<td>CLOSING</td>
<td>DBA</td>
</tr>
<tr>
<td>ARCH 3957</td>
<td>CLOSING</td>
<td></td>
</tr>
<tr>
<td>RFS 0</td>
<td>IDLE</td>
<td></td>
</tr>
<tr>
<td>RFS 3958</td>
<td>IDLE</td>
<td></td>
</tr>
<tr>
<td>MRP0 3958</td>
<td>APPLYING_LOG</td>
<td></td>
</tr>
<tr>
<td>SQL&gt; select name, database_role, open_mode from v$database;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NAME DATABASE_ROLE OPEN_MODE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>VIS</td>
<td>PHYSICAL STANDBY MOUNTED</td>
<td></td>
</tr>
<tr>
<td>SQL&gt; alter database recover managed standby database cancel;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Database altered. Open the standby database</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SQL&gt; alter database open;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Database altered.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SQL&gt; select name, database_role, open_mode from v$database;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NAME DATABASE_ROLE OPEN_MODE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>VIS</td>
<td>PHYSICAL STANDBY READ ONLY</td>
<td></td>
</tr>
</tbody>
</table>

Start media recovery with real-time log apply.

To enable the real-time log apply feature, use the following commands. These convert and validate the standby (read replica) as an active standby database, so you can connect and run read-only queries.

```sql
SQL> alter database recover managed standby database using current logfile disconnect from session;
Database altered
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check the database status.</td>
<td>To check the status of the database, use the following command.</td>
<td>DBA</td>
</tr>
<tr>
<td></td>
<td>SQL&gt; select name, database_role, open_mode from v$database; NAME DATABASE_ROLE OPEN_MODE ------------------------------- VIS PHYSICAL STANDBY READ ONLY WITH APPLY</td>
<td></td>
</tr>
<tr>
<td>Check redo apply mode.</td>
<td>To check redo apply mode, use the following command.</td>
<td>DBA</td>
</tr>
<tr>
<td></td>
<td>SQL&gt; select process,status,sequence# from v$managed_standby; PROCESS STATUS SEQUENCE# ------------------------------- ARCH CLOSING 3956 ARCH CONNECTED 0 ARCH CLOSING 3955 ARCH CLOSING 3957 RFS IDLE 0 RFS IDLE 3958 MRP0 APPLYING_LOG 3958</td>
<td></td>
</tr>
<tr>
<td></td>
<td>SQL&gt; select open_mode from v$database; OPEN_MODE ------------------------------- READ ONLY WITH APPLY</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern shows how to automate SAP systems installation by using open-source tools to create the following resources:

- An SAP S/4HANA 1909 database
- An SAP ABAP Central Services (ASCS) instance
- An SAP Primary Application Server (PAS) instance

Terraform by HashiCorp creates the SAP system's infrastructure and Ansible configures the operating system (OS) and installs SAP applications. Jenkins runs the installation.

This setup turns SAP systems installation into a repeatable process, which can help increase deployment efficiency and quality.

Note: The example code provided in this pattern works for both high-availability (HA) systems and non-HA systems.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Simple Storage Service (Amazon S3) bucket that contains all of your SAP media files
- An AWS Identity and Access Management (IAM) user with an access key and secret key, and that has the following permissions:
  - Read only permissions: Amazon Route 53, AWS Key Management Service (AWS KMS)
  - Read and write permissions: Amazon S3, Amazon Elastic Compute Cloud (Amazon EC2), Amazon Elastic File System (Amazon EFS), IAM, Amazon CloudWatch, Amazon DynamoDB
• A Route 53 private hosted zone
• A subscription to the Red Hat Enterprise Linux for SAP with HA and Update Services 8.2 Amazon Machine Image (AMI) in Amazon Marketplace
• An AWS KMS customer managed key
• A Secure Shell (SSH) key pair
• An Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you install Jenkins (the hostname is most likely localhost)
• Vagrant by HashiCorp installed and configured
• VirtualBox by Oracle installed and configured
• Familiarity with Git, Terraform, Ansible, and Jenkins

Limitations

• Only SAP S/4HANA 1909 is fully tested for this specific scenario. The example Ansible code in this pattern requires modification if you use another version of SAP HANA.
• The example procedure in this pattern works for Mac OS and Linux operating systems. Some of the commands can be run only in Unix-based terminals. However, you can achieve a similar result by using different commands and a Windows OS.

Product versions

• SAP S/4HANA 1909
• Red Hat Enterprise Linux (RHEL) 8.2 or higher versions

Architecture

The following diagram shows an example workflow that uses open-source tools to automate SAP systems installation in an AWS account:
The diagram shows the following workflow:

1. Jenkins orchestrates running the SAP system installation by running Terraform and Ansible code.
2. Terraform code builds the SAP system's infrastructure.
3. Ansible code configures the OS and installs SAP applications.
4. An SAP S/4HANA 1909 database, an ASCS instance, and PAS instance that include all defined prerequisites are installed on an Amazon EC2 instance.

Note: The example setup in this pattern automatically creates an Amazon S3 bucket in your AWS account to store the Terraform state file.

Technology stack

- Terraform
- Ansible
- Jenkins
- An SAP S/4HANA 1909 database
- An SAP ASCS instance
- An SAP PAS instance
- Amazon EC2

Tools

AWS services

- Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud. You can launch as many virtual servers as you need, and quickly scale them up or down.
- AWS Identity and Access Management (IAM) helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- AWS Key Management Service (AWS KMS) helps you create and control cryptographic keys to protect your data.
- Amazon Virtual Private Cloud (Amazon VPC) helps you launch AWS resources into a virtual network that you’ve defined. This virtual network resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

Other tools

- Terraform by HashiCorp is an open-source infrastructure as code (IaC) software tool that provides a consistent CLI workflow to manage cloud services. Terraform codifies cloud APIs into declarative configuration files.
- Ansible is an open-source configuration as code (CaC) tool that helps automate applications, configurations, and IT infrastructure.
- Jenkins is an open-source automation server that enables developers to build, test, and deploy their software.

Code

The code for this pattern is available in the GitHub aws-install-sap-with-jenkins-ansible repository.
### Epics

**Configure the prerequisites**

</tr>
</thead>
</table>
| Configure your SAP system installation parameters. | 1. In Jenkins, choose Manage Jenkins. Then, choose Manage Credentials. A list of credential variables that you can configure appears. 2. Configure all of the following credential variables:  
  - For AWS_ACCOUNT_CREDENTIALS, enter your IAM user’s access key ID and secret access key ID.  
  - For AMI_ID, enter the Red Hat Enterprise Linux for SAP with HA and Update Services 8.2 AMI’s AMI ID.  
  - For KMS_KEY_ARN, enter your AWS KMS customer managed key’s ARN.  
  - For SSH_KEYPAIR_NAME, enter the name of your SSH key pair, without entering the .pem file type.  
  - For SSH_KEYPAIR_FILE, enter the full name of your key pair’s .pem file (for example, mykeypair.pem). Make sure that you also upload the key pairs’ .pem file to Jenkins.  
  - For S3_ROOT_FOLDER_INSTALL_FILES, enter the name of the Amazon S3 bucket—and folder, if applicable—(for example, s3://my-media-bucket/S4H1909) that contains your SAP media files.  
  - For PRIVATE_DNS_ZONE_NAME, enter the name of your Route 53 private hosted zone (for example, myprivatecompanyurl.net).  
  - For VPC_ID, enter the VPC ID (for example, vpc-12345) of the Amazon VPC that you’re creating the SAP resources in.  
  - For SUBNET_IDS, enter two public subnet IDs if you’re working in a test environment (for future HA capabilities). | AWS systems administrator, DevOps engineer |
### Task Description

- You're working in a production environment, it's a best practice to use two private subnets with a bastion host.
- For `SECURITY_GROUP_ID`, enter the ID of the Amazon EC2 security group that allows SSH connection on port 22 from the hostname where you installed Jenkins.

**Note:** You can configure the other nonrequired parameters as needed, based on your use case. For example, you can change the SAP system ID (SID) of the instances, default password, names, and tags for your SAP system. All of the required variables have *(Required)* at the beginning of their names.

### Run you SAP system installation.

1. In Jenkins, choose *Jenkins Home*. Then, choose *SAP Hana+ASCS+PAS 3 Instances*.
2. Choose *Spin up and install*. Then, choose *Main*.
3. Choose *Build now*.

For information on the pipeline steps, see the *Understanding the pipeline steps* section of *Automating SAP installation with open-source tools* on the AWS Blog.

**Note:** If an error occurs, move your cursor over the red error box that appears and choose *Logs*. The logs for the pipeline step that errored out appear. Most errors occur because of incorrect parameter settings.

Automate AWS Service Catalog portfolio and product deployment by using AWS CDK

Created by Sandeep Gawande (AWS) and RAJNEESH TYAGI (AWS)

<table>

<tbody>
<tr>
<td>Open-source</td>
<td>AWS Service Catalog; AWS CDK</td>
</tr>
</tbody>
</table>

Summary

AWS Service Catalog helps you centrally manage catalogs of IT services, or products, that are approved for use in your organization’s AWS environment. A collection of products is called a portfolio, and a portfolio also contains configuration information. With AWS Service Catalog, you can create a customized portfolio for each type of user in your organization and then grant access to the appropriate portfolio. Those users can then quickly deploy any product they need from within the portfolio.

If you have a complex networking infrastructure, such as multi-Region and multi-account architectures, it is recommended that you create and manage Service Catalog portfolios in a single, central account. This pattern describes how to use AWS Cloud Development Kit (AWS CDK) to automate creation of Service Catalog portfolios in a central account, grant end users access to them, and then, optionally, provision products in one or more target AWS accounts. This ready-to-use solution creates the Service Catalog portfolios in the source account. It also, optionally, provisions products in target accounts by using AWS CloudFormation stacks and helps you configure TagOptions for the products:

- **AWS CloudFormation StackSets** – You can use StackSets to launch Service Catalog products across multiple AWS Regions and accounts. In this solution, you have the option to automatically provision products when you deploy this solution. For more information, see Using AWS CloudFormation StackSets (Service Catalog documentation) and StackSets concepts (CloudFormation documentation).
- **TagOption library** – You can manage tags on provisioned products by using TagOption library. A TagOption is a key-value pair managed in AWS Service Catalog. It is not an AWS tag, but it serves as a template for creating an AWS tag based on the TagOption. For more information, see TagOption library (Service Catalog documentation).

Prerequisites and limitations

Prerequisites

- An active AWS account that you want to use as the source account for administering Service Catalog portfolios.
- If you are using this solution to provision products in one or more target accounts, the target account must already exist and be active.
- AWS Identity and Access Management (IAM) permissions to access AWS Service Catalog, AWS CloudFormation, and AWS IAM.

Product versions
- AWS CDK version 2.27.0

**Architecture**

**Target technology stack**

- Service Catalog portfolios in a centralized AWS account
- Service Catalog products deployed in target account

**Target architecture**

1. In the portfolio (or source) account, you update the `config.json` file with the AWS account, AWS Region, IAM role, portfolio, and product information for your use case.
2. You deploy the AWS CDK application.
3. The AWS CDK application assumes the deployment IAM role and creates the Service Catalog portfolios and products defined in the `config.json` file.

   If you configured StackSets to deploy products in a target account, the process continues. If you didn’t configure StackSets to provision any products, then the process is complete.

4. The AWS CDK application assumes the StackSet administrator role and deploys the AWS CloudFormation stack set you defined in the `config.json` file.

5. In the target account, StackSets assumes the StackSet execution role and provisions the products.

**Tools**

**AWS services**

- **AWS Cloud Development Kit (AWS CDK)** is a software development framework that helps you define and provision AWS Cloud infrastructure in code.
- **AWS CDK Toolkit** is a command line cloud development kit that helps you interact with your AWS CDK app.
- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Service Catalog** helps you centrally manage catalogs of IT services that are approved for AWS. End users can quickly deploy only the approved IT services they need, following the constraints set by your organization.

**Code repository**

The code for this pattern is available on GitHub, in the `aws-cdk-servicecatalog-automation` repository. The code repository contains the following files and folders:

- **cdk-servicecatalog-app** – This folder contains the AWS CDK application for this solution.
- **config** – This folder contains the `config.json` file and the CloudFormation template for deploying the products in the Service Catalog portfolio.
- **config/config.json** – This file contains all of the configuration information. You update this file to customize this solution for your use case.
- **config/templates** – This folder contains the CloudFormation templates for the Service Center products.
- **setup.sh** – This script deploys the solution.
- **uninstall.sh** – This script deletes the stack and all of the AWS resources created when deploying this solution.

To use the sample code, follow the instructions in the Epics (p. 546) section.

**Best practices**

- IAM roles used to deploy this solution should adhere to the principle of least-privilege (IAM documentation).
- Adhere to the Best practices for developing cloud applications with AWS CDK (AWS blog post).
- Adhere to the AWS CloudFormation best practices (CloudFormation documentation).
## Epics

### Set up your environment

<table>

</tbody>
</table>
|      | • stackSetAdministrationRoleName – The name of the IAM role used to administer the StackSets configuration. Do not change this value. This role must have this exact name.  
• stackSetExecutionRoleName – The name of the IAM role in the target account that deploys the stack instances. Do not change this value. This role must have this exact name. | App developer, DevOps engineer, AWS DevOps |
| Deploy the solution. | Enter the following command. This deploys the AWS CDK app and provisions the Service Catalog portfolios and products as specified in the config.json file.  
```bash
sh +x setup.sh
``` | |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify the deployment.</td>
<td>Verify successful deployment by doing the following:</td>
<td>General AWS</td>
</tr>
<tr>
<td></td>
<td>1. Sign in to the AWS Management Console with credentials that can access one or more of the portfolios you defined in the config file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. In the navigation pane, under <code>Provisioning</code>, choose <code>Products</code>. Verify that you see a list of products that you specified for the portfolio.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Follow the instructions in <code>Launching a product</code> (Service Catalog documentation) to launch one of the available products. Confirm that the available product versions and tags match the values you provided in the config file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. If you chose to automatically provision products in one or more target accounts by using StackSets, do the following:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>a. Sign in with credentials that give you permissions to view the provisioned products in one of the target accounts.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>b. In the Service Catalog console, in the navigation pane, under <code>Provisioning</code>, choose <code>Provisioned products</code>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>c. Confirm that the expected products appear in the list.</td>
<td></td>
</tr>
</tbody>
</table>
(Optional) Update the portfolios and products.

If you want to use this solution to update the portfolios or products or to provision new products:

1. Make the required changes in the `config.json` file.
2. Add or modify any CloudFormation templates as needed in the `config/template` folder.
3. Redeploy the solution.

For example, you can add additional portfolios or provision more resources. The AWS CDK app implements only the changes. If there are no changes to previously deployed portfolios or products, the redeployment doesn’t affect them.

Skills required: App developer, DevOps engineer, General AWS

### Clean up the solution

(Optional) Remove AWS resources deployed by this solution.

If you want to delete a provisioned product, follow the instructions in Deleting provisioned products (Service Catalog documentation).

If you want to delete all the resources created by this solution, enter the following command.

```
sh uninstall.sh
```

Skills required: AWS DevOps, DevOps engineer, App developer

Automate event-driven backups from CodeCommit to Amazon S3 using CodeBuild and CloudWatch Events

*Created by Kirankumar Chandrashekar (AWS)*

<table>
<thead>
<tr>
<th><strong>Environment:</strong> Production</th>
<th><strong>Technologies:</strong> DevOps; Storage &amp; backup</th>
<th><strong>Workload:</strong> All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services: Amazon S3; Amazon CloudWatch; AWS CodeBuild; AWS CodeCommit</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

On the Amazon Web Services (AWS) Cloud, you can use AWS CodeCommit to host secure Git-based repositories. CodeCommit is a fully managed source control service. However, if a CodeCommit repository is accidentally deleted, its contents are also deleted and cannot be restored.
This pattern describes how to automatically back up a CodeCommit repository to an Amazon Simple Storage Service (Amazon S3) bucket after a change is made to the repository. If the CodeCommit repository is later deleted, this backup strategy provides you with a point-in-time recovery option.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing CodeCommit repository, with user access configured according to your requirements. For more information, see Setting up for AWS CodeCommit in the CodeCommit documentation.
- An S3 bucket for uploading the CodeCommit backups.

Limitations

- This pattern automatically backs up all of your CodeCommit repositories. If you want to back up individual CodeCommit repositories, you must modify the Amazon CloudWatch Events rule.

Architecture

The following diagram illustrates the workflow for this pattern.

The workflow consists of the following steps:

1. Code is pushed to a CodeCommit repository.
2. The CodeCommit repository notifies CloudWatch Events of a repository change (for example, a git push command).
3. CloudWatch Events invokes AWS CodeBuild and sends it the CodeCommit repository information.
4. CodeBuild clones the entire CodeCommit repository and packages it into a .zip file.
5. CodeBuild uploads the .zip file to an S3 bucket.
Technology stack

- CloudWatch Events
- CodeBuild
- CodeCommit
- Amazon S3

Tools

- Amazon CloudWatch Events – CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources.
- AWS CodeBuild – CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy.
- AWS CodeCommit – CodeCommit is a fully managed source control service that hosts secure Git-based repositories.
- AWS Identity and Access Management (IAM) – IAM is a web service that helps you securely control access to AWS resources.
- Amazon S3 – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

Epics

Create a CodeBuild project

<table>

Automate static website deployment to Amazon S3

*Created by Sankar Sangubotla (AWS)*

<table>
<thead>
<tr>
<th>R Type: N/A</th>
<th>Source: Application Development</th>
<th>Target: S3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Websites &amp; web apps; DevOps</td>
</tr>
<tr>
<td>AWS services: Amazon S3; AWS CodePipeline</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Summary

This pattern describes the steps required to add a continuous integration and continuous delivery (CI/CD) pipeline to an existing bucket in Amazon Simple Storage Service (Amazon S3) on the Amazon Web Services (AWS) Cloud. This pattern uses GitHub as a source provider. The pipeline is initiated when new items are committed, and the changes are then reflected in the S3 bucket.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Knowledge of Amazon S3 and AWS CodePipeline
- A static website, including output/source files such as HTML 4/5, CSS 2/4, images, fonts, and icons
- A GitHub repository

Limitations

- This process is recommended for displaying read-only content. It isn’t recommended for collecting or transferring sensitive information, because Amazon S3 uses the HTTP protocol.
- Websites built using PHP, JSP, or APS.NET are not supported, because Amazon S3 doesn’t support server-side scripts.

Architecture

Source architecture

Target technology stack

- AWS CodePipeline
- AWS CodeStar
- Amazon S3
- Any web server

Target architecture
Tools

- **AWS CodePipeline** – A continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process. CodePipeline automates the steps required to release your software changes continuously.
- **AWS CodeStar** – AWS CodeStar is a cloud-based service for creating, managing, and working with software development projects on AWS.
- **Amazon S3** – A highly scalable object storage service. It can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

Epics

Create an Amazon S3 bucket and upload content

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an S3 bucket.</td>
<td>Open the Amazon S3 console and choose <strong>Create bucket</strong> to create an S3 bucket for hosting the website and uploading content.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Enter the bucket name.</td>
<td>Enter a unique DNS-compliant name for your bucket. An S3 bucket name must be globally unique, because the namespace is shared by all AWS accounts.</td>
<td>AWS General, Developer</td>
</tr>
</tbody>
</table>
### Configure the S3 bucket for website hosting

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable static website hosting</td>
<td>In the <strong>Properties</strong> tab for the S3 bucket, choose <strong>Static website hosting</strong>, and then <strong>Use this bucket to host a website.</strong></td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Define home and error pages</td>
<td>Specify file names and extensions for the home page and error page (for example, index.html and error.html). Make sure that the root folder contains these files and that they serve as landing pages.</td>
<td>AWS General, Developer</td>
</tr>
</tbody>
</table>

### Create a bucket policy

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Attach bucket policy</td>
<td>Create a bucket policy so that other AWS applications can access and perform actions on your bucket. In the <strong>Permissions</strong> tab, choose <strong>Bucket policy.</strong> In the <strong>Bucket policy editor</strong>, paste the bucket policy provided in the <strong>Additional information</strong> section.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Access and test the website.</td>
<td>Enter the endpoint URL to access the website; for example: <a href="http://www.spsbuddy.xyz.s3-website-us-east-1.amazonaws.com">http://www.spsbuddy.xyz.s3-website-us-east-1.amazonaws.com</a>. The endpoint follows two formats, depending on your Region. For more information, see the Related resources section.</td>
<td>AWS General, Developer</td>
</tr>
</tbody>
</table>

Create a pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select a CodePipeline name.</td>
<td>Sign in to the AWS Management Console and open the AWS CodePipeline console. Choose Create pipeline and enter a name for the project.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Create a service role.</td>
<td>Create a service role or select from the list of service roles if provided.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Select an artifact store.</td>
<td>Choose a custom location and specify an existing bucket if you want Amazon S3 to create a bucket and store the artifacts in it. If not, use the default location.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Choose a source provider.</td>
<td>Choose GitHub (Version 2) from the list of source providers.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Connect to GitHub.</td>
<td>Authorize GitHub to grant CodePipeline access to your GitHub repository by following the instructions from Step 2: Create a connection to GitHub in GitHub connections from the AWS CodePipeline documentation.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Create repository and branch.</td>
<td>Choose the repository and branch to create as part of the commit step.</td>
<td>AWS General, Developer</td>
</tr>
<tr>
<td>Change detection options.</td>
<td>This automatically starts your pipeline when a change occurs in the source code. If turned off, your pipeline only runs if you start it manually or on a schedule.</td>
<td>AWS General, Developer</td>
</tr>
</tbody>
</table>
Deploy provider.

Choose Amazon S3 as the target from the list of available targets.

        "s3:GetObject"
      ],
      "Resource": [
        "arn:aws:s3:::example.com/*"
      ]
    }
  ]
}
```

Automatically attach an AWS managed policy for Systems Manager to EC2 instance profiles using Cloud Custodian and AWS CDK

Created by Ali Asfour (AWS) and Aaron Lennon (AWS)

Environment: PoC or pilot

Technologies: DevOps; Software development & testing; Management &

Workload: Open-source
Summary

You can integrate Amazon Elastic Compute Cloud (Amazon EC2) instances with AWS Systems Manager to automate operational tasks and provide more visibility and control. To integrate with Systems Manager, EC2 instances must have an installed AWS Systems Manager Agent (SSM Agent) and an AmazonSSMManagedInstanceCore AWS Identity and Access Management (IAM) policy attached to their instance profiles.

However, if you want to ensure that all EC2 instance profiles have the AmazonSSMManagedInstanceCore policy attached, you can face challenges updating new EC2 instances that don’t have instance profiles or EC2 instances that have an instance profile but don’t have the AmazonSSMManagedInstanceCore policy. It can also be difficult to add this policy across multiple Amazon Web Services (AWS) accounts and AWS Regions.

This pattern helps solve these challenges by deploying three Cloud Custodian policies in your AWS accounts:

- The first Cloud Custodian policy checks for existing EC2 instances that have an instance profile but don’t have the AmazonSSMManagedInstanceCore policy. The AmazonSSMManagedInstanceCore policy is then attached.
- The second Cloud Custodian policy checks for existing EC2 instances without an instance profile and adds a default instance profile that has the AmazonSSMManagedInstanceCore policy attached.
- The third Cloud Custodian policy creates AWS Lambda functions in your accounts to monitor the creation of EC2 instances and instance profiles. This ensures that the AmazonSSMManagedInstanceCore policy is automatically attached when an EC2 instance is created.

This pattern uses AWS DevOps tools to achieve a continuous, at-scale deployment of the Cloud Custodian policies to a multi-account environment, without provisioning a separate compute environment.

Prerequisites and limitations

Prerequisites

- Two or more active AWS accounts. One account is the security account and the others are member accounts.
- An existing IAM user or role in the security account with permissions to provision AWS resources. This pattern uses administrator permissions, but you should grant permissions according to your organization’s requirements and policies.
- Ability to assume an IAM role from the security account to member accounts and create the required IAM roles. For more information about this, see Delegate access across AWS accounts using IAM roles in the IAM documentation.
- AWS Command Line Interface (AWS CLI), installed and configured. For testing purposes, you can configure AWS CLI by using the aws configure command or setting environment variables.
Important: This isn't recommended for production environments and we recommend that this account is only granted least privilege access. For more information about this, see Grant least privilege in the IAM documentation.

- The devops-cdk-cloudcustodian.zip file (attached), downloaded to your local computer.
- Familiarity with Python.
- The required tools (Node.js, AWS Cloud Development Kit (AWS CDK), and Git), installed and configured. You can use the install-prerequisites.sh file in the devops-cdk-cloudcustodian.zip file to install these tools. Make sure you run this file with root privileges.

Limitations

- Although this pattern can be used in a production environment, make sure that all IAM roles and policies meet your organization’s requirements and policies.

Package versions

- Cloud Custodian version 0.9 or later
- TypeScript version 3.9.7 or later
- Node.js version 14.15.4 or later
- npm version 7.6.1 or later
- AWS CDK version 1.96.0 or later

Architecture

The diagram shows the following workflow:
1. Cloud Custodian policies are pushed to an AWS CodeCommit repository in the security account. An Amazon CloudWatch Events rule automatically initiates the AWS CodePipeline pipeline.

2. The pipeline fetches the most recent code from CodeCommit and sends it to the continuous integration part of the continuous integration and continuous delivery (CI/CD) pipeline handled by AWS CodeBuild.

3. CodeBuild performs the complete DevSecOps actions, including policy syntax validation on the Cloud Custodian policies, and runs these policies in \texttt{--dryrun} mode to check which resources are identified.

4. If there are no errors, the next task alerts an administrator to review the changes and approve the deployment into the member accounts.

**Technology stack**

- AWS CDK
- CodeBuild
- CodeCommit
- CodePipeline
- IAM
- Cloud Custodian

**Automation and scale**

The AWS CDK pipelines module provisions a CI/CD pipeline that uses CodePipeline to orchestrate the building and testing of source code with CodeBuild, in addition to the deployment of AWS resources with AWS CloudFormation stacks. You can use this pattern for all member accounts and Regions in your organization. You can also extend the Roles creation stack to deploy other IAM roles in your member accounts.

**Tools**

- **AWS CDK** – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- **AWS CodeBuild** – CodeBuild is a fully managed build service in the cloud.
- **AWS CodeCommit** – CodeCommit is a version control service that you can use to privately store and manage assets.
- **AWS CodePipeline** – CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software.
- **AWS Identity and Access Management** – IAM is a web service that helps you securely control access to AWS resources.
- **Cloud Custodian** – Cloud Custodian is a tool that unifies the dozens of tools and scripts most organizations use for managing their public cloud accounts into one open-source tool.
- **Node.js** – Node.js is a JavaScript runtime built on Google Chrome's V8 JavaScript engine.

**Code**

For a detailed list of modules, account functions, files, and deployment commands used in this pattern, see the README file in the devops-cdk-cloudcustodian.zip file (attached).
Epics

Set up the pipeline with AWS CDK

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Set up the CodeCommit repository. | 1. Unzip the devops-cdk-cloudcustodian.zip file (attached) in the working directory on your local computer.  
2. Sign in to the AWS Management Console for your security account, open the CodeCommit console, and then create a new devops-cdk-cloudcustodian repository.  
3. Change into the project directory and set up the CodeCommit repository as the origin, commit the changes, and then push them to the origin branch by running the following commands:  
   - cd devops-cdk-cloudcustodian  
   - git init --initial-branch=main  
   - git add . git commit -m 'initial commit'  
   - git remote add origin https://git-codecommit.us-east-1.amazonaws.com/v1/devops-cdk-cloudcustodian  
   - git push origin main  
   For more information about this, see Creating a CodeCommit repository in the AWS CodeCommit documentation. | Developer       |
<p>| Install the required tools.    | Use the install-prerequisites.sh file to install all the required tools on Amazon Linux. This doesn’t include AWS CLI because it comes pre-installed.                                                                                                                                   | Developer       |</p>
<table>

# Bootstrap the AWS accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boostrap the security account.</td>
<td>Bootstrap the deploy_account with the cloudcustodian_stack application by running the following command:</td>
<td>Developer</td>
</tr>
<tr>
<td></td>
<td><code>cdk bootstrap -a 'python3 cloudcustodian/cloudcustodian_stack.py</code></td>
<td></td>
</tr>
<tr>
<td>Option 1 - Automatically bootstrap the member accounts.</td>
<td>If the cdk_bootstrap_member_accounts variable is set to True in the vars.py file, the accounts specified in the member_accounts variable are automatically bootstrapped by the pipeline. If required, you can update <em>cdk_bootstrap_role</em> with an IAM role that you can assume from the security account and that has the required permissions to bootstrap the AWS CDK. New accounts added to the member_accounts variable are automatically bootstrapped by the pipeline so that the required roles can be deployed.</td>
<td>Developer</td>
</tr>
<tr>
<td>Option 2 - Manually bootstrap the member accounts.</td>
<td>Although we don't recommend using this approach, you can set the value of cdk_bootstrap_member_accounts to False and perform this step manually by running the following command:</td>
<td>Developer</td>
</tr>
<tr>
<td></td>
<td><code>cdk bootstrap -a 'python3 cloudcustodian/member_account_roles_stack.py'</code> \ <code>--trust {security_account_id}</code> \ <code>--context assume-role-credentials:writeIamRoleName={role_name}</code></td>
<td></td>
</tr>
</tbody>
</table>
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Create the IAM roles in the member accounts.</strong> Run the following command to deploy the member_account_roles_stack stack and create the IAM roles in the member accounts:</td>
<td>Developer</td>
</tr>
<tr>
<td>cdk deploy --all -a 'python3 cloudcustodian/member_account_roles_stack.py' --require-approval never</td>
<td></td>
</tr>
<tr>
<td><strong>Deploy the Cloud Custodian pipeline stack.</strong> Run the following command to create the Cloud Custodian cloudcustodian_stack.py pipeline that is deployed into the security account:</td>
<td>Developer</td>
</tr>
</tbody>
</table>

---

**Important:** Make sure that you update the `{security_account_id}` and `{role_name}` values with the name of an IAM role that you can assume from the security account and that has the required permissions to bootstrap the AWS CDK.

You can also use other approaches to bootstrap the member accounts, for example, with AWS CloudFormation. For more information about this, see Bootstrapping in the AWS CDK documentation.
Task | Description | Skills required

Automatically build CI/CD pipelines and Amazon ECS clusters for microservices using AWS CDK

*Created by Varsha Raju (AWS)*

| Environment: PoC or pilot | Technologies: DevOps; Containers & microservices; Modernization; Infrastructure | AWS services: AWS CodeBuild; AWS CodeCommit; AWS CodePipeline; Amazon ECS; AWS CDK |

Summary

This pattern describes how to automatically create the continuous integration and continuous delivery (CI/CD) pipelines and underlying infrastructure for building and deploying microservices on Amazon Elastic Container Service (Amazon ECS). You can use this approach if you want to set up proof-of-concept CI/CD pipelines to show your organization the benefits of CI/CD, microservices, and DevOps. You can also use this approach to create initial CI/CD pipelines that you can then customize or change according to your organization's requirements.

The pattern's approach creates a production environment and non-production environment that each have a virtual private cloud (VPC) and an Amazon ECS cluster configured to run in two Availability Zones. These environments are shared by all your microservices and you then create a CI/CD pipeline for each microservice. These CI/CD pipelines pull changes from a source repository in AWS CodeCommit, automatically build the changes, and then deploy them into your production and non-production environments. When a pipeline successfully completes all of its stages, you can use URLs to access the microservice in the production and non-production environments.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
• An existing Amazon Simple Storage Service (Amazon S3) bucket that contains the starter-code.zip file (attached).
• AWS Cloud Development Kit (AWS CDK), installed and configured in your account. For more information about this, see Getting started with the AWS CDK in the AWS CDK documentation.
• Python 3 and pip, installed and configured. For more information about this, see the Python documentation.
• Familiarity with AWS CDK, AWS CodePipeline, AWS CodeBuild, CodeCommit, Amazon Elastic Container Registry (Amazon ECR), Amazon ECS, and AWS Fargate.
• Familiarity with Docker.
• An understanding of CI/CD and DevOps.

Limitations

• General AWS account limits apply. For more information about this, see AWS service quotas in the AWS General Reference documentation.

Product versions

• The code was tested using Node.js version 16.13.0 and AWS CDK version 1.132.0.

Architecture

The diagram shows the following workflow:

1. An application developer commits code to a CodeCommit repository.
2. A pipeline is initiated.
3. CodeBuild builds and pushes the Docker image to an Amazon ECR repository.
4. CodePipeline deploys a new image to an existing Fargate service in a non-production Amazon ECS cluster.
5. Amazon ECS pulls the image from the Amazon ECR repository into a non-production Fargate service.
6. Testing is performed using a non-production URL.
7. The release manager approves the production deployment.
8. CodePipeline deploys the new image to an existing Fargate service in a production Amazon ECS cluster.
9. Amazon ECS pulls the image from the Amazon ECR repository into the production Fargate service.
10. Production users access your feature by using a production URL.

Technology stack

- AWS CDK
- CodeBuild
- CodeCommit
- CodePipeline
- Amazon ECR
- Amazon ECS
- Amazon VPC

Automation and scale

You can use this pattern's approach to create pipelines for microservices deployed in a shared AWS CloudFormation stack. The automation can create more than one Amazon ECS cluster in each VPC and also create pipelines for microservices deployed in a shared Amazon ECS cluster. However, this requires that you provide new resource information as inputs to the pipeline stack.

Tools

- **AWS CDK** – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- **AWS CodeCommit** – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.
- **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process. CodePipeline automates the steps required to release your software changes continuously.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that is used for running, stopping, and managing containers on a cluster. You can run your tasks and services on a serverless infrastructure that is managed by AWS Fargate. Alternatively, for more control over your infrastructure, you can run your tasks and services on a cluster of Amazon Elastic Compute Cloud (Amazon EC2) instances that you manage.
- **Docker** – Docker helps developers to pack, ship, and run any application as a lightweight, portable, and self-sufficient container.

Code

The code for this pattern is available in the cicdstarter.zip and starter-code.zip files (attached).
Epics

Set up your environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up the working directory for AWS CDK.</td>
<td>1. Create a directory named cicdproject on your local machine.</td>
<td>AWS DevOps, Cloud infrastructure</td>
</tr>
<tr>
<td></td>
<td>2. Download the cicdstarter.zip file (attached) into the cicdproject directory and unzip it. This creates a folder named cicdstarter.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Run the cd &lt;user-home&gt;/cicdproject/cicdstarter command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Set up the Python virtual environment by running the python3 -m venv .venv command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. Run the source ./.venv/bin/activate command.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6. Configure your AWS environment by running the aws configure command or by using the following environment variables:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS_ACCESS_KEY_ID</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS_SECRET_ACCESS_KEY</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS_DEFAULT_REGION</td>
<td></td>
</tr>
</tbody>
</table>

Create the shared infrastructure

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the shared infrastructure.</td>
<td>1. In your working directory, run the cd cicdvpcecs command.</td>
<td>AWS DevOps, Cloud infrastructure</td>
</tr>
<tr>
<td></td>
<td>2. Run the pip3 install -r requirements.txt command to install all required Python dependencies</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. Run the cdk bootstrap command to set the AWS environment for the AWS CDK.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. Run the cdk synth --context</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>--------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>6. The AWS CloudFormation stack creates the following infrastructure:</td>
<td>Monitor the AWS CloudFormation stack. 1. Sign in to the AWS Management Console, open the AWS CloudFormation console, and then choose the cicd-vpc-ecs stack from the list. 2. In the stack details pane, choose the Events tab and monitor the progress of your stack creation.</td>
<td></td>
</tr>
</tbody>
</table>
### Task: Test the AWS CloudFormation stack.

1. After the `cicd-vpc-ecs` AWS CloudFormation stack is created, ensure that the `cicd-vpc-ecs/cicd-vpc-nonprod` and `cicd-vpc-ecs/cicd-vpc-prod` VPCs are created.
2. Ensure that the `cicd-ecs-nonprod` and `cicd-ecs-prod` Amazon ECS clusters are created.

**Important:** Make sure that you record the IDs for the two VPCs and the security group IDs for the default security groups in both VPCs.

### Task: Create a CI/CD pipeline for a microservice

#### Description

1. Name your microservice. For example, this pattern uses `myservice1` as the microservice's name.
2. In your working directory run the `cd <working-directory>/cdkpipeline` command.
3. Run the `pip3 install -r requirements.txt` command.
4. Run the full `cdk synth` command that is available in the *Additional information* section of this pattern.
5. Run the full `cdk deploy` command that is available in the *Additional information* section of this pattern.

**Note:** You can also provide the values for both commands by using the `cdk.json` file in the directory.

### Task: Monitor the AWS CloudFormation stack.

Open the AWS CloudFormation console and monitor the progress of the `myservice1-cicd-stack` stack. Eventually,
### Task | Description | Skills required
---|---|---
Test the AWS CloudFormation stack. | the status changes to CREATE_COMPLETE. | |
1. On the AWS CodeCommit console, verify that a repository named myservice1 exists and contains the starter code.  
2. On the AWS CodeBuild console, verify that a build project named myservice1 exists.  
3. On the Amazon ECR console, verify that an Amazon ECR repository named myservice1 exists.  
4. On the Amazon ECS console, verify that a Fargate service named myservice1 exists in both a non-production and production Amazon ECS cluster.  
5. On the Amazon Elastic Compute Cloud (Amazon EC2) console, verify that the non-production and production Application Load Balancers are created. Record the DNS names of the ALBs.  
6. On the AWS CodePipeline console, verify that a pipeline named myservice1 exists. It must have Source, Build, Deploy-NonProd, and Deploy-Prod stages. The pipeline should also have an in progress status.  
7. Monitor the pipeline until all stages are complete.  
8. Manually approve it for production.  
9. In a browser window, enter the DNS names of the ALBs.  
10. The application should display Hello World in the non-production and production URLs. |
### Task | Description | Skills required
--- | --- | ---
Use the pipeline. | 1. Open the CodeCommit repository that you created earlier and open the index.js file.  
2. Replace Hello World with Hello CI/CD.  
3. Save and commit the changes to the main branch.  
4. Verify that the pipeline initiates and that the change goes through the Build, Deploy-NonProd, and Deploy-Prod stages.  
5. Manually approve the production.  
6. Both production and non-production URLs should now display Hello CI/CD. | AWS DevOps, Cloud infrastructure

```
Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9

Created by Alexandre Nardi (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>DevOps; Serverless; Websites &amp; web apps; Databases</td>
</tr>
<tr>
<td>AWS services:</td>
<td>AWS Cloud9; AWS CloudFormation; AWS CodePipeline; Amazon DynamoDB; AWS CodeCommit</td>
</tr>
</tbody>
</table>

Summary

This pattern demonstrates how to develop a typical web application in a serverless architecture, for developers and development leads who are beginning to test DevOps practices on Amazon Web Services (AWS). It builds a sample application that creates a storefront and backend for browsing and purchasing books, and provides a microservice that can be developed independently. The pattern uses AWS Cloud9 as a development environment, an Amazon DynamoDB database as a data store, and AWS services such as AWS CodePipeline and AWS CodeBuild for continuous integration and continuous deployment (CI/CD) functionality.

The pattern guides you through the following development activities:

- Creating a standard AWS Cloud9 development environment
- Using AWS CloudFormation templates to create a web application and a microservice for books
- Using AWS Cloud9 to modify the front-end, commit changes, and test changes
- Creating and testing a CI/CD pipeline to the microservice
- Automating unit tests

The code for this pattern is provided in GitHub, in the AWS DevOps End-to-End Workshop repository.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Files from the AWS DevOps End-to-End Workshop downloaded to your computer
Important: Building this demo application in your AWS account creates and consumes AWS resources. You are responsible for the cost of the AWS services and resources used to create and run the application. After you finish your work, be sure to remove all resources to avoid ongoing charges. For cleanup instructions, see the Epics section.

Limitations

This walkthrough is intended for demonstration and development purposes only. To use it in a production environment, see Security best practices in the AWS Identity and Access Management (IAM) documentation, and make the necessary changes to IAM roles, Amazon DynamoDB, and other services used. The web application is derived from the AWS Bookstore Demo App; for additional considerations, see the Known limitations section of the README file.

Architecture

The architecture of the bookstore application is illustrated in the Architecture section of the README file for the AWS Bookstore Demo App.

From a deployment perspective, the Bookstore Demo App uses a single CloudFormation template to deploy all services and objects in one stack. This pattern makes a few changes to demonstrate how a particular developer or team could work in a specific product (Books), and update it independently from the rest of the application. For this reason, the code for this pattern separates the AWS Lambda functions and related objects for the Books microservice into a second CloudFormation template, which creates a Books stack. That makes it possible to see the microservice being updated by using CI/CD practices. In the following diagram, the dashed border identifies the Books microservice.
Tools

The source code and templates for this pattern are available on GitHub, in the AWS DevOps End-to-End Workshop repository. Before following the steps in the Epics section, download all the files from the repository to your computer.

Note: The Epics section provides the high-level steps for this walkthrough, to give you general information about the process. To complete each step, see the README file in the AWS DevOps End-to-End Workshop repository for detailed instructions.

Epics

Build the Bookstore web application and the Books microservice

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the front-end and Lambda functions for the Bookstore app. | 1. Log in to the CloudFormation console, and deploy the DemoBookstoreMainTemplate.yml template to create the DemoBookStoreStack stack. This creates the front-end and Lambda functions that are outside the Books microservice.  
2. In the Outputs tab of the stack, note the website URL under the WebApplication label. | Developer        |
| Create the Books microservice.         | On the CloudFormation console, deploy the DemoBookstoreBooksServiceTemplate.yml template to create the DemoBooksServiceStack stack. | Developer        |
| Test your application.                 | Use the website URL from the DemoBookStoreStack stack to access the Bookstore application. | Developer        |
### Use the Cloud9 environment to maintain your application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an AWS Cloud9 IDE.</td>
<td>On the CloudFormation console, deploy the C9EnvironmentTemplate.yml template to create an AWS Cloud9 environment.</td>
<td>Developer, Developer lead</td>
</tr>
</tbody>
</table>
| Create CodeCommit repositories. | 1. Log in to the AWS CodeCommit console, and verify that you have a demobookstore-WebAssets repository, which contains the code for the front-end application.  
2. Create a repository for the Books microservice called demobookstore-BooksService.  
3. Clone the two repositories in AWS Cloud9 (demobookstore-WebAssets and demobookstore-BooksService) by using the `git clone` command. | Developer |
| Change the code in the front-end and check the pipeline. | 1. Using AWS Cloud9, make some code changes in a webpage. This will update the demobookstore-WebAssets repository.  
2. On the AWS CodePipeline console, verify that demobookstore-Assets-Pipeline is running.  
3. Test your web application by refreshing it from the browser (Ctrl+F5 on Firefox). | Developer |

### Implement a CI/CD pipeline for the Books microservice

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Add the build and service update YAML files. | 1. In AWS Cloud9, upload the buildspec.yml and DemoBookstoreBooksServiceUpdateTemplate.yml files.  
   - `buildspec.yml` has building instructions, and also includes testing instructions for automated tests. They are commented | Developer |
### Task | Description | Skills required
--- | --- | ---
| | at this point, and will be used later.  
- DemoBookstoreBooksServiceUpdateTemplate.yml is an updated version of DemoBookstoreBooksServiceTemplate.yml, to be used in the deployment stage of the pipeline.  
2. Commit and push the files. |
| **Create an S3 bucket for the build pipeline.** | To create an S3 bucket, follow the instructions in the Amazon S3 documentation.  
- The bucket name must be globally unique; for example, demobookstore-books-service-pipeline-bucket-<YYYYMMDDHHMM>.  
- Clear the Block all public access check box, and select the I acknowledge... check box. |
| **Use IAM to create a role for CloudFormation deployment.** | Create a demobookstore-CloudFormation-role role and attach the AdministratorAccess policy. In the next epic, you can reconfigure this role for minimum permissions. |
| **Create a new pipeline to automate building and deploying the Books microservice.** | Create a pipeline (for example, demobookstore-BooksService-Pipeline) with Commit, Build, and Deploy stages, as described in the README file. |
| **Test your microservice in AWS Cloud9.** | Make a change in the ListBooks function and see the pipeline working. |
| **Automate the unit test for the ListBooks Lambda function.** | In the AWS Cloud9 IDE, enable the build to run unit tests, and check the test results. For instructions, see the README file. |

(Optional) Implement additional functionality

### Task | Description | Skills required
--- | --- | ---
| **Make your solution secure.** | Configure demobookstore-CloudFormation-role to | Developer |
## Epics

Build and test iOS apps with AWS CodeCommit, AWS CodePipeline, and AWS Device Farm

Created by Abdullahi Olaoye (AWS)

<table>
<thead>
<tr>
<th>R Type: N/A</th>
<th>Source: On-premises DevOps processes</th>
<th>Target: CI/CD pipeline for iOS apps development on AWS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>
<td>Technologies: Websites &amp; web apps; DevOps</td>
</tr>
<tr>
<td>AWS services: AWS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CodeCommit; AWS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CodePipeline; AWS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device Farm</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Summary

This pattern outlines the steps for creating a continuous integration and continuous delivery (CI/CD) pipeline that uses AWS CodePipeline to build and test iOS applications on real devices on AWS. The pattern uses AWS CodeCommit to store the application code, the Jenkins open-source tool to build the iOS application, and AWS Device Farm to test the built application on real devices. These three phases are orchestrated together in a pipeline by using AWS CodePipeline.

This pattern is based on the post Building and testing iOS and iPadOS apps with AWS DevOps and mobile services on the AWS DevOps blog. For detailed instructions, see the blog post.

Prerequisites and limitations

Prerequisites

• An active AWS account
• An Apple developer account
• Build server (macOS)
• Xcode version 11.3 (installed and set up on the build server)
• AWS Command Line Interface (AWS CLI) installed and configured on the workstation
• Basic knowledge of Git

Limitations

• The application build server must be running macOS.
• The build server must have a public IP address, so CodePipeline can connect to it remotely to initiate builds.

Architecture

Source technology stack

• An on-premises iOS application build process that involves using a simulator or manual test on physical devices

Target technology stack

• An AWS CodeCommit repository for storing application source code
• A Jenkins server for application builds using Xcode
• An AWS Device Farm device pool for testing applications on real devices

Target architecture

When a user commits changes to the source repository, the pipeline (AWS CodePipeline) fetches the code from the source repository, initiates a Jenkins build, and passes the application code to Jenkins. After the build, the pipeline retrieves the build artifact and starts an AWS Device Farm job to test the application against a device pool.
Tools

- **AWS CodePipeline** – AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deploy phases of your release process every time there is a code change, based on the release model you define.

- **AWS CodeCommit** – AWS CodeCommit is a fully managed source control service that hosts secure Git-based repositories. It makes it easy for teams to collaborate on code in a secure and highly scalable ecosystem. CodeCommit eliminates the need to operate your own source control system or worry about scaling its infrastructure.

- **AWS Device Farm** – AWS Device Farm is an application testing service that lets you improve the quality of your web and mobile apps by testing them across an extensive range of desktop browsers and real mobile devices, without having to provision and manage any testing infrastructure.

- **Jenkins** – Jenkins is an open-source automation server that enables developers to build, test, and deploy their software.

Check AWS CDK applications or CloudFormation templates for best practices by using cdk-nag rule packs

Summary

This pattern explains how you can use the cdk-nag utility to check AWS Cloud Development Kit (AWS CDK) applications for best practices by using a combination of rule packs. cdk-nag is an open-source project that was inspired by cfn_nag. It implements rules in evaluation packs such as AWS Solutions Library, Health Insurance Portability and Accountability Act (HIPAA), and National Institute of Standards and Technology (NIST) 800-53 by using AWS CDK Aspects. You can check your AWS CDK applications for best practices by using the rules in these packs, detect and remediate code based on best practices, and suppress the rules that you don’t want to use in your evaluations.

You can also use cdk-nag to check your AWS CloudFormation templates by using the cloudformation-include module.

For information about all available packs, see the Rules section of the cdk-nag repository. Evaluation packs are available for:

- AWS Solutions Library
- HIPAA security
- NIST 800-53 rev 4
- NIST 800-53 rev 5
- Payment Card Industry Data Security Standard (PCI DSS) 3.2.1

Prerequisites and limitations

Prerequisites

- An application that uses the AWS CDK
Tools

- **AWS CDK** – Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and you can launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

Epics

Integrate cdk-nag with your AWS CDK application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learn about cdk-nag.</td>
<td>Navigate to the <a href="https://github.com/cdk-nag/cdk-nag">cdk-nag GitHub repository</a> and read through the documentation.</td>
<td>App developer</td>
</tr>
<tr>
<td>Install the cdk-nag package in your AWS CDK application.</td>
<td>To use <a href="https://github.com/cdk-nag/cdk-nag">cdk-nag</a> in your AWS CDK application, you must install it first. <a href="https://github.com/cdk-nag/cdk-nag">cdk-nag</a> is available to download from PyPI, npm, NuGet, and Apache Maven. For the latest information about available versions and download locations, see the <a href="https://github.com/cdk-nag/cdk-nag">Readme file</a> in the repository.</td>
<td>App developer</td>
</tr>
<tr>
<td>Choose your NagPacks.</td>
<td><a href="https://github.com/cdk-nag/cdk-nag">cdk-nag</a> has different packs of rules called <em>NagPacks</em>. Each NagPack contains rules that conform to a specific standard. For example, the AWS Solutions NagPack contains general best practices, and the NIST 800-53 rev 5 NagPack can help with compliance. You can apply multiple NagPacks to your application, and you can add and remove packs as necessary. For a list of available packs, see the <a href="https://github.com/cdk-nag/cdk-nag">Readme file</a> in the GitHub repository. For information about the individual rules in each pack, see the <a href="https://github.com/cdk-nag/cdk-nag">Rules section</a> of the GitHub repository.</td>

</table>
Configure cross-account access to Amazon DynamoDB

*Created by Shashi Dalmia*

**Environment:** Production

**Technologies:** DevOps; Databases; Security, identity, compliance

**AWS services:** Amazon DynamoDB; AWS Identity and Access Management; AWS Lambda

**Summary**

This pattern explains the steps for configuring cross-account access to Amazon DynamoDB. Amazon Web Services (AWS) services can access DynamoDB tables that are in the same AWS account if the service

```javascript
import { App, Aspects } from 'aws-cdk-lib';
import { CdkTestStack } from '../lib/cdk-test-stack';
import { AwsSolutionsChecks, HIPAASecurityChecks } from 'cdk-nag';

const app = new App();
new CdkTestStack(app, 'CdkNagDemo');
// Simple rule informational messages
Aspects.of(app).add(new AwsSolutionsChecks());
// Additional explanations on the purpose of triggered rules
Aspects.of(app).add(new HIPAASecurityChecks({ verbose: true }));
```
has the appropriate AWS Identity and Access Management (IAM) permissions set up in the database. However, access from a different AWS account requires setting up IAM permissions and establishing a trust relationship between the two accounts.

This pattern provides steps and sample code to demonstrate how you can configure AWS Lambda functions in one account to read and write to a DynamoDB table in a different account.

Prerequisites and limitations

- Two active AWS accounts. This pattern refers to these accounts as Account A and Account B.
- AWS Command Line Interface (AWS CLI) installed and configured to access Account A, to create the DynamoDB database. The other steps in this pattern provide instructions for using the IAM, DynamoDB, and Lambda consoles. If you’re planning to use AWS CLI instead, configure it to access both accounts.

Architecture

In the following diagram, AWS Lambda, Amazon EC2, and DynamoDB are all in the same account. In this scenario, Lambda functions and Amazon Elastic Compute Cloud (Amazon EC2) instances can access DynamoDB.

If resources in a different AWS account try to access DynamoDB, they require setting up cross-account access and a trust relationship. For example, in the following diagram, to enable access between DynamoDB in Account A and the Lambda function in Account B, you must create a trust relationship between the accounts and grant appropriate access to the Lambda service and users, as described in the Epics (p. 599) section.
Tools

AWS services

- **Amazon DynamoDB** – Amazon DynamoDB is a fully managed NoSQL database service that provides fast and predictable performance with seamless scalability.

- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
Code

This pattern includes sample code in the Additional information (p. 606) section to illustrate how you can configure a Lambda function in Account B to read and write to the DynamoDB table in Account A. The code is provided for illustration and testing purposes only. If you’re implementing this pattern in a production environment, use the code as a reference and customize it for your own environment.

This pattern illustrates cross-account access with Lambda and DynamoDB. You can use the same steps for other AWS services as well, but make sure that you grant and configure the appropriate permissions in both accounts. For example, if you want to grant access to an Amazon Relational Database Service (Amazon RDS) database in Account A, create a role for that database and bind it with a trust relationship. In Account B, if you want to use Amazon EC2 instead of AWS Lambda, create the respective IAM policy and role, and then attach them to the EC2 instance.

Epics

Create a DynamoDB table in Account A

<table>

Create a role in Account A

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a role in Account A. | This role will be used by Account B to gain permissions to access Account A. To create the role:  
  2. Open the IAM console at https://console.aws.amazon.com/iam/.  
  3. In the navigation pane of the console, choose Roles, and then choose Create role.  
  4. For Select type of trusted entity, choose Another AWS account.  
  5. For Account ID, type the ID for Account B.  
  6. Choose Next: Permissions.  
  7. In the Filter policies box, type DynamoDB.  
  8. In the list of DynamoDB policies, select AmazonDynamoDBFullAccess. This policy allows all actions on DynamoDB. For a list of other policies you can choose instead, see Example policies in the IAM documentation.  
  9. Choose Next: Tags.  
  10(Optional) Add metadata to the role by attaching tags as key-value pairs.  
  11Choose Next: Review. The Review page displays the account number for Account A, the AmazonDynamoDBFullAccess policy, and any tags you entered.  
  12For Role name, type a unique name for your role (for example, DynamoDB-FullAccess-For-Account-B), and add an optional role description.  
  13Choose Create role. | AWS DevOps |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>For more information about creating roles, see the IAM documentation.</td>
<td>AWS DevOps</td>
</tr>
</tbody>
</table>
| Note the ARN for the role in Account A. | 1. In the navigation pane of the IAM console, choose Roles.  
2. In the search box, type `DynamoDB-FullAccess-For-Account-B` (or the role name you assigned in the previous story), and choose the role.  
3. In the summary page for the role, copy the Amazon Resource Name (ARN). You'll use the ARN when setting up Account B and in the Lambda code. | AWS DevOps |

### Configure access to Account A from Account B

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
2. Open the IAM console at https://console.aws.amazon.com/iam/.  
3. In the navigation pane of the console, choose Policies, and then choose Create Policy.  
4. Choose the JSON tab.  
5. Type or paste the following JSON document:  
```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "sts:AssumeRole",
    }
  ]
}
``` | AWS DevOps |
where the `Resource` property contains the ARN of the role you created in the previous story in Account A.

6. Choose **Next: Tags**.

7. (Optional) Add metadata to the policy by attaching tags as key-value pairs.

8. Choose **Next: Review**.

9. For **Policy name**, type a unique name for your policy (for example, `DynamoDB-FullAccess-Policy-in-Account-A`), and add an optional policy description.

10. Choose **Create policy**.

For more information about creating policies, see the [IAM documentation](https://docs.aws.amazon.com/iam/latest/UserGuide/).

## Create Lambda functions in Account B

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
3. In the navigation pane of the console, choose **Functions**, and then choose **Create function**.  
4. For **Name**, type *lambda_write_function*.  
5. For **Runtime**, choose **Python 3.8 or later**.  
6. For **Permissions**, **Change default execution role**, choose **Use an existing role**.  
7. For **Existing role**, choose **DynamoDB-FullAccess-in-Account-A**.  
8. Choose **Create function**.  
9. In the **Code** tab, paste the contents of the *lambda_write_function.py* file, which is provided in the **Additional information (p. 606)** section. Make sure to provide the correct ARN information (from the epic **Create a role in Account A**) for the **RoleArn** field, and change **region_name** according to your requirements.  
10. Run the function by choosing the **Test** button.  
11. Check the output from the function. It should be similar to the output shown in the **Lambda write function** section of **Additional information (p. 606)**. This output indicates that the function accessed the DynamoDB table in Account A and was able to write data to it. | AWS DevOps |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a Lambda function to read data from DynamoDB. | 1. In the navigation pane of the Lambda console, choose **Functions**, and then choose **Create function**.  
2. For **Name**, type **lambda_read_function**.  
3. For **Runtime**, choose Python 3.8 or later.  
4. For **Permissions**, **Change default execution role**, choose **Use an existing role**.  
5. For **Existing role**, choose **DynamoDB-FullAccess-in-Account-A**.  
6. Choose **Create function**.  
7. In the **Code** tab, paste the contents of the **lambda_read_function.py** file, which is provided in the Additional information (p. 606) section. Make sure to provide the correct ARN information (from the epic Create a role in Account A) for the **RoleArn** field, and change **region_name** according to your requirements.  
8. Run the function by choosing the **Test** button.  
9. Check the output from the function. It should be similar to the output shown in the Lambda read function section of Additional information (p. 606). This output indicates that the function accessed the DynamoDB table in Account A and was able to read the data you added to the table. | AWS DevOps |
Clean up resources

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete the resources you created.</td>
<td>If you're running this pattern in a testing or proof of concept (PoC) environment, delete the resources you created to avoid incurring costs.</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td></td>
<td>1. In Account B, delete the two Lambda functions and other resources you created to connect to DynamoDB.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. In Account A, delete the DynamoDB table you created.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. IAM policies do not cost anything, so you can keep them as is. However, for security, we recommend that you delete the following roles and policies you created for this pattern:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Account A: DynamoDB-Full-Access-for-Account-A role</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Account B: DynamoDB-FullAccess-in-Account-A role</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Account B: DynamoDB-FullAccess-Policy-in-Account-A policy</td>
<td></td>
</tr>
</tbody>
</table>

Additional information

The code in this section is provided for illustration and testing purposes only. If you’re implementing this pattern in a production environment, use the code as a reference and customize it for your own environment.
Lambda write function

Sample code:

```python
import boto3
from datetime import datetime

sts_client = boto3.client('sts')
sts_session = sts_client.assume_role(RoleArn='arn:aws:iam::<Account-A ID>:role/DynamoDB-FullAccess-For-Account-B',
                                          RoleSessionName='test-dynamodb-session')

KEY_ID = sts_session['Credentials']['AccessKeyId']
ACCESS_KEY = sts_session['Credentials']['SecretAccessKey']
TOKEN = sts_session['Credentials']['SessionToken']

dynamodb_client = boto3.client('dynamodb',
                                region_name='us-east-2',
                                aws_access_key_id=KEY_ID,
                                aws_secret_access_key=ACCESS_KEY,
                                aws_session_token=TOKEN)

def lambda_handler(event, context):
    now = datetime.now()
date_time = now.strftime("%m/%d/%Y, %H:%M:%S")
data = dynamodb_client.put_item(
    TableName='Table-Account-A',
    Item={
        "category": {
            "S": "Fruit"
        },
        "item": {
            "S": "Apple"
        },
        "time": {
            "S": date_time
        }
    }
)

return data
```

Sample output:

607
Lambda read function

Sample code:

```
import boto3
from datetime import datetime

sts_client = boto3.client('sts')
sts_session = sts_client.assume_role(RoleArn='arn:aws:iam::<Account-A ID>::role/DynamoDB-FullAccess-For-Account-B',
                      RoleSessionName='test-dynamodb-session')

KEY_ID = sts_session['Credentials']['AccessKeyId']
ACCESS_KEY = sts_session['Credentials']['SecretAccessKey']
TOKEN = sts_session['Credentials']['SessionToken']

dynamodb_client = boto3.client('dynamodb',
                      region_name='us-east-2',
                      aws_access_key_id=KEY_ID,
                      aws_secret_access_key=ACCESS_KEY,
                      aws_session_token=TOKEN)

def lambda_handler(event, context):
    response = dynamodb_client.get_item(TableName='Table-Account-A', Key={'category':
                      {'S':'Fruit'}, 'item':
                      {'S':'Apple'}})
    return response
```

Sample output:

```
{'ResponseMetadata':
    {'HTTPHeaders':
        {'server': 'Server',
        'date': 'Wed, 28 Sep 2022 17:35:46 GMT',
        'content-type': 'application/x-amz-json-1.0',
        'content-length': '2',
        'connection': 'keep-alive',

        'x-amz-crc32': '2745901447'},
    'RetryAttempts': 0},
}
```
Configure mutual TLS authentication for applications running on Amazon EKS

Created by Mahendra Siddappa (AWS)

Environment: PoC or pilot
Technologies: DevOps; Security, identity, compliance
AWS services: Amazon EKS; Amazon Route 53

Summary

Certificate-based mutual Transport Layer Security (TLS) is an optional TLS component that provides two-way peer authentication between servers and clients. With mutual TLS, clients must provide an X.509 certificate during the session negotiation process. The server uses this certificate to identify and authenticate the client.

Mutual TLS is a common requirement for Internet of Things (IoT) applications and can be used for business-to-business applications or standards such as Open Banking.

This pattern describes how to configure mutual TLS for applications running on an Amazon Elastic Kubernetes Service (Amazon EKS) cluster by using an NGINX ingress controller. You can enable built-in mutual TLS features for the NGINX ingress controller by annotating the ingress resource. For more information about mutual TLS annotations on NGINX controllers, see Client certificate authentication in the Kubernetes documentation.
Important: This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments. If you want to use this pattern in a production environment, you can use AWS Private Certificate Authority (AWS Private CA) or your existing public key infrastructure (PKI) standard to issue private certificates.

Prerequisites and limitations

Prerequisites

• An active Amazon Web Services (AWS) account.
• An existing Amazon EKS cluster.
• AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
• The kubectl command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see Installing kubectl in the Amazon EKS documentation.
• An existing Domain Name System (DNS) name to test the application.

Limitations

• This pattern uses self-signed certificates. We recommend that you use this pattern only with test clusters, and not in production environments.

Architecture

Technology stack

• Amazon EKS
• Amazon Route 53
• Kubectl
Tools

- Amazon Elastic Kubernetes Service (Amazon EKS) helps you run Kubernetes on AWS without needing to install or maintain your own Kubernetes control plane or nodes.
- Amazon Route 53 is a highly available and scalable DNS web service.
- Kubectl is a command line utility that you use to interact with an Amazon EKS cluster.

<td><code>openssl req -new -newkey rsa:4096 -keyout server.key -out server.csr -nodes -subj '/CN=&lt;your_domain_name&gt; ' &amp;&amp; openssl x509 -req -sha256 -days 365 -in server.csr -CA ca.crt -CAkey ca.key -set_serial 01 -out server.crt</code></td>
<td></td>
</tr>
</tbody>
</table>

Important: Make sure you replace...
### Generate the client key and certificate, and sign with the CA certificate.

Generate the client key and certificate, and sign with the CA certificate by running the following command.

```
openssl req -new -newkey rsa:4096 -keyout client.key -out client.csr -nodes -subj '/CN=Test' && openssl x509 -req -sha256 -days 365 -in client.csr -CA ca.crt -CAkey ca.key -set_serial 02 -out client.crt
```

**Skills required:** DevOps engineer

### Deploy the NGINX ingress controller

**Task**

Deploy the NGINX ingress controller in your Amazon EKS cluster.

**Description**

Deploy the NGINX ingress controller by using the following command.

```
kubectl apply -f https://raw.githubusercontent.com/kubernetes/ingress-nginx/controller-0.32.0/deploy/static/provider/aws/deploy.yaml
```

**Skills required:** DevOps engineer

**Task**

Verify that the NGINX ingress controller service is running.

**Description**

Verify that the NGINX ingress controller service is running by using the following command.

```
kubectl get svc -n ingress-nginx
```

**Important:** Make sure that the field of service address contains the Network Load Balancer’s domain name.

**Skills required:** DevOps engineer

### Create a namespace in the Amazon EKS cluster to test mutual TLS

**Task**

Create a namespace in the Amazon EKS cluster.

**Description**

Create a namespace called mTLS in your Amazon EKS cluster by running the following command.

**Skills required:** DevOps engineer
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubectl create ns mtls</td>
<td>This deploys the sample application to test mutual TLS.</td>
<td></td>
</tr>
</tbody>
</table>

**Create the deployment and service for the sample application**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the Kubernetes deployment and service in the mtls namespace.</td>
<td>Create the Kubernetes deployment and service in the mtls namespace by running the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>kubectl create -f mtls.yaml -n mtls</code></td>
<td></td>
</tr>
<tr>
<td>Verify that the Kubernetes deployment is created.</td>
<td>Run the following command to verify that the deployment is created and has one pod in available status.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>kubectl get deploy -n mtls</code></td>
<td></td>
</tr>
<tr>
<td>Verify that the Kubernetes service is created.</td>
<td>Verify that the Kubernetes service is created by running the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>kubectl get service -n mtls</code></td>
<td></td>
</tr>
</tbody>
</table>

**Create a secret in the mtls namespace**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a secret for the ingress resource.</td>
<td>Run the following command to create a secret for the NGINX ingress controller using the certificates that you created earlier.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>kubectl create secret generic mtls-certs --from-file=tls.crt=server.crt --from-file=tl.key=server.key --from-file=ca.crt=ca.crt -n mtls</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Your secret has a server certificate for the client to</td>
<td></td>
</tr>
</tbody>
</table>
Create the ingress resource in the mtls namespace

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the ingress resource in the mtls namespace.</td>
<td>Open the ingress.yaml file and replace <code>&lt;your_domain_name&gt;</code> with your existing domain name. Create the ingress resource in the mtls namespace by running the following command.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td><code>kubectl create -f ingress.yaml -n mtls</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>This means that the NGINX ingress controller can route traffic to your sample application.</td>
<td></td>
</tr>
<tr>
<td>Verify that the ingress resource is created.</td>
<td>Verify that the ingress resource is created by running the following command.</td>
<td>DevOps engineer</td>

Create a CI/CD pipeline to deploy microservices with AWS Fargate and Amazon API Gateway

*Created by Jonathan Cardoso (AWS)*

**Environment:** PoC or pilot  
**Technologies:** DevOps; Containers & microservices  
**AWS services:** AWS CodeBuild; AWS CodeCommit; AWS
Summary

This pattern describes how to create a continuous integration and continuous deployment (CI/CD) pipeline to deploy microservices in the Amazon Web Services (AWS) Cloud. Traditionally, building a modern application involves decoupling and optimizing business logic into a microservices architecture to reduce complexity and to improve speed and alignment. APIs, which abstract communications among services, are the foundation of microservices. Having a CI/CD pipeline for deploying microservices and APIs can accelerate the development of modern applications and help maintain system stability and security.

This pattern uses AWS Fargate to provision compute resources for microservices and Amazon API Gateway to manage the APIs that handle communications among the microservices efficiently. The CI/CD pipeline is set up by implementing three AWS services: AWS CodePipeline, AWS CodeBuild, and AWS CodeDeploy. The pattern provides AWS CloudFormation templates and Python code to automate most of the steps, and includes a sample application.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI) version 2 or later (see Installing, updating, and uninstalling the AWS CLI version 2 in the AWS documentation)

Architecture

The pattern uses the following AWS services, as illustrated in the following diagram:

- In the private subnets, AWS Fargate manages the compute resources for microservices, to remove the infrastructure burden.
- API Gateway handles API calls and makes it easier to create, maintain, and secure APIs at any scale.
- AWS KMS creates and controls the keys for encrypting content such as artifacts and reports.
- Amazon Simple Storage Service (Amazon S3) is used as a repository to store artifacts and reports that are generated by the pipeline.
The following diagram illustrates the CI/CD workflow.
Tools

AWS services

- **API Gateway** – Amazon API Gateway helps create, publish, maintain, monitor, and secure REST, HTTP, and WebSocket APIs for use in your applications and microservices.

- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that you can use to interact with AWS services from the command line.

- **CodeCommit** – AWS CodeCommit is a fully managed source control service that stores and manages documents, source code, and binary files in the AWS Cloud.

- **CodePipeline** – AWS CodePipeline is a continuous delivery service that helps you model and configure the different stages of a software release process.

- **CodeBuild** – AWS CodeBuild is a build service that compiles source code, runs unit tests, and produces software packages that are ready to deploy.

- **CodeDeploy** – AWS CodeDeploy is a software deployment service that automates deployments to Amazon Elastic Compute Cloud (Amazon EC2) instances, on-premises instances, serverless AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services.

- **Fargate** – AWS Fargate is a serverless compute engine that works with Amazon ECS and provides on-demand, right-sized compute capacity for containers.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that lets you store and retrieve any amount of data at any time, from anywhere on the web.

Code

The code for this pattern is attached. You can download and unzip the project on your computer to use the files that are referenced in the *Epics* section.

Epics

Configure your credentials

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an IAM user.</td>
<td>In your AWS account, create an AWS Identity and Access Management (IAM) user. For instructions, see the IAM documentation.</td>
<td>Developer, Systems administrator, DevOps engineer</td>
</tr>
<tr>
<td>Configure your credentials.</td>
<td>Assign the IAM user programmatic access, so they can use the AWS CLI. For instructions, see the AWS CLI documentation.</td>
<td>Developer, Systems administrator, DevOps engineer</td>
</tr>
<tr>
<td>Test your access.</td>
<td>To validate that you configured the IAM user correctly, use the following AWS CLI command: <code>aws sts get-caller-identity --query Account --output text --profile &lt;profile&gt;</code></td>
<td>Developer, Systems administrator, DevOps engineer</td>
</tr>
</tbody>
</table>
Set up the AWS infrastructure

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Run the CloudFormation template to deploy the infrastructure. | In your AWS account, create a virtual private cloud (VPC) that is configured with public and private subnets across two Availability Zones and an Application Load Balancer. To deploy this infrastructure, use the following AWS CLI command:  
aws cloudformation deploy \  
--stack-name foundation \  
--template-file foundation/ full.yaml \  
--capabilities  
CAPABILITY_IAM \  
--region <region> \  
--profile <profile>  
| Systems administrator, DevOps engineer |

where foundation/full.yaml refers to the template that's included in the code attachment, <region> is the AWS Region to use, and <profile> specifies a profile from your credential file.

Create and deploy the CI/CD pipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a pipeline. | Open the Cloudformation console and create a new stack by launching the pipeline.yaml template, which is in the attachment. Configure the following parameters:  
• Stack name represents the pipeline for the application (default is myapp).  
• ServiceName is the application name, and | Systems administrator, DevOps engineer |
### AWS Prescriptive Guidance Patterns

**Epics**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>should match the service name in myapp/templates/service.yaml (default is myapp).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>BranchName</code> specifies a branch in your code repository (default is <code>main</code>).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>Email</code> is the email address to use for notifications when manual approval is enabled.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• <code>ManualApproval</code> indicates whether manual approval is required for pipeline operations (default is <code>true</code>).</td>
<td></td>
</tr>
</tbody>
</table>

This stack creates the following resources:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• A CodeCommit repository, using the <code>ServiceName</code> parameter</td>
<td></td>

<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Deploy</strong></td>
<td>After manual approval (if enabled), launches the CloudFormation template to deploy this new service version.</td>
<td>Systems administrator, DevOps engineer</td>
</tr>
<tr>
<td><strong>Check the deployment.</strong></td>
<td>You can check each step of your pipeline that was created, from source to deployment, in the CodePipeline console. The pipeline won't run yet because the repository is empty. Next, you set up your sample application and start the pipeline.</td>
<td>Systems administrator, DevOps engineer</td>
</tr>
<tr>
<td><strong>Publish the application</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Clone your CodeCommit repository.</strong></td>
<td>Open the AWS CodeCommit console, select the repository created by the pipeline, and then choose Clone URL and HTTPS (as the protocol) to copy the URL. At the terminal or command prompt, clone the repository by using the command:</td>
<td>Developer</td>
</tr>
<tr>
<td></td>
<td><code>git clone &lt;repoURL&gt;</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>where <code>&lt;repoURL&gt;</code> refers to the clone URL you obtained from CodeCommit. For more information, see the CodeCommit documentation.</td>
<td></td>
</tr>
<tr>
<td><strong>Copy the sample application files.</strong></td>
<td>After you clone your repository, copy the content in the attachment, and place it in your new repository. You can use the following command on Linux or macOS:</td>
<td>Developer</td>
</tr>
<tr>
<td></td>
<td><code>cp -rpf ../aws-cicd-microservices-api/myapp/* &lt;reponame&gt;/</code></td>
<td></td>
</tr>
</tbody>
</table>
Configure your application parameters. Change the following two files to create your microservice.

In the `templates/service.yaml` file:

- ServiceName: myapp (same as in pipeline.yaml)
- ServicePath: /myapp (same as in app/main.py)
- BranchName: main
- AlbRulePriority: 2 (each microservice should have a unique AlbRulePriority number; increase this number by one for each microservice)

In the `app/main.py` file:

```python
mypath="myapp"
```

Commit your changes. Publish the updated files to the repository:

```
git add .
git commit -m "first commit"
git push origin main
```

Check the deployment. Now that you have completed your first commit operation, you can check each step of your pipeline, from source to deployment, in the CodePipeline console.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure your application parameters.</td>
<td>Change the following two files to create your microservice. In the <code>templates/service.yaml</code> file: - ServiceName: myapp (same as in pipeline.yaml) - ServicePath: /myapp (same as in app/main.py) - BranchName: main - AlbRulePriority: 2 (each microservice should have a unique AlbRulePriority number; increase this number by one for each microservice)</td>
<td>Developer</td>
</tr>
<tr>
<td>Commit your changes.</td>
<td>Publish the updated files to the repository: <code>git add .</code> <code>git commit -m &quot;first commit&quot;</code> <code>git push origin main</code></td>
<td>Developer</td>
</tr>
<tr>
<td>Check the deployment.</td>
<td>Now that you have completed your first commit operation, you can check each step of your pipeline, from source to deployment, in the CodePipeline console.</td>
<td>Systems administrator, DevOps engineer</td>
</tr>
</tbody>
</table>

Create a custom log parser for Amazon ECS using a Firelens log router

Created by Varun Sharma (AWS)

Environment: Production  Technologies: DevOps; Containers & microservices  Workload: All other workloads

AWS services: Amazon ECS

Summary

Firelens is a log router for Amazon Elastic Container Service (Amazon ECS) and AWS Fargate. You can use Firelens to route container logs from Amazon ECS to Amazon CloudWatch and other destinations (for example, Splunk or Sumo Logic). Firelens works with Fluentd or Fluent Bit as the logging agent, which means that you can use Amazon ECS task definition parameters to route logs.

By choosing to parse logs at the source level, you can analyze your logging data and perform queries to more efficiently and effectively respond to operational issues. Because different applications have different logging patterns, you need to use a custom parser that structures the logs and makes searching easier at your end destination.

This pattern uses a Firelens log router with a custom parser to push logs to CloudWatch from a sample Spring Boot application running on Amazon ECS. You can then use Amazon CloudWatch Logs Insights to filter the logs based on custom fields that are generated by the custom parser.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account.
- AWS Command Line Interface (AWS CLI), installed and configured on your local machine.
- Docker, installed and configured on your local machine.
- An existing Spring Boot-based containerized application on Amazon Elastic Container Registry (Amazon ECR).

Architecture
**Tools**

- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
- **Amazon ECS** – Amazon Elastic Container Service (Amazon ECS) is a highly scalable, fast container management service that makes it easy to run, stop, and manage containers on a cluster.
- **AWS Identity and Access Management (IAM)** – IAM is a web service for securely controlling access to AWS services.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- **Docker** – Docker is an open platform for developing, shipping, and running applications.

**Code**

The following files are attached to this pattern:

- `customFluentBit.zip` – Contains the files to add the custom parsing and configurations.
- `firelens_policy.json` – Contains the policy document to create an IAM policy.
- `Task.json` – Contains a sample task definition for Amazon ECS.
## Epics

### Create a custom Fluent Bit image

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon ECR repository.</td>
<td>Sign in to the AWS Management Console, open the Amazon ECR console, and create a repository called fluentbit_custom. For more information about this, see Creating a repository in the Amazon ECR documentation.</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>
| Unzip the customFluentBit.zip package.   | 1. Download the customFluentBit.zip package (attached) to your local machine.  
2. Unzip to the customFluentBit directory by running the following command: `unzip -d customFluentBit.zip`  
3. The directory contains the following files that are required for adding the custom parsing and configurations:  
   • `parsers/`springboot_parser.conf – Contains the parser directive and defines the regular expression (regex) pattern for the custom parser. You can add the regex pattern for your specific parser.  
   • `conf/`parse_springboot.conf – Contains the filter and the service directive.  
   • The Dockerfile | Systems administrator, Developer |
| Create the custom Docker image.           | 1. Change the directory to customFluentBit.  
2. Open the Amazon ECR console, choose the fluentbit_custom repository, and then choose **View push commands**.  
3. Upload your project. | Systems administrator, Developer |
4. After the upload is complete, copy the build's URL. This URL is required when you create a container in Amazon ECS.

For more information about this, see [Pushing a Docker image](https://docs.aws.amazon.com/AmazonECR/latest/userguide/push-docker-image.html) in the Amazon ECR documentation.

## Set up the Amazon ECS cluster

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon ECS cluster.</td>
<td>Create an Amazon ECS cluster by following the instructions from the <em>Networking only template</em> section of <a href="https://docs.aws.amazon.com/AmazonECS/latest/DeveloperGuide/task-groups.html">Creating a cluster</a> in the Amazon ECS documentation. <strong>Note:</strong> Make sure that you choose Create VPC to create a new virtual private cloud (VPC) for your Amazon ECS cluster.</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>

## Set up the Amazon ECS task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set up the Amazon ECS task execution IAM role.</td>
<td>Create an Amazon ECS task execution IAM role by using the AmazonECSTaskExecutionRolePolicy managed policy. For more information about this, see <a href="https://docs.aws.amazon.com/AmazonECS/latest/DeveloperGuide/task-execution-iam.html">Amazon ECS task execution IAM role</a> in the Amazon ECS documentation. <strong>Note:</strong> Make sure that you record the IAM role's Amazon Resource Name (ARN).</td>
<td>Systems administrator, Developer</td>
</tr>
<tr>
<td>Attach the IAM policy to the Amazon ECS task execution IAM role.</td>
<td>1. Create an IAM policy by using the firelens_policy.json (attached) policy document. For more information about this, see <a href="https://docs.aws.amazon.com/IAM/latest/UserGuide/gr_create_policy.html">Creating policies on the JSON tab</a> in the IAM documentation. 2. Attach this policy to the Amazon ECS task execution IAM role.</td>
<td>Systems administrator, Developer</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
</tbody>
</table>
| Set up the Amazon ECS task definition. | 1. Update the following sections in the Task.json sample task definition (attached):  
   - Update the executionRoleArn and taskRoleArn with the ARN of the task execution IAM role  
   - Update the image in containerDefinitions with the custom Fluent Bit Docker image that you created earlier  
   - Update the image in containerDefinitions with your application image's name  
   2. Open the Amazon ECS console, choose Task Definitions, choose Create new task definition, and then choose Fargate on the Select compatibilities page.  
   3. Choose Configure via Json, paste the updated Task.json file into the text area, and then choose Save.  
   4. Create the task definition.  
   For more information about this, see Creating a task definition in the Amazon ECS documentation. | Systems administrator, Developer |

### Run the Amazon ECS task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the Amazon ECS task.</td>
<td>On the Amazon ECS console, choose Clusters, choose the cluster that you created earlier, and then run the standalone task.</td>
<td>Systems administrator, Developer</td>
</tr>
</tbody>
</table>
Verify the CloudWatch logs

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Verify the logs. | 1. Open the CloudWatch console, choose **Log groups**, and then choose /aws/ecs/containerinsights/\{{cluster_ARN}\}/firelens/application.  
2. Verify the logs, particularly the custom fields added by the custom parser.  
3. Use CloudWatch to filter logs based on the custom fields. | Systems administrator, Developer |

Create a pipeline and AMI using CodePipeline and HashiCorp Packer

*Created by Akash Kumar (AWS)*

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: DevOps</th>
<th>Target: Amazon Machine Images(AMI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Rehost</td>
<td>Workload: All other workloads</td>
<td>Technologies: DevOps; Modernization; Websites &amp; web apps</td>
</tr>
</tbody>
</table>
Summary

This pattern provides code samples and steps to create both a pipeline in the Amazon Web Services (AWS) Cloud by using AWS CodePipeline and an Amazon Machine Image (AMI) by using HashiCorp Packer. The pattern is based on the continuous integration practice, which automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, create a project and configure your source code by using AWS CodeBuild. Finally, create an AMI that gets committed to your repository.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon Linux AMI for launching Amazon Elastic Compute Cloud (Amazon EC2) instances
- HashiCorp Packer 0.12.3 or later
- Amazon CloudWatch Events (optional)
- Amazon CloudWatch Logs (optional)

Architecture

The following diagram shows an example of application code that automates the creation of an AMI by using this pattern’s architecture.

The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository. Then, CodePipeline uses CodeBuild to initiate the build and add new artifacts that are ready for deployment to the Amazon Simple Storage Service (Amazon S3) bucket.
2. CodeBuild uses Packer to bundle and package the AMI based on a JSON template. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.
Technology stack

- CodeBuild
- CodeCommit
- CodePipeline
- CloudWatch Events (optional)

Tools

- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.

- **AWS CodeCommit** – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.

- **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software.

- **HashiCorp Packer** – HashiCorp Packer is an open-source tool for automating the creation of identical machine images from a single source configuration. Packer is lightweight, runs on every major operating system, and creates machine images for multiple platforms in parallel.

Code

This pattern includes the following attachments:

- **buildspec.yml** – This file uses CodeBuild to build and create an artifact for deployment.
- **amazon-linux_packer-template.json** – This file uses Packer to create an Amazon Linux AMI.

Epics

Set up the code repository

</table>
| Pipeline name     | 1. Sign in to the AWS Management console, open the AWS CodePipeline console, and then choose Create pipeline.  
2. For Pipeline name, enter a name for the pipeline.  
3. For Service role, choose New service role or Existing service role.  
4. For Role name, enter a name for your role.  
5. In the Advanced settings section, for Artifact store, choose Default location if you want Amazon S3 to create a bucket and store the artifacts in the bucket. To use an existing S3 bucket, choose Custom location. Choose Next.  
6. For Source provider, choose AWS CodeCommit.  
7. For Repository name, choose the repository that you cloned earlier. For Branch name, choose your source code branch.  
8. For Change detection options, choose Amazon CloudWatch Events (recommended) to start the pipeline or AWS CodePipeline to periodically check for changes. Choose Next.  
9. For Build provider, choose AWS CodeBuild.  
10. For Project Name, choose the build project that you created in the Create a CodeBuild project for the application epic.  
11. Choose your build options and then choose Next.  
12. Choose Skip deploy stage.  
13. Choose Create pipeline. | App developer, AWS systems administrator |
Create a pipeline and deploy artifact updates to on-premises EC2 instances using CodePipeline

*Created by Akash Kumar (AWS)*

</tbody>
</table>

**Summary**

This pattern provides code samples and steps to create a pipeline in the Amazon Web Services (AWS) Cloud and deploy updated artifacts to on-premises Amazon Elastic Compute Cloud (Amazon EC2) instances in AWS CodePipeline. The pattern is based on the continuous integration practice, which automates the building and testing of code with a Git-based version control system. In this pattern, you create and clone a code repository by using AWS CodeCommit. Then, create a project and configure your source code by using AWS CodeBuild. Finally, create your application and configure its target environment for on-premises EC2 instances by using AWS CodeDeploy.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account
- **User-defined tags** to identify EC2 instances during deployment
- CodeDeploy agent, installed on EC2 instances
- Your required runtime software, installed on EC2 instances
- Amazon Corretto 8 for the Java Development Kit
- Apache Tomcat web server, installed
- Amazon CloudWatch Events (optional)
- A key pair to log in to the web server (optional)
Architecture

The following diagram shows an example Java web application that’s deployed to on-premises EC2 instances by using this pattern’s architecture.

The diagram shows the following workflow:

1. The developer commits code changes to a private CodeCommit Git repository.
2. CodePipeline uses CodeBuild to initiate the build and add new artifacts that are ready for deployment in the Amazon Simple Storage Service (Amazon S3) bucket.
3. CodePipeline uses the CodeDeploy agent to pre-install any dependencies required for the deployment artifact changes.
4. CodePipeline uses the CodeDeploy agent to deploy the artifacts from the S3 bucket to target EC2 instances. If enabled, CloudWatch Events can automatically start the pipeline when a change occurs in the source code.

Technology stack

- CodeBuild
- CodeCommit
- CodeDeploy
- CodePipeline
- CloudWatch Events (optional)

Tools

- AWS CodeBuild – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
AWS Prescriptive Guidance Patterns

Epics

- **AWS CodeCommit** – AWS CodeCommit is a version control service that enables you to privately store and manage Git repositories in the AWS Cloud. CodeCommit eliminates the need for you to manage your own source control system or worry about scaling its infrastructure.
- **AWS CodeDeploy** – AWS CodeDeploy is a deployment service that automates application deployments to EC2 instances, on-premises instances, serverless AWS Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services. CodeDeploy works with various systems for configuration management, source control, continuous integration, continuous delivery, and continuous deployment.
- **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service that you can use to model, visualize, and automate the steps required to release your software.

### Code

This pattern includes the following attachments:

- `buildspec.yml` – This file specifies the actions that CodeBuild requires to build and create an artifact for deployment.
- `appspec.yml` – This file specifies the actions that CodeDeploy requires to create an application and configure a target environment for on-premises EC2 instances.
- `install_dependencies.sh` – This file installs dependencies for the Apache Tomcat web server.
- `start_server.sh` – This file starts the Apache Tomcat web server.
- `stop_server.sh` – This file stops the Apache Tomcat web server.

### Epics

#### Set up the code repository

Deploy a CI/CD pipeline for Java microservices on Amazon ECS

Created by Vijay Thompson (AWS)

<table>
<thead>
<tr>
<th>Created by:</th>
<th>AWS</th>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Containers &amp; microservices; DevOps</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>Amazon ECS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

This pattern guides you through the steps for deploying a CI/CD (continuous integration and continuous delivery) pipeline for Java microservices on an existing Amazon Elastic Container Service (Amazon ECS) cluster using AWS CodeBuild. When the developer commits changes, the CI/CD pipeline is triggered. The build process starts in CodeBuild, and when it's complete, the artifact gets pushed to Amazon Elastic Container Registry (Amazon ECR). The latest build from Amazon ECR is picked up and pushed to the Amazon ECS service.

**Prerequisites and limitations**

**Prerequisites**

- An existing Java microservices application running on Amazon ECS
- Familiarity with AWS CodeBuild and AWS CodePipeline

**Architecture**

**Source technology stack**

- Java microservices running on Amazon ECS
- Code repository in Amazon ECR

**Source architecture**
Target technology stack

- Amazon ECR
- Amazon ECS
- AWS Fargate

Target architecture
CodeBuild buildspec.yml file:

```
version: 0.2
phases:
  pre_build:
    commands:
      - echo Logging in to Amazon ECR...
      - aws --version
      - $(aws ecr get-login --region $AWS_DEFAULT_REGION --no-include-email)
      - REPOSITORY_URI=012345678910.dkr.ecr.us-east-1.amazonaws.com/base-image
      - COMMIT_HASH=$(echo $CODEBUILD_RESOLVED_SOURCE_VERSION | cut -c 1-7)
      - IMAGE_TAG=build-$(echo $CODEBUILD_BUILD_ID | awk -F:" '{print $2}')
  build:
    commands:
      - echo Build started on `date`
      - echo building the Jar file
      - mvn clean install
      - echo Building the Docker image...
      - docker build -t $REPOSITORY_URI:latest .
      - docker tag $REPOSITORY_URI:latest $REPOSITORY_URI:$IMAGE_TAG
  post_build:
    commands:
```

Automation and scale
- echo Build completed on `date`
- echo Pushing the Docker images...
- docker push $REPOSITORY_URI:latest
- docker push $REPOSITORY_URI:$IMAGE_TAG
- echo Writing image definitions file...
- printf '[["name":"cicd-container","imageUri":"%s"]]' $REPOSITORY_URI:$IMAGE_TAG > imagedefinitions.json
- cat imagedefinitions.json
artifacts:
files: imagedefinitions.json

## Tools

### Amazon ECR
Amazon Elastic Container Registry (Amazon ECR) is a fully managed registry that makes it easy for developers to store, manage, and deploy Docker container images. Amazon ECR is integrated with Amazon ECS to simplify your development-to-production workflow. Amazon ECR hosts your images in a highly available and scalable architecture so you can reliably deploy containers for your applications. Integration with AWS Identity and Access Management (IAM) provides resource-level control of each repository.

### Amazon ECS
Amazon Elastic Container Service (Amazon ECS) is a highly scalable, high-performance container orchestration service that supports Docker containers and allows you to easily run and scale containerized applications on AWS. Amazon ECS eliminates the need for you to install and operate your own container orchestration software, manage and scale a cluster of virtual machines, or schedule containers on those virtual machines.

### AWS Fargate
AWS Fargate is a compute engine for Amazon ECS that allows you to run containers without having to manage servers or clusters. With AWS Fargate, you no longer have to provision, configure, and scale clusters of virtual machines to run containers. This removes the need to choose server types, decide when to scale your clusters, or optimize cluster packing.

### Docker
Docker is a platform that lets you build, test, and deliver applications in packages called containers.

### CodeBuild
AWS CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy. AWS CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left in the queue.

### CodePipeline
AWS CodePipeline is a fully managed continuous delivery service that helps you automate release pipelines for fast and reliable application and infrastructure updates. AWS CodePipeline automates the build, test, and deploy phases of the release process every time there is a code change. With AWS CodePipeline, you can rapidly and reliably deliver features and updates. You can integrate AWS CodePipeline with third-party services like GitHub, or use an AWS services such as AWS CodeCommit or Amazon ECR.

### Git
Git is a distributed version-control system for tracking changes in source code during software development. It is designed for coordinating work among programmers, but it can be used to track changes in any set of files. Its goals include speed, data integrity, and support for distributed, non-linear workflows. You can also use AWS CodeCommit as an alternative to Git.

Use AWS CodeCommit and AWS CodePipeline to deploy a CI/CD pipeline in multiple AWS accounts

Created by Kirankumar Chandrashekar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>DevOps</th>
<th>Workload:</th>
<th>All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS CodeCommit; AWS CodePipeline</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern shows you how to deploy a continuous integration and continuous delivery (CI/CD) pipeline for your application code workloads in separate Amazon Web Services (AWS) accounts for DevOps, developer, staging, and production workflows.

You can use a multiple AWS account strategy to provide a high level of resource or security isolation, optimize costs, and separate out your production workflow.

Your application's code remains identical in all these separate AWS accounts and is maintained on a central AWS CodeCommit repository hosted by your DevOps account. Your developer, staging, and production accounts have separate Git branches in this CodeCommit repository.

For example, when code is committed to the developer Git branch in your central CodeCommit repository, Amazon EventBridge in your DevOps account notifies EventBridge in your developer account of the repository changes. In your developer account, AWS CodePipeline and the source stage go into InProgress status. The source stage is configured from the developer Git branch in the central CodeCommit repository and CodePipeline assumes a service role for the DevOps account.

The contents of the CodeCommit repository in the developer branch are uploaded to an artifact store in an Amazon Simple Storage Service (Amazon S3) bucket and encrypted with an AWS Key Management Service (AWS KMS) key. After the source stage's status changes to Succeeded in CodePipeline, the code will be transitioned to the next stage of the pipeline execution.

Prerequisites and limitations

Prerequisites

- Existing AWS accounts for each required environment (DevOps, developer, staging, and production). These accounts can be hosted by AWS Organizations.
- AWS Command Line Interface (AWS CLI), installed and configured.

Architecture
Technology stack

- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- Amazon EventBridge
- AWS Identity and Access Management (IAM)
- AWS KMS
- AWS Organizations
- Amazon S3

Tools

- **AWS CodeBuild** – CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy.
- **AWS CodeCommit** – CodeCommit is a fully-managed source-control service that hosts secure Git-based repositories
- **AWS CodePipeline** – CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
- **Amazon EventBridge** – EventBridge is a serverless event bus service for connecting your applications with data from a variety of sources.
- **AWS Identity and Access Management (IAM)** – IAM helps you to manage access to AWS services and resources securely.
- **AWS KMS** – AWS Key Management Service (AWS KMS) helps you create and manage cryptographic keys and control their use across a wide range of AWS services and in your applications.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.

<td>Repeat these steps for all the AWS accounts that are required as part of your CI/CD strategy.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

**Related resources**

**Create resources in your DevOps AWS account**

- Create a CodeCommit repository
- Set up a CodeCommit repository
- Create and share a branch in your CodeCommit repository
- Create access credentials for the CodeCommit repository
- Create an IAM role for CodePipeline service roles
- Set up rule in EventBridge
- Create an AWS KMS key
- Set up account policies and roles for CodePipeline

**Create resources in your other AWS accounts**
• Turn on EventBridge to receive events from your DevOps AWS account
• Create an S3 bucket for CodePipeline artifacts
• Create all other necessary AWS resources for CodePipeline stages
• Create an IAM role for CodePipeline service role
• Create a pipeline in CodePipeline
• Create a pipeline in CodePipeline that uses resources from another AWS account

Other resources
• Establish your best practice AWS environment
• Authentication and access control for CodeCommit

Deploy an AWS Glue job with an AWS CodePipeline CI/CD pipeline

*Created by Bruno Klein (AWS) and Luis Henrique Massao Yamada (AWS)*

| Environment: Production | Technologies: DevOps; Big data | AWS services: AWS Glue; AWS CodeCommit; AWS CodePipeline; AWS Lambda |

**Summary**

This pattern demonstrates how you can integrate Amazon Web Services (AWS) CodeCommit and AWS CodePipeline with AWS Glue, and use AWS Lambda to launch jobs as soon as a developer pushes their changes to a remote AWS CodeCommit repository.

When a developer submits a change to an extract, transform, and load (ETL) repository and pushes the changes to AWS CodeCommit, a new pipeline is invoked. The pipeline initiates a Lambda function that launches an AWS Glue job with these changes. The AWS Glue job performs the ETL task.

This solution is helpful in the situation where businesses, developers, and data engineers want to launch jobs as soon as changes are committed and pushed to the target repositories. It helps achieve a higher level of automation and reproducibility, therefore avoiding errors during the job launch and lifecycle.

**Prerequisites and limitations**

**Prerequisites**

• An active AWS account
• Git installed on the local machine
• Amazon Cloud Development Kit (Amazon CDK) installed on the local machine
• Python installed on the local machine
• The code in the Attachments section
Limitations

- The pipeline is finished as soon as the AWS Glue job is successfully launched. It does not wait for the conclusion of the job.
- The code provided in the attachment is intended for demo purposes only.

Architecture

Target technology stack

- AWS Glue
- AWS Lambda
- AWS CodePipeline
- AWS CodeCommit

Target architecture

The process consists of these steps:

1. The developer or data engineer makes a modification in the ETL code, commits, and pushes the change to AWS CodeCommit.
2. The push initiates the pipeline.
3. The pipeline initiates a Lambda function, which calls codecommit:GetFile on the repository and uploads the file to Amazon Simple Storage Service (Amazon S3).
4. The Lambda function launches a new AWS Glue job with the ETL code.
5. The Lambda function finishes the pipeline.

Automation and scale

The sample attachment demonstrates how you can integrate AWS Glue with AWS CodePipeline. It provides a baseline example that you can customize or extend for your own use. For details, see the Epics section.

Tools

- **AWS CodePipeline** – AWS CodePipeline is a fully managed *continuous delivery* service that helps you automate your release pipelines for fast and reliable application and infrastructure updates.
- **AWS CodeCommit** – AWS CodeCommit is a fully managed *source control* service that hosts secure, Git-based repositories.
- **AWS Lambda** – AWS Lambda is a serverless compute service that lets you run code without provisioning or managing servers.
- **AWS Glue** – AWS Glue is a serverless data integration service that makes it easy to discover, prepare, and combine data for analytics, machine learning, and application development.
- **Git client** – Git provides GUI tools, or you can use the command line or a desktop tool to check out the required artifacts from GitHub.
- **AWS CDK** – The AWS CDK is an open source software development framework that helps you define your cloud application resources by using familiar programming languages.

Epics

**Deploy the sample code**

## Deploy an Amazon EKS cluster from AWS Cloud9 using an EC2 instance profile

*Created by Sagar Panigrahi (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: DevOps; Containers &amp; microservices</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS services:</strong> Amazon EKS; AWS Cloud9; AWS Identity and Access Management; AWS CloudFormation</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Summary

This pattern describes how to use AWS Cloud9 and AWS CloudFormation to create an Amazon Elastic Kubernetes Service (Amazon EKS) cluster that can be operated without enabling programmatic access for users in your Amazon Web Services (AWS) account.

AWS Cloud9 is a cloud-based integrated development environment (IDE) that helps you write, run, and debug your code by using a browser. AWS Cloud9 is used as a control center that provisions an Amazon EKS cluster by using Amazon Elastic Compute Cloud (Amazon EC2) instance profiles and AWS CloudFormation templates.

You can use this pattern if you don't want to create AWS Identity and Access Management (IAM) users and want to use IAM roles instead. Role-based access control (RBAC) regulates access to resources based on the roles of individual users. This pattern demonstrates how to update RBAC within an Amazon EKS cluster to allow access to a specific IAM role.

The pattern's setup also helps your DevOps team use AWS Cloud9 features to maintain and develop infrastructure as code (IaC) resources for creating Amazon EKS infrastructure.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Permissions to create IAM roles and policies for the account. The IAM role for the user must include the AWSCloud9Administrator policy. The AWSServiceRoleForAmazonEKS and eksNodeRoles roles must also be created because they are required to create an Amazon EKS cluster.
- Knowledge of Kubernetes concepts.

Limitations

- This pattern describes how to create a basic Amazon EKS cluster. For production clusters, you must update the AWS CloudFormation template.
- The pattern doesn't deploy additional Kubernetes components (for example, Fluentd, ingress controllers, or storage controllers).

Architecture
Tools

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications.
- **AWS Cloud9** – AWS Cloud9 offers a rich code-editing experience with support for several programming languages and runtime debuggers, and a built-in terminal.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- **Kubectl** – kubectl is a command line utility that you can use to interact with an Amazon EKS cluster.

</thead>
<tbody>
<tr>
<td><strong>Important:</strong> EKS-DEV2 is the name of the Amazon EKS cluster in the AWS CloudFormation template that you used to create the cluster.</td>
<td>Run the <code>kubectl get all -A</code> command to view all Kubernetes resources.</td>
<td></td>
</tr>
</tbody>
</table>
| **Add the administrator IAM role to the Kubernetes RBAC.** | Run the following command in your AWS Cloud9 terminal to open the RBAC configuration map for Amazon EKS in edit mode:  
  `kubectl edit cm/aws-auth -n kube-system`  
  Append the following lines under the `mapRoles` section:  
  ```yaml  
  - groups:  
    - system:masters  
    roleArn: <ARN_of_IAM_role_from_second_epic>  
    username: eksadmin  
  ```  
  Lint the YAML-formatted file to avoid syntax errors. Save the file using `vi` commands and then exit the file.  
  **Note:** By adding this section, you inform the Kubernetes RBAC that `<ARN_of_IAM_role_from_second_epic>` is to receive full administrator access on the Amazon EKS cluster. This means that the identified IAM role can carry out administrative actions on the Kubernetes cluster. AWS adds the existing section under `mapRoles` while the Amazon EKS cluster is provisioned. | Cloud administrator          |

Deploy code in multiple AWS Regions using AWS CodePipeline, AWS CodeCommit, and AWS CodeBuild

Created by Rama Anand Krishna Varanasi (AWS)

<table>
<thead>
<tr>
<th>Created by: AWS</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: Management &amp; governance; DevOps</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>AWS CodeCommit;</td>
<td></td>
<td></td>
</tr>
<tr>
<td>AWS CodePipeline; AWS CodeBuild</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern demonstrates how to build infrastructure or architecture across multiple Amazon Web Services (AWS) Regions by using AWS CloudFormation. It includes continuous integration (CI)/continuous deployment (CD) across multiple AWS Regions for faster deployments. The steps in this pattern have been tested for the creation of an AWS CodePipeline job to deploy to three AWS Regions as an example. You can change the number of Regions based on your use case.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- Two AWS Identity and Access Management (IAM) roles for AWS CodeBuild and AWS CloudFormation with proper policies for CodeBuild to perform the CI tasks of testing, bundling, packaging the artifacts, and deploying to multiple AWS Regions in parallel. **Note:** Cross-check the policies created by CodePipeline to verify that CodeBuild and AWS CloudFormation have proper permissions in the CI and CD phases.
- A CodeBuild role with the **AmazonS3FullAccess** and **CloudWatchFullAccess** policies. These policies give CodeBuild access to watch events of AWS CodeCommit through Amazon CloudWatch and to use Amazon Simple Storage Service (Amazon S3) as an artifact store.
- An AWS CloudFormation role with the following policies, which give AWS CloudFormation, in the final Build stage, the ability to create or update AWS Lambda functions, push or watch Amazon CloudWatch logs, and to create and update change sets.
  - **AWSLambdaFullAccess**
  - **AWSCodeDeployFullAccess**
  - **CloudWatchFullAccess**
• AWSCodeCommitFullAccess
• AWSCodePipelineFullAccess

Architecture

This pattern's multiple-Region architecture and workflow comprise the following steps.

1. You send your code to a CodeCommit repository.
2. Upon receiving any code update or commit, CodeCommit invokes a CloudWatch event, which in turn starts a CodePipeline job.
3. CodePipeline engages the CI that is handled by CodeBuild. The following tasks are performed.
   • Testing of the AWS CloudFormation templates (optional)
   • Packaging of the AWS CloudFormation templates for each Region included in the deployment. For example, this pattern deploys in parallel to three AWS Regions, so CodeBuild packages the AWS CloudFormation templates into three S3 buckets, one in each specified Region. The S3 buckets are used by CodeBuild as artifact repositories only.
4. CodeBuild packages the artifacts as input for next Deploy phase, which runs in parallel in the three AWS Regions. If you specify a different number of Regions, CodePipeline will deploy to those Regions.

Tools

Tools

• AWS CodePipeline – CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software changes continuously.
• AWS CodeBuild – CodeBuild is a fully managed build service that compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
• AWS CodeCommit – CodeCommit is a version control service hosted by Amazon Web Services that you can use to privately store and manage assets (such as source code and binary files) in the cloud.
• AWS CloudFormation – AWS CloudFormation is a service that helps you model and set up your Amazon Web Services resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
• **AWS Identity and Access Management** – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers.

### Code

The following sample code is for the `BuildSpec.yml` file (Build phase).

```yaml
---
artifacts:
discard-paths: true
files:
  - packaged-first-region.yaml
  - packaged-second-region.yaml
  - packaged-third-region.yaml
phases:
  build:
    commands:
      - echo "********BUILD PHASE - CF PACKAGING**********"
      - "aws cloudformation package --template-file sam-template.yaml --s3-bucket $S3_FIRST_REGION --output-template-file packaged-first-region.yaml --region $FIRST_REGION"
      - "aws cloudformation package --template-file sam-template.yaml --s3-bucket $S3_SECOND_REGION --output-template-file packaged-second-region.yaml --region $SECOND_REGION"
      - "aws cloudformation package --template-file sam-template-anand.yaml --s3-bucket $S3_THIRD_REGION --output-template-file packaged-third-region.yaml --region $THIRD_REGION"
  install:
    commands:
      - echo "********BUILD PHASE - PYTHON SETUP**********"
runtime-versions:
  python: 3.8
post_build:
  commands:
    - echo "********BUILD PHASE - PACKAGING COMPLETION**********"
pre_build:
  commands:
    - echo "********BUILD PHASE - DEPENDENCY SETUP**********"
    - "npm install --silent --no-progress"
    - echo "********BUILD PHASE - DEPENDENCY SETUP DONE**********"
version: 0.2
```

### Export tags for a list of Amazon EC2 instances to a CSV file

*Created by Sida Ju (AWS) and Pac Joonhyun*
Summary

This pattern shows how to programmatically export tags for a list of Amazon Elastic Compute Cloud (Amazon EC2) instances to a CSV file.

By using the example Python script provided, you can reduce how long it takes to review and categorize your Amazon EC2 instances by specific tags. For example, you could use the script to quickly identify and categorize a list of instances that your security team has flagged for software updates.

Prerequisites and limitations

Prerequisites

- Python 3 installed and configured
- AWS Command Line Interface (AWS CLI) installed and configured

Limitations

The example Python script provided in this pattern can search Amazon EC2 instances based on the following attributes only:

- Instance IDs
- Private IPv4 addresses
- Public IPv4 addresses

Tools

- Python is a general-purpose computer programming language.
- virtualenv helps you create isolated Python environments.
- AWS Command Line Interface (AWS CLI) is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

Code repository

The example Python script for this pattern is available in the GitHub search-ec2-instances-export-tags repository.

- Configuring the AWS CLI (AWS CLI User Guide for Version 2)

Generate an AWS CloudFormation template containing AWS Config managed rules using Troposphere

*Created by Lucas Nation (AWS) and Freddie Wilson (AWS)*

**Environment:** Production  
**Technologies:** DevOps; Management & governance; Security, identity, compliance  
**Workload:** Microsoft; Open-source

**AWS services:** AWS Config; AWS CloudFormation

**Summary**

Many organizations use AWS Config managed rules to evaluate the compliance of their Amazon Web Services (AWS) resources against common best practices. However, these rules can be time consuming to maintain and this pattern helps you leverage Troposphere, a Python library, to generate and manage AWS Config managed rules.

The pattern helps you to manage your AWS Config managed rules by using a Python script to convert a Microsoft Excel spreadsheet containing AWS managed rules into an AWS CloudFormation template. Troposphere acts as the infrastructure as code (IaC) and this means that you can update the Excel spreadsheet with managed rules, instead of using a JSON or YAML-formatted file. You then use the template to launch an AWS CloudFormation stack that creates and updates the managed rules in your AWS account.

The AWS CloudFormation template defines each AWS Config managed rule by using the Excel spreadsheet and helps you to avoid manually creating individual rules in the AWS Management Console. The script defaults each managed rule's parameters to an empty dictionary and the scope's ComplianceResourceTypes defaults from THE_RULE_IDENTIFIER.template file. For more information about the rule identifier, see Creating AWS Config managed rules with AWS CloudFormation templates in the AWS Config documentation.

**Prerequisites and limitations**

**Prerequisites**
• An active AWS account.
• Familiarity with using AWS CloudFormation templates to create AWS Config managed rules. For more information about this, see Creating AWS Config managed rules with AWS CloudFormation templates in the AWS Config documentation.
• Python 3, installed and configured. For more information about this, see the Python documentation.
• An existing integrated development environment (IDE) such as AWS Cloud9. For more information about this, see What is AWS Cloud9? in the AWS Cloud9 documentation.
• Identify your organizational units (OUs) in a column in the sample excel_config_rules.xlsx Excel spreadsheet (attached).

Epics

Customize and configure the AWS Config managed rules

Give SageMaker notebook instances temporary access to a CodeCommit repository in another AWS account

*Summary*

This pattern shows how to grant Amazon SageMaker notebook instances and users temporary access to an AWS CodeCommit repository that’s in another AWS account.

Organizations often store CodeCommit repositories in a different AWS account than the account that hosts their development environment. This multi-account setup helps control access to the repositories and reduces the risk of their accidental deletion. To grant these cross-account permissions, it’s a best practice to use AWS Identity and Access Management (IAM) roles. Then, predefined IAM identities in each AWS account can temporarily assume the roles to create a controlled chain of trust across the accounts.

**Note:** You can apply a similar procedure to grant other IAM identities cross-account access to a CodeCommit repository. For more information, see Configure cross-account access to an AWS CodeCommit repository using roles in the *AWS CodeCommit User Guide*.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account with a CodeCommit repository (*account A*)
- A second active AWS account with a SageMaker notebook instance (*account B*)
- An AWS user with sufficient permissions to create and modify IAM roles in account A
- A second AWS user with sufficient permissions to create and modify IAM roles in account B

**Architecture**

The following diagram shows an example workflow for granting a SageMaker notebook instance and users in one AWS account cross-account access to a CodeCommit repository:
The diagram shows the following workflow:

1. The AWS user role and SageMaker notebook instance role in account B assume a named profile.
2. The named profile’s permissions policy specifies a CodeCommit access role in account A that the profile then assumes.
3. The CodeCommit access role’s trust policy in account A allows the named profile in account B to assume the CodeCommit access role.
4. The CodeCommit repository’s IAM permissions policy in account A allows the CodeCommit access role to access the CodeCommit repository.

**Technology stack**

- CodeCommit
- Git
- IAM
- pip
- SageMaker

**Tools**

- **AWS CodeCommit** is a version control service that helps you privately store and manage Git repositories, without needing to manage your own source control system.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **Git** is a distributed version-control system for tracking changes in source code during software development.
- **git-remote-codecommit** is a utility that helps you push and pull code from CodeCommit repositories by extending Git.
- `pip` is the package installer for Python. You can use `pip` to install packages from the Python Package Index and other indexes.

### Epics

#### Configure the IAM roles

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure the CodeCommit access role and permissions policy. | **Note:** To automate the manual setup process documented in this epic, you can use an [AWS CloudFormation template](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/).  

In the account that contains the CodeCommit repository (account A), do the following:  

1. [Create an IAM role](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_create.html) that can be assumed by the SageMaker notebook instance role in account B.  
2. [Create an IAM policy](https://docs.aws.amazon.com/IAM/latest/UserGuide/id_policies.html) that grants access to the repository and attach the policy to the role. For testing purposes only, choose the [AWSCodeCommitPowerUser](https://docs.aws.amazon.com/codecommit/latest/userguide/s3-access-product.html) AWS managed policy. This policy grants all CodeCommit permissions except the ability to delete resources.  
3. Modify the role's trust policy so that account B is listed as a trusted entity.  

**Important:** Before moving this setup into your production environment, it's a best practice to write your own IAM policy that applies least-privilege permissions. For more information, see the [Additional information](#) section of this pattern. | General AWS, AWS DevOps |
| Grant the SageMaker notebook instance's role in account B permissions to assume the CodeCommit access role in account A. | In the account that contains the SageMaker notebook instance's IAM role (account B), do the following:  

1. Create an IAM policy that allows an IAM role or user to assume the CodeCommit access role in account A. | General AWS, AWS DevOps |
### Example IAM permissions policy that allows an IAM role or user to assume a cross-account role

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "VisualEditor0",
            "Effect": "Allow",
            "Action": "sts:AssumeRole",
            "Resource": "arn:aws:iam::accountA_ID:role/accountArole_ID"
        }
    ]
}
```

2. Attach the policy to your SageMaker notebook instance's role in account B.

3. Have the SageMaker notebook instance's role in account B assume the CodeCommit access role in account A.

**Note:** To view your repository's Amazon Resource Name (ARN), see [View CodeCommit repository details](https://docs.aws.amazon.com/CodeCommit/latest/userguide/arns.html) in the AWS CodeCommit User Guide.

---

### Set up your SageMaker notebook instance in account B

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Set up a user profile on the AWS SageMaker notebook instance to assume the role in account A. | **Important:** Make sure that you have the latest version of the AWS Command Line Interface (AWS CLI) installed. In the account that contains the SageMaker notebook instance (`account B`), do the following:  
1. Sign in to the AWS Management Console and open the SageMaker console.  
### Task

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.</td>
<td>Choose <strong>New</strong>, and then choose <strong>Terminal</strong>. <em>A new terminal window opens in your Jupyter environment.</em></td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>Navigate to the SageMaker notebook instance’s <code>~/.aws/config</code> file. Then, add a user profile to the file by entering the following statement:</td>
<td></td>
</tr>
</tbody>
</table>

```
-------.aws/config----------
[profile remoterepouser]
role_arn = arn:aws:iam::<ID of Account A>:role/<rolename>
role_session_name = remotereaccesssession
region = eu-west-1
credential_source = Ec2InstanceMetadata
---------------------------
```

  - Data scientist

---

### Access the repository by running Git commands

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Run Git commands to access the CodeCommit repository. | IAM users that assume the SageMaker notebook instance’s role in account B can now run Git commands to access the CodeCommit repository in account A. For example, users can run commands such as **git clone**, **git pull**, and **git push**. For instructions, see [Connect to an AWS CodeCommit repository](#) in the [AWS CodeCommit User Guide](#). | Git, bash console

For information about how to use Git with CodeCommit, see [Getting started with AWS CodeCommit](#) in the [AWS CodeCommit User Guide](#). |
Related resources

- Configure cross-account access to an AWS CodeCommit repository using roles (AWS CodeCommit User Guide)
- IAM tutorial: Delegate access across AWS accounts using IAM roles (AWS IAM User Guide)

Additional information

Restricting CodeCommit permissions to specific actions

To restrict the actions that an IAM user can take in the CodeCommit repository, modify the actions that are allowed in the CodeCommit access policy.

For more information about CodeCommit API operations, see CodeCommit permissions reference in the AWS CodeCommit User Guide.

Note: You can also edit the AWSCodeCommitPowerUser AWS managed policy to fit your use case.

Restricting CodeCommit permissions to specific repositories

To create a multitenant environment where more than one code repository is accessible to only specific users, do the following:

1. Create multiple CodeCommit access roles in account A. Then, configure each access role’s trust policy to allow specific users in account B to assume the role.
2. Restrict what code repositories that each role can assume by adding a “Resource” condition to each CodeCommit access role’s policy.

Example “Resource” condition that restricts an IAM user’s access to a specific CodeCommit repository

"Resource" : [<REPOSITORY_ARN>,<REPOSITORY_ARN> ]

Note: To help identify and differentiate multiple code repositories in the same AWS account, you can assign different prefixes to the repositories’ names. For example, you can name code repositories with prefixes that align to different developer groups, such as myproject-subproject1-repo1 and myproject-subproject2-repo1. Then, you can create an IAM role for each developer group based on their assigned prefixes. For example, you could create a role named myproject-subproject1-repoaccess and grant it access to all of the code repositories that include the prefix myproject-subproject1.

Example “Resource” condition that refers to a code repository ARN that includes a specific prefix

Automatically detect changes and initiate different CodePipeline pipelines for a monorepo in CodeCommit

Created by Helton Henrique Ribeiro (AWS) and Ricardo Morais (AWS)
Summary

This pattern helps you automatically detect changes to the source code of a monorepo-based application in AWS CodeCommit and then initiate a pipeline in AWS CodePipeline that runs the continuous integration and continuous delivery (CI/CD) automation for each microservice.

This approach means that each microservice in your monorepo-based application can have a dedicated CI/CD pipeline, which ensures better visibility, easier sharing of code, and improved collaboration, standardization, and discoverability.

The pattern uses AWS Cloud9 as the integrated development environment (IDE) and AWS Cloud Development Kit (AWS CDK) to define an infrastructure using two AWS CloudFormation stacks: MonoRepoStack and PipelinesStack. The MonoRepoStack stack creates the monorepo in AWS CodeCommit and the AWS Lambda function that initiates the CI/CD pipelines. The PipelinesStack stack defines your pipeline infrastructure.

Important: This pattern’s workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern’s approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this, see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- Python 3 and pip, installed on your local machine. For more information about this, see the Python documentation.
- AWS CDK, installed and configured. For more information about this, see Getting started with the AWS CDK in the AWS CDK documentation.
- An AWS Cloud9 IDE, installed and configured. For more information about this, see Setting up AWS Cloud9 in the AWS Cloud9 documentation.
- The GitHub AWS CodeCommit monorepo multi-pipeline triggers repository, cloned to your local machine.
- An existing directory containing application code that you want to build and deploy with CodePipeline.

- Familiarity and experience with DevOps best practices on the AWS Cloud. To increase your familiarity with DevOps, you can use the pattern Build a loosely coupled architecture with microservices using DevOps practices and AWS Cloud9 on the AWS Prescriptive Guidance website.
Limitations

- This pattern’s workflow is a proof of concept (POC) and we recommend that you only use it in a test environment. If you want to use this pattern’s approach in a production environment, see Security best practices in IAM in the IAM documentation and make the required changes to your IAM roles and AWS services.

Architecture

The following diagram shows how to use AWS CDK to define an infrastructure with two AWS CloudFormation stacks: MonoRepoStack and PipelinesStack.

The diagram shows the following workflow:

1. The bootstrap process uses AWS CDK to create the MonoRepoStack and PipelinesStack AWS CloudFormation stacks.
2. The MonoRepoStack stack creates the CodeCommit repository for your application and the monorepo-event-handler Lambda function that is initiated after each commit.

3. The PipelinesStack stack creates the pipelines in CodePipeline that are initiated by the Lambda function. Each microservice must have a defined infrastructure pipeline.

4. The pipeline for microservice-n is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.

5. The pipeline for microservice-1 is initiated by the Lambda function and starts its isolated CI/CD stages that are based on the source code in CodeCommit.

The following diagram shows the deployment of the MonoRepoStack and PipelinesStack AWS CloudFormation stacks in an account.

1. A user changes code in one of the application’s microservices.
2. The user pushes the changes from a local repository to a CodeCommit repository.
3. The push activity initiates the Lambda function that receives all pushes to the CodeCommit repository.
4. The Lambda function reads a parameter in AWS Systems Manager Parameter Store to retrieve the most recent commit ID. The parameter has the /MonoRepoTrigger/\{repository\}/\{branch_name\}/LastCommit naming format. If the parameter is not found, the Lambda function reads the last commit ID from the CodeCommit repository and saves the returned value in Parameter Store.
5. After identifying the commit ID and the changed files, the Lambda function identifies the pipelines for each microservice directory and initiates the required CodePipeline pipeline.

**Tools**

- **AWS CDK** – AWS Cloud Development Kit (AWS CDK) is a software development framework for defining cloud infrastructure in code and provisioning it through AWS CloudFormation.
- **Python** – Python is a programming language that lets you work quickly and integrate systems more effectively.
### Epics

#### Set up the environment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a virtual Python environment.      | In your AWS Cloud9 IDE, create a virtual Python environment and install the required dependencies by running the following command:  
  make install                              | Developer         |
| Bootstrap the account and AWS Region for the AWS CDK. | Bootstrap the required AWS account and Region by running the following command:  
  make bootstrap account-id=<your-AWS-account-ID>  
  region=<required-region>                   | Developer         |

#### Add a new pipeline for a microservice

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add your sample code to your application directory.</td>
<td>Add the directory containing your sample application code to the monorepo-sample directory in the cloned AWS CodeCommit monorepo multi-pipeline triggers repository.</td>
<td>Developer</td>
</tr>
<tr>
<td>Edit the monorepo-main.json file.</td>
<td>Add the directory name of your application's code and the pipeline's name to the monorepo-main.json file in the cloned AWS CodeCommit monorepo multi-pipeline triggers repository.</td>
<td>Developer</td>
</tr>
<tr>
<td>Create the pipeline.</td>
<td>In the Pipelines directory for the AWS CodeCommit monorepo multi-pipeline triggers repository, add the pipeline class for your application. The directory contains two sample files, pipeline_hotsite.py and</td>
<td>Developer</td>
</tr>
</tbody>
</table>
### Task 1: Edit the monorepo_config.py file.

You can copy one of the files and make changes to it according to your application’s requirements.

**Description**

In `service_map`, add the directory name for your application and the class that you created for the pipeline.

For example, the following code shows a pipeline definition in the Pipelines directory that uses a file named `pipeline_mysample.py` with a `MySamplePipeline` class:

```python
...
# Pipeline definition
imports
from pipelines.pipeline_demo
import DemoPipeline
from pipelines.pipeline_hotsite
import HotsitePipeline
from pipelines.pipeline_mysample
import MySamplePipeline

### Add your pipeline configuration here
service_map: Dict[str, ServicePipeline] = {
    # folder-name ->
    pipeline-class
    'demo': DemoPipeline(),
    'hotsite': HotsitePipeline(),
    'mysample': MySamplePipeline()
}
```

**Skills required**

Developer

### Task 2: Deploy the MonoRepoStack stack.

**Description**

Deploy the AWS CloudFormation stack with default parameter values in the root directory of the cloned AWS CodeCommit monorepo multi-pipeline triggers.

**Skills required**

Developer
### Task Description

**Validate the CodeCommit repository.** Validate that your resources were created by running the `aws codecommit get-repository --repository-name <repo_name>` command.

**Important:** Because the AWS CloudFormation stack creates the CodeCommit repository where the monorepo is stored, don’t run the `cdk destroy MonoRepoStack` command if you have started to push modifications into it.

**Validate the AWS CloudFormation stack results.** Validate that the `MonoRepoStack` AWS CloudFormation stack is correctly created and configured by running the following command:

```
aws cloudformation list-stacks --stack-status-filter CREATE_COMPLETE --query
  'StackSummaries[?StackName==`MonoRepoStack`].
```

### Deploy the PipelinesStack stack

**Task Description**

**Deploy the AWS CloudFormation stack.** The `PipelinesStack` AWS CloudFormation stack must be deployed after you deploy the `MonoRepoStack` stack. The stack increases in size when new microservices are added to the monorepo’s code base and is redeployed when a new microservice is onboarded.

### Skills required

- **Developer**
### Task Description

**Task**

**Description**

- Deploy the PipelinesStack stack by running the `make deploy-pipelines` command.

  **Note:** You can also deploy simultaneously deploy both pipelines by running the `make deploy monorepo-name=<repo_name>` command.

The following sample output shows how the PipelinesStacks deployment prints the URLs for the microservices at the end of the implementation:

```
Outputs:
PipelinesStack.demourl = .cloudfront.net
PipelinesStack.hotsiteurl = .cloudfront.net
```

**Task**

**Description**

- Validate the AWS CloudFormation stack results.

  Validate that the PipelinesStacks AWS CloudFormation stack is correctly created and configured by running the following command:

  ```
  aws cloudformation list-stacks --stack-status-filter CREATE_COMPLETE UPDATE_COMPLETE --query 'StackSummaries[?StackName == `PipelinesStack`]
  ```

### Clean up resources

**Task**

**Description**

- Delete your AWS CloudFormation stacks.

  Run the `make destroy` command.

  **Skills required:** Developer

- Delete the S3 buckets for your pipelines.

  1. Sign in to the AWS Management Console and open the Amazon Simple Storage Service (Amazon S3) console.

  2. Delete the S3 buckets associated with your pipelines and that use the following
Integrate a Bitbucket repository with AWS Amplify using AWS CloudFormation

Created by Alwin Abraham (AWS)

Environment: Production  Technologies: DevOps  AWS services: AWS Amplify; AWS CloudFormation

Summary

AWS Amplify helps you to quickly deploy and test static websites without having to set up the infrastructure that is typically required. You can deploy this pattern's approach if your organization wants to use Bitbucket for source control, whether to migrate existing application code or build a new application. By using AWS CloudFormation to automatically set up Amplify, you provide visibility into the configurations that you use.

This pattern describes how to create a front-end continuous integration and continuous deployment (CI/CD) pipeline and deployment environment by using AWS CloudFormation to integrate a Bitbucket repository with AWS Amplify. The pattern's approach means that you can build an Amplify front-end pipeline for repeatable deployments.

Prerequisites and limitations

**Prerequisites**

- An active Amazon Web Services (AWS) account
- An active Bitbucket account with administrator access
- Access to a terminal that uses cURL or the Postman application
- Familiarity with Amplify
- Familiarity with AWS CloudFormation
- Familiarity with YAML-formatted files

Architecture
AWS Prescriptive Guidance Patterns

Tools

- **Amplify** – Amplify helps developers to develop and deploy cloud-powered mobile and web apps.
- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS.
- **Bitbucket** – Bitbucket is a Git repository management solution designed for professional teams. It gives you a central place to manage Git repositories, collaborate on your source code, and guide you through the development flow.

Code

The bitbucket-amplify.yml file (attached) contains the AWS CloudFormation template for this pattern.

Epics

**Configure the Bitbucket repository**

<table>
<thead>
<tr>
<th>Task</th>

</tr>
</tbody>
</table>
## Summary

This pattern demonstrates how to asynchronously launch an AWS CodeBuild project across AWS accounts by using AWS Step Functions and an AWS Lambda proxy function. You can use the pattern’s sample Step Functions state machine to test the success of your CodeBuild project.

CodeBuild helps you launch operational tasks using the AWS Command Line Interface (AWS CLI) from a fully-managed Amazon Linux 2 runtime environment. You can change the behavior of your CodeBuild project at runtime by overriding environment variables. You can also use AWS CodePipeline to launch operational tasks, but you can’t override environment variables with CodePipeline. Additionally, you can use CodeBuild to manage workflows. For more information, see Service Catalog Tools on the AWS Workshop website and Schedule jobs in Amazon RDS for PostgreSQL using AWS CodeBuild and Amazon EventBridge on the AWS Database Blog.
Prerequisites and limitations

Prerequisites

• Two active AWS accounts: a source account for invoking a Lambda proxy function with Step Functions and a target account for building a remote CodeBuild sample project

Limitations

• This pattern cannot be used to copy artifacts between accounts.

Architecture

The following diagram shows the architecture that this pattern builds.

The diagram shows the following workflow:

1. The Step Functions state machine invokes the Lambda proxy function (codebuild-proxy-lambda).
2. The Lambda proxy function uses AWS Security Token Service (AWS STS) to assume an IAM proxy role (codebuild-proxy-role) and use an IAM policy (codebuild-proxy-policy) in the target account.
3. The Lambda function launches the CodeBuild project and returns the CodeBuild job ID.
4. The Step Functions state machine loops and polls the CodeBuild job until receiving a success or failure status.

Technology stack
AWS Prescriptive Guidance Patterns

Tools

- **AWS CloudFormation** helps you set up AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle across AWS accounts and Regions.
- **AWS CodeBuild** is a fully managed build service that helps you compile source code, run unit tests, and produce artifacts that are ready to deploy.
- **AWS Identity and Access Management (IAM)** helps you securely manage access to your AWS resources by controlling who is authenticated and authorized to use them.
- **AWS Lambda** is a compute service that helps you run code without needing to provision or manage servers. It runs your code only when needed and scales automatically, so you pay only for the compute time that you use.
- **AWS Step Functions** is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- **AWS X-Ray** helps you collect data about the requests that your application serves, and provides tools that you can use to view, filter, and gain insights into that data to identify issues and opportunities for optimization.

Code

The code for this pattern is available in the GitHub Cross Account CodeBuild Proxy repository. This pattern uses the AWS Lambda Powertools for Python library to provide logging and tracing functionality. For more information on this library and its utilities, see [AWS Lambda Powertools for Python](https://docs.aws.amazon.com/lambda/latest/dg/powertools-python-intro.html).

Epics

Create the Lambda proxy function and associated IAM role in the source account

<table>

<tr>
<td>Create and deploy the AWS CloudFormation stack.</td>
<td>1. Sign in to the AWS Management Console for your source account, open the AWS CloudFormation console, and then choose Stacks.</td>
<td>AWS DevOps</td>
</tr>
<tr>
<td></td>
<td>2. Choose Create Stack and then choose With new resources (standard).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>3. For Template source, choose Upload a template file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>4. For Upload a template file, choose file, and then choose your downloaded codebuild_lambda_proxy_template.yaml file. Choose Next.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>5. For Stack name, enter a name for the stack (for example, codebuild-lambda-proxy).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>6. Replace the crossAccountTargetRoleArn parameter with your &lt;TargetAccountId&gt; (for example, <a href="">arn:aws:iam::123456789012:role/proxy-lambda-codebuild-role</a>). <strong>Note:</strong> You aren’t required to update the default value for the targetCodeBuildProject parameter.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>7. Choose Next, accept the default stack creation options, and then choose Next.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>8. Choose the I acknowledge that AWS CloudFormation might create IAM resources with custom names check box, and then choose Create stack.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:** You must create the AWS CloudFormation stack for the proxy Lambda function before creating any other resources in the source account. For more information, see Creating a role to delegate permissions to an IAM user in the IAM documentation.
## Confirm the creation of the proxy function and state machine.

1. Wait for the AWS CloudFormation stack to reach **CREATE_COMPLETE** status. This should take less than one minute.
2. Open the [AWS Lambda console](https://console.aws.amazon.com/lambda/home), choose **Functions**, and then find the lambda-proxy-ProxyLambda-<GUID> function.
3. Open the [AWS Step Functions console](https://console.aws.amazon.com/stepfunctions/home), choose **state machines**, and then find the sample-crossaccount-codebuild-state-machine state machine.
<table>
<thead>
<tr>

6. To see the output and input of a step in the state machine, expand that step in the Execution event history section. For example, expand the Lambda - CodeBuild Proxy – Start step. The output includes details on the overridden environment variables, the original payload, and the CodeBuild job ID. | -                       |

Created by Vikrant Telkar (AWS), Sajid Momin (AWS), and Wassim Benhallam (AWS)

Environment: Production  
Technologies: DevOps; Containers & microservices  
AWS services: AWS CloudFormation; AWS Config; Amazon ECR; Amazon SNS; AWS Lambda
Summary

On the Amazon Web Services (AWS) Cloud, Amazon Elastic Container Registry (Amazon ECR) is a
managed container image registry service that supports private repositories with resource-based
permissions using AWS Identity and Access Management (IAM).

IAM supports the "*" wildcard in both the resource and action attributes, which makes it easier
to automatically choose multiple matching items. In your testing environment, you can allow all
authenticated AWS users to access an Amazon ECR repository by using the ecr:* wildcard permission in
a principal element for your repository policy statement. The ecr:* wildcard permission can be useful
when developing and testing in development accounts that can't access your production data.

However, you must make sure that the ecr:* wildcard permission is not used in your production
environments because it can cause serious security vulnerabilities. This pattern's approach helps you
to identify Amazon ECR repositories that contain the ecr:* wildcard permission in repository policy
statements. The pattern provides steps and an AWS CloudFormation template to create a custom rule
in AWS Config. An AWS Lambda function then monitors your Amazon ECR repository policy statements
for ecr:* wildcard permissions. If it finds non-compliant repository policy statements, Lambda notifies
AWS Config to send an event to Amazon EventBridge and EventBridge then initiates an Amazon Simple
Notification Service (Amazon SNS) topic. The SNS topic notifies you by email about the non-compliant
repository policy statements.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. For more information about this,
  see Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.
- An existing Amazon ECR repository with an attached policy statement, installed and configured in your
testing environment. For more information about this, see Creating a private repository and Setting a
repository policy statement in the Amazon ECR documentation.
- AWS Config, configured in your preferred AWS Region. For more information about this, see Getting
  started with AWS Config in the AWS Config documentation.
- The aws-config-cloudformation.template file (attached), downloaded to your local machine.

Limitations

- This pattern's solution is Regional and your resources must be created in the same Region.

Architecture

The following diagram shows how AWS Config evaluates Amazon ECR repository policy statements.
The diagram shows the following workflow:

1. AWS Config initiates a custom rule.
2. The custom rule invokes a Lambda function to evaluate the compliance of the Amazon ECR repository policy statements. The Lambda function then identifies non-compliant repository policy statements.
3. The Lambda function sends the non-compliance status to AWS Config.
4. AWS Config sends an event to EventBridge.
5. EventBridge publishes the non-compliance notifications to an SNS topic.
6. Amazon SNS sends an email alert to you or an authorized user.

**Automation and scale**

This pattern’s solution can monitor any number of Amazon ECR repository policy statements, but all resources that you want to evaluate must be created in the same Region.

**Tools**

- **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
- **AWS Config** – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time.
- **Amazon ECR** – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable. Amazon ECR supports private repositories with resource-based permissions using IAM.
• **Amazon EventBridge** – Amazon EventBridge is a serverless event bus service that you can use to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your applications, software as a service (SaaS) applications, and AWS services to targets such as AWS Lambda functions, HTTP invocation endpoints using API destinations, or event buses in other accounts.

• **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients, including web servers and email addresses. Subscribers receive all messages published to the topics to which they subscribe, and all subscribers to a topic receive the same messages.

**Code**

The code for this pattern is available in the `aws-config-cloudformation.template` file (attached).

### Perform a canary-based deployment using the blue/green strategy and AWS Lambda

*Created by Raju Banerjee (AWS)*

<table>
<thead>
<tr>
<th>Created by</th>
<th>AWS services: CodeDeploy; AWS Lambda</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: DevOps</th>
</tr>
</thead>
</table>

### Summary

This pattern guides you through the steps to set up a canary-based blue/green deployment using AWS CodeDeploy. CodeDeploy is a fully managed deployment service that automates software deployments to a variety of compute services such as Amazon Elastic Compute Cloud (Amazon EC2), AWS Lambda, and your on-premises servers. Manually deploying applications to servers can take a long time and often results in errors that lead to downtime.

The purpose of a canary deployment is to reduce the risk of deploying a new version that impacts the workload. The method covered by this pattern incrementally deploys the new version, making it visible to new users in a slow fashion. As you gain confidence in the deployment, you can deploy it to replace the current version in its entirety.

By following this pattern, you can test both old and new application versions. You can use AWS cloud-native tools, with no need to maintain separate tools for deployment and no extra Amazon EC2 machine cost. The pattern supports AWS Identity and Access Management (IAM) authentication and audit features that use AWS CloudTrail to manage user activities.

### Prerequisites and limitations

**Prerequisites**

- An application, with code defined in the AppSpec file
- An active AWS account
- A virtual private cloud (VPC)
- An Amazon EC2 Auto Scaling group
- A key pair (optional)
- An IAM role
- An Amazon Simple Notification Service (Amazon SNS) topic

**Limitations**

- The old version of code will not provide the automatic scaling feature.
- Cleaning up the old environment will require a separate Lambda function. Or, wait 48 hours, and the environment will be cleaned by default.

**Architecture**

**Target technology stack**

- Amazon CloudWatch Events
- IAM
- Amazon SNS
- AWS CodeBuild
- AWS CodeDeploy
- Amazon EC2
- Application Load Balancer
- AWS Lambda

**Target architecture**
Automation and scale

AWS CloudFormation can be used to automate the infrastructure creation.

Cleanup of the pilot environment can be automated by using a Python (Boto) script and the tags of the environment.

Tools

- **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.
- **AWS CodeDeploy** – AWS CodeDeploy is a deployment service that automates application deployments to EC2 instances, on-premises instances, serverless Lambda functions, or Amazon Elastic Container Service (Amazon ECS) services. You do not need to make changes to your existing code before you can use CodeDeploy.
- **AWS Lambda** – AWS Lambda is a compute service that lets you run code without provisioning or managing servers.
- **AWS SNS** – Amazon SNS is a web service that coordinates and manages the delivery or sending of messages to subscribing endpoints or clients. Subscribers, including Lambda functions, consume or receive the message or notification over one of the supported protocols when they are subscribed to the topic.
- **A launch template** – A launch template specifies instance configuration information. Included are the ID of the Amazon Machine Image (AMI), the instance type, a key pair, security groups, and the other parameters that you use to launch EC2 instances.

Code

Python code for the Lambda function:

```python
global code
import boto3
code= boto3.client('codedeploy')
codal = boto3.client('autoscaling')
codal =[]
def lambda_handler(event, context):
    #Define the code-deploy related parameters here or pass it using lambda parameters.
    codeployappname='pattern-test'
codeploymentgroup='pattern-testing'
    albtargetgrouparn='arn:aws:elasticloadbalancing:us-east-1:************:targetgroup/green-target-group/0614b55e********'
    response = code.list_deployments(
        applicationName=codeployappname,
        deploymentGroupName=deploymentgroup,
        includeOnlyStatuses=[
            'Succeeded',
        ],
    )
    #Get the latest deployment event and fetch the id and ignore any autoscale events.
    for i in range (len(response['deployments'])):
        deploymentId=(response['deployments'][i])
        response3 = client.get_deployment(deploymentId=deploymentId)
        type01=(response3['deploymentInfo']['creator'])
        if type01 == 'user':
            deploymentinfo=(response3['deploymentInfo'])
            response4 = client.get_deployment(deploymentId=deploymentinfo['deploymentId'])
```

706
response5 = response4['deploymentInfo']['targetInstances']['autoScalingGroups'][0]
autosg.append(response5)
print (autosg[1])

response = clientasg.attach_load_balancer_target_groups(
    AutoScalingGroupName=autosg[1],
    TargetGroupARNs=[albtargetgrouparn],
)

Perform custom actions from AWS CodeCommit events

Created by Abdullahi Olaoye (AWS)

| R Type: | N/A |
| Source: | AWS CodeCommit Repository |
| Target: | Integration with other AWS Services |
| Created by: | AWS |
| Environment: | PoC or pilot |
| Technologies: | Management & governance; DevOps |

AWS services: AWS CodeCommit; Amazon CloudWatch

Summary

When you use an AWS CodeCommit repository to store code, you might want to monitor the repository and initiate a workflow of actions when specific events occur. For example, you might want to send an email notification when a user comments on a line of code in a commit, or initiate an AWS Lambda function to perform security scans on repository contents after a commit. This pattern outlines the steps for configuring a CodeCommit repository for custom actions. The pattern uses AWS CodeCommit notification rules to capture the events of interest, and then sends these events to a configured target.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Familiarity with Git commands

Architecture
**AWS CodeCommit** – AWS CodeCommit is a fully-managed source control service that hosts secure Git-based repositories. It makes it easy for teams to collaborate on code in a secure and highly scalable ecosystem. CodeCommit eliminates the need to operate your own source control system or worry about scaling its infrastructure.

**Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud. Amazon SNS provides topics (communication channels) for high-throughput, push-based, many-to-many messaging. Using Amazon SNS topics, publishers can distribute messages to a large number of subscribers for parallel processing, including Amazon Simple Queue Service (Amazon SQS) queues, AWS Lambda functions, and HTTP/S webhooks. You can also use Amazon SNS to send notifications to end users using mobile push, SMS, and email.

**Epics**

**Set up AWS CodeCommit**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Complete the initial setup required for CodeCommit.</td>
<td>This task involves creating and configuring an AWS Identity and Access Management (IAM) user for CodeCommit and configuring your local computer for access. You should also install the AWS Command Line Interface (AWS CLI) to manage CodeCommit. For instructions and more information about this task and other epics, see the links in the “Related resources” section.</td>

**Publish Amazon CloudWatch metrics to a CSV file**

*Created by Abdullahi Olaoye (AWS)*

**Environment:** PoC or pilot  
**Technologies:** DevOps  
**AWS services:** Amazon CloudWatch
Summary

This pattern uses a Python script to retrieve Amazon CloudWatch metrics and to convert the metrics information into a comma-separated values (CSV) file for improved readability. The script takes the AWS service whose metrics should be retrieved as a required argument. The AWS Region and AWS credential profile can be passed as optional arguments. If those optional arguments are not passed, the script uses the configured default Region and the default AWS credential that are configured for the workstation where the script is run. After the script runs, it generates and stores a CSV file in the same directory.

Prerequisites and limitations

Prerequisites

- Python 3.x
- AWS Command Line Interface (AWS CLI)

Limitations

The script currently supports the following AWS services:

- AWS Lambda
- Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Relational Database Service (Amazon RDS)
  - However, the script doesn’t support Amazon Aurora
- Application Load Balancer
- Network Load Balancer
- Amazon API Gateway

Tools

- **Amazon CloudWatch** – Amazon CloudWatch is a monitoring and observability service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides data and actionable insights to help you monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, and provides a unified view of AWS resources, applications, and services that run on AWS and on-premises servers.

<tr>
<td></td>
<td>For more information about the optional parameters, see the Additional information section.</td>
<td></td>
</tr>
</tbody>
</table>

Related resources

- Configuring the AWS CLI
- Using Amazon CloudWatch metrics
- Amazon CloudWatch documentation

Additional information

Script usage

$ python cwreport.py -h

Example syntax

python cwreport.py <service> <--region=Optional Region> <--profile=Optional credential profile>

Parameters

- **service (required)** - The service you want to run the script against. The script currently supports these services: AWS Lambda, Amazon EC2, Amazon RDS, Application Load Balancer, Network Load Balancer, and API Gateway.
- **region (optional)** - The AWS Region to fetch metrics from. The default Region is ap-southeast-1.
- **profile (optional)** - The AWS CLI named profile to use. If specified, the default configured credential isn't used.

Examples

- Using default Region ap-southeast-1 and default configured credentials to fetch Amazon EC2 metrics: $ python cwreport.py ec2

Set up a Helm v3 chart repository in Amazon S3

*Created by Abhishek Sharma (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Technologies:</th>
<th>Workload:</th>
</tr>
</thead>
<tbody>
<tr>
<td>PoC or pilot</td>
<td>DevOps; Containers &amp; microservices; Modernization</td>
<td>All other workloads</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>AWS services:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon S3</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern helps you to manage Helm v3 charts efficiently by integrating the Helm v3 repository into Amazon Simple Storage Service (Amazon S3) on the Amazon Web Services (AWS) Cloud. To use this pattern, you must be familiar with Kubernetes and with Helm, which is a Kubernetes package manager. Using Helm repositories to store charts and control chart versions can improve mean time to restore (MTTR) during outages.

This pattern uses AWS CodeCommit for Helm repository creation, and it uses an S3 bucket as a Helm chart repository, so that the charts can be centrally managed and accessed by developers across the organization.

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- Python version 2.7.12 or later
- pip
- A virtual private cloud (VPC) with subnets and an Amazon Elastic Compute Cloud (Amazon EC2) instance
- Git installed on the EC2 instance
- AWS Identity and Access Management (IAM) access to create the S3 bucket
- IAM (programmatic or role) access to Amazon S3 from the client machine
- AWS CodeCommit repository
• AWS Command Line Interface (AWS CLI)

Product versions
• Helm v3
• Python version 2.7.12 or later

Architecture

Target technology stack
• Amazon S3
• AWS CodeCommit
• Helm
• Kubectl
• Python and pip
• Git
• helm-s3 plugin

Target architecture

Automation and scale
• You can incorporate Helm into your existing continuous integration/continuous delivery (CI/CD) automation tool to automate the packaging and version control of Helm charts (out of scope for this pattern).
• GitVersion or Jenkins build numbers can be used to automate version control of the charts.
Tools

- **Helm** – Helm is a package manager for Kubernetes that helps you install and manage applications on your Kubernetes cluster.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **helm-s3 plugin** – The helm-s3 plugin supports interaction with Amazon S3. It can be used with either Helm v2 or Helm v3.

Epics

Install and validate Helm v3

### Upgrade your Helm repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify and package the chart.</td>
<td>In values.yaml, set the replicaCount value to 1, and then package the chart, this time changing the version in Chart.yaml to 0.1.1. Version control is ideally achieved through automation by using tools like GitVersion or Jenkins build numbers in a CI/CD pipeline. Automating the version number is out of scope for this pattern. To package the chart, run the following command: helm package ./my-app/</td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td>Push the new version to the Helm repository in Amazon S3.</td>
<td>To push the new package, version of 0.1.1, to the my-helm-charts Helm repository in Amazon S3, run the following command: helm s3 push ./my-app-0.1.1.tgz stable-myapp</td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
<tr>
<td>Verify the updated Helm chart.</td>
<td>To confirm that the updated chart appears both locally and in the Amazon S3 Helm repository, run the following commands. helm repo update helm search repo stable-myapp</td>
<td>Cloud Administrator, DevOps Engineer</td>
</tr>
</tbody>
</table>

### Search for and install a chart from the Amazon S3 Helm repository

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search for all versions of the my-app chart.</td>
<td>To view all the available versions of a chart, run the following</td>
<td>DevOps Engineer</td>
</tr>
</tbody>
</table>
## Task: Install a chart from the Amazon S3 Helm repository.

**Description:** Automated installation is out of scope for this pattern, but you can manually install. The search results from the previous task show the multiple versions of the `my-app` chart. To install the new version (0.1.1) from the Amazon S3 Helm repository, use the following command:

```bash
helm upgrade --install my-app-release stable-myapp/my-app --version 0.1.1 --namespace dev
```

**Skills required:** DevOps Engineer

## Task: Roll back to a previous version.

**Description:** Automated rollback is out of scope for this pattern. To manually roll back to a previous revision, use the following command:

```bash
helm rollback my-app-release 1
```

This example is rolling back to revision number 1.

**Skills required:** DevOps Engineer

### Roll back to a previous version by using Helm

</table>
Set up end-to-end encryption for applications on Amazon EKS using cert-manager and Let's Encrypt

Created by Mahendra Siddappa (AWS) and Vasanth Jeyaraj (AWS)

<table>
<thead>
<tr>
<th>Code repository:</th>
<th>Environment: PoC or pilot</th>
<th>Technologies: DevOps; Containers &amp; microservices; Security, identity, compliance</th>
</tr>
</thead>
<tbody>
<tr>
<td>End-to-end encryption on Amazon EKS</td>
<td></td>
<td></td>
</tr>
<tr>
<td>AWS services: Amazon EKS; Amazon Route 53</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

Implementing end-to-end encryption can be complex and you need to manage certificates for each asset in your microservices architecture. Although you can terminate the Transport Layer Security (TLS) connection at the edge of the Amazon Web Services (AWS) network with a Network Load Balancer or Amazon API Gateway, some organizations require end-to-end encryption.

This pattern is intended for organizations that require mutual authentication between all microservices in their applications. Mutual TLS reduces the burden of maintaining user names or passwords and can also use the turnkey security framework. This pattern's approach is compatible if your organization has a large number of connected devices or must comply with strict security guidelines.

This pattern helps increase your organization's security posture by implementing end-to-end encryption for applications running on Amazon Elastic Kubernetes Service (Amazon EKS). This pattern provides a sample application and code in the GitHub End-to-end encryption on Amazon EKS repository to show how a microservice runs with end-to-end encryption on Amazon EKS. The pattern's approach uses cert-manager, an add-on to Kubernetes, with Let's Encrypt as the certificate authority (CA). Let's Encrypt is a cost-effective solution to manage certificates and provides free certificates that are valid for 90 days. Cert-manager automates the on-demand provisioning and rotating of certificates when a new microservice is deployed on Amazon EKS.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon EKS cluster.
- AWS Command Line Interface (AWS CLI) version 1.7 or later, installed and configured on macOS, Linux, or Windows.
• The `kubectl` command line utility, installed and configured to access the Amazon EKS cluster. For more information about this, see Installing kubectl in the Amazon EKS documentation.
• An existing Domain Name System (DNS) name to test the application. For more information about this, see Registering domain names using Amazon Route 53 in the Amazon Route 53 documentation.
• The latest Helm version, installed on your local machine. For more information about this, see Using Helm with Amazon EKS in the Amazon EKS documentation and the GitHub Helm repository.
• The GitHub End-to-end encryption on Amazon EKS repository, cloned to your local machine.
• Replace the following values in the policy.json and trustpolicy.json files from the cloned GitHub End-to-end encryption on Amazon EKS repository:
  • `<account_number>` – Replace with the AWS account ID for the account that you want to deploy the solution in.
  • `<zone_id>` – Replace with the domain name’s Route 53 zone ID.
  • `<node_group_role>` – Replace with the name of the AWS Identity and Access Management (IAM) role associated with the Amazon EKS nodes.
  • `<namespace>` – Replace with the Kubernetes namespace in which you deploy the NGINX Ingress Controller and the sample application.
  • `<application-domain-name>` – Replace with the DNS domain name from Route 53.

Limitations
• This pattern doesn’t describe how to rotate certificates and only demonstrates how to use certificates with microservices on Amazon EKS.

Architecture
The following diagram shows the workflow and architecture components for this pattern.

The diagram shows the following workflow:
1. A client sends a request to access the application to the DNS name.
2. The Route 53 record is a CNAME to the Network Load Balancer.
3. The Network Load Balancer forwards the request to the NGINX Ingress Controller that is configured with a TLS listener. Communication between the NGINX Ingress Controller and the Network Load Balancer follows HTTPS protocol.

4. The NGINX Ingress Controller carries out path-based routing based on the client's request to the application service.

5. The application service forwards the request to the application pod. The application is designed to use the same certificate by calling secrets.

6. Pods run the sample application using the cert-manager certificates. The communication between the NGINX Ingress Controller and the pods uses HTTPS.

**Note:** Cert-manager runs in its own namespace. It uses a Kubernetes cluster role to provision certificates as secrets in specific namespaces and that can then be attached to application pods and NGINX Ingress Controller.

**Tools**

- **Amazon EKS** – Amazon Elastic Kubernetes Service (Amazon EKS) is a managed service that you can use to run Kubernetes on AWS without needing to install, operate, and maintain your own Kubernetes control plane or nodes.

- **Elastic Load Balancing** – Elastic Load Balancing automatically distributes your incoming traffic across multiple targets, containers, and IP addresses.

- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

- **Amazon Route 53** – Route 53 is a highly available and scalable Domain Name System (DNS) web service.

- **Cert-manager** – Cert-manager is an add-on to Kubernetes that requests certificates, distributes them to Kubernetes containers, and automates certificate renewal.

- **NGINX Ingress Controller** – NGINX Ingress Controller is a traffic management solution for cloud-native apps in Kubernetes and containerized environments.

**Epics**

**Create and configure a public hosted zone with Route 53**

<table>

Subscribe multiple email endpoints to an SNS topic by using a custom resource

*Created by Ricardo Morais (AWS)*

| Environment: Production | Technologies: DevOps | AWS services: Amazon SNS; AWS CloudFormation; AWS Lambda |

**Summary**

This pattern describes how to subscribe multiple email addresses to receive notifications from an Amazon Simple Notification Service (Amazon SNS) topic. It uses an AWS Lambda function as a custom resource in an AWS CloudFormation template. The Lambda function is associated with an input parameter that specifies the email endpoints for the SNS topic.

Currently, you can use the AWS CloudFormation template objects `AWS::SNS::Topic` and `AWS::SNS::Subscription` to subscribe single endpoints to SNS topics. To subscribe multiple endpoints, you have to invoke the object multiple times. By using the Lambda function as a custom resource, you can subscribe multiple endpoints through an input parameter. You can use this Lambda function as a custom resource in any AWS CloudFormation template.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- An AWS profile configured in your local environment with an access key and secret key. You can also run this code from AWS Cloud9.
- Permissions for the following:
  - AWS Identity and Access Management (IAM) role and policy
  - AWS Lambda function
  - Amazon Simple Storage Service (Amazon S3) for uploading the Lambda function
  - Amazon SNS topic and policy
  - AWS CloudFormation stacks

**Limitations**

- The code supports Linux and macOS workstations.

**Product versions**

- AWS Command Line Interface (AWS CLI) version 2 or later.

**Architecture**

Target technology stack
• AWS CloudFormation
• Amazon SNS
• AWS Lambda

Tools

AWS CLI version 2

Code

The attachment includes the following files:

• Lambda function: lambda_function.py
• AWS CloudFormation template: template.yaml
• Two parameter files to handle multiple or single email endpoint subscriptions: parameters-multiple-values.json (used as the default) and parameters-one-value.json

To deploy the stack, you can use either parameter file. To specify multiple email endpoints:

```bash
deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION>
```

To specify a single email endpoint:

```bash
deploy.sh -p <YOUR_AWS_PROFILE_NAME> -r <YOUR_AWS_PROFILE_REGION> -f parameters-one-value.json
```

Epics

Option 1 - Deploy an SNS topic with one email subscription

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the email endpoint for SNS topic subscriptions.</td>
<td>Edit the file parameters-one-value.json (attached), and change the value of the pSNSNotificationsEmail parameter to reflect the email address you want to use, such as <a href="mailto:someone@example.com">someone@example.com</a>.</td>

Required tools
Use Serverspec for test-driven development of infrastructure code

Created by Sushant Jagdale (AWS)

| Environment: | PoC or pilot | Technologies: | DevOps; Infrastructure; Hybrid cloud | AWS services: | Amazon EC2; AWS CodeBuild; AWS CodeDeploy |

Summary

This pattern shows you how to use Serverspec to use test-driven development (TDD) when writing infrastructure code on the Amazon Web Services (AWS) Cloud. The pattern also covers automation with AWS CodePipeline. TDD will focus attention on what the infrastructure code must do and sets a clear definition of done. You can use Serverspec to test infrastructure created by tools such as AWS CloudFormation, Terraform by HashiCorp, and Ansible.

Serverspec helps with refactoring infrastructure code. With Serverspec, you can write RSpec tests to check installation of various packages and software, run commands, check for running processes and ports, check file permission settings, and so forth. Serverspec checks whether your servers are configured correctly. You install only Ruby on your servers. You don’t need to install any agent software.

Test-driven infrastructure provides the following benefits:

- Cross-platform testing
- Validation of expectations
- Confidence in your automation
- Infrastructure consistency and stability
- Fail early

You can use this pattern to run Serverspec unit tests for Apache software and check file permission settings during Amazon Machine Image (AMI) creation. An AMI will be created only if all the test cases pass. Serverspec will perform following tests:

- Apache process is running.
- Apache port is running.
- Apache configuration files and directories exist at certain locations, and so forth.
- File permissions are correctly configured.
Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS CodeBuild
- AWS CodeCommit
- AWS CodePipeline
- A virtual private cloud (VPC) with a public subnet
- Installation of AWS Command Line Interface (AWS CLI) and Git

Product versions

- HashiCorp Packer version: 1.6.6
- Ruby version: 2.5.1 and later
- AWS CLI version: 1.18.185

Architecture

Target architecture

1. When you push the code to the CodeCommit repository, an Amazon CloudWatch Events event engages the CodePipeline. In the first stage of the pipeline, the code is fetched from CodeCommit.
2. The second pipeline stage runs CodeBuild, which validates and builds the Packer template.
3. As a part of the Packer build provisioner, Packer installs Apache and Ruby software. Then the provisioner calls a shell script that uses Serverspec to unit test the Apache process, port, files, and directories. The Packer post-processor writes a JavaScript Object Notation (JSON) file with a list of all the artifacts produced by Packer during a run.
4. Finally, an Amazon Elastic Compute Cloud (Amazon EC2) instance is created using the AMI ID produced by Packer.

Tools

- AWS CLI – Amazon Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services using commands in your command line shell.
- Amazon CloudWatch Events – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in Amazon Web Services (AWS) resources.
• **AWS CodeBuild** – AWS CodeBuild is a fully managed build service in the cloud. CodeBuild compiles your source code, runs unit tests, and produces artifacts that are ready to deploy.

• **AWS CodeCommit** – AWS CodeCommit is a version control service hosted by Amazon Web Services. You can use CodeCommit to privately store and manage assets (such as documents, source code, and binary files) in the cloud.

• **AWS CodePipeline** – AWS CodePipeline is a continuous delivery service you can use to model, visualize, and automate the steps required to release your software. You can quickly model and configure the different stages of a software release process.

• **HashiCorp Packer** – HashiCorp Packer is a tool for automating the creation of identical machine images from a single source configuration.

• **Serverspec** – Serverspec runs RSpec tests to check server configuration. Serverspec uses Ruby, and you don't need to install agent software.

**Code**

The code is attached. The code uses the following structure, with three directories and eight files.

```markdown
### amazon-linux_packer-template.json (Packer template)
### buildspec.yaml (CodeBuild .yaml file)
### pipeline.yaml (AWS CloudFormation template to automate CodePipeline)
### rspec_tests (RSpec required files and spec)
#   ### Gem-file
#   ### Rakefile
#   ### spec
#     ### apache_spec.rb
#     ### spec_helper.rb
### scripts
    ### rspec.sh (Installation of Ruby and initiation of RSpec)
```

Additional information

Write RSpec tests

The RSpec test for this pattern is located at `<repository folder>/rspec_tests/spec/apache_spec.rb`.

```ruby
require 'spec_helper'

describe service('httpd') do
  it { should be_enabled }
  it { should be_running }
end

describe port(80) do
  it { should be_listening }
end

describe file('/etc/httpd/conf/httpd.conf') do
  it { should exist }
  it { should be_owned_by 'root' }
  it { should contain 'ServerName www.example.com' }
end

describe file('/etc/httpd/conf/httpd.conf') do
  its(:content) { should match /ServerName www.example.com/ }
end

describe file('/var/www/html/hello.html') do
  it { should exist }
  it { should be_owned_by 'ec2-user' }
end

describe file('/var/log/httpd') do
  it { should be_directory }
end

describe file('/etc/sudoers') do
  it { should be_mode 440 }
end

describe group('root') do
  it { should have_gid 0 }
end
```

You can add your own tests to the `/spec` directory.

Create the pipeline
aws cloudformation create-stack --stack-name myteststack --template-body file://pipeline.yaml --parameters ParameterKey=RepositoryName,ParameterValue=<provide repository-name> ParameterKey=ApplicationName,ParameterValue=<provide application-name> ParameterKey=SecurityGroupId,ParameterValue=<provide SecurityGroupId> ParameterKey=VpcId,ParameterValue=<provide VpcId> ParameterKey=SubnetId,ParameterValue=<provide SubnetId> ParameterKey=Region,ParameterValue=<provide Region> ParameterKey=AccountId,ParameterValue=<provide AccountId> --capabilities CAPABILITY_NAMED_IAM

Parameter details

repository-name – The name of the AWS CodeCommit repository

application-name – The Amazon Resource Name (ARNs) are linked with ApplicationName; provide any name

SecurityGroupId – Any security group ID from your AWS account that has port 80 open

VpcId – The ID of your VPC

SubnetId – The ID of a public subnet in your VPC

Region – The AWS Region where you are running this pattern

Keypair – The Secure Shell (SSH) key name to log in to the EC2 instance

AccountId – Your AWS account ID

You can also create a CodePipeline pipeline by using the AWS Management Console and passing the same parameters that are in the previous command line.

Use third-party Git source repositories in AWS CodePipeline

Created by Kirankumar Chandrashekar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>DevOps</th>
<th>Workload:</th>
<th>Open-source</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS CodeBuild; AWS CodePipeline; AWS Lambda</td>
<td>AWS CodePipeline</td>
<td>Open-source</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to use AWS CodePipeline with third-party Git source repositories.
**AWS CodePipeline** is a continuous delivery service that automates tasks for building, testing, and deploying your software. The service currently supports Git repositories managed by GitHub, AWS CodeCommit, and Atlassian Bitbucket. However, some enterprises use third-party Git repositories that are integrated with their single sign-on (SSO) service and Microsoft Active Directory for authentication. You can use these third-party Git repositories as sources for CodePipeline by creating custom actions and webhooks.

A webhook is an HTTP notification that detects events in another tool, such as a GitHub repository, and connects those external events to a pipeline. When you create a webhook in CodePipeline, the service returns a URL that you can use in your Git repository webhook. If you push code to a specific branch of the Git repository, the Git webhook initiates the CodePipeline webhook through this URL, and sets the source stage of the pipeline to **In Progress**. When the pipeline is in this state, a job worker polls CodePipeline for the custom job, runs the job, and sends a success or failure status to CodePipeline. In this case, because the pipeline is in the source stage, the job worker gets the contents of the Git repository, zips the contents, and uploads it to the Amazon Simple Storage Service (Amazon S3) bucket where artifacts for the pipeline are stored, using the object key provided by the polled job. You can also associate a transition for the custom action with an event in Amazon CloudWatch, and initiate the job worker based on the event. This setup enables you to use third-party Git repositories that the service doesn’t natively support as sources for CodePipeline.

### Prerequisites and limitations

**Prerequisites**

- An active AWS account
- A Git repository that supports webhooks and can connect to a CodePipeline webhook URL through the internet
- AWS Command Line Interface (AWS CLI) installed and configured to work with the AWS account

### Architecture

The pattern involves these steps:

1. The user commits code to a Git repository.
2. The Git webhook is called.
3. The CodePipeline webhook is called.
4. The pipeline is set to **In Progress**, and the source stage is set to the **In Progress** state.
5. The source stage action initiates a CloudWatch Events rule, indicating that it was started.
6. The CloudWatch event initiates a Lambda function.
7. The Lambda function gets the details of the custom action job.
8. The Lambda function initiates AWS CodeBuild and passes it all the job-related information.
9. CodeBuild gets the public SSH key or user credentials for HTTPS Git access from Secrets Manager.
10. CodeBuild clones the Git repository for a specific branch.
11. CodeBuild zips the archive and uploads it to the S3 bucket that serves as the CodePipeline artifact store.
Tools

- **AWS CodePipeline** – AWS CodePipeline is a fully managed continuous delivery service that helps you automate your release pipelines for fast and reliable application and infrastructure updates. CodePipeline automates the build, test, and deployment phases of your release process for each code change, based on the release model you define. This enables you to rapidly and reliably deliver features and updates. You can integrate AWS CodePipeline with third-party services such as GitHub or with your own custom plugin.

- **AWS Lambda** – AWS Lambda lets you run code without provisioning or managing servers. With Lambda, you can run code for virtually any type of application or backend service with no administration necessary. You upload your code and Lambda takes care of everything required to run and scale your code with high availability. You can set up your code to automatically initiate from other AWS services or call it directly from any web or mobile app.

- **AWS CodeBuild** – AWS CodeBuild is a fully managed continuous integration service that compiles source code, runs tests, and produces software packages that are ready to deploy. With CodeBuild, you don’t need to provision, manage, and scale your own build servers. CodeBuild scales continuously and processes multiple builds concurrently, so your builds are not left waiting in a queue. You can get started quickly by using prepackaged build environments, or you can create custom build environments that use your own build tools.

- **AWS Secrets Manager** – AWS Secrets Manager helps you protect secrets needed to access your applications, services, and IT resources. The service enables you to rotate, manage, and retrieve database credentials, API keys, and other secrets throughout their lifecycle. Users and applications retrieve secrets by calling Secrets Manager APIs, without having to hardcode sensitive information in plain text. Secrets Manager offers secret rotation with built-in integration for Amazon Relational Database Service (Amazon RDS), Amazon Redshift, and Amazon DocumentDB. The service can be extended to support other types of secrets, including API keys and OAuth tokens. In addition, Secrets Manager lets you control access to secrets by using fine-grained permissions, and audit secret rotation centrally for resources in the AWS Cloud, third-party services, and on-premises environments.

- **Amazon CloudWatch** – Amazon CloudWatch is a monitoring and observation service built for DevOps engineers, developers, site reliability engineers (SREs), and IT managers. CloudWatch provides you with data and actionable insights to monitor your applications, respond to systemwide performance changes, optimize resource utilization, and get a unified view of operational health. CloudWatch collects monitoring and operational data in the form of logs, metrics, and events, providing you with...
a unified view of AWS resources, applications, and services that run on AWS and on-premises servers. You can use CloudWatch to detect anomalous behavior in your environments, set alarms, visualize logs and metrics side by side, take automated actions, troubleshoot issues, and discover insights to keep your applications running smoothly.

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service that lets you store and protect any amount of data for a range of use cases, such as websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. Amazon S3 provides easy-to-use management features to help you organize your data and configure finely tuned access controls to meet your specific business, organizational, and compliance requirements.

## Epics

### Create a custom action in CodePipeline

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a custom action using AWS CLI or AWS CloudFormation.</td>
<td>This step involves creating a custom source action that can be used in the source stage of a pipeline in your AWS account in a particular region. You must use AWS CLI or AWS CloudFormation (not the console) to create the custom source action. For more information about the commands and steps described in this and other epics, see the &quot;Related resources&quot; section at the end of this pattern. In AWS CLI, use the <code>create-custom-action-type</code> command. Use <code>--configuration-properties</code> to provide all the parameters required for the job worker to process when it polls CodePipeline for a job. Make sure to note the values provided to the <code>--provider</code> and <code>--action-version</code> options, so that you can use the same values when creating the pipeline with this custom source stage. You can also create the custom source action in AWS CloudFormation by using the resource type <code>AWS::CodePipeline::CustomActionType</code>.</td>

<tr>
<td>Create a secret in AWS Secrets Manager.</td>
<td>Copy the contents of the private key from the SSH key pair and create a secret in AWS Secrets Manager. This secret is used for authentication when accessing the Git repository.</td>
<td>General AWS</td>
</tr>
<tr>
<td>Add the public key to the Git repository.</td>
<td>Add the public key from the SSH key pair to the Git repository account settings, for authentication against the private key.</td>
<td>Systems/DevOps engineer</td>
</tr>
</tbody>
</table>

## Create a pipeline and webhook

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a pipeline that includes the custom source action.</td>
<td>Create a pipeline in CodePipeline. When you configure the source stage, choose the custom source action that you created previously. You can do this in the AWS CodePipeline console or in AWS CLI. CodePipeline prompts you for the configuration properties that you set on the custom action. This information is required for the job worker to process the job for the custom action. Follow the wizard and create the next stage for the pipeline.</td>
<td>General AWS</td>
</tr>
<tr>
<td>Create a CodePipeline webhook.</td>
<td>Create a webhook for the pipeline you created with the custom source action. You must use AWS CLI or AWS CloudFormation (not the console) to create the webhook. In AWS CLI, run the put-webhook command and provide the appropriate values for the webhook options. Make a note of the webhook URL that the command returns. If you're using AWS</td>
<td>General AWS</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>CloudFormation to create the webhook, use the resource type AWS::CodePipeline::Webhook. Make sure to output the webhook URL from the created resource, and make a note of it.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Create a Lambda function and CodeBuild project.</td>
<td>In this step, you use Lambda and CodeBuild to create a job worker that will poll CodePipeline for job requests for the custom action, run the job, and return the status result to CodePipeline. Create a Lambda function that is initiated by an Amazon CloudWatch Events rule when the custom source action stage of the pipeline transitions to “In Progress.” When the Lambda function is initiated, it should get the custom action job details by polling for jobs. You can use the PollForJobs API to return this information. After the polled job information is obtained, the Lambda function should return an acknowledgment, and then process the information with the data it obtains from the configuration properties for the custom action. When the worker is ready to talk to the Git repository, you might initiate a CodeBuild project, because it's convenient to handle Git tasks by using the SSH client.</td>
<td>General AWS, code developer</td>
</tr>
<tr>
<td>Create an event in CloudWatch</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Create a CloudWatch Events rule.</td>
<td>Create a CloudWatch Events rule that initiates the Lambda function as a target whenever the pipeline's custom action stage transitions to &quot;In Progress.&quot;</td>
<td>General AWS</td>
</tr>
</tbody>
</table>

### AWS services:
Amazon AppStream 2.0; AWS CloudFormation

**Summary**

This pattern provides code samples and steps to automate the creation of Amazon AppStream 2.0 resources in the Amazon Web Services (AWS) Cloud by using an AWS CloudFormation template. The pattern shows you how to use an AWS CloudFormation stack to automate the creation of your AppStream 2.0 application resources, including an image builder, image, fleet instance, and stack. You can stream your AppStream 2.0 application to end users on an HTML5-compliant browser by using either the desktop or application delivery mode.

**Prerequisites and limitations**

#### Prerequisites

- An active AWS account
- An acceptance of AppStream 2.0 terms and conditions
- Basic knowledge of AppStream resources, such as stacks, fleets, and image builders

#### Limitations

- You can’t modify the AWS Identity and Access Management (IAM) role associated with an AppStream 2.0 instance after that instance is created.
- You can’t modify properties (such as the subnet or security group) on the AppStream 2.0 image builder instance after that image builder is created.
Architecture

The following diagram shows you how to automate the creation of AppStream 2.0 resources by using an AWS CloudFormation template.

The diagram shows the following workflow:

1. You create an AWS CloudFormation template based on the YAML code in the Additional information section of this pattern.
2. The AWS CloudFormation template creates an AWS CloudFormation test stack.
   a. (Optional) You create an image builder instance by using AppStream 2.0.
   b. (Optional) You create a Windows image by using your custom software.
3. The AWS CloudFormation stack creates an AppStream 2.0 fleet instance and stack.
4. You deploy your AppStream 2.0 resources to end users on an HTML5-compliant browser.

Technology stack

• Amazon AppStream 2.0
• AWS CloudFormation

Tools

• **Amazon AppStream 2.0** – Amazon AppStream 2.0 is a fully managed application streaming service that provides you with instant access to your desktop applications from anywhere. AppStream 2.0 manages the AWS resources required to host and run your applications, scales automatically, and provides access to your users on demand.

• **AWS CloudFormation** – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.
### Epics

(Optional) Create an AppStream 2.0 image

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install custom software and create an image.</td>
<td>1. Install the AppStream 2.0 application that you plan to deploy to your users. &lt;br&gt;2. Use the Photon create image agent or a PowerShell script to create a new Windows image for your custom software.</td>
<td>AWS DevOps, Cloud architect</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Consider using the Windows AppLocker feature to further lock down the image.</td>
<td></td>
</tr>
</tbody>
</table>

Deploy the AWS CloudFormation template

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Update the AWS CloudFormation template.</td>
<td>1. Save the code in the Additional information section of this pattern as a YAML file. &lt;br&gt;2. Update the YAML file with the required values for the parameters in your environment.</td>
<td>AWS systems administrator, Cloud administrator, Cloud architect, General AWS, AWS administrator</td>
</tr>
<tr>
<td>Create an AWS CloudFormation stack using the template.</td>
<td>1. Sign in to the AWS Management Console and open the AWS CloudFormation console. &lt;br&gt;2. On the navigation pane, choose Stacks. &lt;br&gt;3. Choose Create stack and then choose With new resources (standard). &lt;br&gt;4. In the Prerequisite – Prepare template section, choose Template is ready. &lt;br&gt;5. In the Specify template section, choose Upload a template file. &lt;br&gt;6. Choose Choose file and then choose your updated AWS CloudFormation template.</td>
<td>App owner, AWS systems administrator, Windows Engineer</td>
</tr>
</tbody>
</table>
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>7. Complete the rest of the steps in the wizard to create your stack.</td>
<td></td>
</tr>
</tbody>
</table>

### Additional information

The following code is an example of an AWS CloudFormation template that allows you to automatically create AppStream 2.0 resources.

```yaml
AWSTemplateFormatVersion: '2010-09-09'
Parameters:
  SubnetIds:
    Type: 'List<AWS::EC2::Subnet::Id>'
  testSecurityGroup:
    Type: 'AWS::EC2::SecurityGroup::Id'
  ImageName:
    Type: String
Resources:
  AppStreamFleet:
    Type: 'AWS::AppStream::Fleet'
    Properties:
      ComputeCapacity:
        DesiredInstances: 5
      InstanceType: stream.standard.medium
      Name: appstream-test-fleet
      DisconnectTimeoutInSeconds: 1200
      FleetType: ON_DEMAND
      IdleDisconnectTimeoutInSeconds: 1200
      ImageName: !Ref ImageName
      MaxUserDurationInSeconds: 345600
      VpcConfig:
        SecurityGroupIds:
          - !Ref testSecurityGroup
        SubnetIds: !Ref SubnetIds
  AppStreamStack:
    Type: 'AWS::AppStream::Stack'
    Properties:
      Description: AppStream stack for test
      DisplayName: AppStream test Stack
      Name: appstream-test-stack
      StorageConnectors:
```

Configure a data center extension to VMware Cloud on AWS using Hybrid Linked Mode

*Created by Deepak Kumar (AWS)*

**Environment:** Production  
**Technologies:** Hybrid cloud; Infrastructure; Migration  
**Workload:** All other workloads  
**AWS services:** AWS Direct Connect

**Summary**

This pattern describes how you can use Hybrid Linked Mode to view and manage inventories in an on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC) by using a single VMware vSphere Client interface.

By configuring Hybrid Linked Mode, you can migrate your on-premises virtual machines (VMs) and applications to the cloud SDDC. Your IT teams can then manage your cloud-based resources with familiar VMware tools and without requiring any new tools. You can also ensure consistent operations and simplified administration by using the VMware Cloud Gateway Appliance.

This pattern provides two options for configuring Hybrid Linked Mode, but you can only use one option at a time. The first option installs the Cloud Gateway Appliance and uses it to link from the on-premises vCenter Server to the cloud SDDC. The second option configures Hybrid Linked Mode from the cloud SDDC.

**Prerequisites and limitations**

**Prerequisites (both options)**

- An existing on-premises data center and a cloud SDDC.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN, or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn't exceed 100ms.
• Cloud administrators with access to your on-premises environment.
• The vCenter Server’s fully qualified domain name (FQDN) must resolve to a private IP address.

**Prerequisites for Option 1**

• The on-premises environment should run on vSphere 6.5.0d or later.
• The Cloud Gateway Appliance and vCenter Server can communicate over AWS Direct Connect, a VPN, or both.
• The Cloud Gateway Appliance meets hardware requirements.
• Firewall ports are open.

**Prerequisites for Option 2**

• The on-premises vCenter Server runs on vSphere 6.0 Update 3 or later, or on vSphere 6.5.0d or later.
• Login credentials are available for the on-premises vSphere single sign-on (SSO) domain.
• Users in the on-premises environment have read-only access to the base distinguished name (Base DN).
• The on-premises Domain Name System (DNS) server is configured for VMware Management Gateway.
• Implement network connectivity tests using the VMware Connectivity Validator.
• Firewall ports are open.

**Limitations**

• Hybrid Linked Mode can only connect one on-premises vCenter Server Enhanced Linked Mode domain.
• Hybrid Linked Mode only supports on-premises vCenter Server running version 6.7 or later.

**Architecture**

The following diagram shows both options for configuring Hybrid Linked Mode.

![Diagram of Hybrid Linked Mode architecture](image-url)
Hybrid Linked Mode supports migrating workloads between an on-premises data center and a cloud SDDC by using either a cold migration or a live migration with VMware vSphere vMotion. Factors that must be considered when choosing the migration method include the virtual switch type and version, the connection type to the cloud SDDC, and the virtual hardware version.

A cold migration is appropriate for VMs that experience downtime. You can shut down the VMs, migrate them, and then turn them back on. The migration time is faster because there is no need to copy active memory. We recommend using a cold migration for applications that accept downtime (for example, tier 3 applications or development and testing workloads). If your VMs cannot experience downtime, you should consider a live migration using vMotion for your mission-critical applications.

The following diagram provides an overview of the different workload migration types using Hybrid Linked Mode.

**Tools**

- **VMware Cloud on AWS** is an integrated cloud offering jointly developed by AWS and VMware.
- **VMware Cloud Gateway Appliance** enables a number of hybrid cloud use cases where on-premises resources are connected to cloud resources.
- **VMware vSphere** is VMware's virtualization platform, which transforms data centers into aggregated computing infrastructures that include CPU, storage, and networking resources.

**Epics**

**Option 1 - Use Hybrid Linked Mode with the Cloud Gateway Appliance**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure the Cloud Gateway Appliance. | 1. Log in to the VMware Cloud on AWS console and download the Cloud Gateway Appliance.  
  2. Install the Cloud Gateway Appliance in your on-premises environment with the following two steps:  
  - Choose **Start to configure** and then deploy the Cloud Gateway Appliance. | Cloud administrator      |
### Task

<table>

Configure VMware vRealize Automation to provision VMs on VMware Cloud on AWS

Created by Deepak Kumar (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies: Hybrid cloud; Infrastructure</th>
<th>Workload: All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS Direct Connect; AWS Site-to-Site VPN</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

vRealize Automation is automation software that you can use to request and manage IT resources. By choosing to configure vRealize Automation with VMware Cloud on AWS, you can automate the delivery of virtual machines (VMs), applications, and IT services across multiple data centers and cloud environments.

Your IT teams can then create catalog items to configure service provisioning and operational capabilities that your users can request and use with their existing vRealize Automation tools. You can also improve your IT agility and efficiency by integrating VMware Cloud on AWS with vRealize Automation Cloud Assembly.

This pattern describes how to configure VMware vRealize Automation to automatically build VMs or application capabilities on VMware Cloud on AWS.

Prerequisites and limitations

Prerequisites

- An existing on-premises data center and a VMware Cloud on AWS software-defined data center (SDDC). For more information about the cloud SDCC, see About Software-Defined Data Centers in the VMware documentation.
- An existing connection between the on-premises data center and the cloud SDDC, using AWS Direct Connect, a VPN (route or policy-based), or both.
- The on-premises data center and cloud SDDC are synchronized with network time protocol (NTP) or another authoritative time source.
- The maximum latency of a round-trip time between the on-premises data center and the cloud SDDC doesn’t exceed 100ms.
- The vCenter Server’s fully qualified domain name (FQDN) must resolve to a private IP address.
- Cloud SDDC users with access to your on-premises environment.
- Organization owner access in the vRealize Automation Cloud Assembly service role.
- End users with permission in vRealize Automation Service Broker to consume service.
- The on-premises data center’s Classless Inter-Domain Routing (CIDR) range must be open for the generating of API tokens from the VMware Cloud on AWS console. The following list provides the minimum roles required to generate API tokens:
  - Organization member
• Organization owner
• Service Roles - VMware Cloud on AWS
• Administrator
• NSX Cloud Administrator
• NSX Cloud Auditor

For more information about this, see Connectivity Options for VMware Cloud on AWS SDDCs from the AWS Partner Network Blog.

Limitations

• You can only configure 20 VMware Cloud accounts with public endpoints in one vRealize Automation. For more information about this, see Scalability and concurrency maximums in the VMware documentation.

Product versions

• vRealize Automation version 8.x or later
• VMware vRealize Identity Manager version 3.x or later
• VMware vRealize Suite Lifecycle Manager version 8.x or later

Architecture

The following diagram shows the vRealize Automation services that can use infrastructure from both on-premises and VMware Cloud on AWS environments.

VMware Cloud Assembly components

VMware Cloud Assembly is a core component of vRealize Automation and you can use it to deploy and provision VMs and compute resources. The following table describes VMware Cloud Assembly components that must be configured for provisioning VMs on VMware Cloud on AWS.

<table>
<thead>
<tr>
<th>Components</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Account</td>
<td>The Cloud Account provides connection details (for example, server name, user name and password, access key, and API token). VMware Cloud Assembly uses the Cloud Account to collect an inventory of your resources.</td>
</tr>
</tbody>
</table>
Cloud zones

Cloud zones identify resource boundaries in the Cloud Account (for example, AWS Regions and the cloud SDDC). Cloud zones associate compute resources with the Cloud Assembly project.

Projects

A project is a logical entity that consists of users and resources such as cloud zones. It also consists of resource quotas and VM naming policies that are used when building the VM.

Flavor mappings

Flavor mapping provides information about the VM's capacity (for example, number of CPUs and amount of memory) that are used in the Cloud Template.

Image mappings

Image mapping maps the VMware vSphere VM template and Amazon Web Services (AWS) image that are used in the Cloud Template. For more information about this, see Learn more about image mappings in vRealize Automation in the VMware documentation.

Network profile

Network profile controls the placement decision to choose a network during VM provisioning.

Storage profile

Storage profile controls the placement decision to choose storage during VM provisioning.

Cloud Templates

VMware Cloud Templates are an important component of vRealize Automation because they define cloud infrastructure provisioning and orchestration. The Cloud Templates are specifications for the resources and include the resource type, resource properties, and input to be collected from users.

Tools

- VMware vRealize Automation – vRealize Automation is an infrastructure automation platform with event-driven state management and compliance. It is designed to help organizations control and secure self-service clouds, multi-cloud automation with governance, and DevOps-based infrastructure delivery.
- VMware Cloud on AWS – VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.

Epics

Generate the API tokens

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Generate the API tokens from your VMware Cloud on AWS account.</td>
<td>1. Sign in to the VMware Cloud Console.</td>
<td>Cloud administrator</td>
</tr>
<tr>

<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>2.</td>
<td>On the VMware Cloud Services toolbar, choose <strong>My Account</strong> and then choose <strong>API Token</strong>.</td>
<td></td>
</tr>
<tr>
<td>3.</td>
<td>Enter a name for your API token, provide the required lifespan, and define the scopes for the token.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>Choose the <strong>Open ID</strong> check box and then choose <strong>Generate</strong>.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>Record the API token's credentials.</td>
<td></td>
</tr>
</tbody>
</table>

For more information about this, see [How do I generate API tokens in the VMware documentation](#).

### Install vRealize Automation in your on-premises data center

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Download the required software.</td>
<td>Download the VMware vRealize Suite ISO file from the My VMware Portal. This package contains vRealize Suite Lifecycle Manager, VMware Identity Manager, and vRealize Automation.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>

| Install the software. | Install the software and connect to your cloud SDCC by following the instructions from [Installing vRealize Suite Lifecycle Manager with Easy Installer for vRealize Automation and VMware Identity Manager](#) in the VMware documentation. | Cloud administrator, Cloud architect |

**Important:** Make sure that the following are available for your installation:

- The on-premises VMware vCenter Server setup and login credentials
- The network details for the vRealize Automation IP and subnet
- The vRealize Automation license key
### Connect VMware Cloud on AWS with VMware Cloud Assembly

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure your Cloud Accounts. | 1. On the VMware Cloud Console, open the **Infrastructure** tab, choose **Manage – Cloud Accounts**, and then choose **Add Cloud Accounts**.  
2. Choose **VMware Cloud on AWS** as the type.  
3. Paste the API token information that you recorded earlier. This populates all available cloud SDDCs in your VMware Cloud on AWS organization.  
4. Choose the required cloud SDCC and then provide the vCenter user name and password for the SDDC.  
5. After you are successfully authenticated, you can view the integrated VMware Cloud on AWS account with an **OK** status.  
   
   For more information about this, see [Create a VMware Cloud on AWS cloud account in vRealize Automation](https://docs.vmware.com/en/vsphere/7.0/automate/topic/via-1000565.html) in the VMware documentation. | Cloud architect, Cloud administrator |
| Configure the project.      | 1. On the VMware Cloud Console, open the **Projects** tab and then choose **New project**.  
2. Enter the name of your project.  
3. Open the **Cloud Zones** tab and choose **default VMware Cloud on AWS Cloud Account**. | Cloud administrator |
| Configure cloud zone.       | 1. On the VMware Cloud Console, open **Cloud Zones** and choose the cloud zone for your SDDC data center.  
2. By default, `cloudadmin@vmc.local` (this is the default local user ID for the cloud SDDC's vCenter) only has access to | Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
|      | provision in the Compute-ResourcePool.  
3. Open the Compute tab under Cloud Zones and then choose Compute-ResourcePool. | Cloud administrator |
| Configure flavor mapping. | 1. Open the Flavor Mappings tab and create a new flavor mapping.  
2. Enter the flavor name, choose the VMware Cloud on AWS account, and then provide the number of vCPUs and amount of memory. | Cloud administrator |
| Configure image mapping. | 1. Open Image Mappings and create a new image mapping.  
2. Enter the image name.  
3. Choose the VMware Cloud on AWS account and provide the Cloud Account templates that are required. | Cloud administrator |
| Configure network profile. | 1. Open Network Profile and create a new network profile.  
2. Enter the network profile name.  
3. Open the Network tab and choose the existing network that you want to use for provisioning. | Cloud administrator |
| Configure storage profile. | 1. Open Storage Profile and choose New Storage Profile.  
2. Enter the storage profile's name.  
3. In the Policies section, create a new policy.  
4. Choose Workload Datastore. By default cloudadmin@vmc.local only has access to provision in the workload's datastore. | Cloud administrator |
Create the Cloud Template.

1. Open the **Design** tab, choose **Cloud Templates**, and then choose **New From** and **Blank Canvas**.
2. Provide the name and description of the Cloud Template.
3. Choose the project that you created earlier.
4. From the Cloud Template resources design page, drag components into the blank canvas according to your requirements.
5. Choose **Test** to test the template and fix any issues.
6. Choose **Deployment** and provide the deployment name to deploy the VMs.

For more information about this, see Create a basic cloud template in the VMware documentation.

**Skills required**

Cloud administrator

### Deploy a VMware SDDC on AWS by using VMware Cloud on AWS

*Created by Deepak Kumar (AWS)*

**Environment:** Production  
**Technologies:** Hybrid cloud; Infrastructure  
**Workload:** All other workloads  
**AWS services:** Amazon VPC

### Summary

This pattern describes how to create a VMware-based Software-Defined Data Center (SDDC) that's hosted in the Amazon Web Services (AWS) Cloud. You can deploy an SDDC to migrate your VMware
vSphere-based workloads to the AWS Cloud and take advantage of AWS services while you use your existing VMware tools and skills. You can use this SDDC to run your production applications across VMware vSphere-based private, public, and hybrid cloud environments, with optimized access to AWS services. For example, you can use the SDDC as a secondary site for disaster recovery or to extend your data center to different geographical locations.

VMware Cloud on AWS is a pay-as-you-go (on-demand) service that enables enterprises of all sizes to run workloads across VMware vSphere-based cloud environments by using a wide range of AWS services. You can start with a minimum of 2 hosts per SDDC cluster and scale up to 16 hosts per cluster in your production environment. For more information, see the VMware Cloud on AWS website. To learn more about SDDCs, see About Software-Defined Data Centers in the VMware documentation.

Prerequisites and limitations

Prerequisites

- Sign up for a MyVMware account and fill out all fields.
- Sign up for an AWS account. For instructions, see the AWS Knowledge Center.
- Sign up for an MyVMware Cloud on AWS account. An activation link is sent to the email address you specify when you sign up.

Limitations

- See VMware Cloud on AWS configuration limits pages on the VMware website.

Product versions

- See VMware Cloud on AWS Release Notes in the VMware documentation.

Architecture

Target technology stack

The following diagram shows the VMware software stack, including vSphere, vCenter, vSAN, and NSX-T, running on AWS bare-metal dedicated infrastructure. You can manage your VMware-based resources and tools on AWS with seamless integration with other AWS services such as Amazon Elastic Compute Cloud (Amazon EC2), Amazon Simple Storage Service (Amazon S3), Amazon Redshift, AWS Direct Connect, Amazon Relational Database Service (Amazon RDS), and Amazon DynamoDB.
The basic entity of VMware Cloud on AWS is an SDDC, which includes the following components:

- **Compute**: The compute component is the lowest layer of the VMware Cloud on AWS SDDC. VMware Cloud on AWS runs on Amazon EC2 bare metal instance types. These include `i3.metal` and `i3en.metal` and provide direct access to physical resources such as processors and memory.

- **Storage**: SDDC clusters support VMware vSAN with an all-flash configuration for storage using non-volatile memory express (NVMe) flash storage, which provides fast and high-performance storage.

- **Networking**: Networking capabilities and policies are managed by using VMware NSX-T in the SDDC cluster. Multi-tier virtual networks are created in the SDDC cluster to separate network resources from physical equipment. This enables VMware Cloud on AWS users to create logical, software-defined networks.

**Tools**

- **VMware Cloud on AWS** – VMware Cloud on AWS is an integrated cloud offering jointly developed by AWS and VMware.

**Epics**

Create a VPC and subnet in your AWS account

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign in to your AWS account.</td>
<td>Sign in to your AWS account with an IAM user that has administrator permissions.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>
| Create a new VPC.         | In this step, you define a virtual private cloud (VPC) that links to the SDDC. If you already have a VPC you want to use for the SDDC, skip this step.  
<pre><code>                       | 1. Choose the AWS Region to deploy your VMware Cloud on AWS SDDC. | Cloud administrator      |
</code></pre>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>2. Open the Amazon VPC console at <a href="https://console.aws.amazon.com/vpc/">https://console.aws.amazon.com/vpc/</a>.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. In the navigation pane, choose Your VPCs.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. Choose Create VPC.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. Specify VPC settings such as the VPC name tag, IPv4 CIDR block, Tenancy (keep as Default), and then choose Create VPC.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>6. When the VPC has been created, choose Close.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information, see [Create and configure your VPC](https://docs.aws.amazon.com/vpc/latest/userguide/vpc-create-grow.html) in the AWS documentation.

Create a private subnet. You will now create a private subnet for the elastic network interface (ENI) for each Availability Zone. We recommend that you use a subnet without an internet gateway attached.

1. Open the Amazon VPC console at [https://console.aws.amazon.com/vpc/](https://console.aws.amazon.com/vpc/).
2. In the navigation pane, choose Subnets.
3. Choose Create Subnet.
4. On the Create Subnet page, choose the VPC that you created earlier.
5. Complete the settings for the subnet, including a subnet name, Availability Zone, and IPv4 CIDR block.
6. Choose Create Subnet.

Repeat these steps to create subnets for each Availability Zone in the Region.
# Activate VMware Cloud on AWS

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate the service.</td>
<td>When you sign up for a MyVMware account, VMware sends you a welcome email and activation link to the email address you specified. 1. Open the <strong>Activate Service</strong> link from the welcome email in your browser. 2. Log in with MyVMware credentials. 3. Review and accept the terms and conditions for the use of services. 4. Complete the account activation process. You will be redirected to the VMware Cloud on AWS console. (Note: VMware Cloud on AWS accounts are based on an organization, which represents a group or line of business subscribed to the account. This organization has no relationship to AWS Organizations.) 5. On the <strong>Select or Create Organization</strong> page, create an organization that is linked to the MyVMware account. 6. Enter the <strong>Organization Name</strong> and <strong>Address</strong> for logical distinction. 7. Select <strong>Create Organization</strong> to complete the process. For more information about this process, see <a href="https://aws.amazon.com">SDDC Deployment and Best Practices Guide on AWS</a> in the AWS documentation.</td>
<td>Cloud administrator</td>
</tr>
<tr>
<td>Assign IAM roles.</td>
<td>When the organization has been created, assign privileged access to specific users to access the Cloud Services and SDDC console, SDDC, and NSX components. For instructions, see <a href="https://vmware.com">Assign a VMC Service Role to an Organization Member</a> in the VMware documentation.</td>
<td>Cloud administrator</td>
</tr>
</tbody>
</table>
### Deploy an SDDC

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy an SDDC in your VMware Cloud on AWS account. | 1. Log in to the VMC console at [https://vmc.vmware.com](https://vmc.vmware.com).  
2. Choose **VMware Cloud on AWS Service** from the available services.  
3. Choose **Create SDDC**.  
4. Enter SDDC properties such as **AWS Region**, **Deployment** (Single Host, Multi-Host, or Stretched Cluster), **Host Type**, **SDDC Name**, **Number of Hosts**, **Host Capacity**, and **Total Capacity**, and then choose **Next**.  
5. Connect to your AWS account, and then choose **Next**.  
6. Select your previously configured VPC and subnet, and then choose **Next**.  
7. Enter the management subnet CIDR block for the SDDC, and then choose **NEXT**. For more information, see [Selecting IP Subnets and Connectivity for your SDDC](https://vmware-cloud-blog.com).  
8. Select the two check boxes to acknowledge that you take responsibility for the costs for deploying an SDDC, and then choose **Deploy SDDC**.  
   You’ll be charged when you choose **Deploy SDDC**. You won’t be able to pause or cancel the deployment process, which takes some time to complete. | Cloud administrator, Cloud architect |
Migrate VMs to VMware Cloud on AWS by using HCX OS Assisted Migration

**Created by Deepak Kumar (AWS)**

**Environment:** PoC or pilot  
**Source:** Non-vSphere environment  
**Target:** VMware Cloud on AWS SDDC

**R Type:** Relocate  
**Workload:** All other workloads  
**Technologies:** Hybrid cloud; Migration

**Summary**

This pattern describes how to migrate a virtual machine (VM) from a non-vSphere environment to VMware Cloud on Amazon Web Services (AWS) by using OS Assisted Migration (OSAM).

OSAM is part of VMware Hybrid Cloud Extension (HCX), which is included with VMware Cloud on AWS. You can use OSAM to migrate a non-vSphere environment such as VMware KVM or Hyper-V to VMware Cloud on AWS. OSAM uses Sentinel software, which you install on a Windows or Linux guest VM to assist in replicating the VM from your on-premises environment to a Software-Defined Data Center (SDDC) on VMware Cloud on AWS.

This pattern explains how to enable OSAM, install Sentinel software on a Windows VM, connect and register with an HCX Sentinel Gateway (SGW) appliance at the source site, and establish a forwarding connection with an HCX Sentinel Data Receiver (SDR) appliance at the destination site to initiate migration.

For more information about OSAM, see the [VMware documentation](https://www.vmware.com/).

**Prerequisites and limitations**

**Prerequisites**

- Install HCX in your source and target environments. For HCX prerequisites, see [Migrate VMware SDDC to VMware Cloud on AWS using VMware HCX](https://aws.amazon.com/).

---

**Related resources**

- [Deploying and Managing a Software-Defined Data Center](https://www.vmware.com/) (VMware documentation)
- [VMware Cloud on AWS features](https://aws.amazon.com/vmware/)
- [Accelerate Cloud Migration and Modernization with VMware Cloud on AWS](https://aws.amazon.com/vmware/)(video)
For OSAM prerequisites, see the installation checklist in the VMware documentation.

For OSAM port information, see VMware HCX port requirements on the VMware Ports and Protocols website.

**Limitations**

- VMware HCX 4.2.0 Configuration Limits
- Considerations for OSAM Deployment
- Supported Guest Operating Systems
- Guest Operating System Considerations

**Product versions**

- VMware HCX 4.2.0
- VMware SDDC 1.12

**Architecture**

The following diagram shows how HCX OSAM works with the Sentinel software to replicate non-vSphere VMs from your on-premises environment to VMware Cloud on AWS.

OSAM consists of three components:

- The Sentinel Gateway (SGW) appliance, which is used to connect and forward workloads and applications in the source VMware-based environment
- The Sentinel Data Receiver (SDR), which is used in the destination VMware Cloud on AWS environment to receive migrated workloads from the source
- Sentinel software, which must be installed on each guest VM that you want to migrate
OSAM uses the Sentinel software that is installed on Windows or Linux guest VMs to assist in replicating a VM from on premises to a VMware SDDC. The Sentinel software that you install on guest VMs collects the system configurations from the guest VM and assists with the data replication. This information is also used to create the inventory of guest VMs for migration and helps prepare the disks on the replica VM for replication and migration purposes.

**Tools**

- VMware HCX 4.2.0
- VMware Cloud on AWS SDDC

**Epics**

**Configure HCX**

<table>
<thead>

<tr>
<td>Deploy HCX Cloud and HCX Connector.</td>
<td>Follow the instructions in HCX Connector and HCX Cloud Installations in the VMware documentation.</td>
<td>Cloud administrator, Systems administrator</td>
</tr>
</tbody>
</table>

**Configure OSAM and migrate VMs**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Install HCX Sentinel. | To install Sentinel on Linux:  
1. In the vCenter Server for the HCX Connector, choose Interconnect, Multi-Site Service Mesh, Sentinel Management.  
2. Choose Download Linux Bundle.  
3. Install the Sentinel agent on a Linux machine.  
For more information, see Downloading and Installing HCX Sentinel Agent software in the VMware documentation. | Cloud administrator |
| Migrate VMs.  | To migrate your VMs in groups (called mobility groups), follow these steps:  
1. In the vSphere Client, from the HCX plug-in, choose Services, Migration.  
2. Choose Migrate. | Cloud administrator |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.</td>
<td>Choose <strong>Non vSphere Inventory, Remote connections</strong>. This will show the list VMs that you installed HCX Sentinel on.</td>
<td></td>
</tr>
<tr>
<td>4.</td>
<td>For <strong>Group name</strong>, enter the name of the mobility group you want to create for the VMs.</td>
<td></td>
</tr>
<tr>
<td>5.</td>
<td>Choose the VMs you want to migrate, and then choose <strong>Add</strong> to add them to the mobility group.</td>
<td></td>
</tr>
<tr>
<td>6.</td>
<td>For each VM: a. Select the destination compute container. b. Select the destination storage. c. Select the migration profile. d. Select the destination folder.</td>
<td></td>
</tr>
<tr>
<td>7.</td>
<td>To start the migration process, choose <strong>Go</strong>.</td>
<td></td>
</tr>
</tbody>
</table>

HCX validates your VM selections before migration starts.

For more information, see *Migrating Virtual Machines with Mobility Groups* and *Monitoring and Estimating Migration with Mobility Groups* in the VMware documentation.

Centralize DNS resolution by using AWS Managed Microsoft AD and on-premises Microsoft Active Directory

 Created by Brian Westmoreland (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Infrastructure; Networking</th>
<th>Workload:</th>
<th>Microsoft</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS Managed Microsoft AD; Amazon Route 53; AWS RAM</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides guidance for centralizing Domain Name System (DNS) resolution within an AWS multi-account environment by using AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD). In this pattern the AWS DNS namespace is a subdomain of the on-premises DNS namespace. This pattern also provides guidance on how to configure the on-premises DNS servers to forward queries to AWS when the on-premises DNS solution uses Microsoft Active Directory.

Prerequisites and limitations

Prerequisites

- An AWS multi-account environment set up by using AWS Organizations.
- Network connectivity established between AWS accounts.
- Network connectivity established between AWS and the on-premises environment (by using AWS Direct Connect or any type of VPN connection).
• AWS Command Line Interface (AWS CLI) configured on a local workstation.
• AWS Resource Access Manager (AWS RAM) used to share Amazon Route 53 rules between accounts. Therefore, sharing must be enabled within the AWS Organizations environment, as described in the Epics section.

Limitations
• AWS Managed Microsoft AD Standard Edition has a limit of 5 shares.
• AWS Managed Microsoft AD Enterprise Edition has a limit of 125 shares.
• This solution in this pattern is limited to AWS Regions that support sharing through AWS RAM.

Product versions

Architecture

Target architecture

In this design, AWS Managed Microsoft AD is installed in the shared services AWS account. Although this is not a requirement, this pattern assumes this configuration. If you configure AWS Managed Microsoft AD in a different AWS account, you might have to modify the steps in the Epics section accordingly.

This design uses Route 53 Resolvers to support name resolution through the use of Route 53 rules. If the on-premises DNS solution uses Microsoft DNS, creating a conditional forwarding rule for the AWS namespace (aws.company.com), which is a subdomain of the company DNS namespace (company.com), is not straightforward. If you try to create a traditional conditional forwarder, it will result in an error. This is because Microsoft Active Directory is already considered authoritative for any subdomain of company.com. To get around this error, you must first create a delegation for aws.company.com to delegate authority of that namespace. You can then create the conditional forwarder.
The virtual private cloud (VPC) for each spoke account can have its own unique DNS namespace based on the root AWS namespace. In this design, each spoke account appends an abbreviation of the account name to the base AWS namespace. After the private hosted zones in the spoke account have been created, the zones are associated with the VPC in the spoke account as well as with the VPC in the central AWS network account. This enables the central AWS network account to answer DNS queries related to the spoke accounts.

**Automation and scale**

This design makes use of Route 53 Resolver endpoints to scale DNS queries between AWS and your on-premises environment. Each Route 53 Resolver endpoint comprises multiple elastic network interfaces (spread across multiple Availability Zones), and each network interface can handle up to 10,000 queries per second. Route 53 Resolver supports up to 6 IP addresses per endpoint, so altogether this design supports up to 60,000 DNS queries per second spread across multiple Availability Zones for high availability.

Additionally, this pattern automatically accounts for future growth within AWS. The DNS forwarding rules configured on premises do not have to be modified to support new VPCs and their associated private hosted zones that are added to AWS.

**Tools**

**AWS services**

- **AWS Directory Service for Microsoft Active Directory** enables your directory-aware workloads and AWS resources to use Microsoft Active Directory in the AWS Cloud.
- **AWS Organizations** is an account management service that helps you consolidate multiple AWS accounts into an organization that you create and centrally manage.
- **AWS Resource Access Manager (AWS RAM)** helps you securely share your resources across AWS accounts to reduce operational overhead and provide visibility and auditability.
- **Amazon Route 53** is a highly available and scalable DNS web service.

**Tools**

- **AWS Command Line Interface (AWS CLI)** is an open-source tool that helps you interact with AWS services through commands in your command-line shell. In this pattern, the AWS CLI is used to configure Route 53 authorizations.

**Epics**

Create and share an AWS Managed Microsoft AD directory

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deploy AWS Managed Microsoft AD.</td>
<td>1. Create and configure a new directory. For detailed steps, see <strong>Create your AWS Managed Microsoft AD directory</strong> in the <strong>AWS Directory Service Administration Guide</strong>.  2. Record the IP addresses of the AWS Managed Microsoft AD domain controllers. These</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
## Share the directory.

After the directory has been built, share it with other AWS accounts in the AWS organization. For instructions, see [Share your directory](#) in the [AWS Directory Service Administration Guide](#).

**Note:** AWS Managed Microsoft AD Standard Edition has a limit of 5 shares. Enterprise Edition has a limit of 125 shares.

### Configure Route 53

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create Route 53 Resolvers.</td>
<td>Route 53 Resolvers facilitate DNS query resolution between AWS and the on-premises data center.</td>
<td>AWS administrator</td>
</tr>
<tr>
<td></td>
<td>1. Install Route 53 Resolvers by following the instructions in the Route 53 Developer Guide.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Configure Route 53 Resolvers in private subnets in at least two Availability Zones within the central AWS network account VPC for high availability.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Although using the central AWS network account VPC isn’t a requirement, the remaining steps assume this configuration.</td>
<td></td>
</tr>
<tr>
<td>Create Route 53 rules.</td>
<td>Your specific use case might require a large number of Route 53 rules, but you will need to configure the following rules as a baseline:</td>
<td>AWS administrator</td>
</tr>
<tr>
<td></td>
<td>• An outgoing rule for the on-premises namespace (company.com) by using the outbound Route 53 Resolvers.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Share this rule with spoke AWS accounts.</td>
<td></td>
</tr>
</tbody>
</table>
## Configure on-premises Active Directory DNS

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the delegation.</td>
<td>Use the Microsoft DNS snap-in (dnsmgmt.msc) to create a new delegation for the company.com namespace within Active Directory. The name of the delegated domain should be aws. This makes the fully qualified domain name (FQDN) of the delegation aws.company.com. For the name servers, use the IP.</td>
<td>Active Directory</td>
</tr>
</tbody>
</table>
### Create the conditional forwarder.

Use the Microsoft DNS snap-in (`dnsmgmt.msc`) to create a new conditional forwarder for `aws.company.com`. Use the IP addresses of the AWS Managed Microsoft AD domain controllers for the target of the conditional forwarder.

### Create Route 53 private hosted zones for spoke AWS accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the Route 53 private hosted zones.</td>
<td>Create a Route 53 private hosted zone in each spoke account. Associate this private hosted zone with the spoke account VPC. <td>AWS administrator</td>
</tr>
</tbody>
</table>
| Create authorizations.           | Use the AWS CLI to create an authorization for the central AWS network account VPC. Run this command from the context of each spoke AWS account: `aws route53 create-vpc-association-authorization --hosted-zone-id <hosted-zone-id> \ --vpc VPCRegion=<region>,VPCId=<vpc-id>` where:  
  - `<hosted-zone-id>` is the Route 53 private hosted zone in the spoke account.  
  - `<region>` and `<vpc-id>` are the AWS Region and VPC ID of the central AWS network account VPC. | AWS administrator   |
| Create associations.            | Create the Route 53 private hosted zone association for the spoke AWS account.                                                                                                                                 | AWS administrator   |
Check EC2 instances for mandatory tags at launch

Created by Susanne Kangnoh (AWS)

| Environment: | Production | Technologies: | Infrastructure; Management & governance; Security, identity, compliance; Cloud-native | AWS services: | Amazon EC2; AWS CloudTrail; Amazon CloudWatch; Amazon SNS |

Summary

Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the Amazon Web Services (AWS) Cloud. Using Amazon EC2 eliminates your need to invest in hardware up front, so you can develop and deploy applications faster.
You can use tagging to categorize your AWS resources in different ways. EC2 instance tagging is useful when you have many resources in your account and you want to quickly identify a specific resource based on the tags. You can assign custom metadata to your EC2 instances by using tags. A tag consists of a user-defined key and value. We recommend that you create a consistent set of tags to meet your organization's requirements.

This pattern provides an AWS CloudFormation template to help you monitor EC2 instances for specific tags. The template creates an Amazon CloudWatch Events event that watches for the AWS CloudTrail TagResource or UntagResource events, to detect new EC2 instance tagging or tag removal. If a predefined tag is missing, it calls an AWS Lambda function, which sends out a violation message to an email address that you provide, by using Amazon Simple Notification Service (Amazon SNS).

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) bucket to upload the provided Lambda code.
- An email address where you would like to receive violation notifications.

Limitations

- This solution supports CloudTrail TagResource or UntagResource events. It does not create notifications for any other events.
- This solution checks only for tag keys. It does not monitor key values.

Architecture

Workflow architecture

Automation and scale

- You can use the AWS CloudFormation template multiple times for different AWS Regions and accounts. You need to run the template only once in each Region or account.

Tools

AWS services

- Amazon EC2 – Amazon Elastic Compute Cloud (Amazon EC2) is a web service that provides secure, resizable compute capacity in the cloud. It is designed to make web-scale cloud computing easier for developers.
• **AWS CloudTrail** – CloudTrail is an AWS service that helps you with governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or AWS service are recorded as events in CloudTrail.

• **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near real-time stream of system events that describe changes in AWS resources. CloudWatch Events becomes aware of operational changes as they occur and takes corrective action as necessary, by sending messages to respond to the environment, activating functions, making changes, and capturing state information.

• **AWS Lambda** – Lambda is a compute service that supports running code without needing to provision or manage servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, mobile applications, backups, and data lakes.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a web service that enables applications, end-users, and devices to instantly send and receive notifications from the cloud.

**Code**

This pattern includes an attachment with two files:

• *index.zip* is a compressed file that includes the Lambda code for this pattern.

• *ec2-require-tags.yaml* is a CloudFormation template that deploys the Lambda code.

See the *Epics* section for information about how to use these files.

**Epics**

**Deploy the Lambda code**

<table>
<thead>

### Summary

Amazon Elastic Compute Cloud (Amazon EC2) instances often require access to external resources, such as software repositories and web services. Many organizations require restricting internet connections to authorized websites. Web filtering proxies are commonly used to enforce web policies for internet access.

This pattern uses the Sophos Unified Threat Management (UTM) virtual appliance, which is available in AWS Marketplace, to provide a transparent outbound proxy for EC2 instances. Alternative web proxy solutions may use open-source solutions such as Squid or Apache Traffic Server, which are beyond the scope of this pattern.

Sophos UTM provides multiple security functions, including firewall, intrusion prevention system (IPS), virtual private network (VPN), and web filtering. Sophos Outbound Gateway provides a distributed, fault-tolerant architecture to provide visibility, policy enforcement, and elastic scalability to outbound web traffic.

This pattern provides guidance for one use case: allowing AWS API calls from a virtual private cloud (VPC). This pattern does not cover general installation and software configuration tasks for Sophos UTM. For general guidance and best practices, consult the [Sophos UTM on AWS Administration Guide](#).
This pattern uses the following Sophos software:

- Sophos UTM 9 virtual appliance – Sophos UTM is a security platform that helps you secure your infrastructure in AWS. Sophos UTM provides multiple security tools, such as Next-Gen Firewall (NGFW), Web Application Firewall (WAF), Intrusion Prevention System (IPS), and Advanced Threat Protection (ATP).
- Sophos UTM Controller (Queen) – The Controller is a UTM instance that provides administrative control and configuration management for UTM Workers.
- Sophos UTM Workers – The UTM Workers terminate the Generic Routing Encapsulation (GRE) tunnels from the Outbound Gateways and proxy the traffic to the destination based on the policy configured within the Controller.
- Sophos Outbound Gateway (OGW) on AWS – The OGW is an instance that resides within an Availability Zone where clients need to connect out through the proxy.

This pattern leverages the AWS Quick Start that was developed by Sophos in collaboration with AWS. Sophos is an AWS Partner.

**Prerequisites and limitations**

**Prerequisites**

- Determine the licensing model you want to use for Sophos UTM. Available options are hourly and Bring Your Own License Model (BYOL). If you’re using the BYOL option, you’ll need your license file.
- Confirm that you have an active AWS account, and that your account limits allow you to provision two VPCs and one Elastic IP address.
- Identify the CIDR ranges you want to use for the proxy and application VPCs and subnets.
- In order to administer the Sophos UTM, you will need access to TCP port 4444 from your browser.

**Outbound proxy solution considerations**

Although outbound proxy solutions are widely used, there are implications that you should consider before you implement proxies in your architecture. The Sophos web filtering engine operates in transparent or standard mode. Regardless of the deployment mode, your client applications either need to support the Server Name Indicator (SNI) specification to securely access Secure Sockets Layer / Transport Layer Security (SSL/TLS) endpoints, or you will need to employ SSL decryption and distribute the signing certificate authority (CA) to your clients, as discussed in the Sophos Knowledge Base article. Additionally in standard mode, your client applications will need to be “proxy aware” and explicitly direct requests through the Sophos Outbound Gateway. Sophos provides additional options to control traffic, such as the ability to bypass filtering by source or destination IP. To learn more about this and other considerations, see the Sophos UTM Administration Guide.

**Architecture**

**Source technology stack**

- On-premises Sophos web proxy UTM

**Target technology stack**

- Sophos web proxy UTM on AWS
This is a simple software relocation from an on-premises data center host to an EC2 instance. The following diagram shows how the Sophos Outbound Gateway uses GRE to tunnel outbound network traffic between VPCs.

The following diagram provides a detailed view of the architecture on AWS. This pattern uses a highly available architecture that includes a Sophos UTM Controller, Sophos UTM Workers, and Sophos Outbound Gateways on AWS. In total, it deploys seven instances, including one Controller, two Workers in an Auto Scaling group, two Outbound Gateways, one bastion host, and one client test EC2 instance. To centralize the proxy service for the clients, the Controller and Workers are deployed into a dedicated VPC.

This pattern utilizes one additional application VPC for proxy clients. The Outbound Gateway on AWS is also deployed into the application VPC to support the connections from the clients. Finally, the bastion
host and tester instances are deployed into the application VPC. You can use these instances to test and become familiar with the outbound web proxy functionality.

Deploy a Cassandra cluster on Amazon EC2 with private static IPs to avoid rebalancing

*Created by Dipin Jain (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>

</tr>
</tbody>
</table>
Summary

The private IP of an Amazon Elastic Compute Cloud (Amazon EC2) instance is retained throughout its lifecycle. However, the private IP might change during a planned or unplanned system crash; for example, during an Amazon Machine Image (AMI) upgrade. In some scenarios, retaining a private static IP can enhance the performance and recovery time of workloads. For example, using a static IP for an Apache Cassandra seed node prevents the cluster from incurring a rebalancing overhead.

This pattern describes how to attach a secondary elastic network interface to EC2 instances to keep the IP static during rehosting. The pattern focuses on Cassandra clusters, but you can use this implementation for any architecture that benefits from private static IPs.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Service (AWS) account

Product versions

- DataStax version 5.11.1
- Operating system: Ubuntu 16.04.6 LTS

Architecture

Source architecture

The source could be a Cassandra cluster on an on-premises virtual machine (VM) or on EC2 instances in the AWS Cloud. The following diagram illustrates the second scenario. This example includes four cluster nodes: three seed nodes and one management node. In the source architecture, each node has a single network interface attached.
Target architecture

The destination cluster is hosted on EC2 instances with a secondary elastic network interface attached to each node, as illustrated in the following diagram.
Automation and scale

You can also automate attaching a second elastic network interface to an EC2 Auto Scaling group, as described in an AWS Knowledge Center video.

Epics

</table>
| Create a secondary network interface. | Cassandra generates a universal unique identifier (UUID) for each node based on the IP address of the EC2 instance for that node. This UUID is used for distributing virtual nodes (vnodes) on the ring. When Cassandra is deployed on EC2 instances, IP addresses are assigned automatically to the instances as they are created. In the event of a planned or unplanned outage, the IP address for the new EC2 instance changes, the data distribution changes, and the entire ring has to be rebalanced. This is not desirable. To preserve the assigned IP address, use a secondary elastic network interface with a fixed IP address.  
1. On the Amazon EC2 console, choose Network Interfaces, Create network interface.  
2. For Subnet, select the subnet that you created the EC2 instance in.  
3. For Private IPv4 address, choose Auto-assign.  
4. For Security groups, select a security group, and then choose Create network interface.  
For more information about creating a network interface, see the Amazon EC2 documentation. | Cloud Engineer |

**Mainframe modernization: DevOps on AWS with Micro Focus**

*Created by Kevin Yung (AWS)*

**Source:** IBM z/OS Mainframe  **Target:** AWS  **R Type:** N/A

**Environment:** PoC or pilot  **Technologies:** DevOps; Infrastructure  **AWS services:** Amazon EC2; AWS CloudFormation; AWS CodeBuild; AWS CodeCommit; AWS CodeDeploy; AWS Systems Manager; AWS CodePipeline

**Summary**

**Customer challenges**

Organizations that run core applications on mainframe hardware usually encounter a few challenges when the hardware needs to scale up to meet the demands of digital innovations. These challenges include the following constraints.

- Mainframe development and test environments are unable to scale due to the inflexibility of mainframe hardware components and the high cost of changing.
- Mainframe development is facing skill shortages, because new developers are not familiar and not interested in the traditional mainframe development tools. Modern technology such as containers, continuous integration/continuous delivery (CI/CD) pipelines, and modern test frameworks are not available in mainframe development.
Pattern outcomes

To address these challenges, Amazon Web Services (AWS) and Micro Focus, an AWS Partner Network (APN) Partner, have collaborated to create this pattern. The solution is designed to help you achieve the following outcomes.

- Improved developer productivity. Developers can be given new mainframe development instances within minutes.
- Use of the AWS Cloud to create new mainframe test environments with virtually unlimited capacity.
- Rapid provisioning of new mainframe CI/CD infrastructure. Provisioning on AWS can be completed within an hour by using AWS CloudFormation and AWS Systems Manager.
- Native use of AWS DevOps tools for mainframe development, including AWS CodeBuild, AWS CodeCommit, AWS CodePipeline, AWS CodeDeploy, and Amazon Elastic Container Registry (Amazon ECR).
- Transform traditional waterfall development to agile development in mainframe projects.

Technologies summary

In this pattern, the target stack contains the following components.

**Limitations**
- Building a Windows Docker image is not supported in CodeBuild. This reported issue needs support from Windows Kernel/HCS and Docker teams. The work-around is to create a Docker image build runbook by using Systems Manager. This pattern uses the work-around to build Micro Focus Enterprise Developer for Eclipse and Micro Focus Enterprise Test Server Container images.

- Virtual private cloud (VPC) connectivity from CodeBuild is not supported in Windows yet, so the pattern does not use Micro Focus License Manager to manage licenses in Micro Focus Enterprise Developer and Micro Focus Enterprise Test Server containers.

**Product versions**

- Micro Focus Enterprise Developer 5.5 or later
- Micro Focus Enterprise Test Server 5.5 or later
- Micro Focus Enterprise Server 5.5 or later
- Micro Focus AccuRev 7.x or later
- Windows Docker base image for Micro Focus Enterprise Developer and Enterprise Test Server: microsoft/dotnet-framework-4.7.2-runtime
- Linux Docker base image for AccuRev client: amazonlinux2

**Architecture**

**Mainframe environment**

In conventional mainframe development, the developers need to use mainframe hardware to develop and test programs. They face capacity limitations, for example restricted million instructions per second (MIPS) for the dev/test environment, and they must rely on the tools that are available on the mainframe computers.

In many organizations, mainframe development follows the waterfall development methodology, with teams relying on long cycles to release changes. These release cycles are usually longer than digital product development.

The following diagram shows multiple mainframe projects sharing mainframe hardware for their development. In mainframe hardware, it is expensive to scale out a development and test environment for more projects.
AWS architecture

This pattern extends mainframe development to the AWS Cloud. First, it uses Micro Focus AccuRev SCM to host the mainframe source code on AWS. Then it makes Micro Focus Enterprise Developer and Micro Focus Enterprise Test Server available for building and testing the mainframe code on AWS.

The following sections describe the pattern's three major components.

1. SCM
In AWS, the pattern uses Micro Focus AccuRev to create a set of SCM workspaces and version control for the mainframe source code. Its stream-based architecture enables parallel mainframe development for multiple teams. To merge a change, AccuRev uses the promote concept. To add that change to other workspaces, AccuRev uses the update concept.

At the project level, each team can create one or more streams in AccuRev to track project level changes. These are called project streams. These project streams are inherited from the same parent stream. The parent stream is used to merge the changes from different project streams.

Each project stream can promote code to AccuRev, and a promote post trigger is set up to initiate the AWS CI/CD pipeline. The successful build for a project stream change can be promoted to its parent stream for more regression tests.

Usually, the parent stream is called the system integration stream. When there is a promotion from a project stream to a system integration stream, a post promotion trigger initiates another CI/CD pipeline to run regression tests.

In addition to mainframe code, this pattern includes AWS CloudFormation templates, Systems Manager Automation documents, and scripts. Following infrastructure-as-code best practices, they are version-controlled in AWS CodeCommit.

If you need to synchronize mainframe code back to a mainframe environment for deployment, Micro Focus provides the Enterprise Sync solution, which synchronizes code from the AccuRev SCM back to the mainframe SCM.

### 2. Developer and test environments

In a large organization, scaling more than a hundred or even more than a thousand mainframe developers is challenging. To address this constraint, the pattern uses Amazon EC2 Windows instances for development. On the instances, Micro Focus Enterprise Developer for Eclipse tools are installed. The developer can perform all mainframe code test and debugging locally on the instance.

AWS Systems Manager State Manager and Automation documents are used to automate the developer instance provisioning. The average time to create a developer instance is within 15 minutes. The following software and configurations are prepared.

- AccuRev Windows client for checking out and committing source code into AccuRev
- Micro Focus Enterprise Developers for Eclipse tool, for writing, testing, and debugging mainframe code locally
- Open source testing frameworks Python behavior-driven development (BDD) test framework Behave, py3270, and the x3270 emulator for creating scripts to test applications
- A Docker developer tool for building the Enterprise Test Server Docker image and testing the application in the Enterprise Test Server Docker container

In the development cycle, developers use the EC2 instance to develop and test mainframe code locally. When the local changes are tested successfully, developers promote the change into the AccuRev server.

### 3. CI/CD pipelines

In the pattern, CI/CD pipelines are used for integration tests and regression tests before deployment to the production environment.

As explained in the SCM section, AccuRev uses two types of streams: a project stream and an integration stream. Each stream is hooked up with CI/CD pipelines. To perform the integration between the AccuRev server and AWS CodePipeline, the pattern uses AccuRev post promotion script to create an event to initiate CI/CD.
For example, when a developer promotes a change to a project stream in AccuRev, it initiates a post promotion script to run in AccuRev Server. Then the script uploads the metadata of the change into an Amazon Simple Storage Service (Amazon S3) bucket to create an Amazon S3 event. This event will initiate a CodePipeline configured pipeline to run.

The same event-initiating mechanism is used for the integration stream and its associated pipelines.

In the CI/CD pipeline, CodePipeline uses CodeBuild with the Micro Focus AccuRev Linux client container to check out the latest code from the AccuRev streams. Then the pipeline starts CodeBuild to use the Micro Focus Enterprise Developer Windows container to compile the source code, and to use the Micro Focus Enterprise Test Server Windows container in CodeBuild to test mainframe applications.

The CI/CD pipelines are built using AWS CloudFormation templates, and the blueprint will be used for new projects. By using the templates, it takes less than an hour for a project to create a new CI/CD pipeline in AWS.

To scale your mainframe test capability on AWS, the pattern builds out the Micro Focus DevOps test suite, Micro Focus Verastream and Micro Focus UFT server. By using the modern DevOps tools, you can run as many tests on AWS as you need.

An example mainframe development environment with Micro Focus on AWS is shown in the following diagram.

**Target technology stack**

This section provides a closer look at the architecture of each component in the pattern.

1. **Source code repository – AccuRev SCM**

   Micro Focus AccuRev SCM is set up to manage mainframe source code versions. For high availability, AccuRev supports primary and replica modes. Operators can fail over to the replica when performing maintenance on the primary node.

   To speed up the response of the CI/CD pipeline, the pattern uses Amazon CloudWatch Events to detect source code changes and initiate the start of the pipeline.

   1. The CodePipeline is set up to use an Amazon S3 source.
2. A CloudWatch Events rule is set up to capture S3 events from a source S3 bucket.
3. The CloudWatch Events rule sets a target to the pipeline.
4. AccuRev SCM is configured to run a post promotion script locally after promotion is complete.
5. AccuRev SCM generates an XML file that contains the metadata of the promotion, and the script uploads the XML file to the source S3 bucket.
6. After the upload, the source S3 bucket sends events to match the CloudWatch Events rule, and the CloudWatch Events rule initiates the CodePipeline to run.

When the pipeline runs, it kicks off a CodeBuild project to use an AccuRev Linux client container to check out the latest mainframe code from an associated AccuRev stream.

The following diagram shows an AccuRev Server setup.

2. Enterprise Developer template

The pattern uses Amazon EC2 templates to simplify creation of the developer instance. By using State Manager, it can apply software and license settings to EC2 instances consistently.

The Amazon EC2 template builds in its VPC context settings and default instance settings, and it follows enterprise tagging requirements. By using a template, a team can create their own new development instances.

When a developer instance starts, by associating with tags, Systems Manager uses State Manager to apply automation. The automation includes the following general steps.
1. Install Micro Focus Enterprise Developer software and install patches.
2. Install the Micro Focus AccuRev client for Windows.
3. Install the pre-configured script for developers to join the AccuRev stream. Initialize Eclipse workspaces.
4. Install development tools, including x3270, py3270, and Docker.
5. Configure license settings to point to a Micro Focus License Manager load balancer.

The following diagram shows an Enterprise developer instance created by the Amazon EC2 template, with software and configuration applied to the instance by State Manager. Enterprise developer instances connect to Micro Focus License Manager to activate their license.

### 3. CI/CD pipelines

As explained in AWS architecture section, in the pattern, there are project-level CI/CD pipelines and system integration pipelines. Each mainframe project team creates a pipeline or multiple CI/CD pipelines for building the programs that they are developing in a project. These project CI/CD pipelines check out source code from an associated AccuRev stream.

In a project team, developers promote their code in the associated AccuRev stream. Then the promotion initiates the project pipeline to build the code and run integration tests.

Each project CI/CD pipeline uses CodeBuild projects with the Micro Focus Enterprise Developer tool Amazon ECR image and Micro Focus Enterprise Test Server tool Amazon ECR image.

CodePipeline and CodeBuild are used to create the CI/CDs pipelines. Because CodeBuild and CodePipeline have no upfront fees or commitments, you pay only for what you use. Compared to
mainframe hardware, the AWS solution greatly reduces hardware provisioning lead time and lowers the cost of your testing environment.

In modern development, multiple test methodologies are used. For example, test-driven development (TDD), BDD, and Robot Framework. With this pattern, developers can use these modern tools for mainframe testing. For example, by using x3270, py3270 and the Behave python test tool, you can define an online application's behavior. You can also use build mainframe 3270 robot framework in these CI/CD pipelines.

The following diagram shows the team stream CI/CD pipeline.

The following diagram shows the project CI/CD test report produced by CodePipeline in Mainframe3270 Robot Framework.
The following diagram shows the project CI/CD test report produced by CodePipeline in Py3270 and Behave BDD.

Pass rate: 100%
Report duration: 2.662 seconds
Created: 16 days ago
After project level tests are passed successfully, the tested code is manually promoted to the integration stream in AccuRev SCM. You can automate this step after the teams have a confidence on the tests coverage of their project pipeline.

When code is promoted, the system integration CI/CD pipeline checks out the merged code and performs regression tests. The merged code is promoted from all parallel project streams.

Depending on how fine grain the test environment are required, customers can have more system integration CI/CD pipelines in different environment, for example UAT, Pre-Production.

In the pattern, the tools used in the system integration pipeline are Micro Focus Enterprise Test Server, Micro Focus UFT Server, and Micro Focus Verastream. All these tools can be deployed into the Docker container and used with CodeBuild.

After successfully testing of the mainframe programs, the artifact is stored, with version control, in an S3 bucket.

The following diagram shows a system integration CI/CD pipeline.
After the artifact has been successfully tested in the system integration CI/CD pipelines, it can be promoted for production deployment.

If you need to deploy source code back to the mainframe, Micro Focus offers the Enterprise Sync solution to synchronize source code from AccuRev back to Mainframe Endeavour.

The following diagram shows a production CI/CD pipeline deploying the artifact into Micro Focus Enterprise Servers. In this example, CodeDeploy orchestrates the deployment of the tested mainframe artifact into Micro Focus Enterprise Server.

In addition to the architecture walkthough of the CI/CD pipeline, you can also read the AWS DevOps blog post Automate thousands of mainframe tests on AWS with the Micro Focus Enterprise Suite for more information on testing mainframe applications in CodeBuild and CodePipeline. Refer to the blog post for the best practices and details of doing mainframe tests on AWS.

**Preserve routable IP space in multi-account VPC designs for non-workload subnets**
Summary

Amazon Web Services (AWS) has published best practices that recommend using dedicated subnets in a virtual private cloud (VPC) for both transit gateway attachments and Gateway Load Balancer endpoints (to support AWS Network Firewall or third-party appliances). These subnets are used to contain elastic network interfaces for these services. If you use both AWS Transit Gateway and a Gateway Load Balancer, two subnets are created in each Availability Zone for the VPC. Because of the way VPCs are designed, these extra subnets can’t be smaller than a /28 mask and can consume precious routable IP space that could otherwise be used for routable workloads. This pattern demonstrates how you can use a secondary, non-routable Classless Inter-Domain Routing (CIDR) range for these dedicated subnets to help preserve routable IP space.

Prerequisites and limitations

Prerequisites

- Multi-VPC strategy for routable IP space
- A non-routable CIDR range for the services you’re using (transit gateway attachments and Gateway Load Balancer or Network Firewall endpoints)

Architecture

Target architecture

This pattern includes two reference architectures: one architecture has subnets for transit gateway (TGW) attachments and a Gateway Load Balancer endpoint (GWLBe), and the second architecture has subnets for TGW attachments only.

Architecture 1 – TGW-attached VPC with ingress routing to an appliance

The following diagram represents a reference architecture for a VPC that spans two Availability Zones. On ingress, the VPC uses an ingress routing pattern to direct traffic destined for the public subnet to a bump-in-the-wire appliance for firewall inspection. A TGW attachment supports egress from the private subnets to a separate VPC.

This pattern uses a non-routable CIDR range for the TGW attachment subnet and the GWLBe subnet. In the TGW routing table, this non-routable CIDR is configured with a blackhole (static) route by using a set of more specific routes. If the routes were to get propagated to the TGW routing table, these more specific blackhole routes would apply.

In this example, the /23 routable CIDR is divided up and fully allocated to routable subnets.
Architecture 2 – TGW-attached VPC

The following diagram represents another reference architecture for a VPC that spans two Availability Zones. A TGW attachment supports outbound traffic (egress) from the private subnets to a separate VPC. It uses a non-routable CIDR range only for the TGW attachments subnet. In the TGW routing table, this non-routable CIDR is configured with a blackhole route by using a set of more specific routes. If the routes were to get propagated to the TGW routing table, these more specific blackhole routes would apply.

In this example, the /23 routable CIDR is divided up and fully allocated to routable subnets.
AWS services and resources

- **Amazon Virtual Private Cloud (Amazon VPC)** helps you launch AWS resources into a virtual network that you've defined. This virtual network resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS. In this pattern, VPC secondary CIDRs are used to preserve routable IP space in workload CIDRs.
- **Internet gateway ingress routing** (edge associations) can be used along with Gateway Load Balancer endpoints for dedicated non-routable subnets.
- **AWS Transit Gateway** is a central hub that connects VPCs and on-premises networks. In this pattern, VPCs are centrally attached to a transit gateway, and the transit gateway attachments are in a dedicated non-routable subnet.
- **Gateway Load Balancers** help you deploy, scale, and manage virtual appliances, such as firewalls, intrusion detection and prevention systems, and deep packet inspection systems. The gateway serves as a single entry and exit point for all traffic. In this pattern, endpoints for a Gateway Load Balancer can be used in a dedicated non-routable subnet.
- **AWS Network Firewall** is a stateful, managed, network firewall and intrusion detection and prevention service for VPCs in the AWS Cloud. In this pattern, endpoints for an firewall can be used in a dedicated non-routable subnet.

**Code repository**

A runbook and AWS CloudFormation templates for this pattern are available in the GitHub Non-Routable Secondary CIDR Patterns repository. You can use the sample files to set up a working lab in your environment.

**Best practices**

**AWS Transit Gateway**

- Use a separate subnet for each transit gateway VPC attachment.
Epics

Allocate a /28 subnet from the secondary non-routable CIDR range for the transit gateway attachment subnets.

In each transit gateway routing table, add a static, more specific route for the non-routable CIDR range as a blackhole.

*Gateway Load Balancer and ingress routing*

Use ingress routing to direct traffic from the internet to the Gateway Load Balancer endpoints.

Use a separate subnet for each Gateway Load Balancer endpoint.

Allocate a /28 subnet from the secondary non-routable CIDR range for the Gateway Load Balancer endpoint subnets.

### Epics

#### Create VPCs

### Additional information

The non-routable secondary CIDR range can also be useful when working with larger scaled container deployments that require a large set of IP addresses. You can use this pattern with a private NAT Gateway to use a non-routable subnet to host your container deployments. For more information, see the blog post [How to solve Private IP exhaustion with Private NAT Solution](#).

### Set up integrated DNS resolution for hybrid networks in Amazon Route 53

*Created by Abdullahi Olaoye (AWS)*

<table>
<thead>
<tr>
<th>Created by:</th>
<th>AWS</th>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Infrastructure</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AWS services:</strong></td>
<td>Amazon Route 53; Amazon VPC</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Summary

This pattern describes how to set up a fully hybrid Domain Name System (DNS) architecture that enables end-to-end DNS resolution of on-premise resources, AWS resources, and internet DNS queries, without...
Prerequisites and limitations

Prerequisites

• An AWS account
• A virtual private cloud (VPC) in your AWS account
• A network connection between the on-premises environment and your VPC, through AWS Virtual Private Network (AWS VPN) or AWS Direct Connect
• IP addresses of your on-premises DNS resolvers (reachable from your VPC)
• Domain/subdomain name to forward to on-premises resolvers (for example, onprem.mydc.com)
• Domain/subdomain name for the AWS private hosted zone (for example, myvpc.cloud.com)

Architecture

Target technology stack

• Amazon Route 53 private hosted zone
• Amazon Route 53 Resolver
• Amazon VPC
• AWS VPN or Direct Connect

Tools

• Amazon Route 53 Resolver – Amazon Route 53 Resolver makes hybrid cloud easier for enterprise customers by enabling seamless DNS query resolution across your entire hybrid cloud. You can create DNS endpoints and conditional forwarding rules to resolve DNS namespaces between your on-premises data center and your VPCs.
AWS Prescriptive Guidance Patterns

Epics

Configure a private hosted zone

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a Route 53 private hosted zone for an AWS reserved domain name such as myvpc.cloud.com.</td>
<td>This zone holds the DNS records for AWS resources that should be resolved from the on-premises environment. For instructions, see <a href="https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/hosted-zone-private-creating.html">https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/hosted-zone-private-creating.html</a>.</td>
<td>Network admin, System admin</td>
</tr>
<tr>
<td>Associate the private hosted zone with your VPC.</td>
<td>To enable resources in your VPC to resolve DNS records in this private hosted zone, you must associate your VPC with the hosted zone. For instructions, see <a href="https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/hosted-zone-private-creating.html">https://docs.aws.amazon.com/Route53/latest/DeveloperGuide/hosted-zone-private-creating.html</a>.</td>
<td>Network admin, System admin</td>

Upgrade SAP Pacemaker clusters from ENSA1 to ENSA2

Created by Gergely Cserdi (AWS) and Balazs Sandor Skublics (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Source: ENSA1-based Pacemaker cluster</th>
<th>Target: ENSA2-based Pacemaker cluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Re-architect</td>
<td>Workload: SAP</td>
<td>Technologies: Infrastructure; Modernization</td>
</tr>
<tr>
<td>AWS services: Amazon EC2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern explains the steps and considerations for upgrading an SAP Pacemaker cluster that is based on Standalone Enqueue Server (ENSA1) to ENSA2. The information in this pattern applies to both SUSE Linux Enterprise Server (SLES) and Red Hat Enterprise Linux (RHEL) operating systems.

Pacemaker clusters on SAP NetWeaver 7.52 or S/4HANA 1709 and earlier versions run on an ENSA1 architecture and are configured specifically for ENSA1. If you run your SAP workloads on Amazon Web Services (AWS) and you’re interested in moving to ENSA2, you might find that the SAP, SUSE, and RHEL documentation doesn’t provide comprehensive information. This pattern describes the technical steps required to reconfigure SAP parameters and Pacemaker clusters to upgrade from ENSA1 to ENSA2. It provides examples of SUSE systems, but the concept is the same for RHEL clusters.

Notes: ENSA1 and ENSA2 are concepts that pertain to SAP applications only, so the information in this pattern doesn’t apply to SAP HANA or other types of clusters.
Technically, ENSA2 can be used with or without Enqueue Replicator 2. However, high availability (HA) and failover automation (through a cluster solution) require Enqueue Replicator 2. This pattern uses the term *ENSA2 clusters* to refer to clusters with Standalone Enqueue Server 2 and Enqueue Replicator 2.

### Prerequisites and limitations

#### Prerequisites

- A working ENSA1-based cluster that uses Pacemaker and Corosync on SLES or RHEL.
- At least two Amazon Elastic Compute Cloud (Amazon EC2) instances where the (ABAP) SAP Central Services (ASCS/SCS) and Enqueue Replication Server (ERS) instances are running.
- Knowledge of managing SAP applications and clusters.
- Access to the Linux environment as root user.

#### Limitations

- ENSA1-based clusters support a two-node architecture only.
- ENSA2-based clusters cannot be deployed to SAP NetWeaver versions before 7.52.
- EC2 instances in clusters should be in different AWS Availability Zones.

#### Product versions

- SAP NetWeaver version 7.52 or later
- Starting with S/4HANA 2020, only ENSA2 clusters are supported
- Kernel 7.53 or later, which supports ENSA2 and Enqueue Replicator 2
- SLES for SAP Applications version 12 or later
- RHEL for SAP with High Availability (HA) version 7.9 or later

### Architecture

#### Source technology stack

- SAP NetWeaver 7.52 with SAP Kernel 7.53 or later
- SLES or RHEL operating system

#### Target technology stack

- SAP NetWeaver 7.52 with SAP Kernel 7.53 or later, including S/4HANA 2020 with ABAP platform
- SLES or RHEL operating system

#### Target architecture

The following diagram shows an HA configuration of ASCS/SCS and ERS instances based on an ENSA2 cluster.
Comparison of ENSA1 and ENSA2 clusters

SAP introduced ENSA2 as the successor to ENSA1. An ENSA1-based cluster supports a two-node architecture where the ASCS/SCS instance fails over to ERS when an error occurs. This limitation stems from how the ASCS/SCS instance regains the lock table information from the shared memory of the ERS node after failover. ENSA2-based clusters with Enqueue Replicator 2 eliminate this limitation, because the ASCS/SCS instance can collect the lock information from the ERS instance over the network. ENSA2-based clusters can have more than two nodes, because the ASCS/SCS instance is no longer required to fail over to the ERS node. (However, in a two-node ENSA2 cluster environment, the ASCS/SCS instance will still fail over to the ERS node because there are no other nodes in the cluster to fail over to.) ENSA2 is supported starting with SAP Kernel 7.50 with some limitations. For HA setup that supports Enqueue Replicator 2, the minimum requirement is NetWeaver 7.52 (see SAP OSS Note 2630416). S/4HANA 1809 comes with ENSA2 architecture recommended by default, whereas S/4HANA supports only ENSA2 starting with version 2020.

Automation and scale

The HA cluster in the target architecture makes ASCS fail over to other nodes automatically.

Scenarios for moving to ENSA2-based clusters

There are two main scenarios for upgrading to ENSA2-based clusters:

- Scenario 1: You choose to upgrade to ENSA2 without an accompanying SAP upgrade or S/4HANA conversion, assuming that your SAP release and Kernel version support ENSA2.
- Scenario 2: You move to ENSA2 as part of an upgrade or conversion (for example, to S/4HANA 1809 or later) by using SUM.

The Epics (p. 820) section covers the steps for these two scenarios. The first scenario requires you to manually set up SAP-related parameters before you change the cluster configuration for ENSA2. In the second scenario, the binaries and SAP-related parameters are deployed by SUM, and your only remaining
task is to update the cluster configuration for HA. We still recommend that you validate SAP parameters after you use SUM. In most cases, S/4HANA conversion is the main reason for a cluster upgrade.

**Tools**

- For OS package managers, we recommend the Zypper (for SLES) or YUM (for RHEL) tools.
- For cluster management, we recommend `crm` (for SLES) or `pcs` (for RHEL) shells.
- SAP instance management tools such as SAPControl.
- (Optional) SUM tool for S/4HANA conversion upgrade.

**Best practices**

- For best practices for using SAP workloads on AWS, see the SAP Lens for the AWS Well-Architected Framework.
- Consider the number of cluster nodes (odd or even) in your ENSA2 multi-node architecture.
- Set up the ENSA2 cluster for SLES 15 in alignment with the SAP S/4-HA-CLU 1.0 certification standard.
- Always save or back up your existing cluster and application state before upgrading to ENSA2.

**Epics**

**Configure SAP parameters manually for ENSA2 (scenario 1 only)**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the parameters in the default profile.</td>
<td>If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the parameters in the default profile (DEFAULT.PFL file) to the following values.</td>
<td>SAP</td>
</tr>
<tr>
<td></td>
<td><code>enq/enable=TRUE</code>&lt;br&gt;<code>enq/serverhost=sapascsvirt</code>&lt;br&gt;<code>enq/serverinst=10</code>&lt;br&gt; (instance number of ASCS/SCS instance)&lt;br&gt;<code>enqueue/process_location=REMOTESA</code>&lt;br&gt;<code>enq/replicatorhost=sapersvirt</code>&lt;br&gt;<code>enq/replicatorinst=11</code>&lt;br&gt; (instance number of ERS instance)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>where <code>sapascsvirt</code> is the virtual hostname for the ASCS instances, and <code>sapersvirt</code> is the virtual hostname for the ERS instances. You can change these to fit your target environment.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Note:</td>
<td>To use this upgrade option, your SAP release and Kernel version must support ENSA2 and Enqueue Replicator 2.</td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Configure the ASCS/SCS instance profile.</td>
<td>If you want to upgrade to ENSA2 while staying on the same SAP release or if your target release defaults to ENSA1, set the following parameters in the ASCS/SCS instance profile. The section of the profile where ENSA1 is defined looks something like the following.</td>
<td>SAP</td>
</tr>
</tbody>
</table>

```bash
#--------------------------------------------------------------
# Start SAP enqueue server
#--------------------------------------------------------------
_EN = en.sap
$(SAPSYSTEMNAME)$(INSTANCE_NAME)
Execute_04 = local rm -f $(EN)
Execute_05 = local ln -s -f $(DIR_EXECUTABLE)/enserver $(FT_EXE) $(EN)
Start_Program_01 = local $(EN) pf=$(PF)
```

To reconfigure this section for ENSA2:

1. Change the _EN program prefix to _ENQ based on the latest information from SAP (OSS Note 2501860; requires an SAP ONE Support Launchpad user account).
2. Change the binary for enqueue server from enserver to enq_server.
3. Set the new parameter enq/server/replication/enable to TRUE.
4. Make sure that Autostart = 0.

This profile section would look something like the following after your changes.

```bash
#--------------------------------------------------------------
# Start SAP enqueue server
#--------------------------------------------------------------
_ENQ = enq.sap
$(SAPSYSTEMNAME)$(INSTANCE_NAME)
Execute_04 = local rm -f $(ENQ)
```
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Execute_05 = local ln -s -f $(DIR_EXECUTABLE)/enq_server$(FT_EXE) ${_ENQ}</td>
<td>Execute_05 = local ln -s -f $(DIR_EXECUTABLE)/enq_server$(FT_EXE) ${_ENQ}</td>
<td></td>
</tr>
<tr>
<td>Start_Program_01 = local ${_ENQ} pf=${_PF}</td>
<td>Start_Program_01 = local ${_ENQ} pf=${_PF}</td>
<td></td>
</tr>
<tr>
<td>... enq/server/replication/enable = TRUE</td>
<td>... enq/server/replication/enable = TRUE</td>
<td></td>
</tr>
<tr>
<td>Autostart = 0</td>
<td>Autostart = 0</td>
<td></td>
</tr>
</tbody>
</table>

**Important:** _ENQ must not have the restart option enabled. If RestartProgram_01 is set for _ENQ, change it to StartProgram_01. This prevents SAP from restarting the service or interfering with cluster-managed resources.
<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>Adjust primitives.</td>
<td>You will also need to make minor changes to the ASCS and ERS SAPInstance primitives.</td>
<td>AWS systems administrator</td>
</tr>
</tbody>
</table>

Here is an example of an ASCS SAPInstance primitive that is configured for ENSA1.

```yaml
primitive rsc_sap_SCT_ASCS10
  SAPInstance \ operations
  $id=rsc_sap_SCT_ASCS10-operations \ op monitor interval=120
  timeout=60 on-fail=restart 
  params
  InstanceName=SCT_ASCS10_sapascsvirt
  START_PROFILE="/sapmnt/SCT/profile/SCT_ASCS10_sapascsvirt" \ AUTOMATIC_RECOVER=false 
  meta resource-stickiness=5000 failure-timeout=60 migration-threshold=1 priority=10
```

To upgrade to ENSA2, change this configuration to the following.

```yaml
primitive rsc_sap_SCT_ASCS10
  SAPInstance \ operations
  $id=rsc_sap_SCT_ASCS10-operations \ op monitor interval=120
  timeout=60 on-fail=restart 
  params
  InstanceName=SCT_ASCS10_sapascsvirt
  START_PROFILE="/sapmnt/SCT/profile/SCT_ASCS10_sapascsvirt" \ AUTOMATIC_RECOVER=false 
  meta resource-stickiness=3000
```

This is an example of an ERS SAPInstance primitive that is configured for ENSA1.

```yaml
primitive rsc_sap_SCT_ERS11
  SAPInstance \ operations
  $id=rsc_sap_SCT_ERS11-operations 
```

Use consistent Availability Zones in VPCs across different AWS accounts
Summary

On the Amazon Web Services (AWS) Cloud, an Availability Zone has a name that can vary between your AWS accounts and an Availability Zone ID (AZ ID) that identifies its location. If you use AWS CloudFormation to create virtual private clouds (VPCs), you must specify the Availability Zone's name or ID when creating the subnets. If you create VPCs in multiple accounts, the Availability Zone name is randomized, which means that subnets use different Availability Zones in each account.

To use the same Availability Zone across your accounts, you must map the Availability Zone name in each account to the same AZ ID. For example, the following diagram shows that the use1-az6 AZ ID is named us-east-1a in AWS account A and us-east-1c in AWS account Z.

This pattern helps ensure zonal consistency by providing a cross-account, scalable solution for using the same Availability Zones in your subnets. Zonal consistency ensures that your cross-account network traffic avoids cross-Availability Zone network paths, which helps reduce data transfer costs and lower network latency between your workloads.

This pattern is an alternative approach to the AWS CloudFormation AvailabilityZoneId property.

Prerequisites and limitations

Prerequisites

- At least two active AWS accounts in the same AWS Region.
- Evaluate how many Availability Zones are needed to support your VPC requirements in the Region.
- Identify and record the AZ ID for each Availability Zone that you need to support. For more information about this, see Availability Zone IDs for your AWS resources in the AWS Resource Access Manager documentation.
- An ordered, comma-separated list of your AZ IDs. For example, the first Availability Zone on your list is mapped as az1, the second Availability Zone is mapped as az2, and this mapping structure continues.
until your comma-separated list is fully mapped. There is no maximum number of AZ IDs that can be mapped.

- The az-mapping.yaml file from the GitHub Multi-account Availability Zone mapping repository, copied to your local machine

Architecture

The following diagram shows the architecture that is deployed in an account and that creates AWS Systems Manager Parameter Store values. These Parameter Store values are consumed when you create a VPC in the account.

The diagram shows the following workflow:

1. This pattern's solution is deployed to all accounts that require zonal consistency for a VPC.
2. The solution creates Parameter Store values for each AZ ID and stores the new Availability Zone name.
3. The AWS CloudFormation template uses the Availability Zone name stored in each Parameter Store value and this ensures zonal consistency.

The following diagram shows the workflow for creating a VPC with this pattern's solution.
The diagram shows the following workflow:

1. Submit a template for creating a VPC to AWS CloudFormation.
2. AWS CloudFormation resolves the Parameter Store values for each Availability Zone and returns the Availability Zone name for each AZ ID.
3. A VPC is created with the correct AZ IDs required for zonal consistency.

After you deploy this pattern's solution, you can create subnets that reference the Parameter Store values. If you use AWS CloudFormation, you can reference the Availability Zone mapping parameter values from the following YAML-formatted sample code:

```
Resources:
  PrivateSubnet1AZ1:
    Type: AWS::EC2::Subnet
    Properties:
      VpcId: !Ref VPC
      CidrBlock: !Ref PrivateSubnetAZ1CIDR
      AvailabilityZone: !Join
        - ''
        - - '{{resolve:ssm:/az-mapping/az1:1}}'
```

This sample code is contained in the `vpc-example.yaml` file from the GitHub Multi-account Availability Zone mapping repository. It shows you how to create a VPC and subnets that align to the Parameter Store values for zonal consistency.

**Technology stack**

- AWS CloudFormation
- AWS Lambda
- AWS Systems Manager Parameter Store
**Automation and scale**

You can deploy this pattern to all your AWS accounts by using AWS CloudFormation StackSets or the Customizations for AWS Control Tower solution. For more information, see [Working with AWS CloudFormation StackSets](https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/getting-started.html) in the AWS Cloudformation documentation and [Customizations for AWS Control Tower](https://aws.amazon.com/whitepapers/aws-control-tower-custom-solution/) in the AWS Solutions Library.

After you deploy the AWS CloudFormation template, you can update it to use the Parameter Store values and deploy your VPCs in pipelines or according to your requirements.

**Tools**

**AWS services**

- **AWS CloudFormation** helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **AWS Lambda** is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

- **AWS Systems Manager Parameter Store** is a capability of AWS Systems Manager. It provides secure, hierarchical storage for configuration data management and secrets management.

**Code**

The code for this pattern is provided in the GitHub [Multi-account Availability Zone mapping](https://github.com/aws-solutions/aws-prescriptive-guidance-patterns) repository.

AWS services: Amazon CloudWatch; Amazon OpenSearch Service; Amazon GuardDuty; AWS IoT Core; AWS IoT Device Defender; AWS IoT Device Management; Amazon CloudWatch Logs

Summary

Ensuring that your Internet of Things (IoT) environments are secure is an important priority, particularly because organizations are connecting billions of devices to their IT environments. This pattern provides a reference architecture that you can use to implement logging and monitoring for security events across your IoT environment on the Amazon Web Services (AWS) Cloud. Typically, an IoT environment on the AWS Cloud has the following three layers:

- IoT devices that generate relevant telemetry data.
- AWS IoT services (for example, AWS IoT Core, AWS IoT Device Management, or AWS IoT Device Defender) that connect your IoT devices to other devices and AWS services.
- Backend AWS services that help process telemetry data and provide useful insights for your different business use cases.

The best practices provided by the AWS IoT Lens - AWS Well-Architected Framework whitepaper can help you review and improve your cloud-based architecture and better understand the business impact of your design decisions. An important recommendation is that you analyze application logs and metrics on your devices and in the AWS Cloud. You can achieve this by leveraging different approaches and techniques (for example, threat modeling) to identify metrics and events that must be monitored to detect potential security issues.

This pattern describes how to use AWS IoT and security services to design and implement a security logging and monitoring reference architecture for an IoT environment on the AWS Cloud. This architecture builds on existing AWS security best practices and applies them to your IoT environment.
Prerequisites and limitations

Prerequisites

- An existing landing zone environment. For more information about this, see the guide Setting up a secure and scalable multi-account AWS environment on the AWS Prescriptive Guidance website.

- The following accounts must be available in your landing zone:
  - **Log Archive account** – This account is for users that need to access the logging information for accounts in your landing zone’s organizational units (OUs). For more information about this, see the Security OU – Log Archive account section of the guide AWS Security Reference Architecture on the AWS Prescriptive Guidance website.
  - **Security account** – Your security and compliance teams use this account for auditing or to perform emergency security operations. This account is also designated as the administrator account for Amazon GuardDuty. Users from the administrator account can configure GuardDuty, in addition to viewing and managing GuardDuty findings for their own account and all member accounts. For more information about this, see Managing multiple accounts in GuardDuty in the Amazon GuardDuty documentation.

Architecture

This pattern extends the Centralized Logging solution from the AWS Solutions Library to collect and process security-related IoT events. The Centralized Logging solution is deployed in the Security account and helps collect, analyze, and display Amazon CloudWatch logs in a single dashboard. This solution consolidates, manages, and analyzes log files from multiple sources. Finally, the Centralized Logging solution also uses Amazon OpenSearch Service (successor to Amazon Elasticsearch Service) and OpenSearch Dashboards to show a unified view of all log events.

The following architecture diagram shows the key components of an IoT security logging and reference architecture on the AWS Cloud.

The diagram shows the following workflow:
1. IoT things are the devices that must be monitored for anomalous security events. These devices run an agent to publish security events or metrics to AWS IoT Core and AWS IoT Device Defender.

2. When AWS IoT logging is enabled, AWS IoT sends progress events about each message as it passes from your devices through the message broker and rules engine to Amazon CloudWatch Logs. You can use CloudWatch Logs subscriptions to push events to a Centralized Logging solution. For more information about this, see AWS IoT metrics and dimensions in the AWS IoT Core documentation.

3. AWS IoT Device Defender helps monitor insecure configurations and security metrics for your IoT devices. When an anomaly is detected, alarms notify Amazon Simple Notification Service (Amazon SNS), which has an AWS Lambda function as a subscriber. The Lambda function sends the alarm as a message to CloudWatch Logs. You can use CloudWatch Logs subscriptions to push events to your Centralized Logging solution. For more information about this, see Audit checks, Device-side metrics, and Cloud-side metrics in the AWS IoT Core documentation.

4. AWS CloudTrail logs AWS IoT Core control plane actions that make changes (for example, creating, updating, or attaching APIs). When CloudTrail is set up as part of a landing zone implementation, it sends events to CloudWatch Logs and you can use subscriptions to push events to your Centralized Logging solution.

5. AWS Config managed rules or custom rules evaluate resources that are part of your IoT environment. Monitor your compliance change notifications using CloudWatch Events with CloudWatch Logs as the target. After compliance change notifications are sent to CloudWatch Logs, you can use subscriptions to push events to your Centralized Logging solution.

6. Amazon GuardDuty continuously analyzes CloudTrail management events and helps identify API calls made to AWS IoT Core endpoints from known malicious IP addresses, unusual geolocations, or anonymizing proxies. Monitor GuardDuty notifications using Amazon CloudWatch Events with log groups in CloudWatch Logs as the target. When GuardDuty notifications are sent to CloudWatch Logs, you can use subscriptions to push events to your Centralized Monitoring solution or use the GuardDuty console in your Security account to view the notifications.

7. AWS Security Hub monitors your IoT account by using security best practices. Monitor Security Hub notifications by using CloudWatch Events with log groups in CloudWatch Logs as the target. When Security Hub notifications are sent to CloudWatch Logs, use subscriptions to push events to your Centralized Monitoring solution or use the Security Hub console in your Security account to view the notifications.

8. Amazon Detective evaluates and analyzes information to isolate the root cause and take action on security findings for unusual calls to AWS IoT endpoints or other services in your IoT architecture.

9. Amazon Athena queries logs stored in your Log Archive account to enhance your understanding of security findings and identify trends and malicious activities.

### Tools

- **Amazon Athena** – Amazon Athena is an interactive query service that makes it easy to analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL.
- **AWS CloudTrail** – AWS CloudTrail helps you enable governance, compliance, and operational and risk auditing of your AWS account.
- **Amazon CloudWatch** – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.
- **Amazon CloudWatch Logs** – Amazon CloudWatch Logs centralizes the logs from all your systems, applications, and AWS services that you use. You can view and monitor the logs, search them for specific error codes or patterns, filter them based on specific fields, or archive them securely for future analysis.
- **AWS Config** – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account.
• **Amazon Detective** – Amazon Detective makes it easy to analyze, investigate, and quickly identify the root cause of security findings or suspicious activities.

• **AWS Glue** – AWS Glue is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.

• **Amazon GuardDuty** – Amazon GuardDuty is a continuous security monitoring service.

• **AWS IoT Core** – AWS IoT Core provides secure, bi-directional communication for Internet-connected devices (such as sensors, actuators, embedded devices, wireless devices, and smart appliances) to connect to the AWS Cloud over MQTT, HTTPS, and LoRaWAN.

• **AWS IoT Device Defender** – AWS IoT Device Defender is a security service that allows you to audit the configuration of your devices, monitor connected devices to detect abnormal behavior, and mitigate security risks.

• **Amazon OpenSearch Service** – Amazon OpenSearch Service (successor to Amazon Elasticsearch Service) is a managed service that makes it easy to deploy, operate, and scale OpenSearch clusters in the AWS Cloud.

• **AWS Organizations** – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into an organization that you create and centrally manage.

• **AWS Security Hub** – AWS Security Hub provides you with a comprehensive view of your security state in AWS and helps you check your environment against security industry standards and best practices.

• **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) provision a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you’ve defined. This virtual network closely resembles a traditional network that you’d operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

**Extract and query AWS IoT SiteWise metadata attributes in a data lake**

*Created by Ambarish Dongaonkar (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Technologies: IoT; Analytics; Big data</th>
<th>AWS services: AWS IoT SiteWise; AWS Lambda; AWS Glue</th>
</tr>
</thead>
</table>

**Summary**

AWS IoT SiteWise uses asset models and hierarchies to represent your industrial equipment, processes, and facilities. Each model or asset can have multiple attributes that are specific to your environment. Example metadata attributes include the site or physical location of the asset, plant details, and equipment identifiers. These attribute values complement asset measurement data to maximize the business value. Machine learning (ML) can provide additional insights into this metadata and streamline engineering tasks.

However, metadata attributes can’t be queried directly from the AWS IoT SiteWise service. To make the attributes queryable, you must extract and ingest them into a data lake. This pattern uses a Python script to extract the attributes for all AWS IoT SiteWise assets and ingest them into a data lake in an Amazon Simple Storage Service (Amazon S3) bucket. When you have completed this process, you can use SQL queries in Amazon Athena to access the AWS IoT SiteWise metadata attributes and other datasets, such as measurement datasets. The metadata attribute information is also useful when working with AWS IoT SiteWise monitors or dashboards. You can also build an AWS QuickSight dashboard by using the extracted attributes in the S3 bucket.

The pattern has reference code, and you can you can implement the code by using the best compute services for your use case, such as AWS Lambda or AWS Glue.

**Prerequisites and limitations**

**Prerequisites**
• An active AWS account.
• Permissions to set up AWS Lambda functions or AWS Glue jobs.
• An Amazon S3 bucket.
• The asset models and hierarchies are set up in AWS IoT SiteWise. For more information, see Creating asset models (AWS IoT SiteWise documentation).

Architecture

You can use a Lambda function or an AWS Glue job to complete this process. We recommend using Lambda if you have less than 100 models and each model has an average of 15 or fewer attributes. For all other use cases, we recommend using AWS Glue.

The solution architecture and workflow are shown in the following diagram.

1. The scheduled AWS Glue job or Lambda function runs. It extracts the asset metadata attributes from AWS IoT SiteWise and ingests them into an S3 bucket.
2. An AWS Glue crawler crawls the extracted data in the S3 bucket and creates tables in an AWS Glue Data Catalog.
3. Using standard SQL, Amazon Athena queries the tables in the AWS Glue Data Catalog.

Automation and scale

You can schedule the Lambda function or AWS Glue job to run daily or weekly, according to the update frequency of your AWS IoT SiteWise asset configurations.

There is no limit to the number of AWS IoT SiteWise assets that the sample code can process, but a large number of assets can increase the amount of time required to complete the process.

Tools

• Amazon Athena – Amazon Athena is an interactive query service that makes it easy to analyze data directly in Amazon Simple Storage Service (Amazon S3) using standard SQL.
• AWS Glue – AWS Glue is a fully managed extract, transform, and load (ETL) service that makes it simple and cost-effective to categorize your data, clean it, enrich it, and move it reliably between various data stores and data streams.
• **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

• **AWS IoT SiteWise** - AWS IoT SiteWise is a managed service designed to collect, model, analyze, and visualize data from industrial equipment at scale. AWS IoT SiteWise provides an asset modeling framework for building representations of your industrial devices, processes, and facilities.

• **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code isn’t running.

• **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.

• **SDK for Python** – AWS SDK for Python (Boto3) allows you to integrate your Python application, library, or script with AWS services.

Additional information

Code

The sample code provided is for reference, and you can customize this code as needed for your use case.

```python
# Following code can be used in an AWS Lambda function or in an AWS Glue Python shell job.
# IAM roles used for this job need read access to the AWS IoT SiteWise service and write
# access to the S3 bucket.
sw_client = boto3.client('iotsitewise')
s3_client = boto3.client('s3')
output = io.StringIO()

attribute_list=[]
bucket = '{3_bucket name}'
prefix = '{s3_bucket prefix}'
output.write("model_id,model_name,asset_id,asset_name,attribuet_id,attribute_name,attribute_value
\n")
m_resp = sw_client.list_asset_models()
for m_rec in m_resp['assetModelSummaries']:
    model_id = m_rec['id']
    model_name = m_rec['name']
    attribute_list.clear()  
dam_response = sw_client.describe_asset_model(assetModelId=model_id)
for rec in dam_response['assetModelProperties']:
    if 'attribute' in rec['type']:
        attribute_list.append(rec['name'])
response = sw_client.list_assets(assetModelId=model_id, filter='ALL')
for asset in response['assetSummaries']:
    asset_id = asset['id']
    asset_name = asset['name']
    resp = sw_client.describe_asset(assetId=asset_id)
    for rec in resp['assetProperties']:
        if rec['name'] in attribute_list:
            p_resp = sw_client.get_asset_property_value(assetId=asset_id,
            propertyId=rec['id'])
            if 'propertyValue' in p_resp:
                if p_resp['propertyValue']['value']:
                    if 'stringValue' in p_resp['propertyValue']['value']:
```

848
output.write(model_id + "," + model_name + "," + asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," + str(p_resp['propertyValue']['stringValue']) + "\n")
    if 'doubleValue' in p_resp['propertyValue']['value']:
        output.write(model_id + "," + model_name + "," + asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," + str(p_resp['propertyValue']['doubleValue']) + "\n")
    if 'integerValue' in p_resp['propertyValue']['value']:
        output.write(model_id + "," + model_name + "," + asset_id + "," + asset_name + "," + rec['id'] + "," + rec['name'] + "," + str(p_resp['propertyValue']['integerValue']) + "\n")
    if 'booleanValue' in p_resp['propertyValue']['value']:

### Analyze speech in real time using Amazon Transcribe and Amazon Comprehend

*Created by Suresh Konathala (AWS)*

| Environment: PoC or pilot | Technologies: Machine learning & AI; Websites & web apps; Security, identity, compliance | AWS services: Amazon Comprehend; Amazon S3; Amazon Transcribe; Amazon CloudFront |

**Summary**

Many organizations need to process and analyze conversations with their customers but audio data can be difficult to search and analyze. This pattern describes how to use Amazon Transcribe’s real-time transcription to convert speech into text and then analyze it using Amazon Comprehend to recognize and extract entities such as names, locations, or dates and quantities.

The front-end user interface (UI) is deployed as a static website in an Amazon Simple Storage Service (Amazon S3) bucket and accessed with Amazon CloudFront. When a user speaks, the audio data stream is sent over a WebSocket connection to an Amazon Transcribe streaming API.

This pattern also describes how to use an AWS Identity and Access Management (IAM) role with an attached policy to invoke Amazon Transcribe and Amazon Comprehend.

### Prerequisites and limitations

**Prerequisites**

- Amazon Transcribe
- Amazon Comprehend
- Amazon S3
- Amazon CloudFront
- IAM role and policy
• An active Amazon Web Services (AWS) account.
• IAM permissions to invoke Amazon Transcribe and Amazon Comprehend.
• The `frontend-app.zip` and `lambda_function.zip` files (attached), downloaded to your local computer.

Limitations

• You can improve the transcription's accuracy by providing custom vocabulary files. For more information about this, see Custom vocabularies in the Amazon Transcribe documentation.

• The built-in version of Amazon Comprehend only recognizes entities such as names of people, locations, or dates. You can use Amazon Comprehend’s custom entity recognition to extract business-specific entities that fit your use case (for example, product codes). For more information about this, see Custom entity recognition in the Amazon Comprehend documentation.

Architecture

The diagram shows the following workflow:

1. The contents of a static website are hosted on Amazon S3 and served using a CloudFront distribution. A user accesses the website and the following webpage appears:
2. After the user clicks the microphone icon, the browser makes a REST API call to Amazon API Gateway. API Gateway then invokes an AWS Lambda function.

3. The Lambda function assumes an IAM role with an attached policy that has permission to invoke Amazon Transcribe and Amazon Comprehend. The Lambda function invokes the AWS Security Token Service (AWS STS) API to fetch the temporary access key ID and secret access key credentials. These temporary access credentials are sent to the browser in the REST API call response.

4. The front-end UI captures the microphone's live audio by using a microphone stream npm module. The UI sends the audio stream to an Amazon Transcribe WebSocket API. This API responds with a stream of transcribed text.

5. The transcribed text is sent to Amazon Comprehend for analysis and entity recognition. Amazon Comprehend responds with a list of identified entities (for example, names of people, locations, and specific dates or quantities). The following image shows how the UI uses this information to color code the text and display it:
Technology stack

- CloudFront
- Amazon Comprehend
- IAM
- Amazon S3
- Amazon Transcribe
- ReactJS
- Python3
- Boto3

Tools

- **Amazon API Gateway** – API Gateway is an AWS service for creating, publishing, maintaining, monitoring, and securing REST, HTTP, and WebSocket APIs at any scale.
- **Amazon Comprehend** – Amazon Comprehend uses natural language processing (NLP) to extract insights about the content of documents.
- **AWS Identity and Access Management (IAM)** – IAM is a web service that helps you securely control access to AWS resources.
- **AWS Lambda** – Lambda supports running code without provisioning or managing servers.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is a highly scalable object storage service that can be used for a wide range of storage solutions, including websites, backups, and data lakes.
- **AWS STS** – AWS Security Token Service (AWS STS) is a web service that enables you to request temporary, limited-privilege credentials for IAM users or for users that you authenticate.
- **Amazon Transcribe** – Amazon Transcribe uses a deep learning process called automatic speech recognition (ASR) to convert speech to text quickly and accurately.

Code

The `frontend-app.zip` and `lambda_function.zip` files (attached) contain the source code for this pattern.

Automatically extract content from PDF files using Amazon Textract

*Created by Tianxia Jia (AWS)*

| Environment: Production | Technologies: Machine learning & AI; Analytics; Big data | AWS services: Amazon S3; Amazon Textract; Amazon SageMaker |

Summary

Many organizations need to extract information from PDF files that are uploaded to their business applications. For example, an organization could need to accurately extract information from tax or medical PDF files for tax analysis or medical claim processing.

On the Amazon Web Services (AWS) Cloud, Amazon Textract automatically extracts information (for example, printed text, forms, and tables) from PDF files and produces a JSON-formatted file that contains information from the original PDF file. You can use Amazon Textract in the AWS Management Console or by implementing API calls. We recommend that you use programmatic API calls to scale and automatically process large numbers of PDF files.

When Amazon Textract processes a file, it creates the following list of Block objects: pages, lines and words of text, forms (key-value pairs), tables and cells, and selection elements. Other object information is also included, for example, bounding boxes, confidence intervals, IDs, and relationships. Amazon Textract extracts the content information as strings. Correctly identified and transformed data values are required because they can be more easily used by your downstream applications.

This pattern describes a step-by-step workflow for using Amazon Textract to automatically extract content from PDF files and process it into a clean output. The pattern uses a template matching technique to correctly identify the required field, key name, and tables, and then applies post-processing corrections to each data type. You can use this pattern to process different types of PDF files and you can then scale and automate this workflow to process PDF files that have an identical format.

Prerequisites and limitations

**Prerequisites**
• An active AWS account.
• An existing Amazon Simple Storage Service (Amazon S3) bucket to store the PDF files after they are converted to JPEG format for processing by Amazon Textract. For more information about S3 buckets, see Buckets overview in the Amazon S3 documentation.
• The Textract_PostProcessing.ipynb Jupyter notebook (attached), installed and configured. For more information about Jupyter notebooks, see Create a Jupyter notebook in the Amazon SageMaker documentation.
• Existing PDF files that have an identical format.
• An understanding of Python.

Limitations

• Your PDF files must be of good quality and clearly readable. Native PDF files are recommended, but you can use scanned documents that are converted to a PDF format if all the individual words are clear. For more information about this, see PDF document preprocessing with Amazon Textract: Visuals detection and removal on the AWS Machine Learning Blog.
• For multipage files, you can use an asynchronous operation or split the PDF files into a single page and use a synchronous operation. For more information about these two options, see Detecting and analyzing text in multipage documents and Detecting and analyzing text in single-page documents in the Amazon Textract documentation.

Architecture

This pattern’s workflow first runs Amazon Textract on a sample PDF file (First-time run) and then runs it on PDF files that have an identical format to the first PDF (Repeat run). The following diagram shows the combined First-time run and Repeat run workflow that automatically and repeatedly extracts content from PDF files with identical formats.

1. Convert a PDF file into JPEG format and store it in an S3 bucket.
2. Call the Amazon Textract API and parse the Amazon Textract response JSON file.
3. Edit the JSON file by adding the correct KeyName:DataType pair for each required field. Create a TemplateJSON file for the Repeat run stage.
4. Define the post-processing correction functions for each data type (for example, float, integer, and date).
5. Prepare the PDF files that have an identical format to your first PDF file.
6. Call the Amazon Textract API and parse the Amazon Textract response JSON.
7. Match the parsed JSON file with the `TemplateJSON` file.
8. Implement post-processing corrections.

The final JSON output file has the correct `KeyName` and `Value` for each required field.

**Target technology stack**
- Amazon SageMaker
- Amazon S3
- Amazon Textract

**Automation and scale**
You can automate the *Repeat run* workflow by using an AWS Lambda function that initiates Amazon Textract when a new PDF file is added to Amazon S3. Amazon Textract then runs the processing scripts and the final output can be saved to a storage location. For more information about this, see *Using an Amazon S3 trigger to invoke a Lambda function* in the Lambda documentation.

**Tools**
- **Amazon SageMaker** – SageMaker is a fully managed ML service that helps you to quickly and easily build and train ML models, and then directly deploy them into a production-ready hosted environment.
- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is storage for the internet.
- **Amazon Textract** – Amazon Textract makes it easy to add document text detection and analysis to your applications.

**Epics**

**First-time run**

Create a custom Docker container image for SageMaker and use it for model training in AWS Step Functions

Created by Julia Bluszcz (AWS), Aubrey Oosthuizen (AWS), Mohan Gowda Purushothama (AWS), and Mateusz Zaremba (AWS)

| Environment: Production | Technologies: Machine learning & AI; DevOps | AWS services: Amazon ECR; Amazon SageMaker; AWS Step Functions |

Summary

This pattern shows how to create a Docker container image for Amazon SageMaker and use it for a training model in AWS Step Functions. By packaging custom algorithms in a container, you can run almost any code in the SageMaker environment, regardless of programming language, framework, or dependencies.

In the example SageMaker notebook provided, the custom Docker container image is stored in Amazon Elastic Container Registry (Amazon ECR). Step Functions then uses the container that's stored in Amazon ECR to run a Python SageMaker processing script. Then, the container exports the model to Amazon Simple Storage Service (Amazon S3).

Prerequisites and limitations

**Prerequisites**

- An active AWS account
- A SageMaker AWS Identity and Access Management (IAM) role with Amazon S3 permissions
- An IAM execution role for Step Functions
- Familiarity with Python
- Familiarity with Amazon SageMaker Python SDK
- Familiarity with the AWS Command Line Interface (AWS CLI)
- Familiarity with AWS SDK for Python (Boto3)
- Familiarity with Amazon ECR
- Familiarity with Docker

**Product versions**

- AWS Step Functions Data Science SDK v2.3.0
- Amazon SageMaker Python SDK v2.78.0

**Architecture**

The following diagram shows an example workflow for creating a Docker container image for SageMaker, then using it for a training model in Step Functions:

![Diagram showing the workflow](image)

The diagram shows the following workflow:

1. A data scientist or DevOps engineer uses a SageMaker notebook to create a custom Docker container image.
2. A data scientist or DevOps engineer stores the Docker container image in an Amazon ECR private repository that’s in a private registry.
3. A data scientist or DevOps engineer uses the Docker container to run a Python SageMaker processing job in a Step Functions workflow.

**Automation and scale**
The example SageMaker notebook in this pattern uses an ml.m5.xlarge notebook instance type. You can change the instance type to fit your use case. For more information about SageMaker notebook instance types, see Amazon SageMaker Pricing.

**Technology stack**

- SageMaker
- Amazon ECR
- Step Functions

**Tools**

- Amazon Elastic Container Registry (Amazon ECR) is a managed container image registry service that’s secure, scalable, and reliable.
- Amazon SageMaker is a managed machine learning (ML) service that helps you build and train ML models and then deploy them into a production-ready hosted environment.
- Amazon SageMaker Python SDK is an open-source library for training and deploying machine-learning models on SageMaker.
- AWS Step Functions is a serverless orchestration service that helps you combine AWS Lambda functions and other AWS services to build business-critical applications.
- AWS Step Functions Data Science Python SDK is an open-source library that helps you create Step Functions workflows that process and publish machine learning models.

</tbody>
</table>
| Build your Docker container image and push it to Amazon ECR. | 1. Build the container image using the Dockerfile that you created by running the `docker build` command in the AWS CLI.  
2. Push the container image to Amazon ECR by running the `docker push` command. | DevOps engineer |

For more information, see Building and registering the container in Building your own algorithm container on GitHub. Example Jupyter notebook code cells to build and register a Docker image

**Important:** Before running the following cells, make sure that you’ve created a Dockerfile and stored it in the directory called `docker`. Also, make sure that you’ve created an Amazon ECR repository, and that you replace the `ecr_repository` value in the first cell with your repository’s name.

**Cell 1**

```python
import boto3
tag = ':latest'
account_id = boto3.client('sts').get_caller_identity().get('Account')
region = boto3.Session().region_name
ecr_repository = 'byoc'

image_uri = '{}.dkr.ecr.{}.amazonaws.com/{}'.format(account_id, region, ecr_repository + tag)
```

**Cell 2**

```bash
# Build docker image
!docker build -t $image_uri
docker
```

**Cell 3**

```bash
# Authenticate to ECR
```

</tbody>
</table>
### Example SageMaker processing step definition that uses a custom Amazon ECR image and Python script

**Note:** Make sure that you use the `execution_input` parameter to specify the job name. The parameter's value must be unique each time the job runs. Also, the `training.py` file's code is passed as an `input` parameter to the `ProcessingStep`, which means that it will be copied inside the container. The destination for the `ProcessingInput` code is the same as the second argument inside the `container_entrypoint`.

```python
code = sagemaker_session.upload_data(
    "training.py",
    bucket=bucket,
    key_prefix="preprocessing.py",
)

script_processor = ScriptProcessor(command=['python3'],
    image_uri=image_uri,
    role=role,
    instance_count=1,
    instance_type='ml.m5.xlarge')

processing_step = steps.ProcessingStep("training-step",
    processor=script_processor,
    job_name=execution_input["PreprocessingJobName"],
    inputs=[
        ProcessingInput(
            source=input_code,
            destination="/opt/ml/processing/input/code",
            input_name="code",
        )
    ]
)
```

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>&quot;PreprocessingJobName&quot;: str)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>input_code = sagemaker_session.upload_data(&quot;training.py&quot;, bucket=bucket, key_prefix=&quot;preprocessing.py&quot;)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Example SageMaker processing step definition that uses a custom Amazon ECR image and Python script</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Make sure that you use the <code>execution_input</code> parameter to specify the job name. The parameter's value must be unique each time the job runs. Also, the <code>training.py</code> file's code is passed as an <code>input</code> parameter to the <code>ProcessingStep</code>, which means that it will be copied inside the container. The destination for the <code>ProcessingInput</code> code is the same as the second argument inside the <code>container_entrypoint</code>.</td>
<td></td>
</tr>
</tbody>

Example Step Functions workflow that runs a SageMaker processing job

Note: This example workflow includes the SageMaker processing job step only, not a complete Step Functions workflow. For a full example workflow, see Example notebooks in SageMaker in the AWS Step Functions Data Science SDK documentation.
Train and deploy a custom GPU-supported ML model on Amazon SageMaker

Created by Ankur Shukla (AWS)

Environment: PoC or pilot  Technologies: Machine learning & AI; Containers & microservices  AWS services: Amazon ECS; Amazon SageMaker

Summary

Training and deploying a graphics processing unit (GPU)-supported machine learning (ML) model requires an initial setup and initialization of certain environment variables to fully unlock the benefits of NVIDIA GPUs. However, it can be time-consuming to set up the environment and make it compatible with Amazon SageMaker architecture on the Amazon Web Services (AWS) Cloud.

This pattern helps you train and build a custom GPU-supported ML model using Amazon SageMaker. It provides steps to train and deploy a custom CatBoost model built on an open-source Amazon reviews dataset. You can then benchmark its performance on a p3.16xlarge Amazon Elastic Compute Cloud (Amazon EC2) instance.

This pattern is useful if your organization wants to deploy existing GPU-supported ML models on SageMaker. Your data scientists can follow the steps in this pattern to create NVIDIA GPU-supported containers and deploy ML models on those containers.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An Amazon Simple Storage Service (Amazon S3) source bucket to store the model artifacts and predictions.
- An understanding of SageMaker notebook instances and Jupyter notebooks.
- An understanding of how to create an AWS Identity and Access Management (IAM) role with basic SageMaker role permissions, S3 bucket access and update permissions, and additional permissions for Amazon Elastic Container Registry (Amazon ECR).

Limitations
• This pattern is intended for supervised ML workloads with a train and deploy code written in Python.

Architecture

Technology stack
• SageMaker
• Amazon ECR

Tools

Tools
• Amazon ECR – Amazon Elastic Container Registry (Amazon ECR) is an AWS managed container image registry service that is secure, scalable, and reliable.
• Amazon SageMaker – SageMaker is a fully managed ML service.
• Docker – Docker is a software platform for building, testing, and deploying applications quickly.
• Python – Python is a programming language.

Code

The code for this pattern is available on the GitHub Implementing a review classification model with Catboost and SageMaker repository.

Use SageMaker Processing for distributed feature engineering of terabyte-scale ML datasets

Created by Chris Boomhower (AWS)

Environment: Production  Technologies: Machine learning & AI; Big data  AWS services: Amazon SageMaker

Summary

Many terabyte-scale or larger datasets often consist of a hierarchical folder structure, and the files in the dataset sometimes share interdependencies. For this reason, machine learning (ML) engineers and data scientists must make thoughtful design decisions to prepare such data for model training and inference. This pattern demonstrates how you can use manual macrosharding and microsharding techniques in combination with Amazon SageMaker Processing and virtual CPU (vCPU) parallelization to efficiently scale feature engineering processes for complicated big data ML datasets.
This pattern defines macrosharding as the splitting of data directories across multiple machines for processing, and microsharding as the splitting of data on each machine across multiple processing threads. The pattern demonstrates these techniques by using Amazon SageMaker with sample time-series waveform records from the PhysioNet MIMIC-III dataset. By implementing the techniques in this pattern, you can minimize the processing time and costs for feature engineering while maximizing resource utilization and throughput efficiency. These optimizations rely on distributed SageMaker Processing on Amazon Elastic Compute Cloud (Amazon EC2) instances and vCPUs for similar, large datasets, regardless of data type.

Prerequisites and limitations

Prerequisites

- Access to SageMaker notebook instances or SageMaker Studio, if you want to implement this pattern for your own dataset. If you are using Amazon SageMaker for the first time, see Get started with Amazon SageMaker in the AWS documentation.
- SageMaker Studio, if you want to implement this pattern with the PhysioNet MIMIC-III sample data.
- The pattern uses SageMaker Processing, but doesn’t require any experience running SageMaker Processing jobs.

Limitations

- This pattern is well suited to ML datasets that include interdependent files. These interdependencies benefit the most from manual macrosharding and running multiple, single-instance SageMaker Processing jobs in parallel. For datasets where such interdependencies do not exist, the ShardedByS3Key feature in SageMaker Processing might be a better alternative to macrosharding, because it sends sharded data to multiple instances that are managed by the same Processing job. However, you can implement this pattern’s microsharding strategy in both scenarios to best utilize instance vCPUs.

Product versions

- Amazon SageMaker Python SDK version 2

Architecture

Target technology stack

- Amazon Simple Storage Service (Amazon S3)
- Amazon SageMaker

Target architecture

Macrosharding and distributed EC2 instances

The 10 parallel processes represented in this architecture reflect the structure of the MIMIC-III dataset. (Processes are represented by ellipses for diagram simplification.) A similar architecture applies to any dataset when you use manual macrosharding. In the case of MIMIC-III, you can use the dataset’s raw structure to your advantage by processing each patient group folder separately, with minimal effort. In the following diagram, the record groups block appears on the left (1). Given the distributed nature of the data, it makes sense to shard by patient group.
However, manually sharding by patient group means that a separate Processing job is required for each patient group folder, as you can see in the middle section of the diagram (2), instead of a single Processing job with multiple EC2 instances. Because MIMIC-III's data includes both binary waveform files and matching text-based header files, and there is a required dependency on the `wfdb` library for binary data extraction, all the records for a specific patient must be made available on the same instance. The only way to be certain that each binary waveform file's associated header file is also present is to implement manual sharding to run each shard within its own Processing job, and to specify `s3_data_distribution_type='FullyReplicated'` when you define the Processing job input.

Alternatively, if all data were available in a single directory and no dependencies existed between files,
a more suitable option might be to launch a single Processing job with multiple EC2 instances and `s3_data_distribution_type='ShardedByS3Key'` specified. Specifying `ShardedByS3Key` as the Amazon S3 data distribution type directs SageMaker to manage data sharding automatically across instances.

Launching a Processing job for each folder is a cost-efficient way to preprocess the data, because running multiple instances concurrently saves time. For additional cost and time savings, you can use microsharding within each Processing job.

**Microsharding and parallel vCPUs**

Within each Processing job, the grouped data is further divided to maximize use of all available vCPUs on the SageMaker fully managed EC2 instance. The blocks in the middle section of the diagram (2) depict what happens within each primary Processing job. The contents of the patient record folders are flattened and divided evenly based on the number of available vCPUs on the instance. After the folder contents are divided, the evenly sized set of files are distributed across all vCPUs for processing. When processing is complete, the results from each vCPU are combined into a single data file for each Processing job.

In the attached code, these concepts are represented in the following section of the `src/feature-engineering-pass1/preprocessing.py` file.

```python
def chunks(lst, n):
    """
    Yield successive n-sized chunks from lst.
    """
    for i in range(0, len(lst), n):
        yield lst[i:i + n]

# Generate list of data files on machine
data_dir = input_dir
d_subs = next(os.walk(os.path.join(data_dir, '.')))[1]
file_list = []
for ds in d_subs:
    file_list.extend(os.listdir(os.path.join(data_dir, ds, '.'))
dat_list = [os.path.join(re.split('_|\.', f)[0].replace('n', ''), f[:-4]) for f in file_list if f[-4:] == '.dat']

# Split list of files into sub-lists
cpu_count = multiprocessing.cpu_count()
splits = int(len(dat_list) / cpu_count)
if splits == 0: splits = 1
dat_chunks = list(chunks(dat_list, splits))

# Parallelize processing of sub-lists across CPUs
ws_df_list = Parallel(n_jobs=-1, verbose=0)(delayed(run_process)(dc) for dc in dat_chunks)

# Compile and pickle patient group dataframe
ws_df_group = pd.concat(ws_df_list).reset_index().rename(columns={'index': 'signal'}
ws_df_group.to_json(os.path.join(output_dir, group_data_out))
```

A function, `chunks`, is first defined to consume a given list by dividing it into evenly sized chunks of length `n` and by returning these results as a generator. Next, the data is flattened across patient folders by compiling a list of all binary waveform files that are present. After this is done, the number of vCPUs
available on the EC2 instance is obtained. The list of binary waveform files is evenly divided across these vCPUs by calling chunks, and then each waveform sublist is processed on its own vCPU by using joblib's Parallel class. Results are automatically combined into a single list of dataframes by the Processing job, which SageMaker then processes further before writing it to Amazon S3 upon job completion. In this example, there are 10 files written to Amazon S3 by the Processing jobs (one for each job).

When all the initial Processing jobs are complete, a secondary Processing job, which is shown in the block to the right of the diagram (3) combines the output files produced by each primary Processing job and writes the combined output to Amazon S3 (4).

**Tools**

- **Python** – The sample code used for this pattern is Python (version 3).
- **SageMaker Studio** – Amazon SageMaker Studio is a web-based, integrated development environment (IDE) for machine learning that lets you build, train, debug, deploy, and monitor your machine learning models. You run SageMaker Processing jobs by using Jupyter notebooks inside SageMaker Studio.
- **SageMaker Processing** – Amazon SageMaker Processing provides a simplified way to run your data processing workloads. In this pattern, the feature engineering code is implemented at scale by using SageMaker Processing jobs.

**Code**

The attached .zip file provides the complete code for this pattern. The following section describes the steps to build the architecture for this pattern. Each step is illustrated by sample code from the attachment.

Visualize AI/ML model results using Flask and AWS Elastic Beanstalk

*Created by Chris Caudill (AWS) and Durga Sury (AWS)*

**AWS services:** Amazon Comprehend; AWS Elastic Beanstalk

**Summary**

Visualizing output from artificial intelligence and machine learning (AI/ML) services often requires complex API calls that must be customized by your developers and engineers. This can be a drawback if your analysts want to quickly explore a new dataset.

You can enhance the accessibility of your services and provide a more interactive form of data analysis by using a web-based user interface (UI) that enables users to upload their own data and visualize the model results in a dashboard.

This pattern uses Flask and Plotly to integrate Amazon Comprehend with a custom web application and visualize sentiments and entities from user-provided data. The pattern also provides the steps to deploy an application by using AWS Elastic Beanstalk. You can adapt the application by using Amazon Web Services (AWS) AI services or with a custom trained model hosted on an endpoint (for example, an Amazon SageMaker endpoint).

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured on your local machine. For more information about this, see Configuration basics in the AWS CLI documentation. You can also use
an AWS Cloud9 integrated development environment (IDE); for more information about this, see Python tutorial for AWS Cloud9 and Previewing running applications in the AWS Cloud9 IDE in the AWS Cloud9 documentation.

- An understanding of Flask's web application framework. For more information about Flask, see the Quickstart in the Flask documentation.
- Python version 3.6 or later, installed and configured. You can install Python by following the instructions from Setting up your Python development environment in the AWS Elastic Beanstalk documentation.
- Elastic Beanstalk Command Line Interface (EB CLI), installed and configured. For more information about this, see Install the EB CLI and Configure the EB CLI from the AWS Elastic Beanstalk documentation.

Limitations

- This pattern's Flask application is designed to work with .csv files that use a single text column and are restricted to 200 rows. The application code can be adapted to handle other file types and data volumes.
- The application doesn't consider data retention and continues to aggregate uploaded user files until they are manually deleted. You can integrate the application with Amazon Simple Storage Service (Amazon S3) for persistent object storage or use a database such as Amazon DynamoDB for serverless key-value storage.
- The application only considers documents in the English language. However, you can use Amazon Comprehend to detect a document's primary language. For more information about the supported languages for each action, see API reference in the Amazon Comprehend documentation.
- A troubleshooting list that contains common errors and their solutions is available in the Additional information section.

Architecture

Flask application architecture

Flask is a lightweight framework for developing web applications in Python. It is designed to combine Python's powerful data processing with a rich web UI. The pattern's Flask application shows you how to build a web application that enables users to upload data, sends the data to Amazon Comprehend for inference, and then visualizes the results. The application has the following structure:

- static – Contains all the static files that support the web UI (for example, JavaScript, CSS, and images)
- templates – Contains all of the application's HTML pages
- userData – Stores uploaded user data
- application.py – The Flask application file
- comprehend_helper.py – Functions to make API calls to Amazon Comprehend
- config.py – The application configuration file
- requirements.txt – The Python dependencies required by the application

The application.py script contains the web application's core functionality, which consists of four Flask routes. The following diagram shows these Flask routes.
1. User uploads data.

   Route: / (root)

2. Uploaded data is sent to the /saveFile route to be saved.

   Route: /saveFile

3. After the file is saved, user is redirected to the /dashboard route.

   Route: /dashboard

4. The /dashboard renders an HTML page that initiates JavaScript code to read the JSON-formatted AI/ML response from the /data route.

   Route: /data

5. Results are visualized and returned to the user.

- / is the application's root and directs users to the upload.html page (stored in the templates directory).

- /saveFile is a route that is invoked after a user uploads a file. This route receives a POST request via an HTML form, which contains the file uploaded by the user. The file is saved in the userData directory and the route redirects users to the /dashboard route.

- /dashboard sends users to the dashboard.html page. Within this page's HTML, it runs the JavaScript code in static/js/core.js that reads data from the /data route and then builds visualizations for the page.

- /data is a JSON API that presents the data to be visualized in the dashboard. This route reads the user-provided data and uses the functions in comprehend_helper.py to send the user data to Amazon Comprehend for sentiment analysis and named entity recognition (NER). Amazon Comprehend's response is formatted and returned as a JSON object.

**Deployment architecture**

---

AWS Prescriptive Guidance Patterns

Architecture
For more information about design considerations for applications deployed using Elastic Beanstalk on the AWS Cloud, see Design considerations in the AWS Elastic Beanstalk documentation.

Technology stack

- Amazon Comprehend
- Elastic Beanstalk
- Flask

Automation and scaling

Elastic Beanstalk deployments are automatically set up with load balancers and auto scaling groups. For more configuration options, see Configuring Elastic Beanstalk environments in the AWS Elastic Beanstalk documentation.

Tools

- AWS Command Line Interface (AWS CLI) – AWS CLI is a unified tool that provides a consistent interface for interacting with all parts of AWS.
- Amazon Comprehend - Amazon Comprehend uses natural language processing (NLP) to extract insights about the content of documents without requiring special preprocessing.
- AWS Elastic Beanstalk – Elastic Beanstalk helps you quickly deploy and manage applications in the AWS Cloud without having to learn about the infrastructure that runs those applications.
- Elastic Beanstalk CLI (EB CLI) – EB CLI is a command line interface for AWS Elastic Beanstalk that provides interactive commands to simplify creating, updating, and monitoring environments from a local repository.
- Flask – The Flask framework performs data processing and API calls using Python and offers interactive web visualization with Plotly.

Code
The code for this pattern is available in the GitHub Visualize AI/ML model results using Flask and AWS Elastic Beanstalk repository.

# Epics

## Set up the Flask application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Clone the GitHub repository. | Pull the application code from the GitHub Visualize AI/ML model results using Flask and AWS Elastic Beanstalk repository by running the following command:  
```bash
    git clone git@github.com:aws-samples/aws-comprehend-elasticbeanstalk-for-flask.git
```
  
  **Note:** Make sure that you configure your SSH keys with GitHub.                                                                                     | Developer             |
| Install the Python modules. | After you clone the repository, a new local aws-comprehend-elasticbeanstalk-for-flask directory is created. In that directory, the requirements.txt file contains the Python modules and versions that run the application. Use the following commands to install the modules: 
```bash
    cd aws-comprehend-elasticbeanstalk-for-flask
    pip install -r requirements.txt
```
                                                                                                                               | Python developer     |
| Test the application locally. | Start the Flask server by running the following command: 
```bash
    python application.py
```
  
  This returns information about the running server. You should be able to access the application by opening a browser and visiting http://localhost:5000 | Python developer     |
### AWS Prescriptive Guidance Patterns

#### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> If you're running the application in an AWS Cloud9 IDE, you need to replace the <code>application.run()</code> command in the <code>application.py</code> file with the following line:</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>application.run(host=os.getenv('IP', '0.0.0.0'),port=int(os.getenv('PORT', 8080)))</code></td>
<td>Architect, Developer</td>
<td></td>
</tr>
<tr>
<td>You must revert this change before deployment.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

#### Deploy the application to Elastic Beanstalk

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Launch the Elastic Beanstalk application.</strong></td>
<td>To launch your project as an Elastic Beanstalk application, run the following command from your application's root directory:</td>
<td>Architect, Developer</td>
</tr>
<tr>
<td><code>eb init -p python-3.6 comprehend_flask --region us-east-1</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Important:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• <code>comprehend_flask</code> is the name of the Elastic Beanstalk application and can be changed according to your requirements.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• You can replace the AWS Region with a Region of your choice. The default Region in AWS CLI is used if you don't specify a Region.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>• The application was built with Python version 3.6. You might encounter errors if you use other Python versions.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Run the <code>eb init -i</code> command for more deployment configuration options.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Deploy the Elastic Beanstalk environment.</strong></td>
<td>Run the following command from the application's root directory:</td>
<td>Architect, Developer</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>
<td><strong>Authorize your deployment to use Amazon Comprehend.</strong></td>
<td>Although your application might be successfully deployed, you should also provide your deployment with access to Amazon Comprehend. ComprehendFullAccess is an AWS managed policy that provides the deployed application with permissions to make API calls to Amazon Comprehend. Attach the ComprehendFullAccess policy to aws-elasticbeanstalk-ec2-role (this role is automatically created for your deployment's Amazon Elastic Compute Cloud (Amazon EC2) instances) by running the following command:</td>
<td>Developer, Security architect</td>
</tr>
</tbody>
</table>

```bash
easw iam attach-role-policy --policy-name arn:aws:iam::aws:policy/ComprehendFullAccess --role-name aws-elasticbeanstalk-ec2-role
```

**Important:** aws-elasticbeanstalk-ec2-role is created when your application deploys. You must complete the deployment process before you can attach the AWS Identity and Access Management (IAM) policy.

**Note:** comprehend-flask-env is the name of the Elastic Beanstalk environment and can be changed according to your requirements. The name can only contain letters, numbers, and dashes.
### Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Visit your deployed application.</strong></td>
<td>After your application successfully deploys, you can visit it by running the <code>eb open</code> command. You can also run the <code>eb status</code> command to receive details about your deployment. The deployment URL is listed under CNAME.</td>
<td>Architect, Developer</td>
</tr>
</tbody>
</table>

**Optional) Customize the application to your ML model**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Authorize Elastic Beanstalk to access the new model.</strong></td>
<td>Make sure that Elastic Beanstalk has the required access permissions for your new model endpoint. For example, if you use an Amazon SageMaker endpoint, your deployment needs to have permission to invoke the endpoint. For more information about this, see <code>InvokeEndpoint</code> in the Amazon SageMaker documentation.</td>
<td>Developer, Security architect</td>
</tr>
</tbody>
</table>
| **Send the user data to a new model.** | To change the underlying ML model in this application, you must change the following files:  
  - `comprehend_helper.py` – This is the Python script that connects with Amazon Comprehend, processes the response, and returns the final result to the application. In this script, you can either route the data to another AI service on the AWS Cloud or you can send the data to a custom model endpoint. We recommend that you also format the results in this script for logical separation and the reusability of this pattern.  
  - `application.py` – If you change the name of the `comprehend_helper.py` script or functions, you need to update the application. | Data scientist |
# AWS Prescriptive Guidance Patterns

## Epics

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>application.py script to reflect those changes.</td>
<td></td>
</tr>
</tbody>
</table>
| Update the dashboard visualizations. | Typically, incorporating a new ML model means that visualizations must be updated to reflect the new results. These changes are made in the following files:  
- templates/dashboard.html – The prebuilt application only accounts for two basic visualizations. The entire layout of the page can be adjusted in this file.  
- static/js/core.js – This script captures the formatted output of the Flask server's /data route and uses Plotly to create visualizations. You can add or update the page's charts. | Web developer |

(Optional) Deploy the updated application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| Update your application's requirements file. | Before sending changes to Elastic Beanstalk, update the requirements.txt file to reflect any new Python modules by running the following command in your application's root directory:  

    pip freeze > requirements.txt | Python developer |
| Redeploy the Elastic Beanstalk environment. | To ensure that your application changes are reflected in your Elastic Beanstalk deployment, navigate to your application's root directory and run the following command:  

    eb deploy  

This sends the most recent version of the application's code to your existing Elastic Beanstalk deployment. | Systems administrator, Architect |

Additional information

Troubleshooting list

The following are six common errors and their solutions.

Error 1

Unable to assume role "arn:aws:iam::xxxxxxxxxx:role/aws-elasticbeanstalk-ec2-role". Verify that the role exists and is configured correctly.

Solution: If this error occurs when you run `eb create`, create a sample application on the Elastic Beanstalk console to create the default instance profile. For more information about this, see Creating an Elastic Beanstalk environment in the AWS Elastic Beanstalk documentation.

Error 2

Your WSGIPath refers to a file that does not exist.

Solution: This error occurs in deployment logs because Elastic Beanstalk expects the Flask code to be named `application.py`. If you chose a different name, run `eb config` and edit the WSGIPath as shown in the following code sample:

```bash
aws:elasticbeanstalk:container:python:
  NumProcesses: '1'
  NumThreads: '15'
  StaticFiles: /static/=static/
  WSGIPath: application.py
```

Make sure that you replace `application.py` with your file name.

You can also leverage Gunicorn and a Procfile. For more information about this approach, see Configuring the WSGI server with a Procfile in the AWS Elastic Beanstalk documentation.

Error 3

Target WSGI script '/opt/python/current/app/application.py' does not contain WSGI application 'application'.

Solution: Elastic Beanstalk expects the variable that represents your Flask application to be named `application`. Make sure that the `application.py` file uses `application` as the variable name:

```python
application = Flask(__name__)
```

Error 4
The EB CLI cannot find your SSH key file for keyname

**Solution:** Use the EB CLI to specify which key pair to use or to create a key pair for your deployment's EC2 instances. To resolve the error, run `eb init -i` and one of the options will ask:

Do you want to set up SSH for your instances?

Respond with Y to either create a key pair or specify an existing key pair.

**Error 5**

*I've updated my code and redeployed but my deployment is not reflecting my changes.*

**Solution:** If you're using a Git repository with your deployment, make sure that you add and commit your changes before redeploying.

**Error 6**

*You are previewing the Flask application from an AWS Cloud9 IDE and run into errors.*

**Solution:** For more information about this, see Previewing running applications in the AWS Cloud9 IDE in the AWS Cloud9 documentation.

**Natural language processing using Amazon Comprehend**

By choosing to use Amazon Comprehend, you can detect custom entities in individual text documents by running real-time analysis or asynchronous batch jobs. Amazon Comprehend also enables you to train custom entity recognition and text classification models that can be used in real time by creating an endpoint.

This pattern uses asynchronous batch jobs to detect sentiments and entities from an input file that contains multiple documents. The sample application provided by this pattern is designed for users to upload a .csv file containing a single column with one text document per row. The `comprehend_helper.py` file in the GitHub Visualize AI/ML model results using Flask and AWS Elastic Beanstalk repository reads the input file and sends the input to Amazon Comprehend for processing.

**BatchDetectEntities**

Amazon Comprehend inspects the text of a batch of documents for named entities and returns the detected entity, location, type of entity, and a score that indicates Amazon Comprehend's level of confidence. A maximum of 25 documents can be sent in one API call, with each document smaller than 5,000 bytes in size. You can filter the results to show only certain entities based on the use case. For example, you could skip the 'quantity' entity type and set a threshold score for the detected entity (for example, 0.75). We recommend that you explore the results for your specific use case before choosing a threshold value. For more information about this, see BatchDetectEntities in the Amazon Comprehend documentation.

**BatchDetectSentiment**

Amazon Comprehend inspects a batch of incoming documents and returns the prevailing sentiment for each document (POSITIVE, NEUTRAL, MIXED, or NEGATIVE). A maximum of 25 documents can be sent in one API call, with each document smaller than 5,000 bytes in size. Analyzing the sentiment is straightforward and you choose the sentiment with the highest score to be displayed in the final results. For more information about this, see BatchDetectSentiment in the Amazon Comprehend documentation.
Flask configuration handling

Flask servers use a series of configuration variables to control how the server runs. These variables can contain debug output, session tokens, or other application settings. You can also define custom variables that can be accessed while the application is running. There are multiple approaches for setting configuration variables.

In this pattern, the configuration is defined in config.py and inherited within application.py.

- config.py contains the configuration variables that are set up on the application's startup. In this application, a DEBUG variable is defined to tell the application to run the server in debug mode. **Note:** Debug mode should not be used when running an application in a production environment. UPLOAD_FOLDER is a custom variable that is defined to be referenced later in the application and inform it where uploaded user data should be stored.
- application.py initiates the Flask application and inherits the configuration settings defined in config.py. This is performed by the following code:

```python
application = Flask(__name__)
application.config.from_pyfile('config.py')
```

Identify and alert when Amazon Kinesis Data Firehose resources are not encrypted with an AWS KMS key

Created by Ram Kandaswamy (AWS)

<table>
<thead>
<tr>
<th>Environment</th>
<th>Technologies</th>
<th>AWS services</th>
</tr>
</thead>
<tbody>
<tr>
<td>Production</td>
<td>Management &amp; governance; Analytics; Big data; Cloud-native; Infrastructure; Security, identity, compliance</td>
<td>AWS CloudTrail; Amazon CloudWatch; AWS Identity and Access Management; Amazon Kinesis; AWS Lambda; Amazon SNS</td>
</tr>
</tbody>
</table>

Summary

For compliance, some organizations must have encryption enabled on data delivery resources such as Amazon Kinesis Data Firehose. This pattern shows a way to monitor, detect, and notify when resources are out of compliance.

To maintain the encryption requirement, this pattern can be used on Amazon Web Services (AWS) to provide automated monitoring and detection of Kinesis Data Firehose delivery resources that are not encrypted with AWS Key Management Service (AWS KMS) key. The solution sends alert notifications, and it can be extended to perform automatic remediation. This solution can be applied to an individual
account or a multiple-account environment, such as an environment using AWS Landing Zone or AWS Control Tower.

**Prerequisites and limitations**

**Prerequisites**

- Firehose delivery stream
- Sufficient permissions and familiarity with AWS CloudFormation, which is used in this infrastructure automation

**Limitations**

The solution is not real time because it uses AWS CloudTrail events for detection, and there is a delay between the time an unencrypted resource is created and the notification is sent.

**Architecture**

**Target technology stack**

The solution uses serverless technology and the following services:

- AWS CloudTrail
- Amazon CloudWatch
- AWS Command Line Interface (AWS CLI)
- AWS Identity and Access Management (IAM)
- Amazon Kinesis Data Firehose
- AWS Lambda
- Amazon Simple Notification Service (Amazon SNS)

**Target architecture**

1. A user creates or modifies Kinesis Data Firehose.
2. A CloudTrail event is detected and matched.
3. Lambda is invoked.
4. Noncompliant resources are identified.
5. Email notification is sent.

**Automation and scale**

Using AWS CloudFormation StackSets, you can apply this solution to multiple AWS Regions or accounts with a single command.

**Tools**

- **AWS CloudTrail** – AWS CloudTrail is an AWS service that helps you enable governance, compliance, and operational and risk auditing of your AWS account. Actions taken by a user, role, or an AWS service are recorded as events in CloudTrail. Events include actions taken in the AWS Management Console, AWS Command Line Interface, and AWS SDKs and API operations.
- **Amazon CloudWatch Events** – Amazon CloudWatch Events delivers a near-real-time stream of system events that describe changes in AWS resources.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open source tool that enables you to interact with AWS services using commands in your command line shell.
- **IAM** – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.
- **Amazon Kinesis Data Firehose** – Amazon Kinesis Data Firehose is a fully managed service for delivering real-time streaming data. With Kinesis Data Firehose, you don’t need to write applications or manage resources. You configure your data producers to send data to Kinesis Data Firehose, and it automatically delivers the data to the destination that you specified.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).

**Epics**

**Enforce encryption for compliance**

Automate adding or updating Windows registry entries using AWS Systems Manager
Summary

AWS Systems Manager is a remote management tool for Amazon Elastic Compute Cloud (Amazon EC2) instances. Systems Manager provides visibility and control over your infrastructure on Amazon Web Services. This versatile tool can be used to fix Windows registry changes that are identified as vulnerabilities by the security vulnerability scan report.

This pattern covers the steps to keep your EC2 instances running Windows operating system secure by automating registry changes that are recommended for the safety of your environment. The pattern uses the Run command to run a Command document. The code is attached, and a portion of it is included in the Code section.

Prerequisites and limitations

- An active AWS account
- An AWS Identity and Access Management (IAM) user with access to the EC2 instance and Systems Manager

Architecture

Target technology stack

- A virtual private cloud (VPC), with two subnets and a network address translation (NAT) gateway
- A Systems Manager Command document to add or update the registry name and value
- Systems Manager Run Command to run the Command document on the specified EC2 instances

Target architecture
Tools

**Tools**

- **IAM policies and roles** – AWS Identity and Access Management (IAM) is a web service that helps you securely control access to AWS resources. You use IAM to control who is authenticated (signed in) and authorized (has permissions) to use resources.

- **Amazon Simple Storage Service** – Amazon Simple Storage Service (Amazon S3) is storage for the internet. It is designed to make web-scale computing easier for developers. In this pattern, an S3 bucket is used to store the Systems Manager logs.

- **AWS Systems Manager** – AWS Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS. Systems Manager helps you maintain security and compliance by scanning your managed instances and reporting (or taking corrective action on) any policy violations it detects.

- **AWS Systems Manager Command document** – AWS Systems Manager Command documents are used by Run Command. Most Command documents are supported on all Linux and Windows Server operating systems supported by Systems Manager.

- **AWS Systems Manager Run Command** – AWS Systems Manager Run Command gives you a way to manage the configuration of your managed instances remotely and securely. Using Run Command, you can automate common administrative tasks and perform one-time configuration changes at scale.

**Code**

You can use the following example code to add or update a Microsoft Windows registry name to Version, registry path to HKCU:\Software\ScriptingGuys\Scripts, and value to 2.

```powershell
#Windows registry path which needs to add/update
$registryPath = 'HKCU:\Software\ScriptingGuys\Scripts'
#Windows registry Name which needs to add/update
$Name = 'Version'
```
# Windows registry value which needs to add/update
$\text{value} = 2

# Test-Path cmdlet to see if the registry key exists.
IF(!(Test-Path $\text{registryPath}))
{
    New-Item -Path $\text{registryPath} -Force | Out-Null
    New-ItemProperty -Path $\text{registryPath} -Name $\text{name} -Value $\text{value} -PropertyType DWORD -Force | Out-Null
}
ELSE {
    New-ItemProperty -Path $\text{registryPath} -Name $\text{name} -Value $\text{value} -PropertyType DWORD -Force | Out-Null
}

echo 'Registry Path:' $\text{registryPath}
echo 'Registry Name:' $\text{registryPath}
echo 'Registry Value:' (Get-ItemProperty -Path $\text{registryPath} -Name $\text{Name}).version

Automatically stop and start an Amazon RDS DB instance using AWS Systems Manager Maintenance Windows

*Created by Ashita Dsilva (AWS)*

| Environment: Production | Technologies: Management & governance; Cost management; Databases; Cloud-native | AWS services: AWS Systems Manager; Amazon RDS |
Summary

This pattern demonstrates how to automatically stop and start an Amazon Relational Database Service (Amazon RDS) DB instance on a specific schedule (for example, shutting down a DB instance outside of business hours to reduce costs) by using AWS Systems Manager Maintenance Windows.

AWS Systems Manager Automation provides the AWS-StopRdsInstance and AWS-StartRdsInstance runbooks to stop and start Amazon RDS DB instances. This means that you don't need to write custom logic with AWS Lambda functions or create an Amazon CloudWatch Events rule.

AWS Systems Manager provides two capabilities for scheduling tasks: State Manager and Maintenance Windows. State Manager sets and maintains the required state configuration for resources in your Amazon Web Services (AWS) account one time or on a specific schedule. Maintenance Windows runs tasks on the resources in your account during a specific time window. Although you can use this pattern's approach with State Manager or Maintenance Windows, we recommend that you use Maintenance Windows because it can run one or more tasks based on assigned priority and can also run AWS Lambda functions and AWS Step Functions tasks. For more information about State Manager and Maintenance Windows, see Choosing between State Manager and Maintenance Windows in the AWS Systems Manager documentation.

This pattern provides detailed steps to configure two separate maintenance windows that use cron expressions to stop and then start an Amazon RDS DB instance.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• An existing Amazon RDS DB instance that you want to stop and start on a specific schedule.
• Cron expressions for your required schedule. For example, the (0 9 * * 1-5) cron expression runs in the morning at 09:00 on Monday through Friday.
• Familiarity with Systems Manager.

Limitations

• An Amazon RDS DB instance can be stopped for up to seven days at one time. After seven days, the DB instance automatically restarts to ensure that it receives any required maintenance updates.
• You can't stop a DB instance that is a read replica or that has a read replica.
• You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.
• Service quotas apply to Maintenance Windows and Systems Manager Automation. For more information about service quotas, see AWS Systems Manager endpoints and quotas in the AWS General Reference documentation.

Architecture

The following diagram shows the workflow to automatically stop and start an Amazon RDS DB instance.
The workflow has the following steps:

1. Create a maintenance window and use cron expressions to define the stop and start schedule for your Amazon RDS DB instances.

2. Register a Systems Manager Automation task to the maintenance window by using the AWS-StopRdsInstance or AWS-StartRdsInstance runbook.

3. Register a target with the maintenance window by using a tag-based resource group for your Amazon RDS DB instances.

**Technology stack**
- AWS CloudFormation
- AWS Identity and Access Management (IAM)
- Amazon RDS
- Systems Manager

**Automation and scale**
You can stop and start multiple Amazon RDS DB instances at the same time by tagging the required Amazon RDS DB instances, creating a resource group that includes all the tagged DB instances, and registering this resource group as a target for the maintenance window.

**Tools**
- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources.
- **AWS Identity and Access Management (IAM)** – IAM is a web service that helps you securely control access to AWS resources.
- **Amazon RDS** – Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud.
- **AWS Resource Groups** – Resource Groups helps you organize AWS resources into groups, tag resources, and manage, monitor, and automate tasks on grouped resources.
• **AWS Systems Manager** – Systems Manager is an AWS service that you can use to view and control your infrastructure on AWS.

• **AWS Systems Manager Automation** – Systems Manager Automation simplifies common maintenance and deployment tasks of Amazon Elastic Compute Cloud (Amazon EC2) instances and other AWS resources.

• **AWS Systems Manager Maintenance Windows** – Maintenance Windows helps you define a schedule for when to perform potentially disruptive actions on your instances.

**Epics**

Create and configure the IAM service role for Systems Manager Automation

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure the IAM service role for Systems Manager Automation.</td>
<td>Sign in to the AWS Management Console and create a service role for Systems Manager Automation. You can use one of the following two methods to create this service role:</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>

- Use AWS CloudFormation to configure a service role for Systems Manager Automation
- Use IAM to configure roles for Systems Manager Automation

The Systems Manager Automation workflow invokes Amazon RDS by using a service role to perform start and stop actions on the Amazon RDS DB instance.

The service role must be configured with the following inline policy that has permissions to start and stop the Amazon RDS DB instance:

```json
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "RdsStartStop",
            "Effect": "Allow",
            "Action": [
                "rds:StopDBInstance",
                "rds:StartDBInstance"
            ]
        }
    ]
}
```
### Create a resource group

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Tag the Amazon RDS DB instances.</strong></td>
<td>Open the Amazon RDS console and tag the Amazon RDS DB instances that you want to add to the resource group. A tag is metadata assigned to an AWS resource and consists of a key-value pair. We recommend that you use <code>Action</code> as the Tag key and <code>StartStop</code> as the Value. For more information about this, see Adding, listing, and removing tags in the Amazon RDS documentation.</td>
<td>AWS administrator</td>
</tr>
<tr>
<td><strong>Create a resource group for your tagged Amazon RDS DB instances.</strong></td>
<td>Open the AWS Resource Groups console and create a resource group based on the tag that you created for your Amazon RDS DB instances. Under Grouping Criteria, make sure that you choose <code>AWS::RDS::DBInstance</code> for the resource type and then provide the tag's key-value pair (for example, &quot;Action-StartStop&quot;). This ensures that</td>
<td>AWS administrator</td>
</tr>
</tbody>
</table>
## Task
Configure a maintenance window to stop the Amazon RDS DB instances

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a maintenance window. | 1. Open the [AWS Systems Manager console](https://aws.amazon.com), choose **Maintenance Windows**, and then choose **Create a maintenance window**. Provide a name for your maintenance window (for example, "StopRdsInstance"), enter a description, and then uncheck **Allow unregistered targets**.  
2. Choose **CRON/Rate expression** and provide the schedule expression to define when the Amazon RDS DB instances should be stopped. Enter 1 for the **Duration** and 0 for **Stop initiating tasks**. By default, the **Time zone** shows UTC. You can change the time zone to initiate the maintenance window based on the timestamp defined in your cron expression.  
3. Choose **Create maintenance window**. The system returns you to the maintenance window page and the state of your maintenance window is **Enabled**.  

**Important**: The task to stop the DB instance runs almost instantly when initiated and doesn't span the entire duration of the maintenance window. This | AWS administrator |

---

The service only checks for Amazon RDS DB instances and not other resources that have this tag. Make sure that you record the resource group's name. For more information and detailed steps, see [Build a tag-based query and create a group](https://aws.amazon.com) in the AWS Resource Groups documentation.
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Assign a target to the maintenance window. | pattern provides the minimum values for **Duration** and **Stop initiating tasks** because they are the required parameters for a maintenance window.  
For more information and detailed steps, see [Create a maintenance window (console)](https://aws.amazon.com/documentation/systems-manager/) in the AWS Systems Manager documentation. | AWS administrator |
| | 1. On the **AWS Systems Manager console**, choose **Maintenance Windows**, choose **Actions**, and then choose **Register targets**.  
2. In the **Targets** area, specify **Choose a resource group** and then choose the name of an existing resource group in your account.  
3. For **Resource types**, choose **AWS::RDS::DBInstance** and then choose **Register target**.  
For more information and detailed steps, see [Assign targets to a maintenance window (console)](https://aws.amazon.com/documentation/systems-manager/) in the AWS Systems Manager documentation. | |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Assign a task to the maintenance window. | 1. On the AWS Systems Manager console, choose Maintenance Windows and then choose your maintenance window. Choose Actions and then choose Register Automation task.  
2. For Document, choose AWS-StopRdsInstance.  
3. In the Targets section, choose Selecting registered target groups and then choose the maintenance window target that you registered with the current maintenance window.  
4. For Rate control, specify 100 percent for Concurrency and Error threshold. You can change the Rate control values according to your requirements for task concurrency and error threshold. For more information about this, see About concurrency and error thresholds in the AWS Systems Manager documentation.  
5. In the IAM service role area, you can choose Create and use a service-linked role for Systems Manager or choose Use a custom service role.  
6. In the Input Parameters section, specify the following parameters for the runbook:  
  - **Instanceid**:  
    ```
    {{RESOURCE_ID}}
    ```  
  - **AutomationAssumeRole**:  
    Provide the ARN of the service role that you created for Systems Manager Automation.  
  - **Note**: For **Instanceid**, a pseudo parameter is used to extract the Amazon RDS DB resource ID from the ARN. To learn more about pseudo parameters, see About pseudo parameters in the AWS Systems Manager documentation. | AWS administrator    |
### Configure a maintenance window to start the Amazon RDS DB instances

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure a maintenance window to start the Amazon RDS DB instances. | Repeat the steps from the *Configure a maintenance window to stop the Amazon RDS DB instances* epic to configure another maintenance window to start the Amazon RDS DB instances at a scheduled time. **Important:** You must make the following changes when you configure the maintenance window to start the DB instances:  
  - Use a new name for the maintenance window (for example, “StartRdsInstance”).  
  - Replace the cron expression with the cron expression that you want to use to start the DB instances.  
  - Replace the `AWS-StopRdsInstance` runbook with `AWS-StartRdsInstance` in Task. | AWS administrator             |

Copy AWS Service Catalog products across different AWS accounts and AWS Regions

*Created by Sachin Vighe (AWS) and Santosh Kale (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
<th>Technologies:</th>
<th>Management &amp; governance; Serverless</th>
<th>Workload:</th>
<th>All other workloads</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS services:</td>
<td>AWS Service Catalog; AWS Lambda</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

AWS Service Catalog is a Regional service and this means that AWS Service Catalog portfolios and products are only visible in the AWS Region where they are created. If you set up an AWS Service Catalog hub in a new Region, you must recreate your existing products and this can be a time-consuming process.

This pattern's approach helps simplify this process by describing how to copy products from an AWS Service Catalog hub in a source AWS account or Region to a new hub in a destination account or Region. For more information about the AWS Service Catalog hub and spoke model, see [AWS Service Catalog hub and spoke model: How to automate the deployment and management of AWS Service Catalog to many accounts](https://aws.amazon.com/blogs/management/) on the AWS Management and Governance Blog.

The pattern also provides the separate code packages required to copy AWS Service Catalog products across accounts or to other Regions. By using this pattern, your organization can save time, make existing and previous product versions available in a new AWS Service Catalog hub, minimize the risk of manual errors, and scale the approach across multiple accounts or Regions.

**Note:** This pattern's Epics section provides two options for copying products. You can use Option 1 to copy products across accounts or choose Option 2 to copy products across Regions.

Prerequisites and limitations

**Prerequisites**

- An active AWS account.
- Existing AWS Service Catalog products in a source account or Region.
- An existing AWS Service Catalog hub in a destination account or Region.

If you want to copy products across accounts, you must share and then import the AWS Service Catalog portfolio containing the products into your destination account. For more information about this, see [Sharing and importing portfolios](https://aws.amazon.com/blogs/autoscaling/) in the AWS Service Catalog documentation.

**Limitations**
• AWS Service Catalog products that you want to copy across Regions or accounts cannot belong to more than one portfolio.

Architecture

The following diagram shows the copying of AWS Service Catalog products from a source account to a destination account.

The following diagram shows the copying of AWS Service Catalog products from a source Region to a destination Region.
Technology stack

- Amazon CloudWatch
- AWS Identity and Access Management (IAM)
- AWS Lambda
- AWS Service Catalog

Automation and scale

You can scale this pattern's approach by using a Lambda function that can be scaled depending on the number of requests received or how many AWS Service Catalog products you need to copy. For more information about this, see Lambda function scaling in the AWS Lambda documentation.

Tools

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open-source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.
- **Amazon CloudWatch** – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.
- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.
- **AWS Lambda** – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second.
- **AWS Service Catalog** – AWS Service Catalog helps you create, manage, and distribute portfolios of approved products to end users, who can then access the products they need in a personalized portal.
Typical products include servers, databases, websites, or applications that are deployed using AWS resources.

**Code**

You can use the `cross-account-copy` package (attached) to copy AWS Service Catalog products across accounts or the `cross-region-copy` package (attached) to copy products across Regions.

The `cross-account-copy` package contains the following files:

- `copyconf.properties` – The configuration file that contains the Region and AWS account ID parameters for copying products across accounts.
- `scProductCopyLambda.py` – The Python function for copying products across accounts.
- `createDestAccountRole.sh` – The script to create an IAM role in the destination account.
- `createSrcAccountRole.sh` – The script to create an IAM role in the source account.
- `copyProduct.sh` – The script to create and invoke the Lambda function for copying products across accounts.

The `cross-region-copy` package contains the following files:

- `copyconf.properties` – The configuration file that contains the Region and AWS account ID parameters for copying products across Regions.
- `scProductCopyLambda.py` – The Python function for copying products across Regions.
- `copyProduct.sh` – The script to create an IAM role and create and invoke the Lambda function for copying products across Regions.

**Epics**

**Option 1 – Copy AWS Service Catalog products across accounts**

### Task
Create a Lambda execution role in your destination account.

**Description**
Run the `createDestAccountRole.sh` script in your destination account. The script implements the following actions:
- Creates a Lambda execution role in your destination account
- Creates and attaches the IAM policy for the Lambda execution role

**Skills required**
AWS administrator, AWS systems administrator, Cloud administrator

---

### Task
Create the cross-account IAM role in your source account.

**Description**
Run the `createSrcAccountRole.sh` script in your source account. The script implements the following actions:
- Creates a cross-account IAM role in your source account that is assumed by the Lambda execution role in the destination account to copy products
- Creates and attaches an IAM policy for the cross-account role in your source account

**Skills required**
AWS administrator, AWS systems administrator, Cloud administrator

---

### Task
Run the copyProduct script in the destination account.

**Description**
Run the `copyProduct.sh` script in your destination account. The script implements the following actions:
- Creates and invokes the Lambda function to copy products from the source account to the destination account

**Skills required**
AWS administrator, AWS systems administrator, Cloud administrator

---

Create alarms for custom metrics using Amazon CloudWatch anomaly detection

*Created by Ram Kandaswamy (AWS) and Raheem Jiwani (AWS)*

| Environment: Production | Technologies: Management & governance; DevOps; Operations; Cloud-native | AWS services: Amazon CloudWatch |

**Summary**

On the Amazon Web Services (AWS) Cloud, you can use Amazon CloudWatch to create alarms that monitor metrics and send notifications or automatically make changes if a threshold is breached.

To avoid being limited by *static thresholds*, you can create alarms based on past patterns and that notify you if specific metrics are outside the normal operating window. For example, you could monitor your API’s response times from Amazon API Gateway and receive notifications about anomalies that prevent you from meeting a service-level agreement (SLA).

This pattern describes how to use CloudWatch anomaly detection for custom metrics. The pattern shows you how to create a custom metric in Amazon CloudWatch Logs Insights or publish a custom metric with an AWS Lambda function, and then set up anomaly detection and create notifications using Amazon Simple Notification Service (Amazon SNS).

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- An existing SNS topic, configured to send email notifications. For more information about this, see [Getting started with Amazon SNS](https://docs.aws.amazon.com/sns/latest/dg/sns-creating-topic.html) in the Amazon SNS documentation.
- An existing application, configured with CloudWatch Logs.

**Limitations**

- CloudWatch metrics don't support millisecond time intervals. For more information about the granularity of regular and custom metrics, see the [Amazon CloudWatch FAQs](https://docs.aws.amazon.com/AmazonCloudWatch/latest/monitoring/cloudwatch_faqs.html).
Architecture

The diagram shows the following workflow:

1. Logs that use metrics created and updated by CloudWatch Logs are streamed to CloudWatch.
2. An alarm initiates based on thresholds and sends an alert to an SNS topic.
3. Amazon SNS sends you an email notification.

Technology stack

- Cloudwatch
- AWS Lambda
- Amazon SNS

Tools

- **Amazon Cloudwatch** – CloudWatch provides a reliable, scalable, and flexible monitoring solution.
- **AWS Lambda** – Lambda is a compute service that helps you run code without provisioning or managing servers.
- **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers.

Epics

Set up anomaly detection for a custom metric

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Option 1 - Create a custom metric with a Lambda function.</td>
<td>Download the lambda_function.py file</td>
<td>DevOps engineer, AWS DevOps</td>

<td>Skills required</td>
</tr>
<tr>
<td>---------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------</td>
</tr>
<tr>
<td>(attached) and then replace the sample lambda_function.py file in the aws-lambda-developer-guide repository on the AWS Documentation GitHub. This provides you with a sample Lambda function that sends custom metrics to CloudWatch Logs. The Lambda function uses the Boto3 API to integrate with CloudWatch. After you run the Lambda function, you can sign in to the AWS Management Console, open the CloudWatch console, and the published metric is available under your published namespace.</td>
<td>DevOps engineer, AWS DevOps</td>
<td></td>
</tr>
<tr>
<td>Option 2 – Create custom metrics from CloudWatch log groups.</td>
<td>Sign in to the AWS Management Console, open the CloudWatch console, and then choose Log groups. Choose the log group that you want to create a metric for. Choose Actions and then choose Create metric filter. For Filter pattern, enter the filter pattern that you want to use. For more information, see Filter and pattern syntax in the CloudWatch documentation. To test your filter pattern, enter one or more log events under Test Pattern. Each log event must be within one line, because line breaks are used to separate log events in the Log event messages box. After you test the pattern, you can enter a name and value for your metric under Metric details. For more information and steps to create a custom metric, see Create a metric filter for a log group in the CloudWatch documentation.</td>
<td>DevOps engineer, AWS DevOps</td>
</tr>
</tbody>
</table>
Create an alarm for your custom metric.

On the CloudWatch console, choose Alarms and then choose Create Alarm. Choose Select metric and enter the name of the metric that you created earlier into the search box. Choose the Graphed metrics tab and configure the options according to your requirements.

Under Conditions, choose Anomaly detection instead of Static thresholds. This shows you a band based on two standard default deviations. You can set up thresholds and adjust them according to your requirements.

Choose Next.

Note: The band is dynamic and depends on the quality of the datapoints. When you begin aggregating more data, the band and thresholds are automatically updated.

Set up SNS notifications.

Under Notification, choose the SNS topic to notify when the alarm is in ALARM state, OK state, or INSUFFICIENT_DATA state.

To have the alarm send multiple notifications for the same alarm state or for different alarm states, choose Add notification. Choose Next. Enter a name and description for the alarm. The name must only contain ASCII characters. Then choose Next.

Under Preview and create, confirm that the information and conditions are correct, and then choose Create alarm.

Set up AWS CloudFormation drift detection in a multi-Region, multi-account organization

Created by Ram Kandaswamy (AWS)

Environment: Production

Technologies: Management & governance; Cloud-native; Infrastructure; Operations; Modernization

Workload: All other workloads

AWS services: Amazon SNS; AWS Config; AWS Lambda; AWS CloudFormation

Summary

Customers on Amazon Web Services (AWS) are often looking for an efficient way to detect resource configuration mismatches, including drift in AWS CloudFormation stacks, and fix them as soon as possible. This is especially the case when AWS Control Tower or AWS Landing Zone solutions are used.

This pattern provides a prescriptive solution that efficiently solves the problem by using consolidated resource configuration changes and acting on those changes to generate results. The solution is designed for scenarios where there are several CloudFormation stacks created in more than one Region or more than one account or a combination of both. The goals of the solution are the following:

- Simplify the drift detection process
- Set up notification and alerting
- Set up consolidated reporting

Prerequisites and limitations

Prerequisites

- AWS Config enabled in all the Regions and accounts that must be monitored

Limitations

- The report generated supports only the .csv or .json output formats.
Architecture

Target technology stack

The current guidance will help organizations achieve the goal by using a combination of the following services:

- AWS Config rule
- Amazon CloudWatch rule
- AWS Identity and Access Management (IAM)
- AWS Lambda
- Amazon Simple Notification Service (Amazon SNS)

1. The AWS Config rule detects drift.
2. Drift detection results in other accounts are sent to the management account.
3. The CloudWatch rule calls Lambda.
4. Lambda queries the AWS Config rule for aggregated results.
5. Lambda notifies Amazon SNS, which sends email notification of the drift.

Automation and scale

The solution presented here can scale for both additional Regions and accounts.

Tools

AWS Config – AWS Config provides a detailed view of the configuration of AWS resources in your AWS account. This includes how the resources are related to one another and how they were configured in the past so that you can see how the configurations and relationships change over time. With AWS Config, you can assess, audit, and evaluate the configurations of your AWS resources.
Amazon CloudWatch – Amazon CloudWatch monitors your AWS resources and the applications you run on AWS in real time. You can use CloudWatch to collect and track metrics, which are variables you can measure for your resources and applications.

AWS Lambda – AWS Lambda is a compute service that supports running code without provisioning or managing servers. Lambda runs your code only when needed and scales automatically, from a few requests per day to thousands per second. You pay only for the compute time that you consume—there is no charge when your code is not running.

Amazon SNS – Amazon Simple Notification Service (Amazon SNS) is a managed service that provides message delivery from publishers to subscribers (also known as producers and consumers).

**Epics**

**Automate drift detection for CloudFormation**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the aggregator.</td>
<td>On the AWS Config console, create an aggregator in the management account. Ensure that data replication is turned on so that AWS Config can fetch data from the source accounts. Also, select all applicable Regions and accounts. You can select accounts based on organizations. This is the recommended approach because new accounts in the organization are automatically part of the aggregator.</td>
<td>Cloud architect</td>
</tr>
<tr>
<td>Create an AWS managed rule.</td>
<td>Add the <code>cloudformation-stack-drift-detection-check</code> AWS managed rule. The rule needs one parameter value: <code>cloudformationArn</code>. Enter the IAM role Amazon Resource Name (ARN) that has permissions to detect stack drift. In addition, the role must have a trust policy that enables AWS Config to assume the role.</td>
<td>Cloud architect</td>
</tr>
</tbody>
</table>
| Create the advanced query section of the aggregator. | To fetch drifted stacks from multiple sources, create the following query: ```
SELECT resourceId, configuration.driftInformation.stackDriftStatus
WHERE resourceType = 'AWS::CloudFormation::Stack'
AND
configuration.driftInformation.stackDriftStatus
IN ("DRIFTED")
``` | Cloud architect, Developer |
Task | Description | Skills required
--- | --- | ---
Automate running the query and publish. | Create a Lambda function using the code that is attached. Lambda will publish the results to an Amazon SNS topic that is provided as an environment variable in the Lambda function. Also, to receive alerts, create an email subscription to an existing Amazon SNS topic. | Cloud architect, Developer
Create a CloudWatch rule. | Create a schedule-based CloudWatch rule to call the Lambda function, which is responsible for alerting. | Cloud architect

- Multi-account multi-Region data aggregation
- Detecting unmanaged configuration changes to stacks and resources
- IAM: Pass an IAM role to a specific AWS service
- What is Amazon SNS?

Additional information

Considerations

Using custom solutions that involve API calls at specific intervals to initiate drift detection on each CloudFormation stack or on stack sets is not optimal. It leads to a large number API calls and affects the performance. Because of the number of API calls, throttling can happen. Another potential issue is a delay in detection if resource changes are identified based on schedule only.

FAQ

Q. Should I use an add-on based solution with AWS Landing Zone?

A. With the availability of the advanced queries feature in AWS Config, along with the aggregator, the recommendation is to use AWS Config instead of an add-on.

Q. How does this solution address CloudFormation StackSets?

A. Because stack sets are made of stacks, you can use this solution. Stack instance details are also available as part of the solution.

AWS Prescriptive Guidance Patterns
Enable Amazon DevOps Guru across
an organization with the AWS CDK

Improve operational performance by enabling
Amazon DevOps Guru across multiple AWS
Regions, accounts, and OUs with the AWS CDK

Created by Rahul Sharad Gaikwad (AWS)

Summary

This pattern demonstrates the steps to enable the Amazon DevOps Guru service across multiple Amazon Web Services (AWS) Regions, accounts, and organizational units (OUs) by using the AWS Cloud Development Kit (AWS CDK) in TypeScript. You can use AWS CDK stacks to deploy AWS CloudFormation StackSets from the administrator (primary) AWS account to enable Amazon DevOps Guru across multiple accounts, instead of logging into each account and enabling DevOps Guru individually for each account.

Amazon DevOps Guru provides artificial intelligence operations (AIOps) features to help you improve the availability of your applications and resolve operational issues faster. DevOps Guru reduces your manual effort by applying machine learning (ML) powered recommendations, without requiring any ML expertise. DevOps Guru analyzes your resources and operational data. If it detects any anomalies, it provides metrics, events, and recommendations to help you address the issue.

This pattern describes three deployment options for enabling Amazon DevOps Guru:

- For all stack resources across multiple accounts and Regions
- For all stack resources across OUs
- For specific stack resources across multiple accounts and Regions

Prerequisites and limitations

Prerequisites

- An active AWS account.
- AWS Command Line Interface (AWS CLI), installed and configured. (See Installing, updating, and uninstalling the AWS CLI in the AWS CLI documentation.)
- AWS CDK Toolkit, installed and configured. (See AWS CDK Toolkit in the AWS CDK documentation.)
- Node Package Manager (npm), installed and configured for the AWS CDK in TypeScript. (See Downloading and installing Node.js and npm in the npm documentation.)
- Python3 installed and configured, for running a Python script to inject traffic into the sample serverless application. (See Python Setup and Usage in the Python documentation.)
• Pip, installed and configured to install the Python requests library. (See the pip installation instructions on the PyPI website.)

Product versions
• AWS CDK Toolkit version 1.107.0 or later
• npm version 7.9.0 or later
• Node.js version 15.3.0 or later

Architecture

Technologies
The architecture for this pattern includes the following services:

• Amazon DevOps Guru
• AWS CloudFormation
• Amazon API Gateway
• AWS Lambda
• Amazon DynamoDB
• Amazon CloudWatch
• AWS CloudTrail

AWS CDK stacks
The pattern uses the following AWS CDK stacks:

• CdkStackSetAdminRole – Creates an AWS Identity and Access management (IAM) administrator role to establish a trust relationship between the administrator and target accounts.
• CdkStackSetExecRole – Creates an IAM role to trust the administrator account.
• CdkDevopsGuruStackMultiAccReg – Enables DevOps Guru across multiple AWS Regions and accounts for all stacks, and sets up Amazon Simple Notification Service (Amazon SNS) notifications.
• CdkDevopsGuruStackMultiAccRegSpecStacks – Enables DevOps Guru across multiple AWS Regions and accounts for specific stacks, and sets up Amazon SNS notifications.
• CdkDevopsGuruStackOrgUnit – Enables DevOps Guru across OUs, and sets up Amazon SNS notifications.
• CdkInfrastructureStack – Deploys sample serverless application components such as API Gateway, Lambda, and DynamoDB in the administrator account to demonstrate fault injection and insights generation.

Sample application architecture
The following diagram illustrates the architecture of a sample serverless application that has been deployed across multiple accounts and Regions. The pattern uses the administrator account to deploy all the AWS CDK stacks. It also uses the administrator account as one of the target accounts for setting up DevOps Guru.

1. When DevOps Guru is enabled, it first baselines each resource’s behavior and then ingests operational data from CloudWatch vended metrics.
2. If it detects an anomaly, it correlates it with the events from CloudTrail, and generates an insight.
3. The insight provides a correlated sequence of events along with prescribed recommendations to enable the operator to identify the culprit resource.
4. Amazon SNS sends notification messages to the operator.

**Automation and scale**

The [GitHub repository](https://github.com/aws-observability-code-devopsguru) provided with this pattern uses the AWS CDK as an infrastructure as code (IaC) tool to create the configuration for this architecture. AWS CDK helps you orchestrate resources and enable DevOps Guru across multiple AWS accounts, Regions, and OUs.

**Tools**

**AWS services**

- **AWS CDK** – AWS Cloud Development Kit (AWS CDK) helps you define your cloud infrastructure as code in one of five supported programming languages: TypeScript, JavaScript, Python, Java, and C#.
- **AWS CLI** – AWS Command Line Interface (AWS CLI) is a unified tool that provides a consistent command-line interface for interacting with AWS services and resources.

**Code**

The source code for this pattern is available on GitHub, in the [Amazon DevOps Guru CDK Samples](https://github.com/aws-observability-code-devopsguru) repository. The AWS CDK code is written in TypeScript. To clone and use the repository, follow the instructions in the next section.

**Important:** Some of the stories in this pattern include AWS CDK and AWS CLI command examples that are formatted for Unix, Linux, and macOS. For Windows, replace the backslash (\) continuation character at the end of each line with a caret (^).

## Prepare the AWS resources for deployment

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure AWS named profiles.</td>
<td>Set up your AWS named profiles as follows to deploy stacks in a multi-account environment.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>For the administrator account:</td>
<td></td>
</tr>
</tbody>
</table>
|                               | $aws configure --profile administrator  
AWS Access Key ID [****]: <your-administrator-access-key-ID>  
AWS Secret Access Key [****]: <your-administrator-secret-access-key>  
Default region name [None]: <your-administrator-region>  
Default output format [None]: json                                                                                                                                 |
|                               | For the target account:                                                                                                                                                                                      |                          |
|                               | $aws configure --profile target  
AWS Access Key ID [****]: <your-target-access-key-ID>  
AWS Secret Access Key [****]: <your-target-secret-access-key>  
Default region name [None]: <your-target-region>  
Default output format [None]: json                                                                                                                                 |
<p>|                               | For more information, see Named profiles in the AWS CLI documentation.                                                                                                                                       |                          |
| Verify AWS profile configurations. | (Optional) You can verify your AWS profile configurations in the credentials and config files by following the instructions in Set and view configuration settings in the AWS CLI documentation. | DevOps engineer          |
| Verify the AWS CDK version.    | Verify the version of the AWS CDK Toolkit by running the following command:                                                                                                                                  | DevOps engineer          |
|                               | $cdk --version                                                                                                                                                                                                |                          |</p>
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Clone the project code. | Clone the GitHub repository for this pattern by using the command:  

```bash
$git clone https://github.com/aws-samples/amazon-devopsguru-cdk-samples.git
``` | DevOps engineer |
| Install package dependencies and compile the TypeScript files. | Install the package dependencies and compile the TypeScript files by running the following commands:  

```bash
$cd amazon-devopsguru-cdk-samples  
$npm install  
$npm fund
```  

These commands install all the packages from the sample repository.  

**Important:** If you get any errors about missing packages, use one of the following commands:  

```bash
$npm ci
```

—or—

```bash
$npm install -g @aws-cdk/<package-name>
```

You can find the list of package names and versions in the Dependencies section of the /amazon-devopsguru-cdk-samples/package.json file. For more information, see `npm ci` and `npm install` in the npm documentation. | DevOps engineer |
## Build (synthesize) the AWS CDK stacks

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| **Configure an email address for Amazon SNS notifications.** | Follow these steps to provide an email address for Amazon SNS notifications:  
2. In the DevOpsGuruTopic, Subscription section, update the Endpoint parameter with your email address.  
3. Save and close the files. | DevOps engineer |
| **Build the project code.** | Build the project code and synthesize the stacks by running the command:  
```  
npm run build && cdk synth  
```  
You should see output similar to the following:  
```  
$npm run build && cdk synth  
> cdk-devopsguru@0.1.0 build  
> tsc  
Successfully synthesized to ~/amazon-devopsguru-cdk-samples/cdk.out  
Supply a stack id (CdkDevopsGuruStackMultiAccReg,CdkDevopsGuruStackMultiAccRegSpecStacks,CdkDevopsGuruStackOrgUnit, CdkInfrastructureStack, CdkStackSetAdminRole, CdkStackSetExecRole) to display its template.  
```  
For more information and steps, see Your first AWS CDK app in the AWS CDK documentation. | DevOps engineer |
| **List the AWS CDK stacks.** | Run the following command to list all AWS CDK stacks:  
```  
$cdk list  
``` | DevOps engineer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The command displays the following list:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CdkDevopsGuruStackMultiAccReg</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CdkDevopsGuruStackMultiAccRegSpecStacks</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CdkDevopsGuruStackOrgUnit</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CdkInfrastructureStack</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CdkStackSetAdminRole</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CdkStackSetExecRole</td>
<td></td>
</tr>
</tbody>
</table>

### Option 1 - Enable DevOps Guru for all stack resources across multiple accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Deploy the AWS CDK stacks for creating IAM roles.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>This pattern uses AWS CloudFormation StackSets to perform stack operations across multiple accounts. If you are creating your first stack set, you must create the following IAM roles to get the required permissions set up in your AWS accounts:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWSCloudFormationStackSetAdministrationRole</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWSCloudFormationStackSetExecutionRole</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The roles must have these exact names.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>1. Create the IAM AWSCloudFormationStackSetAdministrationRole role in the administrator (primary) account by running the following CLI command:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$cdk deploy CdkStackSetAdminRole --profile administrator</td>
<td></td>
</tr>
<tr>
<td></td>
<td>2. Create the IAM AWSCloudFormationStackSetExecutionRole role in all target accounts where you want to run the stack instances. To create this role, run these CLI commands:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$cdk deploy CdkStackSetExecRole \ --parameters AdministratorAccountId=&lt;administrator-account-ID&gt; \ --profile administrator</td>
<td></td>
</tr>
</tbody>
</table>
## Task Description

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Option 2 - Enable DevOps Guru for all stack resources across OUs</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Extract OU IDs.</strong></td>
<td>On the AWS Organizations console, identify the IDs of the organizational units where you want to enable DevOps Guru.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td><strong>Enable service-managed permissions for OUs.</strong></td>
<td>If you're using AWS Organizations for account management, you must grant service-managed permissions to enable DevOps Guru. Instead of creating the IAM roles manually,</td>
<td>DevOps engineer</td>
</tr>
</tbody>
</table>

```
$cdk deploy
CdkStackSetExecRole
  --parameters
  AdministratorAccountId=<administrator-account-ID>
  --profile target
```

```
$cdk deploy
CdkDevopsGuruStackMultiAccReg
  --profile administrator
  --parameters
  AdministratorAccountId=<administrator-account-ID>
  --parameters
  TargetAccountId=<target-account-ID>
  --parameters
  RegionIds="<region-1>,<region-2>"
```

Currently Amazon DevOps Guru is available in the AWS Regions listed in the [DevOps Guru FAQ](https://aws.amazon.com/development-tools/cloudformation/features/devops-guru/).
### Option 3 - Enable DevOps Guru for specific stack resources across multiple accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the AWS CDK stacks for creating IAM roles. | If you haven’t already created the required IAM roles shown in the first option, do that first:  
1. Create the IAM AWSCloudFormationStackSetAdministrationRole role in the administrator (primary) account by running the following CLI command:  
   ```bash  
   $cdk deploy 
   CdkStackSetAdminRole --profile administrator  
   ```  
2. Create the IAM AWSCloudFormationStackSetExecutionRole role in all target accounts where you want to run the stack instances. To create this role, run the CLI commands:  
   ```bash  
   $cdk deploy 
   CdkStackSetExecRole --parameters AdministratorAccountId=<administrator-account-ID> 
   --profile administrator  
   ``` | DevOps engineer |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete existing stacks.</td>
<td>If you already used the first option to enable DevOps Guru for all stack resources, you can delete the old stack by using the following command:</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td></td>
<td>$cdk destroy CdkDevOpsGuruStackMultiAccReg --profile administrator</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Or, you can change the RegionIds parameter when you redeploy the stack to avoid a Stacks already exist error.</td>
<td></td>
</tr>
</tbody>
</table>
| Update the AWS CDK stack with a stack list. | 1. Edit the file /amazon-devopsguru-cdk-samples/lib/cdk-devopsguru-multi-acc-reg-spec-stack.ts.  
2. Under Resources, CloudFormation, StackNames, list the stacks for which you want to enable DevOps Guru. For demonstration purposes, the parameter specifies the CdkInfrastructureStack stack, but you can edit this entry based on your requirements.  
3. Save and close the file.  
4. To synthesize and update the stack template, run: | Data engineer |
| | $cdk synth | |
### Deploy the AWS CDK stack for enabling DevOps Guru for specific stack resources across multiple accounts

**Task** Deploy the AWS CDK stack for enabling DevOps Guru for specific stack resources across multiple accounts.

**Description** The AWS CDK CdkDevopsGuruStackMultiAccRegSpecStacks stack enables DevOps Guru for specific stack resources across multiple accounts. To deploy the stack, run the following command:

```
$cdk deploy CdkDevopsGuruStackMultiAccRegSpecStacks --profile administrator --parameters AdministratorAccountId=<administrator-account-ID> --parameters TargetAccountId=<target-account-ID> --parameters RegionIds="<region-1>,<region-2>"
```

**Note:** If you previously deployed this stack for option 1, change the RegionIds parameter (making sure to choose from available Regions) to avoid a Stacks already exist error.

**Skills required** DevOps engineer

### Deploy the AWS CDK infrastructure stack

**Task** Deploy the sample serverless infrastructure stack.

**Description** The AWS CDK CdkInfrastructureStack stack deploys serverless components such as API Gateway, Lambda, and a DynamoDB table to demonstrate DevOps Guru insights. To deploy the stack, run the following command:

```
$cdk deploy CdkInfrastructureStack --profile administrator
```

**Skills required** DevOps engineer

**Task** Insert sample records in DynamoDB.

**Description** Run the following command to populate the DynamoDB table with sample records. Provide the correct path for the populate-shops-dynamodb-table.json script.

**Skills required** DevOps engineer
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>$aws dynamodb batch-write-item \  --request-items file://scripts/populate-shops-dynamodb-table.json \  --profile administrator</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The command displays the following output:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>{</td>
<td></td>
</tr>
<tr>
<td></td>
<td>&quot;UnprocessedItems&quot;: {}</td>
<td></td>
</tr>
<tr>
<td></td>
<td>}</td>
<td></td>
</tr>
</tbody>
</table>
| Verify inserted records in DynamoDB. | To verify that the DynamoDB table includes the sample records from the populate-shops-dynamodb-table.json file, access the URL for the ListRestApiEndpointMonitorOperator API, which is published as an output of the AWS CDK stack. You can also find this URL in the Outputs tab of the AWS CloudFormation console for the CdkInfrastructureStack stack. The AWS CDK output would look similar to the following:  | DevOps engineer  
|      | CdkInfrastructureStack.CreateRestApiMonitorOperatorEndpointD1D00045 = https://oure17c5vob.execute-api.<your-region>.amazonaws.com/prod/  |  |  
| Wait for resources to complete baselining. | This serverless stack has a few resources. We recommend that you wait for 2 hours before you carry out the next steps. If you deployed this stack in a production environment, it might take up to 24 hours to complete baselining, depending on the number of resources you selected to monitor in DevOps Guru.  | DevOps engineer  |
Generate DevOps Guru insights

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Update the AWS CDK infrastructure stack. | To try out DevOps Guru insights, you can make some configuration changes to reproduce a typical operational issue.  
1. Edit the file `/amazon-devopsguru-cdk-samples/lib/infrastructure-stack.ts`.  
2. In the DDB Table section, change the read capacity for the DynamoDB table from 5 to 1.  
3. Save and close the file.  
4. Run the following commands to synthesize and deploy the updated AWS CDK infrastructure stack:  
   ```  
   $cdk synth  
   $cdk deploy  
   CdkInfrastructureStack --profile administrator  
   ``` | DevOps engineer |

| Inject HTTP requests on the API. | Inject ingress traffic in the form of HTTP requests on the `ListRestApiMonitorOperatorEndpointxxxx` API:  
1. Edit the Python script `/amazon-devopsguru-cdk-samples/scripts/sendAPIRequest.py`.  
2. Update the `url` variable with the API link for `ListRestApiMonitorOperatorEndpointxxxx`. You can find this URL in the output of the AWS CDK `deploy` command or on the AWS Cloudformation console, in the `Outputs` tab for the stack.  
3. Save and close the file.  
4. Run the Python script by using the command:  
   ```  
   $python sendAPIRequest.py  
   ```  
5. Make sure that you get a 200 status code. | DevOps engineer |
### Task

<table>
<thead>
<tr>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>6. You might need to run the script through multiple (preferably four) terminals to inject traffic at a high rate.</td>
<td></td>
</tr>
<tr>
<td>7. After the script runs approximately 10 minutes in a loop, you can see an operational insight on the DevOps Guru console.</td>
<td></td>
</tr>
<tr>
<td>Review DevOps Guru insights.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>Under standard conditions, the DevOps Guru dashboard displays zero in the ongoing insights counter. If it detects an anomaly, it raises an alert in the form of an insight. In the navigation pane, choose <strong>Insights</strong> to see the details of the anomaly, including an overview, aggregated metrics, relevant events, and recommendations. For more information about reviewing insights, see the Gaining operational insights with AIOps using Amazon DevOps Guru blog post.</td>
<td></td>
</tr>
<tr>
<td>Clean up</td>
<td></td>
</tr>
<tr>
<td>Clean up and delete resources.</td>
<td>DevOps engineer</td>
</tr>
<tr>
<td>After you walk through this pattern, you should remove the resources you created to avoid incurring any further charges. Run these commands:</td>
<td></td>
</tr>
<tr>
<td>$cdk destroy</td>
<td></td>
</tr>
<tr>
<td>CdkDevopsGuruStackMultiAccReg --profile administrator</td>
<td></td>
</tr>
<tr>
<td>$cdk destroy</td>
<td></td>
</tr>
<tr>
<td>CdkDevopsGuruStackOrgUnit --profile administrator</td>
<td></td>
</tr>
<tr>
<td>$cdk destroy</td>
<td></td>
</tr>
<tr>
<td>CdkDevopsGuruStackMultiAccRegSpecStacks --profile administrator</td>
<td></td>
</tr>
<tr>
<td>$cdk destroy</td>
<td></td>
</tr>
<tr>
<td>CdkInfrastructureStack --profile administrator</td>
<td></td>
</tr>
<tr>
<td>$cdk destroy</td>
<td></td>
</tr>
<tr>
<td>CdkStackSetAdminRole --profile administrator</td>
<td></td>
</tr>
<tr>
<td>$cdk destroy</td>
<td></td>
</tr>
<tr>
<td>CdkStackSetExecRole --profile administrator</td>
<td></td>
</tr>
</tbody>
</table>
### Task

| Description | $cdk destroy CdkStackSetExecRole --profile target |

### Manage AWS Service Catalog products in multiple AWS accounts and AWS Regions

*Created by Ram Kandaswamy (AWS)*

**Environment:** Production  
**Technologies:** Management & governance; Cloud-native; Infrastructure; Modernization  
**Workload:** All other workloads

**AWS services:** AWS Service Catalog; AWS CloudFormation

### Summary

Amazon Web Services (AWS) Service Catalog simplifies and accelerates the governance and distribution of infrastructure as code (IaC) templates for enterprises. You use AWS CloudFormation templates to define a collection of AWS resources (stacks) required for a product. AWS CloudFormation StackSets extends this functionality by enabling you to create, update, or delete stacks across multiple accounts and AWS Regions with a single operation.

AWS Service Catalog administrators create products by using CloudFormation templates that are authored by developers, and publish them. These products are then associated with a portfolio, and constraints are applied for governance. To make your products available to users in other AWS accounts or organizational units (OUs), you typically share your portfolio with them. This pattern describes an alternative approach for managing AWS Service Catalog product offerings that is based on AWS CloudFormation StackSets. Instead of sharing portfolios, you use stack set constraints to set AWS Regions and accounts where your product can be deployed and used. By using this approach, you can provision your AWS Service Catalog products in multiple accounts, OUs, and AWS Regions, and manage them from a central location, while meeting your governance requirements.

**Benefits of this approach:**
- The product is provisioned and managed from the primary account, and not shared with other accounts.
- This approach provides a consolidated view of all provisioned products (stacks) that are based on a specific product.
- Configuration with AWS Service Management Connector is easier, because it targets only one account.
• It’s easier to query and use products from AWS Service Catalog.

Prerequisites and limitations

Prerequisites
• AWS CloudFormation templates for IaC and versioning
• Multi-account setup and AWS Service Catalog for provisioning and managing AWS resources

Limitations
• This approach uses AWS CloudFormation StackSets, and the limitations of StackSets apply:
  • StackSets doesn’t support CloudFormation template deployment through macros. If you’re using a macro to preprocess the template, you won’t be able to use a StackSets-based deployment.
  • StackSets provides the ability to disassociate a stack from the stack set, so you can target a specific stack to fix an issue. However, a disassociated stack cannot be re-associated with the stack set.
  • AWS Service Catalog autogenerates StackSet names. Customization isn’t currently supported.

Architecture

Target architecture

1. The user creates an AWS CloudFormation template to provision AWS resources, in JSON or YAML format.
2. The CloudFormation template creates a product in AWS Service Catalog, which is added to a portfolio.
3. The user creates a provisioned product, which creates CloudFormation stacks in the target accounts.
4. Each stack provisions the resources specified in the CloudFormation templates.

Tools

AWS services
• AWS Service Catalog – AWS Service Catalog helps you create, manage, and distribute portfolios of approved products to end users, who can then access the products they need in a personalized portal. Typical products include servers, databases, websites, or applications that are deployed using AWS resources.
• AWS CloudFormation – AWS CloudFormation helps you model and set up your AWS resources, provision them quickly and consistently, and manage them throughout their lifecycle. You can use a
template to describe your resources and their dependencies, and launch and configure them together as a stack, instead of managing resources individually. You can manage and provision stacks across multiple AWS accounts and AWS Regions.

- **IAM** – AWS Identity and Access Management (IAM) is a web service for securely controlling access to AWS services. With IAM, you can centrally manage users, security credentials such as access keys, and permissions that control which AWS resources users and applications can access.

- **AWS CLI** – The AWS Command Line Interface (AWS CLI) is an open source tool for interacting with AWS services through commands in your command-line shell. With minimal configuration, you can run AWS CLI commands that implement functionality equivalent to that provided by the browser-based AWS Management Console from a command prompt.

## Epics

### Provision products across accounts

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a portfolio.           | A portfolio is a container that includes one or more products that are grouped together based on specific criteria. Using a portfolio for your products helps you apply common constraints across your product set. To create a portfolio, follow the instructions in the [AWS Service Catalog documentation](#). If you're using the AWS CLI, here's an example command:  
```bash
aws servicecatalog create-portfolio --provider-name my-provider --display-name my-portfolio
```  
For more information, see the [AWS CLI documentation](#). | AWS Service Catalog, IAM |
<p>| Create a CloudFormation template. | Create a CloudFormation template that describes the resources. Resource property values should be parameterized where applicable. | AWS CloudFormation, JSON/YAML |
| Create a product with version information. | The CloudFormation template becomes a product when you publish it in the AWS Service Catalog. Provide values for the optional version detail parameters, such as version title and description; this will be helpful for querying for the product later. | AWS Service Catalog |</p>
<table>

</tbody>
</table>
## Task:
Provision the product.

### Description:
A provisioned product is a resourced instance of a product. Provisioning a product based on a CloudFormation template launches a CloudFormation stack and its underlying resources.

Provision the product by targeting the applicable AWS Regions and accounts, based on stack set constraints. In the AWS CLI, here's an example command:

```
aws servicecatalog provision-product \
  --product-id prod-abcdfz3syn2rg \
  --provisioning-artifact-id pa-abc347pcsccfm \
  --provisioned-product-name "mytestppname3"
```

For more information, see the AWS CLI documentation.

## Additional information

When you use the create-product command, the cli-input-json parameter points to a file that specifies information such as product owner, support email, and CloudFormation template details. Here's an example of such a file:

```json
{
  "Owner": "Test admin",
  "SupportDescription": "Testing",
  "Name": "SNS",
  "SupportEmail": "example@example.com",
  "ProductType": "CLOUD_FORMATION_TEMPLATE",
  "AcceptLanguage": "en",
  "ProvisioningArtifactParameters": {
    "Description": "SNS product",
  }
}
```
Migrate an AWS member account from AWS Organizations to AWS Control Tower

Created by Rodolfo Jr. Cerrada (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Production</th>
</tr>
</thead>
<tbody>
<tr>
<td>Technologies:</td>
<td>Management &amp; governance; Modernization</td>
</tr>
<tr>
<td>AWS services:</td>
<td>AWS Organizations; AWS Control Tower</td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to migrate an Amazon Web Services (AWS) account from AWS Organizations, where it is a member account that’s governed by a management account, to AWS Control Tower. By enrolling the account in AWS Control Tower, you can take advantage of preventive and detective guardrails and features that streamline your account governance. You might also want to migrate your member account if your AWS Organizations management account has been compromised, and you want to move member accounts to a new organization that is governed by AWS Control Tower.

AWS Control Tower provides a framework that combines and integrates the capabilities of several other AWS services, including AWS Organizations, and ensures consistent compliance and governance across your multi-account environment. With AWS Control Tower, you can follow a set of prescribed rules and definitions that extend the capabilities of AWS Organizations. For example, you can use guardrails to ensure that security logs and necessary cross-account access permissions are created, and not altered.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Control Tower set up in your target organization in AWS Organizations (for instructions, see Setting up in the AWS Control Tower documentation)
- Administrator credentials for AWS Control Tower (member of the AWSControlTowerAdmins group)
- Administrator credentials for the source AWS account

Limitations

- The source management account in AWS Organizations must be different from the target management account in AWS Control Tower.
Product versions

- AWS Control Tower version 2.3 (February 2020) or later (see release notes)

Architecture

The following diagram illustrates the migration process and reference architecture. This pattern migrates the AWS account from the source organization to a target organization that is governed by AWS Control Tower.

The enrollment process consists of these steps:

1. The account leaves the source organization in AWS Organizations.
2. The account becomes a standalone account. This means that it doesn't belong to any organization, so governance and billing are managed independently by account administrators.
3. The target organization sends an invitation for the account to join the organization.
4. The standalone account accepts the invitation and becomes a member of the target organization.
5. The account is enrolled in AWS Control Tower and moved to a registered organizational unit (OU).

(We recommend that you check the AWS Control Tower dashboard to confirm the enrollment.) At this point, all guardrails that are enabled in the registered OU take effect.

Tools

AWS services

- **AWS Organizations** – AWS Organizations is an account management service that enables you to consolidate multiple AWS accounts into a single entity (an organization) that you create and centrally manage.
- **AWS Control Tower** – AWS Control Tower integrates the capabilities of other services, including AWS Organizations, AWS IAM Identity Center (successor to AWS Single Sign-On), and AWS Service Catalog, to help you enforce and manage governance rules for security, operations, and compliance at scale across all your organizations and accounts in the AWS Cloud.
## Epics

### Remove the member account from the source organization

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Verify that the member account can run as a stand-alone account.</td>
<td>Confirm that the member account that will leave the source organization has the information that is required for it to operate as a standalone account. For example, if the member account doesn't have billing information, it can't operate as a standalone account, because AWS uses the payment information to charge for any billable AWS activity that occurs while the account isn't attached to an organization. Typically, if you created the member account by using the AWS Organizations console, API, or AWS Command Line Interface (CLI) commands, the information required of standalone accounts isn't automatically collected. To add this information, sign in to the account, and specify a support plan, contact information, and a payment method. For more information about what you need to know before removing an account from an organization, see Before removing an account from organization in the AWS Organizations documentation.</td>
<td>Account administrator</td>
</tr>
<tr>
<td>Remove the member account from its source organization.</td>
<td>Follow the instructions in the AWS Organizations documentation to remove a member account from an organization. You can sign in to the organization's management account and remove the member account, or sign in to the member account and leave the organization. If you don't have administrator-level credentials to remove or leave the account, ask</td>
<td>Management account administrator or account administrator</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>---------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>For assistance from your organization's administrator.</td>
<td>If the member account is missing a support plan, contact information, or payment information, you will be prompted to provide and verify that information. When you leave the organization, you are redirected to the <strong>Getting Started</strong> page of the AWS Organizations console, where you can view invitations for your account to join other organizations. <strong>Important:</strong> At this point, your account is a standalone account. If you are running workloads that aren't covered by AWS Free Tier, you will be charged according to the payment and billing information you provided for the account.</td>
<td></td>
</tr>
<tr>
<td>Verify that the member account is no longer part of the source organization.</td>
<td>In the AWS Organizations console, you should no longer see the <strong>Leave organization</strong> button. Instead, you should see pending invitations, if any, from other organizations.</td>
<td>Account administrator</td>
</tr>
<tr>
<td>Remove the IAM roles that grant access to your account from the organization you left.</td>
<td>When you remove the account from the source organization, AWS Identity and Access Management (IAM) roles created by AWS Organizations or by administrators aren't automatically deleted. To terminate access from the source organization's management account, you must manually delete the IAM roles. For more information, see <a href="https://docs.aws.amazon.com/IAM/latest/UserGuide/id_roles_manage.html">Deleting roles or instance profiles</a> in the IAM documentation. When a member account leaves an organization, all tags that were attached to the account are deleted. Standalone accounts do not support tags.</td>
<td>Account administrator</td>
</tr>
</tbody>
</table>
Invite the account to join the new organization with AWS Control Tower

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign in to AWS Control Tower.</td>
<td>Sign in to the AWS Control Tower console as an administrator. Currently, there is no direct way to move an AWS account from a source organization to an organization in an OU that's governed by AWS Control Tower. However, you can extend AWS Control Tower governance to an existing AWS account when you enroll it into an OU that's already governed by AWS Control Tower. That's why you have to log in to AWS Control Tower for this step.</td>
<td>AWS Control Tower administrator</td>
</tr>
</tbody>
</table>
| Invite the member account.          | 1. Sign in to the AWS Organizations console, and navigate to the AWS Accounts page.  
2. On the Add an AWS account page, choose Invite an existing AWS account.  
3. Complete the account information, including the 12-digit account number (without dashes) and the optional description and tags, and then choose Send invitation.  

Important: Verify that no applications or network connectivity will be affected by the account transfer.  
This action sends an invitation email with a link to the member account. When the account administrator follows the link and accepts the invitation, the member account appears in the AWS accounts page. For more information, see Inviting an AWS account to join your organization in the AWS Organizations documentation. | AWS Control Tower administrator        |
| Test applications and connectivity. | When the member account has been registered into the account appears in the AWS accounts page. For more information, see Inviting an AWS account to join your organization in the AWS Organizations documentation. | AWS Control Tower administrator, Member account |
new organization, it appears in the OU within a root. It also appears in the AWS Control Tower console, flagged as not enrolled in accounts, because it hasn't yet been enrolled in the AWS Control Tower registered OU.

Verify the following:

- Check the AWS Control Tower dashboard to see if there are any guardrail violations.
- Check network connectivity (VPN or AWS Direct Connect) to make sure it wasn't affected by the transfer.
- (Application owners) Test the applications that are associated with this account to verify that they run as expected, and that dependencies weren't affected by the account transfer.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prepare the account for enrollment</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Review guardrails and fix any violations.</td>
<td>Review the guardrails that are defined in the target OU, especially the preventive guardrails, and fix any violations. A number of mandatory, preventive guardrails are enabled by default when you set up your AWS Control Tower landing zone. These can't be disabled. You must review these mandatory guardrails and fix the member account (manually or by using a script) before you enroll the account. <strong>Note:</strong> Preventive guardrails keep AWS Control Tower registered accounts compliant and prevent policy violations. Any violation of preventive guardrails might affect</td>
<td>AWS Control Tower administrator, Member account administrator</td>

Additional information

Troubleshooting

Here are two errors you might encounter in AWS Control Tower and their resolutions:

- An unknown error occurred. Try again later, or contact AWS Support. This error occurs when you use root user credentials (management account) in AWS Control Tower to enroll a new account. AWS Service Catalog can't map the Account Factory Portfolio or product to the root user, which results in the error message. To remediate this error, use non-root, full-access user (administrator) credentials to enroll the new account. For more information about how to create an administrator user, see Create an IAM user in the AWS Control Tower documentation.
- The AWS Control Tower Activities page displays a Get Catastrophic Drift action. This action reflects a drift check of the service and does not indicate any issues with the AWS Control Tower setup. No action is required.
More patterns

- Rotate database credentials without restarting containers (p. 322)
- Tag Transit Gateway attachments automatically using AWS Organizations (p. 1981)
- Use BMC Discovery queries to extract migration data for migration planning (p. 1330)
**Automate RabbitMQ configuration in Amazon MQ**

*Created by Yogesh Bhatia (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>Technologies:</th>
<th>AWS services:</th>
</tr>
</thead>
<tbody>
<tr>
<td>PoC or pilot</td>
<td>Messaging &amp; communications; DevOps;</td>
<td>Amazon MQ; AWS CloudFormation</td>
</tr>
<tr>
<td></td>
<td>Infrastructure</td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

Amazon MQ is a managed message broker service that provides compatibility with many popular message brokers. Using Amazon MQ with RabbitMQ provides a robust RabbitMQ cluster managed in the Amazon Web Services (AWS) Cloud with multiple brokers and configuration options. Amazon MQ provides a highly available, secure, and scalable infrastructure, and can process a large number of messages per second with ease. Multiple applications can use the infrastructure with different virtual hosts, queues, and exchanges. However, managing these configuration options or creating the infrastructure manually can require time and effort. This pattern describes a way to manage configurations for RabbitMQ in one step, through a single file. You can embed the code provided with this pattern within any continuous integration (CI) tool such as Jenkins or Bamboo.

You can use this pattern to configure any RabbitMQ cluster. All it requires the connectivity to the cluster. Although there are many other ways to manage RabbitMQ configurations, this solution creates entire application configurations in one step, so you can manage queues and other details easily.

**Prerequisites and limitations**

**Prerequisites**

- AWS Command Line Interface (AWS CLI) installed and configured to point to your AWS account (for instructions, see [AWS CLI documentation](https://docs.aws.amazon.com/cli/latest/UserGuide/what-is.html))
- Ansible installed, so you can run playbooks to create the configuration
- `rabbitmqadmin` installed (for instructions, see the [RabbitMQ documentation](https://www.rabbitmq.com/install.html))
- A RabbitMQ cluster in Amazon MQ, created with healthy Amazon CloudWatch metrics

**Additional requirements**

- Make sure to create the configurations for virtual hosts and users separately and not as part of JSON.
- Make sure that the configuration JSON is part of the repository and is version-controlled.
- The version of the `rabbitmqadmin` CLI has to be the same as the version of the RabbitMQ server, so the best option is to download the CLI from the RabbitMQ console.
- As part of the pipeline, make sure that JSON syntax is validated before each run.
Product versions

- AWS CLI version 1.18.147
- Ansible version 2.9.13
- rabbitmqadmin version 3.8.6 (must be the same as the RabbitMQ server version)

Architecture

Source technology stack

- An RabbitMQ cluster running on an existing on-premises virtual machine (VM) or a Kubernetes cluster (on premises or in the cloud)

Target technology stack

- Automated RabbitMQ configurations on Amazon MQ for RabbitMQ

Target architecture

There are many ways to configure RabbitMQ. This pattern uses the import configuration functionality, where a single JSON file contains all the configurations. This file applies all settings and can be managed by a version-control system such as Bitbucket or Git. This pattern uses Ansible to implement the configuration through the rabbitmqadmin CLI.

Tools

Tools

- rabbitmqadmin – A command line tool for the RabbitMQ HTTP-based API, used to manage and monitor RabbitMQ nodes and clusters.
- Ansible – An open-source tool for automating applications and IT infrastructure.
- AWS CLI – An open source tool that enables you to interact with AWS services by using commands in a command-line shell.
AWS services

- **Amazon MQ** – A managed message broker service that makes it easy to set up and operate message brokers in the cloud.
- **AWS CloudFormation** – A service that helps you set up your AWS infrastructure and speed up cloud provisioning with infrastructure as code.

**Code**

The JSON configuration file used in this pattern and a sample Ansible playbook are provided in the attachment.

**Epics**

**Create your AWS infrastructure**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a RabbitMQ cluster on AWS.</td>
<td>If you don't already have a RabbitMQ cluster, you can use AWS CloudFormation to create the stack on AWS. Or, you can use the Cloudformation module in Ansible to create the stack. With the latter approach, you can use Ansible for both tasks: to create the RabbitMQ infrastructure and to manage configurations.</td>
<td>AWS CloudFormation, Ansible</td>
</tr>
</tbody>
</table>

**Create the Amazon MQ for RabbitMQ configuration**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create a properties file. | Download the JSON configuration file (rabbitmqconfig.json) in the attachment, or export it from the RabbitMQ console. Modify it to configure queues, exchanges, and bindings. This configuration file demonstrates the following:  
  - Creates two queues: sample-queue1 and sample-queue2
  - Creates two exchanges: sample-exchange1 and sample-exchange2
  - Implements the binding between the queues and exchanges | JSON             |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Retrieve the details of the Amazon MQ for RabbitMQ infrastructure. | These configurations are performed under the root (/) virtual host, as required by `rabbitmqadmin`. Retrieve the following details for the RabbitMQ infrastructure on AWS:  
• Broker name  
• RabbitMQ host  
• RabbitMQ user name (the administrator user created during cluster creation)  
• RabbitMQ password  

You can use the AWS Management Console or the AWS CLI to retrieve this information. These details enable the Ansible playbook to connect to your AWS account and use the RabbitMQ cluster to run commands.  

**Important** The computer that runs the Ansible playbook must be able to access your AWS account, and AWS CLI must already be configured, as described in the *Prerequisites* section. | AWS CLI, Amazon MQ |
| Create the hosts_var file. | Create the hosts_var file for Ansible and make sure that all the variables are defined in the file. Consider using Ansible Vault to store the password. You can configure the hosts_var file as follows (replace the asterisks with your information):  
```
RABBITMQ_HOST: "***********.mq.us-east-2.amazonaws.com"
RABBITMQ_VHOST: "/
RABBITMQ_USERNAME: "admin"
RABBITMQ_PASSWORD: "*******"
``` | Ansible |
Create an Ansible playbook.  

**Description**  
For a sample playbook, see `ansible-rabbit-config.yaml` in the attachment. Download and save this file. The Ansible playbook imports and manages all RabbitMQ configurations, such as queues, exchanges, and bindings, that applications require.  

Follow best practices for Ansible playbooks, such as securing passwords. Use Ansible Vault for password encryption, and retrieve the RabbitMQ password from the encrypted file.

**Skills required**  
Ansible

---

## Deploy the configuration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Run the playbook. | Run the Ansible playbook that you created in the previous epic:  
ansiible-playbook ansible-rabbit-config.yaml | RabbitMQ, Amazon MQ, Ansible |
|              | You can verify the new configurations on the RabbitMQ console.               |                                |

---

**Improve call quality on agent workstations in Amazon Connect contact centers**
Summary

Call quality issues are some of the most difficult problems to troubleshoot in contact centers. To avoid voice quality issues and complex troubleshooting procedures, you must optimize your agents’ work environment and workstation settings. This pattern describes voice quality optimization techniques for agent workstations in Amazon Connect contact centers. It provides recommendations in the following areas:

- Work environment adjustments. Agents’ surroundings don’t affect how voice is transmitted over the network, but they do have an effect on call quality.
- Agent workstation settings. Hardware and network configurations for contact center workstations have significant effects on call quality.
- Browser settings. Agents use a web browser to access the Amazon Connect Contact Control Panel (CPP) website and communicate with customers, so browser settings can affect call quality.

The following components can also affect call quality, but they fall outside the scope of the workstation and aren’t covered in this pattern:

- Traffic flows to the Amazon Web Services (AWS) Cloud over AWS Direct Connect, a full-tunnel VPN, or a split-tunnel VPN
- Network conditions when working in or outside the corporate office
- Public switched telephone network (PSTN) connectivity
- The customer’s device and telephony carrier
- Virtual desktop infrastructure (VDI) setup

For more information relating to these areas, see Common Contact Control Panel (CPP) Issues and Use the Endpoint Test Utility in the Amazon Connect documentation.

Prerequisites and limitations

Prerequisites

- Headsets and workstations must comply with the requirements specified in the Amazon Connect Administrator Guide.

Limitations

- The optimization techniques in this pattern apply to soft phone voice quality. They do not apply when you configure the Amazon Connect CPP in desk phone mode. However, you can use desk phone mode if your soft phone setup doesn’t provide acceptable voice quality for the call.

Product versions

- For supported browsers and versions, see the Amazon Connect Administrator Guide.
Architecture

This pattern is architecture-agnostic because it targets agent workstation settings. As the following diagram shows, the voice path from the agent to the customer is affected by the agent's headset, browser, operating system, workstation hardware, and network.

In Amazon Connect contact centers, the user's audio connectivity is established with WebRTC. Voice is encoded with the Opus interactive audio codec and encrypted with the Secure Real-time Transport Protocol (SRTP) in transit. Other network architectures are possible, including VPN, private WAN/LAN, and ISP networks.

Tools

- **Amazon Connect Endpoint Test Utility** – This utility checks network connectivity and browser settings.
- Browser configuration editors for WebRTC settings:
  - For Firefox: `about:config`
  - For Chrome: `chrome://flags`
- **CCP Log Parser** – This tool helps you analyze CCP logs for troubleshooting purposes.

Epics

**Adjust the work environment**

</table>
| Configure the operating system’s sound settings. | The default settings for microphone level and boost usually work fine. If you find that outbound voice is quiet or the microphone is picking up too much, it might help to adjust these settings. Microphone settings can be found in your computer’s system sound configuration ([Sound, Input on MacOS](https://support.apple.com/en-au/HT201696), [Microphone Properties in Windows](https://support.microsoft.com/en-us/windows/windows-10-microphone-properties-9f145dbd-1d8d-4bda-8e96-09181fa9f3d9)). You can access advanced settings that might affect voice quality through system tools or third-party applications. Here are some of the settings you can check:  
  • Sample rate – This value determines how many times the sound is probed per second. The default setting is usually 44 or 48 kilohertz (kHz). The optimal value for Amazon Connect is 48 kHz. You can use your browser settings to override the default value. For more information, see the [troubleshooting section of the Amazon Connect Administrator Guide](https://docs.aws.amazon.com/connect/latest/adminguide/troubleshoot.html).  
  • Gain – This value determines how much the microphone amplifies the sound. If you turn the gain up, your microphone might pick up more background noise.  
  • Bit depth – This digital resolution value describes how many levels of sound amplitude are being recognized. The higher the bit depth, the smoother the voice sounds. However, many traditional telephony networks use the pulse-code modulation (PCM) standard, which supports only 8-bit resolution.  
  • Open threshold – This is the minimal sound amplitude that a microphone picks up. | Agent, Administrator |

| Check CCP logs. | The CCP Log Parser provides an easy way to check application logs.  
1. Download the CCP logs after a call.  
2. Open the CCP Log Parser.  
3. Drag and drop the log file to upload the log for analysis.  
4. When the log has been analyzed, the Snapshots & Logs tab will be selected by default. Choose the Metrics tab next to it to check insights.  
5. In the WebRTC Metrics - audio_input section, check the following:  
  • The Audio Level graph, to see if your received audio level is above 0. This indicates that audio was received from your caller.  
  • The Packets graph for any lost packets. If this chart shows significant increases, contact your IT support team.  
6. In the WebRTC Metrics - audio_output section, check the following:  
  • The Audio Level graph, to confirm that audio was sent out from your device.  
  • The Packets graph. If you see a packet loss spike, report it to your IT support team.  
  • The Jitter Buffer & RTT graph. Round trip time (RTT) values above 300 will affect the call experience. Report these to your IT support team. | Agent (advanced skills) |
| Optimize browser settings |                                                                                                                                                                                                             |                                        |
| Task          | Description                                                                                                                                                                                                 | Skills required                        |
| Restore default WebRTC settings. | WebRTC has to be enabled to make soft phone calls with CCP.                                                                                                                                                  | Administrator                          |
We recommend that you keep the default settings for WebRTC-related features.

- In Chrome, you can set flags by navigating to the URL `chrome://flags`. Type `WebRTC` in the search box to find settings that can interfere with CCP, and set these to Default.
- In Firefox, type `about:config` in the address bar, and then type `WebRTC` in the search box on the configuration page. Non-default settings appear in bold text and can be changed to Default.

Disable browser extensions when troubleshooting.

Some browser extensions might affect call quality or even prevent calls from connecting properly. Use the incognito window or private mode in your browser, and disable all extensions. If that solves the problem, review your browser extensions and look for suspicious add-ons, or disable them individually.

Check the browser sample rate.

Confirm that your microphone input is set to the optimal 48 kHz sample rate. For instructions, see the Amazon Connect Administrator Guide.

---

### Related resources

If you’ve followed the steps in this pattern but you’re still encountering problems with call quality, see the following resources for troubleshooting tips.

- Review [common Contact Control Panel (CCP) issues](#).
- Check the connection with the [Endpoint Test Utility](#).
- Follow the [troubleshooting guide](#) for any other issues.

If your troubleshooting and adjustments don't solve the call quality issue, the root cause might be external to your workstation. For further troubleshooting, contact your IT support team.

AWS services: AWS Application Discovery Service; AWS Migration Hub

Summary

On-premises applications require a transformative approach to help unlock the benefits of the Amazon Web Services (AWS) Cloud. The seven common migration strategies (7 Rs) provide you with transformation options, which vary from making technology changes in on-premises database servers to rebuilding an application by using a cloud-native microservices architecture.
Choosing to use the full 7 Rs model means that you operate at the application and business level instead of only evaluating and preparing the servers for migration. Although you can obtain server data by using tools such as AWS Migration Evaluator, other application information is often not recorded (for example, roadmap status, required recovery time objective (RTO) and recovery point objective (RPO), or data privacy requirements).

This pattern describes how to use AppScore to avoid these challenges by using an application-centric view of your portfolio. This includes a recommended transformation route to the AWS Cloud for each application against the full 7 Rs model. AppScore helps you capture application information, determine the ideal transformation route, identify the risk, complexity and benefits of cloud adoption, and quickly define the migration scopes, move groups, and schedules.

This pattern was created by AWS and AppScore Technology Limited, an AWS Partner.

**Prerequisites and limitations**

**Prerequisites**

- Existing applications that you want to migrate to the AWS Cloud.
- Existing server inventory information from a tool such as AWS Migration Evaluator. You can also import this data at a later stage in your migration.
- An existing AppScore account with Power User privileges. For more information about AppScore user accounts, see How do I assign role-based access control (RBAC) to users? in the AppScore documentation.
- An understanding of how to assign RBAC roles in AppScore. AppScore provides three subject matter expert (SME) roles that align to the questions asked in the Scoring stage. This means that an SME only answers questions relevant to their expertise and role. For more information about this, see How do I assign role-based access control (RBAC) to users? in the AppScore documentation.
- An understanding of AppScore's recommendations, which are based on the following three categories of application attributes:
  - **Risk** – The business criticality of the application, whether it contains confidential data, data sovereignty requirements, and the number of application users or interfaces.
  - **Complexity** – The application's development language (for example, COBOL has a higher score than .NET or PHP), age, UI, or number of interfaces.
  - **Benefit** – The batch processing demand, application profile, disaster recovery model, development and test environment use.
- An understanding of AppScore's four phases of iterative data capture:
  - **Signposting** – Questions that are combined with server data to produce the 7 Rs assessments. For more information, see How to signpost and score applications in the AppScore documentation.
  - **Scoring** – Questions that produce scores for risk, benefit, and complexity.
  - **Current State Assessment** – Questions that provide a current state assessment of the application.
  - **Transformation** – Questions that comprehensively evaluate the application for future state design.

**Important**: Only the Signposting and Scoring stages are required to receive application scores, 7 Rs assessments, and enable group planning. After you group applications and form scopes, you can complete the Current State Assessment and Transformation stages to build a more detailed overview of your application.

**Architecture**

The following diagram shows the AppScore workflow that uses application and server data to create a recommendation for your migration strategy and transformation plan.
Tools

- **AppScore** – AppScore helps you bridge the gap between discovery and migration implementation by providing an application-centric view of your portfolio with a recommended route to the cloud for each application against the full 7 Rs model.

- **AWS Migration Evaluator** – AWS Migration Evaluator is a migration assessment service that helps you create a directional business case for planning and migration.

Epics

Create and load the initial application list

<table>

</tbody>
</table>

### Capture the application and business data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Review and answer Signposting and Scoring questions. | Open the Servers page and choose Import Servers. Choose the .csv file that contains your server data.  

The file can include attributes such as name, data center, operating system, virtual or physical, application name, role, database technology, environment, CPU core count and utilization, RAM size and utilization, disk size and utilization, matched machine type, and current and projected monthly costs.  

Confirm column mapping and choose Confirm and Import.  

Missing information in the imported data is highlighted on the Server page. You can resolve these gaps on this page or by using the Bulk Edit option. Servers are associated with the relevant application. However, if applications don't exist in AppScore, they are automatically created and the servers are then associated.  

You can also use an API connection to retrieve the data with AWS Migration Hub. For more information about this, see [How do I import servers from AWS Migration Hub via API?](#) in the AppScore documentation.  

**Note:** If you used a discovery tool (for example, AWS Migration Evaluator) to capture performance over time, you must load an early extract of the server data as soon as possible and refresh the data. | App owner |

Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel and Python

Created by Venkata Naveen Koppula (AWS)

<table>
<thead>
<tr>
<th>R Type</th>

<tr>
<td>AWS</td>
<td>PoC or pilot</td>
<td>Databases; Migration</td>
</tr>
</tbody>
</table>
Summary

This pattern outlines steps for automatically creating AWS CloudFormation templates for AWS Database Migration Service (AWS DMS) using Microsoft Excel and Python.

Migrating databases using AWS DMS often involves creation of AWS CloudFormation templates to provision AWS DMS tasks. Previously, creating AWS CloudFormation templates required knowledge of the JSON or YAML programming language. With this tool, you only need basic knowledge of Excel and how to run a Python script using a terminal or command window.

As input, the tool takes an Excel workbook that includes the names of the tables to be migrated, Amazon Resource Names (ARNs) of AWS DMS endpoints, and AWS DMS replication instances. The tool then generates AWS CloudFormation templates for the required AWS DMS tasks.

For detailed steps and background information, see the blog post Create AWS CloudFormation templates for AWS DMS tasks using Microsoft Excel in the AWS Database blog.

Prerequisites and limitations

Prerequisites

- Microsoft Excel version 2016 or later
- Python version 2.7 or later
- The xlrd Python module (installed at a command prompt with the command: `pip install xlrd`)
- AWS DMS source and target endpoints and AWS DMS replication instance

Limitations

- The names of schemas, tables, and associated columns are transformed into lowercase characters at the destination endpoints.
- This tool doesn’t address the creation of AWS DMS endpoints and replication instances.
- Currently, the tool supports only one schema for each AWS DMS task.

Architecture

Source technology stack

- An on-premises database
- Microsoft Excel

Target technology stack

- AWS CloudFormation templates
- A database in the AWS Cloud
Tools

- Pycharm IDE, or any integrated development environment (IDE) that supports Python version 3.6
- Microsoft Office 2016 (for Microsoft Excel)

Get started with automated portfolio discovery

Created by Pratik Chunawala (AWS) and Rodolfo Jr. Cerrada (AWS)

<table>
<thead>
<tr>
<th>Environment: Production</th>

</tr>
</tbody>
</table>
Summary

Assessing the portfolio and collecting metadata is a critical challenge when migrating applications and servers to the Amazon Web Services (AWS) Cloud, especially for large migrations that have more than 300 servers. Using an automated portfolio discovery tool can help you collect information about your applications, such as the number of users, frequency of use, dependencies, and information about the application's infrastructure. This information is essential when planning migration waves so that you can properly prioritize and group applications with similar traits. Using a discovery tool streamlines communication between the portfolio team and the application owners because the portfolio team can validate the results of the discovery tool rather than manually collecting the metadata. This pattern discusses key considerations for selecting an automated discovery tool and information about how to deploy and test one in your environment.

This pattern includes a template, which is a starting point for building your own checklist of high-level activities. Next to the checklist is template for a responsible, accountable, consulted, informed (RACI) matrix. You can use this RACI matrix to determine who is responsible for each task in your checklist.

Tools

For more information about discovery tools, see Migration Evaluator, AWS Application Discovery Service, and AWS Migration Competency Partner offerings.

Epics

Select a discovery tool

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Determine whether a discovery tool is appropriate for your use case.</td>
<td>A discovery tool might not be the best solution for your use case. Consider the amount of time required to select, procure, prepare, and deploy a discovery tool. It can take 4–8 weeks to set up the scanning appliance for an agentless discovery tool in your environment or to install agents to all in-scope workloads. Once deployed, you must allow 4–12 weeks for the discovery tool to collect metadata by scanning the application workloads and performing application stack analysis. If you are migrating fewer than 100 servers, you might be able to manually collect the metadata and analyze dependencies faster than the time required to deploy and collect metadata with an automated discovery tool.</td>

### Additional information

**Considerations for selecting an automated discovery tool**

Each discovery tool has benefits and limitations. When selecting the appropriate tool for your use case, consider the following:

- Select a discovery tool that can collect most, if not all, of the metadata you need to achieve your portfolio assessment goal.
- Identify any metadata you need to gather manually because the tool doesn’t support it.
- Provide the discovery tool requirements to stakeholders so they can review and assess the tool based on their internal security and compliance requirements, such as server, network, and credential requirements.
- Does the tool require that you install an agent in the in-scope workload?
• Does the tool require that you set up a virtual appliance in your environment?
• Determine your data residency requirements. Some organizations don’t want to store their data outside of their environment. To address this, you might need to install some components of the tool in the on-premises environment.
• Make sure the tool supports the operating system (OS) and OS version of the in-scope workload.
• Determine whether your portfolio includes mainframe, mid-range, and legacy servers. Most of the discovery tools can detect these workloads as dependencies, but some tools might not be able to get device details, such as utilization and server dependencies. Device42 and modernizeIT discovery tools both support mainframe and mid-range servers.

Migrate an on-premises MySQL database to Amazon RDS for MySQL

<table>
<thead>
<tr>
<th>Created by:</th>
<th>AWS</th>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Technologies:</th>
<th>Databases; Migration</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workload:</td>
<td>Open-source</td>
<td>AWS services:</td>
<td>Amazon RDS</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides guidance for migrating an on-premises MySQL database to Amazon Relational Database Service (Amazon RDS) for MySQL. The pattern discusses the use of AWS Database Migration Service (AWS DMS) or native MySQL tools such as mysqldbcopy and mysqldump for the migration.

Prerequisites and limitations

Prerequisites

• An active AWS account
• A MySQL source database in an on-premises data center

Limitations

• Database size limit: 64 TB

Product versions

• MySQL versions 5.5, 5.6, 5.7, 8.0. For the latest list of supported versions, see MySQL on Amazon RDS in the AWS documentation. If you’re using AWS DMS, see also Using a MySQL-Compatible Database as a Target for AWS DMS for MySQL versions supported by AWS DMS.
Architecture

Source technology stack
- An on-premises MySQL database

Target technology stack
- An Amazon RDS DB instance running MySQL

Target architecture

AWS data migration architecture

*Using AWS DMS:*
Using native MySQL tools:
Tools

- **AWS DMS - AWS Database Migration Service** (AWS DMS) supports several source and target databases. For information about MySQL source and target databases supported by AWS DMS, see [Migrating MySQL-Compatible Databases to AWS](#). If your source database isn't supported by AWS DMS, you must choose another method to migrate your data.

- **Native MySQL tools - mysqldbcopy and mysqldump**

### Epics

#### Plan the migration

<table>

Move mainframe files directly to Amazon S3 using Transfer Family

*Created by Luis Gustavo Dantas (AWS)*

<table>
<thead>
<tr>
<th>Environment: Production</th>
<th>Source: Mainframe</th>
<th>Target: Amazon S3</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: N/A</td>
<td>Workload: IBM</td>
<td>Technologies: Migration; Storage &amp; backup</td>
</tr>
</tbody>
</table>
Summary

As part of the modernization journey, you can face the challenge of transferring files between your on-premises servers and the Amazon Web Services (AWS) Cloud. Transferring data from mainframes can be a significant challenge because mainframes typically can't access modern data stores like Amazon Simple Storage Service (Amazon S3), Amazon Elastic Block Store (Amazon EBS), or Amazon Elastic File System (Amazon EFS).

Many customers use intermediate staging resources, such as on-premises Linux, Unix, or Windows servers, to transfer files to the AWS Cloud. You can avoid this indirect method by using AWS Transfer Family with the Secure Shell (SSH) File Transfer Protocol (SFTP) to upload mainframe files directly to Amazon S3.

Prerequisites and limitations

Prerequisites

• An active AWS account
• A virtual private cloud (VPC) with a subnet that's reachable by your legacy platform
• A Transfer Family endpoint for your VPC
• Mainframe Virtual Storage Access Method (VSAM) files converted to sequential, fixed-length files (IBM documentation)

Limitations

• SFTP transfers files in binary mode by default, which means that files are uploaded to Amazon S3 with EBCDIC encoding preserved. If your file doesn't contain binary or packed data, then you can use the `sftp ascii subcommand` (IBM documentation) to convert your files to text during the transfer.
• You must unpack mainframe files (AWS Prescriptive Guidance) that contain packed and binary content to use these files in your target environment.
• Amazon S3 objects can range in size from a minimum of 0 bytes to a maximum of 5 TB. For more information about Amazon S3 capabilities, see Amazon S3 FAQs.

Architecture

Source technology stack

• Job control language (JCL)
• z/OS Unix shell and ISPF
• SFTP
• VSAM and flat files

Target technology stack

• Transfer Family
• Amazon S3
• Amazon Virtual Private Cloud (Amazon VPC)
Target architecture

The following diagram shows a reference architecture for using Transfer Family with SFTP to upload mainframe files directly to an S3 bucket.

The diagram shows the following workflow:

1. You use a JCL job to transfer your mainframe files from the legacy mainframe to the AWS Cloud through Direct Connect.
2. Direct Connect enables your network traffic to remain on the AWS global network and bypass the public internet. Direct Connect also enhances the network speed, starting at 50 Mbps and scaling up to 100 Gbps.
3. The VPC endpoint enables connections between your VPC resources and the supported services without using the public internet. Access to Transfer Family and Amazon S3 achieves high availability by taking place through the elastic network interfaces located in two private subnets and Availability Zones.
4. Transfer Family authenticates users and uses SFTP to receive your files from the legacy environment and move them to an S3 bucket.

Automation and scale

After the Transfer Family service is in place, you can transfer an unlimited number of files from the mainframe to Amazon S3 by using a JCL job as the SFTP client. You can also automate the file transfer by using a mainframe batch job scheduler to run the SFTP jobs when you’re ready to transfer the mainframe files.

Tools

- **Amazon S3** – Amazon Simple Storage Service (Amazon S3) is an object storage service. You can use Amazon S3 to store and retrieve any amount of data at any time, from anywhere on the web.
- **Amazon VPC** – Amazon Virtual Private Cloud (Amazon VPC) provisions a logically isolated section of the AWS Cloud where you can launch AWS resources in a virtual network that you’ve defined. This
virtual network closely resembles a traditional network that you'd operate in your own data center, with the benefits of using the scalable infrastructure of AWS.

- **AWS Transfer Family** – AWS Transfer Family enables you to securely scale your recurring business-to-business file transfers to Amazon S3 and Amazon EFS using SFTP, FTPS, and FTP protocols.

## Epics

### Create the S3 bucket and the access policy

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the S3 bucket.</td>
<td>Create an S3 bucket to host the files that you transfer from your legacy environment.</td>
<td>General AWS</td>
</tr>
</tbody>
</table>
| Create the IAM role and policy. | Transfer Family uses your AWS Identity and Access Management (IAM) role to grant access to the S3 bucket that you created earlier. Create an IAM role that includes the following IAM policy:  

```json
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "UserFolderListing",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Effect": "Allow",
      "Resource": [
        "arn:aws:s3::<your-bucket-name>"
      ]
    },
    {
      "Sid": "HomeDirObjectAccess",
      "Effect": "Allow",
      "Action": [
        "s3:PutObject",
        "s3:GetObjectAcl",
        "s3:GetObject",
        "s3:DeleteObjectVersion",
        "s3:DeleteObject"
      ],
      "Resource": [
        "arn:aws:s3::<your-bucket-name>/*"
      ]
    }
  ]
}
```
<table>
<thead>
<tr>
<th></th>
<th>General AWS</th>
</tr>
</thead>
</table>

Define the transfer service

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create the SFTP server.| 1. Sign in to the AWS Management console, open the Transfer Family console, and then choose Create server.  
2. Choose only SFTP (SSH File Transfer Protocol) - file transfer over Secure Shell protocol and then choose Next.  
3. For Identity provider, choose Service managed and then choose Next.  
4. For Endpoint type, choose VPC hosted.  
5. For Access, choose Internal.  
6. For VPC, choose your VPC.  
7. In the Availability Zones section, choose your Availability Zones and subnets.  
8. In the Security Groups section, choose your security group, and then choose Next.  
9. For Domain, choose Amazon S3 and then choose Next.  
10. Leave the default options on the Configure additional details page and then choose Next.  
11. Choose Create server. | General AWS                                                        |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> For more information about how to set up an SFTP server, see <a href="https://docs.aws.amazon.com/transfer/latest/userguide/">Create an SFTP-enabled server</a> (AWS Transfer Family User Guide).</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| **Get the server address.** | 1. Open the [Transfer Family console](https://console.aws.amazon.com/transfer/home) and choose your server ID in the **Server ID** column.  
2. In the **Endpoint details** section, for **Endpoint type**, choose the endpoint ID. This takes you to the Amazon VPC console.  
3. On the **Details** tab of the Amazon VPC console, find the DNS names next to **DNS names**. | General AWS |
| **Create the SFTP client key pair.** | Create an SSH key pair for either [Microsoft Windows](https://docs.aws.amazon.com/transfer/latest/userguide/) or [macOS/Linux/UNIX](https://docs.aws.amazon.com/transfer/latest/userguide/). | General AWS, SSH |
| **Create the SFTP user.** | 1. Open the [Transfer Family console](https://console.aws.amazon.com/transfer/home), choose **Servers** from the navigation pane, and then select your server.  
2. In the **Server ID** column, choose the server ID for your server and then choose **Add user**.  
3. For **Username**, enter a user name that matches your SSH key pair user name.  
4. For **Role**, choose the IAM role that you created earlier.  
5. For **Home directory**, choose the S3 bucket that you created earlier.  
6. For **SSH public keys**, enter the key pair that you created earlier.  
7. Choose **Add**. | General AWS |

### Transfer the mainframe file

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Send the SSH private key to the mainframe.</strong></td>
<td>Use SFTP or SCP to send the SSH private key to the legacy environment.</td>
<td>Mainframe, z/OS Unix shell, FTP, SCP</td>
</tr>
</tbody>
</table>
### Task Description

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SFTP example</td>
<td><code>sftp [USERNAME@mainframeIP] [password] cd [/u/USERNAME] put [your-key-pair-file]</code></td>
</tr>
<tr>
<td>SCP example</td>
<td><code>scp [your-key-pair-file] [USERNAME@MainframeIP]:/[u/USERNAME]</code></td>
</tr>
</tbody>
</table>

Next, store the SSH key in the z/OS Unix file system under the user name that will later run the file transfer batch job (for example, `/u/CONTROLM`).

**Note:** For more information about z/OS Unix shell, see [An introduction to the z/OS shells](IBM documentation).
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the JCL SFTP client.</td>
<td>Because mainframes don't have a native SFTP client, you must use the BPXBATCH utility to run the SFTP client from the z/OS Unix shell. In the ISPF editor, create the JCL SFTP client. For example:</td>
<td>JCL, Mainframe, z/OS Unix shell</td>
</tr>
</tbody>
</table>
|                          | //JOBNAME JOB ...  
|                          | //SFTP EXEC  
|                          | PGM=BPXBATCH,REGION=0M  
|                          | //STDPARM DD *  
|                          | SH cp  
|                          | "'MAINFRAME.FILE.NAME'"  
|                          | filename.txt;  
|                          | echo 'put filename.txt' > uplcmd;  
|                          | sftp -b uplcmd -i ssh_private_key_file ssh_username=<transfer service ip or DNS>;  
|                          | //SYSPRINT DD SYSOUT=*  
|                          | //STDOUT DD SYSOUT=*  
|                          | //STDENV DD *  
|                          | //STDERR DD SYSOUT=*  
|                          | **Note:** For more information about how to run a command in the z/OS Unix shell, see The BPXBATCH utility (IBM documentation). For more information about how to create or edit JCL jobs in z/OS, see What is ISPF? and The ISPF editor (IBM documentation). |                                                     |
| Run the JCL SFTP client. | 1. In the ISPF editor, enter SUB, and then press the ENTER key after the JCL job is created.  
|                          | 2. Monitor the mainframe’s file transfer batch job activity in SDSF.  
|                          | **Note:** For more information about how to check the activity of batch jobs, see z/OS SDSF User's Guide (IBM documentation).                                                                 | Mainframe, JCL, ISPF                                 |
## Validate the file transfer.

1. Sign in to the AWS Management console, open the Amazon S3 console, and then choose **Buckets** from the navigation pane.
2. Choose the bucket that’s associated with your Transfer Family.
3. In the **Objects** section of the **Objects** tab, find the file that you transferred from the mainframe.

## Automate the JCL SFTP client.

Use job scheduler to automatically trigger the JCL SFTP client.

**Note:** You can use mainframe job schedulers, such as **BMC Control-M** or **CA Workload Automation**, to automate batch jobs for file transfers based on time and other batch job dependencies.

**AWS services:** AWS Application Migration Service
Summary
AWS Application Migration Service helps simplify, expedite, and automate the migration of your Red Hat Enterprise Linux (RHEL) workload to the Amazon Web Services (AWS) Cloud. To add source servers to Application Migration Service, you install the AWS Replication Agent on the servers.

Application Migration Service provides real-time, asynchronous, block-level replication. This means that you can continue normal IT operations during the entire replication process. These IT operations might require that you reboot or restart your RHEL source server during the migration. If this happens, the AWS Replication Agent will not restart automatically, and your data replication will stop. Typically, you can set Security-Enhanced Linux (SELinux) to disabled or permissive mode to automatically restart AWS Replication Agent. However, your organization’s security policies might prohibit disabling SELinux, and you might also have to relabel your files.

This pattern describes how to automatically restart the AWS Replication Agent without turning off SELinux when your RHEL source server reboots or restarts during a migration.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An on-premises RHEL workload that you want to migrate to the AWS Cloud.
- Application Migration Service initialized from the Application Migration Service console. Initialization is required only the first time you use this service. For instructions, see the Application Migration Service documentation.
- An existing AWS Identity and Access Management (IAM) policy for Application Migration Service. For more information, see the Application Migration Service documentation.

Versions

- RHEL version 7 or later

Tools

AWS services

- AWS Application Migration Service is a highly automated lift-and-shift (rehost) solution that simplifies, expedites, and reduces the cost of migrating applications to AWS.

Linux commands

The following table provides a list of Linux commands that you will run on your RHEL source server. These are also described in the epics and stories for this pattern.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#systemctl –version</td>
<td>Identifies the system version.</td>
</tr>
<tr>
<td>#systemctl list-units --type=service</td>
<td>Lists all active services that are available on the RHEL server.</td>
</tr>
<tr>
<td>#systemctl list-units --type=service</td>
<td>grep running</td>
</tr>
</tbody>
</table>
#systemctl list-units --type=service | grep failed
Lists all services that failed to load after the RHEL server rebooted or restarted.

restorecon -Rv /etc/rc.d/init.d/aws-replication-service
Changes the context to aws-replication-service.

yum install policycoreutils*
Installs the policy core utilities that are required for the operation of the SELinux system.

ausearch -c "insmod" --raw | audit2allow -M my-modprobe
Searches the audit log and creates a module for policies.

semodule -i my-modprobe.pp
Activates the policy.

cat my-modprobe.te
Displays the contents of the my-modprobe.te file.

semodule -l | grep my-modprobe
Checks whether the policy has been loaded to the SELinux module.

---

## Epics

### Install the AWS Replication Agent and reboot the RHEL source server

AWS Prescriptive Guidance Patterns
Convert VARCHAR2(1) data type to Boolean data type

**Summary**

During a migration from Amazon Relational Database Service (Amazon RDS) for Oracle to Amazon Aurora PostgreSQL-Compatible Edition, you might encounter a data mismatch when validating the migration in Amazon Web Services (AWS) Database Migration Service (AWS DMS). To prevent this mismatch, you can convert VARCHAR2(1) data type to Boolean data type.

VARCHAR2 data type stores variable-length text strings, and VARCHAR2(1) indicates that the string is 1 character in length or 1 byte. For more information about VARCHAR2, see Oracle built-in data types (Oracle documentation).

In this pattern, in the sample source data table column, the VARCHAR2(1) data is either a Y, for Yes, or N, for No. This pattern includes instructions for using AWS DMS and AWS Schema Conversion Tool (AWS SCT) to convert this data type from the Y and N values in VARCHAR2(1) to true or false values in Boolean.

**Target audience**

This pattern is recommended for those who have experience migrating Oracle databases to Aurora PostgreSQL-Compatible by using AWS DMS. As you complete the migration, adhere to the recommendations in Converting Oracle to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL (AWS SCT documentation).

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- Confirm that your environment is prepared for Aurora, including setting up credentials, permissions, and a security group. For more information, see Setting up your environment for Amazon Aurora (Aurora documentation).
- A source Amazon RDS for Oracle database that contains a table column with VARCHAR2(1) data.
- A target Amazon Aurora PostgreSQL-Compatible database instance. For more information, see Creating a database cluster and connecting to a database on an Aurora PostgreSQL database cluster (Aurora documentation).

**Product versions**

- Amazon RDS for Oracle version 12.1.0.2 or later.
- AWS DMS version 3.1.4 or later. For more information, see Using an Oracle database as a source for AWS DMS and Using a PostgreSQL database as a target for AWS DMS (AWS DMS documentation). We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support.
- AWS Schema Conversion Tool (AWS SCT) version 1.0.632 or later. We recommend that you use the latest version of AWS SCT for the most comprehensive version and feature support.
- Aurora supports the PostgreSQL versions listed in Database Engine Versions for Aurora PostgreSQL-Compatible (Aurora documentation).

**Architecture**

**Source technology stack**

Amazon RDS for Oracle database instance
**Target technology stack**

Amazon Aurora PostgreSQL-Compatible database instance

**Source and target architecture**

**Tools**

**AWS services**

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- **Amazon Relational Database Service (Amazon RDS) for Oracle** helps you set up, operate, and scale an Oracle relational database in the AWS Cloud.
- **AWS Schema Conversion Tool (AWS SCT)** supports heterogeneous database migrations by automatically converting the source database schema and a majority of the custom code to a format compatible with the target database.

**Other services**

- **Oracle SQL Developer** is an integrated development environment that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments. In this pattern, you use this tool to connect to the Amazon RDS for Oracle database instance and query the data.
- **pgAdmin** is an open-source management tool for PostgreSQL. It provides a graphical interface that helps you create, maintain, and use database objects. In this pattern, you use this tool to connect to the Aurora database instance and query the data.
### Epics

#### Prepare for the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Create database migration report.         | 1. In AWS SCT, create a database migration assessment report. For more information, see [Creating migration assessment reports](#).  
  2. Review and perform the action items in the migration assessment report. For more information, see [Assessment report action items](#).                                                                                                                                                                                                                     | DBA, Developer   |
| Disable foreign key constraints on the target database. | In PostgreSQL, foreign keys are implemented by using triggers. During the full load phase, AWS DMS loads each table one at a time. We strongly recommend that you disable foreign key constraints during a full load by using one of the following methods:  
  • Temporarily disable all triggers from the instance, and finish the full load.  
  • Use the `session_replication_role` parameter in PostgreSQL.  
  
  If disabling foreign key constraints is not feasible, create an AWS DMS migration task for the primary data that is specific to the parent table and child table.                                                                                                                                                             | DBA, Developer   |
| Disable the primary keys and unique keys on the target database. | Using the following commands, disable the primary keys and constraints on the target database. This helps improve the performance of the initial load task.  
  
  ```sql
  ALTER TABLE <table> DISABLE PRIMARY KEY;
  ```  
  
  ```sql
  ALTER TABLE <table> DISABLE CONSTRAINT <constraint_name>;
  ```                                                                                                                                                                                                                                                                             | DBA, Developer   |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the initial load task.</td>
<td>In AWS DMS, create the migration task for the initial load. For instructions, see Creating a task. For the migration method, choose Migrate existing data. This migration method is called Full Load in the API. Do not start this task yet.</td>
<td>DBA, Developer</td>
</tr>
</tbody>
</table>
| Edit task settings for the initial load task. | Edit the task settings to add data validation. These validation settings must be created in a JSON file. For instructions and examples, see Specifying task settings. Add the following validations:  
• To validate that the VARCHAR2(1) data is accurately converted to Boolean in the target database, add the code in Data validation script in the Additional information (p. 1019) section of this pattern. The validation script converts the Boolean values of 1 to Y and 0 to N in the target table, and then it compares the values in the target table to the source table.  
To validate the rest of the data migration, enable data validation in the task. For more information, see Data validation task settings. | AWS administrator, DBA |
| Create the ongoing replication task. | In AWS DMS, create the migration task that keeps the target database in sync with the source database. For instructions, see Creating a task. For the migration method, choose Replicate data changes only. Do not start this task yet. | DBA |
## Test the migration tasks

Additional information

Data validation script
The following data validation script converts 1 to Y and 0 to N. This helps the AWS DMS task successfully complete and pass the table validation.

```
The case statement in the script performs the validation. If validation fails, AWS DMS inserts a record in the `public.awsdms_validation_failures_v1` table on the target database instance. This record includes the table name, error time, and details about the mismatched values in the source and target tables.

If you do not add this data validation script to the AWS DMS task and the data is inserted in the target table, the AWS DMS task shows validation state as Mismatched Records.

During AWS SCT conversion, the AWS DMS migration task changes the data type of VARCHAR2(1) data type to Boolean and adds a primary key constraint on the "NO" column.

**Emulate Oracle DR by using a PostgreSQL-compatible Aurora global database**

*Created by HariKrishna Boorgadda (AWS)*

<table>
<thead>
<tr>
<th>Environment</th>
<th>PoC or pilot</th>
<th>Source</th>
<th>Oracle</th>
<th>Target</th>
<th>Aurora PostgreSQL</th>

<td>AWS services</td>
<td>Amazon Aurora</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Summary**

Best practices for Enterprise disaster recovery (DR) basically consist of designing and implementing fault-tolerant hardware and software systems that can survive a disaster (*business continuance*) and resume normal operations (*business resumption*), with minimal intervention and, ideally, with no data loss. Building fault-tolerant environments to satisfy Enterprise DR objectives can be expensive and time consuming and requires a strong commitment by the business.

Oracle Database provides three different approaches to DR that provide the highest level of data protection and availability compared to any other approach for protecting Oracle data.

- Oracle Zero Data Loss Recovery Appliance
- Oracle Active Data Guard
- Oracle GoldenGate

This pattern provides a way to emulate the Oracle GoldenGate DR by using an Amazon Aurora global database. The reference architecture uses Oracle GoldenGate for DR across three AWS Regions. The
pattern walks through the replatforming of the source architecture to the cloud-native Aurora global database based on Amazon Aurora PostgreSQL–Compatible Edition.

Aurora global databases are designed for applications with a global footprint. A single Aurora database spans multiple AWS Regions with as many as five secondary Regions. Aurora global databases provide the following features:

- Physical storage-level replication
- Low-latency global reads
- Fast disaster recovery from Region-wide outages
- Fast cross-Region migrations
- Low replication lag across Regions
- Little-to-no performance impact on your database

For more information about Aurora global database features and advantages, see Using Amazon Aurora global databases. For more information about unplanned and managed failovers, see Using failover in an Amazon Aurora global database.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A Java Database Connectivity (JDBC) PostgreSQL driver for application connectivity
- An Aurora global database based on Amazon Aurora PostgreSQL-Compatible Edition
- An Oracle Real Application Clusters (RAC) database migrated to the Aurora global database based on Aurora PostgreSQL–Compatible

Limitations of Aurora global databases

- Aurora global databases aren’t available in all AWS Regions. For a list of supported Regions, see Aurora global databases with Aurora PostgreSQL.
- For information about features that aren’t supported and other limitations of Aurora global databases, see the Limitations of Amazon Aurora global databases.

Product versions

- Amazon Aurora PostgreSQL–Compatible Edition version 10.14 or later

Architecture

Source technology stack

- Oracle RAC four-node database
- Oracle GoldenGate

Source architecture

The following diagram shows three clusters with four-node Oracle RAC in different AWS Regions replicated using Oracle GoldenGate.
Target technology stack

- A three-cluster Amazon Aurora global database based on Aurora PostgreSQL–Compatible, with one cluster in the primary Region, two clusters in different secondary Regions

Target architecture
Emulate Oracle DR with an Aurora global database

Tools

AWS services

- **Amazon Aurora PostgreSQL-Compatible Edition** is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- **Amazon Aurora global databases** span multiple AWS Regions, providing low latency global reads and fast recovery from the rare outage that might affect an entire AWS Region.

Epics

Add Regions with reader DB instances

Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL using Oracle SQL Developer and AWS SCT

Created by Pinesh Singal (AWS)

</tr>
</tbody>
</table>

Summary

Many migration strategies and approaches run in multiple phases that can last from a few weeks to several months. During this time, you can experience delays because of patching or upgrades in the source Oracle DB instances that you want to migrate to PostgreSQL DB instances. To avoid this situation, we recommend that you incrementally migrate the remaining Oracle database code to PostgreSQL database code.

This pattern provides an incremental migration strategy with no downtime for a multi-terabyte Oracle DB instance that has a high number of transactions performed after your initial migration and that must be migrated to a PostgreSQL database. You can use this pattern's step-by-step approach to incrementally migrate an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance without signing in to the Amazon Web Services (AWS) Management Console.

The pattern uses Oracle SQL Developer to find the differences between two schemas in the source Oracle database. You then use AWS Schema Conversion Tool (AWS SCT) to convert the Amazon RDS for Oracle database schema objects to Amazon RDS for PostgreSQL database schema objects. You can then run a Python script in the Windows Command Prompt to create AWS SCT objects for the incremental changes to the source database objects.

**Note:** Before you migrate your production workloads, we recommend that you run a proof of concept (PoC) for this pattern's approach in a testing or non-production environment.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon RDS for Oracle DB instance.
• An existing Amazon RDS for PostgreSQL DB instance.
• AWS SCT, installed and configured with JDBC drivers for Oracle and PostgreSQL database engines. For more information about this, see Installing AWS SCT and Installing the required database drivers in the AWS SCT documentation.
• Oracle SQL Developer, installed and configured. For more information about this, see the Oracle SQL Developer documentation.
• The incremental-migration-sct-sql.zip file (attached), downloaded to your local computer.

Limitations
• The minimum requirements for your source Amazon RDS for Oracle DB instance are:
  • Oracle versions 10.2 and later (for versions 10.x), 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c for the Enterprise, Standard, Standard One, and Standard Two editions
  • The minimum requirements for your target Amazon RDS for PostgreSQL DB instance are:
    • PostgreSQL versions 9.4 and later (for versions 9.x), 10.x, and 11.x
  • This pattern uses Oracle SQL Developer. Your results might vary if you use other tools to find and export schema differences.
  • The SQL scripts generated by Oracle SQL Developer can raise transformation errors, which means that you need to perform a manual migration.

• If the AWS SCT source and target test connections fail, make sure that you configure the JDBC driver versions and inbound rules for the virtual private cloud (VPC) security group to accept incoming traffic.

Product versions
• Amazon RDS for Oracle DB instance version 12.1.0.2 (version 10.2 and later)
• Amazon RDS for PostgreSQL DB instance version 11.5 (version 9.4 and later)
• Oracle SQL Developer version 19.1 and later
• AWS SCT version 1.0.632 and later

Architecture

Source technology stack
• Amazon RDS for Oracle DB instance

Target technology stack
• Amazon RDS for PostgreSQL DB instance

Source and target architecture
The following diagram shows the migration of an Amazon RDS for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance.
AWS Prescriptive Guidance Patterns
Incrementally migrate from Amazon RDS for Oracle to Amazon RDS for PostgreSQL

The diagram shows the following migration workflow:

1. Open Oracle SQL Developer and connect to the source and target databases.
2. Generate a diff report and then generate the SQL scripts file for the schema difference objects. For more information about diff reports, see Detailed diff reports in the Oracle documentation.
3. Configure AWS SCT and run the Python code.
4. The SQL scripts file converts from Oracle to PostgreSQL.
5. Run the SQL scripts file on the target PostgreSQL DB instance.

Automation and scale
You can automate this migration by adding additional parameters and security-related changes for multiple functionalities in a single program to your Python script.

Tools

- **AWS SCT** – AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another.
- **Oracle SQL Developer** – Oracle SQL Developer is an integrated development environment (IDE) that simplifies the development and management of Oracle databases in both traditional and cloud-based deployments.

Code
The incremental-migration-sct-sql.zip file (attached) contains the complete source code for this pattern.
## Epics

Create the SQL scripts file for the source database schema differences

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Run Database Diff in Oracle SQL Developer | 1. Sign in to your source Oracle DB instance, choose **Tools**, and then choose **Database Diff**.  
2. Choose your source database in **Source Connection**.  
3. Choose the updated or patched source database in **Destination Connection**.  
4. Configure the remaining options according to your requirements, choose **Next**, and then choose **Finish** to generate the diff report. | DBA             |
| Generate the SQL scripts file             | Choose **Generate Script** to generate the differences in the SQL files.  
This generates the SQL scripts file that AWS SCT uses to convert your database from Oracle to PostgreSQL.                                                                                                    | DBA             |

Use the Python script to create the target DB objects in AWS SCT

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure AWS SCT with the Windows Command Prompt | 1. Copy the AWSSchemaConversionToolBatch.jar file from your pre-installed AWS SCT folder and paste it into your working directory.  
2. Deploy the Python code from the run_aws_sct_sql.py file from the incremental-migration-sct-sql.zip folder (attached). This creates .xml files and .sct files in the projects directory with your source and target database environment configuration details. It also reads the SQL scripts file that you generated in Oracle SQL Developer. Finally, it creates .sql file objects in the output directory. | DBA             |
AWS Prescriptive Guidance Patterns
Load BLOB files into Aurora PostgreSQL-Compatible

Load BLOB files into TEXT by using file encoding in Aurora PostgreSQL-Compatible
**Summary**

Often during migration, there are cases where you have to process unstructured and structured data that is loaded from files on a local file system. The data might also be in a character set that differs from the database character set.

These files hold the following types of data:

- **Metadata** – This data describes the file structure.
- **Semi-structured data** – These are textual strings in a specific format, such as JSON or XML. You might be able to make assertions about such data, such as “will always start with ‘<‘” or “does not contain any newline characters.”
- **Full text** – This data usually contains all types of characters, including newline and quote characters. It might also consist of multibyte characters in UTF-8.
- **Binary data** – This data might contain bytes or combinations of bytes including, nulls and end-of-file markers.

Loading a mixture of these types of data can be a challenge.

The pattern can be used with on-premises Oracle databases, Oracle databases that are on Amazon Elastic Compute Cloud (Amazon EC2) instances on the Amazon Web Services (AWS) Cloud, and Amazon Relational Database Service (Amazon RDS) for Oracle databases. As an example, this pattern is using Amazon Aurora PostgreSQL-Compatible Edition.

In Oracle Database, with the help of a BFILE (binary file) pointer, the DBMS_LOB package, and Oracle system functions, you can load from file and convert to CLOB with character encoding. Because PostgreSQL does not support the BLOB data type when migrating to an Amazon Aurora PostgreSQL-Compatible Edition database, these functions must be converted to PostgreSQL-compatible scripts.

This pattern provides two approaches for loading a file into a single database column in an Amazon Aurora PostgreSQL-Compatible database:

- **Approach 1** – You import data from your Amazon Simple Storage Service (Amazon S3) bucket by using the `table_import_from_s3` function of the `aws_s3` extension with the `encode` option.
- **Approach 2** – You encode to hexadecimal outside of the database, and then you decode to view TEXT inside the database.

We recommend using Approach 1 because Aurora PostgreSQL-Compatible has direct integration with the `aws_s3` extension.

This pattern uses the example of loading a flat file that contains an email template, which has multibyte characters and distinct formatting, into an Amazon Aurora PostgreSQL-Compatible database.
Prerequisites and limitations

Prerequisites

- An active AWS account
- An Amazon RDS instance or an Aurora PostgreSQL-Compatible instance
- A basic understanding of SQL and Relational Database Management System (RDBMS)
- An Amazon Simple Storage Service (Amazon S3) bucket.
- Knowledge of system functions in Oracle and PostgreSQL
- RPM Package HexDump-XXD-0.1.1 (included with Amazon Linux 2)

Limitations

- For the TEXT data type, the longest possible character string that can be stored is about 1 GB.

Product versions

- Aurora supports the PostgreSQL versions listed in Amazon Aurora PostgreSQL updates.

Architecture

Target technology stack

- Aurora PostgreSQL-Compatible

Target architecture

Approach 1 – Using aws_s3.table_import_from_s3

From an on-premises server, a file containing an email template with multibyte characters and custom formatting is transferred to Amazon S3. The custom database function provided by this pattern uses the aws_s3.table_import_from_s3 function with file_encoding to load files into the database and return query results as the TEXT data type.

1. Files are transferred to the staging S3 bucket.
2. Files are uploaded to the Amazon Aurora PostgreSQL-Compatible database.
3. Using the pgAdmin client, the custom function `load_file_into_clob` is deployed to the Aurora database.
4. The custom function internally uses `table_import_from_s3` with `file_encoding`. The output from the function is obtained by using `array_to_string` and `array_agg` as TEXT output.

**Approach 2 – Encoding to hexadecimal outside of the database and decoding to view TEXT inside the database**

A file from an on-premises server or a local file system is converted into a hex dump. Then the file is imported into PostgreSQL as a TEXT field.

1. Convert the file to a hex dump in the command line by using the `xxd -p` option.
2. Upload the hex dump files into Aurora PostgreSQL-Compatible by using the `\copy` option, and then decode the hex dump files to binary.
3. Encode the binary data to return as TEXT.

**Tools**

**AWS services**

- *Amazon Aurora PostgreSQL-Compatible Edition* is a fully managed, ACID-compliant relational database engine that helps you set up, operate, and scale PostgreSQL deployments.
- *AWS Command Line Interface (AWS CLI)* is an open-source tool that helps you interact with AWS services through commands in your command-line shell.

**Other tools**

- *pgAdmin4* is an open source administration and development platform for PostgreSQL. pgAdmin4 can be used on Linux, Unix, mac OS, and Windows to manage PostgreSQL.
## Epics

**Approach 1: Import data from Amazon S3 to Aurora PostgreSQL-Compatible**

<table>

<td>DBA, App owner</td>
</tr>
</tbody>
</table>
## AWS Prescriptive Guidance Patterns

### Load BLOB files into Aurora PostgreSQL-Compatible

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Deploy the custom function. | 1. From the *Additional information* section, copy the custom function `load_file_into_clob` SQL file content into a temporary table.  
2. Log in to the Aurora PostgreSQL-Compatible database and deploy it into the database schema by using the pgAdmin client. | App owner, DBA |

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run the custom function for importing the data into the database.</td>
<td>Run the following SQL command, replacing the items in angle brackets with the appropriate values.</td>
<td></td>
</tr>
</tbody>
</table>

```sql
SELECT load_file_into_clob('aws-s3-import-test'::text, 'us-west-1'::text, 'employee.salary.event.notification.email.vm'::text);
```

Replace the items in angle brackets with the appropriate values, as shown in the following example, before running the command.

```sql
Select load_file_into_clob('aws-s3-import-test'::text, 'us-west-1'::text, 'employee.salary.event.notification.email.vm'::text);
```

The command loads the file from Amazon S3 and returns the output as TEXT.

**Approach 2: Convert the template file into a hex dump in a local Linux system**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Convert the template file into a hex dump. | The Hexdump utility displays the contents of binary files in hexadecimal, decimal, octal, or ASCII. The hexdump command is part of the *util-linux* package and comes pre-installed in Linux distributions. The Hexdump RPM package is part of Amazon Linux 2 as well.  
To convert the file contents into a hex dump, run the following shell command. | DBA |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>xxd -p &lt;/path/file.vm&gt;</td>
<td>Replace the path and file with the appropriate values, as shown in the following example.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>xxd -p employee.salary.event.notification.email.vm</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>tr -d 'n' &gt; employee.salary.event.notification.email.vm.hex</td>
</tr>
<tr>
<td>Task</td>
<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>Load the hexdump file into the database schema.</td>
<td>Use the following commands to load the hexdump file into the Aurora PostgreSQL-Compatible database.</td>
<td>DBA</td>
</tr>
<tr>
<td>1. Log in to Aurora PostgreSQL database, and create a new table called email_template_hex.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CREATE TABLE email_template_hex(hex_data TEXT);</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2. Load the files from the local file system into the DB schema by using the following command.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>COPY email_template_hex FROM '/path/file.hex';</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Replace the path with the location on your local file system.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>COPY email_template_hex FROM '/tmp/employee.salary.event.notification.email.vm.hex';</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. Create one more table called email_template_bytea.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>CREATE TABLE email_template_bytea(hex_data bytea);</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. Insert the data from email_template_hex into email_template_bytea.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>INSERT INTO email_template_bytea (hex_data) (SELECT decode(hex_data, 'hex') FROM email_template_hex limit 1);</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. To return hex bytea code as TEXT data, run the following command.</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>SELECT encode(hex_data::bytea,</code></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Load BLOB files into Aurora PostgreSQL-Compatible

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>'escape') FROM email_template_bytea;</code></td>
<td></td>
</tr>
</tbody>
</table>

Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL with AWS SCT and AWS DMS using AWS CLI and AWS CloudFormation

Created by Pinesh Singal (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Amazon RDS for Oracle</th>
<th>Target: Amazon RDS for PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Re-architect</td>
<td>Workload: Oracle; Open-source</td>
<td>Technologies: Migration; Databases</td>
</tr>
<tr>
<td>AWS services: AWS DMS; Amazon RDS; AWS SCT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides an approach with minimal downtime for migrating a multi-terabyte Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance, without signing in to the Amazon Web Services (AWS) Management Console.

This approach helps your organization avoid manual configurations and individual migrations using the AWS Schema Conversion Tool (AWS SCT) and AWS Database Migration Service (AWS DMS) consoles. Instead, you set up a one-time configuration for multiple databases and perform the migrations using AWS SCT and AWS DMS on the AWS Command Line Interface (AWS CLI).

The pattern uses AWS SCT to convert database schema objects from Amazon RDS for Oracle to Amazon RDS for PostgreSQL and then uses AWS DMS to migrate the data. Using Python scripts in AWS CLI, you create AWS SCT objects and AWS DMS tasks with an AWS CloudFormation template.

Prerequisites and limitations

Prerequisites

- An active AWS account.
- An existing Amazon RDS for Oracle DB instance.
- An existing Amazon RDS for PostgreSQL DB instance.
- An understanding of the following AWS DMS migration task types: full-load, cdc, full-load-and-cdc. For more information about this, see Creating a task in the AWS DMS documentation.
- AWS SCT, installed and configured with Java Database Connectivity (JDBC) drivers for Oracle and PostgreSQL database engines. For more information about this, see Installing AWS SCT and installing the required database drivers in the AWS SCT documentation.
- The AWSSchemaConversionToolBatch.jar file from the installed AWS SCT folder, copied to your working directory.
- The cli-sct-dms-cft.zip file (attached), downloaded and extracted in your working directory.
- The most recent AWS DMS replication instance engine version. For more information about this, see How do I create an AWS DMS replication instance in the AWS Support documentation and AWS DMS 3.4.4 release notes in the AWS DMS documentation.
AWS Prescriptive Guidance Patterns
Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL using AWS SCT and AWS DMS

• AWS CLI version 2, installed and configured with your access key ID, secret access key, and default AWS Region name for the Amazon Elastic Compute Cloud (Amazon EC2) instance or operating system (OS) where the scripts are run. For more information about this, see Installing, updating, and uninstalling the AWS CLI version 2 and Configuring the AWS CLI in the AWS CLI documentation.

• Familiarity with AWS CloudFormation templates. For more information about this, see AWS CloudFormation concepts in the AWS CloudFormation documentation.

• Python, installed and configured on the Amazon EC2 instance or OS where the scripts are run. For more information about this, see the Python documentation.

Limitations

• The minimum requirements for your source Amazon RDS for Oracle DB instance are:
  • Oracle versions 12c (v12.1.0.2, v12.2.0.1), 18c (v18.0.0.0) and 19c (v19.0.0.0) for the Enterprise, Standard, Standard One, and Standard Two editions.
  • Although Amazon RDS supports Oracle 18c (v18.0.0.0), this version is on a deprecation path because Oracle no longer provide patches for 18c after the end-of-support date. For more information about this, see Oracle on Amazon RDS in the Amazon RDS documentation.
  • Amazon RDS for Oracle 11g is no longer supported.

• The minimum requirements for your target Amazon RDS for PostgreSQL DB instance are:
  • PostgreSQL versions 9 (versions 9.5 and 9.6), 10.x, 11.x, 12.x, and 13.x

Product versions

• Amazon RDS for Oracle DB instance version 12.1.0.2 and later
• Amazon RDS for PostgreSQL DB instance version 11.5 and later
• AWS CLI version 2
• AWS SCT most recent version

Architecture

Source technology stack

• Amazon RDS for Oracle

Target technology stack

• Amazon RDS for PostgreSQL

Source and Target architecture

The following diagram shows the migration of an Amazon RDS for Oracle DB instance to an Amazon RDS for PostgreSQL DB instance using AWS DMS and Python scripts.
The diagram shows the following migration workflow using AWS CLI:

1. The Python script uses AWS SCT to connect to the source and target DB instances.
2. The user starts AWS SCT with the Python script, converts the Oracle code to PostgreSQL code, and runs it on the target DB instance.
3. The Python script creates AWS DMS replication tasks for the source and target DB instances.
4. The user deploys Python scripts to start the AWS DMS tasks and then stops the tasks after the data migration is complete.

Automation and scale

You can automate this migration by adding additional parameters and security-related changes for multiple functionalities in a single program to your Python script.

Tools

- **AWS CLI** – AWS Command Line Interface (AWS CLI) is an open-source tool that enables you to interact with AWS services using commands in your command-line shell.
- **AWS CloudFormation** – AWS CloudFormation is a service that helps you model and set up your AWS resources so that you can spend less time managing those resources and more time focusing on your applications that run in AWS. This pattern converts the .csv input file to a .json input file using a Python script. The .json file is used in AWS CLI commands to create an AWS CloudFormation stack that creates multiple AWS DMS replication tasks with Amazon Resource Names (ARNs), migration types, task settings, and table mappings.
AWS Prescriptive Guidance Patterns
Migrate Amazon RDS for Oracle to Amazon RDS
for PostgreSQL using AWS SCT and AWS DMS

- **AWS DMS** – AWS Database Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. This pattern uses AWS DMS to create, start, and stop tasks with a Python script run over the command-line and create the AWS CloudFormation template.

- **AWS SCT** – AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another. This pattern requires the AWSSchemaConversionToolBatch.jar file from the installed AWS SCT directory.

**Code**

The cli-sct-dms-cft.zip file (attached) contains the complete source code for this pattern.

**Epics**

**Configure AWS SCT and create database objects in AWS CLI**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Configure AWS SCT to run from AWS CLI. | 1. Configure the source and target environment configuration details in the database_migration.txt file by using the following format: 

```
#source_vendor,source_hostname,source_dbname,source_user,source_pwd,source_schema,source_port,source_sid,target_vendor,target_hostname,target_user,target_pwd,target_dbname,target_port
ORACLE,myoracledb.cokmvis0v46q.us-east-1.rds.amazonaws.com,ORCL,orcl,orcl1234,orcl,1521,ORCL,POSTGRESQL,mypgdbinstance.cokmvis0v46q.us-east-1.rds.amazonaws.com,pguser,pgpassword,pgdb,5432
```

2. Modify the AWS SCT configuration parameters according to your requirements in the following files: project_settings.xml, Oracle_PG_Test_Batch.xml, and ORACLE-orcl-to-POSTGRESQL.xml. | DBA |
| Run the run_aws_sct.py Python script. | Run the run_aws_sct.py Python script by using the following command: 

```
$ python run_aws_sct.py database_migration.txt
```

The Python script converts the database objects from Oracle to PostgreSQL and creates SQL files in PostgreSQL format. The script also creates the Database migration assessment report.pdf file that provides you with detailed recommendations and conversion statistics for database objects. | DBA |
### Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL using AWS SCT and AWS DMS

<table>
<thead>
<tr>
<th>Task</th>

<td>Description</td>
<td>Skills required</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
</tbody>
</table>
| Configure the AWS DMS replication details to run from AWS CLI. | Configure the AWS DMS source and target endpoints and replication details in the dms-arn-list.txt file with the source endpoint ARN, target endpoint ARN, and the replication instance ARN by using following format:  

```plaintext
#sourceARN,targetARN,repARN
``` | DBA |
<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Run the dms-create-task.py Python script to create the AWS DMS tasks. | 1. Run the dms-create-task.py Python script by using the following command:  
   
   ```bash
   $ python dms-create-task.py database_migration.txt dms-arn-list.txt <cft-stack-name> <migration-type>
   ```  
   - `database_migration.txt` is the database migration text file  
   - `dms-arn-list.txt` is the ARN list for AWS DMS  
   - `<cft-stack-name>` is the user-defined AWS CloudFormation stack name  
   - `<migration-type>` is the migration type (full-load, cdc, or full-load-and-cdc)  
   
   2. Depending on your migration type, you can use the following commands to create three types of AWS DMS tasks:  
   - `$ python dms-create-task.py database_migration.txt dms-arn-list.txt dms-cli-cft-stack full-load`  
   - `$ python dms-create-task.py database_migration.txt dms-arn-list.txt dms-cli-cft-stack cdc`  
   - `$ python dms-create-task.py database_migration.txt dms-arn-list.txt dms-cli-cft-stack full-load-and-cdc`  
   
   3. The AWS CloudFormation stack and AWS DMS tasks are created | DBA |
### AWS Prescriptive Guidance Patterns

*Migrate Amazon RDS for Oracle to Amazon RDS for PostgreSQL using AWS SCT and AWS DMS*

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check that AWS DMS tasks are ready.</td>
<td>On the AWS console, check that your AWS DMS tasks are in <strong>Ready</strong> status in the <strong>Status</strong> section.</td>
<td>DBA</td>
</tr>
</tbody>
</table>

### Start and stop the AWS DMS tasks using AWS CLI

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
</table>
| Start the AWS DMS tasks. | Run the `dms-start-task.py` Python script by using the following command:  

```bash
$ python dms-start-task.py start '<cdc-start-datetime>'
```

*Note:* The start date and time must be in the 'DD-MON-YYYY' or 'YYYY-MM-DDTHH:MI:SS' timestamp data type formats (for example, '01-Dec-2019' or '2018-03-08T12:12:12')  

You can review the AWS DMS task status in the **Table statistics** tab of your migration tasks on the **Tasks** page of the AWS DMS console. | DBA |

| Validate the data. | 1. After the full-load migration is complete, the task is continuously kept running for continuous data change (CDC).  
2. When CDC is complete or no more changes need to be migrated, review and validate the migration task results and data in your Oracle and PostgreSQL databases.  
3. You can validate your data by checking status and count columns (Validation state, Validation pending, Validation failed, Validation suspended, and Validation details) in the **Table statistics** tab of your database migration task on the **Tasks** page of the AWS DMS console. | DBA |
For more information about this, see AWS DMS data validation in the AWS DMS documentation.

Stop the AWS DMS tasks. Run the Python script by using the following command:

```
$ python dms-start-task.py stop
```

**Note:** AWS DMS tasks might stop with a failed status, depending on the validation status. For more information about this, see the troubleshooting table in the Additional information section.

Migrate Oracle external tables to Amazon Aurora PostgreSQL-Compatible Edition

Created by anuradha chintha (AWS) and Rakesh Raghav (AWS)

Source: Databases: Relational  Target: Databases: Relational  R Type: Re-architect
Environment: PoC or pilot  Technologies: Migration; Databases  Workload: Open-source
AWS services: Amazon S3

Summary

External tables give Oracle the ability to query data that is stored outside the database in flat files. You can use the ORACLE_LOADER driver to access any data stored in any format that can be loaded by the SQL*Loader utility. You can't use Data Manipulation Language (DML) on external tables, but you can use external tables for query, join, and sort operations.

Attachments

To access additional content that is associated with this document, unzip the following file: attachment.zip
Amazon Aurora PostgreSQL-Compatible Edition doesn't provide functionality similar to external tables in Oracle. Instead, you must use modernization to develop a scalable solution that meets functional requirements and is frugal.

This pattern provides steps for migrating different types of Oracle external tables to Aurora PostgreSQL-Compatible Edition on the Amazon Web Services (AWS) Cloud by using the aws_s3 extension.

Prerequisites and limitations

Prerequisites

- An active AWS account
- AWS Command Line Interface (AWS CLI)
- An available Aurora PostgreSQL-Compatible database instance
- An on-premises Oracle database with an external table
- pg.Client API
- Data files

Limitations

- This pattern doesn't provide the functionality to act as a replacement for Oracle external tables. However, the steps and sample code can be enhanced further to achieve your database modernization goals.
- Files should not contain the character that is passing as a delimiter in aws_s3 export and import functions.

Architecture

Source technology stack

Oracle

Source Architecture

Target technology stack

- Amazon Aurora PostgreSQL-Compatible
• Amazon CloudWatch
• AWS Lambda
• AWS Secrets Manager
• Amazon Simple Notification Service (Amazon SNS)
• Amazon Simple Storage Service (Amazon S3)

Target architecture

The following diagram shows a high-level representation of the solution.

Automation and scale

Any additions or changes to the external tables can be handled with metadata maintenance.

Tools

• Amazon Aurora PostgreSQL-Compatible – Amazon Aurora PostgreSQL-Compatible Edition is a fully managed, PostgreSQL-compatible, and ACID-compliant relational database engine that combines the speed and reliability of high-end commercial databases with the cost-effectiveness of open-source databases.
• AWS CLI – AWS Command Line Interface (AWS CLI) is a unified tool to manage your AWS services. With only one tool to download and configure, you can control multiple AWS services from the command line and automate them through scripts.
• Amazon CloudWatch – Amazon CloudWatch monitors Amazon S3 resources and utilization.
• AWS Lambda – AWS Lambda is a serverless compute service that supports running code without provisioning or managing servers, creating workload-aware cluster scaling logic, maintaining event integrations, or managing runtimes. In this pattern, Lambda runs the database function whenever a file is uploaded to Amazon S3.
• AWS Secrets Manager – AWS Secrets Manager is a service for credential storage and retrieval. Using Secrets Manager, you can replace hardcoded credentials in your code, including passwords, with an API call to Secrets Manager to retrieve the secret programmatically.
• Amazon S3 – Amazon Simple Storage Service (Amazon S3) provides a storage layer to receive and store files for consumption and transmission to and from the Aurora PostgreSQL-Compatible cluster.
• **aws_s3** – The `aws_s3` extension integrates Amazon S3 and Aurora PostgreSQL-Compatible.

• **Amazon SNS** – Amazon Simple Notification Service (Amazon SNS) coordinates and manages the delivery or sending of messages between publishers and clients. In this pattern, Amazon SNS is used to send notifications.

**Code**

Whenever a file is placed in the S3 bucket, a DB function must be created and called from the processing application or the Lambda function. For details, see the code (attached).

**Epics**

**Create an external file**

<table>
<thead>
<tr>

Migrate function-based indexes from Oracle to PostgreSQL

*Created by Veeranjaneyulu Grandhi (AWS) and Navakanth Talluri (AWS)*

| Environment: Production | Source: Oracle | Target: PostgreSQL |
Summary

Indexes are a common way to enhance database performance. An index allows the database server to find and retrieve specific rows much faster than it could without an index. But indexes also add overhead to the database system as a whole, so they should be used sensibly. Function-based indexes, which are based on a function or expression, can involve multiple columns and mathematical expressions. A function-based index improves the performance of queries that use the index expression.

Natively, PostgreSQL doesn't support creating function-based indexes using functions that have volatility defined as stable. However, you can create similar functions with volatility as IMMUTABLE and use them in index creation.

An IMMUTABLE function cannot modify the database, and it's guaranteed to return the same results given the same arguments forever. This category allows the optimizer to pre-evaluate the function when a query calls it with constant arguments.

This pattern helps in migrating the Oracle function-based indexes when used with functions such as to_char, to_date, and to_number to the PostgreSQL equivalent.

Prerequisites and limitations

Prerequisites

- An active Amazon Web Services (AWS) account
- A source Oracle database instance with the listener service set up and running
- Familiarity with PostgreSQL databases

Limitations

- Database size limit is 64 TB.
- Functions used in index creation must be IMMUTABLE.

Product versions

- All Oracle database editions for versions 11g (versions 11.2.0.3.v1 and later) and up to 12.2, and 18c
- PostgreSQL versions 9.6 and later

Architecture

Source technology stack

- An Oracle database on premises or on an Amazon Elastic Compute Cloud (Amazon EC2) instance, or an Amazon RDS for Oracle DB instance

Target technology stack

- Any PostgreSQL engine
## Tools

- **pgAdmin 4** is an open source management tool for Postgres. The pgAdmin 4 tool provides a graphical interface for creating, maintaining, and using database objects.
- **Oracle SQL Developer** is an integrated development environment (IDE) for developing and managing Oracle Database in both traditional and cloud deployments.

## Epics

### Create a function-based index using a default function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a function-based index on a column using the to_char function.</td>
<td>Use the following code to create the function-based index.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>postgres=# create table funcindex( col1 timestamp without time zone); CREATE TABLE postgres=# insert into funcindex values (now()); INSERT 0 1 postgres=# select * from funcindex; col1 2022-08-09 16:00:57.77414 (1 rows) postgres=# create index funcindex_idx on funcindex(to_char(col1,'DD-MM-YYYY HH24:MI:SS')); ERROR: functions in index expression must be marked IMMUTABLE</td>
<td>DBA, App developer</td>
</tr>
</tbody>
</table>

**Note:** PostgreSQL doesn't allow creating a function-based index without the IMMUTABLE clause.

Check the volatility of the function.

To check the function volatility, use the code in the *Additional information* section. | DBA |

### Create function-based indexes using a wrapper function

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a wrapper function.</td>
<td>To create a wrapper function, use the code in the <em>Additional information</em> section.</td>
<td>PostgreSQL developer</td>
</tr>
</tbody>
</table>
AWS Prescriptive Guidance Patterns
Migrate Oracle function-based indexes

## Create an index by using the wrapper function.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an index by using the wrapper function.</td>
<td>Use the code in the <em>Additional information</em> section to create a user-defined function with the keyword IMMUTABLE in the same schema as the application, and refer to it in the index-creation script. If a user-defined function is created in a common schema (from the previous example), update the search_path as shown. ALTER ROLE &lt;ROLENAME&gt; set search_path=$user, COMMON;</td>
<td>DBA, PostgreSQL developer</td>
</tr>
</tbody>
</table>

## Validate index creation

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Validate index creation.</td>
<td>Validate that the index needs to be created, based on query access patterns.</td>
<td>DBA</td>
</tr>
<tr>
<td>Validate that the index can be used.</td>
<td>To check whether the function-based index is picked up by the PostgreSQL Optimizer, run an SQL statement using explain or explain analyze. Use the code in the <em>Additional information</em> section. If possible, gather the table statistics as well. <strong>Note:</strong> If you notice the explain plan, PostgreSQL optimizer has chosen a function-based index because of the predicate condition.</td>
<td>DBA</td>
</tr>
</tbody>
</table>
**Additional information**

**Create a wrapper function**

```sql
CREATE OR REPLACE FUNCTION myschema.to_char(var1 timestamp without time zone, var2 varchar)
RETURNS varchar AS $BODY$
select to_char(var1, 'YYYYMMDD');
$BODY$
LANGUAGE sql IMMUTABLE;
```

**Create an index by using the wrapper function**

```sql
postgres=# create function common.to_char(var1 timestamp without time zone, var2 varchar)
RETURNS varchar AS $BODY$
select to_char(var1, 'YYYYMMDD');
$BODY$
LANGUAGE sql IMMUTABLE;
CREATE FUNCTION
postgres=# create index funcindex_idx on funcindex(common.to_char(col1,'DD-MM-YYYY HH24:MI:SS'));
CREATE INDEX
```

**Check the volatility of the function**

```sql
SELECT DISTINCT p.proname as "Name",p.provolatile as "volatility" FROM pg_catalog.pg_proc p
LEFT JOIN pg_catalog.pg_namespace n ON n.oid = p.pronamespace
LEFT JOIN pg_catalog.pg_language l ON l.oid = p.prolang
WHERE n.nspname OPERATOR(pg_catalog.~) '^(pg_catalog)$' COLLATE pg_catalog.default AND
p.proname='to_char'GROUP BY p.proname,p.provolatile
ORDER BY 1;
```

**Validate that the index can be used**

```sql
explain analyze <SQL>
postgres=# explain select col1 from funcindex where common.to_char(col1,'DD-MM-YYYY HH24:MI:SS') = '09-08-2022 16:00:57';
QUERY PLAN
------------------------------------------------------------------------------------------------------------------------
Index Scan using funcindex_idx on funcindex  (cost=0.42..8.44 rows=1 width=8)
Index Cond: ((common.to_char(col1, 'DD-MM-YYYY HH24:MI:SS')::text = '09-08-2022 16:00:57':::text))
(2 rows)
```

**Migrate Oracle native functions to PostgreSQL using extensions**

*Created by Pinesh Singal (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
</tr>
</thead>
<tbody>
<tr>
<td>Source:</td>
<td>Databases: Relational</td>
</tr>
<tr>
<td>Target:</td>
<td>Amazon RDS PostgreSQL</td>
</tr>
<tr>
<td>R Type:</td>
<td>Re-architect</td>
</tr>
<tr>
<td>Workload:</td>
<td>Oracle; Open-source</td>
</tr>
<tr>
<td>Technologies:</td>
<td>Migration; Databases</td>
</tr>
<tr>
<td>AWS services:</td>
<td>Amazon EC2; Amazon RDS</td>
</tr>
</tbody>
</table>
Summary

This migration pattern provides step-by-step guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle database instance to an Amazon RDS for PostgreSQL database by modifying the aws_oracle_ext and orafce extensions to PostgreSQL (psql) native built-in code. This will save processing time.

The pattern describes an offline manual migration strategy with no downtime for a multi-terabyte Oracle source database with a high number of transactions.

The migration process uses AWS Schema Conversion Tool (AWS SCT) with the aws_oracle_ext and orafce extensions to convert an Amazon RDS for Oracle database schema to an Amazon RDS for PostgreSQL database schema. Then the code is manually changed to PostgreSQL supported native psql built-in code. This is because the extension calls impact code processing on the PostgreSQL database server, and not all the extension code is fully complaint or compatible with PostgreSQL code.

This pattern primarily focuses on manually migrating SQL codes using AWS SCT and the extensions aws_oracle_ext and orafce. You convert the already used extensions into native PostgreSQL (psql) built-ins. Then you remove all references to the extensions and convert the codes accordingly.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Operating system (Windows or Mac) or Amazon EC2 instance (up and running)
- Orafce

Limitations

Not all Oracle functions using aws_oracle_ext or orafce extensions can be converted to native PostgreSQL functions. It might need manual rework so as to compile it with PostgreSQL libraries.

One drawback of using AWS SCT extensions is its slow performance in running and fetching the results. Its cost can be understood from simple PostgreSQL EXPLAIN plan (execution plan of a statement) on the Oracle SYSDATE function migration to the PostgreSQL NOW() function between all three codes (aws_oracle_ext, orafce, and psql default), as explained in the Performance comparison check section in the attached document.

Product versions

- **Source:** Amazon RDS for Oracle database 10.2 and later (for 10.x), 11g (11.2.0.3.v1 and later) and up to 12.2, and 18c for the Enterprise, Standard, Standard One, and Standard Two editions
- **Target:** Amazon RDS for PostgreSQL database 9.4 and later (for 9.x), 10.x, and 11.x
- **AWS SCT:** Latest version (this pattern was tested with 1.0.632)
- **Orafce:** Latest version (this pattern was tested with 3.9.0)

Architecture

**Source technology stack**

- An Amazon RDS for Oracle database instance with version 12.1.0.2.v18
**Target technology stack**

- An Amazon RDS for PostgreSQL database instance with version 11.5

**Database migration architecture**

The following diagram represents the database migration architecture between the source Oracle and target PostgreSQL databases. The architecture involves AWS Cloud, a virtual private cloud (VPC), Availability Zones, a private subnet, an Amazon RDS for Oracle database, AWS SCT, an Amazon RDS for PostgreSQL database, extensions for Oracle (aws_oracle_ext and orafce), and structured query language (SQL) files.

1. Launch Amazon RDS for Oracle DB instance (source DB).
2. Use AWS SCT with the aws_oracle_ext and orafce extension packs to convert the source code from Oracle to PostgreSQL.
3. The conversion produces PostgreSQL-supported migrated .sql files.
4. Manually convert the non-converted Oracle extension codes to PostgreSQL (psql) codes.
5. The manual conversion produces PostgreSQL-supported converted .sql files.
6. Run these .sql files on your Amazon RDS for PostgreSQL DB instance (target DB).

**Tools**

**Tools**

**AWS services**

- **AWS SCT** - AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another. You can convert relational Online Transactional Processing (OLTP) schema, or data warehouse schema. Your converted schema is suitable for an Amazon RDS MySQL DB instance, an Amazon Aurora DB cluster, an Amazon RDS PostgreSQL DB instance, or an Amazon Redshift cluster. The converted schema can also be used with a database on an Amazon EC2 instance or stored as data on an Amazon S3 bucket.

AWS SCT provides a project-based user interface to automatically convert the database schema of your source database into a format compatible with your target Amazon RDS instance.

You can use AWS SCT to do migration from an Oracle source database to any of the targets listed preceding. Using AWS SCT, you can export the source database object definitions such as schema, views, stored procedures, and functions.
You can use AWS SCT to convert data from Oracle to Amazon RDS for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition.

In this pattern, you use AWS SCT to convert and migrate Oracle code into PostgreSQL using the extensions `aws_oracle_ext` and `orafce`, and manually migrating the extension codes into `psql` default or native built-in code.

- The AWS SCT extension pack is an add-on module that emulates functions present in the source database that are required when converting objects to the target database. Before you can install the AWS SCT extension pack, you need to convert your database schema.

When you convert your database or data warehouse schema, AWS SCT adds an additional schema to your target database. This schema implements SQL system functions of the source database that are required when writing your converted schema to your target database. This additional schema is called the extension pack schema.

The extension pack schema for OLTP databases is named according to the source database. For Oracle databases, the extension pack schema is `AWS_ORACLE_EXT`.

Other tools

- **Orafce** – Orafce is a module that implements Oracle compatible functions, data types, and packages. It’s an open-source tool with a Berkeley Source Distribution (BSD) license so that anyone can use it. The `orafce` module is useful for migrating from Oracle to PostgreSQL because it has many Oracle functions implemented in PostgreSQL.

Code

For a list of all commonly used and migrated code from Oracle to PostgreSQL to avoid AWS SCT extension code usage, see the attached document.

**Migrate a Microsoft SQL Server database from Amazon EC2 to Amazon DocumentDB by using AWS DMS**
This pattern describes how to use AWS Database Migration Service (AWS DMS) to migrate a Microsoft SQL Server database hosted on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon DocumentDB (with MongoDB compatibility) database.

The AWS DMS replication task reads the table structure of the SQL Server database, creates the corresponding collection in Amazon DocumentDB, and performs a full-load migration.

You can also use this pattern to migrate an on-premises SQL Server or an Amazon Relational Database Service (Amazon RDS) for SQL Server DB instance to Amazon DocumentDB. For more information, see the guide Migrating Microsoft SQL Server databases to the AWS Cloud on the AWS Prescriptive Guidance website.

**Prerequisites and limitations**

**Prerequisites**

- An active AWS account.
- An existing SQL Server database on an EC2 instance.
- Fixed database (db_owner) role assigned to AWS DMS in the SQL Server database. For more information, see Database-level roles in the SQL Server documentation.
- Familiarity with using the mongodump, mongorestore, mongoexport, and mongoimport utilities to move data in and out of an Amazon DocumentDB cluster.
- Microsoft SQL Server Management Studio, installed and configured.

**Limitations**

- The cluster size limit in Amazon DocumentDB is 64 TB. For more information, see Cluster limits in the Amazon DocumentDB documentation.
- AWS DMS doesn't support the merging of multiple source tables into a single Amazon DocumentDB collection.
- If AWS DMS processes any changes from a source table without a primary key, it will ignore large object (LOB) columns in the source table.

**Architecture**

**Source technology stack**

- Amazon EC2
Target architecture

![Diagram showing the target architecture]

Target technology stack

- Amazon DocumentDB

Tools

- **AWS DMS** – AWS Database Migration Service (AWS DMS) helps you migrate databases easily and securely.
- **Amazon DocumentDB** – Amazon DocumentDB (with MongoDB compatibility) is a fast, reliable, and fully managed database service.
- **Amazon EC2** – Amazon Elastic Compute Cloud (Amazon EC2) provides scalable computing capacity in the AWS Cloud.
- **Microsoft SQL Server** – SQL Server is a relational database management system.
- **SQL Server Management Studio (SSMS)** – SSMS is a tool for managing SQL Server, including accessing, configuring, and administering SQL Server components.

Epics

Create and configure a VPC

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a VPC.</td>
<td>Sign in to the AWS Management Console and open the Amazon VPC console. Create a virtual private cloud (VPC) with an IPv4 CIDR block range.</td>
<td>System administrator</td>
</tr>
</tbody>
</table>
Create security groups and network ACLs.

On the Amazon VPC console, create security groups and network access control lists (network ACLs) for your VPC, according to your requirements. You can also use the default settings for these configurations. For more information about this and other stories, see the “Related resources” section.

Skills required: System administrator

---

**Create and configure the Amazon DocumentDB cluster**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Amazon DocumentDB cluster.</td>
<td>Open the Amazon DocumentDB console and choose “Clusters.” Choose “Create,” and create an Amazon DocumentDB cluster with one instance. Important: Make sure you configure this cluster with your VPC’s security groups.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Install the mongo shell.</td>
<td>The mongo shell is a command-line utility that you use to connect to and query your Amazon DocumentDB cluster. To install it, run the “/etc/yum.repos.d/mongodb-org-3.6.repo” command to create the repository file. Run the “sudo yum install -y mongodb-org-shell” command to install the mongo shell. To encrypt data in transit, download the public key for Amazon DocumentDB, and then connect to your Amazon DocumentDB instance. For more information about these steps, see the “Related resources” section.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Create a database in the Amazon DocumentDB cluster.</td>
<td>Run the &quot;use&quot; command with the name of your database to create a database in your Amazon DocumentDB cluster.</td>
<td>System administrator</td>

</tbody>
</table>
**Create and configure the AWS DMS replication instance**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the AWS DMS replication instance.</td>
<td>Open the AWS DMS console and choose “Create replication instance.” Enter a name and description for your replication task. Choose the instance class, engine version, storage, VPC, Multi-AZ, and make it publicly accessible. Choose the “Advanced” tab to set the network and encryption settings. Specify the maintenance settings, and then choose “Create replication instance.”</td>
<td>System administrator</td>
</tr>
<tr>
<td>Configure the SQL Server database.</td>
<td>Log in to Microsoft SQL Server and add an inbound rule for communication between the source endpoint and the AWS DMS replication instance. Use the replication instance's private IP address as the source. Important: The replication instance and target endpoint should be on the same VPC. Use an alternative source in the security group if the VPCs are different for the source and replication instances.</td>
<td>System administrator</td>
</tr>
</tbody>
</table>

**Create and test the source and target endpoints in AWS DMS**

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the source and target database endpoints.</td>
<td>Open the AWS DMS console and choose “Connect source and target database endpoints.” Specify the connection information for the source and target databases. If required, choose the “Advanced” tab to set values for “Extra connection attributes.” Download and use the certificate bundle in your endpoint configuration.</td>
<td>System administrator</td>
</tr>
<tr>
<td>Test the endpoint connection.</td>
<td>Choose “Run test” to test the connection. Troubleshoot any error messages by verifying the security group settings and the connections to the AWS DMS</td>
<td>System administrator</td>
</tr>
</tbody>
</table>
### Migrate data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create the AWS DMS migration task.</td>
<td>On the AWS DMS console, choose “Tasks,” “Create task.” Specify the task options, including the source and destination endpoint names, and replication instance names. Under “Migration type” choose “Migrate existing data,” and “Replicate data changes only.” Choose “Start task.”</td>
<td>System administrator</td>
</tr>
<tr>
<td>Run the AWS DMS migration task.</td>
<td>Under “Task settings,” specify the settings for the table preparation mode, such as “Do nothing,” “Drop tables on target,” “Truncate,” and “Include LOB columns in replication.” Set a maximum LOB size that AWS DMS will accept and choose “Enable logging.” Leave the “Advanced settings” at their default values and choose “Create task.”</td>
<td>System administrator</td>
</tr>
<tr>
<td>Monitor the migration.</td>
<td>On the AWS DMS console, choose “Tasks” and choose your migration task. Choose “Task monitoring” to monitor your task. The task stops when the full-load migration is complete and cached changes are applied.</td>
<td>System administrator</td>
</tr>
</tbody>
</table>

### Test and verify the migration

Migrate an on-premises ThoughtSpot Falcon database to Amazon Redshift

Created by Battulga Purevragchaa (AWS) and Antony Prasad Thevaraj (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: On-premises ThoughtSpot Falcon database</th>
<th>Target: Amazon Redshift</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Re-architect</td>
<td>Workload: All other workloads</td>
<td>Technologies: Migration; Databases</td>
</tr>
<tr>
<td>AWS services: AWS DMS; Amazon Redshift</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

On-premises data warehouses require significant administration time and resources, particularly for large datasets. The financial cost of building, maintaining, and growing these warehouses is also very high. To help manage costs, keep extract, transform, and load (ETL) complexity low, and deliver performance as your data grows, you must constantly choose which data to load and which data to archive.

By migrating your on-premises ThoughtSpot Falcon databases to the Amazon Web Services (AWS) Cloud, you can access cloud-based data lakes and data warehouses that increase your business agility, security, and application reliability, in addition to reducing your overall infrastructure costs. Amazon Redshift helps to significantly lower the cost and operational overhead of a data warehouse. You can also use Amazon Redshift Spectrum to analyze large amounts of data in its native format without data loading.

This pattern describes the steps and process for migrating a ThoughtSpot Falcon database from an on-premises data center to an Amazon Redshift database on the AWS Cloud.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A ThoughtSpot Falcon database hosted in an on-premises data center

Product versions

- ThoughtSpot version 7.0.1

Architecture
The diagram shows the following workflow:

1. Data is hosted in an on-premises relational database.
2. AWS Schema Conversion Tool (AWS SCT) converts the data definition language (DDL) that is compatible with Amazon Redshift.
3. After the tables are created, you can migrate the data by using AWS Database Migration Service (AWS DMS).
4. The data is loaded into Amazon Redshift.
5. The data is stored in Amazon Simple Storage Service (Amazon S3) if you use Redshift Spectrum or already host the data in Amazon S3.

**Tools**

- **AWS DMS** – AWS Data Migration Service (AWS DMS) helps you quickly and securely migrate databases to AWS.
- **Amazon Redshift** – Amazon Redshift is a fast, fully managed, petabyte-scale data warehouse service that makes it simple and cost-effective to efficiently analyze all your data using your existing business intelligence tools.
- **AWS SCT** – AWS Schema Conversion Tool (AWS SCT) converts your existing database schema from one database engine to another.

**Migrate an Oracle database to Amazon DynamoDB using AWS DMS**

*Created by Rambabu Karnena (AWS)*
Environment: PoC or pilot  
Source: Databases: Relational  
Target: Amazon DynamoDB

R Type: Re-architect  
Workload: Oracle  
Technologies: Migration; Databases

AWS services: Amazon DynamoDB

Summary

This pattern walks you through the steps for migrating an Oracle database to Amazon DynamoDB using AWS Database Migration Service (AWS DMS). It covers three types of source databases:

- On-premises Oracle databases
- Oracle databases on Amazon Elastic Compute Cloud (Amazon EC2)
- Amazon Relational Database Service (Amazon RDS) for Oracle DB instances

In this proof of concept, this pattern focuses on migrating from an Amazon RDS for Oracle DB instance.

Prerequisites and limitations

Prerequisites

- An active AWS account
- An application connecting to an Amazon RDS for Oracle database
- A table created in the source Amazon RDS for Oracle database with a primary key and sample data

Limitations

- Oracle database objects, such as procedures, functions, packages, and triggers, are not considered for migration because Amazon DynamoDB does not support these database objects.

Product versions

- This pattern applies to all editions and versions of Oracle databases that are supported by AWS DMS. For more information, see using an Oracle database as a source for AWS DMS and using an Amazon DynamoDB database as a target for AWS DMS. We recommend that you use the latest versions of AWS DMS for the most comprehensive version and feature support.

Architecture

Source technology stack

- Amazon RDS for Oracle DB instances, Oracle on Amazon EC2, or on-premises Oracle databases

Target technology stack

- Amazon DynamoDB

AWS data migration architecture
Tools

- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.
- **Amazon DynamoDB** is a fully managed NoSQL database service that provides fast, predictable, and scalable performance.
- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud. This pattern uses Amazon RDS for Oracle.

Epics

Plan the migration

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a VPC.</td>
<td>In your AWS account, create a virtual private cloud (VPC) and a private subnet.</td>
<td>Systems administrator</td>
</tr>
<tr>
<td>Create security groups and network access control lists.</td>
<td>For more information, see the AWS documentation.</td>
<td>Systems administrator</td>
</tr>
<tr>
<td>Configure and start the Amazon RDS for Oracle DB instance.</td>
<td>For more information, see the AWS documentation.</td>
<td>DBA, Systems administrator</td>
</tr>
</tbody>
</table>
## Migrate data

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an IAM role to access DynamoDB.</td>
<td>In the AWS Identity and Access Management (IAM) console, create the role, attach the policy AmazonDynamoDBFullAccess to it, and select AWS DMS as the service.</td>
<td>Systems administrator</td>
</tr>
<tr>
<td>Create an AWS DMS replication instance for migration.</td>
<td>The replication instance should be in the same Availability Zone and VPC as the source database.</td>
<td>Systems administrator</td>
</tr>
</tbody>
</table>
| Create source and target endpoints in AWS DMS. | To create the source database endpoint, you have two options:  
  - On the Amazon RDS console, choose Databases, DB identifier, Connectivity & Security, and choose the endpoint.  
  - On the AWS DMS console, choose Select RDS DB instance.  
To create the target database endpoint, choose the role Amazon Resource Name (ARN) from the previous task to access DynamoDB. | Systems administrator |
| Create an AWS DMS task to load the source Oracle database tables to DynamoDB. | Choose the source and destination endpoint names and the replication instance from the previous steps. The type can be full load. Choose the Oracle schema and specify % to select all tables. | Systems administrator |
| Validate the tables in DynamoDB. | To view the migration results, choose Tables from the left navigation pane in the DynamoDB console. | DBA |

## Migrate the application

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify the application code.</td>
<td>To connect to and retrieve data from DynamoDB, update the application code.</td>
<td>App owner, DBA, Systems administrator</td>
</tr>
</tbody>
</table>
Cut over

<table>
<thead>

Migrate an Oracle partitioned table to PostgreSQL by using AWS DMS

*Created by Saurav Mishra (AWS) and Eduardo Valentim (AWS)*

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>Oracle database</th>
<th>Target:</th>
<th>PostgreSQL 9.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Re-architect</td>

<td>Oracle</td>
<td>Technologies:</td>
<td>Migration; Databases; Storage &amp; backup</td>
</tr>
<tr>
<td>AWS services:</td>
<td>AWS DMS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to speed up loading a partitioned table from Oracle to PostgreSQL by using AWS Database Migration Service (AWS DMS), which doesn't support native partitioning. The target PostgreSQL database can be installed on Amazon Elastic Compute Cloud (Amazon EC2), or it can be
an Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL-Compatible Edition DB instance.

Uploading a partitioned table includes the following steps:

1. Create a parent table similar to the Oracle partition table, but don't include any partition.
2. Create child tables that will inherit from the parent table that you created in step 1.
3. Create a procedure function and trigger to handle the inserts in the parent table.

However, because the trigger is fired for every insert, the initial load using AWS DMS can be very slow.

To speed up initial loads from Oracle to PostgreSQL 9.0, this pattern creates a separate AWS DMS task for each partition and loads the corresponding child tables. You then create a trigger during cutover.

PostgreSQL version 10 supports native partitioning. However, you might decide to use inherited partitioning in some cases. For more information, see the Additional information (p. 1084) section.

Prerequisites and limitations

Prerequisites

• An active AWS account
• A source Oracle database with a partitioned table
• A PostgreSQL database on AWS

Product versions

• PostgreSQL 9.0

Architecture

Source technology stack

• A partitioned table in Oracle

Target technology stack

• A partitioned table in PostgreSQL (on Amazon EC2, Amazon RDS for PostgreSQL, or Aurora PostgreSQL)

Target architecture
**Tools**

- **AWS Database Migration Service (AWS DMS)** helps you migrate data stores into the AWS Cloud or between combinations of cloud and on-premises setups.

**Epics**

**Set up AWS DMS**

<table>

- Table Partitioning (PostgreSQL documentation)

Additional information

Although PostgreSQL version 10 supports native partitioning, you might decide to use inherited partitioning for the following use cases:

- Partitioning enforces a rule that all partitions must have the same set of columns as the parent, but table inheritance supports children having extra columns.
- Table inheritance supports multiple inheritances.
- Declarative partitioning supports only list and range partitioning. With table inheritance, you can divide the data as you want. However, if the constraint exclusion can’t prune partitions effectively, query performance will suffer.
- Some operations need a stronger lock when using declarative partitioning than when using table inheritance. For example, adding or removing a partition to or from a partitioned table requires an ACCESS EXCLUSIVE lock on the parent table, whereas a SHARE UPDATE EXCLUSIVE lock is enough for regular inheritance.

When you use separate job partitions, you can also reload partitions if there are any AWS DMS validation issues. For better performance and replication control, run tasks on separate replication instances.

Migrate and replicate VSAM files to Amazon RDS or Amazon MSK using Connect from Precisely

Created by Prachi Khanna (AWS) and Boopathy GOPALSAMY (AWS)

<table>
<thead>
<tr>
<th>Environment:</th>
<th>PoC or pilot</th>
<th>Source:</th>
<th>VSAM</th>
<th>Target:</th>
<th>Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type:</td>
<td>Re-architect</td>
<td>Workload:</td>
<td>IBM</td>
<td>Technologies:</td>
<td>Migration; Modernization</td>
</tr>
</tbody>
</table>
Summary

This pattern shows you how to migrate and replicate Virtual Storage Access Method (VSAM) files from a mainframe to a target environment in the AWS Cloud by using Connect from Precisely. The target environments covered in this pattern include Amazon Relational Database Service (Amazon RDS) and Amazon Managed Streaming for Apache Kafka (Amazon MSK). Connect uses change data capture (CDC) to continuously monitor updates to your source VSAM files and then transfer these updates to one or more of your AWS target environments. You can use this pattern to meet your application modernization or data analytics goals. For example, you can use Connect to migrate your VSAM application files to the AWS Cloud with low latency, or migrate your VSAM data to an AWS data warehouse or data lake for analytics that can tolerate synchronization latencies that are higher than required for application modernization.

Prerequisites and limitations

Prerequisites

- IBM z/OS V2R1 or later
- CICS Transaction Server for z/OS (CICS TS) V5.1 or later (CICS/VSAM data capture)
- IBM MQ 8.0 or later
- z/OS security requirements (for example, APF authorization for SQData load libraries)
- VSAM recovery logs turned on
- (Optional) CICS VSAM Recovery Version (CICS VR) to automatically capture CDC logs
- An active AWS account
- An Amazon Virtual Private Cloud (VPC) with a subnet that's reachable by your legacy platform
- VSAM Connect license from Precisely

Limitations

- Connect doesn't support automatic target table creation based on source VSAM schemas or copybooks. You must define the target table structure for the first time.
- For non-streaming targets such as Amazon RDS, you must specify the conversion source to target mapping in the Apply Engine configuration script.
- Logging, monitoring, and alerting functions are implemented through APIs and require external components (such as Amazon CloudWatch) to be fully operational.

Product versions

- SQData 40134 for z/OS
- SQData 4.0.43 for the Amazon Linux Amazon Machine Image (AMI) on Amazon Elastic Compute Cloud (Amazon EC2)

Architecture

Source technology stack

- Job Control Language (JCL)
- z/OS Unix shell and Interactive System Productivity Facility (ISPF)
- VSAM utilities (IDCAMS)

**Target technology stack**

- Amazon EC2
- Amazon MSK
- Amazon RDS
- Amazon VPC

**Target architecture**

*Migrating VSAM files to Amazon RDS*

The following diagram shows how to migrate VSAM files to a relational database, such as Amazon RDS, in real time or near real time by using the CDC agent/publisher in the source environment (on-premises mainframe) and the Apply Engine in the target environment (AWS Cloud).

The diagram shows the following batch workflow:

1. Connect captures changes to a file by comparing VSAM files from backup files to identify changes and then sends the changes to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to a target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Apply Engine in the target environment receives the changes from the Publisher agent and applies them to a relational or non-relational database.

The diagram shows the following online workflow:

1. Connect captures changes in the online file by using a log replicate and then streams captured changes to a logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Apply Engine in the target environment receives the changes from the Publisher agent and then applies them to a relational or non-relational database.

**Migrating VSAM files to Amazon MSK**

The following diagram shows how to stream VSAM data structures from a mainframe to Amazon MSK in high-performance mode and automatically generate JSON or AVRO schema conversions that integrate with Amazon MSK.

The diagram shows the following batch workflow:

1. Connect captures changes to a file by using CICS VR or by comparing VSAM files from backup files to identify changes. Captured changes are sent to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Replicator Engine that’s operating in parallel processing mode splits the data to a unit of work cache.
5. Worker threads capture the data from the cache.
6. Data is published to Amazon MSK topics from the worker threads.
7. Users apply changes from Amazon MSK to targets such as Amazon DynamoDB, Amazon Simple Storage Service (Amazon S3), or Amazon OpenSearch Service by using connectors.

The diagram shows the following online workflow:

1. Changes in the online file are captured by using a log replicate. Captured changes are streamed to the logstream.
2. The publisher consumes data from the system logstream.
3. The publisher communicates captured data changes to the target engine through TCP/IP. The Controller Daemon authenticates communication between the source and target environments.
4. The Replicator Engine that’s operating in parallel processing mode splits the data to a unit of work cache.
5. Worker threads capture the data from the cache.
6. Data is published to Amazon MSK topics from the worker threads.
7. Users apply changes from Amazon MSK to targets such as DynamoDB, Amazon S3, or OpenSearch Service by using connectors.

**Tools**

- **Amazon Managed Streaming for Apache Kafka (Amazon MSK)** is a fully managed service that helps you build and run applications that use Apache Kafka to process streaming data.
- **Amazon Relational Database Service (Amazon RDS)** helps you set up, operate, and scale a relational database in the AWS Cloud.

Additional information

Configuration file example

This is an example configuration file for a logstream where the source environment is a mainframe and the target environment is Amazon MSK:

```
-- JOBNAME -- PASS THE SUBSCRIBER NAME
-- REPORT progress report will be produced after "n" (number) of Source records processed.

JOBNAME VSMTOKFK;
--REPORT EVERY 100;
-- Change Op has been 'I' for insert, 'D' for delete , and 'R' for Replace. For RDS it is 'U' for update
-- Character Encoding on z/OS is Code Page 1047, on Linux and UNIX it is Code Page 819 and on Windows, Code Page 1252
OPTIONS CDCOP('I', 'U', 'D'), PSEUDO NULL = NO, USE AVRO COMPATIBLE NAMES, APPLICATION ENCODING SCHEME = 1208;

-- SOURCE DESCRIPTIONS
BEGIN GROUP VSAM_SRC;
```
DESCRIPTION COBOL ../copybk/ACCOUNT AS account_file;
END GROUP;

-- TARGET DESCRIPTIONS

BEGIN GROUP VSAM_TGT;
DESCRIPTION COBOL ../copybk/ACCOUNT AS account_file;
END GROUP;

-- SOURCE DATASTORE (IP & Publisher name)

DATASTORE cdc://10.81.148.4:2626/vsmcdct/VSMTOFK
OF VSAMCDC
AS CDCIN
DESCRIBED BY GROUP VSAM_SRC ACCEPT ALL;

-- TARGET DATASTORE(s) - Kafka and topic name

DATASTORE 'kafka:///MSKTutorialTopic/key'
OF JSON
AS CDCOUT
DESCRIBED BY GROUP VSAM_TGT FOR INSERT;

-- MAIN SECTION

PROCESS INTO
CDCOUT
SELECT
{
SETURL(CDCOUT, 'kafka:///MSKTutorialTopic/key')
REMAP(CDCIN, account_file, GET_RAW_RECORD(CDCIN, AFTER), GET_RAW_RECORD(CDCIN, BEFORE))
REPLICATE(CDCOUT, account_file)
}
FROM CDCIN;

Key pair example

This an example of how to run the JCL to generate the key pair:

//SQDUTIL EXEC PGM=SQDUTIL //SQDPUBL DD DSN=&USER..NACL.PUBLIC, //
DCB=(RECFM=FB,LRECL=80,BLKSIZE=21200), // DISP=(,CATLG,DELETE),UNIT=SYSDA, // SPACE=(TRK, (1,1)) //SQDPKEY DD DSN=&USER..NACL.PRIVATE, // DCB=(RECFM=FB,LRECL=80,BLKSIZE=21200), // DISP=(,CATLG,DELETE),UNIT=SYSDA, // SPACE=(TRK,(1,1)) //SQDPARMS DD keygen //SYSPRINT DD SYSOUT= //SYSOUT DD SYSOUT=* //SQDLOG DD SYSOUT=* //SQDLOG8 DD DUMMY

Migrate from Amazon RDS for Oracle to Amazon RDS for MySQL

Created by Jitender Kumar (AWS)

**R Type:** Re-architect  **Source:** Databases: Relational  **Target:** Amazon RDS for MySQL

**Created by:** AWS  **Environment:** PoC or pilot  **Technologies:** Databases; Migration

**Workload:** Oracle  **AWS services:** Amazon RDS
Summary

This pattern provides guidance for migrating an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance to an Amazon RDS for MySQL DB instance by using AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT).

The pattern covers best practices for handling the migration of stored procedures and code changes to support the application layer.

Additionally, this pattern uses AWS Workload Qualification Framework (AWS WQF) to estimate efforts required to carry out this migration. AWS WQF classifies this migration as workload category 1.

Prerequisites and limitations

Prerequisites

• An active AWS account.
• An Amazon RDS for Oracle source database.
• An Amazon RDS for MySQL target database. Source and target databases should be in the same virtual private cloud (VPC), or you must have the required access permissions if you’re using multiple VPCs.
• Security groups that allow connectivity between the source and target databases, AWS SCT, the application server, and AWS DMS.
• A user account with the required privilege to run AWS SCT on the source database.
• Supplemental logging enabled, to run AWS DMS on the source database.

Limitations

• The source and target Amazon RDS database size limit is 64 TB.
• Oracle is case-insensitive for database objects, but MySQL is not. AWS SCT can handle this issue while creating an object; however, some manual work is required to support full case insensitivity.
• This migration doesn’t use MySQL extensions to enable Oracle-native functions. AWS SCT handles most of the conversion, but some work is required to change code manually.
• Java Database Connectivity (JDBC) driver changes are required in the application.

Product versions

• Amazon RDS for Oracle 11.2.0.4.v20
• Amazon RDS for MySQL 8.0.15
• AWS DMS version 3.3.0
• AWS SCT version 1.0.628

Architecture

Source technology stack

• Amazon RDS for Oracle. For more information, see Using an Oracle Database as a Source for AWS DMS in the AWS DMS documentation.

Target technology stack

• Amazon RDS for MySQL. For more information, see Using a MySQL-Compatible Database as a Target for AWS DMS in the AWS DMS documentation.
Tools

- **AWS Schema Conversion Tool** – AWS SCT makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database.

- **AWS Data Migration Service** – AWS DMS can migrate your data to and from most widely used commercial and open-source databases. AWS DMS supports homogeneous migrations such as Oracle to Oracle, as well as heterogeneous migrations between different database platforms, such as Oracle or Microsoft SQL Server to Amazon Aurora.

- **AWS Workload Qualification Framework** – AWS WQF uses AWS SCT to collect information to model existing Oracle and Microsoft SQL Server database workloads and provides instructions to convert them to an AWS database.

<td>IBM</td>
<td>Amazon Aurora</td>
</tr>
</tbody>
</table>

### Summary

This pattern provides guidance for migrating an IBM Db2 database on an Amazon Elastic Compute Cloud (Amazon EC2) instance to an Amazon Aurora PostgreSQL-Compatible Edition DB instance. This pattern uses AWS Database Migration Service (AWS DMS) and AWS Schema Conversion Tool (AWS SCT) for data migration and schema conversion.

The pattern targets an online migration strategy with little or no downtime for a multi-terabyte IBM Db2 database that has a high number of transactions. We recommend that you convert the columns in primary keys (PKs) and foreign keys (FKs) with the data type NUMERIC to INT or BIGINT in PostgreSQL for better performance.

### Prerequisites and limitations

**Prerequisites**

- An active AWS account
- A source IBM Db2 database on an EC2 instance

**Product versions**
- DB2/LINUXX8664 version 11.1.4.4 and later

**Architecture**

**Source technology stack**
- A Db2 database on an EC2 instance

**Target technology stack**
- An Aurora PostgreSQL-Compatible DB instance

**Database migration architecture**

**Tools**

- AWS DMS - AWS Database Migration Service (AWS DMS) helps you migrate databases to AWS quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. You can use AWS DMS to migrate your data to and from the most widely used commercial and open-source databases. AWS DMS supports heterogeneous migrations between different database platforms, such as IBM Db2 to Aurora PostgreSQL-Compatible. For details, see Sources for Data Migration and Targets for Data Migration in the AWS DMS documentation.
AWS SCT - AWS Schema Conversion Tool (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format that's compatible with the target database. Any objects that are not automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan the application source code for embedded SQL statements and convert them.

Epics

Migrate

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Skills required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an Aurora PostgreSQL-Compatible DB instance.</td>
<td>The Aurora PostgreSQL-Compatible DB instance should be in the same virtual private cloud (VPC) as the source IBM Db2 database.</td>
<td>Amazon RDS</td>
</tr>
<tr>
<td>Create a replication instance and endpoints for IBM Db2.</td>
<td>You must create separate endpoints for the source and target databases. For Aurora PostgreSQL-Compatible, the port will be 5432, and you'll need to get the server name from the DB instance's endpoint. For the source database, the server name must be the public DNS of the EC2 instance where Db2 is running. For user name, you can use db2inst1 followed by the port, which will be 5000 for IBM Db2. You then create a replication instance. For the VPC security group, select both the EC2 instance for Db2 and the Aurora PostgreSQL-Compatible DB instance. This replication instance must be in the same VPC as the source and target DB instances.</td>
<td>AWS DMS</td>
</tr>
<tr>
<td>Create an AWS DMS task to fully load the source IBM Db2 tables to the target PostgreSQL schema.</td>
<td>For source and target, use the source and destination endpoint names. The type can be full load. For the schema rule, you can use the Db2 database's “inst1” schema. For the table name, specify “%” to migrate all tables. When the load is complete, you'll see the Db2 tables of the “inst1” schema appearing in the Aurora PostgreSQL-Compatible database.</td>
<td>AWS DMS</td>
</tr>
</tbody>
</table>
Use AWS SCT to migrate all other objects.

Configure AWS SCT to connect to the source and target DB instances. In AWS SCT, select the views, indexes, procedures, and functions from the “inst1” schema in the source Db2 database, to migrate them to the target database.

Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using SharePlex and AWS DMS

Created by Kumar Babu P G (AWS)

<table>
<thead>
<tr>
<th>Environment: PoC or pilot</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon RDS for PostgreSQL/Amazon Aurora PostgreSQL</th>
</tr>
</thead>
<tbody>
<tr>
<td>R Type: Re-architect</td>
<td>Workload: Oracle</td>
<td>Technologies: Migration; Databases</td>
</tr>
<tr>
<td>AWS services: Amazon RDS; Amazon Aurora</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to migrate an on-premises Oracle 8i or 9i database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora PostgreSQL. AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source, so Quest SharePlex replicates data from an on-premises 8i or 9i database to an intermediate Oracle database (Oracle 10g or 11g), which is compatible with AWS DMS.
From the intermediate Oracle instance, the schema and data are migrated to the PostgreSQL database on AWS by using AWS Schema Conversion Tool (AWS SCT) and AWS DMS. This method helps achieve continuous streaming of data from the source Oracle database to the target PostgreSQL DB instance with minimum replication lag. In this implementation, the downtime is limited to the length of time it takes to create or validate all the foreign keys, triggers, and sequences on the target PostgreSQL database.

The migration uses an Amazon Elastic Compute Cloud (Amazon EC2) instance with Oracle 10g or 11g installed to host the changes from the source Oracle database. AWS DMS uses this intermediate Oracle instance as the source to stream the data to Amazon RDS for PostgreSQL or Aurora PostgreSQL. Data replication can be paused and resumed from the on-premises Oracle database to the intermediate Oracle instance. It can also be paused and resumed from the intermediate Oracle instance to the target PostgreSQL database so you can validate the data by using either AWS DMS data validation or a custom data validation tool.

Prerequisites and limitations

Prerequisites

- An active AWS account
- A source Oracle 8i or 9i database in an on-premises data center
- AWS Direct Connect configured between the on-premises data center and AWS
- Java Database Connectivity (JDBC) drivers for AWS SCT connectors installed either on a local machine or on the EC2 instance where AWS SCT is installed
- Familiarity with using an Oracle database as an AWS DMS source
- Familiarity with using a PostgreSQL database as an AWS DMS target
- Familiarity with Quest SharePlex data replication

Limitations

- The database size limit is 64 TB
- The on-premises Oracle database must be Enterprise Edition

Product versions

- Oracle 8i or 9i for the source database
- Oracle 10g or 11g for the intermediate database
- PostgreSQL 9.6 or later

Architecture

Source technology stack

- Oracle 8i or 9i database
- Quest SharePlex

Target technology stack

- Amazon RDS for PostgreSQL or Aurora PostgreSQL
### Source and target architecture

![Source and target architecture diagram]

### Tools

- **AWS DMS** – **AWS Database Migration Service** (AWS DMS) helps you migrate databases quickly and securely. The source database remains fully operational during the migration, minimizing downtime to applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.

- **AWS SCT** – **AWS Schema Conversion Tool** (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database. Objects that cannot be automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan your application source code for embedded SQL statements and convert them as part of a database schema conversion project. During this process, AWS SCT performs cloud-native code optimization by converting legacy Oracle and SQL Server functions to their AWS equivalents, to help you modernize your applications while migrating your databases. When schema conversion is complete, AWS SCT can help migrate data from a range of data warehouses to Amazon Redshift by using built-in data migration agents.

- **Quest SharePlex** – **Quest SharePlex** is an Oracle-to-Oracle data replication tool for moving data with minimal downtime and no data loss.

Migrate from Oracle 8i or 9i to Amazon RDS for PostgreSQL using materialized views and AWS DMS

Created by Kumar Babu P G (AWS)

<table>
<thead>
<tr>
<th>R Type:</th>
<th>Re-architect</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon RDS for PostgreSQL/Aurora PostgreSQL</th>

<td>Oracle</td>
<td>AWS services: Amazon RDS; Amazon Aurora</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern describes how to migrate an on-premises legacy Oracle 8i or 9i database to Amazon Relational Database Service (Amazon RDS) for PostgreSQL or Amazon Aurora for PostgreSQL. AWS Database Migration Service (AWS DMS) doesn't support Oracle 8i or 9i as a source, so this pattern uses an intermediate Oracle database instance that's compatible with AWS DMS, such as Oracle 10g or 11g. It also uses the materialized views feature to migrate data from the source Oracle 8i/9i instance to the intermediate Oracle 10g/11g instance.

AWS Schema Conversion Tool (AWS SCT) converts the database schema, and AWS DMS migrates the data to the target PostgreSQL database.

This pattern helps users who want to migrate from legacy Oracle databases with minimum database downtime. In this implementation, the downtime would be limited to the length of time it takes to create or validate all the foreign keys, triggers, and sequences on the target database.

The pattern uses Amazon Elastic Compute Cloud (Amazon EC2) instances with an Oracle 10g/11g database installed to help AWS DMS stream the data. You can temporarily pause streaming replication from the on-premises Oracle database to the intermediate Oracle instance to enable AWS DMS to catch up on data validation or to use another data validation tool. The PostgreSQL DB instance and intermediate Oracle database will have the same data when AWS DMS has finished migrating current changes.

Prerequisites and limitations

Prerequisites

• An active AWS account
• A source Oracle 8i or 9i database in an on-premises data center
• AWS Direct Connect configured between the on-premises data center and AWS
• Java Database Connectivity (JDBC) drivers for AWS SCT connectors installed either on a local machine or on the EC2 instance where AWS SCT is installed
• Familiarity with using an Oracle database as an AWS DMS source
• Familiarity with using a PostgreSQL database as an AWS DMS target

Limitations
• The database size limit is 64 TB

Product versions
• Oracle 8i or 9i for the source database
• Oracle 10g or 11g for the intermediate database
• PostgreSQL 9.6 or later

Architecture

Source technology stack
• Oracle 8i or 9i database

Target technology stack
• Amazon RDS for PostgreSQL or Aurora PostgreSQL

Target architecture

Tools
• AWS DMS – AWS Database Migration Service (AWS DMS) helps migrate databases quickly and securely. The source database remains fully operational during the migration, minimizing downtime to
applications that rely on the database. AWS DMS can migrate your data to and from the most widely used commercial and open-source databases.

- **AWS SCT** – **AWS Schema Conversion Tool** (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format compatible with the target database. Objects that cannot be automatically converted are clearly marked so that they can be manually converted to complete the migration. AWS SCT can also scan your application source code for embedded SQL statements and convert them as part of a database schema conversion project. During this process, AWS SCT performs cloud-native code optimization by converting legacy Oracle and SQL Server functions to their AWS equivalents, to help you modernize your applications while migrating your databases. When schema conversion is complete, AWS SCT can help migrate data from a range of data warehouses to Amazon Redshift by using built-in data migration agents.

<td>Configure Oracle networking.</td>
<td>Modify or add entries in listener.ora to connect to the on-premises source Oracle 8i/9i database, and then create the database links.</td>
<td>DBA</td>
</tr>
<tr>
<td>Create materialized views.</td>
<td>Identify the database objects to replicate in the source Oracle 8i/9i database, and then create materialized views for all the objects by using the database link.</td>
<td>DBA</td>
</tr>
</tbody>
</table>
### Deploy scripts to refresh materialized views at required intervals.

**Description**
Develop and deploy scripts to refresh materialized views at required intervals on the Amazon EC2 Oracle 10g/11g instance. Use the incremental refresh option to refresh materialized views.

**Skills required**
DBA

### Convert the Oracle database schema to PostgreSQL

#### Set up AWS SCT.

**Description**
Create a new report, and then connect to Oracle as the source and PostgreSQL as the target. In project settings, open the SQL Scripting tab. Change the target SQL script to Multiple Files. (AWS SCT doesn't support Oracle 8i/9i databases, so you have to restore the schema-only dump on the intermediate Oracle 10g/11g instance and use it as a source for AWS SCT.)

**Skills required**
DBA

#### Convert the Oracle database schema.

**Description**
In the Action tab, choose Generate Report, Convert Schema, and then Save as SQL.

**Skills required**
DBA

#### Modify the SQL scripts.

**Description**
Make modifications based on best practices. For example, switch to suitable data types and develop PostgreSQL equivalents for Oracle-specific functions.

**Skills required**
DBA, DevDBA

### Create and configure the Amazon RDS DB instance

#### Create the Amazon RDS DB instance.

**Description**
In the Amazon RDS console, create a new PostgreSQL DB instance.

**Skills required**
AWS SysAdmin, DBA

#### Configure the DB instance.

**Description**
Specify the DB engine version, DB instance class, Multi-AZ deployment, storage type, and allocated storage. Enter the DB instance identifier, a master user name, and a master password.

**Skills required**
AWS SysAdmin, DBA

#### Configure network and security.

**Description**
Specify the virtual private cloud (VPC), subnet group, public

**Skills required**
DBA, SysAdmin
Migrate from Oracle 8i/9i to Amazon RDS for PostgreSQL using materialized views

### Migrate from Oracle on Amazon EC2 to Amazon RDS for MySQL using AWS DMS and AWS SCT

*Created by Anil Kunapareddy (AWS)*

#### Summary

Managing Oracle databases on Amazon Elastic Compute Cloud (Amazon EC2) instances requires resources and can be costly. Moving these databases to an Amazon Relational Database Service (Amazon RDS) for MySQL DB instance will ease your job by optimizing the overall IT budget. Amazon RDS for MySQL also provides features like Multi-AZ, scalability, and automatic backups.

This pattern walks you through the migration of a source Oracle database on Amazon EC2 to a target Amazon RDS for MySQL DB instance. It uses AWS Database Migration Service (AWS DMS) to migrate the data, and AWS Schema Conversion Tool (AWS SCT) to convert the source database schema and objects to a format that's compatible with Amazon RDS for MySQL.

#### Prerequisites and limitations

**Prerequisites**
• An active AWS account
• A source database with instance and listener services running, in ARCHIVELOG mode
• A target Amazon RDS for MySQL database, with sufficient storage for data migration

Limitations

• AWS DMS does not create a schema on the target database; you have to do that. The schema name must already exist for the target. Tables from the source schema are imported to user/schema, which AWS DMS uses to connect to the target instance. You must create multiple replication tasks if you have to migrate multiple schemas.

Product versions

• All Oracle database editions for versions 10.2 and later, 11g and up to 12.2, and 18c. For the latest list of supported versions, see Using an Oracle Database as a Source for AWS DMS and Using a MySQL-Compatible Database as a Target for AWS DMS. We recommend that you use the latest version of AWS DMS for the most comprehensive version and feature support. For information about Oracle database versions supported by AWS SCT, see the AWS SCT documentation.
• AWS DMS supports versions 5.5, 5.6, and 5.7 of MySQL.

Architecture

Source technology stack

• An Oracle database on an EC2 instance

Target technology stack

• Amazon RDS for MySQL DB instance

Data migration architecture
**Tools**

- **AWS DMS** - *AWS Database Migration Service* (AWS DMS) is a web service you can use to migrate data from your database that is on-premises, on an Amazon RDS DB instance, or in a database on an EC2 instance, to a database on an AWS service such as Amazon RDS for MySQL or an EC2 instance. You can also migrate a database from an AWS service to an on-premises database. You can migrate data between heterogeneous or homogenous database engines.

- **AWS SCT** - *AWS Schema Conversion Tool* (AWS SCT) makes heterogeneous database migrations predictable by automatically converting the source database schema and a majority of the database code objects, including views, stored procedures, and functions, to a format that's compatible with the target database. After converting your database schema and code objects using AWS SCT, you can use AWS DMS to migrate data from the source database to the target database to complete your migration projects.

Migrate from Oracle to Amazon DocumentDB using AWS DMS

Created by Sashikanta Pattanayak (AWS)

<table>
<thead>
<tr>
<th>R Type: Re-architect</th>
<th>Source: Databases: Relational</th>
<th>Target: Amazon DocumentDB</th>
</tr>
</thead>
<tbody>
<tr>
<td>Created by: AWS</td>
<td>Environment: PoC or pilot</td>

</tr>
<tr>
<td>Workload: Oracle</td>
<td>AWS services: Amazon DocumentDB</td>
<td></td>
</tr>
</tbody>
</table>

Summary

This pattern provides guidance for migrating an Oracle database to an Amazon DocumentDB (with MongoDB compatibility) database by using AWS Database Migration Service (AWS DMS). This approach can be applied to an on-premises Oracle source database as well as an Amazon Relational Database Service (Amazon RDS) for Oracle DB instance. This pattern uses an Amazon RDS Oracle DB source instance as an example.

Amazon DocumentDB (with MongoDB compatibility) is a fully managed, MongoDB-compatible document database service that makes it easy to store, query, and index JSON data.

The use case for this pattern is one-to-one replication of an Oracle database table to an Amazon DocumentDB collection. The pattern uses AWS DMS replication tasks to read the table structure of the Oracle database, create the corresponding collection in Amazon DocumentDB, and perform a full load migration. You can view and query your data in Amazon DocumentDB, the same as you would in MongoDB.

Prerequisites and limitations

Prerequisites

- An active AWS account
- Familiarity with using Oracle databases
- Familiarity with using Amazon DocumentDB
- For the Oracle user, SELECT ANY TABLE privilege
- For the Amazon DocumentDB use, the privilege required to dump data

Limitations

The following limitations apply when using Amazon DocumentDB as a target for AWS DMS:
• In Amazon DocumentDB, collection names can’t contain the dollar symbol ($). In addition, database names can’t contain any Unicode characters.

• AWS DMS doesn’t support merging of multiple source tables into a single Amazon DocumentDB collection.

• When AWS DMS processes changes from a source table that doesn’t have a primary key, any large binary object (LOB) columns in that table are ignored.

• If the Change table option is enabled and AWS DMS encounters a source column named "_id", that column appears as "__id" (two underscores) in the change table.

• If you choose Oracle as a source endpoint, the Oracle source must have full supplemental logging enabled. Otherwise, if there are columns at the source that weren’t changed, the data is loaded into Amazon DocumentDB as null values.

Product versions

• Amazon RDS for Oracle version 11.2.0.3 or later

• AWS DMS version 3.1.3 or later (for the latest version information, see Using Amazon DocumentDB as a Target for AWS DMS in the AWS DMS documentation)

Architecture

Source technology stack

• Amazon RDS for Oracle DB instance

Target technology stack

• Amazon DocumentDB

Source and target architecture
Tools

- **AWS DMS** – *AWS Database Migration Service* (AWS DMS) is a web service that you can use to migrate data from a source data store to a target data store. The *AWS DMS User Guide* specifies the Oracle source database versions and editions that are supported for use with AWS DMS. For additional information relevant to this pattern, see *Using Amazon DocumentDB as a Target for AWS DMS*.
