Migrating on-premises servers to AWS over private networks by using AWS Application Migration Service

Mike Kuznetsov and Dipin Jain, Amazon Web Services (AWS)

March 2023 (document history)

Many companies migrate to AWS from isolated or semi-isolated network environments such as on-premises data centers or other cloud or hybrid infrastructures. Such isolated networks typically do not allow any egress traffic to external endpoints, which is required for migration over the network. Other companies do allow HTTPS egress traffic from their internal networks but do not permit specific communications on network ports required by AWS Application Migration Service, which is the primary AWS service for large lift-and-shift migrations. In a third scenario, HTTPS traffic is allowed from both source and staging areas, but data replication traffic is required to go over the private channel for compliance reasons.

Application Migration Service supports these use cases and allows you to migrate from secured isolated environments by using only private or hybrid private/public network connectivity. This guide describes these three scenarios, ranging from the two hybrid public/private models to the fully isolated one, and focuses on detailed steps and infrastructure requirements for the most restrictive, private-only option. It builds on the AWS Prescriptive Guidance pattern Connect to Application Migration Service data and control planes over a private network by providing:

- Additional details on required connectivity in each scenario
- Explanations of AWS resources that must be created
- Automation options for building the testing infrastructure on AWS and deploying the infrastructure during the migration phase
- Options for monitoring and troubleshooting connectivity for each use case

For more information about how Application Migration Service works, see these blog posts:

Scenarios

This guide covers the required infrastructure components to be created to complete the migration for the following scenarios:

- **Replication over private networks only**, which is the most common and restrictive scenario.
- Hybrid scenario where HTTPS egress communication is allowed but all other traffic is restricted. This scenario consists of two options:
  - **Public HTTPS egress at the source and private staging area resources**
  - **Public HTTPS egress at the source and public staging area resources**

For each scenario, the guide provides an example configuration and the full list of required AWS components.

**Replication over private networks only**

The following diagram displays the architecture of the most restrictive scenario, where all traffic goes over the private channel (AWS VPN or AWS Direct Connect) between the source environment and AWS.
The main components of this architecture are:

- **Source environment** in the corporate data center (on the left). This is the environment to migrate from.

- **Staging environment** in AWS with private virtual private cloud (VPC) and subnet (in the middle). This is the environment that Application Migration Service will use to create replication-related resources. These resources might include replication servers, conversion servers, and related Amazon Elastic Block Store (Amazon EBS) volumes and their Amazon Simple Storage Service (Amazon S3) snapshots.

- **VPN connection** from the source environment to the staging VPC and subnet(s) to handle three types of traffic:
  - HTTPS/TCP port 443 for API communication
  - TCP port 1500 for data transfer
  - Domain Name System (DNS) traffic over UDP port 53
• *Target environment* in AWS (on the right). This can be a completely isolated VPC or a subnet in the staging environment. (Note: There’s no network connectivity requirement from the staging environment subnet to the target subnets.)

• *Amazon VPC interface endpoints* for Application Migration Service, Amazon Elastic Compute Cloud (Amazon EC2), and Amazon S3 created in the staging environment, and an *Amazon S3 VPC gateway endpoint* that is accessible from the staging subnet.

• And finally, *DNS resolver inbound endpoint* in the staging subnet. This is required for the source systems to resolve the fully qualified domain names (FQDNs) of the VPC endpoints into private IPs.

**Public HTTPS egress at the source and private staging area resources**

The following diagram illustrates the architecture in the hybrid scenario where HTTPS egress traffic is allowed from any source servers and is used to communicate with Application Migration Service and Amazon S3 endpoints, whereas the replication data on TCP port 1500 goes over the private channel (AWS VPN or AWS Direct Connect) between the source environment and AWS.
This architecture simplifies the requirements for the staging area subnet, because HTTPS communications from agents don't travel through the private channel. Also, there is no need to create additional Amazon S3 interface VPC endpoints or Amazon Route 53 inbound resolver endpoints for DNS traffic, because source servers will use their traditional DNS servers to resolve the standard, public DNS names of Application Migration Service and Amazon S3 endpoints.

However, in this scenario, staging area subnet resources still run on a private and fully isolated network and have no public access to any HTTPS endpoints, so they need to create both Application Migration Service and Amazon EC2 interface endpoints as well as an Amazon S3 gateway endpoint.

Public HTTPS egress at the source and public staging area resources

In cases where staging area resources aren't required to be on a fully isolated subnet, you can use the hybrid alternative that's shown in the following diagram.
In this scenario, only data replication traffic on TCP port 1500 goes over the private channel. The rest of the communication, both from the source subnet and the staging subnet, happen over the public network, to standard public HTTPS endpoints.
Architecture components and requirements for restricted replication

This section provides a detailed description of the most restrictive scenario, where all communication occurs over the private channel only, and includes a detailed explanation of the requirements and corresponding components to be built for each area.

Staging subnet

The staging subnet is the most important part of the replication infrastructure. This is where all Application Migration Service replication servers will be launched, and it contains the IP addresses the replication traffic will be directed to. For inbound private data replication, configure the replication server settings for Application Migration Service with the Use private IP option.

For outbound requirements, you can use the Create public IP option to choose whether replication servers will communicate with required AWS services (Amazon S3, Application Migration Service, Amazon EC2) over private or public IP. The standard options to provide outbound internet connectivity are listed in the Application Migration Service documentation: either a public IP address with an internet gateway or a private IP address with a NAT gateway. Both options allow you to implement a simplified hybrid scenario in which data replication traffic goes over a private connection (AWS VPN or AWS Direct Connect) while replication servers communicate with AWS services over the public network.

However, having public outbound connectivity is usually prohibited in closed corporate environments, and this is the most restrictive scenario discussed in the next section. In this case, you use AWS PrivateLink and configure the following VPC endpoints in staging subnets for replication servers:

- VPC gateway endpoint to communicate with Amazon S3
- VPC interface endpoints to communicate with Application Migration Service and Amazon EC2

To learn more about VPC endpoints, see the AWS PrivateLink documentation.
**Source subnet**

The source subnet is any subnet you are replicating from. This is where your source servers are located and where you will install AWS Replication Agent on these servers. The network requirements for an Agent include:

- Communicating over HTTPS/TCP port 443 with AWS services such as Amazon S3 and Application Migration Service
- Communicating with the replication server's IP address (private or public, based on its settings)

The Agent also supports hybrid scenarios where communication with AWS services can happen over the public network (using standard HTTPS traffic) while replication data is sent over private networks to the private IP of the replication server.

This guide focuses on a more restrictive scenario where even HTTPS traffic to AWS services isn't allowed from source systems, so the following endpoints are configured in the staging subnet:

- VPC interface endpoints for Application Migration Service and Amazon S3 (Regional interface endpoint, not the gateway endpoint that's required for replication servers)
- An inbound DNS resolver endpoint, to allow on-premises sources and DNS servers to resolve private IP addresses for VPC endpoints, located in the staging subnet

**Target subnet**

The target subnet is any subnet that you plan to launch your servers into, including test and cutover instances. These subnets have no network connectivity requirement at all, and could be located in any other VPC in the same AWS account and Region. This is because Application Migration Service uses Amazon EC2 APIs to create new test or cutover instances (which is why replication servers in the staging subnet require outbound HTTPS connectivity to Amazon EC2), and accesses Regional S3 snapshots created from replicated EBS volumes. None of these operations require direct network access to or from the target subnet, so this could even be a completely isolated private subnet.

However, Application Migration Service also automatically installs several tools such as EC2Config or AWS Systems Manager Agents (SSM Agents) on target instances, and these activities require outbound HTTPS/TCP port 443 connectivity from target instances and subnets.
Configuration best practices

This section provides a detailed description of the most restrictive scenario, where all communication occurs over the private channel only, and includes a detailed explanation of the requirements and corresponding components to be built for each area.

This section describes the configuration for the most restrictive scenario (replication over private networks only), as shown in the first diagram, based on the considerations discussed earlier. You can configure both hybrid scenarios by skipping parts of the most restrictive configuration:

- For the hybrid scenario that supports public HTTPS egress at the source and private staging area resources, the Amazon S3 interface VPC endpoint is not required.
- For the hybrid scenario that supports public HTTPS egress at the source and public staging area resources, no VPC endpoints in the staging area subnet are required.

The following sections assume that the initial Application Migration Service configuration is already complete, as described in the blog posts Accelerate your Migration with AWS Application Migration Service and How to Use the New AWS Application Migration Service for Lift-and-Shift Migrations). This discussion focuses on components that are specific to the restrictive scenario, and assumes a private staging subnet that has no connectivity to the internet.

Subnets and routing configurations

For the restrictive scenario, you configure the required AWS resources in the private subnet of a staging VPC. This subnet has no connectivity to the internet (there's no internet gateway attached to the routing table as a default route). Instead, it uses either a virtual gateway associated with an AWS Site-to-Site VPN gateway (connected through an IPsec tunnel to an on-premises gateway), or it's connected to a transfer gateway or to AWS Direct Connect services to provide private interconnectivity to the on-premises data centers.

You will use that private subnet as a staging subnet for replication-related resources managed by Application Migration Service, and you'll configure all required network access through this subnet by using VPC endpoints, as discussed in the next section.
**VPC endpoints configuration**

You now need to create VPC endpoints in the staging subnet to provide connectivity for the replication servers and Application Migration Service Agents from on-premises subnets.

Here's a full list of VPC endpoints you need:

- Application Migration Service and Amazon EC2 interface endpoints, which provide their own elastic network interfaces with private IP addresses and private DNS names to be used by both replication servers and Agents. (Agents will use only the Application Migration Service endpoint.)

- Amazon S3 gateway endpoint that provides a specific route in the subnet route table (though a prefix list). This will be used by replication servers.

- Amazon S3 interface endpoint that provides a specific elastic network interface with a dedicated private IP address in the private subnet. Application Migration Service Agents will use this address through a specific DNS name.

The next sections go into more detail about how VPC endpoints work. The following table lists all the endpoints created for the staging private subnet. (Note that the Amazon S3 gateway endpoint has no network interfaces provisioned but does have specific prefix lists provisioned into the subnet's route table, as will be described later in this guide.)

You can create optional VPC endpoints to enable access to EC2 instances on private isolated subnets through AWS Systems Manager, as discussed in [Creating VPC endpoints](#) in the Systems Manager documentation.

**VPC interface endpoints**

Creating an interface endpoint also creates a specific elastic network interface for each subnet that the given interface endpoint is provisioned for. For example, the Application Migration Service interface endpoint is provisioned in a private subnet in the staging VPC with an elastic network interface that is associated with the IP address inside that subnet, and it also has three DNS names resolvable from the subnet to this IP address:

- A private DNS name, `mgn.<region>.amazonaws.com`
- Two DNS names that are based on the endpoint ID (`vpce-xxx`), with and without the Region included in the name: `vpce-xxx-<region>.<service-name>` and `vpce-xxx.<service-name>`
This allows any instance running in the subnet that is using the default Dynamic Host Configuration Protocol (DHCP) option set configuration in the VPC, and has both DNS attributes enableDnsHostnames and enableDnsSupport enabled, to:

- Resolve the DNS name of Application Migration Service (mgn.<region>.amazonaws.com) to a private IP address assigned to the elastic network interface.
- Connect to Application Migration Service by using the local network only.

That fixes connectivity for any instances running in the staging subnet (such as the Application Migration Service replication server or conversion server) for any AWS service that has interface endpoints provisioned in the subnet (such as Amazon EC2, Application Migration Service, Systems Manager, AWS KMS, and so on).

**VPC gateway endpoints**

For services such as Amazon S3, no fixed DNS name can be provisioned because each bucket has its own DNS name. For this scenario you will use VPC gateway endpoints.

Creating an Amazon S3 gateway endpoint also creates a specific prefix list object with a list of subnet destinations (in CIDR notation), which can be added in the subnet route table. Thus, DNS names of S3 buckets resolved to IP addresses included in this list would be accessible through internal connectivity.

When you provision an Amazon S3 gateway endpoint, you can specify the subnets in the route tables that should include that prefix list ID (PL-<id>). The resulting route table for the staging private subnet must include that prefix list ID, as in this example route table:

<table>
<thead>
<tr>
<th>Destination</th>
<th>Target</th>
</tr>
</thead>
<tbody>
<tr>
<td>pl-&lt;id&gt;</td>
<td>vpce-&lt;id-of-S3-Gateway-VPC-endpoint&gt;</td>
</tr>
<tr>
<td>Any other routes (for example, source subnet CIDRs)</td>
<td>Any targets such as virtual gateway IDs</td>
</tr>
<tr>
<td>Local CIDR</td>
<td>&quot;local&quot;</td>
</tr>
</tbody>
</table>
DNS resolver inbound endpoints

The configuration described in the previous section is sufficient for instances that are running inside the AWS subnets, because they are already configured to use internal Amazon Route 53 DNS servers. However, on-premises source servers require additional steps to be able to communicate with AWS services privately. In particular, Application Migration Service Agent has to download the installer from Amazon S3 and then communicate with Application Migration Service by using DNS names provided in the documentation. On-premises servers use their default DNS servers to resolve these DNS names, resulting in public IP addresses. Communications with these addresses over HTTPS/TCP port 443 are eventually blocked by corporate firewalls.

To prevent this, you need to configure source servers or their default DNS servers to use Amazon Route 53 Resolver for resolution of these specific DNS names or a subdomain zone (that is, the full *.<region>.amazonaws.com zone). This can be configured by creating a Route 53 Resolver inbound endpoint, which, like a VPC interface endpoint, has a dedicated elastic network interface created in the dedicated private subnet on AWS, and is thus able to forward DNS requests to Amazon Route 53 Resolver.

Elastic network interface security groups

Each elastic network interface has a dedicated security group associated with it, which must permit traffic that's expected for this elastic network interface and corresponding endpoint. Thus, the DNS resolver endpoint's security group should permit inbound UDP port 53 (and sometimes TCP port 53) for DNS requests, and the endpoint security groups for most other services (Application Migration Service, Amazon EC2, Systems Manager, and so on) need inbound HTTPS/TCP port 443 enabled.

Installing Application Migration Service Agent on source servers

To install Application Migration Service Agent on source servers, you need to supply the DNS names of the Application Migration Service and Amazon S3 interface endpoints to the Agent's command line parameters (see Installing the Agent on a secured network in the Application Migration Service documentation).

For the Application Migration Service endpoint, you can use any of the DNS names associated with it—a private DNS field (mgn.<region>.amazonaws.com) or a VPC-specific DNS name (vpce-
<VPC-id>-<suffix>.mgn.<region>.vpce.amazonaws.com)—and supply an argument: --endpoint <FQDN>. In fact, if you skip this argument, the Agent uses the specified AWS Region to reconstruct the default DNS FQDN (mgn.<region>.amazonaws.com) and uses the FQDN to access the Application Migration Service control plane. In most cases, that default behavior should suffice, as long as that FQDN resolves from the source server correctly to the private IP address of the elastic network interface for the Application Migration Service VPC endpoint created in the staging subnet.

The Amazon S3 interface endpoint won't have a single private DNS name (because each S3 bucket will have its own), so that option isn't supported. However, an Amazon S3 interface endpoint still has an elastic network interface associated with it. It also has a specific private IP and wildcard DNS names (in the format .vpce-<VPC-ID>-<suffix>.s3.<region>.vpce.amazonaws.com or Region-specific .vpce-<VPC-ID>-<suffix>-<region>.s3.<region>.vpce.amazonaws.com) that are resolvable to this private IP.

That wildcard DNS name can be used for the --s3-endpoint argument, as in the following:

```
aws-replication-installer-init.py --region <region> --aws-access-key-id <MGN_IAM_ACCESS_KEY> --aws-secret-access-key <MGN_IAM_SECRET> --no-prompt \
    --endpoint vpce-<VPC-id>-<suffix>.mgn.<region>.vpce.amazonaws.com --s3-endpoint vpce-<VPC-ID>-<suffix>-<region>.s3.<region>.vpce.amazonaws.com
```

The next section provides an example of configuring Application Migration Service, including all required VPC endpoints, and deploying the Agents by using VPC endpoints on Windows and Linux source servers. The section covers both manual and automated deployment.
Deploying the PoC environment

Many users prefer to thoroughly test all communication channels and migration steps in advance. Testing migration from isolated networks could be a challenge. To address that need, AWS provides two options:

- A CloudFormation template that prepares all required resources on AWS. The template builds a proof of concept (PoC) environment that emulates the components of the data center environment and sets up the AWS infrastructure. It includes isolated source and target VPCs, subnets, and VPC endpoints.
- A dedicated workshop (Migrate the Well-Architected Way) with detailed, step-by-step instructions to create your test environment (see the step Create VPC Endpoints).

Alternatively, you can deploy your PoC environment by following the steps in the next sections.

Manual deployment

The following list outlines the major steps for manual deployments in your environment. For more information, see the AWS Prescriptive Guidance pattern Connect to Application Migration Service data and control planes over a private network.

1. Create the source VPC and staging area VPC with a private subnet.
2. Create the following VPC endpoints in the staging area subnet:
   - Application Migration Service, and enable the private DNS name (shared by the replication server and source server).
   - Amazon EC2, and enable the private DNS name (shared by the replication server and source server).
   - Amazon S3 (private DNS name not supported). Interface endpoints are supported across Direct Connect, AWS VPN, and VPC peering. Therefore, this is required for source servers only (and could be located on premises) to connect to the Application Migration Service control plane over a private network.
### Note

The **ssm** and **ssmmessages** endpoints are optional and currently created to connect the source server through the SSM Session Manager.

- Amazon S3 gateway endpoint in the staging area subnet. This is required by the replication server to connect to Amazon S3. You must update the routes for the staging area subnet.

3. Create an inbound resolver endpoint in the staging area VPC to allow resolution of the private DNS record (for VPC interface endpoints) from the source VPC.

4. Update the source VPC DHCP options with the inbound resolver endpoint of the staging area VPC as DNS server IP.

5. Enable peering between the source and staging VPCs, and update both VPC route tables.

6. Create a security group in the source and staging VPCs to allow the following ports.

<table>
<thead>
<tr>
<th>Source</th>
<th>Destination</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Source data center</strong></td>
<td>Amazon S3 service URLs</td>
<td>443 (TCP)</td>

</tr>
<tr>

</tr>
<tr>

<td>1500 (TCP)</td>
<td>Communication between the source servers and the staging area subnet over TCP port 1500</td>
</tr>
<tr>
<td><strong>Staging area subnet</strong></td>
<td>The Application Migration Service</td>
<td>443 (TCP)</td>
<td>Communication between the staging area subnet and Application</td>
</tr>
</tbody>
</table>
Migrating on-premises servers to AWS over private networks by using AWS Application Migration Service

<th>Source</th>
<th>Destination</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Staging area subnet</td>

<td>443 (TCP)</td>

</tr>
</tbody>
</table>

7. Initialize Application Migration Service in the staging area AWS Region by updating the staging area subnet details and enabling communication over private IP.

8. Create an AWS Identity and Access Management (IAM) role for installing Application Migration Service Agent. Attach managed policies and generate access keys and a secrets key.

9. Create an IAM profile to connect Amazon EC2 via the SSM Session Manager.

10. Install an Agent on the source machines.

**Automating Agent deployments with Cloud Migration Factory**

The Cloud Migration Factory on AWS automates the deployment of the Application Migration Service Agent for the private networks scenario, with additional command line parameters. When you deploy this solution (see options for automated deployment), you can use these scripts and one of the following options:

- Manually run these scripts from the command line, as described in the Run automations from command prompt section of the Cloud Migration Factory Implementation Guide
- Add the scripts to Migration Factory by following the instructions in the Scripts management section for full integration with Cloud Migration Factory

These scripts automate the following:

- Application Migration Service Agent installation on a Windows server using private endpoints
- Application Migration Service Agent installation on Linux servers using private endpoints
Monitoring and troubleshooting

You can monitor Application Migration Service by using Amazon CloudWatch, Amazon EventBridge, and AWS CloudTrail, which collect raw data and process it into readable, near-real-time metrics. For more information, see Monitoring Application Migration Service in the AWS documentation.

If you encounter any issues and want to launch new test or cutover instances, you can revert the test or cutover action. This will revert the lifecycle status of your source servers to the previous stage, indicating that these servers have not undergone a cutover. During a revert, you will also have the option to delete your test or cutover instances for cost-saving purposes. For more information, see Troubleshooting in the Application Migration Service documentation.

When the Agent has been installed, the source server appears on the Application Migration Service console, and you can see the server details to check replication progress.

Testing connectivity and name resolution from the source server

Log in to the source server by using Windows remote desktop protocol (RDP), Secure Shell (SSH), or AWS Sessions Manager, and test the following:

- Connectivity over HTTPS on TCP port 443 to the Application Migration Service endpoint.
  - On Windows (in PowerShell):
    ```powershell
    Test-NetConnection -ComputerName mgn.<aws_region>.amazonaws.com -Port 443
    ```
  - On Linux or Windows (cmd):
    ```cmd
    Telnet mgn.<aws_region>.amazonaws.com 443
    ```

- Connectivity over HTTPS on TCP port 443 to the Amazon S3 endpoint.
  - On Windows (in PowerShell):
    ```powershell
    Test-NetConnection -ComputerName <s3_endpoint_name> -Port 443
    ```
  - On Linux or Windows (cmd):
    ```cmd
    Telnet <s3_endpoint_name> 443
    ```
Telnet <s3_endpoint_name> 443

- Connectivity on TCP port 1500 to the replication server IP:
  - On Windows (in PowerShell):
    
    Test-NetConnection -ComputerName <Replication_Server_Private_IP> -Port 1500
  
  - On Linux or Windows (cmd):
    
    Telnet <Replication_Server_Private_IP> 1500

In addition, make sure that the Amazon EC2 and Application Migration Service API endpoints resolve to private IPs by using the following commands. (You can use the same commands on Windows and Linux.)

- nslookup ec2.<aws_region>.amazonaws.com
- nslookup mgn.<aws_region>.amazonaws.com

**Testing connectivity and name resolution from the staging area network**

To test connectivity from the staging area, launch a temporarily EC2 instance in the staging subnet and test the following:

- Connectivity over HTTPS on TCP port 443 to the Application Migration Service endpoint.
  - On Windows (in PowerShell):
    
    Test-NetConnection -ComputerName mgn.<aws_region>.amazonaws.com -Port 443
  
  - On Linux or Windows (cmd):
    
    Telnet mgn.<aws_region>.amazonaws.com 443

- Connectivity over HTTPS on TCP port 443 to the Amazon EC2 endpoint.
  - On Windows (in PowerShell):
    
    Test-NetConnection -ComputerName ec2.<aws_region>.amazonaws.com -Port 443
If replication initialization stalls at the "Downloading replication software" step after the Agent is installed on the source server, verify the following.

- **Name resolution:**

```
nslookup s3.<aws_region>.amazonaws.com
```

**Note**

The Amazon S3 endpoint will resolve to a public IP but will connect privately through the Amazon S3 gateway endpoint.

- **Connectivity over HTTPS protocol on the TCP/443 port.**
  - On Windows:

```
Test-NetConnection -ComputerName s3.<aws_region>.amazonaws.com -Port 443
```

  - On Linux:

```
Telnet s3.<aws_region>.amazonaws.com 443
```
Conclusion

This guide covered requirements and provided an example configuration for using Application Migration Service for lift-and-shift migration of servers from secured on-premises networks to AWS over private connectivity (AWS VPN or AWS Direct Connect). This is a typical scenario for many corporate migrations. The guide also provided guidance on ways to test by using automated or manual deployment, and monitoring and troubleshooting connectivity issues if they arise.

Numbers

7 Rs

Seven common migration strategies for moving applications to the cloud. These strategies build upon the 5 Rs that Gartner identified in 2011 and consist of the following:

- **Refactor/re-architect** – Move an application and modify its architecture by taking full advantage of cloud-native features to improve agility, performance, and scalability. This typically involves porting the operating system and database. Example: Migrate your on-premises Oracle database to the Amazon Aurora PostgreSQL-Compatible Edition.

- **Replatform (lift and reshape)** – Move an application to the cloud, and introduce some level of optimization to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Amazon Relational Database Service (Amazon RDS) for Oracle in the AWS Cloud.

- **Repurchase (drop and shop)** – Switch to a different product, typically by moving from a traditional license to a SaaS model. Example: Migrate your customer relationship management (CRM) system to Salesforce.com.

- **Rehost (lift and shift)** – Move an application to the cloud without making any changes to take advantage of cloud capabilities. Example: Migrate your on-premises Oracle database to Oracle on an EC2 instance in the AWS Cloud.

- **Relocate (hypervisor-level lift and shift)** – Move infrastructure to the cloud without purchasing new hardware, rewriting applications, or modifying your existing operations. This migration scenario is specific to VMware Cloud on AWS, which supports virtual machine (VM) compatibility and workload portability between your on-premises environment and AWS. You can use the VMware Cloud Foundation technologies from your on-premises data centers when you migrate your infrastructure to VMware Cloud on AWS. Example: Relocate the hypervisor hosting your Oracle database to VMware Cloud on AWS.

- **Retain (revisit)** – Keep applications in your source environment. These might include applications that require major refactoring, and you want to postpone that work until a later
time, and legacy applications that you want to retain, because there’s no business justification for migrating them.

- Retire – Decommission or remove applications that are no longer needed in your source environment.

active-active migration

A database migration method in which the source and target databases are kept in sync (by using a bidirectional replication tool or dual write operations), and both databases handle transactions from connecting applications during migration. Common cloud repositories include GitHub or AWS CodeCommit. Each version of the code is called a *branch*. In a microservice structure, each repository is devoted to a single piece of functionality. A single CI/CD pipeline can use multiple repositories.

Cross-functional teams that streamline the migration of workloads through automated, agile approaches. Migration factory teams typically include operations, business analysts and owners, migration engineers, developers, and DevOps professionals working in sprints. Between 20 and 50 percent of an enterprise application portfolio consists of repeated patterns that can be optimized by a factory approach. For more information, see the discussion of migration factories and the Cloud Migration Factory guide in this content set.

For more information, see the migration readiness guide. MRA is the first phase of the AWS migration strategy.

migration strategy

The approach used to migrate a workload to the AWS Cloud. For more information, see the 7 Rs entry in this glossary and see Mobilize your organization to accelerate large-scale migrations.

For more information, see Strategy for modernizing applications in the AWS Cloud.

modernization readiness assessment

An evaluation that helps determine the modernization readiness of an organization's applications; identifies benefits, risks, and dependencies; and determines how well the organization can support the future state of those applications. The outcome of the assessment is a blueprint of the target architecture, a roadmap that details development phases and milestones for the modernization process, and an action plan for addressing identified gaps. For more information, see Evaluating modernization readiness for applications in the AWS Cloud.

monolithic applications (monoliths)

Applications that run as a single service with tightly coupled processes. Monolithic applications have several drawbacks. If one application feature experiences a spike in demand, the entire architecture must be scaled. Adding or improving a monolithic application's features also becomes more complex when the code base grows. To address these issues, you can use a microservices architecture. For more information, see Decomposing monoliths into microservices.
multiclass classification

A process that helps generate predictions for multiple classes (predicting one of more than two outcomes). For example, an ML model might ask "Is this product a book, car, or phone?" or "Which product category is most interesting to this customer?"

mutable infrastructure

A model that updates and modifies the existing infrastructure for production workloads. For improved consistency, reliability, and predictability, the AWS Well-Architected Framework recommends the use of immutable infrastructure as a best practice.

For more information, see Creating a trail for an organization in the CloudTrail documentation.

organizational change management (OCM)

A framework for managing major, disruptive business transformations from a people, culture, and leadership perspective. OCM helps organizations prepare for, and transition to, new systems and strategies by accelerating change adoption, addressing transitional issues, and driving cultural and organizational changes. In the AWS migration strategy, this framework is called people acceleration, because of the speed of change required in cloud adoption projects. For more information, see the OCM guide.

origin access control (OAC)

In CloudFront, an enhanced option for restricting access to secure your Amazon Simple Storage Service (Amazon S3) content. OAC supports all S3 buckets in all AWS Regions, server-side encryption with AWS KMS (SSE-KMS), and dynamic PUT and DELETE requests to the S3 bucket.

origin access identity (OAI)

In CloudFront, an option for restricting access to secure your Amazon S3 content. When you use OAI, CloudFront creates a principal that Amazon S3 can authenticate with. Authenticated principals can access content in an S3 bucket only through a specific CloudFront distribution. See also OAC, which provides more granular and enhanced access control.

An approach to modernizing monolithic systems by incrementally rewriting and replacing system functionality until the legacy system can be decommissioned. This pattern uses the analogy of a fig vine that grows into an established tree and eventually overcomes and replaces its host. The pattern was introduced by Martin Fowler as a way to manage risk when rewriting monolithic systems. For an example of how to apply this pattern, see Modernizing legacy Microsoft ASP.NET (ASMX) web services incrementally by using containers and Amazon API Gateway.

test environment

See environment.

training

To provide data for your ML model to learn from. The training data must contain the correct answer. The learning algorithm finds patterns in the training data that map the input data attributes to the target (the answer that you want to predict). It outputs an ML model that captures these patterns. You can then use the ML model to make predictions on new data for which you don’t know the target.

trusted access

Granting permissions to a service that you specify to perform tasks in your organization in AWS Organizations and in its accounts on your behalf. The trusted service creates a service-linked role in each account, when that role is needed, to perform management tasks for you. For more information, see Using AWS Organizations with other AWS services in the AWS Organizations documentation.

There are two types of uncertainty: *Epistemic uncertainty* is caused by limited, incomplete data, whereas *aleatoric uncertainty* is caused by the noise and randomness inherent in the data. For more information, see the [Quantifying uncertainty in deep learning systems](https://www.aws.amazon.com) guide.
